sector is the one which offers the greatest potential. Improving the energy efficiency of buildings can also generate other economic, social and environmental benefits. Better performing buildings provide higher levels of comfort, wellbeing and health for their occupants. It also has a major impact on the affordability of housing and on energy poverty, a growing phenomenon since 2008, with 12.8% of the population reporting inadequately heated homes across EU, which rises to 20.0% by considering the ten Central and Eastern European member states (EU10), and 16.6% for the eight EU countries that border the Mediterranean Sea (Bouzarovski, 2014). The European Commission has recognised the importance of buildings performance in the effort to mitigate climate change, and has set regulations to help promoting the use of smart technology in buildings, to streamline existing rules and accelerate buildings renovation. While the Energy Performance of Buildings Directive (EPBD) has set minimum energy performance requirements for all buildings that undergo major renovation (European Commission, 2010), Article 5 of the Energy Efficiency Directive (EED) has set a binding renovation target for public buildings and imposed related obligations, stressing that public authorities, especially governments, shall undertake an exemplary role in the energy retrofit of public buildings (European Commission, 2012). The revision of the EPBD, just entered into force on the beginning of July 2018, aims at accelerating the cost-effective renovation of existing buildings and promoting smart-ready systems and digital solutions in the built environment, therefore providing consumers with more accurate information about their consumption patterns (European Commission, 2018). However, researches have started questioning the effectiveness of retrofitting policies, since they are mainly based on theoretical assumptions (Galvin, 2014) and do not accommodate user energy practices (Gram-Hanssen et al., 2018). In order to achieve real energy reduction, policy instruments need to include considerations on the actual use of buildings rather the theoretical consumption (Visscher et al., 2016).

In this context, the paper presents a methodology based on multi-criteria assessment of different strategies by applying the Analytic Hierarchy Process (AHP), aiming at providing support to policy-makers for their decisions concerning the reduction of energy consumption in buildings. The methodology has been designed to explicitly incorporate the impact of user's behaviour into the assessment of planning strategies and renovation measures. In Section 2 , previous research is presented. Section 3 explains the adopted methodology, the main steps of the AHP, and the selected measures, criteria and scenarios. The alternatives that are more dependent from behaviour are identified, and the way to tackle this uncertainty in the pairwise comparisons is presented. The findings are discussed in Section 4, where the possible steps to unlock the energy saving potential of buildings are presented. In Section 5, conclusions and limitations are shown, and policy implications are drawn.

2. State of the art

On the one hand, the design of energy efficient buildings does not necessarily result in low energy consumption (Stevenson, Leaman, 2010; Guerra-Santin, Itard, 2010; Gupta, Chandiwala, 2010). Whenever the buildings are designed to be energy efficient, it is up to occupants decide how to use them (Gupta, Chandiwala, 2010; Janda, 2011; Feng et al., 2016; Santangelo et al., 2018), introducing a consistent uncertainty on the level of energy savings, very often resulting in a gap between expected and actual energy consumption.

Despite the central role of users to lower energy consumption has been increasingly recognised, more recently in regulatory frameworks and earlier in research field, evidence from research has showed that so far households have not been sufficiently motivated or

supported in undertaking changes, and they are still not enough aware of the impact of their lifestyles and decisions on energy consumption.
On the other hand, public administrations have still to find ways to face the lack of public resources and increase the renovation rate of their building stock. They have so far failed in leading the renovation process on public buildings, while the property fragmentation represents a limit to the implementation of renovation strategies in the private housing sector.
Some past studies show multi-criteria analysis as a powerful tool to identify priorities for energy efficiency measures. A study conducted in Dortmund analysing energy efficiency measures in public buildings (März et al., 2011) has shown as Multi-Criteria Analysis (MCA) can simplify complex situations when it comes to allow decision-makers to include a full range of social, environmental, technical and economic criteria to their decision on measures to be implemented to unlock the energy saving potential of buildings. The results highlight which energy efficiency measures should be implemented to achieve the greatest benefit for the city, resulting in a ranking list of measures and recommended solutions. A similar research has been performed in Italy by considering the Sustainable Energy Action Plan of the city of Melzo (Dall'O' et al, 2013). Results have demonstrated how considering only the economic approach to make decisions on the renovation of buildings leads to results that do not take into consideration the most important objective of the cities – to increase the sustainability of the whole community. However, in both studies, the considered renovation strategies have not explicitly incorporated initiatives addressing user's behaviour among the recommended solutions to be implemented to effectively reduce energy consumption in the housing sector, both prior and after renovation. Without considering energy behaviour has a key factor for the success of strategies addressing buildings renovation, the expected energy savings have been demonstrated to be misleading, and the impact of such measures overestimated.
Policy instruments at different levels (i.e. EU, national, regional and local) are struggling to encourage decision-makers to include information to occupants as a prerequisite to implement effective energy renovation strategies of the housing stock. Measures to promote efficient behaviour can be divided in two groups, psychological strategies and structural strategies (Steg, 2008). While the former (e.g. education, information) are aimed at influencing directly the user, the latter (e.g. new appliances, infrastructures, services) are aimed at changing the context in which decisions are made, to increase the energy saving attractiveness. Policy instruments are responsible to translate these strategies into practices. Four main categories of policy instruments can be identified: information, economic, administrative and physical (Linden et al., 2006). Focusing on information, the importance of tailored information and feedback has been recognised (European Environment Agency, 2013). Feedback plays a significant role in raising energy awareness and changing occupant attitudes towards energy consumption. Among the different types of feedback, this research focus on direct feedback (e.g. smart meters), available on demand and indirect feedback (e.g. informative energy bills, energy awareness campaigns and collaborative learning). Faruqui et al. found that direct feedback provided by in-home displays can encourage occupants to make more efficient use of energy. Energy savings from occupant behaviour range between 3% and 13%, with an average of 7% (Faruqui, 2010). The range of savings achieved through indirect feedback tends to be lower than the one reported in direct feedback studies (5%–15%). Nevertheless, they are important to make users aware of the impact of their daily practices, and are achievable at relatively low cost. Moreover, it has been studied that the combination of different informational feedback may lead to an increase of energy savings up to 20% (European Environment Agency, 2013).

3. Methodology

3.1 The Analytic Hierarchy Process (AHP)

The main issue policy-makers are struggling with is to understand which measures offer the greatest benefit within the framework of interacting environmental, economic and social factors. In fact, when it comes to increase the sustainability of cities, an economically oriented cost-benefit analysis alone is not adequate to take into consideration the multiplicity of determinants towards an energy efficient building stock.

To support decision-makers to design effective energy efficiency renovation policies, a methodology based on the application of the Analytic Hierarchy Process (AHP) is presented. AHP is a theory of measurement through pairwise comparisons and relies on the judgements of experts to derive priority scales. The comparisons are made using a scale of absolute judgements that represents, how much more, one element dominates another with respect to a given attribute. Through these scales, is possible to measure intangibles in relative terms. The judgements may be inconsistent, therefore consistency should be checked and kept within certain values (Saaty, 1990; Saaty, 2008). To generate priorities to support decisions, four main steps have to be followed: i) to define the problem, and to set the goal; ii) to structure the decision hierarchy from the top (the overall objective), through the intermediate level (criteria), to the lowest level represented by the alternatives (measures); iii) to build pairwise comparison matrices and undertake a consistency test; iv) to estimate the relative weighs of the components of each level. AHP scale considered is as follows: 1 for equal importance; 3 for moderate importance; 5 for strong importance; 7 for very strong importance; 9 for extreme importance; pair values are used for priorities in-between the odd ones.

The methodology described in the following paragraphs aims to demonstrate that the measures tackling user's behaviour are the most urgent to be implemented and therefore they should be on the top of the priority list when it comes to design effective renovation strategies of the housing stock. Thus, energy behaviour of occupants needs to be embedded in renovation policies, in order to reduce the gap between expected and actual energy consumption, to raise awareness on the individual impact on the energy consumption and to build sustainable communities. A sensitivity analysis is performed to design different scenarios based on the allocation of priorities among different criteria. The scenarios are intended as multiple ways to achieve the above-mentioned goal.

3.2 Definition of measures, criteria, scenarios and their hierarchy

The overall objective considered as the goal of the AHP application, is to lower energy consumption in housing sector by selecting the measures that more than others can lead to an effective implementation of the energy renovation strategies.

Among the numerous criteria and indicators that are normally used in environmental assessment of buildings, four criteria have been taken into consideration for the aim of this study. The *environmental criterion* is the one aiming at maximising the energy and CO_2 reduction, no matter the economic, social and practicable feasibility of implementing the renovation alternatives. The *economic criterion* aims at maximising the revenues and/ or minimising the loss, thus takes into consideration the cost-effectiveness of measures. The *social criterion* is the one recognising the importance of social and cultural values, and support inclusion of these values in the selection of energy renovation measures. The last criterion considered is the *practicability* of such energy efficiency measures, evaluating how easy and free from operational barriers is the applicability of the foreseen measures.

As results of literature and case studies review, taking as a reference the renovation practices of Italian residential building stock (Semprini et al., 2015; Santangelo et al., 2018), 7 packages of measures – M(1) to M(7) – have been identified as potential alternatives to improve the energy performance of the housing stock (Table 1).

MEASURES	DEPENDENCY FROM BEHAVIOUR
M(1) - Indirect feedback	High
M(2) - Direct feedback/ smart meters	High
M(3) - Replacement of the heating system	Medium
M(4) - Replacement of home appliances/ lights	Medium
M(5) - Replacement of windows	Medium
M(6) - Insulation of building envelope	Low/ None
M(7) - Renewable energy systems	Low/ None

Table 1: List of measures and level of dependency from behaviour

These measures have been clustered according to their levels of dependency from the occupant behaviour. M(1) and M(2) are the two alternatives strongly dependent on occupant behaviour, since they are designed to address directly the behaviour change and the households awareness of their impact on energy consumption. M(3), M(4) and M(5) are dependent to a certain degree on occupant behaviour. In fact, whether the heating system, the home appliances and the windows are efficient or not, it will still be the occupant who decides how to use them, introducing a level of uncertainty of such measures to increase the energy efficiency of housing buildings. On the contrary, M(6) and M(7) have been clustered as non-dependent on behaviour, since they represent the alternatives that more than others are able to reach the target of energy efficiency they are designed for, with limited influence of occupant's behaviour.
The structure of the hierarchy framework described above is drawn in Figure 1. The first level represents the goal of the analysis. The second level is composed by multiple criteria. The last level is made by the alternative choices or measures.

Figure 1: Hierarchy framework

4. Results and discussion

The results report the application of AHP according to the hierarchy of goal, criteria and measures described above. The second sub-section describes the scenarios selected and how the criteria are combined among them to define the five scenarios.

4.1 AHP pairwise comparisons

The consistency test is one of the essential features of the AHP method which aims to eliminate the possible inconsistency revealed in the criteria weights through the computation of consistency level of each matrix. The consistency ratio (CR) is used to determine and justify the inconsistency in the pairwise comparison (Saaty, 1990). The acceptable CR values is assumed 0.10 for matrix larger than 4x4. All the CR values of the matrixes considered are below this limit, therefore the weight results can be assumed as valid and consistent.

The results from the environmental criterion decision matrix are presented, prioritised and ranked in Table 2. In order to highlight the medium-dependency level of M(3), M(4) and M(5) from behaviour, the preference of such measures pairwise compared to M(1) and M(2) have been lowered (i.e. two points decreased in the scale of preference). This assumption has been made to incorporate the somehow dependency on behaviour of such measures. Selecting M(3), M(4) and M(5) without taking into consideration that they are influenced from user's behaviour can lead to overestimate the environmental benefit of such measures.

Tables 3-5 present the results from pairwise comparisons taking into consideration respectively the economic, social and practicable criteria. Each table shows the priority of selected measures according to the results of the decision matrix, and the ranking of the alternatives when each criterion is considered alone, in absolute terms.

ENVIRONMENTAL CRITERION									
DECISION MATRIX	M(1)	M(2)	M(3)	M(4)	M(5)	M(6)	M(7)	**PRIORITY**	**RANKING**

Table 5: Pairwise comparison for social criterion. Consistency Ratio CR = 0.06

Figure 2 shows the priority trend of each criterion. "M(1) – Indirect feedback" and "M(2) - Direct feedback/ smart meters" are the top alternatives considering three out of four criteria, while implementing "M(7) - Renewable energy systems" has the highest priority when the environmental criterion is considered. Beside these three solutions, "M(4) - Replacement of home appliances/ lights" is the measure that shows the most significant changes among the criteria considered.

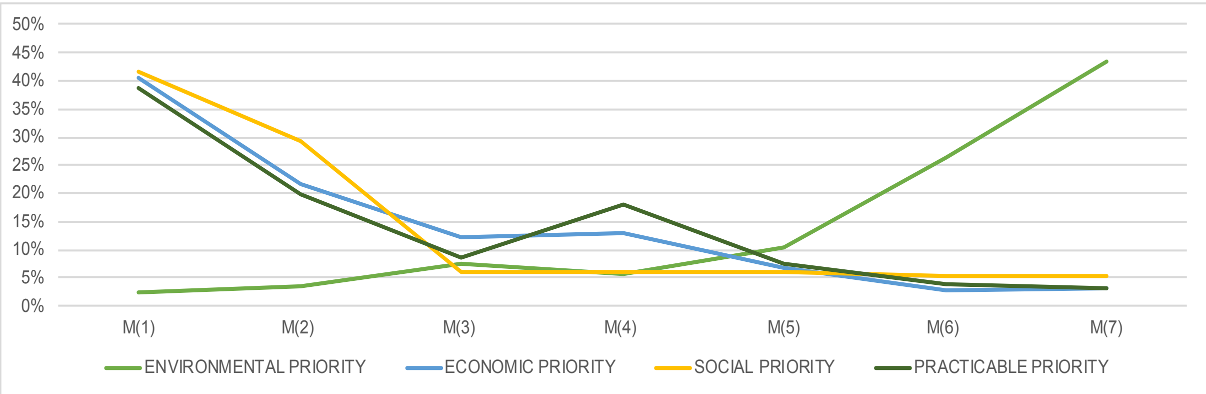

Figure 2: Criteria priority

4.2 Sensitivity analysis

In order to include all the main alternative decisions that policy-makers might face to reach the overall objective of lowering energy consumption in housing sector, a sensitivity analysis has been performed to define 5 possible scenarios that includes different combination of the selected criteria. The weights assigned for each scenario are presented in Table 6. The neutral scenario foresees a decision made by equally evaluate the four criteria. The rest of the scenarios are designed to make one criterion prevail, with a double weight with respect to the other three criteria.

The results of the sensitivity analysis are presented in Table 7. The rows represent the seven measures, while the five main columns show both the priority and the ranking of each scenario. Recommendations on which measures should be selected first are drawn by taking into consideration the results of each ranking list. The traffic light colours from green to red show the priority of recommended solutions.

The evidence of how behaviour is embedded into the measures with the highest scores is presented in Figure 3.

	ENVIRONMENTAL CRITERION	ECONOMIC CRITERION	SOCIAL CRITERION	PRACTICABLE CRITERION
NEUTRAL SCENARIO	25%	25%	25%	25%
ENVIRONMENTAL SCENARIO	40%	20%	20%	20%
ECONOMIC SCENARIO	20%	40%	20%	20%
SOCIAL SCENARIO	20%	20%	40%	20%
PRACTICABLE SCENARIO	20%	20%	20%	40%

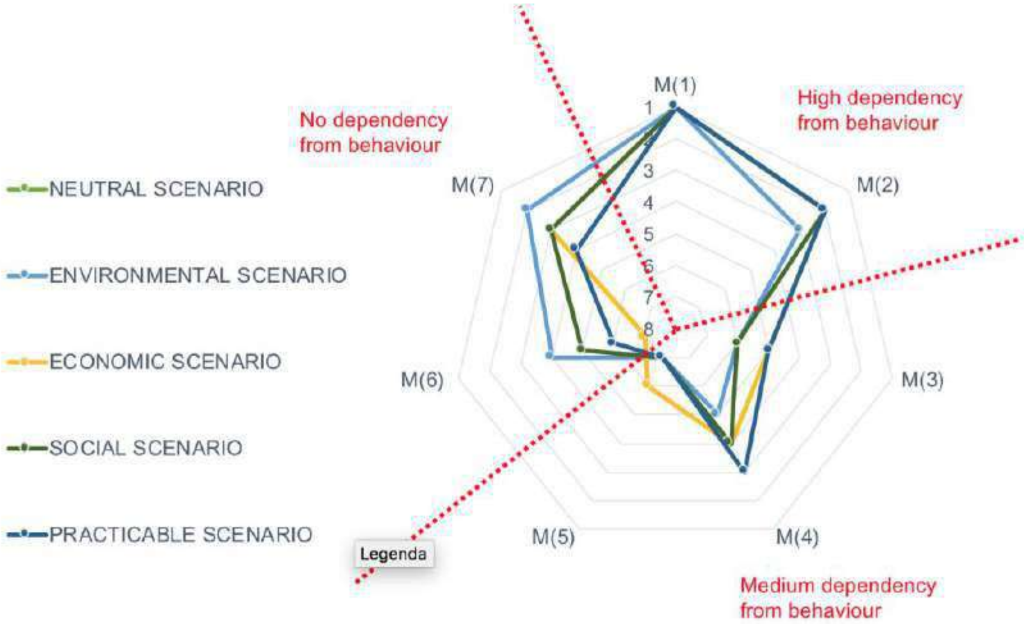

Figure 3: Scenario analysis and evidence of energy behaviour relevance

5. Conclusions, limitations and policy recommendations

This research has contributed to highlight the central role of household behaviour and daily practices to lower energy consumption when it comes to renovation of existing housing buildings. A methodology based on multi-criteria assessment of different strategies by applying the Analytic Hierarchy Process (AHP) has been presented. The methodology allowed to combine quantitative and qualitative attributes and to translate qualitative

preferences into ratio scaled data. The AHP application goal has been defined as selecting the measures that more than others can lead to an effective implementation of the energy renovation strategies and can increase energy efficiency of existing housing stock. Four criteria and seven measures have been identified, respectively as intermediate level and lower level of the hierarchy framework. Results show that "M(1) - Indirect feedback" and "M(2) - Direct feedback/ smart meters", the two measures that more than the other considered rely on user's behaviour, have resulted to be the top alternatives by three out of four criteria. Afterwards, a sensitivity analysis has been performed to define five possible scenarios that includes different combination of the selected criteria. The aim has been to include all the main alternative decisions that policy-makers might face to reach the reduction of energy consumption by renovating the housing stock. The analysis has confirmed the urgency and convenience to implement the first two measures prior to the other alternatives.
The research embeds also some limitations. First of all, the decisions on the scores of pairwise comparisons have been made directly by the authors. Although they come from the evidence of long-lasting collaborations with public authorities (e.g. municipalities and regional authorities), to enhance the robustness of the results, it might be suggested to design a participatory process to directly involve experts in decisions, or to deliver a survey to gather stakeholders' feedback on the priorities. Secondly, to the extent of the study, informational feedback – both direct and indirect – has been considered to lead to behaviour change due to rational behaviour. However, this approach has been criticised for relying on assumptions of consumers as guided by economically rationally decisions, while in practice is not the case. Although the limits of this kind of strategy, informing the users still represent an important element in the implementation of structural strategies intended to increase the energy efficiency of buildings.
Two main policy recommendations can be drawn. On the one hand, as more data on household energy consumption and indoor comfort levels become available, there are more possibilities of providing tailored feedback to occupants. However, there is a limited evidence of post-occupancy evaluation studies in existing literature. Thus, the measures proposed in this research with a high dependency on behaviour are intended as complementary to the others, and first to implement to raise awareness and drive behaviour towards more energy sustainable practices, but they certainly cannot reach the goal if implemented alone. Information, awareness campaigns, feedback and other informative policy instruments should be integrated by other measures addressing the physical renovation. On the other hand, public authorities are seeking for services rather than products to increase the renovation rate of the housing stock. Better integrated complementary approaches to both the technical and social energy transitions are required.

Detecting the Attractive Spots of Hiking Tourism Based on Geo-tagged Photos: The Case of the Northern Outskirts of Guangzhou, China

Ping SHEN, Tongji University, China

Jingyu LIANG, South China University of Technology, China

Miaoxi ZHAO, South China University of Technology, China

Abstract

Hiking in the outskirts of mega cities as a kind of environmentally friendly and sustainable urban tourism is becoming more and more popular in China. The trend of urban residents participating in hiking in China appears to be relatively late comparing with that in Europe. Therefore, the facilities and management for hiking tourism still need to be improved in China. Hiking activities can help citizens keep physically and mentally healthy because it provides the opportunity to experience the tranquility, solitude and pristine beauty of nature, which are recreational qualities that contrast with the stress of urban life. So, going hiking frequently is a green lifestyle. Since hiking activities are often carried out in outdoor areas with no regular path, it is difficult to use traditional methods to research these activities, especially when the research focus on large-scale area.

The social networking sites for hikers have emerged in China in recent years, which provide opportunities to share geo-tagged photos when going hiking. These photos serve as a new source of data for studying hiking activities. Considering that people take photos to record attractions, geo-tagged photos reflect people's memorable events associated with locations. Therefore, these photos provide insights into hikers' preferences and their interactions with the surroundings. Based on these photos, a novel approach is presented to identify the spots which attract the hikers through density analysis and to get the tags representing features of the spots through image recognition.

In this paper, we made a case study of the hiking activities in the northern outskirts of Guangzhou, China. This area is approximately 1797 square kilometers, having rich ecological resources and attracting numbers of hikers. First of all, the shared geo-tagged photos of the area from March 2010 to March 2017 were obtained. After screening, 13157 photos shared by the hikers were gained. Then, the hot spots attracting hikers were identified through density analysis in GIS. After image recognition, tags representing contents of the photos taken within 50m around the attractive spots were found out. Then top two representative tags were selected for each attractive spot. These tags including "Mountain, "Vegetation", "Water", "Rock", "Building" and "Person", introduce the types of the attractive spots and the contents of the most photos taken by hikers when they stay. Finally, the pattern of distribution of different types of attractive spots were studied and summarized. The information of the attractive spots and the tags can serve as an important reference for planning, governance and management of hiking tourism.

Keywords: geo-tagged photos; hiking tourism; attractive spots; representative tags; Guangzhou, China

1. Introduction

The tourism sector which is already one of the fastest growing industries in the world is currently undergoing extensive change (Sørensen & Sundbo, 2014). Among various ways of tourism, hiking is becoming more and more popular in China. The rapid development of outdoor activities and Internet have promoted the popularity of hiking tourism. Hiking in the suburbs of large cities is a typical type of eco-tourism. Citizens from large cities participate in hiking in the outskirts of the cities in order to get exercise, rest and recreation. In this process, they also achieve the purpose of understanding, enjoying and protecting nature. Many developed countries have developed mature systems and commendable facilities for hiking tourism. However, hiking tourism in China appears to be relatively late, and it is still spontaneous. Therefore, the facilities and management for hiking tourism need to be improved in China (Jin, et al , 2012).

The characteristics of tourists' behavior are very important aspects in tourism research (Beeco, et al, 2013). Understanding the tourists' needs and activities is crucial for tourism planning and management (Taczanowska, et al, 2014; East, et al, 2017). However, hiking is often carried out in rural and natural environments so that traditional survey methods are difficult to apply due to the area is lack of monitoring and some hikers lack map reading skills or have difficulties in orientation.

With the development of technology, GPS is integrated into portable equipment, providing new opportunities for tracking travel activities (Nielsen, et al, 2010). With the gradual development of the social networking platform, many hikers share where they are and what they see in the process of hiking by sharing geo-tagged photos on the social networking sites. A large number of geo-tagged photos on the Internet provide a new and valuable source of information for the study of tourists' behavior (Orsi & Geneletti, 2013). The study of the preference and behavior of tourists based on geo-tagged photos has become an important topic in the field of tourism research and management. By analyzing geo-tagged images, we can get information about the places that attract hikers (Arase, et al, 2010). These spots often have charming landscape or interesting things. They are also places that are prone to crowding (East D, et al, 2017). The planning and management of these places need to take into account in terms of both viewing function and security protection.

This study attempts to collect the geo-tagged photos shared on the social networking sites and obtain the attractive spots of hiking tourism through density analysis in the GIS. After using image recognition technology to identify the contents of photos around the attractive spots, the tags which represent the contents interested by the hikers can be gained. The information of the attractive spots and the tags can provide a basis for planning and management of the attractive spots of hiking tourism.

2. Related Research Review

In academia, the study of outdoor tourism activities has a long history. In densely populated areas, providing quality outdoor recreation areas is a particularly important topic. The design methods that explore the balance of the needs of tourists and the services have attracted plenty of attention (Bell, 2008). Traditional studies often use written diaries or telephone interviews to obtain information. These methods have problems including the inability to obtain accurate information of travel time and destination location (Murakami & Wagner, 1999). In addition, some studies have conducted interviews with on-site visitors in order to know about the routes of the tourists and explore the spatial behavior of tourists (Taczanowska, et al, 2006). Some studies also explore monitoring options for tourist numbers in natural areas (Cessford & Muhar, 2004).

However, hiking tourism tends to occur in rural areas. If the hikers have difficulties in orientation, it is probably difficult for them to recall the hiking route and the location of attractive spots after hiking activities. So, traditional methods are not applicable in such cases. In contrast, data with geographic coordinate information shows advantages.

Some scholars tried to extract travel information from geo-tagged photos in order to understand the behavior of tourists (Li, et al, 2013), and to obtain the location of the spaces that attract tourists to stay (Papadopoulos, et al, 2011; Henderson, et al, 2010; Li & Ding, 2015). What's more, some studies used geo-tagged photos to speculate the tourist routes (Arase, et al, 2010; Kurashima, et al, 2013; Orsi & Geneletti, 2013). Furthermore, some scholars used geo-tagged photos to identify the behaviors and needs of tourists and to build

a travel route recommendation system (Okuyama & Yanai, 2013). For managers, the information contented in geo-tagged photos is used as a basis for planning tourism routes and arranging tourism facilities (Yoshikawa, et al, 2010).
In addition, some scholars have tried to use GPS data of the track in tourism research. For example, some studies used these data to research tourists' behavior (Orellana, et al, 2012; Meijles, et al, 2014; Donaire, et al, 2015). Base on the characteristics of tourists' behavior, some scholars generated a tourist route selection model (Bierlaire & Frejinger, 2008) or constructed a new tourism route design method (Li, et al, 2016).
It can be seen that research methods for outdoor hiking tourism are constantly evolving. At present, tourism research based on geo-tagged photographs pays more attention to urban built-up areas and less attention to the outskirts of the cities. These researches based on GPS data of the track pay attention to the feature of the behavior of tourists and the generation of routes, and basically have not advantages in identifying the features of spots that attract tourists. This study focuses on the case of the northern outskirts of Guangzhou in China and make comprehensive use of geographical information and visual information carried by geo-tagged photos to obtain the attractive spots that hikers prefer to stay and to identifies the features of the spots.

3. Research Foundation

3.1 Research Object

Hiking is a walking exercise which always occurs in the suburbs of cities or rural area. In many countries, as leisure time increases, the proportion of people participating in hiking tourism increases (Cole & Buckley, 2004). In China, hiking activities are mainly in short-distance, and their destinations are always in the wild area or rural area (Jin, et al, 2012). Areas that are easily accessible around large cities or densely populated areas often become main destinations for short-distance travel (Bell, 2008).
The Zengcheng District and Conghua District in the northern part of Guangzhou have various ecological and rural resources, attracting a large number of hikers. The “Master Plan of Guangzhou (2011-2020)” introduces that the Liangkou Town, Lvtian Town and Wenquan Town in Conghua District, Paitan Town, Xiaolou Town, and Zhengguo Town in Zengcheng District have advantages in ecotourism. The elevation of this area ranges from 30 meters to 1170 meters and the slope range from 0 degrees to 50 degrees. Thanks to the great change of topography, the ecological resources in this area are abundant. At the same time, this area is in the northern part of Guangzhou and it is relatively convenient to get to. Therefore, this area has been popular for hiking.
This study chose this area as a case, using the geo-tagged photos on the social networking sites to identify the spots that attract hikers to stay and found tags representing the feature of the spots.

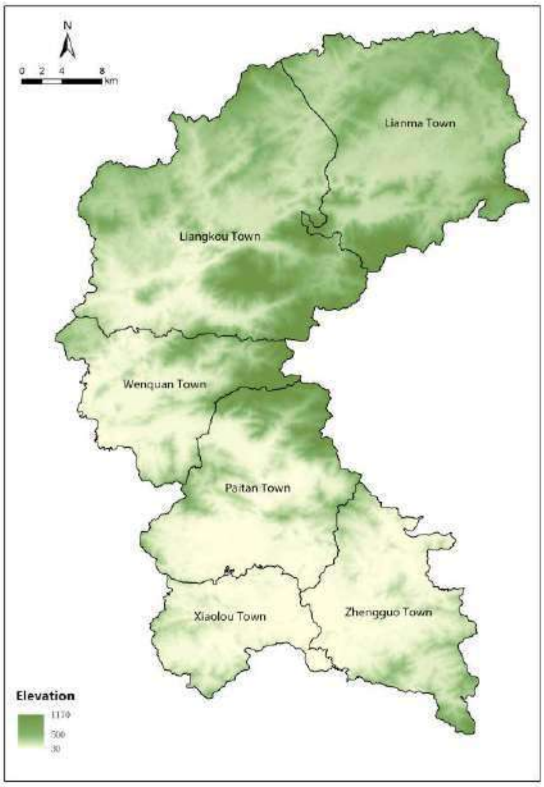

Figure 1: Topographic map of study area

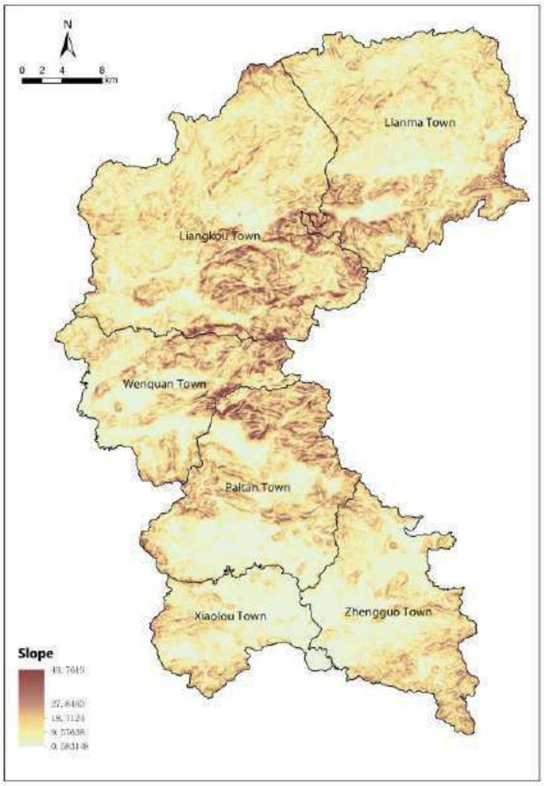

Figure 2: Slope map of study area

3.2 Research Methods

With the development of outdoor travel activities and the popularization of GPS technology, social networking sites for sharing geo-tagged photos have appeared on the Internet. These social networking sites provide an opportunity to share photos with geographical coordinates whenever and wherever users are doing outdoor activities. These sites provide hikers with the opportunity to share GPS tracks and geo-tagged images online. They have been gaining plenty of users in China.

After searching with “Conghua” and “Zengcheng” as keywords, this study used the software called LocoySpider to gain geo-tagged images and corresponding GPS tracks on one popular social networking site for hikers. A total of 19664 geo-tagged photos and 4116 corresponding GPS tracks were collected. After importing the original data into GIS for visualization, the data outside the study area, the abnormal or non-hiking travel data were filtered. Finally, 13157 corresponding geo-tagged photos and 2564 corresponding tracks were obtained.

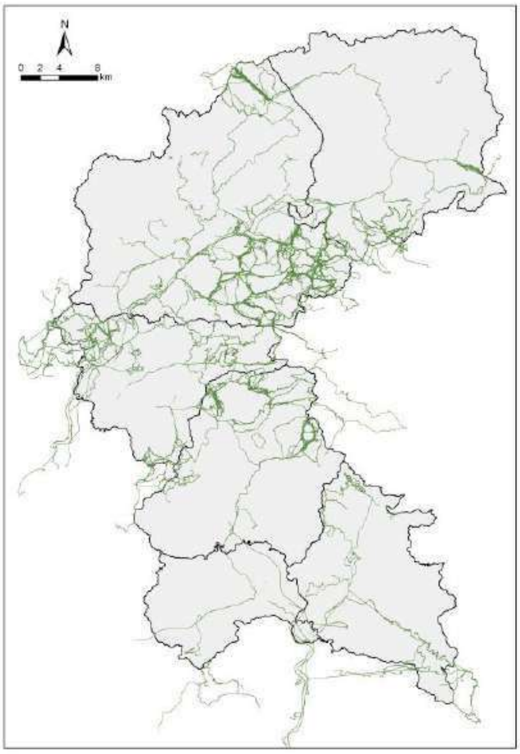
After importing these geo-tagged photos in GIS, we used density analysis to identify places that attract people to stay and take photos. Based on the result of the density analysis, we selected the 100 attractive spots with high density value. Then what people interested in when they stay in these spots was explored. The content of the geo-tagged photos taken within 50m around the attractive spots were studied. Based on the open sources database on the Internet for image recognition, the content of these photos was recognized after running a machine learning model. Then the top two representative tags were selected for each attractive spot. These tags are able to tell us the types of the attractive spots and contents of the majority of photos taken by hikers when they linger at the spot. What’s more, the distribution rules of different types of spots were also summarized.

Figure 3: The GPS track and geo-tagged photos on one social networking site (The blue marks on the map represent the location of the shared photos)

4. Detecting the Attractive Spots of Hiking Tourism

4.1 Identifying the Attractive Spots

A small number of the tracks coincide with the existing county roads, while most of the routes chosen by the hikers are just limited to walking. The hikers prefer the unhardened paths in the wild which are always not recorded on the traditional maps. Many hikers find their ways by tracking the GPS data shared by other hikers before. Thus, some routes have become popular among the hikers through the spread of the Internet. The hiking tracks are unevenly distributed across the study area. They are more intensive in the central area. The dense area is in the southeast of Liangkou Town, followed by the north of Liangkou Town, the south of Lvtian Town, the northwest of Wenquan Town and the north of Paitan Town. Correspondingly, the 13157 geo-tagged photos were mainly distributed in the middle of the study area, which match to the dense areas of GPS tracks. It can be seen that the networking sites can provide a great deal of precise information on the behavior of hikers.



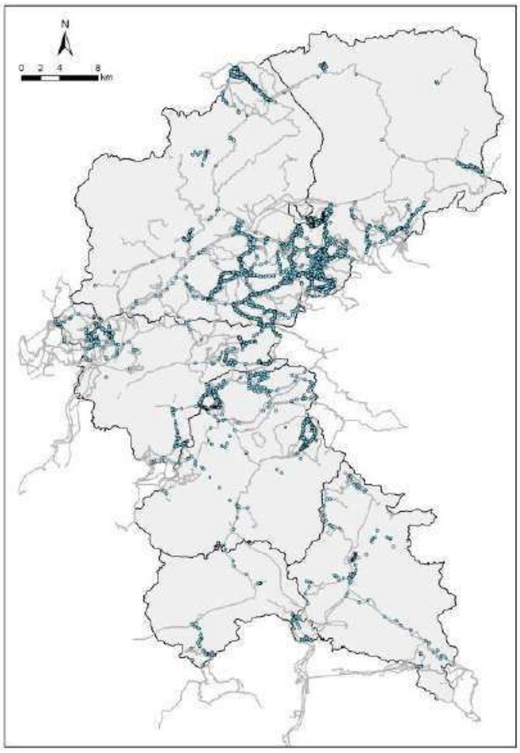


Figure 4: The distribution of GPS tracks *Figure 5: The distribution of geo-tagged photos*

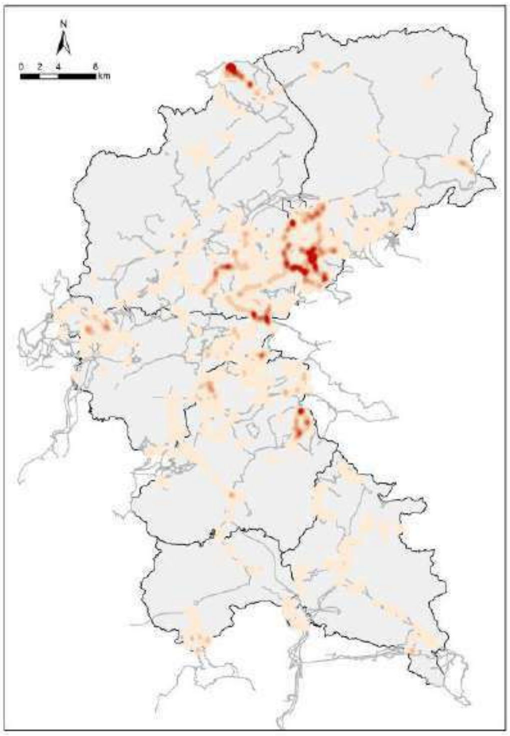
If a place attracts many hikers to take photos, these places are supposed to have high-quality landscapes or special events to attract hikers to stay (Arase, et al, 2010; Henderson, et al, 2010). Based on the density analysis in GIS, 100 attractive spots with high-density value were selected. These spots are mainly concentrated in the central-eastern part of the study area, and a small number are located in the northern part of the area. They are concentrated in the area where the topography changes greatly.



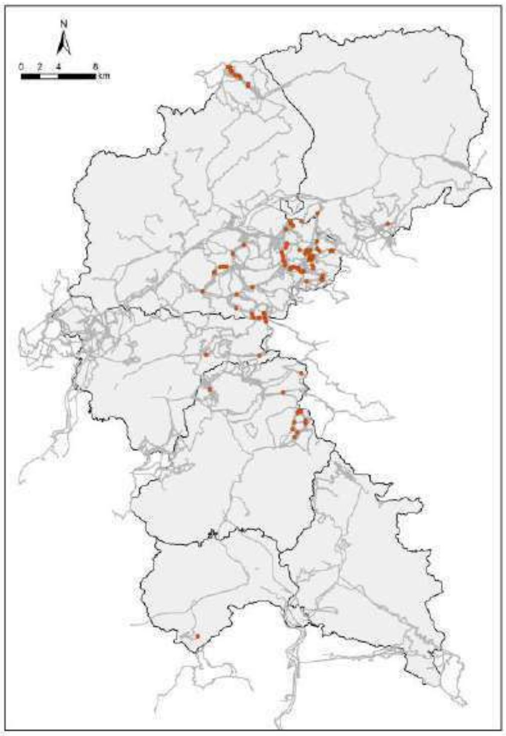


Figure 6: The density of the geo-tagged photos *Figure 7: The 100 attractive spots selected*

4.2 Tags Generation of Attractive Spots

A total of 4403 geo-tagged photos taken within 50m around the attractive spots were selected in this study. Based on the open database called ADE20K[i] for image recognition on the Internet, the contents of these photos were recognized after running a machine learning model.

The most frequently occurring contents include “Mountain”, “Vegetation”, “Water”, “Rock” “Building” and “Person”. For each photo, the proportions of “Mountain”, “Vegetation”, “Water”, “Rock”, “Building” and “Person” were counted.

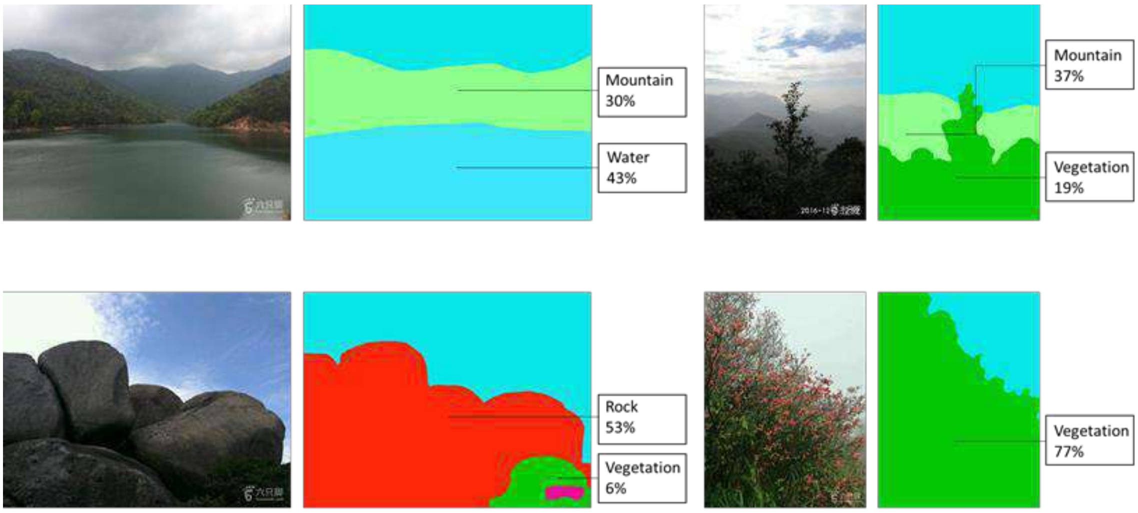

Figure 8: Some examples of photo identification!

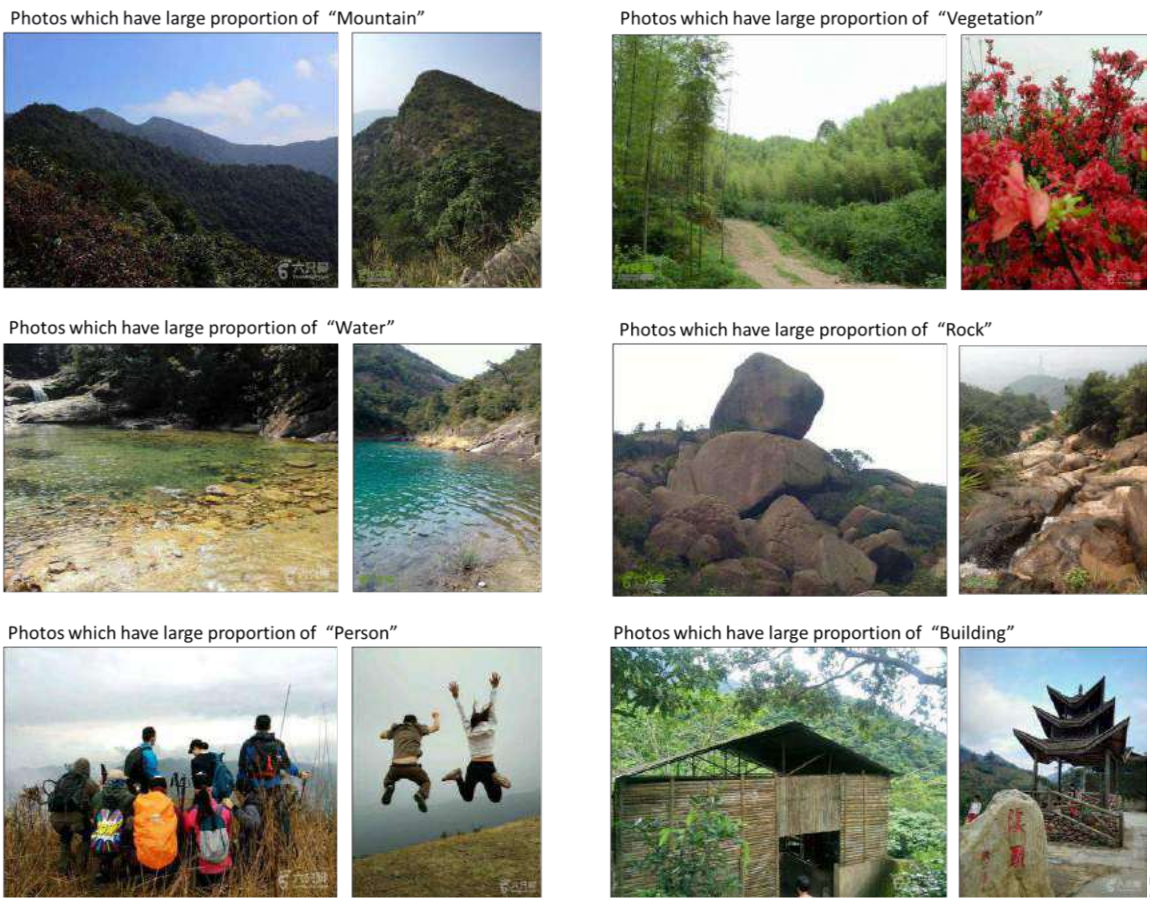

Figure 9: Photos with different main content

For every photos, we calculated the relative proportion of each type of content in all photos to achieve standardization. Since one spot usually has more than one attractive content, we selected two representative tags including a primary tag and a secondary tag for each attractive spot. The primary tag represents the first dominant content of the photos and the secondary tag represents the second dominant content. These tags can tell us the types of the attractive spots and contents of the majority of photos taken by hikers.

4.3 Distribution of Different Types of Attractive Spots

Different types of attractive spots have significant differences in attractive contents and location distribution. For example, the attractive spots with the tags of "Mountain" are generally places for enjoying the distant mountains with a good view; the attractive spots tagged by "Vegetation" often have beautiful plants; the attractions of spots tagged by “Water”, “Stone” and “Building” generally have close view of landscape; the attractive spots with the "Person" tags are places where hikers usually stay for a longer period of time and take portrait photos and they are usually the starting places or the resting stations of the routes.

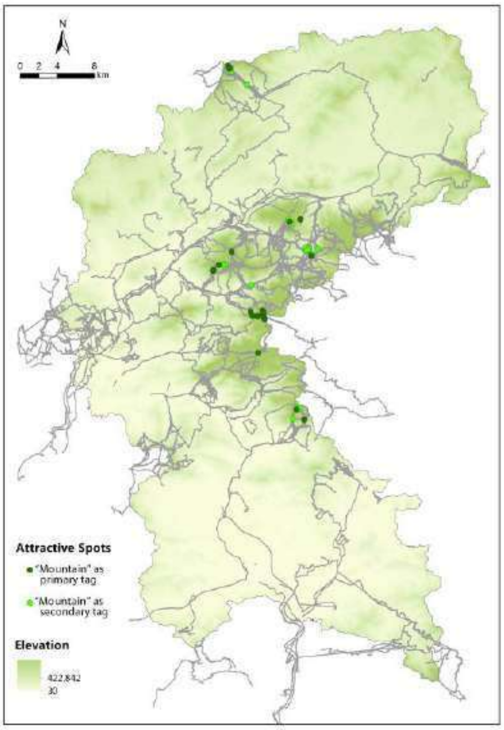

Figure 10: The spots tagged by “Mountain”

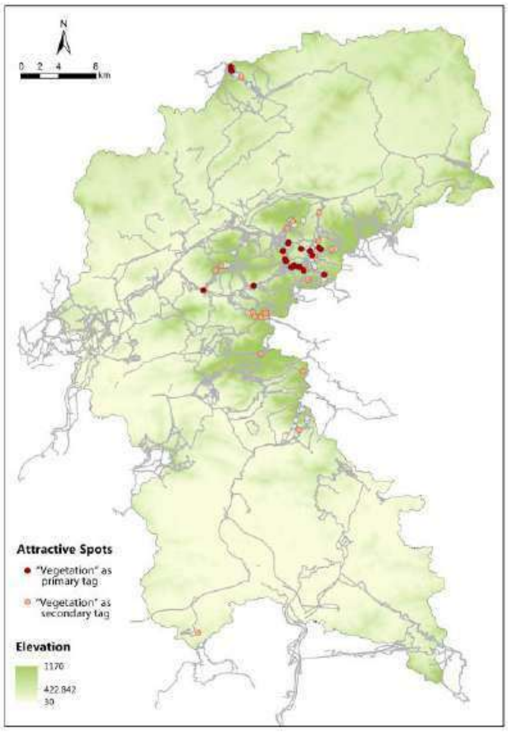

Figure 11: The spots tagged by “Vegetation”!

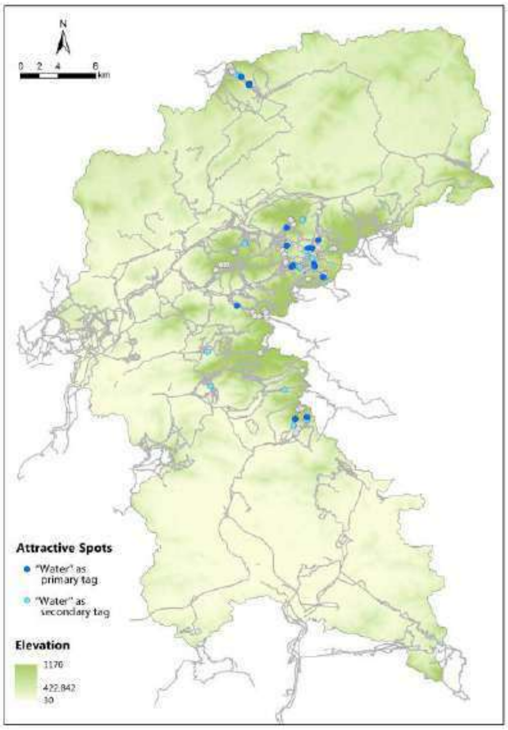

Figure 12: The spots tagged by “Water”

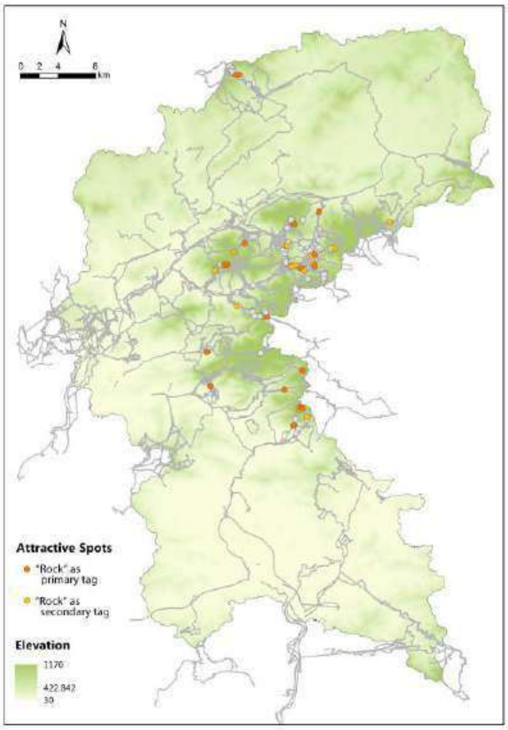

Figure 13: The spots tagged by “Rock”

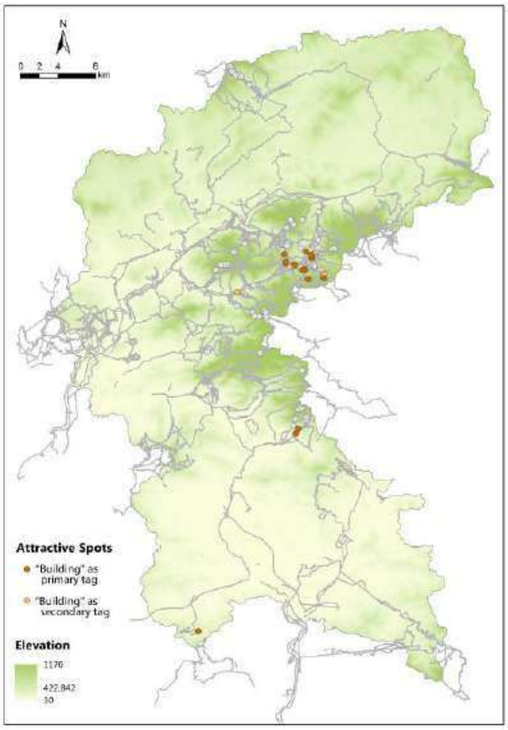

Figure 14: The spots tagged by “Building”

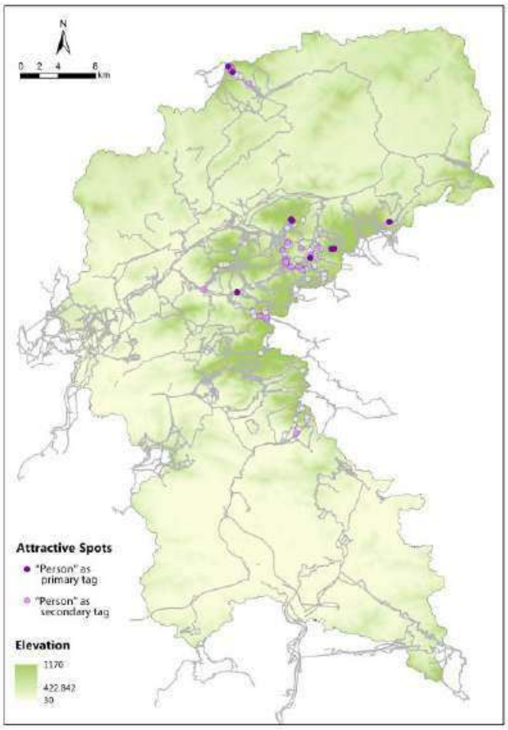

Figure 15: The spots tagged by “Person”

The elevation and slope information of each attractive spot were obtained to analyze the distribution characteristics. It is seen that the attractive spots tagged by “Mountain” are the highest in elevation and slope comparing with other categories. And they mostly occurred on the top of the mountains or on the slopes. The spots tagged by “Vegetation” are widely distributed in various elevation and slope. They are always in mountainous area which is dense with vegetation. The spots with tags of "Water" have wide distribution of elevation but most of them have gentle slope, indicating that the places with charming water view are distributed at different elevations, but the water banks are slow in slope. The spots with tags of "Stone" have low elevation distribution similar to the spots tagged by "Building", but the slopes of these spots are higher. The attractive spots with the " Person " tags where hikers take portrait photos as souvenirs are most widely distributed in elevation and slope. There is not specific relationship between these spots and their topography. They are mainly choices for resting places.

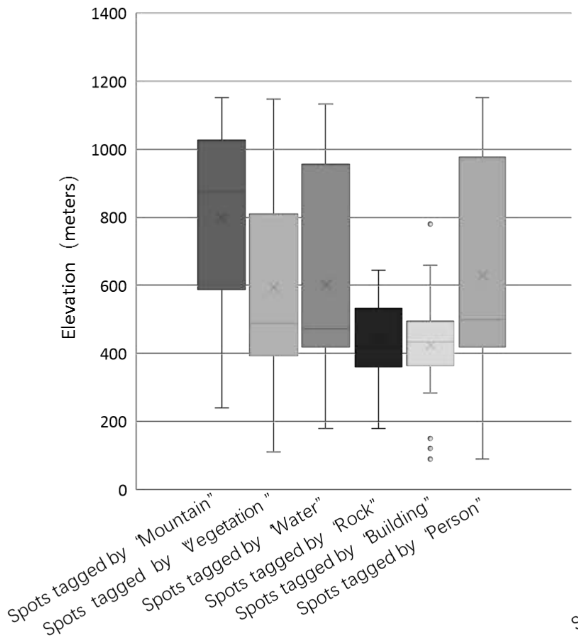

Figure 17: Distribution of elevations of the spots

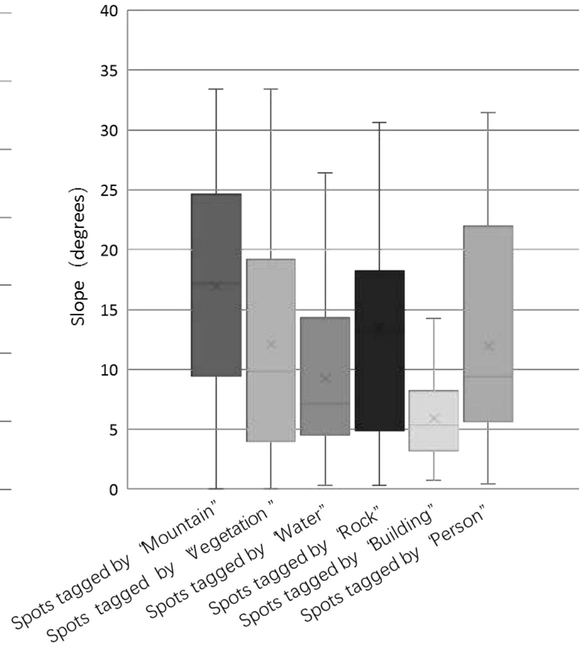

Figure 18: Distribution of slopes of the spots

5. Conclusion and Discussion

Hiking in the outskirts of mega cities as a kind of environmentally friendly and sustainable urban tourism has significant benefits. For a long time, Internet has been the major information media for hiking tourism, continuously expanding the market scale (Huang, 2005). This study used geo-tagged photos on social networking sites to detect the attractive spots of hiking tourism. It provides new ideas and directions for the study of hiking tourism. The attractive spots obtained using this method can provide basis for the planning and management of hiking tourism. For example, these spots can be places to provide travel services after being fully equipped with service facilities. Besides, these places are where the hikers prefer to stay, so they easily tend to be crowded. The security protection facilities and the measures to prevent congestion should also be considered. The improvement of the landscape quality of the spots based on their tags is also very important. For example, the spots tagged by "Mountain" are generally places to enjoy the distant mountains, so they should be ensured to have good visions. While the attractions of spots tagged by "Water", "Stone" and "Building" always have close views, the promotion of the original landscape and the addition of new landscape structures can be taken into consideration.

The method used in this study has great potential in the planning and management of hiking tourism, but there are still some limitations: 1) The chosen social networking site is mainly targeted to groups loving hiking and reflects the information of many hikers, but it cannot fully cover all the information of hikers. 2) If the satellite signals are not good enough in some jungle districts, the geo-tagged information may be biased (Taczanowska, et al, 2008).

With the development of social networking sites and GPS technology, the information of geo-tagged photos shared on the Internet will become more abundant, comprehensive and accurate. In actual planning and management, the attractive spots of hiking tourism obtained by this method can provide effective early guidance. However, in the process of deepening planning and management, this method needs to be combined with on-site investigation because on-site investigation can verify the results obtained using this method and provide corrections.

A study of Japanese neighborhood communities expected to work during climate change-related natural disasters – from the religious diversity perspective

Kasumi SUSAKI, Ryukoku University, Japan

Abstract

In Japan, neighborhood organizations are expected to work during large-scale natural disasters, and municipalities have begun encouraging their activities. Some of their activities are related to shrines or temples. Therefore, the way in which the neighborhood organizations are used as a tool to create social capital by municipalities is an issue from the perspective of religious diversity. Moreover, the relation between neighborhood organizations and municipalities warrants examination. In this study, the issue is investigated and the results are reported.

1. Introduction

1.1 Background and objectives

In addition to climate change, the number of natural disasters has been increasing and it has become difficult to predict where they will occur next. After Higashi-nihon Daishinsai (the Great East Japan Earthquake), the Japanese government began promoting mutual aid with neighbors. Numerous studies have highlighted the importance of social capital when huge disasters occur (Iwagaki, Tsujiuchi and Ogihara, 2017) (Yoshizawa, 2017).

Traditionally, Japanese neighbors establish neighborhood organizations that are based on specific areas. Each neighborhood organization has its own separate area, which does not coincide with the area of another neighborhood organization. Therefore, there are differences in their operations, role sharing within the organization, and relationships with municipalities

Recently, many reports and books have described neighborhood organizations' issues, including a decline in the percentage of households that are organization members and, a shortage of members, who work for the organizations. Therefore, depending on the area, the municipalities have begun encouraging neighborhood organizations. Historically, Japanese neighborhood organizations fulfill functions such as providing mutual aids, accomplishing cooperative work with municipality, representing their area, and conveying the opinions of the community, this is one form of community participation in Japan.

This study focuses on how the municipalities use the neighborhood organizations as a tool for creating social capital. The treatment of these organizations by the municipalities reveals the position on religious matters.

1.2 Previous research

There is considerable research on neighborhood communities and neighborhood organizations in the field of Sociology, and etc. These studies have examined and analyzed as a neighborhood organization as a local organization having historical or traditional meanings (Ajisaka and Komatsu, 2008). They have also analyzed the relations between municipalities and neighborhood organizations. Kamiya (2014) analyzed neighborhood organizations as a tool for encouraging social capital. Neighborhood organizations have also been studied as representatives of community (Nakada, Yamazaki and Kogiso,2017) (Nakada, 2000) (Nawada, 2009). However, few studies have examined neighborhood organizations from the perspective of religious diversity (Susaki, 2016) (Susaki, 2017), and no study has analyzed the relationship between municipalities and neighborhood communities from the religious diversity perspective.

1.3 Research method

In this study, neighborhood organizations of two municipalities the Shinagawa ward, Tokyo, and Kyoto City were compared and analyzed. Both Kyoto City and Shinagawa ward have regulations that encourage local communities and neighborhood organizations, respectively. However, since their aims and contents substantially differ, these two municipalities and their neighborhood communities were compared.

For comparison purposes, documents published by these municipalities were collected from websites or other sources. In addition, phone interviews were conducted with the persons concerned with this matter at both municipalities. Initially, the plan was to distribute questionnaire surveys to neighborhood organizations in both municipalities; however it could not be realized because of the Act on the Protection of Personal Information.

2. General situation of neighborhood organizations

2.1 Neighborhood organizations in Japan

According to The Cabinet Office (2007), 93.6% of Japanese areas have a neighborhood organizations; moreover, the area size of 72.3% of these neighborhood organizations smaller than that of an elementary school. The average number of households that are members of neighborhood organizations is 600 and the membership percentage is 89.2%.

The listed responsibilities of neighborhood organizations include delivering information of their events, distributing their newsletters, and establishing communication among their members; 90.8% of the neighborhood organizations fulfill these responsibilities. In addition , among these organizations, 78.5% inform the community about topics from the municipalities, 71.2% organizing festivals and Bon dancing; notably these are the top three responsibilities of the organizations. The following fourth and fifth responsibilities are managements of street lamps, fulfilled by 66.3% of neighborhood organizations, and reporting requests of members to the municipalities, performed by 64.2% of neighborhood organizations.

There are many areas with other active residents' organizations or associations, such as women's association, children's association, and voluntary local fire brigades.

A major characteristic of Japanese neighborhood organizations is that they historically provide mutual aid. In Japan, there is no period in which mutual aid and corporation with municipalities has not been needed. Mutual aid and corporation with municipalities is the basic responsibility of Japanese neighborhood organizations; this primarily separates them from local communities in European countries.

Even though, neighborhood organizations are responsible for mutual aid and corporation with municipalities, there are no legal ground for fulfilling them. This is the second characteristic of Japanese neighborhood organizations (Nawada, 2009).

2.2 Neighborhood organization in the Shinagawa ward

The Shinagawa ward, Tokyo, has 201 neighborhood organizations. The entire Shinagawa ward area is covered with neighborhood organizations without any over laps. Neighborhood organizations are divided into five groups, depending on their geographical area (Shinagawa, 2016b).

The population of the Shinagawa ward is 392,213, with 379,478 Japanese and 12,735 foreign residents (Shinagawa, 2016c). The average number of households in one neighborhood organization is 595 (Shinagawa, 2016a). Neighborhood organizations in which the number of households is less than 500 is 48.5%; more than half of the neighborhood organizations are constituted by more than 500 households.

The histories of neighborhood organizations vary depending on the geographic location and other factors. The oldest neighborhood organization was established in 1903; 16 (14.3%) neighborhood organizations were formed before World War II. Most of the organizations were established from 1946 to 1989 (after World War II).

The most popular activity of neighborhood organizations is the conducting the "disaster emergency drill." This activity is performed by 95.8% of the neighborhood organizations. The second most popular activity is "a fund-raising campaign for Red Cross," which is carried out by 95.7% of the organizations; organizing "festivals" is the third most popular activity completed by 90.2% of the organizations. Considering the activity list of each neighborhood organization, "festivals" imply not only festivals of shrines but also events such as Hanami (watching cherry blossom and eating and drinking near the trees). The fourth and fifth activities are providing mutual aid for "ceremonial occasion," performed by 87.1% of the organizations, and "cleaning up their neighborhood," undertaken by 86.5%.

According to the recognition of neighborhood organizations, the top two important activities are "disaster emergency drill" and "festivals," as chose by 67.3% and 64.3% of neighborhood organizations, respectively (Shinagawa, 2016a).

As mentioned above, "festivals" are of two types . One is related to shrines or temples and the other has no relation to shrines or temples (Shinagawa, 2016b); it is an event for the community. Festivals related to shrines or temples have religious meanings and there are some members who do not support and participate in them because of their faith (e.g. if they are Christians). According to Susaki (2017), they have less trouble in avoiding participation in these activities

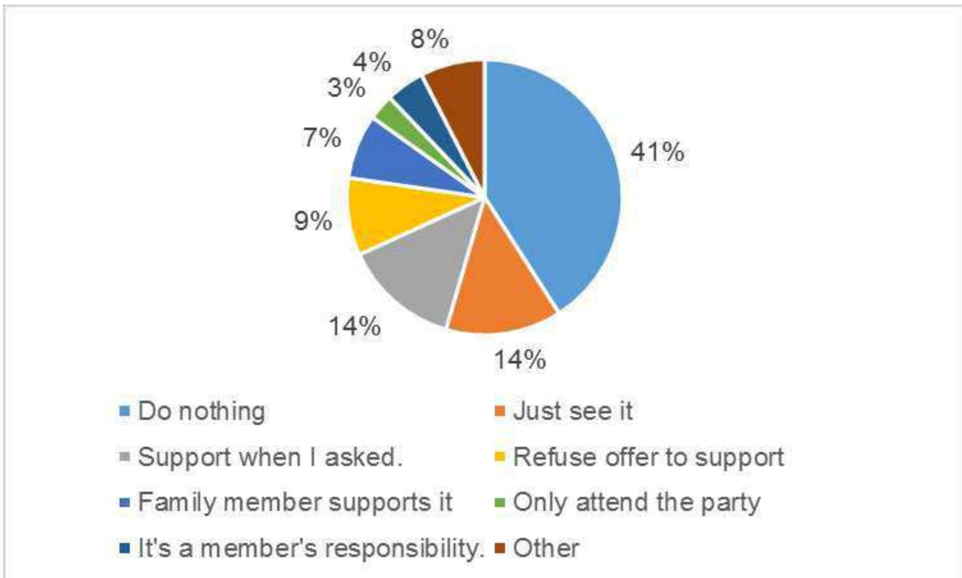

Figure 1:How do you deal with festivals of shrines or temples ?

Reproduced from Susaki (2017)

Figure 1 presents the results of a questionnaire survey administered to the Christian members of neighborhood organizations in all 23 wards of Tokyo (Susaki, 2017).

Some neighborhood organizations have their website on which they announce their activities (Figure 2) or they use the website of the Shinagawa ward municipality, on which there are information pages for all neighborhood organizations.

Figure 2: An information of festival of shrine

Reproduced from Shinagawa (2018)

2.3 Neighborhood organizations in Kyoto City

The inner areas of Kyoto City have a history that date back to 794 (beginning of Heian era) generations of emperors lived there until 1869. In those areas, the masses established very closely connected neighborhood organizations in the 14th century, which laid the foundation for the current neighborhood organizations. In other area of Kyoto City, organizations historically based on communities of shrines are common and some have strong connections (Ajisaka and Komatsu, 2008).

Local communities in Kyoto City have specific feature called “Gakku,” which is based on “Cho-gumi,” a neighborhood organization from the Muromachi era (in 14th century), and “Bangumi-Shogakko (Numbered elementaly school)” from 1870 (the beginning of Meiji era).

Although the “Gakku (or “Moto-Gakku”)” is different from the current elementary school district, they are kernels of local community in Kyoto City. Overall, Kyoto City has 222 “Gakku” and each “Gakku” has neighborhood organizations; in some cases, other local organizations are also included in “Gakku” (Kyoto, 2016).

Kyoto City has 11 wards and each ward office has the most information about “Gakku,” however, the Kyoto City website does not clearly indicate whether one “Gakku” covers two wards or not.

The total population of Kyoto City is 1,412,293, which includes more than 40,000 foreigners (Kyoto, 2018).

Figure 3: Jizo-Bon

(Sakurai, 2015)

The percentage of members in neighborhood organizations is approximately 69.8%. Furthermore, 42.5% and 75.4% of neighborhood organizations have less than 50 and less than 100 households, respectively. Each neighborhood organization performs two types of activities. One is their own activity and the other are activities associated with the Gakku. A total of 76.9% of neighborhood organizations consider “Jizo-Bon” as their own activity while 72.6% and 46.5% of organizations list “providing mutual aid for ceremonial occasion” and “having dinner or undertaking a friendly “ as their own activity, respectively (Kyoto, 2012).

“Jizo-Bon” is organized in two ways; one, as an event for children and the other as a religious event. For the latter, a Buddhism monk is invited to recite sutras and perform several rituals to pray for Jizo; on the other hand, the event for children is similar to a children’s festival (Maeda, 2015). There are members who do not participate in this type of event because of their faith. Susaki (2016) observed that it is difficult to avoid participating in these events.

Figure 3 depicts a Buddhism monk sitting in front of an altar that is enshrined with Jizo; the monk is reciting a sutra. Children participate in this Buddhism ceremony and worship Jizo. This event is organized in the last week of August in most parts of Kyoto City by neighborhood organization.

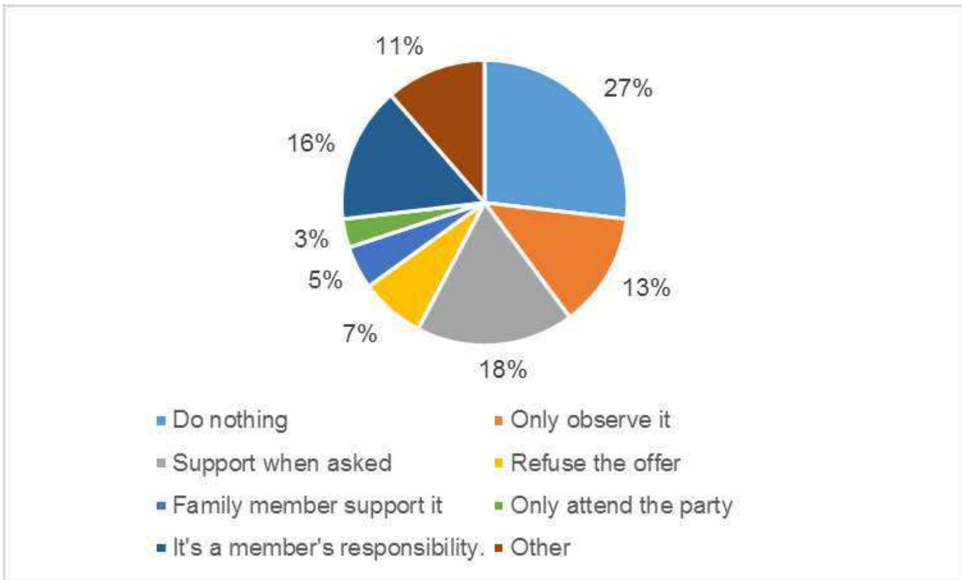

Figure 4: How do you deal with festivals of shrines or temples ?

Reproduced from Susaki (2016)

Figure 4 presents the results of a questionnaire survey administered to the Christian members of neighborhood organizations in Kyoto City (Susaki, 2016).

The most popular "Gakku" associated activity is "A field day or sports events" and it is performed by 71.4% of the "Gakkus," the second most popular activity is the "disaster evacuation drill," which is conducted by and 68.7% of the "Gakkus" (Kyoto, 2012).

2.4 Comparison on neighborhood organization activities in the Shinagawa ward and Kyoto City

In the Shinagawa ward, neighborhood organizations are more recent than those of Kyoto City; no neighborhood organization in this ward has a history that dates back the beginning of Meiji era. Furthermore, some neighborhood organizations in this area conduct festivals of shrines as their events. However, most members of the neighborhood organizations in the ward are not so earnest and members who do not participate can prevent others from participation (Susaki, 2016).

In Kyoto City, neighborhood organizations have long history and, more importantly, they have inherited traditional events. In addition, some of the traditional events have religious meanings, and therefore there are members who participate in such kind of events, although reluctantly (Susaki, 2016). In Kyoto City, a single neighborhood organization has a small member of households., compared with that in the Shinagawa ward. Moreover, the organizations in this city have a specific feature called "Gakku," which is lack in the Shinagawa ward.

3. Relationship between neighborhood organization and municipality

3.1 Shinagawa ward municipality

In 2016, the Shinagawa ward municipality implemented a regulation that encourages neighborhood organizations. The regulation establishes legal position of neighborhood organizations. According to the first interview with the responsible person in the office of the Shinagawa ward in 2016, they are aware that festivals, which have religious meanings, are in the activity list of some neighborhood organizations and that some members of the neighborhood organization want to prevent such kind of activities because of their faith.

According to the second interview with the officer, the regulation was implemented as a result of committee meetings. The aim of the meetings was not to create regulations, but to find a way to promote cooperation between the neighborhood community and the Shinagawa ward municipality. Following the implementation of the regulation, residents of the Shinagawa ward can become a member of their living area's neighborhood organization by simply posting a card without a stamp. One of the effects of the regulation, which the municipality officers had heard from leaders of neighborhood organizations, is that the explanation of neighborhood organization becomes easier than before, when they invite new residents to the organization, because the organizations now have a legal position.

Figure 5: Neighborhood organizations are clearly assigned on the map

Reproduced from Shinagawa (2017)

In addition to the implementation of the regulation, the municipalities has increased the amount of supported money provided to neighborhood communities that fulfill tasks assigned by the municipality. This makes it easier to run the neighborhood organizations. Before the implementation of the regulation, the Shinagawa ward municipality set a committee and conducted meetings. The records of the meetings are available for public viewing on the Shinagawa ward website (Shinagawa, 2014). There were many discussions in these meeting and on typical agenda was changing the boundaries of neighborhood organizations because of the situation of roads that have considerable traffic.

In the Shinagawa ward, the relation between the municipality and neighborhood organization is very clear and visible, it can be easily understood by everyone.

3.2 Kyoto City municipality

The aims implementing regulations include the establishment of a local community in case of disasters, since, in Japan, the number of children is decreasing and the number of elderly people is increasing; moreover, the number of residents who do not become members of neighbourhood organizations was increasing (Kyoto, 2016).

In Kyoto City, the relationship between the municipality and neighbourhood organizations is completely different from that of the Shinagawa ward. The regulation encourages local community activities; however, the neighbourhood organizations are the only actor. Moreover, the Kyoto City municipality and neighbourhood organizations do not have direct contact.

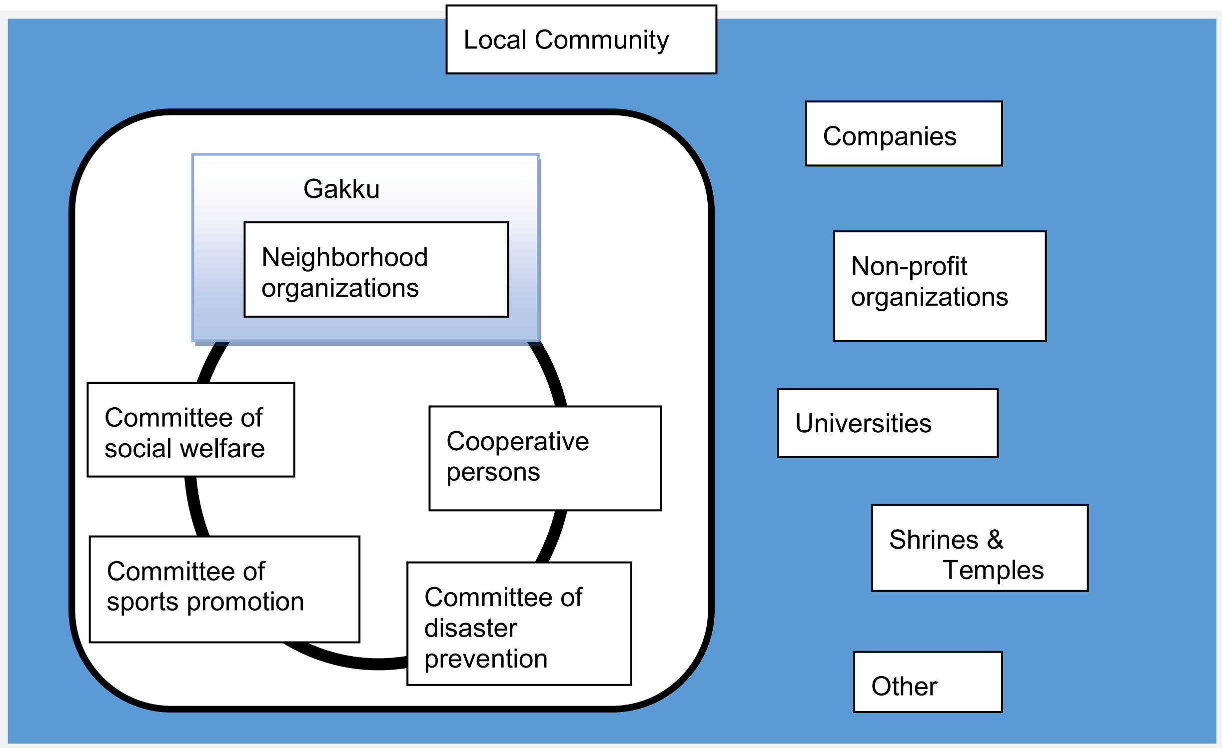

Figure 6: An image of local community

Created and translated in English by referring to Kyoto (2016).

According to the regulation, the Kyoto City municipality developed a plan to encourage local communities, which comprise neighbourhood organizations, other area based organizations, and cooperative persons from Kyoto City municipality, who are part time officers. The regulation assigns a legal position to cooperative persons from the Kyoto City municipality; their responsibilities include delivering municipal documents, collecting information required by the municipality, and communicating the requirements of residents, who are in the assigned area, to the municipality. Cooperative persons are assigned depending on the population of each area and all persons have their assigned area. They are assigned by the Mayor of Kyoto City and they attend the meeting assigned by “Gakku” to communicate with each other. The Kyoto City municipality connects with its residents via these persons.

In the Kyoto City plan (Kyoto, 2016), local communities are organized by neighbourhood organizations, other organizations supported by residents in the area, companies, universities, non-profit organizations (NPO), other organizations supported by non-area based residents, temples, shrines. Figure 6 presents the organization of local communities.

After trying for several years, the Kyoto City municipality is aware that it is difficult to reconstruct organizations in each area; the current position of Kyoto City is to maintain the current structure in each area. Furthermore, the Kyoto City municipality attaches importance to residents’ autonomy, which has a long history; the municipality is proud of this autonomy and considers the strength of the city.

The plan precisely explains how a neighbourhood organization should be constructed. According to the interview responses, new neighbourhood organizations are sometimes constructed in newly developed residential areas or areas with newly built condominiums. However, whether it is better to establish a new neighbourhood organization is another matter. If residents do not establish neighbourhood organizations, there are no neighbourhood organizations in that area. From the beginning, coordinators, who are officers of the Kyoto City municipality, have participated in the discussion on how to do it.

When neighbourhood organization wants to restructure and needs supports, these coordinators provide the necessary support in the process.

According to the plan, the local community includes temples and shrines, which is an important point from perspective of religious diversity. The interview responses related to this point suggested that many neighbourhood organizations have strong connections with shrines or temples and some of them list the activities of shrines or temples as their main activity. Therefore, argument from the perspective of religious freedom, the regulation and plans state that the local organizations are independent of the Kyoto City municipality and that they are organized solely based on the agreement of the participating residents; this seems tricky, but it is legal.

In Kyoto City, local communities, including neighbourhood organizations, are invisible and difficult to understand to individuals from other cities; apparently, it is not easy finding out how to become a member of a neighbourhood organization.

3.3 Comparison between the municipalities of Shinagawa ward and Kyoto City

The Shinagawa ward municipality directly supports neighbourhood organizations; the relationship is clear and visible for everyone. All neighbourhood organizations are introduced on the municipality’s website and the area where a neighbourhood organization is located is clearly indicated, as shown in Figure 5. Moreover, the activities of each neighbourhood organizations are announced both on the website and in the guides of each neighbourhood organization. The restrictions on members to participate in festivals with religious meaning are weak; they can select their place of residence after checking the activity lists of each organization.

The Kyoto City municipality supports many kind of organizations in the local community and each has its own history and background. These organizations are independent and the municipality cannot reconstruct them. The boundaries of the Gakku or neighbourhood organization are sometimes ambiguous, and therefore the Kyoto City municipality is unable to create maps, such as Figure 5.

There are many neighbourhood organizations, that have a strong relationship with shrines and temples. A member of such neighbourhood organizations is expected to support the festivals of shrines.

Unlike the Shinagawa ward, the activities of each neighbourhood organization are not open; moreover, a person who wants to live somewhere in Kyoto City cannot chose his or her best area to live from a religious perspective.

4. Conclusion

The use of neighborhood organizations as a ways to encourage social capital in the Shinagawa ward and Kyoto City differs significantly. The Shinagawa ward municipality uses neighborhood organization as a core of social capital, while the Kyoto City municipality uses these organizations as one actor of social capital.

The Shinagawa ward municipality has begun cooperating with neighborhood organization. The Kyoto City municipality, on the other hand, first planned to cooperate with neighborhood organizations or Gakku, but the neighborhood organizations or Gakku in this area are too independent to be modified. Therefore, the Kyoto City municipality recognizes the value of self-governance of Gakku or neighborhood organizations; moreover, it does not have direct access to these organizations.

From the perspective of religious diversity, everybody can know about the activities of the neighborhood organization and can select the most suited place for residing in the Shinagawa ward. It is presumed that the percentage of neighborhood organizations that have a relation with shrines or temples is higher in Kyoto City than in the Shinagawa ward. Furthermore, obtaining information of neighborhood communities is more difficult in Kyoto City than in the Shinagawa ward. Therefore, it is difficult to find a suitable place to keep their faith .

Which way of encouraging social capital is more effective is another matter.

Citizen participation for increased sustainability and quality of life in cities in Nordland County

Amsale TEMESGEN, Nord University, Norway

Bjørn Vidar VANGELSTEN, Nordland Research Institute, Norway

Mònica Guillen ROYO, TIK Centre for Technology, Innovation and Culture, University of Oslo, Norway

1. Background

About half of the world's population lives in cities today and by 2050 the figure is expected to rise to 70 percent. Seventy per cent of all greenhouse gas emissions and 60 per cent of all energy consumption takes place in cities. Cities also produce 70 per cent of all waste. Cities are thus both the problem and the solution to many of the major environmental and societal challenges, and this fact is reflected in the UN's sustainability development goals (SDG).

Urbanization and centralization are ongoing social processes in Nordland county in Northern Norway, affecting the population and their quality of life. The ten largest cities in Nordland county account for 68 percent of the region's population. They also provide 72 percent of the employment in the region. However, population growth in the county has been modest compared to the national average. Emigration to the capital (and other cities), aging population, and unemployment are continuous challenges for the region. To address these challenges, Nordland County's regional plan for city and regional development aims to develop compact, sustainable and innovative cities. A key element is to strengthen attractivity of the city as a place to visit and to live in.

1.1 Description of study site: Svolvær

The municipality of Vågan, located in the Lofoten archipelago in Nordland county, has a population of about 10 000 people. Its administrative center is the city of Svolvær, the largest city in the Lofoten region with a population of about 5000 people. Key business sectors are tourism, fisheries and aquaculture, fish processing- and mechanical industry in addition to typical urban sectors like finance, insurance and other services (SSB, 2018). About one fourth of the jobs in the municipality are in the public sector (Hjelseth et al., 2016:21). Traditionally being a center for the renowned Lofoten winter fishing, the relative importance of the fisheries sector measured in number of jobs has been reduced in the later years, while the importance of the tourism sector has been growing rapidly. After a dip during the early 2000s, the population has been growing since 2008, caused by net positive immigration (Hjelseth et al., 2016:18).

The growth in the tourism and service sectors have contributed to increased optimism and helped create an urban atmosphere in Svolvær. This, on top of the spectacular nature in the region, attracts not only tourists but also people that wish to establish a new life in Vågan and enjoy the mix of urban and natural qualities. The growth in population, and particularly in tourism has also led to local debates on the sustainability of the development with new challenges like increased housing prices and pressure on land use. During the peak tourism season the local population face challenges with inadequate waste management, pressure on natural resources and overcrowding.

Despite the growth in tourism, Vågan, as is the case for many municipalities in rural Norway, has experienced a steady outflux of Norwegian citizens towards the larger cities. This is particularly the case for young people. Vågan also scores lower than the Norwegian average on indicators for health and quality of life, a common trait for most of Northern-Norway (Vågan municipality, 2017:11). To counter this tendency, Vågan established a project aiming to produce new knowledge on how children and young people can live “the good life” in Vågan. Despite some positive effects, significant results have not been achieved partly because of lack of sufficient dialogue and mobilization of young people in the project (Vågan municipality, 2017:11).

The municipality is currently in a process of revising its community plan for the period 2018-2030, and wish to base this plan on holistic and updated knowledge, including through new and innovative methods for citizen involvement. The key question to be answered are related to how to secure a sustainable development for the citizens. This relates to what type of growth the municipality should promote through its policies, including what type of tourism is sustainable in the long run. Another question is related to cultural heritage and traditional fisheries: what is the significance of this heritage both in terms of local culture and attractiveness as a tourism destination, and how can this sector be protected and developed. Through citizen dialogue, the municipality wants to learn more about key positive and negative aspects of the recent development and the key premises for quality of life in Vågan.

2. Method for citizen participation: Needs based workshops

A sustainable urban development requires the active involvement of citizens and critical reflection on the paths of societal development. Participation of citizens in policy design also increases quality of life. This is because participation in itself is meaningful, builds trust, and not least, because it stimulates policy and planning that facilitates high quality of life. Citizen participation processes are, however, challenging in practice. Although the purpose of citizen participation is to facilitate dialogue between stakeholders with different interests and planning authorities, it has proven difficult for many citizens to understand and participate actively in complex and long-term planning processes. Many politicians and planners have challenges in creating commitment and involvement in more comprehensive decision-making processes. Furthermore, it is demanding to translate inputs that have come through these processes into policy decisions.

In this project, we will adopt Manfred Max-Neef's Human scale development (HSD) approach to involve citizens in identifying paths (and policy recommendations) that satisfy both human wellbeing/quality of life and environmental sustainability. Max-Neef differentiated between needs and satisfiers (Max-Neef 1991). Human needs are essential for wellbeing and are universal across cultures and historical periods. The means to satisfy these needs (satisfiers) vary between cultures, traditions and historical periods. He organized human needs as a matrix with two categories: existential and axiological needs. There are nine axiological needs: (1) subsistence, (2) protection, (3) affection, (4) understanding, (5) participation, (6) leisure, (7) creation, (8) identity, and (9) freedom and four existential needs: (1) having (2) being (3) doing and (4) relating (Max-Neef 1991). 'The key idea here is that humans do not have primary needs for the products of the economy. The economy is only a means to an end. The end is the satisfaction of primary human needs. Food and shelter are ways of satisfying the need for subsistence. Insurance systems are ways to meet the need for protection. Religion is a way to meet the need for identity' (Costanza, Cumberland et al. 2014, p.158).

A community can come together and identify satisfiers that are relevant for their particular context and time. Max-Neef and colleagues designed workshops to assist this process and to identify key institutions, (individual and community) characteristics and actions that satisfy fundamental human needs and increase quality of life. A matrix that contains the nine axiological and four existential needs (see table below) is used in this process.

	Being (individual or collective qualities)	Having (resources, tools institutions, norms)	Doing (personal or collective actions)	Interacting (settings and environments)
Survival				
Protection				
Affection				
Understanding				
Participation				
Idleness				
Creation				
Identity				
Freedom				

Table 1 Matrix of needs and satisfiers (template). Source: Max-Neef (1991)

The workshops are organized in two steps by a group of 12-20 individuals representing their community. In the first step, the group is divided into two. One of the groups identifies hindrances for actualizing fundamental human needs and achieving a good quality life. The matrix they fill in this process is called a negative matrix. The other group identifies the ideal situation for actualizing fundamental human needs, the ideal scenario. The matrix the group produces in this process is called the positive matrix. In the second stage, the two groups come together to discuss how the community can move from the negative to the positive matrix. In this process, they identify the role individuals and communities play in moving towards the ideal situation. They also identify policy measures at the regional and national level that contribute in this process.

The workshops are flexible and effective at identifying challenges and solutions relevant to policy design. They illuminate processes and mechanisms that promote or hinder people's quality of life and the sustainability of the natural environment. Needs based workshops have been used in some regions, cities and communities in Europe, the United States and South America to identify community- and policy relevant measures that contribute both to human wellbeing and environmental sustainability.

3. Results

(Forthcoming)

Following the description given above, we will organize workshops with participation from selected segments of the population to explore the interlinkages between personal, local and global factors that determine current hindrances and opportunities for sustainability and wellbeing in Nordland county. The outcome of the structured workshops are proposals for community/group, local and regional level-policy initiatives and a greater understanding of their interlinkages and trade-offs. The workshops will be implemented in early September and preliminary results from these workshops will be included in the updated paper we will submit 20th September. The results will also be presented at the ISOCARP congress in Bodø, 01- 05 October 2018.

4. Concluding remarks

(Forthcoming)

Multi-dimension urban planning in renewal of the old city ------ a case study of urban renewal project in QuYang, Shangahi ,China

Xia, Huiyi; Qian, Renzan; Yan, Cunay; Xia, Nankai, SHANGHAI, China

ABSTRACT:

Community changes with the development of market economy. The differentiation and diversification trend of residents' needs has become more and more obvious. In the context of China's New Normal, inventory planning requires communities which has been built to improve quality and efficiency. However, the configuration standards we used now are unable to adapt to the needs of both. Under the conditions of traditional community management systems and mechanisms, the ability to integrate community resources is poor. This kind of management tends to cause uneven distribution of resources and waste. Social management and social service network is an important way to solve such problems.

This study is based on the foundation of the old city renovation plan. We build a data platform for third parties, which including: government management platform, property management platform and convenience service platform. We use these data platforms to improve community management and living services. We can improve management systems and mechanisms in communities. We can integrate community management resources and establish a new mode of community "networked" management services. The community's grassroots social management is strengthened by the platform. Social conflicts are resolved. Social harmony is promoted. We use the method of minimal adjustment and multi-dimensional planning to achieve the purpose of the transformation of the old city. After such transformation, the community has improved the functions of community management and services.

The research workflow includes the following steps:

(1) Preliminary demand survey;

(2) Data analysis;

(3) Integration of resources and planning adjustments to form a feasibility plan;

(4) To build a web platform, and setting up a client client and offline services;

(5) Obtaining big data through operation management, according to which data can be adjusted for programs and services, and at the same time form a report.

We conduct surveys on the needs of public services and facilities through established mature communities, establish basic databases, and use the Internet and mobile Internet technologies to build community public service interactive platforms based on this. We provide real-time information on the supply and demand of community public services, and master basic public services in a timely manner. We master the actual needs of basic public services and facilities (ICMP system) timely. Based on these more real and detailed demand information, the demand and structure of community public service and facility resource allocation are forecasted, and relevant planning indicators and planning and design requirements are provided for users, suppliers, decision makers and investors. The basis for reducing the gap between supply and demand provides more efficient and high-quality service (facilities) configuration for community planning and design, community construction, management, and development.

The Framework Research on Sustainable Conservation of Urban Building Heritage: Collaborative Visioning for the Future Based on the Complexity Theory

Guoqiang Wang, School of Architecture, Harbin Institute of Technology; Heilongjiang Cold Region Architectural Science Key Laboratory, China
Songfu Liu, School of Architecture, Harbin Institute of Technology; Heilongjiang Cold Region Architectural Science Key Laboratory, China
Yu Shen, School of Architecture, Harbin Institute of Technology; Heilongjiang Cold Region Architectural Science Key Laboratory, China

1. Introduction

As an important resource for stimulating economic growth, building heritages conservation and sustainable development has received increasing attention. However, the contradiction between urban development and resource protection is still a common problem[1]. Especially, the sustainability of building heritages in the cold regions of China are continually confronted with severe challenges such as the extreme environments anthropogenic effects, as well as the challenges in the process of globalization nowadays. The core is how to effectively coordinate and optimize the relationship between the conservation of heritages and the rapid improvement of economy and tourism. The identification of the priority areas and strategies is the key to realizing the optimization choice of the conservation behavior and achieving the sustainable development of heritages surrounding-environments in the development of urban system. Many experts have proposed attentions to conservation behavior and use empirical analysis methods to study the behavior characteristics that influence the sustainable-conservation of building heritages and their spatial environment, to seek a sustainable planning framework or to support for policy management[2].

Nowadays, with the rise of the scientific paradigm shift and model theory, and the development of the spatial data, the use of the complex model of urban-system and their evolution analysis become one of the important researches of urban theory. Some experts have proposed the new science of heritages drawing strengths from complexity theory. The starting point is the conference organized and chaired by the two authors in Singapore on "Heritages Science as a Complex System" [3]. In the research they proposed the concept that in keeping with the spirit of the entire collection, to use the language of complexity as a lingua franca and observe heritages through the lens of complexity to study emergent properties in human-heritages-landscape systems[4,5]. Some researches aim to address the question of how this acquirable knowledge can be linked to action (policy- and decision-making) by public and private institutions (local communities, government agencies, international organization, corporations) in the framework of a new science for the systematic study of the principle and use of heritages through observation and experimentation.

Though some advances have been made, most focus on individual building, and certain achievements have been made in the protection policies, laws and regulations, as well as individual building protection technology and methods[6,7]. Existing planning strategies mostly biased towards individual buildings maintenance and renovation suggestion rather than from a comprehensive conservation to consider the factors differences between different heritages and their surrounding-environments. In addition, less attention is paid to dynamic changes in the conservation, behavior.

Buildings heritages in cities is influenced by their immediate local environment factors such as local microclimate condition: temperatures, wind speed, air pollution levels, noise, access to daylight, etc. which can result in significant impacts in the sustainability of buildings heritages conservation. The heritages sites, their environment and function optimization are required to maintain a building heritage at acceptable local conditions. As well as the two-way of information transfer between the multi-stakeholder in the relevant cultural heritages sites and the urban planner also results the dynamic interaction the performance of conservation approach. Therefore, combining the Heritages Impact Factor Theory (SHIFT) and behavior-oriented framework are the vital connection between quantification simulation and decision-making, aiming to provide a down- top approach[8].

In this paper we typically referred these as Sustainable Heritages Impact Factors, these are largely anthropogenic, resulting from local agglomerations of density of buildings and population, behavior, activities, and occupant's knowledge and values of a region. We aim to investigate and identify how heritages data can be distilled into knowledge, so as to support political decision-making with scientific methods and evidence to reinforce the identities and values of all stakeholders.

Paper investigates the relative influences of three geospatial parameters by agents: local environment, policy index, and composition of building types (based on their function, values and social preference) in 13 districts of Shenyang Province of China. Based on the dynamic simulation with the multi-agent system, each agent expresses its own characters with the activity and protective behavior. According to the results of ABM proposed in different stages with the model how to choose and how to coordinate the behavior of each agent in a system prospective were proposed, and the protective behavior strategies were also proposed. With the qualitative as well as quantitative results drawn from the analysis, this paper proposes specific suggestions on how to improve the sustainability of buildings heritages sites in the urban context.

2. Method of Model Formulating

The theory of complex adaptability system is the components of functional system, where single agents in the environment and playing individual roles in their interactions and coordination [9]. In the context of the system the Multi-agent simulation method is a technique for bottom-up modeling, providing an alternative perspective to those that can be attained by using optimization approaches. In agent-based simulations, system behavior emerges from the behaviors of interacting agents. Its advantages have been widely recognized by the experts, but the application of heritages conservation and simulation research has just started[10].

Sustainable conservation of building heritages and their surrounding environment in urban system is a challenge, which needs an integrated research platform, and a common language. The decision-making of protection behavior in tourism destinations is a systematic decision-making process that links the executives of various behaviors.

2.1 ABM Model Behavior

As proved by exist research ABM is expected to contribute significantly to the study of behavior-environment interactions, and to provide a valuable tool for exploring the effectiveness of policy measures in city complex environments [11].This characteristic of ABM makes it a practical approach for simulation of policy and meanwhile, revealing the effectiveness of conservation policy.

The purpose of this research is to develop an agent-based analysis model for sustainability conservation of buildings heritages. This new environment is named CBAM from the initial letters of Conservation Behavior Analysis Model of building heritage. The new analysis environment aims at revealing the possibility of reflecting implementation effects of this conservation policy by local city of northwest of China.

An agent is an autonomous and potentially self-directed entity that is characterized by a set of attributes. Agents are situated in a system in which they interact with each other and their environment. The behavior of an agent is usually driven by its goals. The Multi-Agent-Based Modeling (ABM) method starts from analyzing the behavior of the individual agent, and modifying the behavioral characteristics of multiple agents through the system's rules, and the model will ultimately optimizes the system by conducting different behavior selection[12]. It has been widely used in simulation studies of socio-economic-environmental systems such as land use, urban development, and group behavior analysis[13].

We attempt to conduct simulation of conservation behavior strategies of building heritages through ABM in order to reveal the possibility of ABM on analyzing the implementation effects of promoting policy. The policy includes allowances for hierarchical and classification coordination system of conservation behaviors is established by ABM as shown in Tab-1.

Table 1: Conservation promoting policy in famous historical and cultural town or village.

OBJECT CATEGORY	POLICY description	
Building Heritage	Characteristics	The traditional pattern and the historical style and features are preserved in the buildings
	1. protection principles, protection contents and protection scope;	
	2. protection measures, development intensity and construction control requirements;	
	3. requirements for protection of traditional pattern, historical style and features;	
	4. core protection scope and construction control belt of the famous historical and cultural block, town or village; and	
	5. a phased program for implementing the protection planning.

2.2 Description of CBAM

In our research the decision-making of building heritages conservation is a systematic process of decision-making that links the performance of various behaviors. The foundation of multi-agent simulation is that each agent has the abilities of both behavior learning and adjustments, such as the historical buildings and their surrounding environments, tourists, enterprises, residents, local governments, are all in the large city system which have multi-hierarchy and dynamic interactions. Based on the interaction between various agents and the environment, the environment is link to the building heritages sustainable conservation behavior of multiple individuals in a complex urban system (Fig. 1).
In CBAM each building heritages and their surrounding environment will be further defined by a series of special attributes. Agent will make decision on new conservation strategies based

on the conditions of environmental historical culture and socio-economic as well as the local policies. Before conservation strategies are readjust, government agencies will firstly evaluate the utility and condition of current building heritages location. This process will produce a satisfaction evaluation of current building heritages condition location and hereby, decides the readjusted desire.

Therefore, this paper investigates the relative influences of three g eospatial parameters by agents: local environment, policy index, and composition of building types (based on their function, values and social preference) in 13 districts of Shenyang Province of China. Based on the dynamic simulation with the multi-agent system, each agent expresses its own characters with the activity and protective behavior, taking protection behavior preference as the interaction points. By analyzing the behavioral characteristics and interactions, this paper aim to build a multi-objective behavioral decision-making framework and to analyze the differences in conservation behavioral preferences of different agents from the micro-level and their impacts on building heritages and surrounding environmental systems. Then this paper explores the behavior characteristics of the overall behavioral decision-making of the conservation system, and compare with three different scenarios to optimize the selection of sustainable conservation behaviors for building heritages. The results are supposed to reveal the scientific and dynamic differences in decision-making for sustainable conservation of building heritages.

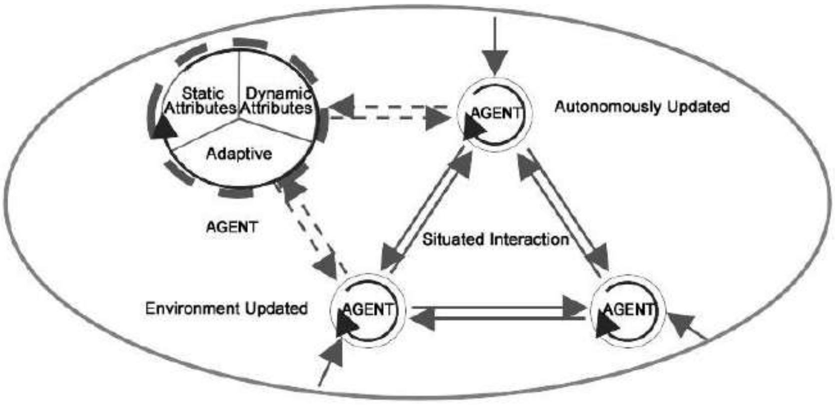

Figure 1: Cconceptual illustration of four interactions in ABM

In this work ,instead of using real persons as individual agents, five types person including Tourist Environmental practitioner government agencies, tourism practitioner Residents are defined as different behavior agents. Physical condition of building heritage and social-economic condition of their surrounding area are defined as agents in CBSM and behavior agents can make decisions after comprising with the attributes of conservation evaluation-indicators for single or groups of building heritages.

In CBAM, the rules of behavioral constraint are determined by three levels: the target level (behavior requirements), the criterion level (behavior preference), and the measure level (decision and measure).CBAM-ABM ranks the importance factors that influence decision making and builds the behavior decision-making matrix to select conservation behavior. Multi-agent simulation is an optimization for static analysis process, emphasizing the adaptability and micro-dynamic changes of the behavioral system from a macro-perspective with considers the interaction of the objects and agents[14].

The CBAM system consists of three layers, input variables, behaviors evaluation and output variables (Fig.2). The first layer is “Input variables” including the behavioral characteristics of the agents that directly influence the evaluation of behavioral performance, including surrounding environmental factors, natural environmental conditions, historical culture, and socio-economic conditions；The second layer is behavior evaluation which mainly indicates the behavioral preferences and influence intensity of different agents under certain conditions including tourists, urban planner, government authorities, community residents under certain conditions. The output variable layer reflects the optimization and adjustment of the system behavior after multi-agent simulation, which is the result of behavior decision.

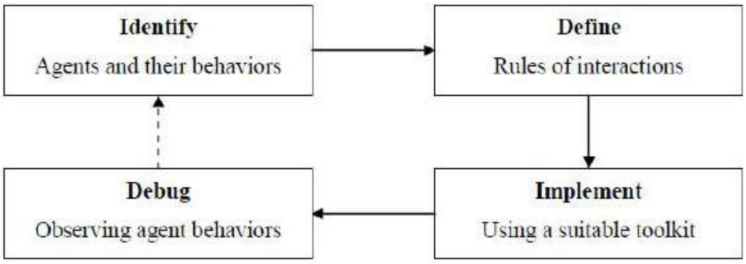

Figure 2: Four steps for the implementation of CSAM- ABMS model

3. Study Area and Data Description

3.1 Testing and Validation in Shenyang province

Shenyang, as capital city of Qing Dynasty, has many cultural relics and historical sites. Shengjing palace, known as "Forbidden City outside the Forbidden City", is a symbol of Shenyang's famous city. Although Shenyang has been rated as a "historic city" in recent years, owing 10 historical and cultural blocks, 46 national first level protection buildings and 4 traditional folk villages, there are still a large number of quasi historical buildings which have been seriously damaged in the rapid construction of the city. Since 2011, Shenyang has strengthened the investigation and appraisal of historical architectural heritage and Archival Protection and archival work, and 113 new historical buildings have been added to the historical buildings. However, these historical architectural heritages are widespread in poor use because of the unclear number of Shenyang quasi historical buildings, the lack of the main body of the implementation and the improper protection measures. In order to accurately analyze the protection and utilization of Shenyang's historic building heritage and its surrounding environment, this paper takes Wu Jia Village in Shenbei as the specific investigation and research area(Fig.3).

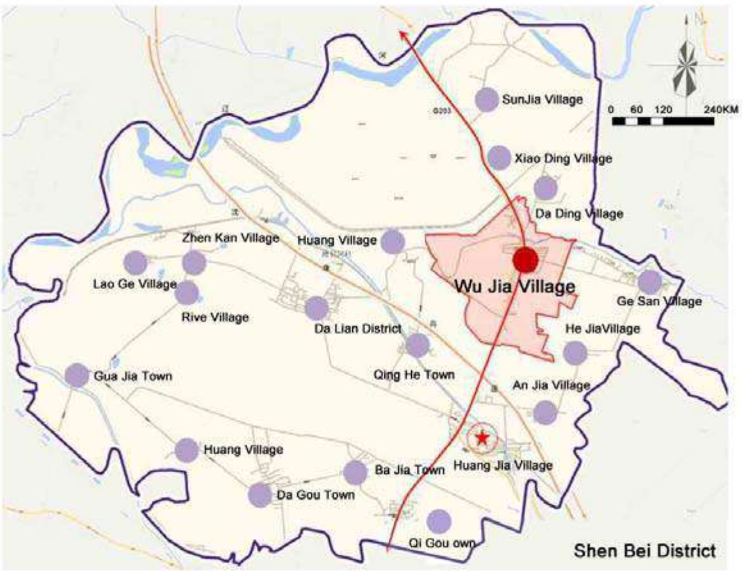

Figure 3: Study Area

Located in the north of Shenyang, Shenbei Wu village is a gathering place of historic architectural heritage and traditional villages. The research area ranges from 123 degrees 16'to 48' in the east longitude, from 41 degrees 54'to 42 degrees north 11', with a total area of 70.2 hectares. Shenbei Wu village is located in the cold area. The annual average temperature is 7.8-9.0 ℃. The average temperature in winter is -12 ℃, and the lowest temperature in winter is -35 ℃. The cold climate is likely to threaten the frost damage to historic buildings, and many existing historical protection buildings have no modern facilities such as heater or air condition, resulting in a decline in the utilization rate of historical protection buildings. Without the utilization and maintenance of human beings, historical protected buildings are hard to maintain properly.

3.2 Description of executive system of conservation behavior

The behavior execution system is divided into five types of agent: tourist, environmental practitioner, government agencies, tourism practitioner, residents. There are different characteristics in behavioral preferences for each agent due to the differences in conservation motivation and desires. Based on the evaluation of the significant priority of various behavioral preferences, and the feedback（influence） of environmental condition, economic, and social factors of the system sort the importance of conservation strategies and improve system behavior accordingly (Fig. 4).

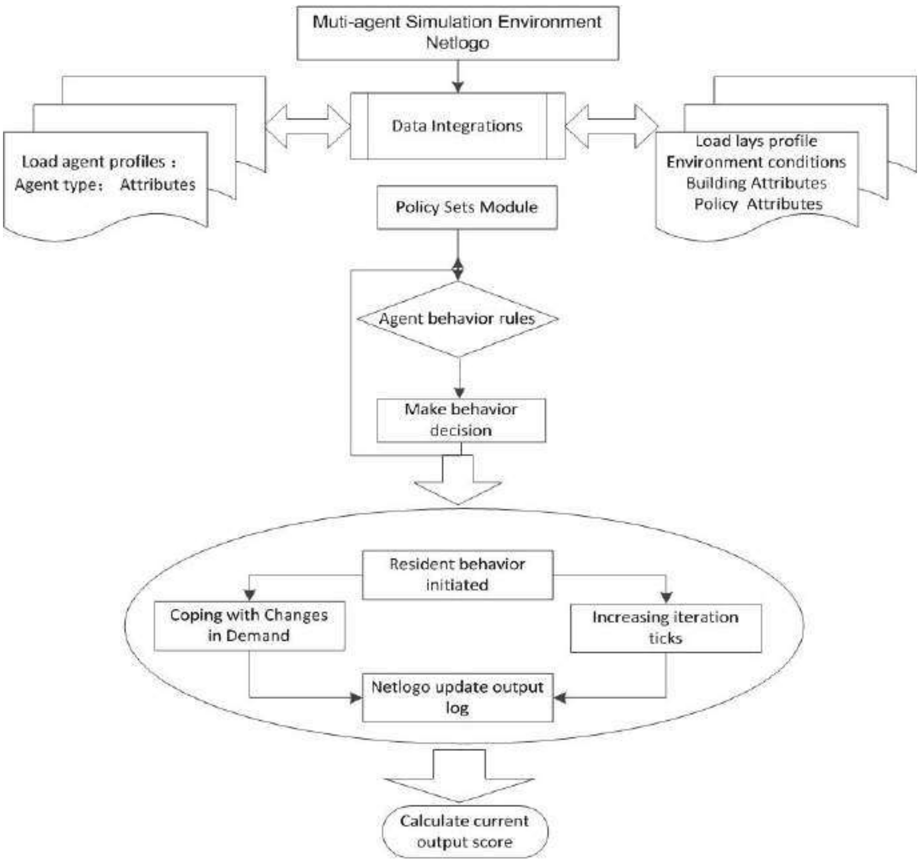

Figure 4: State Diagram for Conservation Behavior Analysis Model of building heritage

3.3 Description of behavioral preferences

CBAM has a series of spatial attributes, which will be inputted in the beginning of simulation, and agents can conduct satisfaction evaluation based on the spatial attributes of their locations. The mechanical models for evaluation on agent can be satisfied with current environment condition of building heritage according to questionnaires as description below. For collecting data, we estimated the necessary coefficients using the questionnaire carried out in Shenyang province,in which 382 persons were selected to be the inquisition object, collecting 330 valid questionnaires, with 86.4% efficiency. In which 190 questionnaires were selected form community residents and 56 are from I Tourists, researchers, government agencies administrators, urban- conservation practitioners. The content of the questionnaire involves the demographic characteristics, the conservation willingness of different career groups, and the satisfaction about the current conditions of building heritages and surrounding environments, and the intention of tourism development. Then we process and analyze the valid questionnaire by applying SPSS, according to the rulers of calculating scores. According to the analysis of sample data, the intention, satisfaction and behavior preference have strong correlation with conservation behavior of different agents which can be used as evaluation indicators of behavior preference. Since the values of behavior preference of each agent are impacted by the difference of sample weight, structure and individual decision, this paper builds the intensity of behavior preference model.

The behavior preference value is calculated as below:

$$S_i = \frac{\sum_{j=1}^{n} i_j \times x_{i,j} + \alpha}{N}$$

$$S_{threshold} = 3, \quad (1-5)$$

$$S_{threshold} = \begin{cases} S_i > S_{threshold}, & \text{(Satisfied by current condition)} \\ S_i \le S_{threshold}, & \text{(Unsatisfied by current condition)} \end{cases}$$

As shown by the equations, variable S_i stands for the satisfaction preference of the respondents i' s current building heritage condition . a_j is a vector of behavior preference coefficients value to variable j, which obeys the order in Tab-1. In addition, i indicates the willingness to protect and the satisfaction of current building heritage condition, which obeys the order from the survey sample data of each agent, the willingness degree of each factor was divided into 0-1(1 indicates the strongest, 0 indicates the weakest).

In order to avoid the influence of the sample size, we select 5 expert evaluation teams which are consisting of geography, urban planning, and tourism economics to score the relevant behavioral preferences of each agent group. The average of the expert scores is taken as the weight of the different sample indicators. Finally, the weights of the questionnaires and experts are averaged to obtain the weight values of each sample. The results are showing in table 2 as below：

Table 2: Preference with the object of conservator behavior in research site

Agent behavior Index	Tourist	Environmental practitioner	government agencies	Tourism practitioner	Residents	Experts
	N-Sample 56	N-Sample 31	N-Sample 15	N-Sample 38	N-Sample 190	N-Sample 30
Willingness (0-1)	0.42	0.89	0.73	0.87	0.69	0.76
index weight	0.20	0.28	0.26	0.31	0.22	0.31
Current satisfaction (0-5)	4.02	3.17	4.10	2.50	3.21	3.56
index weight	0.34	0.28	0.46	0.35	0.32	0.41

General behavior preference (0-1)	0.25	0.59	0.65	0.47	0.28	0.55
index weight	0.32	0.27	0.46	0.25	0.33	0.23
Conservation behavior preference (0-1)	0.22	0.90	0.65	0.58	0.62	0.85
index weight	0.18	0.22	0.20	0.30	0.16	0.21

3.4 Description of weight setting for the index of behavior impact

Wu Jia Village is a typical Manchu area, with a history of more than 400 years. Most of the original residents were Manchu officials, belonging to the Huangqi. At that time, many officials' mansions were built, as well as some relative public buildings, including the government buildings, banks, post offices and leisure places in Manchuria. There are 5 buildings on the historical architectural heritage list in Wu's village. In addition, there are more than 20 buildings to meet the conditions of the historical architectural heritage according to the author's local investigation. These buildings are generally divided into three categories. The first type contains the well-preserved and in-used buildings, which still maintains its original building function, including 1 government office buildings, 2 Yanghang, 2 small post offices, 2 school buildings and 5 private residences. The second contains poor-preserved but still in-used buildings, including 8 private mansions, which have been reformed as commercial buildings like restaurants, cafes and shops. The third contains abandoned buildings, including 1 reclaimed Yanghang, 1 broken small post offices and 6 damaged private houses.

The behavioral preferences of different agents and the difference in satisfaction with the current conditions of building heritage and their surroundings are the rules for conducting impact evaluation of conservation behaviors. In the evaluation, the strength is calculated according to the interaction of input variables and behavioral preferences. Based on the principle of combination of qualitative and quantitative, we build the behavior intensity model by the method of analytic hierarchy process.

3.5 Utility of CSAM in Netlogo Urban Space

At present, the government departments have not put forward the protection and Reform Opinions on the quasi historical architectural heritage, except 5 history buildings in protection list. In the investigation, aborigines have deep memories and feelings about these buildings, and propose that the traditional architectural patterns and cultural atmosphere have influence on the surrounding areas. But in the past rapid construction, at least 30 old buildings have been demolished, and the original courtyard style has changed into a modern apartment, according to the aboriginal people. They urgently hope that the government can protect or transform the remaining old buildings, so as to preserve the cultural characteristics of the Manchu region.

CBAM is tested in Netlogo platform and three scenarios are simulated. Netlogo is chosen in this project because it has many functions, such as scenario-based analysis, GIS (geographic information system) environment, agent-based model[15]. Furthermore, this program is free in public domain and also has several extensions to link with other programs, such as statistical program R, numerical computing environment MATLAB. The first one focused on the model behavior of building heritage conservation by ignoring any policy adjusted influences. The other one inputted the policy influences in the simulation to conduct the interactions between policy implementation and community residents' responses. For considering the impact of planning policy, we define the spatial planning information and behavior information based on the typical urban form of Shenyang China. All the spatial information and building heritages information are taken as external conditions for the simulation model. This study concerns a urban space of 2500 cells (50 x 50) where each cell measures 500 m x 500 m. This hypothetical city has the characteristic of the investigation city of Shenyang. The land use zoning is based on the ratios of different land use types reflecting local urban plan in Shen Yang .

4. Model Result Analysis

4.1 Model Result

Based on the requirements of Netlogo set behavioral preferences for each agent, and the input variables will refer to the value of sample weight, protection behavior impact and condition factors. The optimization results of conservation behavior of multi-agent systems in each stage are obtained in Table 3. Stages 1 to 5 are five different stages of building heritage development. Stages 1 is the baseline scenario output of current data. Stages 2 to 5 are based on the conservation of building heritage and the tourism development policy, and the changes in weight of each agent are adjusted according to the policy of the tourism development.

Table 3: Stage of optimization results of conservation behavior of multi-agent system

Agent System	Stage 1	Stage 2	Stage 3	Stage 4	Stage 5
Tourist (F1)	0.26	0.15	0.34	0.40	0.55
Environmental practitioner (F2)	0.22	0.05	0.10	0.15	0.15
government agencies (F3)	0.14	0.22	0.12	0.18	0.18
Tourist practitioner (F4)	0.30	0.25	0.25	0.30	0.30
Residents (F5)	0.43	0.45	0.26	0.21	0.15
Order of protection behavior	F5＞F2＞F3 ＞F4,F1	F5＞ F1, F2＞ F3＞ F4	F1,F5＞F4＞ F2,F3	F1＞F4＞ F2,F3,F5	F1＞F4＞F2, F3＞F5
Selection of system behavior	F5 ,F2, F3	F5 ,F1, F2	F1 ,F5, F4	F1 ,F4	F1 ,F4

According to the order of conservation behavior, Netlogo recalculate the input parameters and achieve an optimization state of system behavior choice (Fig. 5).

4.2 Scenario analysis

A. Scenario One：baseline scenario without policy adjusted influences.

Based on different stages of tourism development, there are obvious differences for decision-making of conservation behavior. At different stages of heritage conservation, the agent weights are adjusted in Netlogo. Stages 1 to 5 indicate that during the tourism development period, the weight of the tourists increases, and the weights of other related agents will change accordingly, and show strong correlation. Therefore, the conservation planning should focus on the prediction of behavioral decision-making, propose a scientific subject system to protect behavioral decision-making, and formulate differentiated protection action strategies according to different tourism development periods.

B. Scenario Two：Community residents as the significant factor in conservation period.

The expectations of community residents around the architectural heritage for tourism development will affect their attitude towards heritage protection. Community residents play an increasingly role in the balance of tourism development and conservation of architectural heritage.

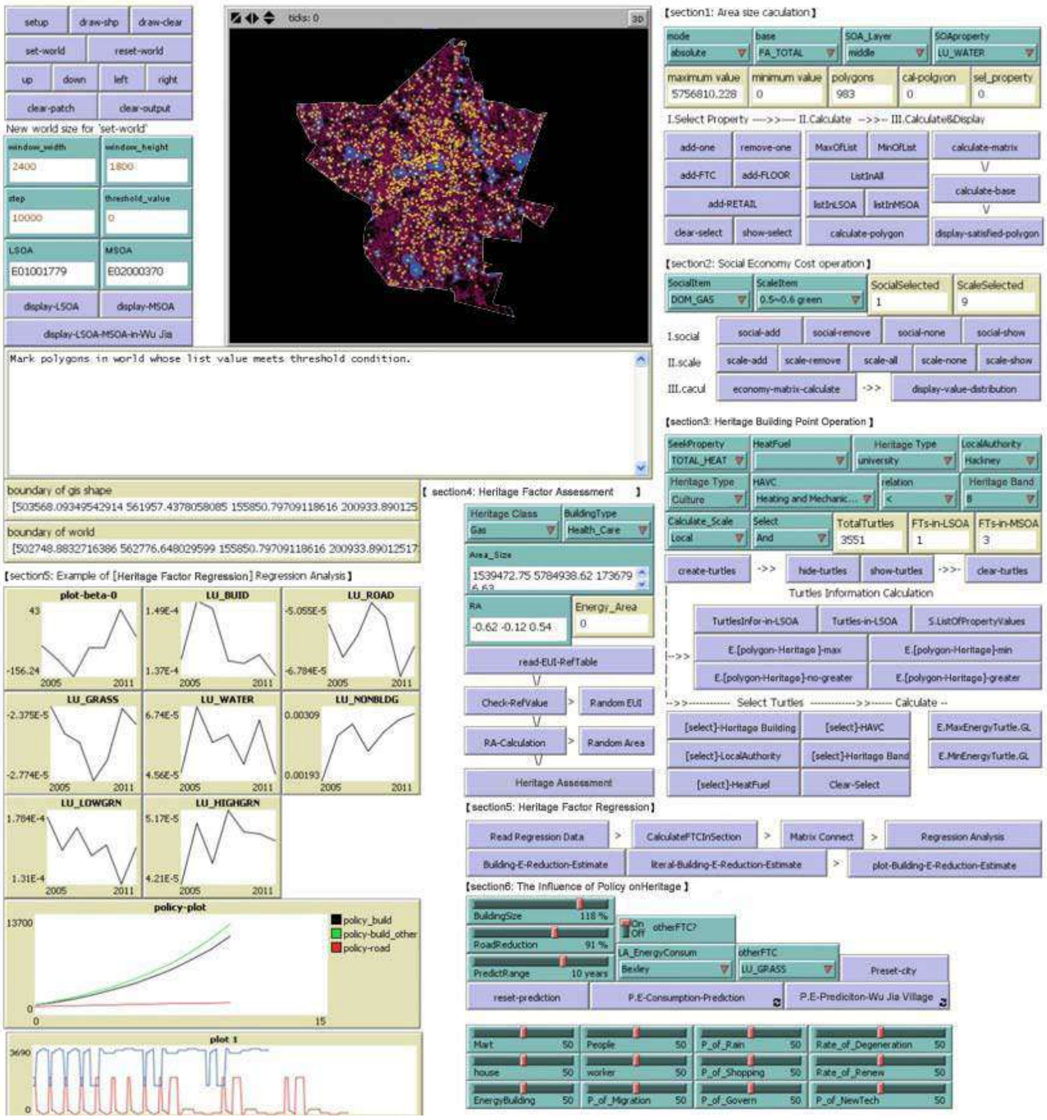

Figure 5: Graphs /Plots in Netlogo

The results show that the impact of positive tourism related to building heritage impact on residents' satisfaction is significantly stronger than that of negative impacts. The action of community residents in the conservation of building heritage and surrounding environmental is the most significant. Tourism development enhances community residents’ recognition of local history and culture. Therefore, the community residents should play a leading role in tourism development and conservation of building heritage by motivating of community residents. In the early stage of conservation planning of building heritage, government agencies should promote the mechanism of participation of community residents. We should actively follow up the mechanisms of community participation and deal with the relationship between development and protection. Government agencies could establish appropriate community participation policies to ensure that community residents can benefit from tourism development and participate in the conservation of building heritage and environments.

C. Scenario Three：The behavior choice of the agent in different characteristics of attitude.

Different from physical buildings and environment, residents are the behavioral perspective of building heritages . Each building heritage is evaluation by their government agencies who decides when and how to retrofit the building heritages. Different government agencies has different attitudes towards building conservation retrofit. It can be seen from Table 2 that external factors such as economic and social development level, and environmental conditions of government agencies will cause different effects on individual agents and have greater impact on environmental conservation. The differences in cognitive behaviors of different agents have a greater impact on the initiative of behavioral decision-making.

For example, the behavior of environmental experts is scientific and plays an important role in formulating specific measures for the conservation of historical and cultural buildings. The behavior of the government agencies play the coordinating roles as an optimization role in tourism development and the conservation, management of the local building heritages. Their attitude concerns on the economic benefits brought by conservation behaviors. The results indicate the differences in protection of investment, strategies implementation. Therefore, the impact of government decisions on the conservation of building heritages and the surrounding environment is increase in the whole period. Taking the Shenyang as an example, the conservation behavior of building heritages is at the basic level in the early stage of tourism development. It is close to nature, architecture and culture. The development is in the middle stage, the awareness of conservation behaviors enhanced, and the conservation strategies are continuously optimized.

5. Conclusions and Future Work

The research of sustainability of buildings heritages should consider the effects of spatial dependence when dealing with sustainability conservation at urban scale. Or at least, the immediate local environment factors should be analyzed to build spatial correlation in the process of urban development and heritages conservation.

Agent-based-model ABM can be a powerful tool to study the emergent properties in human-building heritages-urban developmental systems that typically have strong interactions. The hierarchical and classification coordination system of conservation behaviors is established by ABM. The decision-making conservation behaviors of every agent and system is intervened dynamically in the complex system.

In summary, the paper highlights how comprehensive and systematic research of heritages sustainable conservation becomes important for dynamic innovation in urban evolutionary processes in the coming anthropogenic era, during which decision-making and behaviors is becoming the dominant influence – not only in climate and the environment, but should mutual promotion collaborative visioning for the future.

Urban Beautification in Beijing's Old City from the 1990s to the Present: Taking Housing Regeneration in Beijing Old City as the Case

GAN XINYUE, Tsinghua University, China

Abstract: Urban beautification is the package of urban policies and planning strategies aimed at creating a high quality and orderly urban built environment, so as to develop a competitive and attractive urban investment environment and (re)construct a good city image. This paper explains urban beautification in China as a kind of urban regeneration with spatial exclusiveness. By reviewing the urban regeneration in Beijing's old city since 1992 and taking the case study of ongoing voluntary housing relocation, I argue that urban regeneration in Beijing old city has always emphasized urban beautification to achieve economic or political goals through the spatial exclusiveness against citizens. Because the power structure in this process has not been fundamentally changed, the right to the city is hard to guarantee. From urban beautification to urban regeneration within citizen participation, the core issue is all the social groups should be guaranteed to have democratic participation in the domain of decision making in urban politics. Improving the rental housing system in the process of housing upgrading in historical districts might be one of the solutions.

Keyword: urban beautification, urban regeneration, Beijing old city, housing

1. Urban beautification: concept, evolution and the Chinese reality

What is urban beautification? In this paper, urban beautification is defined as formulating a series urban policies and related planning strategies to pursue the good quality and order of urban built environment, so that the competitive and attractive urban investment environment can be created and the good city image can be (re)constructed.

1.1 urban beautification in western countries

First of all, let's review the origin of this concept. In western countries, in late 19th and early 20th century, it referred to the urban beautification movement, designing city based on the aesthetic to solve the social and economic problems as well as improve the city fame（Hall P., 2009（198-207）；Fenske, G., 2011）. Since 1960s, it means urban gentrification in the inner city , the middle class replaced the working class in some residential areas spontaneously, and made the houses look like elegant and expensive (Smith, N. ,2006). After 1970s, under the context of neoliberalism, the local government, which had to undertake more local economic development than before, began to create the good urban landscape, such as the mega project in the center of the city to attract the investment and improve the city competition (Harvey, D., 1989). The concept of gentrification has expanded from housing sector to urban development. After 1990s, the urban gentrification has become one of the vital urban policies in many cities of the world. The new restaurants, museums, shopping malls were created to make the city become the ideal place to live and consume (Smith, N. ,2006).

1.2 urban beautification in Chinese urban transformation

In China, there are three manifestations of urban beautification. The first is the gentrification along with urban redevelopment. From the beginning of 1990s, under the context of decentralization from central to local government, the separation between the land ownership and land use rights, the increase of private enterprise and foreign investments, the housing privatization, the development of real estate accelerated under the promotion of high demands of luxury residence and office buildings. The local residents who lived in the inner city were replaced by the wealthy people who can afford the commodity housing, and then relocated to the periphery of the city（Wu,1997). The urban redevelopment reshaped the urban landscape, the lifestyle and aesthetic tastes of middle class were embedded in the built environment (He, S.,&Lin, G. 2015).

The second is the cultural-oriented urban regeneration after 2000. Instead of historical buildings demolition, the local government combined the historical area renaissance with modern consume spaces, so that the image of the local as the global city could be intensified, the consumer and travelling market could be stimulated, the value of the residence nearby could be promoted （Yue Zhang,2008，张京祥，2009；季松，2010). Xintiandi in shanghai is a typical case.

The third one is building façade painting. It means that before some urban events such as Olympic game, the local governments always paint the building façades along the streets to make the urban landscape look so good.

Above all, the nature of urban beautification can be considered as a kind of urban regeneration with the spatial exclusiveness.

2. Urban beautification: the urban regeneration with the spatial exclusiveness

How to understand the urban regeneration with the spatial exclusiveness? It can be understood from the relationship between the state, the market and the citizen in the process of urban regeneration. In Chinese researches about urban regeneration, the relationship between the local state and the market is described as the growth machine, which gets the benefit from urban redevelopment（王红扬，2016）. In this model, both the status and the participation of the citizen are not instituted（陈浩等，2010）, so that they have no political power to negotiate with the growth machine. The benefits of the people who are demolished and relocated are less likely guaranteed in the urban redevelopment （He, 2005）. The inequality of the power structure has led to the citizen be excluded from the new spatial reproduction and consumption. The new spatial reproduction refers to the urban beautification aiming at place marketing and the modernization of urban spaces.

in the next section, through reviewing the urban regeneration in Beijing old city since 1992, and taking the empirical research about the housing regeneration in one of the communities in the city center, I attempt to argue: the nature of the urban regeneration in Beijing old city is urban beautification. From 1992 to the present, although the manifestation of the urban regeneration is different, the goal is always the achievement of economy or politics through the spatial exclusiveness against the citizen. Because the power structure of the local state, the market and the citizen in this process has not been changed, the right to the city is always difficult to be guaranteed.

3. the multiple contextualization of urban beautification in the urban regeneration in Beijing old city from 1992 to the present

3.1 the housing issue in Beijing old city

Beijing old city was derived from yuan dynasty, which has a long history, about 800 years, the area is 62.5 km2 (Figure 1). The dilapidated housing regeneration in Beijing old city is one of the vital issues of city planning and construction in Beijing. The serious shortage of infrastructure, the unsafe housing structure and the poor living condition are always the serious problems over the past 50 years (边兰春，2010).

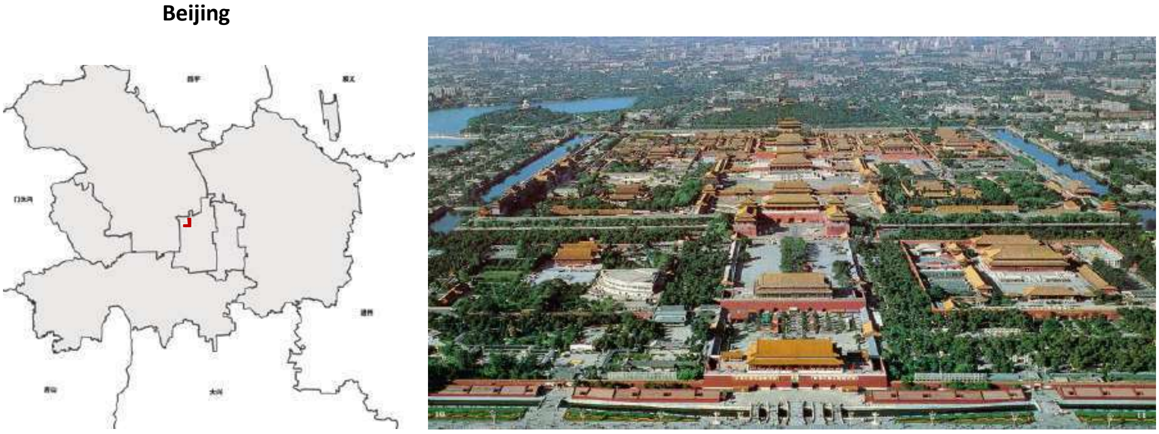

Figure 1: The Site and Image of Beijing Old City

In 1949, the total residential area in this area was 11.60 million square meters, among them the dilapidated housing accounted for more than 60%. The per-capital living space was 4.75m2. in the socialist planned economy period from 1949 to 1976, because of the shortage of the housing, residents built the temporary houses by themselves, the area of which was totally 2 million square meters, the building density was from 4500m2/ha to 6000 m2/ha, eventually. These temporary houses have been reserved until nowadays. By the end of 1988, according to the housing census, the total area of dilapidated houses in Beijing old city was 10.19 million square meters（董光器，2006:179）(Figure 2). A little more than half of traditional residence in the city center had suitable building structure and was safe to live (Zhang Jie,1997).

Figure 2: The Image of Dilapidated Houses in Beijing Old City

3.2 urban redevelopment at large scale: creating the modern image of in the capital

From 1992 to 2003, the city center experienced two phases of urban regeneration, taking the approach of housing demolition (方可，1998). The local government offered the preferential policies and benefited from land leasing and revenue after redevelopment, and private developers were responsible for the compensation of local residents who were demolished and benefited from real estate or mega project development（陈晶，2015）, so that large scale historical areas disappeared totally. From 1992 to 1999, there were 160,900 households being demolished and relocated, only one-third of them got the compensation of the new housing （Shin, H. 2009）. In 2000, the municipal government published the policy to require accelerating the dilapidated housing redevelopment （京政办发，【2000】19 号）， The housing demolition peaked in 2001, about 1,850,000 m2 dilapidated housing was demolished（吴良镛，2003）. At the same time, the luxury shopping mall, the CBD opened up the modern image of the capital city (Figure 3).

Figure 3: The Mechanism of Housing Demolition From 1992-2004 and The City Image After Housing Demolition

3.3 improving the city image in the period of preparation for Olympic game: The landscape promotion and place making of historical area which combined the traditional culture in beijing with the modern consumption and travelling

At the same time, in 2000, the planning of historical preservation in beijing was published. The landscape promotion and place making of historical area which combined the traditional culture in beijing with the modern consumption and travelling was the main approach of the urban regeneration in this phase/z/. This approach was intensified in the period of preparation for Olympic game in 2008. From 2005 to 2008, the city government invested about $52,000,000 to recovered some historical heritages which were demolished, and recovered the historical landscape including building facades and public spaces in some areas which were evaluated to have high historical value（孔繁峙，2004；北京文博，2004）. However, series/z/ policies in this phase focused little on improving the living conditions of the local residence (Yue Zhang,2008) (Figure 4). On the other hand, the residents had to endure the problems of noises, the street safety and the environment which were resulted from the consuming and travelling development.

Figure 4: The Old City Image in the Period of Preparation for Olympic game

3.4 At present: constructing the historical area in Beijing old city as the world-class cultural paradigm

In February, 2014, president Xijinping indicated that "historical culture is the soul of the city, protecting the historical heritage as protecting our lives…. Relocating non-core function of the capital city and controlling the population scale". This statement has become the new ideology of urban development in Beijing at present. In the " beijing master plan from 2016 to 2035" which was published in 2017, integrated conservation, reducing population density, no demolition in historical area in the city center have been proposed (beijing urban planning bearu, 2017). With this background, "housing vacation" and improvement of street built environment have become the main urban policies of urban regeneration at present.

Under the context of constructing the historical area in Beijing old city as the world-class cultural paradigm, in the current urban regeneration, how does the local state, the market, the citizen achieve their own benefits through policies design and mechanism operation? Whether the urban regeneration at present is also the urban beautification?

4. Empirical research: Still urban beautification?——"housing vacation" based on the public-private partnership which is local state-oriented

"housing vacation" is the local state-oriented housing regeneration with public-private partnership. It is applicable to the traditional housing in historical areas in Beijing old city. The local government formulates the policies about housing regeneration, and then authorizes the local state-owned enterprises to be responsible for negotiating with the local residents to vacate their house and give them housing placement in the periphery of the city. For the homeowners, housing vacation and relocation are voluntary. After that, the use rights of vacant houses are transformed from local residents to the enterprises. after being repaired and redesigned, the enterprises rent the houses to the new industries such as boutique hotel or studios. The financial support of housing vacation is from both public subsidies and mortgage from bank (Figure 5). The model of housing vacation was firstly attempted in 2010 in one historical community, and then was promoted in most historical areas in Beijing old city at present.

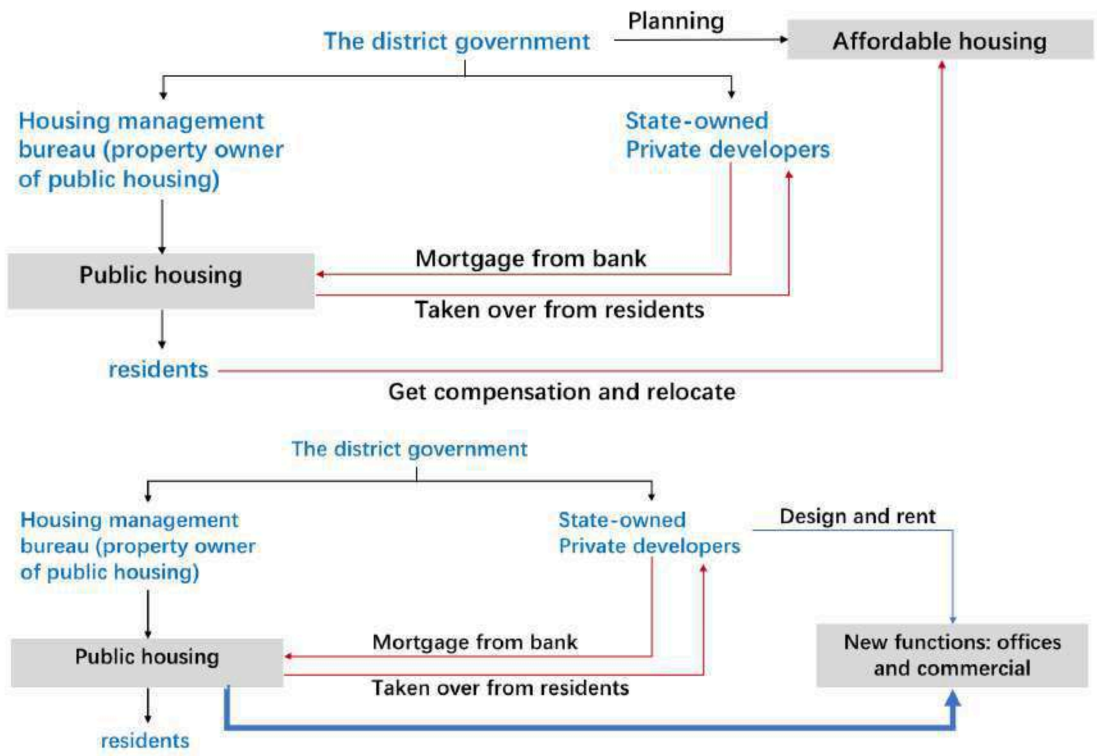

Figure 5: The Process of Housing Vacation and Re-using

The field study was proceeded from July to August in 2017 in BAIMI community, which is located in one of the historical preservation districts in Beijing old city. There are 583 households living in 98 traditional courtyards. The number of households in each courtyard is from 3 to 34. The housing property rights are divided into private and public which are belonged to the housing management department. From September 2013, the local state-owned enterprise began to be responsible for the housing vacation in Baimi community(Figure 6).

Figure 6: The Street-View of Baimi Community

There are four kinds of main participants in this process, the local government, the local state-owned enterprise, the housing management department and the homeowners. After interviewing these four, the paper find that there are three main contradictions in the process of housing vacation. The first one is in each courtyard, only all households are willing to vacate houses and relocate, the housing vacation will be valid. For this reason, the households in each courtyard become the collectives passively which have the common interests. Because many factors such as the public services, the job opportunities, the satisfaction about the standards of housing compensation and the divergence of opinions within the family affected the intentions of housing vacation, it is difficult to come to an agreement among all households in a courtyard. Although the housing vacation is willing, families who wanted to vacate and relocate couldn’t achieve the desires.

The second one is according to the policies, some families can’t be up to the standard of the new housing placement. There was a case when I had the filed study: there are 5 family members, an old woman and her sons who are more than 30 years old, living in a 30m2 room with property rights and another 6 temporary rooms which were self-built. According to the housing vacation policies, the living area of new housing placement is related to the present living area. In this case, there is no enough living area to accommodate these 5 family members if they choose housing vacation. This is one of the reasons why some families experienced the bad living condition, but they don’t want to vacate their houses.

The third one is in the period of housing demolition in 1990s, there was no way for the homeowners to have questions&comments. Whether the homeowners agreed the policies or not, they had no choices but to accept (陈晶，2015:59). In the model of housing vacation, this situation didn't change. From the standard of compensation, to the location of the resettlements, the homeowners just had right to know. local residents are lack of communication channels with local government, and they distrusted the state-owned enterprise, so that some residents missed the opportunities of housing vacation.

For these three main contradictions, there was a large gap between the number of residents who were willing to vacate the house and the real number of housing vacation. According to the investigation in 2014, there were 479 homeowners were willing to vacate, but until August, 2017, only 58 homeowners were successful to vacate.

After housing vacation, according to the planning of state-owned enterprise, there were three new functions being embedded in the vacant houses, the first is boutique hotel, the second one is high-end office and designers' studios, the third one is the public service based on the demand of local government. Taking one courtyard that has been vacated successfully, from housing vacation to the housing repaired and redesigned, the cost that the enterprise invested is about $19,800/m2. For the cost-recovering, the enterprise had no other choices but to rent the vacant houses to the high-end business types.

In the process of housing vacation and housing reuse, comparing with the housing demolition, the model of housing regeneration which is the local government formulated the policies, the enterprise provide the financial support, the local residents relocate in the periphery of the city, the housing get the higher value through spatial reproduction didn't change. The only difference is the local residents can choose vacate their houses or not. Housing placement in the periphery of the city is the only way to improve local residents' living condition. For those people who are not willing to vacant the houses or not up to the standard of compensation, there is no policy and financial support for them to improve their existing living conditions. From demolition-relocation to vacation-relocation, the local residents are marginalized in the urban regeneration.

5. Conclusion: From Urban Beautification to Urban Regeneration within Citizen Participation

According to the new statement of "Relocating non-core function of the capital city and controlling the population scale, no demolition in the historical districts in beijing old city", the urban regeneration in beijing old city gradually from incremental to the stock. At present, the political goal which is achieving the integrated conservation and renaissance in beijing old city is prior to the economic goal.

The case study shows that in the urban regeneration in Beijing old city, the civil rights are difficult to guaranteed because the power structure between the local state, the enterprises and the homeowners and the mechanism of regeneration don't change essentially. It manifested the spatial exclusiveness towards local residents or the tenants.

From urban beautification to urban regeneration within citizen participation, the first is restating the right to the city. All the social groups should be guaranteed to have democratic participation in the domain of decision making in urban politics （Qian, J.,&He, S.，2012）.

Series policies design and the improvement of institution are beneficial for the achievement of urban regeneration within citizen participation. For example, improving the rental housing system in historical districts in Beijing old city, developing the housing vacation and housing rent simultaneously. Taking the differentiated housing policies towards local residents who are (not) willing to vacate and relocate (Figure 7).

Abstract

Many of the problems that arise in the urban renewal projects in old city are due to the neglect of the social cost of the urban planning and u rbanization. Furthermore, the action planning of urban renewal is no longer able to be implemented smoothly with the will of the leadership or the authority. Under the background of the development of the new normal in China's economy, urban and rural planning not only faces a p romising prospect, but also needs reform to meet the new requirements proposed in the new period of urban renewal projects.

Beginning from the public participation in urban renewal projects, this research tries to improve the original planning process of the urban renewal projects in China through enhancing the public participation and publ ic opinion survey process so as to form a framework of PIEA (Participation+ Investigation+ Evaluation+ Action) for urban renewal projects. This framework takes public opinion survey on a certain scale as the core method, which is divided into three stages: (1) the investigation stage; (2) the evaluation stage; (3) the action stage. The main idea is to maintain public participation through the whole process of urban renewal so as to improve the original urban planning process.

The case study of the urban renewal projects (an area of 2.8 square kilometres) in Fanchang County located in Wuhu city, Anhui Province in China, has a certain value both in terms of the complexity of urban renewalas well as for future reference. This research attempts to find revelations through practice and feedback analysis of the first phase of the framework in the hope that they would offer reference values for urban renewal in the future.

1. Introduction

1.1 Perplexity about Traditional Urban Renewal Context: Neglect of Social Cost

Social Cost means the total cost of various social production departments or the average social cost of a product. This concept is first proposed by Swiss-French economist Sismondi (Jean Charles Leonard Simonde) in his book New Principles of Political Economy, and then developed by scholars and 9 gradually applied in political economics, management, welfare economics, institutional economics and other fields. The most representative among the many opinions on “social cost” in China are the following two concepts, i.e. the “Average Social Cost Theory” and the “Social Cost Theory” (Lai’er LI, Xuan ZHAO, 2005) . From the viewpoint of the “External Diseconomy” caused by enterprises’ production and oper ation, scholars (Yi CUI, Wenli SHI, Qiuchan LIU, 2007) from South China University of Technology came to the conclusion that social cost is a negative external effect brought by business activities. They pointed out further that correct understanding of social cost is the basis of sustainable development.

During the development of urban renewal projects in the old city, developers carry out demolition, land development, planning and construction on t he premise that economic efficiency of the projects can be ensured. Furthermore, social friction cost, social management cost, ecological environment cost 23 and cultural value, etc. should also be included. (Yu ZHANG, 2015) Analysing from the external viewpoint of urban renewal projects, we find that the social cost of an u rban renewal project is usually much higher its own economic cost, due partly to rash reconstruction and renewal carried out without having being thought through, which in reality incurs a huge cost burden to the whole region and society.

1.2 New Challenges to Urban Development and Urban Renewal in the Transformation Period

1.2.1 Effect of the New Normal on Urban Development

In 2014, the Central Committee and the State Council pointed out that the development of Chinese economy in the future would appear to be a new normal, under which the growth of Chinese economy will reach a plateau, driving forces would be more diversified, the characteristic of growth would change from speed and quantity to coordination and quality, and a new planning and innovation thinking would be developing gradually (Sen FAN, 2015).

Urban development will go with general trend of the development of the productive force, i.e. transforming from extensive growth to intensive growth. (Yijia YANG, 2015) Henceforth, urban development would pay more attention to internal growth momentum and progressive development models, and the original urban renewal activities would decelerate. With the slowing down of the addition of construction land, urban renewal and ur ban renewal will gradually become a common urban planning project.

1.2.2 Diversified Demands are a New Challenge to Urban Renewal

The stronger emphasis of the society today on citizen's awareness of property rights as well as the diversification of citizen's own demands are a new challenge to urban renewal projects. Generally, with the progression of such awareness and demands, urban planning can no longer be as rigid and monotonous as before, for each person is an independent individual whose demands of daily living would be involved in urban renewal projects of the specific region. Therefore, compared with planning projects of other types, urban renewal planning has a greater requirement for urban planners to use advanced methods and exercise patience and effort to plan and improve living environment of the public in the region where urban renewal is taking place.

1.3 Public Participation in Urban Renewal Returns to the Attention of Academic World

According to Yun HU (Yun HU, 2005) from Peking University, public participation is a coordinative measure taken under the circumstance of social stratification and that requires the diversification of public and interest groups. Since the late 1940s, the theory and practice of public participation has gradually been developed in United Kingdom, Germany, United States and C anada (Zhicheng CHEN, Ronglin CAO, Xingping ZHU, 2003). After nearly 70 years of development, public participation has been practiced repeatedly as a methodology of urban planning and organizational basis of community planning and has a set of its own work models in foreign countries.

However, in China, according to the three types and eight levels of public participation divided categorized by American planner Sherry Amstein, we are now in the primary stage, i.e. symbolic participation (Yun HU, 2005). The reasons behind this phenomenon include not only a consideration of economic efficiency of urban development, but also the impact of the sophistication of the public as the subject of public participation on the effect of urban planning of public participation (Wenjing MO and others, 2012), which cause the mismatch between the theory of public participation in aspect of urban planning and the development speed of practice in our country, i.e. the theory goes ahead of the practice. The originally planned public participation and announ ced participation procedures centering on planning rather neglect public opinion survey in the whole planning process (a consideration based on the original planning and decision-making mode), and results of such planning are often difficult to reflect public opinion or even win support of the public when solving problems in urban renewal projects. In this background, as the basis of urban planning, public participation returns to the consideration about urban renewal projects. Through participation in public events, survey of public opinion and feedback of public feedback, the government plays a r ole closer to the public in urban renewal projects and also directly or indirectly improves the participation and satisfaction of the public, thus successfully implementing urban renewal plans.

1.4 The Function of Public Participation to Reduce Cost of Urban renewal Projects

When reconsidering urban renewal planning in the viewpoint of public resource allocation policy, we could well ascribe the increasing difficulty of urban renewal to its increasing cost, which is actually caused by the fact that the growth of policy-implementing cost (original cost

of project) is much faster than that of policy-making cost (original cost of plan), and these two costs are becoming increasingly inseparable. Although fast and hasty formulation reduces the planning cost of policies, it increases the uncertainty in the implementation of future policies, and policy-implementing cost (original cost of project) is often increased greatly due to resistance from the public and various circles of the society.
See the diagram below for details:

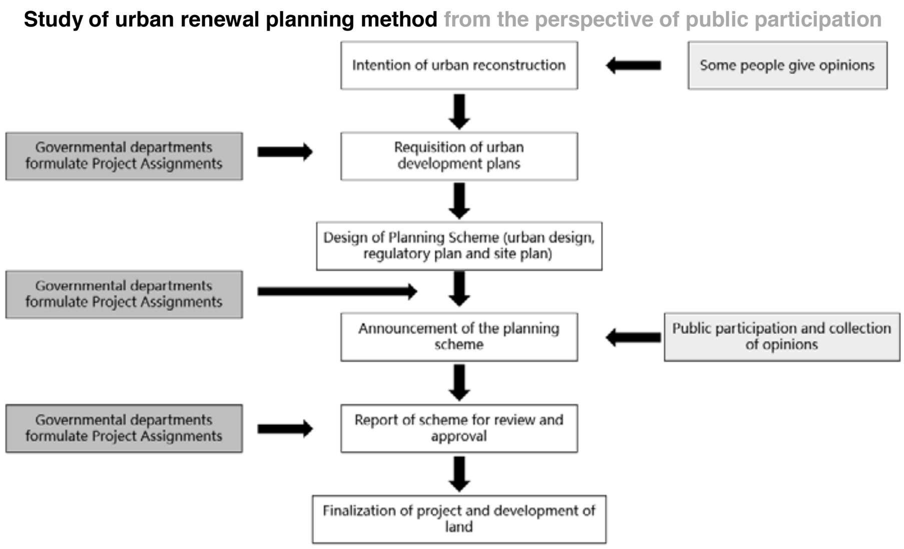
Type	Primary Cost	Primary Effect	Structure of Secondary Cost	Secondary Effect	Calculating Formula of Benefits	Overall Effect
Public Participation in Conventional Urban Reconstruction Projects	Cost of planning	Great increase			Great increase + Slight reduction + Slight reduction	Small loss and small profit
	Risk of projects	Slight reduction				
	Benefits of planning	Slight increase				
Public Participation in Current Urban Reconstruction Projects	Cost of planning	Slight reduction	Formulation cost	Slight increase	Slight reduction + Medium reduction + Great increase	Significant profits
			Execution cost	Great reduction		
	Risk of projects	Medium reduction	Probability	Slight reduction		
			Risk warning ability	Slight reduction		
			Range of risk	Slight reduction		
	Benefits of planning	Great increase	Economic benefits	Slight increase		
			Social benefits	Slight increase		
			Cultural benefits	Slight increase		

Figure 1-1: Comparison of Urban renewal Costs Before and After (Source: the author)

2. Framework of Concept: Structural Analysis of "Fanchang Mode"

2.1 Outline of Framework

This study tries to form a framework of PIEA (Participation + Investigation + Evaluation + Action) for urban renewal projects and analyse the function and mechanism of public participation in urban renewal. This is an attempt to improve the original planning procedures of urban renewal projects. This framework takes public opinion survey on a certain scale as the core method, which is divided into three stages: (1) the investigation stage; (2) the evaluation stage; (3) the action stage. The main idea is to maintain public participation through the whole process of urban renewal so as to improve the original urban planning process. In these three stages, the "investigation stage" is to collect basic attitude and actual requirements of each person in the region so as to conduct a special survey of key districts and surrounding people; the "evaluation stage" is about announcement, feedback and evaluation of planning programs so as to provide support of public opinion for policy decisions of the government; the "action stage" is a trial application according to the investigation and evaluation results, of which measures to prevent risks will be proposed. See the figure below for detailed improvements:



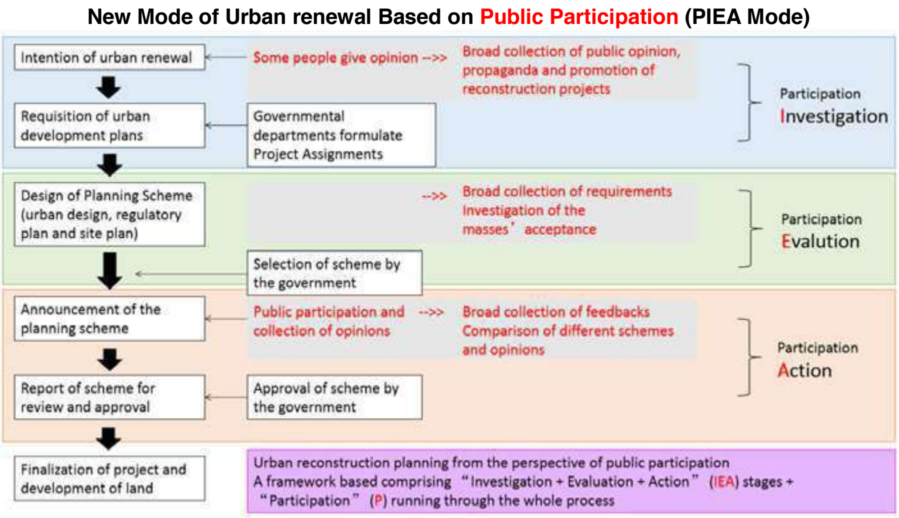


Figure 2–1: Comparison of Urban renewal Costs Before and After (Source: the author)

2.2 Key Issues to be Solved

2.2.1 Adjustment and Improvement of the Relationship between the Government and the People

The first stage of PIEA framework is the Investigation Stage where, in essence, a general pre-reconstruction survey of public opinion will be c onducted on the region to be reconstructed, i.e. the first general survey, which is also a propaganda and promotion activity. In practice, many issues reflected by the public in urban renewal are often resulted by an insufficient communication between the government and the masses, such as the insufficiency of propaganda by the government causes the masses to face demolition unknowingly, or the government fails to give a feedback to the problems that have long been reflected by the masses, or a misunderstanding arises from the gap between works done by the government and e xpectations of the masses, all of which indirectly show that improvement of the relationship between the government and the people in urban renewal projects is in urgent need. In practical cases, this study tries to communicate joint participation with the government in urban renewal to the public from a multi-dimensional angle by adopting a combination of propaganda, study and seminar.

2.2.2 Innovation of Public Opinion Collecting Technology: Fragmented Collection

One of the supporting technologies of this study is an innovative technology for collecting public opinion, i.e. our independently developed online planning and investigation platform ("Planbook Platform" ii), by which the three public opinion surveys as the core of IPA framework can be conducted on a large scale. As an online questionnaire survey platform based on the PHP technology, Planbook Platform may be logged in by mobile client software (Tencent, Wechat, etc.), webpage, pad and other means for completion, submission, collection and analysis of questionnaires for the masses.

Figure 2-2: Comparison of Urban renewal Costs Before and After (Source: the author)

In line with technical thought of other online investigation websites (such as wenjuan.com and SO JUMP, etc.) existing in the market, this platform tries to serve as an effective supplement to the original questionnaire method and makes it convenient for people to complete questionnaires in time fragments. What is more pertinent to urban planning includes the following two points: (1) the development of this DIY platform ensures the safety and full-range controllability of all the data required for urban planning and investigation works; (2) fragmented information provided by the public in their daily lives, after being professionally integrated by the systemic platform, that tries to provide a reference and basis for professional evaluation of urban planning and design through the transformation between the break-down and integration of questionnaires.

Figure 2-3: Schematic Diagram for Background Operation Interface of Planbook Platform (Source: software screenshot)

2.2.3 Design Principle of Questionnaire: Break-down and Integration

One of the objectives for the development of Planbook Platform is to communicate public opinions and governmental decisions. One question that needs to be solved is how possible it is for the public to participate in questionnaire investigation as conveniently as possible to reflect their intentions, and for planning practitioners to sort out fragmented information provided by the public and find out the trends of public opinion behind their choices. Therefore, by learning from the Analytic Hierarchy Process of the System Theory[iii] and the Break-down of Graph Theory, this study tries to introduce the break-down and integration theory of questionnaire investigation to break down the questionnaire into several parts that will be completed by different interviewees and use the logical consistency of the systemic platform to examine and integrate entire concept of the original questionnaire and make a judgment of trend. For example, break down a questionnaire comprising 50 questions into 5 to 10 simple questionnaires comprising 10 questions and integrate the all the results into effective answers to the original questionnaire through the background program. Not only does the results of doing so control the length and effectiveness of answering questions by the public, it also provide a theoretical basis for the exploration of parameterization design of the questionnaire investigation in intermediate and post periods.

2.2.4 Participation and Satisfaction: Pay Attention to Neglected Corners

The main idea of the urban renewal planning based on the PIEA framework is to enhance public participation in the whole process of urban renewal and improve the satisfaction of the public with urban renewal projects by increasing their participation. During the initial research period, we found that there is no statistical correlation between the participation of the public in urban renewal projects and their subsequent satisfaction. However, we also found that their participation in urban renewal projects may firm up and strengthen their attitudes toward such projects[iv].(See the figure below for details)

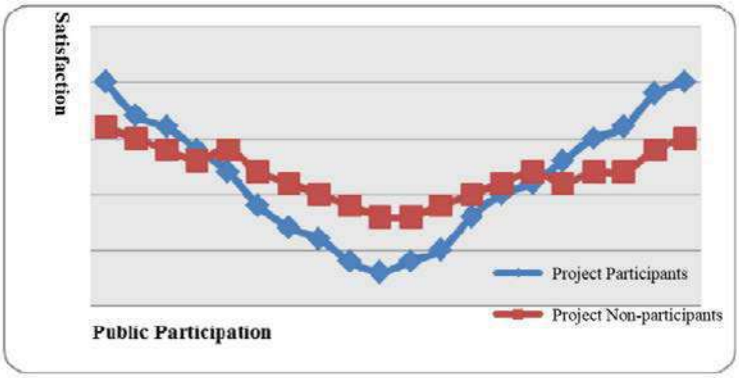

Figure 2-4: Schematic Diagram of the Correlation between Public Participation and Public Satisfaction(Source: the author)

We may explain this phenomenon in such a way: The public tends to express more clearly their satisfaction and disdain for the projects they are familiar with. To those they are unfamiliar with, some people will show an equivocal attitude, and involving the public in the projects is an effective way to increase their familiarity. Based on this assumption, the government may increase satisfaction of the public and communicate their expectations by enlarging the breadth and depth of their participation in urban renewal projects and pre-controlling and reacting to the conditions that may be reflected by the public.

2.3 Exploration on Minimally Invasive Planning Principle in the Field of Urban Renewal

The innovation of questionnaire investigation technology resolves the part regarding public participation in early stage of the PIEA action framework. After the relevant public opinions involving urban renewal projects have been known and collected, conventional urban renewal planning will be conducted. However, one difference from the past is that one of important methodologies of such urban renewal planning is the Minimally Invasive Planning Principle, which is about conducting full investigations and evaluating planned districts with advanced planning technology as well as implementing reconstruction plans with a small degree of intervention without affecting the original main functions of the city where urban renewal is going to take place. Compared with the “push-away style” construction mode in the original urban renewal, the practice of minimally invasive planning is an innovative mode in the background of new normal and transformation period of urban planning. The PIEA action framework with public participation involved may help the urban renewal region conducting minimally invasive planning with comprehensive evaluation of objective information of the region and subjective information of the public so as to guide planners to formulate local plans suited to local conditions.

3. Practical Study: Practice of Urban Renewal Projects in Fanchang County, Anhui Province

3.1 Project Profile

A city of the county level is selected in this study based on the following two considerations: 1. After more than thirty years of economic development since reform and opening up, the development of the material spaces of counties is often behind their economic development, thus showing the urgency of urban renewal; 2. nearly 2,000 administrative subjects of the county level of our country are the main force for the development of urbanization and the reform and opening up, which involve people’s problems in every aspect and have a general representativeness. Therefore, the case study will depart from some basic problems and study the practice of and public opinions about urban renewal in cities of the county level.

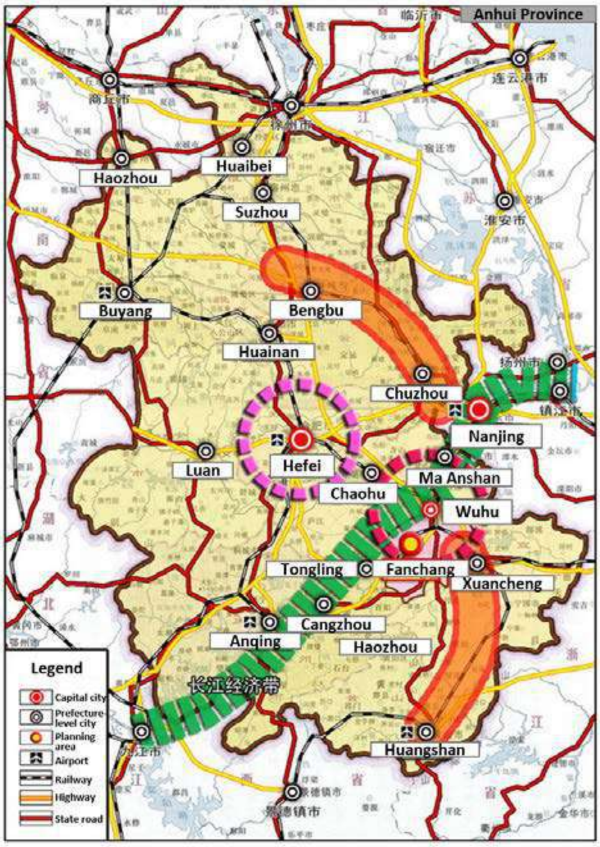

Figure 3-1 Location of Fanchang County in Anhui Province (source: the author)

Known as "Chungu" in ancient times and established as a county in the Xihan Dynasty, Fanchang is a county in southwest Wuhu City, Anhui Province. It is situated on the south bank of the Yangtze River and in foothills of southern Anhui (also the opening door to southern Anhui), where Shanghai-Tongling Railway, G50 Shanghai-Chongqing Expressway and Nanjing-Anqing Intercity Railway meet. The scope of this study includes the old city of Fanchang County to the south of Shanghai-Tongling Rail-way and to the north of Marenshan Road, covering a total area of 2.8 square kilometres. A public opinion survey will be conducted over the whole area of this region.

3.2 Action Planning Practice (Part I Investigation Stage)

The action planning of the project is divided into three stages, which are, respectively the stage of preliminary survey, that of intermediate participation and that of post-evaluation. So far, the primary stage of the project has been completed, and the following study will be conducted continuously under the former theory framework.

3.2.1 Preliminary Survey

The project began in earlier March 2015, and the preliminary tasks focused mainly on:

(1) Communicating with the local government to determine the working framework and confirming the purpose of the first poll, which was for the propaganda and promotion of the urban renewal, as well as carrying out a general survey of the basic opinions and attitudes of the public towards urban renewal.

(2) Onsite survey and the collection of objective materials;

(3) Negotiating key working timetableand time nodes;

(4) The Planning Bureau of Fanchang County, which assisted and cooperated with a symposium that is related to recent situations of the county construction and transformation projects and suggestions of the department for its future development in later March. The symposium was attended by the official authorities.

(5) According to the information above, the project research group designed the questionnaire for three types of targets (local residents and personnel of party and government institutions, foreign tourists, persons visiting their friends and family). More

than90 questions were designed, with each respondent answering approximately 10-20of them based on the automatic distribution of the system platform .The expected sampling rate of this survey was 1.0%-2.0% (of the permanent residents of the county). For detailed information of the questionnaire design, please refer to the diagram below:

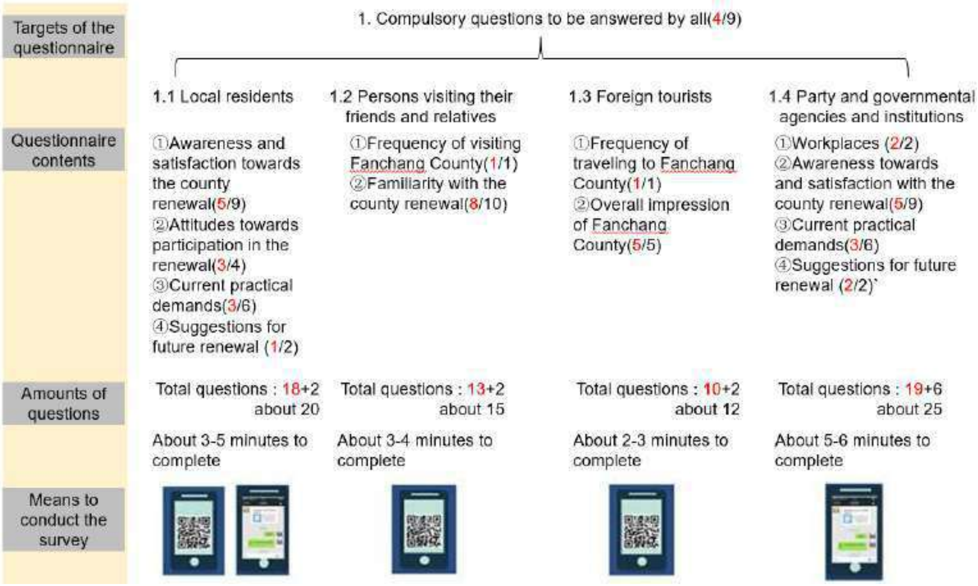

Diagram 3-2 Questionnaire Design Structure of the First Poll (Source: The author)

3.2.2 Preparation for the First Poll

Preparation for the first poll began in earlier April, 2015 lasting for 1 month, which mainly achieved the following goals:

(1) Submitting questionnaires to the government for discussing the related adjustment and modification;

(2) Testing the operating conditions of the service on the Planbook platform;

(3) Setting up an o fficial We Chat account of Planning Bureau of Fanchang County and publishing related information through the local media and Wuhu municipal newspapers and periodicals to propagate the poll and the related promotion activities. (For details, see picture 3-3 as follows.)

(4) Performing a small-scale test survey within the scope of the Planning Bureau.

Figure 3-3 Fanchang News and Wuhu Daily Published Relevant Information of the Poll

3.2.3 Preparation for the First Poll

The whole process of the first poll began in May and w as conducted during the month, lastinga month), which mainly achieved the following:

(1) The Planbook platform was officially initialed at the beginning of May, and the online questionnaire completed by the locals were received on t he online platform with the broadcast of relevant information through newspapers and periodicals and WeChat.

(2) Holding symposiums participated by the members of political parties and government agencies and institutions as well as representatives of community residents respectively,

completing online survey onsite as well as exchanging opinions and communicating adequately. (For details, please refer to picture 3-4 as follows.)

Picture 3-4 Scene of the Public Symposium for the First Poll

(3) Conducting thorough onsite research for all the seven communities in the old urban areas of Fanchang county, and holding symposiums in the communities and carrying out in-depth onsite researches and studies on the practical issues and demands reflected by the public in the process of urban renewal, which was combined with the contents of the former symposiums. (For details, see picture 3-5 as follows.)

Picture 3-5 Scenes of the In-depth Surveys in the Communities

(4) Choosing the places where the residents of Fanchang County usually gather to propagate and promote the poll of urban renewal by means of offering phone charges, little gifts and red envelopes of Zhifubao on Friday, weekends and public holidays. As the project research group from the third party institute, the relevant personnel offering gifts onsite and making inquiries about living conditions of the county is an efficient way for the government to communicate up close with the public. For details, please refer to picture 3-6 as follows.

Picture 3-6 Scenes of the Promotional Activities

3.3 Partial Conclusion of the Poll[v]

3.3.1 Public Awareness of the Recent Urban Renewal, including:

(1) Knowing what government has done;
(2) Knowing the channels of urban renewal;
(3) Level of familiarity with the specific urban renewal projects.

As far as the awareness of the public of the recent urban renewal is concerned, the public have broadened their understanding on the general situations of the recent “urban renewal and c onstruction condition” of Fanchang County. Among the respondents, only 15.2% chose totally don`t know(9.0%)and don’t know or care(6.2%). It can therefore be concluded that 84.8% chose quite familiar(23.8%)and know certain situations(61.0%).

As far as knowing about the approach of the urban renewal project is concerned, quite a large group of the respondents(41.7%)chose to make their own observations on the road, the remaining three most selected are, in order, see on the outdoor government advertisements with the aim of propagation(22.6%), see or hear in the TV broadcasting news(17.9%)and hear from the chats among friends or colleagues(10.3%).Unexpectedly, the least number of people chose (7.5%) the newest and most convenient option for broadcasting see on the website or forum.

As far as awareness of the specific urban renewal is concerned, the top three options of the respondents are, in order: No.1 Environmental remediation along Exi River, construction of Exi Park and Zhongtan Park(86 times);No.2 Renewal project of old communities(71 times);No.3 Construction of Chengguan Kindergarten and Library of the county, whereas top three of the least informed are Landscape regulating along the railway (28 times), Construction of the urban sewage interception project and drainage station(30times)and Renewal of shanty town(40 times)respectively. The main issue seen here is that public attention and awareness is closely related to the status of the project itself.

It is mainly concluded that:

①The survey shows that the publicist willing to know about the government's action in the urban renewal, and it is necessary to strengthen the propaganda and promotion of the urban renewal work among the county people which has both a public foundation and future expectations;

②The survey shows that the approach for the public to know about the urban renewal work is singular and the public is very passive.

③The survey shows that the public awareness of the image projects, nearby projects and frequently-used projects is higher and vice versa. Conversely, their awareness of the projects that are out-of-sight, more distant and in less-frequently-visited places and minor districts is lower.

Key suggested solutions including:

①The means of propagating and promoting urban planning and construction work should be expanded and new media and self-media (e.g. We Chat public numbers, forums, Web and government website,etc.) should be used to publicize the work of planning and construction.

②More in-depth surveys on satisfaction levels can be carried out for the urban renewal projects with higher public awareness.

3.3.2 Basic Attitudes of the Public towards Urban Renewal and Public Participation, including:

(1) Whether urban renewal is necessary;
(2) Whether they are willing to participate in urban renewal;
(3) Depth of public participation;
(4) Channels for the public to participate in the expression of opinions.

As far as the public basic attitudes towards the urban renewal and public participation are concerned, the majority expressed that they would like to play an active role in the process of urban renewal. As far as whether urban renewal is necessary is concerned, 66.3% of the respondents chose Urban renewal is quite necessary; and 23.5% chose Urban renewal is necessary to some extent, but not urgent. The combination of the two groups that thought that urban renewal is necessary made up approximately90%(89.8%)of the total sample size. If those who chose Uncertain and adopt the wait-and-see attitude towards the renewal plan to decide(9.2%)were added, up to 99.0% of the public in the county then agreed upon the good urban renewal projects. In fact, only 1.0% of the public chose the urban renewal is completely unnecessary and the present situation is good. It is necessary to do an in-depth analysis of those options. As far as the respondents who thought the urban renewal is not urgent(23.5%)and those who chose Uncertain and adopt the wait- and-see attitude towards the renewal plan to decide(9.2%)are concerned, it can be predicted that the two groups of the public are not the immediate stakeholders of the urban renewal, and they therefore appeared not to be very concerned. However, if conditions permit, they would join the first group of people.

As far as whether they are willing to participate in the urban renew is concerned, 29.8% of the respondents chose They are quite willing in any case; and 55.9% chose They are willing in the case of convenience and free. Therefore, it can be predicted that if in proper way and form, at least 85.7% of the public is willing to participate in the urban renewal in any and all respects. If the respondents(13.0%)who are willing to participate in such case as relating to their own interests are added, the willingness rate would-be increase to 98.7%.In other words, the public is very willing to participate in the urban renewal process with respect to issues that relate to themselves in most cases.

As far as the depth of public participation is concerned, the opinions of the respondents are scattered with different attitudes towards the means of public participation in the urban renewal, among which the options from the shallow to the deep were all chosen by the respondents. The options from the top to bottom are: To be willing to have a glance at the renewal information by periodically receiving the push messages of WeChat and free text messages(27.8%); Only willing(24.1%)to have a look at the propagate posters put up on the wall by the government; Willing to call a hotline to offer anonymous opinions(17.4%); Willing to attend the public opinion solicitation symposium held by the government and exploiter(16.5%). In fact, fewer chose to Be willing to participate into the whole process of the urban renewal symposium and open seminar of the project(6.6%)and to call a hotline to offer anonymous opinions(7.6%). It is predicted that these may have a greater attributive relationship with the respondents themselves.

As far as the channels of the public participation into opinion expressing are concerned, the channels for opinion feedback reflected by the respondents are not good.30.9% of the respondents chose only express opinions by chatting with friends and 20.8% chose do not normally express opinions owing to the lack of channels. When the above two groups were added together, a total of 51.7% (more than half) of the respondents indicated that it is the expression of opinions is not smooth and unhindered and they have been unable to do that. Among the rest of the respondents, 30.9% chose to reflect situations to the relevant authorities via hotline, mail and online forum, etc.; and 15.8% chose to direct reflect situations to the relevant departments of the county government. That is to say, approximate 85% of the respondents cannot express their own opinions directly to county government and management department.

It is mainly concluded that:

①The survey shows that the demands of the public towards urban renewal is very high, with 60% of the public supporting it directly and 30% adopting the wait-and-see attitude to see who would support the renewal work in case of good projects.

②The survey shows that the public is quite willing to participate in public participation work of urban renewal, however, two realistic problems, namely the lack of depth in the participation of the renewal and the lack of channels to express opinions, need to be solved urgently.

③The survey shows that approximately 80% of the public are not able to express directly their opinions in relation to their own interests to the county government and the management department in the urban renewal.

Key suggested solutions including:

①Persisting in offering multiple channels for participation by the public at the same time and taking in the opinions of the public that participate through the various channels.

②Whatever the circumstances, the enhancement of delivering the information to publicize the renewal through such means as propaganda posters put up on the outside wall by the government as well as sending WeChat messages and SMSes regularly are methods of public participation acceptable to the public and that are of higher efficiency.

③The broadening of means and channels for the public to express their opinions is the first step in resolving the people’s problems. This point alone can improve the issues of more than half of the respondents not being able to express their opinions unhindered and not being able to express their opinions at all.

4. Enlightenment, Conclusion and Prospect

4.1 Revelation of the Case

(1)Issues that need to be taken note of for the work in the primary stage include: Sufficient consideration of the opinions reflected by the representatives from each class and community (whether in large or small scale) within the old county should be taken, and the questionnaire should also be distributed in proportion based on the various classes. In addition, the form and agenda of the public participation in the democratic symposium deserve to be optimized when collecting public opinions on the urban renewal project with reference to Robert's Rules of Order(written by Henry • M • Robert, translated by Hangchang Wang, 1995);(2)As public opinions on the urban renewal project tend to focus on issues that were reflected collectively but had not received replies and those without channels for reflection, it is therefore much more vital to propagate and promote the means of public participation and communicate public opinions than survey questions themselves in the process of the first poll. This is because it is only on the basis of building good faith and mutual trust with the public can it the action planning of the follow-up framework be carried out more smoothly.(3)The planners should assume more transference and communication work in the study of this project so that they could present the professional planning information in formats that are understandable to and attract the interest of the public and collect and integrate public opinions on the one hand, and on the other hand, they could organize the fragmented public information and opinions professionally and analyse the motivation and trend of public opinions reflected by the data so as to offer more professional planning suggestions to the decision-makers of the urban renewal work.

It can basically be concluded that the public opinions and attitudes towards the urban renewal project through the study and practice in the primary stage are mainly determined by the three following aspects:

Firstly, whether and when the practical issues in daily life can be resolved. He issues that the public living and working at the urban renewal district are most concerned about are those related to their own living environment, such as housing maintenance, commercial disturbance and shortage of parking spaces, etc. which are more practical and specific than whether it would become an urban centre. Therefore, to the public, the urban renewal project can be basically classified into three categories: that which improves their own living environment, the urban renewal that has nothing to do with them and the renewal project which improves both their own living environment and the urban functions. They tend to participate more enthusiastically in the first and third projects. As for issues related to their own living environment, the public is more likely to wish to know the governmental timetable for the urban renewal.

Secondly, how the urban renewal project affects them and whether it would bring those benefits or trouble? The second category of the urban renew project mentioned above makes significant adjustment to the urban functions and spaces in the district for renewal. At this time, the public in the renewal district and its periphery tend to present certain worries and express objective opinions toward those changes. In such a case, the government needs to evaluate the driving force and the hindering force adequately, and pre-warn of the risk of public boycott risks so that such a project can be carried out smoothly.

Thirdly, whether participation in the urban renewal project is determined by whether the effect of the participation would affect its outcome. In the current public participation environment, whether providing conditions that make it convenient for the public to participate in the planning and to what extent public participation affects the planning outcomes would determine the means and depth of public participation in the urban renewal project. The general development trend of the planning transformation is to gradually transform public participation from negative emotions and boycott by the public participation to that of the district planning developing towards a more optimized and positive direction through public participation

4.2 Conclusions

More than a decade ago, when the Japanese and the Western community planning patterns were popularized in the Chinese planning college classes, the students did not seem to understand such a panning model that is very low inefficiency at that time when China's high-speed planning and construction pattern emphasized more on the scientificity and reasonability of the planning result. As time went by, with the slowing down of the pace of construction, the academic world started to realize that the scientificity and reasonability of the planning process also guarantees the achievement of the planning outcomes. Therefore, the way of thinking of public participation is being recognized.

Allowing the objects of the planning participate in the process of the decision-making for planning has always been the planning principle upheld in the theoretical field. This thesis explores the operation model of this principle from the perspective of practice and methodology. The predecessors once proposed that urban planning was a kind of work that specifically served the people, the weight of which is gradually felt in the practice of the current urban renewal project. Compared to the other types of planning, urban renewal can engage and communicate with the people more directly and realistically as well as feel the public expectations carried by the phrase 'urban planning 'in each piece of drawing.

Study on Endogenous and Inclusive Development of Old Residential Area

Jianqiang YANG, Southeast University, China

Jingmei WU, Southeast University, China

Abstract: As it concerns many aspects, including urban society, economy, physical environment, etc., regeneration of old residential area is a complicated social system engineering. In the principles of resident participation, equal cooperation, progressive regeneration and inclusive development, the paper studies the substantial connotation, realistic meaning, fundamental principles, community organization, and regeneration mechanism. The paper indicates that old residential area regeneration, as a more inclusive approach aimed at sustainable, harmonic development of a community, is driven by internal demands, participated by local residents and based on public participation, community autonomy and multi-party cooperation, and combines "top-down" and "bottom-up" management. It proposes suggestions like an leading group for old residential area regeneration shall be established on government level to centrally plan the regeneration, a community planner system should be established on the discipline level to help the residents reasonably set regeneration targets and effectively start the program, a community organization shall be set up on community level to motivate and mobilize all residents and improve communication and cooperation among all parties, and a general work route that can take advantage of collective intelligence should be established on technical measure level so that the community organization and community planner will engage throughout the whole course of regeneration. The study has great academic value and positive realistic meaning for improving and deepening the regeneration of old residential areas at the present stage.

Keywords: Old residential area, endogenous urban regeneration, inclusive development, urban planning

1. Objective and meaning of the study

Regeneration of old residential area is a key part of urban regeneration, and a key factor of building harmonic society. However, there still are a lot of issues in the course of the regeneration and unharmonious events constantly occur: When old residential areas are renewed in some cities, approaches like reservation, repair, renovation and reconstruction are not comprehensively taken, but buildings in old areas are usually brutally "dismantled and reconstructed", so that the constructions are done in very large scale at fast speed, harming the interests of local residents and causing extra financial stress to government. When old residential areas are renewed, attentions are usually paid to the physical structure while the impact on the social structure is rarely considered, overlooking the protection of the connotation and social network for those live in old residential areas, especially, the social issues brought about by improper residents relocation are highlighted. Moreover, the planning methodology is outdated, policies and laws are not as good as expected, and systematic policies, laws and regulations are insufficient for government agencies to make planning for and manage the regeneration.

The fact is that in China, old residential areas are, on one hand, built at good locations, where density of occupancy is quite large, so that they can offer housing conditions for many residents. Although the buildings in the areas have been put into service for several decades, as most of them are in brick-concrete structure and are within the service life, the structure and quality are still in good conditions and can be used for the living in general. On the other hand, the social network shaped by the groups in an old residential area is relatively stable, unique social environment has been formed, and the living and social activities took by the residents in the long past use the area as physical carrier where conventional, stable social network is attached. The study aims to reflect the current approaches of renewal under the setting where "harmonious society", "social justice" and "inclusive development" are advocated in the transitional period, propose endogenous urban regeneration for old residential areas, explore the possibilities for "Top-down" regeneration, study old residential areas from the roots of these social issues, especially from the social nature, and expand and improve the contents and approaches taken by existing regeneration planning so that the regeneration can fulfill the material and spiritual demands of the residents as much as possible.

2. Nature and connotative of endogenous urban regeneration

2.1 Origin of endogenous development

Peru (1983) proposed that comprehensive development of man should be the yardstick to evaluation development and the goal of development. The shift of focus from "things" to "people" marks qualitative leap of the concept of development. Since 1980s, theoretic study of endogenous development entered some other disciplines. In sociology, Tsurumi Kazuko (1989) defined "the theory of endogenous development" as "the people and groups in different areas become adopted to the existing natural ecologic system, follow cultural tradition, consult to foreign knowledge, technologies and system, voluntarily achieve approaches of development goals, create ideal social forms and development conscious lifestyle". In the science of environment and regional economy, Japanese scholar Kenichi Miyamoto (1989) believed that old exogenous development would neglect environmental protection and cause huge waste of resources. In addition, European scholars including Friedmann, Musto, Garofoli kept developing the theory of endogenous development during their studies of issues in regional development.

2.2 Connotation and meaning of endogenous regeneration

Endogenous urban regeneration refers to combine the regeneration of an old residential area with endogenous development, take advantage of community planning's organizational approaches and action pattern and explore resources and demands of the area to promote community integration; take advantage of urban planning's work route and implementation system, establish lawful position of the urban regeneration project, and provide fund and policy assurance for the project implementation. In short, endogenous urban regeneration is a work route based on public participation, community autonomy and multi-party cooperation, integrated with urban planning and combining "top-down" and "bottom-up" approaches. From the viewpoint of urban development's long-term target and universal value, endogenous development is significant for sustainable development of an old residential area, mainly in the aspects below:

(1) It can more easily motivate and mobilize the residents.

Residents of a residential area are the owners. An urban residential area with indisputable ownership has everything to do with each and every resident's interests. It takes resident's participation to promote the development of the area in a sustainable way. The residents of a residential area have the right to participate in the decision-making for any issue concerned with development of the area. Only in this way, the activeness and creativity of the residents can be stimulated and activated. Meanwhile, it can promote social activities among neighbors and communication and cooperation among the residents so as to promote sustainable development of the area.

(2) It can effectively cut the costs of regeneration and management.

The prevailing mode to renew old residential areas, in which the renewal is led by government and carried out by developer, is reasonable to some extent. However, its disadvantage is also obvious -- the management costs paid by the government is quite high. In contrast, endogenous regeneration can effectively cut the costs of regeneration, post management and maintenance of the area. A "social" residential area can be built through endogenous regeneration. It can not only effectively reduce the regeneration costs by taking advantage of social power, but also fully utilize the rich human resources. Therefore, it is advantageous for the area's sustainable development.

(3) It can keep and enrich the area's features of its own.

Due to historic reasons, most residential areas have been built in nearly the same patterns. In this construction mode which overlooks regional diversity, distinctive features of the urban residential areas will be lost gradually. Also, it cannot completely fulfill the demands when any residential area is developed in sustainable way. Endogenous urban regeneration is just an effective approach to enrich features of the areas while their diversities are developed. By taking endogenous approach, the residents can decide on regeneration methods and management systems that are suitable for their individual development according to their respective features while the features can be enriched step by step.

2.3 Fundamental principles of endogenous urban regeneration

"Endogenous urban regeneration" is different from the "top-down" regeneration approach taken by government in essence. According to the theory of endogenous development and experiences in organic regeneration, small-scale improvement and "community construction", "endogenous urban regeneration" includes the fundamental principles below:

(1) Residents participation

Residents, as owners of their old residential area, are the most familiar with the environment they live in, and can specifically point out issues in existence. Any old residential area is renewed for the residents to live in a better way. The urban regeneration with resident’s participation can truly fulfill their demands. Therefore, residents should join in the whole course of the urban regeneration. But, as residents are in different levels, have various demands, and cannot easily have control over the real estate and funds, public participation is an evolving progress. The main aim of endogenous regeneration is to expand public participation's depth and breadth as much as possible.

(2) Equal cooperation

Endogenous urban regeneration advocates equal cooperation among residents, professionals, outside investors and government on community level. Therefore, a powerful community organization should be set up in the first place before an urban regeneration. Secondly, the importance of "conformity to the laws" shall be stressed, which means that all participants shall exercise their power and undertake obligations according to relation national laws and policies. Only in this way, equal cooperation will not become empty talk.

(3) Progressive regeneration

The key to steady urban regeneration lie in the control of regeneration scale and progress. Although the residents want changes take place in their old residential area, changes in excessive scale and speed can result in physiological and emotional discomfort, and bring impact on the traditional links from all aspects. Therefore, renewal of housing and environment should be done prudently so that old and new constructions can blend in. This is the only way to build a vibrant residential area.

(4) Inclusive development

The urban regeneration based on the concept of inclusive development is no longer up to the only utilitarian guidance by economic interests, but will emphasize that social rights and interests should be fairly allocated during the course from a more inclusive viewpoint of social progress and justice, fully safeguard the city's overall interests, reflect the public policies, fully realize the legal rights and interests of all residents and property owners, and fulfill their reasonable claims as much as possible, achieving comprehensive balances among social, economic and environmental benefits, between partial and holistic interests, and between individual and collective interests in relation to the overall interest.

3. Specific measures of endogenous urban regeneration

3.1 Organize a complete regeneration design agency

(1) System guarantee

While the management system of the old residential area is streamlined and a community organization is set up, the community organization shall take the lead to set up a full-functioning urban regeneration design committee. As part of the community organization, the committee shall be governed and coordinated by the community organization, and mainly be responsible for handling issues related to the endogenous urban regeneration.

(2) Members

From the very beginning, the committee should engage in the course of urban regeneration. Its members should include an advisory committee (which represents all parties to be involved in the regeneration. Its members shall cover all walks of life, including experts of planning, construction, law, etc., as well as representatives of investing parties), residents living in the area and their neighbors, user representatives (residents in an old residential area where similar regeneration has been done can be user representatives, and will offer valuable suggestions from their experiences in past regeneration), property management (who can offer valuable advises on how should a regeneration be done to offer favorable, lasting living environment from their job experience). With efforts of the committee, claims of the residents living in the area and their neighbors will be fully examined and considered so that the area can be renewed in a healthy, steady fashion.

(3) Choose community planner

Community planner can be one or more relatively fixed planners or professional organizations. As a professional, community planners act between government and residents, and work as the bridge to connect both parties. Community planners need to take part in the whole process of urban regeneration. With the help of community organization, the regeneration design committee chooses community planner(s) under monitoring of the residents. "Community planner" can be either a component of the committee, a professional planner, a member of a NGO, or a volunteer who offers the service free of charge. The community planner's scope of job includes investigating current conditions and existing issues in the area to be renewed and having understanding of the residents' actual demands, taking part in the planning of physical and non-physical space in the regeneration area, coordinating the relations and conflicts among all interest groups like the residents, government and developer, providing the residents with professional consultation services and helping them to renew old residential area, and giving training to improve the residents' professional knowledge and enhancing their awareness and level for participating in endogenous regeneration.

3.2 Improve physical space as need.

The physical space and social space of a residential area have impact on and act against each other. Although, transformation of physical space acts only on the physical environment, it can bring deep impact on the social space of the area. Firstly, transformation of physical space can have impact on the factors in the physical environment in the area that can develop sustainably. Secondly, the transformation, together with the community planning system in which the users take part in, can motivate more residents to pay attentions to and join in the whole course of the transformation, and can fully stimulate their creativity and activeness. Necessary transformation of physical space in an old residential area can be started mainly from the three aspects:

(1) Rebuild security space

Rebuilding security space of a residential area is to improve the psychological security space of the residents by improving its physical environment. While population in cities increases, the gap between the rich and poor expands, and the society is divided, urban residents become more and more insecure by the day. In urban residential communities recently built have hired a lot of security personnel for patrol, and a lot of hi-tech security measures like camera, access control with intercom and trespass alert system, have been used. As old urban residential areas have been built a long time ago, and equipment like these cannot be fitted in, therefore, they can easy become targets of crimes. Meanwhile, even though these passive security measures are adopted, they will consume a lot of money, make the living environment intense and unnatural, disturb normal social activities of the neighbors, and get in the way for them to develop into good relation.

(2) Offer space for the neighbors' social activities

At present, pathways in many urban residential areas have not exert their role as space for the neighbors' informal social space, and are just used by the residents to travel. Therefore, when an old residential area is regenerated, the road system can be re-planned and the space along the road can be improved and further utilized so that the streets can be turned into space for the neighbors' social activities. Firstly, sufficient walkway is the basic condition of rich activities on walkway. The internal road system in an residential area can be regenerated by conditionally separating people flow from car traffic, centrally arranging parking lots, etc. Secondly, in-depth research shall be done to observe the residents' travel habits and informal social activities, offer healthy place for neighbors' social activities so that the walkways in the residential area will be turned into informal place for social activities with rich connotation and affinity.

(3) Expand utilization elasticity of the space

During endogenous urban regeneration, through coordinate of community organization, upon the residents' decision, and under instructions from professionals, some buildings, whose functions cannot meet the demands or are outdated, can be regenerated, so that the space of the building can be utilized in another way. For example, there are too many kindergartens in many old residential areas while the number of senior people increases. Therefore, the building which is formerly used as kindergartens can be turned into elder homes. Or, part of the facilities can be improved to intentionally enhance their functions.

3.3 Vitalize the more inclusive, more humane endogenous development

A community organization set up by the old residential area shall coordinate to integrate resources, find and solve issues arising during the regeneration, improve the area's environment, improve the residents' living quality, create their sense of belongings, identity and community, encourage community participation, stimulate mutual assistance and senses of autonomy, improve community cohesion, establish new, harmonious relations, develop the community, actively initiate mutual assistance in the community and offer job opportunity to the residents by means of training and help provide by the community.

(1) Increase humane care

1) Elderly care

As there are more and more senior people in old residential areas, the issue of elderly care becomes more and more urgent. Therefore, during an urban regeneration, elderly care services shall be improved and facilities built for elderly care, sports, health care, etc. In addition, senior people have stronger desire to participate in social activities, sports, amusement and other public activities. During an urban regeneration, attentions should be paid to improvement of the space and facilities for their activities according to their physical conditions and demands.

2) Offer jobs for laid-offs.

As the residents in old residential areas have not received much education, it is difficult for them to have opportunities of re-employment. Therefore, the community organization can offer job training for the residents on services that do not require much technology but are high in demand, like house appliance repair, haircut, housekeeping, nursing, etc. Pay salary to some of the residents in need through events arranged by the residents themselves, for example, security and elder care activities in the residential area. It can not only promote endogenous development in the area, but also offer job opportunities for the residents.

(2) Improve social environment

1) Organize public events, and encourage residents' social activities

In order to promote the construction of spiritual civilization in an old residential area, enhance the residents' sense of belongings and sense of identity, promote the construction of harmonious neighborhood relationship, various public activities need to be carried out. The community organization shall be responsible for event organization, and arrange related events for different groups. Government agencies should offer some funds. Especially during the regeneration of an old residential area, events like training, participation, report, and public exhibition should be regularly organized to motivate the residents, which may guarantee successful regeneration, and promote residents' relation, improving the area's social environment.

2) Improve service facilities

During the regeneration, attentions should be paid to improve service facilities in the old residential area so as to offer quality services to the residents. For example, additional signs, outdoor furniture, newspaper stands, billboards, phone booth, environmental sanitation facilities should be equipped. Convenient services should be offered to the residents by means of the events arranged by the community organization. Meanwhile, jobs can also be provided.

3) Improve social welfare system

Carrying out and improving social welfare system in old residential areas are important factors for harmonic development of old residential areas, and are significant to social stability and development. Improving social welfare system should be based on social insurance, social assistance and social welfare, focus on basic social security system, social medical system and minimum income system, be supplemented by charity and commercial insurance, so that social stability can be promoted and the residents can live and work in peace and contentment.

(3) Increase resident’s cohesion

Improved residents cohesion can be advantageous in fostering common awareness among residents and improve their relation. First, resident participation shall be encouraged. They shall be motivated to truly participate in the regeneration construction so as to achieve management, construction and investment by them and benefit for them. Meanwhile, the community organization shall host a variety of public events to create favorable living environment. Secondly, the community organization should encourage the residents to voluntarily offer services, initiate independent- and mutual-assistance events to solve difficulties and issues arising in daily life, stimulate the residents' awareness about public welfare and offering, improve public conduct and help with the construction of spiritual civilization.

3.4 Build a holistic route in which collective intelligence should be brought into play

Endogenous urban regeneration is a comprehensive issue that widely involves all levels and interest groups of the society. To effectively carry out the regeneration, collective intelligence should be brought into play and communication and cooperation among all parties be improved. An just and fair operating mode should be set up, in which the government can make overall central plan for regeneration, motivate all parties, and guarantee the interests of all participants. An urban regeneration public participation system open to the public should be established so as to emphasize the course in which a variety of interest groups are involved, including residents, public sectors, enterprise departments, professional institutions and client groups, fully motivate all parties, form consensus and promote healthy development of urban regeneration. In the actual operation, endogenous regeneration is divided into three stages: (1) initial and discussion stage, (2) project and planning establishment stage, and (3) project implementation and feedback stage (Fig. 1). All parties in participation play different roles in different forms in all stages including conception, investigation & research, planning, design, audit, implementation, supervision and management, so that the roles of community organization and community planner will be played in the whole procedure.

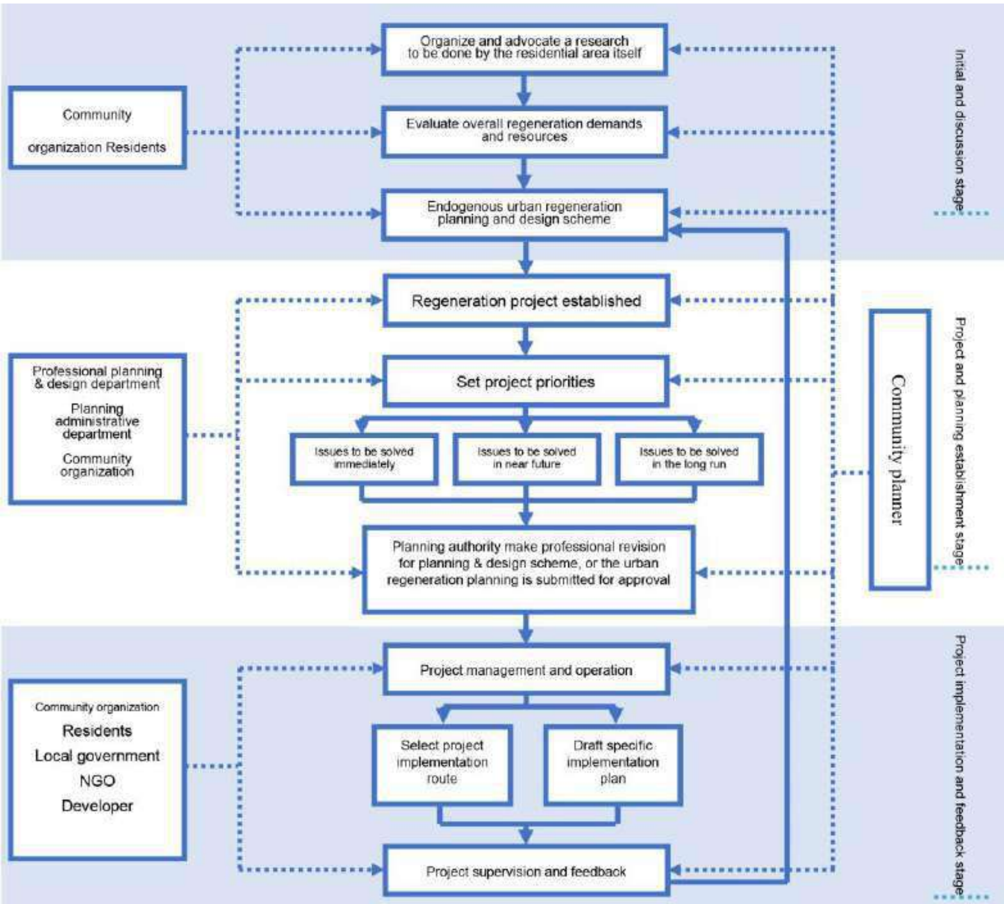

Figure 1: Route of endogenous urban regeneration

4. Conclusion

Endogenous urban regeneration of old residential area, as a more intelligent and inclusive approach aimed at sustainable, harmonic development of a community, is driven by internal demands, participated by local residents and based on public participation, community autonomy and multi-party cooperation, and combines "top-down" and "bottom-up" management. The study has great academic value and positive realistic meaning for improving and deepening the regeneration of old residential areas at the present stage. The paper's opinions and views are presented in the aspects below:

(1) The aim of endogenous urban regeneration is to combine the regeneration of old residential area with endogenous development, take advantage of community planning's organizational approaches and action pattern and explore resources and demands of the area to promote community integration.

(2) Endogenous urban regeneration can effective cut the costs of regeneration and management, can more easily motivate the residents for participation, and is advantageous for the area's sustainable development.

(3) It proposes that a leading group for old residential area regeneration shall be established, a community planner system be established, a community organization be set up, all residents be motivated and mobilized, and communication and cooperation among all parties be improved.

(4) On urban planning implementation level, it proposes detailed workable measure for endogenous urban regeneration, and establishes a holistic route in which collective intelligence should be brought into play.

This work is supported by National Natural Science Foundation of China (No. 51778126).

Track 6

CONTEMPORARY PLANNING PRACTICE:
Projects and Paradigms

Reframing citizen participation for a sustainable city transition – the case of Bodø ByLab

Moderator: BAER, Daniela (Norway)
Speaker: BAHR-SIMONSEN, Marianne (Project manager Bodø ByLab)

ABSTRACT:

Reframing citizen participation for a sustainable city transition – the case of Bodø ByLab

The **aim** of the session is to present and discuss examples for citizen involvement in planning for cities and neighbourhoods with high environmental goals.

The starting point for the session is Bodø. Bodø is in a unique position; having a large piece of land available to expand their city center with the "New Airport – new City" project, a zero emission district wich will be developed over the next 80 years. The city lab 'ByLab' just opened in April 2018 to connect the municipal planning closer with the citizens of Bodø.

The ByLab is a digital platform and a physical meeting place at the library in Bodø, where new technologies as VR-glasses will be in use to test new methods for citizen participation as well as possibility for planners and municipality employees to gain more competence for citizen involvement in planning processes. To show plans of the future development of the area in 3D with the help of VR glasses enables citizens to get a better understanding for the plans. To connect physical plans to other development goals and measures like emission reduction, energy production in neighbourhoods or new forms of transportation could help to shape a better understanding for the vision of "New Airport – new City" project. Especially development goals like emission reduction and energy saving are often difficult to address in participation processes. Based on a better understand, citizen will be enabled to participate in the future planning within the ByLab. Technology is providing new opportunities for how citizen participation can happen, yet we need help to think 80 years ahead on how to think.

In this session we will use design thinking approaches to explore how ByLab and citizen participation can be reframed to become a transitional factor for the city, citizens and other involved stakeholder like industry and academia.

After giving a short presentation about Bodø ByLab, we would like to invite others to present their attempts to involve citizen in planning for city developments with high environmental goals.

What are the good examples for…

Visions: How to develop and communicate the visions?Demand: What kind of participation methods are neededWhich are the greatest challenges - glorious failuresConcrete measuresUse of new technologiesNew meeting places for citizens involvementSensitization for intangible goals like emission reduction

5 cases should be presented as short pitches (5 minutes), leaving room for further discussion.

The hybrid urban renewal model - Entrepreneurship, income, employment, innovation everywhere

Davidovici, Marton, TEL-AVIV, Israel

ABSTRACT:

The urban economy rested upon the basic assumption that sees the residents as an economic "burden", which needs to be covered through profit-making economic activity in the city.

This value concept is a basic, since the city as a whole is meant for its residents and should regard the citizen and the local community as its central and leading asset. Mayors and decision makers lead planning policy to minimize population and maximize employment and business zones; A city that will 'cover' the cost of a citizen. While 'The I generation` and the currant needs are the opposite: urban inspiration, opportunities, sense of belonging and involvement, pushing innovation.

From here it is easy to see that the development of employment parks is not a direct result of market forces, demands, entrepreneurial needs or investments – but rather a tool for municipal management and primarily for the benefit of the city's coffers.

It is not possible to continue to grow in an economic-business fashion, with an approach that continues to add employments zones / parks – who's their existence becomes irrelevant.

. Today, technology and lifestyle needs entrepreneurship and work possibilities from any place and under any land use – from parks and streets, benches and homes, and up to designated employment parks. All these are relevant to entrepreneurship; beyond this, municipal management is needed to cross the conceptual revolution and to recognize that even schools, colleges, community centers or playing fields can be levers for entrepreneurship, innovation, temporary uses and developmental spaces – under management with a new and different outlook.

D.M.R. Planning and Development Ltd. served as the leader of the strategic planning team for the renewal of the city of Bat Yam – a city with a population of about 130k residents, bordering Tel Aviv on the southern edge, and a direct continuation of it along the sea coast, and of its transportation infrastructure. The strategic program is based on an vanguard holistic renewal program; using current tools, to turn the entire municipal space into an urban, entrepreneurial, profit-making space, and thus create a unique economic lever for the entire metropolitan area – including Tel Aviv.

Currently, D.M.R. Ltd., in cooperation with the Bat Yam municipality, to implement the principals and create a holistic renewal planning model – social, economical, environmental and municipal managing. A model which can open new urban management, technology and values.

We will be more then proud to present the process and the principals – as an aspiring case study.

Better Planning Systems for Cooler Countries and Cities

Frank D'HONDT, UN-Planning Expert, Director Territorial Capital Institute, Greece

In this paper, the author presents an indicative Questionnaire to Self-Assess the current planning approach or planning system in each country or city around the warming globe. The Questionnaire is rooted in the International Guidelines on Urban and Territorial Planning, which was acknowledged as a tool to implement the New Urban Agenda and SDG11. The aim is to reform planning systems to effectively enable more compact and inclusive, better integrated and connected, and more climate resilient cities and other territories. Currently, most planning systems tend to result in just the opposite, making it a daunting task to achieve on the key qualifiers of sustainable planning. The paper is based on the author's contribution to UN-Habitat's Handbook to apply the International Guidelines on Urban and Territorial Planning (UN-HABITAT, 2018).

What are planning systems?

A 'system' can be defined as (1) A set of things working together as parts of a mechanism or an interconnecting network; a complex whole – e.g. 'the state railway system', with synonyms such as structure, organisation, order, arrangement, complex, apparatus and network; (2) A set of principles or procedures according to which something is done; an organised scheme or method e.g. 'a multiparty system of government', with synonyms such as: method, methodology, technique, process, procedure, approach, practice, line of action, means, way, manner, mode, framework or *modus operandi*.

Both elements are useful to define urban and territorial or spatial planning systems in general terms: (1) A set of spatial components working together as parts of a mechanism or a complex whole, with components such as spatial structure, spatial organisation, spatial order, spatial arrangement, spatial complex, spatial apparatus and spatial network; (2) A set of spatial principles or procedures according to which spatial planning is done; an organised scheme or method with components such as: planning methodology, planning technique, planning process and procedure, planning approach, planning practice, planning means, planning manner, planning mode and planning framework.

As a matter of fact, the second part is needed to achieve the first part: to achieve a complementary national system of cities, tailor-made planning processes and procedures will be mandatory.

Although 'planning system' is usually associated with the public and governmental sector in a given national context, the above definition does not rule out the way the private sector and people in general shape and make use of the planning regulations, nor that planning systems are confined to more than only national governments and governance – leaving room for subnational and city-specific planning systems or sub-systems. Overall, planning systems can be viewed as the methods and approaches used by the public and private sector to influence the distribution of people and activities in spaces of various scales in a given country or territory.

A recently concluded authoritative ESPON study defines 'spatial planning systems' as "the ensemble of institutions that are used to mediate competition over the use of land and property, to allocate rights of development, to regulate change and to promote preferred spatial and urban form" (ESPON COMPASS, 2018). This is linked with the notion of 'Territorial governance' which comprises the institutions that assist in active cooperation across government, market and civil society actors to coordinate decision-making and actions that have an impact on the quality of places and their development[1]. Formal planning systems thus consist of bundles of public and private development and building rights, agency authority, coordination mechanisms and procedural protocols that are defined by formal political and legal authorities. This, however, is not to suggest that informal planning systems do not exist.

Numerous planning systems exist around the world. While the activity of spatial planning is recognised and practised in most parts of the world, the contexts within which it operates vary greatly. Different urban and territorial issues, different political, economic and institutional systems, and different cultures and value systems all shape the planning system in different ways. Therefore, designing a planning system cannot be readily approached with an ideal template. This is well illustrated by the ground-breaking International Manual of Planning Practice (ISOCARP, 2015). In this manual, planning systems are assessed by planning practitioners on seven components: (1) Where lies the administrative competence for planning? (2) What is the main planning legislation? (3) What are the key planning and implementation instruments? (4) Who is doing development control? (5) How is planning related to sustainability policies? (6) What kind of governance system is applied in planning? (7) How does the planning system work in practice?

This work builds on earlier findings stemming from the 2009 Global Report on Human Settlements: 'Planning for Sustainable Cities' (UN-HABITAT, 2009). While we will further elaborate on the outcomes of these three authoritative publications in the next section, the approach taken here is to suggest an entirely new list of normative principles against which all planning systems can be assessed, reviewed, improved, adjusted or reformed. Planning systems in different parts of the world may meet these principles in different ways, using different institutional structures and processes.

Physical and cultural differences and contexts matter a lot – rendering a one-size-fits all global planning system senseless. Yet, as I will argue, the International Guidelines on Urban Planning (IG-UTP) – underpinned by the Sustainable Development Goals (SDGs) and New Urban Agenda (NUA), provide a coherent set of principles to readjust the locally applied systems to these universal principles. Therefore, a universal approach of what a planning system should contain to better enable sustainable urban and territorial development is worth further exploration. Framing this new planning system approach within the ''Theory of Change' model could be depicted as suggested below in Figure 1.

In this view, planning systems are part of the resources needed to achieve the desired sustainable urban and territorial development goals. They highly depend on national normative, legal and financial frameworks and development polices, but by including all planning actors, planning systems will become more bottom-up and people-oriented, considering all the planning scales, including the transnational and trans-boundary level. A planning system should include the three-pronged approach to planning (plans, legislation and finance), combined with the institutional and human resources and skills needed to operationalise the system through the application of appropriate processes and phases of the planning cycle, to produce outputs, outcomes and desired impacts as results.

Acknowledging the risk that (re)designing such a *multiplex planning system* approach could have a discouraging or even intimidating impact on actors of change, any entry points of discussion, minor or major, large or small scale is meaningful if the environment is conductive to address and redress the issue in an integrated way, by making smart links with other components of the planning system in a given territory.

[1] See unpublished Input paper for the ESPON COMPASS workshop on Comparative Analysis of Territorial Governance and Spatial Planning Systems in Europe, Brussels, 20 March 2018

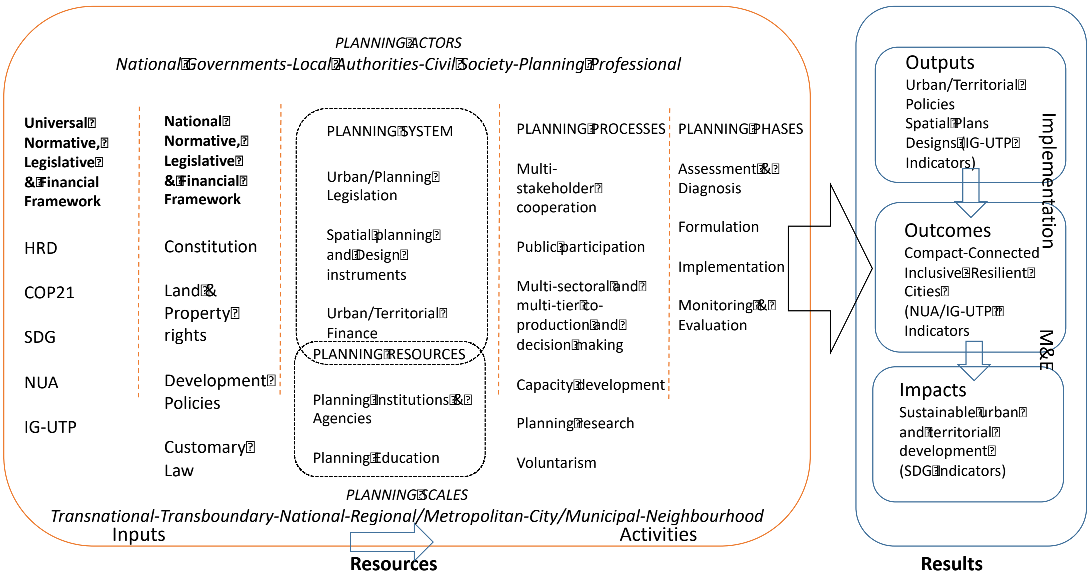

Figure 1 – New planning system approach as part of 'theory of change'

This new planning approach integrates all key elements of NUA/IG-UTP and will provide a reference model to review and redesign planning system anywhere in the world.

What is the problem with planning systems?

The combined conclusion of the three authoritative studies referred to in previous section is clearly that most if not all planning systems are a) outdated, b) not (sufficiently) addressing emerging territorial issues such as climate change and social inequality, c) are no longer synced with decentralisation and new governance arrangements and – last but not least – display a growing mismatch between theory (law) and praxis.

The earlier cited International Manual of Planning Practice (IMPP) draws some critical conclusions on the state of planning systems in the 135 countries included in the 2015 compendium - as experienced by its member-planning practitioners:

- All countries have a physical planning system, only few since recent times. The main aim of planning is to regulate land-use; the most widespread being for the common good, to safeguard property rights, to create harmonious communities, and to protect the environment. Yet, market mechanisms are at work in all IMPP countries. Some are treating land and real-estate as pure commodity, even where all land remains state-owned;
- Planning focuses predominantly on cities while mostly ignoring rural settlements, eco-systems and climate. Attempts at more balanced 'regionalisation' floundered at the weakness of intermediary levels between the state and the local level. Regional planning is weak or non-existent, even in more or less autonomous entities of federal countries. Innovative voluntary regional agreements to tackle polarisation, excess gentrification, as well as shrinking cities lack institutional anchorage in existing power bases to sustain their momentum in the longer term;
- There remains a gap between often complex and bureaucratic planning systems and their effectiveness in the real world. Informal settlements are rife not only in the developing world where they constitute up to 80% of the built fabric; usually in the poorest countries. Often IMPP contributors state that planning systems are not working in practice and that planning seems to be in crisis in many places;

- Popular demand for decentralisation and more local autonomy is a prime contributor to changing governance. Decentralisation remains an illusion as long as the centre retains fiscal powers and planning is subjected to the *ultra vires* principle. For many countries, governance means greater involvement of the private sector, not only in the development process but in the plan making itself;
- While public participation has been incorporated into most planning systems it is ineffective in practice, and often practiced only at the end of a plan making process. Despite rising preoccupation with the environment, due to the debate on climate change and the incorporation of 'sustainability' in the planning system, its meaning and operational competence have to be much more clearly defined to be of use to planning;
- Concrete reasons given for the difficulties with implementation are the lack of planning skills and education, lack of professional planners as well lack of resources attributed to planning. The greatest obstacles of planning when seen as a tool of spatial and social justice are market driven development processes on the one hand and persistent adverse existential conditions, poverty above all, on the other hand.

Enriched by personal planning system experiences in a variety of countries and continents (Europe, Balkan, Middle-East, Asia and Caribbean), I can draw at least five compelling reasons why countries, cities and their citizens should jointly review the way urban and territorial planning and development is organised, managed and practiced to implement the NUA and attaining to the SDGs:

- The legal basis of national or devolved planning systems are often designed and developed in the 20th century and no longer fit for purpose in the fast urbanising and environmentally deteriorating 21st century;
- The planning system might be rooted in colonial times and not designed or developed according to the local context and specific challenges and opportunities of communities and territories;
- The planning system might be designed and developed under a different socio-ideological framework that no longer (should) exist;
- The planning system is only addressing the formal planning while much if not most of the recent and ongoing urbanisation and territorial innovation occurs outside the formal planning system;
- The planning system in place might simply not be up to task to deliver on the SDGs (Goal 11 in particular) and the NUA – think of climate change as one of the most pressing matters!

The bottom line is that any country, city or community taking the effort of having a serious look at the conditions for sustainable urban and territorial planning and development, as laid down in the NUA/IG-UTP, will most likely come to the conclusion – through an open and multi-stakeholder reflective process – that the planning approach and system - with its distinct set of planning instruments, legal rules and regulation, human, financial and technical resources, and its distinct planning practices – will require some sort of adjustment, if not a more fundamental reform in case the initial objectives and ground rules of planning do not longer align with the reformulated objectives and goals to meet the challenges of today and tomorrow. Where there is no coherent or very limited planning system in place, countries and cities can leapfrog towards better designed systems by earning from the hard lessons learnt by older planning systems – see also the ESPON COMPASS study.

What are the international benchmarks for cooler planning systems?

The International Guidelines on Urban and Territorial Planning (IG-UTP) serve both as a source of inspiration and a compass for decision makers and urban professionals when reviewing urban and territorial planning systems. The Guidelines provide national governments, local authorities, civil society organisations and planning professionals with a global reference framework that promotes more compact, socially inclusive, better integrated and connected cities and territories that foster sustainable urban development and are resilient to climate change. Because normative frameworks such as the Sustainable Development Goals (SDGs), the New Urban Agenda (NUA) as well the IG-UTP are by default of a global and universal nature, they do not explicitly address national and subnational planning systems as such. This paper explores the role of national and sub-national planning systems as the contextual tissue to connect all the dots and lines sketched out by the emerging global normative planning frameworks – the first column of the new planning approach as sketched out in Figure 1.

On the pressing issues related to climate change, the IG-UTP promotes climate resilience as one of its five qualifiers for a more sustainable territorial development, while the four other qualifiers also need to contribute to climate resilience (through integrated planning and more compact and better connected cities that are socially inclusive).

The IG-UPT is structured around 12 guiding principles including principle 8 on planning for climate resilience: *"Urban and Territorial Planning contributes to increase human security by strengthening environmental and socioeconomic resilience, enhancing mitigation of, and adaptation to, climate change and improving the management of natural and environmental hazards and risks."*

Therefore, any policies, plans and designs that promote resilience to climate change should specify the expected climate change effects, based on the available climate change science and other data, on the spatial scale of policies, plans and designs, i.e. climate change effects on the national urban system – regional and metropolitans scale, on the city as a whole and down to the neighborhood level. Thy should also include adaptive measures for the expected negative effects if climate change, include mitigation measures for reducing the contributing factors, especially GHG emissions, for climate change; and support, where possible, the development, application and scaling of climate friendly and resilience technology, including eco-system-based adaptation etc.

Sustainable Development Goal 13 commits to *"Take urgent action to combat climate change and its impacts"*, by – *inter alia* – integrating climate change measures into national policies, strategies and planning, implementing the commitment undertaken by developed-country parties to the United Nations Framework Convention on Climate Change, and promoting mechanisms for raising capacity for effective climate change-related planning and management in least developed countries and small island developing states. Also, SDG 11 contains climate change related engagements, linked with risk and disaster management:

"By 2020, substantially increase the number of cities and human settlements adopting and implementing integrated policies and plans towards inclusion, resource efficiency, mitigation and adaptation to climate change, resilience to disasters, and develop and implement, in line with the Sendai Framework for Disaster Risk Reduction 2015–2030, holistic disaster risk management at all levels" (SDG 11.b) – as well *"Support least developed countries, including through financial and technical assistance, in building sustainable and resilient buildings utilising local materials"* (SDG 11.c).

Building resilience demands a whole-of-society approach, especially in cities, where the key sectors of local government must be fully engaged and coordinated. Private sector, the scientific and technical community and community actors (including women, youth and persons with disabilities among others) are increasingly involved in building urban resilience. Efforts to pro-actively engage expertise in issues of economics, environment, health and related areas will help to ensure that resilience building efforts are holistic.

The New Urban Agenda and Guidelines provide guidance on how to operationalise a resilience agenda by providing a positive role for urbanisation - one that connects the physical, social, environmental and economic elements of cities and other territories.

While the international community is still working out the indicators for monitoring the SDGs, NUA and IG-UTP, we could think of specific territorial indicators such as:

- Spatial policies and plans include climate and hazard resilience assessment;
- Spatial plans include climate and hazard resilience indicators/incentives;
- Spatial plans and designs include low carbon and renewable energy indicators/incentives;
- Spatial plans and designs include green building indicators/incentives.

Inspiring practices are part of the international benchmarking and have informed the redaction of the 12 guiding principles and 114 recommendations of the IG-UTP – see for instance the case of Norway in Box 1.

Box 1: Norway – Cities of the Future Integrating Climate Change Adaption

Norway is a Scandinavian country positioned in Northern Europe, with a population of just over 5 million inhabitants. Its economy has been dominated by oil and gas exports, positioning it as one of the top 20 countries with the highest CO2 emissions. According to forecasts made by the Intergovernmental Panel on Climate Change (IPCC), Norway's annual mean temperature is expected to rise by 3.4 degrees Celsius this century and precipitation has already increased by 20% since 1900. Acknowledging the vital role cities play in mitigating climate risk, Norway has adopted a multifaceted urban policy approach. In particular, municipalities were identified as having significant responsibility in influencing the urban environment at a local level and in turn influencing constituent attitudes to energy consumption. The 'Cities of the Future Programme' invited thirteen of Norway's largest cities to take part in a collaborative project to reduce emissions and make cities more liveable. Integral to this was the concept of compact cities, those which favour walking and cycling and promote dense, liveable urban forms. The value added to the programme through integration of urban planning and sectorial policies has improved Norway's resilience to climate change and created an ongoing dialogue between key actors, an important asset in urban management for the future.

Source case: UN-HABITAT, 2015 – Source picture: http://www.uib.no/

Among many other planning issues, the climate resilience policy aims indicate the need to assess the current planning systems on its effectiveness and efficiency to address climate change and other natural and man-made disasters.

A Questionnaire to review planning systems

Basically, planning systems are to be re-defined as the localised 'multi-tier and multi-partner governance framework for improving urban and territorial policies, plans, designs and implementation processes, aimed at more compact, socially inclusive, better integrated and connected cities and territories that foster sustainable development and are resilient to climate change'. Hence, a planning system should also be considered as the combined performance of 'planning in theory' and 'planning in practice'. This section explores an indicative Questionnaire to Self-Assess the current planning approach or planning system in any given country or city, after elaborating on the reasons to review, what to review exactly, who should review and how planning can be reviewed in an organised way. Questions are formulated as positive statements, to allow a scoring along the scale of Likert from 1-5, with an indicative set of indicators on a scale of 0-1.

Although a comprehensive Self-Assessment Questionnaire need to address all issues, Box 2 presents a sample of questions related to climate change and the broader issue of urban and territorial resilience.

Box 2: Self-Assessment of Planning Systems

Self-Assessment for Planning Approach/System in general	
Statements (Score 1-5)	***Suggested indicators (Score 0/1)***
1. The planning approach/system in general aligns with the universal definition of spatial planning as a decision-making framework for improving policies, plans, designs and implementation processes and projects that is:	
a. Better integrated and aiming at a multi-sectoral approach;	*An inter-ministerial territorial coordination in in place*
b. Participatory and aiming at informed and engaged citizens;	*There is a culture of public participation in place*
c. Socially inclusive and aiming at improving the lives of poor and vulnerable people (including slums) through territorial cohesion;	*Plans include Social Impact Assessments*
d. Environmentally sustainable and aiming at protecting eco-systems and bio-diversity;	*Plans include Environmental Impact Assessments*
e. Resilient to climate change and other natural and man-made disasters;	*Policies/Plans include Climate/Hazard Resilience Assessment*
f. Human rights based and aiming at realising development rights for all, with focus on youth, women and minorities.	*Policies/Plans include Human Rights markers*
2. The planning practice is in general in line with the 'planning theory' as enshrined in the legal and customary framework:	
a. Territorial developments and projects are mostly compliant with plans and rules;	*A plan-compliance check is in place for projects*
b. The planning rules and regulations are mostly enforced;	*Inspection of constructions is a common practice*
c. Laws, policies and plans are regularly reviewed through a permanent monitoring and regular evaluation.	*A parliamentary commission on land-use and spatial planning is in place*
3. The planning approach/system recognise and foster a multi-stakeholder participatory approach including partnership with and between:	*A National Urban Commission/Forum is in place*
a. Local and other sub-national planning authorities and institutions;	*Local Authorities takes part in the National Urban Commission/Forum* *A national association of local authorities is in place*
b. Civil society (including vulnerable groups such as children, women, youth, elder, disabled and ethnic minorities);	*Civil Society takes part in the National Urban Commission/Forum*

c. Private sector and business community associations; d. Planning professionals and their associations; e. Planning schools and their teachers and students.	*Granting schemes for civil society incentives are in place*
	Private sector and business community takes part in the National Urban Commission/Forum
	Planning professionals takes part in the National Urban Commission/Forum
	Planning school/academia take part in the National Urban Commission/Forum
4. The planning approach/system or components of it explicitly refer to global or continental policies on sustainable urban and territorial development, climate change or resilience against natural and man-made disasters.	*Your country was involved in drafting one or more of those international policies and guidelines*
5. Overall, there is a planning approach/system in place consisting of three inter-related enabling components: a. Sound and flexible spatial planning and design framework at multiple scales (see question 2); b. Enforceable and transparent legal framework; c. Financial framework to diagnose, formulate, implement and monitor spatial planning.	*The planning system is generally highly repudiated and respected*
Self-Assessment for Resilient City Planning in particular	
6. The local authority promotes the construction, retrofitting and management of "green buildings" through incentives and disincentives, and monitor their economic impacts.	*Plans and designs contain 'green building' indicators/incentives*
7. The local authority uses urban and territorial planning as a tool to improve access to water and sanitation services and reduce air pollution and the amount of water wasted.	*Plans and designs contain access to water/sanitation indicators/incentives*
8. The local authority formulates urban plans as a mitigation and adaptation framework in response to climate change and for increasing the resilience of human settlements, especially those located in vulnerable and informal areas.	*Plans contain area/community-sensitive climate mitigation indicators/incentives*
9. The local authority locates essential urban services, infrastructure and residential developments in low-risk areas and resettle, in a participatory and voluntary way people living in high-risk areas to more appropriate locations.	*Plans contain risk-avoidance/mitigation indicators/incentives*
10. The local authority assesses the implications and potential impacts of climate change and prepare for the continuity of key urban functions during disasters or crises.	*Special climate and disaster resilience plans are in place*

Self-Assessment for the climate resilience qualifier on different scales of planning (1-5)		
National/Regional	Metropolitan/City-wide/Municipal	Neighbourhood
1. Does the policy/plan/strategy assert the role of cities as major contributors to climate change through their increased CO2 emissions and the vulnerability of urban populations and infrastructures to climate change? 2. Does the national policy, plan or strategy address the local impacts of climate change (e.g., sea-level rise, urban heat wave, etc.) and promote cooperation between national and sub-national governments/groups/ organizations? 3. Does the policy, plan or strategy promote low-emissions development (LED) and/or reduce greenhouse gas (GHG) emissions below a specific baseline? 4. To what extent does the policy/plan/strategy place adequate emphasis on the following: a) Climate change adaptation b) Mitigation of emissions	1. Does the policy, plan or strategy address the metropolitan impacts of climate change (e.g. sea-level rise, urban heat wave, etc.)? 2. Does the policy, plan or strategy incorporate an urban resilience profile? 3. Does the policy, plan or strategy promote low-emissions development (LED) and/or reduce greenhouse gas (GHG) emissions below a specific baseline? 4. Does the policy, plan or strategy include a metropolitan-wide or city-wide emissions inventory 5. Does the policy, plan or strategy reflect commitments or agreements to meet metropolitan emissions reductions targets?	1. Does the policy, plan or strategy address the local impacts of climate change (e.g., sea-level rise, urban heat wave, etc.) through adaptation strategies (e.g. floodplain avoidance, emergency preparedness, etc.)? 2. Does the policy, plan or strategy promote low-emissions neighbourhood development strategies (LEDS) (e.g., compact development, mixed-use development, transit-oriented development, etc.)?

This indicative Self-Assessment Questionnaire sample need to be tested and further refined. While customising the statements and indicators to the local context might be required for meaningful response, using a common set of questions will allow exchange, comparative analysis and world-wide monitoring and evaluation – essential for monitoring the implementation of the New Urban Agenda.

This Questionnaire can be combined with a more specific assessment framework targeting the urban and territorial legal frameworks. The Planning Law Assessment Framework (UN-HABITAT 2018b) is a self-assessment tool to be used during focus groups to identify strengths and weakness of all the laws, regulations, and decrees applicable in a city or any other given territory, enacted at different levels.

Reviewing to reform planning systems

Planning System Review methodology

While there can be good reasons to be pragmatic and look at ad-hoc ways to improve the planning system, it is however more effective to follow the classic planning cycle from

is to implementation and
on, at all planning scales,
g all stakeholder groups,
g urban/territorial legislation
ported by adequate human,
l and financial resources. In
ords, moving from an ad-hoc
a more ‘planned’ adjustment
rm of the planning system in
igure 2 illustrates this
l review and adjustment of a
g system on the three-
l-components, starting with a
is, e.g. by using the self-
nent questionnaire (see
by prioritising the most
g issues and formulating
llowed by the implementation
combined with permanent monitoring and evaluation, which can lead to further review and adjustment.

Figure 2 – Planning system review cycle

In addition, the review also need to look into the other resources as well the capacities needed to plan, implement and manage urban and territorial development:

- Institutional review: assessment of the institutional resources and their capacities in place for spatial planning and management – not only the governmental structures at national and sub-national levels; also the para- or non-governmental planning agencies, as well planning professional organisations, related civil society and business community organisations, including the domestic private planning consultancies;
- Educational review: assessment of the national and sub-national educational sector, both public and private, contributing to planning capacity development for all ages and gender, from primary schools to universities. Special attention is needed to review R&D capacities to support evidence-based spatial planning.

Planning legislation and overall planning systems are most commonly established at country level but obviously affect all the other territorial levels, from supra-national to local and neighbourhood level. The Guidelines advocates a subsidiary co-productive governance approach with planning and implementation mechanisms at the appropriate level, driven by partnerships and co-production of policies, plans and designs at all planning levels. Hence, the assessment of a planning system should also consider this territorial urban-rural continuum throughout the different scales and levels of planning and governance. This entails:

- Urban-Rural planning review: assessment of policies, plans and designs for both urban and rural areas, including the hybrid territories where urban-rural linkages or the lack thereof can make or break food-security and resilience to natural hazards and climate change. ‘Rural’ in this case also comprises entirely natural and non-cultivated or inhibited areas;
- Multi-scale planning review: assessment of the national planning scale - including the national land- and planning-relevant legislation – should be complemented by

reviewing planning approaches and instruments – or the lack thereof – at sub-national planning scales, including metropolitan and city-wide planning. Anticipating exponential growth and share of metropolitan urban regions all over the world, tailor-made 'metropolitan planning systems' will be required to meet the specific challenges of each metropolis, with its own set of urban legislation, institutions and resources. But also planning at transnational and transboundary scales need to be reviewed, as well the bottom-up approaches and participatory planning instruments at hand for urban and rural communities.

In the spirit of the NUA/IG-UTP, it is strongly recommended that respondents from all four key stakeholder groups are involved in the Self-Assessment: National Governments, Local Authorities, Civil Society and Planning Professionals. The mobilisation and selection of respondents for the Self-Assessment and the planning review is primarily a local matter. However, some suggestions can be made regarding the four key respondent groups, while keeping in mind that any stakeholder group at any time can address any planning issue to review as a starting point or led by a sense of urgency. The sections below however suggest possible ways to undertake a more comprehensive assessment of the entire planning system or approach. Each country or city can organize the Self-Assessment according to local best practices, inspired by international best practices. The methodological approach as suggested below is therefore indicative. Although it is possible for individual and associated respondents to answer the Questions independently and without further exchange, the preferred situation would be an established Multi-Stakeholder Planning Review Task Force to organize and coordinate the activities related to the Assessment. In the absence of a consensus among the four key stakeholders group to undertake a joint evaluation of the planning system, the partial Self-Assessment can still contribute to raise awareness, provide arguments for advocacy and feed a public debate on review and reform of the planning system in place. The Self-Assessment Task Force will establish a roadmap and workplan according to human and financial resources that are available or can be mobilised – see Figure 3 for an indicative Planning Review roadmap.

Planning System Reform methodology

With respect to ensuring use, the key is found in securing a commitment to the Self-Assessment as a learning and change process - both within and external to the affected stakeholder organisations. Ensuring buy-in on a clearly defined purpose, a credible process that stays focussed on the relevant issues. Findings that are universally understood and meaningful and practical to their users will encourage the adaption and application of the assessment findings. The tools and principles presented in previous section are also readily adaptable to periodic follow-up and monitoring to gauge progress and document changes.

The second element for maximising the benefits of the Planning Self-Assessment lies in building a greater body of knowledge around conducting and using self-assessments. To extend the benefits beyond the primary organisations related to the design and operation of the planning systems, we need to make our experiences accessible, to be shared and built on by others. The resulting synergies and learning can then deepen our understanding of the complexities of planning self-assessment and expand the number of stakeholders and organisations conducting them and learning from them

Linking the Planning Self-Assessment with the Theory of Change, a number of specific steps could be considered to maximise the use of the planning review – see Figure 3.

With Step 1 and Step 2 addressed in the previous section, this section will concentrate on the 'resulting' Steps 3-5. Having designed a self-assessment process and methods consistent with the clearly-defined purpose, established buy-in across the stakeholder-organisations, and secured the participation of ethical, credible evaluators, the exercise then needs to be pursued with rigour. Stakes can be high in changing deep-rooted planning rules and the information on which the changes are based needs to be reliable and complete. Using the technical expertise available to it, the assessment team ensures this by monitoring the design, methods and outputs throughout the process. Quality control to maintain the reliability of the data analysis and interpretation ensures that both the spirit behind the assessment and the methods chosen for its overall design are adhered to. At the analysis and reporting stages, a willingness to rigorously verify the findings with stakeholders strengthens the basis on which the recommended actions are built.

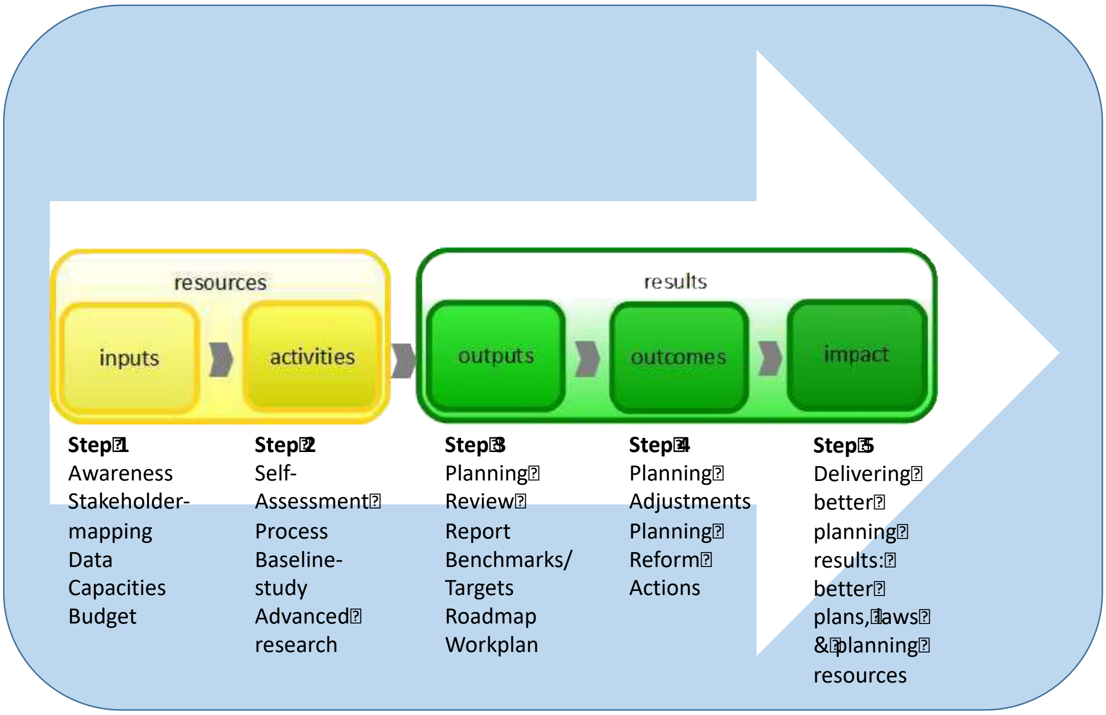

Figure 3 – Step-by-step planning system review and reform process

Step 3 starts with completing and endorsing the Planning Review Report. The modes selected for reporting and disseminating the results need to be tailored to the users and relevant to the organisational environment. Reporting starts early in the assessment process in order to verify accuracy, to increase the volume of the data and to establish a reporting pattern which is comfortable and effective for stakeholders. Depending on the feedback, adjustments can then be made to the way the data is packaged and/or the modes of reporting. Gradually building up knowledge across the stakeholder organisations about the assessment's findings, means that they can be verified and gradually understood and accepted. In the final reporting, the assessment team can then move directly into **action planning** because the stage has been set for the team to move stakeholders to respond to the findings by committing to and scheduling actions. The bridge from reporting tot action planning is the **prioritisation of planning issues** to be redressed through adjusting or reforming the current planning approach/system, while also including new topics to be addressed in a planning reform process.

Steps 4 and 5 is about reaping the incremental benefits of the planned planning review. While Step 5 is only measurable on the longer term – the desired change in urban and territorial deliverables such as more compact-walkable, socially-diverse and healthy neighbourhoods, cities, towns and villages – Step 4 is the real implementation phase of fixing as much as possible and developing new planning tools and instruments as required by the Planning Reform Action Plan. While 'friction' in planning-led urban and territorial development can not and should not be entirely eliminated – effective sustainable societies are usually characterised by planning systems with a set of well-thought publicly controlled and enforecable rules and regulations – adjusted, reformed or entirely planning systems should be primarily designed to enable sustainable devlopment, through multi-stakeholder and participatory co-production of planning outputs and planning outcomes. Co-productive tools and instruments such as multi-stakeolkder 'urban forums' and 'urban pacts' should become key components of improved planning approaches and systems.

Making the change happen

Spatial planning needs to change because the world has changed and keeps changing – a world of 10 billion is a different planetary proposition from one of 5 billion, as much as a world heating up with another 2-4 degrees Celsius will require adaptive territorial responses. "One reason why planning in many countries has not kept abreast of these deep changes is that it has been too parochial. Because legislation, procedures, institutions and policies have been shaped at national or, in federal states at provincial level, planning practice has been locked into the specifics of those systems." (UN-HABITAT/SALGA, 2018). While climate change has created a global awareness among planners and decision makers, the SDGs, NUA and IG-UTP provide the markers for reviewing and reforming outdated or dis-functional planning systems. While there is no ideal template for better performing planning systems, all relevant territorial stakeholders need to partner to review and reform defunct planning systems against the international benchmarks for a more sustainable territorial development. Planning systems in different parts of the world may meet these principles in different ways, using different institutional structures and processes, and different methodologies and outcomes, but using common tools such as the suggested Self-Assessment Questionnaire, can largely enhance communication, peer-to-peer learning and convergence on the planetary development goals. Planners and their professional associations such as ISOCARP must champion this change for cooler planning systems.

The Periodic Table of Urbanism

E. Stephen GOLDIE, RFD, BTP, MPIA, CPP
City Planning Advisor, Abu Dhabi Department of Planning & Municipalities, UAE

Synopsis

Just as the Periodic Table of Chemistry identifies the physical components of our universe and is able to predict the relationships between them, a Periodic Table of Urbanism is proposed. This table provides a comprehensive framework for describing the “general reign of order” in our towns and cities while also enabling the development of an algorithmic framework for planning as a necessary step towards the application of artificial intelligence to urban planning.

1. The Rural-to-urban Transect

Andres Duany and Emily Talen first published the rural-to-urban transect[1] in 2002, a scientific insight that is comparable in importance and structure to the publication, in 1869, of the periodic table of chemistry by Professor Dmitry Mendeleev (1834–1907). It is a planning technique that is both comprehensive and nuanced, but at its core it currently provides six prototype zones in a prototypical progression along a notional transect from rural-to-urban, plus ‘special districts’ (see figure 1).

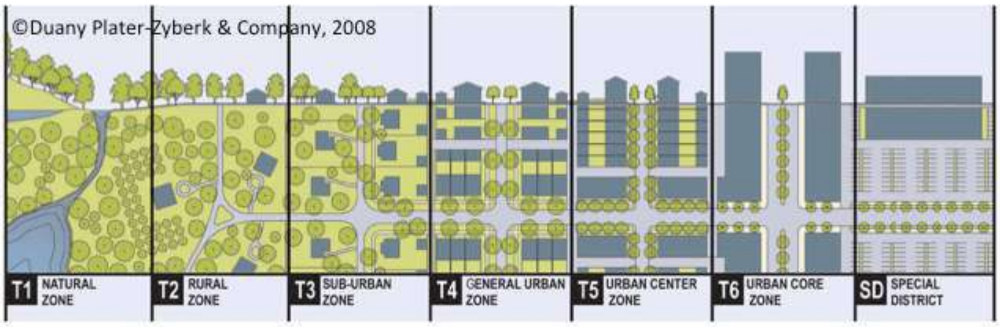

Figure 1: The Rural-to-urban Transect

These transect zones, or urban-ecological zones, are balanced combinations of land use, built form, road design and landscape. They are similar to agro-ecological zones[2], but they should not be confused with the eight ecozones used in environmental science. In this paper the term “urban-ecological zone” will be used when speaking generally and the term “transect zone” (or T1, T2, T3, etc.) will be used when referring to specific zones on either a prototypical or an actual transect.

2. Community Units

In practice urban-ecological zones are usually grouped into community units to ensure greater sustainability through a fine-grained diversity of built form and land use. The urban structure is then formed from these units and their supporting infrastructure in accordance with the principles listed under “The Neighborhood, The District, and The Corridor” in the 1993 Charter of the New Urbanism[3].

The standard community units are:

- Clustered Land Development (CLD), e.g. a hamlet, typically consisting of the transect zones T2 (rural), T3 (suburban) & T4 (general urban) zones;
- Traditional Neighbourhood Development (TND), e.g. a village or a neighborhood, typically consisting of T3, T4 & T5 (urban centre) zones;
- Transit Oriented Development (TOD) e.g. a neighborhood or district centre with good transit, it also typically consists of T3, T4 & T5; and
- Regional Centre Development (RCD), e.g. a regional centre, typically consisting of T4, T5 & T6 (urban core) zones and generally with good transit.

It is a massive oversimplification to say that urban planning is the art and science of specifying and distributing the community units and the "big" infrastructure of the town or city, while urban design is the art and science of laying out the streets, plots and parks, etc., and also specifying the built form and detailed land use within the community units, but it is sufficiently accurate to assist those unfamiliar with transect-based planning to visualise the process in that way.

3. The Planning Cycle

One of the great strengths of transect-based planning is that adopts techniques that are common in environmental science, while adding a method of describing urban places that is applicable at all stages of the planning cycle (figure 2).

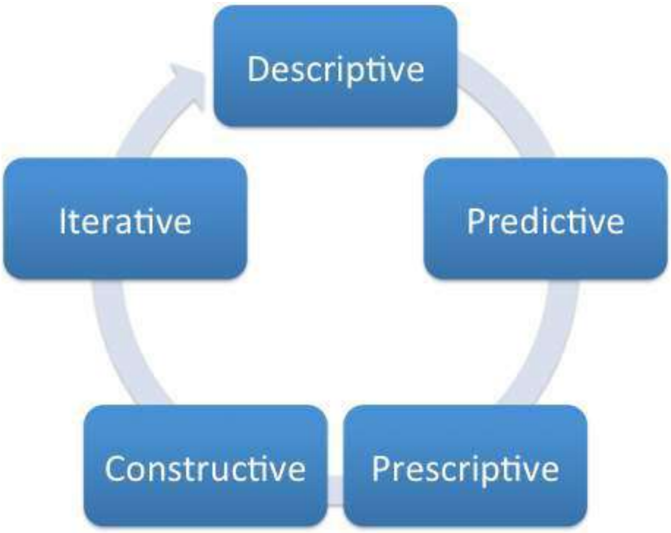

Figure 2: The Planning Cycle Improved by Transect-Based Planning

Transect-based planning starts with detailed observation and a scientific approach to describing an existing urban area. When analysis and design are added to this description then, through comparison with similar transect patterns elsewhere and in history, it becomes predictive. By adding law and governance to a plan developed from such an analysis it becomes prescriptive and, with funding, the responsible surveyors, engineers, architects and landscapers should find it constructive, in that it should produce good, sustainable urbanism and not destructive environments, such as post-WW2 urban sprawl. After the new place has been inhabited for a generation or two it may be appropriate to consider some improvement, repair, or succession to the next transect zone, in which case the cycle may be reiterated.

The core strategic management problem for city planning directors and their mayors is how best to manage the planning cycle efficiently and effectively. Too much emphasis on strategic planning (the descriptive and predictive stages) and the statutory process and economic development (the prescriptive and constructive stages) will be under-resourced, slow and error prone. Too much emphasis on statutory planning and the process of issuing planning consents will be confused, for want of a coherent purpose. Getting this balance right can be greatly facilitated by adopting a planning system that uses common terminology consistently throughout the process, from environmental study to post occupancy survey. A transect-based planning system, such as Smart Code[4] (which is specifically designed to suit United States planning law) is currently, the only planning system that provides for this.

City administrations are responding to this challenge by adopting transect-based planning codes (and their close relation, known as form-based codes) in rapidly increasing numbers. From 1981 to 2017, 387 have been adopted (341 in the United States and 46 across the other inhabited continents); however, 88% of these have been adopted since 2003[5]. In simple terms, this is an average of two form-based or transect-based codes adopted each year over the twenty-two years from 1981 to 2003, jumping twelve-fold to twenty-four each year over the fourteen years from 2003 to 2017. If an exponential rate of increase is sustained, this form of planning control will be dominant across North America within a decade and will become very common across much of the rest of the world during the same period.

If the acknowledged benefits of transect-based planning can be improved upon, as I hope this paper demonstrates, then perhaps the rate of adoption will become even faster, but first it is important to identify the gaps in the current practice by examining transect-based planning in a truly urban environment.

4. Case Study: Palermo, Sicily, Italy (part 1)

The “wedge” illustration of a prototypical transect (figure 3) demonstrates the fact that the area covered by the natural and rural transect elements is usually significantly larger than the area covered by the more urban elements.

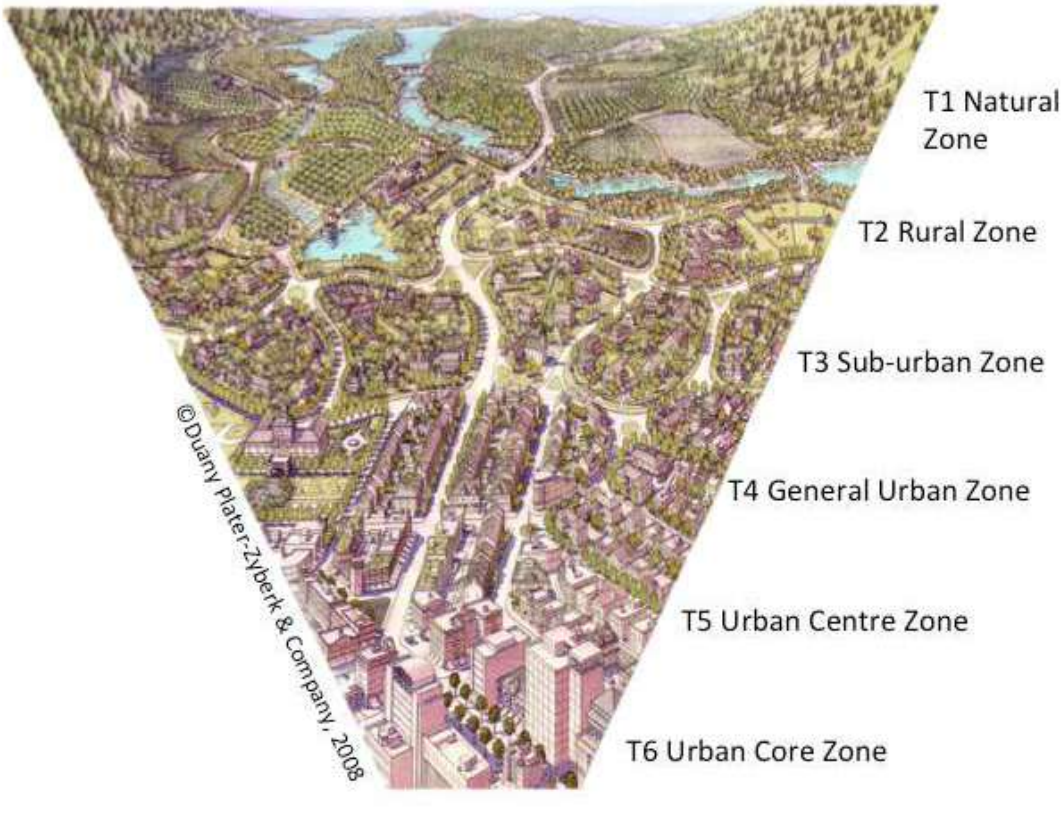

Figure 3: The ‘Wedge’ Transect Illustration (Andres Duany, Sandy Sorlien & William Wright: The SmartCode v9 and Manual, New Urban News Publications, 2008).

Figure 4: Watershed to urban core: Palermo, Sicily, looking west towards Monte Pizzuta.

For comparison, a real example is shown at figure 4 above. It is taken from the roof of the Hotel Ambasciatori on Via Roma in Palermo looking west towards Monte Pizzuta. In the centre of the picture, the dome of the Cattedrale di Palermo is immediately behind the lantern of the Chiesa del Santissimo Salvatore with the bell tower of the Cattedrale di Palermo slightly to the left of centre. The transect from the T1-Natural zone along the watershed, through the T2-Rural just visible in the distant valleys, the T3-Sub-urban along the foothills and the T4-General Urban of the old city is clearly apparent. The T5-Urban Centre Zone is to the right, out of view.

However, looking north from the same vantage point (figure 5, below) the Sicilian Baroque Chiesa di Sant'Anna and its piazza are in shadow, but still dominate the foreground, Monte Pellegrino is in the distance and there are many cranes to the right, along the shore of the Golfo di Palermo. So, while figure 4 shows an almost perfect example of a transect from watershed to urban core, figure 5 shows (from left to right) the urban core to the sea shore, something not well explained by the rural-to-urban transect as it is currently understood.

The Port of Palermo handles around seven million tonnes of cargo and two and a half million passengers a year. It has been the raison d'etre of the city since its founding by the Phoenicians in 734 BC. Figure 6 shows some of Palermo's parks and what transect-based planning would currently classify as special districts in roughly the area covered by the photograph at figure 5. This demonstrates that if the transect at figure 1 was extended to a regional context, from the watershed to the water's edge, then it would currently have significant gaps, as highlighted in figure 7.

Note that 'Special District' in figures 1 and 7 is drawn as a sprawl 'big box',such as a stand-alone hypermarket and massive car park, so before we look for the missing transect zones we need first to consider how to identify sprawl.

Figure 5: Urban core to sea shore: Palermo, Sicily, looking north towards Monte Pellegrino.

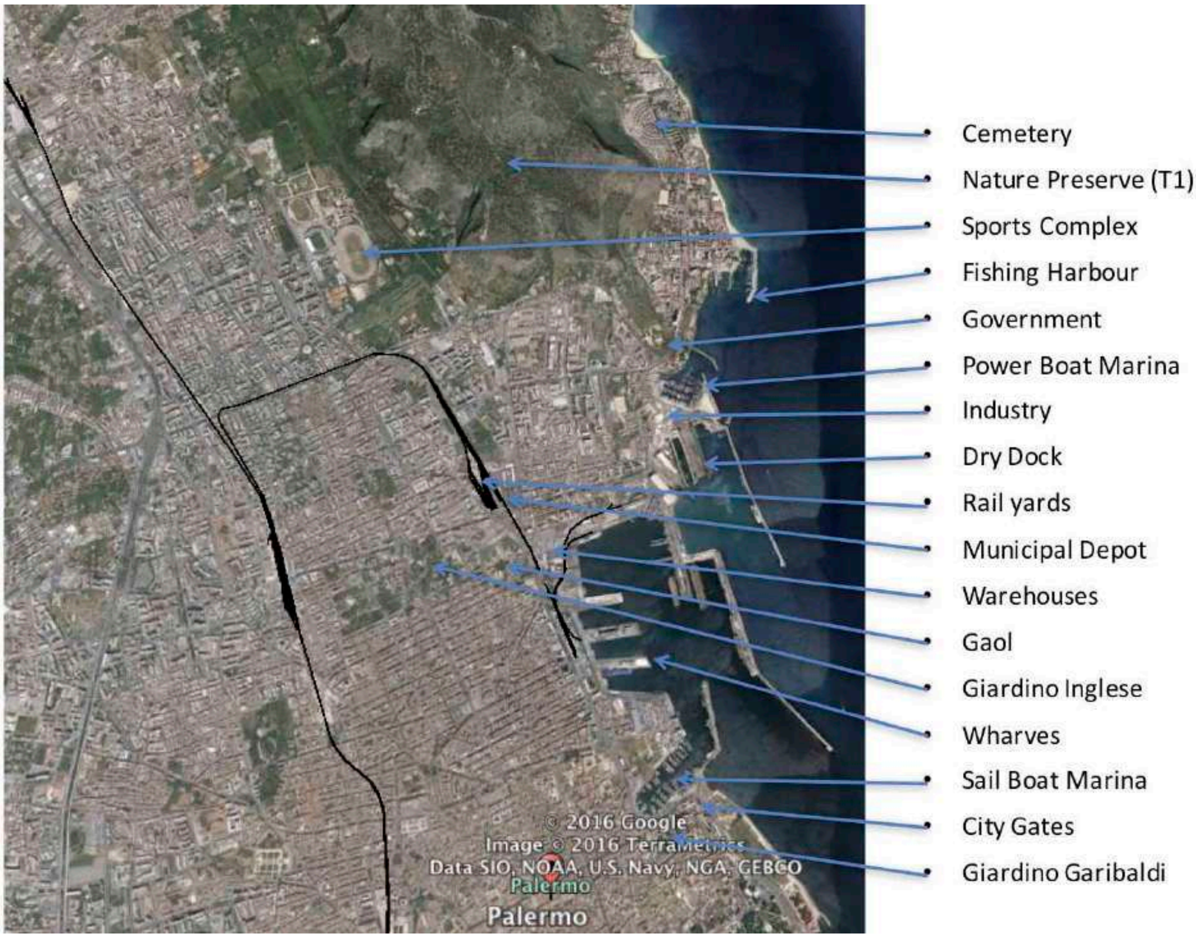

Figure 6: Palermo (courtesy of Google Earth) with possible 'special districts' indicated.

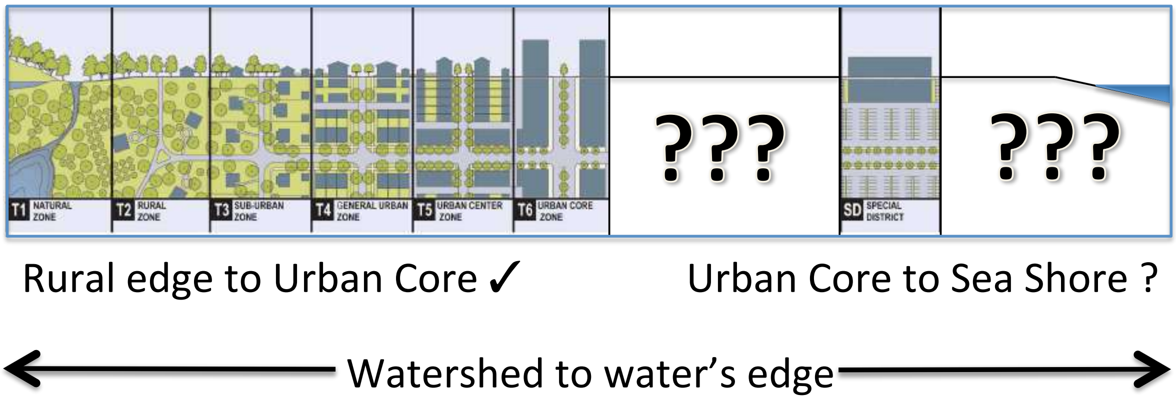

Figure 7: The missing transect zones.

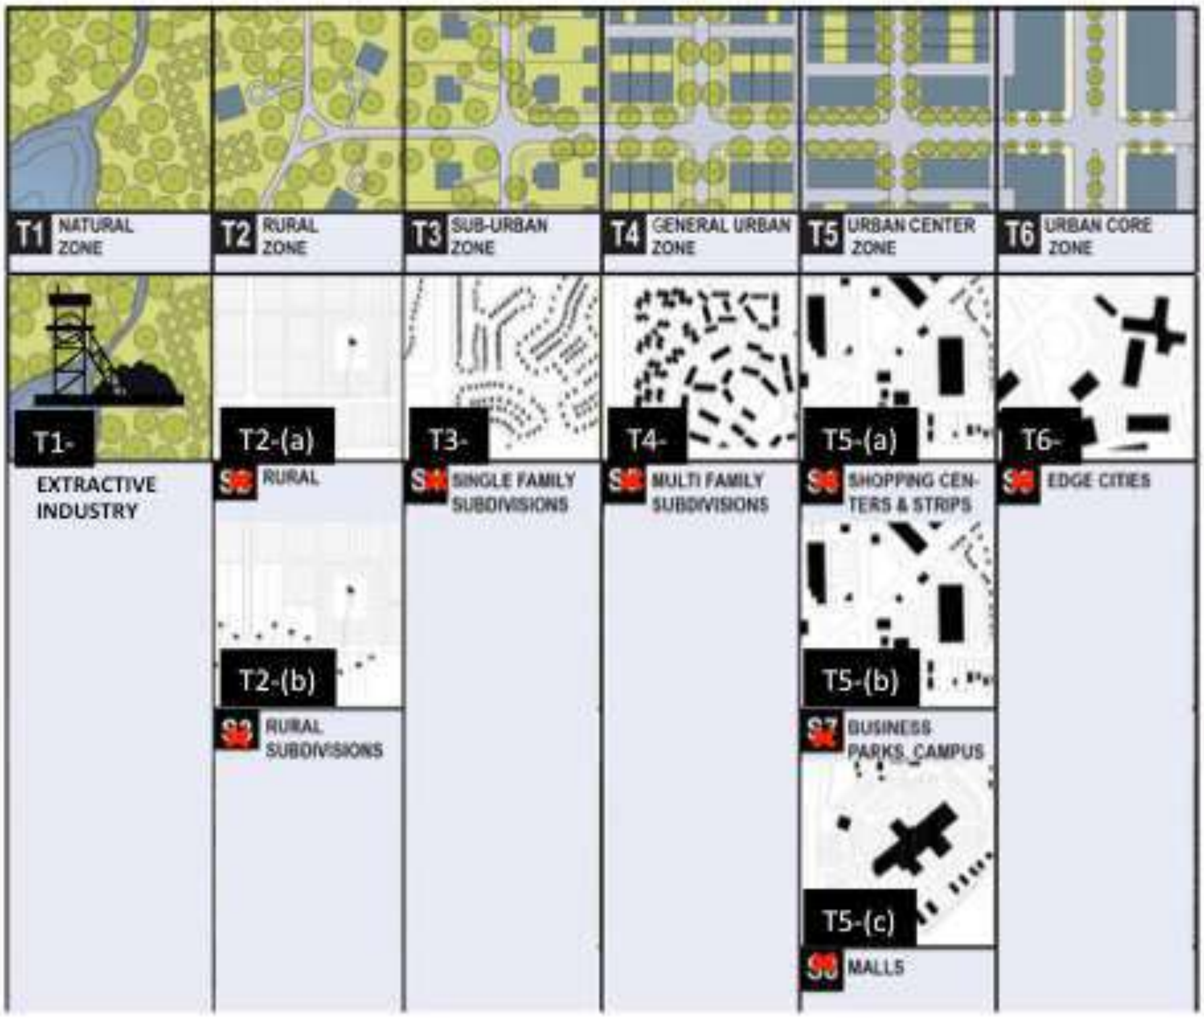

Figure 8: Classifying urban sprawl (© Hazel Borys 2012, but modified by author with permission)

5. Classifying Sprawl

Figure 8 above shows a slightly modified version of a very insightful transect analysis of urban sprawl prepared by Hazel Borys in 2012[6]. It builds upon earlier, ground-breaking work on the sprawl transect done by Galena Tachieva[7]. The only changes proposed here are the addition of the extractive industry and a new numbering scheme. This last change requires some explanation: imagine a natural area that is being mined for some natural resource, while it is being mined it is a degraded area and when the mining stops we would usually like to see it returned to as close to its natural state as possible, so we might designate the area as T1 minus, indicating both its current use and built form, and its intended future.

The same terminology is then applied for all of the sprawl elements, and similarly their present state and likely desired future character are immediately apparent. But note that the future succession to good urbanism is not necessary an automatic move up the diagram, within the same column; it will require analysis and consideration.

Of course, when this system is applied to a statutory plan it will require “existing use” provisions that enable current land uses and built form to continue as they are, while enabling all or part of a ‘minus’ transect zone to up-zone at some time in the future, in accordance with an approved master plan. Up-zoning is used here very generically, it may be that, for example, a sprawl repair masterplan for a T3 minus zone (i.e. single family subdivisions) might both provide street improvements to create something close to a proper block structure (i.e. T3-Sub-urban) for most of the area while also providing a neighbourhood centre of T4-General Urban and T5-Urban Centre zones. This latter component being a more accurate example of “up-zoning”.

Changing the categories from S1 to S9, where ’S’ stands for ‘sprawl’, to T1 minus to T6 minus is also advantageous because the word ’sprawl’ limits and understates the problem. It limits it to certain first-world countries and it does not give enough emphasis to the point that these types of development are at best temporary (e.g. mines until the resource is exhausted) and at worst destructive, locally and globally. In addition, some people see nothing wrong with sprawl. So, there are at least three good reasons for using a much stronger term: aberrant. Sprawl, slums, etc. are unsustainable aberrations from the truly sustainable forms of urbanism that are identifiable throughout the history of civilisation and should be referred to as such.

Note that it is not proposed that this become a system that grades urbanism from outstanding to horrific, because it would involve a massive effort to no good purpose. It is proposed that there is good urban form that is stable over the long term, and aberrant urban form that is unstable over the long term. This is a binary situation, so only normal (T1, T2, T3, etc.) and aberrant or deliberately temporary (T1-, T2-, T3-, etc) are all that are required. A transect of built form with elements coded as T1+, T2+, T3+, etc. is therefore neither warranted nor useful.

Note too that the transect zone ‘Special District’ from figure 1 is identical to T5 minus—type c (i.e. an enclosed retail mall) in figure 8. Clearly, replacing the transect zone ‘special districts’ with nine different categories of sprawl allows a greater understanding of aberrant urban-ecological zones and how they might be repaired. This adds to the strength of transect-based planning, while leaving open the opportunity to use the term ‘special districts’ much more constructively, but before we can make sense of the true nature of special districts it is first necessary to understand boundary conditions.

6. Boundary Conditions

Surveys of existing conditions and similar planning studies rarely pay attention to the boundary condition of large areas devoted to a single purpose, but it is key to how such areas relate to the rest of the urban fabric.

The Acropolis, rising majestically above the central area of Athens, Greece (figure 10) is possibly the archetype of all special districts. It is about the size of three city blocks, so it is not as large an element as it seems. Clearly, the defining feature is its fortified boundary, a wall designed to add to the natural defensive qualities of the hill on which it sits, while also increasing the area within which people could shelter in time of attack. Over the centuries, defenders of the Acropolis have never been defeated by direct assault, only by encirclement and the threat of starvation.

Figure 10: A fortified boundary, approx. 250 x 150 metres or 820' x 490', surrounds the Acropolis.

Buckingham Palace in London (figure 11) occupies a much larger area. The site is irregular in shape, but perhaps it could contain around fifteen city blocks. Unlike the Acropolis it has a secured boundary, one designed to be guarded, but not to withstand a heavily armed assault.

Figure 11: A secured boundary surrounds Buckingham Palace, part of an irregularly shaped complex approx. 520 x 610 metres or 1,700' x 2,000'.

In contrast to the two preceding examples, a fenced boundary is very common. The term ‘fence’ is used here to indicate a demarcated boundary, as in the magnificent hedge around the ΣAE Fraternity House in figure 12. ‘Fenced’ also includes ha-has and the wide expanses of ‘free-fire zone’ lawn and shrubbery used to discourage unregulated pedestrian access to campus style developments, such as a business park. In this context then a “fence” is any form of physical demarcation that is more than a line on a map but less than the sort of fence or wall intended to deter a purposeful intruder.

Figure 12: A fenced boundary (or in this case, a hedge) demarcating the front garden of the ΣAE Fraternity House’s 420’ x 200’ plot (approx 130 x 60 metres).

To complete the set we need only to add the case where the only demarcation of a boundary is by a few surveyor’s pegs or marks. This gives us the simple, but very useful symbology proposed at figure 13, in which the symbols for surveyed and fenced boundaries are standard drawing practice and the symbols for secured and fortified boundaries are standard NATO map-marking practice (respectively a barbed wire fence and a trench line). Finally, when a fenced, secured or fortified boundary encloses an area greater than four hectares (ten acres) drawing these symbols in red will highlight them as potential special districts.

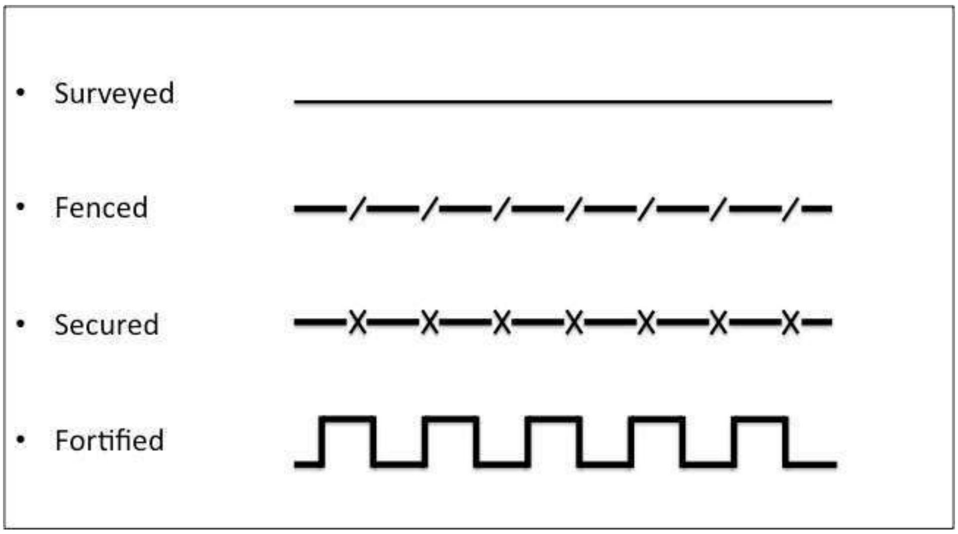

Figure 13: Graphics for boundary conditions.

The key point is that physically defined (i.e. fenced, secured or fortified) boundaries constrain movement. The areas outside and inside might be walkable, but the community is prevented or discouraged from walking from one to the other. When these areas are smaller in size than a large city block (say 200 metres or 660 feet square) there is usually little impact on walkability, but when they cover even slightly larger areas than a single block they have a major impact on the urban fabric. Obviously, the impact is situational, but generally the larger the area enclosed, the greater the impact. This factor allows us to distinguish true special districts from the missing urban-ecological zones and to complete our understanding of the elements of urbanism.

7. Case Study: Palermo, Sicily, Italy (part 2)

Applying the symbology for boundary conditions developed above to our earlier analysis of Palermo (figure 14) allows the list of unclassified uses to be usefully divided into three groups.

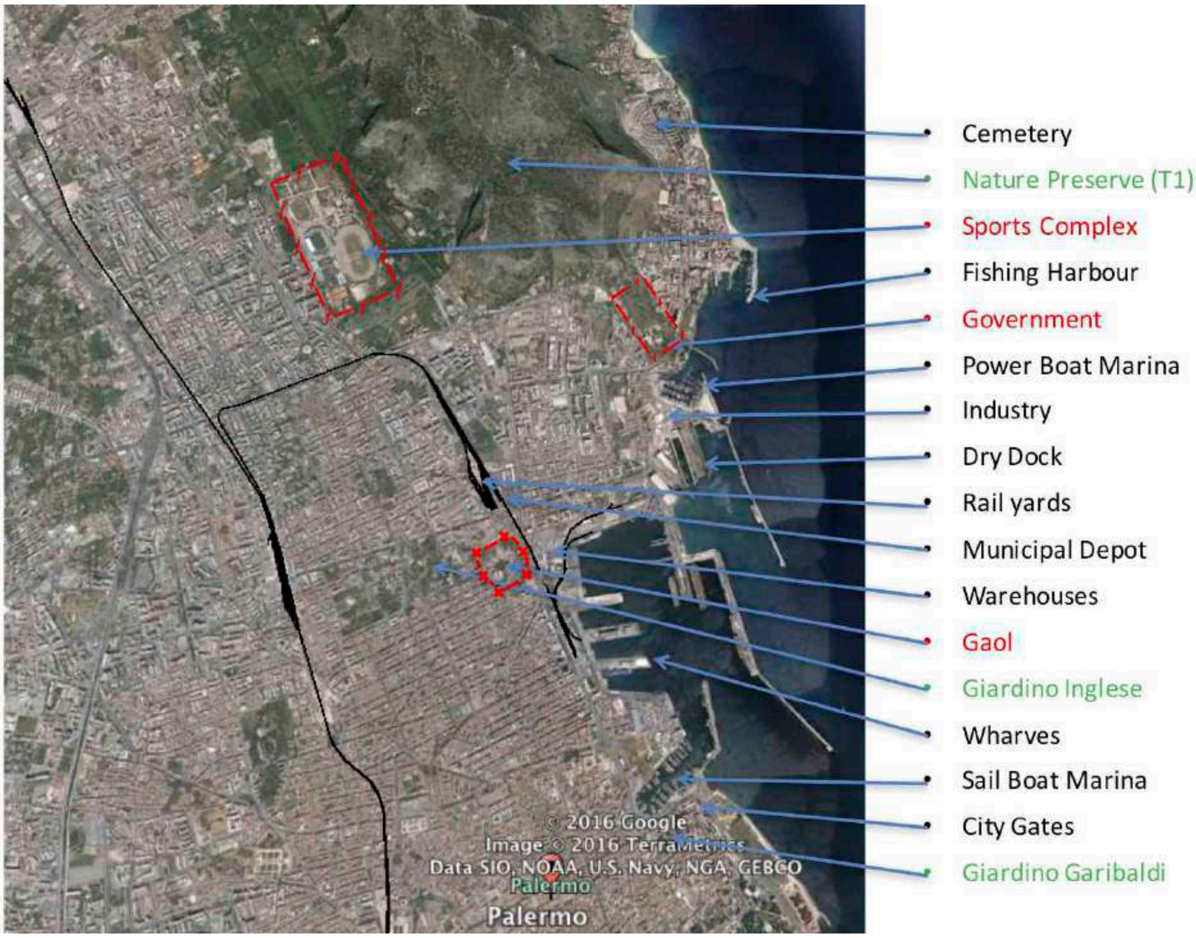

Figure 14: Palermo (courtesy of Google Earth) with fenced and secured boundary conditions

Firstly, special districts (as proposed to be defined): three areas have a boundary condition that is more than just to dissuade trespassers: the Stadio La Favorita sporting complex and the offices of the President of the Sicilian Region based around Villa Belmonte are securely fenced to prevent unwanted ingress, while Ucciardone, Palermo's nineteenth-century Bourbon prison secures its convicted occupants with massive stone walls and guard towers.

Secondly, parks and recreation (as opposed to natural areas): the Monte Pellagegrino nature preserve clearly has very different characteristics to the Stadio La Favorita sporting complex, which is in itself quite different to the formal urban parks in this part of Palermo (the Giardino Inglese and Giardino Garibaldi).

Finally, the missing transect zones: none of the other land uses (cemetery, harbour, marina, etc.) appear to qualify as special districts, they are simply urban-ecological zones that exist in an almost identical form in most urban areas.

8. The Missing Transect Zones

The standard rural-to-urban transect (figure 1) provides for agricultural production, housing and commerce, but towns and cities cannot exist without governance, manufacture and transport. In addition, urban populations usually also demand (or have thrust upon them) utilities, religion and culture. A complete prototypical transect requires that the missing urban-ecological zones, such as warehouses, refineries, ports, universities, etc., which are usually the economic base of a city or town be separately classified. As figure 15 illustrates, they are not difficult to distinguish from each other, in both land use and built form, so it should be quite possible to identify prototypes and to arrange them along a prototypical transect, just like T1-Natural to T6-Urban Core in figure 1. Similarly, distinct urban-ecological zones should also be able to be identified for parks and recreation uses and structures, because - as the Palermo case study demonstrates - a national park and a city park are very different urban-ecological conditions.

Figure 15: Uses that typically constitute the economic raison d'etre of most cities (main building of Hamburg University courtesy of Wikipedia, other photos courtesy of Pixabay).

A complete list of the missing transect elements in a typical progression that builds upon the familiar T1 to T6 rural-to-urban progression, might consist of:

- T7 Major Civic:
    1. Cultural;
    2. Religious;
    3. Government; and
    4. Royal, presidential and ambassadorial.
- T8 Parks & Recreation:
    1. Landscaped;
    2. Sporting;
    3. Structured (stadia, amusement parks, etc.); and
    4. Marinas.
- T9 Major Utility Infrastructure.
- T10 Industry:
    1. Services and trades;
    2. Manufacturing and warehousing (including cleaning, sorting and packing primary produce, and road transport depots); and
    3. Refining and smelting.
- T11 Transport facilities:
    1. Ports and harbours;
    2. Rail yards;
    3. Airports, airfields and helicopter landing zones; and
    4. Space ports.

'Major' in the context of the proposed T7 zone is meant to distinguish large civic buildings and precincts, typically found only in regional centres, from smaller versions of the same function that are typically found in or near to district and neighbourhood centres. In the context of the proposed T9 zone, 'major' infrastructure is any that requires its own plot of land.

One important reason for identifying the missing transect elements is because:

> "Some things will always be separated from residential, but often can still be walkable in context. Just because some uses aren't compatible with residential, doesn't mean they can't be compatible with each other, and the rest of the city."[8]

And a second reason is because transect-based planning is already being applied to places dominated by governance, manufacture and transport, for example the El Paso Airport Regulating Plan, Santa Fe Barrio Capital Regulating Plan and El Paso Medical Centre of the Americas Regulating Plan[7]. While these plans are no doubt individually excellent, the lack of a common language for the civic and economic zones, along with differing interpretations of what a special district is, reduces the ability to transfer knowledge across the profession and thereby learn from one project to the next.

9. Special Districts as a Community Unit

As explained under "2. Community Units" above, the transect zones are usually grouped into community units and the urban structure is formed from these units and their supporting infrastructure. The preceding discussion has now made it clear that the term 'special district' is not required to describe or classify the elements of urban sprawl, nor is it required to provide for the missing transect zones that have been tentatively catalogued above; however, there is a need for a term to describe special groupings of transect elements in circumstances that meet the following proposed definition (see figures 10 to 13 regarding fenced, secured and fortified boundaries):

> *A Special District is a special purpose community unit containing at least three urban-ecological zones within a physically defined boundary.*

Typical examples include airports, boarding schools, citadels (a heritage feature in many European cities), colleges, convents, hospitals, military bases, monasteries and universities, and would be labeled 'special district—airport', 'special district—boarding school' etc. Along with a defined boundary, these urban elements will also have an internal transect structure, as the examples at table 1 above notionally demonstrate. They are almost cities within cities.

Special District - Jail/Gaol	Special District - Barracks/Fort
Secured boundary (–x–x–)	*Secured boundary (–x–x–)*
T5 Administration, classrooms and theatres	T3 Married quarters
T5 Cell blocks	T4 Town centre
T8 Sports fields	T5 Bachelor quarters & barracks
T10 Workshops & stores	T5 Administration, classrooms and theatres
	T10 Workshops & stores
	T8 Sports fields & firing ranges
	T1 Close training area
Special District - University Campus	**Special District - Hospital Complex**
Fenced boundary (–/–/–)*	*Fenced* boundary (–/–/–)*
T5 Dormitories	T4 Specialist treatment & support facilities
T5 Theatres, lecture halls & seminar rooms	T6 Wards, theatres and administration
T6 Administration & libraries	T8 Gardens
T8 Gardens & sports fields	T10 Workshops & stores
T10 Laboratories, workshops & stores	T9 Incinerator
* 'fenced' means anything intended to demarcate private land, but to a lesser degree than 'secured' or 'fortified'.	

Table 1: Likely transect zones across some typical special districts.

Returning to the three examples, the Acropolis (figure 10) can now be classified as a Special District—Heritage with a fortified boundary and mostly containing the transect zone T7(b) Religious—Historic; Buckingham Palace (figure 11) as Special District—Palace with a secured boundary and dominated by the transect zone T7.4 Royal; while the ΣAE Fraternity House (figure 12) is not a special district, just a very nice element within a T4 zone.

10. The Periodic Table of Urbanism

Bringing it all together, figure 16 below shows the expanded transect from watershed to waters edge, within which there will also usually be a number of special districts, such as a jail, university, boarding school, etc.

It is now possible to arrange into one ‘urban periodic table’ (table 2 at page 15) the standard rural-to-urban transect extending from watershed to water’s edge and including the productive, transport and other uses in the city, along with some of the subclassifications that are now commonly used in transect-based statutory planning, the temporary and aberrant types of development, and an expanded range of community units, including special districts as now defined.

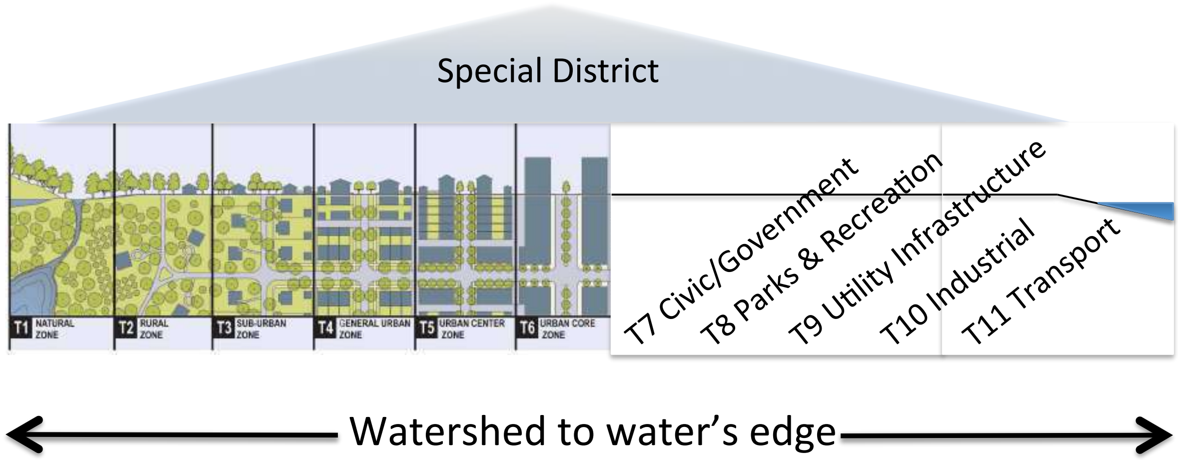

Figure 16: The expanded transect with special districts option.

The Periodic Table of the Elements is deliberately arranged to demonstrate the periodicity and grouping of the atoms. Similarly, the columns in the Periodic Table of Urbanism are all grouped by function, while the core box of twelve transect zones (outlined in lilac) demonstrate the urban equivalent of periodicity. These three rows across four columns (T3.1 to T6.1, T3.2 to T6.2 and T3.3 to T3.6) are typical local transects identifying four distinct, but co-dependent arrangements of built form. For example, suburbs at 5 to 15 units per hectare (2 to 6 units per acre) are only going to support general urban development one to two storeys in height and so on.

Note that within Table 2, in the left hand column, ‘*x*’ represents the relevant T-zone, e.g. T1.1 and so on. Note also that the numerical values given for some transect zones are tentative and require ground-truthing through case studies.

Studies and research to identify the mathematical relationships between each transect element, stable and unstable, are currently underway and may form the subject of a future paper.

11. Conclusion

Whether towns of thousands of people and cities of millions are more or less complex than the 118 chemical elements so far discovered is debatable, but as Professor Dmitri Mendeleev is quoted as saying:

> “It is the function of science to discover the existence of a general reign of order in nature and to find the causes governing this order. And this refers in equal measure to the relations of man - social and political - and to the entire universe as a whole.”[9]

COMMUNITY UNITS:	*Natural*	*Rural*									
		Clustered Land Development									
			Traditional Neighbourhood development								
				Transit Oriented Development							
				Regional Centre Development					*Industry & Infrastructure*		
	Special District (coloured as appropriate to main purpose and containing at least three zones within a physically defined boundary)										
TRANSECT ZONES:	**T1** Natural	**T2** Rural	**T3** Sub-urban	**T4** General Urban	**T5** Urban Centre	**T6** Urban Core	**T7** Major Civic	**T8** Parks & Rec'n	**T9** Major Utility	**T10** Industry	**T11** Transport Facilities
SUBCLASSIFICATIONS											
Key Factor:	**Science**	**Science**	**Density**	**Building Height**			**Use**	**Use**	**Site Area**	**Use**	**Use**

Table 2: The Urban Periodic Table

Just as the Periodic Table of Chemistry identifies the physical components of our universe and is able to predict the relationships between them, the Periodic Table of Urbanism provides a comprehensive framework for describing the "general reign of order" in our towns and cities while also enabling the development of an algorithmic framework for planning as a necessary step towards the positive application of artificial intelligence to urban planning.

The Practical Limitations and the Reference of Key Technology of Mixed Land Use

(A Discussion of Practicing Mixed Land Use in China)

Yuwei HUANG, Hualan Design & Consulting Group, China

Xiaoting YANG, Hualan Design & Consulting Group, China

Cheng YU, Guangxi Zhuang Autonomous Region Development And Reform Commission, China

Abstract: The mixed land use origins from the planning theory and practice in Europe and America, which aims at breaking the mechanical function zoning, reshaping the vitality of urban and community and reducing the pressure on the ecological environment. The mixed land use is a sustainable development model which promotes the compact and efficient use of spatial resources. According to the practice in China, generally the mixed land use is conducted in two scales: the land parcel and the region. At the level of the land parcel, the mix of categories and proportions dominates and at the level of region, the development is leaded by the government. It presents limitations as focusing on the cities and ignoring the communities spatially, focusing on land compatibility and ignoring multiple mixes during planning and focusing on government-led and neglecting collaboration during implementation. By comparing with the practice in America and considering the practice in China, there are three keys to overcome the limitations of mixed use of land. Firstly, in the early planning stage, by demarcating the appropriate range of “walking orientation + spatial mixing”, the living space and public transportation are connected in order to achieve the "people-oriented, pedestrian-oriented" traffic travel goals, promoting the concept of green life. Secondly, in the planning and design stage, establishing a "mass control + market-oriented" planning mechanism, making the regulation of the development of a single land parcel appropriately flexible, the management and control of development behavior will transfer the functional matching and spatial layout to the market to enhance the vibrancy of the hybrid unit. Thirdly, explore the development mode of “multi-party cooperation and government services” in the implementation stage of construction. The government that uses administrative power for supervision and assistance and the public as important group, will provide strategy for project development that suits public opinion and market demand, creating an open and fair environment of mixed development.

Key words: Mixed Land Use, Practical Limitations; Planning Technology, Ecological Environment

1. Introduction

With the rapid process of urbanization, the problems of natural resources consumption and environmental crisis have been increasingly severe. In this case, the focus of urban planning is gradually changing from "increment" to "stock" in urban space, which means the focus of developing new are of urban is changing to optimize the land use in developed are of the city. Thus, finding the planning methods to improve the efficiency of land resources allocation and to reduce the negative environmental impacts has become one of the main concerns of academic society. In the 1990s, the theory of MXD (Mixed-use Development) was introduced into China (Zhu 2014). MXD is an innovative concept of land use, which is based on the reflection of the traditional functional zoning. This theory has been developed from the 1960s to the 1970s in the United States and to some extent it laid the foundation of urban development models such as TOD and TND (Wang and Li 2009). MXD provides a sustainable land use mode, which has significant advantages in breaking the bottleneck of urban land use, promoting the integration of functions and stimulating the social vitality. However, based on the research of the practice of mixed land use in China, it is found that, from the perspective of theory, the discussions of mixed land use mainly focus on the introduction and discrimination of the concepts, the concept of mixed land use and the similarities and differences of the compatibility of land use and the constructability of land, for instance, attempting to improve the operation mechanism of management, planning and implementation during the practice process (Xu et al. 2014). From the perspective of practice, most of the discussions focus on the mix of compatible land use or the development of large scale urban areas or small scale urban areas as land parcels, which are contrary to the original idea of the mixed land use that the development should be started from the communities instead of land parcels. The contraries have reduced the effectiveness of the mixed land use as a sustainable land use mode, in solving the problems of providing job-housing balance and creating vital community and in alleviating the natural environment pressure. Based on the current practice, this paper compares the “present mode” with the “conception of past” in order to explore the approach of adopting the “introduced experience” in the “local practice”.

2. The Supposed Utility of the Mixed Land Use

2.1 Break the Mechanical Function Zoning

In the second half of the 19th century, the traditional methods of urban planning were questioned one after another. At that time, the functional zoning thought was questioned the most, which was one aspect of the Charter of Athens focused on. In 1961, Jane Jacobs criticized that the loss of urban vitality and diversity were caused by the functional zoning thought. She suggested that "Cities should be based on the principle of mixed functions." In 1977, the Charter of Machu Picchu states that "Today, in planning…efforts should be made to create an integrated, versatile environment." The diversified characteristics of mixed land use respond to this trend of development. The mixed land use advocates flexible combination of various functions of modern cities and is an active reflection on the traditional mechanical mode of functional zoning.

2.2 Reshape the Vitality of Urban and Community

From 1940 to 1980, the population in American suburbs increased from 20.2 million to 100 million. The decline of inner cities caused by the lack of urban vitality intensified this trend of suburban sprawl. The "New Urbanism", which rose in 1980s, advocated the creation and reconstruction of diverse… mixed use of community…forming perfect urban, rural and neighborhood units (Talen 1996). Adopting the mixed land use had brought changes, for example, gathering the multi-purpose facilities in urban centers and communities, prolonging the duration of outdoor activities of residents, enhancing communications among neighborhood and promoting a sense of community belonging (Zhang and Wang 2012), thus facilitating the gradual return of suburbanization populations and reinvigorating the inner city.

2.3 Reduce the Pressure on the Ecological Environment

The expansion of urban development has intensified the urban sprawl. During the process of expansion, the boundaries of cities have been approaching the sensitive areas of ecological environment and the single-functional mechanical combinations of land use have resulted in the inefficient use of land resources. The mixed land use promotes more intensive and dense development modes, creating more efficient methods of land use, reducing the consumption of urban resources, such as buildings and spaces, and decreasing the consumption of energy and the pollution caused by commuting traffic, so as to weaken the negative effects on the ecological environment (Steiner and Butler 2006). Through the multi-dimensional mixing of multiple functions within a certain spatial range of area, diverse project functions can be achieved with less land resources, thus reserving more ecological space for urban development and increasing carbon sinks. Finally achieve the goal of building low-carbon cities.

3. Main Methods and Limitations of Practicing Mixed Land Use in China

The original purpose of introducing the concept of mixed land use to China is that “Reduce the working-class daily pendulum between living quarters and working areas” (Qiu 2009). Since introduced, the theory has been practiced in cities for more than 20 years. The theory holds that "the mixed land use should achieve the goals of basic skills, harmony and vitality" (Xu and Xu 2009). There have been many cases of mixed land use at the level of regulatory detailed planning (hereinafter referred to as "regulatory planning"), but the achievements of ecological and vitality goals have not been widely approved yet. By analyzing the cases of mixed land use in various places, the authors find that there are some limitations of the practice of the mixed land use in China. Those limitations are relevant to the space, planning and implementation.

3.1 Current Main methods of Practicing Mixed Land Use in China

3.1.1 At the Land Parcel Level: Based on the Mixed of Categories and Proportions

（1） Mix of Land Categories Based on the Compatibility of Land Use

The mix of land use at the level of land parcel reflects a strong thought of planned economy in terms of category. The government leads to draw the blueprint for mixed development and to define the category of mixed land use within each land parcel when the mixed land is sold publicly. The work basically follows the suggestion of land compatibility in the *Standard for Classification and Planning of Urban Land and Construction Land (GB50137-2011)*(hereinafter referred to “the Standard of Land Use”), such as the categories of R (residential), B (commercial and business facilities) and S (Road, Street & Transportation) (Table 1).

There are two reasons for the departments relevant to land management to specify the categories of the mixed land use. The first reason is to comply with the legal process of land transfer and to consider the price of land, in order to minimize the disputes over interests in the process of land transfer. The second reason is to try to control the market, by combining and arranging the uses which are considered to have greater benefits within the land parcel.

Table 1.Cases of Mixed Land Development in Typical Land Plots

Case	Area(hm^2)	Type of Mixed Land Use
Land Plot of Jiangning Science Park, Nanjing City	9.9	R2+B14
Land Plot of Pukou Science Park, Nanjing City	5.9	B1+R2
Land Plot of Taihu New Town, Wuxi City	22.0	R2+B1+B2
Land Plot of Wuzhong Economic Development Zone, Suzhou City	6.5	R2+B1+B2
Land Plot of Chuan Cotton Factory Phase II, Chengdu City	6.4	R2+B2+S41

Sources of Data:By the Author.

（2） Mix of Proportions Based on the Regulation of Function

There are two ways to limit the proportion of mixed function in the level of land parcel: one is limiting the portion of different land use categories in the Standard of Land Use and the other is determining the proportion of different minor categories of land under the same main land use category. The proportion limitation is usually determined by the government, which is based on two purposes. Firstly, constrain the developers, preventing them from taking advantages in the process to expand the share of the operational land development, and seizing private profits in the name of mixed use. For example, in the *Pilot Opinion on Comprehensive Land Use Planning and Land Management in China (Shanghai) Free Trade Pilot Area (2014) 443,* it is stated that “strengthening the regulation of comprehensive land use, and the composition and proportion of the use shall not be changed without authorization.”Secondly, reach the original goal of the mixed land transfer and achieve the expected functional attributes of the project. For example, in a mixed land sale by Guangzhou Science City, it is stipulated that the proportion of industrial manufacturing land must be equal to or more than 70, so as to ensure that there is sufficient industrial land to support the identified development of Guangzhou Science City, as well as to reserve development space for high-tech enterprises.

3.1.2 At the Regional Level: The Government Lead the Mixed Development

The area of mixed regions is basically above 1km^2 (Table 2), showing the spatial characteristics of "not suitable for walking". This kind of development is generally led by the government and can be roughly divided into two categories. One is a new city or a city-level public central area, whose mode is arranging and combining the pluralistic modern city-level service functions within a specific region, supplemented by appropriate residential functions, in order to create a dynamic space. The other is a park with a certain professional function. Within the park, in order to integrate the park and the city, in addition to the leading function, the mixed use of land and space is advocated, transforming from single land use to mixed land use (Liu and Wang 2013). For example, for the college towns in Guangzhou, in addition to educational and scientific research sites, the teachers and students are accommodated with sports centers, shopping malls, apartments for faculty and staff and other facilities, due to the long distance between the university and the central city.

Table 2. Cases of Mixed Land Development in Certain Planning Areas

Case	Planning Area(km^2)	Main Type of Mixed Functions
College Town, Guangzhou City	34.4	Education and Research (60%), Business (5%), Residence (20%), Convention and Exhibition (2%), Sports Activities (2%)
Smart New Town, Foshan City	1.8	Residence (20%), High-tech Industry (25%), Finance (15%), Business Office (15%)
Zhongxin Ecological Town, Tianjin City	30.0	High-tech Industry (15%), Education and Research (5%), Health Care (3%), Residence (25%)
Zhujiang New Town, Guangzhou City	6.4	Residence (20%), Business & Finance (30%), Culture and Recreation (5%), Administration (10%), Foreign Affair (2%)
Liuhe New Town, Nanjing City	1.3	Residence (30%), Trade and Business (10%), Culture and Recreation (5%), Health Care (5%)
Futian Central District, Shenzhen City	6.1	Business & Finance (35%), Convention and Exhibition (3%), Residence (15%), Administration (18%)

Sources of Data: By the Author.

3.2 Current Limitations of practicing Mixed Land Use

3.2.1 At the Spatial Level: Focus on the Land Parcel or Region and Neglect Community

The mixed land use in China is divided into two spatial scales: land parcel and region / group, but little attention is paid to the mixed use of community / block level. In one study (Linbo Qian, 2000) of the spatial distribution of travel of residents in Nanjing mentioned that "Because the employment is relatively concentrated in the center (area) and the land use of the new area is relatively single…The peak of work travel is mainly flowing into the central area…The contradiction between traffic supply and demand has become quite prominent." According to a report from the government, in the college towns in Guangzhou, the average price of newly built commercial residential buildings has reached 33,333 RMB / m2, which close to the price of those in the old urban area, due to lacking of reserved residential land. As a result, the faculty and staff of the universities can't afford the high price and have to live farther way, which is against the utility of mixed land use to change the separation of jobs and housing.

3.2.2 At the Planning Level: Focus on the Land Compatibility and Neglect the Pluralistic Mix

In China, the modes of mixing adopted in the practice of mixed land use are basically further interpretations of the land use compatibility based on the Standard of Land Use. In the relevant normative documents of land use management issued in various places, there is still no escape from the inherent shackles of traditional mixing of compatible land use only, which is limited to the form of "commercial and residential mixing" (Zhang and Zhou 2015). For example, in the Technical Guidelines for Regulatory Detailed Planning in Shanghai (revised edition 2016), it is suggested that three types of residential group land(residential group land mainly for high-rise residential buildings) are not suitable for administrative office use, scientific research and design use, industrial research and development use and logistics use. Another case is in the Technical regulations of Urban Planning and Management of Foshan City(2015 revision), taking the second class residential land (R2) as an example. It is stated that the land in R2 class shall not be compatible with the second class industrial land (M2), the logistics storage land (W), the urban road land (S1) and the square land (G3). Although the Land Nature Guide Compatibility Table has certain guiding significance, it includes the subjectivity and limitations of the planners or the departments in charge of planning (Zhang and Li 2016), which to a certain extent questions the potential of positive benefits brought by the multiple mixing mode.

3.2.3 At the Implementation Level: Focus on the leadership of the Government and Neglect the Multi-cooperation

Most of the mixed land use and development projects in China are guided by the will of the government. From the planning preparation and approval, planning and construction management to land transfer management, the government is in the role of dominance and the developers are in the role of executors. The public, representing social forces, has little way to participate, although in the context of institutional innovation, there has been a cooperative development mode between government and enterprises, giving the market more autonomy. For example, in the development of Xiongzhou District in Liuhe, Nanjing City, the government only regulated the volume ratio, the green space rate, the public facilities land and other compulsory construction index that involves the public interest. To other construction index, the government only does the guidance control. In the planning of the new area of west coast of Qingdao, it is clear that all the land types can be mixed without conditions, except 9 kinds of land types which involve the public interest and are not suitable for functional mixing and 11 kinds of land types which must be mixed conditionally.

However, at present, the urban planning in China is restricted by the strict and rigid regulation system. The hysteretic system of regulatory planning restricts the development of rational mixed land use. In fact, the new attempts of practicing mixed land use have not fully mobilized the enthusiasm of developers and social forces to participate in the whole process of developing and decision-making. Lacking of the participation is likely to cause the implementation of the mixed land use project to be difficult to carry out in the later stage of development, or likely to make the project have little effect after the completion.

4. Lessons of the Key Technologies for Mixed Land Use

4.1 Early Planning Stage: demarcating the appropriate mixed range under "Spatial Mixing + Walking Orientation"

Identifying a reasonable and suitable scale of land use range is the first challenge to the early planning stage of the project regarding to mixed development. The identified range will impact on the follow - up layout of function, fund - raising and market acceptance.

Since the 1970s, most research on mixed land use in the United States has focused on a community scale, that is, within a 10-minute walking zone or a 0.25 mile-radius core service circle, mixing residential with industrial, cultural, commercial, administrative and other functions. By this means, the scale is smaller and the development cycle is shorter, which is easier to implement (Xing 2005). For example, the grid partitioning model in Los Angeles is based on the community scale. In this case, for each partitioned district, the mixture of residential and non-residential is the main means. As a result, the local absorption rate of traffic demand of residents is very high and the pendulum type of cross-regional traffic is relatively small. Thus the whole transportation system is relatively efficient (Sung and OH 2011). Another example is the planning of downtown areas in Denver. In the planning, one of the key objects is building a pedestrian-oriented city, advocating mixed land use at the community level, arranging retail, catering and recreation along the street areas outside the community and leaving the central community for official and residential use. In the subsequent mixed development projects (such as the Milton Gaines New Town construction),the modes of identifying the range were adopted, by considering the public transport facilities and the major regional highway systems, identifying the areas of mixed development within a certain distance around these public transportation facilities. This mode actually divides the communities into multiple mixed units based on the public transport nodes. Usually the units are pedestrian-oriented and promote a non-motorized lifestyle. With the efficient use of public transport facilities and the transportation of people within the mixed unit, the development and construction of the surrounding areas will be driven and more functional facilities will be attracted. As a result, the benefit of the mixed land use can be radiated to a reasonable service radius.

When identifying the range of land mixed development in China, the thought of either choosing land parcels or regions should be abandon. Combining with the popularization of "block system", planners should make overall arrangement and partition of the mixed units with suitable spatial scale in the city level. There are two recommendations to define the range of a mixed project. The first recommendation is advocating an efficient mix of living space and employment space functionally. Hongyu Zheng et al. (2016) adopted GIS spatial analysis technology to analyze the spatial development characteristics of mixed land use degree in Shanghai, and pointed out that in suburban new city area, the effective matching between residents and service facilities should be ensured and affordable housing supply should be encouraged. Therefore, improving the equalization distribution of affordable housing in the city and promoting deep mixing of residential space and diversified functions are positive responses to the supposed utility of mixed land use. The second recommendation is guiding the integration of mixed units and public transport in space. After an empirical analysis of Shenzhen Metro Line 2, Zhang Yan et al. (2017) found that the higher the mixing degree of land around the station (500m hinterland) is, the higher the ride rate will be. Therefore, in order to create a pedestrian-oriented and non-motorized travel atmosphere, with the new public transport facilities such as the "shared bikes", planners should strengthen the seamless connection of different modes of transportation and identify the mixed units with high walking accessibility. By this means, the interactive mechanism of urban traffic and land use could be formed and the "low carbon" process of the city could be promoted effectively (Deng et al. 2016).

4.2 Planning and Design Stage: Flexible Regulatory Mechanism under "Mass Control + Market-oriented"

The use control measures adopted in the planning and design of the mixed development project affect the rate of future investment and utilization of the project. Because the mixed land use is closely related to the construction use control, the higher the flexibility of the construction use control is, the higher the degree of the mixed land use will be.

When planning and designing a mixed development project in New York City, only an overall target amount is limited and the specific development of a single land plot is not further controlled. Any behavior of development that does not violate the overall development goal and the dominant functional attributes of the project can be allowed. For example, in the long Island mixed-use area, the overall goal is broken down into seven objectives, "encourage medium and high intensity commercial developments in a transportation-oriented area…", according to the City Planning Commission of the City of New York. At the same time, under the overall goal, the mixed development project guides the multiple mixing mode. For example, in the special mixed-use area of the Franklin Street, it is stated that "residential use shall not be located on or below the same layer of industrial or commercial use and a safe circulation system should be provided in the residential use and industrial use mixed area"; This positive planning regulation employs new planning tools to eliminate the interferences among the traditional incompatible uses, to encourage more effective and innovative mixing modes and to break the functional mechanical zoning fundamentally. The multi-purpose mixing of the plane space is extended to the multi-dimensional mixing of the stereo space as well.

At present, in China, because both of the division of land rights and the management of regulatory planning act on the horizontal dimension, there is no standard for the regulation of vertical mixed land use to follow. However, it is necessary to realize that the rise of new industrial space and the improvement of building construction provide the possibility for a new mode of mixed land use. In terms of the industrial and residential land use, the point is not the proportion of residential area that can be mixed with industrial use, but the rules of conduct (such as the sewage discharge standard, the noise standard and the constraint of the transport period, etc.) that should be observed by the main body of the industry in residential area (Yin 2008). In this way, the conflicts between industrial behavior and residential behavior are reduced to form dynamic and efficient mixed units. It is suggested that loosening the regulation of specific development behavior of a single plot appropriately, transfer the allocation of function matching and spatial layout to the market; changing the rigid regulation containing the spatial representation index only, avoid the fuzzy division of the land use to breed market profit space via improving the land classification standard and compatibility regulation system (Zhou and Qi 2008); Setting the bottom line of the standard for the behavior of spatial utilization, ensure the positive development of mixed land.

4.3 Implementation Stage: Shared Construction Mode under "Multi-party Cooperation + Government Services"

In the process of realizing the blueprint framework of mixed land projects, multi-party collaboration becomes a more important strategy, because of the complex problems of the funds, property rights and functions of the mixed projects. An efficient and personalized collaborative development mode is the driving force behind the smooth implementation of a project.

Mixed land use projects in the United States were initially developed and built by the businessmen concerned with the signs of decline in downtown areas, and then real estate companies participated. The government provides services as the main focus. The services include: (1) allocating land resources with administrative authority;(2) making policies supporting land price and tax relief; (3) providing infrastructure, such as parking and other facilities required by the project; (4) revising established development plans and construction standards; (5) optimizing the urban structure and regulating the key roads, etc.; and (6) providing technical support for project development (Schwanke et al. 2003). In the early stage of the project, the developer assesses the typical market potential associated with each of the mixed uses and the market potential generated by the collaboration of various uses within the project, and tailors to different collaborative development programs according to a specific mix of combinations (Miller and Miller 2003). At the same time, the active participation of social forces such as communities, non-profit enterprises, organizations or associations has changed the absolute dominant role of the government or the market, so that the urban public interest and grass-roots demands can be received and responded in time, to avoid the interest disputes among the relevant groups.

In China, for the development of mixed land use projects, the government should guide market forces, appealing to social forces, and reserve channels for the market regulation and public participation, which is an important direction for changing the role of the government in the development of mixed land use. Taking social funds as the main source and combining public sector and public participation, the open and shared construction mechanism is established. The government provides supervise and assist with executive power, taking the lead in formulating land price and tax policies, providing infrastructure, improving planning methods, etc. The public playing an active and important role, provides strategies for project development based on the public opinions and the market demands. This multi-cooperation exploration mode accords with the current trend of market economy reform and makes the environment of mixed development more open and fairer.

5. Conclusion

The mixed land use is not only a technical means of planning, but also a sustainable-development-oriented strategy, which is an innovative strategy in land use and an advantageous approach to realize the coordination and symbiosis of urban life and ecology. The concepts of "compact city", "smart growth strategy" and "ecological city" have affirmed its role in the field of ecological environment. However, the concept of mixed land use, which was introduced from the United States, appears to be “hard to accept” in the Chinese urban planning system as the operating environment is very different with that in the United States. As a result, it is hard to adopt the mixed land use to guild practice.

Furthermore, the limitations of the mixed land use in practice reflect the deviation of government’s role in the market operation. In the near future, the market economy of China will be in the “2.0” era. In this era, there will be a market open to all market players, in which the monopolies and administrative interference from the government are eliminated (Wu 2013).In the context of the transformation of national governance and the deepening of reform, it is more fundamental to optimize the functions of the government and increase the efficiency of the market in allocating resources. Planning as an action of the government, the main responsibility is building a platform and controlling the bottom line. Spatially, the efficiency of the “deployment” of the government is far less than that of the “creativity” of the market. In the process of mixed development, encouraging the active participation of social forces and social capital and constantly improving the technical and institutional support system, is the fundamental way to realize the utility of mixed land use.

Emerging Forms of Neoliberal Governance on Public Space: An Informal Business Improvement District in Istanbul

Dicle KIZILDERE, Istanbul Technical University, Turkey

1. Introduction

The discourse of urban redevelopment and revitalization mutated notably through the past decade. As competition between cities deepened, the buzzwords like “image creation” and “promotion” became the advocates of urban renaissance and new urbanity for cities, especially for the city centres which were at a loss to competition with both suburban developments and other cities, to attract the industries of office, retail, tourism and entrainment (Kotler, 1991; Kearns & Philo, 1993; Fainstein, 1994; Savitch & Kantor, 1995; Bradley, Hall & Harrison, 2002). The market oriented new tropism increased the importance of safety, security, sanitation and place marketing. In other words, creating new “live-work-play” and safe- clean public spaces for attracting potential investors, consumers, tourists is becoming more and more important due to the local governments economic limitations.
A new innovative tool called Business Improvement District (BID) flashed as an answer to these problems. Generally speaking, a BID implementation is based on the levying of charges on businesses to provide local services which could not be efficiently supplied by the municipal government. This means that those municipal services once provided by the public sector, such as cleaning, lighting, maintenance, and security could be offered by the private sector (Steel & Symes, 2003). This new kind of public-private partnership went beyond creating safe-clean environments and, as both declared and mostly criticized by many scholars, became the instrument of creating a new social infrastructure based on privatization, surveillance, governing transaction and police monitoring which most frequently eventuate with the emergence of gentrification, exclusion, discrimination, spatially close but socially-world apart neighbourhoods in city centres. (Briffault, 1999; Steel & Symes, 2003; Hoyt, 2006; Ward, 2007; Minton, 2010; Morçöl & Wolf, 2010; Peyroux, Putz & Glasze, 2012).
In Turkey, there is no legal framework for BID implementations. However, a quite similar BID implementation, like those in UK and America, exists and can be called as “informal BID” in Turkish context. The “informal BID” appeared for the first time in 2005 in the hotel district of Talimhane, a part of Beyoğlu district, which was subject to transformation. In 1994, the central government designated the area as a tourist and hotel zone. Subsequently, an Urban Design Implementation Project was launched by the local government in 2004 which positively affected Talimhane's development as a touristic zone. Meanwhile with the help of Talimhane Hotels & Investors Association the first steps of Talimhane BID Implementation were taken.
The aim of this article is to investigate the evolution and form of “informal BID” in Turkey and evaluate the adaptability of the BID model in Talimhane, Istanbul under these findings. To achieve this, in the first chapter, the evolution and changing characters of BIDS are reviewed with critiques from both supporters and opposites. The second section analyses Talimhane case study, its socio-economic and political transformation and development of “informal BID”. Finally, the article summarizes key research results, draws some conclusion about development of the new concept and its spatial and socio-economic effects in Talimhane.

2. Business Improvement Districts: an Introduction and a Review

As a complex and still evolving phenomenon, there is no standard definition for BIDs in the literature. Due to the differences in the names, objectives and structures of BID model, most scholars and practitioners describe BIDs as self-imposed financing mechanisms implemented by business and property owners for local improvements, specifically the enhancement of public services. As Hoyt (2004) stated the BID model can be also defined as:

> "a flexible form of governance that allows participants to craft solutions in a way that is sensitive to the local context and where state and local funding is limited. The model provides an opportunity for multiple stakeholders to organize, operate with autonomy, and manage programs to improve the physical, economic, and social conditions within their geographical jurisdiction."(Hoyt, 2004, p.3)

It is possible to argue that the BID concepts borrow some elements from Middle Age Europe, in which merchant guilds or associations provided basic security and maintenance services of market places voluntarily (Milgrom & North, 1990). However, BIDs first appeared in city centres in the 1970, as a new downtown model for revitalization, which had lost their economic viability and had difficulty in competing with suburban shopping centres (Mitchell, 2001). After the 1970s, as a result of economic decline and structural changes, the provision of many municipal services became more burdensome for local authorities. In such areas, local businesses organised themselves to collect contributions. Legal arrangements were also made to ensure the continuation and routinization of this process of partnership. As Peyroux, Putz and Glasze (2012) explains, they are legitimized by public law and deliver services that local governments used to deliver.

As a relatively new and so called innovative tool, the first implementation was set at a commercial quarter in Toronto, Cananda in 1970. In US, the first established BID was the Downtown Development District in New Orleans, in 1975. Especially after the late 1980s and 1990s, the BID implementations exploded, the estimated number of BIDs in US, are over 1200 (Hoyt, 2006). BIDs in US, approved and set by the state and according the state they constituted in, the structure, form, function of BIDS varies. This state to state changing arrangements also echoed as different name variations like: "special improvement districts (New Jersey)", "parking and business improvement associations (Washington)", "improvement districts for enhanced municipal sevices (Arizona)", "self supported municipal improvement districts (Iowa) (Mitchell, 1999; Hoyt, 2004, 2006).

In Europe, BIDs have first been implemented in the UK, and later spread to rest. According to Ward (2006, p.68) London acted as a 'centre of persuasion' to diffuse American operations throughout Europe. The first legal arrangement was made in 2003-4 and the first BID started to operate in 2005 (Dawkins & Grail, 2007). Out of 100 applications 53 were chosen, and among them 22 areas were chosen as 'pilot' BID areas (Ward, 2006, p.66). Besides the rapidly increasing number of BIDs in US and UK, BIDs were established in 16 different countries including Germany, Holland, Japan, France and South Africa due to their adaptability, the hegemonic discourse on entrepreneurial city, copy-paste based international imitations and promoting, facilitating activities at international organizations (Hoyt, 2006; Ward, 2006; Peyroux, Putz & Glasze, 2012).

As mentioned before, according to the context of where they are located BIDs might have differ. While in some cities like New York BIDs are solely a private sector initiative, in some cities like London, Tokyo and Hamburg, they take the form of a public-private sector of a business might change in accordance to its scale, revenue, number of employees, area size and rent (Steel & Symes, 2005, p.325-327). For example, BIDs in the UK are more of a public-private partnership than those set up in America. As Hoyt stated "the majority of the initiatives are funded by both the local authority and private sector while others are funded by solely by the public sector." (Hoyt & Glopal-Agge, 2007, p.950). Another important discrepancy between the UK and American BIDs is the veto power of local governments on disbursing the sources (Hoyt, 2006; Hoyt & Glopal-Agge, 2007).

Although there is not one type of model for these BIDs, there are five main elements that can be called as general attributes of BIDs. Firstly, all BIDs are responsible for governing a defined specific area. This means even though the size of the BIDs varies, the borders are defined explicitly. Secondly, BIDs receive most of their funding from the assessments from the business or property owners in the BID area. Also in some BIDs, fixed fees or voluntary donations are paid instead of assessments. Thirdly, BIDs are expected to concentrate on efficiency in their areas. This is achieved by spending their funding on only within a specific BID area, not distributing to whole city.x Another point is, despite the fact that BIDs are controlled by different organizations (governmental, quasi-governmental cooperation, planning departments) they are much more flexible, free and quick in compare to governmental equivalents since the formation and running of BIDs are based on voting system. Lastly, BIDs are quasi public entities as they formed by a specific form of public and private. Even though most of the time BIDs are called as as private non-profit organizations, as a consequence of their economic-funding structure and concentration on improving the quality-of-life and profitability, it is very likely to influence the activities of BIDs and local governments according to economic interests. This characteristic of BIDs also cause to interpret them as the privatized urban development policy tools (Mitchell, 1999; Ward, 2005; MacDonald, 2000; Mitchell, 2008; Briffault, 2010; Peyroux, Putz & Glasze, 2012; Ward & Cook, 2014).
While defined more at length above, the BID model relies on special assessments on a defined specific area to augment services to the area. These services typically include sanitation, security, marketing, and planning efforts. Ward and Cook (2014) describe the main BID activities as a service provider as the most visible elements of BIDs:

a. Public space cleaning and maintenance, in terms of providing basic services and monitoring the appearance of the streetscape
b. Securing public spaces and businesses, often through form of hiring security guards to coordinate with local police and installing surveillance technologies; and
c. Marketing the BID area and organising events to compete with other areas inside and outside of the city (Ward & Cook 2014, p. 13)

After discussing the definition and the general activities of BIDs, it is also interesting to notice that, BIDs are also used for creating integrated successful spaces. As Mallett (1994) mentions, redevelopment projects to produce post-industrial spaces always produced private spaces, but at the same time destroyed the public spaces by leaving them undefined without management or service. “For realizing the full potential of post-industrial city”, BIDs are utilized as a tool to integrate the public spaces with private spaces to (creating united consumption spaces) consume as a whole. This can also be interpreted as a new kind of urbanity, which is formed by new revitalization and entrepreneurial policies both to citizens and spaces. Several issues about BIDs on regulations, democratization, accountability and inequalities are still debatable and will be discussed in the next section (Ward, 2007; Peyroux, Putz & Glasze, 2012).

2.1 Debates on BIDs:

BIDs are often considered to be an outcome of neoliberalism (Hoyt, 2005, 2006; Ward, 2006, 2007; Hoyt & Glopal-Agge, 2007; Ward & Cook, 2014). The state on the one hand downsizes itself by cutting down many responsibilities, and on the other hand it leaves the control of central areas and public spaces to private sector interests, with the rhetoric of revitalization a spur for increased real estate prices (Ward, 2006, p.68-70). In doing so, central governments are criticized for spending public money on the establishment of BIDs and since their establishment, debates and concerns are raised on their formation, structure and effect. They are generally criticized by their lack of accountability, equity and also for privatization and over-regulation of public space (Hoyt, 2006; Hoyt & Glopal-Agge, 2007; Ward, 2007;

Peyroux, Putz & Glasze, 2012; Ward & Cook, 2014; Briffault, 1999; Hochleutner, 2003; Wolf, 2006; Morçöl & Wolf, 2010).

As Hoyt (2006) stated "In a democratic system, elected representatives are accountable to the public for their decisions and activities." As the nature of the structure of BIDs, which gives voting right to business or property owners instead of public electeds, give rise to question their accountability. Through the operation of a BID, property and business owners are given the right to have a say on how BID funds should be spent. This characteristic of BIDs increases the risk of ignoring the needs of local people and thereby causing social discrimination due to the different expectations and needs of local people and business owners (Hoyt, 2006; Morçöl & Wolf, 2010; Ward & Cook, 2014).

Another critical point on BIDs accountability is the BID performances. "To compile a public account of their activities, prove their worth to participating property owners, and bolster their reputation, many BIDs opt to implement and monitor performance indicators like customer surveys, crime rates, occupancy rates, retail sales, number of jobs created, and pedestrian counts" (Hoyt & Glopal-Agge, 2007, pp. 952). Although some models to evaluate the performances are proposed by scholars, thus far no accepted criteria to measure their performances and the real impacts of the BIDs emerged (Briffault, 1999; Hochleutner, 2003; Wolf, 2006; Morçöl & Wolf, 2010).

In return to these critiques BID proponents claim that; BID leaders and advisory boards are not elected through the traditional systems and they also emphasize the weighted voting system as an important part of decision making process. Instead of calling BIDs as "quasi-governmental" entities, they call themselves as a "vital leadership", which creates strategic alternatives and entrepreneurial solutions to urban problems. Additionally, some scholars and BID proponents claim BIDs as one of the most effective and transparent tools for customer oriented urban revitalization with annual reports or interest rules and by improving physical environment creating opportunities through economic development. Although in some cases these could be true, the common use of benchmarks like amount of trash collected, graffiti removed or renovated urban furniture are not enough for claiming accomplishing healthy urban economy or urban policy objectives (Levy, 2001; Hoyt & Glopal-Agge, 2007).

Equity issue is another main concern and criticism on BIDs among many researchers (Zukin, 1995; Mallet, 1995; Hoyt & Glopal-Agge, 2007). Although the presence of BIDs in the Anglo-American world has been explained by the need to renew and regenerate old neighbourhoods in cities, they are criticised for causing disempowerment among local communities. Consequently, while business circles advocate BIDs for regeneration and rehabilitation purposes, local people consider BIDs as more likely to be a process of creeping gentrification (Steel & Symes 2005, p.332). There is also an issue of equity with regard to BID security services.

As the first and foremost aim of the BIDs is the creation of 'safe and clean' environments, this ultimately results in the employment of uniformed private security forces and surveillance cameras. According to the BID managers, not only provision of the safety in the area, but also making sure of the prevention of any activities which are dangerous for commercial interests such as the use of skateboarding, begging, and other anti-social behaviours should be sustained in the area. As a result, BID managers think that, by implying exclusionist policies for objectionable social groups, they can dictate people how to behave in a BID area, so they can force homeless people and beggars to move from the BID area. This way, the poverty in the city is displaced, sterile and uniform places are created at the expense of a true public access and vitality of street life which encompasses all classes, ethnic and racial origins (Zukin, 1995; Minton, 2006; Peyroux, Putz & Glasze, 2012).

In response to equity criticisms, BID advocates defend their actions by demonstrating that they are using their funding, which are mostly gained from self-assessments, for basic service requirements like sanity, security in the whole neighbourhood which is not provided adequately by local authorities (Mithchell, 2001; Levy, 2001). They also plead that, all the investments raised for BIDs are spent for local needs and keeping the local area in the competitive business market. From this point of view, the BID organizers justify the inequality issues in local service provision to an acceptable degree as the DNA of market oriented nature of BIDs. Another justification by BID defenders, on excluding poor and homeless, is creating social services, shelters and outplacement programs in addition to creating job opportunities to unskilled members of society (Levy, 2001; Steel & Symes, 2003; Hoyt & Glopal-Agge, 2007).

Critics also argue the BID effect which sabotages the characteristic of public spaces and result in privatized and over-regulated spaces (Mallett, 1994; Hoyt & Galopal-Agge, 2007; Morcol, Hoyt, Meek & Zimmerman, 2008). It has been suggested that around the world the private sector has become more powerful in the governance of many cities; while the state has gained more control, contrary to claims about its withdrawal. In this respect, BID implementation is the product of neoliberalism, which causes the identification of public and private spaces to become blurred. Neoliberalism has changed the meaning of “public interest”, and under market forces may have redefined it as the “interests of the private sector” (Ward, 2006, p.68). As Marquardt an Fuller stated, BIDs started to play an important role on this new governmentalizing concept of space and bodies, which tries to normalize market and competition approach and commodification of public spaces (Marquardt & Fuller, 2012).

BIDs are trying to be the cultural and entertainment centres of the cities. For this mission they are serving only the interests of high income groups, as new luxury shopping centres replace smaller retailers. However, Steel and Symes (2005) warn against this conception for the simple reason that although shopping centres have the right of turning down proposed tenants and controlling customer access when they want to, BIDs do not because they operate in public spaces, and they do not have opening and closing times. BIDs are also becoming the inexpressive faces of the cities with too much makeup. Similarly Minton (2006) claims that the BID managements perceive urban space as a ‘consumer product’; and therefore, through the BID implementation areas are branded, marketed, sold to the customers and it is turned into a place, ‘a location destination’, which will ‘experienced’. Furthermore this type of transformation or “disneyfication” creates non-place areas, which lose the real authenticity and create a fake and elitist authenticity instead (Minton, 2006; Hoyt, 2007; Zukin, 1995).

In contrast to mentioned critiques, BID practioners say that BIDs can’t be classified as shopping malls because unlike these private properties, BIDs are under the jurisdiction of municipalities and democratic activities like free speech and demonstration are not limited in BIDs border (Warner, Quazi, More, Cattan, Bellen & Odekon, 2002). They also suggest marketing strategies like uniformation and beatification of streets are very important and essential for the nature of doing business for attracting people and reaching the quality. Additionally, BID advocates call “disneyfication” or “loosing authenticity” as poor critics and defend the model by saying: “Were our city centers more authentic when they were abandoned at night with graffiti and plagued by crime?” (Levy, 2001) Although it is a reality that BIDs can be a tool for improving the conditions of urban space; the compatibility of the political activism or expression for all groups of community with the unwritten rules of privately managed or consumption spaces is still questionable (Warner, Quazi, More, Cattan, Bellen & Odekon, 2002; Mac Donald, 1996).

3. Talimhane: an Informal Business Improvement District in Beyoglu, Istanbul

Istanbul is the largest city of Turkey with unique historical and cultural heritage and 14 million people living on it. The continuous growth of Istanbul since 1950s accelerated after 1980s by the impact of neo-liberal policies. In order to promote the city as a “Global City” a series of laws and projects, in the context of “tourism law” were adapted. Whereas in the period after 2000, new laws, prepared within the framework of the process of harmonization to European Union, and related legislation amendments, ensured the legal basis for bringing urban regeneration projects into the agenda of local administrations (Keyder & Öncü, 1994).

So as to reach “World City” level, the current government set the visions of Istanbul for 2023 as tourism, finance and knowledge. In this context, many large scale projects, including water front developments, luxury hotels, and urban revitalization projects have been implemented. These transformations and changes were observed in the Historical Peninsula, Haliç and Beyoğlu district. Istiklal Street in Taksim area is located in the Beyoğlu district, where entertainment, tourism and cultural activities are clustered. The district hosts many local and foreigner visitors and tourists. In this context, Talimhane area, situated next to Istiklal Street and Taksim, has entered into a process of transformation, starting from the 1990s (Berköz, 1991, 2000; Özdemir, 2000; Tokatlı & Boyacı, 1999).

Positioned on an intersection area between Mecidiyeköy, the Historical Peninsula, the Golden Horn, Beşiktaş and Bakırköy,Talimhane in Beyoglu, close to Taksim Gezi Park,a former military parade ground in the Ottoman era, is located to the north of Taksim Avenue, at the point where Cumhuriyet Avenue and Tarlabaşı (Refik Saydam Avenue) intersect. Talimhane, seen principally as a residential area during the post-war period, experienced economic and social changes similar to other central Istanbul districts until the 1990s. The area has a very central and well-connected location, due to its historical and transportation links. Despite having been subject to numerous physical changes, Talimhane remains within the borders of the Beyoğlu district, an area of great architectural importance, particularly for Art Deco and early modernist buildings (Akin, 2005; Polat & Polat, 2006).

The social composition of Talimhane has changed over time as a consequence of political incidents and the change in land use and socio-economic condition of the area. The first residents of the area who were mostly non – Muslims, had to leave Turkey due to 6-7 September incidents. After 6-7 September events, the low-income population from Turkish rural area, started to move into the abandoned residences from 1950s (Polvan & Yönet, 2010). After 1970, due to unwanted activities around neighbourhood like car repair shops, increasing crime rates, the residents of the area sold their properties and moved to Şişli, Nişantaşı or to the Anatolian side. This migration led to another immigration flux to the area. According to Talimahane Mukhtar Metin Sönmez, who was interviewed on 18 June 2009, residents, who are living in residential zone of mostly migrated from Eastern and South-eastern part of Anatolia. Sönmez also indicated that the current residents of the area low income and uneducated groups. These families, with many children, which are struggling with unemployment, live together in a house that has 90-150 euro rent price. Moreover, as a result of financial difficulties, many children often in the area cannot attend school and instead they try to find employment by working at informal jobs like selling water or flowers on the street.

In order to explore the transformation of the area and the establishment of “informal BID” in Talimhane, I employed a mixed methodology, using census data, participant and nonparticipant observation, and in-depth, semi structured interviews with hotel managers, mukthar of Talimhane and the director of Talimhane Hotels & Investors Association. Since it is impossible to find data on current population and because of the informal relationship between Talimhane Hotels & Investors Association and local government, in-depth, semi-structured interviews are the backbone of this research. Such conversations provide insights into the socio-economic transformation and the establishment and structure of “informal BID” in Talimhane neighbourhood.

3.1 The Transformation of Talimhane

Important changes which took place after 1990 were to transform Talimhane, and effectively detach it from its previous urban role as a residential area. In 1988 the opening of Tarlabaşı Boulevard, which connected Istanbul's historic peninsula with Talimhane and the central traffic hub of Taksim Square, cut off the adjacent Tarlabaşı district and its surroundings from commercial districts north and south of Taksim. In the newly-separated Tarlabaşı district drug dealing and crime were to flourish. On the other side of the new boulevard however, a pedestrianization project for Istiklal Avenue, implemented in 1990, was to lead to greatly increased activity, both social and commercial (Enlil, 2000; IBB, 1990; Tekeli, 1994).

Located next to Taksim, at the northern end of the new boulevard, Talimhane was an area of decline, both in terms of physical and social structures. Due to its key location Talimhane nevertheless aroused the attention of the municipality and led to planned improvements to develop a more attractive environment for commerce, and in particular tourism infrastructure. The first initiative involved its designation as a "tourism district" by the Cabinet and the Ministry of Tourism in 1994. Talimhane was also declared as an "urban protected area" in decision number 11437 (7 July 1993) by the Cultural and Natural Heritage Conservation Board No.1 of Istanbul. Later, for the 12 housing blocks comprising the Talimhane area which had started to lose their functional and architectural identity, another decision was taken in 1999 by the same Conservation Board to register the area at a city block and street scale, to ensure integrity before taking decisions on any single parcel scale, and to designate and protect selected "buildings of the early Republic period", as defined in decision number 663 (Polat, 2006; Ozden, 2008; Kizildere, 2010).

The designation of Talimhane as a tourist zone by the central government triggered the process of transformation and started to change the residential identity of the area. Housing was replaced with hotels, commercial units, and offices, which not only changed the identity of the area but also changed its social structure in the long run. With the aim of preventing the deterioration of individual buildings, eliminating illegal and informal parking lots and ensuring safety and increased perceptibility, the "Beyoğlu Talimhane Area Front Rehabilitation Urban Design Implementation Project" was subsequently realized through cooperation between the Istanbul-Metropolitan and Beyoğlu Municipalities, and was put into practice in 2004 (Kizildere, 2010; IBB, 2004).

3.1.1 Beyoğlu Talimhane Area Front Rehabilitation Urban Design Implementation Project

Anticipating the accommodation needs of the Istanbul NATO Summit in 2005, the Area Front Rehabilitation and Urban Design Implementation Project was intensified in Talimhane, not least because of its convenient location close to Taksim, the 'Congress Valley' international hotel district and the expensive shopping district of Nişantası. Formulated with a disregard for social consequences however, and planned as only as a series of physical changes involving urban furniture, facade renovation and pedestrianization (Kizildere, 2010)

The "Beyoğlu Talimhane Area Front Rehabilitation Urban Design Implementation Project" began with a pedestrianization programme, in order to increase security, accessibility, and to provide space for festivals and outdoor activities. In this pedestrianization programme certain hours were allocated for access by service vehicles, with passage of vehicles free between the hours 06:00-10:00 while card access became obligatory at other hours. Entrance into the area is made at two points, and the exit is a controlled passage where Abdülhakhamit and Topçu avenues intersect. Urban furniture and pavements have also been renovated, with the former positioned to avoid inhibiting pedestrian circulation throughout the district (Kizildere, 2010; IBB, 2004).

The project did respond to problems of security and physical deterioration, but failed to offer any solution to the social challenges faced in the low-income and deprived residential sections of Talimhane. After the completion of the project, user profiles and the demand for services in Talimhane have changed. Car mechanics, other small workshops, and cargo companies operating in Talimhane since the pre-1990 period have had to leave the area due to rent increases, the pedestrianization project, and changes in demand (Table 1).These premises were subsequently replaced by cafés, restaurants and souvenir shops used by tourists and people working in the area. Interviews made with hotel managers after the project indicate that business establishments located in the area are very satisfied with Talimhane's development, the reclamation of its prestigious image, and the better use of its central location. Hotels can now offer not only accommodation facilities, but also congress and meetings functions, having many high capacity meeting rooms after re-structuring themselves in conformity with the strategic plan of the central administration (Polat, 2006; Kizildere, 2010).

3.2 Creating the "Informal BID": The Establishment of Talimhane Touristic Hotels & Investors Association

After the complementation of the rehabilitation project, in 2005, to enforce the tourism based transformation and to prevent the re-emergence of security and social problems, hotel owners got together and established "Talimhane Touristic Hotels & Investors Association" which also began to create a type of business improvement district. As mentioned before although there is no legal framework or any legal contract between the Association and Beyoglu Municipality, Talimhane Touristic Hotels & Investors Associations articles of association gives us detailed information about the associations structure, its aim, working principles and forms of work. The prerequisite to be a member of the association is to be an owner of a hotel or commercial enterprise in Talimhane. The decision making system is based on voting system and to make a decision absolute majority vote is needed (TTHIA Article of Association, 2005; Kizildere, 2010).

As stated in articles of association, Talimhane Touristic Hotels & Investors Association is a non-profit organization and its source of income is based on membership fee and donations. Membership fee is composed by two types of fees. First one is entry fee which is equivalent to 500 TL (180 Euro), the other one is annual fee that is 200 TL (70 Euro). Their budget differentiates according to needs of the area but it is reported that their expenditure for 8 years was around 6.6 million Euros. For 2014, the Association's budget is around 720.000 Euros. As can be seen from the numbers, the economic sustainability of the association is based on voluntary assessments by hotel and commercial enterprise owners. The biggest part of expenditure is the security. Mediterranean Security Company which is responsible for areas security, receives payment, which is equivalent to 864.000 Turkish Liras (304.000 Euros) for a year, for its services from the Talimhane Touristic Hotels & Investors Association every month. The amount paid by 32 hotels is divided according to each hotel's number of stars and rooms. The district's infrastructure and repair costs are also covered by the Hotels & Investors Association (TTHIA Article of Association, 2005; Esmer, 2009, 2013).

According to articles of association (2005), apart from hotel needs, the Association is responsible for the district's management including infrastructure, security, repair and most importantly, socio-economic and cultural improvement of Talimhane area in addition to establish partnership with governments, NGOs and public/private institutions to run projects. Emerging from this, it is possible to organize the association's activities in three main groups: 1. Place management of the public environment 2. Production of special events 3. Planning and political advocacy.

The first category of functions which includes security, improving and repairing infrastructure and landscape like lighting, sidewalks, urban furnitures. Talimhane has been protected by the Akdeniz Güvenlik (Mediterranean Security) Company since 2005, even though private security units are not allowed to operate freely in public spaces. Nevertheless, 32 employees of this company have worked with the municipal police since then, but due to lack of authority to apply any penalties, they require close support and monitoring, in addition to this troublesome situation, an interview held in January, 2014 with Security Bureau of Beyoglu Police, showed the broken connection between Akdeniz Guvenlik and Beyoglu Police. In the interview, Security Bureau, which is responsible for private securities, claimed that there can be no security forces other than police at the public spaces which creates contradiction with current situation (Esmer, 2009).

Apart from management of public space, Talimhane is used for place-promotion activities by the association and Beyoglu Municipality. As it is the one few pedestrianized areas in the city centre, activities like opening and closing concerts of festivals, free public concerts take place in the area. Association is also responsible for free accommodation for artists during festivals and organizing free Ramadan Iftar dinners in the area in the name of Beyoglu Municipality (Esmer, 2009, 2013).

Planning and political advocacy is another important responsibility of Talimhane Hotels & Investors Association, including development of site plans, land uses and also to work as a bridge between hotels and municipality on legal issues. In 2009, a land use plan with tourism function designation for Talimhane was issued by municipality. The conservation board approved the plan in 2010 and also documented the buildings with height and façade violations. Although illegally built floors of hotels must be destroyed, no legal action has been pursued. The other crucial point is the legal status of the potential projects. As the area is protected, the new hotel and commercial projects must have the board's approval but as conservation board informed, there are no hotel projects completed or pending at the moment so the legal basis of current projects is questionable and mainly depend on licence or assurance of Beyoglu Municipality (Solano, Geambazu, Soltanzadeh, Swangpol and Mohyeldin, 2013) Talimhane Hotels & Investors Association is aware of the situation and to solve the problematic legal status, they initiated both with Beyoglu Municipality and Tourism to cooperate and reach an agreement. Although, declaration Talimhane as a tourism center by the ministry of tourism and with this declaration transferring the planning authority from the municipal government to the cabinet or central government could solve the legal problems, the Beyoglu Municipality refuses this solution and want to keep the area in their authority. According to Esmer (2013), Beyoglu Municipality doesn't want to lose control on an area like Talimhane which is self-funded and also the associations economic and social support.

Another critic subject in this category is whether the Hotels & Investors Association's efforts are improving the local people's socio-economic statuses including the job training and employment services for the unskilled and poor population living in the area or not. Esmer (2013) stated that although they have plans with local authorities on educating and providing jobs to local people, currently, people working at hotels are not resident of Talimhane and live mostly in the suburbs.

3.3 Outcomes- Impacts and Similarities with BID model

As mentioned before, BIDs are quite successful as a "travelling concept"; it is spreated around the world. Talimhane Hotels & Investors Associations implementation, which is very similar to other BIDs around the world because of its self-imposed and voting system and also service provider mission, however this differs from the other BIDs because of its legal status. As mentioned before, there is no legalized framework for BIDs by local governments in Turkey. This status makes us to declare the implementation as an “informal BID” (TTHIA Article of Association, 2005; Peyroux, 2012).

Like most of the BIDs around the world, the Association activities and concerns are concentrated on “creating safe and clean environment” which includes improvement on physical conditions of properties, the management of buildings and public spaces and also safety and security issues. And again like many BIDs, their assessment criteria is based on improving “physical decline of inner city infrastructure”, “empty building and vacant shops”, “disinvestment from the city centre”, “unmanaged informal trade”; “congested pavement”, “continued corporate exodus” (Peyroux, 2012; Esmer 2013)

With the help of both Urban Design Project and “informal BID” Implementation, Talimhane continued to develop rapidly as a tourist area. During the interview held with the director of the Talimhane Hotels & Investors Association in June 2013, informed that Talimhane is still serving for the affluent tourists and customers, in the line with this concept, the land prices are still continuing to increase with an average square meter of 6.000 Euros. As in the UK (Cook, 2008), the BID model in Talimhane is described as both successful and appropriate due to the improvement of physical conditions and services. Talimhane launched as the “new Shanzelize” by Istanbul Greater Municipality Mayor also used in Beyoglu Municipality commercials as an example of perfect transformation (http://www.ibb.gov.tr/tr TR/Pages/Haber.aspx?NewsID=8062#.U6v5z7FAAqI; Kizildere, 2010; Esmer, 2013).

Although it is impossible to deny the physical improvement and glamorous image of the area, like in mnay BIDs, issues about BIDs on regulations, democratization, accountability and inequalities are questionable for Talimhane as well. Firstly, Esmer (2013) stated their discontent about the street beggars who are mostly from Syria. He claimed that these beggars do not even hesitate from entering the hotels, and damaging the ‘glamorous’ image of the area. The Association acted on the street baggers by photographing and reporting them to the Beyoglu police and Beyoglu Municipality, but in return the authorities informed the Association that they can only impose 86 Turkish Lira (30 Euro) penalty and have no authority on keeping the beggars away from Talimhane. Anoher important point is that the improvement of the conditions has not involved the west part of the neighbourhood, a residential area for poor and unskilled group. Besides the security problems appeared again in Talimhane. Although looseness of security measures played a part in the re-surfacing the security problems in the area, the emergence of unsafe areas where crime becomes widespread would be inevitable in cases where poor, excluded and marginal groups in city centers are not empowered economically and are deprived of social aid and public support, as in the case of Talimhane. It is very likely that these groups will move from one neighbourhood of the city center to less central neighbourhood, as per the changing conditions like transformation process of the poor residential area into boutique hotels (Kizildere, 2010).

4. Conclusion

As Brenner and Theodere (2002) stated, “cities became increasingly important geographical targets and institutional laboratories for a variety of neoliberal policy experiments.” (Brenner & Theodere, 2002, p.21). Business Improvement District concept is one of those policies which goes beyond “clean and safe” environments and as our case study Talimhane indicates BIDs, as a new “urban revitalization” tool, act like a transformative force for the culture, social and physical improvement, still a conflict on academic literature that the ‘revitalized’ areas should be admired rather than avoided or for whom it is made (Mallett, 1994; Hoyt, 2006; Peyroux, 2012)

Even though, the legal framework of implementations such as BIDs has not been set up yet in Turkey, Talimhane Touristic Hotels & Investors Associations efforts, with keeping the area safe and well-maintained, are very parallel to BID implementations in foreign countries. For example, security and maintenance / repair services being paid by the private sector, according to the logic of who pays the piper calls the tune, are only for the areas which are close to the hotels, not for residential areas. As central and local government are incapable of solving the social and economic problems of residents, it is inevitable for the private sector to create its own well-maintained and protected areas. Although, the security company in Talimhane does not discriminate towards the residents living next to the hotels when using the hotel district, these people have no such demand to use or come to this area, which is socially and economically different and whose lifestyles are incompatible with the luxury eating and drinking places. They live as if the hotels area does not exist.

BIDs play a central role in attempts to governmentalize bodies and space (Peyroux, 2012). In our case study Talimhane is one of the most important districts of Beyoglu. Due to its economic importance, influence and unique legal status, Talimhane Touristic Hotels & Investors Associations has a strong relationship with Beyoglu Municipality, which in turn results in actions like lobbying of the hotel owners for a new tourism plan, request for the pedestrianisation of Talimhane or providing free accommodation for Municipality activities. Although interplay activities between interest groups can be useful sometimes like solving time and political obstacles, it does not always reflect the interests of the society. In this respect, although association's decision making process is based on voting system, monotype membership system of the association limits the voice of “others” and also the Beyoglu Municipalitiy's top down planning approach and strong tie with Talimhane Touristic Hotels & Investors Association increase the concern for the well-being of “other” groups living in the area.

Debate on BIDs is very controversial and the same can be said for this case study. Some defend the urban revitalization tools like BIDs in view of increasing financial capacity, stabilization of collapsed areas and improvement of physical and social qualities. But on the other side, these processes contain risks and should be sensitive to the social context which needs to be considered very carefully, to avoid the negative consequences like displacement, loss of social diversity, creating gentrified spaces. It is important to realize that the “informal BID” implementation in Talimhane created the “clean and safe” area, intensified growth, enhanced competition and increased the profits of business and hotel owners. But also unfortunately, the last implementations in Talimhane intensified the problems in terms social aspect of disadvantaged groups. Hence as the gap deepens between Talimhane and its inner circle, as if corroborating the critics, there has been an increase in urban environment structures which are physically near but segregated socially and institutionally.

Analysis of transformation of urban planning practice by mapping changes in economic, social, cultural and built environment of the Neighborhood Level Urban Communities (NLUC): Case study of Kolkata, India

Sudeshna KUMAR, Indian Institute of Technology Kharagpur, India

Haimanti BANERJI, Indian Institute of Technology Kharagpur, India

Synopsis

The study analyses the transformation of urban planning practice through mapping changes in economic, social, cultural and built environment of the selected NLUCs. The study then explores how entrepreneurial urbanism and neoliberalism has dominated planning practice leading to erosion of the cultural patina of Kolkata.

Keywords: urban planning, neighbourhood level urban communities, cultural

1 Introduction

Kolkata has experienced an explosive population growth leading to rapid urbanization. Population is found to be stagnating in the core city as the wards 1 to 100 shows a low growth rate for the last two decades, but the newly added wards, especially from 101 to 110 adjoining to Eastern Metropolitan Bypass, abutting the East Kolkata Wetland is growing at an alarming rate hence the natural growth of the city is higher. This noticeable contrasting urban growth is accounted mainly for the increase in city size, expansion of tertiary and service sector activities especially the IT boom, and the improved transit facilities along the eastern fringe. This population explosion has resulted in an unprecedented boom in the real estate sector imposing verticalization subsequently changing the city skyline and thereby reimaging a large part of Kolkata. The eastern fringes of the city have experienced an incremental growth in population which has helped the architectural profession to thrive but many a time-defying planning norms. An increase in land value and property price along the Eastern Metropolitan Bypass have resulted in an uncontrolled urban sprawl, bringing with it a myriad of Economic, Social, Cultural and subsequent planning challenges. The professions of architecture and urban planning are being largely dominated by driving forces of entrepreneurial urbanism making preservation of built heritage and culture a difficult proposition. This has often resulted in the demolition of historic buildings and subsequent erosion of the cultural patina of Kolkata (Bose, 2016). This urban explosion has started encroaching the eco-fragile areas of the East Kolkata Wetlands, a RAMSAR site resulting in an uncontrolled sprawl. The present paper explores the transformation in urban planning approach of Kolkata based on a timeline of historical events since its inception as an Indian colonial port city to today's IT-driven city.

2 The onset of entrepreneurial urbanism and neoliberal policies in Kolkata

The authors have tried to explore how economic liberalization has instigated the onset of neoliberal policies which has paved the path for entrepreneurial urbanism, responsible for restructuring the spatial urban landscape of Kolkata.

Neoliberalization in India has contributed towards highly polarizing consequences with respect to social welfare and environmental sustainability (Chattopadhyay, 2017). The essence of neoliberal policies is to encourage open competitive and unregulated market logic to pursue large urban development projects in quest of transforming Indian cities into 'world-class city' (Peck et al. 2009) (Ghertner, 2011). As a consequence of the implementation of the Neoliberal policies, the urban development plan was being reshaped and developed by the complex dynamic interplay of global ideals and local factors. Neoliberalization has interacted with the local forces for managing the city and pursuing growth and development which is often termed as 'glocalization'. Swyngedouw (2003) has described 'glocalization' as dichotomous global and local entities which actually complement each other to generate economic prosperity.

The economic liberalization of the 1990s has brought about significant reforms which have changed the lifestyle of Kolkata's middle class and promoted new 'neoliberal policies across Kolkata. The economic liberalization of the 1990s and the issue of foreign investment has brought about reforms which have benefitted the 'new 'middle class and increased the disparity, widened the inequality gap between the urban poor and the middle class. From 1977 onwards, the ruling political party was disregarding the needs of urbanites in favor of their rural vote banks. From 1990 onwards, in order to accommodate the needs of the consumeristic middle-class citizens, the state government began to invest heavily in urban infrastructure intending to gain the support of the middle class who were now interested in state politics in order to stay in power.

The change of reform in policies such as encouraging foreign investment, in the private sector, export-oriented business, the emergence of the bourgeoning IT sector led to the embracement of the global consumerist culture. Consequently, this led to the drastic consequences of 'regeneration' and 'urban restructuring' in Kolkata (Fernandes, 2004). The metros such as Kolkata and Delhi were reshaped and reordered in order to support the needs and demands of the growing urban elite (Donner, 2012). Construction of highways, bridges, malls business parks, suburban housing indicated the changing era. The neoliberal policies began to reshape the imagination of the public and consequently, the city and urban spaces began to be looked upon as economic resources. In order to realize the vision of the middle-class Calcutta of identifying themselves as the future IT hub at par with Bangalore and Hyderabad, Kolkata had to expand beyond its boundaries. The planners and bureaucrats of the entire political landscape were dominated by the hegemonic left front and their appeasement policies for the vote bank to stay in power linked the fate of the city to its hinterland (Donner, 2012). This led to the emergence of luxury residential apartments catering to the needs of the global lifestyles where basic infrastructural facilities were also not available. The government started investing biasedly to develop these new areas while the city core stood neglected.

Few Government policies are explicitly biased towards the interest of the elite by encouraging property development. It has provided investment opportunities in real estate with attempts to include the middle-class to claim their stake in the wealth generated by the new economic order (Shatkin, 2014). Neve and Donner in their article of Revisiting urban property in India has highlighted that the unregulated market values and the influence of neoliberal ethics didn't lessen the role of social aspects during the development of the property regimes but they have endangered transformation in the way property plays a key role in driving contemporary social life (De Neve & Donner, 2015). Entrepreneurial urbanism is largely responsible for changing the urban spatial landscape at the local level (Smitha, 2016) which will eventually erode the intrinsic characteristics of the metropolitan cities of India.

There has been a wave of real estate development of luxury condominiums on the fringes of Indian Metropolitan city of Kolkata. These housing projects are being developed solely to imbibe the status of Global India. This real estate market is mainly targeted to attract overseas Indian communities and local elites who want to acquire the "international" identity (Bose, 2007). Such massive development has not only altered the skyline of Kolkata but also has exerted a significant impact on the social, economic and ecological environment of the city. Such rapid urbanization triggered by the real estate industry is endangering the ecologically sensitive East Kolkata Wetland a wastewater-fed aquaculture (Bunting et al., 2010) constituting an ingenious waste management system of Kolkata which has been also recognized as a Ramsar site since 2002 (Bunting et al., 2002) (Bose, 2007). Moreover, this also affects the livelihood of the workforce who are directly working in co-operative or private fisheries in this wastewater-fed aquaculture including rice fields and vegetable farming on garbage (Chaudhuri, 1990). Thus such development not only did adopt the international aesthetics to attract NRIs which is in contrast to the intrinsic identity of Bengal but also negatively affected the socio-economic structure and displaced population interwoven in this physical space (Bose, 2007).

3 Urban planning transformation in Kolkata

The authors have identified that the spatial planning of Kolkata has been hugely influenced by four incidents which were direct consequences of the rapid urbanization of Kolkata leading to an uncontrolled sprawl. Firstly, colonization by the British in the 18th century, Job Charnock an agent of British East India has laid the foundation of modern Kolkata by consolidating three economically potential villages namely Sutanuty, Gobindapur and Kalikata. It was during the 18th century a white town was built exclusively for the British people in and around old Fort William. The indigenous people were given compensatory lands in the north of the city (Sutanuty) which was referred to as the Native town. In between the white town and the native town, other European, as well as foreign communities started to settle down in the Grey town. Urban growth varied significantly across the White Town and Native Town. The city played an elemental role in extending the 19th-century globalization and imperialist policies of the British empire. In fact, the city has been the pivotal site for resisting and revolting during the anti-colonial and nationalist movement against the British(Chaudhuri, 1990; Chattopadhyay, 2005).

Secondly, the partition of India in the year 1947 led to a huge influx of refugees from East Pakistan to West Bengal. Thirdly the Bangladesh Liberation war in the year 1971 resulted in a huge influx of refugees of Bangladesh in West Bengal, Assam, and Tripura. Kolkata was the capital of India during the British East India Company rule until 1911 (Fazal, 2013), and later became the state capital of West Bengal after independence in 1947. Kolkata had suffered sharp economic decline due to political instability during 1947 and 1971 when the city level infrastructure almost collapsed due to the huge influx of refugees. Fourthly the economic liberalization has changed the Left front hegemony which consequently changed the approach of the planning of Kolkata. Policy makers and urban planners have tried to condemn the colonial arrangement of the city and refugee influx after the liberation war. They have tried to implement urban planning to change the physical layouts of the city which is not yet properly implemented as a result of which the urban growth varies distinctly across various municipalities (Mukherjee, 2011).

After Independence, efforts were made by policymakers to introduce proper planning in Kolkata like many other Indian cities, but till date, the city has failed to achieve uniform urban growth and undergo a well-planned spatial transformation. KMDA has tried to regulate the unprecedented urban growth in Kolkata by introducing a bi-polar strategy of urban growth in Basic Development Plan (1966-86) which was planned (Mukherjee, 2011) by Ford Foundation to promote Kalyani-Bansberia as a counter magnet to Kolkata-Howrah twin city (Nyqvist J. et al., 2013). The bi-polar strategy in 1966 was a complete failure in curbing the unplanned population growth in the City since Ford Foundation tried to apply western systems in developing the city with no consideration of regional context and specificity in Kolkata's case (Mukherjee, 2011).

In 1976 CMDA prepared a development perspective plan which rejected the bi-polarity proposed by Ford Foundation a decade ago and contrastingly they recommended a polycentric strategy. Their main aim was to distribute the population and work in a balanced way for boosting the regional economy. This perspective plan was called into action because of the huge refugee influx after Partition in1971. Kalyani, Saltlake, and Dum Dum are examples of implemented plans (Nyqvist J. et al., 2013). Then in 2001, KMDA launched their perspective plan ‘Vision 2025’ which also adopted a multi-nodal growth strategy (Majumdar & Kait, 2014) in which new urban centers near Kolkata were given stimulus for growth (Mukherjee, 2011). In this perspective vision plan Metro center, Metro Sub Centre and Trans Metro system were given utmost importance. New settlements and New Townships, existing industrial Parks and industries were also identified and proposed (Nyqvist J. et al., 2013).

4 Neighbourhood level urban communities (NLUC)

For the purpose of neighbourhood level assessments, it has been observed that often components at the level of an individual building or certain city level infrastructure are considered thereby neglecting issues at the intermediate levels (Blum, 2007). Along with the built fabric, this study has taken into consideration the diverse social and cultural aspects of the communities residing within them. Hence the authors have used the term neighbourhood level urban communities (NLUC) implying communities or group of people residing within a tangible space i.e. neighbourhood which is well-defined by physical boundaries such as large roads or other manmade structures referring to the built environment which is more or less homogenous in character (Blum, 2007).

4.1 Selected NLUCs

The authors have selected five NLUCs which are spread across the city and each of them is representative of the different periods of development of Kolkata during its transition from a traditional colonial city to an IT-driven metropolis. Three urban NLUCs have been identified within older parts of Kolkata and one urban NLUC from Saltlake, and one gated township named Sukhobrishti from Newtown Rajarhat, a satellite residential town to Kolkata. The selection has been made in order to compare between older and newer NLUCs and also to understand how the later set is different from the former located in the core of Kolkata. The study also tries to understand whether Kolkata has been able to sustain its past cultural glory and whether the older NLUCs are still efficient and sustainable. Administrative unit and well-defined physical and manmade edges have been considered as parameters for defining the boundaries of the neighborhoods.

4.2 Delineation of the NLUCs

The authors have selected three NLUCs differing in socio-economic character. Dhakuria is mostly inhabited by upper-middle-class people whereas Saltlake has a combination of middle to higher income groups and Sukhobrishti is a community designed to accommodate lower and middle-income people with facilities befitting high-end residential complexes. Dhakuria is the most densely populated NLUC followed by Bhowanipore and Saltlake whereas Sukhobrishti is least populated. All the selected NLUCs are diverse in terms of their population density, pattern, grain and texture. The authors have tabulated the demographic details in the following Table 1(Chakraborty and Deb, 2010; KMC, 2018; BMC, 2018; Humayun, 2014)**.**

Table 1: Showing the brief details of each of the selected neighborhoods

SL. No	Neighborhood Level Urban community	Details	Predominant Socio-economic profile
1.	Bhowanipore	Falls within Ward – 70, KMC (Kolkata Municipal Corporation)	Middle-income group (MIG)- High income group (HIG)
		Neighbourhood Area – 205 acres	
		Population density-22367 people per Sq. km	

SL. No	**Neighborhood Level Urban community**	**Details**	**Predominant Socio-economic profile**
2.	Dhakuria	Falls within Ward – 92, KMC (Kolkata Municipal Corporation)	Middle-income group(MIG)
		Neighbourhood Area –160 acres	
		Population density-23143 people per Sq.km	
3.	New Garia	Falls within Ward – 110, KMC (Kolkata Municipal Corporation)	Lower-income group(LIG)-Middle-income group(MIG)
		Area - 130 acres	
		Population density- 15698 people per Sq.km	
4.	Sector, Saltlake	BA, CA blocks falls within Sector 1, BMC(Biddhanagar Municipal Corporation) Ward no 39	Middle-income group(MIG)-High income group (HIG)
		Neighbourhood Area 140 acres	
		Population density – 16062 people per Sq.km	
5.	Sukhobrishti, Rajarhat	Falls within action area III, Rajarhat NKDA (New Town Kolkata, Development Authority)	Low-income group(LIG)-Middle-income group(MIG)
		Neighbourhood area- 150 acres	
		Population density-11532 people per Sq.km	

4.3 Bhowanipore

Bhowanipore is a well-established posh NLUC of Kolkata which is thriving with vibrancy even today after 150 years. The place is bounded by Acharaya Jagdish Chandra Road on its north, Sarat Bose road on its east, Ashutosh Mukherjee Road on its west and Gour Ghosh Road on its south. This is a mixed-use NLUC where residences coherently exist with school, colleges, markets, and hospitals. Many significant shopping markets are located here such as Forum, Brand factory etc. Bhowanipore was part of the white town and it has always shown a positive growth rate since its inception (Mukherjee 2012). This NLUC houses mostly high-income people and few low-income people living in slums. Middle-income people cannot afford to stay in this posh NLUC hence they commute to this place only for work which is well connected to the rest of the city (Guha & Ferreira 2009).

4.4 Dhakuria

Dhakuria is a well-recognized, vibrant, middle-income NLUC of South Kolkata. Dhakuria is bounded by railway lines on its North, Raja Subodh Mullick Road on its West, Prince Anwar Shah Road on its South and Dhakuria Road on its East. The cultural activities hosted throughout the year in a vibrant open type shopping centre named Dakshinapan, keep the neighbourhood bubbling. It's been surrounded by a posh NLUC of Jodhpur park having a strong cultural background.

Durga Puja is the most celebrated annual festival of Hindus especially Bengalis (*Bengali is the native language of West Bengal*) where prayers are offered to Goddesses Durga and the festivity continues for 10 days during Autumn season. Dhakuria hosts quintessential Durga Puja's of Kolkata, at Babubagan and Selimpur and flanked by the surrounding Jodhpur Park, Gariahat Goplark Durga Puja committee. The successful execution of the Durga Puja implies existing harmony and community participation within the neighbourhood. It is significantly inhabited by people having an inclination towards honing their cultural skills.

4.5 New Garia

New Garia is one of the fastest developing NLUCs of Kolkata, situated in Garia. It is bounded to the North and West by Eastern Metropolitan Bypass, to the south by Briji Road and East by Kavi Subhas Metro Station and New Garia railway station. It is also surrounded by the Baishnabghata Patuli Township on its north side. New Garia is situated in the southern tip of the Eastern Metropolitan Bypass and is often referred to as the next 'Chowringhee' of Kolkata. The EM Bypass connects the northern parts of the city to the extended Kolkata, Salt Lake City, and Rajarhat and provides access easy to the airport. The enhanced accessibility facilities have triggered commercialization in the area. Garia became the transport and commercial hub for the region with two major bus terminus, metro stations, and railway stations.

4.6 Saltlake Sector 1, BA & CA blocks

Bidhanagar or Saltlake as it is popularly called is a planned satellite town of Kolkata to accommodate the burgeoning population of Kolkata between 1958-1968. The authors have selected two blocks within Sector 1 for the concerned neighbourhood study.

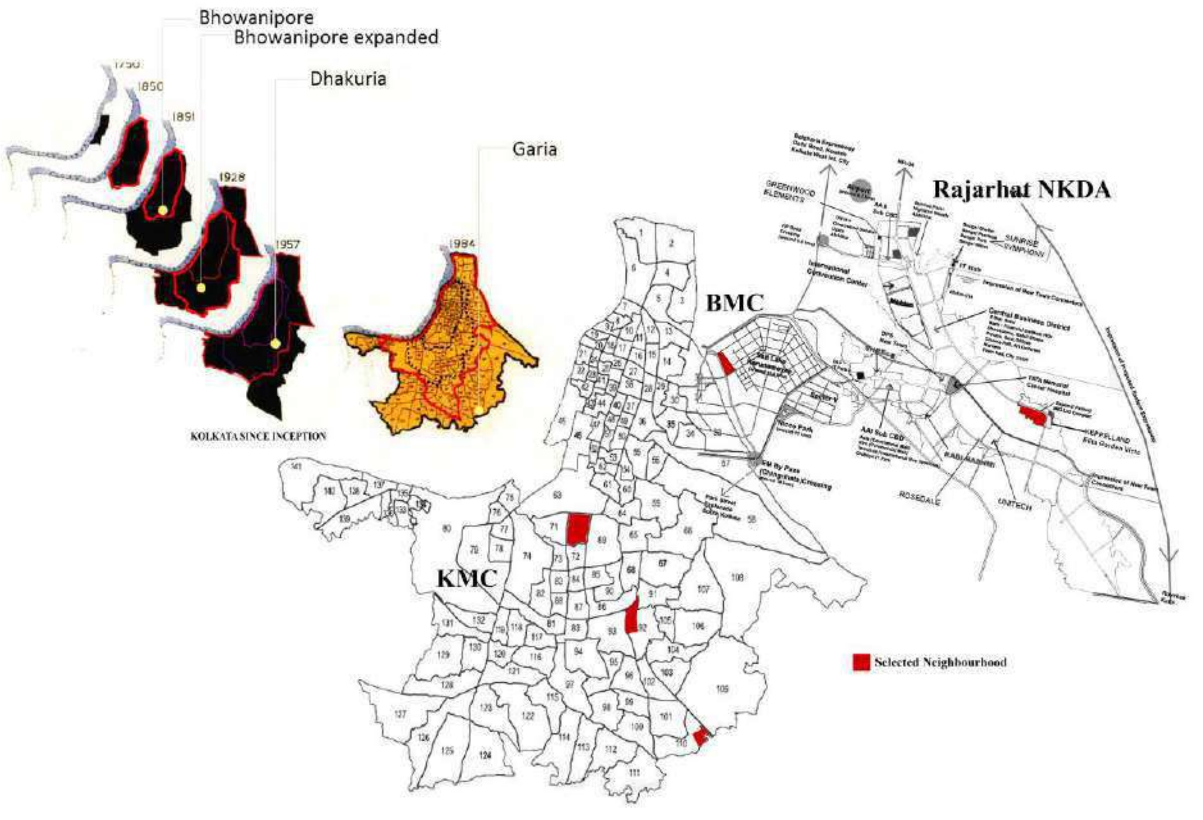

Figure 1: *Showing the evolution of the physical extents of Kolkata and the selected NLUCs*, *Source*: Author, (Guha and Ferreira, 2009; KMC, 2018; Elita Garden Vista, 2018)

The selected CA & BA block NLUC is bounded by Eastern Metropolitan bypass on its North and East, 1stCross road on its East and Manicktala main road, fourth avenue on its South. Saltlake blocks actually exhibit examples of a planned neighborhood in Kolkata although it has been criticized for being associated with a feeling of seclusion. The research will reveal how the planned NLUC in the urban areas of Kolkata are performing compared to the vibrant old organic NLUCs and new NLUC within KMC.

4.7 Rajarhat - Sukhobrishti

"Sukhobrishti" or "showers of happiness" is a township representative of the trend of high rise gated townships which is mushrooming all over Kolkata. It is located in New Town, Rajarhat and has been designed for 1 lakh population. It is predominantly inhabited by MIG group low – upper middle class although it has been designed for LIG and MIG population with facilities amenities associated with high-end residential apartments. It has been developed by Bengal Shapoorji Housing Development Pvt. Ltd. and is considered to be the largest mass housing project in India. It is built on 150 acres and house 20000 apartments. It actually fulfills Clarence Perry's definition of neighborhood in a modern context.

5 Imageability and visual survey

The authors have conducted Imageability and Visual survey of the selected NLUC to get a better understanding of the existing condition of the five elements of Kevin Lynch viz path, edge, district, node and landmark along with the pattern, texture, grain, and density, (Spreiregen, 1965), were considered during the survey. Age, condition of the existing building fabric and land use were also noted.

The observations have been listed down below (refer to Table 2), for a comparative analysis of the same which revealed that these NLUCs s exhibit different architectural, socio-cultural and socio-economic characteristics.

- Bhowanipore is a busy NLUC with significantly less amount of interaction within its communities as compared to Dhakuria. The lanes of Saltlake CA blocks and Sukhobrishti are empty most of the time with not much activity on the streets. Saltlake and Sukhobrishti have a feeling of seclusion associated with them. Dhakuria and Bhowanipore, are very vibrant and bustling with activities and have a significant number of people on the streets which leads to vehicular and pedestrian movement conflicts.
- Saltlake and Sukhobrishti have comparatively lesser traffic and are sparsely populated compared to the other selected NLUCs but both of them are very well maintained compared to Dhakuria and New Garia. Moreover, Bhowanipore is dominated by commercial land use, while the remaining four communities are mostly residential in nature. Bhowanipore mostly contains city level activities.
- The architectural style of Bhowanipore on the other cannot be generalized. It has contemporary buildings along with colonial buildings. Most of the buildings in Saltlake are aesthetically pleasing and are of contemporary in style with few buildings exhibiting traditional embellishments. In fact, ethnically Bhowanipore is very different from other NLUCs. Dhakuria, New Garia, Saltlake blocks and Sukhobrishti are majorly inhabited by Bengali population, but Bhowanipore has a significant number of non-Bengali population.
- Saltlake blocks and Sukhobrishti is considered to be inhabited by upper-middle-class to high-income group population. Dhakuria is predominantly inhabited by middle-income population, New Garia has lower-middle income group population and Bhowanipore is a rich NLUC and the middle-class population cannot afford it, but interestingly lower income group people commute to work in Bhowanipore.
- The quintessential essence of 'para' *(it is a Bengali word for neighbourhood implying a strong sense of community*) culture is lacking in Saltlake and Sukhobrishti, while Dhakuria and Bhowanipore have a strong predominant para culture.

The authors have conducted a pilot survey and asked the residents to give a score on a Likert scale. Observations and perceptions about the neighbourhoods were marked on a five-point Likert scale (from "1=very low" to "5=very high").

Table 2: Showing the imageability analysis of the NLUCs

Neighborhood	Historical inception	Imageability elements								Built Fabric			Predominant land use	Urban Landscape		
		Paths	Edges	Nodes	Landmarks	Density	Pattern	Grain	Texture	Building facade	Average condition of the buildings	Average Building age		Street Furniture	Foliage	Public realm – public space
BHOWANIPORE	Part of the white town	Lee Road Elgin Road Chakraberia Road	Acharya Jagadish Chandra Bose Road –North Sarat Bose Road – East Ashutosh Mukherjee Road- West Gaur Ghosh Road	Ashutosh Mukherjee road	Forum courtyard Notable malls such as Brand factory, forum Bhowanipore education society, Nizam's palace	Mixed use, Medium Density	Organic, irregular street layout, Sheet	Coarse grain	Uneven	Architectural embellishments in some of the of the buildings	Well maintained	Minimum 50 years	Residential, commercial, mix use	Signage No benches	Streetside foliage	Northern Park-Subhas udyan
DHAKURIA	Refugee settlement s	Maharaja Road, Selimpur Road Dhakuria Kali Bari Lane Babubagan Road	Raja Subodh Chandra Mullick Road, It seamlessly blends with the surrounding neighborhood Haltu	Gariahat road towards Gariahat 'more'(crossing)	Dakhinapan Dhakuria railway station,	Mostly Residential, High Density	Organic, irregular street layout, sheet	Fine grain	Uneven	Concrete masses with very few building having embellishments and architectural treatments	Moderately maintained	Minimum 30 years with many new building construction	Residential, Mixed use	Nil	Sparse	Rabindra Sarovar Dakhinapan
GARIA	Refugee settlement s	Internal Baishnabghat a Patuli Township roads	EM Bypass Garia station Road	New Garia station Kavi shubhash Metro station		Residential, Medium Density	Organic, irregular street layout, branching	Fine grain	Uneven	Concrete masses without any embellishments and architectural treatment	Moderately maintained	Mostly new construction. Minimum 15 years.	Residential, ground floor commercial	Nil	Sparse	No designated public space, but abundant open space
SALKTLAKE	Reclamatio n of Saltlakes	Internal roads within the blocks	2nd Avenue –North 2nd cross road- East 1st Cross road- West side 4th Avenue - South	City Centre	City centre, CA park	Residential, Medium Density	Grid Iron, regular street layout, rectilinear	Fine grain, uniform building sizes	Even	Architectural, Aesthetically pleasing	Well maintained	25 years	Residential	Nil	Street side foliage	City centre, central park, CA park
RAJARHAT-SUKHOBRISTI	LIG-MIG mass housing	Internal campus roads	Gated community	Shapoorji cricket association ground	Shapoorji cricket association ground	Residential, Low density	Regular street layout, Linear	Coarse grain, Tall, bulky building blocks	Even	Architectural, aesthetically pleasing	Well maintained	5 years	Residential	No signage	Street side foliage along with playgrounds and open spaces	On campus playgrounds and open spaces, OAT

Table 3: Showing the score matrix based on observations

	Observations	**Bhowanipore**	**Dhakuria**	**New Garia**	**Saltlake**	**Rajarhat-Sukhobristi**
1.	Perceived density/ crowdedness	3	4	2	2	1
2.	Maintenance and upkeep(overall image like clean or dirty)	3	3	2	4	5
3.	Activity on street across the day	4	5	3	3	2
4.	Illumination	4	4	3	3	3
5.	Road signage	4	4	3	4	4
6.	Age-friendly and Universal design	3	3	3	4	5
7.	Are there people seen on street	5	5	4	4	3
8.	Road Approachability	2	4	4	3	2
9.	The occurrence of luxury condominiums buildings	4	2	2	3	5
10.	Hawkers on street	2	3	4	1	1
11.	Presence of wall graffiti and political posters on property walls	3	3	3	2	1
12.	Availability of corner teashops and snacks	4	4	4	1	1
13.	Gathering of people on street for casual conversations	3	4	4	1	1
14.	Perception of approachability towards the residents	3	5	5	2	2
15.	Noise on the streets	4	5	5	1	1

New Garia is the least maintained with respect to the rest of the selected NLUCs and it is still a developing NLUC lacking basic infrastructural facilities. Some areas within New Garia are densely populated while others are sparsely populated. Saltalke blocks and Bhowanipore are well established NLUCs, whereas Sukhobrishti is an isolated NLUC with all facilities available within its boundaries and not blended well with its surroundings. Its interactions and activities are only limited within its closed campus.

Table 4: Showing the score matrix based on perception

	Perception	**Bhowanipore**	**Dhakuria**	**New Garia**	**Salt lake**	**Sukhobristi**
1.	Community engagement in various cultural activities	3	5	3	3	2
2.	The sense of belongingness to the neighbourhood	4	5	3	4	3
3.	Interaction with neighbours	3	4	3	3	2
4.	Location preference	5	5	5	3	2
5.	Coexistence of different types of housing	4	3	4	4	3
6.	Housing affordability	3	4	4	3	3

7.	Access to basic neighbourhood amenities	4	4	2	4	4
8.	Access to city level amenities	5	5	3	3	2
9.	Access to quality &affordable transit facilities	5	5	4	2	2
10.	The perceived sense of security	5	5	3	3	4
	Total	41	45	34	32	27

Dhakuria has scored really well with respect to the aspects of neighbourhood cohesion, location accessibility, and affordability. Some of the residents of Saltlake and Sukhobrishti have expressed that they have faced connectivity issues of their neighbourhood with the city core. New Garia is not at all performing well in the physical infrastructure aspect. They have acute drainage issues.

6 Recommendations

The neoliberal urbanism has brought about a significant change in the urban planning scenario of these NLUCs which has eventually affected their social and cultural strata. The authors have observed that the main reason for the declining social interaction among the residents of the new NLUCs is due to a lack of proper public realm leading to degenerating public life Moreover, the middle-income population is burdened with aspirations of attaining the global identity and threatened with job insecurities This observation is supported by similar research done on public realm and streetscape done by LGA in 2014 and Daley in 2003 respectively.

The authors have observed that among the selected NLUCs, Saltlake and Sukhobrishti lack social cohesion and identity, while Bhowanipore, Dhakuria and New Garia are not pedestrian friendly. The narrow sidewalks in these localities act as a major obstacle to lively street life. The following recommendations have been made by the authors with an idea to restore the essence of the Kolkata ‘para’ culture and enhance neighbourhood cohesion and involvement.

- Encourage community engagement and involvement with the help of local clubs and residence welfare associations. They should organize several activities including cleanliness drives, cultural activities, awareness programmes on social and health related issues.
- Ensure a sense of safety through active vigilance and CPTED(Crime Prevention Through Environmental Design) (LGA 2014).
- Enhance the image of the NLUCs and inculcate a sense of belongingness among the residents. by adequate branding. Building bye-laws, urban design guidelines and development control regulations can be instrumental in this process of image building.
- Improve visual quality through proper illumination, installation of outdoor furniture and art elements. This would aid in increasing legibility and comprehensibility of the neighborhood.
- Revamp the sidewalks with three defined zones. The amenity zone will have all the utilities such as the streetlamps, benches, and trees placed at regular intervals. Walking zone will refer to the unobstructed pedestrian zone. While the merchant zone refers to the frontage of the stores, cafes and can also be used as regulated hawking spaces. Local government should enforce strict rules to prevent occupants of any one of these zones from encroaching any other zone. A first cut implementation of this

design may be introduced in Dhakuria and New Garia which are in dire need of such redesign.

- Restore all natural assets within the NLUCs and connect the communities to those.
- Increase awareness regarding the use of alternate energy, grey water recycling, waste segregation at source and rainwater harvesting at building and at neighbourhood levels. Installation of solar panels in public areas such as local clubs, transit stops, ‘adda’ (a native word used for a particular place where people gather for conversation) zones should be encouraged by the local government with cooperation from the local clubs.

7 Conclusion

The paper confers that the prevailing hegemony of the dominant neoliberal urbanism is neglecting the place making characteristics of the public realm of Kolkata which is eventually eroding the cultural fabric of Kolkata NLUCs. In fact, the newly developed NLUCs have failed to incorporate the cultural aspects in its quest to attain the International identity. The authors strongly opine the redevelopment of the public realm so as to reinvigorate the fading cultural patina of the neighbourhoods and enhance the neighbourhood cohesion.

Plan making in delivering intensification in Auckland, New Zealand: Issues and Challenges

(Plan making in delivering intensification: a case study of Auckland, New Zealand)

Wen LIU, Lee BEATTIE, Errol HAARHOFF, Shaoyao TANG, The University of Auckland, New Zealand

Abstract

Urban growth policies that promote housing intensification and higher density development have been widely embraced in development strategies of many cities in Australia and New Zealand, part of the Europe, and the North America. Typically, this takes the form of intensification development in and around the defined transit nodes and city centres spread across the metropolitan regions. The local government council for the Auckland region (the Auckland Council) also seeks to implement a compact city model, after the amalgamation of the previous regional council and seven territorial authorities into a unitary authority in 2010. It aims to encourage most of its future growth and developments in and around, existing and proposed town and transit centres, with the goal of achieving the 'most liveable city'. However, there are growing concerns that urban planning approaches currently used are not effectively delivering intensification outcomes aspired. The uncertainties on what the future might hold in practice and whether the plan can realise the anticipated outcomes remain as one of the significant challenges both policy makers and planning practitioners are facing.

Drawing on the Auckland experience, this article adds to a relatively small but growing number of studies investigating on the efficacy of urban planning systems to deliver outcomes that are well aligned with the goals of urban growth management strategies. This paper critically reviews and discusses the Auckland case on the delivery of policy outcomes, with particular attention to delivering residential intensification and higher density housing policy outcomes. Connecting with ongoing researches, we contribute to the understanding of the local government land use and its plan making to deliver the anticipated policy goals. We suggest that the land use planning should be accompanied by a more thorough discussion and review of planning tasks and goals, and a deeper understanding on the role of plan regulation and its actual implementation under a market driven planning system.

Keywords: Plan making and implementation evaluation; Land use plan; Plan methods; Policy outcomes; Residential intensification; Rational comprehensive model

1. Introduction

The urban growth strategy of Auckland is aligned with many international planning strategies, such as 'Metro Vancouver 2040: Shaping our Future', 'Melbourne 2030', and 'City of Cities: A Plan for Sydney's Future'. The central goal in each of these policies is the containment of low density, peripheral growth. Although the compact city model may have a wide range of merits ((Neuman, 2005; Breheny, 1997), the extent to which these are actualized largely rely on how intensification actually is delivered. Common to the broad range of literature on urban growth management, the 'gap' between strategic planning and what has been achieved is evident in the argument for the 'compact' urban form (Woodcock et al., 2010). The transformation of the rhetoric of the residential intensification model into reality is of profound influence yet has enjoyed limited empirical analysis. In Auckland's recent metropolitan strategies, the more prominent of the challenges have been concerns on the plan objectives for delivering intensified built environment and the efficacy of planning tools for attaining these associated plan objectives.

As New Zealand's largest city and fastest growing region, Auckland is home to about a third of the population of the country (around 1.5 million people in 2017). It is the principal commercial centre of the country and has a diverse economic base. Historically, development in Auckland urban housing market has been dominated by low density suburban housing built on comparatively large plots (Dixon and Dupuis, 2002; Haarhoff et al., 2012; Beattie, 2010). In Auckland, the compact city model is seen by planners as a key to containing urban growth largely within an urban boundary, through a combination of infill within city boundaries, limited peripheral development, and higher density subdivisions. However, since the adoption of urban growth strategies from 1990s, the new dwelling development in Auckland still focused on standalone dwellings, predominantly in green field space (Berke et al., 2006; Beattie, 2013).

In 2007, under the pressing disputation on the Auckland's governance, the government assembled a Royal Commission to explore the potential to assure long-term sustainable development for Auckland (Salmon, Bazley and Shand, 2009). The Royal Commission concluded in its 2009 report that the Auckland's planning process were complex, lack of integrity and community engagement, and the regional relationship was fragmented and weak (Royal Commission, 2009). The Royal Commission's recommendations included replacement of the previous regional council and seven local authorities with a single unitary Auckland Council, and establishing one integrated planning framework with one new spatial plan (the Auckland Plan, the AP) and one statutory development control plan (the Auckland Unitary Plan, the AUP), to provide the strategic direction creating the basis for integrated and aligned decision making and planning functions (Beattie, 2011). After two weeks, the national government accepted the Royal Commission's recommendations to create a unitary council by publishing 'Making Auckland Greater', aims to make Auckland a 'super city' under one single local authority, and introduced the 'spatial plan' as a new planning approach in Auckland. The establishment of the new 'spatial plan' - Auckland Plan set up the strategies to deliver intensification into diversified arenas, including economic, environment, transport and sustainable developments (Auckland Council, 2012). Turning these visions into reality is operatised through the new statutory land use plan, the Auckland Unitary Plan.

Taking Auckland as an example, this article aims to investigate the efficacy plan making and implementation directed towards higher density development in traditionally sprawl cities. In drawing on the plan-making process and content of the plans, this article critically discusses the plans' capability, issues and challenges to deliver residential intensification. The next section briefly outlines the relevant literature of plan making towards intensification and delivery of intensification strategies. The third section describes the development process of the Auckland Plan and Auckland Unitary Plan, it also critically examines the efficacy of plan making and content of the plans, identifying the issues and barriers of plans to achieve the intended intensification outcomes. The discussions and conclusions on the issues and challenges of the plan making and content to deliver intensification outcomes in Auckland are presented at the end of the article.

2. Plan making and implementation towards intensification

Movement towards the achievement of intensification as a means of improving urban sustainability and enhanced liveability is "a complex process that requires action by both the public and private sectors" (Boon, 2010). Many factors apply in the delivery of housing intensification policies. The exact location, form, pace, and pattern of implementation rely on a combination of specific elements. These elements include, but are not limited to, planning policy, market response, technological tools, and community engagement (Liu et al., 2018; Adams and Tiesdell, 2005; Haarhoff et al., 2012). Managing the process of housing intensification involves balancing the multiple and often conflicting interests of the established and prospective stakeholders, while simultaneously engaging in the pursuit of broader policy objectives when facing contemporary changes (Ruming, 2014). Planning policies and regulations are essential determinants of the effectiveness and implementation of intensification. However, researchers have pointed out that there is a lack of a delineator of the extent to which plans are being implemented after they are adopted ((Liu et al., 2018; Brody and Highfield, 2005).

Therefore, researchers have raised the issues of searching for the means to evaluate planning outcomes (Brody and Highfield, 2005; Berke et al., 2006; Searle and Filion, 2011; Beattie, 2010), and the evaluation of plan implementation (Tian and Shen, 2011; Filion and Mcspurren, 2007). New evaluation models and methods have been applied to examine the effects and results, and also the capacity and effectiveness of planning activities (Brody and Highfield, 2005; Chapin, Deyle and Baker, 2008; Alexander, 2009; Laurian et al., 2010). Khakee (2003), Alexander (2006), Oliveira and Pinho (2009, 2011) articulate the evolution of evaluation methods from three different perspectives: (i) a program policy perspective, (ii) a welfare economics perspective, and (iii) a planning theory perspective. These evaluation approaches provided the foundation for the subsequent improvement in the quality of plans and planning systems.

The existing researches on plan implementation evaluation in New Zealand mainly employed a conformance-based approach, which is concerned with the alignment between the outcomes and the goals of plans (Laurian et al., 2004a, 2006; Beattie and Haarhoff, 2011). Some academics have begun to ask how much influence a plan can have over the urban planning process in New Zealand (Berke et al., 2006; Laurian et al., 2004a). The findings of Laurian et al. (2004a) demonstrate the implementation of plans varies greatly. Laurian et al. (2004b) raised the question of whether the plan quality can influence its implementation. They found that plan implementation is largely driven by the quality of the plan and the resources of the planning agencies. The academics increasingly recognised the quality and strength of the adopted plans are not necessarily correlated with implementation of their contents and rules (Brody and Highfield, 2005).

In order to reflect existing problems and contradictions, some works have attempted to link intensification theory to the local planning innovations (Buxton and Scheurer, 2007; Haarhoff et al., 2012; Janssen-Jansen, 2013), the planning implications (Williams, 1999; Randolph, 2006), as well as the capacities and achieved degree of intensification growth (Woodcock et al., 2010). However, government and urban planners still have difficulty linking the implementation knowledge to actual intensification projects (Berke et al., 2006, Beattie, 2013). There seems to be a gap between policy intention and implementation practice. Also, the mainstream of research on plan implementation has been focused on measurement of land use development patterns, and performance assessment of comprehensive plans (Brody and Highfield, 2005), while a few of them have provided policy improvement for planning performance at the local level (Waldner, 2009). In the Auckland context, “the link between plans and outcomes is at the heart of the urban planning process, that is, it is assumed that the plan will deliver a means of action to achieve its intended outcomes on the ground” (Haarhoff et al., 2012).

3. Issues and challenges of plan making to deliver intensification in Auckland

3.1 The ambition and reality of the Auckland Plan

With the aspirations to make Auckland the most liveable city through ‘quality compact’, the first ever spatial plan in the region – the Auckland Plan was developed to provide a 30-year vision to better “align its internal operations, actions and investments” (Auckland Council, 2012). Auckland Council drafted its first ever spatial plan in the September of 2011, with the public submissions and consultation from 20 September to 31 October of 2011 (Auckland Council, 2011). The vision of the Auckland Plan aims to achieve the ‘most liveable city’ through ‘quality compact’, to achieve its envisaged regional development through aligning its investments and operations (Auckland Council, 2012). In the March of 2012, the Auckland Plan was officially adopted.

The Auckland Plan (2012) is a non-statutory urban growth strategy which aims to implement a compact city model for Auckland so that it can become ‘the most liveable city in the world’ (Auckland Council, 2012). The plan delineates a series of tools to promote urban intensification within the proposed Rural Urban Boundary (RUB) so as to discourage urban expansion at the urban fringe (Auckland Council, 2012). Based on population projections, Auckland needs to accommodate an additional one million inhabitants by 2040, and the Auckland Plan proposes that 60 to 70 per cent of the new dwellings will be located within the existing urban areas and 30 to 40 per cent in new green field and existing rural areas and coastal settlements (Auckland Council, 2012; Duguid and Chan, 2013).

Turning this vision into reality requires the use of a broad range of growth management strategies and planning policies. The delivery mechanisms of the Auckland Plan include the Unitary Plan as one of main tools to define land use activities and zoning to achieve high quality spatial development, “the Long Term Plan (LTP) (which sets out the activities, services and investments planned for the next 10 years) to deliver the outcomes of the Auckland Plan”, and to provide the budget for the implementation of the projects and actions. Local board plans and agreements would emphasize the priorities and projects identified by each local board and community. A range of core strategies and place-based plans are important tools for implementing the Auckland Plan, also in achieving design, social and environmental outcomes (Figure 1) (Auckland Council, 2012). The Auckland Unitary Plan is the major tool to implement the directions of the Auckland Plan. It developed objectives, policies and methods (including rules) which set different goals and provisions to achieve quality urban growth in Auckland (Auckland Council, 2013).

Figure 1: Implementation framework of The Auckland Plan
Source: The Auckland Plan (2012), Auckland Council

However, close analysis of the Auckland Plan’s measures suggests a rather different reality. Firstly, due to the lack of civic participation and limited timeframe for plan making, the plan content and quality is insufficient to deliver high quality intensification strategies. Developed in September 2011, the first Auckland Plan was then officially adopted in the March of 2012, less than 18 months after Auckland Council was established (Auckland Council, 2012). The limited timeframe for plan making raised concerns on how the plan can be delivered in meaningful way in such a limited timeframe, as the plan is dealing with a range of complex transitional issues (Beattie, 2011). The international experience from Vancouver and Stockholm revealed the necessity of the process for civic participation and long timeframe to ensure the quality of policies. As described by Imran and Pearce (2015), a comparatively small proportion of communities engaged in the development of the Auckland Plan.

Secondly, the undeliverable visions in the Auckland Plan and the limited mechanisms and tools for plan implementation make the effectiveness and deliverability of the planning content questionable (Rowe, 2012). A number of academics raised the concerns on whether the planning content of the Auckland Plan is achievable. For example, Gunder (2014) questions that part of the visions in the Auckland Plan consist ‘a range of impossible fantasy outcomes”. He points out the proposition of 5 percent annual GDP growth rate over 30-year period is an example of the fantasy. The effectiveness of the Auckland Plan is also questioned by Imran and Pearce (2015), they claim that the flaws of Auckland Plan include its “plan ownership, lack of civic participation, and the imbalance of transport strategy and institutional inertia” (pp. 25).

Thirdly, the plan content and implementation tools and processes to deliver the spatial planning, in part, are deficient. Due to the lack of government commitment and inadequate funding strategy, the implications of the Auckland Plan and its capacity to achieve intended outcomes are contentious (Beattie, 2011). This raises the question of how an untested planning approach work in practice if there are quality and implementation issues with the existing statutory based plans in the region (Rowe, 2012). Furthermore, the issues of urban amenities, parking zone, and design quality in the developments are questioned in terms of whether the envisaged high-quality outcomes are attainable (Haarhoff et al., 2012).

Lastly, the flaws of plan implementation partly lie in the quality of urban planning practice and the quality of the plans themselves. There was no guiding for the Auckland Plan provided in the Resource Management Act 1991 (RMA), which is the national legislation which outlines the processes of “resource consent, council plans and designations, proposals of national significance” (Ministry for the Environment, 2018). The delivery of an effective infrastructure network will be difficult if there is no a clear, coherent strategic direction. Moreover, the new local governance still has to fund through central government contributions, in particular, for the regional infrastructure programmes, which would potentially make the plans ineluctable to political intervention (Imran and Pearce, 2015).

In sum, the content and implementation of the Auckland Plan remain contentious for the effectiveness of its plan content, lack of citizen participation, the challenges of policy achievement in practices, and the potential political intervention due to the heavily reliant on central government funding. The flaws of plan implementation partly lie in the quality of urban planning practice and the quality of the plans themselves.

3.2 The challenges of the Auckland Unitary Plan to deliver intensification

The AUP has experienced a number of variations in the whole plan making process. The draft Unitary Plan was released in March 2013 to receive 11-week informal feedback from March to May 2013. This was held in seeking to encouraging community engagement to assist in improving the Proposed Auckland Unitary Plan (the PAUP), which was notified on 30 September 2013—18-month time for developing the Plan for notification. The Plan combines provisions associated with management of coastal, air, land and water resources, intending to deliver a quality compact city in the region (Liu et al., 2018).

The Auckland Council then proposed to the national government that it recommend an Independent Hearing Panel (the IHP) to hear and consider submissions on the notified Plan and make recommendations on the final plan. The central government agreed with this proposed change of process, and this notably shortened the timeframe to put the Unitary Plan in place. Between September 2013 to February 2014, over 13,000 submissions from the public, government, developers, planning professionals and community groups are made. The notification of Summary of Decisions Requested report and further submissions were made from 11 June to 22 July 2014 (Liu et al., 2018).

Beginning from the September 2014 to May 2016, the IHP held 249 days of hearings across 60 topics. On the 22nd July of 2016, the Auckland Council received all the recommendations on the Plan from the IHP. The Council decisions and its decision version of the Plan are notified on 19 August 2016. On 8 November 2016, the Council released its annotated decisions version to show the parts that are under appeal and the parts that can now be ‘treated as operative’ (Liu et al., 2018; Auckland Council, 2016) (Figure 2).

The delivery mechanisms of the Auckland Plan include the AUP as the main tools to implement the directions of the Auckland Plan and provide zonings to integrate and prioritize spatial development. The AUP aims to give legal effect to the Auckland Plan, through developing objectives, policies and methods (including rules) which set different goals and provisions to enable quality, sustainable, compact development in Auckland.

Indeed, the AUP is a combined regional policy statement, regional coastal plan, regional plan and district plan (Auckland Council, 2013). The plan tries to provide guidance and serves as the primary document which will be capable of meeting the obligations of the unitary authority and find a new balance between fostering positive natural environment effects and protecting community health and wellbeing. The concept of the plan is the ‘quality compact’, which aims to provide for development both up and out, based on up to 70% of future population growth being located within the existing urban area (Auckland Council, 2013).

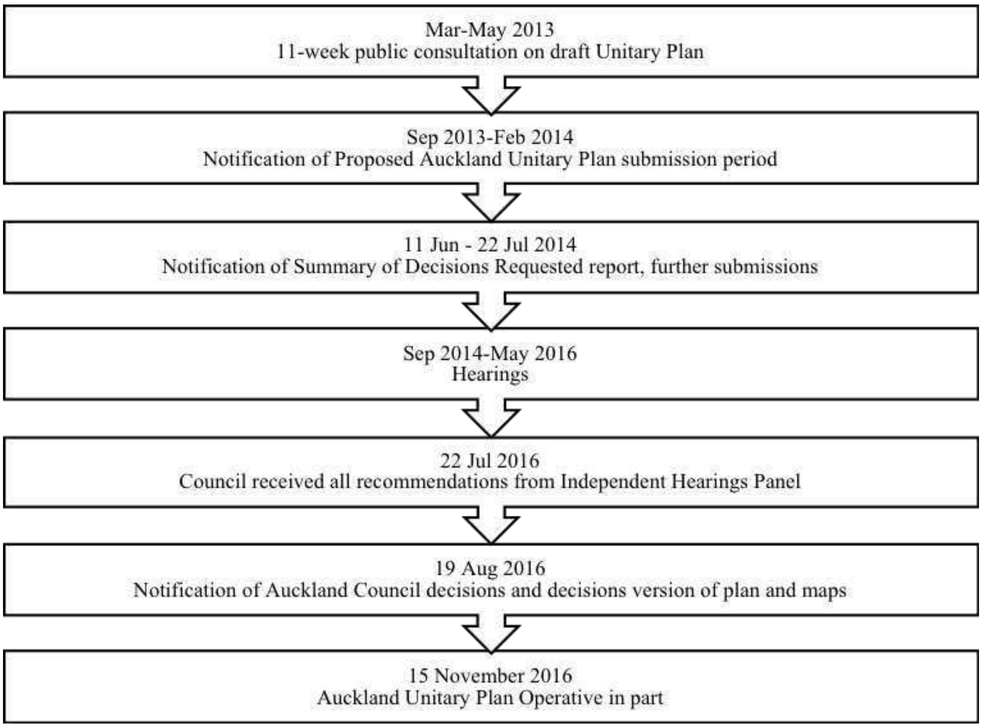

Figure 2: The history and earlier versions of the AUP (Auckland Council, 2016).

Vague and weak objectives and policies

The Auckland Unitary Plan, as a statutory plan, shall provide direct legal effects for land use development, rather than stipulating vague or weak policies for future urban development. However, the objectives and policies of the PAUP are overall inexplicit and weak to present a proposed development and estimate a potential scheme. Some of the objectives and policies are either unclear or non-specific to guide and regulate the development and some of them lack of clear definitions and assessment methods to evaluate whether the proposed development achieve the articulated policy outcomes.

For example, Terrace Housing and Apartment Buildings (THAB zone) in the PAUP is defined as “a high-intensity zone enabling a greater intensity of development than previously provided for”. One objective of the THAB zone is to “achieve development is of a density that is appropriate for the physical attributes of the site, any infrastructure constraints, and the planned urban residential character of the neighbourhood” (Auckland Council, 2013). This is ambiguous to predict the development envisioned by the plan making authority on what is ‘appropriate’. Also, the plan does not provide definition or assessment methods on ‘urban residential character of neighbourhood’.

Another example of unclear objectives and policies in the PAUP is the mixed-use zone. The PAUP does not explicitly put forward that it has to have a mix of residential and business, therefore, developers could have all business or have all residential, or have a mix of business and residential. Further, the plan does not really deal well with how to get that mix. On one hand, it can potentially provide more flexibility, but it relies on the provisions of clear and strong objectives and policies to minimise the interpretation differentials. On the other hand, it raises issues of the possible complexity in assessing in terms of balance and weight.

This altogether leaves uncertainty for development sector and may result in difficulties in understanding among plan users, for example, inconsistent interpretations between developers and their planning consultants, and between planning consultants and planning officials. This could further bring about delay the consenting process due to the difficulties and longer timeframe required for solving different interpretations and discussions on what are acceptable and correct, causing the delivery of residential intensification uncertain. The existing objectives and policies are overall generic and put greater emphasis on development rules rather than policy outcomes, which misaligns with the planning theory and framework in Auckland that adopts a conformance-based plan making model (Beattie, 2010).

Regulations for intensification are weak

In order to achieve intensification, it is essential that stronger regulations and policies that constrain low density developments are developed in the Plan. Nevertheless, in the PAUP, there is no minimum density control or maximum unit size for two or more than two-bedroom units, which means the larger size apartments can still be built in the (zone) areas designated to provide intensified buildings. This is contrary to the plan goals of the PAUP to deliver intensification and higher density housing.

In addition, there is no guarantee to achieve higher densities with a variety of housing types. The direct responding method for building height variations supporting public transport, social infrastructure and the vitality of the adjoining centre are also missing in the PAUP. It seems the local planning authority (Auckland Council in this case) is timid in putting forward strong regulations that need to rely on collaborations and efforts from other sectors and agencies.

It is also worth noting that the PAUP standards concern on the site-specific development rules, other than from the regional and neighbouring scale. For instance, the PAUP sets up rules to protect on-site amenities, however, there is no regulation to protect and enhance the neighbouring amenities. This observation reiterates the central message of the inefficiency of plan making in the PAUP to undertake the entire region and the previous plan and development into plan making process.

Misalignment with the market practice

The historical problem of insufficient provision of intensive housing in Auckland highlights the importance of paying more attention on those responsible for implementing planning policies on the ground: the development sector. The complicated interplays between planning officials, property developers and potential consumers can significantly affect the implementation of the targeted higher density developments, leading to a situation where "different stakeholders had different views on what might constitute 'good' medium density housing" (Haarhoff et al., 2012; Dupuis and Dixon, 2002).

The commitment of urban land developers to planning objectives, and their capacity to meet the objectives of intensified development in practice, can directly affect the plan implementation (Ruming, 2010; Berke et al., 2006; Laurian, 2004a). However, change can be difficult, as the developers may not always comply with the conditions and obligations stipulated by the zoning context and the consumer preferences (Gunter, 2013; Bowman and Thompson, 2009).

It is also critical to recognise that other regulations and policies may be needed to fill in the gaps where plan methods fall short for achieving intensification outcomes, with the minimum density control was not clearly regulated. The flexibility provided to developers through claiming the objectives are achieved leaves them too many chances. The planning authorities shall establish clear and well-defined standards to provide a regulatory option for interested developers as a mechanism for fostering intensification. The complexity of interacting developers and planning system under the rational plan making framework underscores the importance of setting out clear and well-regulated development standards to guide the activities of development sector.

Requires plan evaluation and review

Despite the apparent benefits of plan evaluation on facilitating more effective implementation, better communicating the intentions of decision makers, and ensuring plans include accurate information and reflect community values, the planning professions have been ineffective in applying evaluation methods, particularly the evaluation of achieving the plan outcomes (Guyadeen and Seasons, 2016; Brody et al., 2006). Evaluation in planning has yet generally concentrated on plan development process with limited attention on plan outcomes (Guyadeen and Seasons, 2016; Oliveira and Pinho, 2011).

The urban planning policies in New Zealand context are facing the challenges that issues arise through implementation phase but not through the development of plans. The literature suggests the limited guidance on gauging the success or failure of plans are largely resulted from disagreements on how to evaluate the outcomes of plans (Oliveira and Pinho, 2011). This research reinstates the significance to develop and implement evaluation frameworks that urge plan making department to continually evaluate their efforts.

4. Conclusion and Discussion

This article critically reviews the plan development process, plan content and implementation adopted or proposed by the Auckland Plan and the Auckland Unitary Plan. Delivering on the aims of these urban growth strategies “has been difficult and controversial” in Auckland (Haarhoff et al., 2012). The content of the first ever spatial plan – the Auckland Plan has been pointed out being ambitious and bold (Imran and Pearce, 2015), and its implementation has been questioned for several reasons, including the effectiveness and quality of the plan content, lack of citizen participation, the challenges of policy achievement in practices, and the potential political intervention due to the heavily reliant on central government funding (for examples, Gunder, 2014; Imran and Pearce, 2015; Beattie, 2010).

This research also demonstrates that the plan making and implementation tools and processes to deliver the planning outcomes, in part, are deficient. This research gives rise to three core issues in the plan making and implementation of the Auckland Plan and the Auckland Unitary Plan. Firstly, the plan content and quality of the Auckland Plan is insufficient to deliver high quality intensification strategies. Secondly, the possible fantasies in the Auckland Plan and the inexplicit, weak objectives and policies of the PAUP can potentially lead to the misalignment between the outcomes and plan objectives. This affirms that the plan making processes and tools need to be more clear, flexible and strong to ensure its delivery of plan visions. A more thorough review of planning tasks and goals is required for local planning department (Auckland Council) to implement the intended plan objectives and goals. Thirdly, a deeper understanding on the role of plan regulation and its actual implementation under a market driven planning system are required to ensure the alignment between the Auckland Unitary Plan and the market viable developments in both locations and housing types.

In terms of the connections and mechanisms between the Auckland Plan and the Auckland Unitary Plan, under the political pressure and other factors, there is a risk that some of the policy intervention in the Auckland Plan would be reversed during the preparation process of the PAUP. The potential remains for political pressures for the decisions on the final Auckland Unitary Plan to be inconsistent with the Auckland Plan. Even though the current planning frameworks and their methods are responsible for giving effect to the higher-level strategic policy, however, less clear from this research is that the alignment between the Auckland Plan and its main implementation tool – the Unitary Plan, which would remain as a key field for future research.

Impact of large-scale urban interventions on contemporary city centers

Piotr LORENS, Michał HABIER, Gdańsk University of Technology, Poland

1. Introduction

Large scale urban interventions have become a common development practice in cotemporary cities, allowing achieving rapid changes in their urban structure [Markowski, 2004]. They can be analyzed taking into account various perspectives. Some of them include planning and development models, types of sites transformed (brownfields, greeenfields, densification of urban structures as well as transformation of other types of distressed urban areas) as well as consequences and results of their implementation in existing urban structures.

There is a vast literature on how these transformations are planned, developed and implemented, although there is still not much discussion on the consequences and evaluation of their implementation. Among others, one can mention here works by Swyngedouw and Salet, to name just a few of the key authors. In addition, most of the analysis of these cases was focused on spatial consequences of their development[1].

Therefore, the main aim of this paper is to discuss this issue in the wider context, taking into account also social, legal, economic and infrastructural consequences of these projects, with a special focus on the ones located in city centers and generating major changes in their functional and spatial structure. Within the paper the following issues are discussed:

- Typology of contemporary large-scale urban interventions, located within the city centers;
- Scope of the spatial, social, economic, infrastructural and legal issues associated with contemporary large-scale urban interventions;
- Discussion of the consequences associated with implementation of large-scale interventions within the structure of contemporary urban centers on the basis of the analysis of selected case studies from Gdansk Metropolitan Area (Poland);
- Conclusions regarding future of planning and development of such projects.

On this basis the more in-depth analysis of the cases from Gdańsk, Poland, including the newly created “Forum Gdansk” along with “Olivia Business Center” and “New train station complex in Sopot” projects are discussed. All these are brand new interventions, located within the structure of Gdańsk Metropolitan Area – one of the most important metropolitan areas in the country and in the entire Baltic region.

The locations of these project include distressed site as well as reclaimed area above the existing railway tracks, urbanization of the urban voids and transformation of the distress railway-side area. In addition, each of these are complex urban interventions, meeting the criteria set in definition of the large scale urban interventions, later on referred to as LSUI-s.

2. Characteristics of the large scale urban interventions

Types of intervention within the urban areas may vary and can be described differently due to their size and type of the site, type of the degradation or characteristics of the site as well as functional and morphological composition. But in every case the level of complexity of urban intervention required asks for the comprehensive approach regarding planning and development processes. In case there is a need for more complex functional and implementation solutions, the intervention can meet the criteria described in the definition of the large scale urban interventions (LSUI-s). [Lorens, 2011]

2.1. Definition of the large-scale urban interventions

Large scale urban interventions are not characterized only by the size of the site dealt with or by its location. In fact, what makes these different, is the complexity of intervention. Therefore, the following definition can be applied to the LSUI-s:

"*Complex redevelopment programs associated with introduction of new, substantial portions of urban program or transportation infrastructure, which are planned and implemented in the integrated way by one, clearly defined, entity*".

On that basis one can draw the following characteristics of the LSUI-s:

– Diversified types of land uses

– New, substantial portions of urban program

– Morphological complexity, including various types of structures

– Infrastructure improvements

– Integrated mode of implementation

– Presence of one, clearly identified, „implementation entity"

2.2. Typology of large-scale urban interventions

On the basis of the above mentioned, one could draw a typology of the LSUI-s. This could include:

- Key transportation hubs (associated with railway, road and air transportation) along with other uses (commercial, business and multi-use complexes) including the „railway station complexes"
- Housing complexes along with the basic social infrastructure
- Commercial complexes, which include shopping and other service centers as well as entertainment complexes
- Business and industrial parks, including „airport cities"

Above mentioned typology reflects the contemporary tendencies regarding LSUI-s within European cities and may be further developed in case the new types of issues emerge [Lorens, 2004].

2.3. Role of the large-scale urban interventions in the process of shaping the urban structure

LSUI-s are frequently employed as the vehicles allowing comprehensive transformation of cities. This is due to a number of reasons, which include the facts that LSUIs:

- contribute to focusing the investment efforts in the designated zones;
- can become the trigger for further development processes in its vicinity;
- become locations of the new urban program of over-local importance – including types not yet present in the given city / region;
- allow substantial acceleration of the spatial development processes of both the entire metropolitan area as well as its key parts.

In result, in many cases LSUI-s are understood as key triggers of urban change. This is due to the fact that development of LSUI-s may:

- influence the decisions of other investors / developers / site owners;
- lead to creation of the new spatial development poles – which especially relates to the sites especially attractive for investors;
- contribute to changing the geography of spatial and functional connections and networks within the city and entire metropolitan areas;
- prevent the disordered, spontaneous development – which is due to their ordered structure.

In addition, LSUI-s may also play an important role of shaping the investment strategies both of the public and private stakeholders. This comes from the fact that LSUI-s:

- allow coordinated and carefully planned realization of the extensive investment program;
- provide investment stabilization for both „leading entity" (i.e. land developer, key developer) and other entities/partners (small-scale developers);
- allow creation of the urban space of predictable quality – which contributes to the stabilization of the land market.

2.4. Obstacles for planning and implementation of the large-scale urban interventions

Planning and implementing the LSUI-s is not always an easy task. In many cases it is associated with a number of obstacles and issues that have to be taken into account while considering these as a viable vehicle for urban change [Markowski, 2004]. Among many, one should mention the following key ones:

- lack of interest in undertaking more complex urban undertakings on the side of local/public administration („who does nothing, never makes any mistakes");

- lack of trust in private entities and their activities on the side of the public sector;
- dislike – in many cases due to lack of clear legal framework – in undertaking the public-private partnership schemes;
- lack of highly skilled administration clerks/officials able to initiate/implement/monitor the development of the LSUIs.

Of course, above mentioned obstacles are not always present. In many cases these are considered as one and only type of vehicle able to deliver the major urban transformation projects. The key example here is Hamburg HafenCity project, which since late 1990-ies is successfully implemented[2]. This major waterfront transformation project allowed not only regeneration of the distressed urban area but also retaining by Hamburg its prominent position as key business centre of Europe. In this case it was necessary not only to develop a masterplan itself (see fig. 1), but also to conceptualize a comprehensive implementation scheme based on public-private partnership.

Fig. 1. Visualization of the HafenCity masterplan. Source: *HafenCity Hamburg. Der Masterplan.* Hamburg 2000.

But at the same time one have to note that not always planned interventions are actually fully implemented and not in each case they provide an immediate effect of urban regeneration. In case some of the “success factors” are absent, instead of the comprehensive implementation once can observe partial development of the isolated urban structures, not allowing the fundamental change of the entire site. One of the good examples of such a situation is Glasgow waterfront, which – despite numerous planning and implementation efforts undertaken since late 1990-ties – is still a fragmented urban structure awaiting comprehensive rejuvenation and implementation of the coherent urban structure (see fig. 2). Of course, in each of these cases the reason of partial implementation or even failure may vary, but some of them are associated with not always positive consequences of the planned intervention.

Fig. 2. Image of the Glasgow waterfront (2016) – where newly developed structure are still neighboured by distressed sites awaiting new comprehensive transformation despite the fact that the regeneration process was originated over 20 years earlier. Photo credit: P. Lorens

3. Selected aspects and contexts associated with planning and implementing the large scale urban interventions

As discussed before, the LSUI-s may bring various effects and be associated with numerous types of consequences to the urban structure. Among these one should name the spatial and infrastructural contexts as well as social, legal and economic issues associated with their implementation. Many of them may be considered of negative character to the existing urban structures and local communities.

3.1. Spatial contexts

LSUI-s, due to their scale, may bring significant changes to the urban structure. Despite the regeneration effect for the site itself, it may at the same time cause **disintegration of the existing urban structure and networks**. And this means not only their transformation and creation of the new poles of growth, but also elimination of the existing vibrant urban centers. In many cases, this is also associated with **substituting the "old" centers of urban life with the new ones**, which may also cause substituting the diverse functional structure of those with the facilities focused i.e. on tourism and mass entertainment. The good examples of such the situation is construction of the CentrO center in Oberhausen, Germany (developed in the late 1990-ties) which caused serious functional decay of the neighboring urban centers[3]. To some extend the similar cases can be found in many other European cities like Barcelona, which centers are over-dominated by the tourism industry. In result, the daily needs of the citizens of these areas (associated i.e. with grocery shopping) have to be fulfilled in alternative ways. Another issue is associated with **transformation of the urban landscape** which may include creation of the new landmarks, which in some cases may dominate the historic townscapes and influence the perception of the heritage areas. Moreover, in some cases one can observe the significant **environmental changes**, which may include reshaping the green and blue infrastructures of the site. Finally, in many cases LSUIs are associated with **capturing the vast portions of land** and transforming them into the commercial structures, which may make further spatial improvements leading towards creation of the more human structures impossible.

3.2. Social issues

Although LSUI-s are rarely located within the already inhabited areas, they may also be associated with numerous social issues. The key one is based on impact of the LSUI-s on the local community, with a special focus on these parts of it inhabiting the sites in close vicinity of the intervention. In many cases **members of these communities are not very much welcomed** within the borders of the newly development areas while – at the same time – the redeveloped space gets opened for incomers from more distant places or even from other cities. The good example is Lyon Confluence, which has become a truly international district and a new hub of urban activities while the local community was – to some extend – left behind[4]. At the same time this newly transformed space is – in many cases – much more dense than before which makes it **less friendly for the existing local community**. But at the same time – in many cases – implementation of LSUI-s may effect in **creation of the high quality public spaces,** open and accessible for all citizens and allowing organization of numerous public events – like open-air exhibitions etc. Also, **development of the new cultural offers as well as shopping and entertainment environments** make the surrounding living environments more attractive. But – at the same time – since the urban environments within which the LSUI-s are located get more commercially and touristically attractive, the **real estate prices within their vicinity may rise** and the living environments – gentrified. In result, some of the previous citizens may will to move out from the districts affected. Although at the same time development of the LSUI-s may be associated with **creation of new social housing**, which could be financed from the **fees and taxes** coming from using for the investment purposes the municipal grounds.

3.3. Legal aspects

Development of the LSUI-s is usually associated with numerous legal aspects. Some of them are related to the **changes in land ownership patterns**. In these cases the expropriation and compulsory purchase of land can be executed, although not each of the legal systems allow for such the action. Also, selling **and leasing publically owned land to the private investors** is usually executed. This may take also the form of creation of the public-private partnership scheme, within which each of the partners is contributing with different type of assets. On the public side this is usually publically owned land, which may be in hands of both municipalities, state and other public companies (like i.e. airport or railway companies). In addition, issuing the planning permits allowing development of LSUI-s may be dependent on **making the special development agreements**, within which the private partners may be obliged to develop elements and systems of public and technical infrastructure of the over-local importance. Among others, one can identify here new public transportation networks, public roads and walkways as well as new or rejuvenated public spaces. On the contrary, development of LSUI-s – due to their high commercial attractiveness – may be associated with **increased crime rates**. Finally, in many cases the **environmental standards may be challenged** and the development of LSUI-s may be associated with eliminating some of the environmental values and elements. Of course, in these cases usually the compensation mechanisms are introduced, but in reality these rarely pay back the environmental harms created by i.e. elimination of mature trees or semi-natural creeks or ponds. In these cases, even if the water bodies themselves are preserved, they usually are transformed into some sort of pleasure areas and lose their environmental potentials.

3.4. Economic issues

Also the economic consequences associated with development of LSUI-s are massive. One of the major thing that has to be mentioned here is **development of the commercial offer** within the city and **increase in the number of jobs**. In many cases the new types of urban program that have not been present before in the city or in the vicinity of the site are introduced, which additionally increases the attractiveness of this type of the development. But – on the contrary – this can have also negative effect on the local economy as a number of previously existing local enterprises, small shops as well as service points may go **bankrupt**. Of course one may argue that this effect can be considered real only in part, as the creation of new jobs can compensate elimination of the previously existing ones, but what counts is that usually within this process the locally developed and sustained businesses are specially endangered. So what counts is not just the amount of jobs but their importance to local communities. Another key issue associated with development of LSUI-s is connected with the **increased attractiveness** of both the city and – in some cases – the entire metropolitan area. This has to be considered in three perspectives: attractiveness for tourists, migrants (willing to get permanently relocated) and other investors. All of them are important for local economy as this may further spur economic growth and increased income to municipal budget. Finally, when discussing the economic issues associated with location of LSUI-s, one has to mention the risk of **gentrification and manhattanization**[5] of entire cities, but – predominantly – of the sites in the close vicinity of these interventions. This comes along with **increase of the real estate prices**, both for sale and – predominantly – for rent. It is necessary to mention that this increase in case of the analyzed sites is much higher than in other parts of cities.

3.5. Infrastructure contexts

Finally, implementation of LSUI-s is usually associated with **massive infrastructure improvements**, both on-site and in its vicinity. This process may include creation of new public transportation hubs and multi-story parking lots, which offer **new transportation options** both for the residents and customers of the analyzed developments and for all other city inhabitants and visitors. In many cases these components of the projects are negotiated within the agreements, mentioned in one of the previous parts of this article. On the other hand, increase transportation demands associated with LSUI-s may result in **increased traffic demands**, both in terms of requests for more efficient, safe and reliable public transport and in relation to the demand for parking. The last part is especially visible in case there is a shortage of parking spaces within the planned structure and the system of public transportation is not efficient enough to cater for the increased demand. Also, in many cases there is much greater **demand for supply of media**, like water, electricity etc. Finally, development of LSUI-s may result in **increased pollution**, which include both solid waste, waste water, noise as well as light pollution[6].

All groups of aspects mentioned in this chapter May be further analyzed according to a number of criteria. Also, one has to remember that some of these issues and consequences may be regarded as positive and others as negative to the local economy, society and space.

4. Selected case studies of large-scale urban interventions in Gdańsk Metropolitan Area

In order to present the above mentioned issues three case studies from the Gdansk Metropolitan Area were selected. Each of them has different nature and scale, which make this group and interesting set allowing further comparisons.

4.1. Forum Gdańsk

The project was conceptualized as both retail, entertainment and transportation hub, allowing reorganization of the mobility and land-use patterns in the entire city center. In addition, development of this project extensively influences the future of the city and its central part, changing the development chances of other post-industrial and other brownfield areas. In addition, its scale and level of complexity allows using it as the good case study, on example of which the entire scope of issues associated with contemporary large scale urban developments can be discussed.

Fig. 3. General view of the Forum Gdansk complex (2018). Photo credit: M. Habier

In addition to these general features of the project, this new development created a new city landmark, although perceived in the local scale (as no high-rise building was built within it). The key entrance plaza to the entire complex – a brand new part of public space (although privately owned and operated) – has also immediately become a focal point for the citizens and visitors of the city. This was also a result of the decision to combine the commercial part of the project with the public transportation hub (including new suburban train station and key bus and tram stops) of regional importance. Therefore, the entire complex may be now regarded as not only the huge shopping center (the area of it is over 6ha) but a true sub-center of the entire Gdańsk. Also, what has to be mentioned is the fact that within this project a railway corridor was included, and the existing tracks were covered by the platform on top of which part of the complex was developed. Therefore, also from the landscape point of view this project has a huge importance for the entire city. In result it is possible to conclude that this development contributed to the spatial reorientation of the entire city center.

But the project Has also negative aspects which have to be discussed. First of all, construction of the extensive parking complex in addition to the commercial part has generated a huge increase in car traffic in this part of Gdańsk. Also, since so many public transportation routes were connected to this development, one can observe a rapid decrease of the volume of passengers using the previous hub – associated with Gdańsk main train station. Also, some of the architectural solutions adopted (like incorporating the existing Radunia river in the structure of the complex including rebuilding the historic river bed) generated the extensive discussion on the limits of possible intervention within the historic and natural structures. One has to mention that this part of the project was developed despite the fact that developer in fact did not have a valid permit for this part of works. And the decision of doing this was taken with full understanding of possible consequences, including the extensive fees which developer had to pay.

Despite these, development of the Forum Gdańsk complex definitely contributed towards perceiving Gdańsk as the major Polish metropolis.

Fig. 4. Main entrance to the Forum Gdansk complex (2018). Photo credit: M. Habier

4.2. New railway station complex in Sopot

The new railway station complex in Sopot (a city constituting the Gdańsk Metropolitan Area, located just 10 km to the north from Gdańsk city center) was completed in 2016. This is one of the largest projects in Poland developed within the framework of the public – private partnership. It is also perceived as key example of combining the public and private funds, assets and experience. Within the project the large-scale multi-use complex was developed, combining the new building of the railway station, shopping and gastronomic center as well as culture facilities.

Despite its size, this project has not affected heavily the natural and cultural environments, as well as has not generated major transportation hassle. What is important is that no major increase in traffic was observed after its completion. In addition, its architecture is regarded to be compatible with the surrounding area. In result, this project is perceived as one of the two key hubs of the Sopot center (the other one is so-called Haffner Center near Sopot Pier on the waterfront). It also contributes towards building the image of Sopot as the modern city (and not only nostalgic XIX-century summer resort), which – in conjunction with the fact that Sopot is perceived as one of the top three cities in Poland regarding the cost of life and of high quality of urban environment – makes justified its nickname as "Monte Carlo of the North".

Fig. 5. General view of the new Sopot Railway Station complex (2018). Photo credit: M. Habier

4.3. Olivia Business Center (OBC)

Olivia Business Center is currently the largest office park within the Gdańsk Metropolitan Area, combining seven building of total floor area of 120.000m2 occupying the 3,5ha plot. Its main part is the high-rise building „Olivia Star" – 35-stories high class A office building, scheduled for completion in the end of 2018, which is already perceived as the tallest building within the Gdańsk Metropolitan Area and the new city landmark. Development of the project contributed extensively to the rapid change of the part of the city it is located within, both in terms of architectural and functional criteria. Moreover, Olivia Business Center Has become a seat for many both local and international companies, which contributed towards creation of truly international image of this site. In addition, location of the complex in close vicinity of suburban train station allowed many of the commuting employees to use public transportation as the basic way of getting to their offices.

Despite these features of the project, the key issue associated with its development is jamming the Grunwaldzka Avenue (the main spine of the Tri-City area, in close vicinity of which the OBC complex was located). In addition, extensive usage of private cars by OBC employees led to the situation that every piece of vacant land located in the walking distance from OBC was converted into parking. This resulted in measures undertaken by other site owners in the area – and the largest one is Gdańsk University – aimed at protecting their land from being used as unofficial parking. In this case the university authorities decided to fence its area, which was associated with a very negative response from the academic community. Also, other office park owners in the vicinity of the OBC had to deal with issues coming from increased traffic in the area as well as with heavily increased demand for public transportation. These issues are still to be solved. Another problem is associated with the tallest building of the OBC complex – "Olivia Star". Its extensive illumination caused discussion on how this is polluting the neighboring areas with unwanted lights as – due of its height – it was affecting pretty large part of the city, including the historic districts and heritage areas. This could potentially lead to the court cases put through by unhappy citizens. In addition, the large density of the project (FAR) may cause in future environmental issues (lack of green spaces, no opportunity for the rain water to be retained within the site etc.). Finally, despite its quite central location in close proximity of key transportation hubs as well as other local centers OBC is still perceived as a white-collar workers area, lacking the public space – which in fact is untrue as within the complex a vast public areas were developed and OBC management is trying to bring to this site many public events.

Fig. 6. General view of the Olivia Business Center complex (2018). Photo credit: M. Habier

5. Conclusions

As argued, large scale urban interventions have become a common development practice in cotemporary cities, allowing achieving rapid changes in their urban structure. But at the same time their implementation is associated with numerous issues and consequences, which were outlined in the article. One can identify both social, legal, economic and infrastructural consequences of the development of LSUI-s. Of course, the scope of these depends on the nature, location and character of the particular project, therefore its peculiarities shall be taken in the account in case of the more detailed analysis. And although these interventions are frequently associated with a number of negative influences, still their implementation can help in spurring urban development and making cities more attractive. In many cases these are also the only chance for undertaking the complex regeneration programs for distressed sites, which otherwise would either never be transformed or – in some cases – might have been developed in an accidental way.

Research On the Planning of Community Life Circle in New Town Based on an Evaluation Approach ——A Case Study of Ningbo Eastern New Town in China

(Smart and Quality – a Technical Discussion for Community Life Circle Planning)

Yuan LU, Xiangyi WANG, Urbanspace Planning and Architectural Design Co., LTD (Shenzhen). , China

Abstract: Community life circle (CLC) planning has gradually become an important part of urban space creation in China. This paper focuses on the real project in Ningbo Eastern New Town, aiming to achieve a CLC planning method and a design model, through an evaluation approach. Begin by defining the concept of CLC, relevant planning practices and researches were summarized. Secondly, this research assesses the current life circle from two aspects: social demand aspect and physical space aspect. For social demand aspect, the problems in current living space is obtained through residents' survey. For physical space aspect, a habitable evaluation model was used to refine and summarize the spatial characteristics of high-scoring community among the selected seven residential groups. Finally, four spatial models of CLC are constructed, which are new residential area, old town, business area, and current residential area. In addition, targeted planning strategies are proposed to complement the short boards of new town development, and to achieve the goal of livability.

Key Words: Community, Community Life Circle, Habitable Evaluation, Social Demand, Place Creation

1. Introduction

With the diversified development of urban areas, the research and planning of communities has gradually shifted from treating residents as a homogeneous group to focusing on varied needs of different social groups. Standing on the point of residents' living space, CLC research and planning were gradually becoming a vital tool to meet the needs of residents, to balance resource allocation, and to maintain local life. The Eastern New Town located in Ningbo, China, which is the future political and economic center here, has undergone ten years of construction and development. As a typical case of new city construction in China, the creation of its CLC is representative.

2. Concept definition and Status overview

2.1 The concept of CLC

The concept of "life circle" began in Japan (Xiao, 2014) . It mainly refers to the maturity activities of shopping, leisure, friendship, education, medical care, and culture in mature cities or regions. The concept of "Daily Life Circle", which is correlated with the scale of CLC, refers to the spatial or behavioral space involved in daily activities such as shopping, leisure, commuting, social interaction and medical care (Xiao, 2014). Based on the consensus, the definition of CLC could be refined into three keywords: residents, daily activities, and spatial scope.

The concept of CLC in this research discusses the spatial form and structural system, that covering various daily activities of residents around their living space. Its supporting subsystem includes five areas: living space, employment space, road system, service facilities and public space.

2.2 Planning practice of CLC in Asia

The research and planning of life circle could be traced back to Japan, and then spread to South Korea, Singapore, Taiwan and other countries and regions. Table 1 summarizes the CLC content within each planning practice.

Country or region	Name of Community life circle	Service	Travel time	service radius	Circle range	Population
Japan	Residential Area	basic services, focusing on the facilities used around the residential area	15 minutes walking	Within 1000 meters	1-2 km²	10,000 to 2 0,000
Korea	Middle Life Circle	primary school, daily shopping (neighborhood center)	15 minutes walking	1000-2000 meters	5-6 km²	30,000 to 6 0,000
Singapore	Neighborho od Living Circle	primary school, neighborhood center, daily service	5-10 minutes walking	500 meters	1-2 km²	10,000 to 2 0,000
Shanghai, China	15 Minutes Community Life Circle	Basic service and public event space required for life	15 minutes walking	500-1000 meters	about 3 km²	50,000 to 1 00,000

Table 1 Summary of CLC practices in Asia
Source: Author's summary based on different cases

According to these planning cases, the size of the CLC was supposed to match the street scale and population size, and it is mainly configured to meet the social demand of service facilities and public spaces.

2.3 Overview of research site

The Eastern New City is the geometric center in Ningbo's future urban structure, and it has a total land of 15.85 km². Most of the new city construction in core areas have been completed, while the eastern part is where resettlement area, old town area and farmland located.

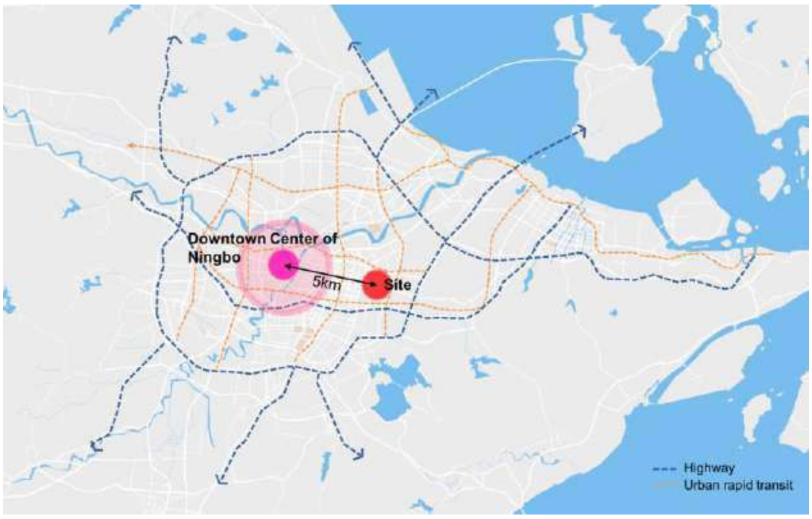

Figure1: Location of Eastern New Town in Ningbo, China
Source: Author's self-drawn, base map from https://www.mapbox.com/studio/styles

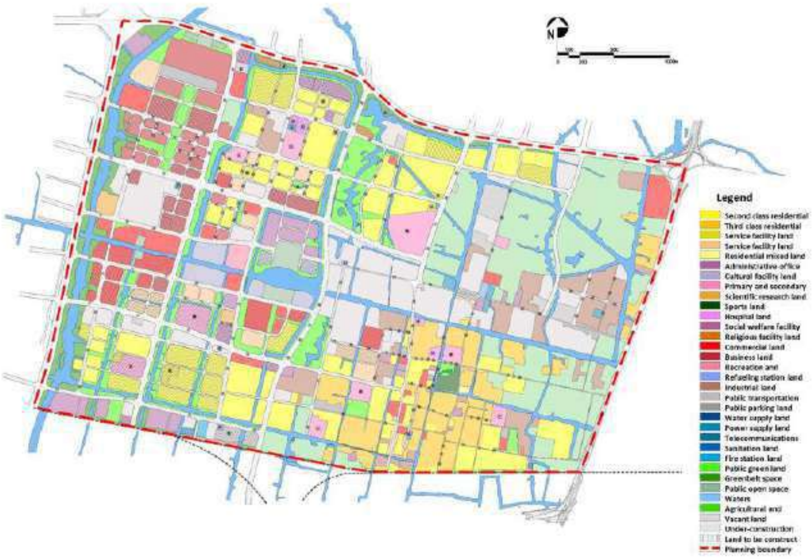

Figure 2: current land use of Eastern New City
Source: Author's self-drawn

2.4 The scale of CLC

The CLC constructed in the Ningbo Eastern New Town includes community-level facilities and open spaces, with a service radius of 500 to 600 meters within 15 minutes walking distance. It serves a population of 10,000 to 20,000 people.

3. Social demands survey and analysis

3.1 Core requirements of each supporting subsystem

Based on questionnaires and interviews (The total number of issued questionnaires were 282, of which 220 were valid), this research analyzes the residents' evaluation on the living space in the Eastern New Town, and different demands that corresponding each subsystem.

(1) Living Space. The focusing facts in living space are high-quality facilities, convenient transportation and a healthy and pleasant community environment. High-quality facilities should concern a whole life cycle services through different products for diverse groups, for example: senior apartments, commercial apartments, and elite apartments. At the same time, environmental friendly housing, renovation of old houses and villages also received highly attention.

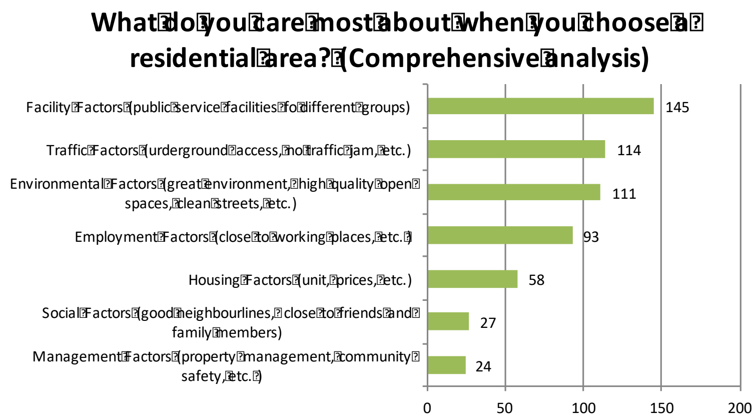

Figure 3: Factors when people choosing a residential area
Source: Author's self-drawn, data collected by survey

(2) Employment space. The most urgent requirements here are parking facilities, and catering services. It is considered that office space in new city is relatively independent and lacks communication with the surrounding environment. This interview also suggests more diversified office space blending surrounding amenities, like makers space, functional composite office and low-cost enterprise communities, to provide a more creative work environment.

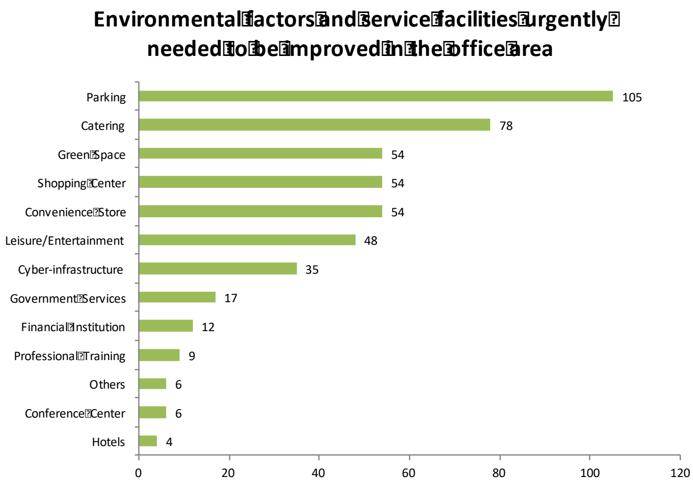

Figure 4: Environmental factors and service facilities needed to be improved in office area
Source: Author's self-drawn, data collected by survey

(3) Road system. The primarily concerned field of residents were walking environment, parking problems and public transportation, which includes limited bus routes, congestion, and traffic transfer. During the interview, residents expressed their desire to provide running path and leisure facilities. As a new type of public transportation, shared bicycles were also highly recommended in the new city. Bus intelligent system is also concerned.

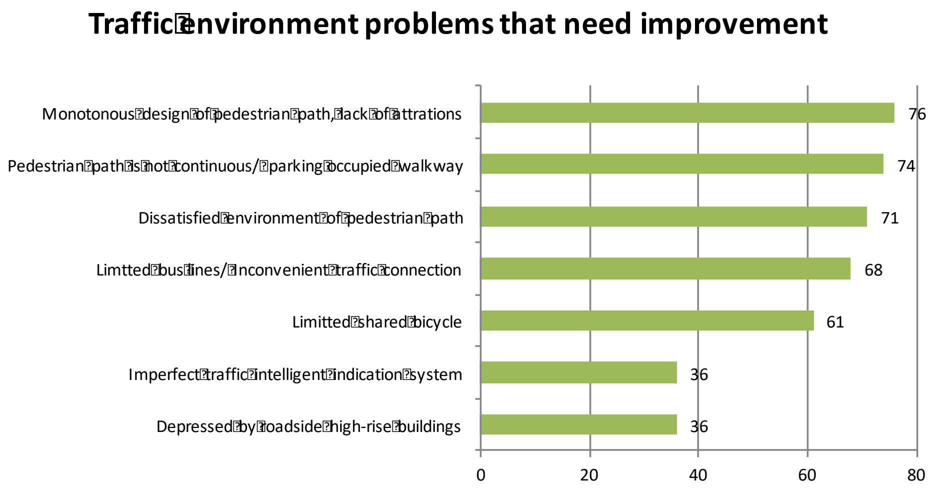

Figure 5: Problems of current traffic environment
Source: Author's self-drawn, data collected by survey

(4) Amenities. The highest demand is to increase fitness and leisure facilities, daily shopping and living service facilities. According to the interview, residents especially require for more flexible service facilities, such as shared facilities, childcare facilities near office and unmanned convenience stores in community, small cafes, etc. Residents also suggest to reuse old buildings as neighborhood activity spaces.

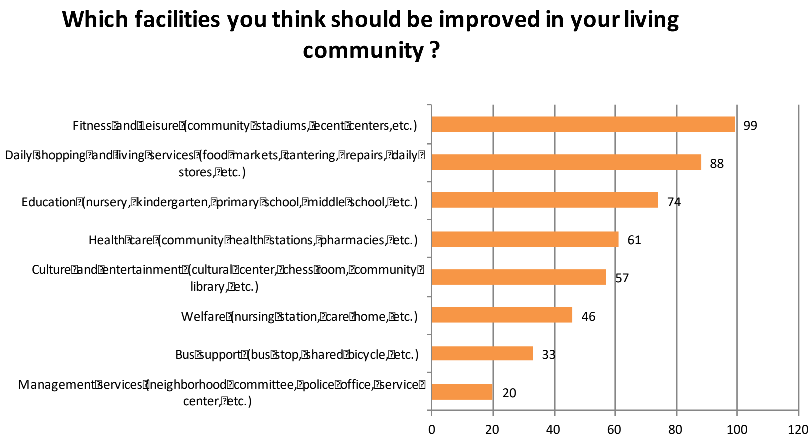

Figure 6: Facilities should be improved in community
Source: Author's self-drawn, data collected by survey

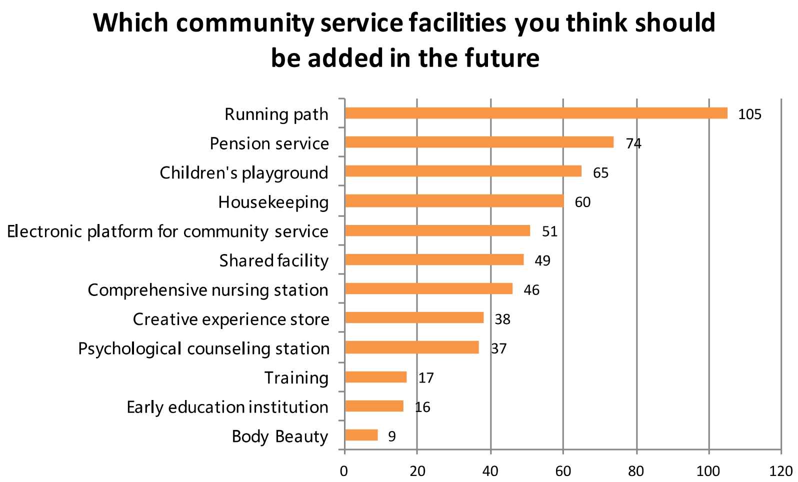

Figure 7: Facilities should be added in community
Source: Author's self-drawn, data collected by survey

(5) Public Space. The principal problem here is the accessibility of green spaces. Most of open spaces lacks recreational facilities and unique characteristics. Thematic public spaces were required while the quantity of green places should be added. At the same time, residents mentioned that private closed space should be shared in the future by breaking the wall-type community mode.

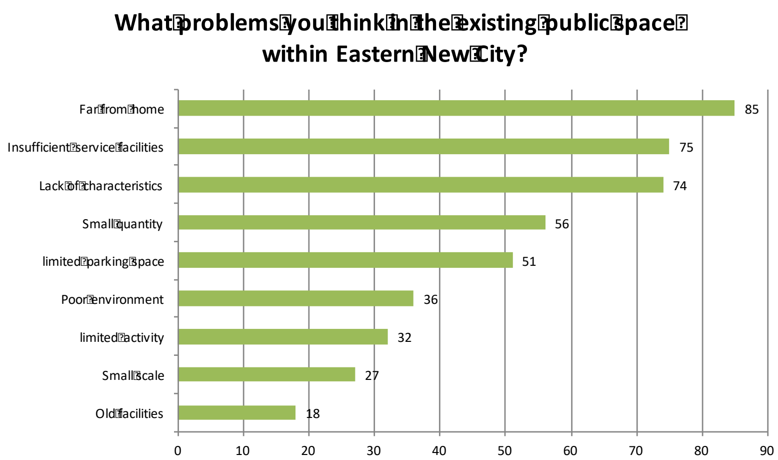

Figure 8: problems of open spaces in Eastern New City
Source: Author's self-drawn, data collected by survey

3.2 Summary of social demands survey

Analysis shows that the main contradiction on existing living space in the Eastern New Town is the top-down resource allocation mode and the residents' high-level requirement. The demands of residents include two major themes: first, to improve basic needs, and second, to increase existing quality of life.

4. Habitable evaluation of community life circle

4.1 Construction of evaluation index system

Corresponding to the five supporting systems of community life circle, the factors were extracted to evaluate the habitability of current life circle (Figure 9). Firstly, based on the living space and employment space, 7 residential groups with different properties were selected. Secondly, 9 evaluation index factors were extracted from the service facilities and public space. At last, accessibility analysis was carried out based on the road system as the path through ArcGIS.

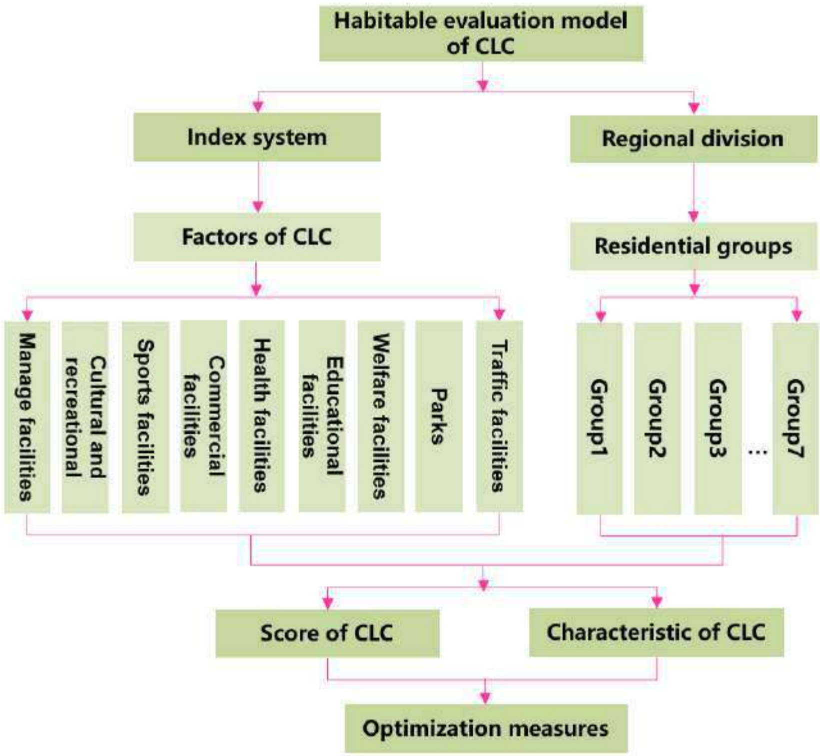

Figure 9: Habitable evaluation model of current CLC
Source: Author's self-drawn

4.2 Evaluation method and process

4.2.1 Selection of index factors

Based on the analysis of current situation and the needs of local residents, nine factors were selected as the main components, which are manage facilities, cultural and recreational facilities, sports facilities, commercial facilities, health facilities, educational facilities, welfare facilities, parks and traffic facilities. Each main factor corresponds to the subdivision factors (Table 2).

4.2.2 Weight assignment

Selected indices were endowed with weights by means of Delphi Method and Analytical Hierarchy Process (AHP). 8 Experts scored the important degree through pairwise comparison. The weight judgment matrix was constructed to get the final weight of each factor. (Comparative evaluation was divided into seven levels: 1=equal importance, 2=weak importance, 3=fair importance, 4=essential importance, 5=very importance, 6=particular importance, 7=absolute importance. Consistency inspection was conducted for each weight judgment matrix.) The result of the weight of each factor is shown in Table 2.

Factor	Weight	Subdivision factor	Weight
Manage facilities	0.34	Community police office	0.06
		Community service center (property service, neighborhood committee)	0.28
Cultural and recreational facilities	0.53	Community cultural activity center	0.53
Sports facilities	0.82	Gym	0.26
		Sport field	0.56
Commercial facilities	**1.53**	Food market	0.45
		Supermarket	0.53
		Restaurant	0.16
		Service facility (bank, barbershop, laundry, etc.)	0.08
		Community shopping (convenience store, groceries, clothing shop etc.)	0.31
Health facilities	0.88	Community health station	0.59
		Drugstore	0.29
Educational facilities	**1.53**	Kindergarten	0.48
		Primary school	0.75
		Middle school	0.30
Welfare facilities	0.67	Care station	0.67
Parks	1.20	Neighborhood green space and square	0.60
		Small parks, Street park	0.60
Traffic facilities	**2.50**	Bus stop	2.50

Table 2: index system and weight for the evaluation on the habitability of community life circle
Source: Author's self-drawn, calculation result of the weight

4.2.3 Selection of residential groups

According to the spatial distribution and different characteristic of living space, four types of residential clusters were selected (Table 3, Figure 10), which are upscale community (group 1), business-living community (group 2, 3), intermediate community (group 4, 5) and rural community (group 6, 7).

Residential group	Name of the community	Land use	Plot ratio	Type of community
Group 1	Jinxiu Dongcheng, Oriental Yipin	R2	2.2	Upscale community
Group 2	Lan Garden	RB	2.79	Business-living community
Group 3	Jiaheng Plaza	RB	4.5	Business-living community
Group 4	Qianshuiwan Urban	R2	1.6	Intermediate community

	Garden I, II			
Group 5	Shuxiang Jingyuan I, II, III, IV	R2	2.0	Intermediate community with resettlement housing
Group 6	Fangzhuang	R2	1.1	Rural community
Group 7	Yinfeng	R2	1.5	Rural community with resettlement housing

Table 3：Properties of different residential groups
Source: Author's self-drawn

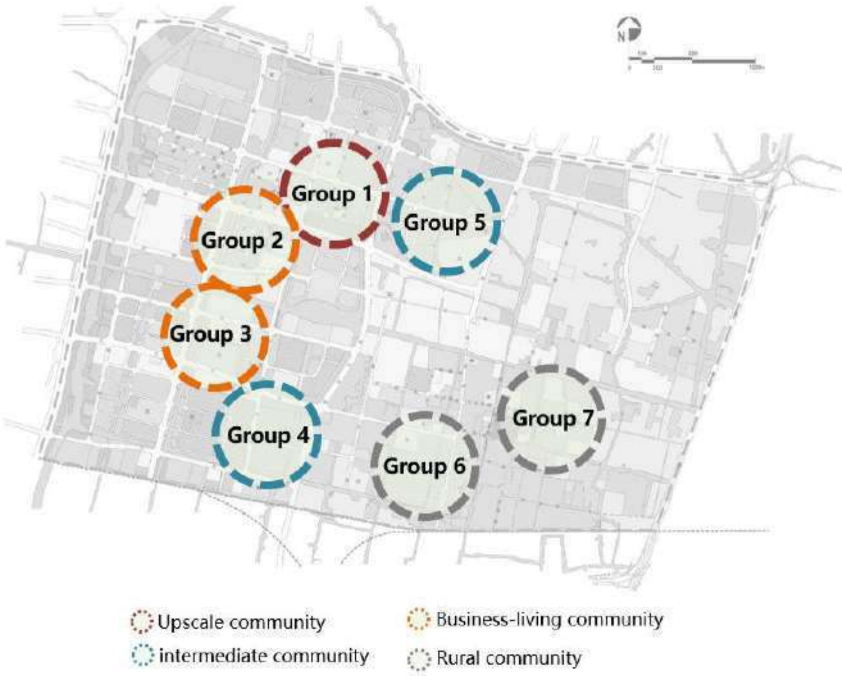

Figure 10: Classification and distribution of residential groups
Source: Author's self-drawn

4.2.4 Scores of the habitable evaluation

Entrances and exits of the residential groups were selected as the starting points. The spatial accessibility map was formed by GIS-based measures. The score was determined by whether the factor could be found in 15 minutes' walk distance or not. Score 1 means yes, while score 0 means no. The result is multiplied by the factor weight, and the total point of each group is the sum of all the factor scores. The calculation model of evaluation is:

$$Q_i = \sum_{j=1}^{n} W_j * X_j$$

Q_i is the total score of ith residential group. W_j is the accessibility score of the factor of the jth residential group (be accessible=1, be inaccessible=0). And X_j is the weight of the jth factor.

The facilities and spatial accessibility distribution are shown in Figure 11. And Table 4 illustrates the habitable scores of evaluation of each factor.

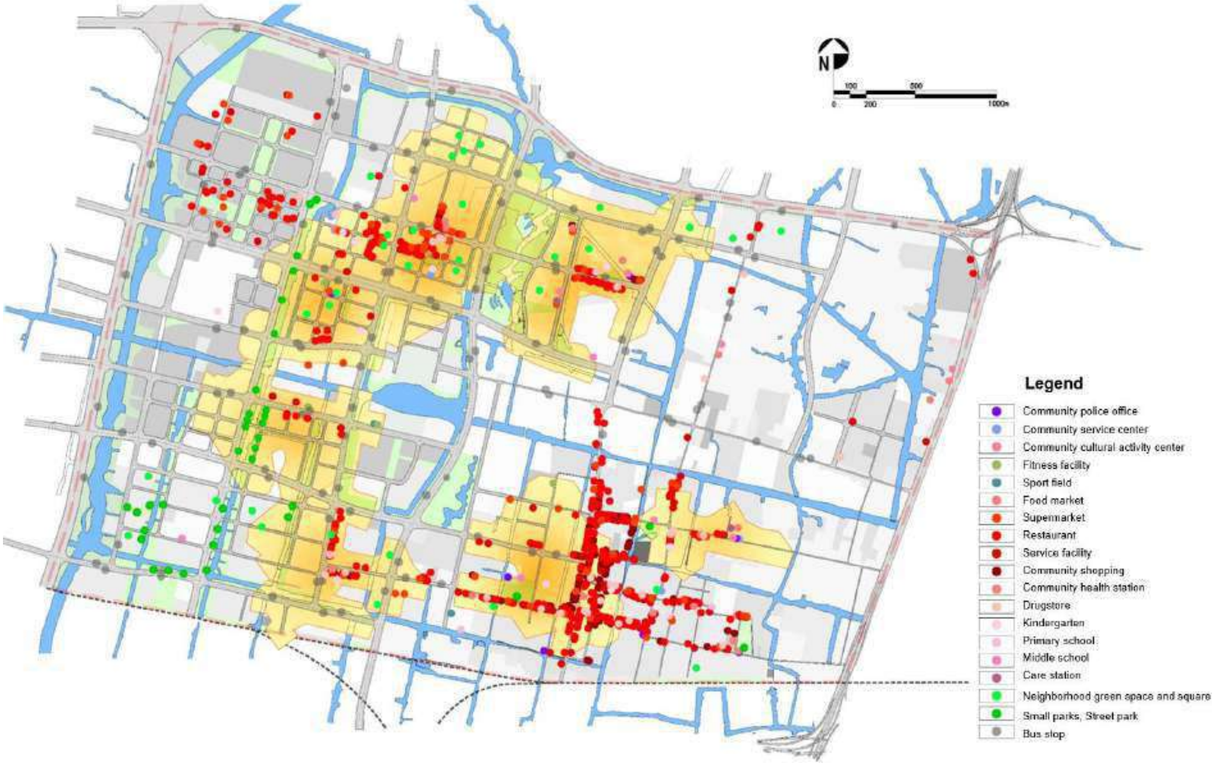

Figure 11: Facilities and spatial accessibility distribution map
Source: Author's self-drawn, according to the accessibility analysis through ArcGIS

Residential group	Manage facilities		Cultural and recreational facilities	Sports facilities		Cultural and recreational facilities					Health facilities		Educational facilities			Welfare facilities	Parks		Traffic facilities	Total score
	Community police office	Community service center	Community cultural activity center	Gym	Sport field	Food market	Supermarket	Restaurant	Service facility	Community shopping	Community health station	Drugstore	Kindergarten	Primary school	Middle school	Care station	Neighborhood green space and square	Small parks, Street park	Bus stop	
Group 1	0.06	0.28	0.00	0.00	0.56	0.00	0.53	0.16	0.08	0.31	0.59	0.29	0.48	0.75	0.30	0.00	0.60	0.00	2.50	7.49
Group 2	0.06	0.28	0.00	0.26	0.00	0.00	0.53	0.16	0.08	0.00	0.00	0.00	0.48	0.75	0.00	0.00	0.60	0.60	2.50	6.30

Table 4：Habitable scores of evaluation of each factor
Source: Author's self-drawn

4.3 Analysis of the evaluation

The evaluation scores of current CLC and spatial characteristics of different residential groups are shown in Figure 12.

Group 5 gets the highest score (7.53), which has large scale communities of enclosed-type with a big community service center (including health station, recreational center, old-age service facilities etc.). And some of the commercial facilities are along the streets.

Group 1 (7.49) ranks second. It is an open community, which has the spatial characteristic of small block and dense network. Most of the service facilities are distributed along the streets. While compared to the gated community of group 4 (6.14), the habitability of group 1 is better.

The rural community (group 6) is close to the center of the old town, ranking the third (7.11). The community is open, and various facilities are distributed along the main street.

The business-living communities (group 2, group 3) have high quality. However, they are located in the newly developed area, which is close to the office area, lacking all kinds of facilities. The overall habitability score of community life circle is relatively low.

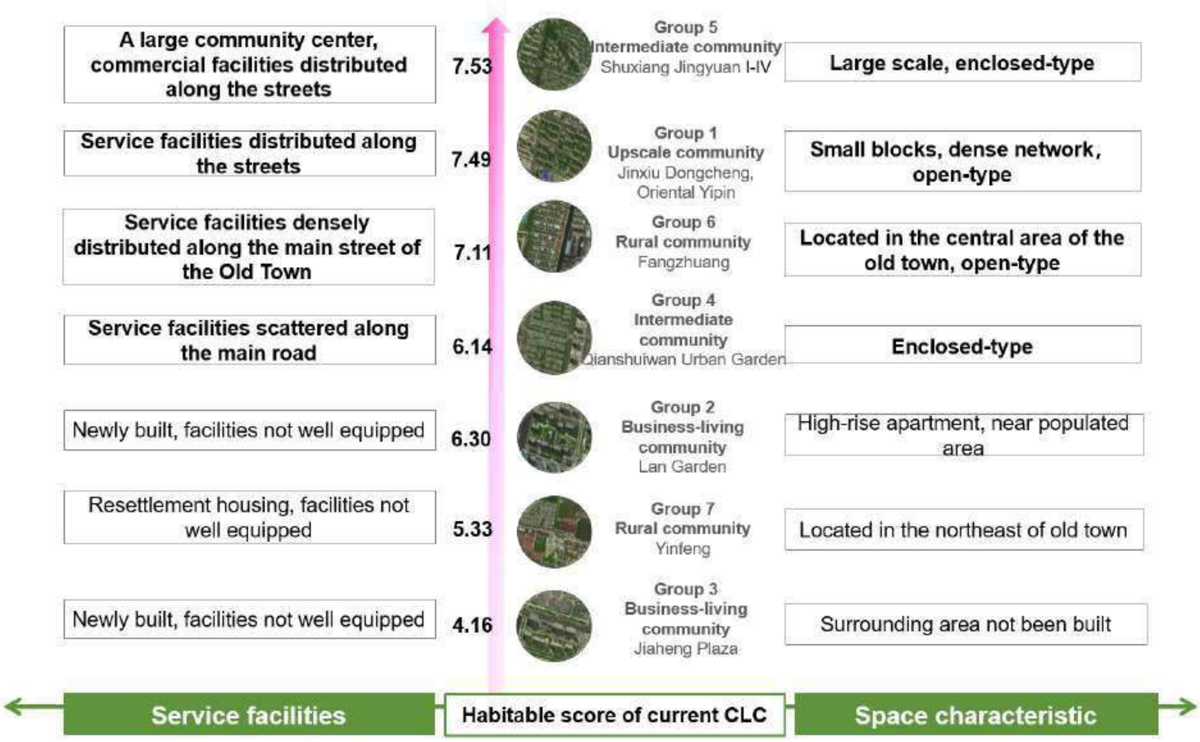

Figure 12：Evaluation scores of current CLC and spatial characteristics of residential groups
Source: Author's summary

4.4 Conclusion of the evaluation

The evaluation conclusion includes two points. First, there is a large gap between each factor, which requires targeted supplement and improvement. Second, the habitability of current life circle differs among different residential groups, which need to be improved separately according to the spatial characteristics.

5. Construction of Community Life Circle

According to the characteristics of the residential group, the eastern new town is divided into four types of districts, business areas, current residential areas, new residential areas and old town. The spatial characteristics of high score groups in the habitability evaluation are extracted for building the spatial models and putting forward the key requirements of each area.

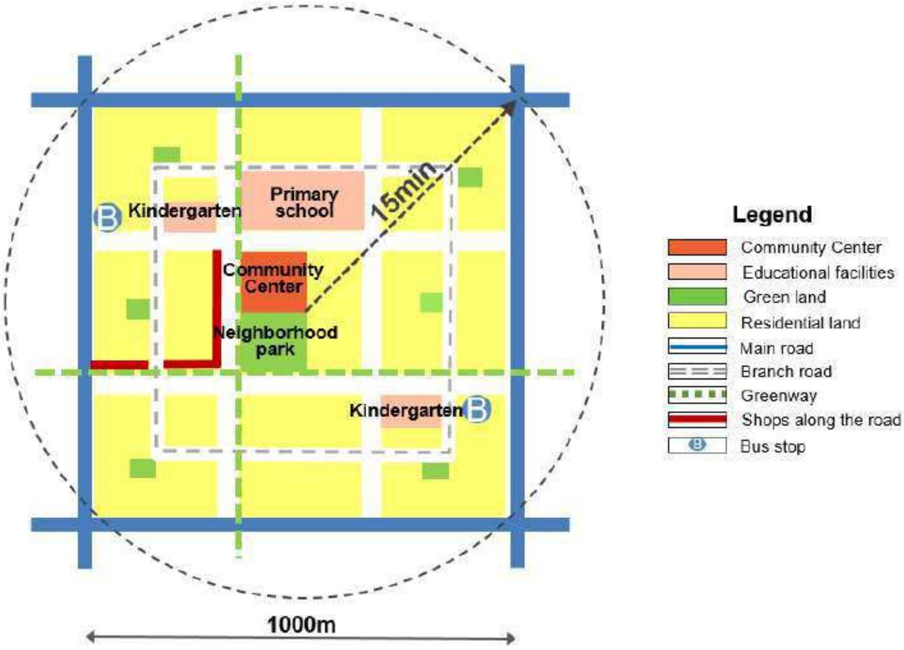

Figure 13: 15-minute community life cycle model
Source: Author's self-drawn

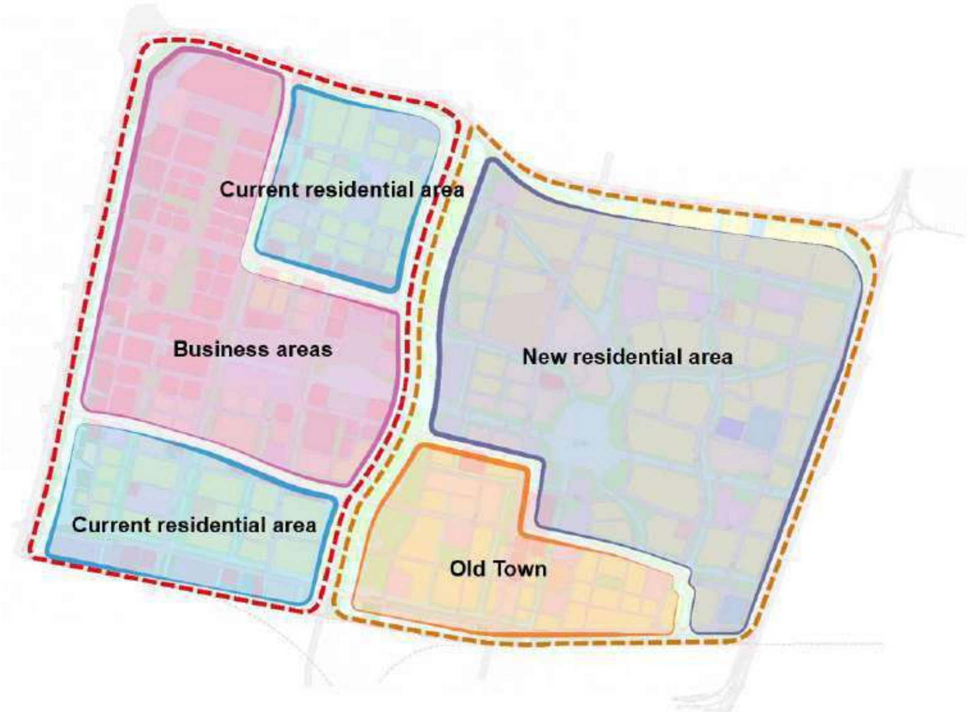

Figure 14: Area classification of Ningbo Eastern New Town
Source: Author's self-drawn

5.1 New residential area

For the new planning areas, the construction of community life circle is goal-oriented, especially focusing on service facilities and road system.

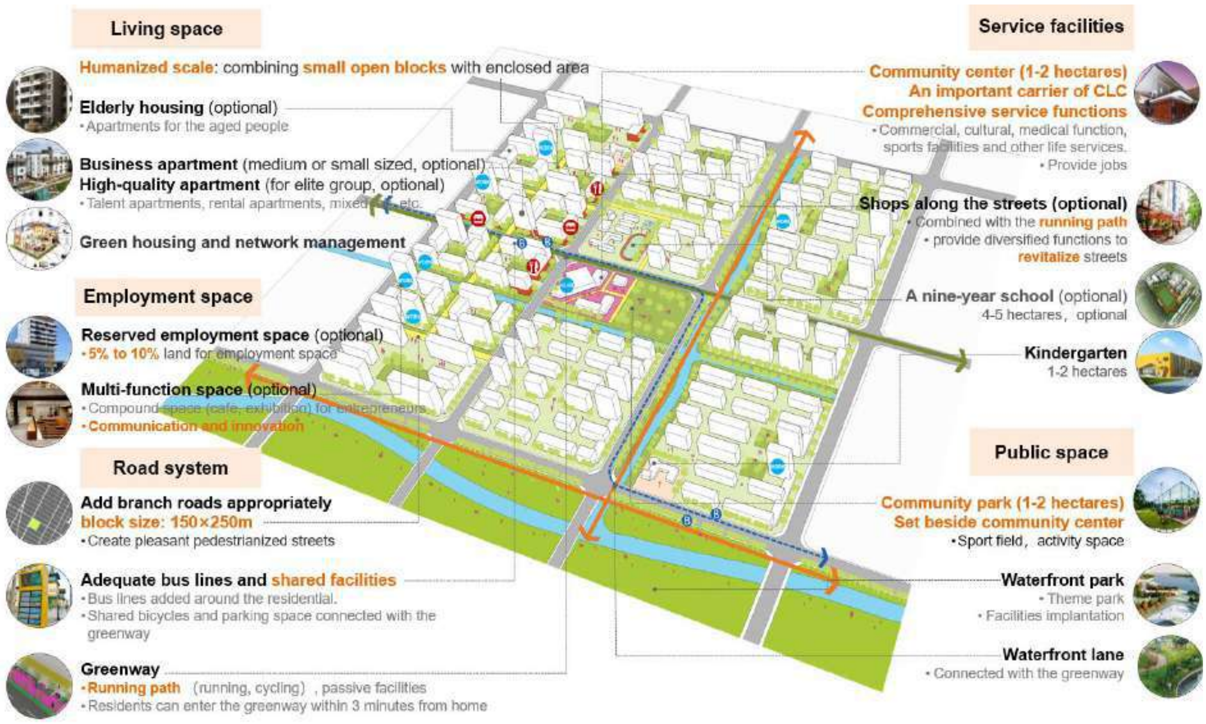

Figure 15: 15-minute community life cycle model of new residential area
Source: Author's self-drawn

For service facilities, the first aspect is spatial distribution. The community center (1-2 hectares) acts as an important carrier of 15-minute CLC with comprehensive service functions, including commercial, cultural, medical function, sports facilities and other life services. Simultaneously, shops along the streets are designed to supplement diverse service function and achieve street vigor. The second focus is the classification of the facilities. Based on the service radius of CLC, a hierarchical facility system is established to eliminate the blind area for pedestrian and to improve the coverage ratio of facilities. In order to meet the different needs of people, not only the basic facilities are provided, but also the ones with high quality and innovative features are considered, such as shared bikes, intelligent management facilities and electronic service platform.

In terms of road system, it is recommended to combine the small block with the traditional enclosed community. Branch roads are encouraged to be added appropriately, and the block size is suggested to be about 150 X 250 meters. As residents have a great need for fitness trails, a greenway system is introduced to the life circle, which provides running path and leisure facilities.

The other supporting systems include living space, employment space and public space. For living space, according to the needs of residents, attention should be paid to the provision of different housing types, such as elderly housing and talent apartments. In terms of employment space, it is suggested to reserve the land (about 5%-10%) for working space in new residential areas. The aim is to create a mixed space for innovation and startups. As for public space, a community park (1-2 hectares) with sport field is planned beside the community center. Parks should be humanized design with service facilities and full of local features with different theme. Cultural activities are introduced to increase the vitality of public space. In addition, attention should also be paid to the utilization and development of waterfront space.

5.2 Old Town

The construction of community life circle in old town keeps the characteristics of high score residential groups, and focuses on organic renewal.

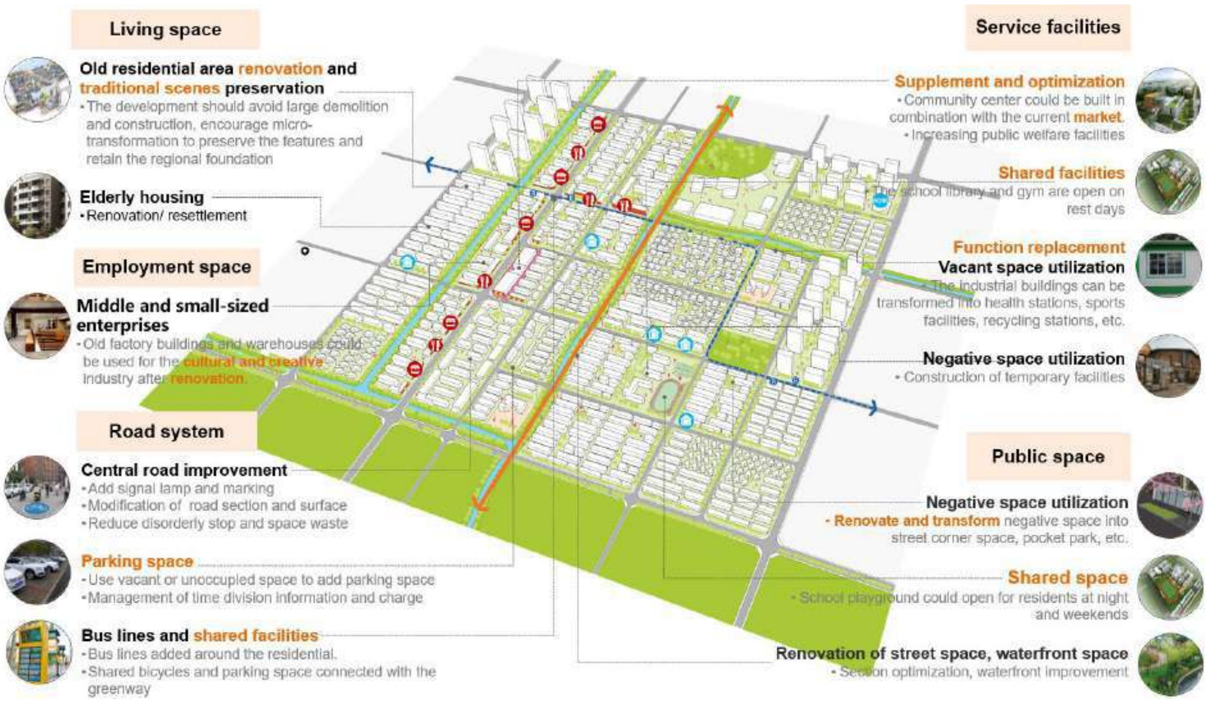

Figure 16: 15-minute community life cycle model of old town
Source: Author's self-drawn

The living areas are restored to preserve the traditional features. The old factory buildings and warehouses could be used for the cultural and creative industry after renovation. In terms of service facilities, it is suggested to transform the market into a compound facility acting as the community center. Roads are being improved and bus lines are being added. As public spaces are limited, negative spaces are encouraged to be used and waterfront should be improved.

5.3 Business area

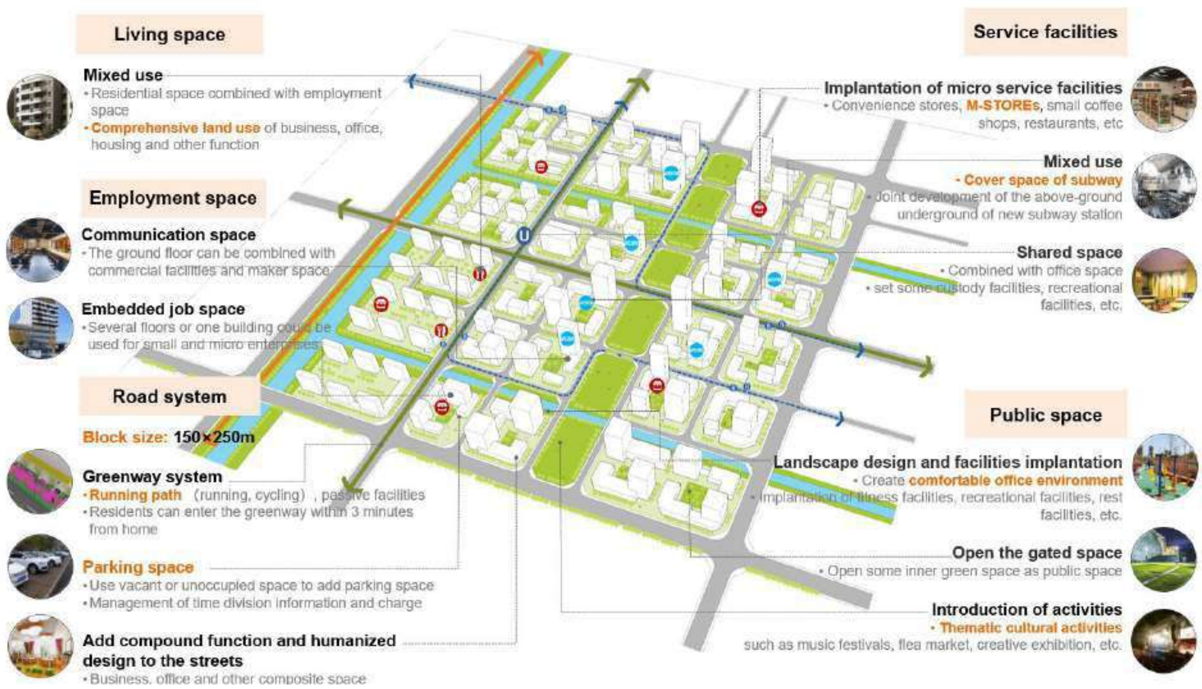

Figure 17: 15-minute community life cycle model of business area
Source: Author's self-drawn

Business areas have basically completed the construction, and the CLC is mainly constructed by micro-renewal.

Scores of the business-living communities are relatively low. The main reason is lack of facilities. Composite use could be implanted into the existing buildings. Daily service facilities could be put in the ground floor, such as convenience stores, coffee shops, newsstands and so on. Meanwhile, the joint development of new subway stations should be planned ahead, which combines the space of the ground and underground. It is recommended to open and share some gated space.

5.4 Current residential area

For residential areas that have already been built, the CLC is mainly constructed by micro-renewal.

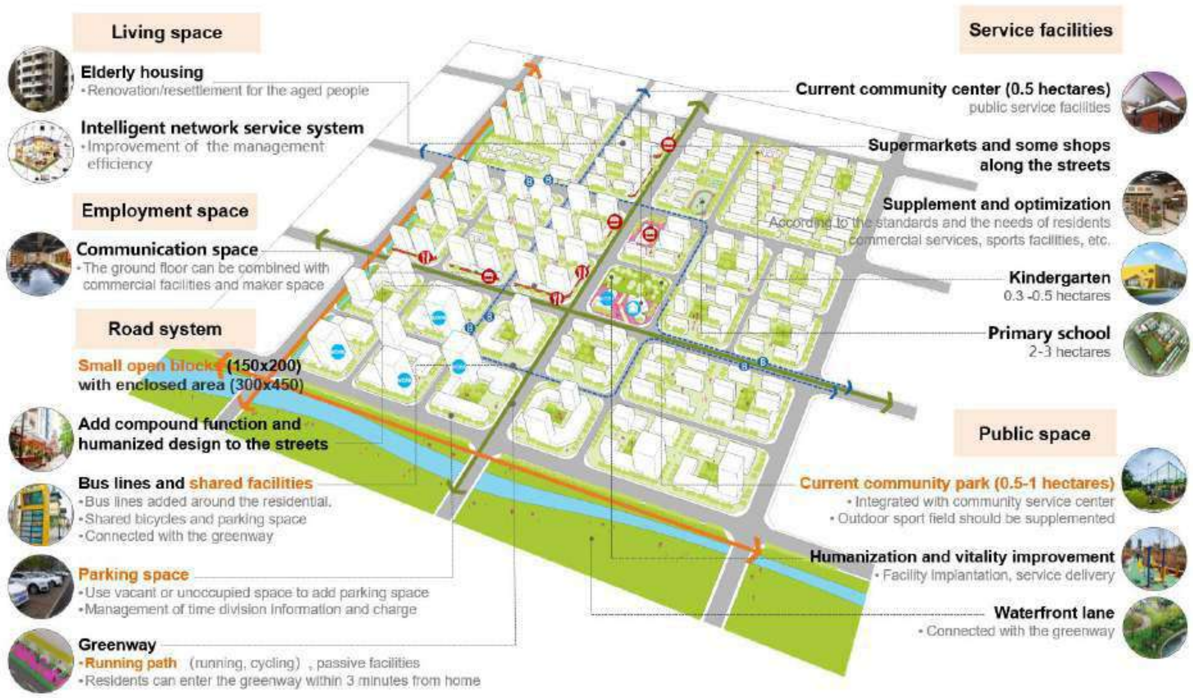

Figure 13: 15-minute community life cycle model of current residential area
Source: Author's self-drawn

In terms of road system, bus lines should be added and shared transportation facilities for shared buses and bicycles should be set up. Parking facilities need to be optimized. Special attention should be paid to adding flexible parking space and popularizing intelligent street management. As for service facilities, the missing types need to supplement, and the quality of facilities needs to be improved to meet residents' high-level requirement. Space along the street floor can be used. In terms of public space, the outdoor sports ground should be supplemented. In addition, waterfront slow lane could be built for leisure and exercise, which could also connect to the CLC greenway.

6. Conclusion

This project focuses on the implementation of residents' living demands via social surveys. It breaks the traditional single model of top-down planning in new city development. This research also builds a spatial model based on the adaptive evaluation of current life circle, and the daily activities of residents. Corresponding planning strategies are proposed as well, which could not only guide the CLC construction for this area, but also interface with control detailed planning, urban design and community planning.

However, the limitations of this research are the acquisition of big data and the characteristics of crowd activity in a larger base. The CLC model should be adjusted in the future with more combination research methods.

How Do Universities React with Cities: the Case Study of Wuhan, China

(Interpretation of the “Univercity” and its spatial Policy in the Case of Wuhan)

Wenjing LUO, Wuhan Planning Design Institute, China
Haijun LI, Wuhan Planning Design Institute, China
Han ZOU, Hubei University of Technology, China

Abstract

Cities and universities have been reacting with each other in a complex conflicting way not only in urban morphology but also in economic, social and culture networks. This paper takes Wuhan for an example to explore the relations between universities and cities not only because Wuhan is famous for college education and has the most graduates all over the world， but also because Wuhan has been positioned as the national innovation center by making it as a “univercity”. Comparison studies on the historic evolvements how universities react with cities are made between the western countries and China. In this way, efforts are made to interpret the meaning of the “university” in aspects of absorbing talents, promoting industries and developing cities. Then the index system of the “univercity” towards the three dimensions mentioned above has been established. Last but not least, the spatial strategies of making a “univercity” have been given accordingly.

1. Introduction

As major spaces to produce local knowledge, universities have become important public facilities to promote regional innovations, so as to make the cities more competitive globally. For examples, cities like Santa Clara, Boston, Cambridge and Oxford have become key nodes of the global innovation network due to their interaction with local universities with top rankings in the world. As the global innovation resources shifting to Asia, Shanghai, Beijing and other cities have put forward urban strategies of making global innovation centers so as to improve their roles in the innovation network worldwide by developing knowledge-based districts such as Yangpu Areas and Zhongguan Village.

As an important educational and technological base in China, Wuhan has long been attempting to transfer its own strength into regional innovation competitiveness. In 2016, To Make it as a “Univercity” has been put forward as one of the ten strategies of Wuhan innovation, which can be illustrated to make universities integrated with the city as a national technological and industrial innovation center. Among all the administrative divisions in Wuhan, Hongshan district has been listed as the core of the “univercity” with the densest resources of key universities, national labs and undergraduates[1] (see Figure 1). However, the district has been confronted with series of problems such as low contribution of universities to industries and isolation between universities with cities leading to traffic jams and facility shortages. Based on this, how do universities react with cities has long been bothering Wuhan especially Hongshan district. This paper attempts to analyze the histories of the interactions between universities and cities, illustrate the meaning of “univercity” and propose exploratory strategies on physical environment.

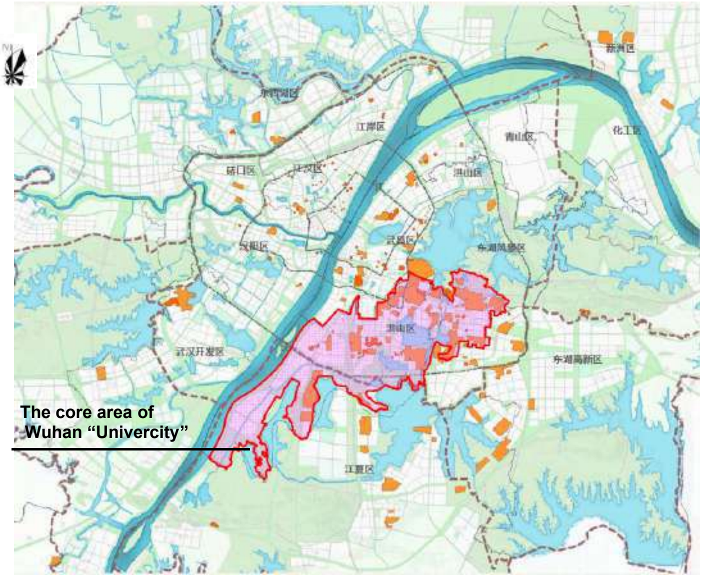

Figure 1: Range of the Core Area of Wuhan “Univercity”

2. The Interaction between Universities with Cities in Historical Perspectives

As the products of western modern civilization, universities can be rooted from the word universus with the meaning of universal, whole, world and universe, which determines that the reactions between universities and cities in China and abroad quite different.

2.1 Experiences in Western Countries

The histories of the reaction between universities and cities in western countries can be divided into the following three stages.

The first stage from the 12th century to the 18th century can be characterized as comparative isolation under the influences of religions. At the beginning of the 12th century, universities have come into being as a new kind of high education facilities especially for government staffs, reverends, noblemen and other elites. Influenced by the Christians, university campuses were almost integrated with churches, which were located besides small towns as enclosures, like the King College of Cambridge University.

Then it was the stage of open public facilities in the ideas of equality and freedom from the 18th century to the 20th century. After the first Industrial revolution, the new emerging business has led to large demands for scientific professionals. As the raise of expenses on high education, universities have expanded themselves for technicians. Greatly influenced by the famous Germany education revolutionist Wilhelm Von Humboldt who advocated the combination of education and research, scientific research has become the responsibility of universities for the first time. As a result, universities which used to be isolated with cities have become open to people especially in the aspects of public facilities. For example, Cambridge University in Britain has torn down the old monasteries and colleges, and instead built a conference center, a library and a museum open to the public. Massachusetts Institute of Technology has set up an opera, a hospital, a gymnasium, parking lots as well as some research centers around the campus.

From the 20th century till Now, it was the third stage characterized as the integration of universities and industries driven by regional innovation. After the third technology revolution, innovation has become the major driven force promoting regional economic developments. With the improving role of scientific research to urban productiveness, the research functions have gradually reached out of campuses and penetrated into the neighboring research institutions. For example, there were more than 8000 technique companies surrounding

Stanford University, Santa Clara University and San Jose University, which has formed a ring of research centers, communities and retail stores (see Figure 2). Under the influences of productivity revolutions and freedom ideologies, the universities in the western countries has transformed from isolated blocks to open neighborhoods sharing public facilities and research institutions, which has not only improved the service efficiency, economic powers and regional innovation competitiveness.

Figure2: Function Analysis of Stanford University and its surrounding areas

2.2 Experiences in China

The histories of the interaction between universities and cities in China can be divided into the following four stages.

The first stage can be characterized as enclosure academies in the ideas of elitism education, which was from the 9th Century to the 19th Century. The oldest universities originated from the academies especially for the gentries, scholars and government staffs in the feudal society. Influenced by the naturism of Taoism and Confucianism, the universities were mostly located in the forest on the outskirts such as Changsha Yuelu Academy. Then to improve the convenience of administration, universities were mostly located in the cities such as Beijing Jingtai Academy. There were one or multiple courtyards in the academies with the functions of teaching, studying and resting.

From the early 19th century to 1949 was the second stage of open campuses under the influences of western education. As the revolutionary change in the traditional education driven by the Westernization Movement, the academies were gradually transferred into schools influenced by the western education thoughts. Later on, campuses become more open to cities, which can be considered as the early forms of the "univercity" in China.

It was the third stage from 1949 to 1978 under the influences of western education, which can be characterized as self-contained compounds. From the foundation of the People's Republic of China to the Reform and Open-up, universities were mostly located on the outskirts which were usually planned as the educational areas in the city master plans. There were multiple defined and connected functional areas such as education, research, libraries and living quarters, which composed the unique self-contained compounds. On one hand, the state encouraged universities to share their gymnasiums and auditoriums with the public. On the other hand, factories and warehouses were built in the campuses to make use of every bit of space, which has led to the disorder of land use. As a result, the self-contained compound model has set back the integration of universities and cities in China.

From 1978 till now was the fourth stage of function overflows under the influences of high education revolutionary movements. After the Reform and Open-up, the high education revolutionary movements have not only inspired the commercialization of research but also promoted the overflows of adjunctive functions to cities. Based on the self-contained compound model, some functions including caterings and retails were gradually shifting outside of campuses where assembled innovative research institutes spontaneously in correspondence to the famous disciplines. After 1998, continuous expansion of universities have led to the popularization of high education with low input and fast speeds. Local governments began to set up new colleges or expand existing universities which also demonstrated different kinds of spatial features. For example, some were located in new towns with abundant land resources as university towns like the Guangzhou University Town or as featured industrial parks like the Hangzhou Eastlake Creative Valley. Some were located in the main cities, like the central Intellectual Area around Shanghai Tongji University and Fudan University with multiple functions of business, retails, leisure and entertainments.

Greatly influenced by western education thoughts, the interactions between universities and cities have transformed from isolation, gradual openness to sharing services and contributing to industries. However, the traditional academies and self-contained compound models have exerted deep influences which demonstrated themselves as fences to keep isolations both physically and mentally. Taking the core area of the “univercity” in Wuhan as an example, most universities were located along the mountains and lakes like compounds or as clusters. Although the expansion of universities in the 1980s have promoted their interaction with research companies, isolation has been still clear both in the functions and forms. On one hand, there was a lack of commercialization of research leading to the massive demands but limited supply of innovation spaces outside campuses. On the other hand, enclosure campuses have not only led to the failure of sharing public services, roads and open spaces with the public, but also resulted into the big city diseases such as traffic jams and service shortages.

3. Interpretation of the “Univercity”

From the historical experiences how universities reacted with cities, the “univercity” should be illustrated as a sustainable mechanism of talents, industries and cities, which operates by transforming the education resources into industry competitiveness and sharing the service facilities with the public. To interpret the idea of “univercity” more concisely, an index system can be established from the dimensions of talents, industries and cites(see Table 1). Based on the *Guidelines of Developing Innovative Cities*[2] issued by the Ministry of Science and Technology and the National Development and Reform Commission, nine categories were made out of the basic index base by learning from the advanced areas and following principles of easy to compare and implement. For every category, two to five indexes were set up to demonstrate the features, goals and processes of making the “univercity”. By the method of type research and comparative studies, quantitative analysis has been made for every index also learned from the references.

Table 1
Key Indexes of the "Univercity"

Dimensions	Categories	Indexes	Types		
			Features -related	**Goals -related**	**Processes -related**
Talents	Input on Education Expenses	Percentage of Technology Input to Public Finance(%)	√		√
		Percentage of R&D Expenditure to GDP（%）	√		√
		Percentage of Basic Research to R&D Expenditure(%)	√		√
		Number of Labs with Nobel Prizes	√	√	√
	key disciplinary &interdisciplinary platforms	Number of World-famous Leading Universities	√	√	
		Number of World-famous Leading Disciplines	√	√	
		Number of National Key Technological Facilities	√	√	
		Number of Research Platforms between Universities	√	√	√
	Personnel Recruitment	Percentage of Graduates to Local Employments(%)	√	√	
		Number of High-level Talents		√	
Industries	R&D Expenditure	Percentage of Enterprise Input to University Research Expenses (%)	√		√
		Number of Key Disciplines Transformed to Industries	√	√	
	Innovation Facility Platform	Number of Innovation Facility Platforms	√		√
		Contribution rate of technology to economy increase(%)	√	√	√
	High-tech enterprises	Number Percentage of High-tech Enterprises to Enterprises(%)	√	√	
		Revenue Percentage of High-tech Enterprises to Enterprises(%)	√	√	
Cities	Urban Quality	Number of Projects for National Garden City	√	√	
		Coverage of Metro Station with a Radius of 500m to Universities (%)	√		√
		Number of Talent Apartments Per Year	√		√
		Number of International Schools	√		√
	Open Campuses	Sharing Rate of Facilities (%)	√	√	√
		Number of Landscape Projects Funded by Governments	√		√
		Network Density(km/km^2)	√	√	
	Urban Regeneration	Percentage of Land used for Innovation (%)	√	√	√
		Percentage of Revenues for R&D (%)	√		√
		Areas of Key Facilities or Labs（m^2)		√	√
		Rewards for New-built Research Facilities			√
		Rewards for New-built Talent Apartments			√

3.1 The Dimension of Talents

Universities were essentially the cradle of talents output to cities. On one hand, the basic interpretation of the "univercity" is to cultivate and raise leading talents especially by nurturing key disciplines of universities and promoting interdisciplinary construction and international corporations , so as to improve the strengths of city human resources. As a result, more talents will be attracted into the city once the competitiveness has been improved. Therefore, the indexes in the dimension of talents include input on education expenses, key disciplinary and interdisciplinary platforms as well as personnel recruitment. For example, key indexes like world-famous leading universities, world-famous leading disciplines and national key technological facilities were chosen for the sub-category of key disciplinary and interdisciplinary platforms. In a goal-oriented way, these indexes can not only represent the overall features in the domain, but also focus on both the qualities and quantities.

Taking the core area of Wuhan "Univercity" as an example, the goal of two world-famous leading universities with twenty first leading disciplines has been proposed based on the resources of current universities and disciplines. According to *the Mid-and-long Term Plan of National Key Technological Facilities(2012-2030)*[3], there will be about fifty facilities nationwide. Based on this, Wuhan "Univercity" has been proposed to establish two national key technological facilities according to the current situations and comparisons with other cities.

3.2 The Dimension of Industries

As an important way to transform the educational resources into urban innovation competitiveness, fostering industries is the foundation of the "univercity". On one hand, key disciplines should be focused on boosting the process of incubation so as to play the leading role in regional innovation network. On the other hand, cooperation between universities and enterprises should be promoted based on the dominant industries, so as to exert backward forces from demands to supplies and improve the effectiveness of commercialization and appliance of research. Therefore, the indexes in the dimension of industries focus on the whole process of innovation and include spending R&D expenditures, building innovation facility platforms and nurturing high-tech enterprises. As an important part of cultivating innovation, building innovation facility platforms can by evaluated by methods of goal-oriented quantification, which can be indexed as the number of public service platforms and contribution rate of technology to economy increases.

As the most potentially innovative area in Wuhan, the core area of Wuhan "Univercity" has been proposed to meet the demands of leading universities and institutes by paying attention to building the platform of innovation facilities so as to keep up with the international levels. According to the *Thirteenth Five Years' Plan of National Technology Innovation*[4], the contribution rate of technology progresses to economy increases has reached an average level of 55.3% in 2015 and proposed to achieve the goal of 60% in 2020. Learning from experiences of other cities home and abroad, the goal of the core area of Wuhan "Univercity" has been set as 70%.

3.3 The Dimension of Cities

If the aspect of industries is only the economic dimension of the "univercity", the aspect of cities can be considered as a comprehensive dimension. On one hand, sharing all kinds of public facilities of universities with cities so as to promote the overflow of adjunctive functions, make most use of the facilities and improve urban living qualities. On the other hand, featured service functions can be set specially surrounding campuses not only to meet the diverse needs of college students and teachers but also improve the efficiency of urban public service facilities. Accordingly, the aspect of cities can be indexed including both improving urban qualities and promoting university openness. Not only the number of international schools which can be comparable to other areas has been listed, but also the sharing rate of college facilities and road network densities which can be used to evaluate the achievement of goals have been included. Besides, the subcategory of urban regeneration has also been proposed to add especially for the built areas surrounding colleges, which does not only focus on controlling indexes like the land use percentages for innovations in urban regenerations and also include improving indexes like FAR bonuses on new built incubators.

As the model of the Wuhan “Univercity”, the core area has been proposed to focus on the improvement of urban qualities so as to increase the attraction for talents. Learning from the references that there are from 2.3 to 3.3 international schools per billion persons in Beijing, Shanghai and Guangzhou, it has been estimated that there should be at least 3 international schools in the core area according to the population. Besides, as the current road network density is less than 2.5 km/km^2 due to the “compound” model of universities, the goal has been set as 5.5km/km^2 after opening campuses based on the national standards and implementation difficulties.

4. Spatial Strategies to React Universities with Cities

No matter the concepts of university towns and university parks proposed by Chinese scholars long ago or the “univercity” are essentially to react or integrate universities with cities. For the spatial elements, there are studies about university educational units and urban expansion units (Duan and Lu,2003), also discussion about the educational districts, adjunctive function districts and creative function districts(Wang, Chen, Yu, Feng and Zheng, 2016). Based on the theories of regional innovation systems[5], the physical spaces of the “univercity” should include universities to output innovating subjects, incubators to provide spaces for innovation activities and all kinds of facilities to cultivate innovation environments(see Figure 3).To achieve the goals in dimensions of talents, industries and cities, three connections should be made between universities, industries and cities.

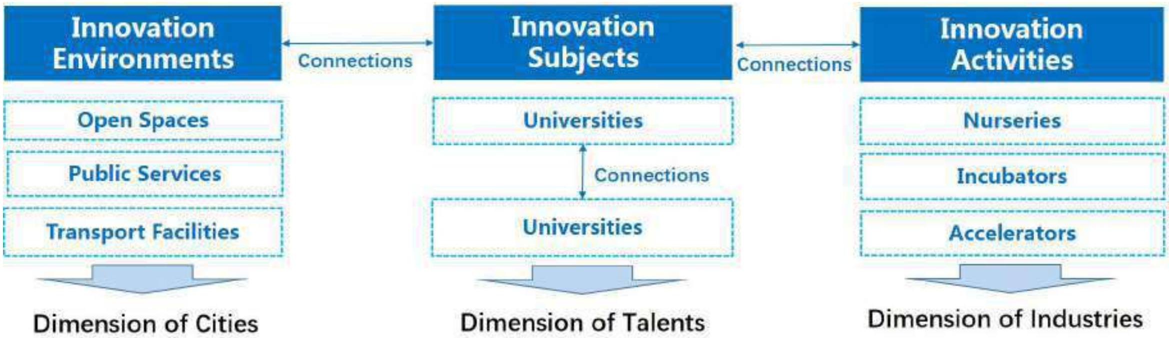

Figure3:Analysis of the Spatial Elements of the “univercity”

4.1 Connecting universities with universities to make use of inner spaces

As the cradle to nurture innovative talents, universities as well as research institutes are in the upper stream of innovation chains, which supply the platform for building disciplines, undertaking research and promoting international academic cooperation. Therefore, adequate spaces should be provided by optimizing inner spaces of campuses to make close connections between universities. For example, residents for teachers and staff, dormitories, cafeterias as well as other logistic service spaces can gradually evacuate their functions out of campuses with the socialization reform of university, so as to provide spaces for key technology facilities and research platforms between universities. With the renovations of classroom, schoolhouses and warehouses, research functions could be added on. Meanwhile, the intensities and densities are encouraged to be improved when educational lands are transformed into key technological facilities so as to promote the intensive utilization of land use(see Figure 4).

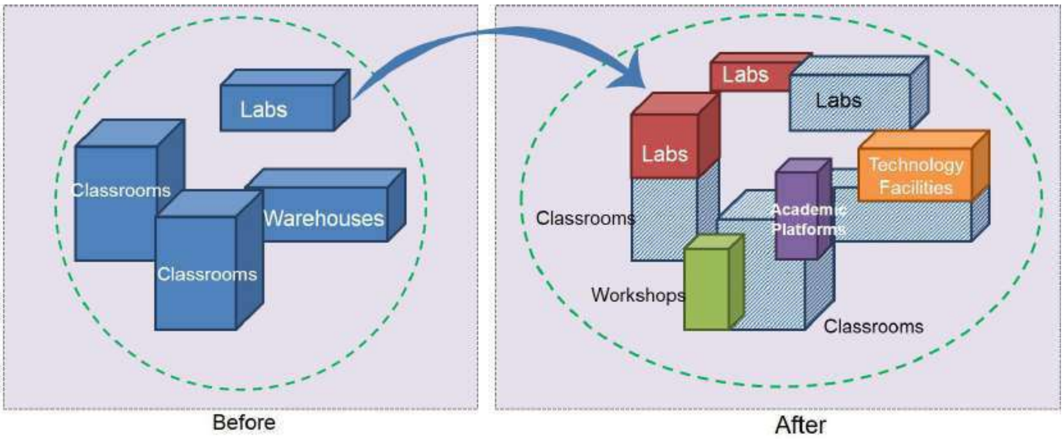

Figure4: Function Analysis of University Inner Spaces

To solve the problems of lacking platforms for key technological facilities such as laboratories, and research platforms in the core area of Wuhan "Univercity", it has been proposed to reconstruct the logistic service facilities with inefficient land use, which can be remade as national key technological facilities and academic platforms between universities. Besides, encouragement has also been proposed to make FAR rewards ranging from 1.1 to 1.2 so as to promote the reconstruction of inner spaces(see Figure 5).

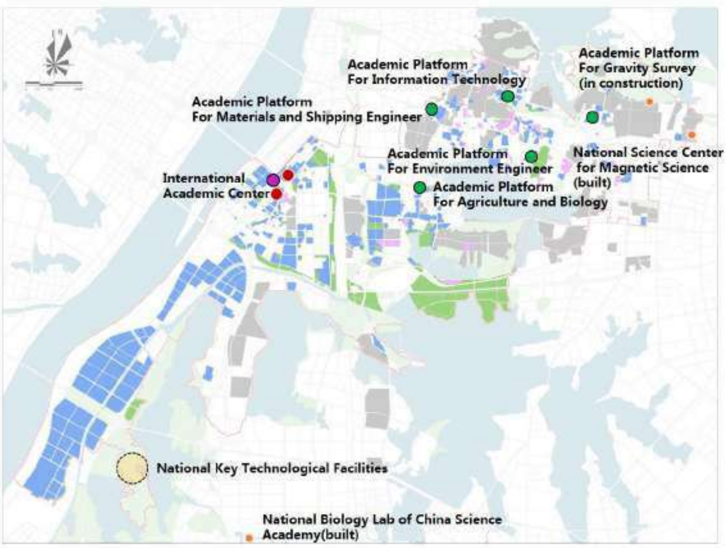

Figure5: Layouts of the Research Facilities in the Core Area of Wuhan "Univercity"

4.2 Connecting Universities with Industries to Set up the Whole Chain of Innovation

As the major physical spaces for innovation activities, incubators will play the determinant role of transforming educational resources into urban innovation competitiveness. Based on the key disciplines of universities and dominant industries of cities, corresponding innovation spaces will need to be provided to complete the whole chain of innovation.

Learning form experiences of innovation spaces home and abroad, it has been proposed that the whole chain of innovation including nurseries, incubators and accelerators needs to be built. On one hand, innovation nurseries especially for new-born start-ups are suggested to be located surrounding old residential areas, commercial facilities and offices, to which it will take 10 to 30 minutes from universities(see Figure 6). One the other hand, incubators for growing start-ups would be better to be located on the lands planned as industries and business with easy access. Accelerators for grown-up start-ups will be suggested to be located in industrial parks with abundant lands. Especially the scales and locations of platforms for innovation activities should be regulated so provide sufficient physical spaces to start-ups(see Figure 7). For the universities with key disciplines of human and social sciences, facilities of culture innovation, creative productions, creative consumption and entertainments should also be established surrounding the current historical districts and open spaces(see Figure 8). Creative industry clusters neighboring universities will be formed so as to provide spaces for the conversion of human and social science to creative industries and also redefine the culture identities of cities.

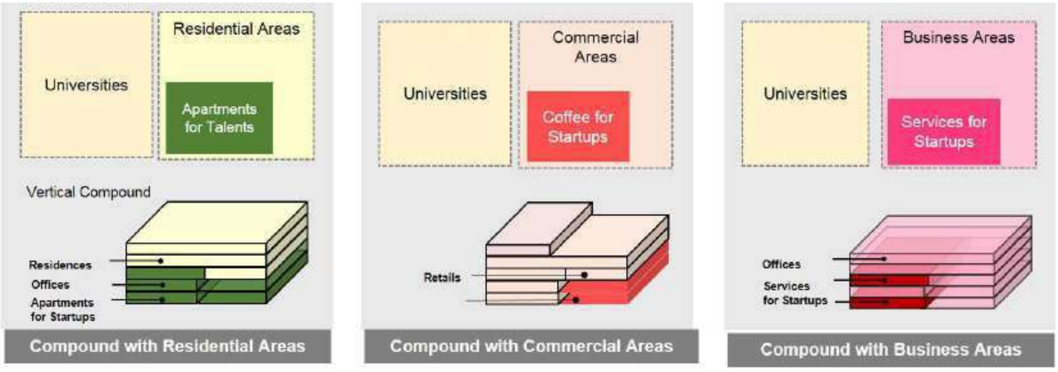

Figure6: Location Analysis of the Nurseries for New-born Start-ups

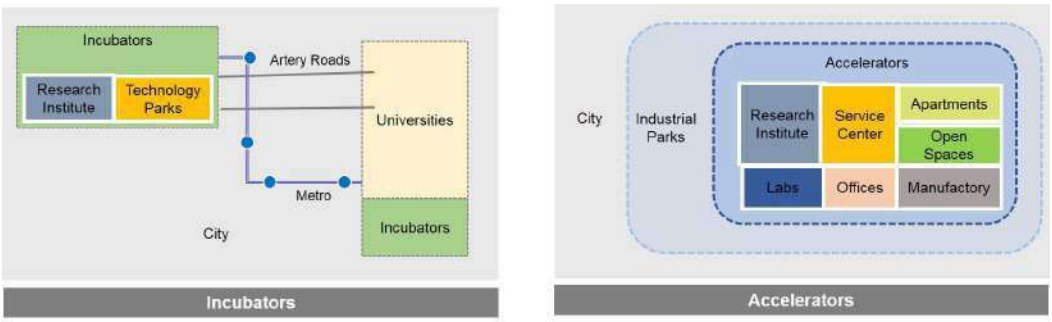

Figure7: Location Analysis of the Incubators and Accelerators

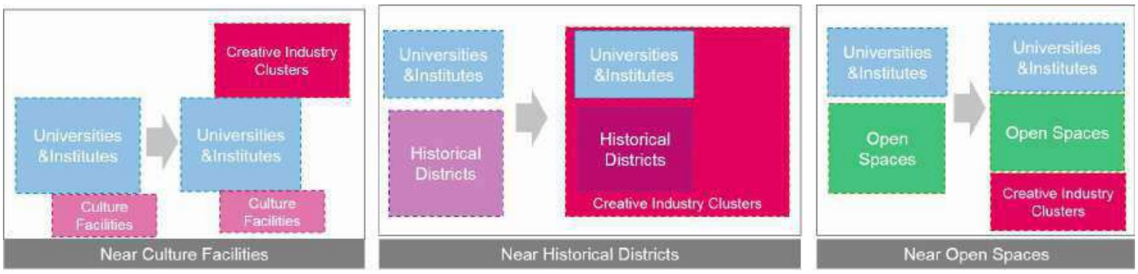

Figure8: Location Analysis of Creative Industry Clusters Surrounding Universities

Aiming at the problems of lacking research commercialization, innovation enterprises, job positions and venture capitals in the core area of Wuhan "Univercity", it has been proposed to layout the innovation spaces along with urban regeneration based on the key disciplines of universities and dominant industries of Wuhan. On one hand, nurseries for new born start-ups have been suggested to locate in old communities and factories neighboring universities. On the other hand, incubators for growing start-ups have been proposed to be located in areas with easy access of public transport. Also, accelerators for grown-up start-ups has been suggested to be locate in industrial parks with abundant land. Based on this, there will be a whole innovation chain from nursery, incubators and accelerators in accordance with the growth of start-ups from the north to the south and the east to the west(see Figure 9). Besides, seven creative industries districts and six innovation service centers has been proposed to be locate based on the social science and humanity disciplines and dominant industries.

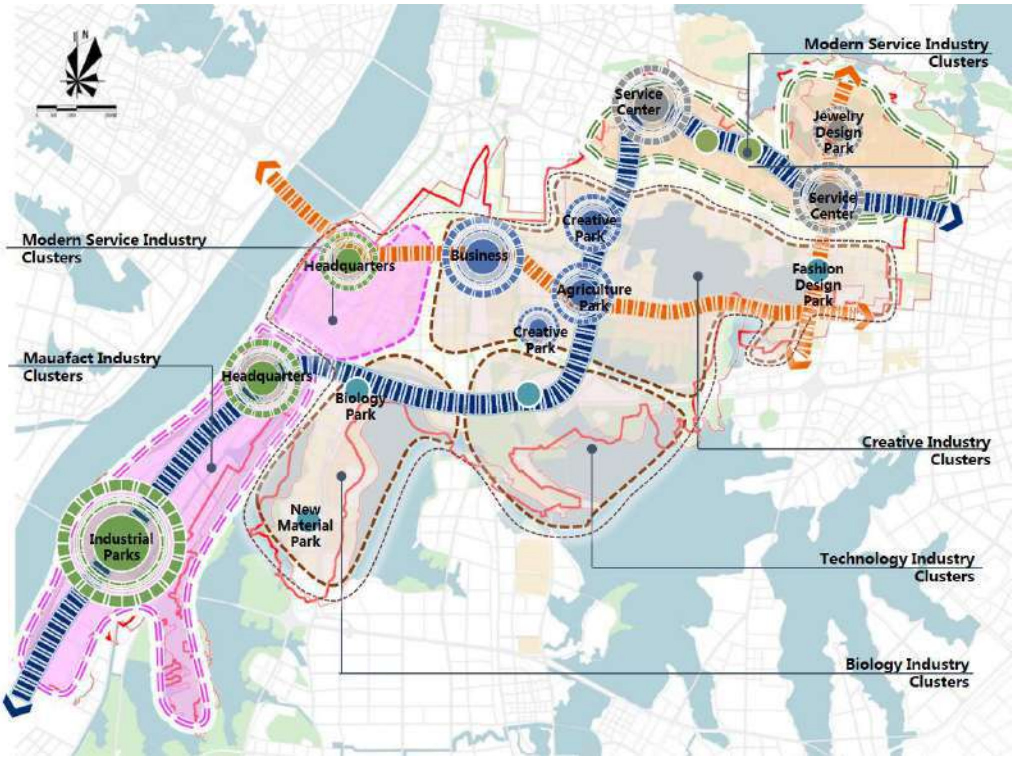

Figure9: Layout of the Industries in the Core Area of Wuhan "Univercity"

4.3 Connecting Universities with Cities to Share Service Facilities

Connecting universities with cities to promote the sharing of public facilities, open spaces, roads and municipal facilities will not only improve the quality of urban environments but also increase the city competitiveness of innovation and attraction for talents.

4.3.1 Providing the sharing spaces of public services

On one hand, activities centers, libraries and gyms in universities have been encouraged to be gradually open to the public with all kinds of culture activities organized in the weekends or holidays to improve the efficiency of campus facilities. Meanwhile, some of university facilities with large scale, high qualities and good accesses located in the areas with a shortage of public facilities would be suggested to be regulated as urban public facilities with incentive mechanisms of co-management between universities and governments. Taking the core area of Wuhan "Univercity" as an example, it has been proposed that the sharing percentage of service facilities in universities should reach the goal of at least 70% in 2020 and 100% in 2030. Once the facilities have been shared with the public, 60% of the residential areas will be covered with an improvement of service efficiency as large as 8 times(see Figure 10). Besides, three gyms of universities have been chosen to be reconstructed and invested by governments and regulated as the land use of urban sports facilities so as to improve the efficiency of lands.

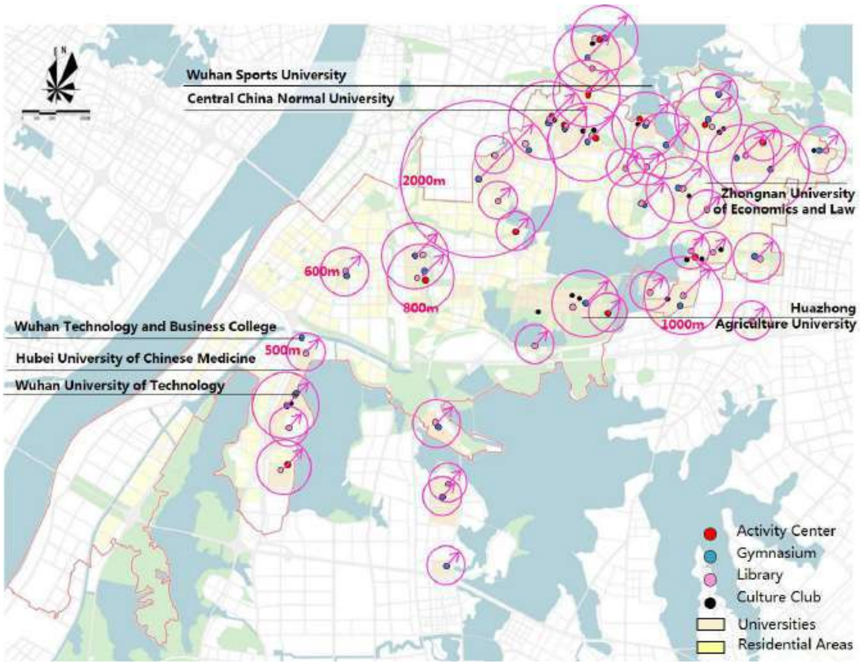

Figure10: Efficiency Analysis of the University Facilities in the Core Area of Wuhan "Univercity"

On the other hand, it has been proposed to focus on the features and provisions of service facilities according to the requirements of innovative talents. To meet the demands of college students, research service facilities which can provide functions including academic communications, talents apartments, retails, leisure, offices, exhibitions and sports have been proposed to be established in the built areas with low efficiency of land use surrounding universities. Not only the current public facilities have been proposed to be upgraded with corresponding incentive mechanism on land use and finance, but also high quality public facilities have been encouraged to supply with larger amounts(see Figure 11).

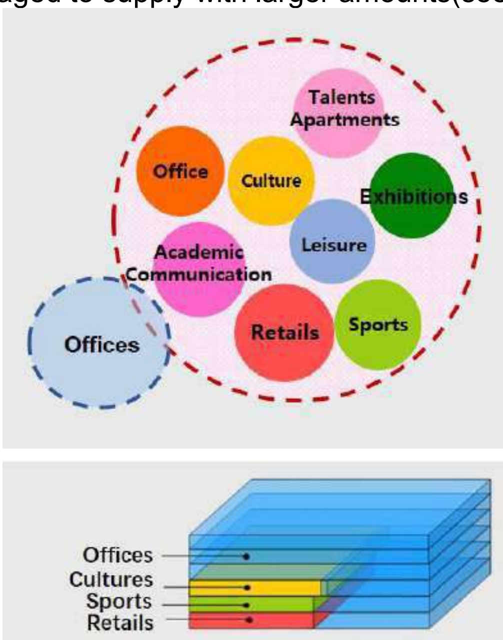

Figure11: Function Analysis of the Research Service Facilities in Universities

For the core area of Wuhan "Univercity" which can be divided into the upgraded district, the supplemented district and the new-built district according to the current public facilities, it has been proposed to build up six research service facilities including talent apartments and communication centers especially in the assembled areas of innovative talents, so as to solve problems of the failure to meet the demands of talents(see Figure 12). Especially for the urban regeneration aiming at building research service facilities, policies have been proposed to give a reward of 1.1 to1.3 times FAR. Meanwhile, building standards of schools and hospitals have also proposed to be improved so as to establish a high quality living circle of facilities within 15 minutes' walk distance.

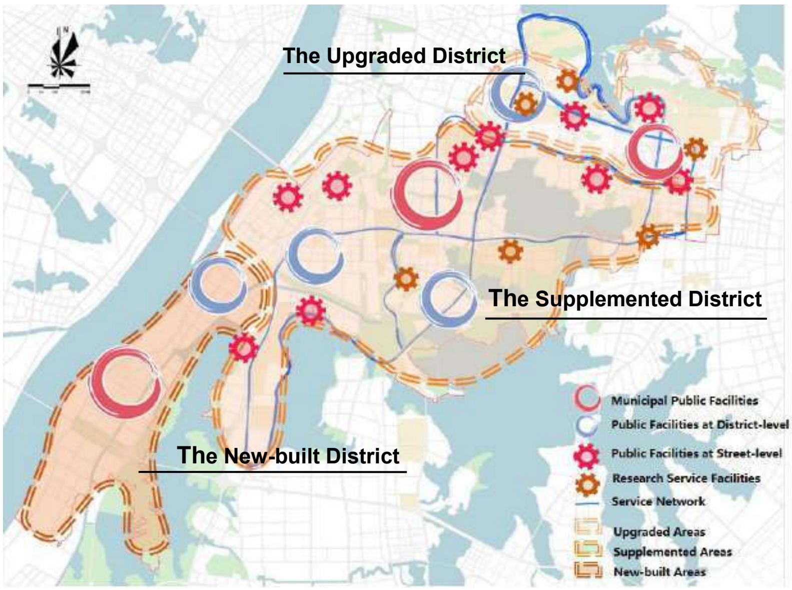

Figure12: Layout of the Public Facilities in the Core Area of Wuhan "Univercity"

4.3.2 Establishing a Green Network System of Transit

The historical spatial model of "Compound" has not only led to the isolation of network system but also urban diseases like failure of implementation. Therefore, campuses should be gradually opened without the influences on teaching and living activities in universities. Driveways should also be opened to the public with the slowing-down design so as to densify the networks and improve the efficiency (see Figure13). Besides, the system of public transport between universities including metros and buses has been proposed to be built to establish a special system of public transport door to door between universities (see Figure14).

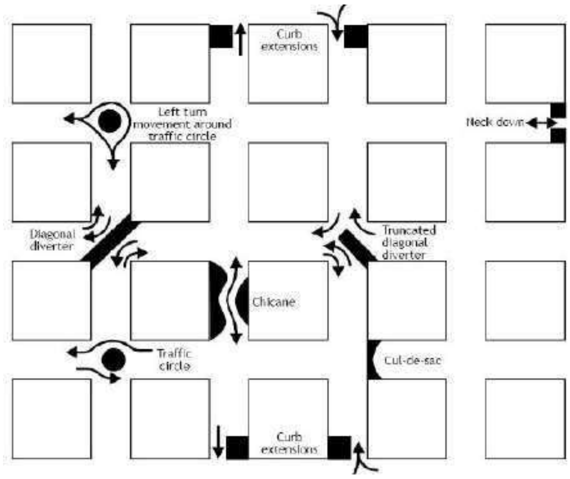

Figure13: Analysis of the Slowing-down Design

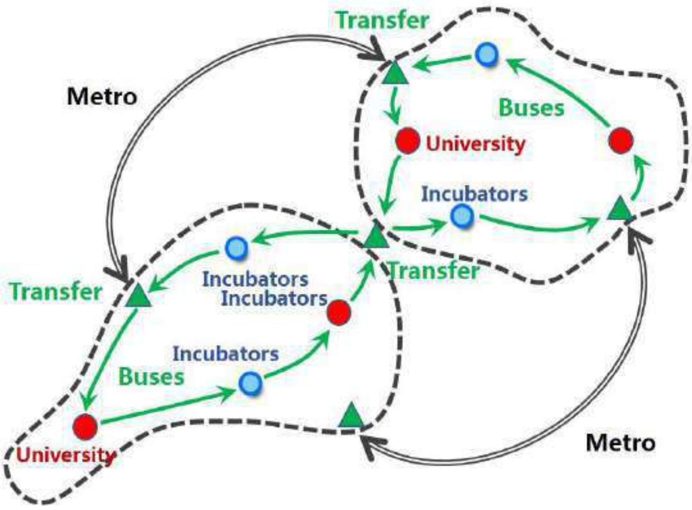

Figure14: Analysis of the public transport door to door between universities

Aiming at the problems including low densities of current networks, lack of minor roads and low efficiency of public transport, it has been proposed to add a new ring of metro surrounding the Wuhan "Univercity" and a special line of buses and water buses, so as to cover all the universities in the core area（see Figure 15）.

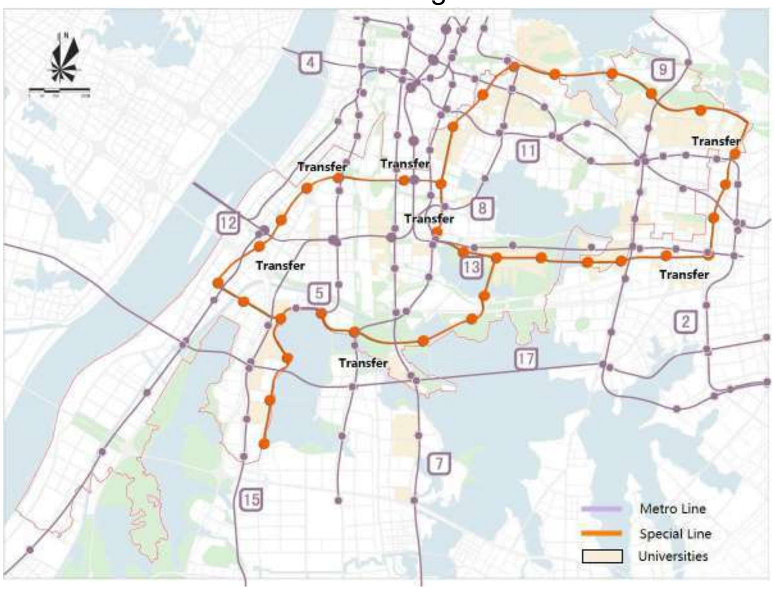

Figure15: Layout of the public transport in the Core Area of Wuhan "Univercity"

4.3.3 Establishing a Network of Open Spaces

Open spaces is not only the public domain for people to talk in informal ways but also the physical spaces to represent the image of the "univercity". On one hand, libraries, squares, green areas and sidewalks have been proposed to make full use of as the landscape node to present the natural and cultural image of universities. It has also been suggested that all kinds of college festivals should be planned and touring routes in campuses should be organized so as to promote the communications between universities and cities. On the other hand, pockets parks with scales ranging from 400 to 10000m^2 have also been proposed to be set around communities, universities, research facilities and other innovation spaces so as to provide spaces of informal communication for creative talents. Accordingly, green networks should be built surrounding mountains, lakes and universities so as to establish a system of landscape in and out of campuses and make the open spaces easy to access(see figure16).

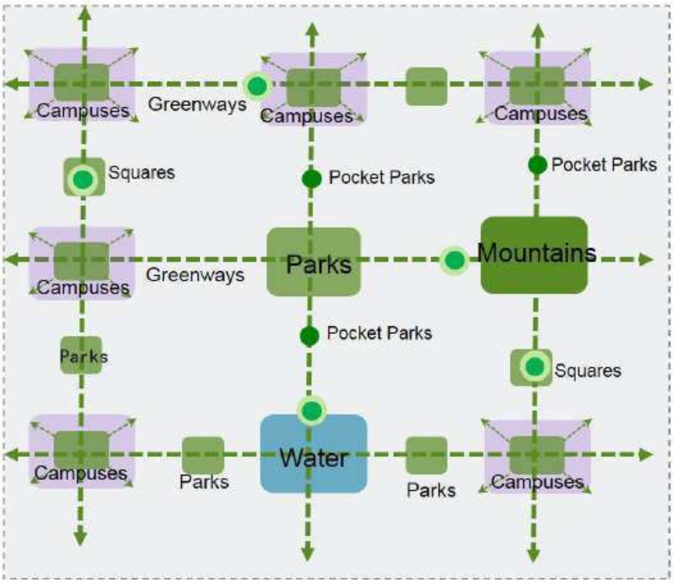

Figure16: Analysis of Open Spaces Network

To make full use of the nature landscape resources of the core area, it has been proposed to connect mountains with cities, link rivers with lakes and build water culture parks surrounding the six lakes, aiming at the problems of isolated landscape, insufficient green areas and obscure image identities(see Figure17). Surrounding universities, there will be loop of innovative culture and six identified areas with three featured touring routes as greenways along with mountains, lakes and universities, which will link the pocket gardens surrounding innovation spaces. Based on this, a network of ecology and culture to integrate cities, universities and nature landscapes will be built so as to rebuild the identities.

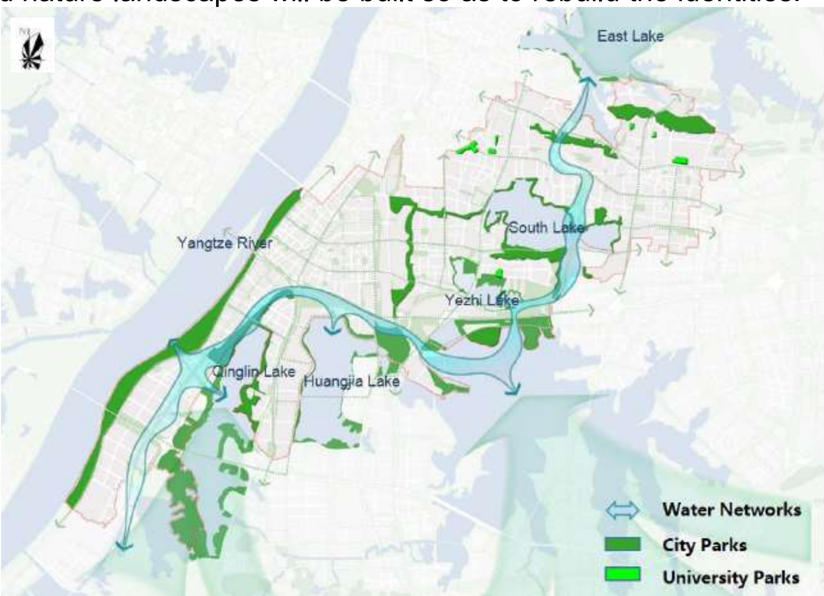

Figure17: Analysis of Open spaces in the Core Area of Wuhan “Univercity”

5. Conclusions

By comparing the historical experiences of universities reacting with cities home and abroad, this paper attempts to interpret the meaning of the “univercity” by both qualitative and quantitative methods, and discuss the spatial strategies by taking the core area of Wuhan “Univercity” as an example, so as to build theoretical and practical foundations for this topic.

One thing to be mentioned is that all the spatial elements of the "univercity" actually overlap each other, which may have been neglected in the discussion in order to analyze their spatial relations and layout requirements as well as define the spatial features. Therefore, it is suggested that a regulation system of indexes should be established especially for the "univercity". In this way, regulations for all the spatial elements of the "univercity" can be implemented in the statutory plans as well as master plans of universities so as to make guidance for environments building in and surrounding campuses. More importantly, the three aspects of the "univercity" do not only need physical spaces but also policies and systems. Therefore, more attention should be paid on the political innovation in the fields of land use, industries, talents, taxation, finance, research commercialization and intellectual property. It has been suggested to make further study on making land use policies and implementation measures as well as encouragement mechanism for sharing university facilities with the public. Influenced by the traditional ideologies, it is a long term process to make universities react with cities , but only the innovation of policy making would open the fences of ideologies.

Analysis on the Working-Living-Entertaining Spatial Relations of New Towns based on Mobile Location Data: The Case of the National Independent Innovation Zone of East Lake in China

(How do New Towns Relate with the Main City in Working-Living-Entertaining Aspects)

Synopsis
This paper offers some structural thoughts of people-centered planning models which are to optimize the space supply according to the current human activities. By using mobile location data, we do not only describe the current human activities and interpret the reasons underneath, but also analyze whether the current model of space use is sustainable and the future model of space supply is necessary to be changed.

1. Introduction

As the new-rising innovation districts all over the world shows, a remarkable shift is occurring that a great emphasis has been put on the integration of working, living and entertaining, which is reshaping the spatial geography of innovation. In China, there has been a mass birth of new towns aiming at developing innovation economies and evacuating over-crowded population from the main city. Due to their common development process, the industries of new towns are often more-developed than residential functions which are still highly dependent on the main city, let alone the leisure ones. In the early 21th Century, new towns have emerged in Wuhan following the *Wuhan Master Plan (2006-2020)* which has proposed the spatial structure composed of one main city, six new towns and multiple centers. At present, revision is being made to the original plan which is becoming due. It has been proposed in the *Wuhan Master Plan (2016-2035)* that three of the six new towns will be promoted as anti-magnetic forces more independent from the main city[2](see Figure 1). As one of the three towns, the National Independent Innovation Zone of East Lake(NIIZEL)which was established in 1988 has been undergoing the transformation from an industrial district to a self-contained new town specialized in innovation economies. Therefore, one of the key questions to be answered is whether the NIIZEL has got the foundations to be promoted as a more independent town, which sets the background for the research.

Figure 1: The Spatial Structure of Wuhan in the Wuhan Master Plan (2016-2035)

As a typical high technology new town, the NIIZEL has been planned to be composed of five functional clusters including the Western Research District, the Central Service District, the Eastern Technology District, the Northern Technology District and the Southern Technology District (see Figure 2). Except the Western Research District is a built-up area, the other four are all new areas in construction. Being in quite different phases of development, those five clusters have all been confronted with problems of lacking residential and leisure functions while the industrial function has been over-developed. Aiming at the goals of a self-contained new town, it is necessary to make reasonable guidance on the space supplies of the NIIZEL based on the current human activities, which location data can be used to describe. In the case of the NIIZEL, we collected location data from mobile devices to evaluate the current working, living and entertaining activities and identify their spatial relations between the new town and the main city, so as to propose suggestions to optimize planning in the perspectives of human behaviors. This paper offers some structural thoughts of people-centered planning models which are to optimize space supply according to the current human activities rather than populations we commonly rely on. By using mobile location data, we do not only describe the current human activities and interpret the reasons underneath, but also analyze whether the current model of space use is sustainable and the future model of space supply is necessary to be changed.

Figure 2: The Functional Clusters of the NIIZEL

2. Study and Methodology

2.1 Literature Review

Most of the previous research on the relations between new towns and the main city focused on the spatial analysis of working and living activities like comparing employment and residence densities by using economic and population census statistics (Niu, Ding and Song, 2017). Recently, there have been some research using cell phone data to record human activities and analyzing the relations of working and living by recognizing the employment-dense and residence-dense areas (Zhou, Liu and Zhu, 2018). These new emerging research has made up for the shortcomings of traditional data which often focus on the relations of spaces, and also established balance indexes such as the ratio of local employment to residence, etc[3](Zhen, Xu, Zhang and Yu, 2015). Generally, there have been certain foundations for the relations of working and living between new towns and the main city. However, there are actually three aspects of basic functions including not only working and living but also entertaining. The previous research has focused on the relations of working and living, but neglected the relations of working and entertaining, or living and entertaining, which would fail to provide sufficient evidences to evaluate the dependency of new towns.

2.2 Thoughts and Framework

Quite like cell phone data, location data from mobile devices are new emerging data which can not only record the activities of working, living and entertaining, but also can be obtained for a duration of time, so as can be used to analyze human behaviors. The relations of working, living and entertaining are influenced by the layout and transit of cities, which in reverse determines the spatial structure of cities (Zhen, Xu, Zhang and Yu, 2015). Therefore, it can play the roles of describing the current spatial structure and optimizing the future planning structure. Moving objects in cities especially like human and their behaviors are as important as still objects and if we do not know the flow, we can never define the evaluation standards of forms(Lynch,2001). Using location data from mobile devices by recording human behaviors, this paper attempts to follow the idea of people-centered planning which can be illustrated as that forms follow flows.

At first, location data from mobile devices can be used to describe current activities. Then the dense areas of working, living and entertaining activities were identified by analyzing the average densities, leading to a comparison about densities and area ranges between the new towns. After identifying the original and influential areas of the working, living and entertaining activities in the NIIZEL, we analyzed the relating directions, strengths and lengths among the original, influential and functional areas themselves. On the basis, an overall evaluation of the amounts, balance indexes and influencing ranges in different scales can be made on the relations of those three functions between the NIIZEL and other areas, which can be compared with the current and planned land use. In this way, problems can be discovered in the space supply, and evidences can be provided to optimize the current master plan scheme. By analyzing the differences between human activities and current spaces, whether the future model of space supply is sustainable can be determined, so as to provide suggestions to optimize the existing planning schemes, which can be considered as an upgradation for the traditional planning thoughts.

2.3 Data Processing

With the location data from mobile devices during five weekdays of 2017, this study has collected and cleaned almost 11 million samples from more than 2.5 million mobile devices in the municipality of Wuhan. In this way, the activity ranges of working, living and entertaining can be defined by setting the standards of occurrence frequencies. For instance, the locations with the occurrences of mobile devices staying in the radius of 1000 meters from 9 to 12 o'clock which reach above 60% can be included in the range of working activities. Likewise, the locations with the occurrences of mobile devices from 19 to 21 o'clock and from 22 to 24 o'clock can be included in the range of entertaining and living activities separately.

3. Research Contents

Based on the statistic of the current residents and employees in the NIIZEL, the activities of living, working and entertaining have been analyzed in the aspects of distributions, relations and comparison with current land use. Then an overall evaluation has been made from the aspects of amounts, balance indexes and influencing ranges, so as to provide suggestive guidance for the planning optimization.

3.1 Current Population

Till the end of 2016, the number of residents in the NIIZEL has reached almost 1.08 million, taking a percentage of 9.8% in the municipality. With the immigrant amounts and resident density ranking top, the NIIZEL has become the area with the rapidest growing population and the largest amount of young people in Wuhan. Besides, the NIIZEL with a number of employees reaching 0.55 million and taking a percentage of 13% in Wuhan, has the densest job positions in Wuhan. Although the NIIZEL has played a key role of the economic development in Wuhan, the current ratio of local employees to residents has only reached 0.63, which is below the acknowledged standard of 0.8(Cervero,1989&1991). With a quite unbalanced distribution, more than 80% of the populations of the NIIZEL have been centralized in the Western Research District (see Figure 3).

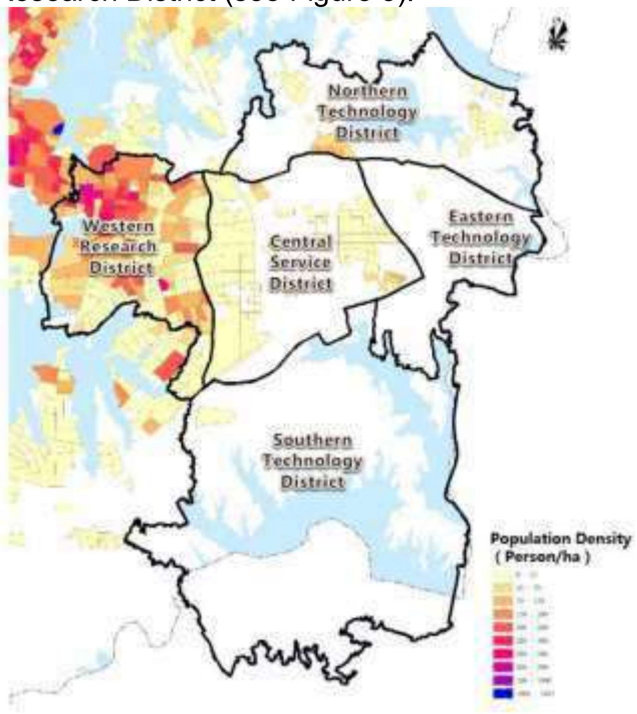

Figure 3: The Population Density Analysis of the NIIZEL

3.2 Activity Ranges

According to the location of mobile devices in the NIIZEL in the designated time, the average and maximal densities of living, working and entertaining activities can be demonstrated by grids of 100m*100m.Then the areas with higher densities in the level of significance by 5% can defined as working-dense areas, living-dense areas and entertaining-dense areas (see Table1 and Table 2). Based on this, the percentage of people coming to the NIIZEL from all the other places in the municipality engaging in all activities can also be defined. Once the percentage reaches above 50%, the places will be considered as the influencing areas of the NIIZEL.

Table 1: Analysis on all the activity-dense areas in the Municipality

Name	Working-dense Areas			Living-dense Areas			Entertaining-dense Areas		
	Percent	Average Density (person /k ㎡	Maximal Density (Person /k ㎡)	Percent	Average Density (person /k ㎡	Maximal Density (Person /k ㎡)	Percent	Average Density (person /k ㎡	Maximal Density (Person /k ㎡)
The NIIZEL	9.59%	153.4	8205.7	11.54%	207.4	11472.1	2.28%	32.2	1998.5

Main City	--	683.4	12049.2	48.97%	907.5	14412.1	——	143.5	3461.8

3.2.1 Working activities

According to the statistics of working-dense areas in the municipality, the scale of the NIIZEL ranks the second with the highest number of area percentage, average and maximal densities. Especially the maximal density of the NIIZEL has reached 1.5 times the one ranking second, which indicates its key role in industrial development (see Figure 4). For all the functional areas in the NIIZEL, the working-dense areas also demonstrates the over-centralized distribution with close to 90% of working activities gathering in the Western Research Area which has the average and maximal densities far above the others (see Figure 5). By comparing the working-dense areas with the maps of enterprises and the current land use, it is evident that there have been unofficial industrial spaces in residential lands with low cost of rents, which can offer finance, information and technology services for medium and small companies. Besides, the industrial lands have the largest area of working-dense areas but with the lowest maximal and average densities, which indicates the inefficiency of industrial land use. While the commercial lands have the highest maximal and average densities, the business lands have much lower densities close to the industrial lands due to the vacancy of current office buildings.

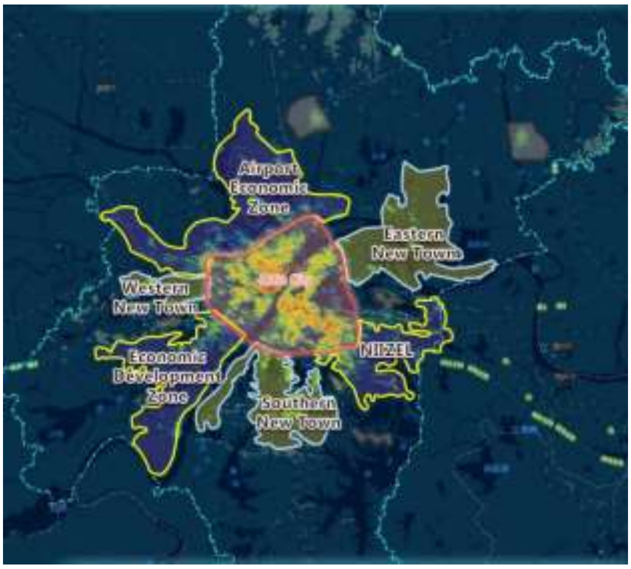

Figure 4: Analysis on the Working Activities in the Municipality

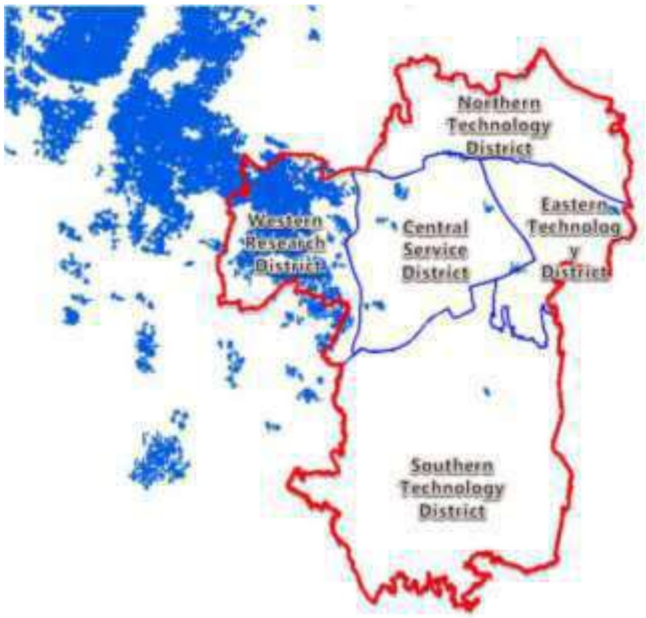

Figure 5: Analysis on the Working-dense Areas in the NIIZEL

It is evident that most of the people working in the NIIZEL come from the neighboring districts, which makes up a large portion with the percentage ranking the second in the municipality. By analyzing the influencing areas, it is estimated that almost 80% of the people working in the NIIZEL live in the circle at a radius of 15km and especially in the circle of 5-10km, which will take an hour to drive. Also there is also 10-20% of the people living almost 3 hours' drive from work, which indicates the strong force of long-distance employment of the NIIZEL. Except the Central Service District, all the other four districts have higher local residential ratios to employment than the average level of the municipality, which also indicates the lack of residential attraction for local employees in the Central Service District. The first choice where people working in the NIIZEL will live in is the Western Research District with its strong connection with the Central Service District. For the Western Research District itself, the ratio of local residence to employment is relatively higher than the other four districts, with a stronger connection outside of the NIIZEL than inside.

For the people working in the NIIZEL, the ratio of local leisure to employment is far behind to residence. Not only do people working in the NIIZEL tend to go entertaining in the neighboring districts and are also willing to drive relatively longer distance for leisure. All the five districts of the NIIZEL have lower ratios of local leisure to employment than the average level of the municipality, which indicates the lack of service functions. The first choice where people working in the NIIZEL will entertain themselves is also the Western Research District with a stronger connection outside of the NIIZEL than inside.

3.2.2 Living activities

Compared with the working activities, the current living activities of the NIIZEL have a larger scale and bigger spatial agglomeration. The scale of the current living-dense area ranks the second in the municipality with the percentage, average and maximal densities ranking the top among the new towns. Especially the maximal density of the NIIZEL is close to the main city and much higher than the other new towns (see Figure6). With a match to the distribution of local residents, the densities of current living activities of built-up areas and new areas are quite different. Especially the current living-dense activities of the Western Research District have larger scales than working-dense activities, with higher average densities than the main city. However, new areas like the Central Service District and the Eastern Technology district are lack of residents and thus have lower densities of living activities due to the implementation of residential lands (see Figure 7).

For the people living in the NIIZEL, the ratio of local employment is relatively higher, which indicates the residential function along with the strong force of employment. Due to the cost and distance, most of the people living outside of the NIIZEL will choose the neighboring districts. It is also estimated that almost 80% of the living activities stay in the circle at a radius of 15km and especially assemble in the circle at a radius of 5-10km.Compared with the working activities, the living-dense areas has been distributed more evenly with a weaker long-distance force than employment. Specifically, there is a higher ratio of local employment for the people living in the NIIZEL, which is higher than the average level of all the other new towns. The top choice that the people living in the NIIZEL will make to work in has proved to be the Central Service District, which indicates its strong force of employment. For the Western Research District, there is a smaller number of people living locally who choose to work outside of the district than people working locally who choose to live outside of the district, which indicates its strongest force for employment. Meanwhile, there is a larger ratio of local leisure to residence than to employment, which ranks top among all the new towns in the municipality. Especially, the Northern Technology District and the Central Service District are well-established with service facilities for residents. Most of the people living in the NIIZEL will choose to entertain in the Western Research District which proves to supply most of the leisure spaces.

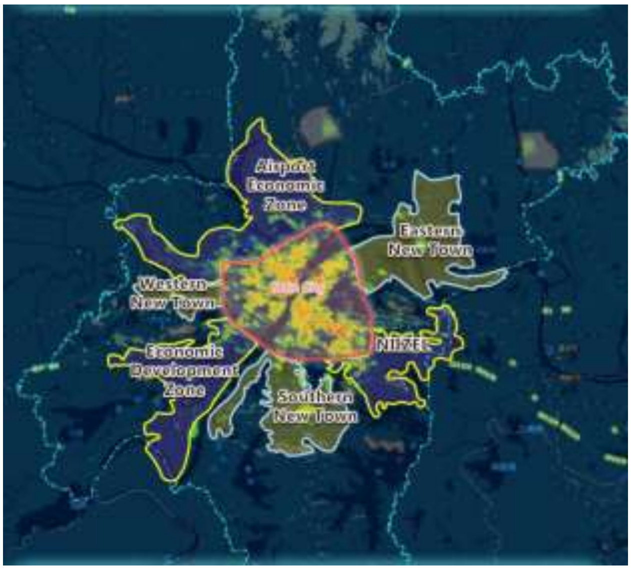

Figure 6: Analysis on the Living Activities in the Municipality

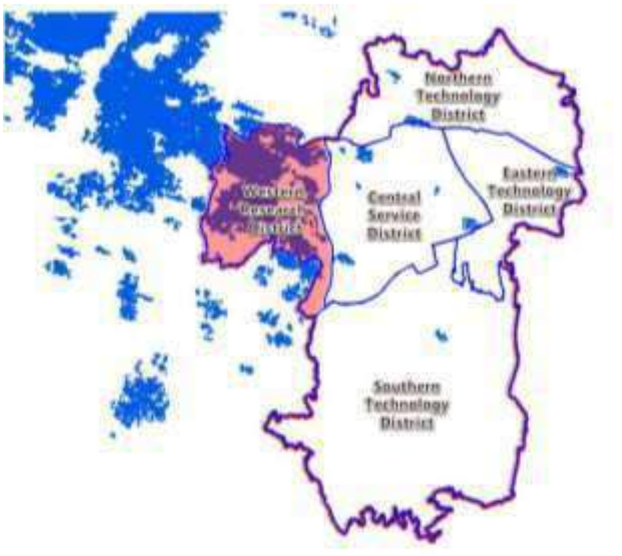

Figure 7: Analysis on the Living-dense Areas in the NIIZEL

3.2.3 Entertaining activities

Compared with working and living activities, the scale of current entertaining activities in the NIIZEL is obviously smaller, which indicates the lack of service functions. Although the percentage of entertaining-dense areas and their average densities rank the top among all the new towns, but are much lower than the main city (see Figure 8). Close to 97% of entertaining-dense areas are centralized in the Western Research District with the average and maximal densities high above the main city. By comparing the entertaining-dense areas with the spatial distribution of current retail facilities, it is evident that there have been a large number of entertaining activities in the non-commercial areas of the Western Research District, which can be considered as unofficial spaces of leisure. On the contrary, new areas like the Central Service District have lower densities of entertaining activities due to the failure of implementation of commercial lands (see Figure 9).

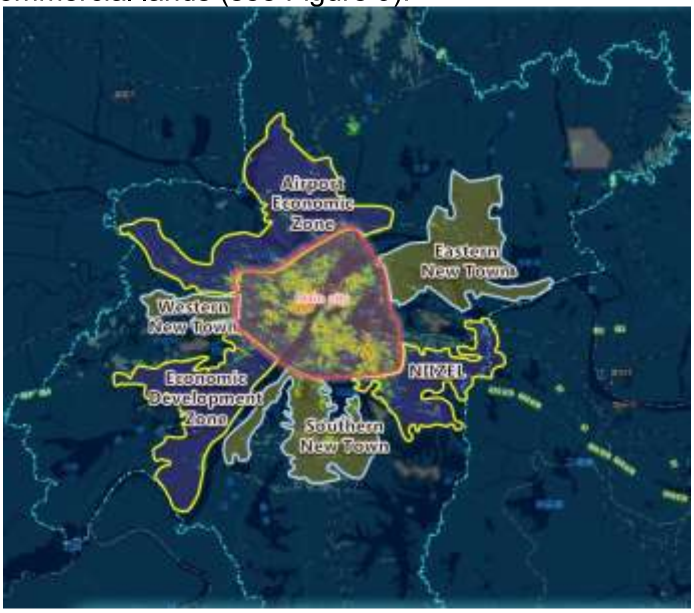

Figure 8: Analysis on the Entertaining Activities in the Municipality

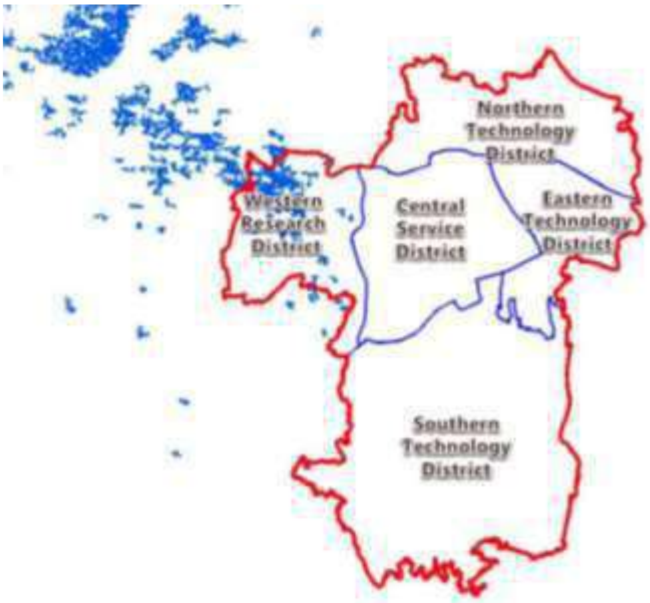

Figure 9: Analysis on the Entertaining-dense Areas in the NIIZEL

Quite unlike the ratio of local leisure to employment, the ratio of local employment to leisure ranks the bottom among the new towns, which indicates that the local service facilities of the

NIIZEL lack of influences. All the functional clusters have relatively low ratios of local employment to leisure, especially new areas like the Central Service District, the Eastern Technology District and the Northern Technology District. Most of the entertaining activities in the NIIZEL are undertaken by the people working in the Central Service District, which proves to be the most service-insufficient cluster. Although there has been a strong force of the service facilities in the Western Research District for the people working in the Central Service District, it still lacks of attraction for people working outside of the NIIZEL.

On the other hand, the ratio of local residence to leisure ranks ahead of most of the new towns, which indicates its stronger influences of service facilities for residents. Although there is an obvious difference in the efficiency of leisure functions for every cluster, the ratios of local residence to leisure for new areas are quite low. Planned as the central activity zone in the NIIZEL, the Central Service District fails to provide leisure functions for people living there who end up going to the other clusters. And the Western Research District proves to be the first choice where people living in the other four clusters who will go to entertain themselves, which indicates the district has equal influences of leisure between employment and residential functions. By analyzing the influencing areas of the leisure function of the NIIZEL, it is evident that more than 80% of the entertaining activities can attract people living and working in the circle at a radius of 15km. More specifically, they are centralized in the circle at a radius of 5km, which indicates that distance is a major factor for leisure function.

3.3 Overall Evaluations

From the scales of the municipality, functional clusters and plots of the NIIZEL, overall evaluations have been made in the aspects of amounts, influencing areas and balance indexes of the working, living and entertaining activities, so as to provide suggestions for the space supply of future activities.

3.3.1 Amounts

The amounts of working, living and entertaining activities can be used as indicators to evaluate the basic functions of employment, residence and leisure. For the NIIZEL, the amounts of working, living and entertaining activities all rank the second among all the new towns. On one hand, the amount ratio of working to living activities is close to 1, which is to some extent different from the amount ratio commuted by populations. On the other hand, the amount ratio of working to living and entertaining is fall behind other new towns, which indicates the lacking of leisure functions (see Figure 10). Specifically, there is quite a difference in the amounts of working, living and entertaining activities for every functional cluster. The entertaining activities of the Western Research District is relatively small to working and living, while the other four districts are all underdeveloped in all the activities (see Figure 11). By comparing the working, living and entertaining activities of every plots, evaluations can be made on the degrees of muti-functions. It is evident that the muti-functional plots have been centralized in the Western Research District while plots of the other four districts are mostly single-functioned. Considering the overall ratio of implementation to plan schemes has reached above 70% with the industrial functions overdeveloped than residential and leisure functions, it has been proposed to improve the degree of muti-functions for every plot unimplemented as plans so as to keep up the supplies of service facilities with rapid urbanization.

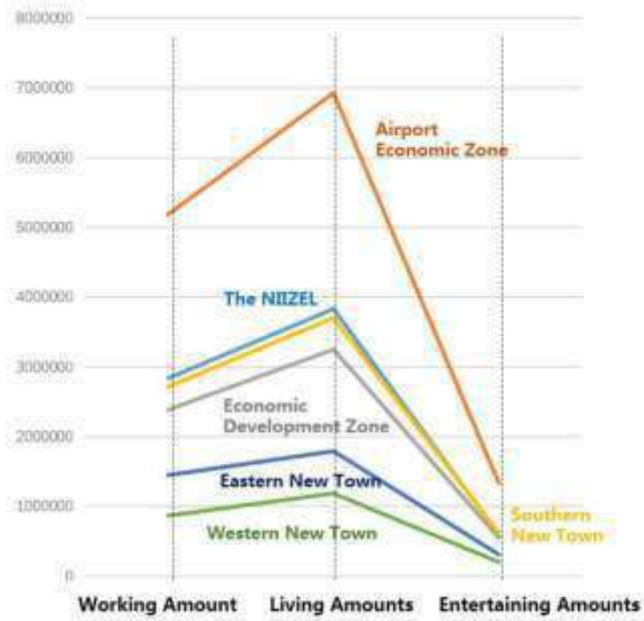

Figure 10: Analysis on the Activity Amounts in the Municipality

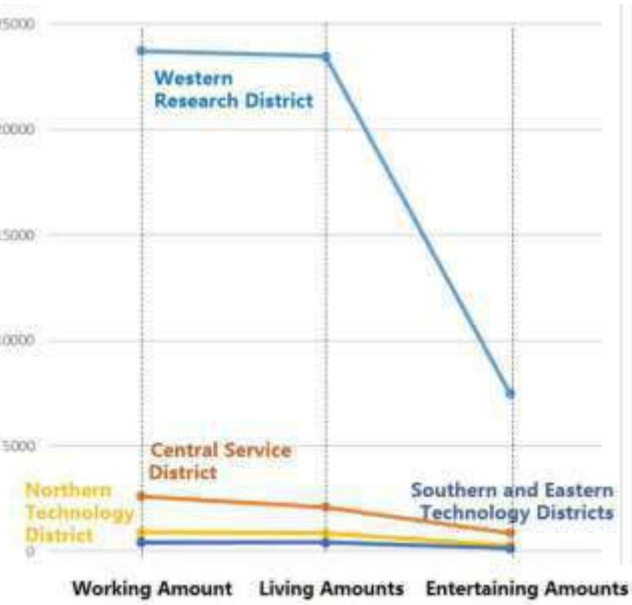

Figure 11: Analysis on the Activity Amounts in the NIIZEL

3.3.2 Influencing ranges

The influencing range can be an important indicator to evaluate the attraction and influence of some function. It is evident that the influencing ranges of the current working, living and entertaining activities are all to the south of the Yangtze River, with their amounts and ranges decreasing one by one. The working activities have the strongest pull for long-distance employment, while the living activities are more dispersed and the entertaining activities are more influenced by walk-able distances. With the implementation of the master plan, the center of the NIIZEL will move to the east. In that case, not only the influencing range of the working activities will enlarge further due to the long-distance attraction, but also the entertaining activities will probably expand the outer ring and shrink the inner ring, leading to more long-distance commutes (see Figure12). Considering the lack of regional transit for the NIIZEL at present, it is proposed that the transport planning need to be optimized at a larger scale.

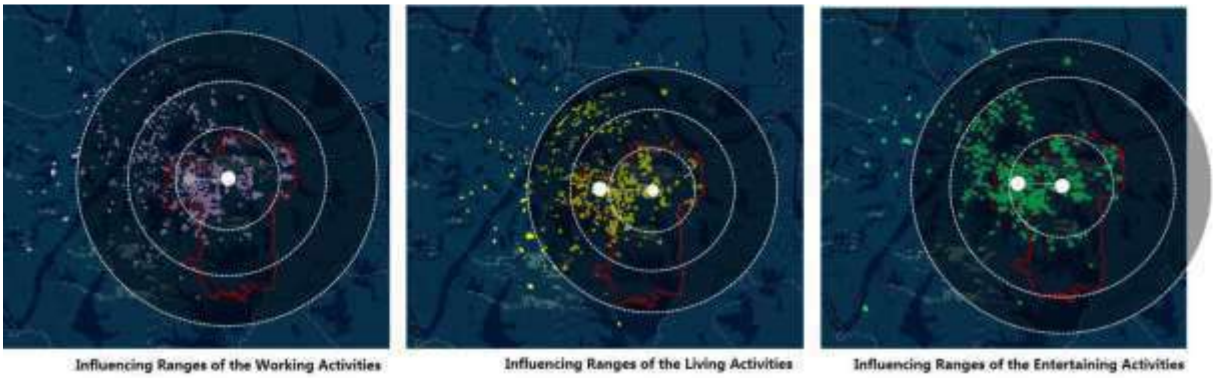

Figure 12: Analysis on the Influencing Ranges of Activities in the NIIZEL

3.3.3 Balance indexes

As an indicator to reflect the relations between the functions, balance index has been commuted as the ratio between every two of the three activities namely working, living and entertaining, which can be used to evaluate the development of new towns[4]. Except the ratios of local residence and leisure to employment are relatively low, all the balance indexes reached above the average levels of the new towns (see Figure13). Among these, the ratio of local employment to residence proves to be the highest, while the ratio of local leisure to employment is the lowest. Especially the Central Service District and the Northern Technology District which can offer large amounts of opportunities for employment though are underdeveloped with their residential and leisure functions (see Figure14). It is also evident that the Western Research District, as the connection node between the NIIZEL with other new towns, has confronted with a series of urban diseases due to its role as the only gateway. Considering the weak links between the NIIZEL with other areas and between the functional clusters, it is supposed that balances between working, living and entertaining should be kept at a smaller scale in every functional cluster or every plot. Following the standards of appropriate commuting distances between working and living as well as between living and entertaining[5], evaluations have been made for every plot of the NIIZEL from the aspects of local residence to employment, local leisure to residence and local leisure to employment (see Figure15). It is evident that the balance index of local residence to employment is relatively higher than the ratios of local leisure to residence and to employment.

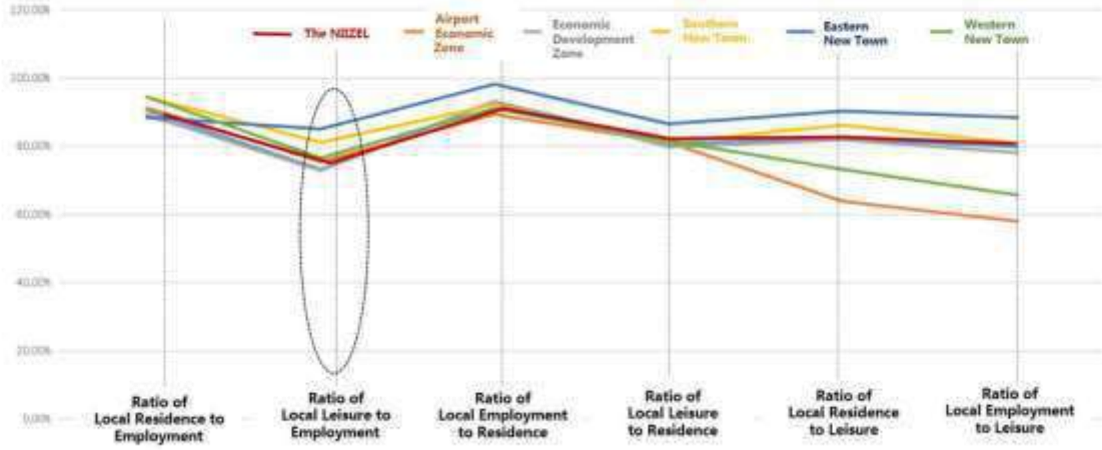

Figure 13: Analysis on the Balance Indexes of the New Towns

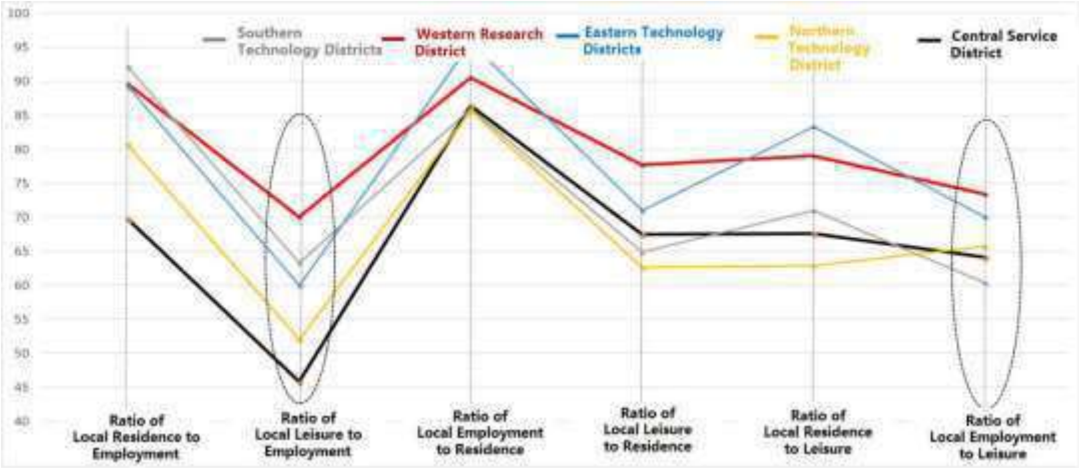

Figure 14: Analysis on the Balance Indexes of the Functional Clusters in the NIIZEL

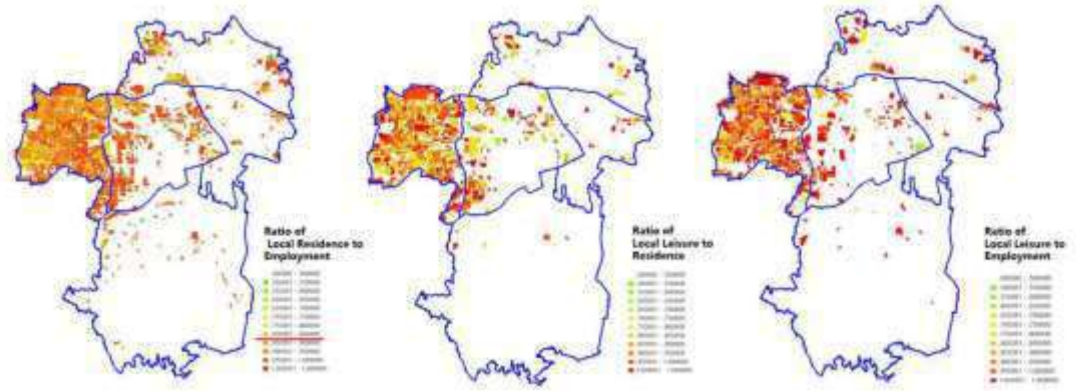

Figure 15: Analysis on the Balance Indexes of the Plots in the NIIZEL

4. Applications of the Results

By the evaluations of amounts, influencing ranges and balance indexes, it is evident that the NIIZEL has the foundations to be promoted as a more independent town. And strategies have been given at different scales to optimize planning as the applications of the results.

4.1 Strategies at the Scale of the Municipality

By analyzing the amounts of current working, living and entertaining activities, it is evident that the NIIZEL ranks far head of the other new towns and proves to be one of the major new towns in the whole municipality but with limited access. Thus the strategies at the scale of the municipality should focus on the regional functional balances to improve the access of the NIIZEL. It is proposed to improve the role of the NIIZEL further in the long-term plan and the NIIZEL should be integrated with its neighboring district considering their close connections. On one hand, the functional axes between the NIIZEL and other new towns as well as the main city should be re-stressed in the existing master plan of the municipality, so as to establish an innovation system centered at the NIIZEL. On the other hand, rapid transit including highways and metros between the NIIZEL and other new towns as well as the main city has also been suggested to make, so as to deal with the future change of the influencing ranges of human activities.

4.2 Strategies for Every Functional Cluster at the Scale of the NIIZEL

Considering the underdevelopment of functions in every cluster of the NIIZEL and the role of the Western Research District as the only gateway, it has been proposed that multiple connections should be set up between every functional cluster of the NIIZEL. Thus the strategies at the scale of every functional clusters in the NIIZEL are proposed to focus on the structural function balances by remaking connections. Based on the existing plans, suggestions have been made about adding two north-south axes on both sides of the original axis and stressing the connections between the clusters. Taking references from other innovation districts, it has been proposed that the functional clusters should be recategorized as knowledge innovation, technology innovation and service innovation models. Besides, all kinds of service centers should be added in every cluster so as to improve the rate of local leisure to employment and residence. According to the statistics of the implementation, the original spatial structure of facilities should also be optimized by upgrading the service facilities for living and adding more service facilities for working.

4.3 Strategies for every plot at the Scale of the NIIZEL

According to the evaluations at the scale of every plot in the NIIZEL, it has been proposed to stress the function balances at human scales by improving the degrees of muti-functions. Based on the current land use, missing functions have been proposed to add to the lands which haven't been implemented as plans and transits have been also suggested to rebuild for the plots with functional connections but lack of access. Then following the latest regulations on land use, optimizing work can be done by regulating the muti-functions of every plot in accordance with the regulatory plans. To fulfill the goals of function balances at human scales, the spatial modes of innovation cells have been proposed and further study will be made to give instructions on land use planning.

5. Conclusions

By using location data from mobile devices, this study attempts to analyze the spatial distributions and relations of the working, living and entertaining activities, so as to reflect the features of human behaviors. After comparing the human activities with the current and planned spaces, it proposes corresponding strategies at different scales so as to play the role of optimizing spatial supplies. As a supportive study for the Master Plan of Wuhan, some suggestions has been absorbed into the undergoing plan so as to give further instructions. Meanwhile, this study also gives a structural framework on the Wuhan Planning Lab[6], so as to play the role of evaluation, monitoring, warning and dynamic regulations. It is also necessary to mention that there is some shortcomings and problems with the data processing. On one hand, the data can only be used to recognize human activities by common senses due to the lack of behaviors information. On the other hand, the statistics can only be used to compared with and need to be expanded with a larger sample.

Endnotes

[1]Han ZOU is the corresponding author, email zouhangogo@qq.com .

[2]It has been proposed that there will be six new towns in the spatial structure of *Wuhan Master Plan (2006-2020)*, including the NIIZEL, Airport Economic Zone, Economic Development Zone, Eastern New Town, Southern New Town and Western New Town. In the Wuhan Master Plan (2016-2035), the NIIZEL, Airport Economic Zone and Economic Development Zone has been promoted as anti-magnetic forces more independent from the main city.

[3]The balance indexes have been established such as the ratio of local employment to residence and the ratio of local residence to employment. The former indicates the ratio of residents who working in a certain range to the residents, while the latter means the ratio of employees who living in a certain range to the employees.

[4]Based on the concepts like the ratio of local employment to residence and the ratio of local residence to employment, this study proposed balance indexes like the ratio of local leisure to

employment, the ratio of local leisure to residence, the ratio of local residence to leisure and the ratio of local employment to leisure.

[5]It has been proposed in the *Research on the Distribution of Current Population and Balance of Local Employment to Residence in Wuhan* that the appropriate distance between working and living is 12km and the one between living and entertaining is 15minites' walk.

[6]Wuhan Planning Lab, funded by Wuhan Planning Bureau, is an intelligent decision-making platform by using big data to describe human activities, monitor city functions, simulate urban systems and predict future space supplies.

Landscape as a service. The potentials of integrating different approaches

Sara MALDINA, University of Bologna, Italy

Abstract

The social and environmental changes that characterize our time and the awareness that has increasingly emerged about their causes, have led to a deeper consideration of the importance of landscape, not just as perceptible expression of the nature but as a provider of services, well being and sense of identity for people. In this sense, the landscape has to be conceived and managed as a driver of regeneration for rural and peri-urban regions. However, the historically transdisciplinary concept of landscape is still the object of a number of different approaches that make its evaluation and management uncertain and varied. The European Landscape Convention (ELC, 2000) is a milestone in the evolution of the meaning of landscape and an attempt to define a European comprehensive vision of the matter. At the core of the ELC definition is the landscape as "interaction of natural and/or human factors", defining it as the junction between the natural-ecosystemic sphere and the anthropic-cultural one. The contribution reports the preliminary results of a doctoral research in progress, whose main objective is to define an innovative methodology for the integration of landscape management in planning policies and practices at regional and local levels, strengthening its strategic role as socio-cultural service and as conveyer of ecosystem services. To this aim, a bibliographic analysis of the concepts of "Cultural Landscape" and "Cultural Ecosystem Services" has been carried out in order to underline the intersections and the differences between them. This conceptual framework has built the basis for a comparative analysis of a range of methods and tools for the interpretation and assessment of landscape, deriving from different approaches and disciplines.
Starting from the results of this analysis, the paper investigates the potentialities of an integrated approach to landscape assessment and management, drawing up a methodology for the integrated evaluation of the landscape.

1. Introduction

The social and environmental changes that characterize our time and the awareness that has increasingly emerged about their causes, have led to a deeper consideration of the importance of landscape, not just as perceptible expression of the nature but as a provider of services, well being and sense of identity for people.
Therefore, the historically transdisciplinary concept of landscape (Palang et al. 2006) is still the object of a number of different approaches that make its evaluation and management uncertain and varied. This has led to the proliferation of many evaluation systems that have attempted to decipher the intrinsic complexity of the landscape according to different approaches and through different lenses. Nevertheless, in many European countries, and among these Italy, these evaluations have not found an effective response in planning and practices.
Moreover, the use of different approaches in a targeted manner and without any kind of integration has led to a functional division of the landscape in which some areas have become representative of the environmental component, others of cultural values and others devoted exclusively to production. The polarization of the characteristics of the different

portions of territory has determined a banalization of the interrelated values of the landscape and the impossibility to elaborate a comprehensive strategy for it.
At the end of the last century, an increased interest in landscape management emerged, which in Europe particularly focussed on its cultural values. The first call for a landscape convention was made at the conference “Landscapes in a New Europe: Unity in Diversity” in Blois, October 1992 (Antrop, 2013). Eight years after, the European Landscape Convention has been a decisive point in the affirmation of the complex and relational nature of the landscape, but no many tools and methods have yet emerged for its application, neither on a regulatory nor operational level.
According to the ELC, the landscape should be assess on the basis of what is perceived by the populations, thus the inclusion of people at each stage of the assessment process is crucial. In the practices, more frequently the citizens are called to participate to the process only at the later stage, when the major decisions concerning the transformation have been made and the space of manoeuvre is reduced.
As Turri (2006) argues, despite the theoretical innovations in landscape studies, these have difficulties to be transferred into actions, both at the level of policies and projects, leaving the inhabitants and users frequently outside the management system. This has led in many contexts in different periods, to what has been called the *landscape crisis*. This term is used to denote the malaise and inquietude people feel because they cannot cope with the increasingly rapid changes of “their” landscape (Antrop 2005).
For these reasons, the contribution argues that there is a need for a novel trans-disciplinary operational framework to integrate the culture-oriented and the ecological approaches at the different stages of landscape evaluation and planning.
To do so the research has investigated in parallel the most advanced approaches and tools. More specifically, on one side have been studied the interrelations and divergences of the conceptual categories of Cultural Landscape and Ecosystem Services, intended as the leading edges of the ongoing process of integration. On the other side a critical analysis of a number of methods currently used for landscape evaluation has been carried out. As a results, a set of operational tools for a more comprehensive assessment of the landscape values have been drawn up. Lastly, a reflection on their applicability in the Italian context, and more specifically in the Emilian Romagna planning framework, has been developed.

2. Different approaches to landscape assessment and management

The constitutive elusiveness of the concept of landscape is reflected also in its semantic openness. The English terms “landscape”, with its related system of interpretations and translations, comprises a multiplicity of meanings that makes its significance ambiguous and intrinsically interpretable, both in the common and in the scientific language. As Antrop highlights the early stage of landscape research focused on the investigation of the exact meaning of the word (Olwig 1996; Claval 2004; Antrop 2005). Due to the impossibility to affirm a unique and exhaustive meaning, a number of adjectives have been progressively added (e.g. cultural, natural, urban, etc.) (Antrop, 2013). By affirming the multiple phenomenology of the landscape and the relation between its comprehension and the subjectivity of the observer/user, this process produced as shortcoming the complexification of the use of the term, leaving unexplained the relation among the general concept of “landscape” and its “sub-categories” (e.g. Cultural landscape, natural landscape, urban landscape, etc.).
However, it is noticed that this vagueness have created space for different disciplinary inputs that have been a stimulus for debates, attracting a wide range of interest (Conrad et al., 2011). At the end of the twentieth century different approaches in landscape research could be identified: landscape ecologist, historical geographer, humanistic and cultural geographer, landscape architects (Antrop, 2013). In parallel, moving the focus from the disciplines to the key lines of division, a number of conflictive relations could be identified: aesthetic versus ecological; preservationist versus functional and productive; special area versus whole

landscape; rural versus urban; qualitative versus quantitative; and expert versus participatory interpretations (Kidd, 2013).
Among these, the major conflict in landscape studies seems to be between the humanities and the natural sciences, which have subdivided over the time the field of landscape studies into two directions (Palang, Fry, 2003). David Cosgrove call these two discourses *ecological and semiotic.* The focus of the first, on the one side, is on the natural processes (geomorphological, climatic, biological, vegetational, etc.), their interrelations and the relations among these and human activities (Cosgrove, 2003). All these processes are studied as factors that, moulding differently portions of the territory, produce different *landscapes*. On the other side, the *semiotic* discourse focuses more on the cultural meanings, human representations and symbols that a specific area or context embodies and how these shape the natural environment. As Cosgrove affirms, while the ecological approach is often charged of an insistent pessimism (considering human activities mostly detrimental for the natural landscape), the semiotic discourse has more generally a politically progressive stance, considering it as a result of social and political dynamics (Cosgrove, 2003).
Since the beginning of the 20th century, these two spheres have produced in parallel a set of definitions, assessment methods and regulations, whose diverse results are still clearly visible in the regulative framework of many European Countries. As Tress argues, although landscape as a concept already implies interdisciplinarity, its study rarely achieves levels of theoretical integration (Tress et al. 2003).
In the last thirty years, a process has been undertaken from both sides directed to combine these two approaches, considering the landscape as a hybrid system (Hein et al. 2006, Bastian et al., 2014).
As a result, a series of *hybrid concepts* have been put forth: among them, the categories of "Cultural Landscape" introduced by the World Heritage Convention in 1992, and the "Ecosystem Services" defined by the Millennium Ecosystem Assessment in 2005, seem the ones that express better the capacities of landscape to play a strategic role in regional development.

2.1 Cultural Landscapes

The German geographer Friedrich Ratzel in the 1890s for the first time defined the term ''cultural landscape'' as ''landscape modified by human activity'' (Jones, 2003). Since then, the concept has acquired a central role in human geography and in the related disciplines.
The Cultural Landscapes, as internationally recognized categories, were introduced in the International Convention for the Protection of the World's Cultural and Natural Heritage (often referred to as the World Heritage Convention) by the United Nations Educational, Scientific, and Cultural Organization (UNESCO) in 1992.
The Convention describes the Cultural Landscapes as "the combined works of nature and of man." [1] This definition contains many of the principles that characterise the innovative approach of the category and which have been progressively in-depth deciphered through subsequent studies and publications.
The innovations led by the Convention can be summarized in three main aspects.
Firstly, the definition given by UNESCO extends the field of heritage, by attributing the Outstanding Universal Value to the relational and associative dynamics (combined works) rather than to physical objects or circumscribed areas detached from their context.
Secondly, it brings the work of man and the one of nature to the same level, affirming that no cultural landscape can be conceived without the interrelated action of the two components (natural and anthropic), and that it is the result of a process of mediation, adaptation and mutual transformation of the two.
Lastly, the use of the term "works" presupposes a process in progress, an evolutionary system that protects and regenerates its value through its transformation over time.
The Convention then defines three categories of Cultural Landscapes:

- Clearly defined landscapes designed and intentionally created by man.
- Organically evolved landscapes in two categories:

(i) A relict or fossil landscape in which an evolutionary process has come to an end but where its distinguishing features are still visible.
(ii) Continuing landscape which retains an active social role in contemporary society associated with a traditional way of life and in which the evolutionary process is still in progress and where it exhibits significant material evidence of its evolution over time.

- Associative cultural landscapes: the inclusion of such landscapes is justifiable by virtue of the powerful religious, artistic or cultural associations of the natural element rather than the material cultural evidence.

This category, especially if related to other declarations and documents issued by UNESCO, marks an evolution of the approach to heritage and the cultural approach to the landscape. In particular, it affirms that the variously defined social body, is a builder, interpreter and custodian of heritage and landscape and that a new approach is need to include into the living dimension of the communities.
The last one is particularly interesting because it strives for the inclusion of heritage and landscape in a project *for the future*.

2.2 Ecosystem Services, Cultural Ecosystem Services and Landscape Services

The ecosystem services framework has been developed in response to the substantially exploitation, degradation, and destroy of ecosystems and natural resources occurred in the last century as consequence of the global increase of economic and societal prosperity (MEA, 2005). At the core of the Ecosystem Services framework there is the awareness that environment provides food, raw material, energy, and other natural resources, but also non-material services such as symbolic and aesthetic values (MEA, 2005).
The concept of ecosystem services can be defined as an interdisciplinary concept, not for its origin, but for its aim to reveal the relation between natural ecosystems and the living community, evaluating the benefits that it can produces. Thanks to the the concept of ‘‘service’’, it converts ecological components and processes into recognizable terms in the social system (Daily, 1997).
The Ecosystem Services have been subdivided in four categories, according to their “functions”: supporting services, provisioning services, regulating services, cultural services. The latter results particularly interesting as *hybrid concept*, connecting the ecosystem with the cultural values, knowledge and experiences that the *users* can benefit.
The Cultural Ecosystem Services (CES) are commonly defined as the ‘nonmaterial benefits that people obtain from ecosystems through spiritual enrichment, cognitive development, reflection, recreation, and aesthetic experience, including, e.g., knowledge systems, social relations, and aesthetic values’ (MA, 2005). In other words, they are ecosystems’ contribution to the nonmaterial benefits (e.g., experiences, capabilities) that people derive from human‐ecological relations (Chan et al. 2012). As Fish argues, the Cultural Ecosystem Services are to be understood not as part of subject-object ontology - as a priori products of nature that people utilize for a particular benefit to well-being - but rather as relational processes and entities that people actively create and express through interactions with ecosystems. Thus, the philosophy behind the framework is relational (Fish et al. 2016).
From this overview emerges that Cultural Ecosystem Services represent a relevant category to investigate and assess the multiple values of landscape. Nevertheless, expanding the analysis to all the range of Ecosystem Services, it becomes clear that the landscape dimension is present also in other categories of ES. While the landscape is intrinsically integrated in CES for their focus on the *experience*, in providing, regulating and supporting services the landscape emerges when they have a spatial connotation.

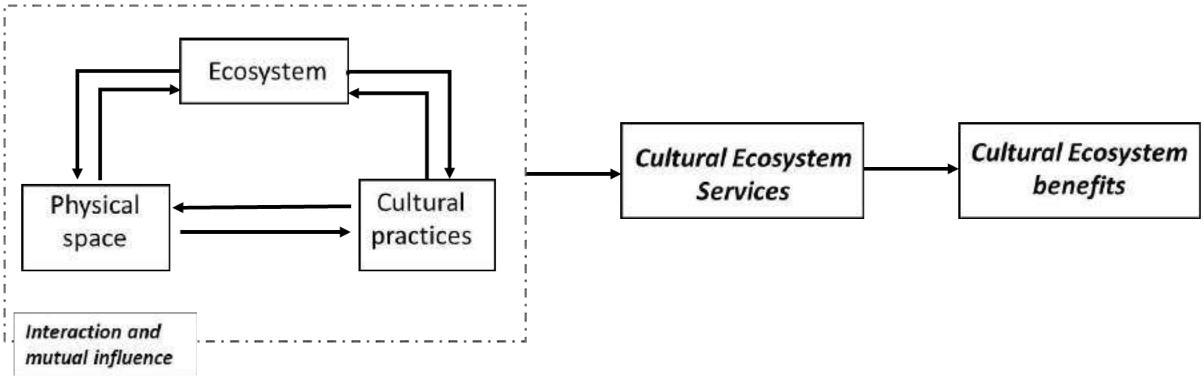

Figure 1: Conceptual framework of the Cultural Ecosystem Services

This reflection has led to delineate a particular transversal sub-category, the Landscape Services, which has acquired relevance in the last ten years (e.g. Burkhardt et al. 2009; Termorshuizen and Opdam 2009; Willemen et al. 2012; Wu 2013; Bastian et al. 2014). These have been defined as the contributions of landscapes and landscape elements to human well-being (Bastian et al. 2014).

According to the literature abovementioned, the Landscape Services, as compared with the general definition of ES, are characterized by a more site-specific and contextual perspective, a stronger focus on human action, a more operational and participative approach. As O'Neill argues, the term *landscape* reveals the importance of the spatial structures and their relation within a specific context (horizontal – on the surface), whereas the word *ecosystem* emphasizes the relationship (vertical – in depth) between ecosystem components (O'Neill 2001). Lastly the term *service* brings out the functional utility of them for the human beings and introduces in the concept the temporal dimension (process relationship).

The category of Landscape Ecosystem Service is not to be considered as an alternative to other ES, but rather a transversal sub-category where are included all the ES having the characteristics outlined (spatial dimension and context specificity, focus on human action, potential to be managed with a strategic and progressive approach).

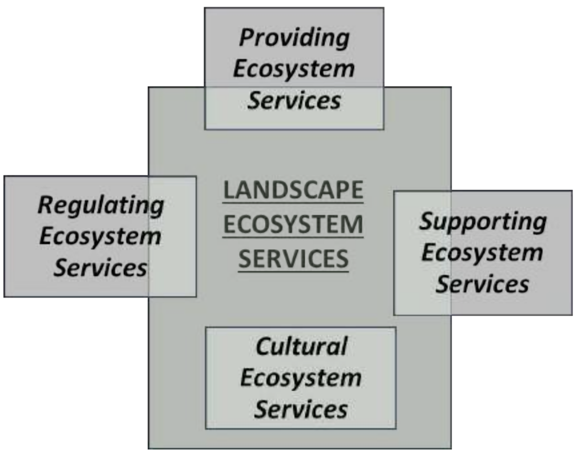

Figure 2: Relation among the Landscape Ecosystem Services and the Ecosystem Services defined by the MA (2005).

In this way the Landscape Ecosystem Services could contribute to shift the approach of ecosystem and landscape management from the pessimistic and conservative perspective (Cosgrove 2003) to a progressive and future-oriented one.

2.3 Heritage or service: a comparative analysis of different approaches

To build a structured comparison of the concepts introduced in the previous paragraphs, they have been analysed in relation to six themes: the areas of application, the types of elements prevailing in the assessment, the types of assets, the temporal dimension, the assessment methods, and the prevailing approach in terms of governance and process management. In relation to these, a reflection on the main advantages and shortcomings of each concept has been developed in order to outline a potential direction for a novel transdisciplinar perspective.

Considering the areas of application, the category of Cultural Landscape, having been introduced by UNESCO, has always appeared apt to be used for areas with exceptional characters, or even reducing the field, with those having Outstanding Universal Value. Nevertheless, in terms of approach, it is possible to apply the concept to non-exceptional landscapes, although the great emphasis given to the material traces of the past makes difficult its application to the "everyday landscapes". Both CES and Landscape Ecosystem Services can be applied to the whole territory. However, as already expressed, the Landscape Ecosystem Services tend to have a better defined spatial dimension and are therefore more suitable for context analysis.

For what concerns the prevailing elements in the evaluation, differences can be detected, depending on the relation between *man* and *nature* that underpins each category. Here the terms *nature* is wide and includes also the ecosystems and the relation among them (following the "dwelling theory" of Ingold, 2000).

The figure 3 briefly shows for each concept if it has relate to a specific landscape context, the relation between nature and man, and the type of assets on which the assessment focuses primarily. It is interesting to note the particular human-nature relation in the framework of LES; as Limburg argues, the landscape services are services usable by man resulting from its interaction with the landscape (Limburg, 2002), emphasizing the interaction between a physical system and the variety of use and non-use values recognized by man. So the landscape services exist only because there is a community using them and giving value to the landscape, in an essentially anthropocentric perspective (de Groot 2010).

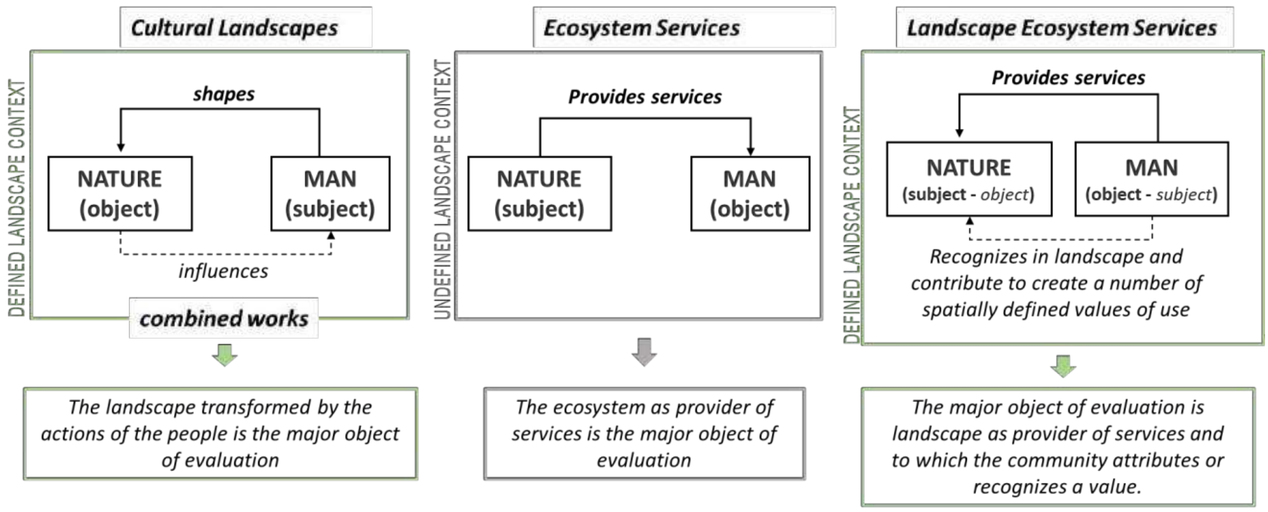

Figure 3: Nature-man relation and major object of evaluation in Cultural Landscape, Ecosystem Services and Landscape Ecosystem Services approaches.

Referring to the temporal dimension, the CL approach, deriving from the long-lasting conservation tradition, focuses on the time-depth detectable experiencing the landscape. The services approach is based on the capacity to respond to current needs and therefore it is intrinsically contemporary. This difference is crucial and determines the use of different evaluation methods. The Cultural Landscape approach privileges the classical methods of the historical geography (e.g. archives research, archaeological research, land use maps and aerial photograph analysis, inventories of historic features, etc.). Differently, in the assessment of cultural ecosystem services, qualitative research (mainly referring to the socio-economics tradition) plays a stronger role.
The temporal dimension analysed and the methods used are in strict relation to the governance models put into place. Due to the conservative approach that implicitly underpins the Cultural Landscape approach (at least in the practices), the evaluation and the actions are mostly defined according to top-down models. Nevertheless is worth noting the emerging of phenomena of bottom-up promotion of cultural landscapes, when it is understood by the people as a way to achieve an economic sustainable development.[2]

	Cultural landscapes	***Cultural ecosystem services***	***Landscape ecosystem service***
Definition	The combined works of nature and of man	The ecosystems contribution to the nonmaterial benefits that people derive from human‐ecological relations.	The contributions of landscapes and landscape elements to human well-being.
Areas of application	Landscapes with distinctive characters	All the territory	All the territory
Elements prevailing in the evaluation	Anthropic elements	Natural / environmental elements	Balance among Natural / environmental elements and anthropic-cultural features.
Temporal dimension	Time evolution (time-depth)	Present situation	Present situation
Types of assets	Mainly tangible heritage	Mainly intangible heritage	Intangible heritage
Evaluation methods	Mainly qualitative (experts opinion)	Quantitative and qualitative (mainly based on questionnaires)	Qualitative and quantitative (depending on the type of ES)
Governance approach	Mostly top-down	Top-down and bottom-up	Top-down and bottom-up

From this analysis, emerge the different shortcomings of the investigated approaches: for what concerns the Cultural Landscape approach the main limitations derive from its difficulty to be applicate to all the territory and a conservatory vision that persists although several publications by UNESCO have underlined the permanently evolving nature of landscapes (e.g. Mitchell N. 2009). In the same way, several shortcomings of the current Ecosystem Services approach have been widely detected: among them the more critical is the inherently exploitative human–nature relationship and the risk of a commodification of the environment. In addition, from an operational perspective, the Cultural Ecosystem Services have a mediated relation to the territory and therefore they seem not able to evaluate the value or the state of a landscape. Landscape Ecosystem Services have the greater potential to innovate the landscape management and planning; nevertheless, at this stage it results still a weak concept (built by the combination of two already hybrid concepts) that has not reach a comprehensive and shared definition.
Lastly, the three approaches, even when have been transferred into operative tools[3], they have been rarely incorporated into planning policies and instruments, so that it is evident a gap between the theoretical framework and the planning practices.

3. The potential of integrating approaches and methods

The limitations and shortcomings identified in the previous paragraphs bring out the potential of incorporating the concept of Ecosystem Services and the more traditional culture-centric

methods of landscape assessment. As de Groot argues, this integration could "enhance landscape performance and make planning become sensitive to the non-linear relations between landscape change and its performance" (de Groot et al. 2010). Moreover the need to understand from one side the characteristic of the landscape at the very local level and from the other side the perceptions of the population makes evident the convenience to embrace a trans-disciplinary approach. The ecosystem services, being very concretely experienced by people, could play a role in building a collective view on the future of a landscape and be a motive for collective actions (Bastian et al. 2014).
To do so a methodology for an integrated landscape assessment has been drawn up. This has been elaborated starting from the conceptual framework described above and based on the results of previous experiences[4], pursuing the criteria of feasibility and effectiveness. With the objective to achieve a strong integration of the methodology into a specific planning, it is being currently implemented in a case study in the Emilia Romagna Region, in Italy. Although this adaptation to a specific context could reduce the replicability of the methods, it greatly increases the possibility of its effective use.
The landscape assessment methodology here proposed aims at integrating landscape planning within the two main levels of governance: the regional level, which identifies the characters of the landscape and defines the general strategies, and the local level that should incorporate in them the specific needs of the related area. Through the trans-disciplinary integration of Landscape Ecosystem Services in planning, the local dimension can acquire greater importance as the one primarily responsible for land management and capable of gather the aspirations and the will of the people.
The methodology consists of two phases, a quantitative analysis through indicators and a consultative-participatory one. This subdivision follows Tudor's assertion that the landscape analysis shall distinguish the characteristics (assessment) from its value (evaluation) (Tudor 2014). The first step aims at identifying the characters of landscape, while the second endeavours to quantify the values deriving from the functions that the landscape performs in relation to the users' needs and aspirations. The indicators used on the first phase have been defined on the basis of the literature (e.g. OECD 2001, Limburg 2002, Feld 2007, Fisher 2009, Nogué 2009, Cassatella and Peano 2011, Cassatella and Seardo 2015, Albert 2016) and validated by a pool of international and local experts. This indicators cover nine specific areas, five referring to the intrinsic characters of the landscape (geographical setting, natural and environmental resources, historical and cultural features, perceptive and aesthetic characters functions and territorial structures) and four to the Landscape Ecosystem Services it provides (cultural, providing, regulating and supporting).
Already in this first phase the methodology envisages a multi-level and trans-disciplinary exchange. In relation to the specific context of the Emilia Romagna Region, it has been verified that most of the data required can be collected and processed at regional level; for few of them field surveys or local consultations could be foreseen. The aim of this phase is to determine the characteristics of the landscape, in an easily representative way and by means of comparable data on a large scale. On the basis of these values, the Regional Authority will be able to determine landscape attributes in relation to which specific regeneration, valorisation and conservation strategies could be defined.
The second phase of participation envisages a first consultative moment in which citizens are called to validate the results emerged from the indicators assessment by proceeding to refine the input data regarding specific issues. Then, a second phase of participation opens for the definition of actions to preserve and enhance the ecosystem services of the specific landscape.

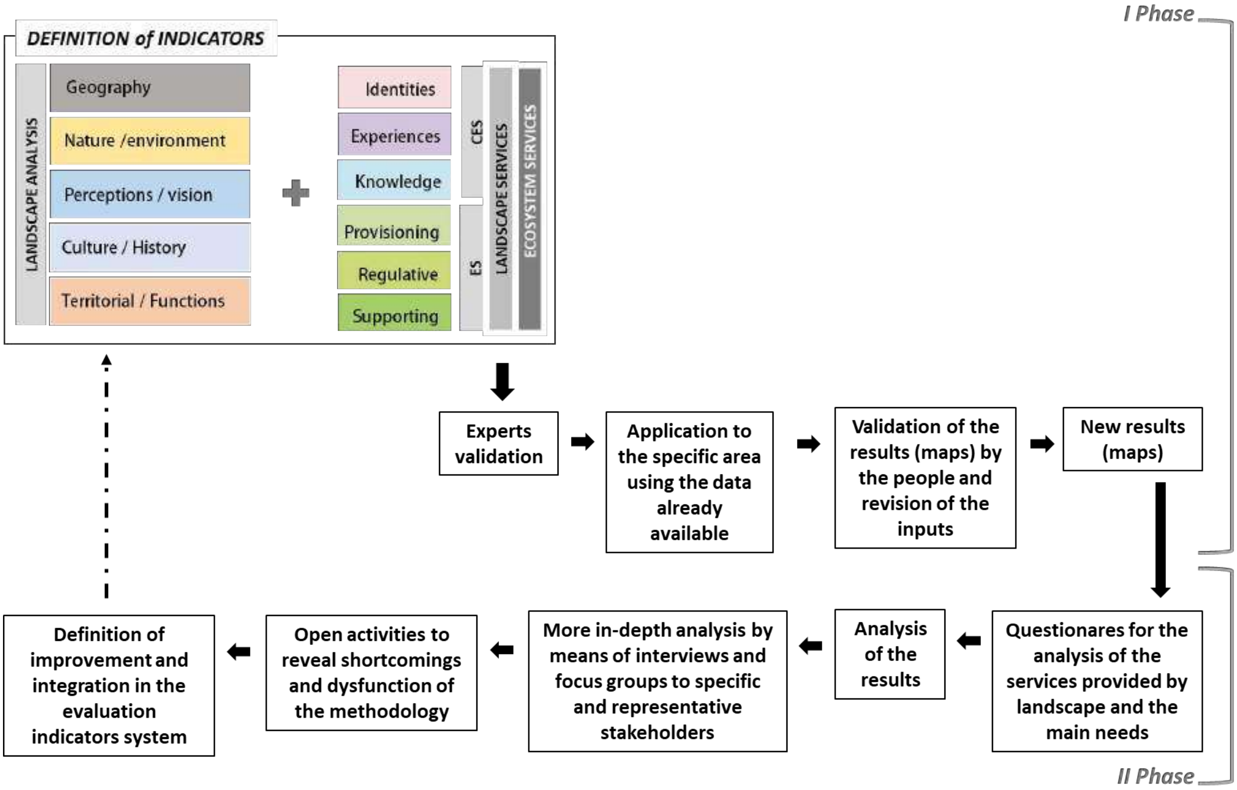

Figure 6: The methodology

This methodology, based on different conceptual frameworks and through the use of very diverse methods has the objective to give to landscape planning a more operational and effective stance. In this direction, in particular:

- It provides a set of quantifiable and comparable data as a base for the definition of grounded strategies;
- The integration of *long-term* conservative approaches and the *ready-to-use* services approaches relates the action of the present-time with the dimension of the *History* and the *future*;
- It comprises data referring to different approaches putting in evidence the interrelation among them;
- It works in parallel at different governance level, transferring to the policies the *multiscale charachter* of landscape and ecosystems;
- The assessment is not meant to define sectors, or landscape units, but variable geometries, enhancing the heterogeneity of landscapes rather than their repetitive patterns;
- The participation of the people in the assessment phase will ensure the inclusion of their perceptions, needs and aspirations and will contribute to refine and adjust the results of the assessment through indicators.

The overall goal of the outlined process is to enhance the role of landscape as provider of services and human values, as sensible representation of the interrelation between the man and the ecosystem, as driver of sustainable regional regeneration.

4. Conclusions

Landscape can play a fundamental role as a driver of sustainable development, not only for rural areas with particular aesthetic, environmental or cultural values, but also for those transformed or *everyday landscapes* that often lack of services, recognition and identity

values. However, despite the interdisciplinary origin of the concept, for a long time the landscape has been sheathed in disciplinary subdivisions, preventing an overall vision and leading to a sectorialization that often finds little evidence in reality.
The integration on the one hand of broader and more progressive approaches to heritage (such as those of Cultural Landscapes) and, on the other hand, of the Ecosystem Services approach can redefine a conceptual framework in which are explicitly manifested the mutual benefits that man and the environment can derive from the correct management of the landscape.
The evaluation methodology proposed and briefly outlined here represents an attempt to combine an objective, replicable and comparable analysis with a participatory approach. This aims to avoid subjective analysis and top-down approaches, which can lead to stereotypizations and banalization of landscapes.
In this sense, the promotion of the landscape as a service seems to be full of potential for different reasons. Firstly, the landscape is brought back from the aural, aesthetic and cultural dimension to the present and the everyday. Secondly, the concept of service allows to express its potential in improving the quality of live, in terms e.g. of needs satisfaction, risks prevention and pollution mitigation, social and economic development.
However, some critical issues should be noted, such as the difficulty in translating these values into policies and projects, which often clash with structural barriers such as the fragmentation of private property, the absence of adequate business and governance tools, the lack of effectiveness of public action. Furthermore, the economic-based evaluation approach of the Ecosystem Services raises the risk of a commodification of the landscape and the radicalization of the tourism exploitation processes already under way in many areas. Finally, the non-implementation of participatory actions or their reduction to consensus building tools can lead to the dissolution of the added value of the services approach, regressing the landscape to a marginal or frozen space in the planning framework. On the contrary, fostering the idea of the landscape as a service for the community, in its broader meaning, can mobilize the participation of citizens, even the activism. This offers the possibility of promoting more inclusive policies, empowering the stakeholders and increasing the collective awareness of the role of human - environment interactions in determining our common destiny, reinforcing a sense of personal responsibility also in terms of sustainability and resilience.

Development of Land-Use Suitability Assessment Criteria for South Africa

Mthobisi MASINGA, Peter NJENGA, Dr Brian MUBIWA, Mac MASHIRI, Maartin FRIEDRICH, KENA Consult (Pty) Ltd, South Africa.

1. Background to the Project

Land as a resource is limited in nature and its use is not only determined by the user but also by the capability of that land to sustain productive activities. Land capability in turn is governed by the different land attributes such as the type of soil, underlying geology, topography and hydrology. These attributes define the extent to which land can be put to competing purposes in order to optimize its return. Currently a criteria or a scientific basis for the selection of the most appropriate and sustainable use of land for a particular area does not exist in South Africa. For example, agriculture, commercial development, creation of conservation areas and urban development are crucial for the growth of South Africa's economy, but when confronted with competing potential uses, it is currently not clear how the choices are to be made in an objective, transparent and consistent manner. It is evident that currently, certain land activities are practiced on unsuitable lands and this problem is likely to persist in future if not addressed. Little has been done to model and project land performance for various competing uses going into the future.

It is against this backdrop that the Department of Rural Development and Land Reform (DRDLR) commissioned a project to develop Land Use Suitability Assessment Criteria (LUSAC) for South Africa. LUSAC is an important tool in bringing to effect the provisions of the recently enacted Spatial Planning and Land Use Management Act (SPLUMA, 2013). SPLUMA seeks to promote consistency and uniformity in procedures and decision-making processes related to spatial planning and land use management. Among the key changes brought by SPLUMA is the confirmation of municipalities as authorities of first instance in matters of land development and land use management. The broad principle is that the vast majority of land use and spatial planning decisions are to be taken at municipal level. Section 20 of SPLUMA requires a municipality to prepare a Spatial Development Framework (SDF) one of whose functions is to guide development and the identification of land that is suitable for various types of developments.

In order to achieve the above, it is necessary that land suitability assessments are carried out on land before any developments are implemented. The tool would also assist municipalities in preparing land use schemes and SDFs as they would have the knowledge of what is more suitable and viable before undertaking the process. The content of Municipal SDF is comprehensively described in Part E Section 21 of SPLUMA. Elements of the SDF require that assessment practices towards future land use demarcation or identification be introduced. The requirements that are relevant to Land Use Assessment criteria and that must be in the SDF include:

- A written and spatial representation of a five-year spatial development plan for the spatial form of the municipality.

- A longer term spatial development vision statement for the municipal area which indicates a desired spatial growth and development pattern for the next 10 to 20 years.
- Estimates of the demand for housing units across different socioeconomic categories and the planned location and density of future housing developments.
- Identify, quantify and provide location requirements of engineering infrastructure and services provision for existing and future development needs for the next five years.
- Identification and designation of areas where a national or provincial inclusionary housing policy may be applicable.
- A strategic assessment of the environmental pressures and opportunities within the municipal area, including the spatial location of environmental sensitivities, high potential agricultural land and coastal access strips, where applicable, and
- Determination of the purpose, desired impact and structure of the land use management scheme to apply in that municipal area.

Equipping municipalities with the tools necessary to undertake these assessments would go a long way in supporting efficiency and effectiveness of the preparation and implementation of land use schemes and SDFs. When applied, the criteria would help rank various potential land uses where the land is capable of being used for multiple purposes. Embedded within the criteria will be clear procedures and processes to be followed to enable the generation of optimal land-use models or a mix of land-uses that yield the *"highest" overall cumulative suitability*.

It is however appropriate to mention here that regardless of the quality and performance of the proposed tool, the final decisions on how land uses are allocated will be based on consultations, and the integrity of the decisions by those vested with the responsibility of making such decisions. This implies that issues of governance, efficient and sustainable use, are among other key underpins of Land Use Suitability Assessment Criteria (LUSAC).

2. The Concept of a Land Use Suitability Assessment

Broadly defined, land-use suitability analysis aims at identifying the most appropriate spatial pattern for future land-uses according to specific requirements, preferences, or predictors of some activities. It relates to land performance when used for a specified purpose, based on an evaluation of the land form, soils type, vegetation, geology, topography and other features in order to resolve competing potential uses within a framework of the applicable proposed developments

Every portion of the Earth's landscape is characterized by a different set of features that render it more suitable for certain uses than others. Land Use Suitability Criteria consist of three main elements:

- ***The Land*** – ground or soil of a specified situation, nature, or quality
- ***Suitability*** – adapted to a use or purpose, and
- ***Analysis*** – the process of separating of the whole into its component parts, and therefore allowing structured decision making.

Based on the above 3 components, land suitability analysis is the separation of the nature or quality of land into its component parts based on the land's ability to serve a particular use or purpose. ***"High land suitability"*** means the land has relatively high numbers of the component parts in favour of its use for a particular purpose, while ***"low***

land suitability" means the land has relatively low numbers of the component parts it needs to serve a particular use or purpose.

Land suitability assessment has two sides to it. It involves classification of characteristics according to their suitability for a particular activity, that is to say, identification of which land use is to apply in some given circumstances. The second element of the analysis defines where the best site to apply a particular type of land use is located given a set of potential alternative sites. The explicit site search analysis determines not only the site's suitability but also its spatial characteristics such as its shape, contiguity, and/or compactness by aggregating the basic units of observations according to some criteria.

The value of land quality is the function of the assessment and grouping of land types into orders and classes in the framework of their suitability – generally categorized as suitable (S) and not suitable (N). These suitability classes can then be further sub-divided, as required. In practice, three classes (S1, S2 and S3) are often used to distinguish land that is ***highly suitable, moderately suitable and marginally suitable*** for a particular use. Two classes of 'not suitable' can usefully distinguish land that is unsuitable for a particular use at present but which might be useable in future (N1), from land that offers no prospect of being so used (N2).

The procedure for optimizing land use allocation will depend on whether the land uses are compatible or conflicting. When the land uses are compatible, technically there is no pressure to allocate land for alternative uses, hence the allocation is based on a descending measure of overall or cumulative suitability for the compatible land uses. However, the optimal land use allocation procedure is a bit more complicated when the objectives are conflicting. In this case, allocations are exclusionary, that is land units can only be allocated to one use only. Mendoza (1997) advised a prioritized allocation to solve this problem that is the land uses are compared in terms of priority. Allocation is done to the land use rated as the highest priority. Then allocation of remaining land units is done for the lower priority land uses.

Land Use Suitability Assessment can be a powerful tool in support of Land Use Planning. It involves all kinds of urban and rural land use such as agriculture, forestry, wildlife conservation, tourism, transportation, water resources and industries among others. It is an important part of forward planning as it provides a predictive framework on the suitability of the land for different demands and the consequences of such demand on the environment. Land suitability inventory provides feasibility information to developers and investors on the possible location of various investments and the limitations therein.

3. Multi-Criteria Decision Analysis as an Underpinning Principle

In our daily lives, we usually use multiple-criteria analysis to implicitly make regular decisions such as what to buy, where to live and what to eat. We are often comfortable with the consequences of such decisions even when they are made based on our mental frame or intuition.

On the other hand, when stakes and the costs of consequences are high, it is important to properly structure the problem into various options and explicitly use a multiple criteria analysis to determine the attendant trade-offs between the choices. In making the decision of whether to build a nuclear power plant or not, and where to build it, there are not only very complex issues involving multiple criteria analysis, but also multiple parties who are deeply affected from the consequences. Structuring complex problems well, and considering multiple criteria explicitly, may lead to more informed and better decisions.

Land use suitability assessment is inherently a multi-criteria issue, that is to say, it is a decision making problem process that involves consideration of a variety of factors to identify the use that leads to the best possible range of outcome for society. The principal problem of land suitability analysis is to measure both the individual and cumulative effects of the different factors on land.

Multi-Criteria Decision Analysis, or MCDA, is a valuable tool that we can apply to many complex decisions. It is most applicable to solving problems that are characterized as a choice among alternatives. It has all the characteristics of a useful decision support tool. It helps in focusing on what is important, is logical and consistent, and is easy to use. At its core, MCDA is useful for:

- Dividing the decision into smaller, more understandable parts
- Analysing each part, and
- Integrating the parts to produce a meaningful solution.

3.1 GIS and Multi-Decision Analysis Criteria

Use of GIS is the centrepiece of the recommended methodological approach. The strength of a GIS environment is that it allows for the development of integrated GIS-based multi-criteria approaches and model(s) which combine the spatial capabilities of GIS with multi-criteria analytical capabilities. Fundamentally, integrated GIS-based multi-criteria approaches to site (land-use) suitability take into consideration the different factors (i.e. both the socio-economic and biophysical land parameters) affecting suitability of the site/land, as well as specific land uses. The factors include (but are not limited to) natural system constraints, compatibility with existing land-uses and development patterns, existing land-use policies, and the availability of community facilities. The map analysis techniques in GIS-based site (land) suitability assessments include (but are not limited to):

- Retrieval and reclassification
- Measuring distance and connectivity
- Characterizing and summarizing neighbourhoods, and
- Overlay (combination of various datasets) techniques.

Within a GIS environment, an MCDA framework is developed for both *site (land-use) suitability analysis* and *land allocation*. Although, one is distinct from the other, the former serves as a basis for the later. The MCDA framework captures the multi-criteria nature of land-suitability assessment/evaluation/analysis, and simultaneously allocates land by maximizing overall suitability of a land area.

GIS is an enabler of site (land-use) suitability analysis as well as the intricately linked land-use allocation. This, it does, by integrating the various elements needed for this entire assessment process (refer to Figure 1). GIS creates a convenient and powerful platform which integrates cross-sectional datasets (i.e. vector and/or raster) and Multi-Criteria Evaluation (MCE) and allocation methods (approaches and indices) all within a MCDM framework. Having linked all these facets, GIS goes on to enable spatial analysis, through both quantitative and qualitative techniques (e.g. reclassification, measuring distance and connectivity, buffering, overlay, etc.). The outcomes of this integrated GIS-based process include: decision making tools/products such as land-use models/scenarios, and optimal land-use mixes (which optimize cumulative suitability).

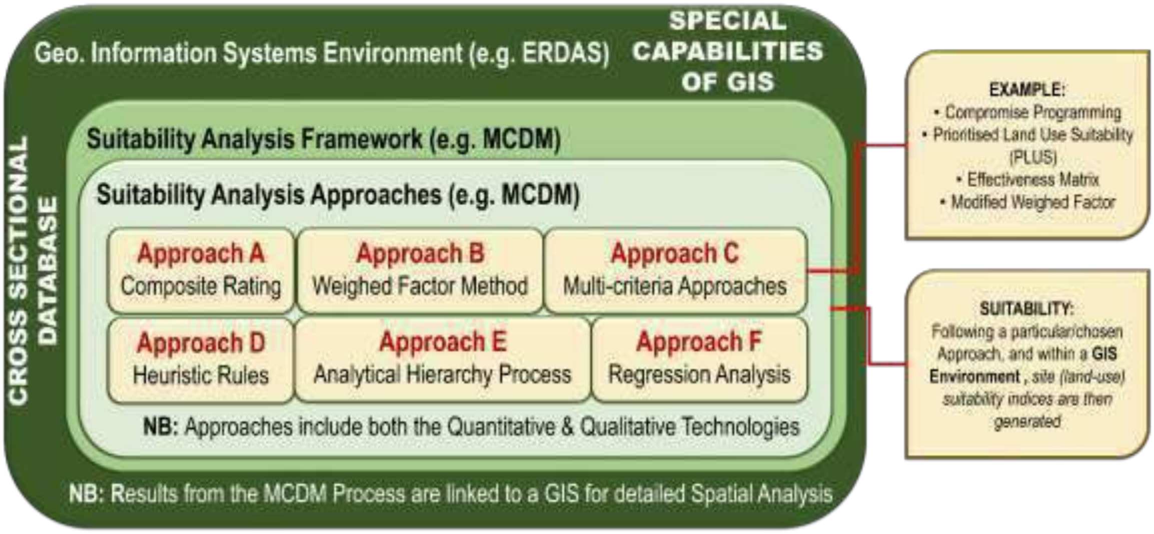

Figure 1: Land Suitability Analysis, MCDM and GIS interface

It should be noted that GIS has been used extensively to develop decision-making tools (particularly maps) to enable the evaluation of site suitability and the assignment of various measures or attributes of suitability to specific sites or geographic areas. Presented in the following sections are a select few exemplar cases from South Africa and elsewhere (international), respectively.

4. The Proposed Tool: A Two-Pronged Sustainability Approach

The proposed and use suitability model consists of two major sub-models. The first is a ***Developability index*** and the second a ***Desirability index*** (refer to Figure 2 below).

Figure 2: The two components of the criteria

4.1 The Developability Index

Developability includes criteria which are in most cases non-negotiable (e.g. very steep slopes). The Developability criteria are mostly natural and policy constraints which makes development impossible or very costly. A non-negotiable criteria item may cause certain areas to be "no-go" areas for development and are removed very early in the process.

4.2 The Desirability Index

Desirability criteria are mostly qualitative in nature. In most cases all the areas are developable, but the degree of desirability differs (e.g. it is more desirable in terms of travel cost to live close to employment centres than far from them). Most desirability criteria are negotiable and different values (weights) can be given to each. A low value (weight) given to an area does not mean it is a "no-go" area.

4.3 The Main Information Pillars of the Model

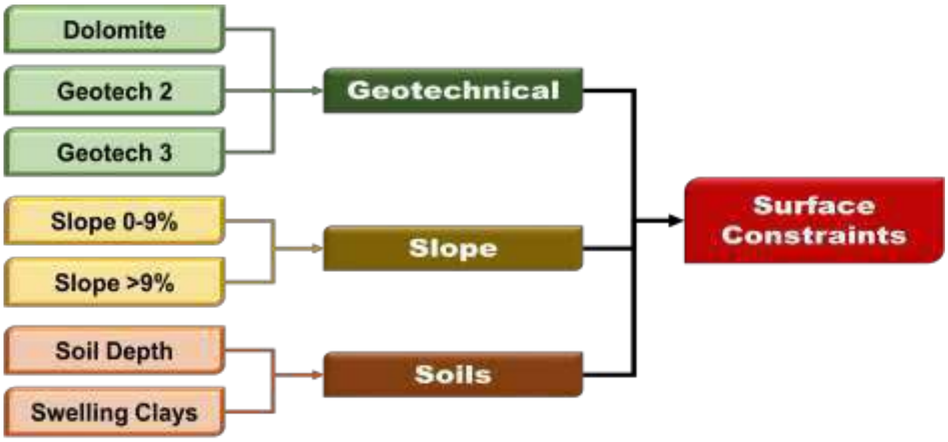
The second level of the proposed land suitability tool is based on major information pillars. The developability and desirability sub-models get informed by various relevant information topics. The following paragraphs describe each of these topics.

4.3.1 Developability

Figure 3: Sub-components of developability index

4.3.1.1 Surface Constraints

Surface constraints includes slope, geo-technical conditions and soils (refer to Figure 4 below) that are in some cases regarded as no-go areas and in other cases may be very costly to develop on.



- ***Geotechnical constrains*** includes no-go areas such as dolomite as well as other geological conditions that either is unsafe or costly to develop
- ***Slope*** has a cost impact on development and un-developability at steeper slopes
- ***Soil*** has a cost impact on development and may also impact on development timeframes

4.3.2 Desirability

As noted previously, desirability criteria are mostly qualitative in nature. They involve value judgments of what is desirable or ideal and even when an area scores low on desirability for a certain development, it does not totally disqualify it. The desirability index consists of the following 4 sub-models as shown in Figure 3 below:

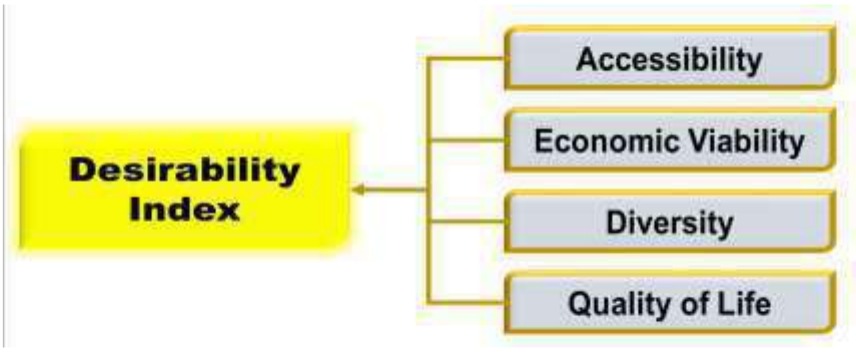


Figure 3: Sub-models of the Desirability Index

4.3.2.1 Economic Viability

Figure 4 below shows that economic viability is underpinned by the assumption that areas with demonstrated economic potential provide greater livelihood and income protection because of a greater diversity of income sources.

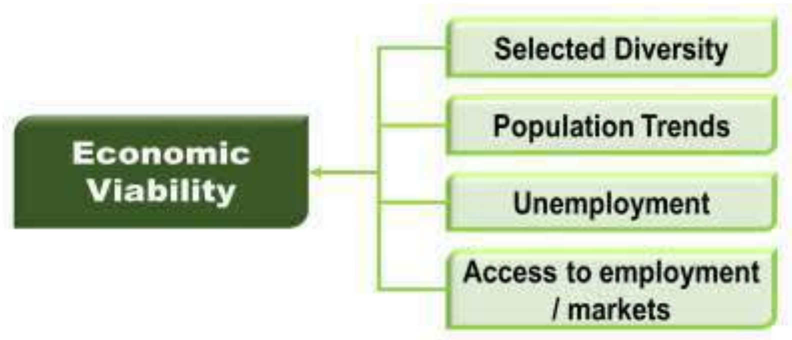

Figure 4: Economic viability considerations

- ***Sectoral diversity*** is a characteristic of a healthy economy. Single sector economies should be highlighted before large scale community developments are planned.
- ***Population trends*** refer to areas of growth and decline.
- ***High unemployment clusters*** should be avoided. More inclusive development without large scale "poverty traps" is preferred, and
- ***Access to employment/markets*** secures greater diversity of income sources and will always be preferable for development.Accessibility.

4.4 The Full Model at a Glance

While the foregoing sections have unpacked in relatively more detail the various criteria relating to the Land Suitability Multi-Criteria Model, Figure 5 below provides an overview of the model as a whole.

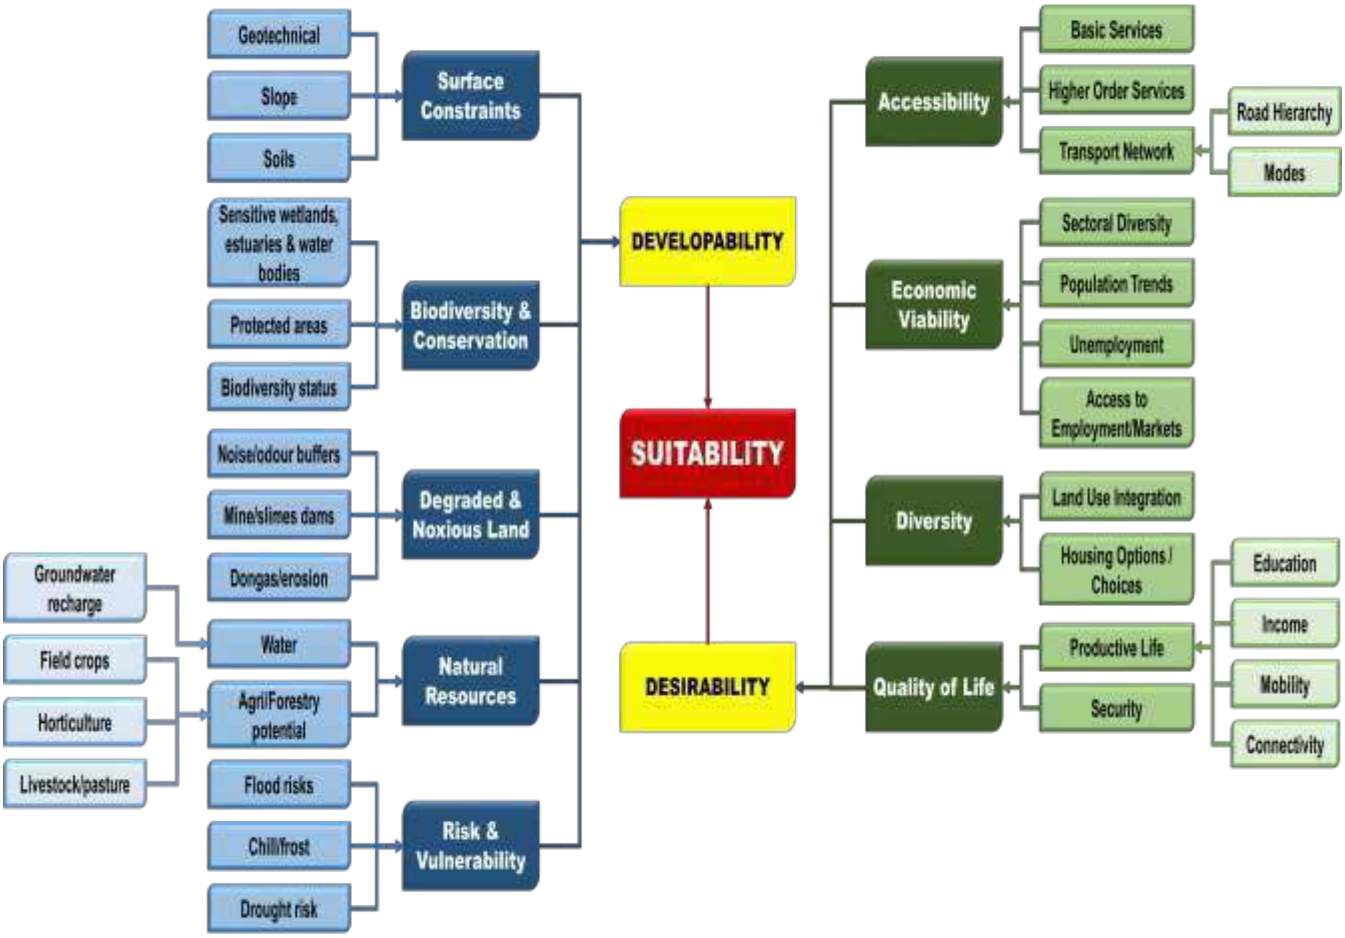

Figure 5: Integrated LUSAC Model

4.5 Interpreting the Results of the Model

As explained in the beginning of the document, the multi-criteria decision-making process is carried out on the basis of creating indices, with the final suitability result expressed as an index. The index can be from 1 to 10 or from 1 to 100. This normally depends on the amount of detail required to make a final decision. The following example is based on suitability assessment for densification in Gauteng. The index is from 1 to 10 with a score of 1 the lowest and a score of 10 the highest level of suitability.

Figure 6 below is a Gauteng example depicting a densification assessment.

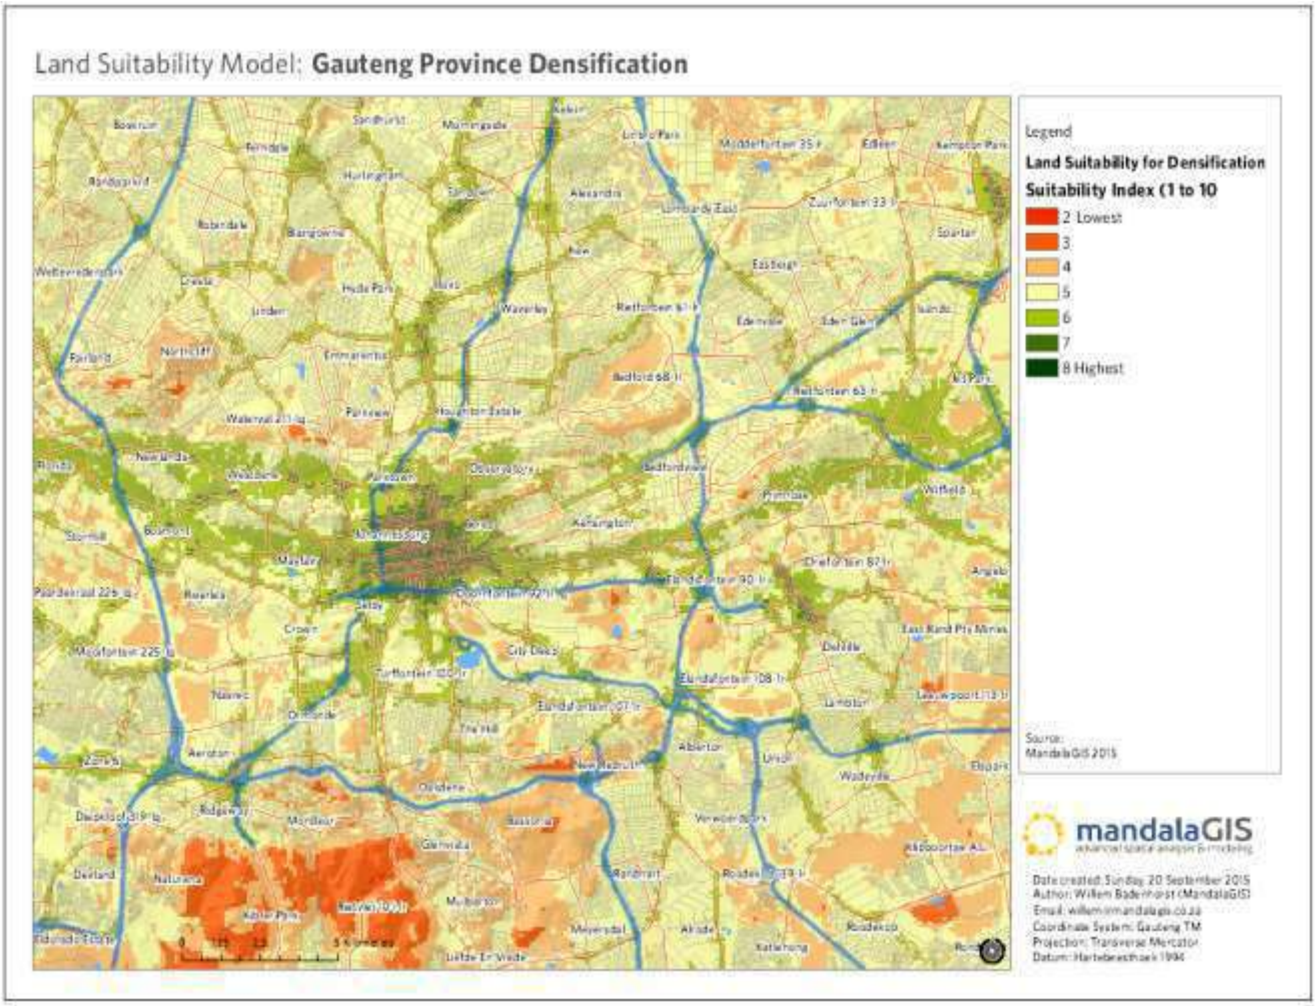

Figure 6: Example of Densification Assessment in Gauteng

Figure 7 below represents a typical result for a proposed development study area.

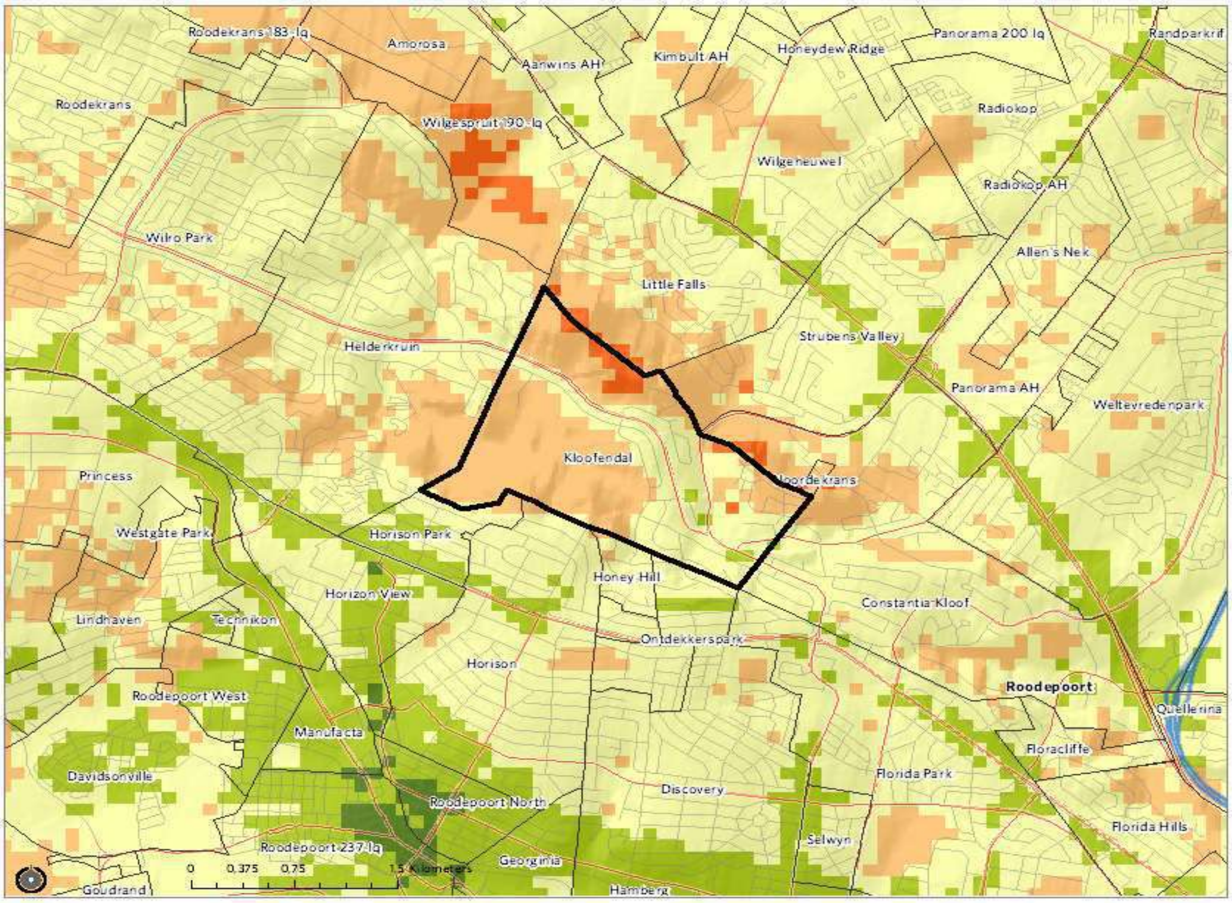

Figure 7: Typical assessment of proposed development

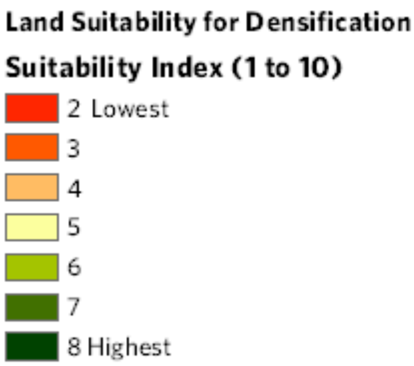

In the above example, the interpretation of the suitability result is that the study area, or proposed development, does not comply with the desired conditions for densification. The reason can then be found in one of the input criteria layers (e.g. a lack of public transport infrastructure).

4.6 Contextualising the Results

It is always be important to remember that the result of the suitability model is only a guideline and should be interpreted with the local context in consideration. A suitability model for use across the whole of South Africa, will not be able to take in consideration all the local nuances and characteristics that differ from place to place. However, the suitability model should very clearly indicate any unsuitable areas that fall in the non-negotiable class (e.g. protected nature areas).

4.7 Software and Skills Challenges

The nature of multi-criteria decision modelling requires two very important sets of conditions. The first is availability and cost of appropriate GIS software packages, and the second, is the appropriate GIS skills and knowledge to interpret the input information.

5. Way Forward and Conclusions

The proposals presented are tailor-made for a simply constructed tool that is easy to use bearing in mind that the capacity for collection and analysis of complex data sets is a bottleneck for most municipalities in South Africa. It has been noted that LUSAC relies on multi-criteria decision modelling which requires two very important sets of conditions. The first is availability and cost of appropriate GIS software packages, and the second, is the appropriate GIS skills and knowledge to interpret the input and output information.

The issue of availability of appropriate GIS skills and knowledge across the country has been highlighted. Multi-criteria analysis as the basis for LUSAC relies on a very rich data environment. Although this is very advantageous, it also requires that the users of the tool should have a very good knowledge of the input information and how to interpret it. Local municipalities with lower skills level may have difficulty in interpreting the input information as well as the output results. This may imply that the “depth” levels of the models may need to be varied to suit the knowledge and capability levels of the users in different organizations.

To address the question of capacity, two scenarios of application have been provided. Municipalities or other entities with high levels of GIS skills may be able to use the full model with all its multiple layers. In the case of lesser knowledge and skills levels, the depth of the model may be offered on a lesser scale with some of the sub-models being pre-processed by sectoral experts. In this case, the organization will only use the First Level of the model to contextualize and make decisions.

Values for Planning.

Olga MAXIMOVA, University of Rome – La Sapienza, Italy, Russia

The paper presents the results of the PhD research of author supported by the Erasmus Mundus Action 2 Programme of the European Union. The PhD research is dedicated to: “The Landscape: comparison between Italy and Russia. The general values for legislative and planning instrumentation”.

1. Introduction.

Values for planning. Values for future. Values for life. Which values have to be the basic for legislative and planning instrumentation? The paper demonstrates the differences of understanding the landscape related to social, linguistic, economic, environmental aspects and its interrelationship depending on the territory. The concept of landscape will be explored from the conceptual and cultural point of view, in the different traditions and in the European Landscape Convention (Florence, 2000), also in case of Russia. The aim is to identify the analogical-related concepts and their importance, for the possible integration of the European Landscape Convention (ELC). The research investigates the theme of the landscape planning after European Landscape Convention, in particularly to the Italian experience, is concerned with the integration of the European Landscape Convention into the Italian legal system and with development of the regional planning system, focusing on its organizational, operational structure, its legislative content, disciplinary and management innovations, the mechanisms and procedures for the elaboration of the general planning instruments (landscape plan) in order to identify criteria, principles and tools to produce the basic model, which can be applicable in different countries, for example, in Russia.

The research investigates the theme of landscaping planning in Italy to answer the main question of the thesis: can be and if how can the ELC's addresses be applied to the Russian case through experience of Italian landscape planning.

2. The Concept ‘Landscape’ Does Exist?

The language is a reflection of our life and culture, shows the importance of the local environment and everything around us. The concept of perception includes the different ways of human perception: visual, sensory, through taste, hearing, smell, touch, temperature, humidity, etc. That is obviously depends on surrounding conditions and characteristic of the environment and of the landscape and of the way of individual and collective perception. Key elements of this influence the cultural policy and development of the territories.

Former Steering Committee for Cultural Heritage and Landscape (CDPATEP) of the European Council has elaborated the document “Landscape policies – synthesis document”[1] based on the information of the landscape policies provided by the Member States of the European Council. The document is based on the information of the previous documents, those that were elaborated from 2002 to 2009: T-FLOR 2 (2002) 11, T-FLOR (2007) Rev[2], CEP-CDPATED (2009) 3 Bil[3] and T-FLOR 3 (2003) 11 rev[4]. Each representative of the Council of Europe member states (those who provided the information) answered the questions related to the landscape and its management in the report "Presentation of the status of landscape policies in the Member States of the Council of Europe", including the relevant legislative system, planning structure and special policies related to the State. Among the questions related to the addresses of the Convention there are the questions of section 5 "General mesures" as: 5.1. How is the term "landscape" defined in your language? 5.2. Is there a legal definition of the term "landscape"?

The question reflects the permanent and indissoluble link between environment, language and culture. About twenty representatives answered the question. This presents the complex and mixed picture of official diversity. From the comparison we can identify 2 types of answers: the first type is based on definitions and native (autochthonous) words, while the second on definitions and words of foreign origin, borrowed those that represent scientific or legislative significance. If instead analyzing these definitions on the basis of linguistic groups, the roots of similar words are found in each group, but at the same time the meaning is not always very much the same.

In the Russian language the term 'landscape' (rus. "ландшафт") derived from German 'landschaft', is not the autochthonous word. There is also the etymological concept of the 'space' in a different way, that is 'prostranstvo' (rus. «пространство»). In the Italian language 'paesaggio' ('landscape') has the colors of the different senses and feelings, as well as the 'taste' ('paesano'). It is the concept with many layers, like Mediterranean climate with ability to cover everything with its humidity. All the two concepts 'prostranstvo' and 'landscape' include the ability of moving, around, between and within. The concept 'prostranstvo' does not directly correspond to 'space', because the concept of 'space' is relative to the concept closed, whereas the concept of 'prostranstvo' is more related to the concept open.

This shows the difficulty of identifying what the 'landscape' is in general, and, in particular, the difficulty of finding direct analogies in different languages and cultures. Therefore, it is evident the difficulty in applying the international documents in the field of the 'landscape' in a homogeneous way. It is necessary for each country to create its language for 'landscape' with specific local tools.

3. Importance of 'Landscape' for Contemporary Life.

The Convention is a result of international collaboration in the framework of the Council of Europe's cooperation. The purpose of this cooperation is the realization of the closest union among its members to safeguard and promote the ideals and principles that are their common heritage, and which is pursued through agreements in the socio-economic field. Where the landscape is represented as 'a resource favorable to economic activity'[5]. So, the Convention presents itself as an economic instrument. It is the important moment that at the international level means 'an area, as perceived by people'[6] has been defined as an economic resource in general. It opens many possibilities for development and collaboration but also creates many risks.

"Aware that the landscape contributes to the formation of local cultures and that it is a basic component of the European natural and cultural heritage, contributing to human well-being and consolidation of the European identity"[5], it addresses such global processes as the problem of the sustainability of local culture and identity in a global society.

Chain:

cultural and natural heritage - landscape - identity - population,

creates a link / connection across the landscape between the European cultural and natural heritage and the local population, thus protecting the 'identity' of the local population.

The document proposes the following questions:

- What are the criteria to define various desires of the people, "the public's wish to enjoy high quality landscapes and to play an active part in the development of landscapes"[5]?

- How the opportunity 'to play an active part' can be on a more intense and professional level?

The European Landscape Convention, on the one hand opens the perspectives, but on the other hand entails risks, raising the following questions of interpretation and possibility of realization at the time of total globalization, economic instability and its practicability, as well as the possibility of being applied in different climatic, cultural, economic and other areas. And, as a result, highlights the questions about the risks and their consequences, emphasizes possible advantages and benefits for a single country or for a participant of the Convention.

4. Goals for Landscape Management.

How the integration of the European Landscape Convention is carried out, for example, in a single state of Italy, which goals have to be achieved for the landscape management? "Landscape management" means action, from a perspective of sustainable development, to ensure the regular upkeep of a landscape, to guide and harmonize changes which are brought about by social, economic and environmental processes[6]". The Italian legislative system, as a Parties to the Convention State, implements its principles by development of its own mechanisms of integration of the Convention into the legal framework, into the system of the management of the territory, in the system of territorial and landscape planning.

DECRETO LEGISLATIVO 22 gennaio 2004, n. 42 - Codice dei beni culturali e del paesaggio (the Code) is a main instrument for carrying out the governance of cultural heritage on the Italian territory. By this Code have been introduces basic concepts for landscape management (main): landscape, cultural heritage, landscape values, cultural values, protection, enhancement. The question is how to perceive the landscape, is essential for the definition of the landscape in the Convention, because it determines that the landscape is perceived by populations. So, it introduces the way how the landscape should be perceived, contemplated and interpreted, that is, the human scale, because it is perceived by man, in this way introduces the problem in the interpretation of the basic concepts.

The goals of the Code can be structured in three groups: introducing the basic concepts for the governance of cultural heritage, cataloging and recognizing national cultural heritage, establishing regulations for use and responsible bodies. That all sets represent the general measures for the governance of cultural heritage, where the main concept is the enhancement of national culture through the protection and enhancement of the cultural heritage of the Nation (Art. 1, c. 2). It can be defined that the enhancement is the new integrated concept to safeguard and protection the territory, to use the land, to develop the territory, to build a new landscape and a new city, that Italy follows to be applied with the Code. The protection and enhancement all together form the principles to activate concepts of the Code in legal framework and planning for the management of the Italian territory.

The definition of the term 'landscape' and its derivatives should still pass the review period in its development if we take into consideration the development of our life, including changes in economic activities, ecological and social situation in the evolutionary process, because the landscape is a dynamic matter.

The Code has introduced a new type of plan on the whole (apart from the regions that have autonomy in this matter) the Italian territory with the main objective that the territory should be adequately known, safeguarded, planned and managed, taking into consideration the different values expressed by the different contexts that it constitutes[7], that can be interpreted that the Italian territory with different values expressed by the different contexts that constitute it, all together represent the landscape of the Nation, with its diversity and complexity.

The Code and the Plan are the main tools of a multilevel governance to realize the landscape policy on the Italian territory. Where the development of culture, the memory of the national community and the territory have been put at the center for 'landscape quality objective' (ELC).

5. Landscape Transformation in Russia.

Russian Federation has not signed the European Landscape Convention and, consequently, does not implement it. But it is completely involved in global processes. It has its own urban planning system, the system of ecological and environmental legislation. The term 'landscape' is not defined in the legal documents, but presents as a natural landscape, or as a cultural landscape, or as a place of interest, or as a natural complex and so on. The framework of laws relating to spatial planning, cultural heritage and ecological legislation presents a complex system of concepts for the protection of the environment, cultural heritage, nature and resources, and has its structure and contents connected to each other.

Is completely involved in global processes, with the same general global problematic statement: fragmentation of landscape, chaotic development, weak programmatic aspect, disappearance of small town and villages, but intensive development of the large cities.

In 2012 in Moscow, there was an important event - *The international Urban competition for the elaboration of the draft concept of the Moscow city agglomeration development*. It was made a significant impact for the future development during the next 6 years: Moscow needs the rethinking the river complex system, the nature and park complex system, the transport system. As the next action there was held *The competition for the concept of the urban development of the territories adjacent to the Moskva-river (2014),* and others competitions. So, the Moskva-river was considered as a unique landscape unit or area. There were defined 5 goals[8] to be achieved in the competition elaborations:
- reorganization of the embankments of the priority of formation of public spaces;
- ensuring permeability and improving links between adjacent areas and river;
- improving the quality and comfort of the urban environment, improving the appearance of the territories in order to improve the overall image of the city and making it more attractive for residents and tourists;
- improving the environment through the rehabilitation of the river and its valley complex;
- improvement of investment prospects for the relevant areas through the enhancement of market value of existing and planned real estate assets.

We can structure those goals into six aspects: public space aspect, requalification aspect, interconnection aspect, ecological aspect, attractiveness aspect for people, and attractiveness for economic aspect. If we make the comparison with the Italian concept of enhancement, which includes such functions: to promote the development of culture, requalify buildings and areas, public use of the landscape, creation the new landscape values; we can define that the goals of the Competition are partly equivalent of the Italian concept of ‘enhancement’, and don’t correspond to the function ‘to promote the development of culture’.

6. Importance of Landscape for Planning in Russia.

During the research there were elaborated the questionnaire on the theme of landscape for the interview of the Russian specialists in the field of landscape planning, urban planning and architecture. The goal of the interview is to analyze how the specialists of the field take into consideration the theme of landscape planning in the Russian Federation. Next will be shown some answers for the one question for the interview:

How important is the 'landscape' for living and everyday life for the contemporary person?

Answer of O.E. DRUZHININA, Architect, associate professor in the Moscow University of Architecture; leading specialist in the Laboratory of Urban Studies of the University of Architecture in Moscow; main research interests - urban and regional planning:

“The landscape for the man - it is at the same time, and a place of life (environment), and the source of life (resources). The landscape contributes to the formation of an individual’s perception of the world around him: of the characteristics of the relief / terrain (mountain / valley), nature (aqua / forest / steppe, etc.), of the forms and activities of human action, of the types and forms of human settlement, of the man-made objects (buildings / structures), of history and culture. In the interaction between man and landscape it develops an active human relationship (responsible) or passive (consumer) to the world”.

Answer of A.V. KHOROSHEV, PhD Geographical Sciences; Member of the International Association for Landscape Ecology (IALE), Member of the Russian Geographic Society, Associate Professor, Lomonosov Moscow State University, Faculty of Geography, Department of Physical Geography and Landscape:

“From the point of view of visual sensations - an exceptionally high value. From the point of view of the understanding of natural processes (movement of matter in a wide sense) - often ignoring of landscaping principles in decisions during the planning”.

Answer of F.S. KUDRYAVTSEV, Architect, General Director of Architectural bureau ArchNOVA LLC, Head of the Laboratory of Urban Studies, Moscow University of Architecture:

“It is important, but there are changes, but to judge by how deep and inclusive they are serves the research. It seems to me, that in our culture, the landscape has always been important, words like expanse, vastness / «раздолье, ширь» have not yet disappeared, if they are still in the language is, then they are also is in our culture. The landscape itself is changing, for various reasons, become less permeable, attitude to the landscape also is changing. Both in natural or uncontrolled manner, but the landscape begins to change much more. The landscape is important, but this is the subject of specific research. Now, a person can create a world completely without landscape, but before he could not”.

Answer of A.A. SKOKAN, PhD, President, Founding Partner, Chief Architect in the Architectural Bureau Ostozhenka (www.ostarch.ru), Corresponding Member of the Russian Academy of Architecture and Construction Science (RAASN, www.raasn.ru):

"The 'landschaft' («ландшафт») is that outside of the city, the countryside (though of course there is the urban landscape, 'paysage') – 'out of town', 'kraiobraze'. And this countryside - is what is essential for the people of the city, what them lacks in their urban existence. This rural landscape should be harmonious and should remember the eternal values of nature – spaciousness, beyond the horizons, open sky (if it is not the forest) – everything that can be contemplated to recover from the hustle and bustle of the city. In other words, from the landscape for us serves its contrast with the city, it is a kind of emotional contraposition with the city".

Answer of A.A. TISHKOV, PhD in Geographical sciences, Deputy Director of the Institute of Geography of the Russian Academy of Sciences (www.igras.ru), Professor, Honored Worker of the Russian Federation for Nature Conservation (2003), Honored Worker of Science (2009):

"In fact, natural or man-made landscape - the basis for the strategy of the life. A person may (1) adapt to the landscape, (2) transform it in the right direction for himself, (3) live, without changing either himself or landscape, while remaining part of it. To save landscapes, landscape diversity - one of the major global problems of humanity. In this – all the diversity, which provides life itself – geological, biological, humanitarian, environmental management systems, languages, countries, people, habits, mentalities and more".

7. Conclusion.

The results of the study can be used as a basis for the preparation of methodological / conceptual guidelines, duly declined to the Russian case, aimed at studying, planning and designing documents and documents at federal level; the guidelines will be aimed at the conservation, conservation and management of landscaping assets and can provide methodological and scientific support for the drafting of some urban planning instruments of the Russian Federation.

Urban Rehabilitation

Realities and paradoxes in Bairro Alto and Bica, Lisbon

Sofia MORGADO[1]; Pedro GEORGE[1]; Jorge NUNES[1]; Carmén COELHO[1]
[1]CIAUD/Murbs, Lisbon School of Architecture, University of Lisbon, Portugal

Synopsis

The paper discusses the current urban reality in Bairro Alto and Bica and under the scope of the next Urban Rehabilitation Plan, as a contribution to the Urban Planning Department of Lisbon. Critical aspects, in the research section, are to be presented.

1. An urban idea rooted in the Renaissance

Despite the unfortunate story involving the acquisition of the land, as a result of the persecution of Jews since the 16th century, Bairro Alto would be designed following a renaissance idea of a new modern and aristocratic neighbourhood.

Bairro Alto is organised, from a boundary defined by the *Moinhos de Vento [Windmill] Road* to the north and the east, along with the Wall of King Fernando, and which today consists of differently named streets: Escola Politécnica [Polytechnic School], D. Pedro V [King Peter the 5th], with extension to Misericórdia [Mercy] and Alecrim [Rosemary] Streets towards the Tagus.

Formosa [Beautiful] Street, marks the western end, known today as O Século (a former newspaper), and by Horta Navia Road, to the south, today called Calçada do Combro and Calhariz (is a local typology in which a road broadens and gain the scale of informal open space). In national urban typology a *Calçada* is the main access road, usually stepped and paved in stone. Bela Vista, as it is known since the 16th century, gave way to *Congro* or the Combro [possible translation is debris or quarry-like].

This road used to be the primary link between the inner wall city (considering the various walls throughout time and own western doors) and Madragoa, the suburb to the west and fisher harbour in Santos.

In its inner area, an orthogonal fabric of streets was laid, with slight adjustments to topography and previous existences. In the centre, a wider street runs entirely from one end to the other: Rosa [Rose] Street.

Adjacent to the western door of the Wall – Santa Catarina Door -, the fabric was to be marked by the width and pavement of its streets where 'even carriages could circulate' (as it became usual to say about Bairro Alto), as opposed to medieval streets, where buildings used to advance onto the narrow passages and even onto other buildings. One palace or other significant building should have occupied each block.

Ideas to urbanise the area between Bairro Alto, the Tagus River and Madragoa were also considered and materialised in due time.

Such a process was seeded by a European idea of an "up-to-date city" in a small but ingenious country, that had already launched the first mundialisation, trough the worldwide

Discoveries. That is, a new residential up-town (*Bairro Alto* means a neighbourhood in a top of a hill) completely different from traditional, busy, probably not very clean, downtown centre (which is what *Baixa* – low/down – means)

However, with the earthquake of 1597, the Hill of Santa Catarina collapses giving place to two different hills and originating severe topographic changes. Harsh cracks of great irregularity, like the one of the Belver Peak between the hilltop of Chagas and the hilltop of Sta Catarina. Hence, severely constraining the 16th-century urban fabric of Bica, Boa Vista and Well of the Negros (an outer Wall pit where, supposedly, African slaves were buried). The urban plan for this area is usually credited to architect Teodósio de Frias. (Calado, Matias Ferreira, p 28-29)

For this reason, Santa Catarina area seems to have kept, for a longer time, its rural character, with Santa Catarina Church as the most critical landmark (lost to a fire, later reconstructed in a slightly different place).

Iconography (usually tiles [azulejos] panels depicting the city from the Tagus, as a scenery) often portrait this area as a significant gap with a church on the top and of distorted proportions, due to its importance at the time. Bairro Alto disappears behind it. The Windmills at the top were also essential landmarks (and economic activity) in the landscape. Hence, the northern boundary's name and recurrent representation in different iconography (Windmills Road).

2. Modern perspectives of the City, in Bairro Alto: from the Enlightenment to the mid-20th century

After the 1755 earthquake that destroyed practically the entire city of Lisbon, Bairro Alto established new relations with the rest of the city as it has been mostly spared to the impact of the event. The reasons lay in its geographical location, the excellent construction of the neighbourhoods' buildings as they were exceptional (Convents, e.g.) and justly, the low rate of built occupation at that moment.

This new relation of the neighbourhood to the city redefined its limits and its internal cohesion. The roads that limited it became more exceptional regarding the architectural trends, working as a kind of border between Bairro Alto and the city.

From then on, Bairro Alto becomes separated from Chagas area. Chagas was the lower area which had been destroyed by the fires and tsunami as a consequence of the earthquake. This part of the city would later be significantly transformed - in quality and social profile – translating a later face of the architecture of Pombal.

As a result of the new plan to rebuild Baixa and further Pombal's interventions, a new set of urban typologies were introduced. The classical square made its first appearance in the city of Lisbon, especially in Baixa Pombalina, the newly designed downtown. There, *Terreiro do Paço* (open area paved by dirt in front of the Royal Palace) would give place to a ravishing Square of Commerce (following a new political age) open to the Tagus.

At Bairro Alto, the connection between O Século Street (or Formosa) and the interior of the neighbourhood resulted in some urban transformations, seeking to a better connexion within the context of the city.

It is a street of exceptional erudition, designed as a scenery to beautify the Marquis of Pombal Palace, absorbing the height difference and hiding a sophisticated aqueduct, between this street and the upper side, at the near level of *Convento dos Inglesinhos*, in the centre of the neighbourhood [Little Englishmen Convent], an exquisite Mannerist set of buildings from the 16th-17th centuries. Unfortunately, in the absence of a better fate, it became a private condominium, by the end of the 20th century.

Thus, some streets were rebuilt, causing the 14th and 15th-century lands to be reconfigured to different plot division, usually narrower to the streets and more extended in depth. The general urban layout was preserved, in any case. Pombal's buildings were later built along the eastern boundary, facing the old Wall, and especially towards the south, in Chagas, an upper-class neighbourhood.

Therefore, by the 18th century, and as usual in most designed/planned urban fabrics, Bairro Alto was shaping and adjusting to new challenges.

It still is.

Architectural typologies and the design of façades from the 18th and 19th centuries may now seem as very similar to 16 th and 17th centuries. However, five-story buildings were only introduced in Bairro Alto with the Marquis of Pombal Plan for the devastated city, after the 1755 earthquake, tsunami, and fire. Until then, buildings in Bairro Alto usually had two to three floors, even the most sumptuous.

Nonetheless, till the 19th century, this area remained somewhat rural, with less population density, and possibly occupied by much smaller buildings and farms. Large religious estates like the Jesus Convent or Cardais Convent, in the vicinity, were walled and these days' preserve of open space within a very dense urban fabric, with which they became intertwined.

In the 19th century, once again Portugal underwent hard times: Napoleon and the French occupation brought Lisbon down to a very different condition, and the Court moved to Brazil.

A civil war related to the succession of the new King of Portugal, state bankruptcy, deprived and derelict urban areas, an utterly delayed industrialisation, marked a challenging period.

Bairro Alto witnessed a socioeconomic change, with the settlement of leading newspapers in old abandoned palaces, generating a new artistic scene that expanded a bit throughout the neighbourhood. A certain bohemian and artistic flair brought the artists, but also prostitution, petty crime, and gambling.

A deprived small aristocracy rented their crumbling buildings to smaller newspapers, bars, and industrial workers for accommodation. Later, and already under the aegis of Fontes Pereira de Mello, a growing bourgeoisie would find new places to live, towards the north of Lisbon in Avenidas Novas [New Avenues], or Boulevards, designed by Ressano Garcia, following to an extent Haussmann Parisian model.

In addition to this expansion of Lisbon towards the north, Ressano Garcia dedicates his time to the management of the existent city as well. Hence, promoting infrastructure upgrade, mainly at the level of basic sanitation and the realignment of facades and pavements. Documents in municipal archives, interalia, show that it also happened in Bairro Alto and other older areas of Lisbon.

With the end of the monarchy (1908), the rise and fall of a very troubled 1st Republic with participation in WWI with significant casualties (1910-1925), a dictatorial regime would start settling from 1926 onwards, bringing profound restraints in architectural and urban design.

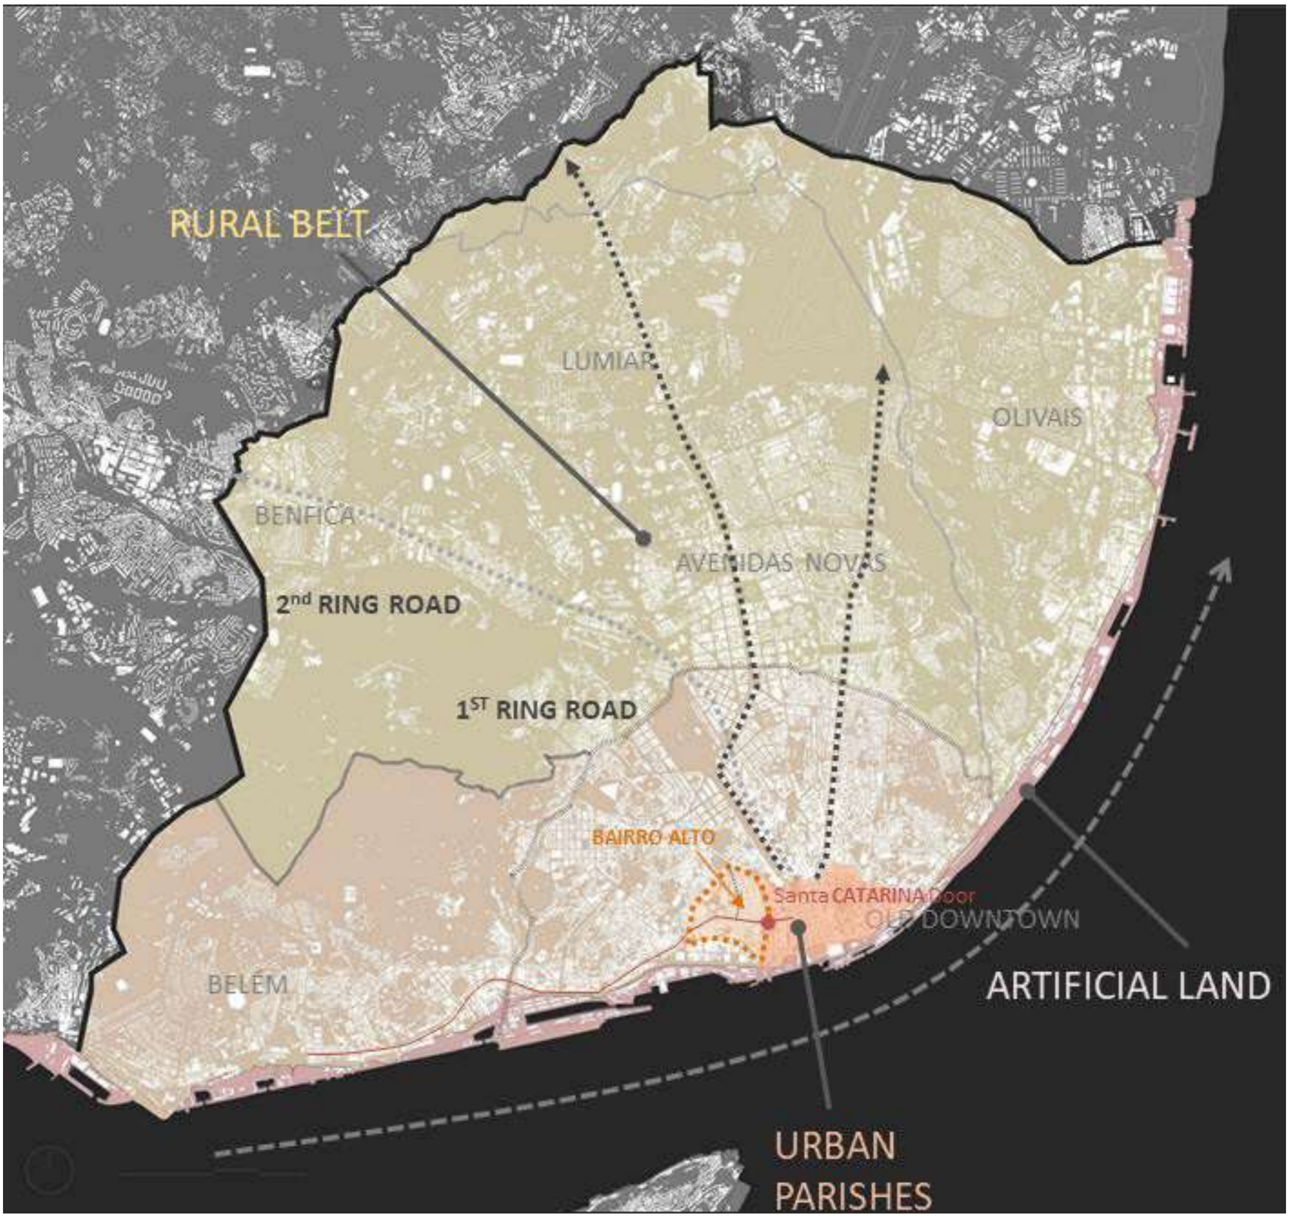
In 1951-52 a Partial Urbanization [Development] Plan was settled to remodel Bairro Alto. A survey was carried out by Sequeira Matos, a renowned connoisseur of the City of Lisbon, who included then a report.

However, Cristino da Silva, Chief Architect of the Plan, concluded that Bairro Alto did not have the necessary sanitary conditions to house the dense population and that was a severe obstacle to the future development of the capital's communications network, given the almost labyrinthine layout of its narrow streets.

Although Sequeira Matos concluded his report by referring to the care that should be taken in the intervention, the measures presented by Cristino da Silva would have definitively eradicated the Bairro Alto, had this Partial Urbanization Plan been implemented!

However, in areas now seen as heritage, similar plans were partially implemented, such as in Alfama, and even before, half of the Mouraria was demolished (in the Valley between Satana Hill and the Castle Hill). In either case, cloaked political motivations against the Regime opponents were well-known. They would endure until 1974, with the Revolution, ending in 1976 with the first free elections and a new democratic regime.

> *One of Bairro Alto's most exceptional qualities results from a complex overlapping of architectural interventions that run for four centuries without establishing ruptures or disarticulating the unity of the first urban structure*. (Carita, 1990, p 57).



Bairro Alto in the context of Lisbon. Source: Morgado, S., 2015, adjusted to this article by herself.

3. Urban Rehabilitation in Lisbon since the end of the 20th Century

By the end of the 20th century, and already since the 40s, Bairro Alto welcomed a new sort of population. Fado houses, bars and discos, restaurants, fashion designers and antique shops put Bairro Alto on the route to a particular intellectual nightlife. (Carita 1990, p 44) While the ground floors received newcomers, the upper floors started losing residents, as the quality of the built environment decayed, and the resident population began to age.

However, this transformation in the neighbourhood's profile would be followed by the exponential increase of tertiary activities and replacing the vacant housing.

Small offices and shops moved into this very central place, following the urban and metropolitan development and the dawn of an economy based on knowledge.

Commuters by day and night activities soon started conflicting with an increasing loss of the heterogeneous local population, with their own identity and social dynamics. Such a trend would increase to the present day with new challenges put by, amongst other situations, austerity and a growing touristic pressure.

The first Urban Rehabilitation Plan in Lisbon was to the historic district of Alfama, in 1986, with the primary objective of promoting the recovery and adaptation of old buildings to current requirements of comfort without harming architecture. In the urban realm, the aim was to provide local shopping, healthcare and education facilities without tampering with the traditional urban environment. The Plan aimed at creating habitable conditions and favouring the permanence of local populations (Gaspar et al., 2006, pp. 397-400).

In the same year, the new Urban Rehabilitation Plan to the historical district of Mouraria and Castelo looked for measures to stop the process of physical and social degradation in the set of parishes of the area. Taking into account the traditional characteristics of Mouraria, it was sought to preserve the identity and memories of the community, primarily by fado singing and taverns and the entire ambience that is its main feature (Gaspar et al., 2006, pp. 397-400).

In 1990, the Municipality launched the Bairro Alto and Bica Rehabilitation Plan. As in previous neighbourhoods, Bairro Alto and Bica is an area where the built environment reached a rather high level of deterioration, while the inhabitants show severe underprivileged social and economic conditions. The primary goals of the Plan would focus on rehabilitating the built environment and improving the living conditions of housing, while maintaining the resident population levels, attracting and fixing younger groups, possibly younger families (Gaspar et al., 2006, pp. 397-400). To that end, several buildings were purchased, in different locations in Lisbon, including Bairro Alto, requalified and put to market, under specific conditions by EPUL (Lisbon Urban Public Enterprise)

4. Urban Rehabilitation as an urban management concept

At the international level, the safeguarding and rehabilitation of historic centres were actively promoted by the 1964 Charter of Venice, which extended the notion of heritage to settlements, sites, and landscapes, hitherto conferred only on monuments.

Additionally, the conservation of a monument implied the preservation of a framework on its scale (art.6, Charter of Venice, 1964). The Charter of Venice and other documents and relevant authors, such as Choay, were sought of to fight practices that had been installed by all Europe, coming from the concepts of heritage developed in the 19th century and early 20th century. In 1910, Portugal would frame the first attempt to preserve unique buildings classified as monuments. However, the journey towards these days' idea of heritage - from tangible to intangible – was still a long one to do.

The principles of the Charter of Venice would later be supplemented, in 1976, with the Nairobi Declaration, on the Safeguarding of Historic Assemblies and their Role in Contemporary Life.

The Charter for the Conservation of Historic Towns and Urban Areas - The Washington Charter (1987, ICOMOS) also reinforced the ideals advocated in previous Charters. Thus, this Charter defines a set of principles and objectives, as well as methods and instruments of action, seen as appropriate to safeguarding the quality of historic cities, ensuring the report to historical towns and centres or districts threatened with deprivation or disruption, (point 1, The Washington Charter, 1987).

Following the newest survey on Popular Architecture, Portugal entails the international recommendations. So, from the 80's onwards, a cycle of safeguarding and rehabilitating the historical centres of cities and towns began, promoting the conservation and restoration of buildings and urban structures with heritage value.

Maintaining the resident population in these places, through the restoration of monuments, the improvement of the living conditions, and the qualification of the public space, was pivotal. Promoting the economic and cultural dynamism of the place was also an essential trait to the process. (Gaspar et al., 2006, p 384).

Thus, the late 20th century would become one of the most passionate periods in architecture and urbanism, in Portugal.

5. Through the lens of democracy

Urban improvement in Lisbon has its origins in the urban struggles of the post-25th of April when inhabitants of disadvantaged neighbourhoods organised to fight for better housing and living conditions. However, it was not until the 1980s that the local technical offices began to appear in the historic districts.

Locating the offices in their area of intervention has changed the relationship between the population and the local administration.

The population had direct access to the support services; the technicians directly involved with the problems of the neighbourhoods allowing participative and personalised management. Since it was not yet possible to carry out the initial plans, the work was developed based on the existing legislation and the provisional norms of the Municipal Master Plan. The areas to be rehabilitated were declared critical sites for urban regeneration and reconversion by the Government, under the proposal of the municipality.

In 1988 a local office was created to coordinate the works of Bairro Alto. Urban rehabilitation was considered a fundamental strategy in the recovery of the city.

Lisbon adopted strategic planning in the 1990s, as well as active urban management. It included a hierarchy of instruments ranging, top down, from the Lisbon Metropolitan Area, *i.e.* regional strategic level to the municipal levels of planning.

Lisbon Master Plan has finally ratified in 1994, tailed by different Development and Detail plans, that only later could be implemented. This shift gave rise to new legislation, mandatorily abided by all municipalities in the country, under the requirements of the structural funds provided by the EU (then EEC).

The approach aimed at maintaining existing structures, through the functionalisation and revitalisation, captivating private investment and appealing to the participation of the resident populations.

Urban planning in Lisbon focused on fundamental aspects such as the re-dimensioning, reorganisation and revaluation of the city centre. Such goals implied a number of actions including (1) recovery and rejuvenation of the population; (2) structuring of the tertiary-directional arc; (3) connecting the city to the river; (4) development and integration of the eastern zone with Expo'98; (5) creation of a system of transport interfaces; (6) build and consolidate the green structure; and finally, (7) the reinforcement and rehabilitation of the central historic areas. Bairro Alto was integrated, with its Development Plan. In short, this was the main layout of the 1st Generation Master Plan for the City in 1994.

6. The scope of the empirical survey

Slowly, but steadily, Bairro Alto - as seen - evolved into a place of taverns, gambling, and prostitution and that is how the 19th century will find it. This trend will last till the 1950's when it starts becoming attractive to artists, dropouts, alternative people in general who benefit from a new direction connected to current fashion joints, antique shops but most of all, revamped taverns, new trendy restaurants, and bars. More recently, hostels, typically "new" old shops and high-class franchising, side by side with entirely refurbished buildings pop out daily.

However, to duly intervene in such an intricate urban, functional, social fabrics, empiric recollection was done, which allowed improving methodological approaches. Throughout the last two years, a team at the Lisbon School of Architecture, University of Lisbon, in its research group Murbs (CIAUD), has been carrying out a broad set of tasks which are to form part of the next Urban Rehabilitation Detail Plan of Bairro Alto and Bica (PPRUBAB),

The officially published Guidelines for the Plan (*Termos de Referência*) frame the study, which consists of a rigorous survey on land use, conservation, and heritage by design, photography and GIS of Bairro Alto and Bica. It will develop under the umbrella of the National Law for Urban Rehabilitation.

The team resorted to information gathered by building and street (with the assistance of drone, laser distance measurers, and a full photography portfolio) and available in GIS thematic cartography (land use, number of floors, construction type, maintenance status, and so forth). Heritage, land use, public space, and conservation state were mapped.

A designed code was applied, street by street. Quantities and qualities are under trial.

In this case, the study is applied to the Area of Intervention of the Urban Rehabilitation Detail Plan of Bairro Alto and Bica (PPRUBAB) and balances, in scientific terms, the work currently carried out by the team in collaboration with the Municipality of Lisbon's Planning Department (CML) for the Urban Rehabilitation Plan.

At the research level, the project aims to study and develop urban intervention strategies and practices in areas to be valued and preserved regarding urban and architectural heritage, lifelong ageing inhabitants and short-term younger residents, under heavy touristic pressure.

Public space, temporary and permanent forms of housing, socio-economic trends induced by a rising touristic curiosity, such as harsh gentrification, management and redesign of minimal-size public space under shortage of parking and car space in an old and delicate fabric, are critical factors to consider.

It gained additional interest, as a Masters' group of students dedicated their Urban design and planning studios (2 semesters), not only to interact with the Planning Department Team but also contributing to the start of the tasks (some of them would later join the team at Murbs) and developing solutions for the area.

While the team is not in the liberty of disclosing privileged information, the paper aimed to explore interrelated contents, drawn by research on current dynamics in the urban realm.

The team expects that this and further work will allow for responsible development of urban design strategies, grounded in heritage, environmental and social dimensions.

7. Debates

Despite the efforts of the technical teams in the elaboration of safeguard plans, there are still problems to overcome, to achieve the expected purposes, about the rehabilitation of these historic neighbourhoods.

The exponential access to culture and social matureness allowed the increase in the demand for cultural and leisure activities, which translate into tourist development as well. Urban rehabilitation and cultural heritage are promoters of wealth (Barata, 2005, p 260 - 269). As such, safeguarding and recovering heritage are no longer a burden but, conversely, a strategic investment. Integrated into a policy framework for tourism development and increasing competitiveness, however.

In the rehabilitation of historic centres, there is still some lack of criteria for the selection of the architectural elements to be preserved, together with measures for the repair of buildings. Very often, options lead to controversial building requalification practices.

The Declaration of Nara, which sets out guiding principles for assessing the authenticity of heritage, reflects the values of the 1964 Venice Charter, stressing the importance of cultural diversity as irreplaceable in the context of humanity (paragraph 5, Declaration of Nara 1994). However, the evaluation and conservation of cultural heritage depend on the ability to understand the intrinsic value to it and the credible degree of the information on the characteristics of the specific object considered as heritage (points 9, 10 and 12, Declaration of Nara, 1994).

One of the aspects of urban rehabilitation in the historic neighbourhoods is, significantly, the qualification of the public space. In short, the strategy adopted should be integrated, and transversal to all sectors - from architecture and public space to accessibility, environment, and heritage. Under the scope of the new generation of Municipal Plans, the Municipal Master Plan of Lisbon ratified in 2012, with several amendments adopted. One may infer, that new perspective promoted rekindling in development and detail plans, especially in those that remained inconclusive for so many years.

The city of Lisbon, under a prolonged demographic loss, joined new processes of urban rehabilitation in the oldest and traditional districts of the city. Later, an increasing urban pressure resurfaces as unexpected forms of gentrification. Nowadays, shortage of affordable housing in the centre and a growing interest in short time residence, mainly associated with a tourist interest of very significant dimensions, are raising the toll to the ones who wish to remain where they were born.

These phenomena, which are beneficial in economic and cultural terms, even to fund urban rehabilitation, have been challenging (or should we say tantalising?) the municipal executive, lashing citizens' movements and, political – either for or against -, to introduce useful tools, especially in the areas of greatest heritage interest, to prevent crude evictions of previous inhabitants.

In this sense, one may say that old problems rise as new. Given fresh perspectives on the urban dimension, new technologies for its management and the necessary valorisation of the public space and the built heritage, they re-emerge as urgent in daily media. With renewed instruments and through different lenses, three Plans would step forward. The first to be implemented, with success and awarded quality, was the Urban Rehabilitation of Mouraria, followed by a Plan to Madragoa. Bairro Alto and Bica, for which this team was called to collaborate in, will be the third. These are prime planning and design examples – that will be intensely scrutinised -, in top sites of Lisbon.

Research on the scopes of eco-tourism development of areas along transregional mega linear projects of China ——a practice study of Yin Jiang Ji Huai Project

Qian, Renzan; Xia, Huiya; Yan, Cunai; Xia, Nankai, SHANGHAI, China

ABSTRACT:

Due to the historical legacy and continuous promotion of the construction of mega infrastructure in
China, China has more and more trans-regional mega linear projects, such as the BeijingHangzhou Grand Canal, the South to North Water Diversion Project, the tourism road along the Yellow river, etc.

As these projects generally have a huge impact on the surrounding ecological environment, meanwhile multi eco-tourism resources are also enriched in the surrounding areas, how to develop eco-tourism which is based on ecological protection is one of the key concern for the decision makers of these projects.

In this context, planning or studies of ecological protection and eco-tourism development of areas along this kind of projects have emerged in recent years. One of the core tasks of these planning or studies is to research and define the controlling, radiation, and linkage scopes of eco-tourism development of the areas along the projects, for providing significant reference to the planning, construction, ecological restoration, tourism development and management of them.

However, this is where the difficulty lies: these projects involve a lot of administrative areas, and the topography, ecological environment, tourism resources and management bodies along them are extremely complex.

This paper attempts to explore an operational method and route for delimitating the scopes of the eco-tourism development of the areas along the trans-regional mega linear projects.

First of all, this paper will research three other relevant planning or studies——the study of national heritage and ecological corridor of Beijing-Hangzhou Grand Canal; the planning of eco-tourism belt along the middle route of South to North Water Diversion Project, the top-level design of the" tourism road along the Yellow river" Project——for studying and summarizing their methods, routes, and theories of delimitating the scopes of eco-tourism development.

Secondly, discussing the common route of delimitating the scopes: determining the priority of influencing factors——determining the scope levels ——determining the planning and control content within each level . Based on the route, we try to construct the theoretical model—— "multidimension flexible scopes". The model includes flexibility of special levels, flexibility of management, flexibility of planning control, etc.

Finally, focusing on the practice case ——the Yin Jiang Ji Huai project (project of diversion water from Yangtze River to Huai River), to explore the application of the theory in practice. The project is China's major water conservancy project after the Three Gorges Project and the South to North Water Diversion Project, which is also the most comprehensive strategic water resource allocation project in China. The project is more than 580 kilometers long, connecting the Yangtze river and the Huai river, and passes through two provinces with 46 counties and districts.

Developing a Conceptual Framework for Planning of Location- Allocation of Schools in Indian Cities

Swechcha ROY, Saikat Kumar PAUL, Vivek AGNIHOTRI, Indian Institute of Technology Kharagpur, India

Abstract

The government of India claims to have provided a school at a distance of 1km for every household in the country. Nevertheless, the majority of the parents do not prefer to send their children to the neighboring school. It is estimated that an additional 200,000 schools will be required in the near future. Hence comes the role of the city planners to control the siting of the heavy surge of the upcoming schools. An in-depth analysis of the current trends of school siting is done. To come up with an efficient approach for siting schools, theories about school effectiveness is studied. This study infers that the neighborhood concept of school is very effective from the locational point of view for an overall development of a child. However, it has its own limitations which makes it difficult to be applied, especially in the countries like India. The study concludes with an approach for the planning of school siting which respects the idea of neighborhood schools.

Keywords- school siting, neighborhood schools, school effectiveness

1. Introduction

Construction of a school requires a huge investment of capital, time, and resources and they are permanent structures having both transient effects on mode choice of children traveling to school as well as perpetual effects on the spatial development of the community (McDonald 2010). Location of schools is important from the perspective of school effectiveness, in terms of academic success and physical health and wellbeing (Angus 1993). A good location can promote community participation in the education of children (Sanders 2001), increase the rate of walkability and control the mode of transportation (McDonald 2008a). If sited in a neighborhood, it can provide space for several community facilities like library, sports ground, and amphitheater which otherwise is difficult to provide in the urban space crunch. It can restrict inequality of social infrastructure (Pal 2010) and most importantly, provide educational facilities according to the spatial characteristics of the region and help in reduction of social disparities (Hallak 1977). However, due to the growing education programs and owing to the need of future expansion and economics of scale, schools require having huge acreage of land which is not possible to acquire in the core urban areas. Therefore, schools tend to shift at the outskirts of the cities, where land is available in profusion and at lower price, a process termed as school sprawl. Nevertheless, this trend is perceived to have a lot of repercussions and the contemporary educationists and planners are making their effort to bring back the principles of neighborhood schools.

The main question addressed in this paper is that are the policy interventions imposed by the Indian government efficient enough for an equitable provision of schools. The discussion starts with the evolution of contemporary school system and how it led to the formation of the school siting guidelines. It then delves into how the concept of neighborhood schools came up along with its advantages and disadvantages. Next, it analyses the current trend of school siting and its repercussions that have come up. The importance of neighborhood schools, from location point of view is established. This is followed by identification of the gap in the policy intervention which does not allow the implementation of the neighborhood schools in Indian Cities.

2. Education: An evolutionary perspective

A profound discussion about the location of schools requires a little apprehension of the evolution of the contemporary school system in order to understand its importance and recognize its flaws. Initially, till the 1700s' the education was very informal in nature, significant only for the elite class(Murphy 1998) and the impartation was the responsibility of the religious institutions rivaling for their students (Bryk et al. 1993). The industrial revolution in the 1800s' brought an upsurge in the economic condition of the people. Therefore, the custom of child labor started breaking off and childhood began to be fathomed as a phase of learning (Gray 2008). The idea of universal education was highly appreciated and the advanced nations enacted laws of compulsory education. A revolutionary system of education was evolved in Prussia which was able to impart mass education, highly inspired by the industrial revolution of that age (Gray 2008; Khan & Noer. 2012). In 1837, Horace Mann, the head of Board of Education of Massachusetts, adopted the same model in the American states in order to produce an egalitarian state. By 1870, this became the most generic model of the education system, throughout the word and by the end of the 1800s', the system was highly formalized by setting a standard time period and curriculum (Khan & Noer. 2012).

3. The Idea of Neighborhood Schools

By the end of 19th century, schools had become important social infrastructures. Also, the industrializing cities had new characteristics that needed new planning principles. Clarence Arthur Perry, came up with a solution with a new planning model having neighborhoods as self-contained and functional planning units, in his paper in the 1929 Regional Plan of New York and Its Environs. One of the core principles of his neighborhood unit was a school-centric design where a school was the focal point of a neighborhood, situated at a walkable distance from all the residences (Perry 1998; Lawhon 2009). This was the first mention of the location of schools in the planning principles. It was universally appreciated and is adopted till present for its successful idea of making schools accessible.

3.1. Advantages of neighborhood schools

Several nations today follow the system of school districts, where every school has a defined attendance zone from which students are entitled to get enrolled. Students from other school zones are not eligible for admission to the school or they are deprived of some facilities. The biggest advantage of a neighborhood school is its practicality in terms of distance, time and other logistics (Beaumont 2000; Beaumont 2003; Allen 1977). Proximity gives parents opportunity to participate in their children's education, by interacting with schools and other parents (Beaumont 2003; Beaumont 2000; Net Industries 2017). Community feeling, which is important for an adolescent's growth is fostered in a neighborhood school since they are able to develop better bonding, belonging to the same location (Allen 1977; Sinha et al. 2005). Research has also shown that a group of adolescents tend to have better academic performance if they attend the same school (Sinha et al. 2005). Schools earlier used to be built as important landmarks to inspire civic pride and sense of community in the children. Neighborhood schools also avert dependence on vehicular transportation which is proved to be one of the reasons for children delinquencies (Beaumont 2000; Net Industries 2017).

3.2. Criticisms of neighborhood schools

Apparently, the system of neighborhood schools has its own limitations, which have been identified by the researchers very well. The first limitation is that there is lack of diversity which restricts children's personality development and tends to propagate social disparity (Sinha et al. 2005). Some argue that it is an outdated concept and it does not let the schools match with the current benchmarks (Beaumont 2003). The small size of the neighborhood schools is also criticized for the poor economics of scale and for not being able to provide enough space for extracurricular activities (Beaumont 2000). It lacks sustainability due to the incessant chance in the school going population of an area (McDonald 2007) and it may not always be possible to meet the threshold population of a school in every neighborhood, and thus, this school system may only be suitable for moderate to high-density neighborhoods (McDonald 2008a). It is also accused of promoting social segregation in the society on the grounds of race and other social classifications (Allen 1977; McDonald 2008a). In response, the United States government had started a bussing system to transport children from one neighborhood to schools in other neighborhoods with different socio-economic characteristics.

However, it was very interesting to note that when these authors had highlighted the drawbacks of the neighborhood schools, at the same time they had given suggestions and some counter-arguments against the criticized points as well, again making us realize the significance of the neighborhood schools. To counter the lack of diversity in the neighborhood schools, Sinha (2005) suggested allocating children from nearby neighborhoods with different socio-economic characteristics in a particular school and schools to encourage pupils in versatile areas. In order to prevent social disparity, there can be fixed lower and the upper bounds to the number of students from the same neighborhood who can take admission in any school. One of the most prominent criticism is about the restrained size of the school which does not let it meet the standards set by the authority. But the renovations of historic schools in Spokane, Washington; San Antonio, Texas; and Boise, Idaho, challenge the notion (Beaumont 2003). Moreover, large school buildings are not desired from design aspect and many educators suggest that smaller scale enables more personalized attention and provides a safer and more secure environment for the students. Research has also shown that though large schools at sprawl areas provide better sports facilities, the increased distance make children dependent on motorized transport which increases the percentage of overweight children (Beaumont 2000; Beaumont 2003). Also, according to Beaumont (2000), appropriate size and community centeredness are the two most important elements of a good school. Neighborhood schools are also condemned for aggravating racial segregation, so much so that the federal court of the United States had taken initiatives like the bussing program for its alleviation. Nevertheless, the initiative itself became one of the most controversial decisions for up surging transportation costs and abolishing the system which was believed to be the finest way of educating children (Net Industries 2017). Parents were concerned about the loss of the sanctified feeling of schools, loss of community feeling which would impede social bonding and the majority of the parent's valued neighborhood schools for practical reasons like cost, comfort, and logistics (Allen 1977). Furthermore, the allegation of impracticality in terms of meeting the threshold population of schools was resolved by MCDonald (2008) by suggesting that though, it is not possible to ideally follow the concept, including children's distance from school as a planning criteria is an effective way to change community design and encourage walking and in low-density areas and planners can optimize school development placement so that maximum number of children live within a walkable distance from their school (McDonald 2008a).

One important revelation from this review is that school choice does not seem to have an easy solution. However, it has its own benefits and the arguments in favor of it make impossible to ignore it. Thus, it becomes an important factor to consider while planning for school location and allocation.

4. Current Trend of School Siting

There are several studies which throw light on the current trend of school siting (Ewing & Greene 2003; Gurwitt 2004). The expansion of education program with every generation, demands for increase in the minimum size standards for school sites, resulting today, in such huge size requirement that is impossible to find in an urban area and thus, schools are forced to locate themselves at the outskirts of the city, away from the high demand region, a trend which is commonly known as school sprawl (McDonald 2007; Langdon 2000). Other reasons for large school campuses are scope for future expansion, space for recreational and sports activities, accommodation of huge admission demand and to harness the economics of scale.

4.1. Reasons behind this trend

Due to this growing concern, planners and social scientists have been trying to find out the reasons behind these trends. Some identified reasons are (a) school choice (Warrington 2005; Grize et al. 2010a), (b) schools shifting to outskirts due to policies like minimum acreage requirement for a school campus (McDonald 2007), (c) lack of consideration of school and residential location at the time of planning new communities or school attendance zoning (Timperio et al. 2006) and (d) trends like closing the current neighborhood schools and opening new bigger schools at the urban periphery for economic efficiency (Mitra & Buliung 2012).

4.2. Repercussions of Current Trend of School Siting

The current trend of school siting, which is increasing the distance of schools from residences is however not generally appreciated (McDonald 2010; McDonald 2007). Countries like Canada (Frenette 2006; Mitra & Buliung 2012), Australia (Timperio et al. 2006), Belgium (Van Dyck et al. 2010), Switzerland (Grize et al. 2010b), U.S. (McDonald 2008a; McDonald 2007), and states of U. S. like Oregon (Schlossberg et al. 2006) and Texas (Lee et al. 2013) have already recognized it as an issue and have started talking about its consequences, finding out the reasons and suggesting practical solutions.

4.2.1. Decline in Trend of Active School Transportation

Active school transportation is the use of active means, such as walking, bicycling and other non-motorized mode of transportation to and from school. They are assumed to be an active source of physical activity in children.

One of the biggest concerns about increasing distance of schools from home is the constant decline in the rate of active school transportation in children around the globe. This impacts children by filching away one of their favorable time of physical activity (Schlossberg et al. 2006; McDonald 2007; Mitra 2013; Black et al. 2001), the consequence of which has been observed as the increasing number of children becoming obese (McDonald 2007; Evenson et al. 2003; Black et al. 2001). It builds a car-dependent lifestyle at the very childhood (Black et al. 2001), which is a critical age for developing healthy habits to continue them lifelong (Schlossberg et al. 2006). It also hurdles children from developing a sense of independence (Banerjee & Lynch 1997). On the other hand, students walking to schools develop a traditional identity of the school in the community, which sadly has ended(Schlossberg et al. 2006). One serious accusation is also about increasing the traffic congestion during the commence and dismissal hours (Schlossberg et al. 2006) and affecting the local environment by adding to the air pollution (Black et al. 2001).The following table shows the declining rate of active school transportation that the researchers in different countries have found out:

Table 1: Declining rate of active school transportation

Country	Statistics	Source
United States	In 1969, 42% American students walked or biked to school whereas, in 2001, it was less than 15%	McDonald 2007; McDonald 2008b
Switzerland	In 1994, rate of active school transportation was 78.4% whereas, in 2000, it was 71.4%	Grize et al. 2010
Australia	In 1971, rate of active school transportation was 44% whereas, in 2012, it was only 22%	Ploeg et al. 2008
Canada	In 1986, rate of active school transportation was 53% whereas, in 2006, it was 42.5%	(Buliung et al. 2009)

United Kingdom	In 1975, rate of active school transportation was 71% whereas, in 1994, it was 662.3%	(Black et al. 2001)
China	In 1997, rate of active school transportation was 96.4% whereas, in 2006, it was 85.9%	(Cui et al. 2011)

4.2.2. Loss of Valuable Time of Children

A generous amount of investment in terms of time, money, psychological and emotional capital is required to grow up a child (Haveman & Wolfe 1995). The way children spend time effect their social and cognitive development (Hofferth & Sandberg 2001). A quality time filled with various social experiences bestow different skills and knowledge to the children. But unfortunately, children lose a lot of valuable time in their ambitious school activities(Goldscheider & Waite 1991), especially in traveling from home to school (André-Bechely 2007) which they can use for other productive activities important for their overall development. This also leads to improper sleep timings of children leading to behavioral problems (Wolfson & Carskadon 1998).The average time spent by children in different activities in different countries is illustrated in the table below:

Table 2: Time spent by children in different activities

Country	Time in School	Time in Sports	Source
United States	2.7 hour per day	48 min per day	(Larson & Verma 1999)
Italy	4.8 hour per day	8 min per day	(Larson & Verma 1999)
Korea	5.6 hour per day	7 min per day	(Larson & Verma 1999)
Japan	8.6 hour per day	1.08 hours per day	(Fuligni & Stevenson 1995)
China	7.3 hour per day	-	(Fuligni & Stevenson 1995)
Taiwan	7 hour per day	3.4 hours in sports	(Fuligni & Stevenson 1995)
Germany	-	52 min per day	(Larson & Verma 1999)
India	4.6 hour per day	4 min	(Larson & Verma 1999)

4.2.3. Community Participation in Schools

School effectiveness is a field of research which quests for analyzing the practices followed in schools and correlating them with student's achievements in academics and social life. Models like overlapping sphere theory(Epstein 1995) are developed to structure the school program highlighting all the interactions required by the children for overall development. This theory states that when school, family, and community work in partnerships, a caring community is formed around the children and helps them gain more developmental benefits. Epstein gave six types of involvement tips of family, school, and community(Epstein 2009).

5. Review of Educational Policies in Different Countries

A brief review of educational policies of different countries was done to check how important the location of schools is regarded at policy level around the globe.

Few people know that apart from Nokia phones, Finland is also known for its outstanding performance in PISA and World Economic Forum. They believe in small but sufficient time to be spent in education and have empowered every child to study in the nearest mainstream school. For this, they follow a decentralized education system in which the municipalities are authorized to take decisions under the supervision of the National Board of Education (Hautamäki et al. 2008; Seppánen 2003; Antikainen & Luukkainen 2008). The United Kingdom promotes sustainable travel and transport and has also recognized walking and cycling to school as effective ways to increase physical activity in children (Department for Education UK 2014). Singapore's Ministry of Education has mandated all primary schools to give priority to applicants who reside within one kilometer of school (Liand & Warrier 2015). South Korea has gone through numerous educational reforms focusing on consumer needs, diversity and school choice, which is realized to be a major concern by the service providers (Seth 2002; Kim 2004). Japan has established walking to school practice since 1953. The Board of Education in each municipality determines the method of commuting by considering geography, climate, and transport situation. This has helped them reduce childhood obesity rates by providing sufficient physical activity (Mori et al. 2012). China implemented its first compulsory education law in 1986 when it ensured the children to get their education in their neighborhood by directing the local governments to setup elementary and secondary schools. The Chinese education system provides free education and advocates school districts by exempting examinations to attend a neighboring school. In 2010, the National Long-Term Plan for Education Reform and Development has mandated the local government to regulate the school distribution to make it convenient for the students to attend neighboring schools (Zhao 2014). The transportation department in Queensland, Australia lays stress on increasing awareness about healthy living and promotes physical activities through walking and cycling to school (Department of Transport and Main Roads State of Queensland 2016). The United States has started to encourage more neighbor centric schools that are closer to students, teachers, and staff. They recommend the use of existing infrastructure for conserving energy and resources and also direct the schools to offer other facilities in the after school hours that can be used by the nearby residents (Ewing & Greene 2003). Chicago follows a multidisciplinary approach to understand the neighborhood schools and their potential impact (Sinha et al. 2005). Schools in Oregon are community focal points that are easily and safely accessible (Ewing & Greene 2003). The walkable communities in Manitoba have schools as their neighborhood landmark which strengthens their social network by providing an interactive space for people of all age. There is a collaborative consultation for site identification of schools which ruminates projected dwellings for new developments, expected timeline for development and the anticipated increase in school-age children (Province of Manitoba 2016).

6. Need of a Robust School Siting Guideline in India

According to census 2011 of India, 28.5% of the Indian population, which accounts for around 373 million, belongs to the age group of 0-15 years, which is the largest school-going population in the world. This has created a huge demand-supply gap requiring an additional 200,000 schools in the country (India Brand Equity Foundation 2017). At the same time, there is an upsurge in demand for education from the consumer side as well. The literacy rate in India has increased from 64.83% in 2001 to 74.04% in 2011. The enrolment ratio in schools has risen by 12.53% from 7th AISES in 2002 to 8th AISES in 2009. The per capita public expenditure on education has increased from Rs. 888 in 2004-05 to Rs. 2985 in 2011-12. (India Brand Equity Foundation 2017; Ghosh 2014).

These statistics show that in near future, the nation, especially the urban areas are going to see a stream of new schools coming up. The current scenario shows that out of the total number of schools in India, 78% of the schools are owned by the government and the rest by the private sector. But still, the percentage of enrolment in the private schools is 35% which is much higher in proportion (Ghosh 2014). Having realized the impending encroachment of private sector in the supply of schools (Pal 2010), it is very imperative to have robust planning guidelines for their siting to avoid an unsystematic emergence of schools which may further lead to a chaotic and inefficient space for society.

6.1. Neighborhood Schools in India

India has incorporated the concept of neighborhood schools in its planning through the enactment of the RTE Act, 2010 which enables every child to attain free and compulsory education up to the elementary stage in a neighborhood school (Ministry of Human Resource Development Government of India 2010). The government of India claims that 99% of the population lives within 1 km from a primary school (Ministry of Human Resource Development Government of India 2012). But the question is how many parents are sending their kids to their nearest school?

According to Larson and Verma, in their research done in 1999, children in India spend only 4 minutes per day in sports and almost 33% of their waking time is spent in school, not counting the breaks and traveling time (Larson & Verma 1999). The figures showing road accidents of school children in India add to the concern.

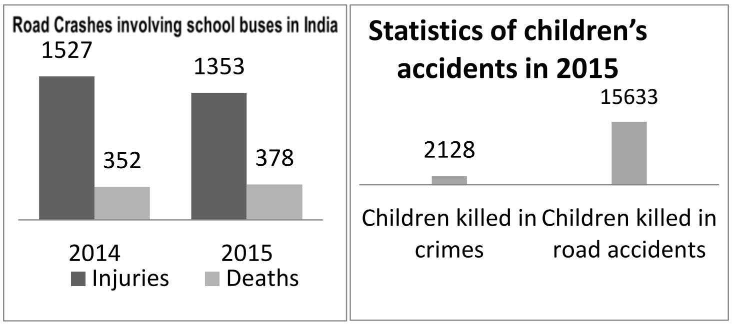

Figure 1: Figure 1: Road accidents of school children in India

Source- (National Crime Records Bureau 2015)

Finding Solution

There is a lot of emphasis in the literature on proximity and accessibility to schools. But it is not enough to provide a school in every neighborhood and provide universal accessibility. For in the countries like India where there is no concept of school districts and the practice of school choice prevails, parents often send their children to far off school even when there are schools in their proximity in search of better options in their view. Similarly, in the countries with school districts where the school is allotted on the basis of addresses of the children, often parents have to compromise a good residential location. Therefore, it is mandatory to understand the factors of every aspect, from personal and cultural to political that influence the school choice decision of parents in order to have an implementable policy.

A good location should allow the school to have the qualities identified by the educationists of a good school. The planners should understand their roles as facilitators and the level of their responsibilities. This requires an understanding of various kinds of needs of the society and the source of their information and bridging the gap in the literature.

6.2. A Good School

A study of different theories in school effectiveness and proficient school practices can show us some aspects which should be expected out of a school. First of all the achievements of a school should not be measured just in terms of mere academic excellence (Elias 1989) but in terms of the magnitude of its students' comprehensive development comprising of personality, social and affective persona and ability to face challenges of life (Sammons & Bakkum 2011). One important responsibility of schools is to distribute cultural capital (Apple & King 1977), which can be achieved by the correlation of family, school, and community in the education system (Epstein 1995). Schools are expected to develop a sense of belonging (Anderman 2003) and build community pride (Beaumont 2000). The physical characteristics of a school are required to be small in size, ensure walkability (Beaumont 2000), and provide a safe environment and positive culture inside the campus (Good & Weinstein 1986; Roeser et al. 1996). Furthermore, in order to represent a community investment and to fit in the over-congested urban spaces, the school building should be able to serve other facilities in the after school hours (Dryfoos 1999). All these qualities can be truncated into three major points of small size, community centeredness, and good location.

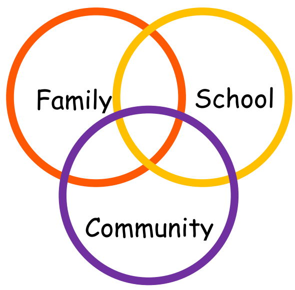

Figure 2:Theory of overlapping spheres

6.3. Roles of a facilitator

The Beetham and Sharpe 'pyramid model' developed to illustrate the progress of digital literacy (Northumbria University on behalf of Jisc 2014) is used to comprehend the different stages in the education development of a student. The same model is perceived in terms education development in general, inferring that there are four phases in education development viz. acquiring access to an institution, learn important skills, be able to practice those skills in life and finally to build an identity with the help of the gained skills and life experience. Also, Mount, Brown and Hibbard prepared a facilitator's manual for planning facilities for people suffering from traumatic brain injury (TBI). However unrelated it may seem, the main aim of these facilities is to lead their clients towards a more qualitative life (Mount et al. 2003), similar to that of a school service provider. The figure shows the superimposed concepts of both the interpreted model of Beetham and Sharpe's literacy development and the different stages of a facilitator's role. It is very interesting to note that all the stages could be directly linked to the four phases of education development of a child. Therefore, an efficient facilitator requires to enhance his responsibility from mere providing accessibility to a more specific provision of services answering to the needs of the diverse consumers.

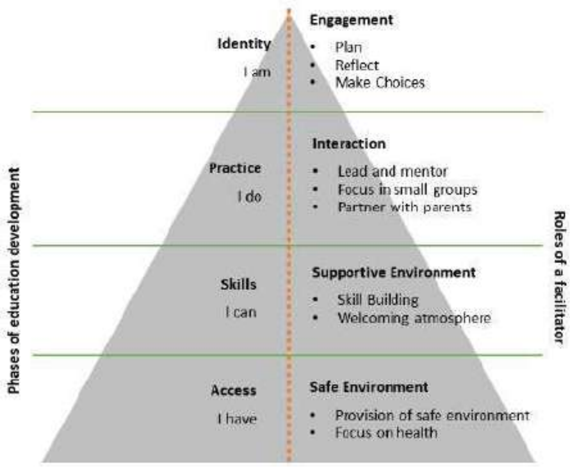

Figure 3: Superimposed concepts of education development and the roles of an education facility provider

6.4. Understanding need

There are five different types of needs, with specific attributes and each having its own source of information, illustrated in the table below:

Table 3: Types of Needs of a population

Types of need	Description	Information source
Felt need	What people say they need	Feedback from the community through meetings, forums, interviews, etc.
Expressed need	Actual demand	Evaluated through waiting lists, number of requests for services
Normative need	Expert analysis	Calculates by analysis of demographic and social trends
Comparative need	Comparable rates of provision	Comparative assessment of existing rates of supply against common rates of provision in other similar communities
Latent need	Needs that user are not yet aware of	Demographic analysis and growth analysis of research and public/ social policy

7. Identification of Gap

A review of works on location techniques of schools was done to identify the parameters used. Most of the studies have used optimization techniques with parameters like school capacity (Schoepfle & Church 1989; Amaya et al. 2016; Church & Murray 1993; Antunes & Peeters 2000; Antunes & Peeters 2001), addresses of students (Church & Murray 1993; Antunes & Peeters 2000; Antunes & Peeters 2001; Robertson 1977; Schoepfle & Church 1989; Teixeira & Antunes 2008), costs of teaching and operating (Amaya et al. 2016), socio-economic characteristics of the students (Schoepfle & Church 1989) and so on. On the other hand, the factors on whose basis parents make school choice decisions are in terms of location, academic performance, shared values, community involvement, personal interests, building condition and child preference (André-Bechely 2007; Cucchiara & Horvat 2014; Goldring & Phillips 2008; Goldring & Hausman 1999; Bosetti 2004; Maddaus 1990; Hanushek et al. 2007). Clearly, there is no relation of the school choice factors to the parameters used for schools also suggested by Pride and May (Pride & May 1999).

8. Way Forward

Literature clearly suggests the importance of neighborhood schools. However, the current trend of school siting confirms some gap in the policies made for neighborhood schools. The reason identified is that there is a lack of connection between neighborhood schools with school choice. Further spatial studies, in educational context, will need to consider social, economic and cultural aspects too. This will help the facility providers to advance their responsibility from providing universal accessibility to a more specialized provision which is customized to the needs of the diverse knowledge seeking population.

Urban Ecological Planning
Principles, value positions and application in practice

Marcin SLIWA, Norwegian University of Science and Technology (NTNU), Norway
Rolee ARANYA, Norwegian University of Science and Technology (NTNU), Norway
Hilde REFSTIE, Norwegian University of Science and Technology (NTNU), Norway

Synopsis

The paper presents the principles of Urban Ecological Planning - an approach of urban practice that challenges and supplements outdated technocratic urban planning methodologies that are still dominant in many developing countries. The value positions of this paradigm are illustrated with examples from an extensive fieldwork in Pune, India.

Introduction

Over the last few decades, the need for a radical shift in planning frameworks has been increasingly addressed by development specialists and researchers, who argue that traditional technocratic urban planning methodologies have proved ineffective in rapidly changing social, economic, cultural, political and environmental contexts. This momentum culminated at the Habitat III conference in Quito in 2016, where the international community agreed on taking a new path, as expressed in the New Urban Agenda and the so-called Quito Papers (UN-Habitat, 2018). Yet, an approach and set of principles of urban practice that addresses this need, challenges business as usual and supplements the outdated planning schemes has already been developed.

This paper aims to unpack Urban Ecological Planning (UEP) as it has been conceptualized and operationalized through practice based research and education activities at the Norwegian University of Science and Technology (NTNU), around an International Master of Science program under the same name.

The term “ecological” refers to both the social and environmental ecologies and their interaction within human habitats. The UEP approach has its roots in the Urban Ecology approach at the Chicago School (Park et al., 1925), which focuses on studies of urban social structures and their evolution based on a solid empirical knowledge. This includes investigating how urban management and politics shape the social and physical urban environments, and vice-versa. It can be said, therefore, that the main components of the UEP paradigm are social ecology, political ecology and urban planning. UEP further builds upon the research and participatory work with underrepresented and marginalized communities by such practitioners as John F. C. Turner (1972, 1976), Nabeel Hamdi (1995, 2010). The UEP study program has also been inspired by the action planning approach as taught and practices by Prof. Hamdi at the School of Architecture at Oxford Brookes University.

Table 1 outlines the main value positions in Urban Ecological Planning in contrast to traditional urban planning discourses. Originally, the UEP approach has been developed primarily as a response to challenges faced in informal settlements in low-income countries, but due to globalization and the rapidly increasing socio-economic inequalities in the capitalist West, examples of its applicability in the so-called “developed” countries are becoming more evident (Healey, 2012; Kaika, 2017; Speer, 2016; Watson, 2009; Watson, 2014a). At the same time, it is important to note that we do not see UEP as a panacea for all urban problems and replacement for traditional planning methods, but rather a supplement and redirection that addresses the shortcomings of “business as usual”.

Table 1

	Position in traditional Urban Planning	Position in Urban Ecological Planning
1	Sectoral planning / Functionalism	Area-based and Territorial planning
2	Top-down vs. Bottom-up	Bottom-Top
3	Problem / Issue based	Value based and Developmental
4	Comprehensive and Rigid	Strategic and Contingent
5	Standardized and Generalized	Contextual
6	Formal vs. Informal	Formal-Informal continuum
7	City as a mechanism	City as an organism
8	Instrumentalism / Structuralism	Social constructivist
9	Planner as an executor / implementer	Planner as a facilitator

Value positions in traditional Urban Planning and Urban Ecological Planning.

Integral to the UEP Master program are extensive student fieldworks (between 6 and 12 weeks), which have been taking place in Nepal (1988 - 2005 and 2009), Uganda (2007 - 2013) and India (from 2015). In each of these fieldworks, students learn about how planning is done by the different levels of government within the jurisdictions of the chosen –most of the time informal and/or marginalized– city neighbourhoods, and then study how, and if not, why does planning fail to contribute to an improvement of the local conditions and quality of life of the communities living there. After involving the residents in participatory planning exercises and conducting intensive situation analysis, students then attempt to come up with alternative, more realistic proposals for physical, environmental and/or policy interventions in these areas. While the tasks undertaken in the earlier fieldwork trips focused on urban upgrading of specific sites and settlements, today students are challenged to consider all the different aspects of urban and community planning at local level, focused on, but not limited to: housing, land, property, water, sanitation, health, education, energy, mobility, infrastructure, environmental sustainability, public space, local economy and livelihoods.

The UEP research and teaching activities at NTNU have been ongoing since 1980s and this paper is not the first attempt to conceptualize this field of knowledge and practice. However, just as other frameworks and approaches, UEP has also been evolving and reshaping to adapt to the economic, technological, demographic and environmental changes and transformations. This evolution can be traced down by looking at previous articles on UEP written by NTNU researchers and teachers who have been connected to the study program.

Basing on their experience in Nepal, China and India, Bjønness and Corneil (1998) emphasized the importance of local cultural, environmental and physical contexts in the urban planning process, and explained how the enablement and empowerment at the community level contributes to a positive change. Work by UEP students in Uganda has also been documented in articles by teachers who led these excursions. Skotte (2014) highlighted the depth of stakeholder engagement of the foreign students and the impact they had on capacity building of the members of local communities, NGOs and academic institutions they interacted with. Archipovaite (2015) focused on the value of context-based teaching for the development of skills and capacity of the fieldwork participants themselves through an in-depth analysis of their reflection notes, which are integral to all UEP excursions.

This paper draws on examples from the project and research work undertaken by 22 UEP students and three staff members during the fieldwork in Pune, India, which took place between September and December of 2017. The empirical data used in this article consist of fieldwork notes by UEP staff and three project reports elaborated by students (Akavarapu et al., 2017; Awusie et al., 2017a and Baracho Teixeira et al., 2017). Each of these reports corresponds to a different settlement chosen for an in-depth study. Besides that, students visited various other sites and projects around Pune to get a broader perspective of the current issues and challenges in urban development in the city.

The three selected areas are located in the central part of Pune (a city of around 3.4 million people) and have qualities of 'formalizing-informal' and 'informalizing-formal', which reflects the different trajectories which built environments can take. Shirole Vasti is a small self-built settlement, which is officially recognized as a slum by the local authorities. It plays an important role by providing different kinds of services to the surrounding middle- and high-income residential neighbourhoods as well the nearby universities and colleges. Kasba Peth is the oldest settlement in Pune and today constitutes a mixture of traditional low- and mid-rise buildings called "Wadas", modern high-rises and makeshift shacks. The third settlement, Raviwar Peth is located in the busiest part of the old town and its predominant use is specialized retail. There are also clusters of housing and street vendors in the area. The locations of these three settlements is shown on Figure 1.

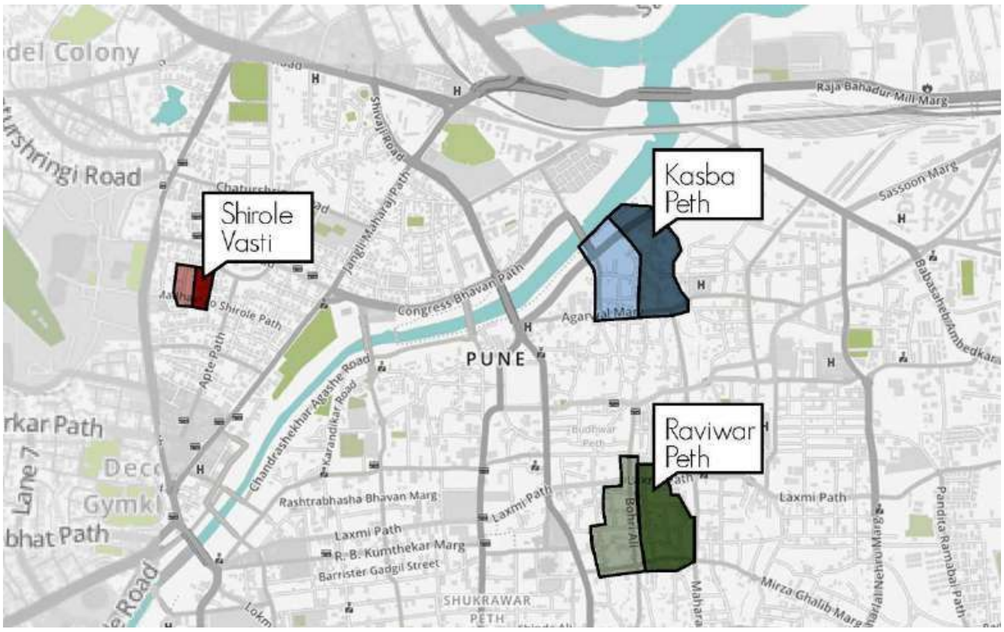

Figure 1. Location of the three selected settlements. Elaborated by Julianti Putri Setiawan.

Value positions in UEP and examples from Pune

In this section, each of the value positions outlined in Table 1 will be elaborated further and illustrated with real-life examples from the 2017 UEP Fieldwork in Pune.

1. Sectoral planning / Functionalism vs. Area based and Territorial planning

Finding the adequate size of planning units remains an open question in planning theory. In principle, we agree with Leung (2003), who claims that planners need to work at different scales from metropolitan to census wards or what he called "zones" as the most local. However, in practice, planning is usually performed at the municipal scale, which is too broad to address real local needs and makes it difficult for planners to comprehend the real urban complexities. The response to this challenge was 'breaking down' of cities into sectors, masterplanning, and the artificial separation of uses for different 'functional' areas. Implementing projects and performing interventions within a particular sector (housing, industry, public space, etc.) or infrastructure network (water, electricity, public transportation, etc.), without considering the context of the surrounding areas and its other uses, may solve the initial problem or challenge, but at the same time it may create many other unforeseen issues. For this reason, the UEP approach proposes that planning for urban interventions should be area-based and territorial, as opposed to sectoral. This requires planners to work not only across different scales, but also different specializations and professions. As Blanco et al. (2009, p. 236) argued, "there is a growing realization that the complexities of large and rapidly growing cities (...) require new knowledge generated by the coming together of different disciplines to solve common problems".

The scale level that is most often omitted or undervalued in urban planning is that of neighbourhood or community. According to Kunstler (1998, p.115), "the basic unit of planning" is a neighbourhood "defined as a five-minute walking distance (or a quarter mile) from the edge to the center". This allows a truly participatory planning processes and makes it possible for planners and decision makers to develop face-to-face relationships and a sense of trust with the people they are planning for (or, as will be argued later, planning with).

Like in many other cities in India, planning in Pune is performed at the municipal level and, sporadically at the metropolitan level. Some decision making is being made on the Electoral Ward level, yet these are still too large and heterogeneous to address local issues in an efficient and truly participatory manner. Even within the selected areas of study (ranging from approx. 0.5 to 6 hectares), students found different and more appropriate ways to define boundaries: by mandals and/or landlords (Shirole Vasti), by professions, kasts and communities (Kasba Peth – see Figure 2) and by streets or street blocks (Raviwar Peth). This allowed them to get a better understanding of functional 'clusters' and find out the interdependencies within and across these areas.

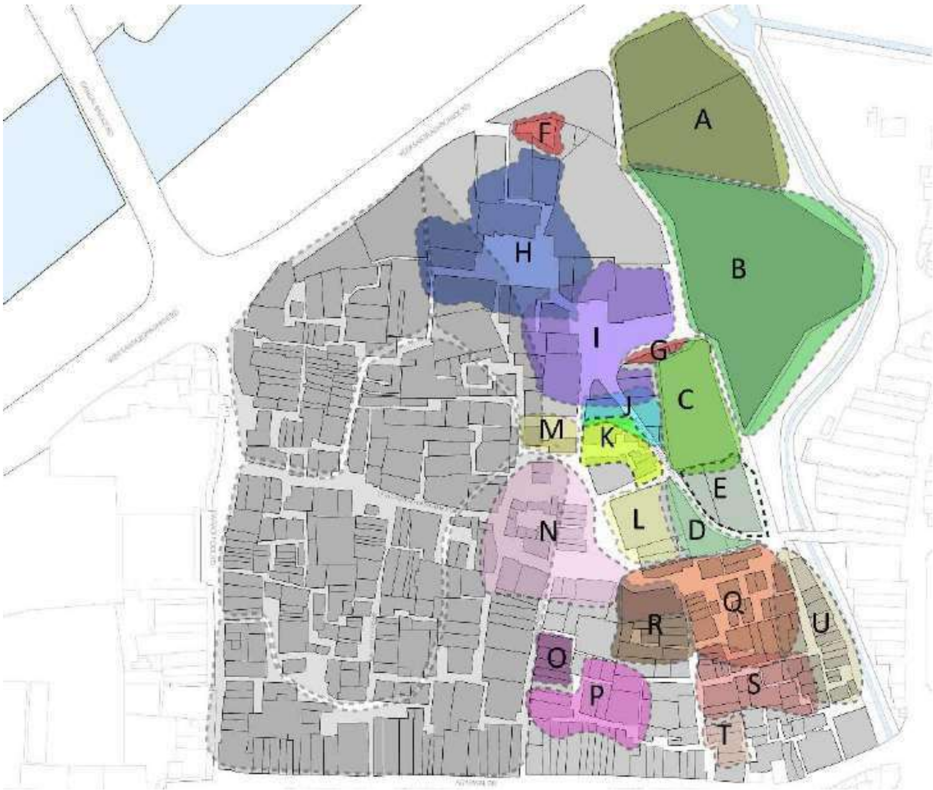

Figure 2. Demarcation of community boundaries in the Eastern part of Kasba Peth, based on participatory mapping performed by the students and local residents. Source: Awusie et al., 2017a.

An example of an issue that requires both multi-sectoral and localized approaches is that of solid waste. In Pune, solid waste and recycling policy and management are centralized at the municipal level and implemented by different levels of garbage collectors - from large automatized trucks to street sweepers. The garbage, however, remains uncollected for longer periods of time in too many areas, and as students discovered - for many different reasons that require inter-sectoral cooperation and localized solutions. Depending on the particular local context, these solutions might range from better solid waste awareness and hygiene education, more attractive incentives for recycling and composting, stricter law enforcement, better placement of garbage and recycling containers on public and private lands to increased involvement of communities in maintenance of shared public spaces (Baracho Teixeira, et al., 2017; Akavarapu et al., 2017; Awusie et al., 2017a).

2. Top-down / Bottom-up vs. Bottom-Top

Mainstream planning theory has recognized a duality of urban processes: top-down (government-driven) and bottom-up (community driven). This oversimplification of development leads to conflicts when plans imposed from the top are perceived as harmful, wasteful or inappropriate by local communities, or, on the other hand, when local demands are rejected by authorities, mainly because the government institutions are either incapable to implement them, or they see these community proposals as incompatible with the overruling existing plans and regulations.

The UEP paradigm rejects this vertical duality in which communities are always disadvantaged, and proposes a more collaborative approach in which a more horizontal partnership between actors in all levels –from the decision makers on top to the most marginalized and underrepresented on the bottom– work together towards the same goals. As Jane Jacobs (1961, p. 238) nicely put it, “[c]ities have the capability of providing something for everybody, only because, and only when, they are created by everybody”.

Urban interventions in such framework can take forms of scaling up and scaling down, which according to Hamdi (2010, p. 224) are “complementary practices”. He argues that

> the best way of scaling up the impact of projects is to scale down the size of units or organization, of management and decision making to make sure that accountability is held locally and that success or failure is measured by those who are affected most. Scaling up then is about federating or networking lots of small relatively autonomous units of organizations (network governance) and not about making entities bigger.” (Hamdi, 2010, p. 223-224)

Many scholars have recently emphasized the importance of decentralizing and scaling up urban interventions, instead of enforcing programs and policies from the top. Kaika (2017) explained how local and community-driven initiatives have a greater potential to address global challenges of social inequality, climate change and economic uncertainties than top-down indicators and ‘remedies’, such as SDGs (Sustainable Development Goals), Smart City programs, etc. While examples from crisis-driven Spain and Greece mentioned by Kaika show autonomous initiatives that emerged from strong community mobilization and common dissensus (ibid.), there are also similar scaling up processes facilitated by specially established government institutions and local or international NGOs, whose role is usually to coordinate joint efforts and provide professional advice to local communities, particularly in slum upgrading projects (Archer et al. 2012; Boonyabancha, 2005; Das & Takahashi, 2009). These initiatives are in line with the ideas put forth by Turner (1972, 1976), who argued that households should have control over housing, both as a commodity and a process (of housing), while the role of the government is to provide support for housing construction, provision of services and regulation of the commons.

One of the most known example of a simultaneous scaling up and down is the Orangi Pilot Project (OPP) which provided sanitation infrastructure to around 300 informal settlements in Pakistan since 1980 (Hasan, 2008). Planning, financing and construction of the local sewer connections was done by residents organized in lane committees and supported by professional engineers, while the trunk sewers and other supporting infrastructure beyond the settlements was financed and implemented centrally by the OPP (ibid.).

Students performing their fieldwork in Pune observed how bottom-up approaches and initiatives in their respective areas, such as providing basic services, extending urban infrastructure, running saving groups, transforming of underutilized common spaces and organizing religious festivals, create additional benefits of community building. They recognized that there is a great potential in exchanging ideas and scaling up such initiatives. Most of the students' proposals for interventions were therefore also based on the ideas of decentralization, community ownership and local initiative. Some examples include a community trust model for land ownership in Shirole Vasti and a community toilet operated by local residents and users themselves under a "Sanitation Company" in Raviwar Peth (Akavarapu et al. 2017). This last proposal will be elaborated later in this article.

3. Problem / Issue based vs. Value based and Developmental

Thinking of urban planning as an unbiased, problem-solving oriented exercise is utopian and wishful thinking. The ambitious goal for urban ecology to seek balance, equity and improvement (Bjønness and Corneil, 1998) requires planners and decision makers to take value stances on behalf of those who are disadvantaged by the dominating economic, political and environmental regimes, such as ethnic minorities, immigrants and refugees, indigenous people, LGBT communities, unemployed, homeless, women, children, etc. Considering that natural and financial resources, land and livelihood opportunities are scarce, these stands may necessarily place limits on property rights and prosperities of the privileged classes. This principle does not only require planners and practitioners to act ethically and compassionately, but as argued by Barry et al. (2018), to change in the way planning knowledge is produced and applied and to reconsider how we define and regulate property.

The UEP framework subscribes to the above statement and the preposition put forth by Blanco et al. (2009, p. 235), who argue that

> [b]uilding an alternative planning praxis rooted in the South demands a progressive value base that is both social and ecologically informed. The concept of universal socio-economic and environmental rights offers a profound moral base for planning, but its application in cities of the global South needs interrogation.

Oftentimes planners and decision makers face difficult choices which require making compromises and innovate, always taking into consideration the factual local necessities and aspirations. Ideologically, many urban and environmental planners are divided based on what McGranahan and Satterthwaite (2000) called the "green" and "brown" agendas. The green agenda focuses on ecosystem health, environmental sustainability, nature protection, climate change mitigation, as well as responsible and reduced consumption. Its main target are future generations, therefore emphasis is placed on long-term planning and education. The brown agenda, on the other hand, is centered about human health and well-being, satisfaction of basic needs and equal access to resources. The prioritized groups are low-income communities who urgently require better services and housing (or shelter) options (ibid.). Considering how the contemporary world becomes increasingly globalized, unequal and unpredictable, the mainstream viewpoint that the more prosperous countries can and should focus on the green agenda, while poorer states should first take care of the basic services to ensure a dignified quality of life through prioritizing the brown agenda goals, is oversimplifying the problem. Therefore, we argue that planners and environmentalists need to work together to go beyond this divide and seek creative solutions that can reconcile both agendas to pursue a world that is not only environmentally sustainable, but also provides good quality of life and opportunities for all.

Middle- and high-income capitalist countries are also facing rapidly growing problems of poverty, homelessness, discrimination, marginalization and oppression, all of which are partly attributed to a planning system and policy making that serve the capital accumulation and private property owners (Harvey, 2013; Mitchell, 2003/2014). Western cities (especially in post-WTC USA) have been characterized by an increasing limitations on freedom of speech, brutal repression of protests and strikes, escalating surveillance measures to control behaviour, privatization of public space, criminalization of homelessness, gentrification and touristification, and other forms of socio-spatial exclusions (Albert & Benach, 2017; Beckett & Herbert, 2010; Blomley, 2004; Harvey, 1989 and 2013; Mitchell, 2009, 2011, 2003/2014, Speer, 2016; Staeheli & Mitchell, 2008).

Scholars and activists who oppose these processes are united under the slogan of the “Right to the City” (Attoh, 2011; Blomley, 2004; Harvey, 2013; Marcuse, 2009; Mitchel, 2003/2014), which originates from the works of French philosopher Henri Lefebvre (1996 [1968]), who called it “a cry and demand” and constant struggle for more democratic and open cities in which all citizens participate. The right to the city is not only about access to public space, but also a universal right to adequate housing, basic services and a generally to inhabit and co-create the city (Attoh, 2011; Mitchel, 2003/2014). Since the early works in 1980s in Nepal, the right to the city principle has also been central to the UEP approach.

UEP takes a stance to first and foremost represent and improve the situation of the marginalized and poor communities, as they are usually the ones that are left out in the mainstream urban planning. Unlike many other universities and colleges performing fieldwork in India, we refused to making proposals in greenfield location or work in more prosperous areas which receive funds from the “Smart City” Program, but instead we chose to work with communities that are below average income and areas that are for different reasons problematic (Figure 3). Students, however, have been taken for short excursions to some of the most prosperous areas and gated communities to see, and compare, the existing inequalities and to learn why and how planning frameworks fail to mitigate them.

Figure 3. Precarious living conditions and overcrowding in Shirole Vasti. Source: Baracho Teixeira, et al., 2017

4. Comprehensive and Rigid vs. Strategic and Contingent

Comprehensive and rigid planning attempts to envision, define and/or regulate a wide range of sectors (housing, transportation, infrastructure, land-use, public space, etc), covering large geographical areas and within a long-term time horizon. Comprehensive plans often take forms of master plans or detailed general plans that are supposed to guide development in a specified area in one and only possible direction. These principles have shaped planning frameworks in many developed and developing countries. However, they rarely achieve the expected results. In times defined by political, social, economic and environmental uncertainties and emergencies, such as natural and man-made hazards, financial crises, armed conflicts, forced displacements, infrastructure breakdowns, epidemics, combined with chronic issues of inequality, poverty and resource scarcity, making rigid plans based on long-term predictions and projections is simply unrealistic.

Cities, similarly to other kinds of ecosystems, function like organisms, which react to shocks and emergencies by attempting to combat their effects within themselves. Bjønness and Corneil (1998, p. 63) wrote about the "carrying capacity" and "the ability of a city as a social system to accommodate social demand and stresses". However, the role of planners should not only be limited to support and maintain the institutional, social, environmental and economic structures which facilitate the recovery and rebuilding processes, but also to seek solutions to resist and prepare for the different kinds of uncertain scenarios in the future.

The alternative we propose is strategic and contingent planning. Nabeel Hamdi (2010, p. 65), who has written about Strategic Action Planning (SAP) defines the principle of strategic planning as "to meet the needs of now, while working toward the aspirations of soon and later". Similarly, contingent planning recognizes that urban development requires incremental and flexible approach, which can respond efficiently to the rapidly changing situations (Rondinelli et al. 1989). In contrast to static policies, contingency planning facilitates adaptive policymaking, interventions and management (Bloemen et al. 2017). It does not follow a predefined, rigid framework and is context-dependent.

The main difference between these value positions is that a comprehensive and rigid plan often starts with defining how space should function and look like at the end of the process, and then seeks ways to achieve it. Strategic and contingent planning, on the other hand, starts with the situation analysis and the definition of main issues to address, and then seeks which interventions, step-by-step can contribute to gradual recovery and/or improvement. It is usually a circular process in which intermediate interventions are followed by monitoring, learning, reflection and evaluation, before deciding for another round of interventions.

Two proposals from student groups working in Raviwar Peth reflect strategic thinking in planning, as opposed to a typical, top-down comprehensive planning. One group identified sanitation as the main and most urgent issue to be addressed in their corresponding area. As a starting point for their proposals, they acknowledged that the city-wide sanitation plan from 2011 lacked sufficient resources to ensure proper provision and maintenance of the toilets it provided, and that toilets are generally maintained better when there is a feeling of ownership of these facilities among communities that use them (Akavarapu et al. 2017). From that, they developed a proposal for a sanitation block not just as a piece of infrastructure, but as a financial model (called a "Sanitation Company"), which would ensure generation of funding for maintenance and further improvement of the toilet block (ibid.). This is not a completely new proposal, as the NGO called Shelter Associated has been doing similar projects in Pune before.

The second group in Raviwar Peth focused on solving traffic issues in their area (Figure 4) and proposed making the streets more pedestrian friendly. They realized, however, that streets cannot be simply closed for cars overnight, because that would seriously interrupt the circulation in the area and in particular, the delivery of goods to the local retailers (ibid.). Therefore, the students suggested a gradual, step-by-step interventions, starting with temporary and partial traffic restrictions for specific festivals and days in a monthly or weekly basis. Only if these pilot-projects prove successful and gain support of the local residents and shop-owners, more traffic restrictions can be tested later (ibid.).

Figure 4. Busy street in Raviwar Peth. Source: Akavarapu et al. 2017.

An example of a contingent behaviour are community saving groups, which help residents mobilize funds for strategic investments and to respond to crisis situations. Existence of these was observed in different forms in all the three studied areas. In Shirole Vasti, where the majority of the working-age population is involved in precarious informal work, women saving groups are supported by the Pune Municipal Corporation (PMC) through the Nagarvasti Vikas Yojana and the City Slum Redevelopment Scheme. Among the incentives are free bicycles for children, financing for entrepreneurial activities for the residents and revolving funding schemes offered to women's self-help groups (Baracho Teixeira et al., 2017). Saving groups in Kasba Peth provide 'crisis' credits and loans for income-generating activities for women. They also help fund housing improvements or construction of new housing for member households. Money is collected on weekly basis and deposited to a bank account (Awusie et al., 2017b). In the Durjan Singh Paga settlement in Raviwar Peth, saving schemes are also managed by women, which operate them at three different levels: personal, small group and community. Money collected by the small saving groups are given monthly to the woman with most needs and when there are no particular needs, the choice of the recipient is made through lottery. Community savings operate in the Janlaxmi scheme. The money is stored in a bank account and is used to fund initiatives and respond to problems at the settlement level (Akavarapu et al., 2017). All these are bottom-up initiatives that are occasionally supported by the local governments and financial institutions. Through savings, the communities invest in assets and increase their resilience and preparedness for different kinds of uncertainties.

5. Standardized and Generalized vs. Contextual

The UEP approach rejects the application of standardized and generalized solutions to urban problems and emphasizes the importance of local contexts. Various authors argued how replication of the same ideas in places defined by different demographic, climatic, economic, environmental, political and/or social urban conditions leads to disasters and wastefulness of resources (Hall, 1982; Healey, 2012; Lieto, 2015; Watson, 2014b). A classic example of this are the disastrous impacts of the Athen's Charter's ideology on cities around the globe, which is among the main themes of the Quito Papers (UN-Habitat, 2018). Planners should be very careful when applying 'good practices' in much different contexts from the ones in which they have been initially tested.

One example of illustrating what we mean by this contradiction is explaining two different approaches to slum redevelopment in Pune - one being more institutionalized and mainstream and the other more experimental and context-based.

Housing conditions and the quality of built structures vary drastically not only between different slums in Pune, but also within the same informal settlements. It is very common to find solid structures made of concrete or bricks with all the modern amenities next to precarious, makeshift shacks built of wood, metal sheets or plastic.

However, these particularities of Pune's slums have not been taken into account by the local and regional authorities under the Slum Rehabilitation Authority (SRA) scheme established in 2005. This scheme is based on assumption that all slum dwellers deserve "better" (or rather "different") housing conditions and the way to do it is through redeveloping the entire plot on which the slum is located and re-house the residents into new high-rise blocks. This is done in cooperation with private developers who get increased development rights that allow them to construct additional residential units that are then sold on market. The same standardized scheme is being applied across the city and similar schemes are functioning throughout the state of Maharashtra. Such redevelopment projects have been implemented in Kasba Peth and have been proposed in Shirole Vasti.

As the students have found out, the actual condition of the housing stock is rarely taken into consideration in the SRA scheme and the slum dwellers are not involved in the planning process, beyond merely giving the majority consent for the developer to proceed with the rehabilitation project (Baracho Teixeira, et al., 2017; Awusie et al., 2017a).

In Shirole Vasti, the SRA development takes long time to materialize, because of a mismatch of the SRA regulations and the local realities, especially in terms of the complex and unclear land ownership and tenure situation. Another unresolved question is that of eligibility for new apartment units for households of different sizes and those who rent in the settlement (Baracho Teixeira, et al., 2017). In Kasba Peth, one slum pocket surrounded by already completed SRA buildings is ineligible for SRA scheme because of the small plot size that does not meet the minimum land coverage requirements (Awusie et al., 2017a).

A radically different scheme to the SRA has been tried in the Yerwada settlement, where the local population rejected the proposal for total redevelopment. Architect Prasanna Desai and his team were invited to come up with an alternative solution. They initiated a participatory process in which residents as well as local and international NGOs developed an in-situ housing improvement project (Desai, 2010), which they later called "Tailor made Slum Transformation" (Figure 5).

In the first step, the team performed extensive surveying of the slum and established links with the community. The structures were then classified into permanent/solid (pucca) and temporary/precarious (kutcha) according to their physical condition. In the next phase, architects in consultation with the residents developed design proposals to replace the kutcha structures with solid housing. Due to the irregularity of the plot sizes and shapes, as well as different preferences of the residents, each site was proposed a customized design. The alternatives varied from cluster developments with apartment units in a larger structures built on up to 3-4 joint plots to individual row-houses on separate plots. Funding for the project was provided in the now discontinued JNNURM program and the beneficiary households had to contribute 10% of the costs (ibid.).

Figure 5. Example of a redeveloped house in Yerwada, Pune. Source: Desai (2011).

Contextual solutions did not only provide a better response to the real needs and necessities of the slum dwellers, but they proved more, or equally as efficient as the standardized solutions, such as the SRA. The apparent advantages of the SRA scheme, which are to cut costs and reduce time in the implementation of the projects have not materialized in Pune. The participatory in-situ slum upgrading initiative in Yerwada was a lengthy and complicated process, but the bureaucracy around the SRA scheme and the challenges in applying the rigid and vague standards and regulations to particular context in our study areas made this scheme more difficult, and in some cases impossible to implement. Therefore, it was not surprising that various student groups referred to Desai's scheme in their proposals for upgrading of the studied settlements.

6. Formal / Informal vs. Formal - Informal continuum

The framework for understanding the relationships between formality and informality in UEP was provided by Uwe Altrock (2012, p. 186), who argued that the "close links between more formal and more informal modes in everyday life have shown that one should speak of an informality-formality continuum, hybrid arrangements and co-production by formal and informal actors rather than a dichotomy".

Altrock explained how the degree of informality can be measured in two dimensions: the strength of imposed regulations and the rigidness of negotiated agreements. Due to the complexity of cities as social ecosystems regulated by a set of laws and policies, most urban activities lay somewhere in in the scale between formal and informal. Informality supplements processes in which formality does not work and complements those where it does not reach (ibid.). Informality, therefore, is not an obstacle in development, but an integral part of it. "Hybrid formal-informal arrangements" –he argues– "are closely related to the regulative self-conception states" (ibid, p. 171). When discussing urban development and architecture, Marshall Berman (1982), argued that modernization attempts to impose a utopia of a total control over the built and social environment, which is impossible to achieve due to the prevailing spontaneity and informality of everyday life. Yet, despite the growing body of literature highlighting the formal-informal dichotomy (for examples, see Hansen & Vaa, 2004; Jenkins, 2004; Koster & Nuijten, 2016 and McFarlane, 2012), the traditional viewpoint that planning should eliminate the informal sphere and/or work only within the formal, is still prevailing in many countries.

While many scholars writing on urban planning in the Global South highlight the process of formalization of formerly self-help and makeshift settlements (De Soto, 2000; Fernandes, 2011; Guevara, 2014; Lall et al., 2009; Nakamura, 2014; Oldfield, 2002), this process also works in reverse. In our previous research, we have demonstrated how land-use in formally planned subsidized housing projects in Delhi, India (Aranya and Ulset, 2016) and Barranquilla, Colombia (Sliwa, 2017) has been gradually informalized and altered by the residents who were seeking better livelihood opportunities and attempted to fill the gaps in service provision.

The Shirole Vasti slum, for example, provides housing for families who could possibly never be able to afford shelter in the formal sector in such a good location, close to their jobs (Baracho Teixeira, et al., 2017). At the same time, its informal economy provides more affordable services to many of the students who attend the numerous local universities and other academic institutions, as well as labour to the residents in this predominantly middle- and high-income area.

An interesting example of formal-informal arrangements can be observed in Kasba Peth, where the Maharashtra Rent Control Act has kept their rent at artificially low levels for many years. The downside to this policy is that property owners have no incentives to maintain theie buildings and invest in upgrading (Figure 6). As a response to this problem, one household negotiated with the landlord and agreed to pay more rent than it is stipulated according to the Act. That way, both sides are satisfied - the owner has reasonable payment for maintaining the property and the tenant has increased security of tenure and higher living standards (Awusie et al., 2017).

Figure 6. Informality and the unsafe living conditions in Kasba Peth. Source: Awusie et al., 2017a.

In another case, the legal status of the Durhan Singh Paga settlement in Raviwar Peth has been unclear for many years, which resulted in a growing informalization of activities happening there. The site is formally owned by the PMC and has connection to the grid of all the basic infrastructure. However, the rent has stopped being collected from the households and the structures have not been updated in official maps for many years, mainly because the municipality gave up their claims to the land when it lost a legal battle with the residents to evict them to redevelop the plots for public facilities in 1960s (Akavarapu et al., 2017).

By including these and other informal structures and aspects in their research projects, students proposed much different solutions to everyday problems of the communities they worked with than the planners and other policy-makers in Pune. Everyday life in India (and beyond) provides many examples where the informal "penetrates" the formal and where formal and semi-formal emerge from informal arrangements. This coexistence of formal and informal is magnified by the fact that the chronic weakness of formal institutions in India spoils their capacities to implement the ambitious, long-term plans which they are required to pursue.

7. City as mechanism vs. City as an organism

As we indicated before, within the UEP framework, a city is not perceived as a functional and static mechanism, but as an organism in constant and complex social, political and environmental interaction. Those who practice comprehensive planning and modernist architecture often like to see their proposals as final products that by no means should be altered or changed by its users. Cities, however, benefit from their abilities to adapt to the changing circumstances and have capacities to react to unforeseen circumstances just like living organisms, which mature, gain strength and develop response systems to 'illnesses' and shocks.

Jane Jacobs called the city an "organized complexity", which simultaneously deals "with a sizeable number of factors which are interrelated into an organic whole" (Jacobs, 1961, p. 432). Planning, therefore should respect the organic nature of the city and support development that maintains human scale, enhances communities and make places safe. This includes, for example, recognizing the 'natural' emergence of a mix in land-uses and the coexistence of old and new (ibid.). Like in an ecosystem, the natural tendency in cities is to grow more complex, as opposed to separating into clearly defined functions.

The aspect of change over time is key to understanding this principle in practice. Mehrotra et al. (2017) challenge the notion of permanence of the built environment and point out the benefits of integrating more temporary, elastic, incremental and reversible (or as he calls them "ephemeral") spaces and uses in contemporary cities to better accommodate different social, cultural, economic and environmental functions, and to increase their preparedness for the uncertain futures.

While these principles gained widespread accepted among scholars and practitioners in recent years, the extent of impact and intervention of planners and architects in the built environment remains a point of debate. As Nabeel Hamdi (2004) frames it: "How much structure do we design before the structure itself interrupts the natural process of emergence?" (p. 73). Performing a proper diagnosis of a particular area and understanding its local context are key to answering this question.

The informal housing development in Shirole Vasti and the establishment of commercial uses in strategic locations in the settlement (Figure 7) show how a multi-functional urban area can emerge organically without any top-down masterplanning. In contrast, the SRA scheme pays little or no attention to the human and social aspects of living environments, but instead it only focuses on the durability of the structure and efficiency in space distribution (Baracho Teixeira et al., 2017). The gradual replacement of the traditional Wada-style buildings in Kasba Peth with their public, semi-private and private spheres by concrete high-rises is also divorcing the human scale from the built environment (Awusie et al., 2017).

Figure 7. Land use map of Shirole Vasti. Source: Baracho Teixeira et al., 2017.

Interesting patterns that resemble organic evolution of spaces and its uses, where interruption by formal planning was limited, has also been observed in the marketplace in Raviwar Peth, where retailers selling similar products cluster along the same streets and street blocks, while many smaller shops and street vendors are selling different products depending on the upcoming festivals, seasons and crops (Akavarapu et al., 2017). Many street vendors also chose locations to compliment the offer of the established retailers in the buildings behind, for example vendors who sell spices and vegetables often set up their carts in front of shops selling kitchen utensils (ibid.) Like in Mehrotra's Ephemeral City (Mehrotra et al, 2017), common spaces in all three settlements served multiple functions, accommodating social and religious events, playing children, community meetings, parking etc.

8. Instrumentalism / Structuralism vs. Social constructivist

The epistemological underpinnings of UEP are social constructivist as opposed to instrumental or structuralist basis of mainstream planning. Social constructivism is a sociological theory of knowledge according to which human development is socially situated and knowledge is constructed through interaction with others. The phrase was coined by Peter L. Berger and Thomas Luckmann in *The Social Construction of Reality* (1966). Instrumentalism on the other hand suggests that theories are tools or instruments able to identify reliable means-end relations found in experience, but not to identify realities beyond experience (first attributed to Dewey, 1925 and Popper, 1956). Structuralism suggests that elements of human culture must be understood by way of their relationship to a larger, overarching system or structure. It works to uncover the structures that underlie all the things that humans do, think, perceive, and feel (first suggested by de Saussure et al., 1916). The last two positions are more characteristic of mainstream physical planning where the emphasis is on finding solutions to measurable problems within the framework of city wide systems – such as traffic networks, water supply and land-use planning.

UEP on the other hand is dependent on the socially situated analysis of local areas, to find both locally relevant and socially contingent solutions for issues which are prioritized by residents in the identified area for engagement. This approach is essential in order to ensure that the needs and priorities of even marginalized groups are represented in the plans, and those that one is planning for actually feel ownership of the plans being made. Consequently, the methods used in UEP are borrowed from disciplines such as sociology and social anthropology, relying heavily on participatory and socially interactive means of evincing knowledge.

These principles in UEP defined fieldwork methods in Pune and previous trips. This has always resulted in a much greater depth of the collected information and greater trust among the participating communities. While traditional planning attempts to ‘operationalize’ data by seeking concrete answers to narrowly-defined questions and assumptions using primarily quantitative methods, surveys and closed-end questions, the UEP approach enables planners to get a holistic overview of the situation with all its complexities and interdependencies. Identification of real needs and necessities and the discovery of alternative paths is possible only when the community is treated as equal partners in the planning process and gets a chance to “unfold” the story through answering open questions and making proposals or suggestions about their own environments. This is not to say that qualitative methods and exploratory research should detach from larger structures and systems, but that the human factor and social processes at local level are at least equally as important in the planning process.

9. Planner as an executor / implementer vs. Planner as facilitator

The final, and perhaps the most important principle that characterizes the UEP approach is the positionality of urban planners in their profession. In too many places, planners assume that people they plan for do not know what they need and what they want, because of their apparent lack of knowledge and understanding of their environments. Such thinking leads planning professionals to a common perception of community participation as unnecessary; which explains why it is so often replaced by manipulation, therapy or in the best cases, ‘consultation’ sessions, which in reality are barely one-way information channels (Arnstein, 1969). These kinds of planners still see their professions as executing and implementing plans.

When tracing the history of the planning profession, Michael Lennon (2017) explained how it evolved from a primarily design-oriented, ‘artistic’ ideology, into a more scientific and technocratic discipline of mapping and predicting urban complexities, to finally reach the current stage where planners advocate “on behalf of those who live, work and use the spaces being planned” (ibid. p. 148). The last stage, however, has not yet become the mainstream, at least not in certain countries, where planners either refuse to give away their status as experts in their professional fields, or follow outdated and obsolete education curricula that still promote the idea of planners being ‘designers’ of spaces, ‘creators’ of plans and ‘implementers’ of their own ideas (Siame & Muvombo, 2016).

The UEP approach is grounded by the principle that planning should be done by the people directly affected by the planning decisions. The planner, therefore, should not plan ‘for’ the people, but 'with' them, as equal partners. In other words, a professional should not be making decisions for communities, but instead facilitate a process in which they can take the best choices for themselves and access resources to improve their own lives and livelihoods. This is based on the (rather banal) idea that the communities actually know their situations and aspirations better than anyone else. As Hamdi (2010, p. 145) argued, "the expert comes to be seen as a special kind of person, rather than that every person is a special kind of expert". He further claims that planners and policy makers who 'provide' actually do more harm than help, because they increase the dependency of the communities on institutions, while a more 'enabling' approach actually increases the capacities and opportunities for them (ibid.).

The application of a participatory and exploratory approach to planning applied by the UEP students in Pune was perhaps what brought the most lasting positive impacts in their respective areas. The most evident was the change in mindset of households and communities in the studied areas. At first, it was clear that local residents were initially discouraged and disappointed by the failed promises of their representatives at the different levels of government, the ineffectiveness of public institutions, and the time-consuming surveys made by students and interns from local universities and NGOs. However, after spending some time with the UEP students, the residents seemed (at least to certain extend) to have restored their faith in planning, collaboration and collective decision making. This was especially visible in Shirole Vasti, where over 50 local dwellers came to participate in the final community meeting organized by the students (Baracho Teixeira et al., 2017; Figure 8).

Figure 8. Community meeting in Shirole Vasti organized by the students. Source: Baracho Teixeira et al., 2017.

Students also practiced a multi-stakeholder approach, where the information and ideas they gained was shared, reconfirmed and compared with other project partners, such as the local NGO Maharashtra Social Housing Action League (Mashal), the Indian National Trust for Art and Cultural Heritage (INTACH) - Pune Chapter, as well as other local architects, planners, politicians and researchers. The result of this collaborative work was that the proposals of most groups were much more localized and different (or directly opposite) to those proposed by the local authorities.

Conclusion

This paper discussed the role urban planners should play in relation to the nine value positions of the Urban Ecological Planning approach as opposed to traditional urban planning. Through examples from urban governance and development work in Pune, we argue that in complex contexts where social, political and environmental issues play out in the interface between the formal and the informal, planners need to stop thinking of their job as executing and implementing plans. They should rather act as facilitators, coordinators and enablers who connect the different actors and stakeholders together. Particular focus should be on the Right to the City and on addressing the needs and aspirations of marginalized communities who are normally underrepresented and excluded from the formal planning and development processes. This exclusion is to a large extend a result of the 'wishful thinking' of technocratic planners who give too much faith in social engineering, while at the same time underestimate the power of communities in shaping their own living environments.

By teaching the above mentioned values to our students and exposing them to some of the most challenging urban environments, we attempt to supplement and fill the gaps in planning education. While the UEP approach and the study program have been evolving to keep up to date with the contemporary issues in urban development, the idea of shaping the right 'mindset' has remained unchanged. Therefore, we propose to end this paper the same way, which Bjønness and Corneil (1998, p. 66) ended their article on UEP principles twenty years ago:

> If we teach students about change and complexity and give them tools and methods to operate effectively in this dynamic context, we can prepare them to have a practical approach to local problem solving, grounded in the deep understanding of urban transformations and the implications of their actions to the direction of future change.

Acknowledgements

We would like to give special thanks to all the students who participated in the 2017 Fieldwork in Pune: Sai Varsha Akavarapu, Mathias Awusie, Danussia Baracho Teixeira, Nitu Bhujel, Idunn Kvande Dagestad, Marie Langsholt Holmqvist, Nataliya Kandratsenka, Kristina Stendal Karlsen, Krishnan Kavungal Anat, André Kraemer Góes, Rachael Letscher, Astrid Moen, Emmanuel Pérez Banda, Solomon Quarm, Abbas Saad, Issifu Salifu, Julianti Putri Setiawan, Penelope Smith, Cinthia Freire Stecchini, Li Xin, Zwestin Gomgom Welfry and Håkon Carlsen Vetlesen. We would also like to thank Prof. Eme. Hans Christie Bjønness for his valuable comments.

Sustainability planning for small border towns entering the global tourism market

Teipelke, Renard, GERA, Germany

ABSTRACT:

Although set in a very different geographic and cultural setting, Mestia in Georgia and Ha Giang in Vietnam make for revealing cases of small border towns that try to reap the benefits of alternative tourism sectors as a driver for their economic development. Due to their location in remote mountainous areas, far away from larger urban agglomerations, service centers, and their capital city, the demands and prospects of development planning for Mestia and Ha Giang pose a number of challenges, while also providing for excellent opportunities in attracting people to seemingly untouched, natural, and traditional destinations.

The case study aims to position Mestia and Ha Giang in a growing global tourism market, analyzing their unique potentials and discussing their challenges and threats with regard to their border location (to Russia and to China, respectively), comparative small size, limited financial and human capital (including issue of migration), as well as increasing climate change risks.

The case study is based on the author's own planning work in these towns as part of larger international development projects in the area of livable city development and integrated regional planning. This allows for a comparative perspective on Mestia and Ha Giang with regard to other, larger cities in Georgia and Vietnam with similar development visions, but vastly different situations in terms of resources and strategic opportunities.

The objective is to show the interlinkages between a globally-oriented tourism-focused economic development policy and the local needs for social and infrastructure development, as well as natural resource management. Embedded in the particular setting of international development urban planning assistance and infrastructure finance, the case study critically reflects on the relation of different actors, including development organizations, consultants, national governments, local decision makers, private sector, and civil society within Mestia and Ha Giang.

The case study will investigate in how far innovative participatory planning approaches can go in cities that have previously been hardly exposed to less traditional planning methods or international good practice. The concepts of sustainability planning – including aspirations for prosperous, inclusive, green, or livable cities – will be contrasted with realities on the ground, affected by local development priorities, power relations, budget constraints, planning traditions, and other internal and external factors.

These aspects will all be presented through a spatial lens, mapping and illustrating the social and physical implications from Mestia's and Ha Giang's development, for instance with regard to periurban growth, real estate development, infrastructure deficiencies, and regional connectivity.

Towards World-class Lakeshore City from Edge County Seat: Wu Xuan's Over-taking Development Strategy accompanying the Construction of Da Teng Valley Reservoir

Wang Jinbai, Xiao Da, Chen Chen

Abstract：Promoting regional development by means of major projects is a developing path that China frequently adopts and should shed light on the over-taking development strategy in less developed regions or economies. Wu Xuan County is a small county in Guangxi Zhuang Autonomous Region in Western China. Due to the construction of a regional infrastructure project——Da Teng Valley Reservoir, Wu Xuan have to deal with the pressure of immigrant resettlement and supporting infrastructure construction, however, Wu Xuan also faces the opportunity to implement an over-taking development strategy at the same time. With the active operation of the local government and the multi Lake situation brought by the storage of water, the development vision of "World Lake City " is put forward. The unique landscape, cultural landscape, cultural tourism development and industrial economic transformation and upgrading of the local areas are linked up, and four characteristic development strategies are constructed to seek the development path of the global market with the characteristic value, and the systematic planning and design has been compiled. Working through the process of this planning and design, this paper holds that, with major projects to promote local development in China, there are relatively superior institutional conditions, centralized leadership is convenient for the implementation of major projects, and can indeed promote the breakthrough of local development in a short time. However, because there are great differences between major projects and the less developed areas in terms of talent reserves and resource calls，the process of promoting major projects may encroach resources and space for local development.
Keywords：major projects; local development; over-taking strategy; Wu Xuan; China

1. Introduction: major project development and Wu Xuan cases with Chinese characteristics

Promoting regional development by means of major projects is a developing path that China frequently adopts and should shed light on the over-taking development strategy in less developed regions or economies.

Western scholars have paid much attention to China's rapid urbanization and its internal mechanism (Ma, 2002, Zhang, 2004, Friedman, 2005, Huang, 2010), but still rarely targeted research and interpretation on the new urban area development, which has played an important role among the urbanization.

Especially since the 2008 financial crisis, Chinese traditional approach of large-scale projects development is increasingly being challenged, such as resources and environment impressing, social fair and stable, policy adjustment, and many other issues become increasingly prominent, indicating that the path may face a major transformation of mechanism. At this time, the reflection and analysis of this development model is very necessary and urgent.

Wu Xuan county is a typical case of development in areas affected by large projects. Wu Xuan County is a small county in Guangxi Zhuang Autonomous Region in Western China. Due to the construction of a regional infrastructure project——Da Teng Valley Reservoir, Wu Xuan have to deal with the pressure of immigrant resettlement and supporting infrastructure construction, however, Wu Xuan also faces the opportunity to implement an over-taking development strategy at the same time.

Through the analysis and arrangement of the main contents of the series planning and design of Wu Xuan county, this paper explores the dual influence of large projects on the local development and provides a reference for the optimization of such development models.

2、Overview of major project development since the founding of the People's Republic of China

Chinese government promote the large-scale regional development has a long history. In the contemporary era, it can be traced back to the period of planned economy.

In the 1950s,156 large projects built with help from the Soviet Union ,the 1960s "Three-Lines" large projects construction and the 1970s complete sets importing large projects ,were some of the projects implemented under government lead(mostly for industrial development).

Since the Reform and Opening up begin from 1978, China has gone through four rounds new large-scale development boom: the experiment of Special Economic Zone in the 1980s, the Industrial Development Zone in 1990s, the development of the new urban area in the early 21st century, and the national big strategies since 2008. (Table 1)

Throughout 7 rounds of the urban development booms, central government’s control of resource has remained at a high level, but local agents participated in the developments differently. In the early period of planned economy, the government implements large projects directly, its agents operated on a relatively simple technical tasks. For instance, the factory director is only responsible for production management, rather than product marketing and profitability. Since the Reform and Opening-up, practice from Special Zone to Development Zone, have formed a new policy driven regional development pattern. In this case, local agents have transitioned into operating semi-independently for profit entities, which functions included project introduction, implementation and so on.

The driving effect of large projects on local urbanization and urban development is reflected in: 1) to break through local resource level and form scale rapidly; 2) bring a large number of non-agricultural population and non-agricultural construction, and rapidly change the appearance of local urban and rural areas; 3) as a result, local urban facilities and urban functions have been significantly improved.

But big projects often focus on their own economic missions, with some adverse effects on local development: 1) most of them are limited to the urban area, but not obvious to the surrounding area as a whole, which often leads to unbalanced local development; 2) large-scale development of large projects brings great pressure on local environment; 3) the dominant pressure of big projects will restrict the development of local diversified creativity, forming a crowding out effect, which makes local governments have to rely on big projects; 4) big projects are often arranged from their own perspective, which is not completely in conformity with the local urban functional order or even leads to big conflicts; 5) excessive reliance on large projects may lead to a single urban economic structure, which may lead to a weak ability of multiple innovation and economic risk resistance.

TABLE I. SEVEN ROUNDS OF THE GOVERNMENT LEAD LARGE-SCALE DEVELOPMENT BOOM SINCE THE FOUNDING OF NEW CHINA

	Times	Backgrounds	Contents of development	Manners of development	Effects	typical representative
Planned economy period	1950s	aided by the Soviet Union, early planned economic system built	156 large projects (effectively 150 projects)	The country investment and operation directly	New industrial urbanization	YTO Group Corporation
	1960s	Implementing “Three- Lines Construction” prepare for the International war clouds	approximately 1100 large projects：military，hemical，machinery manufacturing, etc.	The country investment and operation directly	located scattered across the area and the development later turn into many industrial cities and town	Shiyan Motor City
	1970s	The normalization of Sino-US	Introduce complete set projects from western countries, 26 in 1972; 22 in 1978	The country investment and operation directly	Enrich part of industrial urbanization	Shanghai Baosteel Group Corporation
Reform and Opening up period	1980s	Investment structure reform in initial stage of reform and opening up	Put four special economic zones(SEZ) and 12 development zones into trial	promote local develop dynamic by government’s policy	SEZ develop into new city, development zones are phased in	Shenzhen SEZ
	1990s	the reform and opening up push greatly ,Development Zone policies promote extensively	thousands of national, provincial and local development zone	Under national policy-driven, local introduce and operate projects actively	Development Zone rapidly develop, industrialization and urbanization speed up	Pudong New Area, Suzhou Industrial Park
	early 21st century	reform and opening up systemic, new urban areas large expansion	topics of new urban areas	local plan projects for national policy support	urban and rural areas change, Real estate economy inflate, exacerbating the society imbalanced	Tianjin Binhai New Area, Zheng Dong New District of Zhengzhou
	After 2008	economic crisis, expand domestic demands, develop the middle and west	more than 10 national regional development strategies, several new SEZs, lots of new development zones	Under national policy-driven, local introduce and operate projects actively	the middle and west development, eastern transformation, urban regionalization	national strategy of Wanjiang City-Chain

At present, the development dominated by big projects is still common in all parts of China .Based on the above analysis, it can be seen that large projects can indeed bring effective impetus to regional development, but there are also many adverse effects, which is a development direction worth striving for rather than relying too much on.

In recent years, large projects in some cities in the central region have gradually decreased their share of local economy, which is reflected in: 1) large projects have gradually formed independent industrial clusters.2) in the development of a new type of economy with industrial parks, on the one hand, it absorbs more and more industrial transfer; on the other hand, it absorbs various investments including large projects to form new enterprise groups.3) the rise of urban economy driven by the development of new cities has supported the local fiscal revenue, thus promoting the improvement of local urban public environment .This reflects the direction of local economic structure optimization in the new era, and the rise of new economic forms, which has formed a good remedy and optimization for the traditional large project economy.

From the perspective of the trend of economic globalization, no matter the national capital, civil capital or foreign capital, large-scale economic organization is an important trend to participate in global competition, so big projects are still of great significance .However, only by strengthening the social responsibility of major projects, opening up and stretching the economic chain, cultivating the surrounding small and medium-sized enterprises, and strengthening the environmental impact monitoring of major projects, can the large projects complement the local social and economic development.

3. Wu Xuan county development strategy innovation under the influence of big project

Wu Xuan county is a small county town in Guangxi Zhuang autonomous region of western China. Because it is located on the shore of Qian Jiang river, it is affected by the great Teng Xia water conservancy project, a major project of the Zhu Jiang – Xi Jiang river basin, which not only has to bear the heavy pressure of resettlement and supporting the project, but also brings the opportunity of breakthrough and development.

3.1 development conditions and basis

(1) there are certain characteristic resources, but the economic foundation is weak

Wu Xuan county has world-class natural landscape resources, thousands of years of heritage cultural resources, unique local characteristics of local products and mineral resources, and a growing population resources; However, the economic development foundation is weak, the industrial structure is unbalanced and the economic growth speed is slow.

Wu Xuan county has rich population dividend resources .There are two main trends in the population development of Wu Xuan county .On the one hand, during the 10 years from 2006 to 2015, the growth of the registered population in all areas and counties of Wu Xuan showed a slow rising trend in the fluctuation, at a relatively high level, and there will be a small peak of population fertility .On the other hand, the age structure of the population in Wu Xuan county tends to be younger, and the proportion of the working-age population is increasing, which is at the peak of the labor supply .The construction of the great Teng Xia reservoir will also bring a certain amount of immigration, that is, it is still in the demographic dividend period.

Wu Xuan county has outstanding landscape cultural resources .With the southwest side of the city across the river, the Wu Malan river is beautiful, beautiful and beautiful .In addition, the eastern side of the city will soon form the water surface of Qi Xing lake, covering nearly 10,000 mu. Moreover, the local government intends to connect the water system around the city to form the overall landscape pattern of mountain and lake city, laying a foundation for building high-quality urban areas and expanding the new space for urban space development. There are also unique Pan Gu culture and manor culture, including more than 20 modern manors represented by Huang Zhao Xi manor, the largest courtyard building in Guang Xi, Liu Bing Yu manor combining Chinese and western styles, and Guo Song Nian manor in an elegant form .At the same time, it has formed the shijing dock culture and the characteristic Dato gorge culture supported by Qian Jiang shipping.

In addition, there are abundant material resources in Wu Xuan. The reserves of dolomite and limestone are more than 10 billion tons, and the reserves of lead, zinc and manganese ores are over 10 million tons. The sugar production accounts for 1.87 percent of the national total.

But Wu's economic base is weak. The GDP index is lower than the national and regional average. Investment in fixed assets accounts for 80% of GDP, showing the characteristics of investment-driven development. The proportion of primary industry is high, mainly traditional agricultural production. The development level of the tertiary industry is low, mainly in the traditional service industries such as wholesale and retail, accommodation and catering. The secondary industry has a certain foundation, mainly in mining and processing of agricultural and sideline products. The product processing depth is limited, the added value is not high, the industrial structure is relatively simple, and there is no big enterprise brand.

(2) there are certain location conditions, but the regional support is weak

Wu Xuan county is located in the geographical center of Guangxi province, bordering Liuzhou and Lai Bin. However, it is difficult to effectively attract industrial transfer in large regions due to lack of conditions and basis for economic exchanges with foreign countries.

Around large and medium-sized cities including Liu Zhou, guests, your port, Gui Ping form a "diamond" prismatic area, the area of the total population of 15.5 million people, has great market space, surrounding and Wu Xuan is in the geographical center of the area, through the north-south, east-west closely linked to the two highways and surrounding formation, type hub traffic location characteristics, ease of use of breakthrough in the surrounding market development.

But the overall economic level of the surrounding areas is relatively low. GDP, per capita GDP, total tourism revenue, and the number of domestic tourists are all in the relative depressions of the two regions. The low overall economic level of the surrounding areas restricts the utilization of the surrounding market, requiring Wu Xuan to seek a broader market space through the opportunity of large projects.

(3) Facing major development opportunities, but lack of breakthrough projects to grasp

The new technological revolution, the geopolitical pattern and the deep regional transformation have all brought the opportunity to directly connect with the global first-tier market. Guangdong, Hong Kong and Macao bay area strategy, Bei Bu gulf economic zone strategy, Zhu Jiang – Xi Jiang economic belt strategy will be Wu Xuan and the pearl river delta connected. The development of Dato gorge project has brought the development opportunity of deep transformation for Wu Xuan county.

At the same time, in the new era of consumption, tourism consumption will become a strong driving force for county economic growth. Wu Xuan county is located in the tourism economic circle around Da Yao mountain. Its unique natural and cultural resources will become the growth engine for the development of the tourism industry and promote the development and transformation of the county's economic structure.

In addition, under the condition of the development of new and high information technology, Wu Xuan county and other geographical marginal areas will be able to directly connect with the development strategy of economically developed areas, directly integrate into the global economic system, and realize the leapfrog development of service industry and science and technology industry on the basis of the traditional path of agricultural transformation and industrialization accumulation and development.

However, the local economic foundation of Wu Xuan county is weak and there is no major project to coordinate the economic development. From the perspective of the 13th five-year plan of Wu Xuan, the planned major projects lack the engine projects and breakthrough projects that affect the overall situation, and fail to fully explore and utilize the major change opportunities brought by the major projects in the great Teng Xia.Further planning and planning are needed to seek breakthrough development of large projects.

(4) comprehensive judgment

The basic conditions of Wu Xuan county reflect the common characteristics of underdeveloped counties and cities in western China.

3.2 major projects bring opportunities for strategic breakthroughs

The Da Teng Xia water conservancy hub project is a flood control and control hub project in the pearl river basin approved by the state council. It is also a landmark project for infrastructure construction of the pearl river delta Xi Jiang economic belt and the "west river billion tons golden Water way". The project dam is located at the outlet of the great Teng Xia gorge (namely, Nuo Tan village, nanmu town, Gui Ping city, Guangxi province) in the Qian jiang river section of the pearl river basin, about 6.6 km away from Gui ping Qian jiang bridge and 50 km away from Wu Xuan county town.

According to relevant plans, the normal storage water level of the Da dong xia water conservancy project is 61.0 meters, the total storage capacity is 3.43 billion cubic meters, and the reservoir channelized 279 kilometers of the waterway, enabling the vessels of Liuzhou, Lai bin and Gui Ping of Guangxi to sail over 1000 tons. The number of people affected by the flooding was 9,882, and the number of people relocated and resettled at the planned level was 20,351, covering 113,693 mu of land of various types. Although the dam site is located in Gui ping city, the main flood area and settlement area are located in Wu Xuan county.

One of the most prominent changes is that Qi Xing lake, about 9 square kilometers in the east of the county, has greatly changed the geographical environment and landscape pattern of Wu Xuan county, and provided an opportunity and possibility for Wu Xuan county to find a new development space.

Specifically, the influence of Da Teng gorge on the development of Wu Xuan county is reflected in the following aspects:

Bring about a series of new development opportunities :(1) bring about the immigrant population agglomeration;(2) bring opportunities to the shipping industry;(3) bring opportunities to the tourism industry;(4) bring about great changes in county and city appearance and opportunities for large-scale renovation and construction;(5) great changes in investment.

At the same time, it also brings certain impact and pressure.(2) the impact of large-scale construction on historical and cultural resources and natural ecological fabric;(3) the crowding out of local excellent resources and space by large projects.

Facing the great changes brought by major projects, Wu Xuan county needs to actively grasp the opportunities of major projects, draw on the strengths and avoid the weaknesses, strictly adhere to the bottom line of resources, enlarge the driving effect, and seek breakthroughs and improvements in regional development.

3.3 major adjustments in strategic direction

(1) functional reconstruction: from industrial city to scenic tourism city

In the general plan of the previous edition, the city nature of Wu Xuan was defined as: taking industry as the leading role, vigorously developing landscape garden cities of tourism, logistics and other modern service industries.

In the overall planning of Lai bin city, the urban function of Wu Xuan is defined as a comprehensive town mainly consisting of sugar manufacturing, metallurgy, processing of mineral products, processing of agricultural products, light textile, shipbuilding, commerce, logistics and other industries.

Industrial dominance is the main definition of the development direction of Wu Xuan city. However, under such major changes as the great Teng Xia project and the water storage of Qi Xing lake, the advanced information transportation technology is used to highlight the scenic and cultural value of Wu Xuan, align the trend of the era of tourism consumption economy, and transform the development strategy of Wu Xuan city into a scenic and tourist city.

(2) pattern reconstruction: from a small county town in the west to a lakeside city in the world

Further thinking, to build a scenic tourism city in the new era, it is necessary to break through the relatively weak regional economic pattern around Wu Xuan with the help of modern developed information and transportation technology, and seek the direct connection of large markets in a wide area. Therefore, from the strategic perspective of urban development, it is necessary to change from the western small county town standard to the characteristic tourist city facing the world. According to the resource characteristics of new Wu Xuan, it is an important choice to set up the development vision of "world lakeside city", which echoes this strategic orientation and pushes Wu Xuan to take advantage of the situation.

3.4 path analysis based on the new strategic direction

(1) case study: small cities win the world with their characteristics

Based on the major adjustment of the above two strategic directions, the internationally influential scenic tourism city will be the important target for the further development of Wu Xuan. According to analysis and arrangement, from a global perspective, there are mainly three types of cases of small and medium-sized cities with similar scale and referrability, including:

Industry leaders: Lego city Be Lon, Audi's Ingolstadt, Nestle's Vo we, and glass, the perfume capital of the world. Such cases are all key industries that grasp the characteristics in the process of development and achieve international influence and height of key industries, thus laying the foundation for the world's scenic and tourist cities.

Landscape driven: the lavender home of Provence, the combination of technology and landscape Bozeman, Europe's retirement heaven saint Sebastian. This kind of case is to grasp the opportunity industry from the beautiful scenery, develop the tourism and vacation industry and relevant industries of science and technology, sports and so on, and form the global influence of specific industries and landscapes, so as to realize the development across the globe.

Activity oriented, such as the world economy BBS permanent residence in Davos, Switzerland's water sports mecca Spitz, the world's alpine outdoor sports destination Sha Mu Ni, etc. The breakthrough point of such cases is to hold symbolic activities to attract a large number of people to enter and continue to consume, so as to form a broad influence and sustainable market.

(2) carding path

It can be seen from the above three cases that it is a common feature of such urban development to grasp prominent feature elements as core identification and Engine. This characteristic element may be an IP, an activity, a class of industries and products, but its extension can cover the upstream and downstream industry chain, and link the development of landscape, activities, industry and space at multiple levels.

With characteristics, on the basis of three kinds of cases have different key kinetic energy, respectively is embodied in three aspects of industry, space, activity, the kinetic energy of the three aspects of support is not a single role, but can combine each other nested, and other surrounding elements form a composite, end of the formation of regional development.

Summarizing its experience, the key strategic path is embodied in: constructing the strategy system of characteristic driving, industry-space-activity three-dimensional support.

3.5. The strategic framework of "one feature, three hands" of Wu Xuan was established

(1) a feature driven

As the space carrier that can bear the characteristics of Wu Xuan, the manor garden has the unique cultural spirit. Wu Xuan manor culture dates back to the early Qing dynasty, the Qing dynasty from Hunan, Jiangxi and other places of a strange culture and Wu Xuan local traditional culture blend mutually, makes Wu Xuan ideological culture become more civilized, gradually formed the Wu Xuan people both Geng Dou family heirloom and economy concerning the use of the thought idea, teachers and respecting culture tradition of making Wu Xuan in such aspects as politics, military, business has outstanding talent, and by the Qing dynasty, some struggle, pleasantly surprised, outside Wu Xuan people started in hacienda-style home built residential courtyards, after decades of gathering, form the old China Gui Zhong region during the period of a community is relatively concentrated, the famous estate.

With the change of The Times, most of the manor houses have lost their own living function, but they have left their unique manor spirit :willpower, perseverance, commitment and innovation, and also shaped the manor culture with unique characteristics of martial arts propaganda. At present, there are more than 30 manors in Wu Xuan, mainly distributed in villages around Dong Xiang, Tong Ling, Er Tang and San Li, among which the famous ones are Huang Zhao Xi manor, Guo Song Nian manor, Liu Bing Yu manor.

Based on the manor culture of Wu Xuan, two distinctive manor IP can be built: world manor cultural exchange BBS, world manor residential experience. BBS is a regular BBS which specializes in the world manor culture. It not only discusses the manor culture of Wu Xuan, but also explores the manor culture of other regions of China and even all regions of the world.

In the manor world cultural exchanges on the BBS, invited several different types of institutions or organizations, including the relevant organizations or groups included manor culture society, writers' association and so on, university and scientific research institutes included manor culture research association, universities and research institutes and so on，international organizations or national included leaders, the world organization, the foreign experts and so on, investment and financing institutions, investment institutions, companies and trading firms and so on, through these institutions or organizations, to upgrade the manor world cultural exchange BBS style, should be through online and offline two channels at the same time, all-round display communication BBS, Offline activities include research, communication, social interaction, investment promotion and investment. Online activities include online communication, webcast, e-commerce, online education, etc.

BBS plays an important role in promoting the influence of Wu Xuan and showing the manor culture of Wu Xuan.

Another estate IP is the world's manor living experience, with the development of economy, people's living standards improved rapidly, but the life pressure also increased gradually, pastoral yearning for comfort and leisure gradually strengthen, manor culture combined with rural life, can form a unique experience activity -- world estate living experience. Relying on the space carriers such as the world manor city and the rural complex, the human settlement experience activities of the world manor are carried out, with a focus on making people experience the tranquility, comfort and tranquility of rural life through a series of facilities and activities, including rural activities, parent-child activities and picking activities.

(2) three strategic grips

Key industries - one with two wheels. The main characteristic of the key industry strategy is that "one special apparatus has two wheels". " one special apparatus " refers to a featured cultural activity of the manor, and "double wheel" refers to the strategy of "existing industry upgrading and new industry introduction" of the industry. A featured cultural activity of the manor is based on the cultural activity of the manor by Wu Xuan. In the two rounds, the upgrading existing industries include sugar industry, calcium carbonate industry, commercial logistics industry and agriculture and forestry industry. In the advantage of existing industrial upgrading paths, characteristic farm culture activities can pull the existing advantage in multiple industry upgrade, for example, sugar cane processing products include sugar, wine, rum, sugarcane and condiments such as paper, and these foods or beverages are manor world cultural activities as a source of food; The products of calcium carbonate industry include building decoration materials, stone carving crafts, etc., which can be used as the main materials for the construction of manor city in the world. The world manor cultural activities a large number of logistics, people flow activities, will certainly promote the development of Wu Xuan trade logistics industry; Deep processing of agricultural and forest products can be used as a food source for cultural activities of manor around the world. On the other hand, the introduction of "new industries" mainly includes the introduction of modern service industry and high-tech industry. The modern service industry will introduce the "culture and sports industry, tourism industry and scientific research education industry". The high-tech industry will introduce the "information technology industry, high-tech manufacturing industry and new energy industry".

Scenic towns - urban areas are scenic spots. The core of the strategy of scenic town is the integration of urban landscape and urban area is the scenic area. Landscape, as a carrier of a new way of life, will be integrated with the town to form the strategic content of scenic town: new ecological value, new utilization of landscape, new urban space. From "static protection" to "dynamic utilization", ecological elements should be landscaped, and "ecology", as a static resource, should be utilized as an important landscape in the city. At the same time, landscape should reflect new utilization methods, from "seeing the scenery" to "using the scenery", to reflect the unique "education, sightseeing, experience and production" function of landscape. The landscape and urban space will be integrated to create an ecological space layout of "landscape four flowers with five leaves and seven veins and multiple gardens". The estate cultural activities held in the world, will be the implementation of the strategy of effective drive Wu Xuan scenery town, can create a manor culture characteristics of scenic town, the world garden city itself can become a town and the integration of landscape space carrier, and unique scenery will provide manor world cultural activities "education, sightseeing, experience, production".

Iconic activity - world manor habitat experience. By learning from the development experience of many special towns in the world, the popularity of small towns can be effectively enhanced through the detonation of iconic activities, so as to Wu Xuan has its own characteristics. However, the existing activities such as "March 3rd folk festival, Confucius ceremony" have yet to be improved in terms of popularity, influence and connotation, etc. It is hard to become a symbolic activity to explode the Wu Xuan market at present. Based on the unique manor culture and the rural scenery of Wu Xuan, the cultural activities of manor around the world are built. The cultural activities of the manor can enhance the influence of Wu Xuan, promote the emerging tourism, cultural creativity and information technology market of Wu Xuan, and promote the characteristic scenery of Wu Xuan. Manor world cultural activities mainly includes rural living experience, world estate culture expo, world estate, estate foreign affairs activities, through "BBS" manor world cultural exchanges to promote to the world of Wu Xuan cultural features, landscape features, through the "world estate living experience on" Wu Xuan landscape rural characteristics. Expand the event platform and display the grand event through online and offline channels. The participants include not only local governments, tourists and people, but also various associations and groups, investment and financing institutions, universities and research institutions, national organizations and countries.

3.6 Plan construction of urban spatial layout

(1) the spatial development strategy pattern of "advancing east, expanding north, crossing south, controlling west and upgrading China".

Adhering to the concept of co-existence between city and nature and building a landscape city, this paper puts forward the overall image of urban development integrating landscape with city, rural surrounding city, blue and green weaving city and production and tourism city.Create multiple ecological corridors. In the multi-center banded spatial structure, in order to maintain the urban ecological pattern, we should make good use of and protect the original landform and traffic corridor. Each group should be separated by mountains, rivers and ecological green Spaces, and ecological corridors should be constructed with mountains as the background, and serve as the basis for group spacing, so as to prevent the group from blindly expanding and eroding the ecological green space, and limit the size of each group.Waterfront space is the core area of urban landscape. With the advance of the old city reconstruction and the new district construction, the waterfront space is gradually filled. Efforts should be made to protect the waterfront ecological space.The spatial development strategy of "advancing east, expanding north, crossing south, controlling west and upgrading China" was proposed.

Eastward advance strategy: cross the Qi Xing river to the east and develop the land along the Qi Xing river to the expressway.

North expansion strategy: north along the main road north expansion, development of urban north area.

South crossing strategy: to the south, Wu Xuan county is adjacent to Qian Jiang river and Wu Ma Lan river scenic area, which needs to be protected and controlled in a key way. However, to cross this area, a large area of available space along the Qian jiang river can be grasped.

Western control strategy: control urban expansion in the west, optimize the ecological environment and urban functions, relocate or renovate Hexi industrial area, sugar factory, high-voltage corridor and so on, and form a high-quality development zone.

China's promotion strategy: optimize the spatial pattern of central cities in Wu Xuan district and inherit the historical and cultural space. Protect the historical and cultural blocks with the ancient city as the main place to highlight the historical characteristics of the city. For the old urban areas, we should adopt the strategy of remediation and renewal, improve the living environment and facilities, and create a charming old urban area.

(2) overall layout structure of "four mountains and waters, three cities, seven districts,

four veins and 19 gardens"

Landscape ecological structure: four mountains and waters landscape.

Painting mountains and waters landscape: as the opposite view of the city, the Wu Malan river, Bu Yu peninsula and Qian Jiang river echo the landscape of the waterfront city to form a picturesque landscape.

Urban mountains and waters landscape: with Xian hu lake, Gao Li Shan and ma 'an Shan as the landscape nodes, urban green belt and water network are connected to create exquisite urban green space landscape.

Lake island mountains and waters landscape: with Qi Xing lake and lake island as the core of landscape features, create a clear waterfront lake landscape; Urban and farm mountains and waters landscape: the ecological green belt along the river, the low-density urban functional group, the dock village and other rural complex are integrated to create a landscape with urban rural characteristics.

Urban layout structure: three cities and seven pieces

The three cities, which have different leading functions, are the three major urban areas of the central construction area of the city, namely, the main city of Wu Xuan, the tourist city and the industrial city.

Seven pieces are urban function and construction agglomeration, which can be divided into seven urban areas based on the three urban areas:

Area south of the city: the original old city, north to the south of An shan road, Chao Yang road on the east, south to the Qian Jiang, contains the ancient city of ma on Shan, Wu Xuan, Bin Jiang dock, etc., is a major city Wu Xuan existing activity area, planning for residential activities as the main function, to take advantage of regulation style, Bin Jiang development, history and culture, as the main content of life.

Eastern zone: the main area of the former east new area of the city, from Chao Yang road to Chao Yang road to Chao long road to Cheng Bei road, from Xing Hu west road to Xing hu road in the east and Anning road in the north, is the new city area under large-scale construction by Wu Xuan. The planning is based on the development of modern new city, with human settlement service and landscape environment construction as the main Content. This round of planning should take into account the influence of substations and high-voltage corridors in the region on the construction of world lakeside city, and suggest the land replacement of substations.

The west part of the city: the former sugar factory area, from the north of the city road to the north of the city road – Chao long road – Chao yang road, Qian-jiang road to the west, Anning road to the north, Anshan road to the south, combined with the relocation of sugar factory and the relocation of high voltage substation, planning to take the old industrial base transformation and the construction of new ecological living environment as the main content.

Northern urban area: a new development area extending along the west bank of Qi Xing hu lake to the north, from Anning road to the south, to the man-made river to the north, with good land conditions, the new urban area of Wu Xuan will be formed with the theme of information and electricity industry facing the future and e-commerce industry serving the rural areas, supplemented by high-quality waterfront human Settlements. This round of planning should take into account the influence of the substation and the high-voltage corridor in the east of the city on the construction of the world lakeside city, and suggest the land replacement of the substation, so as to avoid the influence of the high-voltage corridor of the substation on the region.

He Dong district: Qi Xing He area, south of east, seven Xing hu existing farm, Taiwan industrial park regulation reform, combined with the construction of seven Xing Hu, using both close to seven Xing Hu and near the highway portal advantage, at the same time in the future information industry and the rural service oriented electric information industry and the world estate culture as the theme, to build international tourist town, and in Qi Xing He, fairy lake park, the confluence of seven Xing hu, Qian Jiang, brigade CBD planning of modernization.

Hexi district: planned to relocate the former Hexi industrial zone, transformed the original industrial building and mine environment, combined with the winding characteristic landscape environment of the nearby Wu Malan river and Qian jiang river, to create an outdoor sports town.

Industrial city area: depending on the original planned industrial areas of east Gui Zhou and Qian Xi, combined with port construction, the industrial construction of Wu Xuan county and city will be centrally arranged to form the core industrial area of Wu Xuan.

(3) urban landscape structure: four veins 19 gardens

Four veins of lake and river: Qian Ding jiang river and Qi Xing hu lake are the main bodies, and Qi Xing He river is connected with artificial harmony. Four major water veins in the urban area are infiltrated to form a rich and diversified regional water environment System. The water environment system is also a green environment System. Among them, the urban "green corridor" formed by the protection and greening of the city such as the green corridor in Xian hu park forms the open space of the city, with emphasis on greening ecological construction. The width of the green belt is controlled at 50-100 Meters. The "water ring", with the Qian jiang river, Qi Xing lake and the man-made river in the north of the city as the framework, plans to control the open space of about 20-225 meters on each side of the river, and forms the main outer open space ring.

Park 19: urban park green space is divided into urban park, district park and group park, with a total of 23 planned. It plans 3 city-level parks, 7 district-level parks and 13 group parks. At least 19 of the parks should have the reproduction of cultural elements of a certain manor in Wu Xuan county, which can be represented by landscape sketches, architectural imitation, cultural souvenirs, etc., so that the manor culture scattered throughout the county can gather in the urban areas.

4, endnotes

There are relatively superior institutional conditions for promoting local development with major projects in China. Centralized leadership is convenient for the implementation of major projects. Due to the great difference in ability between major projects and relatively underdeveloped areas in talent reserve, resource utilization and other aspects, it is necessary to take a dialectical view and prudent use of local development resources and space in the process of major projects.

Wu Xuan local governments actively operating, combining with big cane gorge project of water lake, put forward the vision of "lakeside city of the world", the local unique scenery, human landscape and cultural tourism development, the industrial transformation and upgrading of economic linkage to build four characteristic development strategy, seek to characteristic value of integration into the global market development path, is a classic case of grasp the big project opportunities actively operating, driving the development of local offers for similar large projects can draw lessons from the experience.

Railway hub area development in Arth-Goldau (Switzerland)

Wirz, Nicole; Schneider, Andreas, BASEL, RAPPERSWIL, Switzerland

ABSTRACT:

Part 1 Stakeholder Process: Prof. Andreas Schneider

Part 2 Urban Design: Nicole Wirz, owner raumplan wirz

Switzerland will finalize its new trans-alpine railway lines in 2020, allowing super-fast passenger traffic and heavier freight trains on the European Corridor 21. Arth-Goldau is the place, where the Rhine-Genova corridor and the Munich-Zurich-Milano corridor merge to one. Therefore, even more than already now, this will become the main public transport hub for the inner part of Switzerland. The municipality of Arth and the canton of Schwyz have the ambition, to make the best out of this, and to reorganize this entrance point for commuters and tourists, to recycle the brownfields south of the station and to redevelop the neighbouring housing areas (total approx. 70 ha).

Since planning in Switzerland is a highly democratic process, information and participation plays an important role in such developments. Therefore there is a long tradition of involving population in planning processes with more or less success. In Arth-Goldau for one of the first times in such developments in Switzerland, a technique that was developed in commercial business during the last decade was applied: The stakeholder process. Compared to widespread “every one interested” participatory approaches, it shows a much deeper involvement of the stakeholder groups into problem analysis, solutions evaluation and masterplanning. It needed more time in getting the masterplan finished compared to more conventional approaches. But in implementation it now shows that it makes political consensus building and planner’s life much easier.

The Masterplan and urban design has been developed in a stakeholder process. Property owners, neighbours and different public groups of interest had been involved in developing the urban design, public spaces, uses and density of the area. One of the most important topics, which was discussed, was the development of high-rise buildings as landmark for the new urban development. Finally the project aims to provide spaces for housing, offices and industry 4.0. A relevant high density and a mix of uses – 120’000 m^2 ground floor area are arranged in different plots aligned along a new main street axes and fixed in the masterplan. For designing the urban development, smart city technologies had been used.

Planning and Construction Practice for Sponge City in Shanghai: Experience and Reference

Dan Ye, Shanghai Blue Town Urban Planning Co. Ltd ,Shanghai
Yidong Yu, Shanghai Tongji Urban Planning and Design Institute, Shanghai

1. Introduction

With the frequent occurrence of extreme weather, various cities in China are facing severe rainstorms and waterlogging threats, which bring strict tests to urban security. According to the survey carried out by the ministry in 2010 about 351 cities' urban waterlogging situation in 32 provinces, there has been more than 60% of urban waterlogging since 2008, and even the northern cities (such as Xi 'an, Shenyang), where there is a lack of rain, have a similar situation; the maximum time of water accumulation in 57 cities exceeded 12 hours[1].The rainstorm water has had a significant impact on the operation of urban public transportation, the safety of residents' travel and public health. Heavy rain in Shenzhen and other cities has often paralyzed subway operations, hampering urban traffic. On July 21st, 2012, severe rainstorms in Beijing even killed 79 people and made a direct economic loss of nearly 10 billion yuan [2]. In the 21st century, Shanghai urban waterlogging occurs almost once a year (even more than once in some years), and causes serious damage to urban ecological system, having an adverse impact on urban operation and residents.

In this background, The Chinese government launched pilot projects of domestic sponge city construction in 2015, aiming to comprehensively improve the resilience of cities in dealing with rainstorms. Shanghai, as one of pilot cities in the second batch, has taken a series of measures related to planning and construction, including the specialized planning at the overall urban level, the compilation of technical guidance, the specialized planning of pilot areas, and the project implementation of the sponge city concept and technology in specific cities, etc. Taking Shanghai as an example, this paper systematically introduces the practice and beneficial experience of Shanghai under the background of sponge city construction in China.

2. Urban water environment and sponge city

Urban development and construction should be based on the natural logic of the water cycle, from the macroscopic hydrology water area to the whole city system and to the specific block, places, as well as the construction of water planning and design. This is the core idea of sponge city construction, involving a series of concepts, working frameworks and technical methods to improve the water system in sequential manners (fig.1).

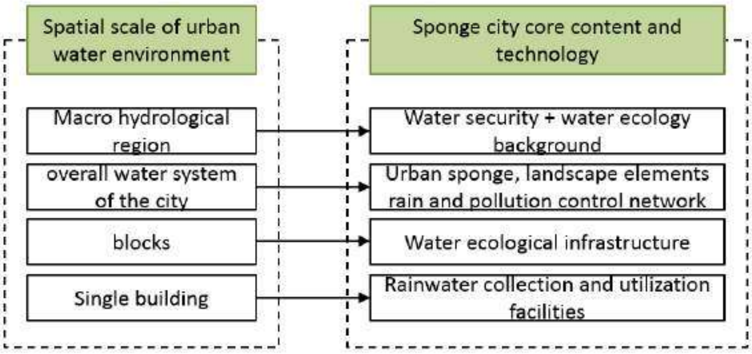

Figure 1: Multi-Scale Sponge City system
Source: Drawn by the author

2.1 Urban water environment system

The construction of urban water environment system needs to consider the comprehensive influence of multiple scale and regional water elements.

At the macro level, we should consider the large rivers, wetlands, the reservoir areas and ecological forests which have an influence on the urban hydrological environment, including water supply, rain flood ecological control, flood control and storage, etc. The construction of the good regional hydrological environment is an important basis for ensuring urban water security.

For the whole city water environment, surface landscape elements, such as river courses, lakes, wetlands, parks, and protective green land, along with the rain sewage drainage pipe network system jointly promote urban development to become ecological "sponge". Among them, the pattern and interrelation of surface landscape elements constitute the water ecological foundation framework of urban "sponge body", which is the infrastructure of ecological rain and flood management. As a traditional drainage engineering facility, the rain sewage pipe network plays a positive and important role in ensuring the sound operation of ecological water infrastructure(fig.2).

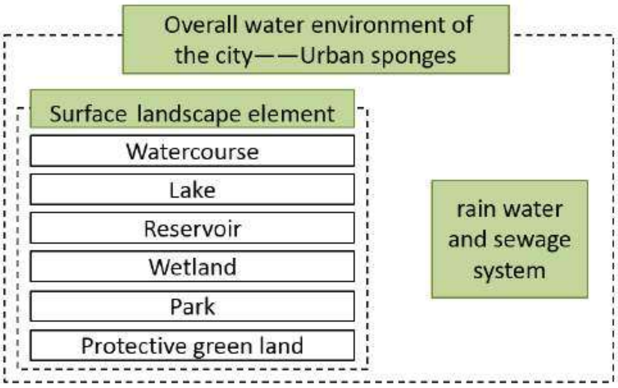

Figure 2: Constituent Elements of Urban Sponges
Source: Drawn by the author

The inner-city blocks are just like the cells of the city's "sponge body", which holds the key to the management of urban rain and flood. Urban green land places which are represented by parks and wetlands have a significant influence on water storage and water purification, while river channels mainly play the role of water catchment and drainage in the construction of urban water environment. Urban construction land (such as land for residential areas, education and industry) and streets have become the rainwater infiltration with low levels of soil suction areas, due to the construction requirements and street activities features; the water environment of these blocks needs to be refined and constructed, improving the capacity of these places' rain-flood management by means of maximizing the infiltration area and designing integrated rainwater collection and drainage facilities.

The collection and reuse of rainwater from roof and window eaves of urban buildings can promote the drainage and storage of rainwater and effectively reduce the occurrence of waterlogging in urban blocks. The construction of water environment at the micro level has a fundamental and elastic influence on the construction of urban water environment system.

2.2 "Sponge city" concept and technology

2.2.1 Concept and connotation of "sponge city

"Sponge city" is to strengthen the construction of urban planning management, to make the most use of ecological systems such as buildings, roads, green areas and water systems in absorbing, storing and releasing rainwater, to effectively control the stormwater runoff, and as far as possible to achieve natural accumulation, natural penetration and the natural purification of sponge city [3]. On the other hand, it is also emphasized to strengthen the capacity of rainwater removal during rainstorms by strengthening the construction of traditional infrastructure drainage facilities. The safe management of urban rain and flood is one of the important factors for comprehensive urban security.

The idea of "sponge city" is essentially similar to the idea of low-impact development (LID) in the United States, Australia's water sensitive city, UK sustainable urban drainage system and Germany's decentralized rainwater management system, which emphasize the realization of "smart" management of rain and flood through comprehensive urban green infrastructure construction and reduce the risk and harm time of urban waterlogging disaster. Sponge cities should pay attention to not only the influence of macro water environment and conform to nature, but also the construction of rainwater storage and drainage system and ecological purification system at different spatial scales to achieve urban rainwater natural accumulation, infiltration and purification.

2.2.2 Core technologies of "sponge city" construction

The core technologies of "sponge city" construction involve multiple spatial scales, such as macroscopic hydrological region, overall city level, block level, and single building. Based on the background and key points of multi-scale sponge city construction, the core technologies adopted in practice are different[4-5].

1) **Macroscopic hydrological level.** Construction of "sponge city" requires detailed water security pattern analysis and fragmentation degree of conserving forest land and wetland analysis, which will lay the regional space foundation of the city "sponge body". The main core technologies include water resources ecological plaque analysis, comprehensive identification of water resources protected areas, space control based on ecological elements, and water network system combing and hydrological water quality analysis.

2) **The overall level of the city**. Constructing city "sponge" needs to systematically plan ecological landscape and promote traditional drainage infrastructure configuration on the basis of the comprehensive analysis of precipitation, catchment, collection of water, water storage, distribution or control, and comprehensively solves the problems in the urban rain flood control. Its main technologies and analytical methods include the analysis of water junction, water network system planning and analysis, green network system planning and analysis, and overall control of ground hardiness rate.

3) **The block level.** The technology at this level is mainly achieved through the design of water ecological infrastructure (including urban design and landscape design), including interception of rain water, rainwater infiltration and rainwater storage. Rainwater interception is mainly to reduce the rainwater runoff rate through the slope of the site and the use of materials. Rainwater infiltration promotion technology mainly refers to the enhancement of water infiltration capacity through the establishment of site infiltration facilities or the non-hardened land area. Rainwater storage is mainly through some massive water bodies, in cooperation with urban rainwater pipe network to control the use of rainwater during rainstorms and drought.

4) **The architectural level**. Rainwater control is primarily achieved by green roofs which build sponge, including green vegetation, water purification and absorption, gentlely slope roofs which can accelerate the rainwater collection, sewer and rainwater tank setting, and so on.

3. Progress in China's pilot sponge cities

3.1 Background of pilot work

In recent years, as one of the important urban development policies, the construction of sponge cities has been highly praised and emphasized by the state and local governments to improve the urban water environment and to alleviate urban waterlogging. In 2013, the central government clearly indicated the importance of building sponge cities. In 2014, the state issued the technical guide for sponge city construction – the notice on the construction (trial) of the low-impact development rainwater system, which further guided the sponge construction in cities at all levels. In 2015, in order to assess the performance of sponge city construction, the ministry of housing and construction issued the notice of sponge city construction performance evaluation and assessment methods (trial), and in 2015 formally started the construction of the pilot sponge cities. By the end of 2016, a total of 30 cities in two rounds have become pilot cities for sponge city construction (the first batch of 16 cities and the second batch of 14). At present, the third batch of sponge city declaration is under way.

3.2 Pilot city distribution and project type and operation

At present, distribution of pilot sponge cities in China covers different regions of the country, but it is mainly concentrated in the east, south, northwest and southwest of China (fig. 3). Among them, there are 10 pilot cities in the east of China (Zhenjiang, Jiaxing, Chizhou, Xiamen, Pingxiang, Jinan, Qingdao, Ningbo, Fuzhou and Shanghai); there are four pilot cities in the south of China (Nanning, Shenzhen, Zhuhai and Sanya); there are four pilot cities in the northwestern region (Xi'an new district, Qingyang, Xining and Guyuan); the Southwestern area has Chongqing, Suining, Guizhou guian new district and Yuxi four cities. A wide range of sponge city pilot projects will be carried out in areas with different natural conditions and rainfall conditions, and this will be conducive to the promotion of sponge city planning and construction experience in the future.

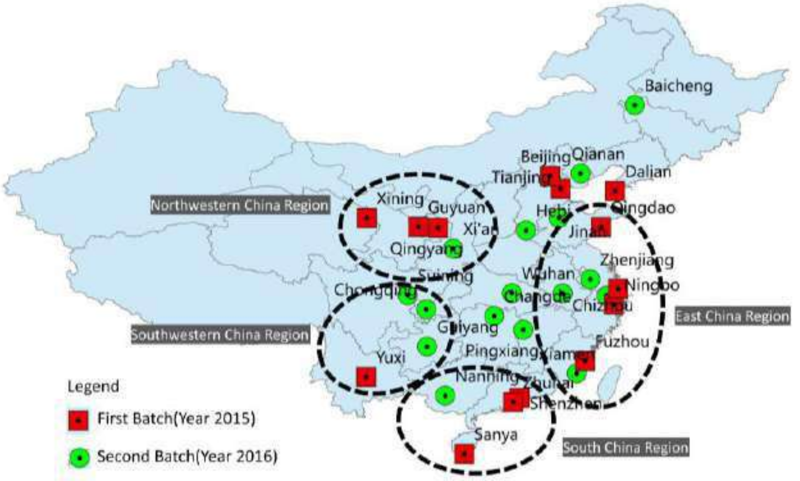

Figure 3: Location of Pilot Cities in China
Source: Drawn by the author

The project types of pilot cities not only involve the macro pattern of water ecological levels and the micro sites and buildings, but also pay attention to the platform of sponge city informatization construction. Different pilot cities choose important pilot projects according to their own conditions. In summary, there are 9 major types and 20 specific types(tab.1).

Tab.1 Pilot Project Category and Types

Pilot project category	Specific types of pilot projects
Water security and water ecology	Lake and river water environment improvement projects
Water network	River ecological restoration project, wetland ecological protection project, ecological corridor construction
Flood control engineering construction	Flood control facilities construction projects, mountain flood protection projects
Sewage network and facilities	Sewage network upgrading and renovation project, rain and sewage diversion project, sewage treatment and construction (reconstruction) project
Road design adapted to water	Sponge road design (including pipe network layout, water seepage and drainage design)
Functional plot construction (transformation)	Sponge community, sponge park and greenbelt, sponge square, sponge school, sponge hospital, water culture tourism hydrophilic project
construction	Roof greening works, rainwater collection and reuse work
New area complex	-- (sponge design with various elements)
Control platform construction	-- (mainly refer to construction supervision, rainstorm and flood control, and coordination between departments)

Source : Pilot City Documents

From the point of project operation, the pilot project has both special funds from the central finance or local government financial support, also have through the Public - Private Partnership (PPP), Refactoring Operate Transfer (ROT), Build Operate Transfer (BOT) model.

3.3 Results of the promotion of pilot work

By making sponge city specialized planning, strengthening financial and policy support and promoting the building of infrastructure sponge and the renovation of green infrastructure in old cites, the promotion of the construction of pilot sponge cities has achieved remarkable results in 2-3 years. Some cities did not experience urban waterlogging after a short period (1-2 years) of sponge city construction. The China economic weekly pointed out that in the summer of 2016, there were 10 sponge cities (Qianan, Xiamen, Hebi, Suining, Guian new district, Xixian new district, Shanghai, Qingdao, Sanya, Guyuan) which did not suffer waterlogging, accounting for one-third of the total pilot cities[6].

4. Shanghai sponge city planning and construction practice

Due to the unique situation of Shanghai city, it is faced with more complicated and difficult rain-flood management conditions (fig.4 and fig.5). Firstly, Shanghai's geographical location dictates that the city have to be subject to frequent typhoons, sudden extreme rainstorms and the effect of tidal waves which pose a great challenge to the management of waterlogging in cities[6]. In addition, Shanghai is characterized by the high groundwater level, the high density of urban development, large impervious surface areas and low soil permeability, which increase the difficulty of sponge city construction.

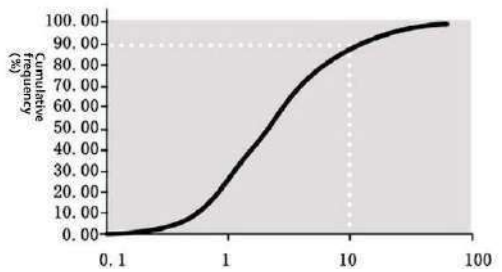

Figure 4: Maximum instantaneous rainfall intensity(mm/h)
Source: "Technical guidelines for sponge city construction"

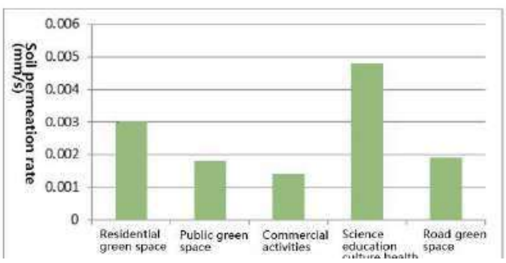

Figure 5: Green space types in Shanghai
Source: "Technical guidelines for sponge city construction"

Since 2016, Shanghai, as one of the important cities in pilot projects of the second batch, has carried out a series of planning and practical work related to the construction of sponge cities, including the specialized planning at the overall level of cities, compilation of technical guidelines, the specialized planning for urban pilot areas and implementation of sponge city concept and technology in specific urban projects, which have played an important and positive role in alleviating urban waterlogging problems and improving urban water environment.

4.1 Sponge city specialized planning

The planning and construction of sponge city should not only consider the construction of green infrastructure, but also strengthen the operational flexibility of traditional "grey" infrastructure in the case of abrupt rainstorms. In recent years, the municipal land and resources department in Shanghai has compiled the specialized planning related to sponge city at the overall level of urban construction, guiding the city partition or sponge-block specific planning and construction work. Relevant plans mainly include Shanghai sponge city specialized planning (2016) and Shanghai urban rainwater drainage plan (2017-2030).

4.1.1 "Shanghai sponge city specialized planning "(2016)

The plan has clear overall goals and sub-goals, the reasonable control structure, highlighted recent development and strong feasibility.

1) First of all, the plan clearly defines the specific goals of Shanghai's construction of sponge city: in the long run (2040), it will build resilient cities that can adapt to the global climate change trend and resist the rain and flood; it will buid a water harmony city where the water environment is of good quality, water ecology and urban landscape coordination, and the water landscape provides open space near water for the public; it will build a green and livable eco-civilized city with sufficient peripheral ecological space and complete ecological corridor in the main urban area and the new city; the main control targets are proposed for the comprehensive ecological, water environment, water resources and water security. Among them, the important target adopts the method of quantitative value control. (tab.2)

Tab.2 Sub-goals of Shanghai Sponge City Construction

Type	First grade	Second grade	Target value
Integrated ecology	Annual total runoff control rate	————	Centralized new area, the reconstruction area 80%
	Ecological shoreline restoration	River and lake water system ecological protection ratio	80%
	The proportion of green space in the centralized community in the construction land	————	≥15%
	Rate of the river	————	≥10.5%
Water environment	Surface water environmental quality	Water quality standard rate of surface water	100%
	Water quality at groundwater monitoring point	————	No less than III standard, and better than sponge city before construction
	Urban non-point source pollution control	Annual runoff pollution control rate	The new area 80%，the reconstruction area 80%
Water resource	Rainwater utilization rate	————	≥5%
	Leakage control rate of pipe network	————	≤10%
Water safety	Prevention and control of urban rainstorms and waterlogging disasters	Design recurrence period of rain water pipe canal	The main urban areas and new urban areas shall not be less than once every 5 years, Other areas are no less than once every three years; the underground passages and the lower city squares are no less than every 30 years
		Regional waterlogging design recurrence period	20-year return period
		Recurrence period of waterlogging prevention and control design	100-year return period
	Flood control standard	————	Meet planning requirements
	The levee's standard rate	————	95%
	Drainage rate	————	95%

Source：Pilot City Documents"Shanghai sponge city specialized planning "

2) Secondly, the spatial structure of Shanghai's urban sponge city is determined by the planning; on this basis, the management and control zones of Shanghai's sponge city are

defined, and mandatory control indicators of sponge construction are proposed for each district. In the spatial structure of sponge city, ecological restoration area and low-impact development area of ecological protection area have been delimited. (fig.6, fig.7 and tab.3)

Figure 6: Shanghai Sponge City Space Constructure

Figure 7: Shanghai Sponge City Control Division
Source : Pilot City Documents"Shanghai sponge city specialized planning "

Tab.3 Shanghai Sponge City Compulsory Index

Compulsory index projects for central area		Index
Water ecology	Annual total runoff control rate（%）	70%
	Ecological shoreline reconstruction rate(%)	75%
Water safety	Recurrence period of waterlogging prevention and control design	100-year return period
	Distribution network standard	5-year return period
	Flood control standard	100-year return period
Water environment	Water quality goal	Target rate of key water functional areas 100%
	Annual runoff pollution control rate（%）	≥70%
Water resource	Rainwater utilization rate（%）	5%

Source : Pilot City Documents"Shanghai sponge city specialized planning

3) At the same time, the plan has also set the goal of building a sponge city of 200 square kilometers by 2020, and implemented the key sponge city construction area (project) in space (fig. 8). Recent construction of key projects involves some important central city parks, green space, protective space and waterfront space, including important new city districts, industrial parks, ancient towns and villages.

Figure 8: Shanghai Sponge City Recent Construction
Source：Pilot City Documents“Shanghai sponge city specialized planning

4.1.2 “Urban rainwater drainage plan of Shanghai (2017-2030)”

"Shanghai urban rainwater drainage plan (2017-2030)" was compiled and published by Shanghai water authority in 2018. The plan realizes the construction of a complete urban drainage system in Shanghai by means of "control of source runoff, combination of process storage and drainage, coordination of the two networks at the end and scientific control of risk". (fig.9 and fig.10)

The plan puts forward: 1) the flood control standard of the main urban area and the new city is not less than once every 5 years and the standard of once every 100 years for the recurrence period of the design of waterlogging prevention; 2) the control rate of rainwater runoff is greater than or equal to 75%, the control rate of rainwater runoff pollution is greater than or equal to 55%, and the utilization rate of rainwater resources is greater than or equal to 2%. The plan also emphasizes the combination of the construction of sponge city through the comprehensive storage, infiltration, stagnation, purification, use and discharge to reduce runoff pollution effectively.

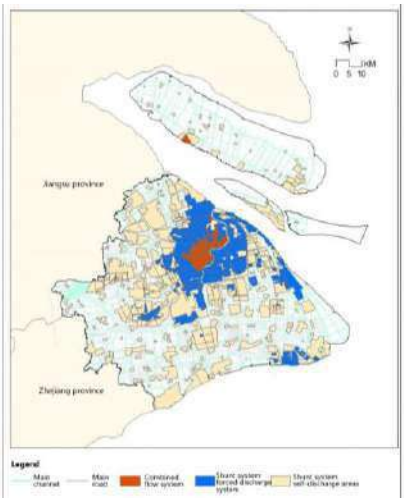

Figure 9: Shanghai Sponge City Drainage System and Patterns
Source: Urban rainwater drainage plan of Shanghai (2017-2030)

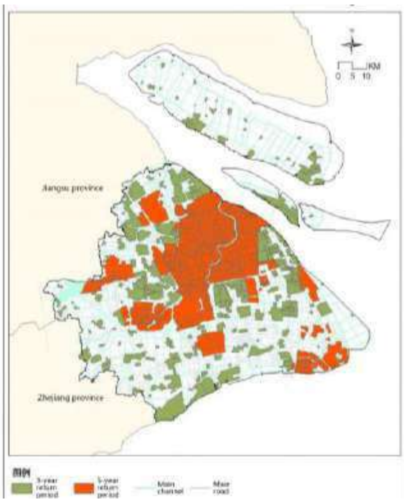

Figure 10: Shanghai Sponge City Drainage Standard
Source: Urban rainwater drainage plan of Shanghai (2017-2030)

4.2 "Technical guidelines for sponge city construction"

National level promulgated the sponge city construction technology guide, the urban waterlogging prevention and control technical specifications and the urban rainwater storage engineering technical specification; Shanghai also compiled the sponge guidelines for the urban construction technology as the guide the concrete practice of Shanghai guide file

This guide puts forward the key technologies and methods of sponge city construction of five aspects of planning, the design, project construction, maintenance management and implementation effective evaluation. The planning level includes three levels: general planning, detailed planning and project implementation plan; the design level includes building and community green roads and square water utilities and facilities scale; the construction part of the project is to further refine the control details of rainwater on the basis of design; the maintenance management section emphasizes the specific operation, control and maintenance of different types of projects; implementation effect evaluation is a comprehensive evaluation of the program implementation effect through several key indicators (including annual total runoff control rate, annual runoff pollution control rate, rainwater utilization rate).

This guide covers multiple planning and design levels, and provides detailed and practical ideas and technical tools for Shanghai sponge city construction by integrating the concept of sponge in macro planning, giving specific guidance to detailed design (fig.11), controlling and evaluating quantitative indicators.

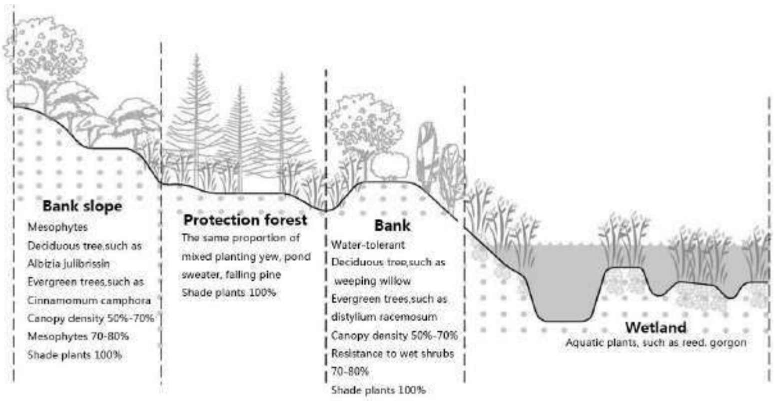

Figure 11: Typical structure of vegetation buffer zone

4.3 The specialized planning of the pilot area and sponge technology application: Lingang New District in Shanghai

4.3.1 Overview

Lingang New District is located in the coastal area in the southeast corner of Shanghai(fig.12). It is the hinterland of Shanghai free trade zone. The new district is more than 50km from the central city and about 20km from Pudong International Airport (fig.13). The total area of Lingang New District is about 315 square kilometers, and the planning includes the heavy equipment area, the logistics park, the main industrial area, the comprehensive area, the Fengxian park, Nanhui new district and other functional.

Figure 12: Location of Lingang New District
Source: Drawed by author

Figure 13: Function Plan of Lingang New Distric
Source: Linggang New District Plan

In order to carry out the pilot project of Shanghai sponge city, Lingang New District, as an important pilot area, formulated specialised planning of Shanghai sponge city in Lingang pilot district and three-year implementation plan in 2016. The planning defines the specific scope of sponge city planning and construction, the objective and concrete strategy of sponge city construction, overall sponge city construction space structure and construction division and 15 pilot projects from 2016 to 2018.

4.3.2 "Shanghai Lingang pilot district sponge city specialised planning" [7-8]

The planning puts forward that :1) the construction of sponge city is mainly achieved by ecological conservation, ecological rehabilitation and low-impact development; 2) consider the distribution of ecological resources, the ecological sensitivity of land use, the risk of waterlogging and topographic elevation in the planning area, and form sponge city natural ecological space pattern——"one core, two rings, six wedges and several areas" (fig. 14); 3) according to the research and exploration of different construction needs and characteristics of sponge cities, the plan delimited 7 different types of demonstration areas— the ecological protection of the typical lake, business district sponge construction, rainwater storage and purification in the ecological corridor, sponge reconstruction in the urban build-up area, sponge construction in the new urban district, ecological protection and utilization in reclamation area, reconstruction of water accumulation in old urban areas and water comprehensive treatment, and it also puts forward clear requirements for the key content and direction of sponge city construction in different areas, including the optimization of ecological vegetation community on the lake, collection and discharge of rain water in commercial areas, upgrade of rain and sewage pipe networks in old residential areas, soil improvement and mobile forest construction.

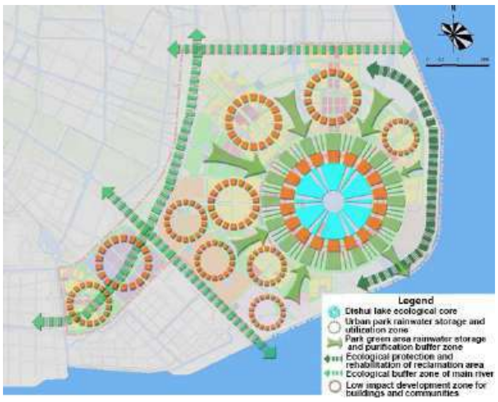

Figure 14: Overall Layout of the Pilot Area of Sponge City Construction
Source： Shanghai Lingang pilot district sponge city special plan

4.3.3 Action plan for 2016-2018

From 2016 to 2018, pilot projects of sponge city construction in lingang include15 project packages, such as the lake water ecological protection and purification projects, main urban river comprehensive improvement projects, old city sponge reconstruction projects, sponge construction projects in the urban build-up area, the expansion projects of the Lingang sewage treatment plant, regional capacity improvement projects, ecological protection, rehabilitation and utilization project in reclamation areas, sponge city park projects in the second ring zone, which can guarantee the attainment of planning objectives and targets effectively.

4.3.4 Construction[9]

a) the lake landscape around Dishui lake

Dishui lake landscape mainly adopts technologies such as permeable paving, permeable blind pipe, ecological wetland and ecological revetment in order to meet the sponge city requirements of local rainwater infiltration and absorption, effectively reduce surface runoff and purify water during rainfall. The specific node spaces, such as squares, footpaths, are laid exposed concrete, permeable asphalt paving, ecological ceramic permeable brick paving and gravel paving, and sets up 150mm wide grass planting belt separation every certain distance (6m), to promote facilitate rapid infiltration of rainwater (fig. 15 and fig.16).

Figure 15: Water permeable green space design
Source: Literature [9]

Figure 16: Water permeable pavement design
Source: Literature [9]

b) Sponge renovation project in area F, Xinluyuan district, Chaogang community

The sponge reconstruction of Xinluyuan in Chaogang community mainly starts from the perspective of public space and construction facilities, including three main ways: ①carry out water quality purification and reduction for initial rainfall; ②disconnect the building pipe in the community, and let the rainwater enter the municipal rainwater drainage pipe after being purified by grass planting ditch and other plant purification, and filtered through the soil media such as pebbly slope protection ; ③ help store some rainwater and reduce runoff by reconstructing inferior fovea through landscape. (fig.17)

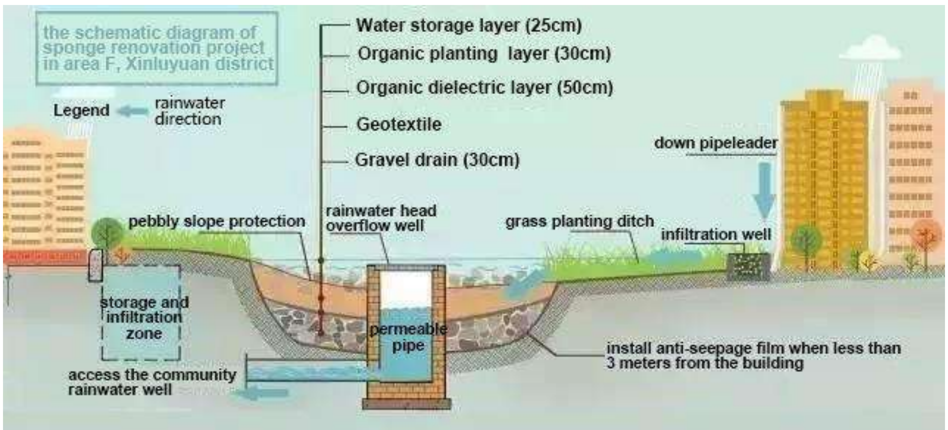

Figure 17: Sponge Community Project
Source: Literature [9]

Through the planning and reconstruction, there is no obvious water accumulation in the community activity square and parking lot (fig.18 and fig.19).

Figure 18: Comparison before and after Square Transformation
Source: Literature [9]

Figure 19: Comparison before and after Parking Transformation
Source: Literature [9]

5. Experience and reference

The construction of sponge city requires comprehensive consideration of the ecological sponge element system at different spatial scales. At the same time, it is necessary to consider the characteristics of precipitation, confluence, water collection, drainage and rainwater reuse and adopt different technical means to build green infrastructure. At present, Shanghai has accumulated rich experience and achieved good results in the construction of sponge city, mainly including macro-level planning guidance and detailed implementation plan (specific project), sponge engineering technical support and indicator control and the demonstration effect of specific pilot areas and projects. From the general specialised planning to the pilot regional specialised planning, from zoning control to specific implementation plans, from technical guides to demonstrations of technical applications, Shanghai is moving towards the goal of "sponge Shanghai" through such a perfect planning control and implementation.

1. Research Background

China has always been in the period of rapid development of urban construction since the reform and opening up, and the level of urbanization has increased from 17.9% in 1978 to 57.4% in 2016, with an average annual growth of 1-2 percentage points(Li,2017). However, in the same time of rapid development, the urban construction activities have also caused a series of ecological security problems, such as environmental pollutions, crowded, waste of land resources, natural disaster, and other ecological damages. These phenomena make people gradually realize the importance of changing the way of urban development, and exploring a road to balance of the quality of ecological and environmental, the benefits of economic and social, and the environmentally sustainable development(Wang,2006). Because of the residential area is not only the closest place to our daily life, but also the key factor of restricting urban ecological security, and can reflect the contradictions and challenges of the urban ecological security crisis caused by the urban construction activities(Huang,2010), the paper tries to explore a planning method of residential area based on the ecological security, and in the process of solving the "urban diseases" and other ecological security crisis, to creating a kind of harmony livable environment between man and nature(Teng,2006).

2. An Analysis of the Concept of Ecological Security

Ecological security is an emerging research field of ecology, and its definition was first proposed by the International Institute for Applied Systems Analysis in 1989, meaning that there are no threaten in human's life, health, well-being, basic rights, source of living, necessary resources, social order, adaptation to environmental changes and so on(Fang et al.,2001). Nowadays, the analysis of the definition of ecological security mainly including general and narrow two levels both at home and abroad. The generalized ecological security is an ideal state, meaning that the city will not have an ecological crisis, nor is it threatened by any potential ecological risk factors. The ecological security in the narrow sense is mainly for a specific research object, focusing on the key factors that constrain its ecological harmony, and by regulating the significant constraints that affect the specific objects, to improve the level of ecological security(Wang,1997).

Based on this, the article systematically combs the existing research results, founding that most of the studies focus on the construction of ecological security evaluation index system and the application of ecosystem management of built residential areas at present(Sun et al.,2012; Yang et al.,2013; Shao,2002), lacking systematic research on the planning theory and method of ecological residential areas under the concept of ecological security. So the paper takes the planning of the Chenjia Town international ecological residential area in Shanghai as an example, by establishing the four in one planning strategy of the compact residential areas, the green travel residential areas, the environment-friendly residential areas, and the low-carbon environmental protection residential areas, to explore the planning theory and method of ecological residential areas under the concept of ecological security. On this basis, the plan tries to make a further subdivision, and to establish the planning system of ecological residential areas, including four secondary indicators and thirteen third-level indicators, and try to combine the concept of ecological security and the planning subsystems of residential areas, and to guide the development and construction of ecological settlements.

Table 1: The planning system of the residential area under the concept of ecological security

3. the planning of the Chenjia Town international ecological residential area

3.1 Development background and current characteristics

In 2008, Shanghai was selected as the first low-carbon pilot city in our country, and then Chongming Island, Lingang, and Hongqiao business district was selected as three low-carbon demonstration areas of Shanghai . The planning area locates in Chenjia Town, and covers an area of about 4.4 square kilometers, which is the key area of development of Chongming Island. The status quo is mainly paddy field and irrigation channel, and the existing planning is difficult to meet the development requirements under the new context in terms of land use, road traffic, green landscapes and public service facilities, urgently needing to construct the international advanced level of ecological residential area under the concept of ecological security. Shanghai Tongji urban planning&design institute undertook the planning and design work of the project, and I had the honor to participate in part of the work. If the relevant date in the article is no references, then they are from the project.

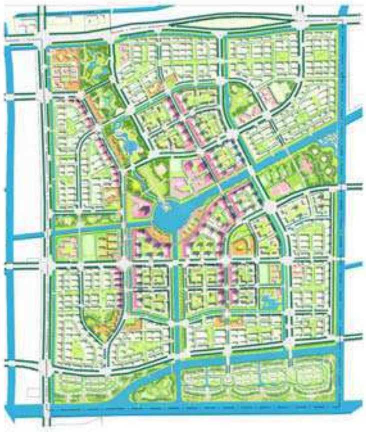

Figure 1: *The land layout planning* Figure 2: The u*rban design*

3.2 The concept of planning

The planning takes the concept of ecological security into the subsystems of the residential area, and propose a more natural, healthier and more enjoyable way of life, specifically including: a compact residential area, the green travel residential area, the environmentally friendly residential area, and the low-carbon residential area.

3.3 The compact residential area

A high density and multi-type residential area.

Reasonable residence density. By drawing on the number of living units on the residential land in the famous ecological residential area at home and abroad, the plan determines the number of living units on the residential land under different volume ratios in reasonable, and achieve a high density of living residential areas, such as the Hammam Newcastle, the Burlington Eco Village, and the Chongming East Beach.

Table 2: List of Recommended Residential Density

Floor area ratio	*Living density (unit / ha)*
1.6	*100-130*
1.2	*70-80*
1.0	*60-70*
0.6	*＞40*

3.3.1Enclosed neighborhoods.

Jane Jacobs once said: “If a city's streets look very interesting, the city will also be very interesting(J.Jacobs,1993).”.Because of the street is an indispensable place for residents' daily life activities, such as pass, neighborhood contacts, shopping, leisure, and entertainment, the plan uses the layout of the neighborhood. Through the enclosed house, the plan creates a street atmosphere, a multi-level communication space, and a vibrant residential street space, and achieve the person car branch at the same time.

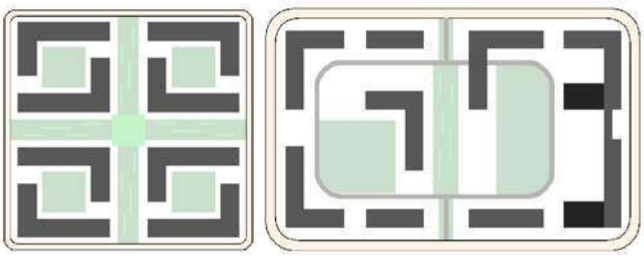

Figure 3: The layout of the enclosed neighborhoods

3.3.2Diversified residential building types.

The plan taking account of the residential needs of residents of different ages and types, including the core family, the single young professionals, and the elderly, etc, and providing a variety of residential building types, such as old - age apartment, micro apartments, affordable housing, SOHO, and townhouses, etc.

Figure 4: The statistics of different types of residential households

3.3.3A Convenient and complex public service network.

By combining the layout of the neighborhood, the plan set up a well-distributed public service facility along the streets, and formating a comprehensive public service network, creating a vibrant residential neighborhood. Also, through the layout of public service facilities, the plan can further increase the residential employment opportunities, and form a sustainable development of living networks.

Figure 5: The layout of the Public service network

3.4 The green travel residential area

3.4.1Walking friendly street network.

Compared with the large-scale neighborhoods, the small-scale neighborhoods have significant continuity and permeability in space form, suitable neighborhoods and street scales, suitable walking and vibrant public spaces and so on. So the plan combines with the core living circle, commercial and residential mixed land and residential land, forming three different types of street scale. In the core life circle to increase the density of street road network, the density of the street road network is 150 * 150m. In the commercial and residential mixed areas, the density of the street road network is 200 * 200m. In the external residential block, the density of the street road network is 300 * 300m.

3.4.2Bicycle friendly road network.

The planning layout different bike road systems in different areas. Firstly, forbidding the entry of motor vehicles and encouraging to use the public transport and bicycles in the scope of the core living environment. Secondly, allowing the bicycles and cars to be mixed, but the *speed limit at road for vehicle* in the general living area, thus encourage residents to use more bike travel, and create a bike movement characteristics of residential areas.

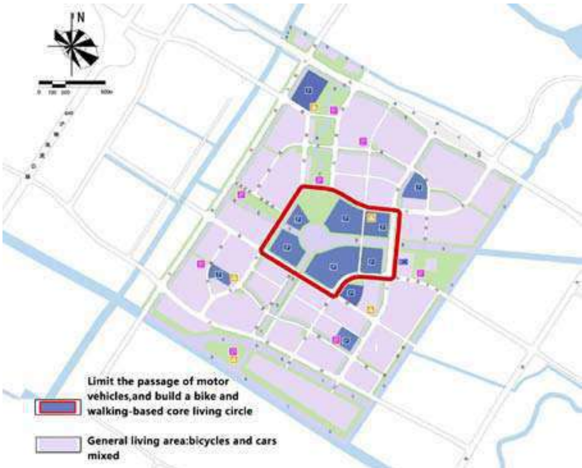

Figure 6: The sub-regional layout of the bike road system

3.4.3Hierarchical layout of the bike road system.

By building a hierarchical bike road system, the plan improves the bike-friendly road network, and by providing bicycle parking facilities, the plan provides bicycle rental, shower, and other services. Regional bike road, the ratio of the bicycle travel accounted for about 40%, the function of the Regional bike road is mainly to contact the residential area and the surrounding parks, commercial center area, and mainly to long-distance commuting, can also be used as a fitness bike lane. To ensure the increasing demands for motor vehicle trips after the floor area ratio increased, the plan tries to reduce the width of the green belt, and change the road section to four lanes, and set a single-sided bi-directional bicycle belt in the same time.! Through the isolated green belt between the bike lane and motor vehicle lane, to ensure the bike travels safely at a higher speed. Neighborhood bike road, the ratio of the bicycle travel accounted for about 60-70%. Controlling the enter of the motor vehicles in the core living area, and constructing the bicycles and walking-based road use system, and the road red line width of 12-15 meters, mainly for bike traffic, and as fire channel in the special case. Priority bike road, the ratio of the bicycle travel accounted for about 40%. Taking into account there are more cars in his part of the road, the planning tries to minimize the vehicles to turn right, and ensure the safety of the bike lane. So the planning puts the bike lane locates on the inside, and the right turn lane locates on the outside, and design protection isolation belt between the two lanes. General bike road, the ratio of the bicycle travel accounted for about 20%. The main roads within the residential area, and use the conventional road sections.

Figure 7: The hierarchical layout of the bike road system

3.4.4Bicycle channel section.

The main bicycle channel section: In order to ensure the increasing demands for motor vehicle trips after the floor area ratio increased, the plan tries to reduce the width of the green belt, and change the road section to four lanes, and set a single-sided bi-directional bicycle belt in the same time. The secondary bicycle channel section: Emphasizing the status of bicycle traffic in the secondary channel, and try to reduce the proportion of road traffic, in the case of Meeting the number of bike lanes and the width of the green belt. The bicycle dedicated section: mainly for bicycle and walk , and for the fire truck in a state of emergency.

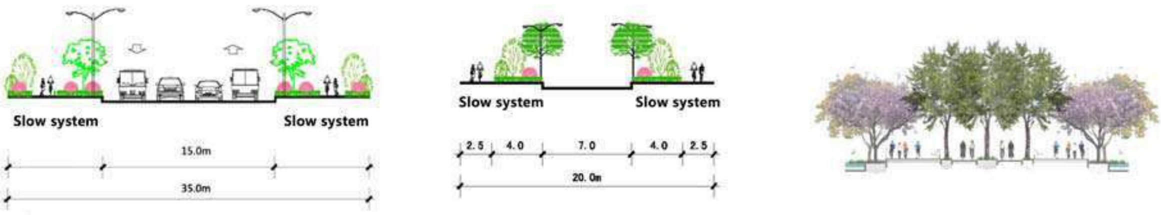

Figure 8: The different types of bicycle channel sections

3.4.5Bus sharing rate of 40%.

Combining with the status quo of the original bus lines, the plan layout a total of twelve bus lines, including one city long-distance bus lines, two island bus lines, seven regular bus lines, and two other bus lines. The layout of the bus station is one for every 600 meters, and the service radius of about 300 meters(5 minutes walk distance), and satisfy the requirement of covering more than 90% of construction land.

Figure 9: The layout of the Bus system

3.4.6Convenient transfer facilities.

Through the layout of the convenient transfer facilities, the plan provide facilities with good facilities. For example, to increase two bus transfer points on the basis of the existing bus terminal, and to provide adequate bike parking spaces and public bicycle rental in the transfer point in order to strength the bike and bus transfer, and finally reach the target of 5 minutes to reach the bus station, 15 minutes to reach the local work point and the transport hub.

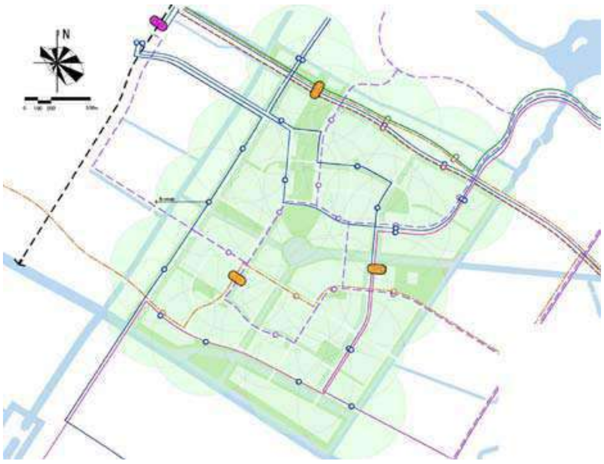

Figure 10: Transfer the layout of the facility

3.5 The environmentally friendly residential area

Take the water as an important part of the ecological and rainwater management system: As is known to all, the density of the river network can reflect the sparse degree of river distribution, and the higher the density, the more obvious the retention of rain, playing an important role in the retention of rainwater. While the water rate reflects the size of the river distribution area, and the higher the water level, the higher the capacity of rain and flood control, playing an important role in the rain and flood transfer. And the two interact with each other, reflecting the richness of river distribution and water storage and drainage and self-purification capacity. Based on the above analysis, the plan tries to promote the status quo of the water system,and the density of the river network is increased by 1.07 (km / km2) on the original basis, the water surface rate is increased by 0.53% on the original basis, and exceeds the average river network density and river network rate. In addition, through the expansion of the internal water ring, and convergence with the residential park, the plan formate the internal and external water ring, and strengthen the flood control and drainage capacity, and through the improvement of water network system, formate the experience of the Jiangnan water dwelling. And the new planning of the water network connected to the network, not only enhance the ability of rainwater storage capacity, but also reduce the urban surface run off.

Figure 11: The layout of river water system

Habitat into a network, strengthen the construction of diversified green space: The plan tries to strengthen the construction of a wide range of green space, and to improve the participation of green space, and to play the role of dot-like green space in a more efficient way. The final realization of the park green service radius of 500 meters, five minutes to reach.

Figure 12: The layout of green space system

Put the farmland as an important part of the open space: Green space is not only exist in the open space, the construction of epidermal planting is also very necessary. These vertical green patches through the green environment with the city as a whole, and can be a reasonable and effective expansion of the entire city's vegetation area, improve the city's comprehensive ecological benefits. In the residential building roof on the introduction of farmland, not only has the production function, as well as the ecological service function and the recreation function and the educational function, which reduces the pollution caused by the transportation of long-distance agricultural products. And can also be a green base for urban landscapes.

3.6 A low carbon green residential area

The research of low carbon green residential area is divided into three levels, including low-carbon housing, low-carbon public buildings and green infrastructure. Due to space constraints, the article only to do a brief introduction, and do not elaborate.

Low - carbon housing. The planning of the Low-carbon housing mainly including five aspects: the planning site and outdoor environment, having land and hydrological environment, Water saving and water use, Saving material and material resources and indoor environmental quality.

Low - carbon public buildings. The planning of the Low-carbon public buildings mainly including three aspects: saving land and hydrological environment, energy conservation and energy use and indoor environmental quality.

Green infrastructure. The planning of the green infrastructure including six aspects: energy, transportation, underground space resource utilization, regional environment, regional greening, and resources.

4. In conclusion

Nowadays, the planning method of the ecological residential area is still in the initial stage of development practice in our country. However, it is undeniable that with the deep implementation of the new urbanization in China, the ecological residential area will be the goal of planning and construction of the future residential area, and is of great significance for the sustainable development of urban economic and society and the construction of healthy, livable, safe eco-city(Chen et al.,2012). The paper take the planning of Chenjia Town international ecological residential area in Shanghai as an example, by establishing the four in one planning strategy of the compact residential area, the green travel residential area, the environment-friendly residential area and the low-carbon environmental protection residential area, to comprehensively explore the planning theory and method of ecological residential area under the concept of ecological security. In the area of the compact residential area, by establishing a reasonable living density, enclosed neighborhoods and diversified residential building types, the planning of the ecological residential areas advocates a different age and type of residents living together, and through the rational distribution of public service facilities, to create a compact and dynamic residential area. In the area of the green travel residential area, the planning of the ecological residential areas pay more attention on walking friendly and bike friendly, through the zoning of the layout of the public transport system, and the convenient transfer facilities, to make the share of public transport to reach 40%. In the area of the environmentally friendly residential area, the planning of the ecological residential areas takes water as an important part of ecological and rainwater management system. By making the water system into a ring, to construct a wide range of green space system, and by making the farmland as an important part of open space, to improve the city's comprehensive ecological benefits. In the area of the low-carbon residential area, the planning of the ecological residential areas pays attention to the low-carbon residential, low-carbon public buildings and the construction of green infrastructure, to achieve saving water, saving land, saving materials and saving energy.

The study of the planning of the ecological residential areas is a deepening subject, so in the process of planning and construction of ecological residential area, we should clearly understand that the development goals, the planning index systems and the planning requirements of the planning and construction of ecological residential area will be different with the difference of regional and the urban socio-economic development stage. Such as cold areas and hot areas, developed areas and underdeveloped areas an so on. Therefore, the planning method of the ecological residential area should also be combined with the development stage, development conditions and overall urban planning of the local cities, and put forward the practical planning and design strategies according to local conditions, which need further in-depth research and innovation.

Chinese Rural Area Natural Resource Oriented Town and Village Cool Planning Practice

Xinxin ZHANG, College of Architecture and Urban Planning,Tongji University, China
Jingsheng LI, College of Architecture and Urban Planning,Tongji University, China

Abstract

The research discusses the rural area's 'refrigerator' role to the urban area. And choosing two real Chinese town and village planning practices which are both natural resource oriented, but they have different methods and strategies.

Key words:
Natural Resource Oriented, Chinese Town and Village, Cool Planning Practice

1. Introduction

Recent years in China, more and more construction work and focus move from urban to rural area. In this process, town and village planning plays an important role. However, because of the rapid urbanization process China has experienced over the past years, urban planning with rapid industrial thinking is the mainstream in Chinese planning practices. But town and village in rural area have different situations from physical space to culture background. Unfortunately, at the beginning of the rise of town and village planning, because of the ignorance of the difference and rapid-develop requirement, planners still use the same methods and ways of thinking which has been proved to fail. Thus, this research is based on the character of town and village and their close relationship with rural area which actually act the cooling-temperature system or the 'refrigerator' role to the urban area where they surround. Two real Chinese town and village planning practice has been chosen. Both of them are natural resource oriented, but they have different methods and strategies in order to keep and strengthen their ecological function on one hand, and on the other hand to guarantee and promote the town and village's living and production purpose.

2. The Role of Rural Area

2.1 Supporting to the Urban Area

China has experienced a very rapid development process in the past more than 30 years. However, this process almost only happened in urban area. And the development of urban area is based on the support of large amount of Chinese rural area. Urban area cannot support themselves without the outside rural area. For example, food, the basic living source, is come from the rural area. And also the eco-system supporting about the fresh air circulation. To some extent, rural area play a 'refrigerator' role to the urban area. Without rural area as 'refrigerator', the urban heat island effect will more severe and worse.

2.2 Facing Problems

Furthermore, the support of rural area for cities is not only about natural resource but also including human resource. Numerous farmers left their land and moved to cities to join in the construction of urban area. Therefore, people who still living in the rural area are almost the aged and children who are not effective workforce. They are not capable to maintain and sustain the large-scale agricultural production and a lot of lands are not farmed and left there with weeds. This is one problem. Another problem is that people changed the function of the land for economy purpose. For example, many villagers who living in mountain area, Zhejiang Province changed their farm or forest land to plant landscape trees. We will have more details about this situation in the case study. And the third problem is the planning and construction problem under the misunderstanding of the rural area. Because in the past 30 years in China, almost all the planning and construction work are focus on cities, most planners do not have the experience of rural planning. So they use the same thoughts and ways in the rural planning without understanding the natural and ecological attributes of rural area and made some mistake to this area. The first case is mainly deal with this problem.

3. Case Study One: South Mountain Rural and Town Area Planning

3.1 Existing State of Affair

The first case is happened in rural area of Liyang City, Jiangsu Province, southeast of China. This planning scope is 113 square kilometers naming South Mountain Area, including two towns and eight villages (Figure 1). This area is most famous for their high quality of natural resource in Southeast of China and even in the whole nation. The local government want to use this advantage and give more impetus to promote this area's economic development, and the planning is the first step.

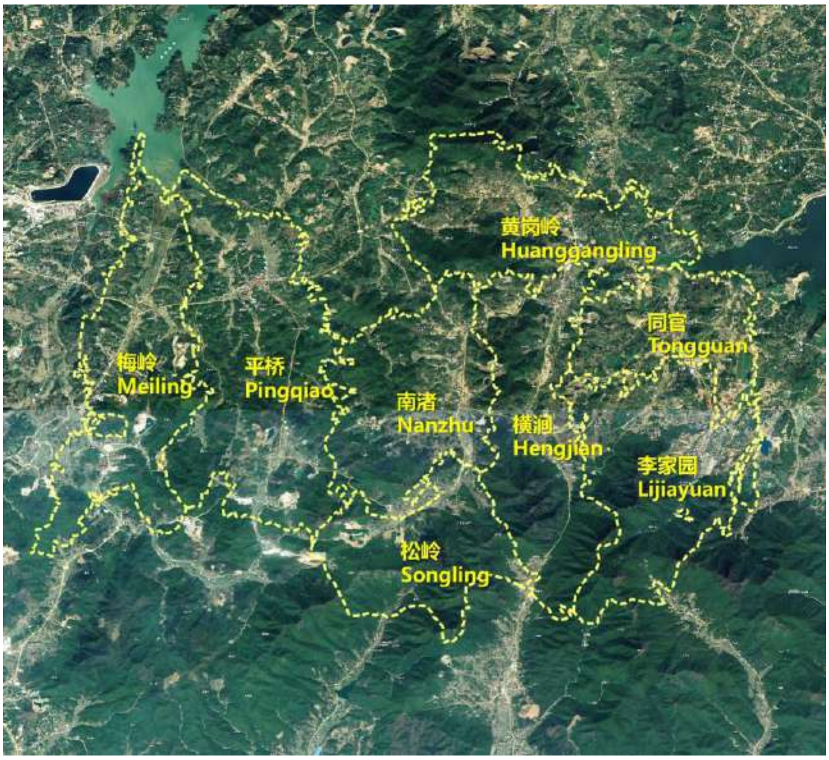

Figure 1: Location Area

3.2 Planning Process and Problem Identification

The origin of this planning is for economy concern and Up-Down push, the purposes of the government are very clear. But, what is the real and main problem of this area is still vague before the planning. Therefore, in order to find out the main problem of this area, the planning has been launched by bottom-up investigation and enquires.

So at the first step of this planning, a meeting has been hold to invite the representatives of the eight villages and two towns (Figure 2). And during the meeting, local people who live in this area gave the feedback that the economy problem is not the first problem they are concerning about, because they are facing the more severe problem of the flood. The whole area is facing very severe flood problem.

Figure 2: Representatives Meeting

Then through the discussion, inquisition and field investigation, it is shown that the flood problem is the result of the overdevelopment for tourism and wrong construction behavior. For this area is belong to the Tianmu Mountain and it is famous for its high quality natural mountain and water resources, especially the hilly terrain and the beautiful rivers and streams between the hills (Figure 3). And the temperature of this area at summer is much lower than the temperature in the cities around. So every summer many people who lives in the cities come to here to avoid urban area’s summer heat. Because of the need of city people, this area has developed tourism many years ago. And the people living in this area are the earlier group that has tourism income adding to their normal income. Therefore, the economy problem is not their first thinking.

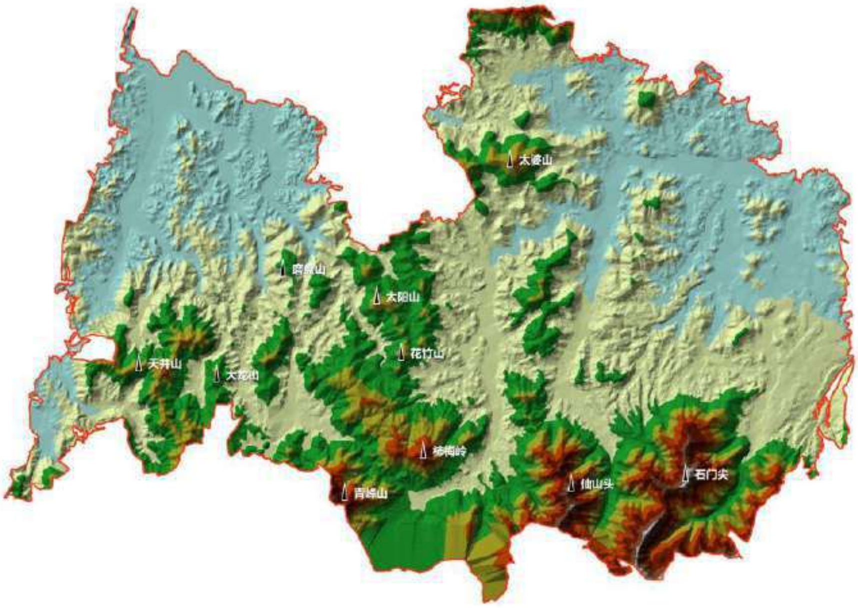

Figure 3: Mountain Topographic Analysis

To support the tourism, many construction has been hastily done without enough thinking which lead to the over-development of land use and mistaken-construction of the embankment. And the result is so many rivers and streams has been polluted, blocked and even disappeared (Figure 4). Without the enough rivers and streams to store and distribute water, whenever in the rainy season, flood began to torture this area. As every summer is the tourist season and is also the rainy season, the flood situation is getting worse in recent years that not only reduce the tourists' passion but also affect the people's normal lives who are living there. Even more, if this situation continues, this area's ecological system will be destroyed and not to mention the 'refrigerator' function.

Figure 4: Polluted River

3.3 Planning Strategies

Based on the survey before the planning and to deal with the flood problems at first, through several rounds discussions with local people and also the local government water resource department, planning strategies have been taken out which are adhere to the principle of natural resource orientation and focus on the water resource and river channel dredging. On this basis, the planning and design is carried out for the landscape and public facilities upgrading.

Strategy I: Keep Intact of the Mainstream Rivers and Basins
There are six main rivers in this area and they divide the whole area into seven basins (Figure 5). So the first step of the planning is to protect and retain the ecosystem pattern of the relationship between the rivers and the mountains. Forbid any constructive behaviors that will endanger and destroy ecological security in the basins. And prevent the different type of non-construction land into construction land through strict construction control by land and construction management department of local government. The planning provide a detailed land classification map to help the government to supervision and management (Figure 6).

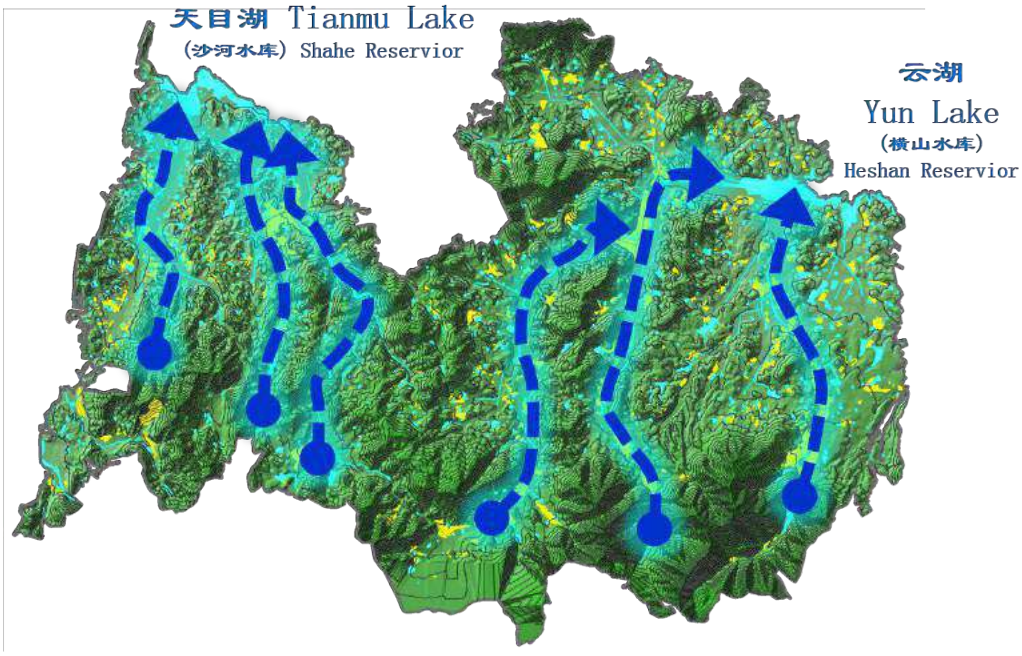

Figure5: Mainstream Rivers and Basins

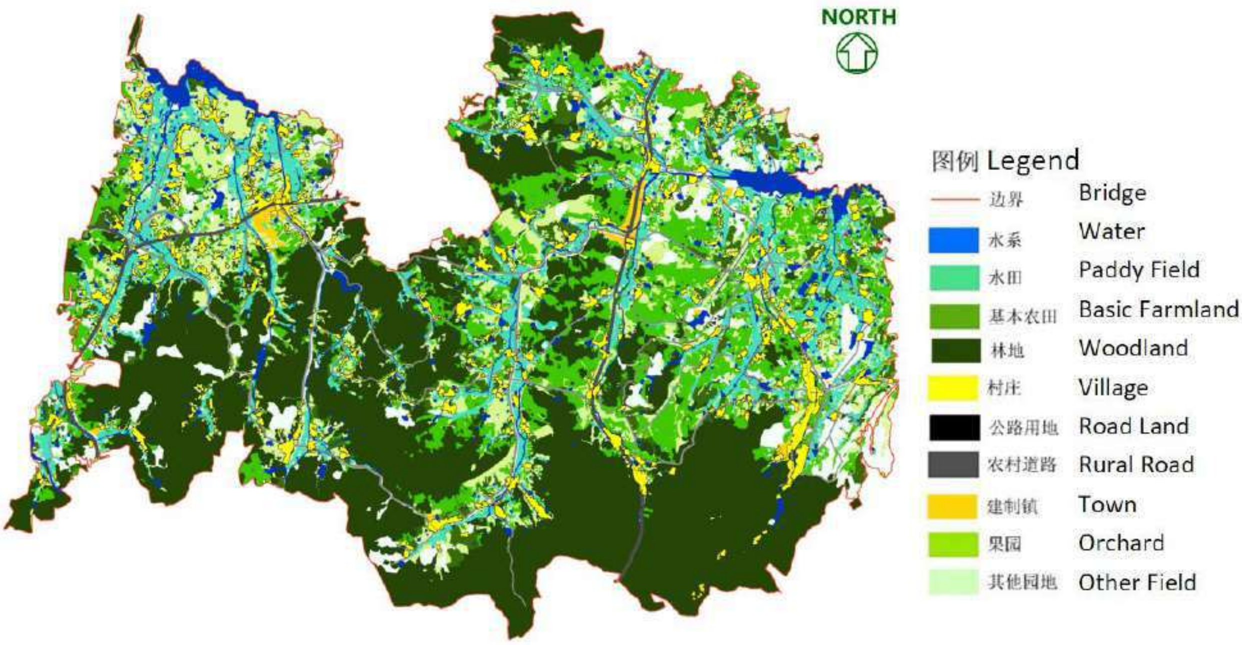

Figure6: land classification map

Strategy II: Core Area Resource Recovering

The whole scope of South Mountain Area is at the door of Liyang South Mountain Bamboo Sea Scenic Area which is an AAAAA national scenic spot, the top level in China's scenic spot rating standards. The east part of the planning scope area is nearer this scenic spot and as the pass way to the spot it attracts more city people than the west part of the scope. And also it has more construction without careful consideration. Its flood problem is also more serious than the west part. Therefore, this part of scope has been chosen to the core area to analyze and reorganize the resource (Figure7).

Figure 7: Core Area Site

Firstly, During the investigation, a special character of the landscape pattern has been found that not like the east China's Jiangnan Water Town, this area which along the river there is always the farmland or the field and it has a very important function that to become the flood buffer to avoid the village to be drowned (Figure8). But during the past years unthoughtful construction, some buffer area has been destroyed. So in the planning, recovering the buffer zone become the first step.

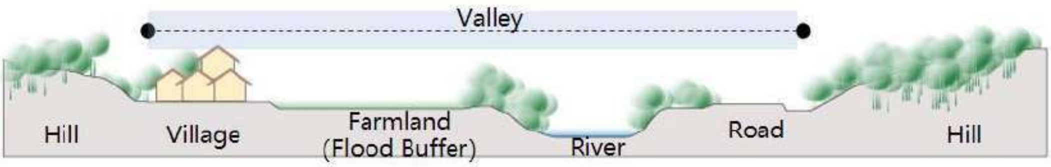

Figure 8: Flood Buffer Pattern

Secondly, recovering the natural river linear. In the past years' development, in order to more efficiency and having more land use, the construction has change the rivers' natural linear to more straight linear. Then, the water has not enough time and space to stay, that is why the flood happened. So, in the planning, the curved natural river linear need to be recovered to let the flood have more buffer space (Figure9).

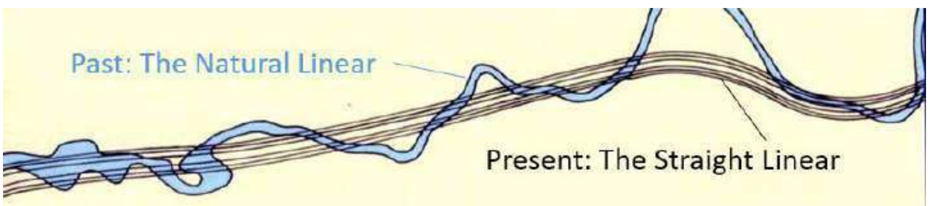

Figure 9: Natural River Linear Recovering

Strategy III: Embankment Detailed Design Demonstration
In the river buffer zone, is not the pure natural space that prohibit human entering. It can join to proper human activity which also can help people to more understand of this area's ecosystem and enjoy the natural landscape. Based on this idea, some detailed design near the river has been done. While recovering the character of natural rivers embankment, some riverside promenade has been added and change the straight line embankment to the resting slope that more people could safely close to the river and enjoy their time near the river (Figure10).

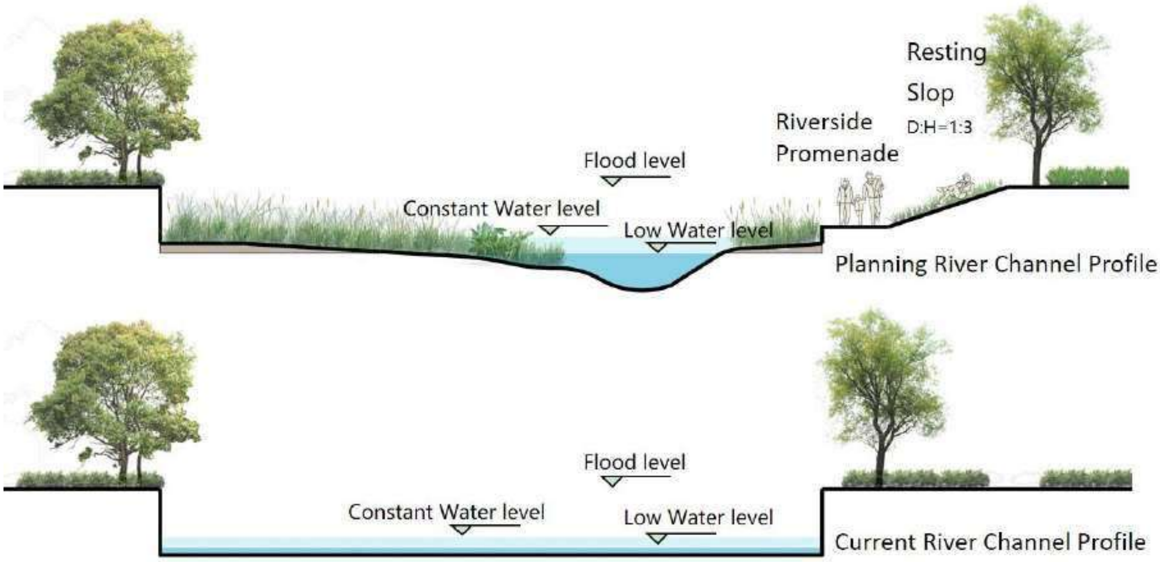

Figure 10: Embankment Detailed Design

4. Case Study Two: Tangxi Village Planning

Compare to the first case's large area, the second case study is specific on a small village which name is Tangxi and located in Siming Mountain area, Zhejiang Province, east coast of China. This village is almost at the top of the mountain, so in the summer, the temperature here is almost eight degrees lower than the average in the surrounding plains. It is a truly a 'refrigerator' village to the urban people. And also near the village only about six miles is the entrance of the Siming Mountain National Forest Park. Every summer, a lot of urban people come to the park and some retired people even live there for the whole summer about two or three months in order to escape the cities' summer heat. Some of these people even from Shanghai.

4.1 Planning Origin
The origin of this planning is bottom-up that is not from governmental will, but from the villager. They have strong willing to change their lives and to increase their income. Because in the last few years, this village has finished a transformation from agriculture to planting. But along with the downturn of Chinese real estate, their planting incomes begin to a dim view. The villagers want to find a new way to change their lives and adding their income. Also they have the wish to improve the living environment of their village.

4.2 Planning Process
Because of the bottom-up origin of the planning, the villagers are very enthusiastic and eager to provide a lot of information about their village. And some of them are not only familiar with the current situation but have abandon of historical knowledge of the village. Therefore, with the help of the villagers, through the planning survey and discussion with them, the village's

natural resource with deep culture heritage come out and become the main driving force for the planning.

4.3 Planning Strategies

The planning strategies making is not limited to village built-up area, but the whole village administrative area has been considered as a whole ecosystem. Its scope is about 14.6 square kilometers. And the village built-up settlement is in the center of the area which living about more than one thousand people. But about half of them are going out for work and not always living there.

Strategy I: Overall Forest Protection of the Whole Village Area

Seen from the area, the village built-up area is only a small part in the center of the whole village administrative scope. Beside and near the built-up village area, the west part is the agriculture planting area and the east part is the natural landscape area which including some small hills that people can climb up and also some reservoirs. And the faraway area is the forest area which people can hardly reach and climb, and also it is not allow normal persons to get into as the ecological protection requirements. So the overall Forest protection of the whole village area is on the basis of the different characters and functions. The build-up village is located and hold by the natural space. Just like in the Tai Chi diagram, only if the natural part be protected well, the whole system can be balanced (Figure 11).

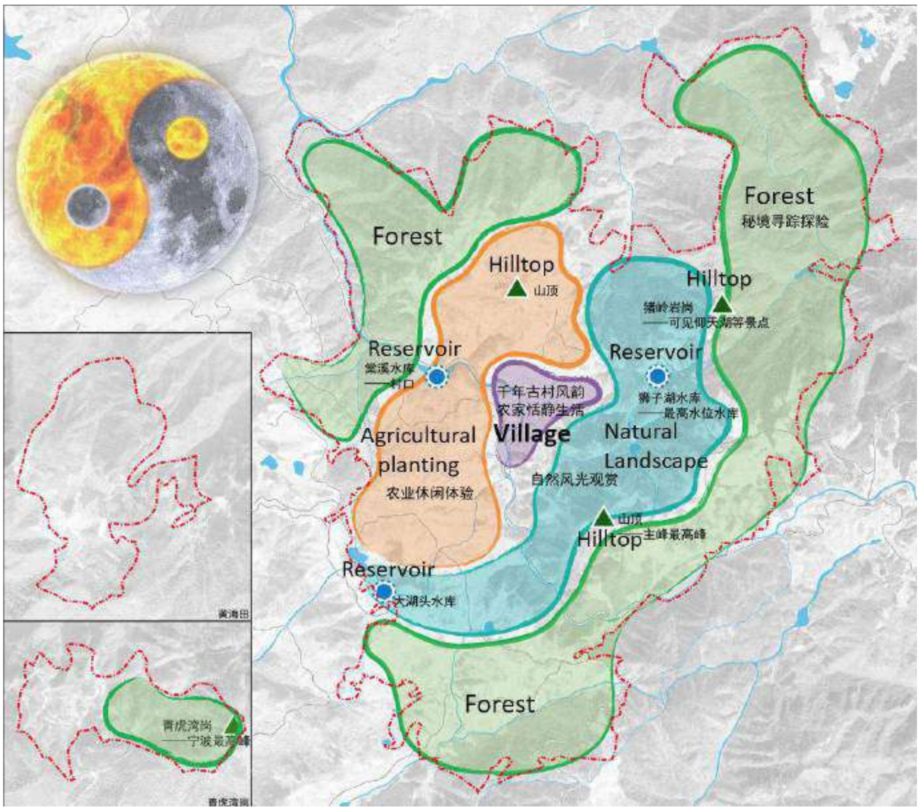

Figure 11: Village Whole Area Function Division

Strategy II: Maintain the Historical and Culture Meaning Landscape

The mountains around the built-up village are not only have the eco-function but also have a long historical meaning in Feng Shui, the deep and long-term China geomantic learning. It is not used very often today, but in the ancient time people use it to choose where they live. And this village been chosen here is because they found the snow in this place is easy to melt and it means it is warm here. And also there are several hills around this place, they give a very good protection from wind and cold air. Even now these hills which can be seen in the village, and the aged villager can call out the meaning names, such as dragon, phoenix and so on. Each hill's name has a symbolic auspicious meaning in Chinese culture. I think it is not superstitious, but actually reflect the relationship between the human and the nature. And shown the respect of the villagers to the nature. To continuation of the tradition, the planning advise to intensely maintain this, not only to protect the physical hills as landscape but the meaningful stories behind (Figure 12).

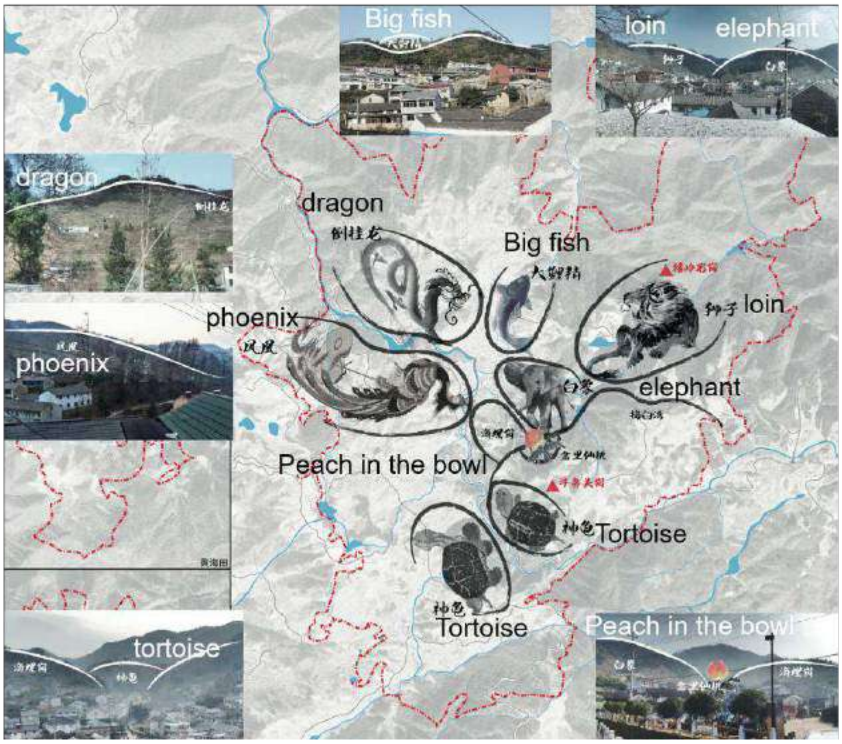

Figure 12: Historical and Culture Meaning Landscape

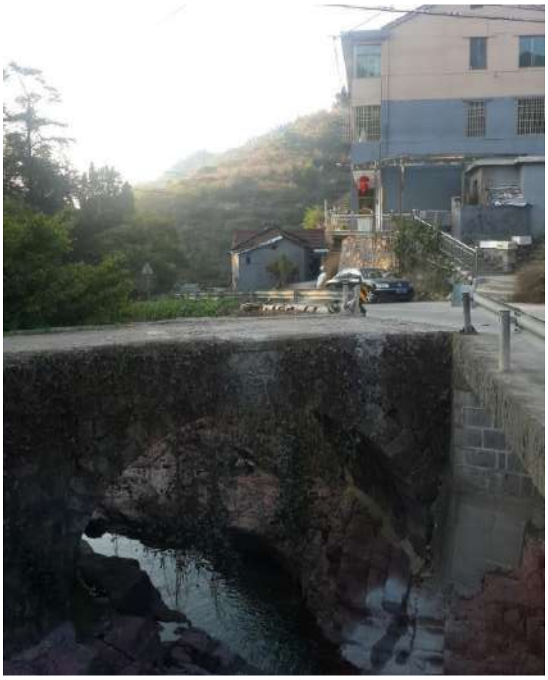
Strategy III: Details Design of the Village's Environmental Facilities

On the basis of the whole eco and natural structure protection and maintaining, the village's build-up environment is the next problem need to be solved. As the analysis before, the village has the natural advantage of temperature in summer and has the location superiority near to the hot scenic spot. And also, it has the accommodation living need of the urban people in the summer. If the village has a clean and characteristic built-up environment, the village will attract the urban people to live and the villagers will add another way of income which will not let them leave their home.

The detailed plan and design also follow the ecological and natural concept, avoiding to familiar with the urban construction and using the local material. For example, there is one place at the cross of the two main roads of the village, and it is upfront the entrance road as a signal place. But before the planning, this place seems like to be wasted, not even to say the landmark of the village. As the village is in the mountain area, it is full of rocks with different shapes. The detailed detail utilize this feature and build up a landscape with local rocks' characteristic (Figure 13). Another example is a public facility which is built on the bridge. Because most people living in the village now is the aged and children, they need some place to rest and talk together. The galleria is planned for this purpose and it is the idea of the village not the planner. We planners just help them to realize their idea and gave them some design advice (Figure 14).

Before Planning *After Planning*

Figure 13: Rock Corner Landmark



Before Planning *After Planning*

Figure 14: Bridge Galleria

5. Conclusion

China has a very rapid socio-economic development after the Reform and Opening up over the past 30 years. In this period of time, economy development has been emphasize too much to ignore the protection and maintaining of the ecosystem and natural environment, especially the support to the cities and careless with the rural area.

Nowadays, with the emergence of various environmental problems, people's consciousness has also begun to transform. From the simple focus on economic and material space development, it has begun to return to respect for the overall natural environment. And it has gradually come to realize that the stability of ecosystems in rural areas is also a guarantee for maintaining urban ecosystems.

Through two real planning practice cases, this study explores the planning strategies for restoring natural ecosystem functions in rural and town areas from system to detail by protection and maintaining the integrity and harmony of the regional system as a whole. In order to guarantee the role of the 'refrigerator' in rural areas will not be destroyed. In China, there is still a long way to do this aspect of work, this study is only a beginning of it.

How Urban Morphology Can Be Optimized? Research on Interactive Mechanism Between Urban Morphology and Urban Micro Climate

Yi ZHENG; Junyan YANG
Southeast University, China

Abstract

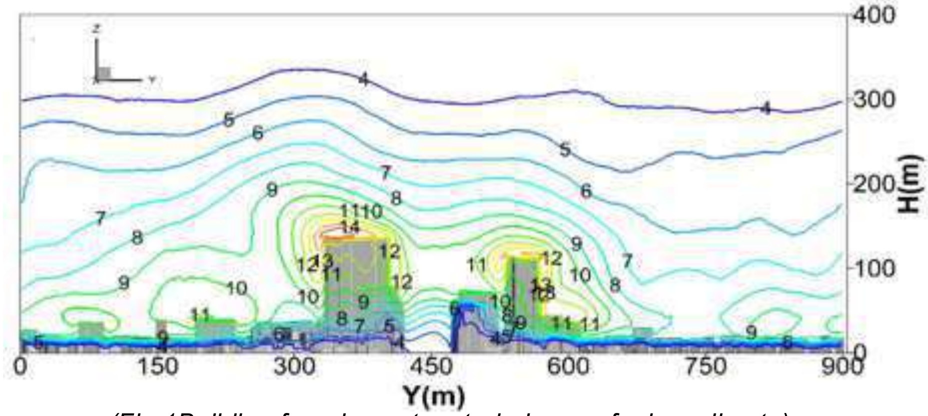
City is a space for people to live, the physical feeling of citizens is direct impacted by urban micro climate, which includes thermal environment, wind environment and acoustic environment. However, traditional urban development pattern, which is led by high-efficiency spatial use result high FAR (Floor Area Ratio), high density and high height urban morphology. Under this spatial development pattern and morphology, which is conducted by this pattern, urban physical environment is impacted negatively. In this study field, the most common research object can be considered is the UHI (Urban Heat Island) effect. Many previous researches have provided many consequences in this area, includes mechanism of UHI and possible resolutions. However, urban spatial is complex system, and UHI only can be believed as a part of urban micro climate. Meanwhile, due to data and analysis techniques limitation, many previous researches are considered lack of quantitative method in some extent. Thus, this research mention to study how to objectively and quantitatively measure the urban micro climate based on urban physical environment big data, and attempt to find out the interaction mechanism between urban 3D morphology and urban micro climate. In addition, attempts to provide possible way which can adopts the research results to guide urban design practice, optimize urban 3D morphology and construct a better urban physical environment.

Key words: Urban Micro Climate, Urban 3D Morphology, Morphology Optimization, Urban Physical Environment, Micro Climate Big Data, Urban Design

1. Introduction

The rapid progress of global climate change and urbanization has caused the city to face a series of city climate problems such as frequent climate extremes, hot summer temperatures, and increased air pollution (Carmin et al., 2012). Therefore, Explore the impact of urban spatial pattern changes on the physical environment of cities, the relationship mechanism between urban 3D morphology and urban physical environment, and use urban micro climate data and law behind these data to guide planning and construction can be considered is a hot topic for current planners, builders, and climatologists. Cities across the world are recognizing increasingly that they will face a growing variety of challenges related to global climate change, and a number of leaders in these cities are starting to adopt some measurement to optimize the urban micro climate (Pelling et al., 2011). However, any researches which keep away from urban 3D morphology to analysis and provide related measurement for optimize urban morphology or urban physical can be believed lack of rationality.

Because many previous researches such as Stathopoulos and Baskaran (1996) and Peter and Richard (1999) have conducted research on urban 3D morphology and urban micro climate, their research consequences prove that the building three-dimensional form is related with urban micro climate directly. The height, form and scale of building will impact on near-surface turbulence, and this effect will influence on urban thermal and wind environment, thus urban micro climate will be changed due to different urban 3D morphology. (Figure 1)



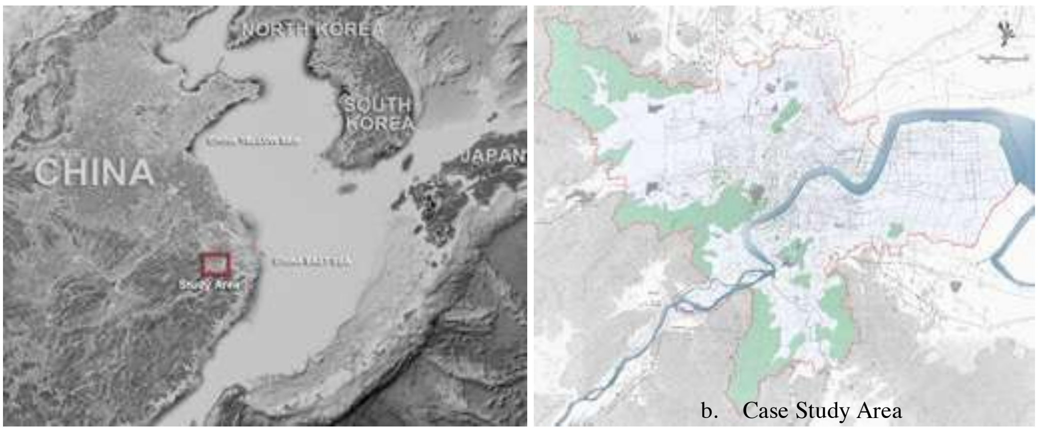
(Fig.1Building form impact on turbulence of micro climate)

Source: Author Made

Based on above expound, what is the interactive relationship between urban 3D morphology and urban micro climate? What is the inner influence mechanism between urban 3D morphology and urban micro climate? How to construct an urban 3D morphology optimization model based on urban micro climate? How to make a better balance between urban physical environment and urban spatial morphology, and to conduct an urban design scheme? These questions are needed answer through in-depth analysis of urban 3D morphology and urban physical environment, and find the law of interactive mechanism between urban 3D morphology and micro climate.

2. Case Study Measurement

According to the previous researches and current computer and urban big data analysis techniques, this research mention to base on urban physical environment big



(Fig.2 The Research Case Study Area)

Source: Author Made

data to measure both urban thermal and wind environment in a large-scale urban site.

2.1. Case study introduction

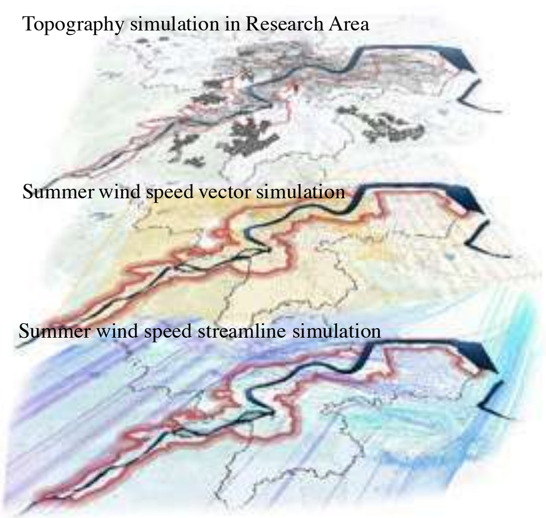
Because the urban micro climate is impacted by the different spatial factors, such as mountain, river, buildings and other urban 3D morphology factors. Thus, this research selected Hangzhou which is a large-scale city with river, mountain, lake and comprehensive urban environment in the east China as the research object in here. The reason for select Hangzhou as the case is there exist all major influence indicators in urban micro climate. Thus, the research consequences can be considered is reliable, effective, and reproducible. The major results of this case can be used to other urban micro climate study, and the core founds can provide positive guide for urban planners or designer to optimize urban 3D morphology globally.

2.2. Method for thermal environment measurement

During the research process, the thermal environment of research area is measured through two steps. Firstly, satellite remote sensing data of 1984, 1991, 2003 and 2015 was acquired through LANDSAT of United States Geological Survey (USGS). Then, Computer simulation technology was adopted to establish urban space model, and software such as ENVI-met, ECOTECT and RayMan were used to simulate and analyze the research area thermal environment. By analyzing the simulation results and comparing the differences of thermal environment under different urban spatial morphological indexes and spatial morphological types, the coupling correlation between urban spatial morphology and urban thermal environment is concluded. Afterwards, site investigation method is adopted to collect Surface temperature, air temperature, relative humidity and other meteorological data, and through combine the land function of the research area and various spatial morphological indicators such as sky visibility to analysis the interactive mechanism between urban 3D morphology and urban micro climate.

2.3. Method for wind environment measurement

Similar with the thermal environment measurement, the method of measurement the wind environment is includes three steps. The first step is Use field research method to calculate the space form indexes such as the scale of land use, number of building stories, density and floor area ratio in research area as the basis of wind environment case study. Afterwards, computer numerical simulation method was also used to establish the space model of the central area, and conduct numerical simulation for the wind environment at the mean wind speed of prevailing wind direction in research area with CFD software scSTREAM to generate the simulation results and comprehensively analyze



(Fig.3 wind environment measurement)
Source: Author Made

the space distribution characteristics of the wind speed at the pedestrian height and evaluate the merits of the wind environment. Then, conduct multivariate linear regression analysis on the wind speed parameters and space form parameters of blocks with data analysis software SPSS, and discuss the correlation between each space form index and the wind speed level at the pedestrian height, further evaluate the characteristics and causes by comparing the differences of wind environment in different types of space units, summarize the influential factors of urban space form on the wind environment and discuss optimization strategies for urban 3D morphology.

3. Measurement Results

Through above method to measure both urban thermal and wind environment in research area, the distribution and data analysis results can be fund. Meanwhile, through the superposition analysis of the elements in the urban 3D morphology, the interactive mechanism between the 3D morphology and the urban microclimate is further analyzed, and on this basis, the optimization strategies and methods of urban spatial form are proposed. According to the optimization strategies, two round urban design schemes have made to optimize the urban 3D morphology for batter urban physical environment.

3.2. Thermal Environment

Based the thermal environment data which is acquired through LANDSAT of USGS, using GIS as the data processing platform, the temperature inversion of the satellite remote sensing data of research area in 2015, and the thermal environment in the urban area was simulated. Based on the measurement results, the high temperature period is concentrated between June to August. (Table 1) In summer, the temperature change is smoothly, (Figure 4) the urban thermal environment distribution different is impacted by urban 3D morphology mainly.

Table 1: The Average Data of Thermal Environment in Research Area

The Average Data of Thermal Environment in Research Area												
Month	JAN	FEB	MAR	APR	MAY	JUN	JUL	AUG	SEPT	OCT	NOV	DEC
Extreme heat	23.9	28.5	32.8	34.8	36.5	39.7	40.5	41.6	38.7	35	31.2	26.5
Average heat	8.3	10.3	14.8	21.1	26.3	29.1	33.6	32.8	28.2	23.2	17.3	11.3
Average degree	4.6	6.4	10.3	16.2	21.4	24.7	28.9	28.2	24	18.8	12.9	7
Average cold	1.8	3.5	7	12.4	17.5	21.4	25.2	24.9	20.9	15.4	9.3	3.7
Extreme cold	-8.6	-9.6	-3.5	0.2	7.3	12.8	17.3	18.2	12	1	-3.6	-8.4

(Fig.4 Research Area Temperature Fluctuation in Summer)

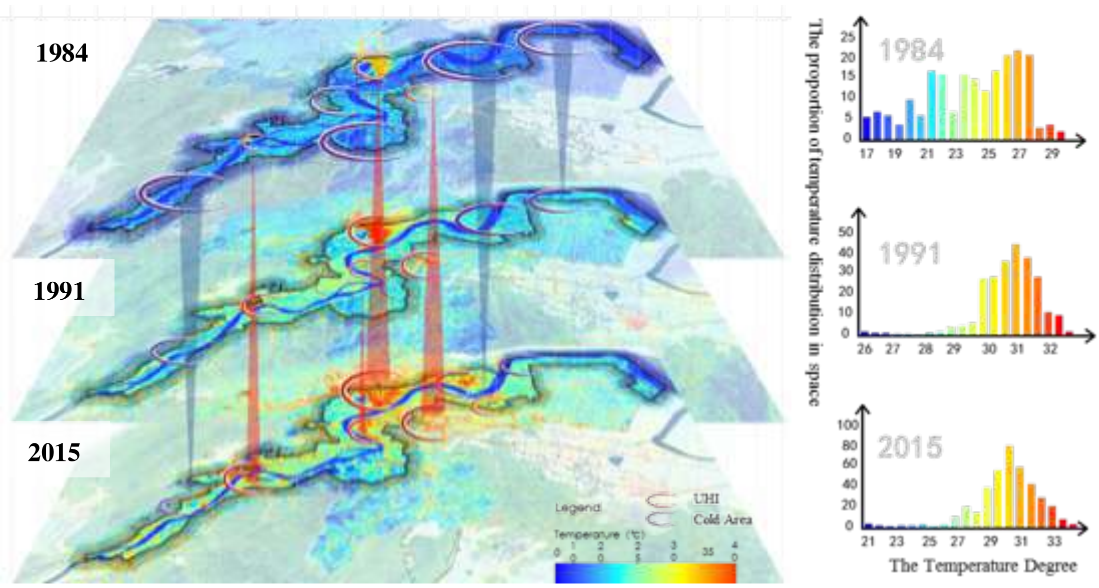
Source: Author Made

In addition, the study also based on the urban thermal environment data of 1984, 1991, 2015 to conduct land surface temperature retrieval through GIS data analysis platform. Based on this, the changing law of urban thermal environment and heat island effect in research area during the past 30 years can be dynamic analysed. As the most direct reflection of interaction between urban 3D morphology and urban thermal environment, the appears of UHI (Urban Heat Island) usually related with the change of urban Spatial. Through observation the measurement results, (Figure5-a) the UHI range in research area illustrates an extensive expansion during the past 30 years. Meanwhile, behind the extensive expansion of UHI, the average temperature in study area also increase 2 to 3 degrees than before. (Figure 5-b)

Through observation the phenomenon of thermal environment distribution transformation and UHI range expansion, the generation mechanism behind the phenomenon is interaction between urban 3D morphology and urban microclimate. During land expansion of urban space, the land surface condition has changed, it direct led the heat capacity of urban surface is changed. Meanwhile, enhancement of building height and density also exacerbated UHI effect. As the Figure 8-a illustrates the all UHI ranges in 2015 is the new developed urban area, the land surface is hardening in these sites. However, in 1984, these sites are all with natural surface.

3.3. Wind environment

Urban wind environment is high related with thermal environment, both wind and thermal environment together constitute the urban microclimate. Based on the computer simulation techniques and practice measurement of wind in research area,



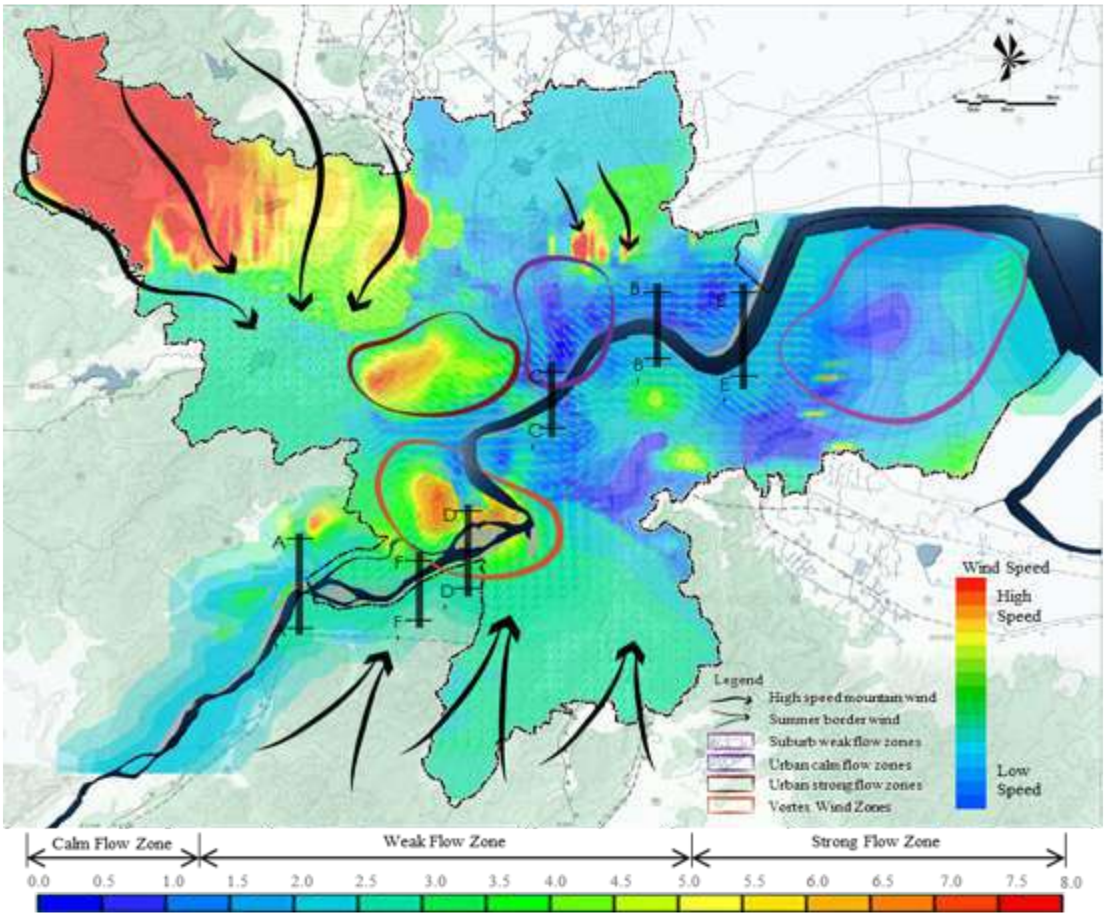
a. Thermal Environment Simulation Distribution b. Temperature Change

(Fig.5 Thermal Environment and Temperature Change in Study Area)

Source: Author Made

this research adopts Phoenics fluid calculation software simulation technology to measure wind environment. Before conducts urban wind environment simulation based on urban 3D morphology, statistical analysis of wind direction, wind speed and wind frequency is conducted in study area in June, July and August firstly. The results indicated that in research area, the dominant wind direction in summer is southwest wind, with a maximum wind speed of 7.2 m/s, an average wind speed of 2.6 m/s, and a minimum wind speed of 0.9 m/s.

According to the above wind environment basic analysis, the computer simulation techniques was selected to conduct the further in-depth measurement of urban wind environment in the area. Through CFD software scSTREAM to generate the simulation results and comprehensively analyze the space distribution characteristics, the wind speed in the study area is concentrated in the range of 2~5m/s, and wind environment illustrates the segmental variation characteristics. (Figure 6)



(Fig.6 Wind environment simulation results in study area)

Source: Author Made

In this extent, the macroscopic wind environment situation in study area is already observed. Similarly, wind environment is impacted by urban factors in some extent, the figure 10 illustrates wind environment is different between urban area, suburb area and country side, thus, compare with thermal environment, the influences of urban 3D morphology on wind environment is more remarkable. (Berghauser and Haupt, 2010)

Based on above, both wind and thermal environment is impacted by urban 3D morphology, the comprehensive interaction between urban 3D morphology and urban physical environment will produce different micro climate. Therefore, based on the interactive mechanism between urban 3D morphology and micro climate, optimal microclimate oriented urban 3D morphology optimization way may be fund.

3.4. Interactive mechanism between urban 3D morphology and micro climate

Through above discussion, there exist some commonly influence indexes of both wind and thermal environment on urban 3D morphology. (Table 2)

Table 2: Common Measures of Both Wind and Thermal Environment

Index	Description	Graphical Representation
Height Index	Under the ideal simulation conditions with a wind speed of 1m/s at the height of 10m and not considering anthropologic heat factors, the surface temperature, mean radiation temperature and air temperature in daytime showed certain negative linear correlation in regular layout blocks within a height ranging from 20m to 60m, while certain positive linear correlation in daytime. For wind environment, the overall wind speed at pedestrian height is directly related to the average height in urban blocks, and there is a positive correlation between the two.	Different thermal environment between 20 and 60m building height  20m 60m Different wind environment between 20 and 60m building height  20m 60m
Density Index	Under the ideal simulation conditions with a wind speed of 1m/s at the height of 10m and not considering anthropologic heat factors, the surface temperature, mean radiation temperature and air temperature in daytime showed certain negative linear correlation in regular layout blocks within a density ranging from 16% to 49%, while certain positive linear correlation in daytime. Similarly, based on the simulation of wind environment in different urban density module, the overall wind speed at pedestrian height is directly related to the building density in urban blocks, and there is a negative correlation between the two.	Different thermal environment between 25% and 49% density range  23.75℃ 23.35℃ Different wind environment between 25% and 49% density  Density 25% Density 49% range

Intensity Index	Floor Area Ratio is usually used to evaluate the urban development intensity. Through simulation and analysis, for thermal environment in the previous section indicate that the mean air temperature at noon in summer will decrease with the increasing of FAR, and in the early morning will decrease with the increasing of FAR. However, due to the experiment, there is no direct correlation between the overall wind speed at pedestrian height and the FAR in urban blocks. But, reasonable combination of space forms is conducive to the optimization of the wind environment in urban blocks	Different thermal environment between 0.27 and 0.81 FAR  FAR 0.27 FAR 0.81 Different wind environment between 25% and 49% density range  FAR 1.1 FAR 13.1
Enclosed Index	Based on the experiment, the enclosure degree has a significant impact on the internal airflow in the block. The greater the degree of encirclement, the smaller the internal wind speed. Under static wind conditions, the heat is more dissipated through the thermal turbulence, and the degree of encirclement has no significant effect on the thermal environment inside the block. In hot and humid areas, proper wind direction in the summer to reduce the degree of enclosure can effectively alleviate the thermal environment inside the block.	Thermal environment between 40% and 70% enclosed degree  40% 70% Different wind environment between 40% and 70% enclosed  40% 70% degree

(Source: Author Made)

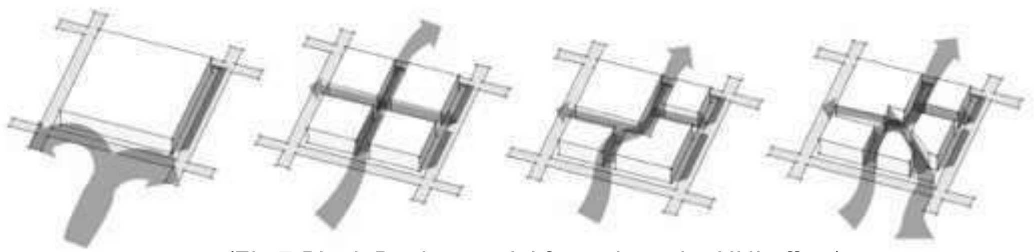
Through above analysis, the interactive mechanism between urban 3D morphology and urban micro climate is complex, the influence indexes are not only included above four indexes. The urban roughness, frontal area index, building slagered height and SVF (Sky View Factor) are also can be considered as index for evaluate the interaction between urban 3D morphology and urban micro climate. However, the urban built environment does not allow to conduct the comprehensive optimize action in each aspect in some extent and construct an absolute best urban micro climate.Therefore, for optimize the large-scale urban 3D morphology, these four indexes which are listed in Table 5 is the main aspect of optimization process.

4. Urban 3D morphology optimization practice

4.2. Thermal environment optimization strategies

Based on the analysis of the mechanism of thermal environment factors set forth in preceding parts, most of the measures for urban design are the guidance and control of urban 3D morphology. Thus, in urban area, street trees, arcades, pulling tent and other continuous shading facilities should be considered to improve body comfort of external space. in the overall design of the block, large volume of podiums should be crushed. Ventilation clearance should be reserved on the frontal area of the block to introduce external airflow into the block to the maximum thus to facilitate heat dissipation within the space. The opening should face the prevailing wind direction in summer (Figure 7).

for more enclosed building layout, the compact form is adverse for ventilation and more anthropologic heat will be generated. Therefore, it is encouraged to keep certain green space within the block for vegetation to release more heat via vegetation transpiration.



(Fig.7 Block Design model for reduce the UHI effect)

Source: Author Made

In addition, excessively low sky visibility or areas with excessively height-width ratio are adverse for air interchange at night. On the main rods, due to the large amount of traffic flow, pedestrian volume and anthropologic heat, building backing distance should be greater to ensure open sky visibility. While for secondary roads, there are less anthropologic heat, sky visibility should be reduced properly to facilitate sun shading and appropriate pedestrian scale.

4.3. Wind environment optimization strategies

Similarly, wind environment optimization strategies are also related with urban 3D environment. However, different with thermal environment, when consider the wind environment optimization, the regional factors may need be involved. Complete protection, restoring natural landscape pattern and establishing networked urban green space system are of great significance to the formation of a good urban climate. It will not only provide more cool and fresh air for the city, but also effectively reduce the urban heat island effect and create a pleasant urban wind environment and thermal environment by protecting and restoring ecological sensitive resources such as rivers, lakes, natural mountains and ecological wetlands, rebuilding the environmental basis of the regional natural background, establishing and preserving urban oases and interlinked green corridor networks, integrating urban artificial greening space with natural ecological space and establishing a complete green ecological network in the city. Thus, the macroscopic strategies for optimization of urban wind environment can be divided into three level, which is planning level, building level and landscape level. (Table 3) Based on the interactive mechanism between urban morphology and micro climate, detailed optimization strategies are detailed provided in these four levels.

Table 3: Macroscopic optimization strategies of wind environment

Optimization strategy of wind environment	**Planning level**	**I. Protect and restore urban landscape pattern and build a networked urban green space system**	
		II. Create large urban air corridor	II-1 Scale and direction of urban ventilation corridor

5. Conclusion

Urban 3D morphology is considered as a comprehensive system, meanwhile, urban micro climate is also complex, it impacts by and on the different factors of urban 3D morphology, the any changes of factors belongs to urban 3D morphology are all results the different urban physical environment, and construct the different feeling of people who live in the city. A reasonable and scientific urban 3D morphology can build a comfortable urban micro climate, reduce the UHI and increase the urban ecological security. For this aim, this research through an urban design practice case to analysis the relationship between urban 3D morphology and micro climate through literature review and computer assisted micro climate simulation based on urban physical environment big data. Based on the measurement results, the interactive mechanism between urban 3D morphology and micro climate has been discovered, the analysis consequences indicated that urban micro climate is impacted by different index of urban 3D morphology. In these influence index, the urban height, density, intensity and enclosed index is considered as the major and common measurements impact on both urban thermal and wind environment. Afterwards, this research through these four major aspects to conduct an attempt in micro-climate led urban 3D morphology optimization. Through empirical urban design practice, some strategies are proved can promote and positive impact on urban micro climate, and these strategies are also suitable for other city or site around the world. Summarize above, the consequences of this research proved the interactive mechanism between urban micro climate and comprehensive urban 3D morphology based on digital measurement techniques and physical environment big data. Additionally, the optimization strategies in here are also contribute for further urban design practice. However, there also exist some limitation. Urban space is complex, there exist more potential index may impact on urban micro climate, these indexed should be analysis more detailed in further research.

About ISOCARP

The International Society of City and Regional Planners (ISOCARP) is a global association of experienced professional planners. It was founded in 1965 in a bid to bring together recognised and highly-qualified planners in an international network. The ISOCARP network brings together individual and institutional members from more than 80 countries worldwide.

The wealth and diversity of professional expertise, knowledge, and experience in the ISOCARP membership is unmatched in the planning field. Although ISOCARP members work in many different fields they share a common interest in the spatial and environmental dimensions of urbanisation. They advise key decision-makers, proposing and supporting projects for intervention in a spatial context through general or specific actions.

ISOCARP encourages the exchange of professional knowledge between planners, promotes the planning profession in all its forms, stimulates and improves planning research, training and education and enhances public awareness and understanding of major planning issues at a global level. The association's main event is the annual ISOCARP Congress, which focuses on a globally-significant planning theme and which takes place in a different country each year.

About Bodø

Few other Norwegian cities and towns have been gifted with such magnificent and spectacular scenery as Bodø. The town provides a fascinating mixture of superb nature and a modern, urban and vibrant lifestyle. Right at the heart of all this you will sense the informal and friendly atmosphere amongst its population. It is a vibrant town, excellent for shopping, cultural and sports and leisure activities.

The regional capital of the County of Nordland has apparently been reaching for the stars in recent years, rapidly closing in on citizen number 52,000. This makes Bodø the second largest town in the North of Norway, beaten only by Tromsø. Bodø is currently one of the fastest growing towns in the whole of Norway.

Bodø's location has put the town right in pole position when it comes to communication, trade and services. Travellers by air, rail and sea all meet in the heart of this city. This is, however, just one of the things that has made our town one of Norway's most popular locations for events, meetings, conferences and get-togethers of all kinds.
