INTRODUCTION

Dushko Bogunovich
General Rapporteur

Dushko Bogunovich is Professor of Urban Design and Planning, and Dean of the Faculty of the Built Environment, Arts and Science at BA ISAGO University in Botswana. He now lives in Gaborone. His permanent residence is in Auckland. There, Dushko was Associate Professor of Urban Design at Departments of Architecture, and Landscape Architecture, at New Zealand's largest polytechnic, Unitec Institute of Technology. He taught under- and post-graduate courses, and conducted research and consulting in: urban planning, environmental policy and sustainable development. His research focus is on Auckland, Christchurch and the NZ urban system in the context of global urbanisation and the challenges posed by the acceleration of climate change. Dushko has been a member of ISOCARP since 1984.

Perhaps the year 2018 will go down in history as the year the global community finally realised that climate change is an existential and imminent threat to human presence on Earth. As the UN Secretary General, Antonio Guterres, put it at a meeting at the UN Headquarters in New York on September 10th: ***"The world risks crossing the point of no return on climate change, with disastrous consequences for people across the planet and the natural systems that sustain them."***

Strong words for a professional diplomat. But how many of the 7.3 billion people on the planet will have heard them? And grasp the dire urgency? It is more likely that the extraordinary weather events of this year's Northern summer will produce the needed awakening impact on public opinion and government action, than yet another political speech.

In the same week that Mr Guterres was raising the alarm over the paralysis of world leaders and voicing his dismay at the slow implementation of the Paris Agreement, two colossal super-storms were spinning at either side of the globe – hurricane Florence in the Atlantic, and typhoon Mangkhut in the Pacific. Tens of millions of people in the cities, towns and villages in the eastern US, The Philippines and southern China stood in the way of these two monster-storms.

The Call for Papers for this congress was written in January 2018. It contained a few bold statements. The Call announced that the congress agenda would be ***'one of the most ambitious in ISOCARP's history'*** and declared that the aim of the congress was 'nothing less than to save civilisation'. It asserted urban planners' critical role in this undertaking, arguing that ***'the future of civilisation now more than ever depended on the way we plan and manage our cities and towns'.***

The Call also introduced the host city, Bodø, describing it as ***'cool in both senses'.*** This was a dual reference to its attraction to visitors and investors as a 'cool place', and to the fact that it is a cold city, due to its location Europe's and Norway's far north, inside the Arctic circle.

However, in the meantime - as the weird Northern Hemisphere summer of 2018 would have it - Bodø became unusually warm. Along with its region, Nordland, and the rest of Arctic Norway and Sweden, Bodø experienced temperatures of around 30 degrees Celsius (the normal for July is about 15). What was even more anomalous for this region of the world, was that it had more than 50 forest wildfires, something normally associated with Mediterranean parts of Europe.

In fact, the entire Northern Hemisphere has been affected by unusually weather phenomena. Heat waves, forest fires, storms and floods were fierce and widespread all over North America, Europe, Asia and northern Africa. Heat waves in July and August affected Ireland, Wales, England, France, Spain, Portugal, Turkey, Pakistan, China, the Koreas, Canada and California. In early August, temperatures in western Spain and southern Portugal reached 47 degrees. Meanwhile, forest wildfires were raging in the United Kingdom, Sweden, Denmark, Estonia, Finland, Latvia, Malta, the Netherlands, Poland and Germany. In Greece 90 people died in one wildfire near Athens. This is almost as many as Portugal in 2017, when more than 100 people died in wildfires. In California, some 5,000 recorded wildfires killed 10 people, burned 3,000 sq km of land, destroyed over 1,000 homes and forced evacuation orders on 20,000 residents. In Asia, storms and floods battered regions of Japan, China and India.

But while the attention of the media and the public is understandably on the populated areas, the scariest harbingers of the new climate in 2018 are in the Arctic. In December and January this past winter, the area between the North Pole and the Svalbard Islands had weeks of above zero temperatures. It even rained. By the time we all gather in Bodø, we will know if the long predicted 'blue ocean event' happened, or didn't. At the time of writing this report, a completely ice-free Arctic Ocean seemed unlikely. But that is of little consequence. The fact is that the Arctic sea ice is almost gone and the ***albedo effect*** – more solar heat gain from the darker surface of an ice-free ocean – is now accelerating. This means the permafrost areas of the coastal plains and shallow seas of Siberia, Canada and Alaska are irreversibly thawing. And that means the dreaded 'methane clathrate bomb' is ever more likely to go off and change our planet forever.

So, the situation with the global climate system is indeed alarming. No more are we facing the 'prospect' of climate change – the climate HAS changed. In this new reality, what concerns our profession is that cities and towns worldwide will face the consequences in a disproportionate way. Not only because urban areas now contain more than half the human population, but also because urban inhabitants are heavily dependent on that clever human invention called 'urban infrastructure'. The trouble with urban infrastructure is that when it works, life is good and easy; but when it gets destroyed or disabled, life quickly turns to hell.

So what can Planning do? What can town, city, regional and spatial planners do to mitigate climate change processes that can still be prevented or slowed down, and to prepare us for all those that are now inevitable?

This is what this 54th Congress of ISOCARP is about. 500 planners from all over the world will gather in Bodø for five days to try to answer the two big questions of 21st century urbanism:

1) how can we make cities more ***sustainable*** and thus prevent even more global warming - given that 'cities are heat engines' (as succinctly and profoundly stated in the language of thermodynamics and its Second Law – the Law of Entropy);

2) how can we make cities more ***resilient***, so that they can withstand the shocks and crises that seem inevitable regardless of how soon we take drastic action to curb our carbon emissions.

However, there is an even harder question, implied in these two, which we intend to put in front of delegates towards the end of the congress. Which of these two agendas - sustainability or resilience - has (or should have) priority for your planning department or consultancy? Or for your mayor and your city council? Or in the opinion of your citizens?

We do not expect a clear cut and definitive answer. Nor are we asking because we think somebody knows the exact answer. We are asking because we think this is the most important question for governments – central and local - and the planning profession to consider at this moment in history.

The Congress delegates are coming from 53 nations and some 160 cities and towns. Contributions will come in the form of papers, case studies and special sessions.

The plenary sessions will be addressed by the Norwegian and ISOCARP dignitaries, as well as by three extraordinarily qualified, internationally renowned keynote speakers:

• ***Jeremy Rifkin,*** globally acknowledged economist, futurologist and expert on technology, cities and industrial revolutions, author of several seminal books;

• ***Peter Newman,*** professor and author from Australia, leading world expert on sustainable cities, and transport and technology policy;

• ***Herbert Girardet,*** author and educator, from the UK, and world's leading expert on urban ecology and the imperative of 'regenerative urbanism'.

But of course, the engine room of any conference are the presentation sessions. These will be delivered in six concurrent tracks, each one a sequence of between five and seven sessions. Each track will be monitored by a pair of rapporteurs chosen from different corners of the world.

• ***Track One*** is about the ***Global View*** – comprised of papers which are not rooted in a particular city or town or region, but are global in scale and consequence. They aim to interrogate the general question of impacts of climate change on urban areas and these areas' generic capacity for sustainability/mitigation and resilience/adaptation.

Tracks Two, Three, Four and Five are about climate and specific cities and towns - their issues and projects, and the main strands of their climate response:

• ***T2 - Spotlight Cities*** – as defined by their somewhat specific locations and geographies (coastal; mountainous, remote; Arctic; tropical…);

• ***T3 - Climate-proof Cities*** – defined as urban areas where the basics such as food, water, energy and shelter are deemed vital in readiness for future extreme weather events;

• ***T4 - Technology and Infrastructure*** – is focused on engineering and how the design concepts of 'clean', 'green' and 'smart' can support the objective of being a resilient and sustainable city;

• ***T5 - Social Networks*** – is about the human factor and politics; it interrogates models of citizen participation, urban governance and cultural transformation required for transition to sustainability and resilience.

Track Six is about examples of ***Contemporary Planning Practice*** worldwide which are not necessarily focused on the climate/global warming issue. It offers insights into the diversity of the planning profession's current issues, methods and solutions worldwide.

There will also be several special sessions, including on:

• ***UN's Sustainable Development Goals in Norwegian Planning;***

• ***Strategic Research and Innovation Agenda;***

• ***The Next City (an ISOCARP seminar); and***

• ***Global Resilience Networks.***

Finally, thanks to our hosts, the City of Bodø, there will be a stream of session open the public – at the ***ByLab*** venue. ***ByLab*** will cover topics like:

Planners for Climate Action (an UN initiative); New Generation of Planners (an ISOCARP initiative); Reframing Citizen Participation for Sustainability Transition; Planning for Diversity; and Legitimacy of Urban Governance.

Does this look promising? Will this congress ***'save the world'***?

As clearly stated in the Call for Papers, ***'the root cause of, and the solution to the global climate crisis, are fundamentally urban'.*** In plain language: cities will determine the fate of the world. Their rampant metabolism is powerful enough to throw the entire biosphere into a death spiral - and this may happen well before 2100. But their extraordinary concentration of human intelligence (planners included!) offers the hope that we'll figure out how to save ourselves before breachingw of which the UN General Secretary warned us on 10th September.

We are coming to the realisation that Cool Cities are a historical imperative. Either our cities get Cooler, or our planet gets Warmer.

This imperative will not happen by itself. It is a task which must be planned. This makes urban planning the coolest profession on the planet.

Short outlines

Papers

Track 1. The global view: climate change impacts, sustainability and resilience

Track 2. Spotlight cities: planning for coastal cities, remote towns and high north cities

Track 3. Climate-proof cities: planning for weather, water, food and energy

Track 4. Technology and infrastructure: clean, green, smart and resilient

Track 5. Social networks: citizen participation, urban governance and cultural transformation

Track 6. Contemporary planning practice: projects and paradigms

Authors are responsible for the content of the short outlines and the full papers which are listed in the order of their presentations in each track.

Track 1: The Global View: Climate Change Impacts, Sustainability and Resilience

Location: Scandic Havet – Storhavet 1

by Kate Holmquist and Evren Ulker Kacar

Track 1 takes a global look at climate change, exploring how urban and rural areas worldwide are tackling challenges regionally, and how solutions can be applied globally. Presentations from five continents will approach the conference theme of climate change holistically, acknowledging the scale of this phenomenon, and the global collaboration necessary to comprehensively and effectively respond. Participants will be introduced to the impacts of climate change affecting communities, and challenged to think globally about strategies for sharing knowledge, scaling up solutions, and addressing issues of equity that disproportionately affect some populations over others. Sessions will explore planning approaches being employed to mitigate climate change and plan for more resilient cities and communities at different scales and levels of government, in parts of the world where planning for climate change is well underway to countries still striving to raise awareness on the impacts of climate change.

Congress Abstracts: Assessment/ Commentary

The Global View Track looks at the big picture. We expect lively discussions as diverse view points highlight important challenges, disparity, and fragmented approaches – and offer a global forum for understanding a global issue, and identifying opportunities to strategically reduce the effects of climate change through collaboration, idea sharing and coordination. Diverse case studies will offer valuable lessons in what has worked and what hasn't; and practitioners and academics across a range of organizations will evaluate and discuss the potential of spatial planning, land use management, and technologies for risk assessment to inform policy and practice – from different perspectives.

What can we expect at the congress

The Global View Track will feature over 30 speakers, organized into six sessions that explore the impacts and assessment of climate change, policy challenges at the national level in the context of global climate goals and agendas, and present planning methodologies for and case studies in sustainability and resilience.

Session 1: Global Goals & National Planning Policy – Part I

How are governments responding to global climate agendas and sustainability goals? Two sessions will explore challenges of national, state and local coordination on policy and planning to ensure action and progress. Part I will focus on intergovernmental coordination and the hurdles to implementation, and actionable policy to address energy efficiency and production, green-house gas emissions, sea level rise, and achieving Zero Carbon cities.

Session 2: Cultural Impact of Climate Change: Norway multi-dwelling lifestyle.

Researchers from the Norwegian University of Life Sciences will present on shifting cultural patterns in homeownership, and the link to climate change. More than one out of five households in Norway own a vacation home in addition to their primary homes. Case studies in this session will focus on mobility and housing consumption patterns including the effects of climate change on travel modes and future land use patters.

Session 3: Global Idea Sharing – Case Studies in Sustainability & Resilience

In the spirit of the 54th Congress we will create a global forum for idea sharing, presenting a variety of case studies that take a critical look at what works and what doesn't in planning for sustainability and resilience.

We will hear about successful spatial planning approaches for reducing greenhouse gas emissions in three developed nations, the role of spatial planning and land use management in Africa, and the effects of changing weather patterns and rapid glacier retreat on water availability in Andean Cities, and New York City, Doha, Qatar will discuss their strategies for a resilient future.

Session 4: Planning Methodologies for climate adaptation & resilience

Presenters and participants are invited to take a high-level look at the planning profession and rethink methodologies for climate adaptation and resilience. We will hear from topical experts about environmental planning, spatial planning, and land use management approaches, such as endogenous resilience, volcanic river basin management and the use of indigenous knowledge as a tool for water resource management. This session will look at methodologies ranging from place-based solutions to systems level planning strategies, illuminating a natural tension between contextual approach and the need for scalable solutions.

Session 5: Global Goals & National Planning Policy – Part II

How are strategies measuring up in meeting national and global climate targets? Part II will dive into coordination of climate action and planning policies across borders and political boundaries. Presentations will look at spatial planning and regulation at the local level in African and Asian cities, to understand their effectiveness in addressing national climate policies.

Session 6: Assessment & understanding the Impacts of Climate Change

World-wide, the impacts of climate change vary widely and are experienced differently. For planners to address climate change holistically and strategically, the assessment of regional effects of climate change and the data to project future impacts are critical. Session 6 explores efforts by government agencies, NGOs, and academic institutions to measure and understand the problem to make data-driven solutions possible.

Session 1: Global goals & national planning policy - *Part I*

2 October (Tuesday), 11:00 - 12:30

TK *Chris Gossop, National Energy Foundation (NEF), Milton Keynes, United Kingdom*
London and climate change - a zero carbon city for 2050 - achievable or just hot air?
The new London Plan sets the target of London becoming a zero carbon city by 2050. The paper explores the realism of this - will the prescriptions of the plan and the likely results on the ground suffice to meet that target?

Mooza Al-kuwari; Khonokze Rahaman, Doha, Qatar
Climate change strategy for the urban planning and development sector in Qatar
The Ministry of Municipality and Environment has developed a Climate Change Strategy for the Urban Planning Sector for the State of Qatar that will regulate developments in the country.

Serena E. Alexander, San Jose State University, San Jose, USA
Harnessing the opportunities and understanding the limits of America's state-level climate action plans
This research is an evaluation of America's current state-level climate action plans focusing on their emissions reduction outcomes as well as their development procedure and foundations; goal setting, policy coverage and regional coordination; implementation provisions and conditions; and implementation mechanisms and monitoring results.

Sisi Liang, Tsinghua University, Beijing, China
From green to resiliency: A review of evolution, experiences and implementations of American Climate Change Action Plan
Through a deep review of city-level climate action plans in the United States, this paper discusses the evolution, implementation, and performance of green efforts cities made during the past decade. It calls for a transformation of policy from green development toward improvement on resiliency.

Olga Chepelianskaia, Uniciti, Toulouse, France
Climate resilience through land use regulations in Asian CIties
Climate resilience is a critical imperative for Asian cities and it needs to be mainstreamed into land use regulations to achieve a durable and cost-effective result. The presentation outlines how to put this approach in place in a context of developing Asian cities' political, institutional, economic and societal challenges.

Session 2: Cultural impact of climate change: Norway multi-dwelling life-style

2 October (Tuesday), 13:00 - 15:00

TK *Jin Xue; Petter Næss; Rasmus Steffansen; Harpa Stefansdottir; Tim Richardson, Norwegian University of Life Sciences, ÅS, Norway*
Multi-dwelling home lifestyle and climate change
Drawing on the concept of multi-dwelling home lifestyle, the paper aims to analyze the associated mobility pattern, housing consumption pattern and the impacts on climate change.

Rasmus Steffansen; Jing Xue; Harpa Stefansdottir; Petter Næss; Tim Richardson, Ås, Norway
Vacation home planning, perceptions of nature and climate change
This study focuses on perceptions of nature and climate change in relation to Norwegian vacation home planning, ownership and use. The data (qualitative/quantitative) largely reveals an anthropocentric outlook from both the planning side and the user side, resulting in a neglecting of nature and climate changes related impacts and effects.

Petter Næss; Jin Xue; Rasmus Steffansen; Harpa Stefansdfottir; Tim Richardson, Norwegian University of Life Sciences, Ås, Norway
Travel modes for visits to non-primary dwellings: considerations and justifications
Based on qualitative interviews of Norwegian users of non-primary dwellings, supported by a questionnaire survey among a larger sample, this paper addresses travel modes when visiting non-primary dwellings and the reasons stated for choosing the relevant modes of transportation.

Harpa Stefansdottir; Jin Xue; Petter Næss; Rasmus Steffansen; Tim Richardson, Norwegian University of Life Sciences, Ås, Norway
The impact of climate change on potential use of vacation homes
The aim of the study is to lay out how changing climate may affect the future use pattern of three selected vacation home areas in Norway. This study is mainly based on eleven qualitative in depth interviews with vacation home owners in Trysil, Oppdal and Kragerø.

Session 3: Global idea sharing - Case studies in sustainability and resilence

2 October (Tuesday), 15:30 - 17:00

TK *Deborah Heinen, Hafencity University, Hamburg, Germany*
The role of regional planning in the US, Canada and Germany in spatial climate mitigation actions
Land use and transportation patterns are significant factors impacting greenhouse gas emissions. They are also factors that are governed differently in nations across the globe. Therefore this paper seeks to compare the regional capacities to govern land use and transportation in Hamburg (Germany), Seattle (USA) and Vancouver (Canada).

Rolf Schuett, Systemarchi, Nochowo, Poland
Climate change impact in Andean cities in Bolivia: the Tiquipaya case and a community led New Urban Agenda for resilient planning
This paper discusses how it may be possible to implement important impulses of the New Urban Agenda in communal collaboration strategies. It suggests as well how low tech landscape and urban design can improve resilience and community involvement.

K. Emmanuel Letebele, EThekwini Municipality, Durban, South Africa
The impact of climate change on spatial planning, the case of Durban, eThekwini Municipality
The Municipality developed the Spatial Development Framework underpinned by New Urban Agenda, Sustainable Development Goals, and the Paris Agreement. It also has climate change responses such as the Durban Climate Change Strategy and Climate Resilience Implementation Plan. The paper will explore coordination, main streaming and implementation of climate change.

Sagwata Manyike, South African National Biodiversity Institute, Pretoria, South Africa
Incorporating climate change resilience into spatial development tools in South Africa
The Biodiversity and Land Use Project, which is funded by the Global Environmental Facility through the United Nations Development Programme is piloting various ways in which South African Cities can become more resilient towards climate change through interventions in their spatial planning and land use management systems.

Track 1

Tjark Gall, Urban Framework, Germany

A methodological approach to measure interrelations between urban form and flood-related risks in Kampala, Uganda

This paper aims to develop a method to examine the relationship of spatial characteristics to the often-unjust distribution of climate change risk exposure and test it in the case of Kampala, Uganda. The research intends to increase the understanding of spatial injustice to support better-informed policy and spatial intervention strategies.

Ali A. Alraouf; Jomaa A. Marzouq, Urban Planning Doha, Doha, Qatar

Revisiting the concept of resilient cities: the case of Doha, Qatar

Using the case of Doha, the paper illustrates a new conceptual understanding of cities' resilience. The paper analyses the contemporary evolution in Doha and highlights the milestones in structuring the new vison for Doha's development as a resilient city holistically.

Ingrid Young, New York City Mayor's Office, New York, United States of America

New York City- environmental review and planning for a sustainable future

NYC Planning and Environmental Review- Creating a more Sustainable and Resilient City. How rethinking one major city's regulatory framework can better shape sustainable growth over the next century.

Session 4: Planning methodologies for climate adaption and resilience

3 October (Wednesday), 13:30 - 15:00

TK *Alexei Trundle, The University of Melbourne, Parkville, Australia*

Endogenous resilience: integrating urban informality with climate change planning in Pacific Small Island Developing States

This paper demonstrates pathways for building on the resources, networks, and latent capacities of urban informality to enhance the climate resilience of urban systems. Post-disaster case study research from two Pacific Small Island Developing States is used to illustrate conceptual and practical opportunities for urban planning to complement endogenous resilience.

Vicky Ariyanti; Jurian Edelenbos; Peter Scholten, Erasmus University Rotterdam/ IHS, Rotterdam, Netherlands

Future direction for a volcanic basin planning

Governing water in an active volcanic basin requires inter-faceted views and integration of water, lahar (volcanic debris flow) and volcano management. This paper addresses these issues simultaneously using a case of Opak Sub-Basin in Mt. Merapi region, Indonesia.

Guri Venvik, Geological Survey of Norway, Trondheim, Norway

The ground beneath our cities

The subsurface is important for cities. Cities not only expand outward and upward, but also downward. The more use we make of subsurface space, the more surface space we free for the one function that cannot do without daylight and fresh air: living

Willemien Van Niekerk; Amy Pieterse; CSIR, Pretoria, South Africa; Jacques Du Toit, University of Pretoria, Pretoria, South Africa

Place-based adaptation solutions for South African settlements

This paper explores how climate change adaptation was mainstreamed into South African local government planning instruments by comparing two case studies. One drove integration internally while the other received support from national government to enable and drive integration. The challenges and opportunities for mainstreaming are discussed.

Ehsan Ranjbar, Tarbiat Modares University, Tehran, Iran; Najmeh Motalaei, Iran

Climate change and the effects on urban planning and design in Iranian cities

Iran is one of the countries that touch the effects of climate change. This article is trying to elaborate the challenges resulting from climate change in Iranian cities, assess the consequences and effects on everyday life of cities and introduce new policies in urban planning and design.

Nasim Iranmanesh, Islamic Azad University East Tehran branch; Kouros Etaati, Jarf Sanat, Tehran, Iran

Indigenous knowledge as solution against drought in cities of Iran (case study: Qazvin city)

This paper will review the indigenous knowledge in harvesting and supplement water in historical cities of Iran to get to know some sustainable solutions to challenge the drought which is the result of global warming of the earth.

Session 5: Global goals & national planning policy - *Part II*

3 October (Wednesday), 15:30 - 17:00

TK *Anneloes van Noordt, Environment Department Flanders, Brussels, Belgium*

The role of spatial development in the energy and climate transition

This paper is centered on how spatial development can contribute to the energy and climate targets. Focus points will be defined to indicate the role spatial development can play and a research by design exercise will be discussed. To conclude, policy recommendations in general and specifically for Flanders are formulated.

Bilge Aydin; Azime Tezer, Istanbul Technical University, Istanbul, Turkey; J. Joerg Knieling, HafenCity University, Hamburg, Germany

How to combine resilience theory with regional policies? A network based methodology

The aim of this study is to develop a new, network-based methodology for regional resilience analysis in order to analyze interconnected risk factors in a complex world. There has been explained, how system approaches can be combined with network theory to evaluate regional resilience with a multi-dimensional, multi-scale and multi-temporal perspective.

Nada Tandoh, Land Use and Spatial Planning Authority, Accra, Ghana

The effect of climate change in Ghana's cities

Ghana is not isolated from the changes in climate the world over. Impacts of climate changes include floods, drought, heat waves etc. Policies and strategies have been developed, and also mainstreamed into governance to ensure implementation. This paper reviews Ghana's perspective of climate change impacts, sustainability and resilience.

Patrick Apraku, Land Use and Spatial Planning Authority, Accra, Ghana

Governance, management, administration and planning systems in Ghana

The Government of Ghana has demonstrated commitment to mainstreaming climate change into key planning processes at the national, regional and local level. Ghana's resolve to mainstream climate change into the development agenda is through the Ghana Shared Growth Development Agenda I&II (2010-2017) attest to this commitment.

Ana Maria Fernandez Maldonado, Delft University of Technology, Delft, Netherlands

Addressing climate change in European spatial planning

The study investigates how climate change related issues have modified European spatial planning in two ways: how spatial planning systems have included climate change-related issues; and which main planning instruments are being used to achieve to tackle the risks associated with climate change. It uses data from the ESPON-COMPASS project.

Session 6: Assessment & understanding the impacts of climate change

4 October (Thursday), 11:00 - 12:30

TK *Shahadat Hossain Shakil, USAID, Dhaka, Bangladesh; Mohammed Hamidul Hasan, Bangladesh Institute of Planners, Dhaka, Bangladesh*

An assessment of effective approaches for adapting to the impacts of climate change on urban poor communities to make the urban area more resilient. - Perspective from Bangladesh

Is a bottom-up or top-down approach more effective for adaptingto the impacts of climate change on urban poor communities in the cities of global south?

Saikat Paul; Raj K., B. Bhaskar Rao; Ritu Roy, Indian Institute of Technology Kharagpur, Kharagpur, India

Application of low-rank sparse decomposition method to study urban heat island

This study establishes use of Low-Rank Sparse Decomposition Method to assess trends or patterns in Urban Heat Island (UHI) phenomenon in the metropolitan city of Kolkata. This would help in UHI mitigation and adaptation planning strategies in tropical regions.

Irina Shmeleva, Institute of Design and Urban Studies, Saint-Petersburg, Russian Federation; Stanislav Shmelev, Environment Europe, Oxford, United Kingdom

Global urban sustainability assessment: a multidimensional approach

Environment Europe database includes 90 global cities and allows to benchmark sustainability performance on 20+ social, economic, environmental and smart indicators.

Luisa Batista; Miguel Lopes; Paulo Pinho, University of Porto, Faculty of Engineering, Porto, Portugal

Metabolic Impact Assessment for strategic urban planning

This presentation intends to show the potentials of Metabolic Impact Assessment (MIA) of urban development proposals to strategic urban planning. The introduction of MIA into SEA fosters the implementation of climate change mitigation strategies.

Robert Cichowicz; Malgorzata Hanzl, Technical University of Lodz, Lodz, Poland

Measuring CO2 emissions - implications for spatial development

Air pollution measurements and analyses indicate the relationship between built form and urban development and the presence of concentrations of CO2 and other pollutants. The current study examines these relationships in quest of the recommendations how to transform urban development and users behaviour to decrease CO2 emissions.

Track 2: Spotlight Cities: Planning for Coastal Cities, Remote Towns, and High North Cities

Mumbai, India
Photo by Marjam Ahmadi

Location: Scandic Havet – Storhavet 2

by Kevin King and Sofia Morgado

What is the track about?
The Spotlight Cities track takes a careful look at some of the most vulnerable cities in the world. The track examines the main risks and the associated adaptive strategies for coastal, remote, and Arctic cities.

The authors have collectively assembled insights, analysis, and techniques for responding to climatic events and mitigating against future risks.

What has been the response?
Adaptive strategies for vulnerable waterfronts are described through the lens of both policy and design. Spatial strategies that take into account the complexity of the city are evaluated with consideration for both urban and natural systems.

Papers and workshops in this track address a diversity of geographic locations and city scales. New York City, the Gold Coast of Australia, the severe cold regions of China, Buenos Aires, Delhi select European cities, Doha, Jakarta, Lagos, Sjøgata, and others all provide examples that will shape our understanding of resiliency.

Through the papers in this track, we consider strategies for urban infrastructure that will mitigate against risk associated with climate change. These strategies may address street design, drainage systems, regional greenway networks, or flood protection. Alternatively, these strategies may be driven more by land-use strategies or policy approaches and discuss the city from macro-level development patterns.

The track also presents an emerging palette of methodologies – sometimes driven by technological innovations – that better enable practitioners to understand current conditions and advocate for effective change. Papers include information on computer simulated models that aid in the site selection process. Other topics include a description of how public spaces or social solutions play a role in effective strategies for adaptation.

How do you deem / assess the response?

A diversified set of perspectives, methodologies, geographical conditions, and case studies indicate a very positive reaction to the challenge casted by the Congress call. The breadth of the contributions resulted in a rich array of possible Session formats – a remarkable outcome indeed.

With the Sessions finally outlined, lively debates are expected to develop between presentations. Questions, related to either research or practice, may give rise to future collaborations and partnerships. Content drawn by presenters and contributions from the audience will be pivotal to creating a shared set of conclusions at the closing of the Congress.

What can we expect at the congress?
The congress will engage participants through workshops, presentations, debates, and discussion. In particular, the Spotlight Cities Track will contribute to the lively interaction between delegates with different backgrounds and cross-cutting topics within each of the 5 different Sessions.

Session 1 will provide an opportunity for up to 30 participants to meet 'underground' for an exploratory workshop for potential underground uses in Bodø. This workshop will be preceded by knowledge sharing on popular uses and possibilities to repurpose underground spaces.

Session 2 dives into matters related to resiliency along vulnerable waterfronts. Recent and significant weather events have highlighted the inherent challenges and risks associated with urban development along the waterfront. Residents' vulnerability and resilience to flooding in Lagos, Nigeria is examined through a lens of adaptive governance. A Recovery and Rehabilitation Plan for Tacloban City in the Philippines following the destruction of the world's strongest typhoon to make landfall is evaluated. Storm impacts and flooding controls in Hong Kong and NYC are analysed.

Session 3 focuses on urban infrastructure, the built environment, and landscape in the face of climate change. Street design in the Gold Coast of Australia, drainage systems in Delhi, and the effectives of urban expansion on utility services in Akure, Nigeria are included papers. An evaluation of a demonstration city – Qi'an in China – that uses a 'sponge' greenway as an ecological buffer is provided. Lastly, climate readiness strategies from New York City and Boston are discussed.

Session 4 will discuss broad techniques and macro-scale analysis of the City. Urban form and development strategies – including ecological buffering - will shape the discussion. Emerging research, knowledge networks, and calls for citizen engagement are shaping our cities. This session will highlight potential solutions to working within the rapidly changing contexts of our urban environments.

Lastly, **Session 5** is directly related to cold cities and cities of the north. The series of papers in this session explore unique aspects associated with designing for climate change that these cities, towns, and villages face.

Session Proposal
Making the most of underground spaces

2 October (Tuesday), 11:00 - 12:30

This event will take place at a short walking distance from the congress venues in a former underground shelter, last used as the 'G Nattklubb'. The address is 'Sjøgata 16B'. Please allow yourself some time to walk over to this location.

Moderators: Han Admiraal (ITACUS/Enprodes), Netherlands; Antonia Cornaro (ITACUS/ISOCARP Swiss ND/Amberg); Elizabeth Reynolds (URBEN/Think Deep UK)

Cities are more and more being challenged by lack of space whilst at the same time having to cope with the reality of climate change. In this session we will ask ourselves how to make the most of underground spaces through repurposing.

How can we repurpose existing underground spaces in such a way that they regain a new life and become beneficial again for a city? In this session, we will look for inspiration at the many bunkers that Bodø has and analyse and discuss what new uses they could serve.

After introductions/input statements by the moderators we will hold an interactive workshop with the audience as well as with local representatives. These will be from the local municipality, the real estate department of the Ministry of Defence, the local aviation museum; and the airport authority. Together, we will look at possibilities to repurpose these underground spaces. The outcome will be a report to be presented to the local representatives at a later date. Also, the event will be the kick-off of a new ISOCARP group on underground urbanism.

Session 2: Rising tides: resiliency and the waterfront in the face of extreme climatic conditions

2 October (Tuesday), 13:30 - 15:00

TK *Gitte Schreurs; Kris Scheerlinck; Erik Van Daele; David Burney, KU Leuven, Ghent, Belgium*

Countering the current paradoxical redevelopment of New York City's vulnerable waterfronts

The research aims to develop novel spatial strategies for the reconfiguration of vulnerable industrial waterfronts, defined by climate change and economic decline. The paper aims to counter the current 'tabula rasa' developments in New York City, by taking into account climate change and the waterfront's existing spatial qualities and fragilities.

Olusola Olufemi; Olufisayo Ogunmodede; Pinremola Olufemi; Oluwabukola Somoye, Independent, Oakville, Canada

A resilient coastal mega city, a resilient people: Flooding as a climate change threat in Lagos, Nigeria

From affluent neighbourhoods to impoverished communities, flooding resulting from climate change remains an existential threat in Lagos. Planners have a major role in facilitating resilience thinking and collaborating with various stakeholders to build resilience against flooding and other environmental disasters by developing capacity to learn, adapt, self-organize, and transform.

Gerald Paragas, Municipal Government of Sta. Barbara, Pangasinan, Philippines

Challenges and lessons learned after Supertyphoon Haiyan in Tacloban City, Philippines

The report follows the experiences, challenges, successes and lessons of Tacloban City in the Philippines as the coastal city moved from humanitarian response to the recovery and development phases after the Supertyphoon Haiyan.

Chui Ying Tracy Wong, University of Cambridge, Cmbridge, United Kingdom

Climate change adaptation in Hong Kong from urban planning perspective: flood zoning as control mechanism

Flood zoning is suggested to be a better solution than engineering-led measures to cope with risks of sea level rise and storm surge under climate change for the planning of coastal communities in Hong Kong.

Naniek Widayati Priyomarsono; Rudy Surya; Ninawati Ninawati; Theresia Budi Jayanti, Universitas Tarumanagara , Jakarta, Indonesia

The development of Juwana Settlement as a Northern Java coastal city in Indonesia has the potential to support global maritime axis

Juwana is strategic city in the northern Java coastal area. It has many resources, linier settlement alongside Gonggo river, and radial settlement in the outback. This city can be a prototype of a coastal city to create an economy networking. It has the potential to support Indonesia to be the global maritime axis.

Ali Alraouf; Mubarak AL Nuaimi, Urban Planning, Doha, Qatar

Cool waterfronts and coastal cities: how Qatar's peninsula develops a resilient future?

This paper illustrates a shift in contemporary urban development in Qatar. The shift stems from a deeper understanding of the vulnerability of Qatar as a peninsula facing the consequences of climate change in an inevitable manner. It sheds light on planning approaches which characterize the new waterfronts development paradigm.

Session 3: Cold Cities: Challenges and strategies for cities of the North

2 October (Tuesday), 15:30 - 17:00

TK *Han Li; Benchen Fu, Harbin Institute of Technology, Harbin, China*

Study on renovation planning and residential design of the resilient village in forest areas of severe cold region in China

Based on resilience concepts, this paper carries out an in-depth study and demonstration on resilient renovation strategies of village planning and residence design in forest areas of severe cold regions of China, from theoretical and practical perspectives, in order to deal with climate change and reduce regional energy consumption.the future challenges.

Hong Leng; Cunyan Jiang, Harbin, China

Study on the relationship between urban climate change and urban development construction in severe cold areas

Based on the particularity of climate environment in severe cold areas, the paper discusses the relationship between urban climate change and urban development construction, advancing some urban planning strategies and suggestions.

Artem Nikolaev; Sergei Kudinov, ITMO, Saint-Petersburg, Russian Federation

Development of recommendations on the planning structure and street design in the cities with cold climate

This paper is aimed to make an analysis of Russian regulatory documents for city planning and to find ways how to improve them from the aspect of planning in a cold climate.

Ida Marie Granmo, Vefsn Municipality, Mosjøen, Norway

Between fjords and mountains: Climate changes vs. cultural heritage sites in northern Norway – an example from Mosjøen in Nordland county

The new weather conditions in northern Norway are threatening local cultural heritage sites. Urban planners in Mosjøen are now trying to develop a zoning plan for the cultural heritage site Sjøgata, that both functions as a protection plan and as an adaptive strategy to climate change.

Track 2

Piotr Lorens, Gdansk University of Technology, Gdansk, Poland
Planning for the north-European waterfront cities – issues and strategies
Redeveloping urban waterfronts is subject of common practice globally. Although, as one of the major driving forces in this process is tourism development, climate issues play an important role in design and functioning of these structures. Therefore, waterfront cities located in less climate-privileged parts of the world, require alternative design strategies.

Viktoria Khokhlova
The case of Teriberka. Arctic present
Once experienced the thinning of the overbuilt physical structure, Teriberka shall turn back to the dynamic lifestyle. Unlike the settle towns with constantly increasing demands, Teriberka is in need of the principles and structures capable to vary in scale or to be moved whenever needed - intellectually and physically.

Session 4: Form and technique: City and region shaping through analysis and technology

3 October (Wednesday), 13:30 - 15:00

TK *Pedro Ressano Garcia; Ana Claudia Oliveira, LEAU Lisbon, Portugal*
S.O.S. - sustainable open solutions to climate waterfront
S.O.S. Sustainable Open Solutions to climate waterfront mission is to develop affordable research environment and efficient operational tools to schools of Architecture, Entities to interact directly with the market. The aim is to make use of the existing strategic network to face the future challenges.

Xin Li, Tianjin University, Beijing, China
Using Computer Simulation to Plan and Design Traditional Dong Towns & Villages in Mountainous Areas of Tongdao, Hunan, China
We will present an automated computer planning and design simulation of Dong nationality's towns & villages. Our bottom-up planning and design simulation program can characterize cultural customs, community structures, and spatial features of traditional Dong towns & villages. It is significant for protecting traditions and landscapes in rural-urbanization.

Chengcheng Liu, Tianjin Urban Planning & Design Institute, Tianjin, China
Research on potential disaster risk & countermeasures in China's coastal rapid urbanization area
The urban planning strategy of China's action plan for urban adaptation to climate change has been actively practiced in the China's coastal rapid urbanization area. This paper analyzes the potential disaster risk in these areas and the specific measures in three aspects of urban planning.

Simbarashe Chitapi, Aurecon, Tshwane, South Africa
A comparison of the utility of urban strategies for small towns: The Cases of Lobatse and Arandis
This paper compares the regeneration strategies put forward by two small towns in decline. Each town, although somewhat remote is within 100km of a significantly larger town. The paper assesses and scores the plans' resilience and sustainability response, its utility and implementatibility and proposes improvements for future plans.

Mirela Thaise Malta Purim; Fernando Domingues Caetano; Jeronimo Paulo Cunha Pimentel de Meira, Paranacidade, Curitiba, Brazil
The annulment of urban perimeter as a technical tool for urban planning: the unsustainability of the cities in the Brazilian state of Paraná
This paper analyses the urban perimeter legislation annulment as a planning instrument in the cities of the State of Parana – Brazil. This annulment results in urban perimeter oversizing, reinforcing widespread occupation and the conversion of rural land into urban land, leading to unsustainable settlements.

Jennifer Ailen Choi; Laura Corbalan Viero; Mitchell de Sousa; Rocio Di Corrado Analia Fernandez, University of Buenos Aires, Ciudad Autónoma de Buenos Aires, Argentina
Perception, territory and urban planning: perceptive studies over the south border of the city of Buenos Aires, Argentina
The development of the city throughout Riachuelo left traces on the territory that cannot be read by traditional cartography, there is a halo in the collective memory reflected by different perceptions through time that cannot be mapped traditionally. New representation methods are required for these dynamic, complex and fragmented borders.

Session 5: Urban works: Infrastructure, the built environment, and landscape in the face of climate change

3 October (Wednesday), 15:30 - 17:00

TK *Mario Shllaku, Hassell, Brisbane, Australia*
Planning for cooler streets; functions and elements for cooler coastal cities, the case of gold coast, Australia
The paper presents the case of Nerang Street in Gold Coast, Australia, as an example where the application of urban canopy and urban biome concepts along with the adequate urban planning and design strategies aims at dropping the temperatures by 5 degree Celsius.

Lucia Ilieva, CSDCS, Sofia, Bulgaria
Adaptive strategies for mobility planning in remote and coastal cities and towns - "LAST MILE" project case
Mobility and Accessibility are vital elements for sustainable urbanisation with a direct impact on climate change. The INTERREG Europe Project "LAST MILE" is presented with its focus on developing adaptive strategies providing user oriented services for the travel chain's last segment in remote tourism destinations and coastal cities and towns.

Mahak Agrawal, New Delhi, India
Climate risks and urban drainage: a case of National Capital Territory of Delhi
Urban Development blind to natural drainage for decades, aggravates natural climate variability of Delhi. Multiplier effect is profound on vulnerable population with least adaptive capacity-villages located within the flood plains. Need for adaptive strategies is realized to make the city and its population resilient to climate risks of floods.

Opeyemi Aladekoyi, University of Medical Sciences Ondo, Ondo, Nigeria; Micheal Oyinloye, Federal University of Technology, Akure, Nigeria
Effects of urban land use change on selected public utilities for sustainable development in Akure, Nigeria
One of main driving forces of global environmental change is urban expansion, which is central to the sustainable development debate. This research aims at examining the impact of urban expansion on utility services in Akure Nigeria, with a view to improve strategies to protect these utilities for sustainable development.

Track 3: Climate-Proof Cities: Planning for Weather, Water, Food and Energy

Photo by iau-idf

Location: Radisson Blu, Room 1
by Eric Huybrechts and Lena Niel

Cities are facing new challenges, related to social and demographic changes, innovations, the effect of finance on the economy and - climate changes. Seventy percent of the world population will live in cities by 2050, mostly in large metropolises. The urban population will double, of which 50% will be living in unplanned areas. Financialisation of the economy will produce more empty cities for speculation purpose and increase social and spatial exclusion. Smart cities and artificial intelligence will change the job distribution with the emergence of new skills and new ways to manage cities. But climate change – or climate 'shift', as some scientists now warn about due to acceleration of dangerous trends – appears to be the biggest threat. It will increase natural hazards, making large populated coastal areas and cities particularly vulnerable. The effects will be extreme in sensitive areas due to heavy rains, storms, water shortage, landslides, drought, heat waves, and sea level rise - as already observed in New York, Paris, Dacca, Cairo, Shanghai, Cape Town or Chennai.

How can urban planning propose new management models for the cities facing these challenges? How should planners change their practice in order to reduce vulnerability of human settlements, better manage crisis periods and mitigate cities' natural resource over-consumption and GHS emissions? What is a 'climate-proof' city and how do we plan for it?

We believe that we, as urban planners and designers of future cities, have to change our way of looking at the city. The city is not a collection of buildings, open spaces, technical networks and people anymore. We must adopt the perspective of a 'living urbanism': the city is an ecosystem. As derived from biological ideas, an ecosystem exists of many dynamic and static flows. All of them count. The city should be analysed from different perspectives, before one can make truly resilient cities. People, biota, water, food, energy, information - should all be understood before making an urban plan. But also transportation infrastructure, waste and material resources like sand, gravel and other building material – they are all part of our profession. By analysing the entire system, one can understand how flows run through a city or a territory and where, and in what way, they should be altered in order to achieve a resilient urban ecosystem. Only by following this approach we can create cities that will remain liveable when climate change becomes worse.

The idea of the city as an urban ecosystem and its urban metabolism is not new. It originated in the Chicago School of urban sociology (E.W. Burgess) in the early 20th century, was further developed in the 1960s (A. Wolman), and then, in practice, got applied by Richard Forman, Ian Mc Harg and other practitioners and academics in landscape and urban planning. But the idea didn't survive the era of economic changes (liberalisation, financialisation) and comprehensive or strategic planning. Now is the time to shed a new light on this philosophy. Not only because we can give a new, deeper, layer to our profession as urban planners, but because we have to change our view on city and regional planning in the face of climate challenge, new economy and socio-demographic changes. We have to make our cities climate-proof. We should even strive to enable our cities to restore the climate!

Overview of the abstracts

We have received a large amount of abstracts on climate-proofing cities. This demonstrates how many urban planners and designers realise that we have to change our current way of approaching the city. The main themes that have been addressed are the flows of energy and biota. Regarding energy, the main questions are: how are we going to provide sufficient sustainable energy to our growing cities? What will be the impact of this energy production and consumption on the carrying capacity of our planet? With regards to biota, the topic of Urban Nature-based solutions is the main theme. Since this topic is becoming very popular amongst landscape architects, urban planners and designers, but also policy makers and governments, most abstracts are giving a literature overview of the definitions that are being used. Also, questions regarding the application of Urban Nature-based solutions in cities seem relevant amongst our profession from a global perspective.

With regards to representation, it seems that the topic of climate-proofing cities is a relevant topic world-wide. We have received a lot of submissions from China, Europe, South America and North America, but also from India (where the bigger cities are very much involved in Urban Nature-based solutions and sustainable energy production). Only a few submissions came from the African continent and Australia.

Our view on the accepted abstracts and our ideas

This track is looking at how to make cities climate-proof. The abstracts that have been submitted are very good examples of cities that are busy implementing the themes of energy production/consumption and greening the cities. As stated as a problem in our introduction, we note that most abstracts are only stressing one specific flow of the urban ecosystem. To make a truly resilient city, it is important to link the specific flow of energy and biota towards other flows and generally pursue a holistic view of the city. How are people going to live in the city? E.g. how will Urban Nature-based solutions make a better living space for people? How will it affect the urban heat island is a positive manner? It might be that we do not have enough qualitative information on the effects of the flows on our cities. It is necessary to develop these as soon as possible, to enable urban planners to make cities climate-proof in the future.

Few contributions are dealing with the management of crises: how to secure human settlements during natural events. There are questions to be discussed on the capacities of cities and region to implement institutional coordination, the efficiency of this coordination between administrations (civil security, telecommunication, health…), the effectiveness of the alert systems, the robustness of the strategic infrastructures are crucial to save life and reduce vulnerability of human settlements during natural events. The increase size of city-regions due to demographic changes (metropolization + population growth) makes the coordination more complex and less efficient, and increases the vulnerability.

Expectation for the Congress

With about 40 contributions and a large diversity of subjects and approaches, Track 3 will be very rich for debates, analysis and solutions for climate-proofing cities. More than just a platform for presenting case studies, Track 3 will enable important discussions. Delegates will be encouraged to go further, to stress common points on the diagnosis and solutions and to create a dynamic discourse between planners. However, while these debates will be interesting, they will have a limited positive impact if there is no follow up. The Congress is a key moment to mobilize collective intelligence to launch initiatives, to forge networks around a question and to empower urban professionals with key messages to deliver to UN-Habitat, UNEP, OECD, Habitat Professional Forum, ICLEI and other multilateral organizations. Many international initiatives and programmes already exist - such as Resilient Cities, Climate Action… - but this ISOCARP Congress should open the opportunity to give direct access to our planners to the entire international debate on proofing cities facing climate change.

The cities that are expected to grow the most are located in Africa and South Asia. As International Planning Society, we must strive to collaborate with these continents and large regions as much as possible, to design climate-proof cities where the vulnerability is the highest.

Authors are responsible for
the content of their work

TK track keynotes

Session 1: Green infrastructure and urban design

2 October (Tuesday), 11:00 - 12:30

TK *Juan A. Demerutis-Arenas; Jesús A. Escobosa-Burgara, University of Guadalajara, Guadalajara, Mexico*

Green infrastructure for metropolitan areas in Mexico

The paper defines main features of green infrastructure for metropolitan cities.

Xin Feng; Jin Yunfeng, Tongji University, Shanghai, China

Case Study: urban green belt planning in Foshan City, China

How do Chinese planners plan green belt in order to make cities resilient to adapt to climate change? - especially in the Chinese context, where accelerated urbanization has generated continuous rapid growth creating a series of environmental problems.

Rune Skeie, Asplan Viak AS, Oslo, Norway

Urban Ecology – Achieving sustainable urban development through multifunctional blue and green infrastructure

Through urban projects on different scales, from development of districts (XXL) to blue and green roofs (S) Skeie shows that a key to achieve sustainable urban development may be to consider the city as an ecosystem.

Karolina Czyzewska, Zabrze, Poland

Green Warsaw - the future of green vegetation

Green balconies, green roofs and green walls as a solution for: reducing stress of habitants; reducing air pollution in the city; solving the problem of urban heat islands.

Abdelwehab Alwehab; Firas Alrawi; Falah Almosawi, University of Baghdad, Baghdad, Iraq

Localizing Imperatives of Sustainable Neighborhood Models: Iraqi Cities as a Case Study

Green buildings design models offered new opportunities to augment the paradigm of sustainable urbanism. The research incorporates local physical and environmental elements and attempts to extract significant indicators within models intended to improve urban environmental quality at the microscale and identify confluence areas to advance sustainable urbanism objectives.

Session 2: Green infrastructure and habitats

2 October (Tuesday), 13:30 - 15:00

TK *Claudia De Luca; Elisa Conticelli; Simona Tondelli, University of Bologna, Bologna, Italy*

Nature-based solution, green infrastructure and ecosystem services: a framework for understanding and creating resilient urban ecosystems

Climate-proof cities rely on nature-based solutions, green infrastructures, ecosystem-based adaptation and ecosystem services to create resilient urban ecosystems. Nevertheless, the relation among these concepts is still fuzzy. This paper provides a better understanding of these concepts and their integration into planning instruments to support cities embedding those within their plans

Han Admiraal; Antonia Cornaro, ITACUS & Enprodes Management Consultancy, Delft, Netherlands

The contribution of urban underground space to climate-proof and resilient cities

Integrating underground space into the urban fabric is a necessity as part of climate proofing our cities. We need to develop an underground urbanism to ensure the peculiarities and advantages of underground space are appreciated. In that way, cities can become resilient and climate-proof within their area constraints.

Song Liu; Song Yao Huai; Hongting Pan, Tongji University, Landscape Architecture Department, Shanghai, China

Construction of Green Infrastructure Based on Water Ecological Security Pattern, A case study of Songtao River Catchment in Guizhou Province, China

Based on an evaluation of the regional water ecological security pattern, green infrastructure is constructed to achieve Songtao river catchment ecological security.

Xin Lian; Jun Zhou, Planning Institute of China Center for Urban Development, Beijing, China

Towards a sustainable and eco-civilized era: a national-wide project of pairing Ecological Restoration with Urban Repair (ERUR) in China

A Chinese national-wide project called "Ecological Restoration and Urban Repair (ERUR)" creatively pairs the traditional ecological restoration with efforts to tackle with urban habitats issues, which is a pilot step for Chinese cities to restore urban ecological system challenged by both the massive urbanization as well as global climate change.

Meltem Delibas, Delft University of Technology/ Istanbul Technical University, DELFT, Netherlands; Azime Tezer, Istanbul Technical University, Istanbul, Turkey; Taneha Kuzniecow Bacchin, Delft, Netherlands

Soil Ecosystem Services (SoES) in urban planning

Soil as the foundation of all terrestrial ecosystems on Earth gives urban planners wise advises for a sustainable future.

Anna Starzewska-Sikorska, Institute for Ecology of Industrial Areas, Katowice, Poland

LUMAT project – integrated environmental management of land resources as contribution to enhancement of urban areas resilience to climate change

Project LUMAT is concerning integrated environmental management of land resources in functional urban areas. Cases of the LUMAT project functional urban areas in 7 countries present solutions of integrated environmental management which can be considered as activities contributing to the enhancement of urban resilience to climate change.

Session 3: Food & Heat

2 October (Tuesday), 15:30 - 17:00

TK *Olusola Olufemi, Independent, Oakville, Canada*

Cascading threats of climate change on the food system in Nigeria: an overview

Integration of the food system and food planning within the Green and Brown agenda through participatory governance, collaboration and authentic dialogue provides an eco-efficient approach to minimising the ecological footprint and foodprint. A secure ecological foundation guarantees food planning within a complex, cascading and interconnected threats of climate change.

George Thomas Kapelos, Ryerson University, Toronto, Canada

"Heat!" – testing design approaches to mitigate excessive heat exposure for vulnerable populations in Toronto apartment buildings

With climate change, excessive summer heat will impact Torontonians, especially residents in older, high-rise buildings, not designed to anticipate extreme heat. Researchers documented the issues on film. They presented data to students who designed prototypes for outdoor cooling centres. Community members provided feedback on proposed designs.

Teresa Marat-Mendes, Lisbon University Institute ISCTE-IUL, Lisboa, Portugal

Planning for Change: The Forms and Flows of Lisbon Metropolitan Area Food System

Integrating food within urban planning, from a metabolic perspective, is critical to catalyze an urban sustainability transition. This presentation discusses the theoretical and methodological framework of SPLACH Project to approach the food system, while dissecting the urban forms and social-economic flows that affect the metabolic function of the urban realm.

Jakob Schackmar, University of Kaiserslautern, Kaiserslautern, Germany

Substitute industries and economic change as a chance for cities to become more sustainable

Urban farming, as bio-economy, can be a sustainable approach to revitalize cities effected by structural economic changes and transform them into future oriented and livable places.

Pierre Renault, Independant consultant, Paris, France

Past knowledge and new strategies: Are Iranian cities ready for climate change?

Iran cities used to adapt to arid climate with old technical knowledge as Qanats or Badgir. The river restoration program could be an opportunity to solve urban heat island issues in Tehran.

Xin Li, Beijing Forestry University, Beijing, China

Construction of resilience in urban fringe based on sponge city: an example of green space planning of Shahe in Beijing, China

Based on the rainfall characteristics of northern China, the elastic design of water is used to give space for the river within the embankment, to provide site for the storm-water outside the embankment, and to create an elastic landscape in the urban periphery.

Session 4: Energy

3 October (Wednesday), 13:30 - 15:00

TK *Pengjun Zhao, Department of Urban and Regional Planning, Peking University, Beijing, China*

Reduce residents' transport energy use in China: Comparing the impacts of land use planning, public transit improvements, and low-carbon-city initiatives

The paper is about how to reduce residents' transport energy use in China.

Gema Hernández Moral; Victor Serna González; Giulia Massa; César Valdemaseda Tranque, Fundación CARTIF, Valladolid, Spain

ENERGIS: tool for demand characterisation in urban settings to support energy planning at different scales.

Only with adequate knowledge on the energy status in the city (in particular of the residential sector, main contributor to CO2 emissions in cities) it is possible to plan for a low carbon environment. The ENERGIS tool will support planners by mapping energy demand information of cities at different scales.

Hong Leng; Xi Chen; Zhe Diao, Harbin Institute of Technology, School of Architecture, Harbin, China

Evaluation of the impact of the urban morphology on building energy consumption in cold region cities - take the office building in Harbin, China as an example

The aim of this work is to quantitatively analyze the impact of urban morphology on building energy consumption in cold region cities. The results can provide a theoretical reference for the energy-saving oriented urban planning strategies in cold region cities, and are of significance for the mitigation of climate change.

Martin Tzou; François Courtot; Jingbo Guo; Sijie Liu; Yili Xiong; Jiashuo Xiu, EDF China, China; Shu Du, China Center for Urban Development, China

District cooling in Sanya Haitang Bay: energy integration in urban planning from theory to practice

Climate change initiatives undertaken in the city Sanya in China reveal the importance and the challenges of integrating energy issues at the urban planning stage, considering the significant contribution of district energy systems in reducing cooling demand and carbon emissions in hot and humid cities.

Adriano Bisello; Silvia Tomasi; Daniele Vettorato, EURAC research, Bolzano, Italy

Sustainable and smart energy transition in cross-border territories. Insights from the European Alpine macro-region

This paper discusses the results of an ongoing research on energy strategies in the European Alpine macro-region (EUSALP). It suggests the steps to set up an effective planning and monitoring system for the strategies implementation that is replicable in cross-border regions promoting a sustainable and smart energy transition

Session 5: Water

3 October (Wednesday), 15:30 - 17:00

TK *Yann Leclercq, MRTPI, London, United Kingdom*

Mitigating the effects of climate change in strategic development: The Ibadan City Masterplan

Nigeria's third largest city, Ibadan, is anticipated to grow from 6 to over 13 million by 2036. One of the impacts of the city's sprawling growth is increasing flooding. Upon the initiative of the Oyo State Government, Dar was commissioned in 2016 to the city's first masterplan.

Daniela Baer; Edvard Sivertsen; Nathalie Labonnote, Rebecka Snefuglli Sondell, Sintef; Terje Skjeggedal, NTNU; Trondheim, Norway

Planners' information need in adaptation to climate-induced floods

This study investigates urban planners' need for information to adapt to climate change. Interviews with planners in Trondheim and Stavanger disclose gaps in the provision of data and needed tools. A newly developed GIS-based tool for estimating flood damage costs as part of city planning is presented.

Lulu Chen; Su'ning Xu; Xiaohe Hou; Binxia Xue, Harbin Institute of Technology University, Harbin, China

Study on the framework of environment layers in the urban layer system

This paper proposes the concept of 'urban layer', and studies urban environment layers in the urban layer system and builds the structure of it. It applies the study on environment layers to the project of Comprehensive Urban Design of Waterfront Areas of Beijing, especially the water layer and climate layer.

Willemien Van Niekerk; Amy Pieterse, L. Louiza Duncker; Kea Maditse; CSIR, Pretoria; Claire Davis, Natural Resources and Environment, Pretoria, South Africa

Water sensitive urban design as adaptation strategy

Cities in areas getting hotter and drier have to find alternative approaches to manage the increased demand for water versus the shrinking supply, while also climate proofing their cities. Water sensitive urban design as an adaptation strategy integrates the management of urban water resources with urban planning.

Hong Geng; Yue Li, Wuhan, China

A climate-adaptation based study on the comprehensive planning strategy of urban water systems

When it comes to improving urban climate adaptability, it is of vital importance to conduct researches on both how to adapt to and how to mitigate the impacts of climate change upon urban water systems.

Peilun Li; Zhiqing Zhao; Lu Zhang, School of Architecture, Harbin Institute of Technology, Harbin, China

Urban new districts' toughness development under the sponge infrastructure project: The case of Jinan, China

As a response to urban rainwater disasters, the paper summarizes the three themes; urban flood control, drainaige pollution control and rain resources utilization touching upon technical, organizational, economic and societal challenges of the themes. New district of Jinan city project is discussed as the case study together with the challenges of the sponge infrastructure.

Session 6: Data and modelling

4 October (Wednesday), 11:00 - 12:30

TK *Geraud Bonhomme, Perspective.brussels - Brussels Planning Agency, Brussels, Belgium*

Usquare.brussels a resilient planning approach

Usquare.brussels is an innovative project to convert former urban barracks with a remarkable heritage into an international university resilient district. The site, property from the Brussels Region since 2018, will be a pilot operation linking a new spatial planning tool with the principles of the Regional Plan for Circular Economy.

Xiang Liu; Jian Zeng; Yanan Fang, Tianjin, China

Study on the microclimate of seaweed houses in Jiaodong - the case of Dongchudao Village

Seaweed house is a very ecological dwelling in Shandong peninsula, China. This paper uses data measurement, numerical simulation and other means to study the microclimate environment of seaweed house.

Ge Sun, Shanghai Tongji Urban Planning& Design Institute, Shanghai, China

A study of human ecology and resources network

The case will demonstrate a biological self-organize algorithm, which is based on the new human ecology, makes an effective contribution to help with the existing resource oriented network urban morphology. It gives design proposals of Liwa Oasis, UAE, which is a future optimized network plan of resource distribution.

Fujun Xia, Shanghai Tongji Urban Planning &Design Institute, Shanghai, China

Study on the performance of sponge city construction based on land use planning - Cases of Canghai new area in Wuzhou

In order to solve the problems of the deterioration of water environment in China and frequent waterlogging disaster, the methods of performance evaluation in the planning stage of land use planning is explored in this paper, and some strategies to improve the performance of sponge city construction are put forward.

Silja Tillner, Architects Tillner & Willinger, Vienna, Austria

Downtown Cairo urban regeneration - a model for future urban regeneration plans with energy efficiency interventions

The Implementation Plan is intended as a future prototype to explore new models for urban regeneration in historic zones that integrate energy-efficiency into the plans, thereby linking planning and urban design measures for the improvement of mobility and the public realm with public and private investments in energy-efficient buildings.

Croce Silvia; Daniele Vettorato, EURAC Research, Bolzano, Italy

Urban surface use optimization for climate resilience improvement

The optimization of the urban surface use is very relevant for the maximization of urban resilience to climate change. The paper proposes a method to optimize the urban surface use in order to improve the climate resilience capacity of cities.

Session 7: Governance and economics

4 October (Thursday), 13:30 - 15:00

TK *Ningjing Xu, School of Architecture, Tsinghua University, P.R.China, Beijing, China*

Investigation of regional coordinated development based on watershed comprehensive management for Greater Beijing Municipality Area

This paper is to provide a feasible plan for the ecological and economic coordinated development of the Greater Beijing region in the predictable future by comprehensive management in ecological watershed units.

Roman Pomazan, Urban Sustain Architecture design group; Alexandr Khvan, Frame Art Ltd; Pavlo Ostapenko, Geography department of Kyiv State University, Kyiv, Ukrain

Shymkent City

Shymkent City is a project of the new urban district of the third million city of Kazakhstan. Shymkent is the fastest growing city of Kazakhstan, that has large amount of urban issues to be solved. Shymkent City was envisioned as the key urban driver of the most young-populated megalopolis of Shymkent. This new neighborhood is going to represent new comfortable urban environment that should became the specimen for urban transformations of Shymkent in the future.

Karin Hiltgartner, TU Wien, Vienna, Austria

Climate protection and environmental Impact assessment: could climate protection be seen as an 'overall public interest'?

This contribution analyses how differently Austrian courts valued climate protection within the Environmental Impact Assessment on the enlargement of Vienna's Airport. While the court of second instance rejected the project due to international obligations on climate protection, the Constitutional Court found that these were not to be taken into consideration.

Alexander Marful; Elom Ayeke; Rexford Assasie Oppong, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana

Strategies for making peri-urban coastal communities resilient in sub-saharan Africa: the case of Ningo-Prampram

This paper focuses on Prampram, a Peri Urban community found in the Ningo Prampram district. The research investigated necessary interventions required in developing a resilient coastal Peri-urban community in Ghana, amidst the vast infrastructural deficit usually found in Sub-Saharan African countries.

S. Mohsen Hosseinifarhangi; Margherita Turnavi; Gerrit J. Carsjens; Arnold van der Valk, Università iuav di Venezia, Hummelo, Netherlands

Actor-network analysis of transition towards urban hi-tech horticulture. A comparative study of development and adoption of urban high-tech horticultural practices in Shanghai and Amsterdam

This paper firstly studies the development trajectories of technological novelties and secondly, analyzes the process of adaptation and preparation of niches for adoption in urban practices. It tries to find the gaps between these development trajectories and their adoption in urban practices.

Amarjeet Kumar; Saikat Kumar Paul, Indian Institute of Technology, Kharagpur, India

A framework to identify risk level of areas for the formation of evacuation zones during cyclones

The paper proposes a framework for formation of evacuation zones during disasters.

Session Proposal
Cool Planner: The role of urban planning and design within global resilience frameworks

4 October (Thursday), 13:30 - 15:00

Location: Radisson Blu, Room 2

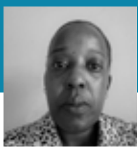
Moderators: Milena Ivkovic, Vice President ISOCARP and Director Blok74 Rotterdam, Netherlands, and Lena Niel, urban and landscape designer, Deltares, Delft, Netherlands

Speakers: Christine Auclair, Climate Change Planning Officer, Urban Planning and Design Branch UN-HABITAT; **Jon Kher Kaw**, Senior Urban Development Specialist at The World Bank; **Irina Shmeleva**, Institute of Design and Urban Studies, ITMO University, Saint Petersburg & Director of Institute of Sustainable Development Strategies (NGO), Saint Petersburg, Russia; **Bernardus Van Heerden**, Strategic Development Manager at eThekwini Municipality, Durban, South Africa

Cities are facing new types of challenges, because of the effects of climate change and densification in cities. The Sendai Framework, Sustainable development goals and The New Urban Agenda are trying to address these challenges for cities. Cities have to become inclusive, climate-proof and economic hubs. Hence, the city is approached as an urban ecosystem instead of a blue print that exists of different layers and flows. Only a truly resilient and inclusive city could be achieved if one understands the functioning of this system. This shift of planning and design also asks for a new type of urban planner and designer. But what is exactly this new role of urban planning and design to achieve these climate-proof cities in line with these frameworks?

As a preparation of this session, the ISOCARP Dutch National Delegation, ISOCARP Europe and Deltares Nederland organized an expert workshop on the 3rd of July 2018, under the title: Cool Planners and the Global Climate Change Resilience Networks. At the end of this expert meeting, several statements about the role of urban planning in the climate change were formulated. These statements will be used as a kick-off for the session.

Track 4: Technology and Infrastructure: Clean, Green, Smart and Resilient



Location: Radisson Blu, Room 2
by Adriano Bisello, Wanjiku Macharia, and Ana María Fernández-Maldonado

After two decades of discussion about smart cities, a globally shared definition of smart urban development and the identification of the most effective approach to urban sustainability and climate resilience are still missing. Undoubtedly, the traditional smart city approach is strongly rooted in an ICT-driven approach, but urban sustainability requires many more components. Above all the human one, as latest interpretations show. The future, smartness and resilience of our cities and their infrastructures are calling for citizen-oriented adaptable and accessible solutions. Only by enabling new behavioural and business models will our cities finally shift focus from adaptation and mitigation costs to smart low carbon development opportunities.

Discussing technologies and infrastructures may appear somewhat "out of topic" in an urban and regional planning congress, bearing in mind the complexity and specifics each system, solution or even single component deserves. However, it is not. Infrastructures are even more interconnected thanks to ICTs platforms and IoT; technologies turn-over is fast; disruptive solutions may lead to great leaps forward; private-public partnership are asking for bankable investments; communities are willing to be part of the decision-making process; the sharing economy is calling for new value models; energy utilities are suspicious of energy prosumers; infrastructure endowments are ageing quickly; green areas are now understood as ecosystem services providers. These and many other factors affect how urban planners should think innovatively about technologies and next-generation infrastructures, looking more at "soft", adaptable and citizen-centered solutions rather than "hard", monolithic and preconceived tools to solve standardized problems.

Cities aspiring towards resilience must make an important cultural shift to a model of urban planning which empowers the citizens. This is also an opportunity for city managers to develop leadership by developing a deeper understanding of its citizenry. Through collaboration and sharing, cities can propagate clean, green and smart infrastructure and technologies right until the neighbourhood level, thus creating and supporting successful, climate-resilient communities.

Overview and Assessment of the abstracts

Research findings and innovative approaches contributing to Track 4 come from all over the world, offering a broad perspective on these topics and contributing to shedding light on cross-cutting issues.

The following topics and research questions were suggested by the call for contributions:

• How does the 'urban technology nexus' affect urban metabolism?

• Infrastructure systems: how do we reinvent the concept and the configurations?

• ICT and the 'smart city'; 'sentient city; 'wise city'; 'green intelligence'

• Disaster preparedness and 'smart resilience'

• The future of transport technology and infrastructure

• The future of energy technology and infrastructure

• The future of building and construction technology

• Urban form, urban flows and the design for smart, adaptable spaces

• What are the economic opportunities in technological innovation for sustainability and resilience?

As a reaction to that, Track 4 presents the use of smart technologies and how next-generation infrastructures will affect urban ecosystems - both their form and flows – thus helping cities become cleaner, greener, smarter and more resilient to climate change.

The first session on planning next-generation infrastructures for innovative solutions highlights some illustrative examples. There is a study that aims at linking infrastructure designs, ecology, water and soil cycles for the development of adaptive, transformative designs and strategies in public works. In addition, the session has a paper that illustrates the role of landscape planning in managing flood response. There is a proposal to validate regulations for wind energy generation in Russian Federation focusing on wind farm planning, design, construction, operation and remediation. Next, an evaluation of the built greenway network using big data analysis and strategies for improvement will be presented. Finally, we will hear a proposal that reviews and addresses the equity and fairness dimensions for policy makers to consider when integrating green infrastructure in spatial planning to maintain a balance between economic and environmental goals.

The session on planning next-generation infrastructures for adaptation, mitigation and disaster preparedness highlights innovative solutions to adapt to and mitigate against climate change. There is a research that posits that Geographic Information Systems (GIS) and Remote Sensing Technology allow urban planners and policymakers model for flood risks to gain critical insights on the real impacts of climate change and adopt sustainable resilient and smart solutions, providing examples from South Africa. There are also two case studies from China. One demonstrates how the cooling effect of green space can be improved by controlling the green area perimeter, shape and community structure of the tree species. The other examines a city's symbiotic relationship with its rivers and the management of flood response through landscape planning including reclamation and restoration of an urban riverfront.

The session on shaping urban form and flows in smart cities design highlights some illustrative examples of different concepts to consider. There is a paper that builds the case for Transport Oriented Development (TOD) as a climate adaptation strategy, the challenges and proposed solutions to mainstream TOD at policy, fiscal and operational levels. Another research presents the main challenges when planning for Zero Emission Neighbourhoods. Looking at examples from Norwegian cities, it observes that to successfully plan, the project developers must consider not only energy and emissions, but incorporate the interests and ideas of a broad range of "new" stakeholders at the early planning stage, such as utility companies. There is a paper that explores what the urban structure looks like when individuals' mobility are aggregated into spatial analysis units using large-scale cell phone data to emphasise the dynamic relationship between human mobility and urban structure, which is key to planning housing, community development and transportation. Another research suggests to develop a Land Suitability Evaluation model focusing on the quality of infrastructure and ecosystems that protect, provide and connect people. The aim is for the model to support resilient urban planning providing decision makers with a comprehensive picture of the urban infrastructure and ecosystems in order to make better informed decisions to deliver cooler cities. To get further insight into urban flows, a study evaluates a Shared Farm model looking at the operating mechanism, core features that facilitate urban-rural reciprocal flow that is circumvented by China's binary urban-rural structure, which hinders the free-flow by a separated property right systems.

The session on turning technological innovation in urban and community values highlights some illustrative examples of planning for and leveraging meaningful technological innovations in the city and the community. There is a proposal to develop a methodology which identifies local windows of opportunity from a spatial and economical perspective, to systematically identify where smart city solutions could be applied within the current urban fabric while planning its management and maintenance to ensure a transformation urban project rather than a transient novelty. There is a paper that llustrates how disruptive technology for urban governance and decision-making offers major opportunities for engaging multi-disciplinary partners and integrating evidence based decision-making into the governance process. There is also a proposal to explore the challenges and potential of new technologies and their application in an urban setting by surveying urban innovation units and living labs to determine the effect of new technologies on city planning and its users.

In addition, this paper analyses the set of key principles that define the concept of living labs. Then there is a presentation on how disruptive technology applications for urban governance and decision-making offer major opportunities for engaging multi-disciplinary partners and stakeholders, and integrating evidence based decision-making in governance process addressing societal challenge. An exploratory research to investigate whether the transformation that comes with the IoT and smart cities could serve as a catalyst for promoting culture and reducing marginalization will be presented. A study also examines the development of technology application for tourism activities that disseminate information and facilitate the appropriation of the urban space, analysing some of the new challenges to urban planning and city management, created by tourist activity at the local level which is not ready for it.

Finally, a presentation on planning and designing outdoor spaces in Qatar to be running-friendly in response to weather conditions.

Track 4 will feature two supplemental Sessions:

1. How to develop a new public service based on the "Smarticipate Platform".

2. Urban mobility in transition: perspectives and challanges on urban living and public space in china

Session 1: Planning next generation infrastructures for innovative solutions

2 October (Tuesday), 11:00 - 12:30

TK *Taneha Kuzniecow Bacchin; Filippo La Fleur,Delft University of Technology, Delft, Netherlands; Richard Ashley, University of Sheffield, Department of Civil and Structural Engineering, Sheffield, United Kingdom*

Next generation infrastructure design under conditions of extremes

Design and programming of next generation hybrid green/blue/grey infrastructures for the adaptation and/or transformation of urban areas and (metropolitan) regions to extreme climate change (e.g. sea level rise, river peak discharge and intensive rainfall patterns).

Dmitry Boyko; Valeriya Patueva, GeoClever, Volgograd, Russian Federation

Planning issues of wind farm siting in the Russian Federation

The paper will show main planning regulations and approaches of wind farms in Russia.

Li Tan, Beijing Forestry University, Beijing, China

Evaluation of built greenway network in Beijing based on big data analysis

This paper evaluates the built greenway network in Beijing based on two types of big data: travel trace data from bike-sharing applications and the point of interest data from Micro-blog. Core problems and strategies are summarized for a better plan and design of greenway network responding to climate change.

Ifeoma Ukonze; Donald Okeke, Department of Urban and Regional Planning, University of Nigeria Nsukka, Enugu, Nigeria; Collins Nnamani, Department of Estate Management University of Nigeria Nsukka, Enugu, Nigeria / presented by Mahak Agrawal, New Delhi, India

Integration of green infrastructure into transportation planning in African cities

This study gives a review of the integration of the concept of green infrastructure into the transportation policy framework which could serve as a tool for achieving sustainable transport development. It will also help show an alignment between the socio-economic and environment gains of this concept in African cities.

Zhejing Cao, Tsinghua University, Beijing, China

Resilient slow traffic system planning based on traffic survey data and comparative study: evidence from Wenyu River area in Beijing

This paper aims at taking Wenyu River area in Beijing as an example, to analyze the slow traffic demand, trip pattern, land use mode of the periphery of urban center, for proposing resilient slow traffic system planning strategies through comparative case studies.

Track 4

Session Proposal
Urban Mobility in Transition: Perspectives and Challenges on Urban Living and Public Space in China

2 October (Tuesday), 13:30 - 15:00

Moderator: Sebastien Goethals, Vice President ISOCARP

Speakers: PAN Haixiao, Tongji University; WANG Hongyang, Nanjing University, China

The current transition of urban mobility is about to transform our daily commuting habits and energy consumption modes in both urban and rural environments.

Since digital connectivity has opened new windows of opportunities for communities and commuters through the sharing economy, the way we use together and individually our streets and public spaces might be less (or more?) segmented and informal, as a result of real-time and collective decision-making.

An optimized scenario of mobility transition, integrating automation, sharing and electrification by 2050, presents a reduction from 4,600 to 700 megatons of CO2 and from 2,1 to 0,5 billion vehicles worldwide.

But only few cities are now starting to test smart mobility systems, and most of them dramatically lack of urban planning strategies in terms of integration of public transport and new mobility services and public spaces.

Chinese cities are the places where the change happens at the fastest pace. Shared and free-floating bicycles have become a popular trend in China and worldwide, but the massive amount of bicycles that recently invade the streets of Chinese cities has shown the limits of such solution.

This session proposes to identify the major coming challenges of the urban mobility revolution in China and worldwide.

During the first part of the session, Sebastien Goethals will introduce the relation between smart mobility and urban metabolism, through integrated planning and design strategies, followed by a quick introduction of the scale and speed of China's urbanization and mobility transformation.

During the second part, two Chinese major experts in urban planning and mobility, PAN Haixiao (Tongji University) and WANG Hongyang (Nanjing University) will give a presentation about their approach of the mobility transformation and its potential to improve livability in Chinese cities.

The third and last part of the session will be dedicated to a rapid visioning exercise with the public, putting in perspective the role of city planners in the technological transition of cities.

Session 3: Planning next generation infrastructures for adaptation, mitigation & disaster preparedness

2 October (Tuesday), 15:30 - 17:00

TK *Sabelo Mahlangu, University of Witwatersrand, Johannesburg, South Africa*

Planning for a changing climate: A GIS and remote sensing approach to urban flood modelling in the Gauteng City Region
A GIS and Remote Sensing approach to urban flood modelling will be presented.

Menghan Zhang; Beiijng, China

Symbiosis with rivers: the management of flood response to future climate change from the perspective of landscape planning
We should find solutions to disasters based on the idea of resilience by establishing a place that can adapt to the temporal dynamics. As means of flood management and symbiosis with rivers, in both low-urbanization areas and urban areas, two different detailed strategies of landscape planning are provided.

Binxia Xue; Xiaohe Hou; L. Lulu Chen; S. Su'ning Xu, Harbin Institute of Technology, Harbin, China

Study on the optimized strategy of resilient spatial pattern from the perspective of sponge city - Taking Garden Street Historic Block in Harbin City as example
In order to solve the most serious rainwater problem in old urban areas of China, this paper redesigns green infrastructures which are compatible with the architectural style of old city and then combined with gray infrastructures. The program optimizes space in a resilient way and builds a three-dimensional spatial pattern.

Wale Alade; Femi Adeniji, University of Lagos, Lagos, Nigeria; Mobolaji Olaseni, Yaba College of Technology, Yaba, Lagos; Olubukola Alade; Bukola Alade, Bells University of Technology; Olajuwon Olaseni, Vistaplan Consulting Nigeria

Making Lagos a cool city: a study of transport system and travel behaviour
Lagos transport system threatens peoples' survival and climate. Urgent and full implementation of the Lagos strategic transport masterplan which makes provision for multimodal transport system, transport and land use integration among others is recommended with urban planning strategies such as Transit Oriented Development for land use and travel demand management

Zhong Yujia; Tan Li, Beijing, China

Study on vegetation in Haidian District of Beijing based on heat island effect
By studying the data combined with the law of cooling effect of green space, we found that the cooling effect of green space can be improved by controlling the green area, perimeter, shape coefficient and community structure. Based on this, we will guide to improve the urban ecological green network.

Session 4: Shaping urban form and flows in the smart cities

3 October (Wednesday), 13:30 - 15:00

TK *Daniela Baer, SINTEF, Trondheim, Norway; Brita Nielsen, Norwegian University of Science and Technology, Trondheim, Norway*

Challenges and Best Practices for the planning of zero emission neighborhoods and smart energy communities – the case of seven Norwegian cities
We will present challenges which occurred when planning for Zero Emission Neighbourhoods in seven Norwegian cities as well as best practice examples how to cope with them.

Track 4

Olga Chepelianskaia, Uniciti, Toulouse, France

Climate adaptation: transit oriented development as a strategy in Asian cities

Increasing vulnerability to climate change in Asian cities has made adaptation a critical matter. While successful Transit Oriented Developments (TOD) in developed Asian cities have uncovered significant benefits, its adaptation potential is yet to be analysed. The presentation outlines the climate change adaptation role of TOD in Asian cities.

Xiyuan Ren, Tongji University, Shanghai, China

Research on urban spatial structure in Shanghai from a human mobility view based on cell phone data

Four characteristics of human mobility in spatial analysis units: flow strength, influential area, flow composition, and law of time. A dynamic urban form is then described to support the future design for smart spaces.

Xin Kai, Shanghai Tongji Urban Planning and Design Institute, Shanghai, China

Land suitability evaluation for resilient urban planning: a planning practice of Pingdingshan City, China

This paper proposes a land suitability evaluation model for resilient urban planning in the dimension of infrastructure and ecosystems. In the process of ecological strategy planning in Pingdingshan, the model used to identify the ecological valuable and sensitive areas, providing an ecological basic framework for land-use planning.

Jun Zhou; Xin Lian Beijing, China

Shared Farm: an approach to achieve urban-rural reciprocity based on sharing economy

The sharing economy, featuring the access-based consumption without the transfer of ownership, offers a perfect therapy for rural area in China to bypass the institutional obstacles of land transaction and participate in the game of market economies. Shared Farm was born based on such concept.

Session Proposal
How to develop a new public service

3 October (Wednesday), 15:30 - 17:00

Moderator and Speaker: *Larissa Guschl, urban planner based at participatory planning and design office WeLoveTheCity, Rotterdam, The Netherlands*

Citizens have plenty of ideas for the neighbourhood in which they live, work and play. Unfortunately, they don't always have access to the right information to develop their ideas into a concrete proposal. That's why Freie und Hansestadt Hamburg, Roma Capitale and The Royal Borough of Kensington and Chelsea want to share a combination of open data and expert knowledge. The smarticipate platform allows citizens, entrepreneurs, NGOs and city officials to submit their proposal for a sustainable neighbourhood and to receive immediate feedback. This means everyone can get involved, even those who have never interacted with local government before. Some citizens and entrepreneurs even want to go further and demand access to the technological core of the digital platform to plug in their own topic.

During the hands-on session you can test the smarticipate prototypes (Plant a Tree App, Urban Transformation App, 3D Planning App). Besides that, we will challenge you to think about which kind of New Public Service you would like to introduce and how the smarticipate platform could help in achieving that goal.

Session 6: Turning technological innovation in urban and community values

4 October (Thursday), 11:00 - 12:30

TK *Judith Borsboom-van Beurden, Norwegian University of Science and Technology, Trondheim, Norway*

Windows of opportunity for smart city solutions

For a real urban transition, a systematic scan of the windows of opportunity for smart city solutions is needed, not only during urban (re)development, but also in asset management in the built environment.

David Ludlow, European Smart Cities, Bristol, United Kingdom

Smart city governance – co-creating urban planning and inclusive communities

Disruptive technology applications for urban governance offer major opportunities engaging multi-disciplinary partners and stakeholders, integrating evidence based decision-making addressing societal challenge. Research questions to be addressed include the specifications for a user-defined framework of interconnected strategic policy, and how best to ensure development of a common model of urban governance?

Ozge Celik, Özhan Ertekin, Istanbul Technical University, Istanbul, Turkey

Re-thinking the city: Living Lab concepts in Turkey

The paper examines living labs in Turkey to find out cooperation between labs and local government and its influences and contributions on local planning.

Alexander Boakye Marful; Daniel Duah, Kwame Nkrumah University of Science and technology; Joseph Agyei Danquah, Building and Road Research Institute, Kumasi, Ghana

Smarting the cities: a catalyst for acculturation in Ghana?

This paper seeks to investigate whether the transformation that comes with smarting cities could serve as a catalyst for acculturation or a strategy for resilience. As an exploratory research, a mix method approach was adopted in collecting data from persons within Kumasi and a microcosm of a city in Kumasi.

Maria da Graça Moreira, Universidade de Lisboa, Lisboa, Portugal

Tourism and ICT; a new urban challenge to planners

Tourism is one of the economic activities that have developed most in urban space. The number of people who make tourism along with the changes in ICT is having a great impact on the appropriation of urban space. The APPs about climate are a value on the tourist activities.

Sławomir Ledwon, Vice President ISOCARP, Doha, Qatar; Mubarak Al-Naimi, Ministry of Municipality and Environment, Doha, Qatar

Hot climate and runnability: how climate affects outdoor running activities. A case study of Doha, Qatar

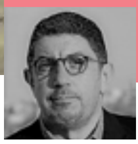
This article discusses runnability - the relation between built environment and outdoor activities of citizens, in particular running. Correlation to changing weather conditions throughout the year in hot climate is made by analysing the case study of Doha, Qatar. Examples of the latest infrastructure and its features are also presented.

Giovanni Sergi, Department Architecture and Design Genoa University, Senigallia, Italy; Paolo Rosasco, Department Architecture and Design Genoa University, Genoa, Italy

The use of Living Lab in some Italian urban settings to test the feasibility of the Smart City. Making the needs of communities compatible with applications of new technologies

Since 2007 several Italian Municipalities have tested the Smart City model. With reference to the EU Manifesto of Helsinki which outlined the Living Lab in 2006, some Municipalities have worked to check the consistency of the Smart City model with the primary role of inhabitants within such processes.

Track 5: Social Networks: Citizen Participation, Urban Governance and Cultural Transformation



Location: Stormen Concert Hall – Sinus

by Ali Alraouf and Nupur Prothi Khanna

As is clearly manifested in the call for abstracts, this track focuses on people. The main question is: how can communities and citizens be engaged in the planning process, while acting as part of a formal or non-governmental system?

This track is extremely valuable and we are anticipating that the selected papers and case studies would initiate a fresh, engaging and timely discussion underpinning the relevance of people, communities and citizens in the way cities are designed, planned and used today.

This track will also stage two session proposals.

The submitted abstracts were assessed for their relevance to the track and its subthemes, research merit, contribution to global discourse on the subject, sharing valuable local experience, comprehensively analyzed case studies and good practices. The selected papers showcase a wide spectrum of planning knowledge and experience.

Overview of abstracts

This track received the highest number of abstracts, a fitting indication that people form the core of equitable, smart and sustainable planning. The diversity of discussions ranging from theoretical analyses to good practices from across geographies, offer a well-rounded contribution to the climate change discourse. Based on particular emphasis, the sessions were organized around six themes: sustainability and local stewardship; planning places for people; inclusive cities; planning policy, governance and management; heritage in context; smart city.

Topics discussed in the different papers allowed the track team members to divide the sessions in a way which would holistically cover the interdisciplinary and interrelated nature of the contributions.

A discussion on themes and sessions

Sustainability and local stewardship forms the heart of the discussion on citizen participation in planning for 'cool cities'. The discussions centers on people engagement in diverse contexts, from mapping their natural landscape, to safeguarding their commons, to coming together in the face of natural disasters. Engagement, protection and preparedness are demonstrated in three different national contexts (Japan, China, Flanders) as part of this session.

Planning places for people puts citizens in the heart of the green initiatives in today's fast urbanising world. From designing participatory landscapes to measuring environmental benefits of open spaces, deliberations from Europe and China illustrate the relevance of people to the transformation of these spaces into places and their relevance to health and community well-being.

Inclusive cities addresses the reality of migration, changing population typologies and new and transforming communities that are beginning to dilute the political borders in our world today. Addressing concerns around segregation, this session brings forward views from the developing nations (Asia, South America, Europe, Sudan) related to the central role of women and children in sustainable practices as well as addressing the challenge of aging communities in Europe.

Planning policy, governance and management is an engaging session on the role of non-governmental actors in the diverse scales of planning and development. Ranging from master planning in West Asia, to housing concerns in Asia, to community based space management in Africa, this session focuses on public participation in policy and governance for safeguarding our urban future.

Heritage in context elicits interest amongst many papers in assessing the unfortunate loss of urban heritage in the absence of understanding its significance, imminent pressures of the fast paced development, and lack of engaging and incorporating our past in our present development. Cases from Asia (China and Istanbul) highlight the role that participatory processes are playing in re-appropriating heritage in planning and giving it a place of significance in the monochromatic urban form taking over our historic environment.

Smart City lays out possibilities around the potential of renewable energy. Innovative ways for urban planning to create cities that can prepare for a sustainable future form the core of discussions from Asia and Europe in this session.

Session proposals

01 Constructed and contested legitimacy in urban governance

Academics and practitioners from Norway will present the challenge for urban governance in facilitating sustainable cities. The negotiations around legitimacy claims from different stakeholders, planners and decision makers to enable this transformation will be the main subject of the discussions in this session.

02 Planning for Diversity

Comprising of short presentation from Norway, this session addresses the capacity of cities to live with differences, to ensure social, economic and environmental sustainability of cities. The deliberations will relate to new theories, methods and tools for planning for diversity, supported by good practices and case studies.

Way forward

Planning, like democracy is for the people, by the people and of the people. Also like democracy, the choices that we make impact us directly - as demonstrated by climate change in the recent past and in the present. Climate change is central to the future direction we need to take for planning our cities, spaces and places. The opportunities are diverse, considering indigenous knowledge systems on one end of this spectrum, down to using AI and digital media as enablers to visualize and actualize a better world. This track contributes a new perspective for the planning discipline as a facilitator to actualize this vision of a cooler, livable earth, safeguarding our future and that of the generations to follow.

TK track keynotes

Session 1: Sustainability and local stewardship

2 October (Tuesday), 11:00 - 12:30

TK *Kasumi Susaki, Ryukoku University, Kyoto City, Japan*

A study of Japanese neighborhood communities expected to work during climate change-related natural disasters - from the religious diversity perspective

In Japan, neighborhood communities are expected to work during large-scale natural disasters, and municipalities have begun to encourage their activities. Some of their activities are related to shrines or temples. Therefore, neighborhood communities should examine diversity. This paper reports the result of the examination of this issue.

Amsale Temesgen, Nord University, Bodø, Norway; Bjørn Vidar Vangelsten, Nordland Research Institute; Mònica Guillen Royo, University of Oslo, Oslo, Norway

Citizen participation for increased sustainability and quality of life in cities in Nordland County

Nordland county in Northern Norway aims to increase both attractivity and sustainability of its cities. This paper presents preliminary results from a workshop method based on Max Neef's Human Scale Development theory using citizen participation to propose policies for improved quality of life and sustainability in selected cities in Nordland.

Aase Kristine Lundberg; Mathias Reinar, Nordland Research Institute, Bodø, Norway

Urban living lab: towards more legitimate and inclusive participation in urban planning? experiences from Bodø living lab

Urban Living Labs have been promoted around the world as a desirable approach to public participation in urban planning. In this paper, Bodø Living Lab is used as a case to explore how such initiatives contribute to secure and improve the legitimacy of urban planning faced with climate change.

Ping Shen, Tongji University, Shanghai, China; Jingyu Liang, Guangzhou, China; Zhao Miaoxi, Guangzhou, China

Detecting attractive spots of hiking tourism based on geo-tagged photos: the case of northern outskirts of Guangzhou, China

Based on geo-tagged photos shared online by hikers, we detected attractive spots and obtained tags reflecting landscape features of the spots in order to provide references for planning, governance and management of hiking tourism.

Annette Kuhk, Katholieke Universiteit Leuven, Leuven, Belgium; Guy Vloebergh, Omgeving cvba, Antwerp, Belgium

How local re-commoning initiatives set a spark for global challenges

Three landed commons initiatives in Flanders (Belgium) on organic farming, social housing and slow roads illustrate how (re-) commoning practices of active land use stewards lead to a more sustainable use of scarce land and of fertile soils, and as such also to a contribution in the mitigation of climate change.

Session 2: Planning places for people

2 October (Tuesday), 13:30 - 15:00

TK *Yuting Guo, College of Architecture and Urban Planning, Tongji University, Shanghai, China*

Space production: the interaction between social network and community garden

This paper investigates urban community gardens as spaces of citizenship through a case study of the Paraquat garden in Anshan Four village to find out the interaction that urban agriculture brings to citizens' participation and the residents' lifestyle as public space.

Iris Gommers, City of Antwerp, Antwerp, Belgium

A green tool to measure the environmental and ecological benefits of green areas and to involve different stakeholders

Antwerp's "Greentool" allows urban planners to explore the potential of green to improve the living environment (heat stress, water run-off, air quality, noise perception, biodiversity, carbon sequestration) in a specific area. The application shows which nature based solutions can be used where in the city and gives the potential impact.

Longduoqi A; Hang Ma, Harbin Institute of Technology, Shenzhen, China

Evaluation of public space vitality of based-scenic villages in a subtropical climate region: Case study of Guanhu Village in Shenzhen

This study aims to establish a method to evaluate the public space vitality (PSV) of coastal villages in urban fringe through tourist preference. It has some theoretical significance to guide the self-organized development of coastal villages in urban fringe.

Lihua Li; Lingling Li, School of Architecture, Harbin Institute of Technology, Harbin, China

Adaptable planning strategies of urban sport spaces in cold regions for climate and citizens' needs: case study of Songyuan, China

Based on investigating and analyzing citizens' needs of recreation and physical activities under the influence of climate, planning strategies of urban sport spaces in China's cold regions are explored to improve the regional and climate adaptability.

Session 3: Inclusive Cities

2 October (Tuesday), 15:30 - 17:00

TK *Paola Rizzi, University of L'Aquila, L'AQUILA, Italy, Pongpisit Huyakorn, UDDI, Thammasat University, Bangkok, Thailand*

Gaming simulation as a policy planning tool in a racially diverse neighborhood: a case study of Lardproaw district, Bangkok

The researcher implemented Gaming Simulation as a method to assess the awareness toward climate change and the perception regarding the collaboration for local policy development from different local racial groups which include Thais, South East Asians, Europeans, etc. Ultimately, we recommend the progressive approach for elevated local community-based planning.

Mitchell de Sousa, University of Buenos Aires, Ciudad Autónoma De Buenos Aires, Argentina

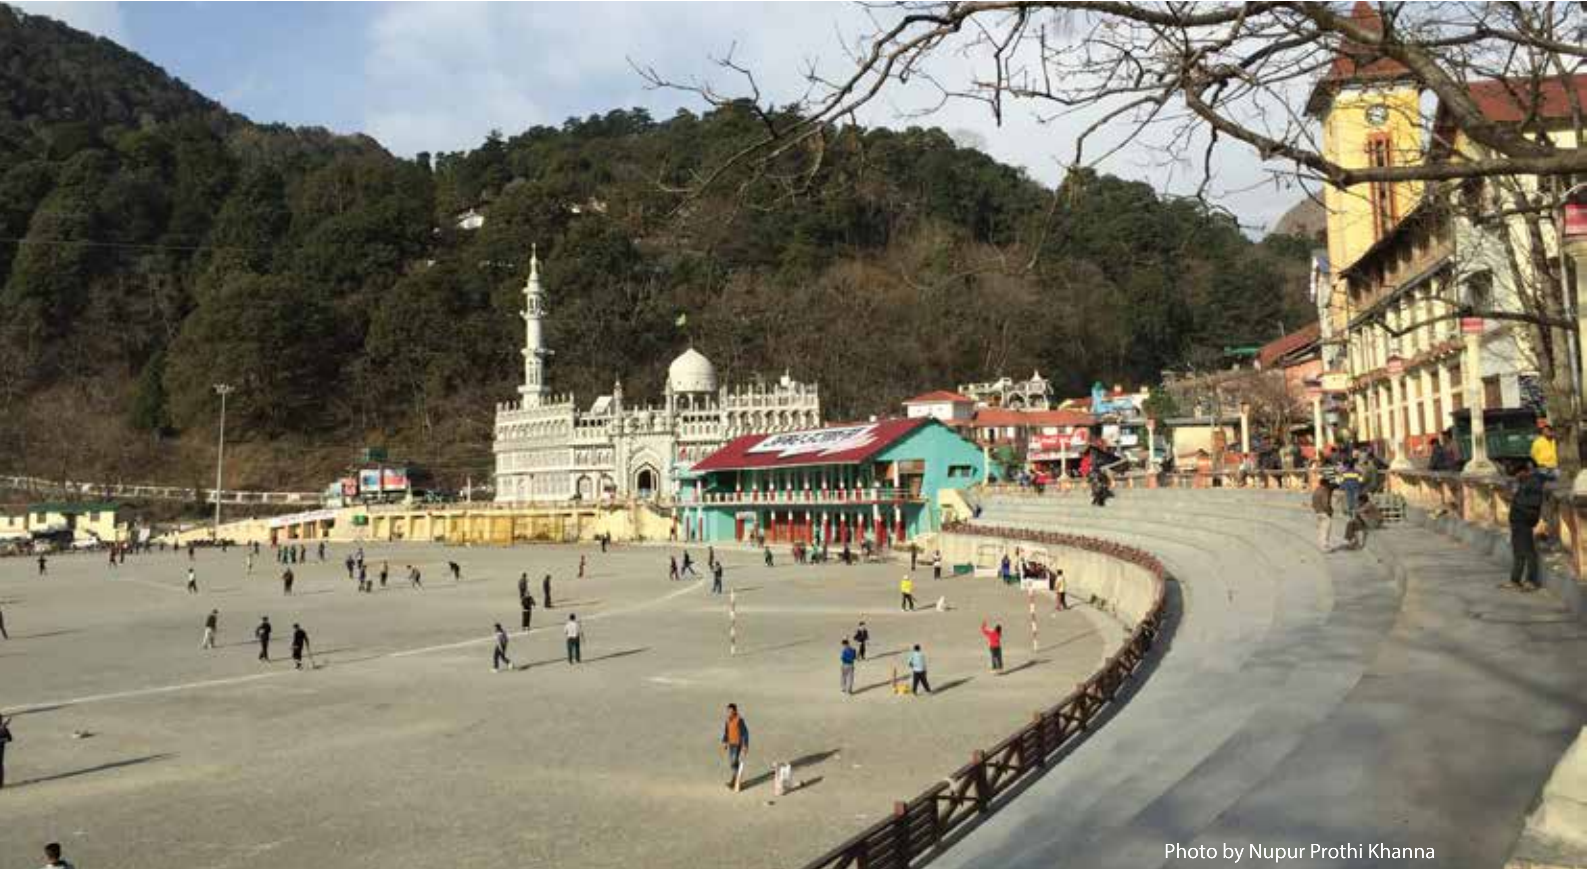
Beyond urban seggregation: social reproductions and territorial frames of popular sectors in middle-sized towns of Latin America: the case of the neighborhood "Planta De Gas" in the Patagonian-Argentine city of Trelew

This work studies the characteristics and the specific themes that are located between the dynamics of the popular sector and the socio-spatial process. The main objective is to identify the transformations of the territorial organization on informal settlements in middle-sized towns on the Latin American context.

Lekshmy Hirandas, School of Planning and Architecture, New Delhi, New Delhi, India

Child in the City: Understanding the role of children in community engagement, Case of Chara Mandi, New Delhi

The case study will introduce an understanding of the role of children in Participatory Planning. It is a well-established fact that children are much more perceptive to their environments than adults.



Maria da Graça Moreira, Universidade de Lisboa, Lisboa, Portugal
Associations of active aging; a potential tool for local development
This paper presents a research on the role that 'senior universities' can play as tools for the preservation of tangible and intangible heritage in some urban or rural areas.

Session 4: Planning, policy, governance and management

3 October (Wednesday), 13:30 - 15:00

TK *Piotr Lorens, Gdansk University of Technology, Gdansk, Poland*
Civilizing the public participation practice in post-transition countries
Public participation is nowadays commonly understood as the key issue in contemporary planning theory and practice. It can be noted that in post-transition countries the local communities are much more demanding in this respect, and – in result – new tools and approaches to this are being developed.

Mahesti Okitasari, UN University Institute for the Advanced Study of Sustainability, Tokyo, Japan
Spaces of non-state actors in the urban development process: Rethinking the community-based planning in the housing sector
This paper examines how community-based planning in Indonesia changes with the shifting roles of non-State actors in the development process, particularly in urban settlement, and the introduction of international urban development agenda and approaches in the last two decades (1999-2017).

Nagy El Gritly; Noora Al Suwaidy, Ministry of Municipality and Environment, Doha, Qatar
Towards setting up a contemporary planning system that adopts a participatory planning approach, enhances good governance, and delivers cool planning for Qatar urban future
The paper will show the importance of the role of Consultation and Community Engagement with all concerned stakeholders during the preparation of urban development projects. Such findings would represent a fundamental and decisive progress in the development and consolidation of Qatar's emerging Planning System.

Ekaterina Maleeva, Project Director at Strelka KB, Moscow, Russia
Standards for the integrated development of territories
The Integral Guidelines for Urban Development is designed to make 1114 Russian cities modern, resilient, and responsive to the needs of residents. This is the first such document in Russian practice. The guidelines combine a flexible approach to regulation, while at the same time integrating existing norms and rules and set the bar for high quality development of the urban environment.

Session Proposal
Planning for diversity

(Session Proposal as part of track 5)
3 October (Wednesday), 15:30 - 17:00
Location: Stormen Library – Bodø ByLab
(see page 39)

Session 5: Heritage in context

3 October (Wednesday), 15:30 - 17:00

TK *Serin Geambazu, Ion Mincu University, Bucharest, Romania*
Local identities on change- urban waterfront regeneration within the global city Istanbul
The study reveals the dimensions of an urban waterfront regeneration project in which the rights of the future users of the space are lost behind a fight between the government and strong opposition parties gaining ground of governance landscape, motivated by their stake in the development.

Zihan Cai; Ming Lu, Harbin Institute of Technology, Harbin, China
Research on sustainable design of historical blocks based on inhabitant social integration measurement: a case study of Harbin in China
In order to solve the conflict between inhabitant life and commercial tourism in the renewal of Chinese historical blocks, this paper uses the confirmatory factor analysis to construct an evaluation model of inhabitant social integration measurement and proposes a sustainable design strategy for historical blocks from the perspective of inhabitant social integration.

Track 5

Cunai Yan; Chenchen Ren; Huiyi Xia, Shanghai Tongji Urban Planning & Design Institute, Shanghai, China

Applied research on public participation in urban renewal planning based on the 'Fanchang Model'

This research tries to improve the original planning process of the urban renewal projects through enhancing public participation and public opinion survey process so as to form a framework of PIEA (Participation + Investigation + Evaluation + Action) for urban renewal projects.

Jianqiang Yang, Southeast University, Nanjing, China

Study on endogenous and inclusive development of old residential area

In the principles of resident participation, equal cooperation, progressive regeneration and inclusive development, the paper studies the substantial connotation, realistic meaning, fundamental principles, community organization, and regeneration measures. It proposes workable measures for endogenous urban regeneration, and establishes a holistic route in which collective intelligence should be brought into play.

Xinyue Gan, Tsinghua University, Beijing, China

Urban Beautification in Beijing's old city from the 1990s to the present: Taking housing regeneration in Beijing old city as the case

From 'housing demolition' in 1990s and early 2000s, to 'housing vacation' at present in Beijing old city, how does the mechanism of housing regeneration transform? At present, whether the living conditions of the local residents have been improved in the process of 'housing vacation'?

Huiyi Xia; Renzan Qian; Cunai Yan; Nankai Xia, Shanghai Tongji Urban Planning & Design Institute, Shanghai, China

Multi-dimension urban planning in renewal of the old city - a case study of an urban renewal project in QuYang, Shangahi, China

It is mainly based on community governance, adding data platform services and data analysis, using the Internet to provide residents or users with more effective and comprehensive public supporting services, and providing management with data control and big data analysis in the background.

Session 6: Smart City

4 October (Thursday), 11:00 - 12:30

TK *Miguel Fernández-Maroto; Juan Luis De las Rivas Sanz; Sergio Cantero Celada; Ángel María Marinero Peral, University of Valladolid, Valladolid, Spain*

INTENSSS-PA: a governance approach for integrating energy and spatial planning - its results in Castilla y León (Spain)

The INTENSSS-PA project aims to develop and implement an institutional capacity building approach related to energy and spatial planning, addressed to public authorities and societal stakeholders in order to support them to enter in a new era of holistic planning through a participatory, multi-level, interdisciplinary decision-making process.

Evgenii Aleksandrov; Elena Dybtsyna; Anatoli Bourmistrov; Giuseppe Grossi, Nord University Business School, High North Center for Business and Governance, Bodø, Norway

Opening Smart City 'fairy tale' to Critical Scrutiny: insights from dialogic accounting literature

Smart City idea becomes a 'fairy tale' with smart IT-solutions, smart people and smart collaboration for sustainable future. However, it is still unclear how to develop Smart City management which somehow should balance between interests of financial sustainability, citizens, environment and business or/and political elites.

Anniken Førde, Tromsø, Norway

Enhancing urban encounters - the transformative powers of creative integration initiatives

This paper explores innovative integration initiatives in cities in the north, emphasizing how new forms of engagement and responsibility might be engendered. The cities are seen as sites of experiments, where new relations across difference are developed.

Guoqiang Wang; Liu Songfu; Shen Yu, Faculty of Architecture, Harbin Institute of Technology, Harbin, Heilongjiang Province, China

The framework research on sustainable conservation of urban building heritage from the collaborative visioning for the future based on the complexity theory

This paper highlights how heritage sustainable conservation becomes important for dynamic innovation in the urban evolutionary process in the coming anthropogenic era, during which decision-making and human behaviour is becoming the dominant influence.

Angela Santangelo; Simona Tondelli, University of Bologna, Bologna, Italy

Embedding energy user's behaviour into multi-criteria analysis: Providing scenarios to policy-makers to design effective renovation strategies of the housing stock

The paper aims at contributing to the discussion about promoting urban regeneration through energy-related policies able to incorporate user behaviour. The outcomes shall support policy-makers to design and implement energy policy instruments to regenerate the existing built environment, to increase urban resilience, quality of urban spaces and quality of life.

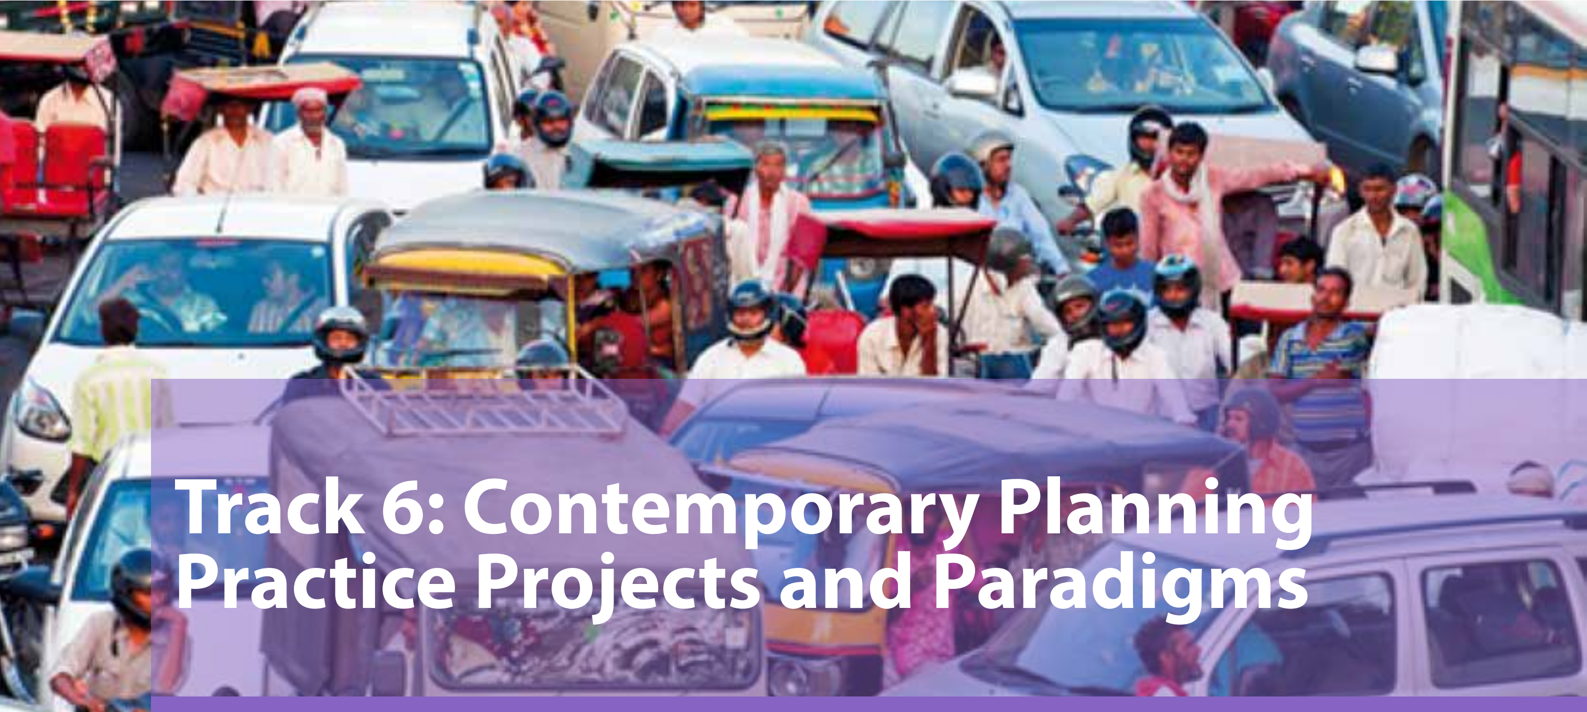
Constructed and contested legitimacy in urban governance

(Session Proposal as part of track 5)

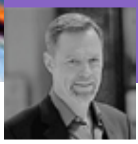
4 October (Thursday), 13:30 - 15:00

Location: Stormen Library – Bodø ByLab

(see page 40)



Track 6: Contemporary Planning Practice Projects and Paradigms



Location: Stormen Library – Litterature Hall
by Frank D'hondt and Andreas Schneider

This track reflects the diversity of 'less-climate-related' planning issues that drive contemporary planning researchers and practitioners. Weaving common threads is not easy, let alone a pattern or paradigm in contemporary planning. There are recurrent topics such as preserving cultural and natural heritage, the need for quality over quantity, (real) public space making, TOD-planning, etc. But there are also some newer fields such as 'UniverCity'/School Planning, Entrepreneurial Planning, Mobile-data-based Activity Planning, Community Life Cycle Planning, Sponge City-Planning, Urban Eco-Planning, Dual Planning System approach and …the 'Periodic Table of Urbanism'. In other words, if eclectic 'diverCity' is your thing and climate change is not necessarily the primary focus of your work and research - this track is yours!

Session 1: Urban Innovation 1
The lead paper explores the transformation in the urban planning approach of Kolkata/India based on a timeline of historical events since its inception as an Indian colonial port city, to today's IT-driven city. The paper confers that the prevailing hegemony of the dominant neoliberal urbanism is neglecting the place-making characteristics of the public realm of Kolkata, leading eventually to erosion of the cultural fabric of Kolkata neighbourhoods. The authors strongly opine the redevelopment of the public realm to reinvigorate the fading cultural patina of the neighbourhoods and enhance the neighbourhood cohesion. Other papers in this session struggle with the same consequences of urban transformation driven by neoliberalism and authoritarianism. Papers exploring eco-neighbourhoods and UniverCity complete this first session.

Discussion could be centred around following keywords: urban communities, urban transformation, neoliberalism, eco-neighbourhoods, UniverCities and public space.

Session 2: Urban Innovation 2
The lead paper analyses working, living and leisure activities in metropolitan Wuhan/China and identify their spatial relations between the old city and the East Lake new town. It then proposes optimizing suggestions for the current spatial plan of the new town in view'of a more people-centred approach to planning and urban development. Other papers advocate the idea of neighbourhood schools in India; people-centred entrepreneurial planning is Israel; the impact of large-scale urban interventions on contemporary city centers, with the Polish harbour city Gdansk as the case; and the concept of 'community-life-cycle in urban planning, with Ningbo Eastern new town development as case-study.

Discussion could be centred around following keywords: mobile-data mining, activity-planning, new town development, people-oriented/entrepreneurial planning and urban redevelopment.

Session 3: Eco-Planning System
The lead paper, taking Shanghai as an example, introduces the theory and praxis of Water-based Planning within the context of the Chinese Sponge-City Programme. Other papers argue for a global dual planning system, addressing both urbanized and non-urbanized territories; for a paradigm shift towards Urban Ecological Planning as tested in Pune/India; for centralized leadership to implement major projects that can jump-start local development, as demonstrated in the case of Dateng Valley Redevelopment in rural Wu-Xuan/China; and for an urban morphology optimization model to address the Urban Heat Island effects, with Hangzhou/China as the case.

Discussion could be centred around following keywords: water-based planning, planning system assessment and reform, urban ecological planning and urban island heat mitigation.

Session 4: Heritage Planning
The lead paper presents research on win-win strategies for ecological heritage protection and eco-tourism development along trans-regional mega linear projects of China, resulting in new guidelines for the planning, construction, ecological restoration, tourism development and management of them. Others papers are dealing with sustainability planning for small border mountain towns entering the global tourism market, with case studies in Georgia and Vietnam; with Landscape as a cultural ecosystem service and guiding administrations and professionals in incorporating landscape management into the different stages of regional and local planning and design; with Landscape planning in Russia; and with the challenges of urban rehabilitation of heritage districts under heavy touristic pressure, such as the Bairro Alto and Bica neighbourhoods in Lisbon/Portugal.

Discussion could be centred around following keywords: urban and ecological heritage, eco-tourism, landscape planning and ecosystem services, urban rehabilitation and gentrification.

Session 5: Landuse & Planning Systems
The lead paper presents issues and challenges in delivering compact development and densification in Auckland/New Zealand. It suggests that the land use planning should be accompanied by a more thorough discussion and review of planning tasks and goals, and a deeper understanding on the role of plan regulation and its actual implementation under a market-driven planning system. Other papers are presenting land-use suitability assessment criteria for South Africa, carried out on land before any developments are implemented; the practical limitations of mixed land use as a sustainable development model which promotes the compact and efficient use of spatial resources, comparing Chinese and American practices; the 'periodic table of urbanism', providing a comprehensive framework for describing the "general reign of order" in our towns and cities, whereby planners and related professions are able to reach a fuller understanding of cities – and thereby plan them better, with Palermo/Italy as the case study; and the case of a Railway hub area development in Arth-Goldau/Switzerland, with innovative participatory methods on Stakeholder Process and Urban Design.

Discussion could be centred around following keywords: compact development, land-use suitability assessment, mixed land-use, planning system rethinking and smart/participatory TOD.

Authors are responsible for the content of their work

TK track keynotes

Session 1: Urban innovation part 1

2 October (Tuesday), 11:00 - 12:30

TK *Sudeshna Kumar; Haimanti Banerji, Indian Institute of Technology Kharagpur, Kharagpur, India*

Analysis of transformation of urban planning practice by mapping changes in economic, social, cultural and built environment of the Neighborhood Level Urban Communities (NLUC): Case study of Kolkata, India

The study analyses the transformation of urban planning practice through mapping changes in economic, social, cultural and built environment of the selected NLUCs. The study then explores how entrepreneurial urbanism and neoliberalism has dominated planning practice leading to erosion of the cultural patina of Kolkata.

Xiaoping Zhang; Fengying Yan; Haiyan Lei, Tianjin University, Tianjin, China

The planning methods of Chenjia Town international ecological community in Shanghai based on ecological security

With the planning of ecological community from the theoretical discussion into practical exploration, the paper takes the Chenjia Town international ecological community in Shanghai as an example to explore the planning methods of residential areas based on the ecological security, so as to provide reference for the construction of an ecological community.

Wenjing Luo; Haijun Li, Wuhan Planning & Design Institute, Wuhan, China; Han Zou, Hubei University of Technology, China

How do universities react with cities: the case study of Wuhan, China

Cities and universities have been reacting with each other in a complex, conflicting way not only in urban morphology but also in economic, social and cultural networks. This paper takes Wuhan as an example to explore the spatial relationship between universities and cities.

Dicle Kizildere, Istanbul Technical University, Istanbul, Turkey

Emerging forms of neoliberal governance on public space: an informal business improvement district in Istanbul

This paper investigates the birth and evolution of a Business Improvement District (BID) in Talimhane, Istanbul, which is the first case of the use of this instrument of neoliberal governance in the city.

Session 2: Urban innovation part 2

2 October (Tuesday), 13:30 - 15:00

TK *Wenjing Luo; Wei Xiong, Wuhan Planning & Design Institute, Wuhan, China; Han Zou, Southeast University, Wuhan, China*

Analysis on the working-living-entertaining spatial relations of new towns based on mobile location data: the case of the national independent innovation zone of East Lake in China

By using mobile location data, we proposed a people-centred planning model which does not only describe the current human activities and interpret the reasons underneath, but also analyzes whether the current model of space use is sustainable and the future model of space supply is necessary to be changed.

Swechcha Roy; Saikat Kumar Paul; Vivek Agnihotri, Indian Institute of Technology Kharagpur, Kharagpur, India

Developing a conceptual framework for geo-spatial planning of location-allocation of schools in Indian cities

The current trends of school siting, theories about school effectiveness and approaches for meeting the social infrastructure requirement of a community is reviewed and inferred that the neighborhood school is very effective but has own limitations. The study proposes to include consumer choice in the concept of neighborhood schools.

Ronit Davidovici Marton, D.M.R Planning & Development, Tel-Aviv, Israel

The hybrid urban renewal model - Entrepreneurship, income, employment, innovation everywhere

Urbanism requires the development of economic infrastructure that places the person and a todays lifestyle as a leading asset for the city renewal. Therefore, the major goal of renewal planning is to encourage entrepreneurship, innovation, employment - everyone and everywhere. Bat Yam renewal plan is a modelling case.

Piotr Lorens; Michal Habier, Gdansk University of Technology, Gdansk, Poland

Impact of large-scale urban interventions on contemporary city centers

Large scale urban interventions have become a common development practice in contemporary cities, allowing achieving rapid changes in their urban structure. The main aim of this paper is to discuss this issue in the wider context, taking into account also social, legal, economic and infrastructural consequences of their development.

Yuan Lu; Xiangyi Wang, Urbanspace Planning And Architectural Design Co.Ltd(Shenzhen), Shanghai, China

Research on the planning of community life circle in new town based on an evaluation approach - A Case Study of Ningbo Eastern New Town in China

A research explores the evaluation and construction of community life circle, which reflects the interaction of people's daily life and space.

Reframing citizen participation for a sustainable city transition – the case of Bodø ByLab

(Session Proposal)

2 October (Tuesday), 15:30 - 17:00

Location: Stormen Library – Bodø ByLab

Planning and construction practice for Sponge City in Shanghai: experience and reference

Shanghai has carried out a series of "Sponge City" planning work, including the specific planning of overall urban level, compilation of technical guidelines, special planning of pilot areas, and the implementation of the concept and technology of sponge city. This paper systematically introduces its concrete practices and useful experiences.

Frank D'hondt, Territorial Capital Institute, Glyfada, Greece

Better planning systems for cooler countries and cities

International research made clear that most if not all spatial planning systems are not (longer) fit for the purpose of a more sustainable urban and territorial development. Based on the UN Urban Agenda and UN-Habitat's Planning Guidelines, a new method will be presented to review and reform Spatial Planning Systems.

Marcin Sliwa; Aranya Rolee; Refstie Hlilde, Norwegian University of Science and Technology, Trondheim, Norway

Urban ecological planning: principles, value positions and application in practice

The paper presents the principles of Urban Ecological Planning - an approach of urban practice that challenges and supplements outdated technocratic urban planning methodologies that are still dominant in many developing countries. The value positions of this paradigm are illustrated with examples from an extensive fieldwork in Pune, India.

Track 6

Jinbai Wang; Da Xiao; Shanghai Tongji Urban Planning and Design Institute, Shanghai, China; Chen Chen, Tongji University, Department of Urban and Rural Planning, Shanghai, China

Towards world-class lakeshore city from edge county seat: Wu xuan's over-taking development strategy accompanying the construction of Dateng Valley Reservoir

Promoting regional development by means of major projects is a developing path that China frequently adopts and should shed light on the over-taking development strategy in less developed regions or economies.

YI Zheng; Junyan Yang, Southeast University, Nanjing, China

How Urban Morphology Can Be Optimized? Research on Interactive Mechanism Between Urban Morphology and Urban

Micro Climate

This paper focusses on analysing the mechanism and effect relationship between urban micro climate and urban morphology under a global climate change background. Through an urban design project to explain the interaction between urban mirco climate and urban morphology, and how urban physical environment can be improved by optimizing urban morphology.

Session 4: Heritage planning

3 October (Wednesday), 13:30 - 15:00

TK *Renzan Qian; Huiyi Xia; Cunai Yan; Nankai Xia, Shanghai Tongji Urban Planning & Design Institute, Shanghai, China*

Research on the scopes of eco-tourism development of areas along transregional mega linear projects of China – a practice study of Yin Jiang Ji Huai Project

This paper attempts to explore an operational route and theoretical model for delimitating the scopes of the eco-tourism development of the areas along trans-regional mega linear projects, for providing significant reference to planning, construction, ecological restoration, tourism development and management of such kind of projects in China.

Renard Teipelke, Independent Consultant, Gera, Germany

Sustainability planning for small border mountain towns entering the global tourism market

This case study of sustainability planning in Mestia (Georgia) and Ha Giang (Vietnam) will reflect on the opportunities and challenges of small border towns in remote mountainous areas that are trying to enter the global tourism market as a driver for their economic development.

Xinxin Zhang; Jingsheng Li, Shanghai, China

Chinese rural area natural resource oriented town and village cool planning practice

The research discusses the rural area's 'refrigerator' role to the urban area. Two real Chinese town and village planning practices are chosen which are both natural resource oriented, but have different methods and strategies.

Sara Maldina, University of Bologna, Bologna, Italy

Landscape as a service. The potentials of integrating different approaches

The categories of "Cultural Landscape" and "Cultural Ecosystem Services" represent the leading edges of a reconceptualization process of landscape, tending to combine the environmental approach and the cultural one. Through bibliographic and comparative analyses, the contribution aims at demonstrating the potentials of an integrated approach in landscape assessment and management.

Olga Maximova, University of Rome La Sapienza, Roma, Italy/ Burundi

Values for planning

The paper presents the results of the PhD research of the author supported by the Erasmus Mundus Action 2 Programme of the European Union. The PhD research is dedicated to: The Landscape: comparison between Italy and Russia - general values for legislative and planning instrumentation.

Urban rehabilitation: realities and paradoxes in Bairro alto and Bica, Lisbon

The paper discusses the current urban reality in Bairro Alto and Bic and under the scope of the of the next Urban Rehabilitation Plan for, as part of a contribute to the Urban Planning Department of Lisbon. Critical aspects, from the research part of the work are to be presented.

Session 5: Landuse & planning systems

3 October (Wednesday), 15:30 - 17:00

TK *Wen Liu; Lee Beattie; Errol Haarhoff; Shaoyao Tang, Auckland, New Zealand*

Plan making in delivering intensification in Auckland, New Zealand: issues and challenges Drawing on Auckland experience and practice, this article investigates on the efficacy of urban planning systems to deliver outcomes well aligned with the goals of urban growth management strategies, with particular attention to delivering residential intensification and higher density housing policy outcomes.

Mthobisi Masinga; Peter Njenga; Brian Mubiwa; Maartin Friedrich, KENA Consult (Pty) Ltd., Pretoria, South Africa

Development of land-use suitability assessment criteria for South Africa

Land as a resource is limited in nature and its use is not only determined by the user but also by the capability of that land to sustain productive activities. This has led to the development of a Land Use Suitability Criteria for more appropriate and sustainable use of land.

Yuwei Huang; Hualan Design & Consulting Group Nanning, China; Cheng Yu; Xiaoting Yan, Nanning, China

The practical limitations and the reference of key technology of mixed land use

By comparing with the practice in America and considering the practice in China, there are three keys to overcome the limitations of mixed use of land.

E. Stephen Goldie, Abu Dhabi Department of Urban Planning and Municipalities, Wembley Downs, Australia

The periodic table of urbanism

Just as the Periodic Table of Chemistry identifies the physical components of our universe and is able to predict the relationships between them, a Periodic Table of Urbanism is proposed to provide a comprehensive framework for describing the "general reign of order" in our towns and cities.

Nicole Wirz, Raumplan wirz gmbh, Basel, Switzerland; Andreas Schneider, HSR University of Applied Sciences Rapperswil, Rapperswil, Switzerland

Railway hub area development in Arth-Goldau (Switzerland)

Arth-Goldau is a railway hub with a lot of development potential. To activate this a participatory approach was necessary. For the first time, a Stakeholder Process methodology was applied for the masterplanning. This double case study will report about the experiences from the project manager's and the urban planner's perspective.

Track 1

THE GLOBAL VIEW:
Climate Change Impacts, Sustainability and Resilience

Harnessing the Opportunities and Understanding the Limits of America's State Level Climate Action Plans

Serena E. ALEXANDER, San Jose State University, the United States of America

Synopsis: This paper is an evaluation of America's state-level climate action plans focusing on their emissions reduction outcomes as well as their development procedures and foundations; goal setting, policy coverage and regional coordination; implementation provisions and conditions; and implementation mechanisms and monitoring results.

1. Introduction

Climate change is one of the most daunting problems of our time requiring innovative responses to its causes and consequences. In the United States, the long absence of strong federal leadership along with growing public awareness of the problem created a fertile ground for state-level climate action planning. To date, 34 states have adopted Climate Action Plans (CAPs). The question that this paper addresses is: Does state-level climate action have the potential to reduce carbon emissions significantly? This question was examined by assessing the relationships between CAPs, emissions reduction targets, plan implementation and emissions mitigation.

Evaluation of state level CAPs is important and interesting as it: 1) highlights the potentials and constraints of sub-national level action as laboratories of democracy and incubators of innovation; and 2) provides an opportunity for the planning profession to realize its new role of making global impacts while acting innovatively at local and regional levels. Moreover, evaluation of state CAPs will identify areas of strength and weakness in sub-national climate action. This can help to design a more effective federal level policy. By focusing on CAP implementation, this evaluation can also provide lessons for sub-national entities about implementing such plans and policies.

This paper is the first evaluation of the current generation of state level CAPs that focuses on implementation and actual reductions in GHG emissions. Wheeler (2008) systematically reviewed the first generation of state-level CAPs in terms of their goals, their basic strength and weaknesses, included or left out measures, and ultimately issues and problems likely to impact implementation. Yet, Wheeler's study did not assess the relationship between CAPs and actual GHG emissions reductions. Drummond (2010) compared states with and without CAPs, asking the question of whether or not these plans have been successful in reducing GHG emissions significantly. While Drummond (2010) identified some of the elements within CAPs that are associated with the greatest reductions, the author did not assess the relationship between implementation and GHG emissions mitigation. Drummond (2010) also focused on CO_2 energy emissions generated for use in the residential, commercial, and transportation sectors, and excluded the industrial sector of the economy—which is among the most controversial. The scholarly literature does not provide an assessment of possible relationships between variations in climate action plans across the nation, implementation of state CAPs and their effectiveness in reducing GHG emissions, which is one of the goals of this paper.

This paper is part of a two-pronged evaluation of state CAPs with two major components: 1) an assessment of CAP implementation and GHG mitigation potential through a content analysis of plan documents and available information about planning processes; and 2) a panel regression model depicting and assessing the relationships between CAP types based on the stringency of targets, rigor of implementation, and reductions in energy related carbon dioxide emissions from all end-use sectors (i.e. transportation, residential, commercial, industrial, and electric power). The general hypothesis that this phase sets out to investigate is: CAPs result in GHG emissions mitigation beyond the trend.

2. Research Methods

2.1 Phase 1: Content Analysis of State-level Climate Action Plans

The goal of this phase was to systematically assess implementation and GHG emissions mitigation potential of state-level CAPs through a content analysis of plan documents and publically available information about planning and implementation processes on state websites. Broadly speaking, the content analysis involved four major themes: 1) General information about the CAP and its development and adoption processes; 2) CAP GHG emissions mitigation potential claimed to be achievable through its goals, array of policies, mitigation targets, and adherence to any regional initiative; 3) Implementation provisions or conditions that have been suggested by the literature to be linked to successful implementation, such as identification of funding sources and agencies responsible for implementation; and 4) Implementation mechanisms, such as voluntary programs, financial incentives, carbon tax or cap-and-trade, recommended and employed by the CAP to reach goals and/or targets.

The CAP evaluation framework used for this study was developed in three steps: 1) a preliminary evaluation framework was derived from the literature on plan evaluation and principles of sub-national climate action planning; 2) the preliminary framework was then validated through three in-depth interviews with climate action planning experts; and 3) it was tested and refined through double coding four plans in two stages—double-coding two plans to test the reliability of the coding instrument and making necessary changes for the clarity of questions; immediately followed by double-coding two additional plans to assure consistency in coding throughout the coding process. The framework includes four major elements as discussed below and presented in Figure 1.

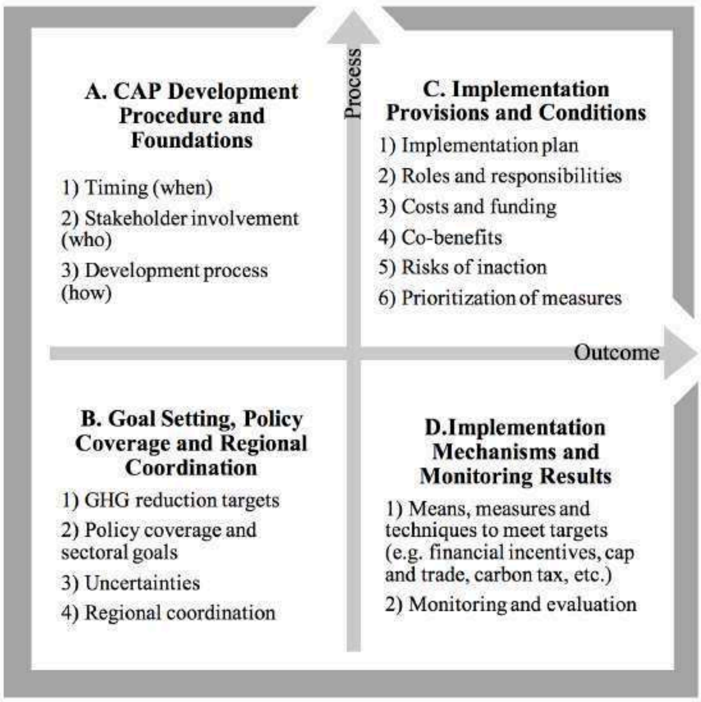

Figure 1. CAP Evaluation Framework

A. CAP Development Procedure and Foundations

The first element focuses on three main qualities of the planning process: 1) timing (when): when was the plan developed, adopted and updated; 2) stakeholder involvement (who): a) what agencies and organizations were engaged in the development of the CAP?, b) what entities provided leadership, facilitation, funding and technical support, and c) procedures through which input was received from entities representing government, industry, nongovernmental organizations, academia and the public; and 3) development process (how): what techniques were used to develop a plan and select specific policy recommendations.

B. Goal Setting, Policy Coverage and Regional Coordination
The second element deals with four key dimensions of CAPs: 1) targets: what are the nearest-term, intermediate and ultimate targets; 2) policy coverage and sectoral goals: what emission sectors have been considered, and what goals have been set for each sector; 3) uncertainties: whether uncertainties in Business as Usual (BAU) emissions and impacts of policies have been considered, and what measures or analyses have been used to take uncertainties into account; and 4) regional coordination: which of the multi-state climate initiatives (if any) has the state participated in.
C. Implementation Provisions and Conditions
The third element assesses conditions linked to implementation success, according to the evaluation literature. These provisions and conditions are: 1) implementation plan; 2) roles and responsibilities; 3) funding and cost of policy measures; 4) specification and analysis of externalities or co-benefits of each action or the entire CAP; 5) identification and analysis of risks of inaction; and 6) selection and prioritization of policy measures.
D. Implementation Mechanisms and Monitoring Results
The final element of the CAP evaluation framework is implementation mechanisms recommended or employed by the CAP to reach its goals and targets. In contrast to the previous element that solely relies on the content of the CAP to assess its implementation potential, this step also includes an analysis of other available evidence regarding the implementation of the plan. More specifically, evidence of CAP implementation or the lack thereof was found through searching the websites of governmental agencies or other organizations and entities that have either developed or published the CAP or are identified in the CAP as the responsible entity for implementation. This information was then crosschecked with state-specific data available through U.S. EPA, C2ES and the Center for Climate Strategies websites.
Implementation is defined as specific commitments made by the state to carry out policy actions recommended by the CAP, such as legislation to mitigate climate change. Implementation mechanisms are means, measures and techniques through which the state plans to reach CAP targets or goals. These include: voluntary and negotiated agreements; technical assistance, financial incentives; targeted spending (e.g., on public transportation); codes and standards; cap and trade; carbon tax; pilots and demos; information, education and outreach; research and development; emissions reporting and disclosure; and any hybrid combination of these mechanisms. In addition to implementation evidence, this step includes examining methods used to monitor and evaluate CAP implementation, such as progress reports, and plan and emissions inventory updates.
Once I completed the CAP evaluation form for each state, I then organized the collected data into four tables. The analysis of these tables revealed that while state CAPs vary in the details of their processes, components and characteristics, they can be classified into six major CAP types. These 6 types were not predefined; instead, they emerged from the analysis of collected qualitative data. The CAP types were used as an input to the regression model of the second phase. CAP categories are based on two important variables: targets and implementation. The findings section explains in detail what these categories are. There were several reasons to focus on these two variables. First, there is a gap in the literature about the relationship between targets, implementation and emissions mitigation. Second, the plan evaluation literature stresses the importance of goal-setting (i.e. targets) and implementation (see, for example, Baer, 1997; and Berke and Godschalk, 2009). Third, interviews with experts in the field indicate that targets are important as they serve as "the starting point," "the vision," "a motivational factor," "guide to achieving the objectives" and "[a] link between scientific [mitigation] requirements and planning." Implementation, on the other hand, is "extremely" important because "the plan is not the end goal, but a way to actually achieve the emissions reductions," and "[implementation is] the area that almost every place falls down on." Finally, comparing targets and implementation is realistically achievable, whereas details about the CAPs (e.g. the specific combination of policy packages) and planning processes (e.g. rigor of stakeholder engagement) cannot be practically reduced to simplified yet valid categories.

2.2 Phase 2: State-level CAPs and Energy-Related Carbon Dioxide Emissions

The second phase builds upon the data and analysis of the first phase. After assigning each state a CAP category based on the rigor of targets and stringency of implementation, I used a panel regression model to isolate and assess the impact of state level CAPs on carbon emissions. The regression coefficients, if statistically significant, show a reduction in per capita energy-related CO_2 emissions, holding all other variables constant. The specific regression model that I have used is random-effects Generalized Least Squares (GLS) regression model for panel (time-series) data. This model is appropriate when there is reason to believe that differences across entities have some influence on the dependent variable. Random-effects GLS model is suitable in this case because specific characteristics of states are most likely related to their energy-related CO_2 emissions. Another advantage of this model is that one can include time-invariant variables, such as geographic location.

The panel regression model includes 48 continental states and years 1990 to 2013, yielding a dataset of 1,104 observations. I excluded Alaska, Hawaii and Washington, DC due to lack of data for a number of independent variables and uniqueness of circumstances of these entities. Year 1990 was selected because it is the most common baseline year adopted by state level CAPs. This is because the Kyoto Protocol used 1990 as its base year, and because most states adopted the Kyoto goal or its revised versions, they also picked 1990 as their baseline year (Wheeler, 2008). Table 1 lists the dependent and independent variables as well as variable explanations, expected sign of regression, and data sources.

The dependent variable measure is derived from EIA State Energy Data System (SEDS) that is annual time-series data extending back to 1960. Emission estimates are based on energy consumption data from EIA's State Energy Consumption, Price, and Expenditure Estimates (SEDS). The dataset includes energy-related emissions for five energy-use sectors (i.e. transportation, residential, commercial, industrial, and electric power) and emissions from all sectors combined.

Several changes were made to the combined emissions to develop an appropriate dependent variable. First, I divided emissions by population to obtain per capita emissions. By doing so, I normalized emissions between small and large states and controlled for possible effect of population increase or decrease (e.g. in-migration vs. out-migration) on emissions. Second, I calculated change in emissions as a measure of progress towards emissions reductions. The change was calculated compared to most popular baseline year emissions (i.e. year 1990) because the baseline year is what plans compare their progress with. Furthermore, this controls for the effect of historic dependency on coal for producing electricity (coal-fired power plants). If I were to use emissions as opposed to change in emissions, I would have to control for differences in initial energy endowments (e.g. coal-fired power plants, hydroelectric power, and nuclear power).

The model involves a number of independent variables to explain part of changes in emissions. I am particularly interested in the potential impacts of climate action plans, their targets and implementation on emission changes. I treated state level CAPs--categorized into 6 groups--as a nominal variable. Thus, the model compares each category to a No-CAP alternative. I assigned the appropriate CAP category to each state the year the plan was adopted. Therefore, the model also compares each state before and after the adoption of the plan.

Another independent variable that attracts planners' interest is urban compactness as opposed to sprawled development. There is considerable evidence in the planning literature that sprawl is linked to higher levels of emissions when compared to a more compact development pattern (see for example, Ewing, Bartholomew, Winkelman, Walters, & Chen, 2008, pp. 107–111; Ewing & Rong, 2008; Glaeser & Kahn, 2008; and Randolph & Masters, 2008, among others). My compactness variable is derived from a multi-factor sprawl index published by the Metropolitan Research Center at the University of Utah in April 2014 and later in the year by Smart Growth America. This research is an update and refinement of a sprawl measure released in 2002. Using the refined method of 2014, sprawl indices are calculated for years 2000 and 2010. The average compactness score is 100, and greater values indicate that an area is more compact. I used the county-level sprawl indices to compute average state-level compactness for years 2000 and 2010. I interpolated sprawl indices for the missing years. Because sprawl indices changed slightly between 2000 and 2010 (with the same most compact, most sprawled or average areas in both years), linear interpolation is an appropriate method.

Variable	**Explanation**	**Expected Sign of Regression Coefficient**	**Source & Date Downloaded**
Change in emissions per million persons (DV)	Energy CO_2 emissions for current year minus same for 1990	Not applicable	U.S. Energy Information Administration
Climate action planning (CAP Types)	Categorical variable for state climate action planning efforts	Negative, since climate action planning is meant to reduce emissions through a wide array of policy options and increasing awareness	U.S. Environmental Protection Agency (EPA) list of states with CAPs; and Data collected through Phase 1 of this study
Change in unemployment rate	Unemployment rate (%) for current year minus same for previous year	Negative, due to decreased economic activity, and by extension, emissions	Bureau of Labor Statistics (BLS)
Change in per capita income	Per capita income for current year minus same for previous year	Positive, since states with higher income tend to consume more energy	Bureau of Economic Analysis (BEA)
Change in regional energy prices	Change in regional energy prices for current year minus same for previous year	Negative, since higher prices reduce consumption	Bureau of Labor Statistics. Consumer price indices program.
Democratic presidential vote %	% of vote for Democratic presidential candidate in nearest election	Negative, since states with higher percentage of democratic vote tend to be more concerned about the environment	Presidential Elections Data extracted from UC Santa Barbara's The American Presidency Project
Heating degree days (HDDs)	Annual heating degree days weighted by population as a measure of heating energy demand	Positive, since greater number of HDDs means greater demand for energy	National Climatic Data Center
Cooling degree days (CDDs)	Annual heating degree days weighted by population as a measure of cooling energy demand	Positive, since greater number of CDDs means greater demand for energy	National Climatic Data Center
Change in percent GDP from carbon-intensive manufacturing industries	GDP from carbon-intensive manufacturing divided by the size of the economy for current year minus same for previous year	Positive, since states with larger share of carbon-intensive industries relative to the size of their economy tend to consume more energy	Bureau of Economic Analysis (BEA) NAICS
Change in percent GDP from carbon-intensive non-manufacturing industries	GDP from carbon-intensive manufacturing divided by the size of the economy for current year minus same for previous year	Positive, since states with larger share of carbon-intensive industries relative to the size of their economy tend to consume more energy	Bureau of Economic Analysis (BEA) NAICS
Compactness index	State level average compactness calculated from county level composite sprawl score that considers density, land use, activity centering and street connectivity	Negative, since urban compactness reduces VMT and thus transportation emissions	Smart Growth America Measuring Sprawl 2014
Interstate energy trades	Controls for the effect of interstate electricity trades by creating a credit for electricity exporting states and debit for importing states	Positive, since energy exporting states emit carbon for producing electricity	U.S. EIA
Regions	Regions as defined by BLS consumer energy price indices	--	Bureau of Labor Statistics (BLS)

Table 1. Variables

It is also important to control for other variables that can potentially be correlated with the dependent variable, and thus, can provide a plausible alternative explanation for reductions in emissions. Change in energy prices, unemployment, income, and industrial mix are the most important of these variables. The logic behind including these variables comes from the potential relationship between the economy and changes in emissions. Explanation of these variables are provided in table 1, but two of them require further clarification. Following Drummond (2010) I used change in regional energy prices as opposed to state-level energy prices because change in energy prices is one of the major effects of CAP implementation. If I were to use change in state-level energy prices, this could have dramatically underestimated the impact of the CAPs. One limitation of this method, however, is the potential autocorrelation problem. I controlled this effect by adding the regions--where the states were assigned to in the regional consumer energy prices dataset--to the model. Regions are also considered geographic variables, and therefore also control for the potential relationship between location and emission changes.

Change in industrial mix is another variable that can potentially impact emission changes. For example, a shift in industrial output from energy- or carbon-intensive products (e.g. steel) to low-energy products (e.g. computer equipment) can result in emissions reductions. It is very difficult, if not impossible, to track industries within states to know whether a switch in industrial output is responsible for emissions changes. However, it is possible to measure the dependency of a state's economy on carbon-intensive industries and its changes over time. To control for potential effects of industrial mix changes, I calculated change in percent Gross Domestic Product (GDP) from carbon intensive industries. I included two variables related to change in industrial mix in my model: change in percent GDP from carbon-intensive manufacturing and non-manufacturing industries. Generally, carbon intensive industries emit large amounts of GHGs per unit of good produced, and their energy costs are a large portion of their total costs (Zabin, Buffa, & Scholl, 2009). According to the most recent U.S. EPA inventory of GHGs, which is based on an analysis of EIA energy consumption data, several industrial activities consume a lot of energy and emit large amounts of GHGs. Within manufacturing activities, the most carbon-intensive industries are: Petroleum refineries; primary metals (e.g. iron, steel, and aluminum); chemicals; pulp and Paper; nonmetallic mineral products (e.g. cement and glass); and food (EPA 430-R-15-004, 2015; Zabin, Buffa, & Scholl, 2009). Among non-manufacturing industries, construction, mining, and agriculture are considered energy and carbon-intensive (EPA 430-R-15-004, 2015).

In my models, I also included two climatic variables: heating degree days and cooling degree days that show heating or cooling fuel demand on a state-wide basis. The logic behind including these two variables is that greater number of heating or cooling degree days result in greater demand for energy consumption.

Lastly, I controlled for the effect of interstate electricity trade. In most states, electric power generation is the largest source of CO_2 emissions from fossil fuel combustion. Some states are net exporters of electricity, whereas others are net importers of electricity. One way to account for the effect of interstate electricity trades is by constructing interstate carbon credits and debits and calculating an indicator of the full carbon effects of a state's electricity consumption by adding or subtracting emissions with traded electricity. Jiusto (2005) has offered a complex method to deal with carbon emissions from cross-border power flows that has been used for this research.

3. Findings

3.1 Phase I Findings: CAP Types

Broadly speaking, there are two major types of CAPs based on targets: 1) CAPs that set a GHG emissions reduction target—often following an executive order from state governor that sets such targets or appoints a climate change sub-cabinet or advisory group to do so; and 2) CAPs that do not set any emissions reduction target. The vast majority of state level CAPs (30 out of 32) set at least one target for GHG emissions reduction within their jurisdiction; however, sometimes the targets are tied to multi-state climate change planning commitments. For example, the states that partnered in The Western Climate Initiative (WCI), Midwest Greenhouse Gas Reduction Accord (MGGRA) and Pacific Coast Collaborative (PCC), to name a few, agreed to collectively set a regional emissions target. This resolution is either based on targets originally established by participating states or otherwise are reflected in state level plans, with states proposing to either meet or exceed the regional target. Several states have also chosen to join such multi-state initiatives as observers. Observer states often set matching or comparable reduction targets, but normally do not commit to the implementation mechanism set by the regional initiative—such as a regional cap-and-trade program.

State CAPs have set targets that may be single-step, two-step or multiple-step. Typically, CAPs with two- or multiple-step targets set a long-term goal to be reached by 2050 with a midterm target to be achieved by 2020 or 2025. 2050 marks the middle of the century; it is a date often used—in addition to the end of century mark--in scientific scenario analyses to illustrate the impacts of climate change and/or define necessary reductions to possibly avoid the most catastrophic impacts. A number of states also set interim target(s)--to help them make progress towards the midterm target. For example, New Hampshire sets a midterm goal of reducing emissions 20% below 1990 levels by 2025 and specifies five interim targets to reach the 2025 goal. Following the Kyoto Protocol, the most common baseline year is 1990 for state level CAPs, with some states setting emissions of the year 2000, 2005 and 2006 as their baseline. Thus, the first step commonly involves either going back to 1990 emissions levels or lower than that (5%, 10% or 20% lower).

I define long-term ambitious target as: aiming at or close to scientific requirements for emission reductions in the United States by mid-century as interpreted by the CAPs. It is important to note that scientific requirements vary based on different targets for stabilization of atmospheric GHG concentrations. In other words, emission allowances for all industrialized nations (including the U.S.) are different for various GHG concentration levels. Therefore, scientists have developed several scenarios for stabilization levels and mitigation requirements. Gupta et al.'s (2007) systematic analysis of the literature suggests that under low and medium stabilization levels, developed nations would need to cut their emissions substantially (i.e. 40% to 95% below 1990 levels)--even if developing nations achieve significant reductions. Nonetheless, virtually all states with an ambitious target have interpreted scientific requirements for emission reductions as approximately 75% to 85% below 1990 levels in the long run (around 2050).

A short-term target, on the other hand, does not meet the requirements of a long-term ambitious target. A short-term target does not preclude a state from adopting rigorous policy measures or developing an ambitious target in the future. Yet, in and of itself a short-term target is insufficient to guide the state emissions reduction efforts in the long run to meet the scientific requirements. In other words, a short-term target lacks a long-term vision. Additionally, since state level short-term targets tend to be low, having a short-term target only can imply elimination of rigorous policy options from consideration. For instance, South Carolina sets a target to reduce emissions to 5% below 1990 levels by 2020; no long-term goal is set.

In addition to the targets, CAPs differ in terms of the stringency of their implementation. I classified a CAP in the "strong evidence of rigorous implementation" group if: there is stringent state level legislation governing the implementation of the CAP with lead or other responsible agencies identified and clear monitoring and evaluation mechanism, or otherwise, there is evidence of extensive programmatic interventions with progress toward goals clearly documented in some type of a progress report, implementation plan, updated inventory or online tool. I classified a CAP in the "some evidence of implementation" group if: there is some evidence of early actions or programmatic interventions; yet, there is evidence of stopped funding, discontinued or sporadic climate council or advisory group meetings or documents clearly showing that the state is not on track to reach its goals although some programs have been implemented. I classified a CAP in the "no or limited implementation" group if: I found no evidence of implementation whatsoever, insufficient evidence of implementation, or evidence of lack of implementation—meaning that it is clearly stated on the relevant state agency website that the state has stopped the CAP process after its adoption. I considered evidence of implementation insufficient if: there were either very limited information provided and/or I found a few programs that seemed relevant but these were not tied to the CAP or its other documents whatsoever. Considering the type of CAP targets and the rigor of their implementation, plans can be broadly categorized into 6 groups described below and illustrated in Table 2.

CAP Type	Key Identifiers		States with a CAP (Total Analyzed: 32)
	Target(s)	Implementation	
Type 1	No Target	No or limited evidence of implementation	4 CAPs: Missouri, Nevada, Ohio, Utah
Type 2	A short-term target only	No or limited evidence of implementation	5 CAPs: Arkansas, Illinois, Kentucky, North Carolina, South Carolina
Type 3	A long-term ambitious target	No or limited evidence of implementation	5 CAPs: Arizona, Iowa, Montana, New Mexico, Wisconsin
Type 4	A short-term target only	Evidence of some implementation	3 CAPs: Florida, Pennsylvania and Virginia
Type 5	A long-term ambitious target	Evidence of some implementation	7 CAPs: Maine, Michigan, New Jersey, New York, Rhode Island, Vermont, Washington
Type 6	A long-term ambitious target	Stronger evidence of rigorous implementation, monitoring and evaluation	8 CAPs: California, Colorado, Connecticut, Maryland, Massachusetts, Minnesota, New Hampshire, Oregon

Table 2. A Summary of CAP Types

3.2 Phase 2 Findings: CAPs and Change in Energy-related Carbon Dioxide Emissions

This section focuses on findings from the second phase of the study: Analyzing the relationship between state level CAPs and change in energy-related carbon dioxide emissions from all sectors (i.e. dependent variable). Sectors that contribute to energy-related carbon dioxide emissions include commercial, industrial, residential, transportation and electric power. Based on findings from the first phase, I examined the relationship between six types of CAPs and change in energy-related carbon dioxide emissions controlling for other economic, climatic, geographic and political variables. Table 3 provides descriptive statistics for the independent variables.

Variable	**Mean**	**Standard Deviation**	**Minimum**	**Maximum**
Cooling degree days (CDDs)	1071.74	804.68	42.00	3827.00
Heating degree days (HDDs)	5243.83	2085.25	430.00	10810.00
Change in % GDP from carbon-intensive manufacturing	0.00	0.01	-0.05	0.07
Change in % GDP from carbon-intensive non-manufacturing	0.00	0.01	-0.08	0.05
Change in regional energy prices	6.23	15.43	-45.84	34.31
Democratic presidential vote %	0.46	0.09	0.25	0.68
Compactness	95.07	11.24	64.29	129.03
Change in per capita personal income	1081.94	953.06	-5781.00	7527.00
Change in average unemployment	0.05	0.99	-2.54	5.51
Change in interstate energy trade	1008.41	3928213.00	-25200000.00	26600000.00

Table 3. Descriptive Statistics for Independent Variables

My goal with this model was to explain variations in emissions with CAP types as well as a set of control variables. The direct way that CAPs can result in carbon emissions reduction is through implementation of CAP policies and measures. I collected information about implementation of state level CAPs in the first phase. CAP types include information about implementation. For example, I found evidence of rigorous implementation for type 6 CAPs. However, implementation is only one way that CAPs can impact carbon emissions. There are a number of indirect ways that CAPs can lead to reductions in carbon emissions. Perhaps the most important of these indirect mechanisms is the planning process. Altschuler argued that "planning is more important than any plan" (quoted in Baer, 1997, p. 336; and in Drummond, 2010, p. 416). The planning process, especially when various interest groups and the public are actively involved, can yield outcomes. Innes and Booher (1999) argued that a good consensus building process can have outcomes beyond the immediate and/or identifiable results at the end of the project. These outcomes, according to Innes and Booher (1999), can appear after the completion of the plan development process or outside its boundaries in the form of new collaborations, new discourses, learning that extends into the community, and so forth. In the case of state level CAPs, this means that the planning process can indirectly yield outcomes outside the boundaries of the plan in the form of other relevant policies or programs that reduce carbon emissions. Indeed, analyzing these indirect

mechanisms is beyond the scope of this study. Yet, acknowledging the possibility of these indirect effects can help us understand why a CAP may result in carbon emissions reductions even the implementation has quickly faded away after the plan development process, or there is no evidence of direct implementation whatsoever.
Table 4 shows the results of the first regression model. Total number of observations are 1,104, and the number of groups, which is the number states included in the model, is 48. The overall R2 is a reasonable .25, meaning that the model explains a quarter of the variations in state level energy related carbon emissions.

Variables	**Coefficient**
CAP Type 1. No target; No or limited implementation	-2.738705**
CAP Type 2. Short-term target; No or limited implementation	-1.160499**
CAP Type 3. Ambitious target; No or limited implementation	-0.8332563*
CAP Type 4. Short-term target; Some implementation	-2.36251**
CAP Type 5. Ambitious target; Some implementation	-1.546992**
CAP Type 6. Ambitious target; Rigorous implementation	-1.096547**
Cooling degree days (CDDs)	-0.0004712

Table 4. Effects of State CAPs on Per Capita CO_2 Energy Emissions

All CAP types are statistically significant at the 0.01 level (p<.01) except for type 3 CAPs (long-term ambitious target, and no or limited evidence of implementation), which is significant at the 0.05 (p<.05) level. Coefficients are negative for all CAP types indicating that, in the years since 1990, all state level CAPs reduced emissions compared to the states without CAPs, holding all other variables constant. CAP coefficients for all groups range from -0.83 to -2.74. This means that, in the years since 1990, on average states with a CAP reduced per capita emissions by about 1.79 metric tons, when compared to the states without CAPs and controlling for other economic, climatic, geographic and political variables. Ironically, what this model shows is that CAPs, regardless of their targets and implementation, result in carbon emissions reduction. Nevertheless, the model does not reveal mechanisms through which these CAPs work. In other words, the model does not show how exactly CAPs with no or limited evidence of implementation lead to carbon reductions. Although causal mechanisms between types 1, 2 and 3 CAPs (with no or limited evidence of implementation) and emissions reductions are uncertain and unknown, there are a number of possible explanations. One explanation for the statistical significance of the relationship between all types of CAPs, including the ones with no sign of implementation (i.e. types 1, 2 and 3), is the possibility of indirect effects of the planning process on carbon emissions reduction. State level climate action planning is typically a complex process involving numerous stakeholders. It is likely that these CAPs have resulted in other environmental policy measures or programs with similar carbon reduction benefits. Considering that most state CAPs have benefitted from fairly extensive consensus-building processes, the possibility of indirect effects should not be disregarded.
One surprise is that type 6 and 5 CAPs, which have an ambitious long-term target and stronger evidence of implementation, have a slightly smaller coefficient than the type 1 CAPs with no specified emissions target and no or limited evidence of implementation. One possible explanation is that the states with a types 6 or 5 CAP had already achieved lower carbon emissions through other environmental policy measures with emissions reduction

benefits, making it difficult to reduce emissions after the adoption of the CAP. Another possible explanation is related to a general critique of state level CAPs: low short-term targets (Alexander, 2016). Because of these low 2015 or 2020 targets, it is possible that implementation of the CAPs have not yet resulted in reductions significant enough to reveal potential strengths of types 6 and 5 CAPs. The effects may appear later, if these states continue to rigorously implement the ambitious long-term goals set by the CAPs. Ultimately, the reason behind these findings may simply be a lag between implementation of measures and appearance of results.

Interestingly, type 4 CAPs, with a short-term target and some evidence of implementation, have the second largest coefficient (after type 1 CAPs). This suggests that CAPs with a short-term target may also be successful in reducing emissions—at least in the short run. Again, the possible advantage of having an ambitious long-term target may not be apparent yet—especially because CAPs with a stringent long-term target still have a weak near-term target.

Among other variables of interest, compactness is also statistically significant at the 0.01 level ($p<.01$). Its negative coefficient is indicative of an inverse relationship between compactness and emissions, or a positive relationship between sprawl and emissions. This means that the development decisions of communities can have measurable impacts on emissions.

From the set of economic variables, year-to-year changes in per capita personal income and energy interstate trade are statistically significant at the 0.01 level ($p<0.01$). The positive coefficient of these two variables indicates that increases in per capita personal income and energy interstate trade are associated with greater energy related emissions. Because per capita personal income is a measure of personal wealth, this means that, when all other variables are held constant, increase in personal wealth results in greater contribution to emissions through increased consumption of energy. Energy interstate trade is a measure of interstate electricity exports and imports. For net exporters of electricity, this variable is positive; and for net importers, it is negative. In the process of electric power generation, producers of electricity emit carbon dioxide.

Two other economic variables, percent GDP from carbon-intensive manufacturing and non-manufacturing, are measures of dependency of a state's economy on industries that emit large quantities of GHGs per unit of goods or services produced. The first of the two, percent GDP from carbon-intensive manufacturing is not statistically significant in explaining variation in per capita carbon emissions. However, the second variable--percent GDP from carbon-intensive manufacturing--is statistically significant at the 0.05 level ($p<0.05$), and its coefficient is 12.55. Thus, a 1% increase in GDP from carbon-intensive manufacturing leads to an increase of 12.55 metric tons of carbon emissions per capita. This means that the higher the dependence of a state's economy on the three carbon-intensive nonmanufacturing industries--construction, mining, and agriculture—the greater their energy-related carbon emissions would be, when all other variables are controlled for. From a policy perspective, this could also represent an opportunity for significant emissions reduction, for example, through encouraging the use of efficiency measures in these industries.

The remainder of economic variables--namely changes in average regional energy prices, and average unemployment--are not significant at the 0.05 level. The two climatic variables--heating degree days and cooling degree days--as measures of need for energy consumption to air condition buildings are not statistically significant either. Among regions, being geographically located in the West Region is negatively correlated with changes in per capita carbon emissions ($p<0.01$). Lastly, percent democratic vote in the nearest presidential elections is not statistically significant in the model.

4. Conclusions and Implications for Climate Action Planning

Across America, states have taken a range of approaches to mitigate greenhouse gas emissions within their boundaries and beyond. Findings from this study show that all types of CAPs, regardless of the targets and status of their implementation, result in measurable yet modest reductions in carbon emissions, when a set of economic, climatic, political, and geographic variables are controlled for. This can be explained by the fact that climate action planning is a complex process, and can yield outcomes beyond implementation of policy measures specified in the CAP. Mechanisms such as learning that extends into the lower levels of government and the community as a result of the involvement of the public and various interest groups in the planning process, or the development of other related plans, policies or frameworks (with the potential to reduce emissions) that can emerge from a CAP process. Analysis of these mechanisms including the dynamics between CAP processes and indirect outcomes is beyond the scope of this study, but the findings suggest that this can be an interesting topic for future research. One limitation of CAP content analysis is that data about stakeholder processes are limited to what is provided in the plan, and there is a wide variation in the breadth and depth of information included in different CAPs. In-depth interviews with stakeholders involved in CAP processes would enhance our understanding of CAP dynamics beyond what is publically available through documents.

Another limitation of the model presented in this study is that it does not include a local climate action variable. Municipal and community level CAPs may or may not be an extension of the state level CAP. In California, for example, many cities adopted a CAP due to a state level mandate. In Ohio, on the other hand, Cleveland and Akron adopted a CAP in 2009, two years before the state of Ohio released its first CAP. Unlike Ohio's CAP, Cleveland's plan set two goals for GHG emissions reduction, and provides evidence of progress. Regardless of their relationship with the state level CAP, these local plans can be successful in reducing emissions. Future research can assess the potentials, effectiveness, strengths and weaknesses of these local CAPs. Collecting comparable monthly or annual emissions data at the city and metropolitan levels can provide an opportunity for evaluation of these CAPs.

Currently, state CAPs with an ambitious target and evidence of implementation have not proven greater emissions reductions than those with a short-term target and limited evidence of implementation. As explained earlier, this can be due to weak short-term targets, a lag between implementation and results becoming visible, the possible effect of indirect CAP processes, and/or the difficulty of emissions reductions beyond what has already been achieved through other actions by the states with a type 5 or 6 CAP. This finding is another evidence that CAPs are very complex involving many factors, and their success in significantly reducing emissions can be influenced by various dynamics. It is important to note that the regression model presented in this study is exploratory. Better understanding of possible mechanisms that link CAPs to emissions reductions are needed to develop an improved model.

Evidence from the content analysis of state CAPs shows that climate action is a heterogeneous phenomenon within various jurisdictions across the nation—ranging from no action at all to rigorous implementation of stringent climate regulations. This heterogeneity, in and of itself, irrespective of potentials and constraints of individual action taking jurisdictions, can be problematic and highlights the importance of federal level action. This is not only because of carbon leakage potential, but also due to sending mixed messages about our stance on climate action as a nation—which can hinder global efforts to mitigate emissions. Lack of strong federal leadership on climate planning has created an opportunity for innovative bottom-up climate action; however, this has also resulted in a patchwork of climate action across the nation. A robust federal leadership on climate protection can level the playing field for all jurisdictions, diminish possible carbon leakage to the states with minimal regulations, support the implementation of lower-level CAPs, and finally enhance chances of global cooperation against the threat of climate change.

Lastly, we should move beyond energy efficiency measures to be able to reduce emissions sharply. Findings from this analysis show that CAPs are reducing energy-related carbon emissions in a measurable but modest amount. Continuing the current trend of emissions reductions is insufficient to reduce emissions dramatically to meet the long-term targets. Achieving greater reductions involves major technological and policy innovations as well as lifestyle changes. A content analysis of state CAPs shows that Transportation and Land Use

(TLU) targets are low compared to the sector's contribution to total emissions (Alexander, 2016). This suggests that we have not yet developed the tools and measures to reduce emissions from TLU significantly and efficiently. This is a great opportunity for planners, policymakers and urban scholars to develop creative solutions for smarter urban living. It is impossible to illustrate what future innovations will exactly entail or what can be achieved through major technological advancements. However, planning tools and techniques that involve wide stakeholder participation and scenario planning that challenges current thinking, can be used as a framework to create an ecosystem amenable for innovation. Through these techniques, various decision-making alternatives--ranging from urban development decisions to lifestyle choices—are converted into dynamic stories that involve "credible series of external forces and actors' responses" (Peterson, Cumming, & Carpenter, 2003, p. 361). Additionally, these techniques can provide a forum for not only policy creation but policy implementation and evaluation. Stakeholders involved in the visioning process are likely to find that some outcomes or processes represent a future or a situation that is more desirable than others. And then the question is: how do we get from the present to the desired situation. The excitement about climate action planning simply begins there.

Climate Change Strategy for the Urban Planning and Development Sector in Qatar

Author: Mooza Al-Kuwari
Co-Auther : Khondker Rahaman

1. Introduction

The State of Qatar lies between latitudes `27 24° and `10 26° north of the equator and longitudes `45 50° and `40 51° east Greenwich line. Qatar is a peninsula situated in the middle of the west coast of the Arabian Gulf and extends northward into the Arabian Gulf. (MDP&S, 2017)Qatar is about 160 km in length from the south to the far north and about 89 km in width from east to west. Its total area is about 11,627 square kilometers. (MDP&S, 2017)Most of Qatar is a flat and rocky, sandy plain. Low hills punctuate the landscape, west and central, with massive sand dunes in the southeast.

The climate of Qatar is of a desert nature with high temperatures especially in the summer. The mean high temperatures in the summer are characterized with a relatively high humidity, especially in coastal areas. Winter in Qatar is warm in general with a drop in temperatures to low levels from time to time. Qatar suffers from scarcity of rainfall throughout the year. (MDP&S, 2017)

In the last 30 years Qatar has seen immense growth in industry, population and urban settlements. This has been driven by the oil and natural gas reserves that have been developed, contributing to one of the highest per capita Gross Domestic Product (GDP) in the world (Forbes, 2012). In response to this growth, a number of documents have been developed to guide and manage the impacts associated with these changes, including:

- Qatar National Vision 2030 (QNV 2030)
- Qatar National Development Strategy 2011-2016 (QNDS 2011-2016)
- Qatar National Masterplan (QNMP)

Qatar National Vision QNV 2030 has paid a special attention to the environmental theme, which is unparalleled in many Middle Eastern countries, and has dealt with the environmental development pillar on an equal footing with the rest of QNV four pillars; human development, social development and economic development.

Recent studies in the region reveal that the urban development and the economic growth in Qatar will be adversely affected by the impacts of climate change in near future. The 2009 report of the Arab Forum for Environment and Development on the Impact of Climate Change on Arab Countries (AFED, 2009) reveal that Qatar will be subject to high risk of inundation of its coastal areas, due to predicted Sea Level Rise (SLR) in the Arabian Gulf. Qatar's geography consists of a relatively flat terrain and as such, the inundation of the coastal areas stretches into its vast urban development, posing risks to life and causing significant property damages. Another study conducted by Qatar University in collaboration with the University of Portland, USA identified a large section of the urban settlements in Qatar that will be subjected to Heat Island Effect (HIE)[1] from climate change impacts, meaning extended period of relatively high temperature in certain areas, causing elevated level of discomfort, diseases and health issues. In terms of Green House Gas (GHG)

[1] Heat Island Effect :describes built up areas that are hotter than nearby rural areas (USEPA, 2016).

emission from all the relevant activities, including urban development, Qatar has the highest per capita emission in the world. Whilst the total volume of emission has not been considered significant on a global scale, the highest per capita emission poses a leadership challenge for country's leaders, as Qatar is a signatory to international protocols to reduce its GHS emission.

A number of studies and initiatives addressing climate change have been undertaken by the community and private entities in Qatar. For example, 'A climate change and temperature warning in Qatar' study was undertaken by Qatar University's Social and Economic Survey Research Institute (SESRI). From the different studies and initiatives, it can be summarized that there is a general acknowledgement and understanding of climate change and its effects in Qatar by its citizens and commercial entities. However, knowledge of certain impacts and how they may be mitigated seems limited.

Following the lead of the Qatar National Vision (QNV2030) and the Qatar National Development Framework (QNDF) a strategic spatial land use framework of the Qatar National Master Plan (QNMP), the Ministry of Municipality and Environment (MME) in 2018 has developed its Climate Change Strategy (CCS) for the Urban Planning and Development Sector for the state of Qatar.

The primary objective of the Climate Change Strategy is to address how urban planning and urban development can be managed effectively to reduce the impact of climate change. The focus on urban planning and development is achieved by concentrating on aspects directly or indirectly related to spatial land use in Qatar. Four key sectors that the strategy focuses on are: (i) adaptation to the risks of Sea Level Rise (SLR), (ii) reduction of Heat Island Effect (HIE), (iii) reduction of GHG emission and (iv) ensuring relevant emergency management systems are in place to avoid risks on life and properties.

The paper highlights the methodology and the process for developing the strategy with necessary actions and recommendations to reduce the impacts of climate change in the urban planning and development sector in Qatar. It also lays out a plan to progressively implement the proposed actions.

2. Climate change impacts in Qatar

It is a global phenomenon that climate change would have issues such as sea level rise and coastal flooding, temperature rise and Greenhouse gas (GHG) emissions affecting the development and infrastructures.

2.1 Sea level rise and flooding

All human settlements are either in or near the coastal areas, similarly, Qatar's major population centers and urban expansion also lie near the coastal areas. Therefore, Qatar's population is vulnerable due to the sea level rise. Currently, the data shows that the mean sea level at Qatar is already at an increasing rate of approximately 1.5 mm/year in Doha which is the capital city of Qatar. Within the Middle East and North Africa (MENA) countries, Qatar is the most vulnerable to sea level rise and associated flooding, as a 1m rise in sea level would affect about 3% of its area, while a 3m rise would affect 8% (UNDP,2010). The critical issue here is all these affected areas are within the current urban settlement zones that comprise approx. 8.5% of the total area of Qatar.

Climate change is almost certain to result in both higher sea levels and an increase in the frequency or magnitude of coastal flooding due to extreme weather events. Qatar currently receives a minimal quantity of rain at approximately 80 mm per year, with the majority falling in the winter months. In any case, rainfall is increasingly likely to arrive as short, intense events, with an increased likelihood of flash floods.

Much of Qatar's land area is low lying and vulnerable, including parts of several municipalities and notably some critical public facilities e.g., major hospitals and police stations in Doha. The highest point in Qatar is only 103 m above sea level (Figure 1) and is relatively flat along the coast with relief increasing to the southwest. Urban and industrial development in Qatar has been concentrated in the low-lying coastal areas. As large tracts of land have also been reclaimed in the past 30 years, it is more likely to have increased coastal flooding from the sea level rise. The idea is that the risks and cost of flood damage can be reduced through planning by a range of methods through:

- Implementing appropriate planning regulations to guide the development in order to reduce flood risks from SLR
- Installing strategically located flood defenses
- Planning for future development away from flood-prone/flood-risk areas
- Including flood-resilient features in future designs

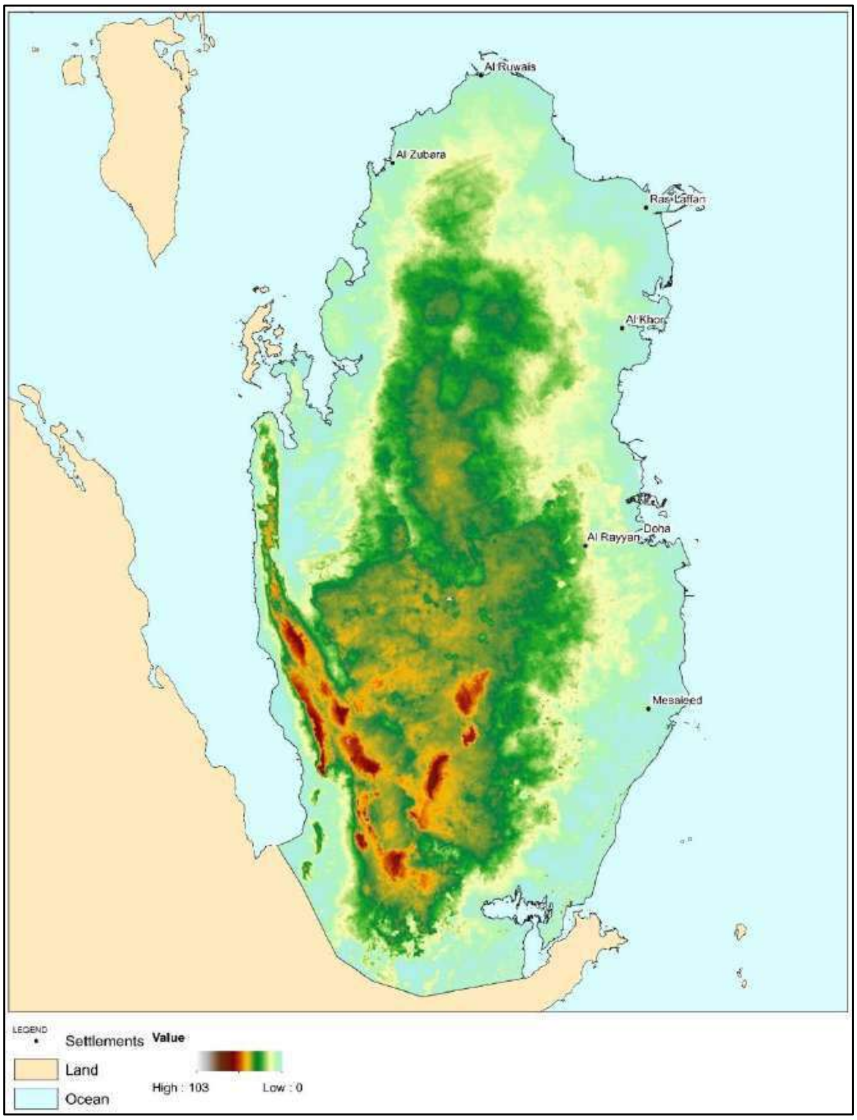

Figure 1 :The highest point in Qatar is only 103 m above sea level

Source : Ministry of Municipality and Urban Planning (2014a) Integrated Coastal Zone Management Plan for the State of Qatar: Climate change and sea level rise study, Ref: MA 2.1. Dated 17 May 2014.

2.2 Increased Temperature

The International Panel for Climate Change (IPCC) expects temperatures in the Middle Eastern countries (including Qatar) to rise by about 2°C in the next 15-20 years, and by more than 4 °C by the end of the century. Recent modelling work reported in Nature Climate Change suggests that:

"By the end of the century, annual wet bulb temperatures in Doha will exceed 35°C several times in the 30 years, and the present-day 95th percentile summer (July, August, and September) event becomes approximately a normal summer day."(IPCC, 2001a)

35°C is the threshold wet bulb temperature beyond which any exposure for more than six hours would be intolerable for most humans, resulting in hyperthermia which becomes a medical emergency requiring immediate treatment to prevent disability or death. In the current climate, the wet bulb temperature rarely exceeds 31°C. Figure 2 represents an annual temperature profile between 1962-2013 showing the minimum, maximum, mean and the highest recorded temperatures.

In urban areas, increasing temperatures will be exacerbated by "heat island effect" and the key factors leading to the heat island effect include:

- Population density: Higher density corresponds to more heat (although not everywhere)
- Tower blocks with glassed outer walls
- Percentage of impervious surfaces
- Industrial activity
- Vehicular activity
- Increased frequencies of heat waves

Factors that may aid in reducing the heat island effect for future developments include:

- Parks, green areas, and water features for reducing temperatures – this is the most consistently considered factor.

- Wind flow management/ urban ventilation – consideration of urban design/planning for spaces that allow wind to flow through, especially coastal wind as this is cooler than the adjacent land areas.
- Environmental friendly city/neighborhood layouts – i.e. breaks between areas of the city through green/ shaded areas.
- Reduction of large impervious areas, particularly outdoor parking areas and wide roads with photovoltaic pavements
- Reducing traffic levels.
- Technical approaches like roof coatings, green walls, roof gardens, etc

2.3 Increased Green House Gas (GHG) Emission

According to the United Nations Climate Change Secretariat (UNFCC, 2015), Qatar has the highest per-person CO2 emissions in the world. Based on available data from Kahramaa (utility provider) and publicly available national greenhouse gas emissions inventory for Qatar, a baseline per capita GHG emissions of 14.7 metric tons CO_2e (CO_2 equivalent) is estimated.

The total baseline per capita GHG emissions include water and power (72%), transportation (18%), waste management and treatment (9%), and domestic use (1%). Approximately 90 % of the GHG emissions result from water and power consumption and transportation. Utility consumption data for commercial facilities/operations such as restaurants, hospitals, malls, etc. are not readily available.

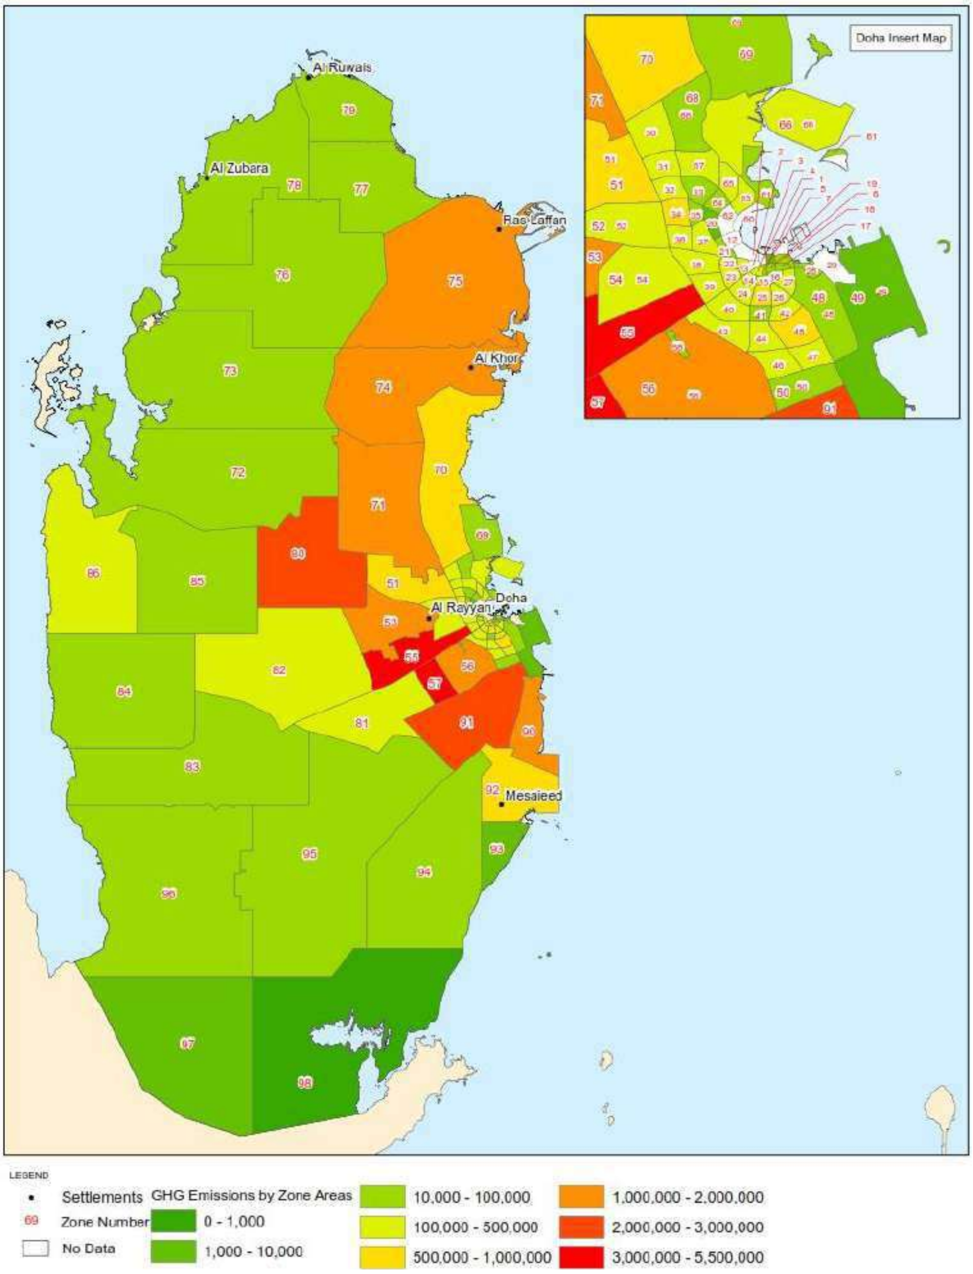

Figure5 : Baseline GHG emissions by zone

Source : MME (2017). P. 2016/2: Climate Change Strategy for the Urban Planning and Urban Development Sector in Qatar. Stage 3: Situation Analysis Report. GHD Pty. Ltd.

3. Climate Change Challenges for Qatar's Urban Planning and Development Sector

The Qatar National Vision 2030 aims to Transforming Qatar into a developed country by 2030, given that Qatar has the highest GDP in the world, capable of sustaining its own development and providing for a high standard of living for all its people for generations to come (GSDP, 2008).

This is a high level document for Qatar identifying a range of challenges it seeks to manage and address by the year 2030. It also provides roadmaps on development trends of Qatar by 2030.

There are challenges relevant to the Climate change. The aspects and relevance of these challenges to the Climate Change are detailed in Table 1 below:

Challenge	Aspect	Relevance to CC
The needs of this generation and the needs of future generations	This challenge identifies that continued dependence on hydrocarbons without developing other 'sources of renewable wealth' could be detrimental to Qatari society as hydrocarbons are a finite resource.	Utilizing hydrocarbons and associated GHG will influence the proposed mitigation and adaptation relating to land use planning.
Managed growth and uncontrolled expansion	Stress from rapid and/or uncontrolled growth can lead to financial vulnerabilities, environmental damage and widening social gaps and stresses.	Shows the value of planning and implies that the uncontrolled/ unplanned urban expansion is detrimental to the environment.
Economic growth, social development and environmental management	Acknowledges that development is likely to have a negative impact on the environment but states that development should be compatible with protecting and conserving the environment. If an environmental cost is identified from economic development, it should be "compensated with investments in technologies that help improve the environment" (GSDP, 2008).	Introduces the concept of compensation in spatial land planning and development. Places the economy before the environment, in some circumstances.

Table 1 : QNV challenges relevant to the Climate change

Source : MME (2017). P. 2016/2: Climate Change Strategy for the Urban Planning and Urban Development Sector in Qatar. Stage 2: Data and information collection and assessment Report. GHD Pty. Ltd.

The main challenges relating to Climate Change for Qatar is the development pressures for FIFA 2022 and massive infrastructure development while the ratification status on Climate Change convention that was in place since 1996 as part of the Kyoto Protocol and came into force since April 2005. Amendments to the Kyoto Protocol (https://unfccc.int/process/the-kyoto-protocol/the-doha-amendment) requires Doha's commitments to comply with some of the UNFCCC's requirements. In 2012, Qatar hosted the Doha Amendment on Kyoto Protocol reassuring its commitments towards climate change. In November 2015 [https://unfccc.int/news/qatar-submits-its-climate-action-plan-ahead-of-2015-paris-agreement], Qatar submitted its new climate action plan to the UNFCCC. The Intended Nationally Determined Contribution (INDC) was submitted to set the target and direction of how Qatar is going to address climate change.

The commitment stated in QNDS 2011-2016 stipulates that the legacy of the FIFA 2022 must be considered when commissioning any projects, particularly in relation to the long- term socio-economic and environmental impacts. These include climate change impacts into industrial sectors to reduce CO2 emissions in Qatar; as well as improving governance on climate change impact of air pollution, environmental degradation.

For a developing country like Qatar, since there has been INDC being submitted to UNFCCC, the Ministry of Municipality and Environment (Urban Planning Department) has recognized the vulnerability of the footprint of urban sprawls and structures being constructed and developed maybe under future threats from potential climate change impacts; hence the initiation of this strategy is especially tailored for the urban planning and development sector.

4. Existing Climate Change Management in Qatar

At present, there is significant lack of awareness of the potential impacts of climate change in the region. As such no tangible initiatives have been undertaken to initiate relevant research to ascertain credible assessment of the impacts.

It should also be noted that there is a significant gap in Qatar's existing legislation and planning framework to specifically address the impacts of climate change such as sea level rise, increased flooding, and increased temperatures. Within the existing regulations and initiatives, there are no actionable measures to be implemented or supporting monitoring and review mechanisms to mitigate (if not eliminate) the identified climate change impacts.

The Climate Change Strategy (CCS) for Urban Planning and Urban Development Sector in the State of Qatar is aiming to engage stakeholders and citizens to mitigate some of the Climate Change impacts.

5. Proposed Climate Change Strategy

The Climate Change Strategy aims at comprehensively addressing how the built environment can effectively mitigate against and respond to Climate Change.

The role of the Climate Change Strategy is to:

- Guide and influence where development takes place
- Regulate urban planning, land uses and urban design
- Encourage and support household and community actions that reduce risk

Coordinate and support links between protection (disaster avoidance), disaster preparedness and post disaster response and rebuilding

Develop tools to estimate and predict GHG emissions and climate change impacts from the spatial urban planning and urban development activities in order to explore ways to minimize emission and at the same time support Qatar's commitments in the international platforms.

5.1 Strategy Vision

"*Urban development in Qatar will progressively reduce average per capita greenhouse gas emissions and be resilient to the potential impacts from climate change*"

5.2 Strategy Objectives

The strategy objectives are based on adaptation (i.e. managing the adverse impacts of current and potential future climate change to reduce associated risks) and mitigation (i.e. reducing the GHG emission to support Qatar's international commitments and its leadership) opportunities. Table 2 categorizes the key objectives as per the adaptation and mitigation potentials:

No	Strategy Objectives	Nature of the Objectives
1.	Protect members of population from effects of climate change	Adaptation
2.	Reduce travel demands and improve access to public transport in new developments	Mitigation
3.	Facilitate the optimal siting of solar energy installations through land use planning and integrate small scale solar energy generation into all new developments and major projects	Mitigation
4.	Facilitate emergency response at the planning and building permit stage for developments within high risk flood and heat island affected areas	Adaptation
5.	Design new and retrofit existing developments to be resilient against increasing sea level rise and associated flood events	Adaptation
6.	Monitor GHG emission in urban developments and make information publicly available	Mitigation
7.	Retain and protect sensitive ecosystems that sequester carbon	Mitigation
8	Incorporate 'Green Building' measures to improve the energy and water efficiency of homes and businesses	Mitigation
9	Design the urban form to reduce the urban heat island effect and energy demand	Adaptation

Table 2 : categorizes the key objectives as per the adaptation and mitigation potentials

5.3 Action plans

Specific Actions have been developed for each category of key impacts, namely:

- Responding to Sea Level Rise and Flooding
- Responding to Increasing Temperatures
- Reducing Greenhouse Gas Emissions
- Protecting Biodiversity

An example of built environment mitigation/adaptation measures for each category of impact is provided below:

	Responding to Increasing Temperatures
Establish Vulnerable Coastal Zone to communicate risk and regulate development • Utilize the 1% AEP mapping to identify the Vulnerable Coastal Zone (VCZ) • Develop MSDP Zoning Regulation for VCZ to prohibit new development (with certain exceptions) • Update the existing and future zoning maps to incorporate VCZ • Continually update the 1% AEP contour as new sea level rise projections are made available with IPCC releases.	Improve green space in areas vulnerable to the Heat Island Effect • Utilize the finalized Qatar University UHI ongoing study to determine areas subject to the heat island effect and generate a hot spot map. • Overlay the hot spot map over future zoning maps to identify the need for any additional publicly accessible green space. Reallocate land use (if needed) and ensure the implementation of the green space. • Incorporate requirements for vegetation around buildings.
	Protecting Biodiversity
Create higher densities and mixed use to reduce travel demand • Require compact, mixed use development to the densities necessary to promote public transport	Introduce buffer zones to protect sensitive ecosystems • Commission a study into appropriate buffer zones and a need for migration corridors for

use • Require development to involve a mixed use (i.e. medium and high density residential and non-residential uses), with non-residential uses on the ground floor • Integrate walking, cycling and public transport networks into existing mega-projects • Implement higher residential density targets for new development. • Require new development to be sequenced, such that with development further from existing urban areas is permitted only after areas nearer the existing urban areas have been developed.	Qatar's Protected Areas and mangroves. • As an interim measure, prohibit development within 250 m of Protected Areas, mangroves, seagrass and coral reefs. • Include requirements in the MSDPs to identify and protect the buffer zones from any future development. • Provide a minimum of 250 m width 'escape routes' from Protected Areas. Where this is not possible due to existing development, provide a continuous wildlife corridor that is as wide as possible.

Table 3 : built environment mitigation/adaptation measures for each category of impact

5.4Implementation of the Strategy

The Climate Change Strategy will be implemented by developing specific initiatives to support the above action plans. These initiatives include the following:

1. Development of a 'planning overlay flood layer' that represents the areas subject to specific categories of risks from the SLR and increased rainfall intensity. This overlay layer will then be supported by a series of land use regulations. (An example of the Policies and Policy Actions outputs of the strategy : Establish Vulnerable Coastal Zone (VCZ) to communicate risk and regulate development)

Output from actions	**SL1: Establish Vulnerable Coastal Zone (VCZ) to communicate risk and regulate development**
Specific Actions	**SL1-1**: Utilize the 1% AEP mapping to identify the Vulnerable Coastal Zone (VCZ). **SL1-2:** Develop regulations for VCZ to prohibit new development (with certain exceptions). **SL1-3:** Update the existing and future zoning maps to incorporate VCZ as an overlay. **SL1-4:** Continually update the 1% AEP contour as new sea level rise projections are made available with IPCC releases.
Mechanism	Overlay on existing and future Zoning maps (SL1-3)
Implementation responsibility	MME-UPD
In coordination with	MME-IPD (SL1-1 and SL1-4)
Timeframe	Immediate
Resource implications	Low cost (SL1-1, SL1-2) Medium cost (SL1-3, SL1-4)
Performance Indicator	Establishment of a VCZ

Table 4 : Establish Vulnerable Coastal Zone to communicate risk and regulate development

Source : MME (2017). P. 2016/2: Climate Change Strategy for the Urban Planning and Urban Development Sector in Qatar. Stage 4: Strategy Report. GHD Pty. Ltd.

2. Development of specific urban design guidance and tools that will be included in the Qatar Urban Design Compendium (currently under development phase). These tools will propose with benchmark examples the best practice neighborhood and building design guidance/ requirements that considers climate friendly design options including conservation of resources, climate friendly building materials, environmentally friendly infrastructure, waste minimization etc.

3. Specific planning requirement (with specific template) for submission of a “Climate Change related Disaster Management Plan” in the event of an anticipated emergency.
4. Tools to estimate and predict GHG emissions and reducing climate change impacts for the spatial urban planning and urban development activities. The proposed tools include the following modules:
   - **Urban Planning Module**
     Key function: To estimate and project GHG emissions and GHG intensity based on land use categories. It compares GHG emissions associated with current land use, as well as projected future land uses, for a particular parcel of land. It also has the capability to display heat island and building floor level information.
   - **Building Application Module**
     Key function: To estimates the GHG emissions associated with construction activities and materials (e.g. demolition, site preparation, and construction portion of the real estate development process). It is intended to be used once in the lifecycle of each project to evaluate the expected GHG impacts, both from emissions during the construction process and embodied carbon in the materials used. It has the capability to capture greenhouse gas emission associated with the construction process.
   - **GHG Emission Tracking Module**
     Key function: To collect annual CO2e emissions resulting from specific reportable activities undertaken by major urban emitters. This tool has the ability to capture greenhouse gas emissions associated with ongoing operations at a site.

6. Conclusion

- Qatar is subject to considerable risks from climate change impacts that poses significant threats/ hazards to life, properties, infrastructure and necessary services
- Urban planning and development sector needs to play an important role to address the impacts of climate change because careful planning with regulatory instruments can prepare a safe and resilient spatial urban settlement.
- Ministry of Municipality and Environment, being the urban planning legislative body in the State of Qatar has recognized and evaluated the risks from climate change impacts and proposed a comprehensive strategy supported by specific action plans and tools for implementing the strategy.
- Public awareness and understanding of the climate change related risks are not that strong at present, hence a comprehensive education and awareness program would be necessary at all levels of public and private sectors including the citizens through all ages and educational backgrounds. The awareness would influence taking ownership of the issue by the general public and assist in welcoming the implementation of the strategy.
- Current institutional and planning regime is already facing major challenges in implementing a recently introduced new planning regulations and planning system. The climate change related regulatory instruments are yet to be included in this new planning system and is expected to face considerable difficulties in understanding let alone implementing them. Stakeholder consultation at the time of developing the strategy and actions plans was an integral part of the project, however, because of lack of understanding and lack acknowledging the problem, the participation was not very effective.

- A comprehensive plan for on-the-job training is currently being planned for its execution for all relevant internal and external stakeholders.
- The next amendment of the planning regulations that is due in less than six months would include all the regulatory requirements of the climate change strategy.
- There will be a need for establishing an inventory to capture the GHG emission from the land use and development activities.
- The MME management needs to demonstrate a significant leadership role in facing the challenges posed by the climate change in Qatar and take ownership of the strategy actions to support implementing them

7. Acknowledgements

The authors would like to acknowledge and thank for valuable contribution from **Sophie Hagan**, Environmental Planner and Mr **Eslam Shaheen**, Urban Planner with Qatar National Master Plan team in completing this paper.

Abstract

Given the mixed interpretations of the concept of "Resilient Cities", this paper calls for a more comprehensive understanding of the concept and its holistic impact on the way cities are designed, planned and developed. By labelled as resilient, cities should transcend the limited definition of the resilient cities concept which focuses on merely environmental and readiness for climate change impact and other forms of natural disasters. Resilience as an attribute for cities and as will be shown in the case of Doha, the capital city of Qatar, should be holistic and inclusive to embrace all aspects of city development including economical base, cultural assets, social structure and urban development. Using the case of Doha, the paper illustrates a new conceptual understanding of cities' resilience.
The paper analyses the contemporary evolution in Doha and highlights the milestones in structuring the new vison for Doha's development as a resilient city holistically. In the last decade, the city was subjected to a number of radical transformations started from winning the bid to host the 2022 FIFA world cup, decrease in oil prices and finally the sea, air and land blockade imposed on Qatar by its adjacent neighbors. The paper illustrates Doha's model in providing an interesting case of resilience which allows the city to successfully cope with the consequences of all the major shocks, stress and unforeseen challenges, the city have faced in the last decade.

Selected Congress Track
1 THE GLOBAL VIEW: Climate Change Impacts, Sustainability and Resilience.
Keywords: Resilient Cities – Holistic Resilience – Doha, Qatar – Urban Resilience - Doha Sustainable Development – Climate Change Urban Impact.

1- Introduction

Cities worldwide are challenged by a high complexity of acute and chronic problems, including challenges related to economic development, social polarization and segregation as well as climate change and ecological degradation. Hence, cities must become resilient to a wider range of shocks and stresses. The notions of urban resilience and the resilient city have gained considerable attention and interest over recent years**.** Urban resilience is a broad concept that is sometimes blurred and abstract. We are also interested in the scope of this research to relate the concept of urban resilience with the concept of urban sustainability. Our positon as explained in the case of Doha, Qatar suggests that the resilience of cities facing variable conditions, threats and forces should also consider the sustainable future of the local communities and the urban territories they belong to. As Zhang and Li (2018) indicate that rational urban development can be achieved only when it is both resilient and sustainable, and conclude that urban planners, policymakers and researchers should pay equal attention to both urban resilience and urban sustainability before decision-making. In current studies, some scholars hold the view that urban resilience has already replaced of urban sustainability as the mainstreaming concept in the discipline of urban studies.

2- Interrogating the Standardization of Planning Concepts: The Case of Resilience

The most recent terminology used in the realm of urban planning and development is resilience. Accumulated literature, particularly conferences and journal papers, are discussing the topic in the domain of urbanism and planning. Conferences are organized around the globe to discuss how to make cities resilient? Yet, we never pause and question the validity of having a sequence of concepts that each would emerge every decade or so. Lately, resilience has become an important goal for cities, particularly in the face of climate change. Yet, for a lot of cities around the world, the concept of resilience is still ambiguous. Cities are deeply complex, sophisticated and adaptive systems. The city is the most complex and typical social-ecological system shaped by human beings. Hence, every single city has its own narrative. The mechanistic model of urbanization which is merely using globally accepted concepts coined by international organizations like UN-Habitat should be contested. During the last four decades, UN Habitat, World Bank, International Monetary Fund and other development agencies supported by researchers and academics maintain the ritual of inviting a description for the successful city and change it every five to ten years. Cities in the whole world and particularly in the developing countries were kept confused whenever a new concept emerged; modern, sustainable, smart, green or resilient city. Once a city tries to use its local resources to fully understand the concept and how it will positively affect its development, a new one and even more sophisticated and ambiguous is introduced.

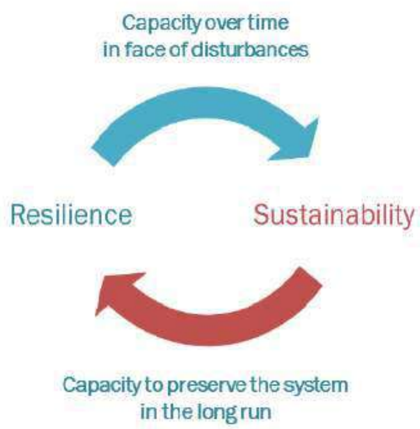

Figure 1: The dynamic relation between resilience and sustainability.

In an increasingly complex and changing world where global problems are felt locally, the approaches used to plan, design, and build our urban neighborhoods are failing due to the adoption of standardized planning concepts. Primarily, the evolution of cities through rigid, top-down action proved ineffective particularly with the continuation of the same problems including environmental threats, urban poverty, housing crisis, car dominance urbanism and other constant challenges. Campbell (2018) argues that the key to fixing our broken patterns of urban development does not lie in grand plans or giant projects; rather, it lies in the collective wisdom and energy of people harnessing the power of many small ideas and actions to make a big difference. He calls this making “Massive Small” change. Such perspective is significant to the discussion on the emerging concept of resilience in cities and urban areas. A shift towards a holistic understanding of the local context and engaging the local community would pave the way to an authentic and credible urban resilience related to people and places.

In order to create resilience in urban systems, cities need to be able to learn, adapt and transform across sectors and levels. One definition of urban resilience is the capacity of individuals, communities, institutions, businesses, and systems within a city to survive, adapt, and grow regardless of the kinds of long-lasting pressure and severe shocks they experience. Cities are very vulnerable when any of their subsystems are destroyed or fail to adapt to new challenges. Such a situation may lead to a fatal crisis or even destruction. Uncertain factors, such as natural disasters, climate change, energy crises, political instability, financial crises, food security and terrorist attacks play an important role in threatening urban development (Spaans & Waterhout, 2017). In other words, the concept of resilience should be overextended and transcend the main topic it is associated with; climate change. As explained, cities face plenty of negative and positive challenges which require resilient policies and strategies articulated from within and not imposed by outsiders.

3- Conceptualizations of Resilience

Resilience is the ability of a system, community, or society exposed to hazards to resist, absorb, accommodate to, and recover from the effects of a hazard in a timely and efficient manner (Jha and al., 2013). The paper initiates a discussion of how the definition might serve as a boundary object, with the acknowledgement that applying resilience in different contexts requires answering: Resilience for whom and to what? When? Where? And why? Using general terms and global concepts won't help in achieving any level of tangible change as long it is not coupled with a sincere attempt to fully understand the local condition and adopt the concept to the realities on the ground. In the work of great urban theorists such as Jane Jacobs, Christopher Alexander, and E. F. Schumacher, the main invitation for urban planners is to consider locality and value small actions and humble interventions. After reviewing the scholarly literature on urban resilience (Meerow and el., 2016) have concluded that the term has not been well defined. Their justification was based on that Existing definitions are inconsistent and underdeveloped with respect to incorporation of crucial concepts found in both resilience theory and urban theory. (Pizzo, 2015) problematizes the introduction of the concept of resilience into the planning domain from three main starting points: 1. The nature of the events which are said to require resilience; 2. The different nuances in meaning that resilience assumes according to those different events, and 3. The theoretical and operational problems the concept entails. The paper sustains that: Multiple sub meanings are embedded within one interpretation of resilience that leave the concept open to rather large margins of ambiguity, which emerge considering its operationalization; 3. The concept seems to fit and to be appropriate within different paradigms, planning traditions and policy frameworks. Its alleged 'neutrality' is one of the main reasons of its pervasiveness, but also of its ambiguity, showing latent controversial implications, which are progressively emerging in critical planning theory.

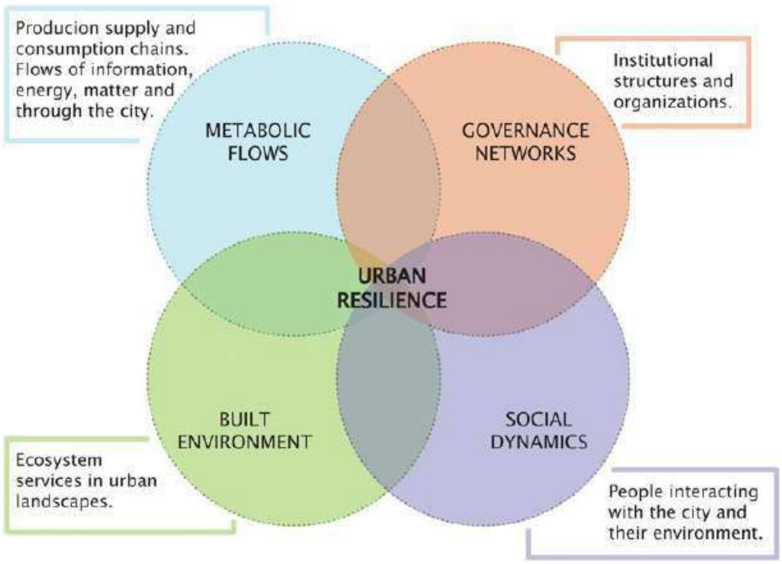

Figure 2: The holistic approach to urban resilience.

3-1- Resilience in Urbanism and City Planning

This paper provides an overview of the development of the resilience concept in the domain of urban development and planning. Over the last two decades the concept of resilience has experienced escalating interest. However, due to a lack of consistency in defining and measuring this theoretical construct within and across disciplines, the recent explosion of literature on resilience has contributed more to confusion than clarity among researchers and policy makers. The notion of resilience is gaining increasing prominence across a diverse set of literatures on cities and climate change. Although there is some disagreement among these different literatures about how to define and measure resilience, there is broad consensus that: (1) cities must become resilient to a wider range of shocks and stresses in order to be prepared for climate change; and (2) efforts to foster climate change resilience must be bundled with efforts to promote urban development and sustainability (Leichenko, 2011). Hence, the paper calls for a need to revisit the concept and its utility to the prosperity of cities. However, resilience has been closely associated with sustainability for more than a decade, although without precise meaning and often as an additional label attached to pre-existing research (Timon, 2014). Urban resilience is a broad concept that is sometimes blurred and abstract. Part of the effort to render the concept to a more clear interpretation is first to assert that Urban resilience addresses adaptation as well as mitigation. It is associated with spatial planning policy-making in the context of different levels and forms of uncertainties. Therefore, urban resilience provides a new way of framing and responding to uncertainty and vulnerability. In light of this interpretation, urban resilience offers an alternative paradigm for planning strategies.

4- Contextualizing Doha: The Rising Competition between Gulf Cities

Before discussing the experience of Qatar, this section is contextualizing the State within the Gulf context and elaborates on the notion of the regional competition. While most people think of cities developing organically over hundreds of years, many who live in the Gulf are aware of how quickly some cities can grow, expanding exponentially in terms of buildings, infrastructure, and population. Much of the rapid transformation has been guided by an intense inter-city competition to attract investments, human resources and tourism particularly as a consequence of oil prices decline. The states in the Gulf region have grown rapidly due to their large reserves of oil and gas. Being aware of ending resources, the era after the oil is already being planned by the governments in the Gulf region (Höselbarth, 2010). The Gulf States while mostly young and small, they are the largest builders and developers in the world. Every single capital Gulf city is characterized with shopping malls, skyscrapers, artificial islands, gigantic airports, real-estate fantasies and signature museums. Yet, they have also realized that another transformation is needed from oil-based to post-oil societies. With oil resources running out, a focus on the post-oil era is a priority.

As these cities compete with each other, aiming to highlight their unique offerings and attempting to clearly distinguish themselves from other cities, they have chosen to rely on place-branding as a tool. The staging of events of international importance (such as Formula One Races in Abu Dhabi, upcoming World Expo 2020 at Dubai and prospective 2022 FIFA World Cup at Qatar), the emphasis awarded to star-architecture and the emergence of strongly themed mega-projects characterize such development. Thus city-positioning and place-branding begin to assume the status of urban development models (Mishra, 2016). All Gulf cities are in the process of diversifying their economic base, with the vision of transitioning to a sustainable post-oil future, they are positioning themselves as places to visit, work and live. Place-branding has emerged as a significant trend across the Gulf cities in the construction of this image and consequently in the production of places.

Questions about the future of contemporary Gulf cities are important as the drastic changes taking place particularly in the economic side, indicates a necessity to consider a new blueprint for Gulf cities' future. Replacing glittering facades, high-end hotels, artificial islands, huge shopping malls, and the tallest constructions of the world, the region nowadays need to attract people from all over the world to contribute in a different kind of economy. The catalyst for the old model of development was the discovery of huge amounts of oil and gas resources in the 1960`s leading to prosperity (Gremm and els., 2015). But oil reserves will be exhausted in the near future. How do the cities of the Gulf region respond to this drastic change? Are they, like so many other cities in the world, trying to reach the status of a knowledge or creative city? Is it indeed a target of these wealthy oil-based cities to set up a knowledge society based on knowledge economy not mere natural resources?

5- The Narrative of Qatar: A Small State with Big and Legitimate Aspirations

The skeptical positon regarding Qatar's ability to construct an inspiring model of development is based on its small size, limited population and the massive presence of expatriates. Roberts (2015) stresses the concept of "brand Qatar" as a catalyst which helped the small size State to gain global recognition and changed its character so completely in so short a period of time. He based his interpretation on shifting the leadership in 1995 to an emerging leader with a progressive vision for the future. The pillars of this progressive vision are diversified and balanced foreign relations, establishing a leading role in media through Al Jazeera network, and extensive investment in gas production and liquefaction. Ultimately, bold initiatives require bold leadership and Qatar is yet again, blessed with this resource (Richer, 2014). Additionally, Kamrava (2013) argues, Qatar's enormous oil and gas wealth has permitted the ruling Al Thani family to exert a disproportionately large influence on regional and even international politics. Qatar is, as Kamrava (2013) explains is a "tiny giant": although severely lacking in most measures of State power, it is highly influential in diplomatic, cultural, and economic spheres. He presents Qatar as an experimental country, building a new society while employing what he calls "subtle power." It is both the headquarters of the global media network Al Jazeera and the site of the U.S. Central Command's Forward Headquarters and the Combined Air Operations Center. Qatar's effective use of its subtle power, Kamrava argues, challenges how we understand the role of small states in the global system.

Figure 3: Al Jazeera News Network is one of the most effective tools for Qatar's plan to achieve big aspirations regionaly and internationally.

Figure 4&5: Doha's Evolution from a humble traditional settlement to a metropolitan urbanity (Source: MME).

6- Contesting Doha's Model of Resilience

In this section, an analysis of the most dominant forces that challenged the development of Doha city in the last decade will be provided. Hence, all the strategies, processes and policies which were adopted by the city will be shared to illustrate the city's resilience model. Interestingly, some of these dominant forces were celebrated like winning the bid to host the 2022 FIFA World Cup, while other were a substantial shock and have created a seismic impact on the city's people, economy and development. Hence, Doha was alert for the critical need for a flexible and dynamic approach to building resilience that goes beyond risk mitigation. Therefore, in the coming sections, three main challenges will be narrated and Doha's answer to each of them will be illustrated.

6-1- Challenge One: March 2008; The Inevitability of the Post-Oil Paradigm

A major challenge which the paper addresses is the fluctuation of oil prices and how Doha is structuring a vison for the city in the post-carbon paradigm. Such paradigm implies a move from oil-based economy to a knowledge-based economy and how to plan the city to facilitate such a new economical paradigm. With an unprecedented financial resources, creative strategic thinking and political commitment, Qatar is constructing a new development and urban brand; *Dohaization* which is a brand but also a continuous dynamic process[1]. The case of Doha is stimulating as new mega projects are made to pave the way for a new development vison structured upon the value of knowledge economy and knowledge-based urbanity. By any measure, Qatar's growth is phenomenal; in the past decade the population has trebled, and the size of metropolitan Doha has increased fourfold. From its humble origins as fishing and pearling village, Doha has emerged as an expanding world city, where ambition and means are fueling exciting experiments in education, health, sports and culture (Framherz, 2012; Jodido, 2014; Alraouf, 2016). For a better understanding of how Doha came to structure its current identity, an investigation into the State's main strategy and the articulation of Qatar's role regionally and internationally is crucial. In this section, we will discuss the State main strategies which affected the development of Doha. The Paper sheds light on the concept of Doha's attempt to construct a new identity which transcends the model that was created by Dubai's iconic development and real-estate fantasies. Then, the notion of knowledge economy as adopted by the State and clearly articulated in QNV 2030 will be analyzed to illustrate the quantitative and qualitative shift towards knowledge-based urban development in Doha. Evidently, in the last decade a new pattern of planning interventions can be clearly observed in the urban fabric of Doha. These new interventions described as the city's mega projects due to its size, location, population served and visual and urban impact.

[1] The term *Dohaization* was coined and used for the first time in Gulf Research Meeting at Cambridge and later published in Alraouf, Ali. 2016. "Dohaization": An Emerging Interface between Knowledge, Creativity, and Gulf Urbanity. Pp.: 47-68. In Katodrytis, G. and Syed, S. Gulf Cities as Interfaces. Cambridge: Gulf Research Centre Cambridge.

Figure 7: The post-oil urbanism suggests a paradigm shift towards walkability and tranisti oriented developmt in Doha.

Doha is considered by many indicators as the most advanced city within the Middle East to adopt knowledge economy as a conceptual base for its 2030 vision. Qatar did a radical transformation to go beyond the typical image of a Gulf city relaying on presumably endless assets of oil and gas. A move towards being a regional center for education, knowledge and culture is the new aspired sense of identity for the Gulf State. A major investment in knowledge-based urban development characterizes major projects in the country during the last five years (Alraouf, 2008; 2014). This new identity of Qatar paved the way for a new paradigm in Doha's urbanity which can be best described as the Knowledge-based urban Development Paradigm. Qatar has become a showplace for renowned architects, several U.S. universities have established campuses there, and it will host the FIFA World Cup in 2022. The quantity and the quality of architectural and urban projects which will be added to the city's urbanity to facilitate hosting the 2022 FIFA World Cup would definitely make Doha a very unique world destination. Significantly, Doha has gained global significance through the growth of knowledge economy related projects. The city's new urban development and its spatial qualities contribute to the global attractiveness of Doha for knowledge economy investments, firms and people. Such urbanism fulfills the requirements of Knowledge workers coming to the city from literally every spot of the globe anticipating an attractive smooth quality of life which would foster their creativity and innovation.

Figure 8&9: The new cultural districts help Doha in establishing a new form of Knowledge-based Urban Development (KBUD).

With increasing awareness about the carbon emissions and the negative impacts of climate change, the paper evaluates Doha's attempt to transform its urban movement pattern from purely car-dependent city to a model for a transit-oriented development with the vitalization of connected network of public transportation, pedestrian streets and bicycle routs. Doha's model of urban resilience as reflected in the city's masterplan is answering the fundamental question of how to design and operate the city so it can withstand major threats and how to recover from them? Yamagata and Maruyama (2016) argue that land-use planning and carbon-neutral scenarios for urban planning are fundamental tools in urban management leading to a better urban resilience.

6-2- Challenge Two: October 2010; Winning the Bid for Hosting FIFA 2022

Qatar's interest to brand itself as an appropriate choice to host mega sports events started with preparing Doha to be the sports capital in the Middle East. A fact which was successfully demonstrated when the country organized the 2006 Asian games and gained the world respect. Doha was the first city in its region and only the second in West Asia (following Tehran in 1974) to host the games. Later, Qatar has lost its bid for the 2016 Olympics, but has vowed to try again. On the second of December, 2010, Qatar was selected as the host country for the 2022 FIFA World Cup. The model of Qatar hosting a major global world event generates number of interesting issues. All the lessons learned from analyzing the different world experiences in hosting major global sports inspired Qatar to take a different route. One can observe the transformation in strategic thinking towards the whole process of hosting the FIFA event in Qatar. When Qatar was declared as the host country for the 2022 FIFA World Cup, an immediate decision to form an organizing committee with outstanding authorities and capabilities was issued. The committee was called 2022 FIFA World Cup Supreme Committee and it has an excellent team of consultants, advisors, strategic thinkers, logistics experts and some members from the team who prepared the successful file that won the bid. Later and in light of the new understanding that hosting the event is a catalyst for future progress and community development, the whole conceptual approach has changed. Also, the title and the responsibilities of the committee have altered. The new title for the 2022 FIFA World Cup organizing body in Qatar is Supreme Committee for Delivery and Legacy (SCDL). The model as discussed in the outcomes of the supreme committee has learned profoundly from recent experiences in hosting the FIFA cup particularly in Brazil and South Africa. The main responsibilities of the committee are being confident that Qatar will provide a state of the art experience in hosting the event but more significantly that the event will positively affect the future prosperity of the country and create a sustainable legacy that would last for generations to come.

Figure 10: Doha is balancing hosting the 2022 FIFA World Cup with the future aspirations of the city.

Qatar is consciously aware of the day after oil and is using the unprecedented opportunity of hosting the 2022 FIFA world cup as an engine to inspire a new blueprint for the future of its people and cities (Nadine, 2014). The strategic thinking transformation towards how to host a global sports event in Qatar resulted in a new blueprint and a road map. This blueprint was based on a number of integrated aspects. All of which were designed and assembled in a way to guarantee that the process of hosting the event will be successful not only during the thirty days of the competitions but for decades to come. Qatar has been using sports strategically as a foreign policy tool that contributes to national security and allows the country to gain soft power. Even on the level of enhancing the global image after the blockade, Qatar smartly used sports to deliver a positive message about its stability and commitment to global investment. Current evidences particularly during the events of the 2018 FIFA world cup in Russia and the excellent presence of Qatar suggests that The 2022 World Cup in Qatar will happen, although not everybody might like that. As explained earlier, hosting the Cup will be a turning point for Qatar and would substantiate its global reputation but it is not the ultimate goal. The goal as explained in the paper is to use hosting the event as a catalyst for a better post 2022 Qatar.

6-3- Challenge Three: June 2017; A City under Siege: A Plight or a Historical Opportunity

One of the major forces which led to unprecedented challenge for Doha and Qatar as a whole is the blockade imposed by its close neighbors. The blockade as the paper illustrates opened new dimensions in the city's acknowledgment and comprehension of resilience. Ironically and surprisingly, in the 50 anniversary of the six days war in 1967 where Arab armies were humiliated and defeated, four Arab States decided to activate an unprecedented sea, air and land blockade against Qatar. The whole Middle East and the world wake up on the fifth of June 2017 reading the news about the decisions imposed by Saudi Arabia, United Arab of Emirates, Bahrain and Egypt on their neighbor and founding member of the Gulf Cooperation Council (GCC), Qatar. Pressure mounted further after relations with its regional neighbors hit rock bottom last June. Since then, Saudi Arabia has led a boycott of Qatar, with full participation from Bahrain, the UAE and Egypt. Planes have been prohibited from flying to Doha, banks from dealing with Qatari banks, and the country's influential satellite TV channel, Al-Jazeera, remains off the airwaves throughout most of the Arab World.

Figure 11: On the 5th June 2018, Qatar's nighboors imposed an unprecededted bloackade against the whole State.

6-3-1- The Social Cohesion as a Catalyst for City Resilience

Baldwin and King (2018) emphasize that strong social networks and social cohesion can be more important for a community's resilience than the actual physical structures of a city. That what was exactly noticed in Doha after the activation of the blockade. More significantly, urban planning and design support these critical collective social strengths by stressing the necessity of creative spaces for all and enhance the inclusivity of the city's urbanity. In the process of realizing the goal of both sustainable and resilient development, we should see the dominant role of social factors such as urban governance in the process of urban adjustment and adaptation. The social aspect will be also addressed in the paper as Doha, similar to most of Gulf cities, has a much diversified population coming from all corners of the world.

Figure 12: The city spaces are planned to accommodate the different social groups and emphasize the social cohesion.

The city is taking a number of measures to create better connections between expatriates and the city significantly sense of belonging and ownership which would radically help in inspiring the city's overall population of locals and expatriated to better defend the city and take a solidifying position towards realizing its future aspirations. The paper concludes with articulating a more holistic framework for city resilience which takes into consideration the multifaceted nature of the city and better prepare it for different forms of changes and transformations which might occur in the future. Coaffee and Lee (2017) examine how the concepts and principles of resilience exert increasing significant influence over the form and function of planning. Their discussion of the 'politics of resilience' in which fundamental questions of social and spatial justice are posed is relevant to the notion of social cohesion in Doha after activating the blockade.

Conclusion

The Model of Doha, Qatar extends the conceptualization of resilience to go beyond the well-known risks and move to planning the city to face different forms of crisis. More significantly, prepare the city to face uncertainty as the case with oil prices fluctuation and its impact on the economic stability of the country as a whole. Such a model matches with Coaffee and Lee (2017) call for a focus towards an integrated and adaptable model for coping with risk, crisis and uncertainty. In such time of uncertainty, urban planners are increasingly tasked with the responsibility of safeguarding the future of urbanized centers and those that live in them. In facing an unprecedented blockade from closest allies and adjacent neighbors, getting ready for hosting the biggest sports event on earth; FIFA world cup and coping with radical changes in its economic base as a rentier capital, Doha provided a worth analysis and appreciation case. The experience of Doha after the blockade asserts that an urban rational and holistic development mechanism could help improve the urban capability more effectively to cope with the various crises involved. The model of Doha illustrates the difference between process-oriented resilience than an outcome-oriented. Hence, Doha provides a rational urban development model because it is both resilient and sustainable. Part of the city' success story stems from the fact that social cohesion was considered as a pillar in enhancing the resilience capabilities of the city. It describes and illustrates the ideas, tools, and tactics being used to help engaged citizens, civic leaders, and urban professionals to work together to build viable urban society.

Governance, management, administration and planning systems in Ghana

Apraku, Patrick, ACCRA, Ghana

ABSTRACT:

Since Rio, climate governance has gradually been subjugated by contestations between developed and developing countries. Africa has been mandated to develop national and regional climate governance frameworks in line with the UNFCCC mandating Ghana to do likewise. However, these policy frameworks may not be implemented meaningfully or developed national institutional capacities to respond organically to climate change. This paper seeks to address the following objectives:

To understand climate governance in Ghana

To review the management and administration of climate change in Ghana,

To determine the extent climate change has been mainstreamed in the planning system in Ghana

Africa has been mandated to develop national and regional climate governance frameworks in line with the UNFCCC mandating Ghana to do likewise. The Ghana National Climate Change Policy developed seek to enhance coordination, establish clear mandates and roles for the various stakeholders, including the policy oversight role of the Ministry of Environment, Science, Technology and Innovation, the coordination of climate finance by the Ministry of Finance and the Economic Planning (MoFEP), and also measures to support small farmers and safeguard food security by the Ministries of Agriculture and Health. The establishment of a statutory coordination unit, the National Climate Change body would minimise the duplication and maximise synergies, overseeing all climate-related policy areas and coordinating activities. Also, governance mechanisms established to meaningful implement the National Climate Change Policy include the essence to ensure coherent, cross-sectoral action; address local level priorities; ensure the transparency and openness of the responsible agencies, and to allow public participation and access to information.

In order to ensure the successful implementation of policies and strategies on climate change, the government is not the sole institution responsible for the success of interventions on climate change. Non-governmental agencies including Civil Society Organisations and the private sector are the implementing bodies at the national, regional, district and community levels.

It is worth noting that planning in Ghana dates to the first National Development Plan, (1920-1930) under the British colonial rule. Over the years these development plans lacked the spatial dimensions of socio economic visions and policy goals focused at planning and managing human settlements. Post-independence planning focused on the path to broaden the spatial coverage and to strengthen institutions, and this led to the establishment of the Town and Country Planning Department in the country. Spatial planning prior to the new act, Act 925 has been restricted to the traditional function of land use zoning and development control at the level of MMDAs. Therefore, with the enactment of the Land Use and Spatial Planning Act, Act 925, a three (3) tier spatial planning system is enforced. Accordingly, the introduction of contemporary planning system since the beginning of the Fourth republic has mainstreamed climate change in decisions, policies, and programmes and of the country.

The Government of Ghana has demonstrated commitment to mainstreaming climate change into key planning processes at the national, regional and local level. Ghana’s resolve to mainstream climate change into development agenda is through the Ghana Shared Growth Development Agenda I&II (2010-2017) attest to this commitment. The government through the Ministry of Finance and Economic Planning (MoFEP), Environmental Protection Agency (EPA), and the

National Development Planning Commission (NDPC) has carried out a number of measures to reflect climate change mainstreaming efforts in budget formulation, implementation, monitoring and evaluation in line with the medium term climate change objectives.

In conclusion, an overview of the governance, management, administration and planning systems in Ghana would portray the country's commitment to climate change issues, adaptation and mitigation measures established by the various institutions.

Future Direction for a Volcanic Basin Planning
(Case Study of Opak Sub-Basin, Yogyakarta, Indonesia)

Vicky ARIYANTI, LPDP, Indonesia and Erasmus University Rotterdam, Netherlands
Jurian EDELENBOS, Scholten PETER, Erasmus University Rotterdam, Netherlands

1. Introduction

There are about 1,500 volcanoes with potential activity in the world (USGS, 2018) and out of this, at least 500 are known to have historical eruptions. Out of this 500, many of them are located within 10 to 80 km radiuses of urbanized areas, with more than 1 million populations (ESRI, 2018) meaning that they could get direct impact from a volcanic eruption. A volcanic eruption produced the pyroclastic flow, lava, and lahar (Trenberth and Dai, 2007, Wood and Soulard, 2009, Chester, 1994, Bignami, Bosi, et al., , 2013). Nowadays, more scientific research has proven that climate change may induce more frequent volcanic activities (Swindles, Watson, et al., 2018). As climate change progressed, this meant that more volcanic eruption risks are faced by these cities. Appeals for living in these cities by the volcano consists of the volcano's beautiful scenery, the fertile soil, and the good groundwater sources (Chester, 1994, Cashman and Giordano, 2008). Many cities in developing countries are located in the active tectonic belts or in the location of the most explosive volcanoes. A study had calculated more precisely on the urbanization rate and population growth of these volcanic cities in 2001. It proposed about 9% of the world's population lived within 100 km of a historically active volcano, while 12% lived within 100 km of an eruptive volcano in the last 10,000 years, while the density decreased within 200 km (Small and Naumann, 2001).

Lahar is the Indonesian word for the volcanic debris flow, which is a natural phenomenon for an active volcanic river basin when an eruption produced materials and combined with rainwater. For those cities located in these locations, there is a need for a paradigm shift to integrate this lahar condition into our river basin planning. This need on the shift is because most river basin planning is based on general geological condition, for the non-volcanic region and does not address this issue. Examples of lahar strategies management in Japan, US, New Zealand and the Philippines (Pierson, Wood, et al., 2014a, Major, Pierson, et al., 2000, Rodolfo, 1991) are used by the Indonesian government in deciding their lahar management.

In this paper, Mt. Merapi is chosen as the case study as it is one of the most active volcanoes in the world, recently erupted in 2010 marking a-100years periodical cycle and also located near a highly populated urbanized area of around two million in Yogyakarta-Sleman-Bantul agglomeration (BPS Provinsi D.I. Yogyakarta, 2018). The standard measurement for an eruption is the Volcanic Explosivity Index (VEI), ranging from 0 to 8, where the 2010 eruption was at 4 VEI. The lahar in Opak Sub-Basin is handled with Sabo Dam System(Chanson, 2004, De Bélizal, Lavigne, et al., 2013), combined with the land use plan and early warning system. This paper aims to tackle the complexities of lahar management planning in the Opak Sub-basin located in an active volcanic river basin, with relation to water resources management, by means of answering the research question on "What are the interrelations of lahar management in integrated water resources management?" This study signifies the importance of learning from the lessons from a volcanic river basin management to shape future plans.

2. Conceptual Framework

2.1 Lahar definition

In this research, due to the location, Opak river basin faces threats concerning the volcanic activity. The most posing threats in the relation between water and volcanic activity would be lahar hazards or volcanic debris flows (Marso, J. N., 2013, Pierson, Wood, et al., 2014b). Hazards do not always happen in extreme natural phenomena; however, when it occurred in the human surrounding, it may threat life, environment, infrastructure, and property. Hazards in themselves do not constitute disasters. A volcano has an immediate hazard; the pyroclastic flow and the non-immediate hazards; the earthquake and the lahar. Pyroclastic flow as the most dangerous hazard is a fast flow (up to 700 km/h) of hot gas (1,000'C) and molten rock or tephra (Lavigne et. al., 2000). The earthquake happens as volcanic eruption blows this tephra and during the process of eruption in low tremor movement. Lahar is developed as volcanic materials build-up on the flank of a volcano after eruption is triggered with heavy rainwater, creating a debris flow with speed up to 100 km/h, and volume up to the unlimited amount depending on the scale of eruption (Lavigne and Thouret, 2003, Marso, J. N., 2013, Rodolfo, 1991).

As a term, lahar has been used as an international term since 1929 in addressing mudflow from volcanic activities deposit (Scrivenor, 1929). However, this definition is too narrow, as it does not explain the composition of water and volcanic materials, also as it refers mainly to sand and clay, while in reality it also contains rocks, pebbles and even boulders. Another definition explains the character of lahar as mudflow, which contains volcanic materials transported by water, including "debris and angular blocks of volcanic origin" (Bemmelen, R. W. v., 1956). This more "loose" definition fits better with the lahar terminology used in this research. As mentioned earlier, the generation of rain lahar can be seen as an iterative process of water and volcanic material mix (Pierson and Scott, 1985). The differentiation of the percentage of composition cannot be measured in detail as lahar continuously changes its composition throughout its flow downstream. The phase of formation can be explained in the following diagram(Rodolfo, 1991), each phase of the rain lahars may form differently in each condition as it also varies based on the condition of sediments and geomorphology of the volcano slopes. This condition shows the process of lahar formation as partly water induced. Only some literature relates to water and lahar hazard in water management issues (Jakob, Hungr, et al., 2005) those that are addressing lahar, most are in the field of geology or volcanology. Most literature in water management addresses water-related hazards as a climate-related hazard, but does not include lahar (Parry, Canziani, et al., 2007, Viviroli, Archer, et al., 2011, Yusuf and Francisco, 2009). Therefore, to pinpoint this issue, it would be wise to see the relation as lahar characteristics have fluidity in which relate to the rainwater composition (Rodolfo, 1991). The starting point would be seeing lahar as rain derived, which therefore creates the link to water management in general. Lahar may be directly related to eruption, but in the case of Merapi it more related to high precipitation after eruption, which can add up to several years after the actual eruption happens (Lavigne and Thouret, 2003, Lavigne et. al., 2000, Pallister, Schneider, et al., 2013). This kind of lahar is also known as rain lahar (Rodolfo, 1991).

In this regards, lahar hazard is mostly dealt with common water infrastructures (Marso, J. N., 2013), such as retention dams and check dams (Pierson, Wood, et al., 2014a). Indonesia adopts Japanese Sabo dam system since the 1970s (Chanson, 2004). Under this arrangement, water resources managers are amongst the most influential stakeholders in lahar mitigation (Lavigne et. al., 2000). As analysis result for lahar hazard, a hazard map is usually produced (Jakob, Hungr, et al., 2005), it indicates peak flow, sediment concentration, sizes of rocks, depth of flow, movement directions, speed, distribution, frequency, duration, destructive magnitude, distribution, and predictability. This lahar hazard map would be used to analysis further chance in merging lahar management to water resource management.

Lahar as part of water-related disaster is treated as a form of a flood in reality. The engineering approach answer to lahar risks mitigation is employing sediment check dams or retention dams, which in Japanese is termed as Sabo Dam. This term is used for this case study. This condition presented lahar to be tackled as normal floodwater in river channels, which is not enough, as the magnitude of the water discharge with the debris easily could destruct these dams (Pierson, Wood, et al., 2014b). As one of the focuses on water resources management is to mitigate water-related hazards, it would be more economical and less costly to focus on preparedness, than relying on emergency responses. New implementation in disaster risk reduction framework represents an opportunity to larger stakeholders. Water-related hazard risks need to be addressed in operational plans, such as the water resources management plan (Ndirangu, Kabubi, et al., 2009, Renaud, Sudmeier-Rieux, et al., 2013).

2.2 Conceptual Interrelation of Lahar in Integrated Water Resources Management

As lahar in this study refers to rain lahar, the relationship of the lahar is part of water-related disaster as the base of IWRM (integrated water resources management) to include lahar as part of its problem (Pierson and Scott, 1985). The IWRM, in general, would point out the flood, drought, and landslide as the water-related disaster, yet there is not much mentioned in the literature on managing lahar as part of IWRM. Rain lahars are the most common features of lahar in the world, as 46 percent or about 400 active volcanoes are located in te tropical region, however, they are poorly documented as most are occurred in developing countries where not many trained scientist can be found (Rodolfo, 1991). Lahar is specifically formed in volcanic river basin as part of indirect eruption cycle activities, and therefore should be addressed as part of one of the main challenges in managing water resources in the volcanic area.

The IWRM approach implemented in this case study is using its four dimensions (Savenije and Zaag, 2008): (1) natural: types of water resources (Graefe, 2011, Savenije and Zaag, 2008, Gleick, 2003), (2) spatial: characteristics of up, mid, downstream river basin and their interrelations (Molle, 2009, Hofwegen and Jaspers, 1999, F. G. Jaspers, 2003), (3) temporal: water and seasonal cycle (F. G. W. Jaspers, 2014, Savenije and Zaag, 2008), and (4) human: actors in water governance multi-levels interrelationship (F. G. Jaspers, 2003, Medema, McIntosh, et al., 2008, Edelenbos and Teisman, 2013). Additionally, within a volcanic river basin, the lahar (volcanic debris flow) as part of water-related hazards is also addressed. In the context of the lahar management, it is placed under the IWRM implementation in this volcanic river basin (VRB). Therefore, the lahar management dimensions follow the same structure: (1) natural: volcanic activities leading to lahar production, geomorphological characters leading to lahar flow and lahar's characteristics (Pierson, Wood, et al., 2014b, Bignami, Bosi, et al., , 2013), (2) spatial: map of distribution and direction in recorded history and future prediction (Bignami, Bosi, et al., , 2013), (3) temporal: volcanic cycles, hydro-meteorological cycles (Lavigne, Thouret, et al., 2000, Case, Ardiansyah, et al., 2007), and (4) human dimensions: components of relationship and stakeholders in lahar management (Edelenbos, Bressers, et al., 2013). Based on these dimensions, the patterns of management for the volcanic river basin are characterized.

Water in volcanic river basin has a major role in the eruption process, but volcanoes are also water storage (Delcamp, Roberti, et al., 2016). This interrelation is the departure point of addressing the study with the Nexus approach. As the dimensions are interrelated directly, they suggest the existence of Nexus (Kurian and Ardakanian, 2015, Schreier, Kurian, et al., 2014, Herath, 2014) between the water-lahar-volcano management. Therefore, the authors choose to address this interrelations using multi-level governance framework (Edelenbos, Bressers, et al., 2013, Gupta and Pahl-Wostl, 2013, Moss and Newig, 2010, Termeer, Dewulf, et al., 2010) starting with policy setting, managerial context (divided into national, regional, municipal) and interaction attempts, finally the integration level of the lahar management with water. The integration level is divided into coordination, collaboration, and cooperation. Each level is based on the shared 'things' the stakeholders are commonly working on. The coordination is the lowest level, which meant when there is information sharing. While for collaboration in the intermediate level, this is proven by sharing of information and aim. The cooperation is the highest level with sharing of information, aim and aligning budgeting supports. This analytical framework is used to explain the research findings.

2.3 DRR framework for Lahar

By including the lahar management into IWRM, the DRR framework for lahar hazards should be incorporated. The concept of disaster risk reduction (DRR) aims in reducing statically expected loss from a particular type of risk, by mean of reducing likelihood of hazards, reducing the expected loss, or both, with prerequisites of clear understanding on cultural and organizational character in society and active involvement of NGO and local communities (Ingleton, 1999 in(Wisner, Blaikie, et al., 2004)). The risks mitigation of water-related disaster is one amongst challenges of water resources management. The DRR framework is divided in the stages of disaster: pre, onset, and post-disaster. These stages are used with the lahar management dimensions, which are explained in the next concept. Due to the nature of rain lahar, this hazard has similar characteristics of a flash flood, i.e. the tendency of high volume in short period, flowing from up to downstream, and high magnitudes of force, which may destruct anything on its path. Reducing risks of natural disasters should give more attention to social than physical approaches, it should be more pro-active than reactive, it must focus more on the reduction of vulnerability, as part of on-going policies and programs (Weichselgartner, 2001).

3. Methods

The case study as a research strategy is used for the volcanic river basin of Opak Sub-Basin in the slope of Mt. Merapi. The multi-level governance framework is used to divide, the case study into national, regional, and municipal levels. In the municipal level, the representation is done by selecting three villages with worse lahar impact post-2010 eruption for up, mid and downstream locations, based on damage report provided by the disaster management agency (BPBD DIY) and the river basin organization (BBWS SO). These three villages are Argomulyo (upstream), Gowongan (midstream), and Kebonagung (downstream). Meanwhile, the organizations selected were based on the criteria of directly link to the volcanic river basin management, by means of resources and authority. This paper uses a qualitative approach, with ethnographic intentions, based on 57 open-ended and in-depth interviews, with two months of fieldwork in 2016 and one month in 2018. Additionally, the secondary data (maps, minutes of meetings, planning documents, regulations, etc.) is used to support the interviews. These secondary data were referred by the respondents or by other document or regulations. The respondents' samples were chosen based on the position in the organizations or community and their length of minimum five years tenure using the snowballing method of referral from main respondents.

The analysis process uses axial coding based on the conceptual frameworks, especially the dimensions of lahar and water management combined with the multi-level governance framework. With the help of Atlas.ti and constant comparative analysis on the research materials: 57 interviews, three sub-cases observations, the implementation of lahar management in the case study of a current volcanic river basin Indonesian condition were investigated. The interviews were audio recorded, transcribed, and to be coded in the Atlas.ti software. The observations of the villages were photographs and video recorded, some notes were also taken during the fieldworks. The analytical framework is later on used to present the research findings.

4. Results

4.1 Planning Policy Settings for Water and Lahar Management in a Volcanic River Basin

The Indonesian policy sets the boundary of a river basin based on geomorphological characteristics, in which rivers drain in its catchment toward the sea. However, to define the boundary for this case study, a volcanic river basin is characterized by a volcano at its upstream. Thus, the volcano policy setting should be explained as its hold a specific natural character to the river basin. In this section, the policy settings for lahar management are not directly stated in a law, but dispersed in several related policies on the volcano management, the disaster risks reductions (DRR), the hazard zone spatial planning, and the river basin management, especially on water-related hazard control.

On the volcano management, the Indonesian policy setting belongs to the Ministry of Energy and Mineral Resources (Kemen-ESDM) and to be exact under the Geological Agency at the Centre for Volcanology and Geological Disaster Mitigation (PVMBG). Moreover, being the most active volcano in Indonesia, the Merapi has a special office: BBPTKG (Centre for Investigation and Development of Geological Disaster Technology for Merapi or Volcano Centre for short). The Merapi is a Strato-volcano (a cone-shaped mountain), with effusive-lava flow and eruptive-sudden burst type of activities. The policy sets to manage a volcano include the monitoring and prediction of the volcanic activity status. It is legalized as Minister's ESDM no. 15/2011 on Guidelines of Disaster Mitigation for Volcano, Land Movement, Earthquake, and Tsunami. It stemmed from the Law no. 24/2007 on Disaster Management. Based on these policies, the main duty of volcano management is monitoring the volcanic activities, which falls under the PVMBG. The above mentioned minister's regulation states the 127 active volcanoes in Indonesia are divided into 3 types: (A) those which still erupted after the year 1600, (B) those which does no longer have any magmatic activity after the year 1600, but still has some mild activities such as solfatara crater, (C) those with remnants of mild volcanic activities, such as solfatara field. Merapi is categorized as type A, along with 75 other volcanoes are actively affecting the river basin they located on.

Meanwhile, the Law no.24/2007 explained the framework of disasters risks reduction (DRR) as both human and natural caused. It calls for the implementation of disaster management:

> "... A series of efforts covering the establishment of development policies at risk of disasters, disaster prevention activities, emergency response, and rehabilitation."

Based on this law, the BNPB (National Disaster Management Agency) was established. The agency is an organization at a ministerial level that steers and implements the disaster management policy. It aims to "formulate and determine disaster management policies and the handling of refugees by acting quickly, appropriately, effectively and efficiently; and also to coordinate the implementation of disaster management activities in a planned, integrated, and comprehensive way." The management of the DRR in Indonesia is based on the establishment of a new agency: BNPB (National Disaster Management Agency) in 2007. Since it was established, the command line during disaster became clear and more systematically organized. Its function will be explained more in the national level managerial contexts. The following diagram presents the main disaster management cycle translated from a report by BNPB 2011 and adapted for this research.

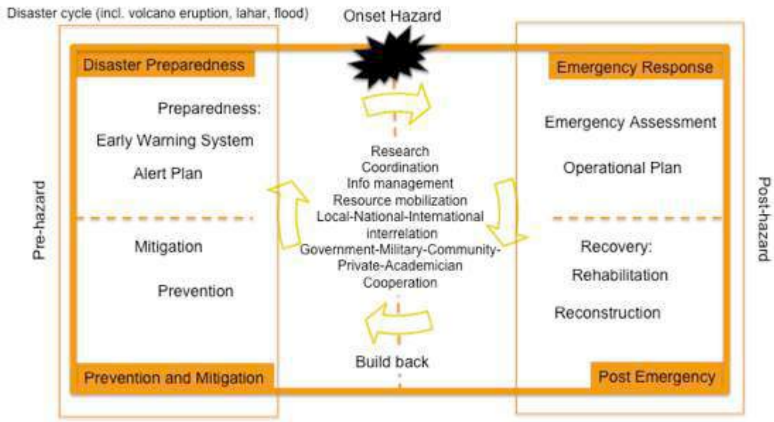

Figure 1 Model of disaster management with author's adaptation (BNPB, 2011)

Another relevant law on the water-related hazards in a river basin planning would be Law no.7/2004 on water resources management. This law is the Indonesian version of the integrated water resources management (IWRM), which appoints the ministers and departments related to water management to control water hazards, under this responsibility the disasters referred to are:

> "… Floods, lahar floods, landslides, ground surface sink, drought, change of characters chemical, biology, physical of water, threats of endangered species and animal, the epidemic of a disease; intrusion; and seepage."

Although not explicitly pointing the Ministry of Public Works and Housing as the ministry to be in charge with this, it is common with the kind of formal language used in Indonesian law, as changes of names and merging or splitting of ministries are likely to happen throughout changes of the Presidency. Thus, the law refers to the mandate to "the minister who is in charge of water resources," and to be more exact it also explains:

> "… Ministers or heads of non-regional government agencies, which are those whose field of duty relates to the field of water resources, including the functions of forest management, groundwater, agriculture, fisheries, water transportation, spatial planning, meteorology, environment and weather modification technologies."

The overlapping of policy in lahar and water management is happening taking place in the disaster management. Although, each stakeholder has a role in lahar management, the Law for DRR does not directly refer to the Ministry of Public Works and Housing. Instead, it puts 'all related ministries,' but the Law for Water Management does this referring. This ministry is responsible for coordinating with the BNPB and BPBD to decide the status of disaster. This broad undertaking by one ministry is hoped to be addressing is already signaling the expectations of collaboration between ministries and agencies. The rationale here is: this ministry builds most of infrastructures on water resources; hence the way to mitigate disasters using the technical approach should also be handled through the same ministry.

The policies and concepts are inadequate in addressing these interrelations, but interestingly on the managerial level, the implementation of these policies are working organically based on experiences towards solutions, as presented in the following section. Based on these stages, the managerial contexts in each level of governance as follow are explained with pre, onset, and post-hazards.

4.2 Planning in Managerial Contexts

National

For pre-eruption, the volcanology department at the Ministry of Energy and Mineral Resources (KemenESDM) has the leading role. Its role is also extended during onset and post-eruption as volcanic. This ministry has the responsibility to monitor the geological activities, which is implemented in the form of Geology Agency (Badan Geologi). This Agency performs the following functions: conducting research, investigation, and service in the fields of geological resources, volcanology and mitigation of geological, groundwater, and environmental geological disasters, as well as geological surveys. The Center for Volcanology and Geological Disaster Mitigation has the task of conducting research, investigation, engineering, and service in the field of volcanology and geological disaster mitigation. The central office of this agency has many branch offices: the PVMBG directly monitor all the volcanoes in Indonesia.

During onset hazards, as presented in the policy setting, the BNPB is the main actor. Although not specifically relate to lahar, this actor is also the commander in times of other disastrous conditions. Using the law on disaster management, the implementation of this law is the establishment of BNPB and the formulation of Renas-PB (National Plan on Disaster Management). Under this law, the implementation can be seen during the 2010 eruption, where the BNPB took over the command line collaborating with BPBD DIY established orders in the emergency condition. In the occurrence of a disaster, the Bappenas is also a part of the coordinated stakeholders by the BNPB, while in normal condition is vice versa. The type of roles for each the disaster may differ. Using this overarching framework, the BNPB operations' are limitless as long as the main idea is to maintain safety and order during disaster events. In the event of 2010 Mt. Merapi eruption, the BNPB and the ministries were involved as the eruption hazards areas consists of the whole Java Island. On the week of the eruption, all the flights went and came accross Yogyakarta sky was canceled, as the ash was flown to east and west of the Java Islnd, limiting visibility. The hazards area also covered two provinces, thus, inter-provinces authority belongs to the national government. Another ministry, which relates to technical assistance on water-related disaster management, would be the KemenPUPR or the Ministry of Public Works and Housing. This role has to do with their tasks in mitigation of water hazards (pillar no. 3 of the Indonesian IWRM). However, this ministry has more roles during pre and post-hazards (normal condition), as the water resources management is its domain, where two other pillars: conservation and utilization of water are also managed. Each of the pillars supported by the information system and community development. The management includes the planning, implementation, operation, and maintenance of irrigation, dams, and weirs, rivers and other water resources infrastructures. Consequently, this ministry implements the IWRM approach. In the case of water-related disaster, this is managed through coordination with the BNPB. In the lahar disaster, the KemenESDM will provide their technical assistance to determine the status of volcanic activities, while the KemenPUPR give the status for water level in the rivers. Thus, for lahar, both ministries will give input to the BNPB. The involvement of JICA (Japan International Cooperation Agency) on the DRR of volcanic basin management is grounded on the experience cooperation, between the two countries: Japan and Indonesia especially with the Director General of Water Resources within the Ministry of Public Works and Housing. For the case of Merapi lahar, as already being introduced before, the JICA (Japan Indonesian Cooperation Agency) has been the Indonesian's partner since 1976. Based on the JICA master plan for volcano disaster mitigation plan, there are two types of hazards against rainfall (secondary impact) and volcanic eruption (direct impact). The master plan directs the direct impact to be managed with non-structural measures (evacuation plan, land use plan, early warning system, disaster response training, etc.), while for the secondary hazard; it is possible to have structural (lahar management infrastructures) and non-structural measures. The volcanic disaster mitigation plan by the national government is oriented strongly with the recommendations made by the JICA. Even though, the Ministry of Energy and Mineral Resources have made regulations on volcano management, but the forms are not as rigid as a plan. Therefore, this arrangement shows the flexibility of the Indonesian government in adopting foreign influence; yet at the same time also propose flexibility of different stakeholders to engage and taking roles with during various stages of a disaster.

Regional

The planning for lahar management is dealt with the BPBD DIY (regional level disaster management agency), with the hazards zone map being developed with many other differences. Although not established in one roof (not originated from the national government), the BPBD DIY is the regional partner of the BNPB (national level). The command line goes through the Ministry of Home Affairs, and the highest commander is the Governor or the Sultan. However, the BPBD has its Chief, and it uses the RPB as the document to address all disasters potentials that are belonging to the region, either natural or man-made. The document is valid for 20 years from 2013 to 2017. As the BPBD DIY was newly established in 2011, consequently, there is only one RPB (Disaster Management Plan) for all kinds of disasters in the region. The priority zone of the disaster management of the Yogyakarta Special Region (BPBD DIY, 2013) is based on historical records. It consists of all potential disasters in Yogyakarta, including earthquake, tsunami, flood, landslide, volcano eruption, extreme climate, and drought. But, for this sub-section, the priority for Opak Sub-Basin consists of the volcanic eruption and its relation to lahar flood and water management.

The BPPTKG (Volcano Center) as the KemenESDM branch office has the main task is to prepare plans and programs, and manage the cooperation and information, also implementation. This office monitors the Mt. Merapi disaster mitigation, provision of recommendation on activity level, and technical recommendation of Mt. Merapi eruption mitigation, implementation of research, investigation and development of geological disaster methods, technology and instrumentation, management of geological disaster management laboratory, and the facilities and infrastructures. Using the example of Mt. Merapi, the monitoring uses International standards and observation posts, remote sensing and UAV (unmanned area vehicle).

> “Monitoring, for Merapi the standard is international, it is seismic, deformation, geochemical, visual… Yes, the visuals are represented by observation posts of our volcanoes. Depending on each volcano… In Merapi, there are 5, because it (the eruption direction) moves around and active, but if the direction is the same, one is enough.” Respondent BPPTKG.

Essentially, this monitoring explains that sophisticated and remote sensing technology with international standard is also used by the PVMBG (national level) to monitor other Indonesian volcanoes. However, there is also the need to visit the sites (observation posts), when the device is not working or cannot be remote from the office or when they need to crosscheck measurements directly. The following hazards zone plan is derived based on the types of volcano eruptions impacts: direct and indirect. The map collaborated the works of the volcano center (BPPTKG), the river basin organization (BBWS SO), and the development-planning agency (Bappeda DIY). Based on the status, the Merapi is not only a provincial level threat but also a national concern, where two provinces were involved: DIY (Yogyakarta Special Region) and Jateng (Central Java). Thus, the BNPB (National Disaster Management Agency) has agreed the 2010 Merapi disasters map produced by the BPPTKG to be used as the main reference (figure 2).

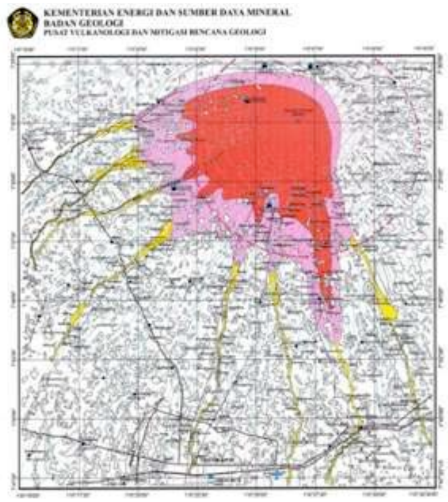

Figure 2 Hazard Map of Mt. Merapi (KemenESDM, 2011)

This map presents the hazard zone of Merapi is divided into three categories post-2010 hazard. The policy for the spatial plan for this disaster location is as follow:

Table 1 Hazard Zone Delineation

Zone	Zone characteristics	Spatial plan policy
KBR3 (most dangerous) ~4 km Red	Very close to the summit of Merapi volcano with threats: pyroclastic flow, lava, rock avalanches, incandescent stones hurls, and heavy ash rains (directly impacted). Recommended not to be used as a non-fixed residential area, When volcanic activities escalated, prioritized to evacuation.	Direct volcanic activities impacts, recommended to be used as conservation area or limited cultivation. Non-direct volcanic activities impacts recommended as zero growth zones. The facilities and infrastructures are used only for the existing residential and limited cultivation, research and community's safety Directly impacted zones are assigned by the local Regents up to hamlet scales
KRB2 (dangerous) ~4-15km Pink	Areas with pyroclastic flow, lava, lahar threats. The community has to take care of evacuees from KRB 3 when escalated volcanic activities. Based on 2010 eruption the hurls of incandescent stones reach up to 10 km of the Merapi summit	Recommended as limited cultivation zone, in accordance to related regency's RTRW
KRB1 (less dangerous) >15km Yellow	Areas with potential lahar flood, lava, and pyroclastic flow. During high precipitation, lahar flood will inundate settlements, agricultural land, and infrastructure. During lahar flood in big scale, the community has to be evacuated. Safety strategy by to move away from the catchment (wrongly used terminology, supposedly river channel).	River boundaries should be made in segments, not generalized for the whole river channel. The segment is based on the river morphology and with regards to lahar impacts. The budget for relocation to directly impacted areas (non-urban), includes compensation for land by National Government. Urban area policy needs further studies

The BPPTKG explains that in a way share the role in calculating the lahar potential at post-disaster is better, as it was done in the 90's. There were instances in the past that both (BPPTKG and BBWS SO) were working together in the calculation lahar potential.

> "Our sharing was good, actually. Yes, in the 90's, about four times. It happened with the collaboration with the ProMer (Merapi Project under BBWS SO) to calculate the lahar (volume potential)… We worked together then … that time we are 'one word' (consensus)." Respondent BPPTKG.

In terms of lahar though, the authority falls under the BBWS SO (RBO-river basin organization of Serayu Opak), especially lahar in the river channels, which have been studied thoroughly by the JICA as mentioned in the national level. Thus, the results of their studies proposed the Sabo Dam System, with a series of consolidation dams and sub-dams in all rivers originated at Mt. Merapi. The concept of Sabo Dams is adapted in the Indonesian context adding multi-functions (temporary bridge, irrigation intake, etc.) and uses the sand mining activities as sediment management. These Sabo dams were prepared based on a calculation for 100 years return period of lahar (DGWR, JICA, 2001), however, as proven in 2010, the calculation may have not properly predicted the amount can reach up to 140 million m3. There are two types of Sabo dams implemented at Mt. Merapi: closed and open. The closed type is used to completely stop the lahar sediment flow, at which the dead storage condition can happen. Meanwhile, the open type has the conduit/slit pass, which still let pass smaller rocks and sand up to 50% of discharge. It is clear in this figure that the lahar is controlled using Sabo dam system as a whole throughout the river systems, which located in the Mt. Merapi. Thus, the volcanic river basin characteristic management, in this case is quite developed and anthropogenic controlled. The infrastructures damaged the natural condition of the rivers to secure the settlement and agricultural area. It is also clear that the upstream will suffer for the benefit of residents who live in the mid and downstream. This information may not be disseminated, as it is considered as a sensitive matter to the upstream village communities, but they do deserve to know this risk. By presenting this figure 6, the perception of lahar management is based mostly on a technical solution, while in reality; the most important thing is the readiness of communities to evacuate on time.

This means that lahar management, although has high priority comes second to daily needs of water and transportation. These other functions can be established, as there are similarities of dam function for water and lahar, which is a cross-river body infrastructure.

> "Of course…. Converted into multifunctional, the main function is the sediment control, but second (function) is an intake for irrigation, because it has the same principal form, only with a gate (irrigation gate)… We do have a vision of a direct impact on the community. If it's that (the bridge- described with hand movements), it has a direct impact, the public could directly benefit from it." Respondent BBWS SO

Thus, with the multi-function, it favors permission from the villagers, as many protests were drawn after the 2010 eruption when the BBWS SO proposed to rebuild the Sabo dams. However, after discussions with the community, all of them want the Sabo dams to be rebuilt. The way the Sabo dam system in Mt. Merapi works in managing lahar is philosophically using filtering strategy from bigger boulders using open type and the sand pocket for upstream Sabo; closed type with holes between up to mid-stream with the help of diversion channel; embankments for mid-stream. The whole river basin territory (WS) is supposedly managed based on the land use plan made by the Bappeda DIY (Regional Development Agency) as the highest in the hierarchy. But, during hazards, the BPPBD DIY took main commander of all scale of management. In summary other stakeholders are explained in figure 3: (1) BBWS SO (RBO): all the rivers, lahar and flood, including floodplains and the infrastructures to manage them. (2) BNTGM (Merapi National Park Manager): under the Ministry of Forestry and Environment or KemenLHK –with 4 km radius from the summit. (3) BPPTKG (Volcano Centre): the Mount Merapi's volcanic activities monitoring – scales of management: the whole mountain up to its flank and the rivers where the volcano channels its debris flow. (4) PU-P ESDM DIY (Regional Agency on Public Works, Housing, Energy, Mineral, and Resources): all infrastructures belonging to the provincial government and management. (5) BPDAS SOP (Catchment Management of Serayu Opak Progo): also under the KemenLHK, for all catchment managements especially for water retention inland

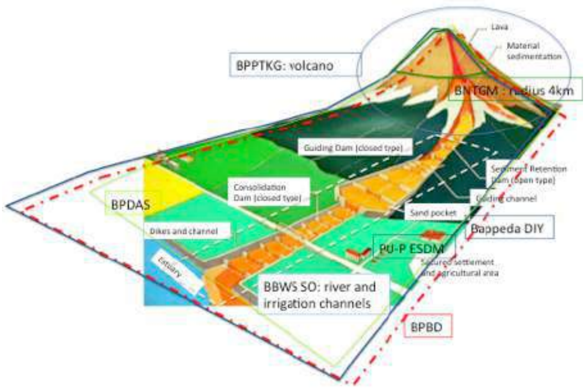

Figure 3 Arrangements of a Volcanic River Basin in Mt. Merapi

Municipal

For the onset lahar occurrences, the municipal BPBD is to evacuate as many people as possible from the riverside. The BPBD at Sleman Regency is more actively engaged as lahar potential in the upstream is still an eminent hazard potential. Most of the time during rain lahar, the victims were sand mining trucks and their teams. The EWS (early warning system) alarm sometimes is not being regarded, as it made too much sound, but, when visual on the lahar is seen, it is usually already too late to evacuate from the river. The Tagana is the disaster response personnel at the village level. Its role is to maintain safety in the village in the case of hazards occurrence. For this study, the hazards are related to lahar flood.

> "At Adem stream (upstream Opak), there was already there. Here, (in Argomulyo) we have the SKSB, luckily. If there were victims, those were breaking the rules. As (the incident with) the truck was carried by the lahar, that is because they did not obey us (*Tagana*)." (Respondent Argomulyo).

During onset hazard of lahar, the river channels are filled with the volcanic materials. Depending on the locations, the severities of impacts are based on the distance from the volcano, the closest the distance the biggest the impact will be. The BPBD at the municipal level works together with local communities regarding monitoring the lahar. In Opak Sub-Basin, the municipal includes Sleman Regency, Yogyakarta City, and Bantul Regency. Although each municipal has their disaster management agency, they relied heavily on the aids from the national (also international aids through national government) and regional level. Especially for locations on the riverside, the BBWS SO aid for heavy equipment is needed all around. During onset lahar, there are no activities relating to water resources management conservation and utilizations.

As for the post-hazards condition, the direct impact of lahar would be the submerging of riverside locations and the sedimentation. In the upstream, the lahar may fill up the river channel and submerged existing spring, except for one by the Sabo GE-D, upstream of the village. As the lahar sedimentation was dredged, the underground water channels were cut off, and the post-eruption hot spring water stops producing. Even if lahar cannot exist without water, but water can also be interrupted by the lahar. This condition is especially related to the quantity of water diminishing and hot temperature; also the water quality changed with the volume of volcanic materials submerging the wells, such as Fe and Sulfur. The lahar sedimentation impacted the water springs by the, some were buried, some moved, some newly emerged. The case of 2010 eruption changed the conditions of springs by the upstream village. However, the river base flow is still utilized as an alternative water source. Concerning water utilization, the lahar infrastructures (Sabo Dam) in the upstream village can also be used as an irrigation weir. However, for the upstream sub-case, the Sabo Dam is only used to control lahar flow and a temporary bridge. In the mid-stream, the lahar in 2010 devastated the homes of the communities who live on the riverside. The lahar filled up the houses up to 1 meter deep. As the Code River has been built with a fixed embankment, people felt safe to live by the riverside. But, during that occurrence, all was affected, and the lahar is tackled momentarily, using temporary dikes (gabion-mesh), which seems to last longer than temporary as of during the fieldwork in 2016, this still existed. The lahar submerged most of the Riverside water wells and low elevation settlements, resulting in the whole elevation of the kampong, being uplifted to 1meter. Consequently, the wells needed to be dredged from the lahar sediment before being re-utilized. In the downstream, lahar impacts were not as severe as the first two locations. The locals were more concerned about the sedimentation of the Opak River, especially near the Tegal Weir, as the villagers used to use the river for water tourism attraction. The lahar flows to the fork of Opak from Mt. Merapi and Oyo from Karst Gunungsewu. Most of the sediment from 2010 is still fully intact as no significant dredging activities were done in this part, as it never received any aid for dredging from BBWS SO or anyone.

On water conservation, the lahar management has a relation as the river channels filed with volcanic materials. In the upstream village, the conservation is highlighted as the main activities especially because most of the area is located in the hazard zone and being resettled elsewhere in safer locations. These areas are conserved as both hazard zone and water permeation area. In the midstream, the conservation is not taken into consideration as the land is mostly used for settlements. The lahar control is more dominant than conservation, for this sub-case, it is presented by means of dikes and dredging the river channel. Meanwhile, the downstream village was not so aware of the need for water conservation. This village never had any problem of irrigation supply shortage due to the existence of the weirs and irrigation canals in the Opak River.

Another side effect of the lahar post-hazard is the existence of the sand mining industry. Unfortunately, the municipal government paid more attention towards the income generated by this industry, than the sustainability of the river regimes. More permits than necessary were given to gain access to the lahar materials. The river channels were dug up, deeper than the original condition pre-2010 eruption. Initially, in 2010, the municipal governments are responsible for declaring permits for the sand mining or the C type mining, but during the fieldwork of 2016, this has changed to the regional government. The sand mining industry in downstream is also not as burgeoning as in the upstream, this is due the quality of the sediment is not as good as those in the upstream area for construction material. The sand mining activities in the upstream village is still very much active, with hundreds of trucks going back and forth daily to the channels to collect sand and other aggregates of the volcanic materials (observed both in 2016 and 2018). The upstream sand mining uses machinery, such as the backhoe, pump and stone splitters. This sand mining is not the case for mid-stream and downstream. The mid-stream respondents explained that the sand was used to elevate the riverside area up to 1meter above its original elevation or to build their own homes. However, traditional sand mining activities downstream were reported and observed nearby the Tegal Weir. This activity is using simple tools such as bamboo boat and human diver with a bamboo knitted container, which can drain the sand as soon as it gets to the surface. Additionally, the lahar sedimentation in the river channels, which was not being part of the sand mining industry were used as temporary farmlands during the dry season.

The training for preparation of pre-eruption is dealt, by addressing the readiness and tasks planning are proposed by training of the CBO with the local BPBD. The training was more often took place in upper stream areas, than the midstream and downstream. The training is more intense in the upper stream due to the impact of the hazard are greater there compared to other locations. More focus on Sabo Dam training is also given to the villagers by the RBO in collaboration with the community-based organizations (CBO). The CBO in the upstream area is based on their awareness towards safety during hazards. In relation to the training, evacuation routes and meeting points are also prepared for each location.Especially for lahar, the hazard zone is mapped based on historical review of earlier lahar. However, lahar safe zones are not yet implemented A system of sister village is also established for the upper stream villages.

> “It exists, fortunately, we have for some time now, a sister village program from the BPBD. The sisterhood exists between villages. Like here in Argomulyo, from upstream we have Glagaharjo….There is already an agreement. The MoU has already been signed.“ (Respondent FGD Argomulyo).

Meanwhile, for the upstream village, the initiative relates more to the disaster information with the Forum SKSB (Shared Social Communications Channels). Although training for Sabo Dam monitoring does exist, the setbacks of rivers in the upstream area are unknown for certain. Hence, people living in this area do not know for sure what is the safe distance from the river. Another attention is given to the awareness of residents in the mid-stream area, as post-hazards, by delineating the riverside setback to 3 meters from the current dike. Although this is not safe zone from inundation of lahar, it can give some buffer time to evacuate the riverside residents. The residents have also developed an informal gathering of the lower level of government under the village administrative into the *paguyuban RW* to address riverside Kampong's issues, especially with respect to the river and flooding. The kampong in this sub-case study is characterized by its location by the riverside. Normally, a village consists of several hamlets, where each is consisting of several RW (community), and under this, there is also RT. However, the RW does not usually form a gathering. This mid-stream village presented an example of self-governance by means of formulating the *paguyuban.* The downstream village is more active in tourism, especially agro-tourism, by forming community-based organizations of the secretariat of tourism village initiative and the agricultural museum. The setback in this area is decided on the embankments along the river, with buffer zones of farmlands up to 100 meters. Based on historical experience, this distance is safe for flood and lahar zones.

The planning for future volcanic river basin should consider these conditions, which presented more vividly in the village level. Even if the volcanic activity considered by the villagers in the downstream area as a danger and sad occurrence for the victims upstream, but for the downstream area this had advantages. The volcanic ashes are considered as a natural fertilizer, and so is the lahar sedimentation, made up fertile land for the non-irrigated crop.

4.3 Interaction Attempts and Integration Levels in Lahar Management

Interaction Attempts

For these attempts during onset lahar, it is termed as the disaster interaction attempt, called as Disaster Task Force. In this task force, the members are ministerial level. At the national level, this coordination attempt for lahar risk management is dealt at BNPB, the national disaster management agency. This lahar management is done through mapping of lahar and the KRB (hazard zone) delineation in collaboration with other ministries and also to the regional level. For the case of Merapi 2010, the eruption was of a national scale priority as its ash also impacted the whole Java Island's flight routes. Even as the KRB's are inter-regional or inter-provincial delineation, the attempts are collaborative works across vertical and horizontal levels. The core of disaster management coordination lies heavily on the BNPB. However, the collaboration works is no longer integrated at post-reconstruction phase. As the coordination is not as frequent, the command line of interaction attempts is through the Development and Planning Agency (Bappenas). This attempt is termed as general development interaction attempt and active during pre and post-hazard. This attempt through the Bappenas proposes the annual budget as preparation for disaster finance. This mechanism of budget preparation is commonly known as the disaster funds. In each of the level, the funds exist, but the higher level of government can support lower levels, through transfer mechanism. The Musrenbang and the Rakorbang are the forms of this attempt, which existed in all level of governance. The first consists of supposedly two ways discussion between government and the people, while the second consists of only governmental agencies. The interaction attempt is coordinating provinces within the national government and also the different ministries. However, this attempt is shared with other development programs, not just water and disaster. It is also about other issues in development, meaning that the time to focus on one subject is very limited, even though the interaction attempts are done several times a year. Meanwhile, for the water interaction attempt, this is through the meetings of the Water Council (DSDAN). The council meets at least three times a year focusing on different aspects of water management. The members consist of 50% government and 50% of non-government representatives. The attempt is not relating directly with the water development fund, but hosted by the General Directorate of Water Resources in KemenPUPR. This attempt handles general water management, which is active during pre and post-hazards. It is not active during lahar onset or other water-related hazards, which became the domain of the BNPB.

At the regional level, the BPBD DIY (the Provincial Disaster Management Agency) acts as the leading actor for the commander during the onset disaster response implementation. The lahar is intersecting two main actors at the regional level: the BBWS SO and the BPPTKG. Both have the sound technical expertise needed to decide the lahar status and when to evacuate. During an eruption, both works along under the BPBD DIY, coordinating and collaborating data towards cooperation in deciding the status. The coordination meetings during an eruption are held and led by the BPBD DIY, which aiming all sectors cooperation. However, during normal condition, this coordination line is missing. There is a need to create a mechanism in which the BBWS SO and the BPPTKG can coordinate, even collaborate in providing their expertise and prepare the technical recommendations, even during normal condition. Again, as happened at the national level, the regional also experiencing the same thing. The fragmentation occurs of the disaster management in the precondition. This fragmentation is again based on the inexistence of responsible actors to manage the lahar. The coordination works better through direct communication during eruption and rain lahar occurrence right after the eruption, which heightens the integration level. The Musrenbang and Rakorbang exist at the regional level connecting the municipal levels within the provincial governments. The same mechanism is copied from the national level, also for the disaster funds. The leading stakeholder is the Bappeda DIY. A similar approach also occurred in water development funds for the regional level. However, due to current division of roles, the rivers are no longer become the responsibility of the regional level, but national level through the river basin organization. During rain lahar occurrence at pre and post-hazards Mt. Merapi's condition, this is the task of BBWS SO at the PPK PLG Merapi, a branch office of the RBO, which manages the lahar hazards control. Although, coordination is also done with BPBD's at municipal and regional level through the disaster task force headed by the BPBD. The main tasks of the PPK PLG Merapi are to operate the Sabo dam system, for that to function, the infrastructures are needed to be built and maintained. As discussed earlier, due to the limitation of personnel, the PPK PLG Merapi cannot monitor the 259 Sabo dams on the whole Merapi slope. For this task, the JICA suggested community level monitoring approach. Direct coordination between the local communities to PPK PLG Merapi can be done informally through calls, walkie-talkie report, or chat apps. However, also due to the limitation of local community members who have communication access to this office, especially for Sabo dams in a remote area (secluded upper stream), not all areas are covered. Still, this points out that along the rivers, the management belongs to BBWS SO, through the PPK PLG Merapi for those related to Sabo and the main office for the whole river regime. In this sense, the coordination is crossing levels of regional-municipal coordination.

In the regional level, the water interaction attempt also exists in pre and post-hazards, especially for the conservation and utilization through the meetings of water councils of TKPSDA, DSDAP and Forum DAS. These are hosted by different government agencies. The TKPSDA WS POS, based on the river basin territory and is hosted by the BBWS SO (RBO under the KemenPUPR). The DSDAP DIY is by the PU-P ESDM DIY (regional public works agency), based on the administrative boundary of the regional government. The Forum DAS by the BPDAS SOP (catchment management by the KemenLHK) is based on the catchments boundary. Specifically, on irrigation, the irrigation commission or the Komir deal this. The members of such councils are copying the structure of the national level in DSDAN. The members are representative of government: national (the branch of ministries), regional and municipal, combined with the private and communities (ration of 50%: 50%). Out of these attempts, only the TKPSDA discussed the lahar occurrence in their 2011 meeting, but no apparent results of the recommendations were taken into direct actions. However, as the RBO is the host of this council and rivers are one of the main responsibilities of it, it does make sense to discuss this in this council rather in the others.

At the municipal level, this attempt is also made through municipal level BPBD's. Although at this level, there is no coordination line with BBWS SO and BPPTKG, they work directly with SAR (search and rescue team) and community organizations (for example the Tagana or the Forum SKSB). More active works are done for lahar management in the upstream and mid-stream area, as the hazard level is still considered high. For the downstream area, the Tagana does not work with lahar, but more with the flood as the lahar has slowed down in this area and sedimentation is formed, which filled the river's channel. Crossing boundaries attempts (international-municipal, without national-regional intervention) can also happen, as international humanitarian activities have the flexibility to go directly to the impacted area during the lahar. At this level, local communities are more active in seeking ways to reach out for aids at any level of the management. The water interaction attempt takes form only in the Komir, as the water council became inexistent. Similar general development interaction attempt with the Musrenbang and Rakorbang exist with the municipal representatives given more participatory approach in this level. The two ways discussions occurred more frequently than in the other two levels.

Integration Level

The integration levels are also differs based on three stages: pre-lahar, onset lahar, and post-lahar. At the national level, the pre-hazard coordination disintegrated due to the inexistence of lahar management focused regulations, and the directive position of the BNPB is no longer at the focal point. Thus, making the approach in disaster management as reactive and not pro-active. Based on this, the national integration level is ranged as partial coordination only. At the regional level, the tasks of the BPBD is to study the possible hazards and coordinating EWS during the time the fieldwork was done, coordination between these different agencies for EWS has not been established, but meetings to discuss this possibility is ongoing. The case in 2016 fieldworks shows that the almost normal condition of the Merapi river basins proposes no strong connection between each actor who has the EWS. The attempts in coordinating are still at the beginning, yet, there seems to be just still at the level of discussion and no concrete actions have taken place. So at this stage, the integration level is still non-existent.

During onset lahar, the integration level for national, regional and municipal are high towards cooperation. This is due to the urgency of saving as many lives as possible and the volunteerism values towards one another. Many actors are more aware of the importance of integration and work collaboratively and cooperatively aiming the same target. Based on the experience of 2010 eruption, the line of communication is busied with the BNPB organizes the expertise of each institution, government, private, or community organization and either from international, regional and municipal levels. Surprisingly, the integration level at the regional under the BPBD is cohesively merged; this is not due to the law of integration, but more to the characteristics of the people in this case study in Yogyakarta. The *gotong royong* (collective action) spirit is almost gone, but due to the 2006 earthquake, this regains the momentum. Cultural values and local wisdom in this case are embodied into *gotong royong*, which include volunteerism, reciprocity, helping one another, collective action, and cooperation. In this regard, the *gotong royong* is seen as a latent composition, which is activated most commonly during difficult times. However, this may not be the case in other parts of Indonesia. At post-lahar condition, long after there is no lahar is flowing in the river, the lahar management is transformed into resources management. In this case it became the sand mining activities and the use of lahar sediment in the river channel into agricultural lands. The sand mining permission process is done previously (up to 2014) through the municipal agency of water and natural resources (DSDAEM) Sleman, but after the Law no.23/2014 on Local Government, the task for giving permit is at the regional level by the PUP-ESDM DIY.

The integration at the municipal level for lahar is not yet established, especially as the transferred responsibility like this requires implementation mechanism. During the process between 2014-2015, all of the rivers belong to BBWS SO, where the sand mining locations are located. This sand mining acquires technical recommendation, whether certain location can be mined or not. But, since 2015, the permit is processed is by the Licensing Office (Dinas Perizinan) at the regional level, with the technical recommendation by PUP-ESDM. Again, the integration is striving to coexist with the current fragmented institutional framework. However, the level of integration is also still at the beginning of coordination.

5. Conclusions

A volcanic river basin planning for water resources management should take into consideration the volcano activities, especially the lahar management. The current approach in implementing the IWRM in a volcanic basin proposed alternatives of combinations using spatial and temporal plan. There is a shift within the IWRM dimension priority for lahar management, which also impacted on the shift of command role. For example, during the pre and post-eruption, the RBO has the command for the river, but during eruption and lahar flow the disaster management agency became the commander for all aspect. The findings proved that in the current condition there is little proof whether integration exists between water and lahar management. There are 'boxed' managements according to the statuses of volcano eruption. These boxes created segregation, but integration could still be detected in the interaction attempts. First, the LRM is termed as lahar risk and resources management. Within this context, the risks management oversees the whole status of pre, onset, and post, while the lahar resources management belongs in the post-eruption only. This status has to do with the activities of extracting the lahar sediment or the sand mining activities, which is also part of the later status. Second, there are overlapping interrelations, which for this paper is termed as VRBM (volcanic river basin management) styles, where the LRM condition and the pillars of IWRM are put in the order of the second. This is in line with the findings that the Disaster style includes not just eruption, but also other onset disaster related to water is focusing on the hazards control, where the focus is disaster relief. Meanwhile, the conservation and utilization pillars at the moment would be stopped due to circumstances.

The Normal style is where the water utilization and water conservation are fully implemented and lahar risk management is at the preparatory stage. During this style, utilization of water is in full optimized condition, while the water conservation, includes both on land and water. The water discharge in the rivers and springs is at average capacity, not being interrupted by the volcanic activities. The lahar sediment would already be removed and no more sand mining activities are allowed, as the riverbed also required a minimum amount of sediment transfer for ecological function. The RBO and the catchment authority are taking control of the management. During the Disaster VRBM, includes both water-related hazards on normal volcano condition and the water-related hazards during a volcano eruption. The primary hazard (pyroclastic flow, lava, hot flames, and ashes) and the secondary hazard (lahar flow) may take place according to the severity of the eruption. This VRBM style is when the function of the volcano and lahar risks management is activated to reduce risks. But, as the focus of this research is more about the water-related hazards, the primary hazards are not part of the main findings, although still plays a role in the Sabo management. The disaster management agency is taking control with the help of the RBO and the volcano center.

Meanwhile, for the Normal+ is when the eruption stops, but then the lahar flow may still take place, due to the deposit of volcanic materials triggered by the rain. This is where the lahar risks and resources management are overlapping. This style may already include the water utilization from the river, wells, etc. yet the conservation pillar implementation would still wait after the condition is walking to Normal. The additional function of the Normal+ is the extraction of lahar sedimentation in the form of sand mining activities. This Normal+ is the consequence of having Sabo Dam system in the rivers; it needs to be dredged to pre-eruption condition, so the volume of the dam can function. The RBO is taking control for determining the volume of extraction and distance to the Sabo facilities.

How to combine resilience theory with regional policies? A network based methodology

Bilge AYDIN, Istanbul Technical University Urban and Regional Planning Department, Turkey
Azime TEZER, Prof. Dr. Istanbul Technical University Urban and Regional Planning Department, Turkey
Joerg KNİELİNG, Prof. Dr. HafenCity University, Institute for Urban Planning and Regional Development, Germany

1. Introduction- A Brief Look to Resilience Theory

Resilience theory has appeared at the same time as sustainability in the science arena by following the global environmental problems in the 1970s; however, it has begun to take part in the planning science since last 10 years. This transformation can be explained by the despite of continuum of sustainability studies for fifty years in the international ground, efforts could not prevent the arising of inevitable natural, economic and political global crises since the beginning of 21cc. Along with globalization, the nature of crises has also changed. It is seen that the causes and consequences of crises are related to each other and trigger each other, both from global to local and from ecology to the economy. With this new phenomenon there is required a new perspective to understand the causes and interactions of crisis within a complex perception (Pendall, Foster, & Cowell, 2009).

Therefore, the resilience approach will present a new perspective for the analysis of complex problems and systems. Within this scope, targets of sustainability and resilience approach cannot be separated. Moreover, while resilience approach includes the targets of sustainability, additionally it provides a holistic, systematic and relational perception for preventing and taking action to alarming global changes (Schipper & Langston, 2015).

In order to understand these global complex relations in a given system, resilience theory combines different disciplinary of studies, such as ecology, economy, and social knowledge. Besides, historical evolution of resilience theory grounded in different sciences, such as, it initiates in engineering science with *bounce-back* concept by systems approach (Bertalanffy,1951), continues in ecology with *multi-equilibrium point* (Holling, 1973) and at last it league together ecological, economic and social sciences by *beyond the equilibrium state concept* (Gunderson & Holling, 2002). The last phase of resilience theory *"socio-ecological complex adaptive systems"* term has been used to explain the complex relations between human and natural environment. This terminology provides evidence that the resilience approach has strong links with other contemporary disciplines such as system approach and complexity science (Pendall et al., 2009). Together with, the complexity science comprises various methodologies and theories that use for understanding and assessment of complex systems. These theories can be listed as system theory, network theory, nonlinear systems theory and game theory. In addition that, these methodologies have advanced along with the development of computer science technologies and computational models (O'Sullivan, 2009).

On the other hand, there are some ongoing discussions that resilience theory has no clear definition, wide conceptual context and it is hard to assess resilience of a system. However, despite the decades of work, there is a similar situation for sustainability. There are still deficiencies, such as the lack of a negotiated definition of sustainability, the uncertainty of its boundaries and the inability to measure it (William A. Brock, Karl-Göran Maler, & Perrings, 2002).

In order to overcome these theoretical and practical struggles, resilience as a new emerging theory in the planning studies can be an efficient and holistic approach to develop new perspectives in order to achieve the goals of sustainability. Especially in the context of system approach and complexity, it has the potential to develop new methodological tools in examining the cross-scale relations of social, economic and ecological systems. However, it should be noted that it is a new area of research and needs to progress particularly in practice and assessment studies (Levin et al., 2013; B. Walker & Salt, 2006).

Furthermore, the multi-disciplinary aspect of the resilience theory has common similarities with planning science. This similarity can form a strong link between the two disciplines. Thus, resilience approach expected to provide new theoretical and methodological perspectives and contributions to the planning science (Scott, 2013).

1.1 Research Aim, Questions and Content

From that point of view, the general aim of the study is to develop a new methodology in order to integrate the resilience theory in the planning science for understanding the complex socio-ecological systems inter-relations, risk factors and develop resilient policy measures. Specifically it has been taken into consideration that this new methodology has the capability of being reproducible, compact and simple in order to assess the resilience of any given system.

Thus, the main question of this study is "*how can resilience theory contribute to regional development policies?"* In addition, sub-questions defined as; "How can the systems approach and network theory be combined to evaluate regional resilience?" , "How can we assess the resilience of a regional system in multi-dimensional, multi-scale and multi-temporal approach?" , "What are the different sub-sytems of a complex SES's?" ,"How can we describe the sub-sytems by networks?", "What are the nodes and edges of the SES's networks? ", And "Can resilience attributes be assessed by network analysis? "

In order to develop a compact resilience assessment methodology, firstly key-concepts of resilience theory clarified with "socio-ecological complex adaptive systems" terminology in the chapter two. Results pointed out that with the relation of complexity science, network theory can be an analytical tool to analyses the resilience of complex systems. Then to understand the contribution of the resilience theory to the planning science, the theoretical and practical resilience assessment examples and recent international spatial development policies examined under chapter three. Results shows that, to assess the resilience of any given system, there is a need to understand the system in two way. One is assessment of specified resilience and the other is generalized resilience. Thus with the findings from literature, two-step analytical methodology developed. In chapter four, a network based resilience assessment methodology in SES's and key concepts of network theory and analysis explained. In chapter five assessment of specified resilience and relational network analysis explained. In chapter six assessment of general resilience and spatial network analysis methodology explained. In chapter seven discussion of future studies and contributions described. Finally in the chapter eight summary of the study is given.

2- Socio- Ecological Complex Adaptive Systems: Multi- Scale, Multi- Dimensional and Multi- Temporal Complex Interrelations

The components of the "socio-ecological complex adaptive systems" (SECAS) give an outline of the basic characteristics of resilience (Figure1). These characteristics highlight the systems multi-dimensional, multi-scale and multi-temporal properties and relationships while evaluating the resilience of a system. These multiple features are examined separately in relation to the

SECAS term, in order to contribute to the resilience assessment methodology to be developed for planning science.

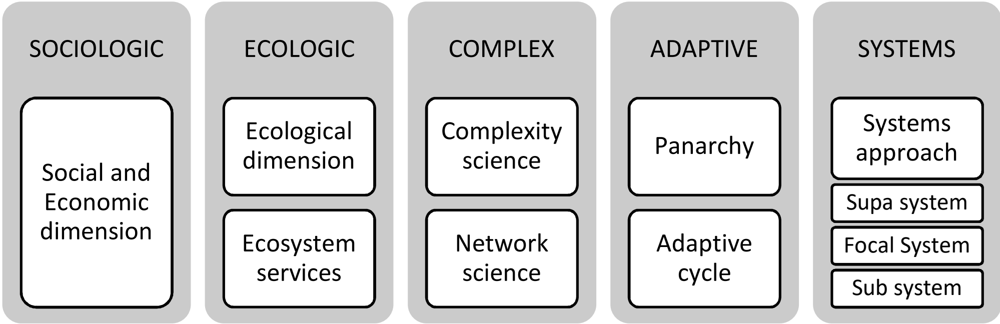

Figure 1: Main components of the "Socio-Ecological Complex Adaptive Systems" Term (SECAS)

The multi-dimensional aspect of resilience is composed by the socio-ecological context. The sociological dimension of this term includes economic, social, cultural, managerial and economic relations ranging from individual scale to social organizations, companies to the entire economic system. Under the ecological dimension, the relationship between ecosystems and ecosystem services are explained (Heide & Heijman, 2009; Rizzi, Graziano, & Dallara, 2017).

The multi-scale content of resilience is based on system theory. It examines the relationship between upper system and subsystems where the focal system scale is engaged. It allows the boundaries of these systems to be determined and considers to cross-scale interactions by a combination of different scales that vary globally, regionally and locally (Folke et al., 2011; Gotts, 2007; Straussfogel & von Schilling, 2009).

Multi-temporal relationships are represented by the adaptive cycle concept, which is take part under the Panarchy term. According to the Panarchy term, the cyle of systems are defined in four phases, exploitation, conservation, release and reorganization (Gunderson & Holling, 2002). This concept, also called system dynamics (ResilienceAlliance, 2010) and can be adapted to social, economic, ecological systems behaviors.

Adaptive Cycle is a metaphor to classify systems, order events, and suggest specific questions and testable hypothesis for understanding transformations in linked systems of people and nature (Gunderson & Holling, 2002). In order to specify connections between planning studies and resilience theory more detailed information will be given about this key metaphor of resilience.

In adaptive cycle, first and second phases are expressed as the front loop, while the third and fourth phases are defined as the back loop and these two loops have opposite characteristics (B. Walker & Salt, 2006). The characteristic of the front loop is slow and can be predicted while the backside is fast, sudden and unpredictable (Table 1).

Loops	Front loop		Back loop	
	System connectedness		System potential	
Phases	1. Phase	2.Phase	3.Phase	4.Phase
	r	K	Ω	α
	Exploitation	Conservation	Release	Reorganization
Properties	Predictable and certain and slow Maximum production and accumulation		Unpredictable, uncertain and fast Maximum invention and reassortment	

*Table 1 Adaptive cycle phases and properties Source**:** Generated From Book, Panarchy; Ch 2 (Gunderson & Holling, 2002)*

Knowing which stage the system is in, gives important information about the system dynamics. For example, on the front side, connectivity and the maximum level of production and accumulation can be defined in the system, on the contrary in the backside while the system in a fragmentation it has a high potential for creativity, innovation and discoveries. This metaphor is also adapted to the planning process. Accordingly, a policy plan is prepared in the first stage, policy decisions are made in the second stage, then failure occurs in the third stage, and then alternative plan decisions are made in the fourth stage.

The complex structure of the system refers to the "Complexity Science" which is used to understand inter-relations of systems components (Holling, 2001) . It also provides information about the methods to be used in the analysis and assessment of socio ecological systems by establishing relationships with current scientific field of studies, such as system theory, network theory, nonlinear system theory, game theory.

Addition to the multiple characteristics of SECAS , *general characteristics of resilient systems* are explained in different theoretical studies of resilience (StockholmResilienceCentre; B. Walker & Salt, 2006) and in the methods for empowering resilience of cities (ARUP, 2015; Eraydın & Taşan-Kök, 2013). Among this variety of sources, the most common and repetitive resilience attributes are diversity, connectivity, modularity, robustness, redundancy and flexibility. Given the fact that these attributes are part of a complexity science terminology, it can be concluded that the general resilience properties can be analyzed by complex system analysis methods.

3- Contributions of Resilience Theory to Spatial Planning

The resilience of human environment aims at preventing the occurrence of unwanted surprises in the face of external disturbances and at the same time targeting the continuity of the quality of services and products, i.e. ecosystem services (B. Walker & Salt, 2006). In order to fulfill this goal it is important to enable the integration of planning concept and resilience theory for future studies.

From this point of view, main influences of the resilience approach to planning science are emphasized as providing new perspectives for both methodological studies and policies, taking in the account the local and global scales at the same time during planning decisions, to provide a holistic view of social, economic, ecological and governmental relationships at multiple scales (Scott, 2013).

However, up to now in the planning science resilience theory generally has been studied separately at different scales and different issues. Resilience assessment studies have shown that economic vulnerabilities (Anthopoulou, Kaberis, & Petrou, 2017; Rizzi et al., 2017), natural disasters (Eraydın & Taşan-Kök, 2013; Skerratt, 2013) and social problems are studied at different scales (Müller, 2011). But these particular studies are not enough to understand the interactions between scales and problems of complex systems. This gap in the literature needs to be filled (Kinzig et al., 2006; B. H. Walker, Anderies, Kinzig, & Ryan, 2006).

In addition, examples of applied resilience researches deliver notable contributions to planning science. One of them is, *Workbook of Assessing Resilience in Socio-Ecological Systems* produced by Resilience Alliance (2010). In this workbook, the iterative cycle of five steps of resilience assessment described in a comprehensive way. First step starts with describing the system with the question of resilience of what and resilience to what and identifying key issues, scales above and below. Second step understands system dynamics, thresholds, transitions, change and multiple-system states. Third step explores cross-scale interactions, general resilience status, cascading changes. Fourth step is defining system governance, adaptive governance and institutions, and analyzing social networks and at the fifth step is acting on the assessment, synthesis of findings and starting the transformation. These steps of resilience practice have a strong link with the planning process and this resembles the opportunities for building strong links between resilience approach and planning intelligence.

Another key intersection between resilience and planning decision making described by Béné, Headey, Haddad, and von Grebmer (2015) is the correlation between the impact of shock and the period and content of responses. It is highlighted there is three capacities that that the system can develop as a response to the disturbances or shocks. These are absorptive, adaptive and transformative capacities. As an example, against a mild intensity shock relates with the system absorptive capacity or stability which it requires short-term humanitarian interventions in a short term. On the other hand, it will be necessary to develop adaptive capacity and flexibility of the system against moderate shocks, which can be achieved with mid-term projects and strategies. In order to be able to cope with a severe impact, systems will need to improve the transformative capacity and this change can be successful with long-term development programs.

In addition to these examples, another contribution that the resilience theory can make to the planning science comes up with the need from the policy objectives. Recent international, regional and spatial planning objectives and priorities in planning science are focused on enabling regional development through spatial cohesion thus empowering rural-urban integration and connectivity (ESPON, 2017; OECD, 2017; UN-HABITAT, 2017). In order to realize these policy objectives, it is important to understand complex spatial relationships and analyze the links of components with network analysis, which is part of the resilience and complexity literature.

Conversely, it has been pointed out that in resilience assessment studies there is lack of strong hypotheses and clear concepts, and necessity of developing holistic approaches, understanding the factors and processes affecting resilience of the system are important (Schipper & Langston, 2015). Additionally for future studies, it is recommended to develop strong definitions of resilience in regional systems and prepare applicable criteria and matrices, exploring resilience with reproducible methods based on quantitative and qualitative data, and identify the roles of social actors (Pendall et al., 2009).

Consequently, there are many new fields of study and development possibilities and synergies arising from the needs and shortcomings of these two sciences. It is important to conduct studies that evaluate these opportunities and provide new approaches by contributing to both disciplines. The literature survey results shows that, the most important outcomes are that the perspective of resilience determines the problems faced by human settlements in multi dimensions, at multi scales and in multi temporal characteristics, and takes into account the complex relationships between them. Thus, it is important to develop policies within this approach in terms of producing effective solutions.

4- A Network Based Resilience Assessment Methodology in SES's

From the findings of literature of resilience theory, recent planning agendas and workbooks of resilience implementation and assessment studies two main approach has been deduced in order to integrate resilience theory to planning science. One is assessment of *specified* resilience, and the second is assessment of *general* resilience.

First, in the specified resilience assessment model, for a given system, "Resilience for whom and for what?" and "Resilience to what?" questions are answered. After that there is tried to reveal inter-relational risk factors with network analysis. Thus, this methodology can contribute as a decision support systems to the determination of risk factor in the SES's and making the plan objectives.

Secondly, general resilience assessment model, try to understand general attributes of the specified system, such as diversity, modularity, openness and redundancy. This approach will contribute to understand complex feature of the socio-ecological systems by spatial interrelations, components, and connectivity of the system and this will allow making comparative studies for to understand the factors that influence the formation of resilience in different systems.

Within this direction, the study target is to develop a new compact, holistic and practicable methodology for resilience assessment in socio-ecological complex adaptive systems. The network theory that emerged in the 1990s is one of the most commonly used tools to evaluate complex interrelations of a system. Thus, network theory and analysis method will be used in the study as a resilience assessment tool. In the next section, essential information about the network theory and analysis method and the contributions it can provide will be explained.

4.1 Network Theory and Analysis

Network analysis provides information about the interrelations of sub-components in the system and helps to visualize the complexity of the system in a simple way (Barabási, 2016). This method is also referred as "Graph Theory" in mathematic science. Two basic components that constitute network are named as nodes (vertices) and edges. While nodes represent the connected entities, edges describe the connection between these two entities.

	Node 1	Node 2	Node 3	Node 4	Node 5
Node 1	0	1	1	1	1
Node2	1	0	1	1	0
Node3	1	1	0	0	0
Node4	1	1	0	0	0
Node5	0	0	0	1	0

Figure 2 Adjacency Matrix

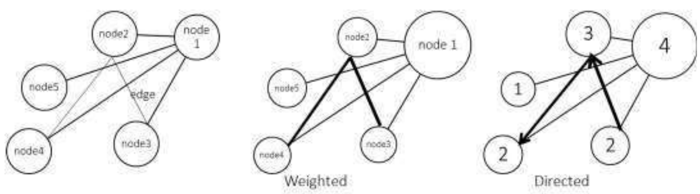

Figure 3 Network Elements; nodes and edges

Adjacency matrix is one of the methods used to determine relationship between nodes in a network. The adjacency matrix (Figure 2) is formed by determining the points in the system and then placing the names of the points in the row and column headings of the table. If there is a relation for each node pair, it is filled with value 1; otherwise, it is filled with value 0 (Estrada & Knight, 2015). Different computer programs are used to visualize the network as a graph (Figure 3), and one of them is the open source R Programming language. The I-Graph library in the R program is a widely used tool for analyzing and visualizing the network. In this study, R programming and I-graph library were used in the network visualization.

After generating the network, it is possible to analyze some basic and complex calculations with network measurement tools. For example, the node with the highest connection number can be specified by *node degree*. It may also be possible to grasp the relationships between edges and nodes more precisely by weighting and orienting the edges according to their quantitative or qualitative value. In addition to these network measures, with more complex algorithms it is possible to identify the flow and spread of the effects, the robustness of the system or the scheme of the organization by defining the global topology of the network. Another network metric is calculation of centrality according to different features. This can help to understand the connectivity of the system, most critical nodes and distributions of weakly connected parts in the system (Estrada & Knight, 2015).

5- Assessment of Specified Resilience

The scope of resilience can vary according to the different problems, different relationships and characteristics of the region. For this reason, there is a need to develop a reproducible method that allows identification of the specific resilience.

In this study, a new matrix has been developed by combining the key priorities from the examples and the features highlighted in the resilience literature for to analysis of systems resilience. This matrix provides a method for describing the system and risks and examining the relationship between administrative measures and components in multi-dimensional, multi scale and multiple temporal way. This model has been developed with a compact and holistic characteristic that can be applied easily and reproducibly in complex systems.

This methodology has two steps: the first is to create the resilience assessment matrix and the second is the development of the relational network. These steps will be explained in detail in the subtitle of the fifth chapter.

5.1 Resilient Assessment Matrix

The matrix investigates the social, economic and ecological dimensions of the system under three different scale macro, meso and micro scale. In each column, five questions ask for describing the systems resilience.

MULTI - TEMPORAL / MULTI – SCALE/ MULTI - DIMENSIONAL	DISCRIBING THE SYSTEM						
	BOUNDRIES OF THE SYSTEM		1-RESILIENCE OF WHAT?	2-RESILIENCE TO WHAT?	3-SYSTEM DYNAMICS	4-SYSTEM GOVERNANCE	5-DEVELOPING CAPACITIES
			What are the key components and priority issues in the social-economic-ecological dimension for the different system levels?	Which are the slower/ fast risks that change the system?	In which phase is system positioned in the adaptive cycle ? 1-Exploation 2-Conservation 3-Release 4-Reorganization	What are the current Govermental and institutional affects	What type of measures can be taken by the management units?
	MACRO (UPPER) SYSTEM		MAIN ISSUE- KEY COMPONENTS OF SES'S	RISKS-DISTURBANCES-SHOCKS	ADAPTIVE CYCLE PHASE	INSTITUTIONS-MEASURES	CAPACITIES
	SLOW-LONG TERM	SOCIAL	SOC-1	A1		X1	TRANSFORMATIVE – (POLICIES)
		ECONOMIC	ECN-1	B1		Y1	
		ECOLOGICAL	ECL-1	C1		Z1	
	MEZO (FOCAL) SYSTEM		**MAIN ISSUE- KEY COMPONENTS OF SES'S**	**RISKS-DISTURBANCES-SHOCKS**	ADAPTIVE CYCLE PHASE	**INSTITUTIONS-MEASURES**	**CAPACITIES**
	MID-TERM	SOCIAL	SOC-2	A2		X2	ADAPTIVE – (STRATEGIES)
		ECONOMIC	ECN-2	B2		Y2	
		ECOLOGICAL	ECL-2	C2		Z2	
	MICRO (SUB) SYSTEM		MAIN ISSUE- KEY COMPONENTS OF SES'S	RISKS-DISTURBANCES-SHOCKS	ADAPTIVE CYCLE PHASE	INSTITUTIONS-MEASURES	CAPACITIES
	FAST-SHORT TERM	SOCIAL	SOC-3	A3		X3	COPING-PERSISTANCE-(ACTIONS)
		ECONOMIC	ECN-3	B3		Y3	
		ECOLOGICAL	ECL-3	C3		Z3	
	CROSS-SCALE INTERACTIONS						

Table 2 Resilient Assessment Matrix

The first question is "Resilience for whom and of what?" to determine the main components, limitations, and priority issues of the system. Second question is" resilience to what" in order to determine the risks against the system resilience for each scale and dimension. Third question is "What is the phase of the system in the adaptive cycle?" It is asked to provide information on the level of connectivity and substance concentration in the system or the innovation potentials of the system and to ensure that policy decisions are taken according to the characteristics of the adaptive phase. In the fourth question, "Which institution is responsible and what are their effects?" Is asked in order to determine the management system and understand the institutions and policies that have an impact on the formation of risks. And at fifth question, "What is the targets of system capacity and how it will be realized?" is asked in order to determine the types of measures, plan decisions and interventions to be carried out according to scales and dimensions in the prevention of identified problems and in ensuring resilience.

5.2 Building Relational Networks

After defining the components of the system and risk factors for each scale and dimension, a relational network analysis can be conduct between these titles, in order to understand key factors that shape the system resilience. One of these kind of example has been prepared by B. Walker and Abel (2002) in the study of “Resilient Rangelands: Adaptation in Complex Systems”. In this example factors affecting the resilience of rangelands areas were determined by the complex adaptive system framework at national, regional and local scale and a relationship diagram was established. The important factor in selecting the factors that affect system resilience is that these factors can be adapted and changed by humans. This rangelands example shows that, defining the relationship between the factors that influence the resilience of the system, points to the important intervention factors and reveals the multidimensional complexity of the system.

Based on these examples in the literature, to provide a methodologically reproducible model for the specified resilience assessment, defined titles in the resilience assessment matrix will be analyzed by network analysis method. In order the understand cross-scale interactions that affects system resilience, an exemplary case study developed, in the context of climate change risk effects on rural areas (Table 3).

	System Boundries	**Resılıence Of What?**	**Resılıence To What?**
MULTI DIMENSION MULTI SCLAE	**Macro-Upper System (Regıon)**	**Key Components Of SES’S**	**Rısks-Dısturbances-Shocks**
	Social	Rural Population Dynamics	Rural Shrinkage
	Economic	Agricultural Sector Diversity	Loss Of SME's
	Ecological	Biodiversity	Climate Change
	Mezo-Focal System (Rurban)	**Key Components Of SES’S**	**Rısks-Dısturbances-Shocks**
	Social	Local Culture Diversity	Rural Out-Migration
	Economic	Agricultural Business Number	Loss Of Products
	Ecological	Agricultural Land Cover Types	Seasonal Instability
	Mıcro-Sub-System (Villages)	**Key Components Of SES’S**	**Rısks-Dısturbances-Shocks**
	Social	Rural Population Size	Rural Aging-Loneliness
	Economic	Income Level	Poverty
	Ecological	Agricultural Product Types	Flood-Drought

Table 3 Case Study- Climate change effects on rural areas as risk factor

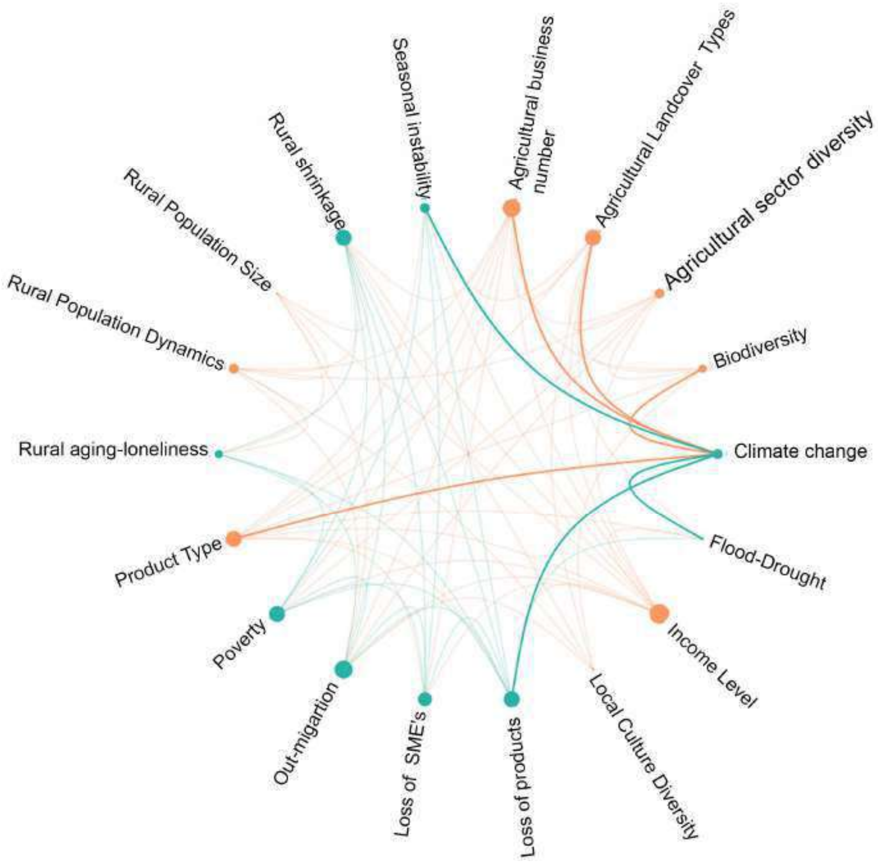

Figure 4 Circle Relational Network Graph

According to this example, key components of the SES's and risk factors defined for each scale and dimension. After that, defined titles inserted in the adjacency matrix and related titles marked with 1 in the adjacency matris. Next, this matrix placed in R program and by using I graph, edgebundleR libraries, circle type network graphic delivered (Figure 4). In these graphic, orange nodes represents the key systems components, while blue nodes represents the risk factors.

Results shows that climate change risk factor effects mostly at meso-scale. These are at economic dimension the number of agricultural business and at ecologic dimension the agricultural landcover type and at micro scale the product type. These components are also the most connected nodes in the whole network with highest node degree.

Thus, in order to ensure system resilience, priority issues for policy measures can be identified by recognizing high node degrees according to their different scales and dimensions. The results from this example show that, in order to prevent climate change effects on rural areas, policy measures must be taken especially at mezzo-scale. This requires the development of strategies to develop adaptive capacity and flexibility of the system, accordingly mezo scale projects need to be developed particularly to strengthen the agricultural businesses.

6- Assessment of General Resilience

General resilience properties of a system, such as connectivity, diversity, robustness, flexibility and modularity are associated with complexity science therefore they can be assessed by network analysis. Network analysis methods are widely used for understanding the complexity of systems.

On the other hand, in planning science, network analysis method has been used separately for different purposes, both in the analysis of tangible and intangible relations. Especially it has been used in the context of social networks with actor-network theory (Grabher, 2009; Jóhannesson & Bærenholdt, 2009) likewise physical networks usually studied with transportation or infrastructure networks (Yazdani, Otoo, & Jeffrey, 2011) as well the geographical analyses has been measured by ecology network (Bergsten & Zetterberg, 2013; Rüter, Vos, van Eupen, & Rühmkorf, 2014)

However, within the context of planning science, due to the fact that complexity and network theory is a progressing scientific disciplines, there has not yet been established a multi-dimensional and multi-scale approach that practice network theory in analyzing the complex relationships of socio-ecological systems.

For this purpose, examining complex socio-ecological systems with the network analysis methods through multi -dimensional and multi-scale approach will be a novel approach, which has been proposed in this paper. To achieve this, initially there is a need to define the sub-systems that constitute the socio-ecological system. Afterwards it is necessary to define the nodes and edges of networks of the specified sub systems.

The following subtitles, describe the findings and compilations from the literature search on the formation of spatial networks in order to assess to general resilience of a system.

6.1 Defining sub-systems- City as a Network

In order to analyze the complex relationships of socio ecological systems, determination of sub-systems prerequisite. In different sources sub-systems are referred as social, cultural, governmental -institutional, economic, physical economy, technological and ecologic (Heide & Heijman, 2009; Janssen, 2002) which also show similarity with the sustainability components. Based on these studies and in accordance with sustainability essential components, sub-systems of complex adaptive systems can be classified under three main subject, social, economic and ecological. Social system can be detailed by cultural, governmental, institutional systems, and the economic system can be detailed by physical and infrastructure systems.

After specifying the sub-systems, to be able to create the system as a network, conception of the city network need to be clarified. About this scope, in network theory literature, there are theoretical contributions to understand city as a network. In the book named "The connected city, How Networks are Shaping the Modern Metropolis" Neal (2013) delineate the urban networks under three scales of macro, mezo and micro interrelations. This approach is also corresponding to the multi-scale method of resilience theory. According to his representation, macro-scale networks establish among the cities, at the mezzo-scale networks are as the city system itself, and in the micro-scale, networks are defined as sub-connections within the city (Neal, 2013).

6.2 Defining Nodes and Edges of the Network

After understanding the city system as a network, the nodes and edges of the urban or spatial network should be determined. In this regard, in different sources spatial linkages has been defined with the flow of elements from different localities (Neal, 2013; OECD, 2017; UN-HABITAT, 2017). These spatial linkages has been described through the different functions, such as social, economic, politic, and cultural. They have also similarities as content with the sub-system definitions and consist of the flows of capital, people, goods, services, information and expertise. These flow elements can be specified as the edges between different localities, i.e nodes of the networks.

Within this approach, for every each network type, different flow characteristics defined as in in the Table 4. In first column social network defined by flow of services, information and human, also intangible governmental networks can be defined as institutional connections by laws and policies. Economic network identified by flow of monetary, labor, product, waste and energy. In addition to economic network physical economy of the given region can be determined by the existing infrastructure such as transportation roads. At last ecological network of the region can be described by the raw-material, biological material and water flow.

	Network Types				
	Social Network	**Institutional Network**	**Economic Network**	**Physical Network**	**Ecologic Network**
Flows	Information	Capital	Trade	Transportation	Raw material
	People	Service	Labor	Stations	Biological Material
	Culture	Expertise	Products-Goods	Broad band	Water
		Policy	Energy		
			Waste		

Table 4 Network Types and Flows Source: Compiled from(Neal, 2013; OECD, 2017; UN-HABITAT, 2017)

Additionally, while making the definition of spatial network of complex socio-ecological systems, essential group of questions should be asked in order to understand the linkages more deliberately. Briefly, these questions are; "What is moving?"," Where does it move from?" "for what purpose does it move? ". "While moving which connection is being used?". In addition to these questions, the quantity (number) or quality (importance) and direction of the moving objects will enable a more detailed analysis of the network edges.

After defining the edges between different localities, nodes of the network will be specified based on the Neal's definitions, within multi-dimensional and multi-scale approach. An example of this approach is given in the Table 5. In this example, macro-scale network nodes can be described as cities, regions, countries. Meso scale network nodes in the urban system can be defined as districts, neighborhoods, villages or functional regions such as industrial regions,. At micro-scale, network nodes can be represented in the city as companies, administrative institutions, households and buildings.

Furthermore, nodes and edges of networks can be varied due to different dimensions. For instance, in the macro-scale social network can be defined by international policies and laws, which will constitute a link between the nations and regions and cities. Also directions of global migration and location of governmental investments will define the macro-scale social linkages. These linkages can be detailed with mezo and micro scales, such as regional and local policy linkage and migration flow, regional investments, local NGO's-projects and local service buildings.

		MULTI-DIMENSION		
		SOCIAL	ECONOMIC	ECOLOGIC
MULTI-SCALE	MACRO	**Nodes as nations, regions or cities**		
		International Policy Linkage	Industrial regions	Land cover
		International Migration Flow	Global Transportation	Regional Corrıdors
		National Investments	Technological Infrastructure	Cross-border rivers
	MEZO	**Nodes as towns, districts, neighborhoods, villages, functional zones**		
		Regional Policy Linkage	Functional zones (touristic-industrial)	Agricultural zones
		Regional Migration Flow	Transportation Network	Forest zones
		Regional Investments	Main Stations	Rivers
	MICRO	**Nodes as institutions, business, buildings, household**		
		Local Policy Linkage	Transportation Network and Stations	Agricultural Product
		Local Migration Flow	Business	Vegetation Type
		Local Service Buildings	Energy Plants	Water bodies
		NGO's-Projects	Cultural Touristic Areas	Natural Touristic Areas

Table 5 Definition of nodes and edges of the spatial network (linkages) within multi-faceted network approach

Nodes and edges in the economic dimension in the macro-scale, can be identified as, industrial regions, global transportation network, and technological infrastructure. These features can detailed in meso-scale by functional zones of the city (touristic-industrial), city transportation network and main stations, and at micro scale by business, energy plants, and cultural touristic areas.

Ecologic dimension's nodes and edges in the macro scale can be represented as regional land cover characteristics and land-cover types, cross-border corridors, and in meso-scale main land-cover types of the city, forest and agricultural zones and rivers can be assessed. At micro-scale, agricultural product type, natural vegetation type, water elements and natural touristic zones will be represents the nodes.

7- Future Studies- Assessing Resilience Attributes and Interdependent Networks

In the further studies of spatial network analysis, there can be used network analysis metrics as explained before in the Chapter 4.1. These network metrics will help to assess the critical or weak nodes for interventions, strong connected parts of the network and critical stakeholders' positions for to understand cascading effects.

While evaluating the general resilience attributes of the system, for example, the diversity of the system can be defined with the node types and the level of connectivity in the system will be proportional to the number of edges. Additionally, in order to define key components or localities the centrality betweenness can be used. Likewise, the number of hubs can determine the robustness of the system and clusters will show the modularity and flexibility of the system. Also, the number and types of clusters can determine system redundancy. Furthermore, feedback and percolation of the system can be identified by network topologies.

Moreover, recent studies in network analysis realm continues on interdependent network analysis. This type of analysis will contribute to the understanding of the relationships and dependencies between the different network layers such as social, economic and ecological networks in the near future.

8- Summary

In consequence of this study, a network based resilience assessment methodology has been developed to provide the integration between planning and resilience theory. This reproducible resilience assessment method consists of two steps, namely "specified resilience" and "general resilience" assessment, using multidimensional approach and network analysis method in order to evaluate and analyze complex SES's.

Firstly, in the context of specified resilience assessment, the system components and risks of study-area are determined by the matrix prepared according to multi-scale, multi-dimension and multi-temporality approach. Afterwards, a relational network was established between the identified components and the risks, so that critical issues could be recognized before the policy decision-making process. Thus, priority policy measures and targeted system capacities can be determined by understanding complex multi-temporal, multi-dimensional and multi-scale interrelations.

In the second step of the methodology, nodes and edges of spatial networks and their components are determined by multi-dimensional and multi-scale approach in order to assess the general resilience in the region.

In the further stages of the study, this methodology will be applied in an exemplary study. Therefore, after the formation of the spatial network model, network analysis metrics will be carried out by using R program. Thus, in the resilience literature, a reproducible method has been proposed to provide comparative studies and to determine the factors affecting resilience. This method can contribute both theoretically and practically to the creation of regional plans.

Metabolic impact assessment for strategic urban planning

Batista, Luisa; Lopes, Miguel; Pinho, Paulo, PORTO, Portugal

ABSTRACT:

The success of climate change policies is strongly dependent on the rational and socially sensitive use of natural resources, namely land, water, energy and materials. In this respect, strategic urban planning plays a decisive role in the definition and implementation of sustainable development models to promote resilient, efficient and inclusive territories.To understand climate governance in Ghana

The effectiveness of spatial planning, taking into account different urban development alternatives and scenarios, depends heavily on the overall quality, representativeness and responsiveness of decision-making processes. In this regard, the evaluation of the metabolic performance of planning proposals, urban development projects or urban policy options is crucial to enhance the overall balance and efficiency of a city or metropolis.

Applying Metabolic Impact Assessment (MIA) in the planning process, particularly through Strategic Environmental Assessment (SEA), enables the emergence of a distinctive spatial dimension provided by the urban metabolism approach. Despite the wide range of studies and approaches to urban metabolism, various practical limitations and barriers involving usability, data collection and comparability, have been limiting its dissemination in the planning profession.

In face of these challenges, this presentation intends to: i) describe a methodological approach to metabolic impact assessment, encompassing four main components - energy for buildings and transports, water, materials, and land use; ii) guide its future application to municipal development plans in different contexts (in terms of urban size, alternative territorial models and development goals), as part of current SEA procedures; and iii) critically appraise the added value of the metabolic impact assessment model as a strategic planning support tool.

The presentation concludes with a set of case-studies of urban development plans in Lisbon (master plan, urbanization plans and detail plans), aiming to illustrate the potential of a decision-support tool such as MIA in the framework of the whole decision making process. It will be possible, from real cases, to show the main added value of this pragmatic, operational and ready to use instrument. The production of useful, objective and tangible information (on the metabolic impact of each planning alternative), with the application of the metabolic model to planning alternatives, provide political decision-makers an important decision support tool. We believe this plug-in proposal of MIA into SEA will be also a relevant contribution to solve an environmental impact assessment insufficiency (extensively debated both in strategic urban planning and in strategic impact assessment literature), namely how to deal with the climate change challenge, beyond vague and inconsistent considerations. In that sense, and having in mind the central role of cities to climate change, MIA is presented as an important contribution focused on local urban mitigation strategies, in the framework of strategic urban planning. This is a non-negligible aspect of the proposal, considering strategic urban planning a particularly adequate forum to implement climate change policies.

Climate Resilience through Land Use Regulations in Asian Cities

Olga CHEPELIANSKAIA, UNICITI, France

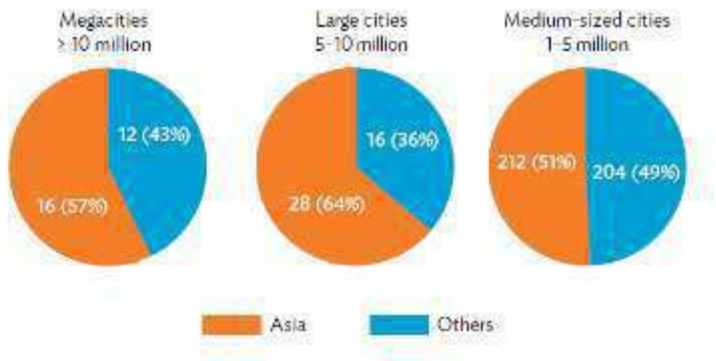
Synopsis

Climate resilience is a critical imperative for Asian cities and it needs to be mainstreamed into land use regulations to achieve a durable and cost-effective outcome. The present paper demonstrates why developing and implementing climate resilient land use regulations is the first, essential and most cost-effective step to urban climate resilience. It analyses successful national and local examples from selected Asian countries and shares insights into how this critical approach may be put in place in a wider context of developing Asian cities' political, institutional, economic and societal challenges.

Structural measure alone have failed Asian cities

Asia has been rapidly urbanising and half of Asia's population will be living in cities by the end of 2018. As a result, Asian cities face an unprecedented population load. The population of Dhaka increased from 10,3 million in 2000 to 17.6 million in 2015 and the population of Bangkok grew from 6.3 million in 2000 to 9.3 million in 2015 (World Population Review, 2018). This trend will further accelerate in the next 35 years, in which additional 1,2 billion Asians will move to cities (UN-HABITAT, 2015).

This pattern has been taking place in an often sporadic and unplanned manner, creating significant vulnerabilities. As per UN Habitat, over 40% of South Asian urban population lives in slums. Less than 50% Asian urban dwellers have direct access to water supply. Less than 75% of the Asian urban population has access to improved sanitation. Over 60% of urban population in Nepal and Bangladesh live in inadequate housing (UNESCAP, 2015). Basic infrastructure and housing needs are tremendous: ADB estimates that between 2010 and 2020 over USD 8 trillion need to be invested into infrastructure in Asia (ADB, 2009).



1: World Urbanization Prospects of the United Nations 2014 revision, New York, UN 2014

In this context, climate change and increasingly intense and frequent extreme weather events create a major threat in Asian cities. Asia has been recognised the most climate vulnerable region in the world: 6 out of 10 most affected nations are in Asia-Pacific, summer temperatures are projected to increase by 6°C by 2100 if there is no slowdown in the global warming trend. Global mean sea-level (GMSL) rise is projected to reach 5-8 millimetres per year by the end of this century (Bhandari, 2017). South-East Asian coastlines will experience sea-level rise about 10‑15% higher than the global mean level (Schaeffer, 2017). Coastal and low-lying areas in Asia are prone to increased flooding and fresh water salinization while other regions face heat waves and concentrated precipitations. These threats could significantly compromise economic development and living standards' achievements in the region (ADB, 2017).

Asian cities are particularly vulnerable to this climate risk. Over 410 million Asian urban dwellers will be at risk of coastal floods by 2025: 19 of the 25 world cities most exposed to a 1-meter sea-level rise by 2100 are in Asia, and 7 in the Philippines alone. Indonesia may have nearly 6 million people affected every year until 2100 (Gupta, 2017). **The climate risk is severely enhanced by extremely affected natural coping ecosystems in cities**. Indeed, most cities have grown at the expense of their natural eco-systems: infrastructure development often took place over water bodies, forest and green areas or urban agricultural land. Cities such as **Bangalore and Chennai** have respectively lost 79% and 90% of their water bodies in the last four decades (CSE, 2016). As a consequence, Bangalore faces severe floods regularly since 2000 (IISC, 2017) and the massive 2015 flood in Chennai caused an estimated damage of USD 2.2 billion. As per the Niti Aayog report, released in June 2018, both cities are expected to run out of ground water by 2020 (NITI Aayog, 2018). The **Manila** 2012 disastrous floods were aggravated by the lack of trees and open soil to absorb torrential rainfall water. The urban heat island (UHI) effect in the city further intensified the southwest monsoon impacts (Singh, 2012). In other words, **weakened natural ecosystems make cities simultaneously exposed to floods, water shortages and UHI effect.**

To address this challenge, most climate resilience efforts have been put into structural engineering solution, such as a water retention wall along a canal, water pumping stations in low lying areas, a river desilting. Such solutions punctually address a specific challenge, however are **very costly and have significant limitations since they rarely holistically build urban climate resilience** in the medium-long run.

Dhaka is located in the world's largest delta system and experiences severe annual floods since the capital has mushroomed over a series of wetlands. Particularly devastating flood years include 2004 and 2007, during which over 30 million people became homeless in Bangladesh, with over 40% of Dhaka inundated (IRIN, 2012). The city invested into flood protective embankments, flood walls, elevated roads along with flood control barriers, sluices and pumping stations. These structural solutions have punctually helped control flooding in several parts of Dhaka, but have gradually become less and less performant: steadily damaged embankment walls, internal flooding due to increased pressure on outdated drainage networks, inefficiency of temporary pumping systems, etc. These flood control measures' effectiveness has been severely challenged by increasing urban encroachments over retention pond zones, settlements in low lying areas or increased social conflicts around flood control structures (Bala, et al., 2010).

A 2014 ADB commissioned study highlighted that in South-East Asia most highly flood prone areas are protected by some structural measures such as levees, however the quantity and quality of such measures are not sufficient because these are not often linked to critical non-structural measures (Osti & Nakasu, 2014).

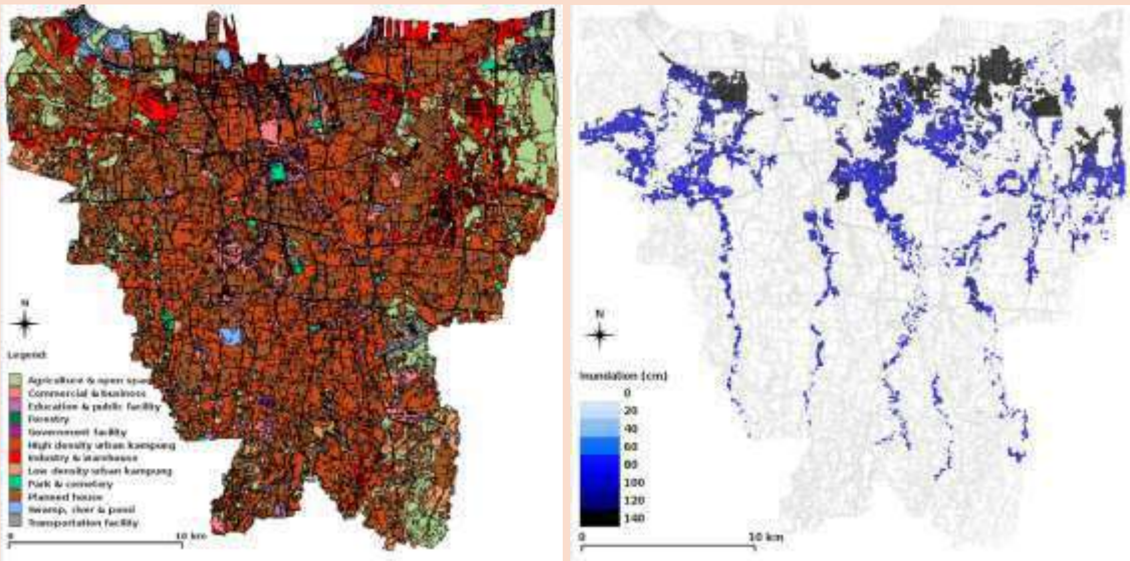
Mainstreaming climate resilience into land use regulations proves highly effective

The international development community recognised the need to strengthen climate resilience through spatial planning as of prime importance. The ***New Urban Agenda (NUA)*** links environmentally sustainable and resilient urban development to planning and urban spatial development management (NUA, paragraphs 72, 77, 80, 81, 93, 94, 95, 96, 98, 99, 102, 111, 113, and 117). **Spatial planning primarily contributes to climate resilience through preserving and reviving natural coping ecosystems**. As Alejandro Iza, Director of the Environmental Law Centre, stated at the COP 23: "As the impacts of climate change gradually increase, there is a need to provide effective tools to ensure the integrity of ecosystems and livelihoods... Land use planning should be one of these tools" (IUCN, 2017). ***Guiding Principles for City Climate Action Planning, UN HABITAT***, stress that urban climate action integrated into long-term urban planning processes increases the effectiveness of adaptation strategies.

More specifically, **land use regulations are a highly effective** way of ensuring that natural ecosystems are protected from urban development encroachments. Indeed, various city development plans have low binding capacity in developing Asian countries due to a high degree of informality and weak enforcement systems. Over 55% of Bangladesh's population, 54% of Nepal's and 38% of Philippines populations live in informal settlements (World Bank, 2014). These countries' cities' Master Plans and other urban development plans rarely include consultations with informal communities, which makes urban development plans disconnected from the reality and hardly enforceable. Land use regulations are usually legally binding and better enforced. Legal penalties for violations of land use regulations typically involve a court-order injunction, criminal fines or civil lawsuits depending on a country's system. In **Thailand**, land use plans and other land use controls are enacted under the Town Planning Act (1975) and are further regulated by sub-regulations and planning laws such as The Land Development Act (2000) and The Building Control Act (1979). However, spatial plans both regional and urban level are not enacted under laws and regulations (CPD- Bangkok, n.d.).
In India, urban land use regulations take the form of Urban Land (Ceiling and Regulation) Act adopted in 1976. Non-compliance with land use laws, such as FARS, building height limitations etc. leads to heavy fines and, if timely identified, construction permissions are declined.

The land use regulations instrument has been used by a number of Western countries, such as Canada and the Netherlands, to preserve urban green and blue areas and reduce climate vulnerability in cities. **The Asian region, while most affected by climate change and extreme weather events, however still presents only a few selected examples**. In most Asian cases, urban development happens at the expense of natural ecosystems rather than in line with them, both in urban and peri-urban areas.

Jakarta faces land subsidence as a result of compaction due to loading from new skyscrapers in sensitive areas along with an increased groundwater extraction. As a result, the city is sinking 10 times faster than the Java Sea is rising (Short, 2015). About 40% of Jakarta now lies below the sea level, North Jakarta being most affected. Natural aquifers are not replenished despite heavy rains and the abundance of rivers. Indeed, over 97% of Jakarta is covered by concrete and asphalt surfaces. Ardhasena Sopalheluwakan, Indonesian climate scientist, claims that reintroducing mangroves and rejuvenating reservoirs in the old city would be the best way of addressing the issue (Kimmelman, 2017).



2: Jakarta's official land use plan 2002. There are hardly any green and blue spaces to counter the effects of inundation. The second map of Jakarta shows the modelled hazard zones for a 50-year flood return period. (Budiyono, et al., 2015)

Climate sensitive land use measures

Climate sensitive land use measures can be looked at in three major categories: land use zoning, land use planning and building by-laws and regulations. While solutions are very tailored to a specific local context, generic land use guidelines may prove helpful:

Land use zoning helps identify and protect natural ecosystems by categorising land into specific uses and specify what is and is not allowed within each category. It can hence reflect climate threats in specific areas (e.g. low lying areas prone to floods or soil subsidence) and direct uses that will both reduce human vulnerabilities and allow each ecosystem play most useful role for the city.

Land use planning can incorporate:

- Identifying and securing community spaces to be used as refuge areas: open spaces in earthquake prone zones, raised areas in flood or cyclone prone zones, etc;
- Mixed land use and high density compact development in low risk areas while limiting development in low rise zones;
- Floodway fringe zones – parks and open spaces, detention ponds wetlands, urban forests, etc.

- Defining FARs, ground coverage ratios, setbacks and building heights taking into account changing climate and rainfall patterns.

Building by-laws and regulations may need to include:

- Relocations/replacement of highly unsafe structures to climate proof and affordable engineered housing
- Retrofitting measures in existing buildings to increase climate resilience.

An example of climate sensitive land use regulations would be a zoning by-law restricting development along a coast based on risk of erosion due to projected sea level rise and more frequent typhoons, or massing and clustering a built-up area and pavement surfaces to minimize the UHI effect. In parallel, green building codes, improved watershed management and land use practices that absorb and store water can increase the ability of an urban region to cope with water stress (Otero & Richardson, 2012). A variety of statutory and non-statutory measures – by-laws, tax incentives, information and guidance to developers – may be applied to control how land is used.

Climate sensitive land use regulations: overview of advancements in Asian countries

An initial screening of 26 countries in East, South and South-East Asia showed that only 10 countries had adopted climate resilient urban planning through national policies and only 5 had incorporated climate resilience into land use regulations: Singapore, South Korea and Taiwan among high income countries; China and the Philippines among lower middle and middle income countries. The Global Climate Risk Index 2017 however points out that low and middle income countries are at a higher risks than high income countries, which leads to two conclusions: countries that adopted a climate sensitive spatial planning approach are ripping the benefits of it while countries that follow a more ad hoc and structural measures oriented approach are exposed to more climate vulnerabilities, and this despite having to an extent comparable climatic conditions with the first category of countries.

Region	Country	Is climate resilience mainstreamed into spatial planning?	Is climate resilience mainstreamed into land use planning?	Income Group (World Bank)	Climate Risk Index- Rank (Germanwatch CRI, 2017)
East Asia					
	China	yes	yes	Upper middle income	23
	Japan	yes	no	High income	36
	Mongolia	no	no	Lower middle income	59
	South Korea	yes	yes	High income	135
	Taiwan	yes	yes	High income	NA
South Asia					
	Afghanistan	no	no	Low income	28
	Bangladesh	no	no	Lower middle income	35

resilience into urban planning policies and land use regulations

Climate sensitive land use regulations: successful case studies from Asia

Looking at the limited number of countries that address climate threats with special planning / land use regulations solutions, one could question the extent to which the approach works. The following few examples demonstrate its high effectiveness.

Taiwan

Till early 2000s, Taiwanese cities have relied on engineering solutions to combat floods caused by typhoons. Policy support went for structural solutions such as dykes instead of natural retention ponds even though various laws, acts, regulations and decrees included planning tools as adaptation measures (Lin, 2015). In 2009, Typhoon Morakot brought a 50-hour continuous rainfall at 1,623 mm daily, which caused 623 deaths and USD 6,2 billion worth economic damages. The disasters occurred despite the country had heavily invested into structural adaptation measures**.** Devastating effects of typhoons Morakot in 2009 and Fanapi in 2010 generated a policy shift towards spatial planning solutions such as water retention ponds, adaptive land use plans or waterfront landscape projects (Wen, 2014). As a result, Taiwan's Council for Economic Planning and Development developed **national climate adaptation policy guidelines with a focus on non-structural interventions in 2012**. The objective was to incorporate climate adaptation into relevant laws, regulations and procedures at all levels of spatial planning. Measures included:

- Revising national spatial plans in light of climate change projections;
- Incorporating the concept of an environmentally sensitive area into the demarcation and management of national conservation areas;
- Establishing a land use performance control and management system for conservation areas and increasing the cities' managing efficiency and adaptive capacity in flood control by improving permeability, establishing metropolitan blue and green belts and detention basins;
- Regularly monitoring changes in land-use and land cover, and renewing geographic information system (GIS) databases;
- Constantly monitoring weaknesses and deficiencies of climate change adaptation in current spatial planning.

In addition, land use control is also addressed through a variety of **natural resources management laws**, such as the Tap Water Act, drinking water management statutes, the Soil and Water Conservation Act, the Slope Land Conservation and Utilization Act, the Forest Law and the Environmental Impact Assessment Act (Lin, 2015). Some specific projects taken across Taiwan since 2012 are: initiatives to establish a disaster catalogue and ecosystem conservation database, promoting and educating stakeholders about slope-land conservation and disaster prevention, watershed management and recovery through ecosystem conservation (Huang & Lee, 2015).

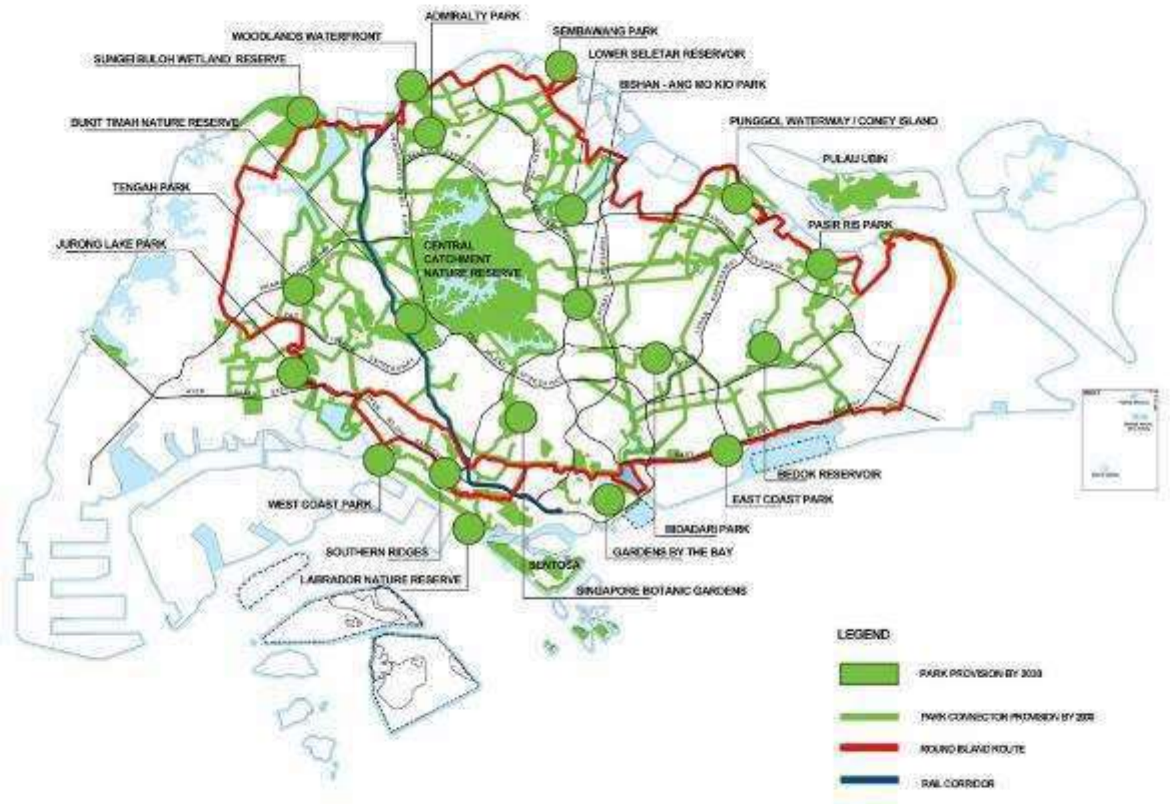
Looking at the outcomes of such measures, Taiwan has achieved better climate resilience than when it focused on structural solutions only. The 2015 typhoon Soudelor, comparable to typhoon Morakot in intensity, generated 10 times less deaths and USD 3.84 billion in damages.

Singapore

Town planning was legislated in 1959 and a dedicated planning body – Urban Redevelopment Authority – was established in 1974 to oversee physical planning, preparation of a long-term development plan, Master Plan, and implementation of the development control. All spatial planning related plans and regulations integrated ecological urbanism and green strategies to achieve climate resilience and sustainability from as early as the 1960s. Some examples of **land use measures** taken in Singapore towards climate resilience are:

- **Protecting and expanding biodiversity areas and natural reserves**. The green cover of Singapore increased from 36% in the 1980s to 47% now (Senthilingam, 2016). The water catchment area also expanded to as much as 2/3 of the country by 2011.
- **Landscaping for Urban Spaces and High-rises (LUSH) program** combines green initiatives to strengthen Singapore's identity as a tropical *City in a Garden*, this along with a high density development. Under the LUSH initiative, new buildings, such as JEM in Jurong, provide landscaped areas equivalent to the development site area (URA, 2018). This counters UHI, provides cooler local environments and increases pervious surfaces to capture rain water runoff.
- The **Active, Beautiful, Clean Waters (ABC Waters) program** builds community spaces around water bodies, integrates canals with the urban landscape, and improves water quality by using natural cleansing features. For example, at the Bishan-Ang Mo Kio Parka, large concrete drain was transformed into a natural river integrated with the adjacent park. After redevelopment, the naturalised river's carrying capacity increased by 40%. The river system now accommodates fluctuating water levels and protects surrounding built up areas from flooding during heavy precipitations (Zheng, 2017)
- In 2005, the Building and Construction Authority (BCA) launched a **Green Mark ating scheme** to assess buildings' environmental performance. BCA set a target to achieve these standards for 80% of Singapore's buildings by 2030. The 3rd Green Building Masterplan, published in 2014, encourages building owners and tenants to become more energy-efficient. Incentives such as gross-floor-area bonuses and financing are used to encourage the adoption of sustainable practices (SSB, 2015). Developments with land size of 0,2 ha or more have to implement on-site measures, such as detention tanks and green roofs, to slow down runoff entering the public drainage system.

Singapore's integrated land use policy increased the green cover by 1/3 between 1986 and 2007 (NParks , 2016). Singapore reduced its flood prone area from 3,178 ha in 1970s to only 34 ha in 2013 (IWRM, 2014). The ND Gain index, which ranks countries on their ability to leverage investments and convert them to climate adaptation actions, places Singapore on the top of the list (ND-GAIN, 2018).



4: Singapore's green and blue spaces – land use plan 2030.

The Philippines

The Philippines is the 5th most affected by extreme weather events country (2015 Global Climate Risk Index). After the super typhoon in 2006 (more than 2500 causalities), the Philippines institutionalized mainstreaming of climate change into national policy-making, planning, and other decision-making processes of the government through the Climate Change Act of 2009. Simultaneously, the government integrated the country's climate adaptation and disaster risk reduction goals by enacting them in the Disaster Risk Reduction and Management Act of 2010. Specifically, this national legislation dictated that climate change and DRR must be mainstreamed into the national and local governments units' (LGUs) development decision-making and planning process (Cuevas, et al., 2015). Subsequently, in 2013, the National Climate Change Commission (NCCC) developed supplementary **Comprehensive Land Use Plans (CLUP) guidelines that require cities to incorporate climate change and disaster risk reduction into local land use plans obligatorily**. The CLUP – a long-term plan for 10 to 15 years – is to be submitted to the review of the Housing and Land Use Regulation Board (HLURB) every 10 years. Alongside, the Comprehensive Development Plan – a medium term plan for 3 to 6 years – is to be submitted to the Department of Interior and Local Governments (DILG).

CLUP climate sensitive land use measures include:

- Protecting people and investments from hazards by selecting safe sites for development: taking into consideration setbacks from flood lines, prohibiting development in hazard prone areas, restricting development in environmentally critical zones.

- Protecting and managing valuable natural resources and environmental processes: demarcating natural ecosystems and applying standards or guidelines to preserve them; controlling development density and protecting underground water from septic discharges and landfills contamination (Deocariza, n.d.);
- Protecting critical facilities (schools, hospitals, public buildings) through spatial planning: e.g. elevate them or prohibit their construction in hazard-prone areas;
- Removing or relocating buildings from floodplains to safer grounds with government acquisition/buying out of properties, especially those in hazard prone areas (Deocariza, n.d.).

The model was first tested in the province of Albay, which is highly prone to climate related disasters. As a result of good governance and local leadership, forest cover in the province increased by 88% and the coastal mangrove cover increased from 700 ha to 2,400 ha in the last 7 years, thereby creating a crucial buffer between the land and the sea (Pearsall, 2017). The Albay LGU played an active role in setting up best practice examples for other provinces and proved successful: Albay stood against subsequent typhoons without reporting any casualties. A surge in private investments and increased revenue from eco- tourism has followed.

5: Typhoon effects in Albay 2006, CLUP guidebook and sample impact area map for sea level rise as in the CLUP guidelines.

Benefits of the approach over engineering solutions

A *climate sensitive spatial planning first* approach has a number of valuable advantages over a *structural solutions first* approach: it is significantly less cost intensive and brings a number of important co-benefits.

Cost effectiveness of spatial planning solutions

Structural climate resilience measures require heavy public investments, implementation time and technical capacity. Jakarta proposed a Giant Sea Wall is estimated to cost up to USD 40 billion and require 30 years to build and create a vast man-made lagoon. The financial model includes a mix of public funds, international soft loans and private investments. The required funding hasn't been disbursed due to a number of controversies related to a poor implementation record of such projects, corruption and financial constraints in the country (Sherwell, 2016). Experts claim that it is an unnecessary intervention and non-structural measures would serve the city better (Sherwell, 2016). Non-structural solutions require much lesser capital investments while generating long-term outcomes. These are hence to be seen as most financially viable solutions, especially in the context of low to middle income countries.

Sustainability quotient

Engineering solutions such as dams, flood walls etc. are often invasive and damage blue ecosystems. They use high embodied energy construction materials such as cement and steel. Non-structural measures are in better agreement with the essence of sustainable development, being more reversible and, by definition, environment friendly. Climate impacts bear a degree of uncertainty and a greater flexibility of resilience strategies is particularly advantageous for long term sustainability.

Public realm, health and wellbeing

Land use tools not only regulate the use of physical spaces but also influence a city's economic and social development. The built environment shapes and structures everyday life of its citizens. When nature based solutions are adopted through land use regulations, these add green and blue spaces to the urban environment. Green public spaces play a critical role in cooling cities, and provide safe routes for walking and cycling as well as places for physical activity, social interaction and recreation. In fact, WHO recommends a minimum of 9m2 of green space per person for adequate mental and physical health balance of urban citizens. These green spaces along with a well-designed built environment offer innovative approaches to increasing the quality of urban settings, enhancing local resilience and promoting sustainable lifestyles, improving both the health and well-being of urban residents. To share a few examples:

- **Shanghai** is one of the largest metropolitan areas in the world with a territory of 6,340 km2 and a population of over 24 million. It is often referred to as an urban canyon, consisting of numerous narrow streets surrounded by tall buildings. Rapid urbanization and expansion have produced a strong UHI effect reaching 7°Celsius more than in surrounding rural areas. As a mitigation strategy, the city planned greenbelts in the downtown areas. Urban greenery per capita increased to 12,5 m2 in 2008 from 1,0 m2 in 1990, making Shanghai stand above the WHO recommended 9 m2. The shade provided by trees and bushes has reduced the heat island effect by dropping the average temperature in the city by 5%. By 2020, Shanghai's land use plan envisions 30% of the city being covered with greenery (UCCRN, 2011).

- In **Seoul**, the government removed the Cheonggye highway built over the river and instead built a sunken, natural corridor of park space along the river in 2005. Opening up the stream

6: Cheonggyecheon Stream Restoration Project, before and after. Source: (MDPI, 2016) and installing the park cooled the surrounding area in the city by 3.6° C and significantly reduced air and water pollution, dropping local levels of airborne particulate matter by about 20%. The revived stream provides flood protection for up to a 200-year flood event and can sustain a flow rate of 118mm/hr. The park attracts over 60,000 daily visitors now and has boosted the local economy with tourists' inflow (Nicodemus, 2016).

Beautification of cities
Natural ecosystems not only create a more climate resilient environment, but primarily create **livable places** desirable for businesses to settle in, for tourists to visit and for citizens to connect with and take care of. Singapore, for example, is the second most visited destination in Asia (Hui, 2017).

Reduced greenhouse gas emissions and energy consumption
Protecting natural ecosystems in a high density urban environment usually means gradually embracing a **compact and transit oriented urban development model**, which encompasses all related benefits such as a reduced number of private vehicles or a reduced use of air conditioners (APTA, 2007).

Economic and livelihood opportunities
Revised land use zoning and regulations give an opportunity to identify land for a range of economic activities that complement sustainable urban development. These could be urban farming, informal activities on land parcels that are otherwise too risky for habitats. On a much larger scale, private investment can be invited into land parcels that are in low risk zones for mixed use and high-density developments within city boundaries.

Challenges associated with implementing climate sensitive land use regulations

A. Technical challenge: existing settlements in disaster prone areas

In most Asian cities, built developments have already cropped up on high risk zones. Introducing land use planning climate resilience solutions will often come to planning relocations with all the challenges and cost it encompasses. Indeed, over 50% of Asia-Pacific's urban population lives in cities and towns that are located in low-lying, coastal or riparian areas. In Ho Chi Minh City, over 25% of the population is currently affected by extreme storms, and this could climb to over 60% by 2050. During the 2011 floods, 1/3 of Bangkok's population was directly affected, which included 2/3 of the city's poor.

Climate risk prone zones are most often populated by the urban poor, most likely to live in low-lying areas, on steep slopes, in ravines, etc. They lack resources and, often, information to prevent and mitigate disaster related damages. During the 2011 flash flood in Cagayan de Oro (Philippines), 95% of the city's deaths and housing damages affected informal settlers (UN-HABITAT, 2014).

Resettlements related to climate responsive land use regulations are hence a very sensitive social challenge. It needs to be approached in a long term, holistic and sensitive manner, which requires sustained political support and private investments. Both are often lacking at present in developing Asian countries.

B. Bottom up challenges: lack of awareness and empowerment

Lack of citizen awareness results in a lack of a public demand

Awareness of climate change is overall very low in developing Asia. As per a recent poll, in North America, Europe and Japan, over 90% of the respondents said to be aware of climate change. In India and Bangladesh, however, over 60% adults have never heard of it (Leiserowitz & Howe, 2015). Lack of comprehensive public data on climate projections and consequences. For example, in Asian countries, UHI assessments are mainly conducted in cities where long-term data records are available. There is a lack of research on increasing thermal burdens related to reducing natural ecosystems in cities in rapidly urbanising and populating countries, such as India and Philippines (ADB, 2017).

Awareness about potential land use solutions for climate resilience is even lower. Concerns over low incomes, unstable housing, health and education take the frontline and linkages with these challenges and climate resilience are not understood. Supporting NGOs and CSOs hence rarely advocate for climate resilience.

Finally, local media coverage is majorly confined to traditional disaster reporting of casualties. There is little contextual reporting on why these natural disasters are happening more frequently and how effectively spatial planning can palliate them. Media's role in reporting climate stories remains largely untapped (Shah, 2016).

All these matters combined create a very **low recognition environment for decision makers** who'd want to make spatial planning interventions.

Low empowerment of civil society

Negotiating land use decisions requires co-operation at different institutional and stakeholder levels. **In developing Asian countries, the civil society is often a hardly empowered stakeholder** in comparison with real estate investors, big businesses and elected politicians. The later tend to actively advocate for their interests, which don't always match the interests of vulnerable communities. Referring back to Chennai, real estate developers successfully lobbied local decision makers and were allowed to build upon essential ecosystems such as Pallikarnai marsh or the Velachery lake-bed (which became the Phoenix mall) despite protests by civil society groups (Anuradha, 2016). Another example: the Kolkata High Court ordered that East Kolkata Wetlands are to be preserved for fishing and farming in 1992. This ruling has not been enforced till today. Illegal developments are instead coming up over the wetlands. "A local environment society has alleged a nexus between political leaders and developers leading to inaction in safeguarding the water bodies. In some cases, the government authorities themselves built slum rehabilitation dwellings on the wetlands only to evict them later in anti-encroachment drives and hand over the land to developers" (Anuradha, 2016). This situation makes climate sensitive land use regulations very difficult to put forward.

C. Top down challenges: limited decision maker capacity and political will

Limited capacity and expertise

Climate resilience is a relatively new concept at the urban planning level in developing Asian countries. Manipulating it requires urban local bodies to have specific technical know-how and data, which is often not dedicatedly collected and systemised. A few pioneering international programs, such as Capacity Development for Adaptation to Climate Change & GHG Mitigation (C3D+), 100 Resilient Cities or, formerly, the Asian Cities Climate Change Resilience Network (ACCCRN) help improve national research and training and government agencies' institutions' technical capacity. These programs include risk mapping and data collection activities, climate proofing city plans, raising general awareness.

Data availability and its accuracy at the local level remain a challenge. Broad aspects of climate change in Asia are for example simulated by the Atmosphere Ocean Global Circulation Models (AOGCM), however uncertainty remains and data is not localised enough. Asian region has a very complex topography and marine influences, local climate changes hence vary significantly from regional trends (IPCC, 2007). There is a clear need for a more localised climate data to enable a better climate sensitive local planning.

Lack of political motivation

Spatial planning's de facto strong connection to short-term electoral cycles obstructs its whole purpose, which is to prevent risks and ensure resilience in the long run. Short-term electoral mandates push local politicians to demonstrate tangible results in order to increase re-election chances. Land use regulations protecting natural eco-systems are seen as less tangible actions compared to engineering solutions: installing pumping stations in low lying areas, construction of embankments, etc.

Political economy is another determining component when it comes to a spatial planning approach to climate resilience. It is a commonplace scenario that personal interests influence approvals of construction proposals. Developing countries' public sector administrations often receive inadequate pays, long duty hours, interference from political organisations and outdated reporting arrangements. Coupled with relatively weak checks and balances systems, these factors significantly contribute to the political economy factor.

To illustrate, nearly 900 million, or over 1 in 4 people, across 16 countries in Asia including some of its biggest economies such as China and India are estimated to have paid a bribe to access a public service. Transparency International representatives blame low civil service salaries coupled by systems that allows little or no access to redress mechanisms as main reasons behind this situation. (Goswami, 2017). The matter is all the more magnified when it comes to attributing large real estate development contracts. This is how natural ecosystems are further and further encroached upon.

Solutions to overcome challenges related to mainstreaming climate resilience into land use regulations

As demonstrated above, mainstreaming climate resilience into spatial planning and land use regulations is an essential approach, yet hardly taken forward by concerned national and local authorities. The reason is that it requires **making key institutional and policy shifts**. The international development community vastly supports climate resilience with internal, external, grant, loan and investment funding. To leverage maximum benefits from this effort and achieve more tangible results on the ground, it needs to help mainstream the approach. Five major ways of doing so can be listed: 1. Raise awareness and build capacity; 2. Build local leadership for climate resilience; 3. Generate public demand for climate resilience; 4. tailored financial support; and 5. Build upon existing national and international efforts.

1. Raise awareness and build capacity

Both citizens and decision makers are insufficiently aware of the scale of climate threats as well as of the role land use can play in mitigating these, especially in in small and medium size cities. A number of international agreements and annual events contribute to raising such an awareness, however a more **dedicated effort needs to be made with a focus on the national and sub-national levels in partnership with governments and on the grass root level in partnership with relevant NGOs**. In Canada, workshops and training sessions are frequently used as a mechanism to stimulate local climate adaptation. These typically bring together experts in climate science and adaptation with community leaders, municipal staff and the general public. Goals of these workshops vary, and may include, for example, identifying priorities, setting the stage for ongoing collaboration and dialogue for adaptation capacity (Warren, 2014).

Building municipal staff’s capacity requires a very tailored approach given the fact that municipalities are often heavily understaffed and can hardly participate in dedicated trainings. A **hands on cooperation between experts and local authorities** have revealed to produce best on the ground outcomes. For example, the 100 Resilient Cities (100 RC) program typically introduces a Chief Resilience Officer (CRO) in partner cities, usually a local influencer well connected to key local decision makers and stakeholders. Local leaders and administration also have access to technical assistance and training as per their specific requirements (The Rockefeller Foundation, 2017)

2. Strengthen the top down approach: build local leadership for urban climate resilience

The importance of an incentivizing system to foster local political and decision maker leadership for climate resilience cannot be over-estimated. Yet, it is nearly never a direct component of a national or an international climate resilience program. The international community has however a number of effective instruments to increase visibility of highly performing politicians, both at the national and at the international level.

The **Mayor of Surabaya** (Indonesia), Tri Rismaharini, won several national, regional and international awards after she successfully transformed one of the most neglected cities of the country – earlier called *Concrete Dumb* - through a series of highly attractive public parks, good practices in solid waste managements, improved education and tackled infrastructure challenges through public participation. She converted bare land and selected gas stations' locations into green public spaces by doing so making 20% of Surabaya's territory green. This intervention played two major functions: the city was no longer affected by floods during heavy rains and public parks greatly contributed to reducing social segregation and improving safety. Indeed, parks were strategically located to connect high and low income areas. Public participation has won the city a number of environmental awards. Such a leadership brought two strategic outcomes: Mayor Tri Rismaharini is a continuously re-elected Mayor since 2010, hence harnessing personal career benefits from her strong stand for the environment and for social justice; in addition, her leadership attracted attention and motivated Mayors of other Indonesian cities to follow her path (IE Singapore, 2016).

3. Strengthen the bottom up approach: generate citizen demand

Political mandates – typically 3 to 5 years – are far shorter than the timeframe to be considered when building climate resilience through spatial planning – from 10 to 50 years. **Citizen ownership is the most effective way to ensure a beneficial intervention will continue beyond a potential political change**. Building such an ownership implies involving citizens at all stages of the planning and implementation process. In particular, communication between local authorities and citizens needs to take a shift so that citizens value less 'visible' spatial planning interventions by doing so rewarding decision makers by their support and so that citizens can convey their concerns and priorities in an impactful manner. Organizing **dedicated trainings for the media** on how to better understand and cover climate matters in the urban context is, for example, a very effective way to both reach out to citizens and incentivise politicians.

Batticaloa, a coastal city of Sri Lanka, is a highly flood prone. A 2010 UN-Habitat project encouraged cooperation between local authorities and residents. The later participated in the development of a green belt near the sea as a protective buffer against natural disasters and a recreational area for the communities. "By being directly involved in decision making about what facilities should be prioritized and the type of vegetation to support, they developed a much greater sense of ownership over the project, including a protected public space that is better suited to their needs" (UN-HABITAT, 2014, p. 44).

8: Google earth imagery in 2008 and 2018 showing increased green cover along coastal line zone that is most prone to tsunamis and sea level rise in Batticaloa.

Organised citizen feedback is another example of effective communication: Citizen charters is an example of a widely used user satisfaction rating system assessing the quality of municipal services. In Bangalore, the Citizens' Report Card (CRC) was first initiated by a civil society organisation – Public Affairs Center – in 1993 to monitor government services in terms of efficiency and accountability. Since then, the CRC has been adopted and tested in several developing countries such as Pakistan, Philippines or Tanzania (World Bank, 2013). These charters and public feedbacks have demonstrated that such measures could hold the public sector performance more accountable (UNESCAP, 2015, p. 165).

Online social spaces are a valuable addition to conventional physical ways of connecting with citizens. Social media pages in the local language have widely paid off in terms engaging citizens. For example, the municipality of Hat Yai, Thailand, launched a page *I love Hat Yai*. On a regional scale, the World Water Monitoring Challenge encourages people to record their local water quality and share results (www.worldwatermonitoringday.org).

4. Incentivise through funding attribution systems

Allocation of national and international funding is both a key component and a key instrument of rightly sequencing planning and engineering solutions. Local governments show an overwhelming interest for funding opportunities and tend to largely tailor their urban interventions to funding access conditions. Here, funding entities and schemes could make a major difference in terms of helping cities first recurring to non-structural solutions through special planning and land use regulations, and only then identifying structural/engineering solutions required in complement to special planning rather than instead of it. Project finance could for example be linked to the necessity of an engineering project after the targeted outcome related non-structural solutions have applied. This approach will strengthen municipal finance, save very limited national and international resources, and even help avoid harmful infrastructure projects come to life.

5. Build upon existing national and international efforts

As demonstrated in this paper, **climate resilience needs to be part of planning efforts and can hardly be achieved when tackled as a stand-alone subject**. In ACCCRN's monitoring and evaluation report, it was acknowledged that the program overlooked the importance of national policy context for the engaged cities. "More supportive policy environments (as in Vietnam) have stimulated better uptake of UCCR than less-well oriented environments (as in India). The weaker awareness of the policy and governance contexts for UCCR in the earlier stages of the Initiative hindered progress" (Verulam Associates, 2014, p. 70).

Yet, many key urban development programs don't include climate resilience provisions. For example, the Indian Smart Cities mission and AMRUT mission cover 600 Indian cities and are allocated a USD 22,5 billion budget. These major programs do not have dedicated climate resilience provisions despite high vulnerability of many covered cities, however one can identify entry points to bring the matter into these existing schemes, as was done by Chennai, Guwahati, Bhubaneswar and Vishakhapatnam. This appears to be driven by the cities' experiences of past disaster events (Jogesh, et al., 2017).

Such a mainstreaming can also be a form of cross-sectoral policy integration. The expected benefits of mainstreaming climate adaptation into existing development activities include avoided policy conflicts, reduced risks and vulnerability, greater efficiency compared to managing adaptation separately and leveraging the much larger financial flows in common sectors affected by climate risks than the scarce resources available for financing adaptation solely (Lebel, et al., 2012). There are a few positive cases emerging in Asia in this context.

Indonesia's Mid-term National Development Plan for both 2009-2014 and 2015-2019 have included climate adaptation and disaster risk reduction (DRR) as part of development policy priorities. The latest development plan (2017) added improved spatial planning, enhanced organisational and institutional mechanisms, and better human resources as the foundation for cities' climate resilience. As a result, 122 districts and cities in Indonesia have already developed their contingency plans for multiple hazards.

Similarly, the **Malaysian National Policy on Climate Change** calls for climate-proof and climate-resilient development, and envisions the integration of climate measures into DRR policies, plans, programmes and projects. (Lassa & Sembiring, 2017).

Climate resilience reflected in land use calls for inter departmental communication and coordination. Complementary responsibilities typically lie within different Ministries and agencies. In Thailand for example, the Department of Local Administration, Ministry of Interior, plays a key role in mainstreaming national policies into the local level, however it does not include climate resilience experts and coordination with the Office of National Resources, Environmental Policy and Planning (ONEP), Ministry of Natural Resources and Environment, does not take place often enough. International programs needs to systematically include the institutional component into all cooperation and technical assistance programs.

8. Conclusion

In conclusion, a major approach shift is required to successfully tackle urban climate resilience in Asia. As a first and fundamental step, climate sensitive land use regulations need to support spatial planning that protects and revives urban and peri-urban natural ecosystems. As a second step, structural solutions can build upon the laid foundation. Reverse the order and the city is condemned to endless heavy expenses while facing increasing climate threats. Respect the order and the city has all chances to create a healthy living environment while mitigating and adapting to climate threats to a good extent, by doing so attracting economic opportunities. Each stakeholder – be it the international development community, national and sub-national governments, businesses or civil society – need to carry their part of contribution and responsibility in this process.

Addressing climate change in European spatial planning

Fernandez Maldonado, Ana Maria, DELFT, The Netherlands

ABSTRACT:

Since the year 2000, spatial planning systems and territorial governance in European countries have been visibly transformed and adapted due to different issues. The most profound changes have been the product of the new political-economic context, stemming from neoliberal political orientations in the own European countries. Additionally, although the European Union does not have direct competence in national planning, the several EU directives in different policy sectors, have definitely shaped European spatial planning. Furthermore, the challenges brought about by the evident risks associated with climate change have also become an important factor of change, turning the confrontation to these risks as an important policy objective.

The main aim of the study is to investigate how climate change related issues have modified the European planning field. The study will answer two main questions. The first refers to how formal spatial planning systems in Europe, represented by the institutions and instruments that are established by law, have included climate change-related issues. Addresses the actual planning practice, the second questions explores the extent to which planning instruments are used to achieve the objectives implemented to tackle the risks associated with climate change.

To answer these questions, the present study uses data gathered by the COMPASS project (Comparative Analysis of Territorial Governance and Spatial Planning Systems in Europe). COMPASS was commissioned by ESPON (European Territorial Observatory Network) to investigate the most significant trends in territorial governance and spatial planning systems across 32 European countries. This includes the 28 EU member states and the 4 associated countries. The period under study was the 2000-2016 period.

The study found that the way the countries address climate change is very mixed. Some countries have included climate change related objectives in the legal definition of spatial planning, while others have created specific instruments that fight the associated risks from different perspectives. Countries which count with a mature spatial planning system and more stable conditions have incorporated climate change issues in a more thorough and comprehensive way. Furthermore, among the 14 sectoral policies under study, environmental policies showed to have the highest degree of integration with spatial planning.

A methodological approach to measure interrelations between urban form and flood-related risks in Kampala, Uganda

Tjark GALL, Urban Framework, Germany

Keywords: Urban form, Climate Change Risk, Spatial Equity

This paper[i] aims to examine the interrelations of spatial characteristics to the often-unjust distribution of climate change risk and vulnerabilities and develop a methodological approach for Kampala to redress this situation. The research intends to increase the understanding of spatial equity and proposes a method to quantify it in environments of limited preceding research and data availability to support better-informed policy and spatial intervention strategies.

1. Introduction

Fifty per cent of the world population is already living in cities. By 2050, it is expected, that more than two-thirds will live in urban settlements. The growth will mostly occur in African countries where one billion people live at present. More than four billion people are expected to live in Africa by the end of the century and thus make up more than one-third of the world's population (United Nations 2015).

This rapid growth steadily increases the importance of sustainability in urban planning while it also contributes to rising spatial injustice, mostly in sub-Saharan Africa (SSA). Access to land, services, employment opportunities and therefore also the city itself vary strongly between different income and social groups (Parnell and Walawage 2010). These gaps are significant and disadvantage the already most vulnerable groups even more, specifically under the increasing threat of climate change and its accompanying risks. The understanding thereof as well as realising which factors positively or negatively influence spatial equity is crucial for tackling these inequalities.

This paper analyses the specific situation in the capital of Uganda, Kampala, and the distribution of flood-related urban risks to investigate this spatial injustice, as well as its driving forces and consequences. It results in a methodology which attempts to establish a relationship between internal and external spatial characteristics of settlements and their correlation with the level of spatial equity within. Answering the following research questions is central to the study:

- How can the quantification of risk exposure, adaptive capacity and sensitivity can be simplified and carried out at small-scale spatial resolutions and locations with limited data?
- Which spatial characteristics of urban form are measurable with restricted spatial data and correlate with social vulnerability?

The objective is to expand the existing literature by applying it to the dynamic context of urban Uganda. Additionally, existing approaches, as well as newly developed methods are integrated by retrieving various spatial indicators from GIS data/aerial photos and relating them to statistical data (e.g., vulnerability, socio-economic profiles) and qualitative results of household studies. The anticipated outcome of the research is an improved understanding of urban dynamics, justice, and accessibility, specifically in the context of Kampala, and to build a better basis for informed policy decisions, as well as spatial interventions. Even if the methodology is context-specific, generalisations can be made for other urban areas in sub-Saharan Africa and assist in the quantification of socio-spatial inequalities in the field of climate change.

2. Background

The global population continues to increase rapidly and is mostly concentrated in the urban areas of the global south. More specifically, the African continent is experiencing the highest population rise in the present century. Adding to the pressure on cities by more residents and spatial expansion, climate change further stresses these urban systems. Cities became the centre of the current development and sustainability debates. Their importance is widely acknowledged and continuously highlighted by international and national institutions around the world, representing a central aspect in the Sustainable Development Goals (SDGs) of the United Nations. SDG 11 focuses on making "cities and human settlements inclusive, safe, resilient and sustainable" while the city itself functions as the arena for achieving nearly all the other goals (UN 2015, p. 14).

The questions arise, what this development will mean for the population within cities and how it can be managed and steered into a sustainable direction. The report 'Our common future' already highlighted spatial injustice in 1987, together with the necessity to identify the most vulnerable groups and tackle the social and environmental risks which accompany the population surge (WCED). However, more than three decades went by, and even if sustainability is a primary concern nowadays, more people than ever before are living in risk-prone circumstances, and environmental depletion does not slow down either (Adger 2006; Brecht et al. 2013; UN-Habitat 2014; UN 2015 & 2016).

With urban areas as the primary habitat of the world's population, fast urbanisation patterns in sub-Saharan Africa (SSA) increase the demographic pressure, while climate change stresses the cities, and their adaptation is challenging because the responsible institutions often lack resources and capacity to tackle the rising complexity and quantity of issues (Pieterse and Parnell 2010; Myers 2016). In 'Africa's Urban Revolution', Parnell and Pieterse emphasise the general growth which occurs in both urban and rural areas but its strong concentration in urban agglomerations. This development is not only about the increase of the number of residents but comes along with "severe overcrowding, lack of sanitation, constant threat of bodily harm and abuse" and is "linked to the structural poverty and systemic exclusion experienced by a large proportion of the urban population in most African cities". Unequally distributed pressures on age, income and gender groups result in negative externalities on health, productivity and economic behaviour (Pieterse and Parnell 2010; Bartlett 2008; Fainstein 2010). Furthermore, climate change and global environmental change are leading to more rural-urban and/or trans-national migration of climate refugees, unequal distribution of land, hazard risks for settlements in the shape of floods, landslides, droughts or heat waves, to just name a few which highlights the "dynamic processes and the interplay" of these elements (Parnell and Walawage 2010).

However, inequality does not only exist amongst different social groups within the cities but also on the global scale. Climate change itself is a global challenge, mainly induced by the industrialised countries while the most impoverished countries contributed the least but suffer the most from its consequences (Althor et al. 2016). The suffering is further intensified due to a widespread lack of adaptive capacity, meaning the "potential, capability, or ability of a system to adapt to climate change stimuli or their effects or impacts" (IPCC 2001).

Parnell and Walawage (2010) further stress the importance in these complex circumstances of creating the capacity to ensure urban resilience so that the livelihood of everyone in the city is not negatively affected by the broader global demographic and environmental processes. Another important aspect is the interplay between the social and ecological systems and their cultural understanding which varies fundamentally between the western and most societies in SSA. While the dominant western notion sees them as separate entities, in most SSA cultures nature and society are interwoven. The consequences of the development in industrialised nations lead to the destruction of locally much higher valued ecosystems, while differing perceptions result in complications in cooperation, the transfer of 'knowledge' and coping mechanisms (Myers 2016).

All these issues emphasise the plethora of challenges which cities in SSA are facing. Tackling them will be one of the critical tasks for policy makers and planners of the coming decades. Starting with the predominant injustice and its spatiality in urban agglomerations, this research tries to contribute to the understanding thereof by looking at ways to quantify the interrelation between urban form and social vulnerability with a focus on risk exposure and adaptive capacity. UN-Habitat (2014) called the development in SSA cities an "urbanisation of poverty". This led to plenty of unplanned and underserviced settlements with fundamental and increasing material injustice and lack of opportunities between them and their affluent neighbourhoods. Understanding these different settlements patterns and their integration in the urban fabric will be the core of the analysis of urban form, while the varying level and types of risk exposure and the interdependence between social variables and adaptive capacity will serve as comparative values.

Urban form, defined by Williams as "the physical characteristics that make up built-up areas, including the shape, size, density and configuration of settlements" (2014, p. 6) is moving towards the centre of interest in the sustainability debate, while its importance on the social and ecological risk exposure is further emphasised (Jabareen 2006; Hillier 2009; Louf and Barthelemy 2014; Fragkias et al. 2013; Oliveira et al. 2014; Pelling and Wisner 2009 and others). Myers adds to the definition of urban form, in his words *cityshape*, that in the context of SSA it is the physical as well as the "socially and culturally produced environment" (2016, p. 19), highlighting non-spatial characteristics. Jane Jacobs already described the strong interrelation between the built environment and social dynamics of cities in 'The death and life of great American cities' (1961), where she states that cities should be a place for people, even if that is often not the case (anymore). Building upon Jacobs' perspective, Gehl (2010) further embraces the interconnection of urban form and social life, sustainability and health through variables of density, compactness, and diversity while also highlighting its relation to risk (e.g., traffic accidents, robbery). Additionally, he argues that high-quality urban space can fuel interaction and social inclusion, and therefore a higher sense of community which again can lead to better cooperation and assistance in case of disaster regardless of their type or scale. He also states the importance of shared urban space since overpopulation and rising poverty put pressure on the livelihood of people (Gehl 2010). Jacobs continues to describe the impact of being better interconnected on adaptive capacity, further supporting the interrelation between the spatial and social dynamics of cities.

The issue of justice in cities, in which context this research is situated, was famously put into focus by Susan Fainstein in 'Just Cities'. She gives a broad overview of different notions of justice, how it can be conceptualised and quantified and also states that injustice rises and the poor, mostly women and children, represent the most vulnerable groups (2010). This link between poverty and vulnerability in the field of environmental risks was further studied by UN-Habitat (2014), naming the lack of decision-making power and resources, mostly in time of disasters, as the primary reasons. They also emphasise the disproportionate distribution of risk exposure among different age and gender groups (see also Bartlett 2008).

What do urban risks or vulnerability mean and what do they encompass? Brooks (2003) distinguishes generally between social and biophysical vulnerability. Social vulnerability includes everything related to the human and is the focus of this research, while biophysical vulnerability focuses on the ecosystem and biophysical environment. Risk, on the other hand, is normally composed of different types of hazards, their occurrence and scale, but has numerous definitions which are further discussed below. The last two aspects are adaptive capacity as the "potential, capability, or ability of a system to adapt to climate stimuli or their effects or impacts (IPCC 2001, p. 881) and sensitivity as "how affected a system is after being exposed to the stress" (Engle 2011, p. 649, compare to Adger 2006 and IPCC 2001).

The proposed methodology in the case study of Kampala aims to measure the key elements – urban form, climate change related risk exposure, adaptive capacity and sensitivity – with a view to understanding their interplay in the context of socio-spatial justice as shaping elements of urbanisation and livelihoods. The example of Kampala provides a compelling case, due to its fast urbanisation and current as well as predicted spatial expansion but early development stage in comparison with other Eastern African cities (Karolien et al. 2012; UN-Habitat 2014). At the same time, it experiences severe climate change-related consequences, and has high levels of informality, low levels of land tenure security and building regulations, basic service provision and faces institutional challenges which further complicate the situation (Karolien et al. 2012; Nyakaana et al. 2008; Insunju 2016; Richmond et al. 2018; UN-Habitat 2014). Therefore, it is an interesting case study to analyse itself while its comparability to many other cities in SSA provides the opportunity to transfer and apply the same approach in other geographical contexts.

2.1 Urban form

The first central concept is urban form. It can mainly be conceptualised as the built embodiment of urban society, generally divided in macro, meso- and micro-scale (city, settlement/neighbourhood, building) and is constituted by different layers, including street networks, build environment, and land use/division (Pont and Haupt 2009; Oliveira 2016; Hillier 2009). Two different levels of urban form are distinguished to measure urban form. Firstly, the city level (macro scale) includes the demarcation of the urban agglomeration and is necessary to understand larger interrelations, e.g. the accessibility to the economic centres or differences between core and peripheral areas. The second level is the settlement area (including both meso- and micro-scale), which looks more at the built environment and includes built density, space allocations, proximities, or the density of street intersection. The measurable characteristics of the latter are divided into the three layers. There are various claims about the interrelations of urban form and sustainability. For example, they state that smaller or denser more interconnected cities might be more sustainable (see for example Adolphe 2001, Oliveira 2014, Jabareen 2006, Fragkias et al. 2013; Dave 2010; Louf 2014). The latter would be interesting to analyse in Kampala, but this would require partly non-available data. Also, due to the overall performance of cities as systems (i.e. emission, GDP) they would only produce compelling results if compared with other cities.

2.2 Social vulnerability

The second central concept is social vulnerability. There are countless definitions of vulnerability and its constituting parts, mainly depending on the time, context and background of academic research. Therefore, it is crucial to define the various parts of social vulnerability and conceptualise them in a coherent and commonly agreed upon manner. To start with, vulnerability is conceptualised in a broader context than either "the amount of (potential) damage caused to a system by a particular climate-related event or hazard" or as the "state that exists within a system before it encounters a hazard event" (Jones and Boer 2003 and Allen 2003 in Brooks 2003). Currently, the most accepted definition follows the latter. Furthermore, a distinction between different types of vulnerability can be made, even if there is no consensus on the actual separations or terminology. The most common types which can be found in the context of urban climate change vulnerability are social (also referred to as human) and biophysical (or natural) vulnerability. However, various studies also examine, for example, economic or institutional vulnerability (Brooks 2003). Vulnerability, in general, is defined by Adger (2006), building upon the definition of the Intergovernmental Panel on Climate Change (IPCC) as the "state of susceptibility to harm from exposure to stresses associated with environmental and social change and from the absence to adapt". In the case of social vulnerability, the system which is vulnerable encompasses all socially connected elements, while biophysical vulnerability can be defined as the vulnerability of the natural environment to climate change-related stressors. A quick overview of the definitions of the constituting elements (Table 1) is provided, together with a diagram showing its connections (Fig. 1).

Hazard	While there are also different types of hazards, the focus here is on natural hazards, which can be defined as "physical manifestations of climatic variability or change" (Brooks 2003, p. 3). The primary natural hazards are cyclones, floods, earthquakes and landslides (Adger 2006; Brecht 2013).
(Hazard) event	A hazard describes the initial stressor / physical manifestation of climate change, while an event is the more precise occurrence of a hazard which takes the exposure of the system into account (Adger 2006; Brecht 2013).
Disaster	A disaster takes the probability into account and further incorporates the consequences of events of natural hazards (Adger 2007; GIZ 2014).
Risk	The combined outcome of exposure, the sensitivity of a system and its adaptive capacity. As higher the vulnerability in general or risk exposure and sensitivity, as higher the risk. As stronger the adaptive capacity, as lower the risk (Adger 2007; Cardona et al. 2012; Dickson et al. 2012; Brecht 2013; GIZ 2014; Pelling 2016).
Risk exposure	"Character, magnitude, and rate of change and variation in the climate. Typical exposure factors include temperature, precipitation, evapotranspiration and climatic water balance, as well as extreme events such as heavy rain and meteorological drought" (GIZ 2014, p. 21).
Adaptive capacity	No generally applicable definition exists, as the adaptive capacity dependent heavily on the type of hazard, environment, and system which is looked at. However, often constituting or influencing elements are generally resources, knowledge, institutions, and the economy (Adger 2006; Adger 2007; GIZ 2014).
Sensitivity	"Degree to which a system is adversely or beneficially affected by a given climate change exposure […and] shaped by natural and/or physical attributes of the system including topography, the capacity of different soil types to resist erosion, land cover type. But it also refers to human activities which affect the physical constitution of a system" (GIZ 2014, p. 21).

Table 1: Definitions of social vulnerability elements

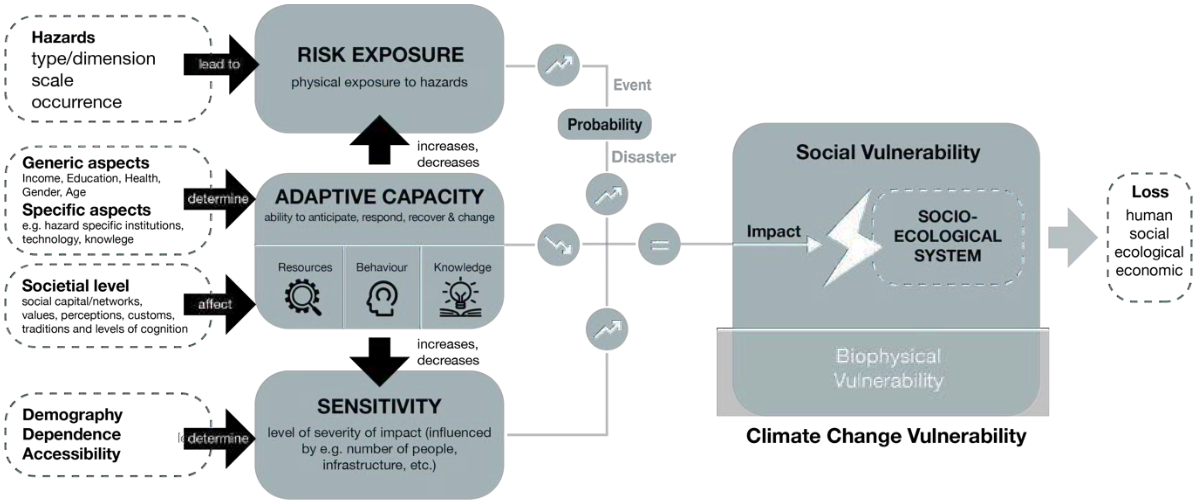

Figure 1: Conceptualisation of vulnerability and its connections (Author 2018)

2.3 Flood-related risks in Kampala

The focus of this research is on Kampala, the capital of Uganda. While it is the second least urbanised country in Eastern Africa (2011: 31.2%; UN-Habitat 2014, pp. 147-150), the urbanisation rate is significant in comparison to other countries in sub-Saharan Africa, and even more at a global level. These developments lead to an assumed current urban population of Kampala of somewhere between 1.6 and 2 million (1.66 m in 2011) and predictions of about 100,000 new urban inhabitants which lead to an expected population of 3.5 m by 2025 (UN-Habitat 2014). This high urbanisation rate leads to a sprawling urban agglomeration even outside the jurisdictional boundary of the Kampala Capital City Authority and furthermore to densification and (formal as well as 'informal') infill in areas which are either due to their soil texture and/or proximity to flooding areas, not suitable for residential areas (Karolien et al. 2012; Nyakaana et al. 2008).

In 2009 only 9.1 % of the national population was living below the poverty line, one of the lowest in Eastern Africa (UN-Habitat 2014). However, the countrywide number of people who are living in self-planned settlements increased from 1.5 m in 1990 to 2.5 m in 2007 (UN-Habitat 2014). These self-planned settlements are often experiencing the most severe livelihood challenges, are situated in inappropriate and inaccessible locations and lack access to basic services and critical infrastructure (UN-Habitat 2007). Nyakaana et al. (2008) furthermore point out that growth brings about a "lack of infrastructure, social services and poses planning and environmental problems" and emphasise the interrelationships between population, development and environmental issues (UN-Habitat 2014). While the Kampala Structure Plan was prepared in 1972 and mainly implemented, it catered essentially for the European and Asian residential and economic areas and did not consider the less privileged society. A revised plan from 1994 tried to cope with these arising challenges but was only partly realised and let to the evolution of more self-planned settlements without much institutional steering (UN-Habitat 2007, pp. 9-10).

The Poverty Probability Index was applied amongst others in Uganda with a globally standardised assessment method and highlights the comparatively high national poverty while pointing out the missing overall access to facilities as well as basic sanitary instalments (Schreiner 2012a, Richmond 2018). It also shows the unequal distribution of poverty over age, with an intense concentration in the age groups under 29 (Schreiner 2012b, detailed in Cannon et al. 2014). A more in-depth study of the most marginalised groups (street children, 'squatters', 'slum' dwellers) further stresses various deficiencies and challenges sorted according to their significance: flooding and infrastructure access; pollution; health issues (mainly related to the aforementioned); sanitary facilities; and social networks (Dimanin 2102). These rising pressures on the urban population of Kampala are strongly linked to the increasing climate change impacts Uganda is experiencing (MoGLSD 2017; Mabasi 2009). While the climate of Uganda always led to floods and droughts in the past with accompanying consequences for livelihoods, infrastructure and the economy, recent changes intensify these pressures. The average temperature of Uganda is expected to rise by 1.5 °C until 2027 and up to 4.3 °C until the 2080s. More frequent and extreme rainfalls are projected as well. However, they are more difficult to quantify. While the rising temperatures will have substantial effects on "water resources, food security, natural resource management, human health, settlement and infrastructure" and lead to more heat waves (MoGLSD 2017, p. 12), the rising rainfalls will result in even more flooding events which will be simultaneously more severe.

The occurrence of a variety of disasters increased in the last decades in the whole of Eastern Africa (UN-Habitat 2014, pp. 160-162). Osuteye et al. (2017) attempted to compare the number and severity in countries of sub-Saharan Africa and counted 14 natural disasters in Uganda between 2010 and 2015 which led to over 700 deaths and affected more than 1 million people. While these numbers are higher in several other countries, Uganda has a comparatively low overall population which leads to 1 in 40 of the national population being affected by disasters. These statistics show the significance of natural disasters and the tremendous effect they have on lives and national development in general. Furthermore, they compare different types of events and how many houses were destroyed or damaged. In the case of Uganda, floods (5,595), hailstorms (1,786) and landslides (1,663) are by far the highest numbers (Osuteye et al., p. 26). While hailstorms can barely be avoided and only dealt with through better adaptation, the severity of floods and landslides is largely influenced by the infrastructure, spatial location and built environment, which will be further discussed below.

UN-Habitat prepared two expansive vulnerability assessments of Kampala (2009 and 2011) in which they highlight floods and related risks as the primary stressors, but also analyse which factors contribute to the severity of, and sensitivity to disasters. They point out the importance of better and more detailed vulnerability assessments and how they increase understanding and thereby permit better adaptation measures. In the second assessment, more detailed measurements and spatial distributions of vulnerability were undertaken which led to a country-wide and Kampala-specific scoring. While this method cannot thoroughly assess and predict the vulnerability to future disasters, it provides a good overview of how and where people are most affected. The compound vulnerability score is constituted of descriptive information like the elevation and slope of the environment, combined with climate prediction data (rainfall, sea level changes) and are overlaid with the population and infrastructure (roads, hospitals, schools, health facilities) at risk (UN-Habitat 2011).

This confirms that from experience flood-related risks prove to be the highest challenge for Kampala and are, therefore, the focus of this study (Fig. 2). The direct risks include the destruction of property due to flooding, as well as landslides as results of heavy rains and more spatially concentrated floods. The secondary effects are more difficult to assess but include rising water-spread diseases (Malaria, Dysentery, Cholera), pollution due to inadequate waste management (Mukama et al. 2016) and its distribution during floods and resulting challenges after the destruction of critical infrastructure or the temporal inaccessibility (KCCA 2016).

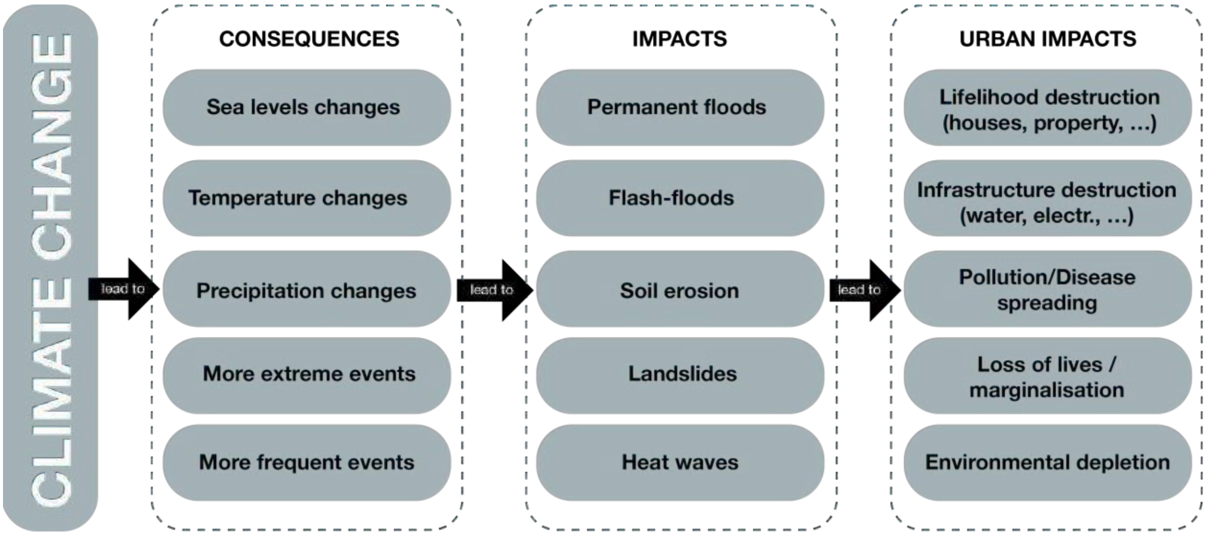

Figure 2: Climate Change impacts on urban Kampala (Author 2018)

Why are so many people living in areas which are affected by these disasters? Isunju et al. 2015 blame the overall population growth and rural-urban migration in combination with unclear boundaries and land-ownership, as well as the "long-term failure of government regimes to enforce development control" (p. 276) which led to a large number of people encroaching on wetlands. In a study of several of these affected communities, Isunju et al. found that over 55 % were female and over two thirds 30 years and younger, which again shows the unequal exposure to disaster risks. Additionally, the majority (73.3 %) of the surveyed households were only earning between 40 and 120 USD (assumed conversion rate of 1 USD = 2,500 UGX in 2015) and nearly half without secondary education. Furthermore, the perception of vulnerability to hazards was enumerated and shows that more than 50 per cent perceive themselves as very vulnerable to disease vectors and floods (Isunju et al. 2015; Isunju 2016). Lastly, there is a risk of floods negatively affecting the water quality of both tap water and even more well water which, combined with the rising water shortages endanger the water provision for the (mostly poor) population while contributing to the spread of diseases due to poisoned water and less preventive sanitary actions in times of clean water scarcity (Godfrey et al. 2003).

While a strong interrelation between the risk exposure to floods and the socio-economic characteristics of the affected population seems to exist, proving it requires an improved method to distinguish the flood-prone areas – an endeavour which is always challenging in environments of less detailed databases and due to its predictive character. Different approaches have been developed and applied to model run-off water and the effects of land use changes on the Murchison Bay Catchment area (catchment area of Lake Victoria incorporating most of central Kampala). However, limitations of the underlying data and spatial inaccuracies make them only attractive as a basis but insufficient to produce a more comprehensive representation (Fura 2013; Anaba et al. 2017). Therefore, the most promising approach is currently the overlay of three layers, including the elevation and slope of the topographical, its distance to the next flood-prone area as distinguished by the Municipality and the soil type.

3. Methodology

In order to measure and compare the various elements mentioned above, they are translated into concepts, variables and indicators (Table 2). The four main concepts of urban form, risk exposure, adaptive capacity and sensitivity are subdivided into several variables whose definitions are included in the operationalisation table. Each of these variables is further divided into one or several measurable indicators. These indicators are further defined by the following attributes[ii]:

The measurement level (1) is generally divided into two groups because the jurisdictional boundaries do not represent spatial-functional relationships. Therefore, the Greater Kampala Metropolitan Area (GKMA) and the Selected Areas (SA) are studied with two different grid sizes of 500 x 500 m and 100 x 100 m respectively. These were chosen for the study on city and neighbourhood level. The 500 x 500-meter grid spans over the whole populated area of the GKMA. The 100 x 100-meter grid is used for the in-depth study of the SA. Both cell-sizes are chosen to establish a balance between large enough cells to guarantee a certain level of representativeness while still being small enough to distinguish high-resolution differences in the urban fabric.

Another indicator attribute is the unit (2) which represents the type of the final value and forms the basis for the ensuing normalisation. The indicator type (3) distinguishes between descriptive and performance indicators. Descriptive indicators describe a certain situation without giving any indication about a negative or positive impact on the overall score, while the value of the performance indicators has either a positive or negative impact. The shown distinction is based on the literature; however, the expert interviews attempt to give a more locally-adapted understanding and can lead to minor changes of the categorisation.

Limitations of the current methodology are the risk modelling. A more advanced risk modelling method would result in more elaborated findings and could bring more differentiated interrelations to light. Lastly, due to broad conceptualisations of adaptive capacity, indicators which better describe the social networks or available resources and access to information could further enhance the comprehensiveness. However, this would require an in-depth study of the studied households through a specialised household survey which could not be conducted as part of this research. While the variety of selected and measurable indicators should be able to draw a comprehensive picture of the actual situation, these limitations need to be considered and provide a potential for further studies when more information is available.

4. Application

Before the methodology can be used, several steps need to be undertaken. They include defining the sample selection and size. Furthermore, the application can be divided into data assessment, which includes underlying steps and calculations, and the analysis, which interprets the resulting variables.

4.1 Sample size and selection

The spatial analysis is conducted at two levels, firstly the GKMA and secondly the SA. The latter is selected through a two-step sample process. As a first step, the EARF research team established a purposive sample of some parishes to cover a wide variety of land development patterns. Two corridors were distinguished: one from the centre to the north-west (along Hoima Road), and one to the east (along Jinja Road). For the household survey which was carried out as part of the research compendium, about 2800 households were enumerated which are equally distributed over eight strata (four different residential housing types and core and peripheral locations). Inside these, the households were selected through a random generation of coordinates. The enumerators started off from these coordinates and then approached the closest household.

In the second step, areas were selected inside these corridors through another purposive sample for the in-depth analysis of this thesis. This selection was done based upon a broad coverage of the different housing types, levels of centrality and vulnerability and distances to flood-prone areas, as well as the availability of in-depth spatial data. The data collection method is a mixed-method approach using existing quantitative secondary data and semi-structured expert interviews, observations to distinguish the public transport nodes, as well as the conducted EARF household survey. These strategies were chosen to garner a broad data set of both quantitative and qualitative data to understand the distribution and prevalence of risk and its interrelation with urban form. Furthermore, the interviews are used to weigh the various indicators according to their importance to achieve a representative weighting as part of the aggregation process. This process is done through a participatory multi-criteria decision analysis which lets the participants compare and assign values for each indicator in comparison to the other indicators in the same sub-group[iii] (Scott 2005, pp. 705-706). Lastly, papers and reports which focus on the climate change related risk improve the data input for the analysis of the data. The gathered qualitative data mainly assist the interpretation of the quantitative findings while also supporting the process of quantitative data collection as well as the focus, selection and weighting of the secondary data indicators.

The collected secondary quantitative data comes from various sources. Firstly numerous information from governmental institutions: i.e. the jurisdictional boundaries, the national household survey of 2014 as well as the flood-prone areas. Secondly, information produced as part of the EARF project is integrated: mainly the different housing typologies and the household survey. Additionally, other data sets are imputed from a range of recent datasets and reports which examine one particular issue in detail: amongst others, the reports on the vulnerability of Kampala (UN-Habitat 2011) and the World Bank report on economic centres (Goswami and Lall 2016). Lastly, for quantifying urban form and accessibility to various facilities, in-depth spatial data is required which is mainly collected from OpenStreetMap and extended through own mapping.

4.2 Data assessment

The conducted data assessment of the spatial elements consists of mainly four different parts:

1. Assigning existing geo-referenced data to cells.
2. Incorporating various types of spatial analysis and including basic calculations like counting the number of buildings or the length of streets per cell.
3. The Urban Network Analyst Toolbox for ArcGIS of the City Form Lab is used to calculate integration, choice and depth distance, based on infrastructure data from OpenStreetMap.
4. The Variable-width Floating Catchment Area (VFCA) method which builds upon the Two-step Floating Catchment Area Method (2SFCA) is used to calculate accessibility to economic centres, different facilities or functions.

The latter method was originally developed to calculate the accessibility of the population to health facilities. However, Dony et al. (2015) adapted the methodology to include other types of functions and takes varying weights or levels of attractiveness into consideration (in their case for example the size and number of amenities of parks). It is therefore seen as the most appropriate method to calculate accessibility to various functions which differ between their characteristics. As an example, this research calculates the accessibility to public transport nodes. However, one node just serves a few city-wide transport modes while others also cater for national or international routes. Therefore, an adapted weighting is required to take these differences into consideration. Lastly, the VFCA like the 2SFCA depends on the selection of the calculation method of distances. For this, different approaches exist, amongst other the Euclidean distance, the time-distance or network distance (Kanuganti et al. 2016). The Euclidean distance is chosen[iv] and measured through the Network Analyst Toolbox of ArcGIS.

4.3 Data analysis

The resulting geo-referenced quantitative data of the selected areas allow for regression analyses to distinguish patterns and understand which factors are interrelated. Through the qualitative data of the interviews and previous reports and articles, the quantitative results can be further explained, interpreted and situated into the larger context of risk distribution and the resulting spatial (in-)justice. To be able to compare all data with varying units, the values are normalised before further analysis after which each value is represented by a number between 0 and 1. Furthermore, to reduce the number of indicators to a manageable size and eradicate non-essential ones, two steps are undertaken. First, a redundancy analysis is conducted to identify indicators which nearly completely correlate and, therefore, mainly provide the same information. Secondly, the various indicators are aggregated to compound scores for each variable to simplify the comparison and regression analysis.

Afterwards, mainly two analysis approaches are applied. In the first step, the Ordinary Least Squares (OLS; Hutcheson 2011) method is applied, which distinguishes the unknown factors in a linear regression. This means, that for example the compound score of urban form of each cell is compared to the variables of risk exposure, adaptive capacity and sensitivity and the impact value of each aggregated indicator are calculated based on the minimal average coefficient of determination (R^2). Based on the findings of the OLS analysis, the most significant factors can be distinguished and further studied individually through selected multiple regression analyses. This regression analysis is conducted in several steps and afterwards scaled down. This anticipated regression analysis is conducted in several steps and afterwards scaled down. The general formula of the OLS-regression is as follows:

$$\mathbf{y^1 = ß^1x_i^1 + ß^2x_i^2 + \ldots + ß^px_i^p + \varepsilon_i}$$

In the first two separate analyses, the aggregated scores of the two concepts (Urban Form and Flood-related urban risks) represent the $\mathbf{y^1}$ on the left and the aggregated variable scores constitute the $\mathbf{x_i^p}$ values on the right with the objective to distinguish the broader $\mathbf{ß^p}$ values. Afterwards, a more detailed analysis is conducted which looks at the different variable interrelations independently by again keeping the two concept scores as $\mathbf{y^1}$ but splitting the variables into the constituting indicators. The latter has the objective to distinguish the strongest correlations and simultaneously exclude possible non-correlated indicators from further analysis. Lastly, the strongest correlations are studied by multiple regression analysis to investigate them in greater depth.

As a second step, a classification of the cells is undertaken in order to distinguish patterns and expand the findings to the whole city based on shared characteristics. This is done through a Principal Component Analysis, which combines correlating elements and combines them with linearly unrelated aspects and therefore creates a categorisation based on similarity and difference of all input values. The method can be best understood by imagining a coordinate system in which the principal component axis represents the first correlating elements and every further mostly unrelated component results in a perpendicular axis to the first one. The same process is repeated for each element until all axes are situated in relation to each other and the individual studied subjects are located in a multi-dimension coordinate system. This distribution then leads to a categorisation which best represents the similarities and differences of the various input variables.

The expected outcomes are an indication of the interrelations of various sub-variables as well as the interdependency of particular factors to all other relevant ones. Furthermore, the Principal Component Analysis shall lead to a classification of the studied cells and therefore visualises patterns and can allow generalisations up to a certain degree for the whole urban area of Kampala. Therefore, the outcomes of the study are partly descriptive and partly prescriptive. Some outcomes solely represent already existing information in combined and more detailed manners, while others, like specific interrelations between factors, give an indication about expectable developments in the future and how one might affect another one and therefore also where and what kind of interventions might be most fruitful to anticipate further marginalisation and spatial inequalities.

5. Conclusion

This methodological approach to measure risk exposure, adaptive capacity and sensitivity and contrast it with urban form, allows for a quantification of spatial climate change injustice in the context of limited data availability and needs considerably less information and technological resources than existing approaches. However, it results in spatial pattern distinction and assists to better understand the social and environmental urban development. Furthermore, whenever new data becomes available or information is updated (spatial information), the model can be extended and adapted to make temporal studies and analyse how the urban areas develop over time.

However, the current limitations of the methodology are on the one hand the flood-risk model and secondly the assessment of social networks as part of the adaptive capacity. However, the findings should be able to paint a better picture of Kampala's current situation while also helping to understand the spatial injustice of climate change consequences in similar urban contexts of SSA. Based on the results of the analysis, which is currently conducted, better and more precise policy decisions and spatial interventions can be developed by the responsible organisations and their success assessed over time.

---

[i] This paper builds upon and contains sections of the author's master thesis research at the Institute for Housing and Urban Development Studies (IHS), Erasmus University Rotterdam, and is integrated in the broader research project 'Spatial Inequality in Times of Urban Transition', conducted by the IHS, the Development Planning Unit (University College London) and IPE Tripleline and is funded by the British Government's East Africa Research Fund.

[ii] Indicator attributes are not included due to the scope of paper but available upon request.

[iii] The most important indicator gets a score of 100 points, and other indicators are compared to the first and given scores according to the relative importance.

[iv] Euclidean distance, defined as the distance in meters by using the existing network in the shortest possible way, does not consider varying infrastructure densities and time-distance. Therefore, it is challenging to select the right network-distance due to strongly varying modes of transport. Even if different qualities and sizes of roads (e.g., paved/unpaved) are not accounted for, it appears to be most accurate under the given circumstances.

London and Climate Change

A zero carbon city for 2050 – achievable or just hot air?

Dr Chris GOSSOP

Abstract

London is about to have a new spatial development strategy that will take it towards the 2050s. This third version of the London Plan is the vision of Mayor Sadiq Khan, and it stems from the establishment of the Greater London Authority in 2000. The target for the environment is of a zero carbon city by 2050. This paper analyses the policies and proposals that underlie that target, focussing on the challenge for housing. That challenge is formidable. For one thing, London is set to grow from its present population level of 8.7 million to possibly 11.1 million by 2050 which adds to the scale of what needs to be done. For another, as the independent Committee on Climate Change has warned, progress on securing greenhouse gas (GHG) emissions across the UK has stalled and we need a steeper trajectory if national and international targets are to be met.

Some four fifths of current emissions result from London's buildings – its 3.4 million homes in particular. The draft Plan charts a 'zero carbon pathway' that combines national measures – such as the decarbonisation of the gas grid – with increased action at the London level on - energy efficiency, renewables and local, decentralised energy production. New build properties will need to be zero carbon from the start and the current 'performance gap' will need to be greatly reduced to enable that. But it will be harder still to achieve the effective retrofitting of the millions of existing properties, many of which perform poorly in energy terms. This will require a step change in terms of implementation beyond anything that has been achieved so far. Can the new London Plan succeed? This paper addresses these matters, looking both at the policy base and at some encouraging achievements on the ground.

****

Introduction

London is preparing a new spatial development strategy that will take it towards 2050. By that date, according to Mayor Sadiq Khan, London is to be a zero carbon city. That will have profound implications for the way Londoners live, work and travel; it will also necessitate big improvements in energy efficiency in buildings and changes in the sources of energy and the way that energy is used (*The Mayor of London, 2017*).

It entails the city becoming decarbonised within the next three decades, moving from the present 38 megatons of greenhouse gases (GHG) emitted annually (about seven per cent of the UK's total emissions) to near zero by 2050. Some four fifths of that total comes from London's buildings, primarily its 3.4 million homes, and it is on housing, both present and future, that this paper concentrates.

The emerging London Plan, the third such plan since the Greater London Authority (GLA) was established in 2000, is of key importance for the transformation of London's housing stock, guiding both the housing to be built and the stock that will have to be upgraded. As will be reviewed below, progress right across the United Kingdom on pushing energy efficiency higher has stalled in recent years, casting doubt on whether London's own aspirations are realistic ones.

Also, current ways of boosting efficiency are not always giving us the progress that we need, as is seen in the reality of the 'performance gap'. However, new ways of securing energy efficient properties have emerged and these approaches will also be described. The paper concludes with some comments about the likely effectiveness of the new London Plan in helping realise the zero carbon aim. Will the Plan's policies, together with other related action be enough?

Context – The UK's housing stock

The UK has some 25 million homes. These have the oldest age profile in the European Union with some 60% being built before 1960 and only 10% in the twenty years between 1991 and 2020 (*BPIE, 2011*). One of the fastest periods of growth was in the inter-war years when many millions of, typically, semi-detached dwellings were built, creating the low density suburbs which form a major part of most urban areas today and, in London's case, are so evident from the flight paths serving Heathrow. While such housing provided an attractive and comfortable environment for its new occupants (and continues to do so today), these properties, and, even more so, the terraced housing of the nineteenth century, are notoriously 'leaky' in energy terms. They are a product of the coal era and cheap fuel for keeping families warm through the British winter.

While winter comfort is now provided mainly through gas central heating and upgraded insulation, the higher temperatures expected today mean that such properties are typically costly to heat and significant emitters of GHGs; overall, they remain some of the most expensive homes to heat in Europe (*The Guardian, 2013).* The English Housing Survey confirmed that the majority of the least energy efficient homes were the oldest ones, built before 1919 (*HM Government, 2013*).

Context – The Energy Efficiency Agenda

The 1973 oil crisis was a wake up call and it led eventually to improved insulation standards for new housing. Forty Years on the Government's English Housing Survey was able to report a significant rise in average energy ratings from 46 in 2001 to 60 in 2013, based on the Standard Assessment Procedure (SAP) ratings used in the UK to assess and compare energy and environmental performance in dwellings. Over this period there had been an almost doubling of the number of homes with cavity wall insulation from 5.8 million (39%) to 10.8 million (68%) and, similarly, in the proportion that were fully double glazed from 51% to 80% (*HM Government, 2013*).

Improvements in energy performance have also resulted from changes to the UK's building regulations, and from technological advances, notably the condensing gas boiler with its 90% efficiency (also suitable for retrofit). The 21st century has seen moves at European level to measure and certify the performance of buildings – through the EU's Energy Performance of Buildings Directive; one outcome of this is the Energy Performance Certificate (EPC) required in the UK for all newly built properties and as part of the documentation in property sales (*Mashford, K. 2016*).

Other innovations in the UK included the 2006 Code for Sustainable Homes with its six code levels spanning levels of performance beyond the requirements of Part L of the Building Regulations, Level 6 being a 'zero carbon home'). (Communities and Local Government 2006*).* However, while the intention had been to drive 'a step change in sustainable building practice', in 2015 the Code was withdrawn by the Government as a deregulatory measure.

The Committee on Climate Change

A further driver of improvements was the UK's Climate Change Act 2008 which committed the UK Government to reducing GHG emissions by at least 80% on 1990 levels by 2050. It set legally binding carbon budgets, each capping UK GHG levels emitted over a five year period. These budgets are the responsibility of the independent Committee on Climate Change (CCC) which has steered the first five such budgets, taking the UK up to 2032.

However, this June, this highly respected Committee found itself having to issue a severe warning to the UK Government that the UK is not on course to meet the fourth or fifth carbon budgets, taking us to 2023-2027 and 2028-2032 respectively, despite the legal requirement to meet them (*CCC, 2018*). The CCC acknowledged that, since 2008, the UK had seen a rapid reduction in emissions from the electricity sector as coal fired plant is retired and as renewables become mainstream. However, that success 'masks a marked failure to decarbonise other sectors, notably transport, agriculture and buildings'; in the last five years, emission reductions in these areas had stalled. In its 2018 Progress Report to Parliament it sets out four key messages for Government – see also the 'Infographic' below.

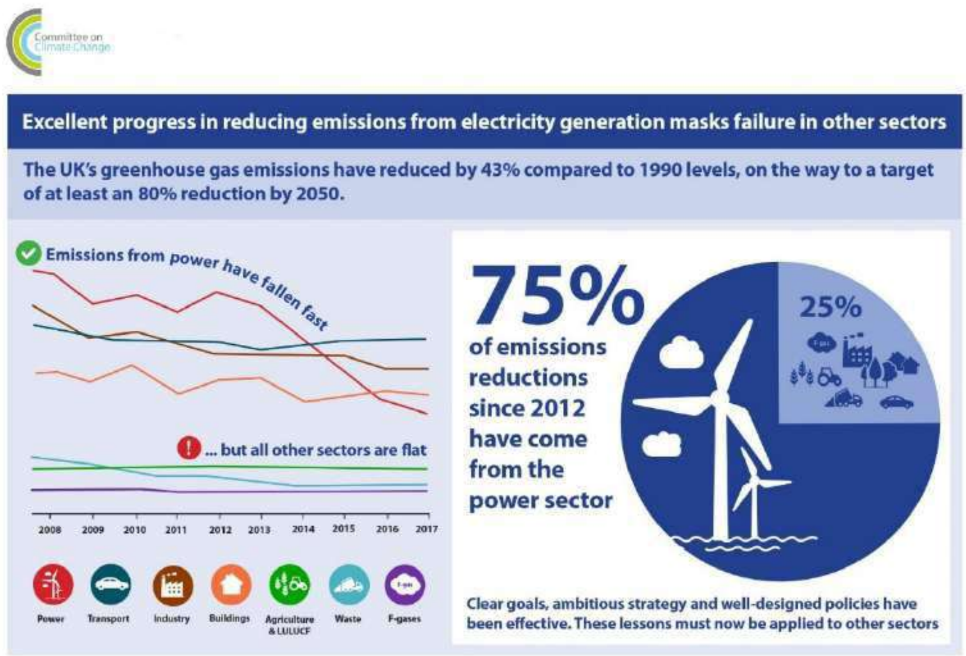
First, Government needed to support 'the simple, low cost options'. In terms of the energy and buildings sector, the withdrawal of incentives had cut home insulation schemes to 5% of their 2012 level, while the Government had failed to provide a route to market for cheap onshore wind. The whole economy cost of meeting the legally binding targets would be higher without cost-effective measures in every sector.

Secondly, they should 'commit to effective regulation and strict enforcement'. Tougher long-term standards for construction, for example, would cut emissions, while driving consumer demand, innovation and cost reduction. And, as with motor vehicles, the proper enforcement of regulations would safeguard the consumer when (in this case) property emissions exceeded the quoted test-cycle numbers.

Thirdly, they needed to end 'the chopping and changing of policy'. In recent years, important programmes had been cancelled at short notice. These included Zero Carbon Homes and the Carbon Capture and Storage (CCS) commercialisation programme. A consistent policy environment was needed to keep investor risk low, reduce the costs of capital and give businesses the confidence to build the necessary supply chains.

Fourthly, they should act now to keep long term options open. That 80% reduction in emissions had always implied the need for new national infrastructure – for example, to transport and store CO_2 or to provide decarbonised heat, and the deeper Paris Agreement made such steps even more important. The Government needed to show that it was serious about the long term need for new technologies such as carbon capture, and the electrification of heat.

Overall, the Government needed to learn quickly from its mistakes and by the end of 2018 introduce concrete policies to secure, among other things, improvements in residential energy efficiency, a deployment pathway for CCS and new incentives to people to buy electric vehicles. Such action was now urgent in order to meet the UK's legally binding climate change targets and the obligations of the Paris Agreement (*CCC, 2018*).



The Way Ahead for London?

Those four messages are notable for their emphasis on buildings and energy policy. And recent news, principally on the Government's decision to scrap the proposed Swansea Bay tidal barrage (*BBC News, 2018*) - ironically made on the same day as Parliament announced a go ahead for the third Heathrow runway (*BBC News 2018*)- casts doubt on the Government's commitment to respond properly to the very long term responsibilities of the Climate Change Act.

The CCC was in no doubt that big improvements in the energy efficiency of our buildings would have a necessary part to play in meeting budget targets. It commended the ambition set out in the Government's Clean Growth Strategy published in October 2017 but expressed disappointment that there were 'few new specific policies to deliver real emissions reduction' (*CCC, 2018*).

In the meantime, the Mayor of London is planning five year carbon budgets for London as a way of driving action towards his zero carbon target for 2050; these would align with the CCC's carbon budgets. His draft policies for the building sector cover both new build and retrofit (*Mayor of London 2017*).

New Build for London - Density

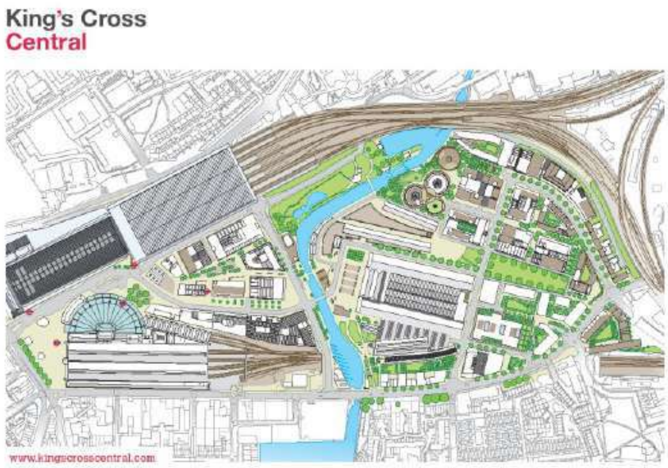
By 2050 London will need some 1.3 million new homes (together with some ten million m^2 of new schools, hospitals and workplaces). The Green Belt and London's Parks and other designated Open Spaces will remain in place and these new buildings will typically be built at a high density, on previously used brown field land. While draft Policy D6 of the new London Plan is now about optimising density rather than specifying appropriate density ranges (as in the first London Plan), in practice, the current high (for the UK) densities of recent development are likely to prevail. This is the continuing response of the market to the general shortage of land; the low densities typical of the pre-war period are very clearly at an end.

Draft Policy D6 indicates that the optimum density of a site should be determined by a design led approach whereby the appropriate form and scale of new development is established through a design process that takes account of the surrounding built form, proximity and access to services and infrastructural capacity, particularly public transport.

In practice, much of the new housing, and often the workplaces, will continue to be concentrated in the designated Opportunity Areas (for example at King's Cross), and other growth areas which are places of high accessibility for public transport. As electric buses gradually replace diesel and as the electricity supply is progressively decarbonised we can look forward to both better air quality and a reduction in GHG emissions from transport; that sector is currently responsible for some 20% of overall GHG emissions across London. And these concentrated areas are often especially suitable for locally based energy systems generally associated with lower GHG emissions. King's Cross is a notable example.

Case Study 1. King's Cross – an energy efficient Urban Quarter for London

King's Cross is one of the largest and most challenging urban regeneration projects in Europe. It is a recognised standard setter for masterplanning and integrated transport planning, and for the creation of a new London quarter reaching new heights in terms of urban design and sustainability. Structured around its two railway terminals, King's Cross and St Pancras International, and bisected by the Grand Union Canal, it will accommodate upwards of 20,000 workplaces and some 2000 homes, plus the student accommodation associated with the new base for the University of the Arts (see drawing to right). These uses are served by the King's Cross Energy Centre with its Combined Heat and Power Plant (CHP) supplying both electricity and hot water via a network of district heating pipes.



This system provides for some 80% of the quarter's electricity needs and 99% of its heating and this means that the individual developments - a mixture of new build and refurbished historic buildings - have no need for conventional boilers. All this work is being completed to high sustainability standards; by 2016, seven of the King's Cross buildings had been delivered certified as either Outstanding or Excellent under the BREEAM assessment scheme. Sustainability measures other than the CHP system, include much use of photovoltaic panels and green roofs. The aim is to reduce carbon emissions by at least 50% relative to 2005 levels. (King's Cross Central Limited Partnership, 2016/17)

New Build – the Energy Hierarchy

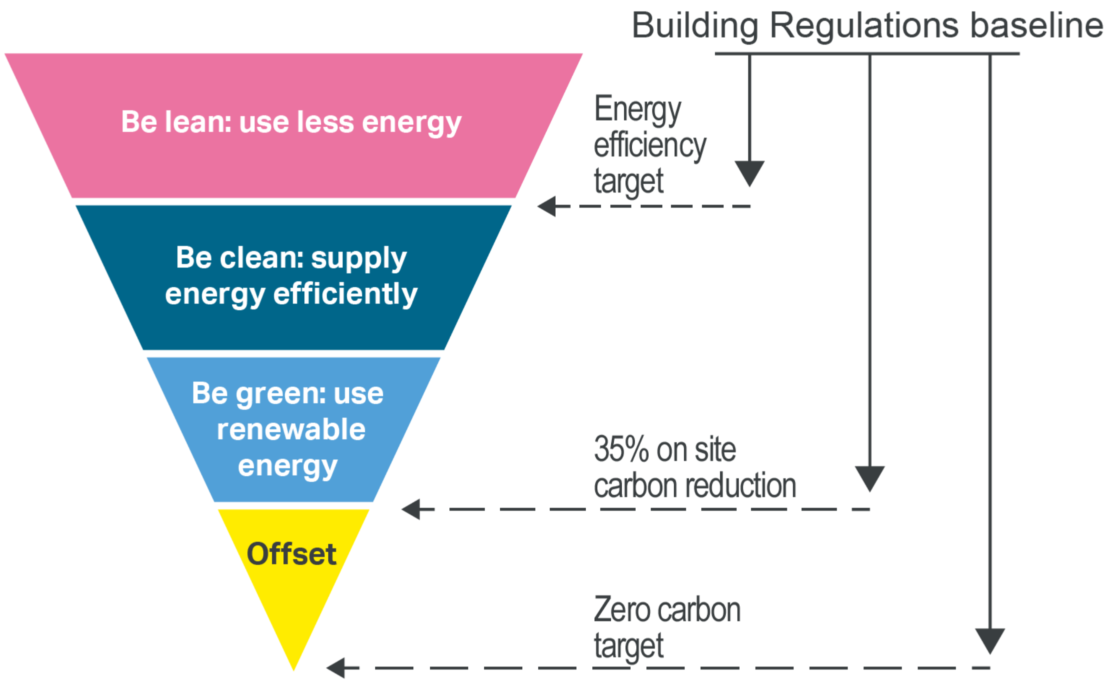
The Building Regulations Part L establish the required baseline for carbon emissions from new buildings in England and Wales. Successive iterations to Part L have raised the required performance under this baseline, the intention being to ratchet up standards over time in the light of technological advance and improved building practices.

For some time, London has sought to go further, the 2011 London Plan specifying a trajectory to zero carbon development and building in a target for a 35% improvement beyond Part L. This reflects the Mayor's responsibilities under the 2007 amendments to the Act that established the GLA which gave him the duty 'to contribute towards the mitigation of, or adaptation to, climate change in the United Kingdom'. A related responsibility (embodied in Policy S11 of the draft new London Plan) is to improve London's air quality and to reduce the concentrations of harmful emissions, notably in 'hot spot' areas where human health is particularly at risk.

Policy S12 of the draft Plan requires all major development to meet the zero carbon target. It is to be met in three ways, as shown in the GLA's energy hierarchy reproduced below (Mayor of London 2017, Figure 9.2). The first way is through energy efficiency measures (be lean), the second is through an efficient and low carbon energy supply (be clean) and the third is to include renewable energy (be green). Any residual emissions are to be offset into the particular borough's ringfenced carbon offset funds.

The hierarchy is based on a minimum level of onsite carbon reduction of 35% beyond that specified in Part L of the Building Regulations (2013 iteration). Residential developments are to aim for a 10% reduction towards that 35% through **be lean** measures, the aim for non-residential being 15%. GLA commissioned research found that those be lean targets are technically achievable and that in the case of the domestic sector 'they would help lock in long term carbon reductions based on an improved building fabric' (Mayor of London, 2017) .

The Energy Hierarchy – Draft London Plan, Figure 9.2



Source: Greater London Authority

Be Lean and the Performance Gap

But are those 'technically achievable' targets actually achieved in practice? Studies undertaken in the UK on behalf of Innovate UK on almost 4000 new dwellings provided initial indications that energy in use was typically some two to four times that predicted. This discrepancy between predicted and operational performance is widely recognised and is now referred to as '**the performance gap'**. One of its main sources derives from the *realisation* of the building - its translation from drawing, through to contractual requirements, and then to physical form. This can result from a range of factors, including: 'accidental' design changes, for example from product and material substitution; lack of precision in construction; and poor communication of design intent. Getting this right will require a major change of culture and practice across the construction sector.

Closing the performance gap will require better testing and verification methods so that building performance can be checked by all the stakeholders – against what has been specified at the design stage - and those delivering the buildings thus held to account. (*Mashford. K, 2016*).

Be clean – energy supply

After minimising demand through energy efficiency, the next stage in applying the energy hierarchy is to **be clean** through utilising energy generated from clean low carbon and renewable sources, such as waste heat and solar. Currently London sources about 95% of its energy from outside the GLA boundary. As the UK's remaining coal fired power stations are shut down and as increasing quantities of renewables come on stream, the UK's national electricity grid is progressively becoming decarbonised. However, as is the case with the country as a whole, London still remains heavily dependent on natural gas as its main energy source, especially for winter heating. While much cleaner than coal, gas burning remains a significant source of GHGs as well as contributing to nitrogen dioxide levels in the capital.

The London Plan seeks a shift from this reliance on gas to a more diverse range of low and zero carbon sources. This will align to moves nationally to change the way we heat our homes as we switch away from the use of natural gas. The options are to use a decarbonised alternative, using hydrogen or biogas in the present gas grid, to electrify our heating, or to develop heat networks; there are pros and cons for each of these choices and the likelihood is that a combination will be required. And, if we are to secure a cost effective transition, such change will need to be coupled with measures to reduce energy demand. (*Energy Research Partnership, 2017*).

In addressing how the future city should be heated, the new London Plan places considerable emphasis on the important role that decentralised energy could play in many of London's denser areas. As has long been practised on the European continent – and already in a few places in the UK, including London - these green or waste resources can be brought together and connected to buildings through district heating. That heat can come from a range of places – for example from industrial processes and through the recycling of waste - and can also be associated with local electricity generation through combined heat and power (CHP) systems. UK examples include the use of geothermal energy in buildings in central Southampton and energy recovery from trains on the London Underground *(TfL 2015)*

The new draft London Plan seeks to promote the development of heat networks through encouraging future proofed building designs for communal heating and requiring the energy masterplans needed for major schemes to identify decentralised energy opportunities (Policy S13). Where feasible, developments should connect to existing heat networks and/or areas prioritised for heat networks by the London Boroughs – these are areas identified for growth and regeneration and with high heat densities .

Heat pumps are seen as the technology that can increasingly serve as the energy source for district heating. Compared to present options such as the gas engine, heat pumps save more carbon over the medium to long term and they need have no adverse impacts in respect of air quality.

Be Green – Renewable energy

The third part of the equation to reach towards zero carbon levels is to fit renewables to individual houses, or collectively. There is greatest scope for photovoltaic panels (PV). Countering the earlier savage cuts in the government's feed-in tarif, technological advances, coupled with reducing costs from manufacturing at scale and the introduction of battery storage, have improved the competitiveness of solar electricity, and made PV a serious proposition for many householders. Solar thermal installations to produce hot water can also be attractive.

This installation of panels on buildings, and the use of roofspace generally, is one component of the Mayor's draft Solar Action Plan for London which would also embrace publicly owned buildings and land, including railway land. His target is a tenfold increase in solar generation beyond the scope of existing programmes – reaching 1 Gigawatt by 2030 and 2 Gigawatts by 2050 (*Mayor of London, 2018*).

Carbon Offsets

Returning to the GLA's energy hierarchy, the final component covers any shortfall between Building Regulations compliance plus the minimum 35% figure and zero carbon. In those circumstances, developers are required to make a cash in lieu payment to the carbon offset fund of the local planning authority concerned. In the case of Camden Council, for example, this enables grants to be paid for renewables and energy efficiency measures to residents and landlords, community groups and businesses (*Camden Council, 2017*).

The offset sum is calculated by subtracting the regulated carbon savings – the total of be lean, clean and green - from the target savings, multiplying this first by 30 (years) and then by a carbon offset price to reach the required cash in lieu contribution. At present, the GLA continues to recommend boroughs to use the nationally recognised non-traded price of £95 per tonne, the viability of which has been tested through the Local Plan process.

Retrofitting London's homes

So far this paper has concentrated on the new housing that London will need to accommodate to cope with growth up to 2050 and restricting that to zero carbon will be a major responsibility for the planners and everyone else involved. However, beyond that challenge there is the even bigger one of retrofitting the existing housing stock so that it can be made significantly more energy efficient, as well as more comfortable for those poorer occupants who cannot at present afford to heat their homes properly.

The vast majority of London's present 3.4 million homes are likely to still exist in 2050 and its upgrading represents London's largest single challenge in moving towards the zero carbon goal. How do we achieve this in practice? We already know what has to be done. The main things are insulation that really works, active thermal mass to absorb temperature gain, effective draught proofing to keep the heat in and heat recovery from ventilation (*Dunster.W.2018*).

But just as we have been designing new properties for good energy performance but failed to achieve that performance in use, the same has happened with refurbishment and retrofit. To achieve significant improvements at scale we need a professional approach embracing: proper knowledge of the pattern of energy use before refurbishment (the base line); validating the improvements made to fabric and services during the works; and monitoring the delivered performance so as to verify it (*Mashford.K, 2016*). We also need many more accredited firms with the range of skills able to tackle this work across the many types and ages of housing they will encounter. These will include properties in conservation areas where architectural considerations, such as ornate detailing, will often preclude external insulation, especially to front elevations.

But why should those responsible for the buildings – especially the private owners and landlords - choose to invest in complex and often disruptive building works where the pay back may be several years in the future? As mentioned earlier this last five years has been a period of little apparent interest by central government in energy efficiency matters, leaving householders with limited incentive to invest. Instead, inspiration has had to come from other bodies and from committed individuals to demonstrate what can be done. The SuperHomes network is a prime example of this.

Case Study 2 - SuperHomes

SuperHomes, has brought together a community of dedicated homeowners who have succeeded in reducing their CO_2 emissions by at least 60% and were willing to share their experience with others through open house events and web exchanges. To date the UK wide network is about 200 houses strong, about half of which are in London. The programme has enabled several thousand people to visit their local SuperHome and to benefit from the practical advice from the owners in considering their own improvements (*National Energy Foundation, 2018).*

Open Day for a SuperHome

London is of course an international city, well connected to the European mainland and well able to exchange ideas with its neighbours on technological advancement. As an incoming idea, Energiesprong is a Dutch Government supported approach to whole house refurbishment that is guaranteed to secure significant energy savings.

Case Study 3 Energiesprong

This Dutch approach to mass refurbishment features customised, off site manufactured walls and roofs pre-fitted with windows and doors, and a new energy system including renewables. Each renovation takes just a week with no need for the occupants to move out. With the cost covered long term by the guaranteed energy savings, these 'new look' retrofits aim to secure the upgrading of whole terraces, streets and blocks, regenerating entire neighbourhoods.

Energiesprong UK seeks to bring this Dutch approach to the UK, London included. Founded in July 2015 as a group of social housing providers, construction companies, trade bodies and expert organisations, this new body aims for refurbishment solutions that provide: guaranteed performance over 30 years; financial viability for both landlords and tenants; and desirability – in terms of limited disruption, aesthetics and comfort levels, and enhanced asset value.

As in The Netherlands, the starting challenge in the countries that are seeking to adopt Energiesprong is to bring down the unit cost through industrialised mass roll out and volume

Some of the first ten Energiesprong homes in

Nottingham, England – Melius Homes

prefabrication. Already, the first UK scheme, in Nottingham, is up and running. Ten 1960s homes have been refurbished through a partnership between the City Council, Nottingham City Housing (the management organisation, Melius Homes (the contractor) and Energiesprong UK, aided by funding through two EU programmes. In addition to super thick insulation for the walls and solar roofs, the upgraded houses come equipped with battery storage and ground source heat pumps (*Smith.A.2018*).

London will soon follow suit with a further ten hard to heat homes built between 1950 and 1980. As with the Nottingham project, this pilot will be supported by the EU, in this case under the Transition Zero programme; the purpose of that support is to help deliver the right market conditions for net-zero energy refurbishment in the UK.

In terms of future scaling up, Energiesprong UK currently envisages a programme of 5000 refurbishments, while an analysis by the Energy Saving Trust suggests that London has some 250,000 properties that would lend themselves to this sort of upgrading.

One of the beauties of Energiesprong is that it looks at real life performance over a long period and not just at modelled performance. And those desired outcomes – for example, perhaps maintaining a temperature of 21 degrees C in the main living room, 18 degrees elsewhere have to be delivered to the tenants. So to be viable for the providers the building has to perform as specified and there is no room for the sort of performance gap which so often afflicts the new and retrofitted homes delivered under the present ways of working. If that gap can be eliminated or reduced substantially, the approach can make a big contribution to the upgrading of our older housing stock and to reductions in emissions.

Discussion

There is no doubt that it will be a massive challenge for London to attain zero carbon by 2050. A level higher, the same goes for the United Kingdom and for the world's nations, the vast majority of which are signed up to the Paris Agreement. As the Climate Change Committee has revealed in its rebuke to the UK Government, it is all too easy to 'get your eye off the ball' for something as apparently far off as climate change, to forget about, or to put off the awkward decision, or perhaps leave it to the next administration! But this imperative isn't that far off, and already important deadlines have been missed.

To focus back on London, and London's housing, several of the necessary ingredients are in place, at least. There is a Plan with a requirement for zero carbon housing and, while this is challenging , we know what has to be done. The Passiv House approach is one way to achieve this and architect Bill Dunster has detailed another (*Dunster.W, 2018*). Now, all new houses need to be built to zero carbon standards.

What is worrying though is the apparent persistence of the 'performance gap' and the evidence that we may be achieving rather less than we thought we were achieving. As stated earlier this has to be comprehensively addressed and one fundamental is a change of culture and practice across the construction sector. While it is being developed initially for the social rented sector and for major refurbishment, the Energiesprong approach with its pre-fabrication and special funding mechanism may be of wider application.

The first examples of Energiesprong renovated homes are now being delivered in the UK and the initial results are promising. Rather than just another pilot this is an industrial scale programme with potential to make a big, area wide, impression on retrofit – and on some of London's least energy efficient social housing. At the same time this is comparatively modern housing with plenty of space around it for the cranes needed to install those pre-fabricated walls and roofs. There are question marks about how it would work in more densely developed areas characterised by bumper to bumper kerbside parking, and in areas of Victorian era terraced housing with thin walled rear extensions which would be complicated to envelope. Clearly, there is much variation in the existing stock and each type of area will require its own retrofit solution.

It might be argued that the scale and complexity of the retrofit task for London is such as to suggest that, beyond a certain 'lower hanging fruit' level we might concentrate instead on another part of the energy hierarchy - **be clean -** in which the supply is decarbonised. However, that other part which entails moving away completely from the use of natural gas is itself hugely complicated and it is a challenge for which we do not yet have a complete answer. By pursuing a scaled up energy efficiency programme London can reduce its overall energy demand in buildings as an essential part in the transition to low carbon heat.

And that **be clean** part of the agenda will itself be multi-stranded. It will involve a combination of action at national level – moving towards reuse of the gas grid using hydrogen (with a small contribution from biomethane) and local decision making on decentralised heating, with a likely special role for heat pumps.

There is much more that would need to be done; bringing down buildings emissions across the capital will be a huge organisational task. And it will be essential to work closely with residents on these solutions so that families and individuals can help to reduce demand (and themselves save money) making use of smart technology and better knowledge.

To achieve a zero carbon London by 2050 would, of course, require many more strands of action than are described in this paper. But the housing sector is one of the more challenging and, if London can succeed on this complex front, there is every reason to believe that the other ones would be manageable too; the decarbonisation necessary for zero carbon buildings would work across to other areas too, notably transport.

If London is to succeed in this goal both with the housing sector and overall, this is going to require massive commitment and working together on the part of the local authorities, other relevant organisations and the people of London. It will also require close working with UK Government departments and progress on the key decisions and actions called for by the CCC to get the UK back on course to meet the legally binding fourth and fifth carbon budgets, covering the period up to 2032. The five year carbon budgets being considered for London by the Mayor will align with these and will be another indicator of progress towards the 2050 goal.

It should become clear within the next year or two whether the budgets up to 2032 are going to be met. If the answer is positive, then one can be optimistic about the 2050 zero carbon city. But, if we are still falling seriously short, we remain in 'just hot air' territory, and getting back on track will be significantly more difficult.

Measuring CO_2 emissions - implications for spatial development

Robert CICHOWICZ, Małgorzata HANZL, Lodz University of Technology, Poland

1. Introduction

The effects of climate change can be felt in all spheres of contemporary life, often exacerbating existing challenges. Extreme weather requires that we reconsider risk management, with the development both of immediate responses and long-term strategies. Steps to mitigate the effects of climate change are being taken at the local, national and global levels. However, they are widely considered insufficient (Solomon et al. 2009). Only one of the four scenarios presented in a 2014 Report by the IPCC (RCP2.6) assumes a moderate increase in global surface temperature (1.5°C) by the end of the century (2100), compared to before the industrial revolution (1850-1900). Even this scenario predicts that many regions of the world will be vulnerable to extreme atmospheric events. The other scenarios, especially the continuation of business-as-usual, project much higher levels of uncertainty and risk.

This paper summarises the results of measurements of CO2 emissions on the campus of Lodz University of Technology in Poland between March and April in 2012, 2014 and 2016. The concentrations of CO2 were measured as a function of temperature, air pressure and wind speed. The measurements also considered the season and the time of day. This data was combined with an analysis of urban development, enabling assessment of the actual emissions relative to the architectural surroundings. These included tall, isolated buildings and denser, lower structures, parking lots and streets, greenery (neighbourhood parks and lawns), a nearby power plant and an electrical power and heating plant. In the next section, the rationale for measuring CO2 will be explained and the precedents for doing so internationally and in Poland will be examined. The case study of Lodz University of Technology campus B will then be presented. The measurement methods and the results will be discussed, followed by conclusions which will also point to avenues for future research.

2. Green House Gasses emissions - research rationale and precedents

Over 97% of scientists recognise that human activities are an important cause of climate change, through the emission of greenhouse gases (GHG). International accords such as the Paris UNFCCC Agreement of December 2015 reflect the widespread consensus that the current and predicted consequences of global warming should not be ignored. Research relating to GHG emissions, including systems for monitoring and protecting air quality, has therefore gathered pace worldwide.

2.1. *Role of GHG emissions*

According to an IPCC Report (2014, p.10), in order to limit human-induced warming to 2°C relative to 1861-1880 the cumulative CO2 emissions from all anthropogenic sources since 1870 should remain less than 2900 Gt CO2. Since 1900 Gt CO2 had already been released by 2011, the probability of achieving this goal has been estimated at around 66%. Global climate change has been strongly associated with the emission of GHGs, of which CO2 is the most important (IPCC 2014). Analysis shows that the most common coal isotope in the atmosphere has an atomic weight of 12 (12C). Carbon-12 can be absorbed by plants during photosynthesis and is also released when fossil fuels (which consist of organic matter) are burnt. The observable decrease in 13C atoms in the atmosphere is seen by some as proof that human activity has had an impact on CO2 concentrations (Burch, Harris 2014, pp. 134-135).

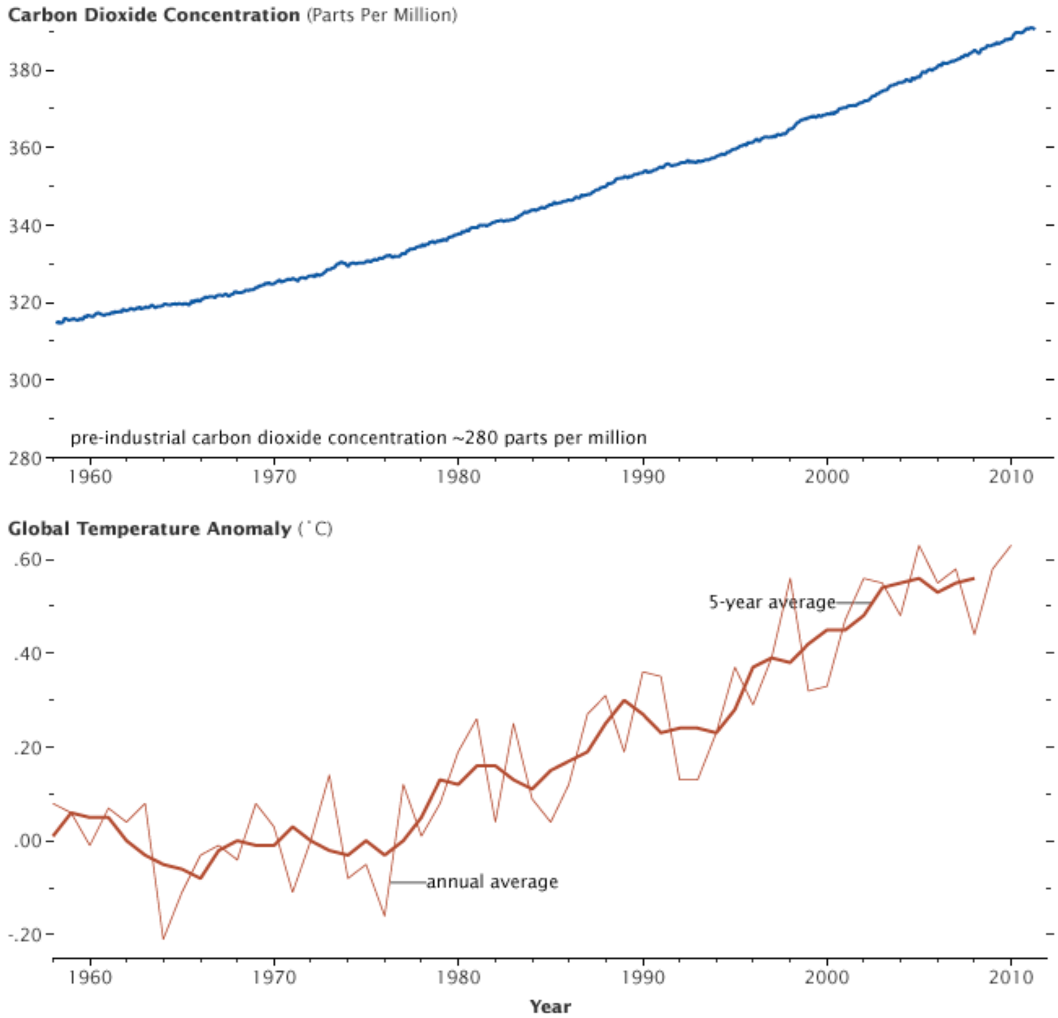

Figure 1.Changes in the concentration of carbon dioxide and Global Temperature Anomalies (source: https://earthobservatory.nasa.gov/Features/CarbonCycle/page5.php, data 2011, access 12.07.2018).

The United Nations Framework Convention on Climate Change (UNFCCC) in 1992 was the first global agreement regarding the reduction of GHG emissions. In the Kyoto Protocol of 1997, signatory governments agreed to comply with rules constraining the emission of GHG, including carbon dioxide. In 2016, the United Nations Framework Convention on Climate Change adopted the Paris agreement, which aims to mitigate the effects of GHG emissions, assist adaptation to climate change and finance the transformation process starting from 2020. The signatories of the agreement aim to keep 'the global temperature rise this century well below 2 degrees Celsius above pre-industrial levels and to pursue efforts to limit the temperature increase even further to 1.5 degrees Celsius.'

In Poland, the Environment Protection Law regulates issues relating to air quality, such as the conditions of energy production and the release of substances into the atmosphere. The principal regulation defines limits for NO2, SO2, O3, CO and particulate matter PM10. The law does not require measurements of CO2. Protection of air is defined as keeping the emission of pollutants below the defined limits and reducing them to levels considered not to be harmful to human health. Since the law does not recognise carbon dioxide as having a direct negative impact on human health, it is not covered by State Environmental Monitoring. In the environment protection law approved before EU accession in 1999-2001, the Polish parliament adopted the regulations of the European Union. This law has since been considerably updated, including adjustments in line with the regulations of Directive 2008/50/EC of the European Parliament and of the Council of 21 May 2008 on ambient air quality and cleaner air for Europe. The law defines emissions as *'substances or energy such as heat,* *noise, vibrations or electromagnetic fields introduced directly or indirectly into the atmosphere, water, soil or earth as a result of human activity.'*

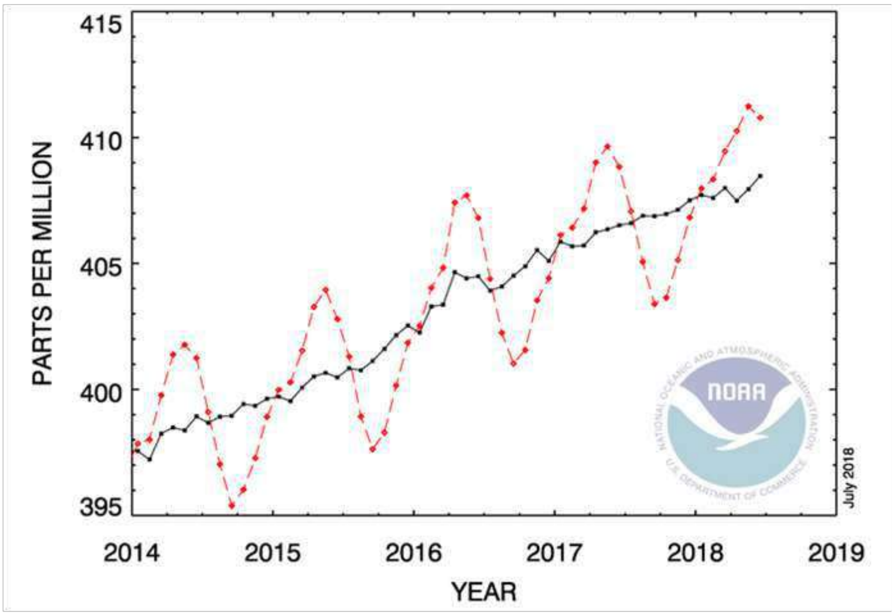

Figure 2. Recent monthly mean C0$_2$ at Manua Loa, June 2018: 410.79 ppm, June 2017: 408.84 ppm, source https://www.esrl.noaa.gov/gmd/ccgg/trends/index.html accessed 12.07.2018

2.2. CO_2 measurements

The Mauna Loa observatory in Hawaii has performed systematic measurements of atmospheric CO2 concentrations since 1955. A yearly rise has been recorded from around 315 particles ppm in 1958 to over 380 ppm in 2006 (after the data of SCRIPPS Institution of Oceanography: https://scripps.ucsd.edu, accessed 12.07.2018) up to around 408 ppm in 2017 (Fig. 2). Systematic measurements of CO2 concentrations in the atmosphere in Poland began in September 1994, at the KASLAB laboratory located in the IMGW meteorological observatory of Kasprowy Wierch in the Tatra Mountains. This is the only station to have kept such a long record of GHG concentrations in Central and Eastern Europe. Until 1996 it analysed air samples on a weekly basis. Since then, an automatic gas chromatograph (HP 5890) has been used (Chmura et al 2008).

3. Emissions and ambient concentration

Another indicator used to quantify levels of pollution is *'immission'* (Cichowicz et al. 2017) or ambient concentration, defined as a 'measure of environmental quality indicating the amount of pollutants found per unit volume in different environmental media' (https://unstats.un.org/unsd/environmentgl/gesform.asp?getitem=106…). It requires taking into account multiple emissions from diverse sources and comparing them with the permissible levels (Cichowicz et al. 2017).
Heating systems are a commonly recognised source of air pollution and GHGs. Smaller facilities, which serve individual households, buildings or close neighbourhoods, emit pollutants exclusively during the heating season. They are usually privately-owned are often called 'low emission' heat sources due to the actual height of the facilities (Adamczyk et al. 2017). The lack of compulsory emission controls constrains the measurement of emissions from these facilities. Moreover, the actual emissions depend on weather conditions and the availability of local fuel. For district facilities, which emit all year round, estimates of emissions are possible based on the amount of fuel used.
Transportation is another major source of pollutants and GHGs. particularly in the centres of large cities, leads to lower air quality. Measurements by the Central Statistical Office show that CO2 emissions from transportation in Poland increased from 26,403.76 thousand Mg in 2000 to 46,465.74 thousand Mg in 2010 (CSO 2012).

Ambient concentrations of CO2 show daily, seasonal and annual cycles depending on the use of local heating sources and road transportation. The location of emission sources does not influence concentrations at the district scale.

Figure 3. Measurement points in campus B

4. Case study

Measurements of ambient concentrations of CO2 were taken on campus B of Lodz University of Technology. This area is located in the southern part of the university, adjacent to Archbishop Klepacz park. Wólczanska Street, Wróblewskiego Street and Politechniki Avenue surround it on the remaining sides (Fig. 3). The municipal power plant EC2 stands to the south-west of the campus site. The 16 ha plot includes the historical nineteenth-century textile factory of Schweikert, complemented by several newer structures. In total, there are 19 buildings in this part of the campus.

While most of the site is paved and used as access roads and parking lots, there are also green areas, in the form of expansive lawns with some trees and bushes. The most densely built-up zone is in the eastern part of the site, and contains the most significant post-industrial development – a building home to three faculties: the Centre of Diagnostics and Laser Therapy of Lodz University of Technology, the Institute of Turbomachinery and the Faculty of Process and Environmental Engineering. The Dean's Office of the latter faculty features the lowest density of development in its surroundings and the highest share of pervious surfaces and vegetation. The construction of a huge sport centre next to Politechniki Avenue took place in 2017, after the measurements had been taken and so did not affect the results (Fig. 4).

Measurements were carried out at points located at the corners of each of the buildings in March and April of 2012, 2014 and 2016. The much smaller and more irregular structures on the eastern side of the site meant that more measurement points were used (Fig. 3). In March of both 2012, 2014 and in 2016, 83 measurement points were used. In April of both years, three more locations were included: two points along Politechniki Avenue and one in Wróblewskiego Street.

Figure 4: Changes to the physical development of Campus B in years 2011, 2013, 2015 and 2017. source http://mapa.lodz.pl*, accessed 01.07.2018*

5. Measurement methods

Measurements were taken using a VEGA-GC micro chromatograph (Pollution S.p.A., Italy), according to the method developed by Cichowicz (Cichowicz and Wielgosiński 2015a, Cichowicz and Wielgosiński 2015b). The VEGA-GC micro chromatograph is suitable for analyses in the field. It consists of a computer module, a tank with a carrier gas (helium), a pump for samples and two batteries. Two parallel columns can be used. A thermal conductivity detector (TCD) enables sample analysis at a minimum concentration of 500 ppb (0.005 ppm) for 6 to 300 s, depending on the type of gas. Measurements of carbon dioxide concentrations were performed at 90 s intervals on a PPQ-packed column, installed in the VEGA-GC micro chromatograph. Before the actual measurements, the chromatograph was calibrated using a test gas. Fig. 5 presents the calibration curve.

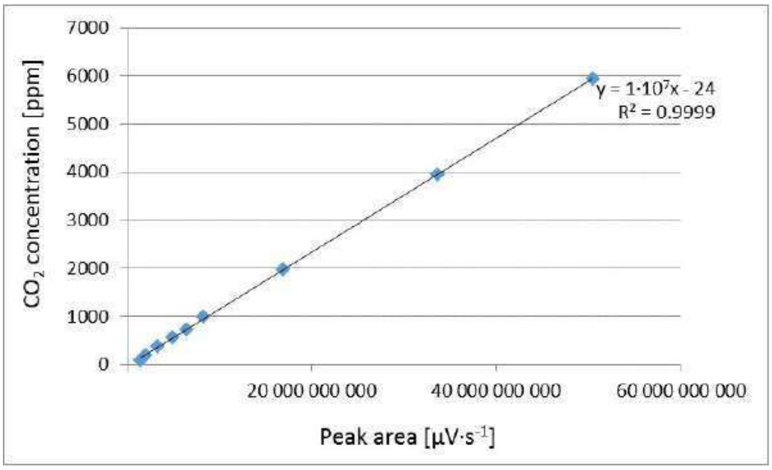

Figure 5: Plot of the calibration curve for carbon dioxide.

Once the batteries had been charged and inserted, a portable bottle with the carrier gas (helium) was installed. The operator then started the system and connected the MC2 and MC-Plan to tune the device. The operator launched the program for CO_2 measurement and headed to point number 1. While the measurements were being performed, the device was directed towards open space (the pavement).

An external GPS device was used to record the date, time and coordinates of all points. The carbon dioxide measurements were compared with a map showing the Floor Area Ratio (FAR) and Building Coverage Ratio (BCR). The relationships between the measurements and the FAR and BCR values were examined. The FAR and BCR values were defined for units associated with each specific zone of the campus, including overhang on the ground floor in the external perimeter.

Data from the weather station in the Władyslaw Reymont airport in Lodz were used to determine the meteorological conditions when the measurements were taken [21]. The station is approximately 5 km in a straight line from campus B. Table 1 summarises the meteorological data recorded at the Lodz-Lublinek station when the measurements were taken.

ArcGIS 10.3 was used to visualise the results. A TNT surface was generated based on the recorded points, with the Z parameter describing the CO_2 concentration (Fig. 7). Due to the irregular distribution of measurement points the surface is distorted, which influences the quality of the visualisation. Moreover, the resulting image does not take into account the volume of the buildings. The same symbology has been assigned to all six images, using equal intervals and the most extreme data spectrum, from April 2012. The background base map was provided by the Municipal Surveying Office and shows the site in 2012.

6. Carbon dioxide ambient concentrations - results and discussion

The ambient concentrations of carbon dioxide were measured in relation to two collector streets: Politechniki Avenue and Wólczańska Street (Fig. 6). The distance from these two linear emitters was assumed to impact the levels of CO2 in the air. In order to verify this assumption, the values associated with the measurement points were aggregated in four buffer zones: 0-50, 50-100, 100-150 and 150-200. Arithmetic means of the carbon dioxide concentrations were calculated for each of these zones. As a result, the impact of transport emissions on GHG levels could be observed.

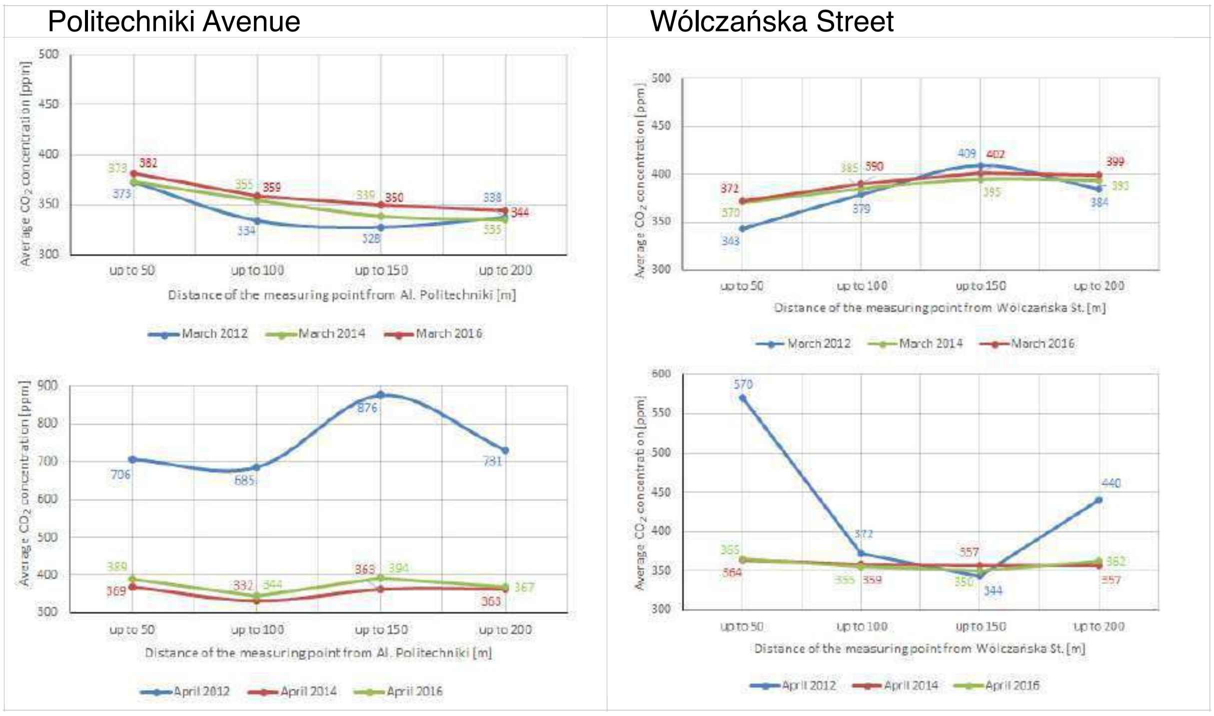

Figure 6: Average CO_2 concentration [ppm] in March and April 2012, 2014 and 2016 in relation to Politechniki Avenue and Wólczańska Street

The structures of the buildings in the vicinity of Politechniki Avenue required fewer measurement points than those next to Wólczańska Street. The average concentration of CO2 in the buffer zone adjacent to Politechniki Avenue in March 2012 and 2014 was 373 ppm. In April 2012 it rose to 706 ppm and in 2014 it was 369 ppm. In March 2012 and 2014 the values decreased with further distances from Politechniki Avenue. In March 2012 and 2014 the levels of CO2 rose as the distance of the measuring point from Wólczańska Street increased. In April 2012, the ambient concentration of CO2 grew with the distance from Politechniki Avenue and decreased with greater distances from Wólczańska Street. In April 2014, the average levels of carbon dioxide varied irrespective of the distance from Politechniki Avenue. The range of values remained the same. In April 2014, the levels lowered with increasing distances from Wólczańska Street (Cichowicz and Wielgosiński 2015b). The measurements were repeated in the same months of 2016.

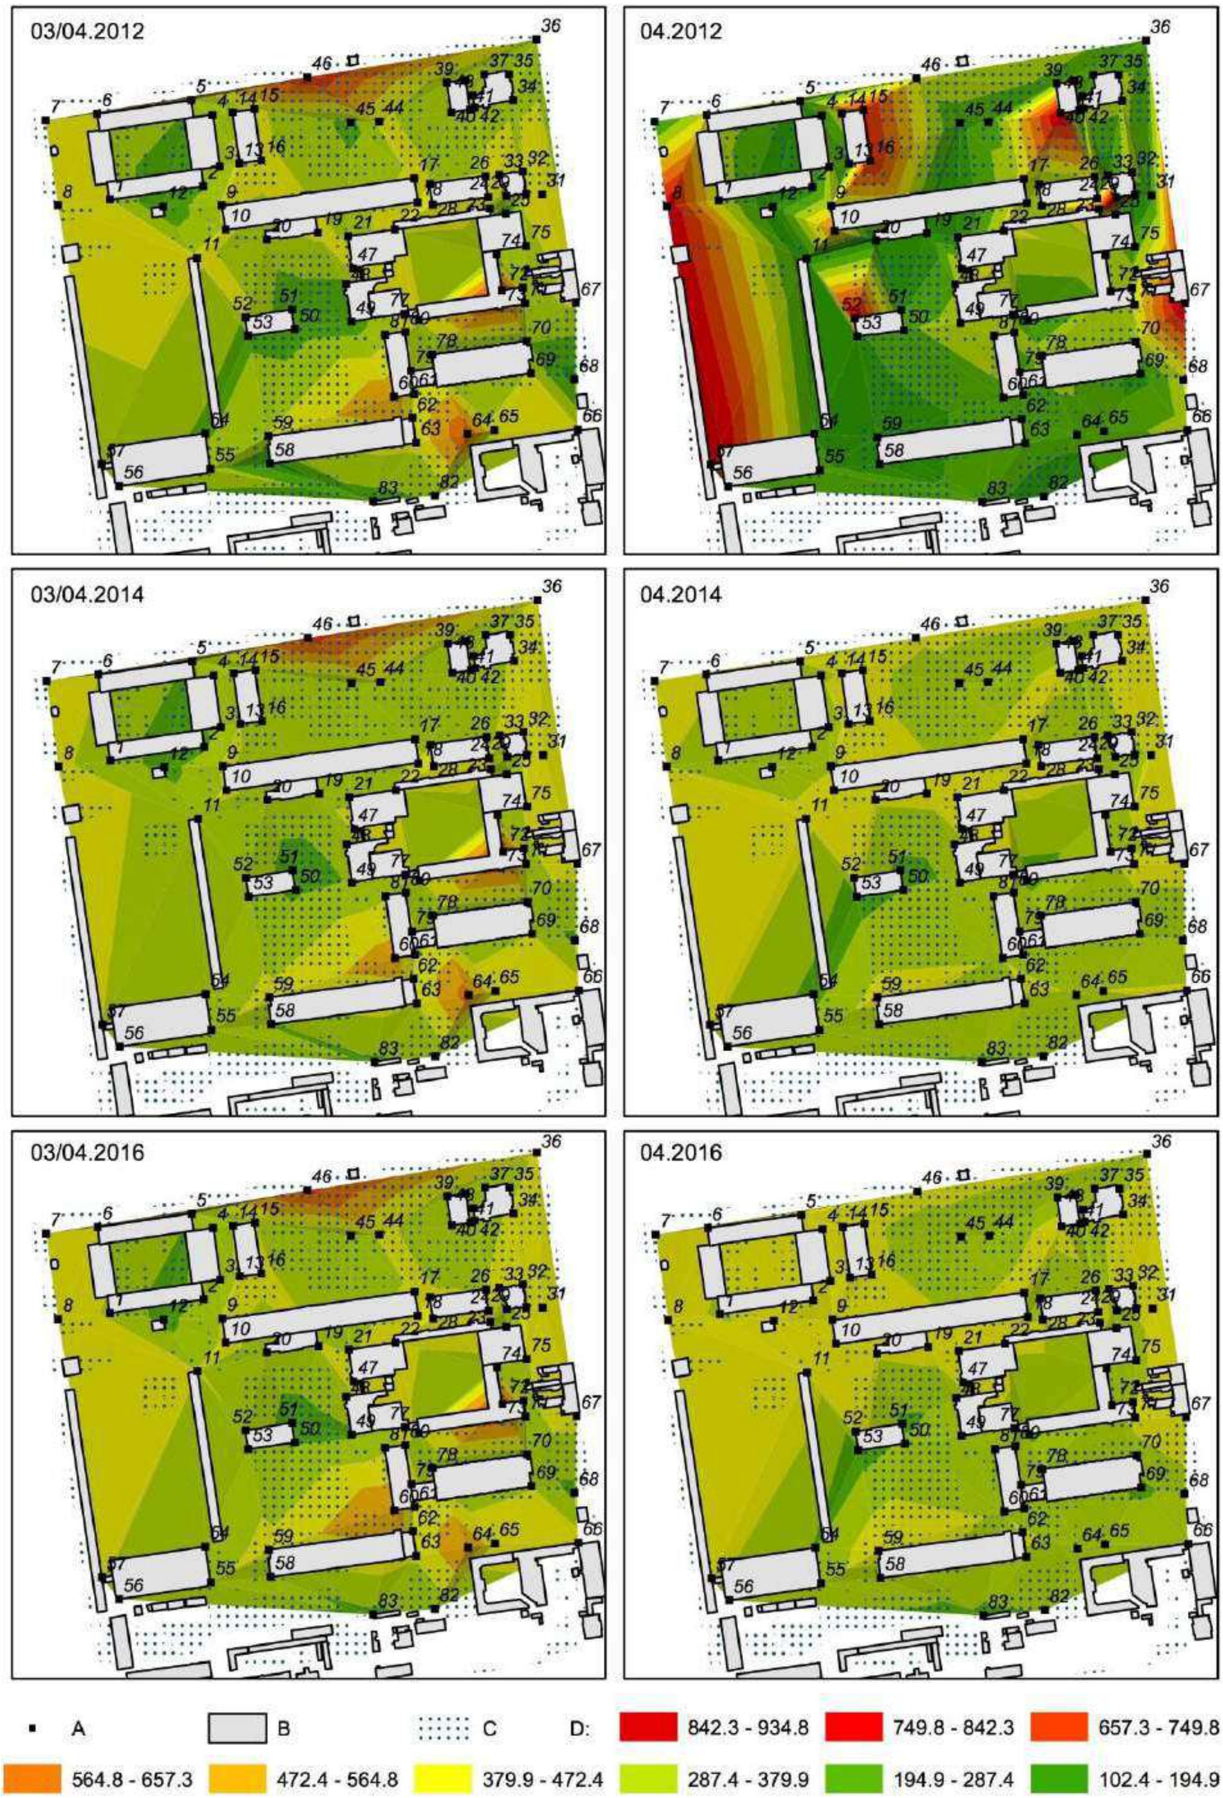

Figure 7: CO_2 concentration [ppm] in March and April 2012, 2014 and 2016

The variations in the levels of carbon dioxide observed in this study (Fig. 7) may result from a combination of several factors. Firstly, there is the obvious impact of street traffic both on Politechniki Avenue and on Wólczańska Street. In March, before the growing season, the impact of street traffic is more linear. In April, due to the appearance of vegetation and photosynthesis, large amounts of CO2 are absorbed (Allen 1990). This lowers the overall levels of this gas in the air. Another factor influencing emissions inside the campus is the circulation of cars within the campus, especially in the student and staff parking lots (Figs. 3 and 4). The direction of the wind, which during the measurements was mostly West and South West, may have carried some CO2 from the parking lots next to the old sports hall and the crossing of Politechniki Avenue and Radwańska Street nearby. This is probably the reason for the higher levels of CO2 in the Northern part of the campus. During the vegetation period, this difference does not occur because CO2 is absorbed by trees in Klepacza Park, north of the campus. A third element which could have affected CO2 levels is building density (Cichowicz and Wielgosiński 2015a). In general, the highest CO2 concentrations overlapped with the impermeable surfaces of the parking lots and pavements. This correlation was shifted due to the wind. The greatest differences in the CO2 levels in April 2012 may have resulted from the fact that the highest wind velocity and the lowest temperatures were recorded during this period. Our measurements demonstrate the impact of transportation emissions and of internal traffic circulation within the site and confirm the results of parallel research (Idso, Idso, Balling 2013, Nemitz et al. 2002, Gurney et al. 2012, Vogt et al. 2006). Other factors which may have had an influence the ambient concentrations of CO2 include the arrangement of the built structures, the amount of vegetation in surrounding areas and the distances between the buildings. Empty spaces form corridors which increase the displacement of air and therefore of pollutants (Chang et al. 2003). Emissions from the power plant and the electrical power and heating plant did not directly influence the results (Cichowicz 2018, Wielgosiński et al. 2018).

7. Conclusions and future research perspectives

The results of this study confirm a spatial correlation between the ambient concentrations of CO2 and the distribution of pavements and vegetation. This information could be used not only to improve the organisation of Campus B of Lodz University of Technology, but also to inform wider efforts to reduce greenhouse gas emissions in urban areas. Our results confirm empirically the influence of transportation arrangements on ambient CO2 concentrations. Transportation is estimated to contribute around 13 percent of total GHG emissions (Metz et al. 2007, p.52). The influence of corridors between buildings and of empty pathways between vegetation areas was also noted. In order to reduce emissions, transportation habits should first be changed, by encouraging the use of public transport and soft modes, such as walking and cycling, instead of individual vehicles. This would also require fewer on-surface parking lots. The hard surfaces should be rearranged and pavements replaced with more permeable solutions. The impact of the arrangement of various forms of built structure and the distribution of voids should be further analysed.
The gas micro-chromatograph provides exact records of carbon dioxide levels. Analyses of ambient concentrations of CO2 should be continued and improved by adding more measurement points distributed more regularly, in the form of a grid. This would eliminate visualisation distortions and improve the legibility of the outcomes.

The role of regional planning for spatial climate mitigation actions

Regional governance of land use and transportation in the US, Canada and Germany

Deborah HEINEN, PhD Candidate, HafenCity University, Germany

Abstract:

The multi-level governance of land use and transportation shift into focus when trying to reduce carbon emissions from commuting. To reduce travel distances between home and work, experts suggest urban containment and transit-oriented development as spatial development strategies. However, land use and transportation are governed differently in nations across the globe making the implementation of these strategies challenging and regionally unique. Therefore this paper seeks to understand and compare the regional capacities to govern land use and transportation in Seattle (USA), Stuttgart (Germany), and Vancouver (Canada).

1. Introduction

Reducing the carbon footprint of urbanized areas is one of the key challenges for urban planners in the 21st century. Within the climate mitigation discourse, several sectors are relevant for reducing GHG emissions, including energy supply and efficiency, transportation, land use, and waste (Verbücheln & Dähner, 2016; DIFU, 2011; Boswell, et.al, 2012). Each sector has varying potentials for emissions-savings. For instance in Seattle, Vancouver and Stuttgart, transportation emissions account for between 18% and 50% of total emissions. These emissions can partly be reduced through better fuel efficiency and an increase in electric vehicles, but there are underpinning land use patterns that (re)create the need for transportation. Especially at the city-wide and regional level, the mix and density of activities impact the demand for transportation (Banister & Jillian, 2009, p. 58; Pizzaro, 2009; DIFU, 2011; IPCC, 2014, p. 947; SKKK, 2014). To reduce distances between jobs and housing, climate action plans suggest spatial development strategies such as urban containment and transit-oriented development. Theoretically, these strategies should be implemented at the regional level (IPCC, 2014, p. 959) but this can be a difficult task given multi-agency settings with non-aligned organizational responsibilities (IPCC, 2014; Fröhlich & Knieling, 2013; Brunnengräber, 2013; Boswell et al., 2012; Heinen, 2018). Therefore, the question is: What are the legal and organizational capacities at the regional (US-metropolitan) level to actually implement urban containment and transit-oriented development?

Comparing the metro-regions of Vancouver (British Columbia, Canada), Seattle (Washington State, USA) and Stuttgart (Baden-Württemberg, Germany), this paper examines land use and transportation governance at the metropolitan regional level. Particularly, the paper tries to understand the regional governance capacities, based on the planning system, to make integrated decisions in an effort to implement urban containment and transit-oriented development. The following sections examine the national and state climate efforts, review the statutory responsibilities of the metropolitan (regional) planning organizations, and analyze their commitment to climate action and the leveraged planning mechanisms. The paper will conclude by discussing implementation challenges and opportunities based in the planning system.

2. Method

The analysis focusses on three administrative regions from the federal[1] states of Canada, Germany, and the USA. Seattle, Stuttgart, and Vancouver are best-case scenarios with a climate commitment for almost 10 years (see Table 1 for selection criteria). The three cases are comparable because of their similarities in population in the core cities and administrative regions (See Table 2 for data). This paper presents the results of a review of official government documents. Interviews with planners and elected officials to gather further insights will be conducted in August and September 2018 and will be published in a forthcoming paper. For this paper, the author analyzed climate action, growth management (land use), and transportation plans at all levels of government as well as state and federal laws in all three countries. For the climate action plans, the review focused on land use and transportation related mitigation actions and is not a comprehensive review of actions in all sectors. Within the other documents, a particular focus was placed on climate objectives, urban containment, and transit-oriented development as well as funding for transit infrastructure.

Selection Criteria	**Explanation**
1) State government (*Landesebene*, Province) is committed to climate action.	E.g. has adopted GHG emission reduction targets or has signed the Under 2 MOU Coalition.
2) Region or core city has had a Climate Action Plan for at least 5 years.	This allows examining the actual implementation of actions committed in the Climate Action Plans.
3) Core city has more than 500,000 residents and regional administrative area covers more than 2 million people but less than 5 million.	This establishes commonalities in the scale of spatial issues. Furthermore, the ratio between core-city population and administrative region population often impacts voting within the regional organization. This ensures similarities in interest representations at the regional level.
4) There is some form of state planning legislation (Growth Management/ *Raumplanung*).	States without growth management usually delegate all land use authority to the local level, thus having no regional government with any land use authority.
5) The region is growing not shrinking.	Shrinking regions have many other challenges and face different planning conditions (population loss, financial constraint, vacancies of buildings and neighborhoods).

Table 1: Explanation of case study selection criteria

Core-City	**Country**	**State** (Province, *Bundesland*)	**Population 2010/2011 (Pop)**			**% of pop in core-city to admin. region**	**Area (in km²)**	
			Core-City	**Admin. region (MPO)**	**Statistical region** (MSA, CMA, statistische Regionen)		**City**	**Admin. Region**
Stuttgart	Germany	Baden-Württemberg	585.890	2.668.439	3.914.359	22%	207	3.654
Vancouver	Canada	British Vancouver	603.502	2.313.328	2.313.328	26%	115	2.883
Seattle	USA	Washington State	608.660	3.690.866	3.439.809	16%	217	16.534

Table 2: Data on Regions
(Sources: US Census 2010, Destatis - Statistisches Bundesamt 2011, Statistics Canada 2011)

3. National and state climate support

In each country we find very different starting conditions for climate mitigation actions (Table 3). While the federal governments in Canada and Germany support climate action through various measures, the US regions rely on mostly voluntary local and regional actions. For instance, the Pan-Canadian Framework (GoC 2016a) includes $25 billion set aside for investment in public transit (GoC 2016b, p. 13f.). Germany's National Transportation Program (Bundesverkehrswegeplan) commits 42% of the EUR 240 billion in funding for rail projects over the next 12 years (G-BVWP 2030; Klimaschutzplan 2050, p. 55). For the United States, there is currently no federal monetary support and most recently, under the current Trump Administration, the United States has withdrawn from the Paris Climate Agreement (in effect by 2020; Romo & Parkes 2017). In response to the national shift away from climate commitment, 2500 US businesses, government entities, and organizations signed the "We are still in" initiatives, including 9 US states of which one is Washington State (which itself has set emission targets as early as 2008).

Climate Action Plans at	Vancouver, BC, CA	Seattle, WA, USA	Stuttgart, BW, DE
Federal-level	Pan-Canadian Framework on Clean Growth and Climate Change (2016)	NO	G-Klimaschutzplan 2050 (2016)
State-level (Provinces, *Länder*)	Climate Leadership Plan (BC CAP 2016; update to 2008 CAP)	NO (Executive orders Inslee 2014, Gregoire 2008)	Integriertes Energie- und Klimaschutzkonzept Baden-Württemberg (BW IEKK 2014)
Regional-level	NO (MV-Climate 2050-DP is underway)	NO	NO (Adaptation strategy VRS Klima 2016)

Table 3: Climate Action Plans (CAPs) by level of government

In the US context, state governments are usually very conscientious of local rights and avoid any infringement of the land use and zoning responsibilities of the local level. For instance, Washington State only committed state agencies to meet legislative GHG reduction targets (see RCW 70.235.020, 050 and 060; see Table 4), whereas British Columbia (BC) committed all levels of governments to reducing emissions (Bill 44 (2)(1)(a) and (b); see Table 4). In BC, the communities and regional districts are legally required to include targets, policies and actions to reduce greenhouse gas emissions in Official Development Plan and Regional Growth Strategies (Local Government Act Sections 473 and 429; Vancouver Charter 652.01). In addition, BC engages its local governments through the BC Climate Action Charter (BCCAC), a voluntary agreement which 187 of the 190 communities in BC have signed (BC CSCD 2018a). Signing the agreement is incentivized by funding through the Climate Action Revenue Incentive Program (CARIP; BC CSCD 2018b).

In Germany, climate action is voluntary for communities (G-Klimaschutzplan 2050, p. 77). The federal government does encourage communities with the German "National Climate Initiative". Since 2008, over 3,000 communities received a total of EUR 560 million for over 12.500 projects to create climate action plans and implement climate actions such as installing bike racks and switching to LED street lights (G-Klimaschutz 2018a). Baden-Württemberg finances 35 regional and countywide energy consulting agencies for home-owners (BW KEA 2018), funds increased energy efficiencies of public buildings at the local level (Program Klimaschutz Plus), and authorizes regional planning organizations to determine locations for wind energy plants and for other energy related facilities (BW Drucksache 15/3842, Artikel 2, §11; BW IEKK 2014, p. 145)

Table 4: State-level GHG Reduction Targets and estimated emissions in transportation (Sources: BC CAP 2016, p. 14; G-Klimaschutz in ahlen 2017, p. 37; PSCAA Strategic Plan 2014, p. 21; PSRC Vision 2040, p. 40)

In the transportation sector, Washington State is committed to climate mitigation but the implementation support for regions and communities is significantly lower than in Baden-Württemberg and BC. For example, the expansion of the regional transit systems is supported by state financing in BC and Baden-Württemberg, whereas it is supported by a regional tax levy in Seattle (WSDOT – VMT MPO Report 2011, p. 5; BC CAP 2016, p. 5 and p. 18; Sound Transit 2018; BW ÖPNV-Pakt 2014). In an effort to reduce emissions from transportation, the Washington State legislature set benchmarks (not requirements) to reduce vehicle miles travelled across the state by 18% by 2020 (RCW 47.01.440). As the agency responsible for building and funding federal and state roads, the Washington State Department of Transportation (WSDOT) funds transit with only 6.3% of a total operating and capital budget of $ 5.7 billion (WSDOT-Budget 2017, pp. 7, 40, and 64). In contrast, Baden-Württemberg is allocating 60% of transport funding for transit and bike infrastructure and 40% for regular road projects (BW IEKK 2014, p. 104; *Ma nahme* 69).

Overall, for communities in the Vancouver and Stuttgart regions there is strong support by state (and partly federal) government through regulations, funding and programs for climate action. While there is an intention at the state level in Washington State to reduce GHG emissions and Vehicle Miles Travelled, the available implementation support appears to be significantly lower. Washington State is pursuing other actions like capping emissions from large emitters and reduce emissions from state government operation but when it comes to implementing compact urban development (urban containment) and transit-oriented development, the responsibility is seen at the local level. While zoning is also a local responsibility in Canada and Germany, communities in these countries have financial and institutional support for implementation.

4. Legal (statutory) responsibilities of regional planning

When it comes to reducing emissions by implementing transit-oriented development and urban containment, regional and metropolitan planning organizations are key actors to facilitate coordination across communities in a region. The following table (Table 5), highlights the statutory responsibilities and services (*Aufgaben/ Handlungskompetenzen*) provided by the three regional planning organizations. All three agencies are responsible for Broad Planning (growth management, spatial planning/ *Raumplanung*)[2]; Metro Vancouver bundles together the most additional services and PSRC the least.

		Broad Planning/ Growth Management/ Spatial Planning	Transportation Planning	Transit Operation	Water	Sewer	Waste	Housing	Parks	Clean Air	Economic Development

	Deutsche Bahn AG			x							
	Stuttgarter Straßenbahn AG			x							

Table 5: Services provided by regional agency (statutory responsibilities)

4.1 Metro Vancouver and regional planning in British Columbia

Metro Vancouver is responsible for growth management, water, sewer and drainage, air quality management as well as housing (MV-Board Strategy, p. 6). Furthermore, Metro Vancouver approves the use of federal gas tax funds (Greater Vancouver Regional Fund), approximately $130 million per year (MV-Climate 2050-DP, p. 34). As a 2007 merger of previously separate organizations, each entity still has its own governing board composed of elected representatives from each participating municipality in the service areas. As a regional district under BC law, Metro Vancouver prepares regional growth strategies (RGS) in cooperation with 21 municipalities, one treaty first nation, one electoral area for matters that “spill across local government boundaries” (BC RGS Guide 2005, p. 33 and p. 15). The intent of BC’s “interactive planning system” is to foster local autonomy and achieve agreement between communities and the regional district. Prior to an RGS taking effect, each community has to accept the RGS and potential disputes have to be resolved through a set of state-defined procedures (BC RGS Guide 2005, pp. 2 and 17-20). For implementation of an RGS, municipalities have to include Regional Context Statements (RCS) with their Official Community Plan (also called Official Development Plan) which relates the local to the regional strategy.

4.2 Puget Sound Regional Council and metropolitan planning in Washington State

Puget Sound Regional Council (PSRC) is the designated Metropolitan Planning Organization (MPO by federal law) and the transportation planning organization (state law) of the Seattle region for the counties of King, Kitsap, Pierce, and Snohomish and the 86 local jurisdictions in these counties (PSRC – Plan Review 2014, p. v). Based on federal and state law, its primary responsibility is to plan the regional transportation system and to ensure cooperation between the state and local jurisdictions (USC 23 Sec 134; RCW 47.80.010). MPOs across the United States select regionally significant transportation projects within urbanized areas for federal transportation funding. Additionally, MPOs can be imbued with more powers if the state decides to grant them or if the locals decide to defer powers. The PSRC’s board of locally elected officials decided to develop a regional growth strategy as the multicounty planning policy (Vision 2040 adopted 2008, Vision 2050 underway). Based in state law, multicounty planning policies establish a framework for county and city comprehensive plans (RCW 36.70A.100; RCW 36.70A.210 (1) and (7)) but cannot “alter the land-use powers of cities” (RCW 36.70A.210). For implementation of an RGS, PSRC can certify aspects of local and county plans (RCW 47.80.023, PSRC-Plan Review 2014, p. v).

4.3 Verband Region Stuttgart and regional planning in Baden-Württemberg

The Verband Region Stuttgart (VRS) is responsible for growth management (*Raumplanung*), open space planning (*Landschaftsrahmenplan*), transportation planning, waste management, economic development, and tourism marketing (GVRS §3(1)(1)-(7)). The VRS is governed by a board of 80 regionally elected officials (GVRS §8 und §12) and encompasses the city of Stuttgart and 178 local jurisdictions in 5 counties. Within Germany, VRS is in a special position as it has extensive authority for transportation planning and is governed by a body of regionally elected officials. VRS prepares the regional plan (*Regionalplan*) in collaboration with communities and the state government (ROG §7 and 13). Once finalized the regional plan is approved by the state (Fürst 2010, p. 71).

Additionally, VRS participates in the development of statewide goals, and participates in sectoral planning (Goppel 2005, p. 566; Fürst 2010, pp. 96f.). In Germany, regional planning acts as an intermediary between local and state interests (Schmitz 2005, 965). While the local governments control zoning and implementation of the land-use component of plans, the state controls sectoral agencies and infrastructure investments (Fürst 2010, p. 76; see Buehler and Schmidt for more detail). For implementation, VRS works with municipalities through the *Fl chennutzungsplan* (Land Use Map prior to zoning code development) and with the state through specific procedures (*Raumordnungs- and Planfeststellungsverfahren;* ROG §15; Fürst 2010, p. 166)

5. Organizational capacity to regulate land use and transportation to mitigate climate change

Despite not having specific climate action plans[3], all three organizations include GHG reduction as primary objectives in their regional growth strategies (*Regionalplan*) and other plans (see Table 6 for a list). The three regional growth strategies promote development and mobility patterns that focus new growth within compact and complete centers along transit corridors[4] in existing communities. To achieve this, the recommended strategies include urban containment[5] and transit-oriented development.[6]

	Metro Vancouver	**PSRC**	**VRS**
Regional Plans: Growth Strategies (Regionalplan)	Regional Growth Strategy: Metro Vancouver 2040 – Shaping our Future (MV-RGS 2011)	Vision 2040	VRS-Regionalplan 2009

Others	Regional Parks Plan; Board Strategy 2015-2018		VRS-Klimaatlas 2008; VRS Klima 2016

Table 6: Plans at regional planning organization containing climate objectives

In all regions, there has been a prior commitment to this type of development (PSRC Vision 2040, p. 15; VRS-Regionalplan 2009; MV-RGS 2011). With increasing concerns over climate change, the three regional planning agencies stress the importance of reducing vehicle miles travelled by changing development and mobility patterns. However, the implementation of these changes looks very different across all three regions. In all cases, implementation depends to some extent on transit providers and local jurisdictions, but the legal planning frameworks provide different mechanisms to ensure plan consistency, solve disagreements, and provide financial resources for transit investments.

5.1 Implementation for Metro Vancouver

> "Metro Vancouver and its member municipalities are working to reduce GHGs by focusing growth in a network of transit-oriented urban centres and building compact, complete communities that offer amenities close to home." (MV-Climate 2050-DP 2018, p. 45)

In implementing the regional growth strategy, Metro Vancouver relies on its member jurisdictions' land use and zoning authority and on TransLink for long-term investments in transit and regional roads (MV-Climate 2050-DP 2018, p. 18 and 35; MV-RGS 2011, p. 52; TL 2018). Metro Vancouver can work with municipalities through the Regional Land Use Designation Map which is part of the RGS (MV-RGS 2011, p. 46). Within their Regional Context Statement, municipalities have to interpret the Regional Land Use Designation Map for their own Official Community Plan and identify the Urban Containment Boundary, Frequent Transit Development Areas and Urban Centers (MV-RGS 2011, p. 9). Furthermore, Metro Vancouver does have direct authority over sewer and water extensions, therefore in implementing the RGS they do "not allow connections to regional sewerage services to lands with a Rural, Agricultural or Conservation and Recreation regional land use designation" with a few exceptions (MV-RGS 2011, p. 14).

Metro Vancouver works with TransLink through the authorization of federal gas tax funds and by commenting on TransLink's transportation plans (MV-RGS 2011, p. 53; MV-FGT 2016, pp. FGT 6). But overall TransLink has a multitude of funding sources including property taxes, fuel tax, charges and fees, and a tax on parking rights (Part 3 of TransLink Act). TransLink works toward integrating land use and transportation decisions and references climate objectives at the Metro Vancouver and state level without setting out its own climate objectives (TL-RTS 2013, p. 2, 3 and 14). The performance measures (headline targets) of the agency are to make "it possible to make half of all trips by walking, cycling and transit; and […] to reduce the distances people drive by one-third" (TL-RTS 2013, p. 14).

5.2 Implementation at Puget Sound Regional Council

> "The region will focus growth within already urbanized areas to create walkable, compact, and transit-oriented communities that maintain unique local character. […] Rural and natural resource lands will continue to be permanent and vital parts of the region." (PSRC Vision 2040, p. xi)

For implementation, PSRC relies on communities, counties, and Sound Transit (the transit provider in the region). PSRC voluntarily set up a certification process for county and community comprehensive plans that go beyond the conformity requirements of state law (PSRC – Plan Review 2014, p. v). By state law, PSRC can certify if the transportation component of local plans is consistent with the regional transportation plan (RCW 47.80.023). Based on an internal agency policy, PSRC can also certify countywide planning policies which are usually developed by the counties in cooperation with communities but that do not alter the land use powers of communities (PSRC – Policy 2003, p. 1; PSRC's Interlocal Agreement 1993, p. 10f.; RCW 36.70A.210). To establish the consistency of countywide policies, local comprehensive plans and Vision 2040, PSRC set up their own procedures engaging communities early in their planning process (PSRC-Plan Review 2014, p. iv; WAC 468-86-150). Only jurisdictions with certified plans are eligible to apply for funding for transportation projects (PSRC Vision 2040, pp. 29f).

Additionally, PSRC can use its powers in the transportation sector by prioritizing investment in pedestrian, bicycle and transit-oriented facilities in urbanized area (PSRC Vision 2040 Goals MPP-T-11 to 16 and MPP-EN-21 and 23 on pp. 41 and 83). For the implementation of the long-range transportation plan, PSRC selects projects proposed by local governments for funding and adds the selected projects to the Transportation Improvement Program (USC 24 Sec 134). Furthermore, PSRC engaged its communities and Sound Transit in the Growing Transit Communities effort. This was a 2-year planning effort funded under the Obama administration's Sustainable Communities Initiative that created a transit-oriented development strategy for the region, identified new corridors and stations, and identified land use changes (PSRC-GTC 2013). Communities are committed to implementing the Growing Transit Communities effort through the Regional Compact – a voluntary memorandum of understanding among participating communities. As part of implementing Growing Transit Communities, Sound Transit will build 62 miles of new rail between 2021 and 2035. Funding for the new rail construction was approved by voters in 2016 who agreed to a slight increase in sales and property taxes (Sound Transit 2018). Furthermore, Sound Transit also has the Transit Oriented Development Program which coordinates the development of land near transit stations on Sound Transit owned land with community zoned land.

5.3 Implementation at Verband Region Stuttgart

> "The regional plan is a key mechanism to protect open spaces to bring fresh air into the communities, to foster compact urban development along transit corridors and to identify wind energy sites" (own translation; VRS-Klimaatlas 2008, p. 5 and 10).

VRS operates within the *Raumordnungsgesetz* (Federal Spatial Planning Law) which stresses the importance of preserving open spaces and concentrating development in urban and rural centers (ROG §2(2)(2))[7]. From the state level the regional planning organization is charged with two tasks regarding climate mitigation: to increase wind energy production (reserve land for wind energy) and to help foster compact urban patterns that reduce VMT (BW IEKK 2014, p. 101). The implementation of regional plans is a collaborative process between state-run sectoral agencies, the regional planning organization, and local communities. The *Gegenstromprinzip* is supposed to achieve a balance of statewide and local interests (ROG §1(3)). While it is mandatory (§4 Abs. 1 ROG) for sectoral agencies to comply with regional and state-wide plans, there are procedures for variances because sectoral plans (and local zoning codes) do have strong autonomy in the German constitution (Art. 65 GG (constitution); see also Fürst, 2010, p. 48f; §14 and §15 ROG). Therefore when preparing more detailed plans like *Fl chennutzungspl ne* and transportation studies, there is an extensive set of legally defined procedures to ensure coordination across levels and sectors of government (Fürst 2010, p. 137). A core concern is to make decisions that balance the various interests of using space in a way that will better the region overall. Coordination is mandatory across levels (vertical) and sectors (horizontal) of government.

Expanding the transit network has been an issue in the Stuttgart region since 1996 (VRS-Verkehrsplan 2016, p. 18). In an effort to increase transit ridership by 20% by 2025, the state government, VRS, county governments and the city of Stuttgart formed the "ÖPNV – Pakt" (transit alliance) in 2014 (BW ÖPNV Pakt 2014). The efforts primarily focus on increasing the service and reliability of the existing lines, adding park and ride stations, and improving the multi-modal infrastructure of the last mile of getting to and from the train stations. The transportation plan also stresses the need to more rigorously align developed land with existing infrastructure and to increase density and mix of uses along existing transit corridors (VRS-Verkehrsplan 2016, p. 22). To identify future transportation projects, the transportation plan assesses the emissions of 10 potential scenarios for the development of the transportation system (VRS-Verkehrsplan 2016, p. 64). The implementation of the project is the responsibility of Deutsche Bahn AG and Stuttgarter Straßenbahn AG.

6. Implementation challenges and opportunities for regional planning organizations

When it comes to implementation of urban containment and transit-oriented development to reduce GHG emissions, all three regional agencies rely on the land use and zoning powers of local governments and transit operators for transit expansions. While VRS and PSRC have control over transportation planning, Metro Vancouver almost entirely depends on TransLink for planning and implementation. For Metro Vancouver, there is no horizontal (across-sectors) integration of decision-making for growth management and transportation. VRS and PSRC have the ability to coordinate both sectors based on state law.

In the land use sector, Metro Vancouver pursues an interactive planning process (based on state law) and VRS pursues the *Gegenstromprinzip* ensuring procedural coordination (based on federal and state law). Metro Vancouver can negotiate with communities on land use issues through the interactive planning process which makes coordination mandatory (vertically integrated). VRS has the ability to engage in implementation procedures with statewide sectoral agencies and local communities based on federal and state law. Coordination is mandatory across sectors and levels of government (*Gegenstromprinzip*; ROG §1(3)). Both systems are designed to ensure consistency of goals and efforts across different levels of government. In both instances, state laws are designed to help resolve conflicts between levels of governments and to balance different interests through a set of predefined collaboration procedures. Therefore, both systems have mandatory vertical (across levels of government) integration of decision making.

For PSRC in Seattle, decision making is voluntarily integrated for growth management and mandatory for transportation. As the MPO, the planning process has to be collaborative, comprehensive, and continuous (Also referred to as the 3C-Process) (USC 23 Sec 134(c)(3)). Based on state law, the regional certification process of local and countywide plans is mandatory for the transportation component but not for the land use components. However, PSRC has voluntarily set up a certification process that also covers growth management aspects. This makes vertical coordination on growth management voluntary. If the certification process is based on municipalities giving the MPO these rights, there may be a reverse incentive for the MPO to strongly enforce compliance.

Overall, in the Seattle region the regional level has been very inventive with implementation tools such as the Regional Compact, the Plan Review Process, and the tax levy for transit funding. In a way, the lack of state support, requires broader expertise and capacities at the regional and local level, including procedural (administrative), tax, and legal in addition to spatial planning and transportation needs. Therefore, a key difference for implementation is the additionally required capacities at the regional level. Furthermore, differences are the state support for spatial climate mitigation actions, as well as legislative coordination requirements across levels of government (vertical integration) and across sectors/ scales (horizontal integration).

7. Conclusion

This paper reviewed the commitment and capacities to implement climate friendly regional development and mobility patterns at the regional level in Seattle, Vancouver and Stuttgart. While Vancouver and Stuttgart have national and state support for climate action, the institutional structures in the United States leave metropolitan regions to take mostly voluntary actions. In an effort to reduce emissions, all three regions are committed to spatial development patterns that protect open space and focus growth in mixed-use centers along transit-corridors, however, the implementation of these patterns follow different pathways.

In Germany coordination on implementation is mandatory (legally defined procedures) across sectors and levels of government; in British Columbia coordination is mandatory across levels of government; in the US coordination is voluntary (regional policy defined procedures) across sectors and levels, except for the transportation sector. There is a need to further study the actual coordination and implementation of urban containment and transit-oriented development in each region to fully grasp the relevance of the state planning system. Furthermore, there needs to be more research to understand if the climate discourse has led to systematic changes in the planning system or if climate mitigation efforts benefited from existing systems. Furthermore, the underpinning cultural context of the planning system needs to be examined to understand the differences in outcomes. Understanding potentials and challenges at the regional level may help improve conditions for more collaborative climate actions across sectors and levels of government as part of a multi-level climate governance reforms.

Acknowledgements

I would like to offer my special thanks to Prof. Dr.-Ing. Jörg Knieling (HafenCity University) for his valuable and constructive suggestions. I would like to express my very sincere appreciation to Dr. Madina Junussova (University of Central Asia) for comments that greatly improved the manuscript.

Endnotes

1 Canada, Germany, and the USA are organized as federations with strong state governments (Province, Landesebene) in contrast to central states such as France and the Netherlands (Heinz, 2000, p. 3)

2 Broad planning is the Canadian term, growth management the US-American term and spatial planning (Raumplanung) the German/ European-English term. PSRC is actually in a fairly unique position in the US to be responsible for growth management. In most US states, all planning responsibilities reside at the local level. Metro Vancouver is a special case in Canada, too, as the BC Local Government Act is not common in the other provinces. In Germany, having growth management (spatial planning) authorities is a core responsibility of regional planning. VRS is a special case having transportation planning responsibilities by state law.

3 Metro Vancouver is currently working on an Integrated Regional Climate Action Strategy (MV-Climate 2050-DP 2018). VRS has a climate adaptation strategy but no mitigation strategy.

4 To reduce emissions, Metro Vancouver's RGS plans to accommodate the anticipated population growth of 1 million residents by 2040, "in a network of transit-oriented urban centers and […] compact, complete communities that offer amenities close to home" (MV-Climate 2050-DP 2018, p. 45). PSRC's Vision 2040 plans to focus the forecasted population growth of 1.7 million people by 2040 in centers within existing cities in the urban area which is projected to reduce emissions by 6% (Vision 2040, p. 13). VRS aims to reduce VMT by defining primary transportation corridors (*Festlegung von Entwicklungsachsen*) and by concentrating retail and housing developments in centers (*Verortung von Wohnbau- und Gewerbeschwerpunkten*) in the regional plan (WIV 11617, p. 5).

5 A common critique on growth boundaries is the housing affordability problem. In all three regions this issue is addressed within the regional growth strategy and through separate plans or policies.

6 To create a compact urban area (Goal 1), the Metro Vancouver's RGS establishes an Urban Containment Boundary (Strategy 1.1), Urban Centers and Frequent Transit Development Areas (Strategy 1.2), and rural areas to be protected from urban development (Strategy 1.3) (MV-RGS 2011, pp. 13, 45). A core of PSRC's Vision 2040 is to develop mixed-use pedestrian-oriented centers along transit-lines (p. 14). By focusing growth in already built-up areas, farmland and resource lands are to be permanently protected (Vision 2040, p. 14). Infrastructure investments prioritize transit and nonmotorized transportation facilities for urban areas (Vision 2040, p. 14 and 82).

7 The federal government in Germany has little influence over implementation as zoning authority is a right of local municipalities, however, the Spatial Planning Law provides a framework of coordinated land use decision making across sectors and levels of government.

Indigenous knowledge a solution against drought in cities of Iran (the case study: Qazvin city)

PhD. Prof. Nasim IRANMANESH - Eng .Kouros ETAATI
Islamic azad university east Tehran branch
Jarf Sanat Sayna company
Iran – Tehran

Iran has been located in hot and dry region and water scarcity is always a permanent problem in this country. In recent years by global warming of the earth the water resources of Iran have been decreases so much and there will be a serious crisis in Iran. In past years Iranian harvested water from underground water by a more sustainable technique which called "Qanat". This technique was more sustainable than deep wells in harvesting water to irrigate cities and farms. The morphology of cities obeyed from the track of water of Qanat as well.

Harvesting and supplement of water in historical cities in Iran (hot and dry regions of Iran) was according an indigenous knowledge which was so innovative and intelligently.

Iranian harvested and used water in the most effective and efficient ways which can have some good lessons for recent generation which uses water in an uneconomical and illogical way.

This paper will review the indigenous knowledge in harvesting and supplement water in historical cities of Iran to learn some sustainable solutions to challenge with the drought which is the result of global warming of the earth.

The case study of this paper is Qazvin city. This city has been located in semi hot and dry region in Iran which was irrigated by several Qanats and a traditional supplement of water in city which determined the morphology of the city.

Key words: global warming, traditional urban planning, Qanat, indigenous knowledge

Introduction

Water is a scarce element in most parts of Iran and there are few rivers and lakes in Iran specially in central parts of Iran.

Iran has been covered with vast desserts and Iranian earned water by an intelligent technique which called "Qanat".

This system is the most prevalent system to earn water for settlement and agriculture. Iran has been survived by “Qanat” or “Kariz”. Actually we can notice a “Karizian civilization” in Iran which is an ancient civilization in a hot and dry region. Cities and villages was formed according the recourses of water and path of Qanat. In the other word cities were formed based on the path of Qanat and water was an important factor in morphology of cities.

The location of many buildings of the cities especially hydraulic structures was determined according the path of Qanat.

Old Iranian has a rich knowledge in harvesting water and supplement of water in cities. By this indigenous knowledge water was earned and supply in a most efficient way which water was consumed in the optimum way. This paper is about indigenous knowledge in harvesting and supplying water which enabled Iranian to maintain and spread their cities for a long time.

Methodology

Methodology of research is descriptive – analysis and by an exploring and surveying method study the role of water in the morphology of the historic city of Naragh. In the other word traditional harvesting of water (Qanats and wells) and traditional water supplement have a very important effect in morphology of city which in this paper was described.

……………………………………………

1- Qanat and its elements:

This system contains a horizontal corridor to transfer water to a settlement or farms. Other elements of Qanat are a mother well and some shafts which enable pitmen to construct and maintain the Qanat.

Water appears in mouth of Qanat on the ground then transfers to everywhere which need water such as houses, hydraulic structures and farms.

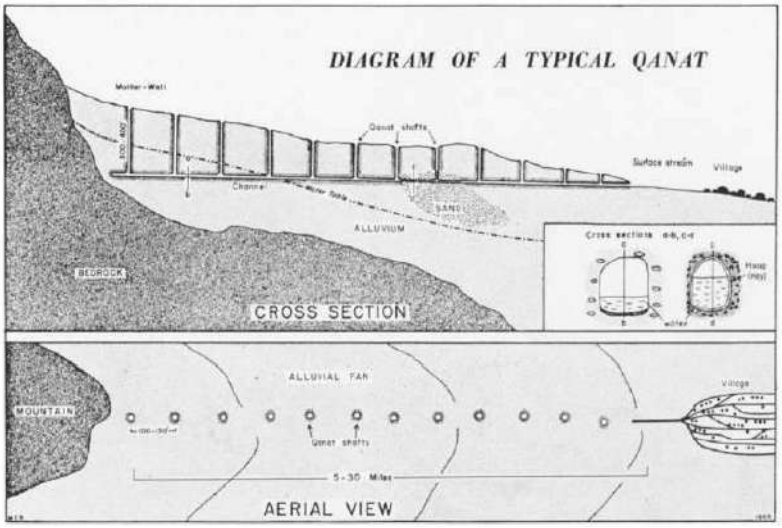

Fig 1- The section and plan of Qanat (source : English)

2- Hydraulic structures:

The most relevant historical hydraulic structures in Iran were Payab, traditional bath, water reservoirs, ice houses, water mills. The location of these structures were obeyed from the path of water which mostly was from the water of Qanats. Sometimes cities obtain their water from rivers or streams. However, these hydraulic structures were feed by water and were located next to the path of water. The water sometimes followed underground. Some houses of cities have this score which water passed through their courtyards. Usually these kind of houses were more expensive and belonged to elite and rich citizens.

2-1 Payab:

To reach the underground path of Qanat people construct a building which is called Payab contains some steps, which lead to underground water and there was a room which water pass through it and there was a hole on the roof to let the sunshine come in. There were public and private Payab both. The number of steps which lead to water depended on the depth of underground water of Qanat.

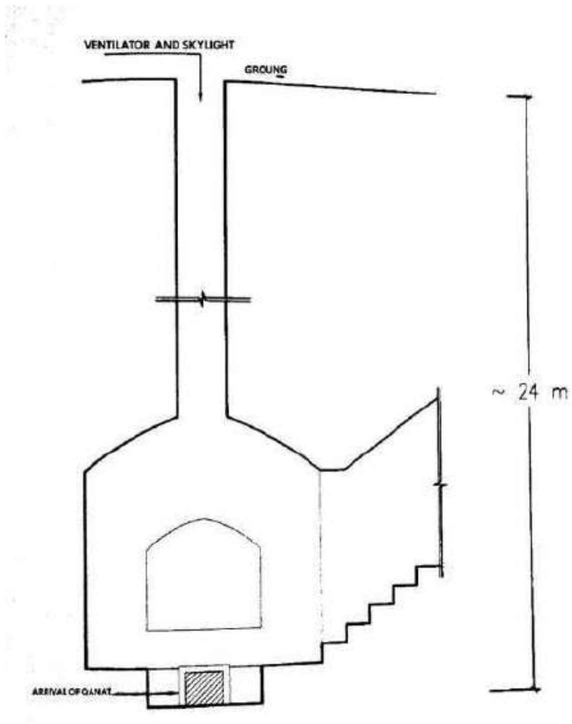

Fig 2. Section of a Payab (source:semsar Yazdy)

2-2 Water reservoir (Ab Anbar):

Water should be reserved in large structures which was called water reservoir (Ab Anbar).
The elements of this building consisted as large tank which was constructed inside the ground and a large doom covered this tank and the air of this building was ventilated by some wind tower (badger).

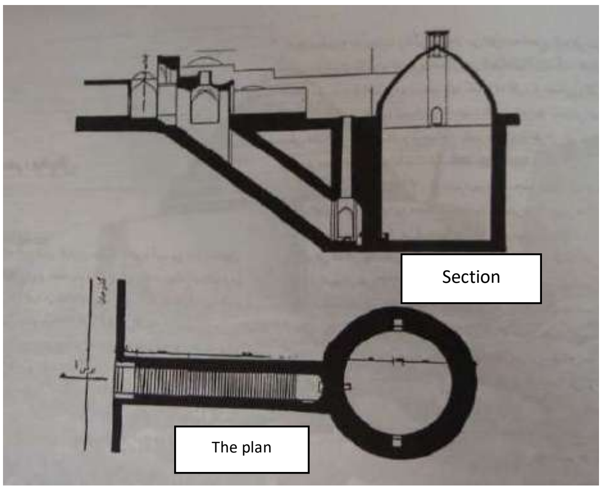

Figure3: section of a water reservoir in Kashan city (source: Ghobadian)

2-3 traditional bath:

Traditional bath is another building type in hydraulic structures. In Islam there is an important emphasis on washing and cleaning. According to Islam roles people should clean and wash themselves so in cities there were several bath to serve citizens. As usual the bath was fed by water of Qanats and traditional bathes had a plan but in this paper there isn’t enough space to describe them.

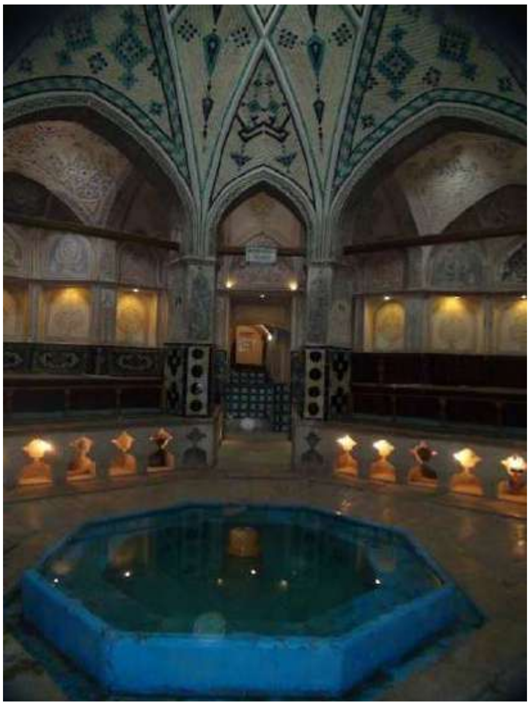

Fig 4. Amir Mhammad Bath in Kashan (source : author)

2-4 Ice houses:

Iran has hot and long summer. There is an intelligent system to produce ice for hot days. In ice houses there are two main elements: a tall wall and a storage. In winter water froze in shallow pools which was in shadow of a tall and long wall.

People cut the ice and stored it in a huge structure which was erected inside the ground and was covered by a large doom. In summer people brought out the ice and consumed it.

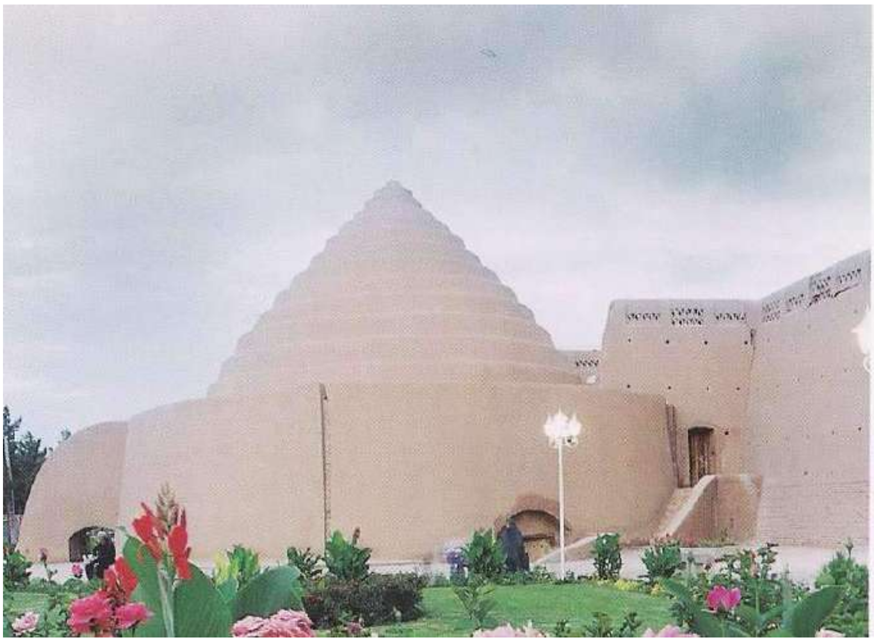

Fig 5: Ice house Kerman city (source: author)

2-5 water mill:

In past time most of water mills worked by hydraulic power. As there are few rivers in Iran people use the hydraulic power of water of Qanat. So there were several water mills in the path of water of Qanat and the wheel of water mill moved by the power of water and produced the flour of people.

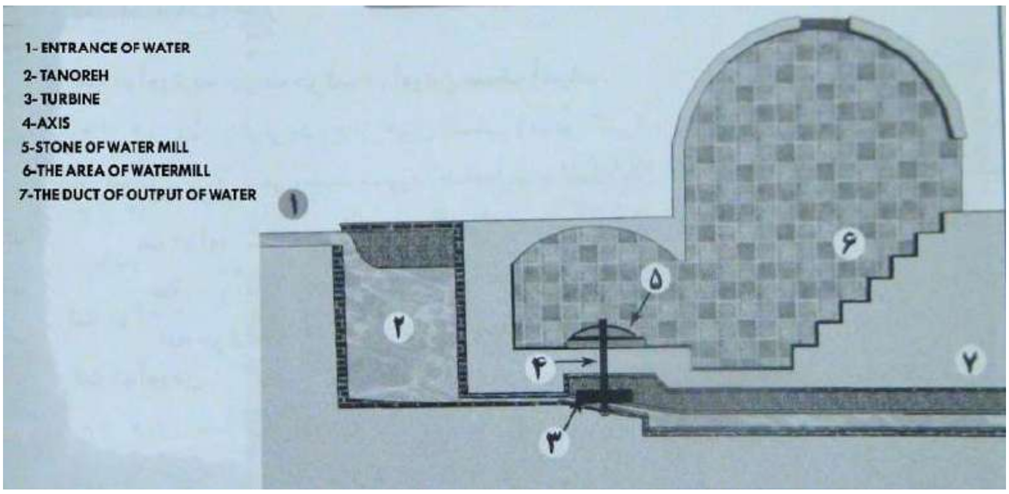

Figure 6: section of a watermill in rout of Qanat (source:Semsar Yazdy)

3- The location of hydraulic structure in cities:

As it was mentioned before, the location of hydraulic structure was determined by the path of water in cities either followed on the ground or underground.

However, usually first of all water mills were located on the path of the water and then water passed through some public and private Payabs, traditional bathes, ice houses and water reservoirs. Mosques usually reached to water by Payab to achieve a ritual of praying (vozu). Of course water was used in a hierarchy in hydraulic structures and finally was lead to farms and gardens.

In two below maps the path of two Qanats of Qazvin city in Iran and its hyrulic structures have deen shown.

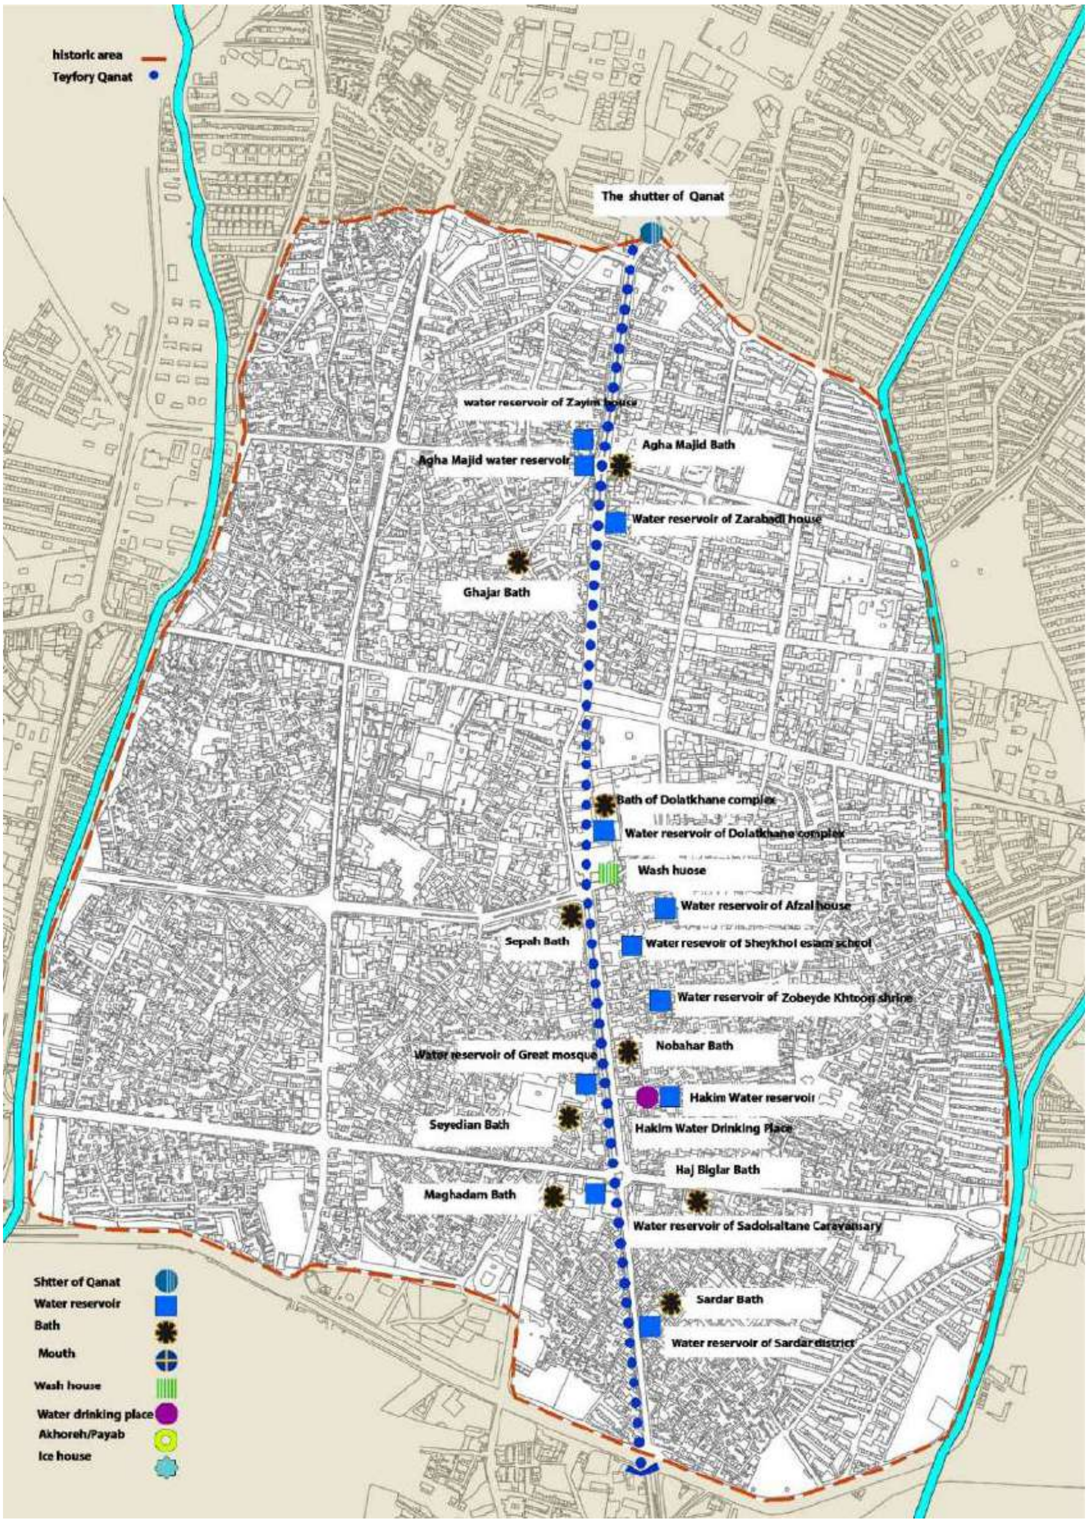

Figure 7. The rout of Teyfory Qanat in historic area of Qazvin and location of hydraulic structures on it (source : authors)

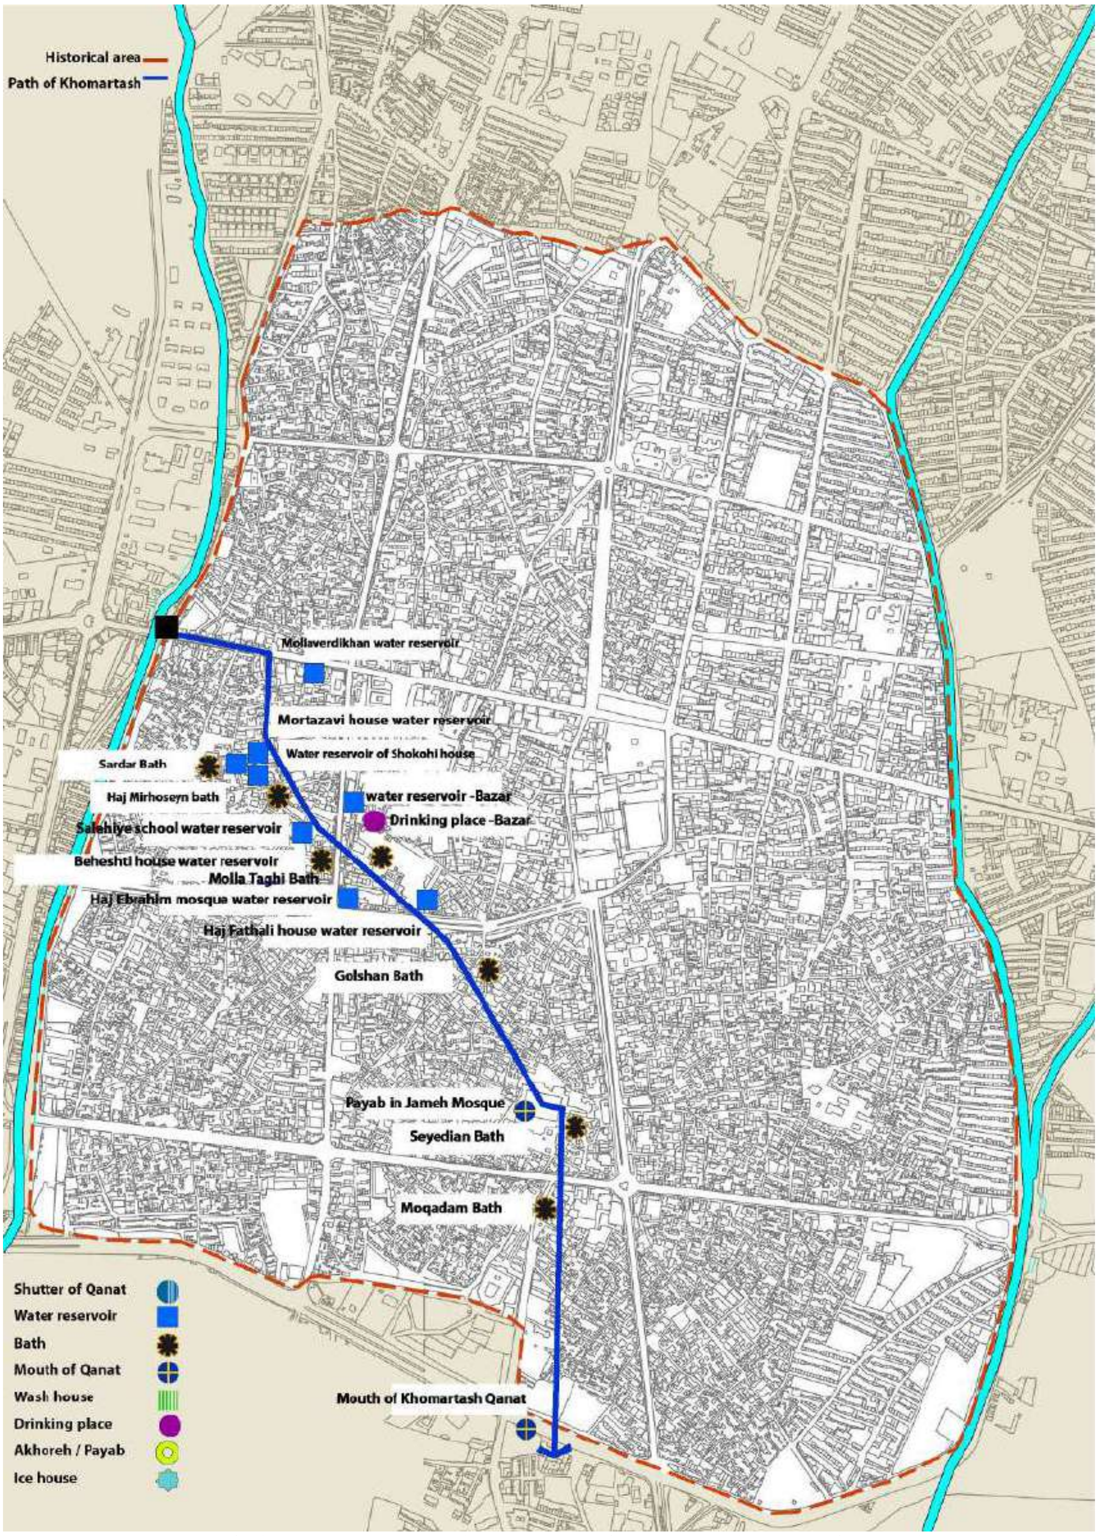

Figure 8 - The rout of Khomartash Qanat in historic area of Qazvin and location of hydraulic structures on it (source : authors)

4-Comparing Qanat with wells in harvesting underground water:

Water harvests mainly by two systems: Qanat or deep wells. In comparison harvesting water by Qanat is more sustainable than wells.

Qanat harvested water from alluvial fans and the amount of water directly depends on the water of alluvial fan.

But deep wells discharge the water of alluvial fans so fast so its water will finish and can’t be back anymore.

5-Conclusion:

Water is the main factor to survive a settlement. Iran in spite of scarcity of water has an old civilization which was based on the water of Qanat. Qanat and hydraulic structures invented by a rich indigenous knowledge.

Reviewing this knowledge will be very useful and can lead us to more sustainable ways to achieve more efficiency in harvesting and consuming water.

In the other word we need the best solutions to achieve two major problems: the water scarcity and drought and referring to indigenous knowledge will be a good solution.

Main Title

The Impact of Climate Change on Spatial Planning, the case of Durban, eThekwini Municipality.

Author: Mr Ketlaodirelang Emmanuel Letebele
eThekwini Municipality, Durban, South Africa.

1. Introduction

It is said that by 2050, 6.5 billion people, or two thirds of the world's population, are expected to live in sprawling metropolises. To safeguard this future urban way of life new forward-thinking strategies for mitigation and adaptation to the impacts of climate change need to be integrated into conventional concepts of urban development. To that end eThekwini Municipality has developed a Spatial Development Framework which outlines a development trajectory for short, medium, and long-term planning scenarios. The Spatial Development Framework presents a long-term (20+ years) vision and plan of the desired spatial form of our Municipality, and thus, is critical for infrastructure planning.

The Spatial Development Framework guides the desirable spatial distribution of land uses within a Municipality to give effect to the spatial vision, goals, and objectives of the Municipality. It prioritises areas for spatial interventions and is aligned with National and Provincial strategies to achieved both horizontal and vertical alignment. When completed, the Spatial Development Framework is adopted by the Municipal Council. Our Spatial Development Framework has been informed by key international, national, provincial, and local influences, as shown in the following diagram. Each of the strategies discussed later in this paper should not be seen in isolation, but as integrated components of an overall framework for sustainable development of the city.

Figure 1: Key Spatial Development Framework informants

The plans for the development of our Municipality and its built environment are underpinned by global, national, and regional policy. The objectives of these policies have influenced the strategic and spatial direction of our Municipality. The most recent and relevant international developmental policies that informed our Spatial Development Framework are listed and described below.

- The **New Urban Agenda** officially adopted in Quito, Ecuador in November 2016. This agenda provides a 20-year "roadmap" to guide global sustainable urban development. The 2030 agenda is built around a series of Sustainable Development Goals. Most relevant to the New Urban Agenda is Sustainable Development Goal 11, which aims to “make cities and human settlements inclusive, safe, resilient and sustainable”.

- The **Sustainable Development Goals**’ intention is to be a universally shared common and globally accepted vision to progress to a just, safe, and sustainable space for all inhabitants.

Figure 2: An image of the Sustainable Development Goals

- **Sendai Framework for Disaster Risk Reduction 2015-2030:** The Sendai Framework is a 15-year voluntary, non-binding agreement which recognizes that the State has the primary role to reduce disaster risk, but also finds that this responsibility should be shared with other stakeholders including local government, the private sector, and other stakeholders. It aims for the following outcome: “The substantial reduction of disaster risk and losses in lives, livelihoods and health and in the economic, physical, social, cultural and environmental assets of persons, businesses, communities and countries”.

- **The Addis Ababa Agreement -**The Addis Ababa Action Agenda provides a foundation for implementing the New Urban Agenda. The agreement was reached by the 193 United Nations Member States attending the United Nations Third International Conference on Financing for Development.

- **Paris Agreement -**The Paris Agreement is universally regarded as a seminal point in the development of the international climate change regime under the United Nations Framework Convention on Climate Change (UNFCCC). The Paris Agreement was adopted on 12 December 2015 at the 21st session of the Conference of the Parties to the United Nations Framework Convention on Climate Change Conference of the Parties 21. The Agreement was the result of four years of intense negotiations mandated by the United Nations Framework Convention on Climate Change Conference of the Parties, held in Durban in 2011.

  The Agreement is a comprehensive framework which guides international efforts to limit greenhouse gas emissions and to meet all the associated challenges posed by climate change. The main objective of the Agreement is to limit the global temperature increase to well below 2 degrees Celsius, while pursuing efforts to limit the increase to 1.5 degrees. South Africa is a signatory to the Paris Agreement and has an obligation to limit temperature increases to 1.5°C, above pre-industrial levels.

We have customised the above global documents to suit the prevailing conditions in Durban and their key outcomes informed the development of our Spatial Development Framework. For example, the Spatial Development Framework contains strategic responses to climate change, including the Durban Climate Change Strategy, which is part of the Municipal Climate Protection Programme. This programme defines a city-wide approach to adapting to climate change and mitigating Durban's contribution to climate change. It covers 10 themes: water; sea level rise; biodiversity; food security; transport; energy; waste and pollution; health; and economic development as well as recognizing knowledge generation and understanding as cross-cutting fields.

The vision of the Durban Climate Change Strategy is: "To transform Durban's governance, social, development and economic systems in order to effectively respond to climate change". It guides the implementation of climate related work done within the Municipality, its governance framework and the subsequent development of implementation plans, supported through the C40 2020 Climate Action Planning Programme. It enables better co-ordination between municipal sectors and structures helping to build a climate smart city.

2. Governance structure that responds to Climate Change within eThekwini Municipality

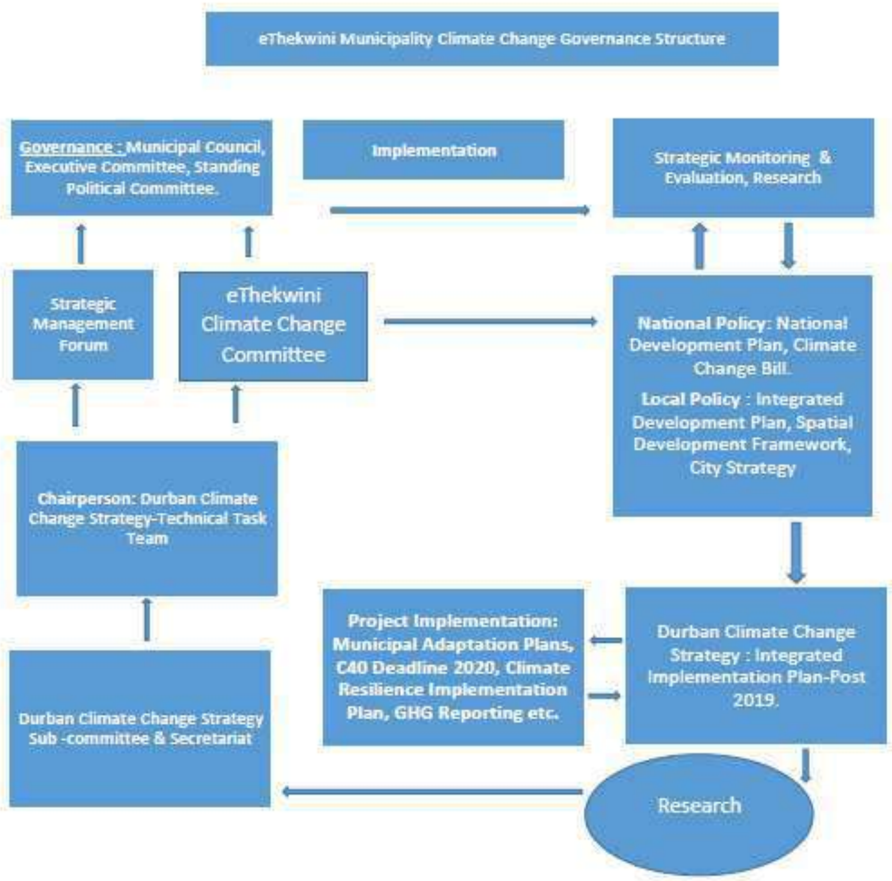

Figure 3: An image of the eThekwini Municipality Governance Structure that deals with Climate Change

Governance of local climate action

As outlined in figure 3 above, the eThekwini Municipality Climate Change Governance is led by Her Worship the Mayor of the City of Durban, and she is the C40 Vice Chairperson for Africa. The Mayor has delegated the responsibility of climate change political oversight role to the eThekwini Municipality Climate Change Committee. The Strategic Management Forum plays the administrative oversight role on the Durban Climate Change Strategy implementation. The Durban Climate Change Strategy Technical Task Team comprises of Heads of Departments and fulfils a coordination and implementation of the Durban Climate Change Strategy between line functions and reports to the eThekwini Municipality Climate Change Committee. The Task Team is supported by the Sub Committee which comprise largely of Senior Managers from different line functions, the Sub Committee also oversees the implementation of various climate change projects working with network partners such as C40 Climate Change Leadership Group, Cities Fit for Climate Change, as well as other projects with their respective steering committees.

There are intentions to review the Durban Climate Change Strategy in 2020 which will be informed by the Monitoring and Evaluation Framework to be completed by mid-2019. This governance structure is supported by officials who serve on a number of climate change networks or partnerships. The knowledge derived from all climate change work streams is fed into the Governance Structure with the intended outcome being integrated and effective climate change response by the eThekwini Municipality. The concept of Network Density becomes applicable if this structure is viewed as a Network Map. Density refers to the number of interconnections between members in the network map. Effectiveness is increased by density, because the more the interconnections there are, the better the communication of new ideas between network members. Everybody is talking to each other, and nobody with potentially useful information is isolated.

3. Cities as actors of sustainable development

Our plans have also been influenced by the participation of the Municipality in international partnerships and learning exchanges. These events have informed our spatial planning response to climate change and mitigation. The following section describes one such partnership we have entered to mainstream our climate change response work.

3.1 Global Project Cities Fit for Climate Change Project:

The global project 'Cities Fit for Climate Change' implemented by GIZ on behalf of the Federal Ministry for the Environment, Nature Conversation, Building and Nuclear Safety (BMUB) cooperates with various international partners, in Germany, and with its three partners cities. The partner cities, Santiago (Chile), Chennai (India), and Durban (South Africa) were selected in agreement with the relevant national ministries and authorities. The decisive selection factors were the commitment of the mayors and city councils, and the cities' level of climate change vulnerability. Each city determines their project priorities, which might be, for example, the climate-proofing instruments, strategies, regulations, the implementation of participatory city development strategies, or the development of financing options for realising available climate protection and adaptation concepts. Each partner cities exchanges knowledge with each other and with other cities within the framework of the exchange workshops.

Figure 4: A global map illustrating the location of Cities Fit for Climate Change Partner Cities

Cities Fit for Climate Change aims to strengthen cities as actors of sustainable development, and to assist cities in the development of integrated, resilient, and low carbon instruments for sustainable urban development. The development of these instruments will facilitate a Climate Proof Urban Development Model, which promotes a new urban design vision. With this model, the project supports innovative approaches for urban planning and makes cities "fit for climate change". A fundamental question is how can cities, as drivers and victims of climate change, cope with the risks and become custodians of a livable climate? This project is focused on finding answers to this question. Because there are no universally applicable solutions, existing concepts for resilient low carbon urban development are being analysed and compiled in a sourcebook. Selected cities develop case-specific, climate-friendly, locally adapted strategies which are derived from this knowledge base. This work was guided by the 'Leipzig Charter on Sustainable European Cities' and the BMUB Memorandum 'Urban Energies-Urban Challenges'.

It is the intent of the program to share the collected knowledge at international conferences, such as the International Society of City and Regional Planers (ISOCARP) Congress, and to support the United Nations Framework Convention on Climate Change process. The Program also contributes to the implementation of the 'New Urban Agenda', the international agreement of the Habitat III process.

3.2 International Learning Exchange Workshop of the Cities Fit for Climate Change project in partnership with Connective Cities. Durban, South Africa, February 2017.

Three 'inter-connected' workshops were planned in each of the participating partner cities. At each workshop new elements of climate-sensitive urban planning would be incrementally developed into a new urban development model that draw on real city-level case studies. The first was held in Durban in February 2017. It hosted urban practitioners from the partner cities together with representatives from the German cities of Hagen, Nuremberg and Stuttgart, the Swedish City of Malmö, the South African Local Government Association (SALGA) and members from GIZ SA (Climate Support Program).

Figure 5: An image of the City of Durban.
Source: Letebele, K.E. (2018) Photographic Image.

These exchange sessions were intended to enable and facilitate peer-to-peer knowledge sharing, support and collaboration, the joint generation of new knowledge, and the promotion of innovation with regards to the planning of low-carbon and resilient urban development. The workshop discussions were centred on analysis tools, city development strategies, planning approaches, implementation frameworks etc. revised to reflect climate change considerations with the resultant outcome - to make cities low-carbon and resilient to the impacts of climate change.

The workshop objectives were:

- To establish the status quo regarding the integration of climate change issues in urban development instruments and strategies of the partner cities;
- To learn from existing practices and innovations in climate sensitive urban development;
- To identify synergies between the existing urban development instruments and strategies;
- To develop a roadmap for the workshop series with the intermediate steps needed for conceptualizing a new climate-sensitive urban development model.

To generate workable solutions for the next workshop, the primary aim of the Durban workshop was to discuss lessons from successful efforts that can be replicated on the various projects and programmes presented by the participating cities. A key outcome of the Durban workshop was the realization that for climate change adaptation and mitigation strategies to gain traction in cities, they need to be main-streamed into urban planning development and not viewed as a separate discipline or add-on.

After the Durban workshop, the eThekwini Municipality developed a meaningful implementation plan for the Durban Climate Change Strategy, which mainstreams climate adaptation and climate resilience into the planning processes, such as the Spatial Development Framework and lower order spatial plans. The Climate Resilience Implementation Plan is an outcome of the Cities Fit for Climate Change (CFCC), a global programme implemented by GIZ on behalf of the Federal Ministry for the Environment, Nature Conversation, Building and Nuclear Safety (BMUB) of the Federal Republic of Germany.

In general, our implementation plan aims to assist in the development of integrated, resilient, and low carbon instruments for sustainable urban development. The development of these instruments will promote a new urban design vision, which supports innovative approaches for urban planning and makes cities "fit for climate change". Furthermore, our approach ensures that the implementation of the Climate Resilience Implementation Plan is undertaken through agreed municipal procedures and integrated into relevant municipal planning and decision-making processes.

The integration of the Climate Resilience Implementation Plan outcomes will feed into the Non-Motorized Transportation and active mobility strategy for eThekwini amongst others. Efforts are underway to lobby support from all municipal departments to prioritize and incorporate climate change responses into their mid -term budget review in line with their respective mandates. This stems from the fact that the Spatial Development Framework is a multi-sectoral plan, and therefore when each sector implements an action linked to climate change then the outcome of the Climate Resilience Implementation Plan will be seen through to implementation as part of that process.

We also recognized that we need to think globally, but act local, to take meaningful steps towards climate change mitigation and adaptation. Furthermore, we learned that cities should not work in isolation of each other, their nation-states, or the global community. We recognized that solutions for climate changes need to address a multiplicity of issues for a city and cannot merely be about climate change protection and or mitigation alone.

3.3 International Dialogue Forum on Climate-Proof Urban Development, Santiago De Chile, September 2017.

The International Dialogue on Climate Proof Urban Development was held to map trajectories for a climate-friendly future. This dialogue forum involved the participants from seven different cities, including the three partner cities and four German cities (Leipzig, Nuremburg, Frankfurt and Munich). The German cities were invited to share information regarding their work on climate-proof urban development and to learn from the Cities Fit for Climate Change partner cities.

The main objectives of the Santiago Cities Fit for Climate Change dialogue forum were to:

- Generate networking opportunities between Cities Fit for Climate Change partner cities; and,
- Learn about and exchange information regarding municipal practices and climate-proof urban development experiences from the participating cities.

Figure 6: An image of Santiago de Chile.
Source: https://www.gettyimages.com/photos/santiago---Chile.

The Santiago International Dialogue on Climate Proof Urban Development concentrated on how to change institutional patterns to achieve enhanced integrated urban development. A cross cutting theme of the workshop was "The Governance of Local Climate Action and How to Foster Multi-Stakeholder Collaboration". It was at this International Dialogue session that emphasis was placed on the definition of Climate-Proof Urban Development as follows:

> ´In connection with spatial planning and spatial development, climate proofing includes methods, instruments and procedures that ensure that plans, programmes and strategies, as well as the associated investments towards the current and future impacts of climate change will be more resilient and adaptable, and that they also aim for the corresponding plans, programmes and strategies to take into account the aim of climate change mitigation' (Birkmann and Fleischhauer, 2009).

The above definition points out that to achieve a climate proof urban development a collective action from all stakeholders responsible for urban development is required. Two site visits in the city of Santiago were undertaken to showcase urban development projects and the climate considerations that come with them. The real-life examples, Bajos de Mena, in the municipality of Puente Alto, and Ciudad Parque Bicentenario, in the municipality of Cerrillos, were discussed to illustrate the challenges and opportunities of climate-proofing urban development in district neighbourhoods or infrastructure projects. Both projects were selected to represent examples of national policy implementation in urban development, as well as to stimulate conversation regarding the challenge of integrating climate change related elements into such projects.

Bajos de Mena

Bajos de Mena is a historically neglected area, 20 kms away from Santiago with more than 120,000 inhabitants. It was built to provide social housing, but without territorial planning. Bajos de Mena is a social housing condominium area located in the southern periphery of the city of Santiago. It is a neighbourhood of high complexities with the following characteristics: "precarious condition of habitability with serious problems of violence and insecurity; lack of infrastructure and public - private services; and, above all, deteriorated relationships with authority and feeling of abandonment by the State".

One of the primary challenges was to incorporate climate change adaptation into the new plan by generating pilot development projects which include renewable energy and water efficiency among other actions. The plan was to evaluate the impacts of these interventions and to determine the feasibility of scaling up such approaches. The plan is led by the Regional Government of the Metropolitan Region of Santiago, in direct coordination with various public and private services.

Figure 7: An image illustrating the built form in Bajos De Mena
Source: Letebele, K.E. (2017) Photographic Image.

The Second Chance Plan for this area was incorporated into the Bajos de Mena Integral Plan, under the direction of the Integral Plans Unit of the Metropolitan Intendencia. It proposed housing and neighborhood improvements, more transport infrastructure, services, green areas, and new security prevention plans. It also seeks to provide the area with services (banks, supermarkets, police, public, services, etc.), improved housing quality (isolation, bigger spaces), connectivity, and public areas focused on sustainability in terms of living standards, both in social and environmental terms. The project highlights the co-benefits and synergies between the various social and climate related challenges, by incorporating adaptation initiatives that respond to both social and climate problems identified by the local community, such as flooding in certain areas of the various neighbourhoods. However, there is still work to be done in terms of transportation and connectivity, as well as energy efficiency and supply.

The experience generated by the project points towards a recommendation to clearly understand the pertinent climate change risks prior to any urban intervention, by performing a vulnerability and risk assessment. This allows for climate change related challenges to be integrated from the beginning of the project, instead of having to integrate such considerations after the development phase has begun.

Ciudad Parque Bicentenario

Ciudad Parque Bicentenario (CBT), also known as the Bicentennial Park of Cerrillos, is an urban-real estate project located in the commune of Cerrillos within the metropolitan area of the city of Santiago, Chile. The project was designed to commemorate the Bicentennial of the Country in 2010. CPB is an integral urban project led by the Ministry of Housing and Urban Development (MINVU). The project program consists of the reconversion of 250 hectares of the former Los Cerrillos Airport into: a 50 ha park; a proposed development of about 16,500 homes to be developed over the next 20 years; the development of Sports Village for the Pan-American Games to be held in Santiago on February 2023; the development of homes to be transferred to the Chilean Air Force; and, apartments for the institution's members. Due to its size and location, the CPB provides an opportunity for implementation of public policies that promote the improvement of the quality of life of its inhabitants and the environment.

Figure 8: Plan City Bicentenario Plan

This project attempts to consolidate a new form of city, which enhances the role of the state in guiding urban development with an emphasis on building socially integrated, environmentally sustainable neighbourhoods, fully equipped with quality public spaces and a very good standard of green open spaces. Emphasis was given to initiatives such as water collection in the lagoon, the integration of urban gardens and organic waste management into the courtyards, climate modelling of the structures and their orientation, and connections with surrounding neighbourhoods.

As a demonstration project for Santiago, this project seeks to set a benchmark for Chile and the Latin American countries in terms of three primary pillars: sustainability and a response to climate change; urban design; and, social integration. It is perceived as an urban laboratory where new urban policies are and will be tested. A mixed-use approach will be employed to assimilate changes that are happening in Santiago into this project. It will be developed by both public and private entities. It is interesting to note that the incorporation of climate change considerations into the project was an outcome of the practitioners from Santiago participating in the Cities Fit for Climate Change.

Figure 9: An image depicting the public open space within Ciudad Parque Bicentenario
Source: Letebele, K.E. (2017) Photographic Image.

A key finding that emerged from Santiago was that Climate change is not an environmental issue, it is about politics, planning and it is a transversal phenomenon. It was also emphasized that it is important to convince political leadership to address Climate Change issues beyond their political term of office to ensure that new leaders assume their predecessor's role and continue advocating for Climate sensitive spatial planning.

3.4 International Dialogue Forum -Chennai, India

The Dialogue Forum in India, Chennai will be held in August 2018. This the third in the series of comprehensive workshops and will build on the outcomes of the previous Dialogue Forums. The third Dialogue Forum will focus on the process that spans from Policy to Action. After having intensively looked at urban development approaches and concepts, urban stakeholders and actors; the idea is to jointly sketch out the path that leads from theory into practice. The focus of the Dialogue will be the Rehabilitation of the Buckingham Canal in Chennai. This process has been generating various social conflicts, related to high levels of pollution as well as periodic floods. The restoration is planned for 3 km of the canal in the southeast sector of the city, and consists of cleaning the river, fencing it off, constructing tracks for running and protecting dikes and other activities. Following the implementation of this project, the restored area could be used as a model for the rest of the canal.

Concluding remarks

The following important lessons were derived from our participation in the Cities Fit for Climate Change program: how to conceptualise and frame climate change responses; how national and city-level policies can support cities in dealing with the impacts of climate change; how valuable the contributions of civil society can be, working in partnership with government; the value of hard science and building scenarios; and, what institutional arrangement within cities and across government are helpful in promoting climate change resilience at the local level.

A strong coherent and coordinated future vision that is owned, not only by city officials and politicians, but by the residents, will assist in embedding climate change adaptation and mitigation measures into local level planning and hold leaders accountable. A common vision can pull together communities, departments within a city and the various government agencies that operate at the local level and galvanise these actors into action.

The climate-proof urban development approach represents an important framework for how to pursue climate change adaptation and mitigation in the context of urban planning. Based on the experiences of the participating German cities, many interesting ideas, urban development processes and lessons learned were identified as being of great use for the cities involved Climate Change projects, as well as for other cities experiencing similar difficulties regarding climate-proofing urban development.

From Green to Resiliency: A Review of Evolution, Experiences and Implementations of American Climate Change Action Plan

LIANG SISI

Tsinghua University. China

1 Introduction

Among the inducements to global climate change, cities with its artificial environment play the most important roles. On the other hand, cities suffer a lot from threatens of global warming, followed sea level rise, and shortage of energy sources. Consequently, urban areas are pivotal to global adaption and mitigation efforts. In the past decades, there has been a lot of countries throughout the world signing agreements as well as launching climate change actions plans. But how do cities actually perform in terms of climate change response? What are the plan visions, how to implement, through what approaches and strategies? This research sheds light on city-level climate action plans in the United States. Since 2000s, there have been over 170 local authorities and municipalities participating into CCP movement (Cities for Climate Protection). Almost all cities in America enacted related climate action plans at least five years ago, and have released a series of reviews and reports in following years. While the review and investigation of plans is beneficial for cities in other countries that are willing to make efforts as response to climate change, there is a lack in current relative literatures that focus on systematically reviewing the planning implementation as well as the policy-making process.

Through reviewing hundreds of climate action plans, this research aims to answer the following questions: (1) how have the values and targets of climate action plan evolved during the past couple of years? (2) which authorities take charge of making the plans, and (3) how to guarantee the implementation and how do plans perform? This paper makes a comprehensive analysis of the plans quantitatively and qualitatively in terms of policy-making stakeholders, planning targets, constitutions, implementation mechanism, and socio-economic guarantee. It then makes a deep review on a series of sustainable plans of New York City from 2007 to 2016.

2 Climate Action Plans in American Cities

2.1 Development of Cities Climate Protection Program

At the federal level, the U.S. has been a slow starter on climate change policy but has shown progress during the Obama administration, with the Clean Power Plan, investments in renewable energy, fuel efficiency standards for cars and the recent refusal of the Keystone XL pipeline. Yet, despite a politically gridlocked congress, 74 percent of Americans favor federal regulation on greenhouse gas emissions, according to a 2015 poll. This reality makes city action all the more important as local governments are able to push for the climate action that Americans are hoping for.

With cities responsible for more than 70 percent of global greenhouse gas emissions, there is an acute need to capitalize on local solutions to climate change, particularly in the lead up to the COP21 climate conference in Paris. American cities are positioning themselves as the true leaders when it comes to tackling climate change, making it clear that action is wanted, needed and possible. Within recent years, U.S. cities have started reducing their greenhouse gas emissions, as their citizens are feeling the impacts of climate change, such as floods, storms and droughts. Local leaders are well-poised to address these problems with adaptation and mitigation measures due to the fact that city governments are smaller and more agile in their decision-making and more directly accountable to their constituents than their national counterparts, making them more able and willing to act. Action at local levels also has the benefit of yielding near-immediate results, while nationwide changes can take a number of years—and political terms—to materialize.

The Cities for Climate Protection program (CCP) is one of three major global transnational municipal networks aimed at reducing urban greenhouse gas emissions. Established in 1990 by the International Union of Local Authorities and the United Nations Environment Program, one of the largest global transnational networks, the International Council for Local Environment Initiatives (ICLEI), presented a framework to represent local government environmental concerns internationally. The ICLEI strives to ‘establish an active and committed municipal membership… that promotes environmental and sustainable development initiatives within…[a] framework of decentralized cooperation’. In 1993, subsequent to an ICLEI successful pilot scheme, the Urban CO2 Reduction Project, the CCP program was established during the post-Rio Earth Summit era. The CCP program illustrates itself within local climate policy, as a transnational governance network. So far, ICLEI USA has worked in hundreds of cities and towns around the country, in red states and blue states, in communities wealthy and underserved. At the local level nearly everywhere is inspiring in its connectivity, tolerance, and dedication to keep and maintain relationships.

100 Resilient Cities (100RC) is an innovative global network pioneered by the Rockefeller Foundation to help cities around the world become more resilient to the physical, social, and economic challenges that are a growing part of the 21st century. New York City was in the first wave to join the network in 2013, and through its participation, demonstrates leadership in resiliency and takes advantage of the resources and opportunities it presents.

2.2 Exemplars

Together with Los Angeles, Chicago, and New York City, the three largest American cities now boast the “80 by 50” target. This signifies the fact that in the U.S., cities are taking lead on developing and implementing the solutions needed to take action on climate change.

Figure 1. Some large cities in the US taking climate action plans

Washington, DC has entered into a 20-year power purchase agreement (PPA) that greens the district’s electricity supply while saving taxpayer money. Under the PPA, the nation’s capital does not pay for the wind farm itself, but rather, agrees to purchase wind electricity every year at a fixed rate 30 percent lower than fossil fuel power. Wind power procured under the PPA will supply roughly one-third of the District government's electricity from a 46 megawatt wind farm.

Portland, Oregon has been an American leader on climate change for many years and its 2015 Climate Action Program takes an innovative step further by analyzing how Portland residents' and businesses' purchasing habits influence greenhouse gas emissions elsewhere in the world. This consumption-based emissions inventory methodology enables the city to track the emissions it is responsible for regardless of where those emissions took place, and to better comprehend exactly how the city contributes to climate change in order to develop additional mitigation opportunities.

According to a recent study, New Orleans, Louisiana is the most at risk of all American cities from rising sea levels, since, by the most conservative estimates, more than 98 percent of its population will live below sea level in the future. Facing complex climate change-related challenges—including diminished protective wetlands, intense storm threats, land subsidence and regular flooding—the City of New Orleans has improved collaboration between agencies to close gaps in services, which has led to a reduction of 135,000 tons of CO2 in municipal energy use related to water management and reconstruction the city's streets, drainage and sewer systems.

In a hallmark challenge to make Philadelphia "The Greenest City in America," Mayor Michael Nutter has committed to reducing the City's exposure to rising energy prices, to limiting the City's environmental footprint, and repositioning the workforce and economic development strategies to leverage an enormous competitive advantage in the emerging green economy. He created the new cabinet-level Office of Sustainability and a Sustainability Advisory Board representing public, private, and nonprofit interests from across the metropolitan area. In April 2009, the City launched "Greenworks," an innovative action plan focusing on Energy, Environment, Equity, and Economy. PWD's Green City, Clean Waters plan integrates management of Philadelphia's watersheds into this larger context. It is designed to provide many benefits beyond the reduction of combined sewer overflows, so that every dollar spent provides a maximum return in benefits to the public and the environment. Philadelphia's Green City, Clean Waters plan is a unique and fresh approach that supports numerous EPA initiatives at a time when our nation's cities need 21st Century solutions to aging infrastructure problems.

3 Evolution of Green Plans in New York City

3.1 PlaNYC 2007-2013

A growing population, aging infrastructure, a changing climate, and an evolving economy posed challenges to the city's success and quality of life. New York City Municipality recognized that they will determine the city's own future by how the citizens as well as local authorities respond to and shape these changes with their own actions.

In 2007, Mayor Michael R. Bloomberg released the first PlaNYC, which focused on responsibly meeting the city's growing population and infrastructure needs. It is a bold agenda to meet these challenges and build a greener, greater New York. Titled 'A Greener, Greater New York', it included the City's initial sustainability strategy, and became the model for other large global cities. PlaNYC outlined measures to address the city's aging infrastructure, support parks, improve the quality of life and health for New Yorkers, and for the first time ever, commit to a goal for reducing greenhouse gas emissions. PlaNYC 2011 expanded on these initiatives by strengthening the City's commitment to environmental stability and livable neighborhoods, launching brownfield cleanups, and improving the quality of our air and water.

Since the first PlaNYC in 2007, the City has made considerable progress on reaching its goals. The city has reduced greenhouse gas emissions 19 percent since 2005, invested billions of dollars to protect our water supply, planted nearly a million trees, installed 300 miles of bike lanes, and passed regulations and developed programs to phase out polluting heating oils. The City also strengthened coastal defenses, fortified crucial infrastructure such as wastewater treatment facilities, and worked to make buildings and neighborhoods more resilient. In just four years the city has added more than 200 acres of parkland while improving existing parks. More than 64,000 units of affordable housing were created or preserved. The government has provided New Yorkers with more transportation choices, and has enacted ambitious laws to make existing buildings more energy-efficient.

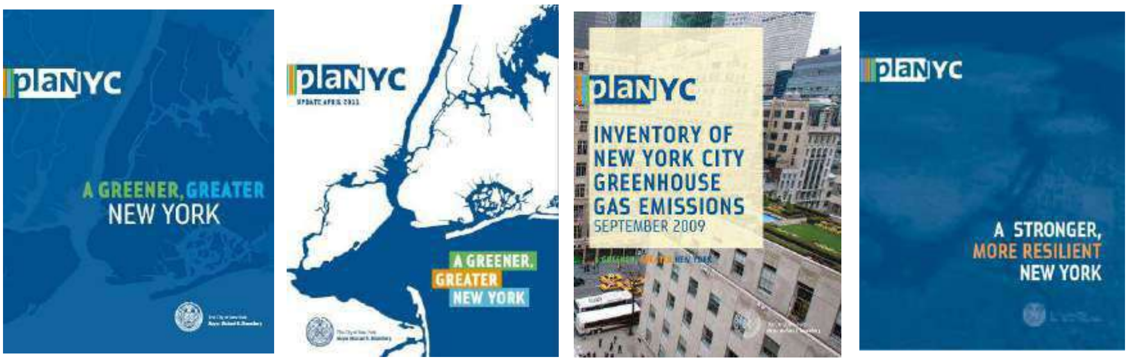

Figure 2. Plans about PlaNYC

In 2013, after Hurricane Sandy, the City released PlaNYC: A Stronger, More Resilient New York, which documented the lessons learned from Sandy, developed a strategy for the city to build back, and developed recommendations to adapt the city to the projected impacts of climate change, including rising sea levels and extreme weather events.

3.2 GIs in New York City

City climate action plans are steering cities in their implementation of policies and actions providing both tangible local benefits and contributing to global impact. Case in New York City shows that cities can leverage the benefits of green infrastructure in their climate action planning.

New York City's efforts to improve water quality are a critical part of PlaNYC, Mayor Bloomberg's blueprint for a greener, greater city. Already the Harbor is cleaner than it has been in over 100 years, and millions of people enjoy the City's waterfront and waterways every year, thanks in part to the New York City Department of Environmental Protection's (DEP's) investment of billions of dollars in sewer and wastewater treatment plant upgrades. But in those waterbodies that do not yet meet water quality standards for pathogens, the biggest remaining challenge is to further reduce combined sewer overflows (CSOs) that discharge a mixture of untreated sewage and stormwater runoff when it rains. Traditional approaches to reduce CSOs further would include the construction of additional, large infrastructure, but the remaining opportunities for such construction are very expensive, and do not provide the sustainability benefits that New Yorkers rightly expect from multi-billion dollar investments of public funds.

The Green Infrastructure Plan presents an alternative approach to improving water quality that integrates "green infrastructure," such as swales and green roofs, with investments to optimize the existing system and to build targeted, smaller-scale "grey" or traditional infrastructure. This is a multi-pronged, modular, and adaptive approach to a complicated problem that will provide widespread, immediate benefits at a lower cost. The green infrastructure component of this strategy builds upon and reinforces the strong public and government support that will be necessary to make additional water quality investments. A critical goal of the green infrastructure component is to manage runoff from 10% of the impervious surfaces in combined sewer watersheds through detention and infiltration source controls.

This Green Infrastructure Plan builds upon and extends the commitments made in PlaNYC and the Sustainable Stormwater Management Plan. This plan provides a detailed framework and implementation plan to meet the twin goals of better water quality in New York Harbor and a livable and sustainable New York City. The analysis in this Green Infrastructure Plan is based upon the predicted impacts of the strategy on CSO volumes in individual watersheds and upon the City's estimates of capital and operating costs. Further analysis, which is substantially under way, will refine the modeling and projections in this report by using more updated geospatial impervious data, incorporating detention technologies, and assessing the impact of CSO reductions on water quality. It will also present data about the operating costs, maintenance, and performance of the green infrastructure projects currently underway. This Green Infrastructure Plan forms a framework for CSO reduction strategies and investments over the next 20 years and will lead to both clean waterways and a greener, more sustainable city.

3.3 Evolution of a Solid Foundation

New Yorkers have a long and proud tradition of confronting tough issues head on, with determination and heart, and having the skills to get the job done. Through it all, the city has remained tolerance and diversity, one that has drawn people from around the world since the origins as a Dutch settlement. The government has a noble history of innovating urban policies that have been adopted across the country and around the world. The city created the first fire districts and a Board of Health committed to eradicating cholera and other epidemics, a system of reservoirs to bring water to the city and engaged creative designers to build great public parks, a citywide zoning ordinance that became a worldwide model. The government pioneered school meals programs, settlement houses for a booming immigrant population, and social programs that became a template for the New Deal and the Great Society. Today, it is leading the way in curbing greenhouse gas emissions and preparing for climate change.

From 2012 to 2014, the de Blasio administration of New York City presented a series of long-term goals and strategies, and launched comprehensive initiatives across City agencies. For instance, Pre-K to all is a plan to create a truly universal pre-kindergarten system, with a seat in a high-quality pre-kindergarten class for all four-year-olds in need of such services. Vision Zero commits the City to using every tool at its disposal to improve the safety of our streets and to reduce traffic fatalities to zero. One City: Built to Last commitment to cut its greenhouse gas emissions 80 percent by 2050 focusing on reductions in buildings, which are responsible for nearly three quarters of the city's contribution to climate change. Housing New York is an ambitious ten-year plan that addresses New York's housing crisis by building our next generation of affordable housing and supporting the quality of life in our neighborhoods. Career Pathways is a plan to create a more comprehensive, integrated workforce development system and policy framework focused on skills building and job quality. One City, Rebuilding Together aims to overhaul the Build It Back program to accelerate the Sandy recovery process for homeowners and establish targets for reimbursements and construction starts. It also established a first-ever Mayor's Office of Recovery and Resiliency to lead the City's climate adaptation and resiliency program.

The city released a series of plans in 2015. IDNYC provides a free identification card to every city resident, including the most vulnerable populations who may have difficulty obtaining other government-issued ID, and provides access to services and programs offered by the City and other businesses. New York City Community Schools Strategic Plan provides key system-building efforts that will be implemented over the next three years to achieve and surpass the City's initial goal of establishing 100 fully developed Community Schools to improve student achievement through strong partnerships among principals, parents, teachers and Community Based Organizations. The CEO Poverty Measure Report is an annual report by the Center for Economic Opportunity in the Office of the Mayor that measures poverty in New York City and is aligned with OneNYC's focus on anti-poverty goals. The CEO measure improves on the official methodology by considering the cost of living in New York City and the resources available to households after tax and social policy is taken into account. Ten-Year Capital Strategy provides a blueprint for capital spending over the next decade. OneNYC and the Ten-Year Capital Strategy are aligned to ensure funding for OneNYC goals.

These initiatives have already begun to show results, which become a solid foundation for city mission transforming from single green toward resilient development.

Figure 3. Evolution of several long term goals and strategies after PlaNYCs

4 From Green to Resiliency: One New York

As a pacesetter in sustainable American city development, New York City faces more opportunities and choices for urban development. It cannot fully predict its vulnerability because of the difficulty in foreseeing urban disasters, risk degree, and potential losses. Coupled with its high susceptibility and low adaptability, any serious disaster may be disastrous. Consequently, it is significantly important to ensure the safety of New York City. Resilient city aims to make citizens and property perform better than those relatively lack of flexibility and adaptability under extreme pressure while subjected to major disaster attacks (Bolin and Stanford, 1998).

From the perspective of etymology, the word of "resilience" first came from the Latin word "resilio," with the meaning of "returning to the original state" (Alexander, 2013). After going through the three stages of engineering resilience, ecological resilience, and evolution resilience, it has been formally applied to urban studies. At present, evolution resilience is more academically accepted. Shao Yewen et al. (2015) argue that resilient city emphasizes the continuous adaptation, learning ability, and innovation, and has the attribute of dynamic systems closely related to continuous adjustment. Xu Jiang et al. (2015) proposes the issue that resilient city has to solve is adaptability when social ecosystem faces "uncertain disturbances," laying more emphases on the systematic and long-term city security and showing more respects for the evolution law of urban systems. Jha et al. (2013) argue that resilient city should have four characteristics involving infrastructure resilience, institutional resilience, economic resilience, and social resilience, so as to mitigate urban crisis in a number of aspects. Although domestic and foreign scholars differ in their interpretations on resilient city, there is a general consensus on the idea that resilient city should have dynamic learning ability, multi-dimensional dispersion of external disturbance, and the ability to mobilize social forces (Davoudi, Shaw, and Haider, 2012; Allan and Bryant, 2011; Jabareen, 2013; Campanella, 2008; Ahern, 2011; Zheng, 2013).

With 45 percent of residents at or near the poverty line, New York City recently launched OneNYC—a comprehensive plan to for sustainable development in the Big Apple with a special focus on socioeconomic equity that aims to lift 800,000 New Yorkers out of poverty by 2025 as well as reducing CO2 emissions by 80 percent by 2050. The plan: One New York: The Plan for a Strong and Just City builds upon these initiatives as a launching point for the ambitious goals set forth in this plan. With the launch of OneNYC, the municipality builds on New York City's global leadership when it comes to growth, sustainability, and resiliency—and embrace equity as central to that work. The plan includes adaptation measures to protect vulnerable, low-income communities from flooding and long term displacement after shock events, like Superstorm Sandy. OneNYC will also ensure that, by 2040, 90 percent of New Yorkers can reach at least 200,000 jobs by transit within 45 minutes by 2040.

Figure 4. Cover of OneNYC

4.1 Concepts and Focuses

OneNYC is a citywide effort. Nearly all City agencies came together in cross-cutting working groups that examined underlying trends and data in order to develop new initiatives. The working groups were tasked with envisioning how the physical city should be shaped to address a range of social, economic, and environmental challenges on the municipal and regional scale.

Extensive pre-launch discussions with New Yorkers directly shaped the goals and initiatives detailed in this plan. When nearly 3,500 people submitted comments to the online survey about housing and affordability, the research group affirmed the affordable housing commitments in Housing New York, the City's ten-year housing plan. That plan lays out strategies to create and preserve 200,000 affordable housing units over the next ten years. OneNYC now sets a goal of creating 240,000 new housing units—both market rate and affordable—within the next decade. It also calls on governments across our region to support efforts to create new housing throughout the metro area. Other feedback focused on providing New Yorkers with transit access from their homes to good jobs. Through transit investments, job creation in diverse locations, and transit-accessible housing construction, this plan will ensure that by 2040, the average New Yorker will be able to reach 1.8 million jobs by transit within 45 minutes. Survey respondents requested that to reduce garbage in New York because it's good for the environment and our neighborhoods. Consequently the city has responded with a strategy to achieve Zero Waste by 2030.

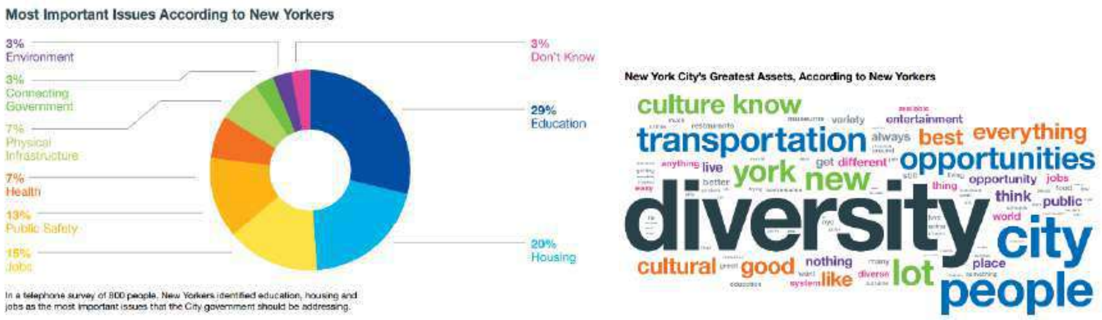

Figure 5. Survey of New Yorkers about most important issues and Keywords

Previous PlaNYC reports have focused on the pressing issues of growth, sustainability, and resiliency. All of these goals remain at the core of OneNYC, but there are three significant differences in the approach taken with this plan: focus on inequality, a regional perspective, and leading the change in need.

With the poverty rate remaining high and income inequality continuing to grow, equity has come to the forefront as a guiding principle. This plan envisions a city that is growing, sustainable, resilient, and equitable—a place where everyone has a fair shot at success. The explicit addition of equity is critical, because a widening opportunity gap threatens the city's future. These four pillars, growth, equity, sustainability, and resiliency together will spur the innovation we will need for the next century.

To make the changes we need, OneNYC recognizes that citizens need to reach out to the neighbors so that the whole region may thrive. The strength of the city is essential for the strength of the region, and strong communities around the city make it more competitive nationally and globally.

Figure 6. Development of New Visions for OneNYC

While New York City has a vast and complex government, even one of its scale cannot accomplish all that needs to be done on its own. While City government will take the lead in every single aspect of OneNYC, this plan also calls for action from other levels of the public and even private sector. That means calling for some actions that are not entirely within the control of the City government, but they are all steps that are credible and necessary.

4.2 Visions and Strategies

New York City's success has brought many benefits, but the city also faces significant challenges. Thus it is time to build on the strengths and address these challenges and opportunities. The city is at risk when so many New Yorkers struggle to find living-wage jobs, good schools for their children, affordable housing, and neighborhoods and communities they can proudly call their home for years to come. OneNYC builds upon the four core challenges addressed in past PlaNYC reports, and now includes growing inequality, the importance of the region, and New York City voices.

The plan runs the risk of becoming two New Yorks: one for the affluent and one for those who are left out of the city's success and lack access to good schools or good wages for hard work. Now the plan chooses to confront these challenges will define the future of New York City and what kind of city left to our children.

OneNYC conducts four principles which informed the plan's goals and initiatives: growth, equity, sustainability, and resiliency. "Growth" refers to population growth, real estate development, job creation, and the strength of industry sectors. "Equity" is about fairness and equal access to assets, services, resources, and opportunities so that all New Yorkers can reach their full potential. "Sustainability" contains strategies improving the lives of our residents and future generations by cutting greenhouse gas emissions, reducing waste, protecting air and water quality and conditions, cleaning brownfields, and enhancing public open spaces. Finally, "resiliency" is related to the capacity of the city to withstand disruptive events, whether physical, economic, or social.

Figure7. Four Pillars of OneNYC

In each vision, the OneNYC sets up a series of goals, followed by deep description on each goal. The descriptions includes indicators, target, and figure for most recent year in each goal. Furthermore, there are about 3-5 initiatives in each goal, accompanying with the departments and authorities which enact the initiatives as well as sources of budget. The table below shows the funding status and funding source for each OneNYC initiative and supporting initiative. Specific funding details for newly funded initiatives are available in a separate table featured in the FY'16 Message of the Mayor, and are marked with an asterisk.

Figure 8. Vision, goals and initiatives

Vision 1: Our Growing, Thriving City

VISION 1

INDUSTRY EXPANSION AND CULTIVATION

Initiative 1 Maintain New York as the global capital for innovation by supporting high-growth, high-value industries	A. Maintain and grow New York City's traditional economic sectors.	DCP and others	Budget neutral	N/A
	B. Ensure that businesses in emerging sectors are able to find and fit out the space they need to start, grow, and scale their companies.	EDC	In planning	N/A
Initiative 2 Make triple bottom line investments in infrastructure and City-owned assets to capture economic, environmental, and social returns	A. Support a state-of-the-art food production and distribution industry.	EDC	Funded*	City capital
	B. Activate the City's industrial assets to support the creation of quality jobs.	EDC	Funded*	City capital
Initiative 3 Foster an environment in which small businesses can succeed	A. Reduce the regulatory burden on small businesses through the Small Business First plan.	SBS	Funded*	City capital

WORKFORCE DEVELOPMENT

Initiative 1 Train New Yorkers in high-growth industries, creating an inclusive workforce across the city	A. Establish and expand Industry Partnerships.	SBS	Funded*	City operating
	B. Use Common Metrics for workforce programs.	Mayor's Office	Funded*	City capital and operating
	C. Create bridge programs to prepare low-skill job seekers.	DYCD, Mayor's Office	Funded*	City operating
	D. Ease path to employment for formerly incarcerated people.	Mayor's Office	Budget neutral	Regulatory/ legislative
Initiative 2 Leverage OneNYC investments to train and employ New Yorkers of all skill levels	A. Leverage City investments to create jobs and training opportunities for New Yorkers, and encourage targeted hiring.	SBS	Funded*	City capital and operating
	B. Capitalize on the Career Pathways Construction Industry Partnership to create and expand construction training and employment opportunities for traditionally underrepresented New Yorkers.	SBS	Funded*	City operating
	C. Support the creation of, and training for, green jobs	DEP, Mayor's Office	Funded	City operating
Initiative 3 Ensure that all New York City students have access to an education that enables them to build 21st century skills through real-world, work-based learning experiences	A. Significantly expand access to computer science/technology education across New York City public schools by 2020.	DOE	In planning	N/A
	B. Strengthen and expand Career and Technical Education programs.	DOE	In planning	N/A
	C. Expand Transition Coordination Centers to every borough by 2020 to improve postsecondary outcomes for students with disabilities.	DOE	In planning	N/A
	D. Explore the opportunity to create bilingual learning environments to promote multilingualism among New York City students.	DOE	Budget neutral	City operating
Initiative 4 Increase postsecondary attainment	Increase postsecondary attainment by promoting high-school graduation, college matriculation and degree completion.	CUNY, DOE	Funded	City operating

Figure 9. Initiatives, Implementation Authorities, and Budget

4.3 Progressive Evaluation

OneNYC emphasizes the initiatives and milestones for the pillar of "resiliency". At the end of this plan, it reported the progressive outcomes of each initiatives in the aspects of resiliency, following with description of initiative status, 2014 milestones, and status of milestones. It is worthy to mention that the plan divided each initiative into detailed approaches and strategies. For instance, in the initiative of “strengthen the quality of available climate analysis”, there are six steps, such as “Work with FEMA to improve the flood-mapping process” (in progress), “Call on the State and Federal governments to coordinate with the City on local climate change projections” (completed), and so on.

Chapter	Initiative No.	Initiative	Initiative Status	Initiative Status Description	2014 Milestone	Milestone Status
CLIMATE ANALYSIS	**STRENGTHEN THE QUALITY OF AVAILABLE CLIMATE ANALYSIS**					
	1	Work with FEMA to improve the flood-mapping process	In Progress	The City continues to work with FEMA to improve the flood mapping process and provided expert analysis in FEMA's most recent release of Preliminary FIRMs. The first Technical Mapping Advisory Council meeting, on which the City sits, was held in September 2014. The next one will be held in May 2015.	Implement technical and process improvements	Completed
	2	Work with FEMA to improve the communication of current flood risks	In Progress	The City has partnered with the Center For New York City Neighborhoods (CNYCN) on its interactive webtool (floodhelpny.org), which was launched in September 2014. Additionally, the City is conducting a consumer education campaign and developing tools for explaining flood risk and the changes that are coming to the maps and insurance programs. Finally, the City continues to advise FEMA on its local flood risk messaging and online tools.	Launch a new interactive tool	Completed
	3	Call on the State and Federal governments to coordinate with the City on local climate change projections	Completed	NOAA and the USACE have agreed to incorporate the most recent NPCC projections into their climate models.	Obtain Federal agreement to rely on NPCC	Completed
	4	Continue to refine local climate change projections to inform decision-making	Completed	The City released expanded NPCC projections to include humidity and new projections through 2100. NPCC3 will focus on the following: enhancing coordination across the entire New York metropolitan region, looking at a neighborhood scale, and studying the interactions of mitigation, adaptation, and equity.	Issue expanded NPCC projections; release evaluation metric for climate change	Completed
	5	Explore improved approaches for mapping future flood risks, incorporating sea level rise	In Progress	The City, with Stevens Institute of Technology, has completed its study of Sea Level Rise mapping, which was incorporated into the NPCC's most recent report. NPCC has also developed future flood maps to show the projected floodplains.	Develop revised future flood maps	Completed
	6	Launch a pilot program to identify and test strategies for protecting vulnerable neighborhoods from extreme heat health impacts	In Progress	The City, in partnership with the Nature Conservancy, has launched a new urban heat island working group to develop new monitoring methods and tools for mitigating heat risk.	Launch pilot program	Partially Completed

Figure 10. Detailed analysis of resiliency development

5 Conclusion

One trend we’ve identified is that American cities are positioning themselves as the true U.S. leaders in combating climate change, making it clear that action is wanted, needed and possible. American cities are positioning themselves as the true U.S. leaders in combating climate change, making it clear that action is wanted, needed and possible.

Based on a series of green plans, the climate action plans have moved their targets from simply reducing GHG toward creating a resilient city that not only mitigating hazards to environment but also improving social performance. The stakeholders involved in the plan vary a lot, depending on different local circumstance. But there is an increasing number of cities calling for collaboration among market, government and public citizens. With regard to the content of climate action plans, strategies have evolved from simply reducing energy consumption and gas relief toward multiple approaches in addressing social and economic vulnerability involving neighborhood, building, urban infrastructure, and specific geographic issues. The efforts for sustainable development require a transformation of policy from green development toward improvement on resiliency. Thus, further changes to planning implementation in terms of financial support, public participation, and post-evaluation mechanism will be still needed.

Case Study: incorporating climate change resilience into spatial development tools in South Africa

MANYIKE, Sagwata

South African National Biodiversity Institute, South Africa

Abstract

The Biodiversity and Land Use Project, which is funded by the Global Environmental Facility through the United Nations Development Programme aims to support improved regulation and land use management that ensures that biodiversity continues to provide essential ecosystem services at the municipal scale. South Africa has a rich history in systematic biodiversity (conservation) planning and the output of that process is a Map of Critical Biodiversity Areas and Ecological Support Areas (CBA Map). When these maps are developed, they incorporate climate change adaption areas, ecological infrastructure, as well as a host of priority biodiversity features such as threatened ecosystems and species of special concern. The Biodiversity and Land Use Project is piloting several ways in which the CBA Map can be integrated into the tools which municipalities (local governments) need to develop in terms of the recently promulgated Spatial Planning and Land Use Management Act. The key tools which the Project is aiming to integrate the CBA Map into are the municipal Spatial Development Frameworks and Land Use (Zoning) Schemes.

1. Introduction

South Africa recently promulgated its Spatial Planning and Land Use Management Act (no 16 of 2013) (SPLUMA) which aims to bridge the gap between spatial planning and land use management within the country. This paper will first explore the changes that the new planning Act brings to the spatial planning and land use management arena within the country. Then an explanation of how the Map of Critical Biodiversity Areas and Ecological Support Areas (CBA Map) are developed, including how they have incorporated both climate change adaptation and ecological infrastructure will be provided. CBA Maps are defined as a map which represents spatial sustainability (SANBI, 2017). Lastly, a discussion on how the Biodiversity and Land Use Project will attempt to integrate the CBA Map into Spatial Development Frameworks and Land Use (Zoning) Schemes will be discussed.

The Biodiversity and Land Use Project is based within the South African National Biodiversity Institute (SANBI) which is a parastatal body which provides science based policy advice to the Department of Environmental Affairs. The Project is funded by the Global Environmental Facility through the United Nations Development Programme. This is a five year project which began in 2015 and aims to support improved regulation and land use management to ensure that biodiversity continues to provide essential ecosystem services at the municipal scale. The Project is operating in four District Municipalities in South Africa: Ehlanzeni in Mpumalanga, uMgungundlovu in Kwa-Zulu Natal, Amathole in the Eastern Cape and Cape Winelands in the Western Cape.

Figure one below provide the project sites in South Africa.

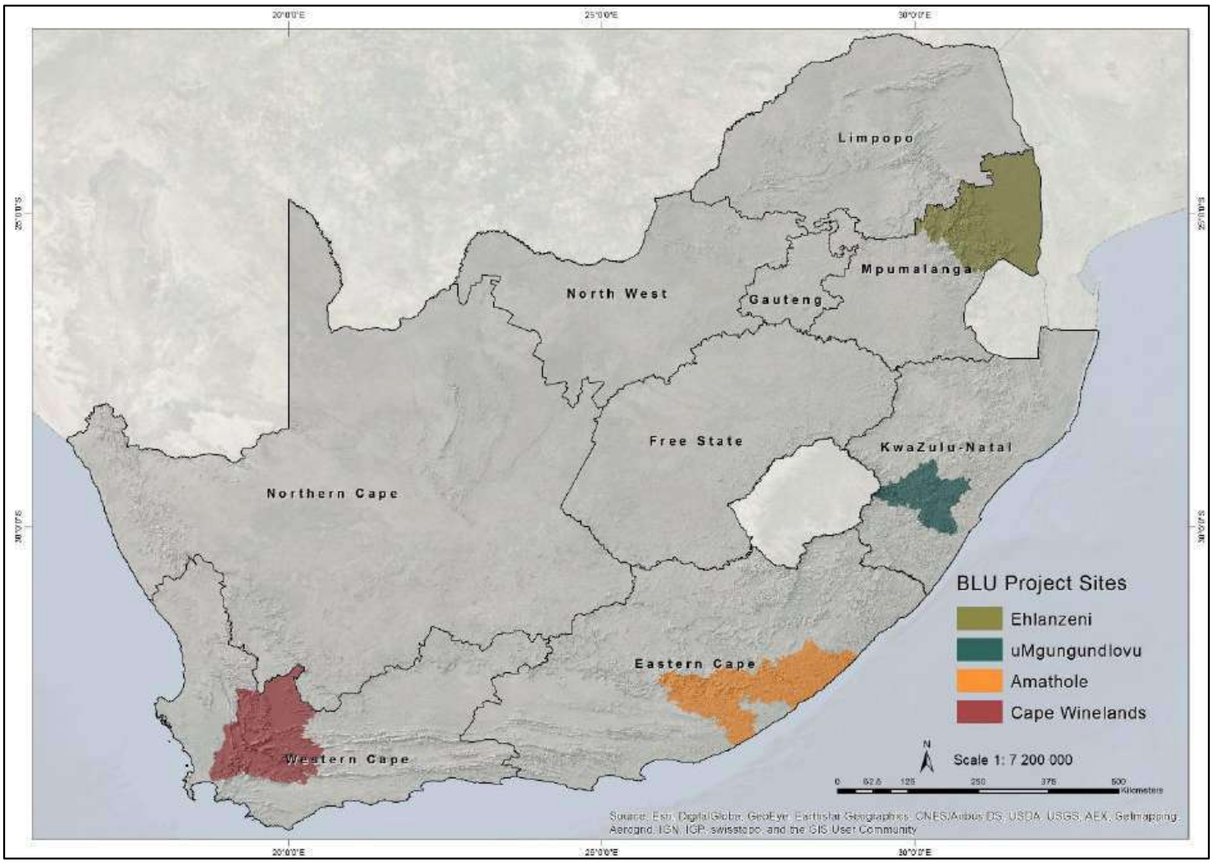

Figure 1: Biodiversity and Land Use Project sites (SANBI, 2018)

2. Spatial Planning and Land Use Management in South Africa

Before South Africa enacted the SPLUMA, provincial governments were responsible for both spatial planning and land use planning. In some areas, provinces delegated decision making powers over certain categories of land development applications to municipalities (Nel, 2016). However, most provincial governments maintained their ability to adjudicate appeals. Municipal Planning is listed under Part B of the South African Constitution as part of the local government competencies (Constitution of RSA, 1996). However, the Constitution does not provide a definition of municipal planning, resulting in provincial governments continuing to make municipal planning decisions. It was only in 2010 that municipalities began asserting their rights in making decisions with regard to municipal planning. As a result a number of Constitutional Court challenges were instituted among others are the Johannesburg Metro (a municipality) vs Gauteng (a Province) Development Tribunal, Shelplett 47 Pty Ltd vs Member of the Executive Council for Environmental Affairs & Development Planning (Western Cape) (Nel, 2016). The Constitutional Court in these instances ruled in favour of municipalities which are responsible for municipal planning. These judgements set out rules on what municipal planning should entail and these included land use decisions. The judgments further clarified that national decisions cannot override municipal ones. Through these judgements, provincial governments were also barred from deciding on the appeals that dealt with municipal planning. SPLUMA was therefore a response to all of these judgements and as South Africa had never had a national planning Act before, SPLUMA defined how spatial planning and land use management should operate within the country, while also taking the Constitutional Court judgements into account.

Although SPLUMA was signed into law in 2013, it only came into effect on the 1st of July 2015 after a Presidential Proclamation. SPLUMA seeks to create a uniform way of addressing land use management and spatial planning in the country. It further specify the relationship between spatial planning and land use management systems (SPLUMA, 2013). The current SPLUMA Regulations deal with Chapter 6 of SPLUMA, Land Development Applications.

Unlike the previous provincial planning legislation of South Africa, SPLUMA proposes 5 normative principles which are aimed at guiding spatial planning and land use planning in the country and these are:

- Spatial Justice-*past imbalances need to be addressed through improved access to and use of land*
- Spatial Sustainability-*promote land development that is within the fiscal, institutional and administrative means of the country while adhering to environmental management instruments*
- Efficiency-*decision making procedures are designed to minimise negative financial, social, economic or environmental impacts*
- Spatial Resilience-*whereby flexibility in spatial plans, policies and land use management systems are accommodated to ensure sustainable livelihoods in communities most likely to suffer the impacts of economic and environmental shocks*
- Good Administration-*all spheres of government ensure an integrated approach to land use and land development that is guided by the spatial planning and land use management systems as embodies in this Act.*

Some of the changes that SPLUMA brings are among others are as follows: a) it makes municipalities the authority of first instance in all land development applications; b) if a land development application requires approval from another government institution, such as environmental authorisation in terms of the National Environmental Management Act (no 107 of 1998), then both approvals need to be obtained before the commencement of such development; c)in addition, SPLUMA mandates that land development applications be approved by either an authorised official or a Municipal Planning Tribunal. This was a move away from previous practice wherein, the executive authority of the municipality was responsible for the authorisation. However, appeals are still decided by the executive authority of the municipality or the executive authority can delegate this responsibility to an institution/tribunal. SPLUMA also requires all municipalities to have wall to wall land use schemes (previously known as zoning or town planning schemes) within 5 years of the implementation of SPLUMA. This means that areas which were previously excluded from schemes now need to be included, such as rural areas and areas under traditional authority.

The changes that SPLUMA has brought has presented the ideal opportunity for the Biodiversity and Land Use Project to ensure that CBA Maps get incorporated when those wall to wall land use schemes are developed. Details around how the CBA Map is developed will be discussed in more detail below.

3. Climate Change and Biodiversity Planning in South Africa

South Africa has moved away from conservation planning towards biodiversity planning as conservation planning has a protected areas connotation and the CBAs which we develop are not protected areas. Also, protected areas have a long history of excluding certain racial groups during the former Apartheid government and as such, we have moved towards biodiversity planning which is more inclusive.

Although South Africa is a signatory to the Convention on Biological Diversity and is compelled to adopt the principles embedded in Local Agenda 21, the implementation of these within the country has had some challenges. According to Pierce, Cowling, Knight, Lombard, Rouget, and Wolf (2005) some of the challenges with local governments adopting environmental sustainability principles in Agenda 21 is that local government decision makers lack an awareness of the importance of planning to protect biodiversity priority areas as identified through conservation assessments. Pierce *et al* (2005) go on to argue that there is a disjunction in the structure and content of conservation plans and those required for land use planning; and that municipal land use planners lack the capacity to effectively integrate biodiversity into planning products.

Biodiversity planning in South Africa has since moved to incorporate some of the challenges which Pierce *et al* (2005) identified. As a result, as of 2017, all the provinces and some municipalities in South Africa have Provincial Biodiversity Sector Plans (SANBI, 2017). The Biodiversity Sector Plans are the CBA Map with land use guidelines, which indicates what land uses are compatible within the various CBA Map layers and these layers will be discussed in more detail below.

The concept of ecological infrastructure has recently gained traction within the country. Ecological infrastructure can be defined as naturally functioning ecosystems that deliver valuable services to people and ecosystems (SANBI, 2013). A single piece of ecological infrastructure often has several benefits such as a wetland providing both water purification and flood attenuation services. Although mapping ecological infrastructure is still in its infancy in South Africa, many CBA Maps already include elements of it as either part of their Critical Biodiversity Area or Ecological Support Areas layers (SANBI, 2017). According to SANBI (2017) South Africa has been able to map ecological infrastructure for water source areas, wetlands, riparian zones, coastal dunes, spawning grounds, and natural forage for pollinators. Given that many of the elements above are directly related to climate change adaptation and disaster risk reduction, these have been used as a proxy for climate change adaption mapping within this paper.

According to SANBI (2017), the CBA Map identifies a set of biodiversity priority areas, called Critical Biodiversity Areas (CBAs) and Ecological Support Areas (ESAs). Both of these as well as the protected areas (national parks, nature reserves, etc.), are important for the persistence of a viable representative sample of all ecosystem types and species as well as the long-term ecological functioning of the landscape as a whole. SANBI further indicates that the CBA Map is made up of 5 key features:

- Protected Areas (*areas that have been formally declared or recognised in terms of the National Environmental Management: Protected Areas Act (57 of 2003), including National Parks, Nature Reserves, etc.*)
- Critical Biodiversity Areas (*areas outside the Protected Areas network and must be maintained in a good ecological condition (natural or near-natural state) in order to meet biodiversity targets)*
- Ecological Support Areas (*areas that must be maintained in at least a fair ecological condition (semi-natural/moderately modified state) in order to support the ecological functioning of a CBA or Protected Area, or to generate or deliver ecosystem services, or to meet remaining biodiversity targets for ecosystem types or species when it is not possible or necessary to meet them in natural or near-natural areas*)

- Other Natural Areas (*areas in a fair or good ecological condition that fall outside the protected area network and fall outside of CBAs and ESAs. However, these areas can be demarcated as CBAs or ESAs if the existing CBA's and ESA's are destroyed)*
- No Natural Remaining (*areas with no natural habitat remaining and include areas that have been irreversibly modified (transformed) such as urban and industrial areas)*

Areas for climate change adaption which can act as climate change refugia at the local scape or areas which provide landscape scale gradients for the movement of species in response to climate change are all also important for ecological processes. (SANBI, 2017). Therefore, climate change is intricately integrated into the development of the CBA Map.

SANBI (2017) recommends that the input layers for developing a map of CBAs and ESAs should, at least, include the following:

- Biodiversity features
    - Ecosystem types (classified and mapped)
    - Species of special concern
    - Unique or special habitats or features
    - Areas important for ecological infrastructure
- Protected areas
- Ecological condition, including land cover
- Socio economic constraints and opportunities in the landscape

Below is an example of the CBA Map for the Western Cape Province (Pool-Stanvliet, Duffell-Canham, Pence and Smart: 2017)

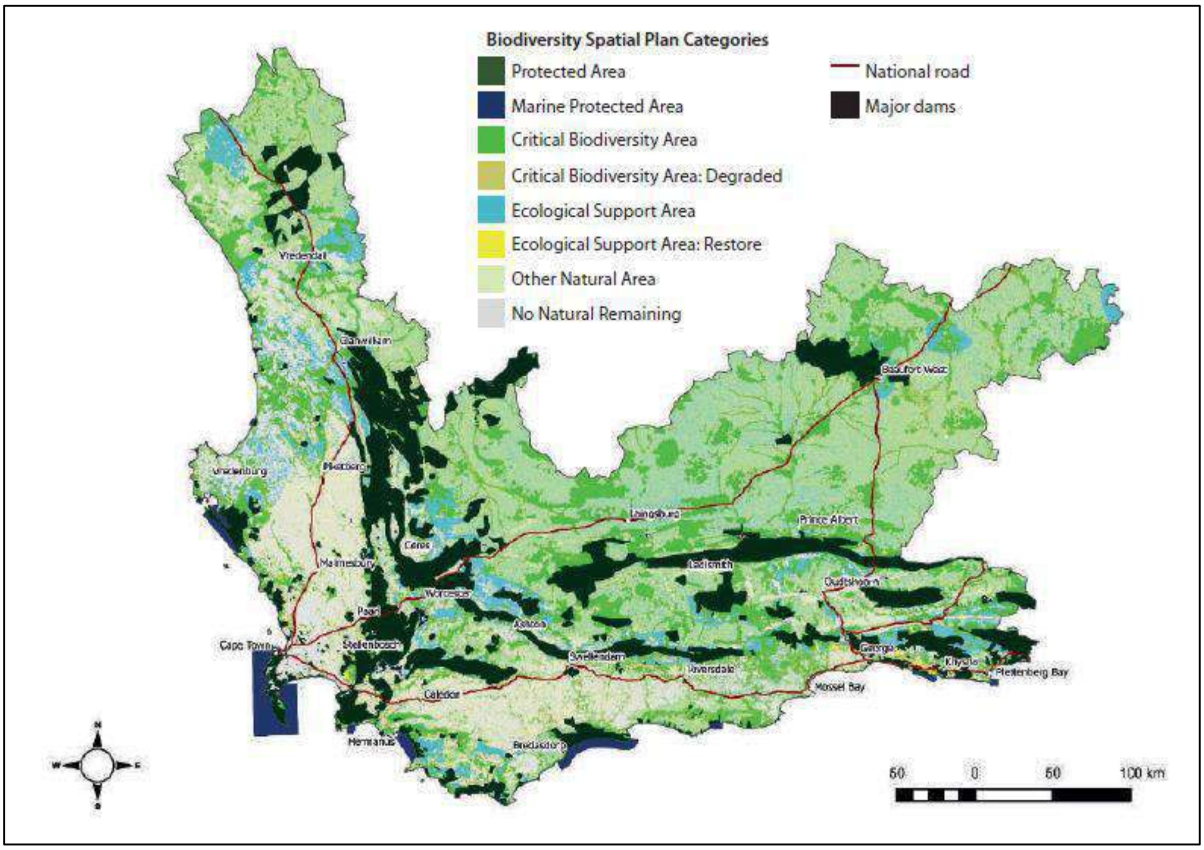

Figure 2: Biodiversity Sector Plan for the Western Cape, 2017 (CapeNature, 2017)

In this paper the Biodiversity and Land Use Project argues that within the South African context, the best tool to incorporate both climate change and biodiversity considerations into municipal spatial planning and land use process is through the integration of the CBA Map into spatial development processes. Therefore, the Biodiversity and Land Use Project has been integrating the CBA Map into both Spatial Development Frameworks and Land Use Schemes which are discussed in the section below.

4. Integrating the CBA Map into Spatial Development Frameworks

Although SPLUMA governs the development of Spatial Development Frameworks (SDFs), because the SDF's are still a core component of the municipal Integrated Development Plans (IDP), they are also governed by the Local Government: Municipal Systems Act (no 32 of 2000). According to Ruwanza and Shackleton (2015), the IDP is the primary tool to achieve integrated territorial development and guide the work of municipalities. This severely limits the effectiveness of SDF's in South Africa as IDP's are updated every 5 years, linked to general political elections cycle. However, attempts are currently underway to decouple the SDF from the IDP process as the SDF's are long term plans which should not be overly tied to the political term of a particular political party.

One of the key ways in which we have been integrating biodiversity and climate change into SDF's is by incorporating it as part of either the open space system or as part of the environmental management area of the municipality. Within some of the municipalities we have been working with, we found that they prefer to flatten out the various layers from their CBA Map and treat all of the layers the same way. Bushbuckridge Local Municipality, which falls within Ehlanzeni District in Mpumalanga is an example of such a municipality which has chosen to go this route. In Figure 3 below, the large protected area to the west of the municipality is the Kruger National Park which is one of the largest national parks in Africa. The municipality has decided to treat both the Protected Areas and the CBA's and ESA's as a single layer and they have called this new layer the Environmental Management Area. Although SANBI finds this to be an effective approach as it helps to protect CBA's, this approach has some disadvantages such as being externally land hungry and not allowing the town planners in that municipality to make full use of the compatible land uses within the CBA Map. However, as this is a predominantly rural municipality which suffers from a lack of capacity, this is seen as an ideal way to protect biodiversity and to allow the municipality to plan for climate change.

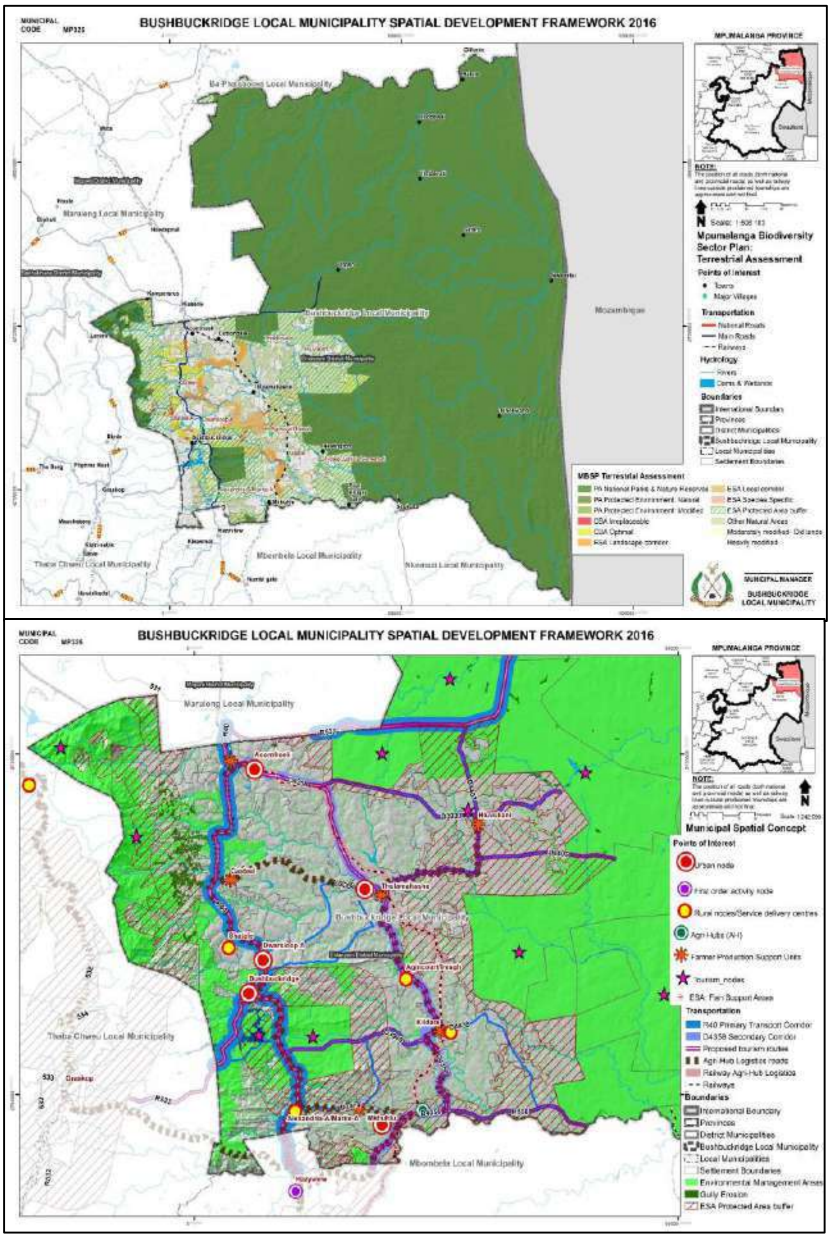

Figure 3: Bushbuckridge Local Municipality Conservation Plan and SDF, 2017 (Bushbuckridge Local Municipality, 2017)

Msunduzi Local Municipality in uMgungundlovu District in Kwa-Zulu Natal has chosen to refer to its environmental framework as ecological infrastructure. This is a more urban and a relatively well capacitated local municipality. Their ecological infrastructure framework is primarily based on their Metropolitan Open Space System (which includes the CBA Map), the findings of some of their Strategic Environmental Assessments and the various types of ecological infrastructure as discussed above. Within their final SDF, they have incorporated it into their Green Structure category. As the Biodiversity and Use Project, we have found that calling their environmental framework ecological infrastructure is a very useful as it ensures that climate change is integrated into their SDF.

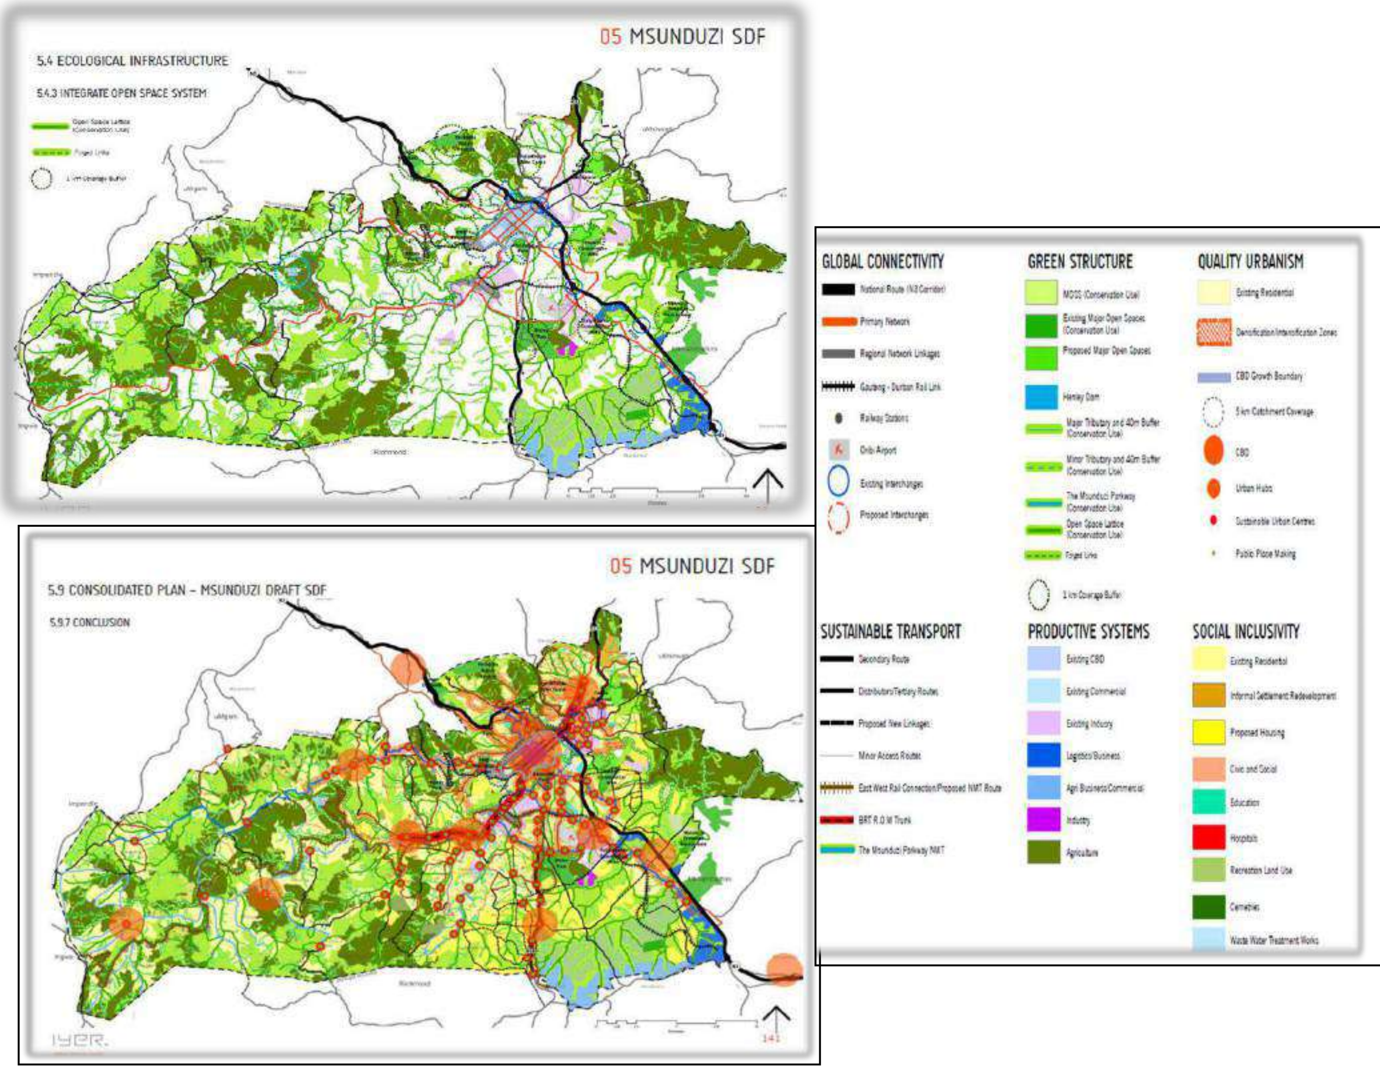

Figure 4: Msunduzi Local Municipal Spatial Development Framework, 2014 (Msunduzi Local Municipality, 2014)

5. Integrating the CBA Map into Land Use Schemes

Nel (2016) claims that, although SPLUMA allows for municipalities to develop land use schemes, these are in conflict with the normative principles which it proposes, mainly spatial justice which aims to promote integration and inclusion. However, these are challenges which we have chosen not attempt to address through the Biodiversity and Land Use Project as these are structural in nature and would take longer than the Project's lifespan to attempt to resolve.

Accordingly to Nel (2016) zoning drives land value as it determines properties development potential, along with its location. Therefore, municipalities in South Africa have traditionally looked at the properties which have been zoned for public open space under their ownership as the first pieces of land which they auction off to private developers. In an attempt to counteract some of this inherent bias of municipalities, particularly in the more rural ones, the Biodiversity and Land Use Project has been undertaking extensive capacity development interventions to inform municipal officials and politicians of the benefits of appropriately managing their biodiversity and planning for climate change. This is where we have found the term ecological infrastructure to be particularly beneficial as it speaks directly to the mandates of municipalities in providing services for their inhabitants.

The Biodiversity and Land Use Project has further been funding the development of land use schemes within some of the municipalities that we are working in. This has provided us with the opportunity to influence the process which we ordinarily would not have had as most conservation agencies are regulated to a commenting authority within the development of municipal schemes. The Biodiversity and Land Use Project has proposed that the CBA Map within our municipalities be used as an overlay zone within the schemes. Therefore when a land owner applies to have their rights upgraded, the overlay zone will come into effect. The requirement of this overlay allows the municipality to determine the location of buildings to be constructed within the property. This allows the municipality to ensure that structures avoid sensitive biodiversity areas and they can also request that the portions of the property which are not to be developed be rezoned to open space as part of the conditions of approval.

The overlay proposals discussed above are only applicable when a land owner applied to upgrade their existing land use rights as within the legislative framework of South Africa, there is no way for a municipality to deprive a land owner of their existing rights without financial compensation. Given the financial health of many of the country's municipalities, this is not an option that we believe the municipality would be willing to entertain.

Within the City of Mbombela local municipality, which is also in Ehlanzeni District in Mpumalanga Province, as part of the project, we have proposed onsite verification of the CBA Map. As part of the development of their land use scheme, the City needed to conduct a land use audit. We supported the process of the land use audit by requesting that they also conduct a basic verification of the CBA Map to see if those areas shown on the CBA Map are still undeveloped. The obtained information will be used to update the land cover layer and it will also be use during the revision of the CBA Map.

In terms of how CBA's are zoned within the land use schemes, we proposed that these either be zoned as part of the conservation/environmental zones or as open space. The advantage of using the term open space is that it is a well understood town planning term and is regarded as an area where urban development should not occur. Therefore, it would be an ideal space for CBA's to be included into the land use scheme. In terms of the categories that we have recommended for Open Space, we recommended to our municipalities that they subdivide open space into Passive Open Space (CBA Map) and Active Open Space (other green features such as sports fields and golf courses). In addition, we recommended that within urban areas, buildings should face these open to not only provide a hard boundary for those spaces, but to also provide passive surveillance.

The main reason that we have focused on Land Use Schemes is that they grant real rights to land owners. Therefore, unlike the SDF which neither grant nor removes rights, the schemes are a powerful tool for ensuring that municipalities are better prepared for climate change.

6. Conclusion

The above paper has looked at how the opportunities provided by South Africa's recently promulgated Spatial Planning and Land Use Management Act has enabled the Biodiversity and Land Use Project to achieve its goals. The paper first explored the changes that the new Act has brought and then discussed how the CBA Map is developed and how it incorporates both climate change adaptation and ecological infrastructure. The paper then explored the various ways that the Project has been integrating the CBA Map into Spatial Development Frameworks and Land Use Schemes.

Travel modes for visits to non-primary dwellings: considerations and justifications

Paper for the ISOCARP 2018 congress in Bodø, October 1 – 5, 2018.

Petter NÆSS, Jin XUE, Harpa STEFANSDOTTIR, Rasmus STEFFANSEN and Tim RICHARDSON, all from Norwegian University of Life Sciences, Department of Urban and Regional Planning, Norway.

Abstract

Travel in connection with visits to non-primary dwellings represents considerable carbon footprints. Based on qualitative interviews of Norwegian vacation home users, supported by a questionnaire survey including also other types of non-primary dwellings, this paper addresses travel modes when visiting non-primary dwellings and the reasons stated for choosing the relevant modes of transportation. Car is the dominant mode for travel to, from and within the areas of non-primary dwellings. Interviewees travel by car to vacation homes mainly because they bring much baggage and/or travel with kids, need the car for travel within the local area, and because of poor transit connections on the last part of the journey from the primary dwelling to the vacation home. Transit users emphasize environmental concerns and qualities of the journey itself and often combine train or express bus with taxi, or are driven by relatives on the last part of the journey. The reasons stated by interviewees for their choices of travel modes when visiting vacation homes are in line with rationales for travel mode choice found in studies of transport rationales for daily-life travel. Better shuttle bus and taxi provision in vacation home areas could enable less environmentally harmful travel to such areas.

Introduction

The purpose of this paper is to provide a nuanced picture of travel modes for visits to non-primary dwellings[1] and the reasons for using the respective modes of transportation for such trips, based mainly on qualitative interview data from a Norwegian study supplemented with some of its survey results. By doing this, we also aim to contribute to wider debates about the climate impacts of the multi-dwelling home lifestyle (Paris, 2006; Arnesen et al., 2012) and how it could possibly be made more environmentally sustainable.

More than one out of five Norwegian households own one or more dwellings in addition to their primary home. A nearly equally high number of households have regular access to non-primary dwellings that they do not own themselves. Most non-primary dwellings are located at some distance from the users' primary dwellings, and visits to non-primary dwellings may therefore involve considerable travel. According to Farstad et al. (2011), Norwegian users of vacation homes (which make up the dominant part of all non-primary dwellings) spent on average 36 days at such dwellings in 2007. Seventy percent of the vacation homes were located more than one hour driving distance from the user's primary home address, and 28 % more than three hours driving distance away. A more recent study of non-primary dwelling users whose primary dwelling is located in Greater Oslo shows a somewhat higher number of annual days stayed at non-primary dwellings (46), with an average of 14 separate stays per year (Xue et al., 2018).

Although the number of trips annually to and from non-primary dwellings is much lower than, for example, workforce participants' commuting trips during a year, the long distances covered when visiting non-primary dwellings imply that the CO_2 emissions from such trips can still be considerable (Aall, 2011, 2014; Adamiak et al., 2015). This is especially the case for non-primary dwellings located abroad, which are often accessed by long-distance flights, but also for non-primary dwellings located in Norway, domestic users' trips to and from such dwellings represent considerable carbon footprints. On average, each of the Greater Oslo respondents using non-primary dwellings emitted 585 kg of CO_2 for their trips between their primary and non-primary dwellings during the last 12 months. This corresponds to 7.5 % of the mean total CO_2 emissions per year among Norwegians (including domestic as well as international aviation but excluding the oil and gas production sector). If looking only at trips to non-primary dwellings located in Norway, Oslo respondents' trips to and from such dwellings produced about 360 kg of CO_2 emissions annually, or about 4.5% of the total per capita emission among Norwegians (Xue et al., ibid.). Travel within the non-primary dwelling areas when staying there comes in addition.

Travel to and from non-primary dwellings thus represents a non-trivial contribution to the climate impact of the users of such dwellings. For visits to vacation homes located in Norway visited by Norwegian residents, private car is the all-dominating travel mode (Aall, 2014). Still, many visitors to non-primary dwellings also use other means of transportation, and some trips to non-primary dwellings include a combination of different travel modes.

In this paper, we will discuss why the car has such a prevalence for trips in connection with visits to vacation homes. Apart from some very rough national-scale or regional studies, travel modes in connection with visits to vacation homes is a rather under-researched topic. In particular, this applies to visitors' travel within the vacation home area when staying there. Moreover, no study has so far, to our knowledge, investigated the visitors' motivations, justifications and reasons for using their chosen travel modes for trips to, from and within vacation home areas[2].

In the next section (2), we present the data and methods of the study. Section 3 offers an overview as well as a more detailed picture of travel modes among Greater Oslo survey respondents and interviewees for their trips between primary and non-primary dwellings. Considerations and motivations stated by the interviewees as reasons for their choices of travel modes are also presented. Based mainly on qualitative interview data, section 4 shows examples of the various travel modes that interviewees use when staying in their vacation home areas, and their reasons and motivations for choices of travel modes for these trips. In section 5, the interviewees' reasons for travel mode choices are discussed in comparison with rationales for travel mode choices found in studies of daily-life travel in urban areas. A few concluding remarks finalize the paper, including a discussion of possible policy measures that could change travel modes in connection with visits to vacation homes in a more environmentally friendly direction (section 6).

Data and methods

The empirical material on which this paper is based stems from a questionnaire survey among inhabitants of Greater Oslo, and eighteen qualitative interviews with persons with access to vacation homes. The survey and the qualitative interviews were both conducted in 2016. The survey respondents were recruited among inhabitants living within 45 postal zones in Greater Oslo. These zones were chosen in order to ensure variation in terms of housing types, neighborhood densities, centrality (distance from the city center of Oslo) and district-scale income levels. In total, we sent 10,000 invitation letters to the web-based questionnaire survey to addressees randomly selected among the residential addresses within the selected postal zones. We received 707 completed responses, yielding a response rate of 7.1 %. While rather low, such a response rate is not uncommon in social science studies nowadays, especially for extensive and complex questionnaires such as the one used in the present study. Since the questions focused on the use of non-primary dwellings, persons who did not use or have access to any such dwellings were less prone to answer. This is reflected in the high share of persons with access to non-primary dwellings among the respondents (68%), which is considerably above the national average of about 40%. However, since the present paper focuses only on the owner/user group, we still consider this group as fairly representative of the population of second home owners/users among Greater Oslo residents.

Apart from questions about ownership and access to non-primary dwellings, the questionnaire included questions about, among others, motivations for going there, duration and frequency of stays, the address, type, size and standard of primary as well as non-primary dwellings, modes of traveling between primary and non-primary dwellings, and how far from the primary dwelling each non-primary dwelling was located. Thirteen percent of the non-primary dwellings available for the respondents are located abroad and the remaining 87% in Norway.

We also asked if the respondents were willing to participate in a follow-up qualitative interview. After a preliminary analysis of the survey data, we decided to focus on non-primary dwellings that are mainly for recreational use, since this is the dominant type in the survey. Among the 244 respondents that stated their willingness, nine who had access to vacation homes located at various places in Southern Norway were selected as interviewees. Subsequently, nine additional interviewees were selected among owners/users of vacation homes located in the municipalities of Oppdal, Trysil and Kragerø. The interviewees of Oppdal (a mountain municipality) all lived in Trondheim, whereas the additional interviewees with vacation homes in Kragerø (a coastal municipality) and Trysil (a mountain municipality) all lived in Greater Oslo, like the interviewees who were recruited through the questionnaire did. All interviewees had a Norwegian ethnic background. Persons with an immigrant background, who often have access to non-primary dwellings in their own or their parents' country of origin (Duval, 2004), were thus not represented among the interviewees.

Several interviewees had access to more than one vacation home. Figure 1 shows the locations of the vacation homes owned by or accessible for the interviewees[3]. Although we attempted to include interviewees with different socioeconomic characteristics, persons with high income and particularly long academic education are, similar to the survey respondents, overrepresented among the interviewees, compared to the populations in the city regions in which they live.

The interviews lasted for 60 to 90 minutes and were semi-structured, addressing several pre-identified topics. Each interview was conducted in an open manner, where the interviewees were first given the opportunity to speak freely for some minutes about their visits to vacation homes. Six interviews were conducted in Norwegian and the remaining twelve in English language. The interviews were all audio-recorded and subsequently transcribed word by word. An important tool in the subsequent analysis of interview data was an interpretation scheme developed in studies on residential location and travel conducted earlier by some of the project team members (Næss, 2013; Næss et al., 2018; Næss, 2018) and adapted to the present study. The interpretation scheme requested the interpreters to state what each interview could tell about each of 37 detailed research sub-questions Each interview was interpreted by one member of the research team while another research team member who had read the same transcript acted as a quality-checker. Synthesizing across the 18 interviews was conducted separately for seventeen different question groups formed from the original 37 research questions of the interpretation scheme. The present paper is based on the information elicited from two of the question groups, “Travel modes between primary dwellings and vacation homes” and “Travel mode within vacation home areas”, which together included five separate research questions.

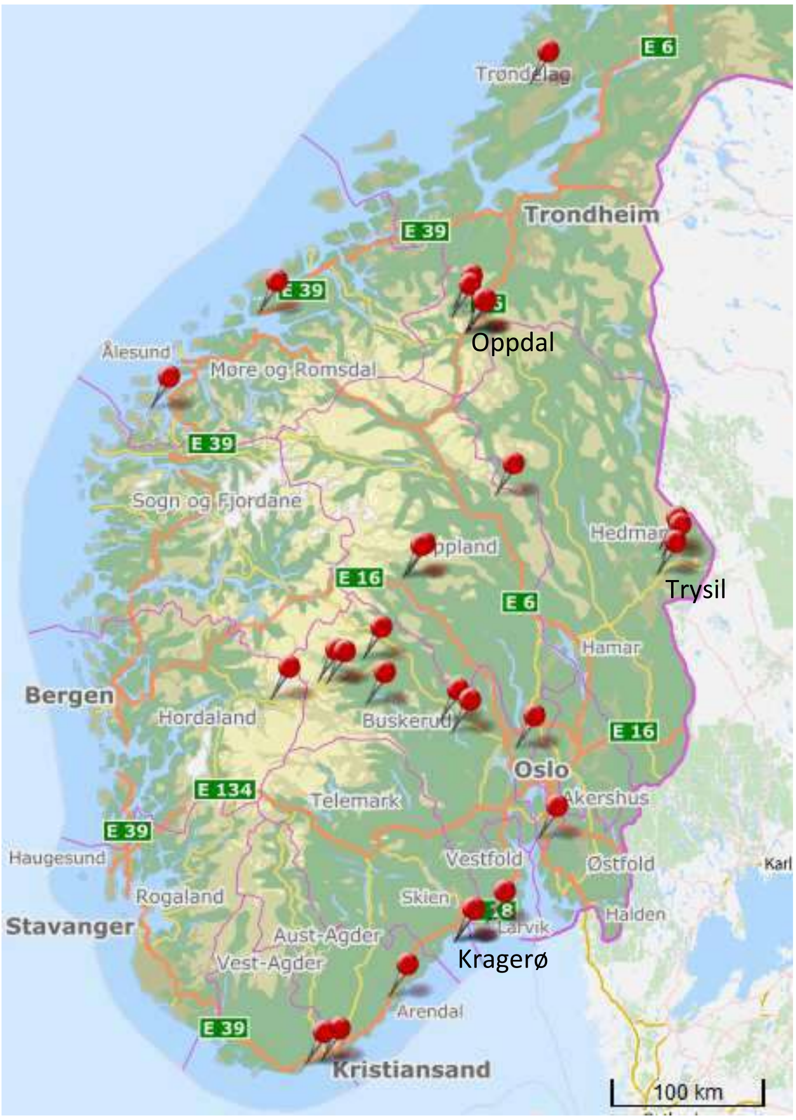

Figure 1: Locations of the vacation homes owned by or accessible for the interviewees

Travel modes for trips between primary and non-primary dwellings

Results from the survey

Figure 2 shows the main travel modes[4] used for respondents’ trips between their primary and non-primary dwellings. Car is by far the main travel mode used by most respondents, accounting for 79% when trips to the first (i.e. most frequently used) as well as any second and third non-primary dwelling are taken into consideration. Airplane is the main travel mode for 11% of the respondents[5], whereas train and bus account for 4% each. The dominance of the car is especially strong (81%) for respondents’ trips to the first non-primary dwelling, with somewhat lower shares for trips to the second and third non-primary dwelling (75%). For respondents who travel to their second or third non-primary dwelling, flights play a more important role, reflecting that a higher share of the second and third than the first non-primary dwellings are located abroad. This also implies that the role of the airplane becomes more important if we compare the travel *distances* accounted for by different modes instead of just comparing the *number* of trips.

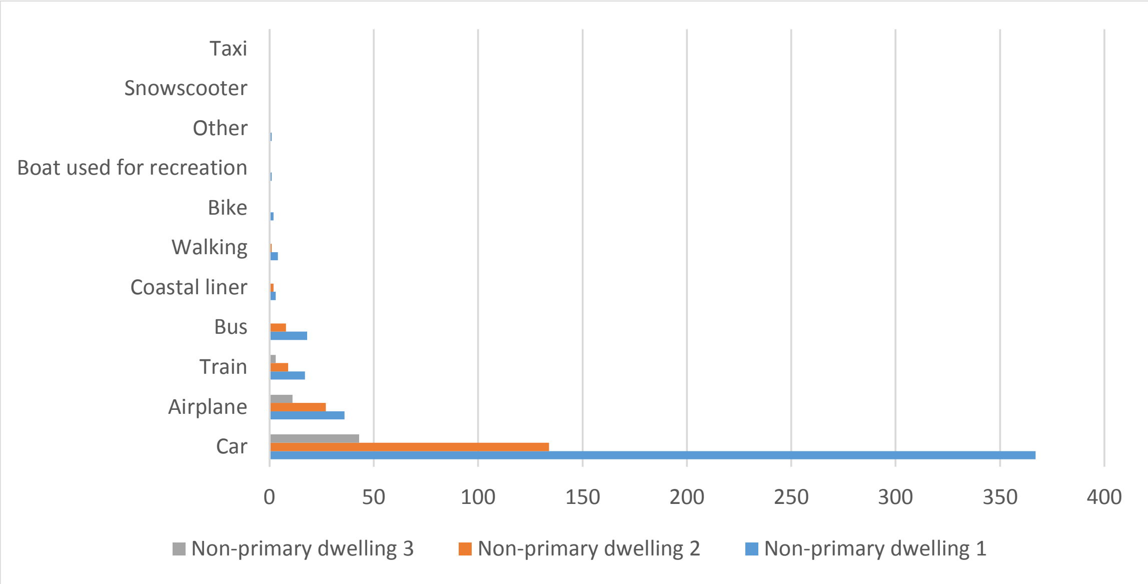

Figure 2: Main travel modes normally used for trips from primary to non-primary dwellings. N = 417 respondents.

A closer look at the material shows that travel modes such as bus, taxi and train play a somewhat larger role than indicated in Figure 2, since respondents sometimes combine the main travel mode with these modes for a shorter part of the journey. For example, respondents who go by airplane for the longest part of the journey may combine this with trips by bus or train to their final destination, or they may rent a car. Similarly, some respondents travel by bus or train for the longest part of the journey and supplement this with taxi, coastal liner/ferry or leisure boat for the last part before they reach the non-primary dwelling.

Whereas Figure 2 was based only on the number of respondents stating a particular mode as the most important one for trips to non-primary dwellings, Figure 3 shows the number of kilometers that the respondents traveled per capita by the four main travel modes (car, airplane, bus and train) when visiting non-primary dwellings over the last 12 months[6]. The car is still the dominant mode, but airplane plays a greater role now than in Figure 2, especially for trips to respondents' second and third non-primary dwellings. In total for all non-primary dwellings, trips by car as the main travel mode account for 71% of the kilometers traveled, airplane 24% and the remaining amount of travel equally distributed between bus and train. For trips to the first non-primary dwelling, car accounts for 77% and airplane for 18%, whereas the shares of air travel are as high as 41% and 40% for trips to respondents' second and third non-primary dwellings.

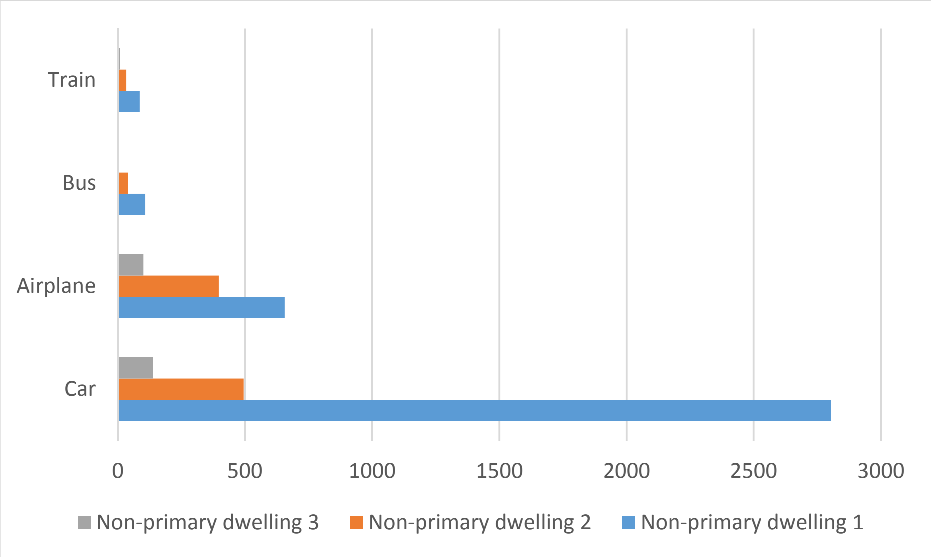

Figure 3: Person kilometers per capita traveled by car, airplane, bus and train to respondents' non-primary dwellings. N = 426 respondents.

As shown in the qualitative interviews (see below), one reason for the dominant role of the car as travel mode for trips to non-primary dwellings is that many such dwellings are difficult to access by public transportation. In order to assess the transit accessibility of the respondents' non-primary dwellings, we asked how close they could come to their non-primary dwellings by public transportation (not including taxis). The results (Table 1) show that the non-primary dwellings are on average located far away from the closest transit stop, with mean distances of 12 km, 13 km and 27 km for the first, second and third non-primary dwellings of the respondents. Some non-primary dwellings located very far (300 km or more) from the closest transit stop pull these mean values upward. But the median distances are also long, with 5 km for first and second non-primary dwellings and 12 km for third non-primary dwellings. Some non-primary dwellings are still located close to transit stops. Among the respondents' first, second as well as third non-primary dwellings, 10% can be accessed within a distance of 500 m or less from the closest transit stop, and for first and second non-primary dwellings, 25% can be reached within 1 km from a transit stop. Moderate distance from the non-primary dwelling to the closest transit stop does seem to contribute to somewhat higher share of travel by transit. Leaving out air-traveling respondents, 15% of those whose non-primary dwellings are located less than 1 km from the closest transit stop travel by bus or train, compared to 8% among those with more than 1 km distance to the closest transit stop.

	First non-primary dwelling	Second non-primary dwelling	Third non-primary dwelling
Mean	12.0	13.2	27.1
10% percentile	0.50	0.43	0.47
25% percentile	1.0	1.0	2.6
50% percentile (median)	5.0	5.0	12.0
75% percentile	15.0	15.0	24.0
N	386	142	48

Table 1: Distance (in km) from non-primary dwelling to the closest opportunity for public transportation (taxi not included).

Poor transit accessibility is especially the case for mountain cabins. Non-primary dwellings in coastal areas are often easier accessible by transit, since some of them are located in villages and towns (but many are still located on small islands or other places not served by transit). For respondents' first non-primary dwellings in Norwegian mountain areas, only 10% are located within 1 km from a transit stop. For respondents' first non-primary dwellings located elsewhere in Norway, 25% are located 1 km or less from a transit stop, and 10% have a distance to such a stop of 300 m or less. Respondents' first non-primary dwellings located abroad have similar accessibility by transit as those located in non-mountainous parts of Norway. Similar differences in transit accessibility between locations in Norwegian mountainous areas and elsewhere in Norway or abroad exist for also respondents' second and third non-primary dwellings.

Results from the qualitative interviews

The qualitative interviews can shed light on the more detailed practices when traveling to and from vacation homes, as well as the motives, considerations and justifications underlying such practices.

Among the eighteen interviewees, fifteen use private cars as their main mode of travel between primary dwellings and vacation homes, while three normally go by transit, two of which by train and one by bus. These interviewees combine transit with taxi, rented car or travel as passengers with friends or relatives for a smaller part of the journey (closest to the vacation home). One interviewee has one of his vacation homes in Turkey and travels by airplane to an airport near the vacation home.

Some of the car travelers have occasionally used transit but do not normally do so. One interviewee who now uses the car intends to shift to transit in the future.

Reasons for going by car

The main considerations that interviewees refer to as reasons for traveling to their vacation homes by car are: A need to bring heavy/voluminous things with them (mentioned by eight interviewees), poor transit connections (seven interviewees), need for car travel within the vacation home area (four interviewees), time-saving (four interviewees), flexibility (three interviewees), convenience, money-saving and pro-car habitus (two interviewees each), and feeling of freedom (one interviewee).[7]

The reason that the interviewees most frequently refer to for traveling between primary dwellings and vacation homes by car is the need to bring with them baggage and/or other items that it would be cumbersome or impossible to transport if traveling by other modes. The following quote by the latter interviewee is illustrating:

> "I didn't use it [the bus from Oslo to Trysil], but my wife has used it a few times, and it's have been working fine for her. It's just that when we go there, or at least nowadays, we have a three-year old, we tend to have a lot more thing with us." (Male interviewee, 34, with access to cabin in Trysil and two other vacation homes)

The items that the interviewees bring with them include foodstuff, equipment for sports and outdoor life, clothes and laundry. One interviewee also says that they need to bring garbage from the vacation home to a container at some distance. A couple of interviewees mention that they were refurbishing or extending their vacation homes and needed to bring materials with them.

For many of the interviewees, the transit connections to the vacation home are poor, but some of those interviewees would have traveled by car also if the transit connections had been better. Some interviewees who can travel to their vacation homes relatively easily by transit also prefer to travel by car anyway. For example, one interviewee can travel by bus from Oslo to a bus stop only 150 m from the vacation home but always travels by car. However, for about half of those interviewees who normally travel to their vacation home by car, poor transit connections are mentioned as one of the reasons for their choice of travel mode. For many interviewees, going to the vacation home by other modes than car would require transfers between several transit lines (with related waiting times) and the use of taxi (if available) for the last part of the journey. For example, the bus stop closest to one of the vacation homes of one interviewee is 10 km from the cabin and there are no taxis. Another interviewee tells that the bus stop is located far away from and at an altitude 500 m lower than one of their the cabins and that it would not be tempting to take a bus for a short stay.

Four interviewees say that they travel to the vacation home by car (also) because they need to drive from the vacation home to various activities within the vacation home area. This will be discussed in Section 4.

For most interviewees, traveling to the vacation home by modes other than car would be more time-consuming. This is mentioned explicitly by only four interviewees but is probably an underlying concern also for those who refer to poor transit accessibility to the vacation home as a reason for traveling by car.

Only three interviewees explicitly mention flexibility as a reason for traveling to vacation homes by car, but a wish for flexibility is plausibly also an underlying reason when interviewees state that they travel to their vacation home by car because they want to drive to facilities within the vacation home area (see section 4). The illustrations given by interviewees about their wish for flexibility are all related to travel within the non-primary area and not to the journey between primary dwelling and vacation home *per se*.

Convenience as a reason for traveling between primary dwellings and vacation homes by car is related to the concern about bringing items to/from the vacation homes as well as to perceiving transit connections as poor, and is probably one of the underlying rationales for both these concerns. Two interviewees explicitly mention convenience as a reason for traveling by car, and it is implicitly indicated by another interviewee. The wife of one of these interviewees used to take the bus sometimes before, but now the bus does no longer stop just outside the neighborhood where their cabin is located.

A few interviewees say that it is economically more favorable to travel by car to their vacation homes than going by transit. This is especially the case when many people go together to the vacation home, as one of them stated.

A couple of interviewees also indicate that they have a long-standing habit of car driving and a predilection for using this travel mode. Both these interviewees belong to households that have for long periods had two or more motor vehicles (cars and motorcycle), and for one interviewee, driving seems to be so self-evident that the reasons for choosing this travel mode go without saying.

Finally, one interviewee likes the freedom provided by the car and mentions this feeling of freedom as one of the reasons for traveling by car to the vacation home.

Reasons for going by transit

Among the three interviewees traveling to their vacation homes by transit, the main reasons given for this choice are: Environmental concerns, easiness/convenience, non-ownership of private car, no driver's license, good transit connection and money-saving.

All the three interviewees who use transit as their main travel mode for trips between primary dwellings and vacation homes mention environmental considerations as one of the reasons for this choice of travel mode. In addition, another interviewee, who now travels by car but intends to shift to transit, mentions environmental concerns as one of the reasons for making this shift. Interestingly, all the four interviewees who mention environmental concerns as important to their travel mode choice when going to vacation homes are female.

The interviewees who talk about transit as a convenient and easy travel mode all refer to train travel. One of them says that life is much easier on a train than when driving, since in the latter case you cannot rest. She mentions their experiences of being stuck in traffic jam as an example of what she can avoid taking the train. On the other hand, she thinks bus travel is not very convenient, especially on winding roads, which makes them car sick. Another interviewee emphasizes the convenience of train travel and mentions that her kids like to take the train whereas they feel restless in a car. One important condition for her judgment of train travel as convenient is that they do not need to bring all stuff with them (bed linen, towels, skis, clothes, etc.), so the baggage is small, which makes it easier to go by train.

None of the three interviewees who travel to vacation homes by transit owns a private car, which is an important contributory reason for their travel modes for these trips. They all live at quite central locations in Oslo, inside Ring 3, and two of them explicitly say that their non-ownership of cars is because they do not need to travel by car at their primary dwellings, as illustrated by this quote:

> "It's important for us to live here [at the primary dwelling] without a car, and of course we could have borrowed a car going there, but life is much easier on a train, yeah. It's three and a half hours with rest, and when you drive a car there is no rest. … we take the bus here, from Sagene down to Oslo S, that's the first part, 10 minutes. And then it's 3.5 hours on the train, and then we walk just to the store, buy all the stuff, put it in a taxi and then we are up there." (Female interviewee, 41, one self-owned cabin (Ål) and one family-owned cabin (Åfjord)

All three non-car-owning interviewees mention environmental awareness as important reasons for not having a car, and one of them, who does not even have a driver's license, says that her non-possession of driver's license is an environmental choice. Non-ownership of car as a reason for traveling by transit is thus closely related to the above-mentioned environmental reason for choosing transit as travel mode when traveling between primary dwellings and vacation homes.

Only one of the transit-traveling interviewees explicitly mentions good transit connections as a reason for their travel mode choice. Another interviewee says that the transit connection to one of her vacation homes has worsened and is more of a challenge, since the travel time has increased from one hour to two hours. This interviewee, who does not possess a driver's license or a car (cf. above), is a car passenger with her mother when she visits her other, more distant vacation home, apart from when she travels alone. Then she travels by bus despite the long travel time of 12-13 hours.

For those interviewees who do not own a car and do not have the opportunity to travel as car passenger with other visitors to the vacation home, the alternative to transit travel is to rent or borrow a car. Compared to renting a car, travel by transit will then be cheaper, as stated by one interviewee.

One of the interviewees who often travels by transit between the primary dwelling and vacation homes sometimes does borrow a car (from her parents or parents-in-law) when traveling to their two least transit-accessible cabins. The reason for this is the relatively poor transit access to these cabins, where the train journeys must be combined with relatively long taxi trips at the end or they must make an agreement with local people to drive them.

Taxi, car, boat and ferry as supplementary travel modes
As already mentioned, three interviewees who travel by transit for most of the journey between their primary dwellings and vacation homes normally combine the transit trip with other travel modes (taxi or car passenger) for the part of the journey between the closest transit stop and the vacation home. Although not stated explicitly, the reason for the use of these means of transport is obviously that the distance between the transit stop and the vacation home is longer than acceptable non-motorized travel distance. This can in its turn be related to poor transit connections on the last part of the trip from primary dwelling to vacation home.

Three interviewees have their vacation homes on an island and take a taxi boat or ferry from the closest pier on the mainland after having traveled most of the distance from the primary dwelling by car. The following quote illustrates this:

> "I drive to Valle, it's a bit before Kragerø, ….. And I have parking place there. And from there I take a taxi boat. The only way to get there is either by a taxi boat or ferry, but then you have to go all the way to Kragerø." (Female interviewee, 50, one self-owned cabin (Jomfruland) and one family-owned cabin (Haugastøl))

Their reason for combining car travel with another travel mode is thus topographical. Another interviewee uses a car ferry as a shortcut across the Oslo fjord on his car trips between primary dwelling and vacation home, which can partly be attributed to topographical reasons. In addition, he likes the relaxation during the ferry trip.

Air travel
Only one interviewee has a vacation home outside Scandinavia. This interviewee, who besides his Norwegian mountain cabin owns a dwelling in Turkey, travels by airplane to an airport 20 km from the latter vacation home. Avoiding too much time spent on traveling is the obvious reason for this travel mode choice.

Travel modes within vacation home areas
The questionnaire survey did not include questions about the respondents' travel during their stay at the non-primary dwelling. This section is therefore based solely on the qualitative interview material.

Among the eighteen interviewees, fifteen use private cars when traveling within vacation home areas, i.e. all interviewees except three whose cabins are on an island. A slight majority of the car users combine driving with other travel modes within their vacation home areas, depending on trip destinations, purposes and other circumstances. However, nearly half of the car-using interviewees travel only by this mode when traveling to activities within their vacation home areas (recreational walking, skiing and biking starting directly from the vacation home not included).

Apart from driving, the interviewees make use of the following travel modes to reach activity locations within their vacation home areas: Walking (six interviewees), taxi boat or ferry (three interviewees), private boat (two interviewees), skiing (two interviewees), ski lift (two interviewees), and snow scooter, bike, bus, and rented or borrowed car (one interviewee each).

Reasons for going by car

The main considerations that interviewees refer to as reasons for traveling within their vacation home areas by car are: Long trip distance (eleven interviewees), bringing kids (three interviewees), flexibility (three interviewees), unsafe biking conditions along the roads (two interviewees), and social contact and altitude differences (one interviewee each).

To some extent, the use of cars for travel within the local areas of vacation homes seems to be the default option. Rather than giving explicit reasons for using this travel mode, the interviewees' explanations of their travel mode choices tend to focus on their reasons for using any modes other than the car. For example, none of the interviewees explicitly mentions poor transit connections as a reason for traveling within vacation home areas by car, although poor possibilities for using transit to local destinations is a widespread feature in many vacation home areas, particularly in the mountains. In addition to being the travel mode accounting for the largest number of trips, the dominance of car travel is even stronger in terms of travel distances, since each car trip is on average longer than those by other modes.

As mentioned above, the reason mentioned by most interviewees for driving to destinations within the non-primary area is that the trip distance is long. This includes trips to get supplies during the stay as well as trips to facilities for sports, outdoor recreation and other leisure activities. The length of the trip of course depends on what activity opportunities exist near the vacation home (such as grocery stores, alpine skiing facilities, etc.). However, some interviewees who can reach opportunities for a given kind of activity without needing to travel by car still sometimes drive to carry out this activity type at farther locations for the sake of variety. Similarly, some interviewees state that weather conditions determine the distances to activity locations. For example, one interviewee says that weather and snow conditions influence whether they go directly from the cabin to skiing trips or hiking tours. They prefer to go directly. If the weather is bad around the cabin, they go to other places and then use the car.

Another relatively frequent reason for driving to destinations within the vacation home area is that the interviewees bring children with them to the activities in question. One of these interviewees puts it this way:

> "… last winter we started to ski all together when he was 4 years old then, my son, and then we need to take a car because it's too much like flat skiing, and it's too long to take him here, so then we take the car and we drive up here, and then we do all the skiing all around the mountain."
> (Male interviewee, 42, with self-owned cabin in Trysil)

This reason is related to the above-mentioned trip distance reason, since the need to drive kids reflects that the distance to the activity is considered too long for the children to go on foot, ski or by bike even if the destination would be within acceptable non-motorized travel distance for a grown-up person.

This interviewee also mentions altitude difference between the vacation home and the trip destination as a reason for traveling by car. Both this criterion and the trip distance criterion reflects an underlying rationale of avoiding too much physical efforts. The distance criterion plausibly in most cases also reflects concerns about time consumption.

Three interviewees point at flexibility as a reason for choosing to travel by car. One of them says that he prefers driving because he likes to be flexible and to be able to visit the local shop and acquaintances. Another interviewee states that traveling by transit would require that they would have to plan their shopping very carefully. A third interviewee points to the possibility of visiting various places for outdoor recreation activities when staying at his vacation home in the mountains:

> "… during the stay .. I drive a little bit to go fishing or maybe go, to go alpine skiing I have to drive 10 minutes so, it's the freedom when I'm up there to have a car to get around to different places, because if I didn't then I had to use very much the same path in and out of the cabin all the time just going skiing and all." (Male interviewee, 55, with self-owned cabin at Heggenes and access to another vacation home in Søgne)

When staying at his second vacation home (at the coastline), this interviewee says that it is more flexible to visit his family by car. Otherwise, his family would have to visit him at the cabin.

Two interviewees say that they use the car for trips where they could otherwise have cycled because of unsafe biking conditions. One of them tells that they need to travel some distance to visit relatives, and that it is not safe to bike with children on narrow roads where everybody drives really fast. Therefore, they go by car for these trips:

> "… around my parents' house … we just use the bikes, and we can visit a lot of people, but the farm and my grandfather they are 20 kilometers up in the valley. And sometimes we can take a bike, but with children, it's a really narrow road, and everybody is driving really really fast … it's a lot less safer than biking in town, so then you just, everybody needs a car there." (Female interviewee, 41, one self-owned cabin (Ål) and one family-owned cabin (Åfjord))

The same interviewee also points at social contact as a reason for choosing to travel by car. Since she is at the vacation home with her family, they use her relatives' car to get around for some trips. Social contact is still probably not the only reason here, since this interviewee does not have a car or driver's license and therefore depends on someone else to drive her and her kids to destinations that cannot be reached by non-motorized modes or transit.

Reasons for going by transit
Five interviewees travel within their vacation home areas by different types of public transportation (bus, ordinary taxi, taxi boat and ferry). The main reasons given for traveling by these modes are: Topographic situation, with the cabin located on a small island, weather conditions and number of co-travelers, non-ownership of private boat, and long and steep distance back from shop and lower price for taxi than renting car. It should be noted that the latter interviewee travels from the primary to the vacation home by train and therefore depends on other modes than private car for motorized travel within the vacation home area.

Except for the interviewees who stay at vacation homes on a small island without any bridge or tunnel to the mainland, transit plays a very modest role for the interviewees' travel within their vacation home areas. For those with island vacation homes, the situation is very different, since there is no grocery store on the island where their vacation homes are located (Jomfruland). Boat transport is therefore the only opportunity to reach stores and other facilities not present on the island.

Two of the interviewees whose vacation home is located on an island own private boats and alternate between using these boats and public boat services. One of them states that strong wind/bad weather at sea can make him take the public boat rather than his own. The private boat is quite small, and he uses the public boat when traveling together with friends/relatives, probably because of the limited size of the private boat.

Reasons for going by non-motorized modes
Six interviewees state that they more or less often use non-motorized modes of travel (walking, skiing or biking) to reach activity locations within the vacation home areas. Here, non-motorized movement as the activity itself is not included.

Short distances to destinations is the most common reason given for choosing non-motorized modes. Two interviewees mention this as a main reason for reaching activities on foot as well as on ski. In addition, another interviewee states short distance as a reason for walking to shops and yet another one for skiing to activity locations.

Three interviewees mention the legislation against driving under the influence of alcohol as a reason for walking to and from destinations in the vacation home area instead of traveling by car. When visiting friends living in cabins in the surrounding areas, one interviewee and his wife sometimes walk so that they can have a glass of wine there. Indirectly, this concern also influences the travel modes of another interviewee as one of the reasons for choosing a location of the vacation home as close as possible to the alpine skiing facility. This interviewee says that they wanted to be able to have some wine on Friday nights without having to wait until the next afternoon to drive to the lifts. Similarly, yet another interviewee says that the location of their cabin not far from the alpine skiing hill is nice also because if you don't need a car you can take a beer when you go alpine skiing.

Two interviewees whose mountain cabins are located at some distance from the closest road, have to walk or go skiing one or two kilometers each direction between the car parking and the cabin. (One of them sometimes uses snow scooter instead of walking during winter time, see below.) Walking can also in some cases be shorter and more convenient than driving since the latter may include long detours along the road network. This is the case for one interviewee's visits to some of their friends who live in cabins just up the hill from their own, easier accessible on foot than if they were to walk to the parking place and then drive.

Finally, one interviewee states that he walks to local destination on the island where his vacation home is located because there is a ban against driving on island (except when arriving at and leaving the vacation home, which is allowed against a high fee). None of the two other interviewees with vacation homes on the same island mentions walking as a local travel mode, but they obviously have to walk at least the distances between their cabins and the piers for public and/or private boats.

Reasons for traveling by other modes
Some interviewees also use other travel modes than those mentioned above for transportation within their vacation home areas. These modes include ski lift (two interviewees, use of ski lift for alpine skiing not included), private boat (two interviewees), rented car (one interviewee) and snow scooter (one interviewee).

For some of their hiking/skiing trips, two interviewees take the ski lift from the valley bottom to the top of the mountain where they start the skiing or hiking activity. The obvious reason for this is to overcome altitude difference. This concern can in its turn be traced back to a wish to avoid too much physical efforts and probably also time-saving, which enables the interviewees to visit more distant and varied hiking and skiing areas than possible if they were to start the trips directly from the cabin. A rationale of variety-seeking may therefore also be an underlying reason for using the ski lift in connection with hiking and cross-country skiing.

As mentioned above, one interviewee sometimes uses snow scooter between the parking lot and the cabin, which is located 1 km away. She does this particularly when she brings food to the cabin after having visited the grocery store. The reason for using the snow scooter for these trips instead of skiing thus seems to be to avoid having to carry heavy shopping commodities.

Two interviewees sometimes use private boats for travel within the vacation home areas. These boats are largely used for trips where being on the sea is the recreational activity pursued (including doings such as water skiing, fishing and bathing during the trip), but they are also used for instrumental travel purposes. A main reason for using the private boat is that it is fast.

The only interviewee who uses a vacation home in a foreign country rents a car for his travel within his vacation home area at the Turkish south coast. They use the car for all destinations except those very close to the vacation home. Trip distance beyond acceptable walking distance is thus a reason for using the rented car. In addition, driving appears as more or less the default option of this interviewee for motorized travel – the possibility of using local transit does not seem to be considered.

Discussion

The most common reasons stated by the interviewees for their choices of travel modes when visiting vacation homes are in line with rationales for travel mode choice found in studies of daily-life travel (Næss & Jensen, 2005; Næss, 2005, 2013 and 2015b; Næss et al., 2018). By transport rationales, we refer to the backgrounds, motivations, and justifications that agents draw on when they make transport-relevant decisions about their participation in activities, location of these activities, modes of transportation, and the routes followed.

Six of the interviewees of the present study explicitly mention *convenience* as a reason for their travel mode choice. Moreover, reasons stated by the interviewees concerning flexibility, bringing baggage, quality of transit connections, bringing children, weather conditions and altitude difference are all related to this overall rationale. Both the need to bring baggage on the trip and altitude difference make certain modes of travel physically exhaustive, these concerns are thus related to a sub-rationale of avoiding too much physical effort.

Interestingly, we find some quite distinct differences between travel to/from and within vacation home areas in the occurrence of the different reasons. For travel between primary dwellings and vacation homes, the reasons indicated in most interviews are about baggage, quality of transit connections, convenience in general, and time-saving. Some interviewees also emphasize environmental concerns, expenses and habits. The importance attached to time-saving is very understandable from a time-geographical perspective (Hägerstrand, 1970). If traveling to the vacation home by modes other than car takes long time, the journeys between the primary dwelling and the vacation home will consume a high proportion of the time budget, for example the available days off from work during a weekend. The time allocated to travel may then replace other, desired activities at the vacation home. By traveling by car, some of the ‘capacity constraints’ (Hägerstrand, ibid.) are relieved and higher travel speed is obtained.

For travel within the vacation home areas, concerns about bringing children, flexibility and altitude differences come to the fore, and some also mention safety and weather conditions. However, what is really striking is the large number of interviewees referring to trip distance as a circumstance influencing their travel mode choice. This reason is mentioned particularly for situations where the options are whether to use non-motorized or motorized transportation (where the latter in most cases means car, since transit is usually poorly aligned with interviewees' travel needs within the vacation home areas). This corresponds to the findings in studies of residential location and travel where trip distance has been identified as an important intermediate criterion triggering the activation of (sub) rationales such as time-saving and avoidance of too much physical effort. Bringing children also involves a need to reduce non-motorized trip length and physical effort, compared to what would be acceptable for a grown-up person.

Social contact as a reason for travel mode choice (car) is mentioned by only one interviewee but is in line with a rationale encountered for daily-life travel and is also pointed at in an earlier study of second home mobility (Ellingsen & Hidle, 2012).

Some interviewees have their travel mode options constrained because of non-ownership of mobility resources possessed by most other interviewees (private car) or by most users of vacation homes in a particular area (private boat). At least for the three interviewees without a car, this appears to be a self-imposed constraint motivated by environmental concerns and could thus be regarded, in these cases, as a derivative of an environmental rationale.

In addition, the interviewees give some very context-dependent reasons for travel mode choice, such as missing road connection and local ban against driving. Such conditions are very unlikely to appear in an urban context and have thus not been encountered as reasons for travel mode choice in studies of residential location and travel in urban areas. For travel to non-primary areas, missing road connection on the last stretch before the destination can require that a car trip is combined with another travel mode for the final part. If car is the preferred travel mode, this can in its turn make up a pressure for road building to vacation homes presently unconnected with the road network.

Concluding remarks

Travel to, from and within non-primary dwelling areas represents considerable carbon footprints by those involved. Distances between primary dwellings and vacation homes are often long, since a main motivation for having vacation homes is to stay in a geographical environment different from that at the primary dwelling and to be able to access places and activity opportunities that are too far away for an ordinary day-trip from the primary dwelling. Most Norwegian vacation homes are also located in areas poorly accessible by ordinary public transportation. Private cars play a more dominant role for visits to vacation homes than for most other travel purposes (Hjorthol et al., 2014). Our interviews with users of vacation homes illustrate why this is so. Interviewees travel by car to vacation homes mainly because they bring much baggage and/or travel with kids, need the car for travel within the local area, and because of poor transit connections the last part of the journey from primary dwelling to vacation home. For these reasons, the car is often considered the default mode of travel when going to vacation homes.

Some interviewees stated that they considered it impossible to use their vacation homes without having a car at their disposal. Although none of the interviewees said explicitly that their use of vacation home had made them acquire cars they would otherwise not have needed, it seems plausible that at least some inner-city residents would have preferred not to own a car if they did not need to drive to their vacation homes. In these cases, being a vacation home user has ramifications on car driving practice far beyond the visits to vacation homes, since a car, once acquired, tends be used for trips for a number of purposes and to destinations that would otherwise be reached by other modes.

One could thus question whether the Norwegian vacation home phenomenon is at all compatible with environmental sustainability (Steffansen, 2017). It has not been the purpose of the present paper to answer this question, but the CO_2-intensive travel that the use of vacation homes often involves at least represents a serious sustainability challenge.

Our material still shows that some interviewees and survey respondents do travel in environmentally less harmful ways when visiting their non-primary dwellings. Transit users emphasize environmental concerns and qualities of the journey itself and often combine train or express bus with taxi, or are driven by relatives on the last part of the journey. These interviewees are often motivated for their travel choices by high environmental awareness and are willing to make some efforts to reach their vacation homes by other modes than the car.

A larger number of vacation home users might be able to travel in a more environmentally friendly way if three main difficulties could be alleviated: long distance from the closest transit stop to the vacation home, the need to bring baggage, and the need for transportation within the vacation home area. For spatial planning, this points toward more densely developed vacation home areas to facilitate more frequent and easily accessible transit service. For existing vacation home areas, one way to relieve the above-mentioned difficulties could be to establish more extensive, 'on demand' shuttle bus services between the closest train station or main bus stop and relevant vacation home areas. "On demand" here means that the driving route of the shuttle bus would pass the vacation homes of the actual passengers of each particular trip. Regular food deliveries organized by the local grocery stores is another idea. Such shuttle and delivery services would probably only be possible in areas with a relatively high number of vacation homes. In areas with less concentrated vacation homes, better taxi provision could be helpful. A possible way to finance such shuttle bus and taxi services could be to establish (increased) toll fees on the local roads leading to the vacation homes and earmark some of the revenues to run the conveyance systems at subsidized fares.

For trips to and from vacation homes, such shuttle services would be particularly useful on Friday and Sunday afternoons. However, since several interviewees mention that they need to use cars for trips within the non-primary areas, 'on-demand' shuttle bus services between vacation home areas and the nearest village should also be available during the most common vacation periods when people often stay for a longer period at their vacation homes and want to go to grocery stores, alpine skiing facilities or other activities located beyond acceptable non-motorized travel distance from the vacation home.

While the above-mentioned improvements might facilitate a shift from car to transit among those vacation home users who are motivated for changing their travel mode, many users would probably still prefer to drive. In order to induce a stronger shift to more climate-friendly travel when visiting vacation homes, "carrot" instruments should be combined with "stick", for example new or higher tolls on the main highways between the largest cities and the most important vacation home areas.

Notes

[1] By non-primary dwellings, we refer to stationary dwellings other than the dwelling registered in the national census as a person's official home address, to which the person or household in question has regular access (Farstad et al., 2008), and regardless of whether the dwelling is located in Norway or abroad. The vast majority of the non-primary dwellings used by the survey respondents are vacation homes, but some are also dwellings used for other purposes such as work, studying or by couples living apart. All the non-primary dwellings used by the interviewees are vacation homes. In this paper we therefore use the term 'non-primary dwellings' when referring to the survey material and 'vacation homes' when referring to the qualitative interviews.
[2] A study on second home mobility in Norway (Ellingsen & Hidle, 2013) represents a possible exception, but his study focuses mainly on how different practices are linked to different home locations and to a lesser extent on the travel between or within these locations.
[3] One of the non-primary dwellings owned by one of the interviewees was located at the southern coast of Turkey and is not shown on the map. At three locations (Oppdal, Kragerø and Trysil), the number of interviewee non-primary dwellings within a concentrated area was too high to enable each such dwelling to be represented by a separate pin on the map.
[4] If the trip involves more than one travel mode, the main mode refers to the travel mode used for the longest part of the journey.
[5] Most of the non-primary dwellings to which respondents travel by airplane (63%) are located abroad.
[6] Travel distances by the different modes are calculated as if the main travel mode mentioned by the respondents accounted for the whole distance between the primary and non-primary dwellings. We consider this inaccuracy to be small, since a travel mode underestimated for one trip where it is the second or third most important mode may be overestimated for another trip where it is the main travel mode. Still, the length of flights may be somewhat overestimated since this travel mode is usually the main mode if chosen at all. We also ignore that some trips go directly between non-primary dwellings and workplaces/places of education. We consider this inaccuracy too to be modest, since the workplaces of most respondents are in the same urban area as their residences (Greater Oslo), and there is therefore usually little difference in travel distance to the non-primary dwelling from the primary dwelling compared to from the workplace.
[7] The number of interviewees who explicitly mention a concern does not mean that these interviewees are the only ones for whom the concern mentioned is of some importance. Therefore, the occurrence of the various concerns may be more widespread than indicated by the number of interviewees who explicitly talk about each concern.

Towards Evaluating The Management Of Climate Change Impact On Rural Communities Of Edo State, Nigeria

By

ABSTRACT

In the last few years, rising temperatures and rainfall has characterized the climate pattern of Nigeria and no doubt it is a clear evidence of climate change. The attendant effects among others have been the increased heat and rainfall regimes which have resulted in the increased infection of heat related diseases and rainfall related problems such as the loss of crops and farmlands. While these effects are on the increase, studies have shown that urban centres are given more attention than the rural areas by way of mitigation. The rural areas are the largest in terms of land size, resources and population and they suffer as much environmental problems as the urban centres. But because they are administered by the local government councils which in themselves are characterized poor financing, the rural areas are therefore besieged with inadequate or lack of administrative mechanism and framework for climate change effects. The aim of this research is to evaluate the management of climate change effects in rural areas in Edo State, Nigeria. To accomplish this, the study examined the change pattern of the elements of temperature and rainfall, the effects of the change, the management of the effects by the local council authority, the impact problems. The study utilized primary and secondary sources of data. For the primary data, questionnaire and direct interviews were conducted. A total of 363 questionnaires were made and administered on the population of the study area

while interviews were conducted on the heads of environmental units of the local government councils. Secondary data were sourced from documentary sources such as text books and articles in journals. Data on temperature and rainfall for 15 years were got from weather station in the Cocoa Research Institute, Uhonmora, Edo State which is about 15 kilometres from the study area. The data collected were analyzed descriptively and statistically using tables. The findings were that rainfall and temperature pattern were changing and this change was having impact on farming, the physical environment, infrastructure and health in the study area. The **study** also identified the management techniques employed to ameliorate these impacts and the problems. Useful recommendations that will help reduce and ameliorate the effects of climate change and problems were therefore made.

INTRODUCTION

Awareness of climate change in Nigeria is very low and this is because over 70% of the population do not know about this phenomenon and are not also aware that it is the cause of excessive heat and rainfall in the last few years. The problem of awareness according to Nzeadibe, Egbule, Chukwuone and Agu (2011), include poor sensitization by government agencies and inadequate information from media sources like radio and television. Climate change according to Wu, X. and Xu, B. (2016), is the long term statistical shifts of the weather, including changes in the average weather condition or in the distribution of weather condition around the average.

According to the European Environment Agency (2008) the global average surface temperature has risen by 0.74^0c in the 20^{th} century. The global sea level has been rising 1.8mm per year since 1961 and the arctic sea ice berg been shifting by 2.7% per decade. Also different observational records of global average annual near-surface (land and ocean) temperature; the last decade (2008-2017) was 0.89^0c to 0.93^0c warmer than the pre-industrial average, which makes it the warmest decade on record (European Environment Agency 2008). The intergovernmental panel on climate change in 2001 predicted an average temperature rise of 1.5^0c -5.8^0c across the globe during the 21^{st} century accompanied by increase and anomalous weather events including heat waves, floods and droughts. The effects of climate change are quite noticeable and according to Beyioku (2016), these include disastrous erosion and flooding, rising heat waves, drought, rising sea levels, melting ice caps, wind storms, land and mud slides, rising sea temperatures among others.

Climate change is principally a major problem caused by human activities such as gas flaring, carbon emissions, bush burning, deforestation, burning of carbons and urban growth and development and other activities. The consequences of these in heat mortality, dehydration, spread of infectious diseases, malnutrition, migration and damage to public infrastructure Beyioku (2016).

The enormity of this problem has challenged the governments around the world to take certain actions with the view of curbing global warming and reduce its effects. On September 3rd, 2016 the CNN Television News had reported a signing of the Paris Climate Change agreement by both the United States and China. This agreement sought to cut carbon emissions by half within the next fifteen years. This signing was declared significant because the two countries are said to account for about 40% of global carbon emissions. In the same vain other developed countries have taking measures to reduce burning of gases and other chemicals with changes in technology that is environment friendly. Solar heat material, batteries and solar driven cars and machines and the replacement of carbon coolants in air conditioner and fridges are now been manufactured. In most developing countries, not much effort has been made technologically much effort is however been made to ameliorate the effects.

In Nigeria the evidence of climate change is massive. Few decades ago Lake Chad which covered an area of 40,000 square kilometres now encompasses about 1,300 square kilometers. Also rising temperatures has led to the rapid southward expansion of the Sahara Desert. Farmlands and surrounding villages have become barren and there is now the emergence of derived forest or grasslands. Excessive Logging and over dependence on firewood is rapidly devouring the guinea Savannah of Nigeria. Excessive rainfall leading to gully erosions has completely devastated the lands in most parts of the east of Nigeria while rising sea levels are threatening the coastal regions with floods. These occurrences are having negative impacts where farmlands have become uncultivable, increasing disease infections, migration, violent clashes between herdsmen and farmers, flooding, heat related diseases, destruction of infrastructure such as roads among others. Due to low level of technology, Nigeria's effort has been on ways and means to ameliorate the impacts of these occurrences. The management of these occurrences and their impact has been through the Federal Ministry of Environment and the National Emergency Management Agency.

While these bodies are doing their responsibilities, not much can however be said to have been achieved due to problems such as lack of funds due to low budget allocation, lack of continuity in programmes by successive governments and poor infrastructure. At the local government level, these problems are worse. It must be noted the local government council in Nigeria administer the rural areas of Nigeria. The rural areas are as affected by climate change as the urban centres. But because of poor funding of the local government councils and poor infrastructural development, these local councils through the departments of environment have achieved very little in managing climate change impact.

The study area is essentially a rural environment and it is administered by five local government councils. The impact of climate change is also very evident. The local government councils are saddled with the responsibility of managing the effects of climate change. What they are doing, which programmes are in place and how much they have achieved and the challenges they have is not known. It is upon this that this study wants to evaluate the management of climate change impact in this study area.

STUDY AREA

The study area is the five local government areas of Edo Central Senatorial District of Edo State Nigeria. The Senatorial District is located within Latitude 6^{0}17’ and 6^{0}45’ north of the Equator and Longitude 5^{0}45 and 6^{0}17’ east of the Greenwich Meridian. It is bounded in the north by Etsako west and central local government areas, in the north-west and west by Owan west and Uhunmwode local government areas, in the south by Delta State and in the east by the River Niger.

The five local government areas are made up of several settlements. Apart from the headquarters which are the only urban settlements, all other settlements are rural. For the purpose of this study, the headquarters and three rural settlements from each local government area are used for this study. The rural settlements were selected by stratified sampling method where the highly populated, medium and the least populated were selected. Table 1 shows the local government areas and their headquarters, selected rural settlements and their population.

METHODS OF STUDY

Primary and secondary data are used in this study. Primary data were sourced from the Department of Environments in the secretariat of the local government areas and the field of study, that is, the residents of the selected settlements of study. To get primary data from the secretariat, five Interview schedule were distributed and administered on the Heads of Department of Environment in the five local government secretariats. Among others they were used to ascertain the level of climate change awareness created and the impact, the resources used, the measures adopted, the impacts and the common problems. On the other hand, questionnaires were used to obtain data from the residents of the study area. To this end, 363 questionnaires were made and distributed among the settlements. As shown in Table 1, 114 questionnaire were distributed in the local government headquarters (the urban settlements) while 249 questionnaires were distributed among the rural communities. In all 283 were farmers while 80 are into secondary and tertiary occupations. The systematic random sampling technique was used to distribute questionnaires among the sampled residents of these settlements. Among others, the questionnaires were used to get data on residents' awareness, the common problems of the change and the impact. 0.001% of the population of each selected settlement was used for questionnaire distribution as shown in Table 1.

Secondary data on the other hand were collected from relevant documentary materials, published and unpublished books, journals and internet sources. Data collected were analyzed descriptively and using tables.

Temperature and Rainfall Pattern of the Study Area

Characteristically the study area experiences the humid tropical climate which has two distinct seasons, the wet and the dry seasons. The dry season lasts between November and March and this period usually coincide with the period of low sun while the wet season lasts between April and October of each year and it is the period of high. This wet season is brought about by the South-West monsoonal winds which blows across the Atlantic Ocean into the hinterland while the dry season is brought about by the North-East trade winds which blows across the Sahara as at the time of winter in the northern hemisphere.

The mean annual rainfall is about 1915mm while the mean monthly temperature is 27^{0}c (Adejuwon 2011). The months of July and September have the highest rainfall while the months of December and January experiences the lowest rainfall of the year. The highest temperature in this area is recorded between January and March while the lowest temperature occurs in June and July. This shows that temperatures are relatively high all year round while rainfall is also heavy in the period especially May to October of every year. Table 3 and 4 shows annual rainfall and temperature records of the study area between 2003 and 2017. The data shows general but fluctuated high rainfall.

Table 2: Annual and Mean Rainfall of Study Area 2003-2017

Year	***Annual Rainfall (mm)***	***Mean Annual Rainfall (mm)***
2003	*1703.00*	*141.90*
2004	*1925.00*	*160.70*

Effect of Rainfall and Temperature Pattern in the Study Area

This study shows that high temperature and heavy rainfall causes flooding, erosion and heavy storms in the study area. Its associated impacts in the area include traffic congestion, poor infrastructural services, environmental degradation, poor yield on farmlands, and diseases infection.

Farming: The people of the study area are predominantly farmers. Farming is practiced more in the rural areas due to availability of land. Crops cultivated and produced include food crops such as yam, cassava, tomatoes and maize and tree crops such as cocoa, kola nuts and oranges. Temperature and rainfall change pattern in last few years is affecting farming. Responses from farmers show that high temperature and rainfall has caused disease infection on crops, poor soil fertility, farm and crop loss due to erosion and flooding which ultimately has led to low farm output.

Of the 363 questionnaires distributed 283 or 78% respondents are farmers who practice mainly crop farming on full time and part time basis. Of the 283 farmers 249 or 88% are rural farmers while 34 or 12% are in the urban centres. Using the impact of rainfall pattern on rural farming, the 249 farmers agreed that the impact was high. They identified erosion and flooding as the commonest which in the last few years have not only made farm roads impassable due to gullies created, but has consistently washed away farm lands and crops. Among the farmers, 102 or 41% remarked that they have witnessed continuous flooding and the washing away of their farmlands and crops in the last 7 years. Farmers in Esan South East made particular reference to the devastating floods of 2014 and 2015 caused by heavy rains that saw the increase in the waters of the River Niger which overflowed its banks and washed away several communities and their farmlands. Also, 27 or 10.8% of the farmers remarked that they have witnessed crop failure and poor harvest as excessive rainfall make tuber crops like yam and cassava rot in the ground.

***Physical Environment**:* Land and farming are the most valued in most rural areas. In the study area, rural lands have been devastated by erosion and flooding. Rural areas at proximity to urban centres are worst as they are places receiving waste water from urban centres. Emuhi community lands have become heavily fragmented due to excessive erosion from Ekpoma town. As a result of the fragmentation, the earth roads are difficult to use while houses and farmlands are severely affected. Most of the roads in the rural areas are earth roads which served mostly the purpose of transporting farm produce to the urban markets. Because the roads are not tarred, heavy rain often washed them and create gullies in them that make them almost impassable for most time of the year. In the urban centres, about 87% of the roads are also untarred and because of this, urban movement is often a serious task. Poor accessibility has grievous socio economic consequences. The rural farmers are all affected by the condition of rural roads. Apart from longer time spent on the roads, the cost of transporting goods is increasing while vehicle accidents are also very common. Of the 149 rural farmers, 36 or 24.% have been involve in vehicle accident in the process of moving from the rural to urban centres. Average cost of transportation between rural areas and their local government headquarters is on motor vehicles is ₦200 or 0.68 Dollars. It is of note to mention here that because of the nature of rural roads, motorcycle and tricycles are the most preferred means of transportation in the rural areas as accounted by 231 or 92.8% of respondents. This means is popular because it is faster on the roads and also has the ability to meander through bad spots on the roads. Average cost of movement per person to the urban centres is ₦400 or 1.2 Dollars. This means is also popular in the urban centres and is the most used within the urban centres as accounted for by 96 or 84.2% of the urban respondents.

***Infrastructure**:* According to Onokerhoraye (1982) over 65% of infrastructure in the Nigeria is located in the urban areas. This is also true of the study area where 62% of amenities are located in the local government headquarters of Edo Central Senatorial District (Omofonmwan, 2004 and Emily, 2011). Amenities in the study area and particularly the urban centres include hospitals, housing, tarred roads, electricity, schools, telephone, police stations, prisons, courts, post offices and banks. Using roads as an amenity of climate influence, it can be seen that roads and particular the urban roads are in deplorable conditions. The roads are characterized with pot holes and failed portions. A major cause is the constant flooding as can be seen in Ihumudumu road in Ekpoma and the Uromi-Ubiaja road. When it rains these and other roads are flooded and become almost impassable. Worse still the poor drainage system that are inadequate and lack good depth and network are always unable to drain the volume of heavy rain water. Apart from roads, many houses have also been affected. From the questionnaire survey, 9 houses in the rural areas and 5 houses in the urban areas have collapsed since the year 2008. The removal of soil around the foundation of such buildings for long year has partly been attributed. Some areas are erosion and flood prone. Examples are Ukpenu in Esan West, Ubiaja in Esan South East and Uwalor and Ukomi in Esan North East.

Health**:** The impact of climate change on health cannot be overemphasized. Temperatures affect virtually every aspect of the environment. The effect on man is mostly health related and according to Doerr, (2018), temperatures between 28-35^{0}C can cause problems such as heat rashes, heat stroke, exhaustion, cramps and syncope in man. From the questionnaires distributed, 86% of respondents agreed that heat rash was the commonest problem that people suffer as a result of excessive heat from high temperatures. On the diseases which are influenced by high temperature and rainfall pattern in the area, 82% of the respondents identified malaria, 14% identified typhoid fever while 4% identified other diseases like cholera and diarrhea. These diseases come about when accumulated floods from heavy rainfall become breeding places for malaria causing pathogens or when water consumed is contaminated by fecal microorganisms that have been spread during heavy rainfall (Oredola, 2016 and NCDC, 2017). It should be noted that temperature impact on the life cycle of pathogens. For example temperature of 21^{0}c to 23^{0}c is very suitable for the development of mosquitoes that causes malaria fever (Harvell et al 2002). To ascertain the claim of the respondents on these diseases, 5 year record of the diseases from the Primary Healthcare Centres in the study area were obtained as shown in Table 4.

Table 4. Reported Cases of Malaria, Typhoid and Heat Rash between 2013 and 2017 in the Study Area

Year	*Malaria*	*Typhoid*	*Heat Rash*	*Total*
2013	*43,783*	*18,436*	*53*	*62,272*
2014	*48,417*	*17,338*	*49*	*65,804*
2015	*37,615*	*21,855*	*118*	*59,588*
2016	*54.952*	*24,675*	*34*	*79,661*
2017	*54,413*	*28,016*	*72*	*82,501*
Total	*239,180*	*110,320*	*326*	*349,826*

Source: Primary Healthcare Centres in the Study Area (2018).

From the Table 4, malaria fever is obviously the most suffered disease in the study area and this accounted for 68% of the diseases listed. Typhoid fever accounted for 31.5% while Heat Rash accounted for 0.09% making it the least reported case. Let it be stated that 72% of the cases are from the rural communities in the study area while only 28% are from the urban centres. From the Table 4 also, one can see a general progression in the infection of these diseases which portend that more persons will be infected except adequate measures are taking.

Urban Environment. One of the commonest problems in the urban centres of the study area is indiscriminate waste disposal. The study of Ojeifo and Uwadiae (2005) shows that waste ranging from papers, plastics, metals, food remnants and wood material are usually disposed indiscriminately in the market places, open spaces, along roads, in drains and in other public places. Because of poor waste management practices by the people and the local government authorities, most parts of the towns are usually littered with wastes whenever there is heavy rainfall. Apart from creating poor aesthetics, the littered wastes create opportunity for bad smell and the breeding of pathogens that cause diseases. In a study of the problem of refuse disposal in Ekpoma and Irrua towns in Edo State, Ojeifo and Uwadiae (2005) observed among others, that lack distance to dumpsites, attitude of inhabitants and the local government council's inadequacies as responsible for the poor waste management in the area.

Management of Climate Change Effects and Problems in the study Area.

The management of climate change effects involves weather data gathering, dissemination of information based on data, awareness creation, response to effects of weather condition and the provision of facilities and equipment to ameliorate the effects. In the study area, the departments of environment in the local government councils are responsible for the management of climate change conditions. The techniques for administration include creating awareness for climate change and effects, responding appropriately to severe weather conditions and effects, facility provision and rehabilitation and the provision of equipment and personnel. From the field survey carried out however, it was discovered that very little of these goals are being pursued and achieved in the study area.

Field investigation shows that there is no form of climatic data gathering and information dissemination by the local government councils in the study area. The reason for this is that none of the councils have weather facilities from which data is gathered. Without weather data and information, it is practically impossible to disseminate information about weather conditions and possible effects.

For lack of data and information, awareness on climate change and effects was discovered to be low in the study area. The interview schedule administered on the local council authorities shows that they have little knowledge about the changing pattern of these climatic elements. Although they indicated that they are aware that temperatures are high all year and rainfalls are heavy in their periods and also know that effects occur from their occurrences but that they have never carried out any campaign to sensitize or create awareness about this.

For lack of information on weather data in the area, some residents now rely on mobile phones, print and electronic media for weather information. From the questionnaires administered, 44 or 12% of respondents have access to climatic data and information. Among this number, 36 or 82% get their data and information from their mobile phones while the remaining 8 or 18% gets theirs from other media sources such as radio, newspapers and television. The residents also remarked that the local authorities have never engaged the people in any awareness campaign to sensitize them on this change pattern and effects.

Management also involves quick response and inspection of places affected by climate change effect especially the action of heat waves, erosion, flooding and rainstorms. At the local government level, there exists Local Emergency Management Agency (LEMA). The department of environment is responsible for coordinating the objectives of this agency. The principal assignment is to provide quick response to emergency situations and take action that will prevent a reoccurrence. In the study area, this assignment is seldom made by the local government when there is emergency situation. Even when steps are made, they are often of non effect. For example, the local council authorities were not able to manage the floods that occurred in the study area in 2014 when the river Niger over flooded its banks as a result of excessive rainfall. As at today, no concrete measure has been taking either in terms of feasibility studies, attending to the river banks, construction of adequate drainages system for the area, provision of relief materials or empowering local farmers who were worst affected by the floods.

Effective management involves the provision, replacement or repair of facilities to ameliorate the effects of climate change. For example, facilities negatively affected by the action of erosion and flooding such as roads and drainages which result in damages and make them channels for flooding are expected to be fixed. In the study area, most tarred roads of which 65% are in the urban centres have potholes and failed parts. The rural untarred roads which are over 10,800 kilometers are constantly been washed. The interviews on the local council shows that only 13 kilometres of roads have been constructed and tarred by the local government council since 2012 while only 52 repairs were carried out on potholes and failed portions of existing tarred roads. On the rural roads, no new construction has been carried out since 2012, only re-grading of existing roads has been carried out in few communities. On the whole very little is been done by the local government to respond to road situation affected by climate change.

Availability of equipment and personnel are basic for effective management of climate change effects. For example, waste disposal trucks are essential for environmental sanitation. In the study area, weekly sanitation by the local government is done every Mondays but restricted to market places for the purpose of revenue generation. General sanitation is also done in the area once every month. The success of the monthly sanitation especially in the urban centres has been adjudged to be fairly higher than of the rural areas (Okhai 2017). The success has largely been attributed to residents' participation rather than the local government councils. This is because apart from the general sanitation announcement which the council makes to the public prior to the exercise and the physical presence of men of the department of environment to coordinate and do surveillance, all collection and disposal are done by the residents'. Therefore most of the refuse disposed indiscriminately and spread by erosion and floods are often disposed by residents" Table 5 shows types and number of some sanitation equipment owned by the local councils in the area.

Table5: Types and number of some Waste Management Equipment and Personnel in the Local Councils

Source Field Survey (2018)

Column 7 of Table 5 here shows the inadequate qualified personnel in the department of environment in the local council authorities. This is one of the reasons why the study area and particularly the rural areas are not always covered for inspection and sanitation. The consequence is that these rural communities are dirty and filled with refuse of all kinds.

Finally, the management of climate change effects also involves managing victims of floods, erosion and heat related diseases. The study area has 54 Primary Healthcare Centres that are owned and operated by the local government councils. Although there are doctors and other medical personnel and equipment, they are however inadequate, Also the Primary Healthcare Centres cannot handle severe cases. As shown in Table 4, malaria, typhoid and heat rash are the frequently reported cases associated with climatic influence. Victims of weather related cases often handle their cases by themselves as the local government does not take any responsibility in this regard

Problems of Climate Change Management in the Study Area

The problems of the management of climate change effects in the study area are many. They are inadequate facilities, inadequate manpower, lack of action plan for climate change effects and the problem of funding the environmental department. The department of environment is responsible for environmental data gathering, plan formulation, enforcement and execution of plans and monitoring. This study has revealed that the departments in the local council areas have not been able to effectively handle most environmental challenges due to inadequate funding. For example budgetary allocation to this department has not exceeded 3 Million Naira or 855 Thousand Dollars in the last 15 years. This is rather too small for meaningful response to environmental problems. The highest budget ever presented by any council in the study area is 2 Billion Naira or 54 Million Dollars and this was in 2014. Every year, recurrent expenditure takes about 80% of budgets and what is usually left for capital and other developments is usually too meager to meet the aspirations of the people. Table 6 shows budgetary allocation to the departments of environment in the council authorities between 2013 and 2017.

Table 6: Percentage of Budgetary Allocation **(in Million Naira)** to the Departments of Environment of the five Local Government Council Areas

CONCLUSION AND RECOMMENDATION

This study is an evaluation of the management of climate change impact on rural communities of Edo State Central Senatorial District. A process approach was followed in which rainfall and temperature conditions and their effects were examined while the role of the local authorities in mitigating and ameliorating these effects was ascertained. Primary and secondary data were used in the study and these data were analyzed descriptively with results presented in tables. The findings were that temperature and rainfall patterns are high or intense which is an evidence of climate change in the study area. On the impact of temperature and rainfall pattern, the study observed that these elements have great impact on farming, the physical environment, infrastructure development, the health of the people and the urban environment.

The study observed that the department of environment in the local council authorities was responsible for the administration and management of climate change effects. In managing these effects therefore, this unit adopted the techniques of awareness creation, response to occurrence, facility provision and the provision of adequate equipment and personnel. However, the study discovered that the department of environment in the local council authorities was not able to effectively manage these effects due to inadequacies in all the areas of management. For example the departments of environment do not have facilities for climate data collection, awareness creation and dissemination of weather information, waste disposal facilities, enough personnel to respond to effect occurrence and funding. It is against these operational problems that the following recommendations believed to be capable of ameliorating the effects of climate change in the study area are made

First it is recommended that the five local government areas jointly build an automated digital weather station where daily reading and recording of rainfall, temperature and other climate elements data could be carried out. This station can be located in any of the local government areas provided it is build by experts in the field with clear adherence to installation provisions. Climatologist or meteorologist can therefore be employed to do the recording of data.

Secondly, upon the location of a weather station, information from the station on daily data recorded and weather outlook should be disseminated to the general public through the television or the internet so those with mobile phones can easily access them. This innovation can easily prepare people ahead in the case of any severe weather occurrence and effects.

It is also recommended that the local government councils should wake up to their responsibility in the areas of the provision and rehabilitation of facilities. As observed, many roads particularly rural roads are not tarred and the few urban roads that are tarred are dilapidating very fast with potholes and failed portions. Drainages are broken and wearing away and creating opportunities for flooding and erosion in the study area. The local government must therefore engage in the construction and rehabilitation of roads and drainages so as eliminate the problem of flooding and its effect on traffic and the health of the people.

The environmental department is grossly underfunded. For this reason it is unable to function effectively and efficiently in the study area. For lack of or inadequate funds vital materials and equipments needed for regular operations such as personnel carriers, waste disposal trucks, fire service trucks, pail loaders, graders and even simple shovel and diggers are not adequate Also the number of trained personnel are inadequate to handle . The occurrence of severe weather condition or any other environmental problem must be attended to by qualified persons who have the requisite training. As it is presently the number of trained personnel is inadequate therefore it is recommended that more personnel be employed, that is a minimum of 10 qualified personnel in each department of environment in the local government areas who should be sent on regular training.

Finally, the effects of rainfall and temperature in the area are enormous. As rural areas, their major occupation is farming. The threat of high temperatures and rainfall on farming in the last few years has been very great. In the process, crops and lands have been lost. If famine and hunger must be avoided in the area, the local government must give support to the rural farmers. The support should be in the form of financial assistance, provision of improved seedlings, land reclamation and other extension services to boost food production in the study area.

Application of Low-Rank Sparse Decomposition Method to Study Surface Urban Heat Island of Kolkata

Saikat PAUL, SARATH Raj K., B. Bhaskar RAO and Ritu ROY
Department of Architecture & Regional Planning
Indian Institute of Technology, Kharagpur, India

Abstract

In image data analysis Principal Component Analysis (PCA) performs well when the noise is small and Gaussian in nature. However, when the data is non-Gaussian in nature and may contain outliers and spikes, PCA fails. The intrinsic low ranked structure of the datasets can be used to reduce the dimensionality, remove noise and complete missing values by solving a convex Principal Component Analysis (PCA). Surface Urban Heat Island derived from Landsat 8 ETM+ data of Kolkata has been separated into a set of low-rank and sparse components. The Low-rank components depict the linearly correlated data the sparse component represents the perturbation with respect to the mean in the data set. This property is thus useful to assess trends or patterns in the data. Low-rank Sparse Decomposition Method has been used in the field of image processing, bioinformatics, data ranking problems. This study is an attempt to establish RPCA method for studying the trends in Surface Urban Heat Island (SUHI) phenomenon in the metropolitan city of Kolkata.

Key Words: UHI, Low-rank Sparse Decomposition Method, RPCA

1. Introduction

Low rank and sparse decomposition method have been used in data compression and dimension reduction. This study uses the RPCA to assess the evolving pattern of Surface Urban Heat Island for the city of Kolkata. Urban Heat Island (UHI) is a climatic phenomenon which results in an increase of air temperatures in cities compared to the immediate rural areas (Sobstyl et al. 2018; Dos Santos et al. 2017). Surface Urban Heat Island (SUHI) is used to measure the temperature difference between the land surface in rural and urban areas. UHI and SUHI significantly alters the comfort conditions in the urban area thereby increasing the energy requirements for cooling. The land use composition, emissivity and albedo of the surfaces, the storage heat, the energy balance between latent and sensible fractions, and the anthropogenic heat contribute to this phenomenon. This condition is exacerbated by pollution and global climatic perturbations in the form of Climate Change and the ensuing Global Warming. Changes in land surface characteristics of urban areas has also led to increase in the storage heat component in the net energy balance and the temperature within urban areas show hysteresis which is associated with time lag and decrement factor. Energy consumption in different urban processes has led to intensification of SUHI. Peng et al. 2012, studied that vegetation cover assumes a key role in attenuating SUHI in cities thereby mitigating the UHI effect. Several authors have contributed to the research on urban heat Island which has been summarized in table 1.

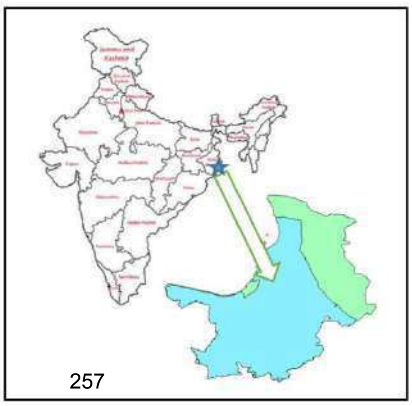

Figure 1: Location map of the study area (Kolkata Metropolitan Area)

Table 1 Factors affecting UHI

S.No.	***Authors***	***Factors affecting UHI in Cities***
1	Peng et al. 2012	Difference in albedo of urban in comparison to rural areas and attenuation effects of vegetation in rural areas
2	Sobstyl et al. 2018	City texture measured by building distribution function and the sky view factor is correlated to UHI
3	Dos Santos et al. 2017	Amplifying effects of developed areas for UHI
4	Menberg et al. 2013	Anthropogenic heat flux contributing to Ground Surface Temperature (GST)
5	Wu et al. 2017	Higher concentration of atmospheric aerosol particles PM2.5 over urban areas reduced UHI intensities by 1°K attributed to the radiative exchanges by the particles
6	Kumar et al. 2017	Urban rural temperature modulations mainly attributable to moisture availability from irrigation in rural areas and atmospheric aerosols
7	Battaglia et al. 2017	Temperature and RH increase as a result of UHI in urban areas affect semivolatile atmospheric species as nitric acid, ammonia and water affecting the aerosol pH (urban rural aerosol pH differences during intense summer ranging from 0.8 for Baltimore and 0.65 for Chicago)
8	Zhou et al. 2017	Studied the effects of city size and urban form on UHI phenomenon and observed that UHI intensity increased with the logarithm of city size and fractal dimension
9	Ward et al. 2016	Studied Europe wide heat wave and the effects of size of heat island, regional climate and central urban green spaces were found to be significant on Surface Urban Heat Island Magnitude (SUHIM)
10	Martin et al. 2015	Identified the hysteresis effect of global solar radiation (GSR) on surface intra-urban heat islands (SIUHI)
11	Yue and Liu 2016	Green ratio, Plot area, Building density and building height affected the land surface temperature significantly and the urban thermal environment
12	Heaviside et al. 2017	Studied health related risks in urban population compared to rural population due to heat exposure attributable to the UHI effect
13	Zhan et al. 2014	The subsurface urban heat island (SubUHI) intensity reaching first and second extremes in a diurnal temperature cycle lags by about 3.25 and 1.97 hrs per 0.1m

This research explores the daytime variations of Surface Urban Heat Island Intensity (SUHI) in the Kolkata Metropolitan area (figure 1). The correlation of normalised difference vegetation (NDVI) and fractional vegetation cover vis-a-vis the SUHI establish the relationship between the land cover types with the SUHI.

1.1 Low Rank Sparse Decomposition Method

Decomposition of low-rank and sparse components (LRSD) from partial or corrupted measurements is possible for separation of background and dynamic components. LRSD can be used in both static (Hou et al. 2014; Yang et al. 2018; Wen et al. 2016) and dynamic applications (Otazo et al. 2015; Hu et al. 2016; Chen et al. 2015). LRSD method have been used in several application areas including interpreting of MRI scans (Baete et al. 2018; Otazo et al. 2015), to detect voxelwise group differences, CT image sequence restoration (Gou et al. 2013), moving object detection (Hu et al. 2016), face recognition (Hou et al. 2014), discriminating between various sound classes in auditory signals (Lyon et al. 2010) etc.

The LRSD separates the sparse individual variability in the sparse matrix (S) and the essential features in the low rank matrix (L). This method can be applied for studying Surface Urban Heat Island phenomena where input data is temporal in nature and can be separated into background component and sparse component create scenario of deviation from the mean.

2. Methodology

Moderate resolution Landsat 8 ETM+ satellite data has been used for this study. Cloud free satellite data of Kolkata Metropolitan Area was downloaded from the Earthexplorer website for 6th April 2014, 11th April 2016 and 14th April 2017 which corresponds to the summer month having pronounced elevated temperature and clear sky conditions in comparison to other months.

The Landsat data has been corrected for atmospheric attenuations using a dark object subtraction (DOS) method (Nguyen et al. 2015). Dark objects can be assumed to reflect no light, and values greater than zero must result from atmospheric scattering and this is the basis of the DOS method.

The Landsat 8 image Digital Numbers (DNs) were then converted to spectral radiance using appropriate gain and bias values in the image header of the data file, based on equation 1.

$$L = L_{Max} - L_{Min} * 255 * DN + L_{Min} \quad (1)$$

Where,
DN is the degree of greyness of the pixels
$L(\lambda)$ is radiance in ($W/m^2/sr/mm$)
L_{Max} and L_{Min} are the calibration constants of the sensor, equal to the maximum and minimum values of the spectral radiance (in $W/m^2/sr/mm$) detectable for each band, by the sensor Landsat TM.

The noise equivalent delta temperature (NEΔT) of TM/ETM sensors is around 0.2-0.3K. Land Surface Temperature (LST) was calculated from brightness temperature using a single channel method using the band 10 based on the following equations (Jiménez-Muñoz et al. 2014).

$$LST = \gamma[\varepsilon^{-1}(\varphi_1 L_S + \varphi_2) + \varphi_3] + \delta \quad (2)$$

$$\gamma = \left\{\frac{C_2 L_s}{T_b^2}\left[\frac{\lambda^4}{C_1} L_S + \lambda^{-1}\right]\right\}^{-1} \quad (3)$$

$$\delta = -\gamma L_S + T_S \quad (4)$$

where,
L_S = at pixel radiance
T_s = brightness surface temperature
λ = effective wavelength, which was regarded to be 11.5 μm in this research,
ε = surface emissivity,
C1 and C2 = constant values of 1.19104 × 108 μm 4 m^{-2} sr^{-1} and 14387.7 μm K, respectively, and
ϕ_1, ϕ_2, ϕ_3 = atmospheric functions that are calculated using Eqs. (5)–(7) and the amount of water vapor in the atmosphere at the time of imaging.

$$\varphi_1 = 0.14714W^2 - 0.15583W + 1.1234 \quad (5)$$

$$\varphi_2 = -1.1836W^2 - 0.15583W + 1.1234 \quad (6)$$

$$\varphi_3 = -0.04554W^2 - 1.18719W + 0.39071 \quad (7)$$

The SUHI has been derived by differencing the LST with reference to average LST values of rural areas for each dataset.
The satellite images were classified using a maximum likelihood approach in Erdas Imagine Software and classification accuracy was determined by applying Kappa coefficient (Sharma et al. 2015; Li et al. 2011; Shishir & Tsuyuzaki 2018) using the following equation:

$$K = \frac{N\sum_{i=1}^{r} x_{ii} - \sum_{i=1}^{r}(x_{i+} * x_{i+})}{N^2 - \sum_{i=1}^{r}(x_{i+} * x_{i+})} \quad (8)$$

where,
r = number of rows in the error matrix,
xii = number of observations in the ith row and column,
x+i = total number of observations in the ith column, and
N = total number of observations

The fractional vegetation index has been estimated from NDVI using the following linear relationship (Gutman & Ignatov 1998):

$$FVI = \frac{NDVI - NDVI_S}{NDVI_V - NDVI_S} \quad (9)$$

where, $NDVI_S$ and $NDVI_V$ correspond to representative values of NDVI for bare soil (FVC=0) and a vegetation (FVC=1)

$$NDVI = \frac{\rho_{nir} - \rho_{red}}{\rho_{nir} + \rho_{red}} \quad (10)$$

where ρ_{nir} and ρ_{red} are the at-surface reflectivities obtained from sensor bands located in the near infrared (NIR) and red spectral regions of Landsat 8 ETM+.

The mixed pixel emissivity has been determined using an empirical relationship based on an exponential function which is NDVI dependent as proposed by Sobrino et al. 1996.

$$\epsilon_\lambda = \epsilon_{V_\lambda} - \left(\epsilon_{V_\lambda} - \epsilon_{S_\lambda}\right)\left(\frac{NDVI - NDVI_V}{NDVI_S - NDVI_V}\right)^k \quad (11)$$

where, λ represents the spectral band, ϵ_{V_λ} is the vegetation emissivity (0.99) and ϵ_{S_λ} is the soil emissivity (0.96 Ref. JPL Library Database). $NDVI_V$ is the maximum NDVI for fully vegetated pixel (0.99) and $NDVI_S$ is the minimum NDVI for bare soil (0.15).

Low Rank and Sparse Decomposition (LRSD) is a robust method for separating a rectangular (i,j) matrix $\mathbf{I}$ into a Low Rank Component (**L**) and a Sparse Component (**S**) :

$$\mathbf{I} = \mathbf{L} + \mathbf{S} \qquad (12)$$

This has been applied on SUHI Images using an inexact augmented Lagrange multiplier method (IALM) (Lin et al. 2011; Erichson et al. 2016) using RRPCA model of RSVD module in R.

3. Results and Discussions

Temporal changes in the extent of vegetation cover has been studied using NDVI for the 3 datasets. Significant changes (improvement in the vegetation content) can be observed in 2016 compared to the 2014 and 2017 when the NDVI values were significantly lower (having lesser vegetation content) due to more intense summer. The implication of this is reflected in the Surface temperature where the increased latent heat fraction results in lowering of the LST on 6th April 2016. The corresponding Fractional Vegetation Index is also high for the 2016 dataset (figure 2).

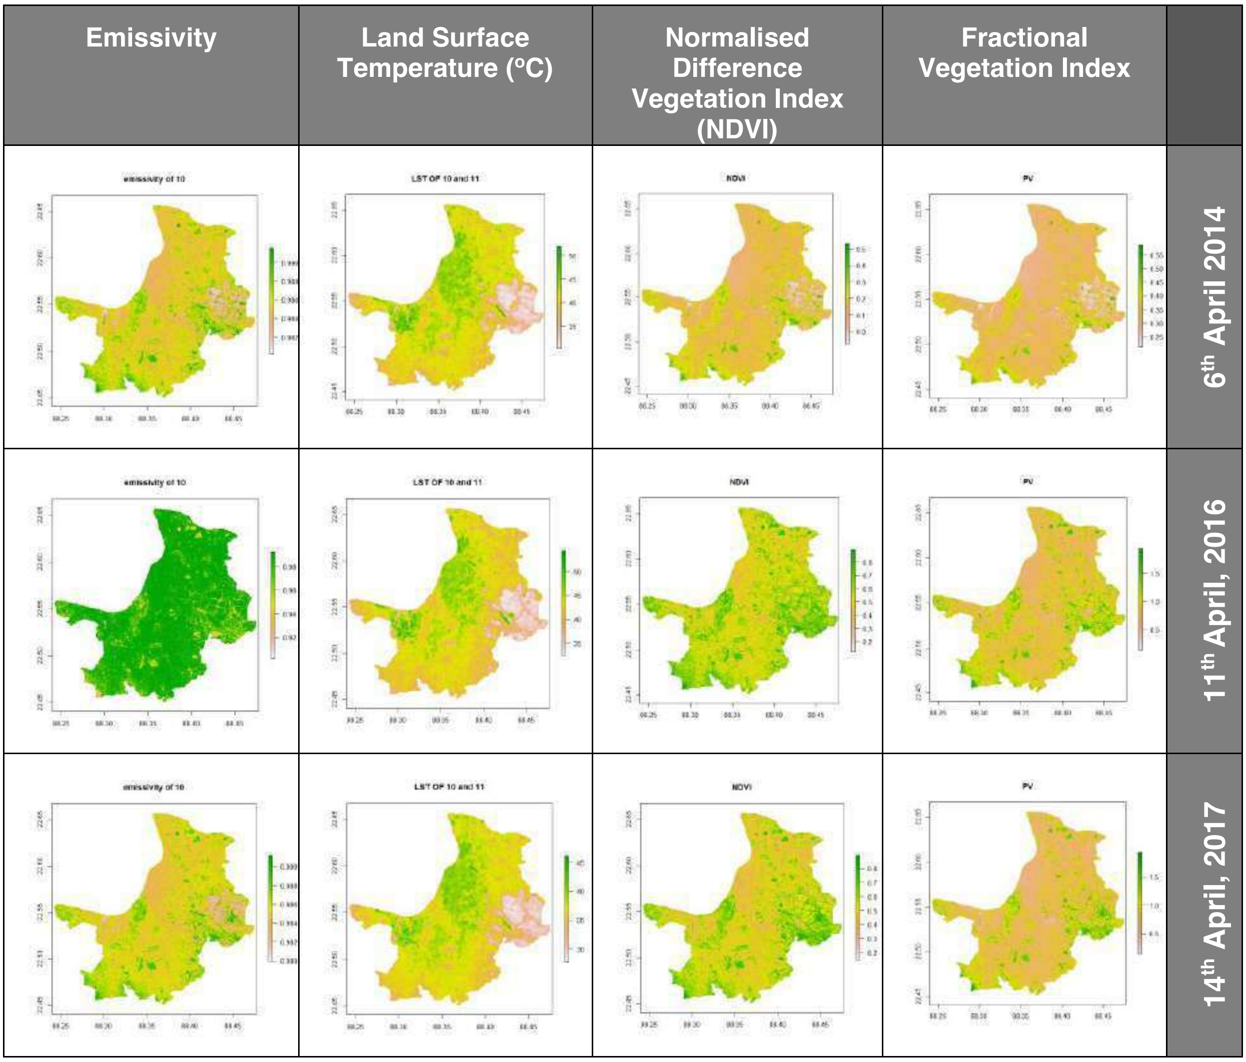

Figure 2: Emissivity, LST, NDVI and Fractional Vegetation Index Maps of Kolkata Metropolitan Area

Temporal changes in the extent of vegetation cover has been studied using NDVI for the 3 datasets. Significant changes (improvement in the vegetation content) can be observed in 2016 compared to the 2014 and 2017 when the NDVI values were significantly lower (having lesser vegetation content) due to more intense summer. The implication of this is reflected in the Surface temperature where the increased latent heat fraction results in lowering of the LST on 6th April 2016. The corresponding Fractional Vegetation Index is also high for the 2016 dataset (figure 2).

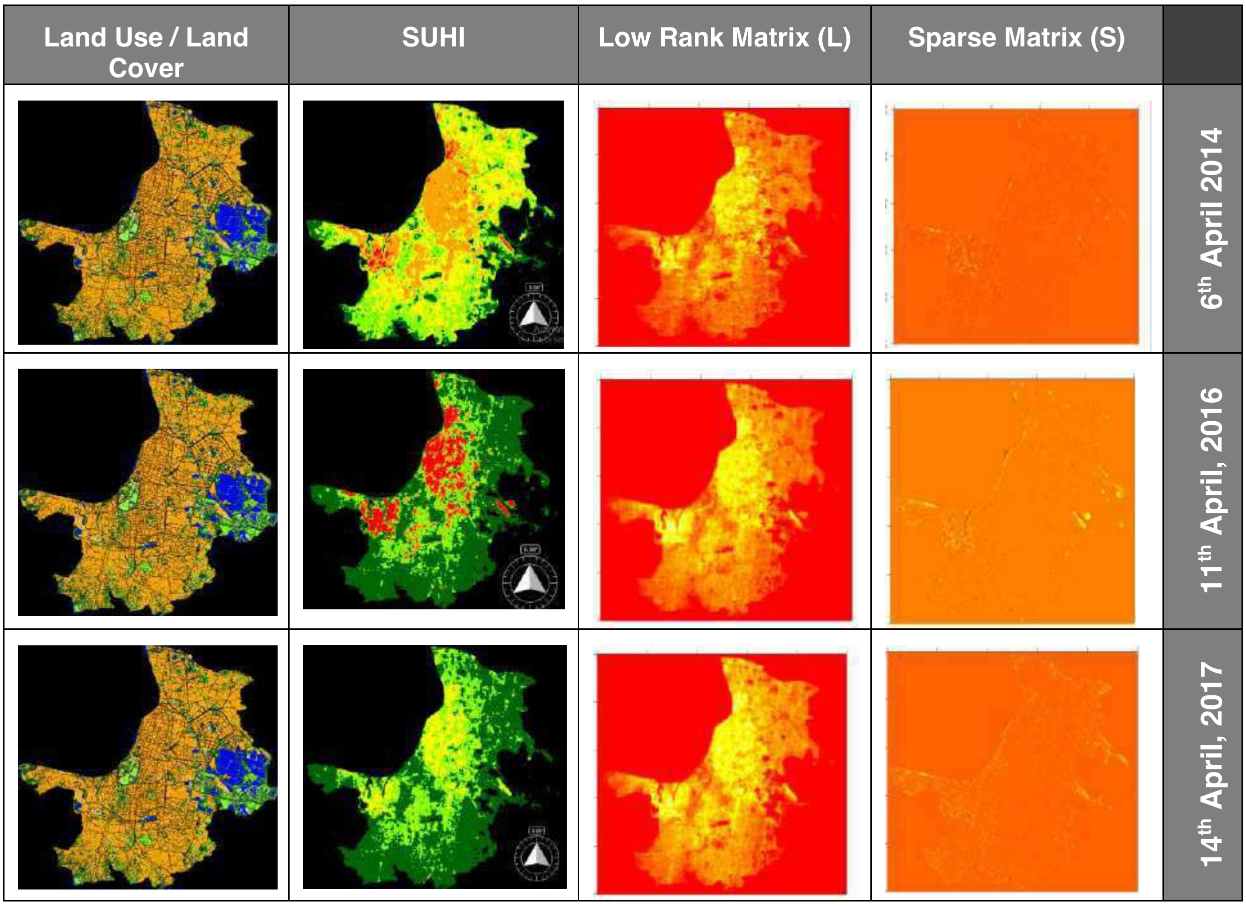

Figure 3: Land Cover, SUHI, Low Rank Matrix and Sparse Matrix of Kolkata Metropolitan Area

4. Conclusion

Low Rank Matrix and Sparse decomposition method can be applied for studying Surface Urban Heat Island (SUHI) phenomena. The temporal data and can be segregated into Low Rank or background component, which depicts commonalities between the time steps and Sparse component, which depicts the dynamic changes in terms of SUHI. The Sparse Component corresponds to changes in SUHI manifested due to changes in either or all parameters of emissivity & albedo which are characteristic of building materials and paved or natural surfaces and built form geometry which signifies re-densification and sprawl or intensification of energy use such as industrial activities or heat emissions due to adoption of cooling or cooling systems.

Thus low rank and sparse decomposition method is a very effective tool to study urban growth and its impact on the s u h i phenomena. this method can be implemented for Big Data Analytics of large volume of satellite derived surface temperature information at a global scale and detect anomalies and device strategies to control and mitigate the effects of these changes.

Climate Change and the Impacts on Urban Planning and Design in Iranian Cities

Ehsan RANJBAR, Tarbiat Modares University, Tehran, Iran
Najmeh MOTALAEI, University of Applied Science, Tehran, Iran

Abstract

Climate change is a key challenge 21th century that many countries are facing with and everywhere has different consequences based on local characteristics. Referring back to the substance of the century as century of cities, it's time to do a paradigm shift in urban planning and design. Such transformation in urban planning and design thoughts is critically needed in those countries which has a background of climate change geographically and historically. Iran is one of these countries that is touching the effects of climate change. Having different microclimate in the country, the challenge has been emerged in different face.
This article, first, is trying to elaborate the challenges resulting from climate change in Iranian cities and second assess the consequences and effects on everyday life of cities. Then, the text is directing to the introducing new solutions which is relating more to the process of urban planning and design.
As a methodology of the research two cities Tehran (the capital) and Ahvaz (the main reference city of dust storm) will be analyzed based on content analysis of official documents, environmentalist ideas and public opinions in social networks media. Also, some evidence of historical urban innovations adapting climate challenge will be analyzed based through case studies of Isfahan and Bushehr.
Some results demonstrate that complexity of climate challenge is more in metropolitan areas of Iran because combining the challenge with social challenges. Also, it is needed to change educational dimension of urban planning and design at universities, institutes and urban government section relating to climate change. To accelerate urban change according climate change, Iranian cities needs more engagement of people and urban-based NGOs.

Keywords: climate change, Iran, urban planning, urban design

1. Introduction

Starting period of 21th first century is an inspiring and disappointing ear for cities. It's a paradoxical situation because of the role of cities as main places of living, economy, and creativity and innovation one hand and crucial places for living, health and happiness because of complex, continuous and increasing challenges. Climate change is one these challenges which is encompassing and surrounding all of other challenges. Somehow it's more critical and essential than others. Such challenge is effecting on cities because of changes out of cities in regional, national and global level and also it has creating because of changes resulting of human actions in urban spaces and architectural level. Cities of this century tend to be extremely resource intensive and contribute hugely to increases in greenhouse gas emissions and consequently, climate change.
The impact of urban systems on climate change is illustrated by the fact that 75% of all greenhouse gas emissions are generated in the world's urban areas (UN, 2007); while only approximately half of the planet's population live in closer settlements. In other words, urban systems are a principal source of emerging climate threats (ESPACE, 2008 and Shalaby & Aboelnaga, 2017). The Third Assessment Report of the 'Intergovernmental Panel on Climate

Change' (IPCC) brought world attention to the likely impacts of climate change (Metz 2001). Climate change is now at the forefront of debate with dire warnings that worldwide temperatures may rise from 5 to 11 degrees C. over the next 50-100 years (Blakely, Edward, 2017) The extent of future climate change depends on a number of variables including the pace of greenhouse gas emissions, deforestation rates, and the response of ecosystems to the changing climate (Jeremy G. Carter. et al 2015) The specific effects of climate change on urban systems will vary depending on location, but may include reductions in potable water, more regular and severe weather events such as heavy rain-falls and cyclones, increased incidences of flooding, inland storm surges and an increase in extreme heat events.(Shalaby & Aboelnaga, 2017)

Referring back to the nature of climate change, the challenge is connecting local and global level of thinking on cities coherently which is opportunity and threat in the same time. Despite this role of climate change, knowledge of urban planning and design as a main discipline related to everyday life of cities is not well equipped. While urban planners are mostly seen as responsible and capable of adapting to disasters and climate risk (IPCC, 2007) their role, the actions to be accepted, and the responsibilities of city agencies are often unclear (Greiving & Fleischhauer, 2012). From urban design point view despite the discipline is the most effective discipline on urban form, climate change is not a key issue in urban design practices. This weakness can be seen also in urban planning and design pedagogy, so that's why we need a massive change in urban planning and design thoughts in the era of climate change.

Such need is more emergency and critical in the cities which have a prior context of climate change geographically and historically. Middle-east countries like Iran has this background from ancient times that's why we can see urban and architectural innovations adaptive to climate in Iranian cities during the history. We have different climate in Iran and the effects of climate change on cities in each climate are different. Mostly water tension or aridity is a key challenge for most cities of Iran especially those are in the deserts.

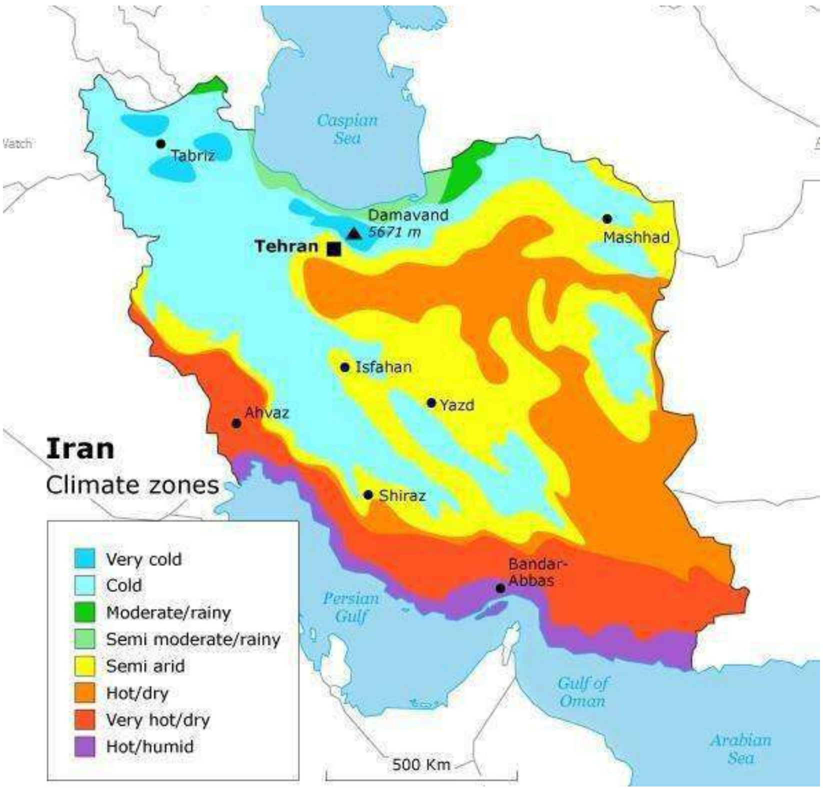

Figure 1: Climate zones of Iran (Alizade Govarchin Ghale, 2014)

But it's not all, there is another face of the challenge when we look at the water conflicts in the Middle East and the results are emerging in Iranian cities in the form of dust storm. For example environmental changes in Iraq including disappearing ponds effects on south-west part of Iran in the form dust in Iranian cities. Moreover, inappropriate national and regional policymaking in water management in Iran has created new challenges locally for instance the salt storm in north-west of Iran because of water tension of Uremia Lake. Adding everyday challenges related to pollution, traffic, quality of life, etc. especially in metropolitan cities of Iran, it's time for Iranian cities to make new decisions. Looking to Iranian cities situation according to face climate challenges in modern era especially in recent four decades reveals that they are directing in a way versus their history. With the enrich background of Iranian cities, they can recognize, recreate and regenerate facing climate change challenge.

This article is trying to highlight the climate change challenges in Iranian cities from urban planning and design point of view. After analyzing the impacts on urban spaces and everyday life, beyond formal and physical solutions like increasing green areas of the city, the article introducing approaches to change the way of thinking urban planning and design of contemporary Iranian cities.

2. Methodology

As a first step two case studies have been chosen to show the historical background of climate adaption knowledge in Iranian cities. Isfahan is one of these cases which is notable because of intelligent distribution of water in the city. The other one is Bushehr which is significant because smart design of city according to wind in sever hot humid climate. The goal of this analysis is demonstrating Iranian people awareness of mutual interaction of climate situation and form of city. The content analysis of selected previous studies is main method in this step. The second step of the research is concentrating on two contemporary cities in which the effect of clime change is crystal clear in different faces. Tehran (the capital) is first case in which we can see the effects of urban planning actions on intensification of climate change impacts. Ahvaz, the center of Khuzestan province, is the second case in which we can consider impacts of climate change happening out of the city in regional level but affecting on everyday life people. Content analysis of official documents, environmentalist ideas and public opinions in social networks media are methods in this step. These combination of case studies provide a basis to think about future of Iranian cities in climate change era.

3. Discussion

3.1. Urban innovations adaptive to climate in the history of Iranian cities

- **Isfahan; "Madi" an innovation of flowing water in a desert city**

Isfahan is a city in the central desert of Iran. Nowadays, Isfahan is one metropolitan cities of Iran in which water tension and aridity have caused a lot of changes. The river as the main element of city during the history has no water because of establishing a dam on the river. Water transferring projects from the source of Isfahan river (Zayanda-rud) to other cities in desert like Yaz has been effected on current situation Isfahan. In other word human intervention in ecosystem intensified climate change effects which in Isfahan mostly reflected in lack of precipitation. The climate situation of the city has not been changed a lot but human thinking about urban and regional planning of the city has been changed enormously in comparison to Safavid period (17^{th}-18^{th} century) when a scientist implemented a plan for flowing the river water in the city. He introduced new water ways with the name of "Madi" which was part of a greater plan of irrigation. Madi-s had a role of channeling water from the river into the city and its main elements like mosques, public baths and private houses. They were also used in cultivating fields and orchards (Falahat, 2014). Different studies have been analyzed the effect of Madi-s on urban structure of Isfahan in different periods where most of main elements of city like mosques, gardens and square have been shaped according to Madi-s direction. (Falahat,2014and Namdarian, 2016) From perspective of thermal comfort we can understand the unique impacts of Madi-s in urban spaces of Isfahan coherent with the impacts on aesthetical qualities of urban spaces. Nowadays, most of Madi-s are empty of water and we need to refer back on the thoughts behind Madi-s such as urban- evironmtal planning and design and multi-knowledge urban planner and designers.

Figure 2: (left) Madi-s and some of main urban and architectural spaces of Isfahan (Namdarian, et al., 2016), (right) creating special urban spaces in a desert city based on Madi-s

- **Bushehr; climatic urban design from site selection to architectural details**

The Northern side of Persian Gulf has a special climate which is hot and humid. The average humidity is 70 percent and the temperature increases to 40 centigrade between May and July. The old Bushehr somehow is a contemporary city in comparison to long history of Iran. The city has been created around 300 years ago with a special plan to tolerate the effects of such climate on everyday life. We can see clearly climatic design initiatives according to wind in old Bushehr. The unique value of these initiatives is related to a deep connection between public and private space to use wind. It has caused a unique townscape in old Bushehr. In other word there is a hierarchy of climatic design respect to wind from whole city to buildings. Different ways of using maximum wind have created a visual diversity in urban facades (Ranjbar, et al.2011). The urban innovations regarding climate condition in old Bushehr can be summarized in these points:

- The location and site selection of Bushehr as a peninsula is a first step to catch wind in the city. In comparison with linear form of city it is more complicated to conduct wind into the city but the amount of wind is more. The special urban open spaces network has changed this threat to opportunity of catching maximum wind.
- According to effect of topography on wind flow, Bushehr position has a windward topography.
- With regard to climatic effects of density and height of built up area old Bushehr has an appropriate roughness that creates dentate texture in the face of wind flow in the sky. This specific height distribution provides the context for more wind disturbance and conduction of it to lower level.
- According to locating high-rise buildings among lower buildings, review of plazas in old Bushehr present this principle. The height difference sometimes is four floors.

- Location of high building at the edge of plazas in Bushehr conducts regional winds to pedestrian level and specific form of plaza provide more movement of wind and its distribution to streets that connects to plaza.
- Specific design of streets in Bushehr like their orientation, special profile, wall projection at first floor, special facad design, organic form, etc. increase the wind disturbance in main streets and alleys.
- There are a few dead ends and buildings have four side that relates to open space. So each side can catch different winds in different directions.
- The external walls of buildings in Bushehr are climatic facades. Different forms of windows, Shenshirs, Boons, etc. shows various methods of absorbing and conducting wind into residential spaces.

So, old Bushehr is an important case that presents a maximum use of wind for creating thermal comfort in both urban public spaces and residential spaces. The next importance is mixing these climatic designs with specific customs and daily life. (Ranjbar, et al.2011)

Figure 3: old Bushehr, smart design of a city where a climatic design integrated with townscape design and everyday life planning

These two case studies of Isfahan and Bushehr show the record of Iranian cities mitigation with difficult climate condition all over the country in the history. It means there was local knowledge about adaptation to climate because in the history general people were urban planner and designers. So a big question is rising that what happened in these days that Iranian cities are not so successful to mitigate and adapt to climate change? In other word there was a culture of mitigating climate changes in Iranian cities which we need to remind the memory of people about this culture. The next two sections analyze contemporary mitigation with climate change in two cities of Iran to provide a better context of comparing past, present and future of Iranian cities regarding mitigation and adaptation of climate change.

3.2. Tehran; an urban lab for environmental challenges

Based on our living experience in Tehran and data from virtual social networks, from a decade ago one term has been fixed in everyday dialogue of people of Tehran which is the air quality. Mostly in winter time when the inversion phenomenon is accruing more. Having 200 polluted days in recent years of Tehran highlights the environmental challenge of Tehran. Researches on the effects of climate change on Tehran microclimate reveals these change in different classification (Saligheh, 2015):

- Air stability
- Increasing average temperature
- Changing pattern of wind flow

These consequences of clime change have been intensified because of urban planning actions especially in terms of mobility plans and land use planning. Death rate resulted from air pollution around 4800 people a year, shows the impacts on health and everyday life in

Tehran. Through different researches the effects of urban planning actions on creating urban heat islands in Tehran has been understood. In other word, urban changes inner the city intensifies the climate change impacts. Looking at to the data of Tehran Municipality tell us that during the recent 12 years, highways has been developed from 304 Km to 548 Km with 80 percent growth. In comparison to pedestrian public spaces area, the data about highways show a parallel planning policy that is not consistent to pedestrian mobility. (Ranjbar&Motalaei, 2017) Critics are raise up when we look at Sadr's Elevated highway. A lot of money has been spent on the project that it was better to use such resource for developing public transport. Ranjbar & Mashhadi Moghadam (2017) research " Upgrading urban highways: issues and negative impacts based on a case study of Sadr's Elevated highway" results showe the highway has significant negative impacts in ecological dimension, including air and noise pollution and energy-consuming parameters. Versus the highway projects, developing pedestrian spaces and zones in Tehran has been increased during the last decade and it has been successful, but it's not sufficient for an 8 million inhabitant city. According to Samavati & Ranjbar (2017) research "The Effect of Physical Stimuli on Citizens' Happiness in Urban Environments: The Case of the Pedestrian Area of the Historical Part of Tehran", pedestrianization of the area has been effective in overall happiness. So, there is a need to dramatic change from car oriented mobility to clean types of mobility in Tehran. Tehran Municipality planning policies regarding to climate change in recent decades are paradoxical. This can be related to lack of a comprehensive plan mitigating and adapting climate change issue. Lack of a comprehensive mobility master plan is affecting in this way. It's time for Tehran to make a new decision because each year the air quality is decreasing. The case of Tehran is a significant urban lab which confirms the interaction of urban planning and design policies and climate change impacts. Besides doing researches to scrutinize this interaction, there is a massive need to change urban government thoughts which is the main problem of creating such situation.

Figure 4: comparison of a clean day and polluted day in Tehran, 2015

3.3. Ahvaz; maximum impacts of climate change on quality of life

Looking at virtual social networks in Iran like Twitter, Facebook, Telegram, etc. brings up climate change issue when a name is repeating; city of Ahvaz. Around 50 million Iranian people are active in virtual networks. Comparing with total population of Iran (80 million people) a repetitive issue can explain their concerns. The case of Ahvaz completely stimulated Iranian people about climate change impacts. Ahvaz is not big as Tehran, the city has 1.3 million population but the impacts of climate change somehow is more severe than Tehran. We can see the effects of climate change in terms of dust and sand storm which is coming into the city from the sources out of the city. The immigration statistics of Iran shows Khuzestan Province is on top of main regions which are losing their population. There is not 100 percent reliable research which shows the source of dust storm in Ahvaz but speculations introduces aridity and drought as a main source. This face of climate change has created land without green coverages as hotspots of dust and sand. Also has affected on decreasing surfaces of ponds and lagoons in regional level and international level in Iraq. So, a part of the challenge is in other country which is creating a hard situation to mitigate the problem. The effects of such phenomenon are a part of everyday life of people in Ahvaz. Staying long time at home, loosing electricity because of dust effects on urban electrical facilities, closing schools, changing detail of windows and doors, using masks for breathing, etc. in warm days that Ahvaz is experiencing 50 centigrade degree a non-place is creating.

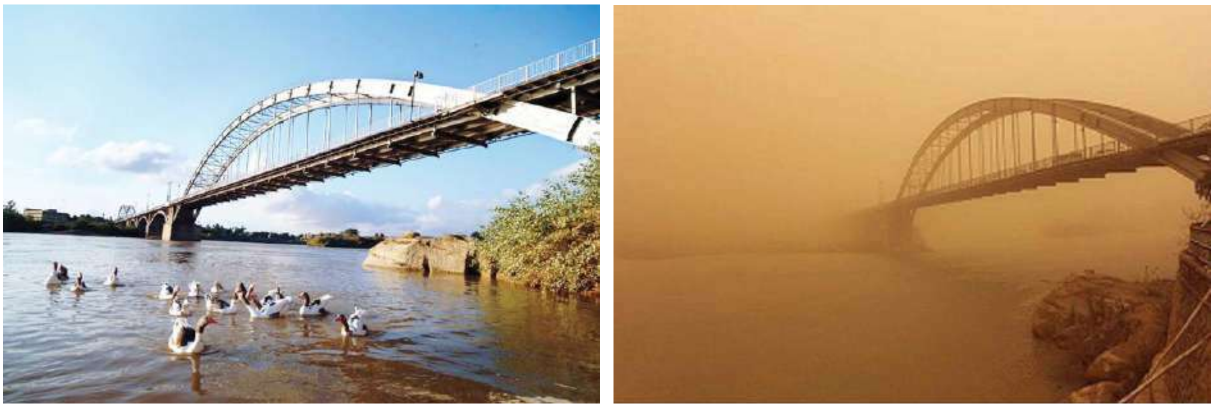

Figure 5: comparison of a clean day and polluted day in Ahvaz

What urban planning and design can do in this situation? Although with some solutions we can adapt the city to this change but the case of Ahvaz introduce a new perspective for urban experts to think in a wider context, to broaden their minds, to have comprehensive knowledge and to be more intellectual for walking beyond classic, formal and temporary solutions. Thinking on Ahvaz can be a valuable opportunity for other cities of the world to mitigate such effects of climate change.

4. Results

Seeking climate change impacts on urban planning and design in Iranian cities reveals an interactive dynamins. A fundamental issue which is leading to maximize hazardous effects of climate change in Iranian cities, is an emergent need to provide new urban planning and design guides and laws regarding this challenge. Nowadays, main urban planning document in Iran is “comprehensive plan” which is quite old and classic in substance and process. the nature of these guides is relating back to 3 decades ago. Iranian cities need climate change action plans in level of national regional and international. From urban design point of view, it’s needed to introduce new guidelines in green area management, street design and public spaces quality.

There is no ministry of environment in Iran which is compulsory for saving cities at this time. From educational point of view academic institutions in Iran need to change their syllabus regarding climate change. There is a lack of special course in teaching of urban planning and design discussing climate change in official syllabus. Convergence of urban faculties with environmental faculties in Iran should pursued as a key approach. So, urban planners and designers in Iranian cities should experience a massive change in broadening their thoughts to face urban challenge from international levels to local levels. It means classic education of urban planning and design should change regarding climate change issues.

Moreover, the Iranian Government should work on Iranian people public opinion to refer their origins in history regarding climate change. In other word the “Iranian culture of mitigating and adapting climate change” should be represented. In this way, we need more urban-based NGOs which are rare in Iran nowadays. Recognizing this culture by such NGOs facilitate to spread it out in Iranian people mind. So, more than temporary ideas we need to change people mind because climate change impacts are not temporary. Based on the historical background of Iran, the country should initiate an idea of Middle-east cities alliance to solve the challenges of cities like Ahvaz. It means that climate change mitigation and adaption is an urban-environmental-social-political process in Iranian cities.

5. Conclusion

Looking at the current literature of interaction of climate change and urban planning and design demonstrates more attention to “how to do “not “how to think”. The nature of climate change should be discovered more by urban planners and designers. This phenomenon is removing borders of cities, regions and nations. So, planners mind should be flexible and flowing in these scales. It’s also removing borders of knowledge. Maybe working in a group of planners, environmentalist, social experts, etc. is a good idea but it’s not enough for urban planning and design in climate change era. Planners and designers should sit on the center of environmental knowledge to be able to have innovative and long term solutions. It means it’s time of paradigm shift in urban planning and design theory regarding climate change because environment is encompassing cities whereas urban planning and design discipline is more concentrated what’s happening inner cities. Also, in the current literature the impacts of climate change on urban planning and design are general. We need to analyze more especially in urban design level where real life is happening. Urban design as main discipline related to urban form needs such change more than planning. If we should be more pioneer these two discipline should be mixed in form of “urban-environmental design”. New urban qualities should be introduced because of tangible impacts of climate change on urban spaces. It means starting a new urban knowledge. From administrative point of view, we should start a practical “Cities Alliance Mitigating and Adapting Climate Change” (CAMACC) because it’s a massive and enormous issue.

Climate change impact in Andean cities in Bolivia: the Tiquipaya case and a community led New Urban Agenda for resilient planning

Rolf SCHUETT, Systemarchi, Poland

Abstract

According to several UN (FAO Aquastat) featured studies, Bolivia belongs to the twenty countries with the highest renewable internal freshwater resources per capita and total renewable freshwater supply. Paradoxically, the rapid glacier retreat in the Tropical Andes is compromising the fresh water provision in many important urban centres in the middle term, including the large cities of La Paz and Cochabamba. The beginning of the rainy season during the last austral summer was again marked by several natural events in some of the most fragile urban and rural areas in the mountainous as well as plain regions. One of these events was the flash floods in Tiquipaya, Cochabamba. In this paper these elements are described, analyzed and possible solutions are proposed.

Keywords: climate change, vulnerability, land use, new urban agenda

1. Introduction

The rapid glacier retreat in the Tropical Andes of Bolivia is compromising the fresh water provision in many important urban centres in the middle term, including the large cities of La Paz and Cochabamba. At the same time, changes in the rain patterns in practically the whole country are causing severe damage to agriculture, farming and urban infrastructure, compromising as well the production of food, an economic branch in which more than 60% of the population works. Climate experts of the Global Atmosphere Watch monitoring system coincide in that Bolivia and other Andean countries are in urgent need to implement effective measures to improve their resilience to climate change impacts (Hoffmann, 2012). The recently adopted Habitat III New Urban Agenda is an example of what these measures should imply schematically. But what can this imply in practical terms is such a poor and vulnerable country?

The Tiquipaya flash floods is considered by the author very symptomatic. It is the result of the mixing of several elements, most of them human made, into a chain of events that resulted in a foreseeable tragedy for locals and destructive for their infrastructure. These include insufficient management of a fragile system of watersheds, human led destruction of natural ecosystems, overuse of agricultural soil, reduction of soil permeability, and a permissive (perhaps corrupt) attitude of authorities to settlements in vulnerable areas.

This paper discusses the threats caused by uncontrolled changes of land use in these fragile ecosystems, which are specially exposed to climate change impact. It discusses how it may be possible to implement effective impulses of the New Urban Agenda, some of them corresponding to traditional communal collaboration uses in this region. As well it suggests how low tech landscape and urban design measures should be incorporated to improve resilience and commit authorities and the local population to cooperate to reach results.

2. Climate Change Effects in Bolivia

Bolivia can be divided into three topographical regions: Andean, Subandean and Plains regions. They feature different average precipitation rates: Andean 500mm, Sub Andean 950mm and Plains 1870mm. The endorheic basins of the Altiplano region around Titicaca lake have a higher ETP (potential evapotranspiration) than precipitation, indicating vulnerability to water scarcity in these regions. According to a government study from 2007 (Ministerio de Planificación del Desarrollo, 2007), climate change will also contribute to glacier melting in the endorheic basins area.The fresh water availability per capita and year is 160m³ (year 2000), comparable to the one in Norway, one of the highest in the world. Therefore Bolivia is considered a world fresh water reservoir.

A World Bank study from 2013 based on remote sensing data, primary data of 268 weather stations and modelled climate change impacts on water balance identifies regions with potentially critical water availability. It recommends a "countrywide integrated national plan" for improving watershed management (Escurra, 2013). The study confirms that the mountainous regions may experience draughts and the lowlands floods. The data indicates a temperature increase 0,11℃ per decade in the Andean region of Bolivia, which is 0,05℃ higher than the global average.

In general terms, the World Bank funded study concludes that climate change will have an impact in both dry and wet scenarios, a decrease of average renewable surface water in the Altiplano and an increase of floods in the northern plains of the country.

To understand the effects for the poorest population of the country it is worth to mention that forty percent of the main water collection surface and water sources are concentrated in rural areas in Bolivia. Around 60% of the population depend from these resources in agriculture and food production, and here also most of the poor population is concentrated.

2.1 Climate Change Effects on fresh water availability in the Cochabamba region

Cochabamba and its surrounding valleys are a visible example of how rural poverty and poor watershed management are correlated.

The geology of the valley of Cochabamba will be described in the next section, but climate change effects can be named here.

- Secondary rivers' waters rarely reach the Rocha River during the dry season. Rocha is the main river in the central valley of Cochabamba;

- Lakes in the lower sites of the central valley, together with lagoons on the Tunari Cordillera are today water reservoirs. Some of them dry out during the dry season.

- Calculations of the beginning of the 2000s predict an overall deficit from 2015 onwards, which should be covered by the extraction of underground reservoirs. The cities in the mountains in Bolivia have been consistently served by glacier melting water. Climate change puts this balance since many years under threat.

- The public company SEMAPA has no other option but to purchase water from community reservoirs during the driest months of the year. Yet some of the distribution ducts are in bad condition and water drains into the ground before reaching treatment plants.

3. The Cochabamba valley, its environment and water situation

This section describes briefly the background mix of elements, some of them natural, some of them human made, that summarize the current technical, geological and environmental framework of the water provision in the metropolitan area of Cochabamba. These elements include the geology, geomorphology, rural poverty and insufficient water management and infrastructure. The social aspects and the commitment of the local population in the water issue can be described through the Cochabamba Water War of the year 2000. Further on, the Misicuni dam has to be mentioned, which can be understood as light at the end of the tunnel, but not yet the final solution.

3.1 Geology and Geomorphology of the Valley of Cochabamba

The valley of Cochabamba is geologically a very interesting setting. For long periods of time, this tectonic basin was occupied by a lake. It contains distinctive sediments in the deepest sites. The deepest point is 2470m, the highest is mount Tunari at 5030m. The average central basin plain height is 2600m.

Regrettably, literature with detailed information about the geology of the Cochabamba valley is very limited. This section is based on a study financed by the German Bolivian Agreement on Groundwater published in 2000 (Renner & Velasco, 2000).

Regarding its geomorphology, the central valley can be divided in three zones: (1) a mountainous zone, with high peaks and deep slopes that are prone to originate landslides and rock material that is carried down to the valley; (2) a zone of slope and piedmont, with mostly coarse grained material with high hydraulic permeability, coarser in the higher areas at the mountain edge and finer in the lower areas down the valley; and (3) a plain zone with older sedimentation, fluvial lacustrine deposits, fine materials where most populated areas are located. These areas are swampy and contain salt efflorescences.

Consulted Landsat imagery shows some alluvial cones or fans that are produced by stormwater carrying sediments and flowing at high speed due to the deep slopes. Under these cones water deposits have evolved as important reservoirs. (See document graphs and charts (Annex): rivers in the valley; geological map; schematic geological section; sediments map).

The zones of slope and piedmont and some central parts in the basin are important groundwater host formations. They contain complex multilayered aquifers with confined and semi-confined characteristics. However, not all these reserves are favourable for exploitation of fresh water.

3.2 Water balance and management in the Tiquipaya basin

All water provision systems in the Tiquipaya basin are used for crops irrigation, except the water from deep wells, which is mainly used for consumption. Outside the urban areas there is an important community involvement in irrigation water management. One example is the community water distribution of the river Khora called Machu Mit'a. This is one of the only rivers with a permanent flow throughout the year. The Machu Mit'a isi used to manage also lagoons, dams, small reservoirs and distribution trenches. The locals distribute water as equally as possible but use superficial irrigation, which is considered less efficient. The availability of water has dropped according to records since 1986.

There is also a growing number of private wells in the valley area and overall water scarcity. A study from 2004 estimates a deficit of 2 to 4% in ground water recharging every year (Sáenz et. al., 2005). Therefore management and water storing capacities need to be improved.

The economy in the rural Tiquipaya region is based on agriculture (mainly potatoes, quinoa, barley, beans) and cattle growth (sheeps, camelides). Sewage, drink water and electricity service is practically absent. Only the rural neighbour cities of Titiri and Totora have primary schools.

Even though the Cordillera of Tiquipaya has available water resources, they don't cover the demand of intensive agriculture. Urban developments are more profitable, which contributes to urban sprawl. Studies and infrastructure development for agricultural water provision did not change this. With new urban developments poping up in the area, the demand for domestic water and the need for sewage infrastructure will increase considerably in the next decade, which represents a serious challenge for planning and environment.

3.3 Cochabamba's water war of 2000

Cochabamba, neighbour municipality and the capital city of the department to which Tiquipaya belongs, witnessed the well remembered Cochabamba Water War in February 2000.

Bolivia's hyperinflation crisis of 1985 led to the adoption of last instance economic measures taken to avoid economic meltdown, most of them forced by global financial institutions, the World Bank being the main player. Among these was the privatisation of pivotal state assets, such as railways, communications, and hydrocarbon and aviation corporations.

As single bidder, an international consortium of construction giants and a minority of Bolivian investors acquired a 40 year concession to provide drink water, electricity and irrigation for agriculture. They were guaranteed 15% annual return of investment, adjusted to the US consumer price index. The subsequent law that was necessary to regulate the concession and the first contract executions of the company caused substantial social rejection. The unwillingness of government and company executives to negotiate a settlement heated up the tension to an extreme. After weeks of strikes, clashes and a toll of at least six deaths, the concession was revoked.

Cochabamba's water war is today a symbol of Bolivia's government traditional anti globalisation rhetoric, supported by the majority of the population. It was at the same time a platform for several work union leaders who joined years later current president Evo Morales in power. However at the same time it represents the failure of political leaders to find solutions, because the fresh water provision is still insufficient and the management poor.

Since then, the public water company SEMAPA has severe difficulties to negotiate credits by financial institutions.

According to last census data, only 46% of the urban population has a connection to the drink water services, the rest being serviced by cisterns to a much higher end user price.

3.4 The Misicuni Dam, some light at the end of the tunnel?

The Misicuni dam and complimentary infrastructure is a reservoir with connected turbines for electricity generation and provision of fresh and irrigation water with a capacity of around 800M m³ in its main dam.

The planning started in the early 1960s and could not be completed until 2017 for diverse financial and technical reasons. The installed generation capacity is 120MW and the projected fresh water provision for the region of Cochabamba is 1200l/s. Misicuni is meant to solve the water scarcity problems of the region for the next decades.

Misicuni was never considered financially viable, which made it nearly impossible to acquire credits for completion. Eventually, available cash from the revenue of natural gas exports and a redesign of the infrastructure to incorporate electricity generation improved the success perspectives and the project was concluded with national funds. Today the dam is serving for irrigation purposes and delivering energy to the national network. It does not provide fresh water for household consume because of a lacking proprietary pipe connection and missing capacities in existing treatment plants.

4. The Tiquipaya Flash Flood Disaster

The Tiquipaya flash flood of sixth of February 2018 occurred after a sequence of days of rainy weather that saturated the soil in the upper areas of the Tiquipaya Cordillera, which eventually collapsed as landslides. The accumulated sediments slid down to the valley covering streets and buildings very early in the morning, surprising most victims in their sleep.

But this is the short sight version of the story. A more detailed perspective reveals a series of elements, which combined generated an explosive cocktail. Because of the awareness about the fragile geology of the Tiquipaya Cordillera, as described in the previous section of this paper, and the ongoing deforestation, reduction of permeability and indolence of local authorities towards settlements in vulnerable areas, the Tiquipaya flash flooding and its outcome was a foreseeable event.

Nonetheless it is fair to mention that proprietary measures had been implemented long before the area became populated. Around 30 years ago, the watershed management was implemented by the PROMIC initiative. PROMIC was a watershed management project initiated by the Belgian development programme in Bolivia. It was established in Cochabamba in 1990 and discontinued its cooperation with Bolivian authorities in 2009. It was replaced by a local office called *Servicio Departamental de Cuencas*. It focused on five of the nine watersheds within the Tunari Cordillera.

According to PROMIC project descriptions, the Tiquipaya watershed area (27,23 km²) has suffered soil degradation and erosion in its higher streambed, which increases the risks of floods in the valley flats. Even though floods occur every year, the situation becomes more critical with the growth of illegal settlements and uncontrolled change of soil cover (Méndez Torrico, 2004).

Erosion in productive soils in the Tiquipaya Khora watershed is caused by inadequate soil management (high pressure on natural resources) and poorly prepared crops on inclined grounds. The natural and irregular topography intensifies the erosion process because of steep slopes, since only 10% of the topography has a slope under 18% (10°=. A reform of land ownership regulations adopted in the 1990s and its consequent land use changes meant a loss of 10% natural vegetal coverage, and half of the naturally dense grass cover was also lost. Agricultural productivity has still dropped due to bad quality seeds, inefficient water management, uncontrolled firewood use, lack of adequate technology, insufficient road connections, pests/ parasites, etc.

4.1 Aftermath reactions and analysis following the Tiquipaya event

Experts coincide that since 2009, when the cooperation contract with the Belgian project PROMIC finished, the watershed monitoring was not continued by the local authorities, thus the risks were not detected.

The unstable topography of the 39 micro watersheds of the Tunari National Park is acknowledged and a constant monitoring is mandatory to prevent disasters. A logical task in zones like this is to manufacture a risks map. This was not undertaken by authorities (Mazaneda, 2018).

The Tiquipaya flash flood from 6th of February 2018 killed five and damaged or destroyed 122 houses, most of them built in buffer zones along the river, which were foreseen as washland in the urban plan of 1981. Despite of existing regulations, some buildings had received build permit, a fact that may be related to corruption and land trafficking (Callapa Cabezas, 2018). One of the experts of the local engineers association warned about corruption tainted watershed management and irresponsible decisions taken to serve political interests. Despite of identified urban developments within washland areas, permits were issued in favour of political support (Carrillo, 2018).

5. Analysis and suggested interdisciplinary solutions in different domains

Water is no doubt a complex matter of multiple dimensions in Cochabamba, and not only there. As mentioned before, the recommendations for an improvement of conditions for water provision, environmental protection and soil consolidation need to be based on a common vision and combined measures. This means that authorities, citizens, farmers and other stakeholders need to hold an interdisciplinary collaboration that aims to create integral plans of operation.

The interdisciplinary discussion should contribute to elaborate integral strategies for improvement in at least three different levels: Agricultural areas, Tunari Natural Park and Urban setting.

The World Bank study mentioned before summarizes the importance of solving water issues in Bolivia because of four reasons: self reliance, increasing population regionally oriented economic development and preservation of local identities (Escurra, 2013).

The same study also warns that the increase on CO_2 concentration in the atmosphere will affect the canopy conductance negatively, leading eventually to an increasing annual river discharge by 3 to 16,5%. This confirms that green coverage reduction contributes to reducing evapotranspiration and floods.

5.1 Rural areas, Agriculture and Farming

The above mentioned PROMIC programme suggested a series of measures that should be implemented and would have a large impact on different issues (see annex table/ matrix).

Additionally, a constant erosion control would create long term jobs for local population in activities such as construction of chipas (gavions) for terrain strengthening, retention dams and water distribution trenches and general maintenance work.

Past examples in the area have shown that a proper watershed management has to start at the source of the basin up the mountain, instead of trying to mitigate effects in the lower valley. As well it is important to improve the framework conditions for a smooth implementation of activities. Because of bureaucracy and slow implementation, not all the objectives of past projects were met.

Previous changes in water and soil management techniques did improve productivity and soil quality. This was corroborated by local farmers, who obtained higher yields (2x - 4x) and benefited by more affluent water springs. This pays back any efforts.

Proposed Improvement measures on rural areas of the Khora Tiquipaya watershed would benefit as well from measures undertaken in the Tunari National Park (see below).

A proper Management/ recovery of degraded soil will:

- reduce superficial soil loss (humus),
- control water flooding energy/ flows of stormwater using cross-cutting dams built with rubble and timber,
- strengthen slopes and banks mechanically and with vegetation,
- speed up natural regeneration with the use of native species.

5.2 Soil consolidation and forest regeneration in National Park Tunari

The National Park Tunari has to establish its necessary institutional structure, as well as design a management plan and work on inventories of flora and fauna and protection guides. The park's role goes beyond the natural heritage protection. The impact of the Park in issues such as awareness building and participation can be crucial for the general soil and air quality preservation in the region of Cochabamba. Proper protection measures are necessary to control the urban sprawl of neighbour municipalities, especially Cochabamba, and also to use the chance to bring environmental education to a broader population.

More than that, the Park is an asset with opportunities for economic activity in areas such as eco-tourism, adventure tourism, science, sport and leisure activities, etc.

The University of San Simon in Cochabamba used freely available remote sensing data to count bush and forest fires of the last 10 years. The number of fires doubled in the last five years to about two hundred per year in average. Among the reasons are lack of control, slash and burn clearing techniques and negligence (Challapa 2, 2018). Forest fires at the edge to urban areas have as an effect an increased number of informal settlements that can barely be controlled with reduced budget of local authorities. An improved landscape design at the urban edge shall provide clearer boundaries. It could as well motivate more involvement of the population in reporting fire events. Vegetation loss also contributes to erosion and landslides.

Even though these observations relate to the region around Cochabamba, this phenomenon occurs country-wide.

In a newspaper interview, Prof. Ramiro Uriarte Ardaya, agronomist at the University of San Simon, recommends a stepwise reforestation, according to the adaptability of native species to increased altitude. This means more bushes in the summits, endemic trees in the mountain slopes as fauna habitat and decorative native species in the forest borders.

Native species that can be re-introduced, proposed location

- K'apa K'apa (*Lippia boliviana*): aromatic shrub. All heights, especially mountain summits
- Thola (*Baccharis dracunculifolia*). All heights, especially mountain summits
- Moto Moto (*Senna aymara*): flowering shrub. All heights, especially mountain summits.
- Retama (*Spartium junceum*): medicinal plant, deciduous shrub with yellow flower
- Kishwara (*Buddleja hypoleuca*): shrub/ tree with 4m max height. Middle heights, Lower slopes and riverisdes up to 3200 m above sea level:
- Aliso (*Alnus acuminate*): tree up to 20 height, good for city borders and forests at middle altitudes.
- Sauce (*Salix humboldtiana*): along water courses, up to 25m height, landscaping at city borders
- Alamo (*Populus nigra*): it is not a native tree, probably Asian, but it is well adapted and was introduced centuries ago. It grows up to 3500 m above sea level and can be used to cut winds at city borders.
- Molle (*Schinus molle*): evergreen tree, up to 15m height, ideal as ornamental tree at city boundaries with the park.
- Kehuiña (family *Polylepis*): robust shrub that can grow at all heights within the park, it used to cover ancient Andean forests, before extensively being sacrificed as firewood.

Other species already available in the national park to be considered: Chirimolle (*Fagara coco*), Algarrobo (*Prosopis juliflora*), Lloke (*Kageneckia lanceolata*), Chacotea (*Dodonaea viscosa*) K'inhi (*Acacia macracantha*).

A detailed study of existing species and extensive inventories, also for living fauna in the National Park Tunari are necessary to evaluate biodiversity issues and make proper decisions.

5.3 Applying the New Urban Agenda principles to improve Urban design, adaptation and reduction of vulnerability

On the urban scale the strategies to reduce vulnerability have to be integral as well. This relates to the first of five focus areas of the New Urban Agenda (NUA), namely *improving existing urban policies*. In developing countries the boundary between urban and rural zones on the plan is seldom clearly visible on site. In Tiquipaya authorities set in 1991 the elevation contour 2750 as the south boundary between the Tunary National Park and the urban zone. Along the rivers, also the washland boundaries have not been successfully implemented, as mentioned before.

The author of this paper considers that the solution should incorporate strong community participation and start with a horizontal discussion. Neighbours need to understand that they have the right to have a place to settle down as much as authorities have the obligation to make sure it is safe, but this can only happen when both sides cooperate.

Because of slow recharge and the few aquifer recharge sites, diverse studies estimate a deficit in seasonal recharge of 8,5M m³/year in the Tiquipaya watershed area (Saenz, 2005). For this reason, land use in the northern edge of the valley should not interfere water recharge neither threaten water extraction sites. Industrial use with potential soil contamination must not operate here. Agricultural activity must keep the amount of pesticides and fertilizers under strict limits. Contaminated waters must not pass through protected areas and industrial land use must be limited to the south of the valley, where water treatment plants should be located. This is addressed by the second NUA focus area: *designing and applying a solid urban legislation with rules and regulations*.

The buffer distance for the washland areas along the river within the urban limits of Tiquipaya is 60m (at the city outer line), 40m and 25m at its narrowest site, between the center line of the river and the outer border of the washland area. After last February floods however experts recommended increasing the buffer to 90, 60 and 30m (Pimienta, 2018).

Local planners urge to persuade settlers to move away from vulnerable sites or give up areas of their parcels that intersect the buffer zones. Authorities announced instead that settlers shall state to assume responsibility for any personal or material damage in their private property in case of being affected by floods. Proper landscape design and community collaboration can help to persuade more social responsibility in this issue. This point is addressed by the third focus area of the NUA: *Urban Planning and Design* with which locals can identify. Here especially guaranteeing a sustainable use of public space is crucial. The ancient community water distribution management Machu Mit'a is a perfect example.

The absence of reliable information, inventories, digital cadastres, etc. shows also the lack of proper data acquisition and management. Increasing the efficiency of the city implies better information about the existing resources. This relates to the NUA focus area four: *Urban Economy and Municipal Finance*. Also Weather and climate models cannot rely on interpolated data generated with a low density of monitoring stations. It is imperative to increase the number of weather stations extensively in the country to make sure reliable data is available, a better accuracy is possible and climate change effects can be more closely monitored. Only a reliable observation of climate change effects will improve decision making on vulnerability and adaptation.

The fifth focus area of the NUA addresses *local physical implementation*, which groups all the issues mentioned before into a proper preventive and smart planning, which is an investment towards a resilient and inclusive city.

6. Concluding Remarks

In the sense of the NUA, urbanization of the Tiquipaya valley is a logical development that may not be stopped any more. Planners should see it as an opportunity, a *tool for sustainable development* (New Urban Agenda, 2017), which improves social integration and equity.

The Economy in Bolivia has substantially improved in the last decade. Yet there is still a lot to do in terms of basic services, sanitation and transparency. It is urgent to educate, build and invest. And now that the dependency on foreign cash has changed, it is an opportunity to educate, build and invest.

An assessment of effective approaches for adapting to the impacts of climate change on urban poor communities to make the urban area more resilient. - Perspective from Bangladesh

Shahadat Hossain SHAKIL, USAID Bangladesh, Bangladesh
Mohammed Hamidul HASAN, Bangladesh Institute of Planners, Bangladesh

1. Introduction

Climate change is imposing multi-dimensional threat to the humanity (IPCC 2014). This threat is compounding with unplanned rapid urbanization triggered by climatic events and disproportionate development pattern between rural and urban areas (UN-Habitat 2012). In the year 2008, more than half of the world's population started living in the urban areas and this trend will be upwards as per the projection (United Nations 2013). Additionally, majority of this urban population (three-quarter) and most of the mega cities (12 out of 23) are in low and middle-income nations of Asia (United Nations 2011). This extraordinary increase of urban population has been accompanied with high percentage of poverty (Satterthwaite and Mitlin 2013). Low income population living in the marginalized areas of the city faces various threats – tenure insecurity, extreme and variable weather, health risk, temporary pattern of livelihoods (Baker 2012). They are constantly adapting from the 'bottom' with their limited capability which is also challenged regularly by the disaster events and absence of appropriate policy and resource support from the 'top'(Dodman and Satterthwaite 2008).

Climate change is a multi-faced problem risking the cities of global south due to poor infrastructures and high investment agglomeration (WWF 2009). Governments in the global south are still portraying their adaptation strategies neglecting the urban poor (Banks et al. 2011). On the other hand local innovation and social-capital of low-income communities showing promising dimensions to integrate within the mainstream adaptation planning (Boyd and Ghosh 2013; Assheuer et al. 2013). In this study the potentials and drawbacks of 'top-down' and 'bottom-up' approach of climate change adaptation will be explored. The next section will demonstrate the theoretical arguments behind this debate. Pros and cons of both approaches will be investigated. Following that, empirical arguments will be presented largely from the context of Bangladesh. Insights from three field level case studies in three vulnerable cities (Dhaka, Khulna and Chittagong) will be drawn. Subsequent to it, the arguments will be reinforced with the findings of some other case studies in different context and scale. Finally recommending note will be drawn in the concluding section on the basis of both theoretical and empirical arguments recognized earlier.

2. Theoretical Arguments

In political science literature, a top-down method considers that, legislation and policies defined in the top-level will set precise goals and objectives. Through that explicitly provided framework it will be then directly converted into action 'on the ground'. On the other hand, a bottom-up approach addresses the significance of additional actors, other than 'policy makers' at the top, in determining the detailed specification of policies as they interact with one another in congested policy spaces and are finally implemented (Elmore 1979 cited in Urwin and Jordan 2008)

Sherman and Ford (2014) illustrated this debate for the context of climate adaptation– "*top-down* approaches are interventions in which local participation is highly managed and communities are viewed as the recipients of project outcomes, rather than partners in project implementation and design. Projects can be considered to be *bottom-up* when community members actively collaborate in the design and implementation of adaptations, as both project participants and staff members".

Literatures of policy implementation suggests that the merits of implementing top-down and/or bottom-up approaches depend upon the type of issue or policy under consideration (Sabatier 1986 cited in Urwin and Jordan 2008). To generate community awareness and support about the project top-down approach may work better initially, although it is essential to carefully judge the utility, appropriateness, and relevance of the project in a particular context (Sherman and Ford 2014).

Dutta-Koehler (2013) argued that local authorities do not have the complete knowledge about the impact and adaptation need in the field (city). They also fail to exchange knowledge with the peoples and share the experience of best practice. In contrast only focusing on the bottom-up approach or CBA (community based adaptation) in this particular context without criticism may lead inappropriate assumption and misleading judgement through not taking into account the nature and political implications of this approach (Ayers 2011; Dodman and Mitlin 2013).

In addition, both in the adaptation and development literatures dependence on external human resources has been usually discouraged by the bottom-up approach (Amaru and Chhetri 2013). This can be argued reversely by the deficiency of technical knowledge and management skills for the projects by the locals which can be complemented by the external trained stuff, through a top-down approach (Sherman and Ford 2014).

Furthermore, it is argued that active participation of the field level stakeholders, i.e. households and communities, in articulating and implementing climate change adaptation policies and programs (bottom-up approach) is critical because vulnerability is experienced locally and adaptive capacity and actions are best observed and realised locally (Fünfgeld 2010) However, the extent and effect of local action against climate change related threats remains inadequate without actions at other levels of governance (top-down approach) that address underlying drivers of vulnerability (i.e. emission mitigation, reducing poverty and inequality, appropriate land use and housing policy, tenure security etc.). Therefore, an integrated approach (combination of top-down and bottom-up) to build resilience among the urban poor is needed (Middelbeek et al. 2014).

Moreover, Baker (2012) advocated for "bridging communities and local governments to work together on local problems and prospective solutions". According to this proposition, for the urban poor or bottom-level actors, this imply, considering what the city can and cannot afford and its limitation is the primary step. Communities should proactively demonstrate what resources and capabilities they have rather than making demands and opposing government policies or programs that go against their requirements. For local governments, this means recognizing the contribution that the urban poor make to a city's economy and society and involving them in discussions about problems and priorities while formulating policies and programs. Through this amalgamate approach both immediate and long-term crisis in the urban poor communities can be addressed within the backdrop of limited resources and administrative capacity of the local governments (Satterthwaite et al. 2007).

Finally, Adger et al. (2005) stated that any adaptation to climate change policy/program can be appraised through standard principles of policy evaluation in quest of promoting *effective, efficient, equitable* and *legitimate* action in agreement with wider sustainability. However these criteria's are contested and context specific and are based on competing values.

3. Empirical Arguments

3.1 Bangladesh Perspective

Bangladesh – the top threatened country due to climate change induced sea-level rise, and extreme and variable weather events (flood, heat, storm, cyclone etc.) according to recent projections (Bondeau et al. 2013; IPCC 2013). The three major cities of the country - Dhaka, Khulna and Chittagong (inhabits more than 50% of urban population; Kawsar 2012); fall within the low-elevation coastal zone (LECZ) and ranked higher in terms of potential disaster risk by several predictive studies (Nicholls et al. 2008; WWF 2009; Maplecroft 2014). Echoing the global trend, disaster risk is compounding in the urban areas for the rapid urban population growth rate (2.96% for 2010-2015; United Nations 2011; 2013). This is followed by more low-income population (21.28% at urban poverty line in 2010; World Bank 2013) in the urban slums and squatters and adapting to climate variability with their limited capacity in the absence of any dedicated policy measures and integration within mainstream adaptation and urban planning (Banks et al. 2011; Roy et al. 2011).

3.1.1 Grassroots Coping Strategies in Karail Slum, Dhaka

Dhaka megacity currently resides 36% of the country's urban population (United Nations 2011; 2013), among which one-third (35%) lives is urban slums (CUS 2005; Angeles et al. 2009). *Karail* is one of the biggest slums of Dhaka, currently holding a population more than 100,000 (CUS 2005). Its location beside the high-end residential and commercial area (Gulshan, Banani and Mohakhali) and consequent opportunity in the service industry attracted this high amount of low-income people. Additionally, it location just beside and in some cases on the Gulshan lake poses both threat of flooding to the communities as well as pollution and encroachment to the lake.

Jabeen et al. (2010) conducted empirical work in Korail to investigate different types of coping strategies that people use. They explored that low-income (30% below 1USD/day/person), high population density, lack of proper utility services and tenure insecurity is the main driver of vulnerability. Inhabitants reported climate change as extreme and irregular climatic events such as – increased heat, irregular patterns and increased volume of rainfall and flooding. To adapt they employ mainly impact-minimizing actions such as - barriers across the fronts of doors, increase the height of furniture's, construct higher plinths and arrange higher storage facilities. To reduce the heat in the rooms creepers (leafy vines) are grown in the courtyards to cover the roofs and false ceiling material or canopy made out of cloths are used (see also Ahsan 2012). During the disaster they remain in their house for the fear of eviction. They cooperate and use their social capital during and after disaster to rebuild the structures, share foods and borrow loans to cope with the shock (see also Assheuer et al. 2013).

Tenure insecurity underpinning the vulnerability to the highest degree in case of Karail. Majority of its houses built on disputed government land and controlled by local political leaders. There is no formal provision of water, electricity and gas from the local government and inhabitants pay higher prices for this services (see also Hossain 2013). Different NGOs work in the area for providing water-sanitation, education, health care and micro-credit.

Jabeen et al. (2010) recommended supporting the local adaptation strategies by the inhabitants through providing utility services (for which recognizing their right by the city authority will be the first step) and government managed savings and credit system. They also argued existing coping strategies (local knowledge) utilizing the readily available materials and skills should be integrated in the urban/adaptation planning of city government (which is still undefined). This combination of top-down and bottom-up process will address the adequacy of both sides (resources scarcity of the local government and management skill of the local community).

3.1.2 Responses to Climate Change by Low-Income Households in Khulna

Khulna is the third largest city in Bangladesh located in the coastal region in the southwest. Currently inhabiting near about 1.7 million people, which is projected to be 2.8 million by the year 2025 (United Nations 2011; 2013). Near about 190,000 people living in 520 low-income settlements and slums during the year 2005 (CUS 2005; Angeles et al. 2009).

To analyze the individual, communal and institutional responses by the low-income households in Khulna, Haque et al. (2014) investigated questionnaire survey data of 550 households conducted by an INGO for one of their continuing projects and also performed several focus group discussions. They have stated that, residents of informal settlements in Khulna face a wide range of climate-related hazards. Some of these are sudden-onset events, including heat waves and cyclones; river flooding and water-logging; while others are slow-onset processes, including increased water salinity and rising average temperatures. In addition, the blending of minimal financial resources, poor quality of housing due to inadequate provision of basic services and increasing health cost burden create conditions in which people have extremely limited capacity to deal with any climatic shocks and stresses (see also Roy et al. 2012; 2013).

Align with people elsewhere in Bangladesh (Jabeen et al. 2010; Ahammad 2011; Mallick 2013) low-income inhabitants in Khulna are already taking a wide range of activities to react to climate related hazards. These are largely spontaneous or “impact-minimizing” rather than planned or “preventive”. To protect from heavy rain polythene sheets or empty cement bags are put on the roof and walls. Elevated plinth and building house on tilts technique is used to avoid water logging. During the flooding furniture’s are raised and stuffs are putted high near the ceiling. Perforated bamboo partitions are used as interior walls to allow the flow of air around the dwelling; and allowing vegetation to grow on the roof helps to keep the interior cool. The Khulna City Corporation (KCC) is mostly engaged in post-disaster relief works. The NGOs work in the city are more generally focused on community development (which can be seen as a way of strengthening adaptive capacity), as well as on providing emergency services during disasters (see also Roy et al. 2012; 2013)

However, Haque et al. (2014) argued that, “...none of these existing responses address the underlying social and political marginalization of the communities, which is the single most important feature contributing to their vulnerability” (see also Roy et al. 2011). Illegal inhabitants face the threat of eviction and absence of utilities, whereas legal tenant suffered due to very poor housing service offered by the owners in the absence of monitoring. First group do not want to invest for economic risk (eviction) and the second group do not receive NGO support due to nature of the settlement (Roy et al. 2013).

Haque et al. (2014) emphasised the permutation of top-down and bottom-up approach for effective adaptation planning through – ensuring tenure right by the KCC to encourage self-investment; using the skills and knowledge of the communities as the basis for far-reaching adaptation planning and action (bottom-up); development of climate-resilient livelihood strategies and providing autonomy and resources to local authorities to address local and urban development concerns (top-down).

3.1.3 Constraints of Pro-Poor Adaptation in Chittagong

Chittagong is the second largest city in Bangladesh currently inhabits more than 5 million population (United Nations 2011; 2013). Due to its hilly topography and close proximity to sea, it was affected severely in the last decade by storms, cyclones, flooding and land slide. Severe urban flooding due to poor drainage structure is now a common phenomenon. Exponential population growth around the port activities and high value of land, drive the low-income communities (more than 1.5 million; CUS 2005; Angeles et al. 2009) to live in the slums and squatters developed by the local elites through cutting down the hills (Ahammad 2011). Rainfall induced landslide is the major climatic threat for urban poor in Chittagong, evidenced by 128 person killed in June 2007 and affected 2,072 families in five informal settlements (Ahmed and Rubel 2013).

Ahammad (2011) conducted a review of existing literature as well as focus group discussions and interviews in three informal settlement areas that were affected by the landslides in 2007, namely *Matijarna*, *Batali Hill* and *Lebubagan*; with the goal to explore the constraints of pro-poor adaptation in Chittagong through the lens of – disaster preparedness, urban planning, NGO initiatives and national policy framework.

Ahammad (2011) stated that disaster risk reduction amid the low-income groups living in informal settlements is constrained by poorly defined roles for urban government agencies and little coordination between them (top-down approach). He also concluded that, “the roles of urban government agencies in Chittagong have not evolved [yet] in relation to climate change adaptation”. In addition, it has been surveyed that the adaptation capacity of low-income groups in Chittagong is highly correlated to the quality of their housing and the sites on which it is located. In contrast, urban government departments failed to take any initiative for arranging secure sites for relocating communities at risk. Moreover, informing communities about the potential risk and training them about emergency temporary relocation has been initiated by the authority, but failed due to weak institutional capacity and resources.

On the other hand, PROMISE–Bangladesh is a pilot project funded by the USAID and coordinated by the Asian Disaster Preparedness Centre (ADPC) has been initiated during 2008–2009. The project set up ward disaster management committees, which included community members, school teachers, a local ward commissioner and local residents from higher-income groups (bottom-up approach). Each committee sits once a month to discuss disaster preparedness. But how this committee will coordinate with the other government agencies is not defined. Additionally, the Urban Partnerships for Poverty Reduction (UPPR) project funded by DFID and UNDP (2007-2015), implemented in major urban centres of Bangladesh aimed to improve the livelihoods and living condition of urban poor, failed to incorporate most risked communities as the beneficiaries due to selecting only those settlements which do not have land tenure conflict. Though the official objective of the project is to include the communities at the highest risk.

3.1.4 Supplementary Arguments

- Sherman and Ford (2014) carried out a research to explore the ability of institution-oriented, top-down and community-oriented, bottom-up stakeholder engagement approaches to enable or constrain the implementation of adaptation projects in developing nations. They evaluated 18 adaptation projects performance from three Global Environment Facility's (GEF) adaptation programmes in light with the criteria's *effectiveness, efficiency, equity, legitimacy, flexibility, sustainability,* and *replicability*. This comparison revealed that community stakeholder engagement during project design and implementation, led to higher degree of performance in evaluation criterias of projects. In addition it has been explored that bottom-up approach in adaptation projects creates spin-off effects among the local stakeholders to inititate and run adaptaion interventions by themselves. This study also criticise the participatory method to be unsuccessful to actually empower the communities in both approaches as well as bottom-up approach for having a narrow focus, which prevents scaling up and replication (see also Dodman and Mitlin 2013).
- Amaru and Chhetri (2013) identified 45 adaptation projects through a bibliometric analysis to explore the degree of institutional intervention. They have considered only those projects which have a combination of top-down and bottom-up approach. Through rigorous further filtering and classification they have analyzed in detail 4 projects according to adaptation strategy employed (science, technology or information, experience and managerial). Finally they have concluded for the quest of combined approach as - "...the types of adaptation measures implemented primarily from the top-down may not promote local resilience in the long term; likewise, those measures implemented from the bottom-up require some level of collaboration from the top to maximize their effectiveness".

4. Conclusion

The combination of bottom-up (institution led) and top-down (community oriented) approach is more effective for adapting to the impacts of climate change on urban poor communities in cities of Bangladesh. This result can be echoed for the other countries of global south due to the resemblance in wider socio-economic context and governance characteristics. Urban poor communities in Bangladesh are adapting with their incredibly limited capacity. But this success in individual or communal level can be more strengthened as well can be scaled up (i.e. city/national level) if proper support (i.e. finance, management, tenure right) is provided by the local government. Conversely, resource scarcity and weak institutional capability of the city government can be compensated through utilizing local communities' knowledge and labour during adaptation policy planning and implementation. On the contrary, Community Based Adaptation (CBA) is still rural focused and urban climate change adaptation is still undervalued in global south. CBA can be an ideal combination of top-down and bottom-up if real empowerment or participation can be ensured and inappropriate assumption and mal-adaptation can be filtered. Which in turn will make the adaptation action more equitable, legitimate and efficient, the criteria's for 'effective adaptation'. In conclusion, urban climate change adaptation is still undermined in Bangladesh, with single dedicated project in NAPA

(MoEF 2009b), while nothing mentioned specifically in BCCSAP (MoEF 2009a). Moreover, in both of the policies specific actions to address the vulnerability of urban poor is still to develop. Developing appropriate policies simultaneously with addressing the immediate need of the poor is needed to achieve the current and future pro-poor adaptation goal.

Global Urban Sustainability Assessment: A Multidimensional Approach

Stanislav E. Shmelev, Director, Environment Europe, Oxford, UK and Lecturer, University of St Gallen, Switzerland

Irina A. Shmeleva[1], Associate Professor, ITMO University, St Petersburg and Director, Institute of Sustainable Development Strategy

Abstract. This paper examines a database of over 140 global cities including London, New York, Hong Kong, San Francisco, Los Angeles, Sao Paolo, Rio de Janeiro, Buenos Aires, Paris, Berlin, Stockholm, Moscow, Beijing, Seoul, Singapore, Shanghai, Sydney and Tokyo exploring linkages between different sustainability and smart city dimensions. It builds a comprehensive global CO_2 emissions model explaining 80% of the variance in urban CO_2 emissions across the globe. The results point towards a range of important variables capable of characterising urban CO_2 emissions: share of coal energy in the electricity mix, share of renewables, recycling rates, travel patterns and so on. Examples of the three leading cities, San Francisco, Stockholm and Seoul are discussed from the point of view of policies and performance. The assessment could be a valuable tool for policy makers and investors, and could help identify linkages between different sustainability dimensions as well as investment opportunities in cities with sustainability potential.

Keywords: multi-criteria decision aid, sustainable cities; indicators; sustainable development; environmental policy; smart city

1. Introduction

UNEP Green Economy Report highlighted urban sustainability as one of its important dimensions (UNEP 2011). This topic receives a lot of attention in the EU, USA and increasingly China and Latin America since the Rio Summit of 1992, the Rio+20 Summit in 2012 and, especially, in the light of the recent HABITAT III forum held in Quito, Ecuador in 2016. The new UN Habitat World Cities Report firmly links the New Urban Agenda with Sustainable Development Goals (UN Habitat, 2016). SDG 11 'Sustainable Cities and Communities' aims to 'make cites and human settlements inclusive, safe, resilient and sustainable' (UN, 2015b). UNECE and ITU have launched a new United for Smart and Sustainable Cities initiative in 2016.

Urban sustainability is defined as a multi-dimensional capacity of a city to operate successfully in economic, social and environmental domains simultaneously. Sustainable urban policy developments have been explored by Girardet (1993, 2004, 2014), Naess (1995), Hall and Pfeiffer (2004), Bithas and Christofakis (2006), Shmelev and Shmeleva, (2009), Hall et al (2010), Dassen, Kunseler and van Kessenich (2013), Hall (2014), Martin and Rice (2014). The multidimensional nature of an urban system defines a central analytical approach for sustainability assessment of cities used in this paper, namely the methodology of Multi-Criteria Decision Aid (Roy, 1996), following an approach outlined in (Shmelev, 2017).

The Rome declaration adopted at the UN Forum on "Shaping smarter and more sustainable cities: striving for sustainable development goals" in May 2016 declared that 'cities need to become smarter, with technological solutions deployed to address a wide range of common

[1] Participation of Dr Irina Shmeleva, ITMO University, in this research is financially supported by The Russian Science Foundation, Agreement #17-71-30029 with co-financing of Bank Saint Petersburg

urban challenges' of sustainable development (UNECE & ITU, 2016). The EU's European Economic and Social committee considers smart sustainable cities to be a tremendous source of growth, productivity and employment. A smart sustainable city, according to UNECE, is an innovative city that uses information and communication technologies (ICTs) and other means to improve quality of life, efficiency of urban operation and services, and competitiveness, while ensuring that it meets the needs of present and future generations with respect to economic, social, environmental as well as cultural aspects (UN ECOSOC, 2015).

Cities are contributing a significant share of global CO2 emissions (75%) and will experience tangible effect from its consequences. Bai et al. (2018) asserts that by 2030 millions of people and US$4 trillion of assets will be at risk from climate-change-induced extreme events. Founded in London in 2005 at the summit of representatives of 18 leading megacities, the C40 partnership currently numbers 89 cities from over 50 different countries aimed at taking action against climate change. ICLEI, Local Governments for Sustainability is uniting over 1500 cities towns and regions to build a sustainable future.

In this article we start by exploring a large database of over 140 global cities and search for meaningful relationships between various indicators in the global dataset. We then build a cross-sectional linear regression model, linking urban CO_2 emissions and various external, infrastructure, policy, behaviour and technology variables. The article concludes with a description of sustainability strategies and policies adopted in the leading cities of the world, which could help us to understand its success. The article is organized as follows. Section 1 offers an introduction to the topic. Section 2 discusses data and indicators used. Section 3 presents the results of regression analysis of linkages among sustainability indicators. Section 4 discusses the application of cross-sectional linear regression model for CO_2 to 71 global cities. Section 5 explores the sustainability strategies and policies in the most sustainable cities identified in our research. Section 6 concludes.

2. Indicators for Smart Sustainable Cities

Existing smart and sustainable cities indicator frameworks include the United Nations Guidelines and Methodologies on Sustainable Development Indicators (UN, 2007), EU Sustainable Development Indicators (EC, 2009), a Sustainable Development Indicators Frameworks (UNECE, 2013), a new ISO 37120 standards on Sustainable Development of Communities (ISO, 2014), a Sustainable Development Goals framework (UN, 2015), a Smart Sustainable City Indicator Framework (UN ECOSOC, 2015). These frameworks are discussed extensively in a range of comparative reviews: (Valentin & Spangenberg, 2000), Spangenberg (2002a,b), Spangenberg (2005), Kierstead and Leach (2008), Monfaredzadeh & Berardi (2015), Hara et al (2016), Manitiu & Pedrini (2016), Ahvenniemi et al (2017), Garcia-Fuentes et al (2017), Girardi & Temporelli (2017), Spangenberg (2017), Klopp & Petretta (2017) and Pierce et al (2017).

Recently there has been a growth of interest in indicator-based sustainability assessments for cities: (Shen and Zhou, 2014), (Mori and Yamashita, 2015), (Wong, 2015), (Yigitcanlar et al, 2015), (Wei et al, 2015), (Wei et al, 2016). The indicators following the International Urban Sustainability Indicators List proposed in (Shen, 2011) include the economic characteristics, such as income per capita; social and cultural dimensions, including unemployment rate, income differentiation rate in the form of a Gini coefficient and higher education level, and, finally, a wide range of ecological-economic or environmental dimensions, including the share of green space, CO_2 emissions, average PM_{10} concentrations, water use per capita per day, waste generation per capita per day and recycling rates.

Our comparative analysis of the three assessment frameworks (UN SDG indicators, ISO 37120 Sustainable Development of Communities and UNECE-ITU Smart Sustainable City Indicators) has shown a difference in focus, balance between economic, social and environment dimensions and some inconsistencies. The UN SDG indicator framework is more focused on the problems of developing countries and with its 249 indicators that are often defined in an imprecise way could become unmanageable. The ISO 37120 standard shows more precise definition of indicators, although social and environmental aspects are given slightly greater prominence at the expense of economic and smart indicators. On the contrary, the UNECE-ITU Smart Sustainable Cities Indicator framework is more balanced between different dimensions of sustainability and formulated with a lot of clarity and a forward-looking strategic vision in mind.

Selection of individual indicators for cities, chosen for the present paper, was based on an earlier sustainable cities framework (Shmelev and Shmeleva, 2009), inspired by our dynamic sustainability assessments carried out for countries (Shmelev, 2011, 2015) and adapted for the urban scale Shmelev (2017). The process of indicator selection for the study was performed in two parts. First, a large set of criteria was analysed, including economic indicators (income per capita at PPP, number of large companies headquartered in the city, creative industries employment), environmental indicators (CO_2 emissions per capita, share of nuclear energy, PM_{10} emissions, water use per capita, waste generation per capita, recycling rates) and socio-cultural indicators (unemployment rate, Gini Index of income inequality, life expectancy). After performing a Principal Component Analysis (Shmelev, 2017), identifying redundant variables and adding relevant dimensions, the set of criteria took its final shape numbering twenty criteria as a result of several iterations.

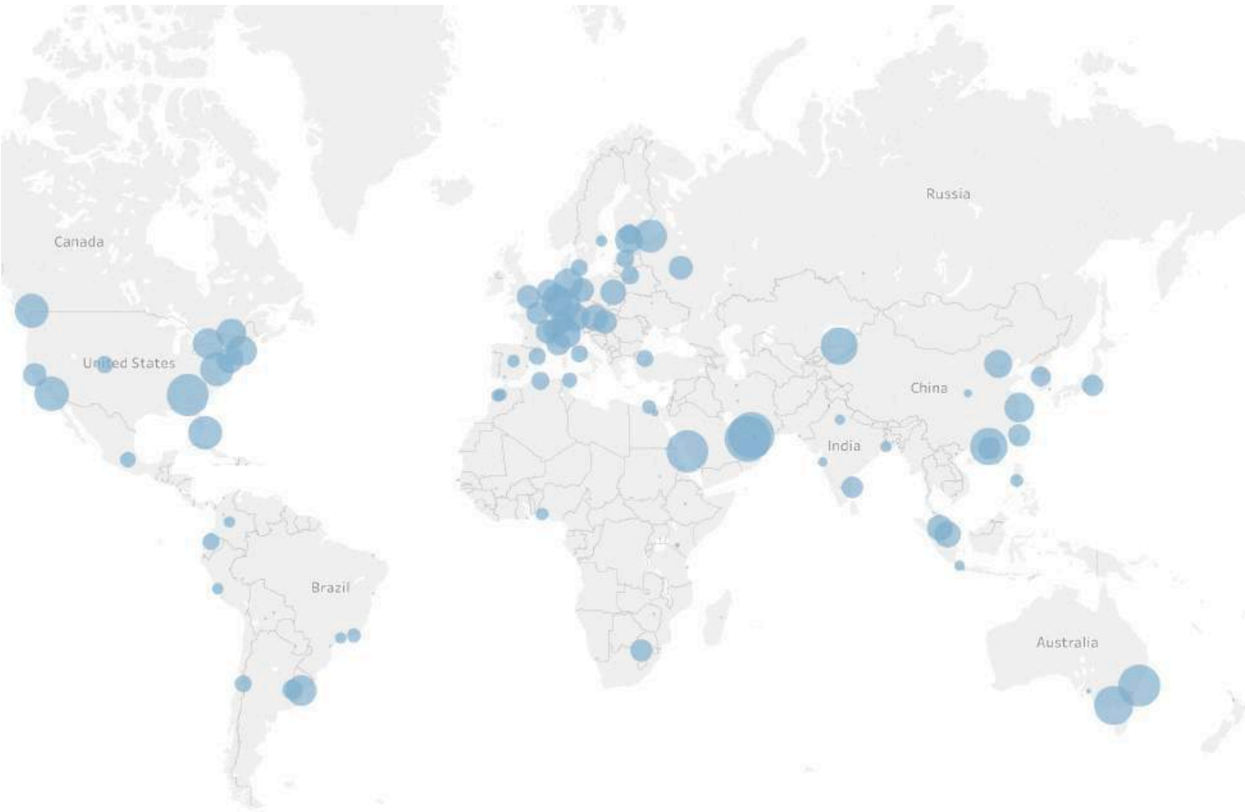

Figure 1. CO_2 emissions. Source: Environment Europe™ Sustainable Cities Database, http://environmenteurope.org/, 143 global cities, 2018

The Environment Europe™ Sustainable Cities database includes 143 cities in Europe, North America, South America, Africa, Asia, and Oceania. Our study draws on a wide range of sources from Eurostat (2016), city governments, UN Habitat, World Bank, CDP, Bloomberg. As a matter of example, we would like to illustrate the geographical spread of the Environment Europe database with CO_2 emissions data (Fig 1). CO_2 emissions are very high in Melbourne and Sydney, Dubai and Doha, Miami, Shanghai, Almaty and much lower in Stockholm, San Francisco, New York, Tokyo, Rio de Janeiro, Paris and Madrid.

3. Cross-Section Regression analysis

Our goal in this section was to test several hypotheses regarding the inter-disciplinary links among urban sustainability dimensions. The hypotheses were derived from the assertion in the UN Guidelines on Sustainable Development Indicators (UN, 2007), which emphasised the interdisciplinary connections between sustainable development indicators. The exact formulation of the hypotheses is based on our previous research outlined in Shmelev and Shmeleva (2009), Shmelev (2017) and Shmelev and Speck (2018).

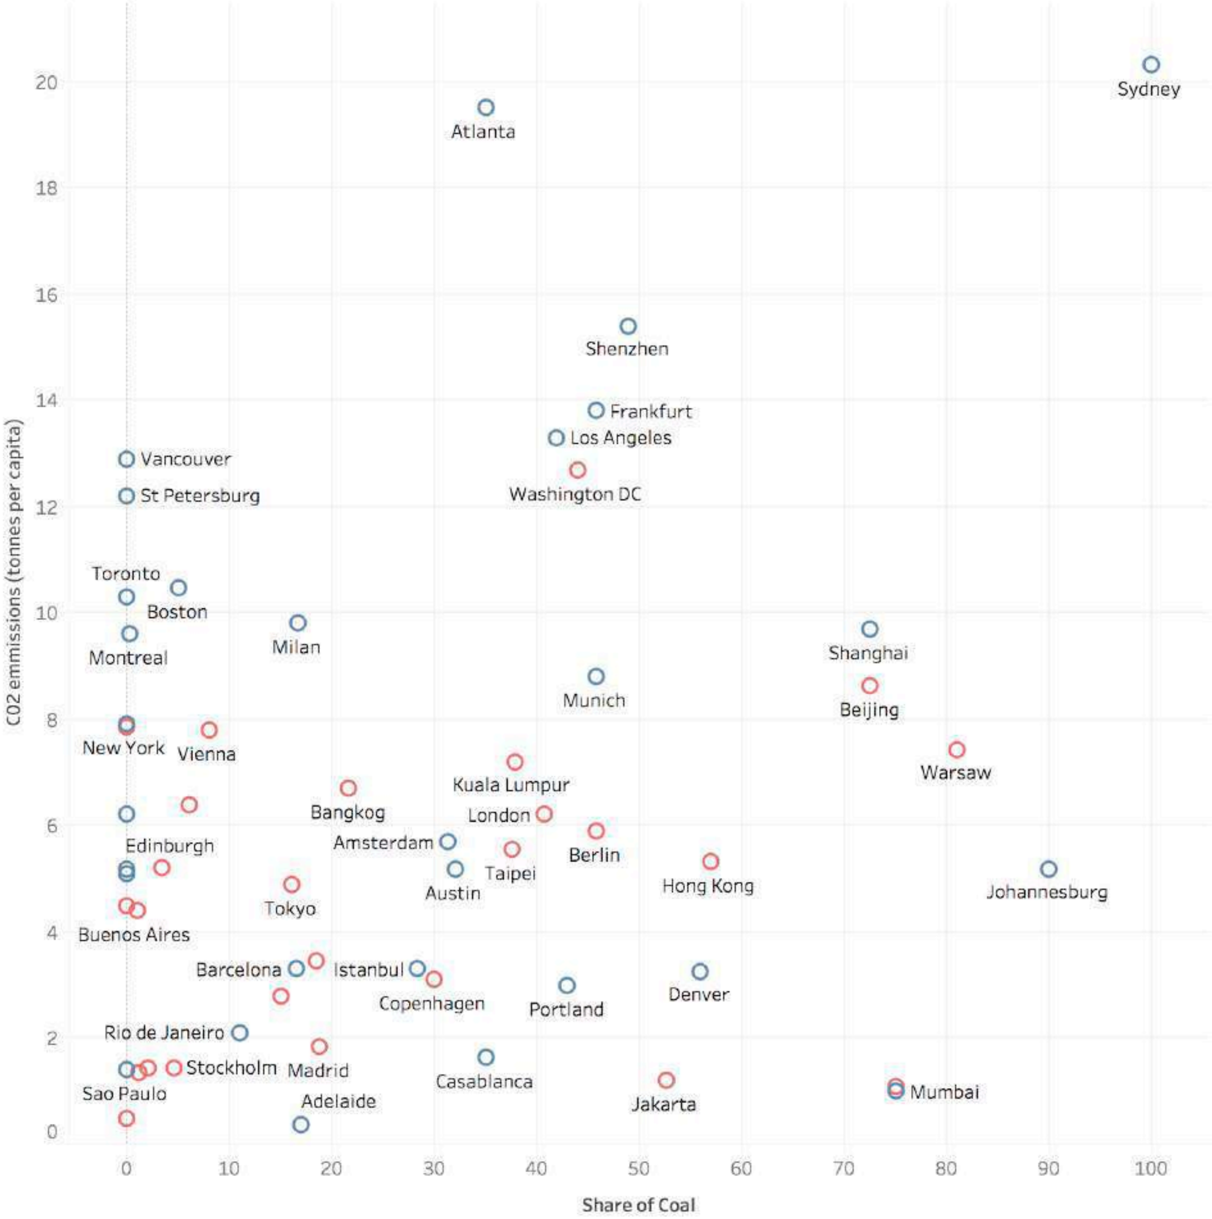

Figure 2. Correlation between CO_2 emissions and the share of coal in the energy mix for global cities. Source: Environment Europe™ Sustainable Cities Database, 2018.

The confirmation of our hypothesis of a highly significant correlation between the amount of CO_2 emissions and the share of coal, the most carbon-intensive technology at present in the energy mix (Figure 2), reinforces the need for an urgent transformation and decarbonisation of the energy sector. Such cities as Sydney, Warsaw, Hong Kong, Denver, Portland, Los Angeles, Washington, Shenzhen have above-average levels of coal in the energy mix and exhibit high per capita CO_2 emission. On the other hand such cities as Sao Paolo, Rio de Janeiro, Bogota, Quito, Madrid, Adelaide, Copenhagen, Rome have relatively low share of coal in the energy mix and lower levels of CO_2 emissions per capita.

A significant correlation between CO_2 emissions and the share of trips made by walking, cycling and public transport has been confirmed (Figure 3), which enriches our understanding of this wonderful urban planning tool for improving air quality and making the cities greener.

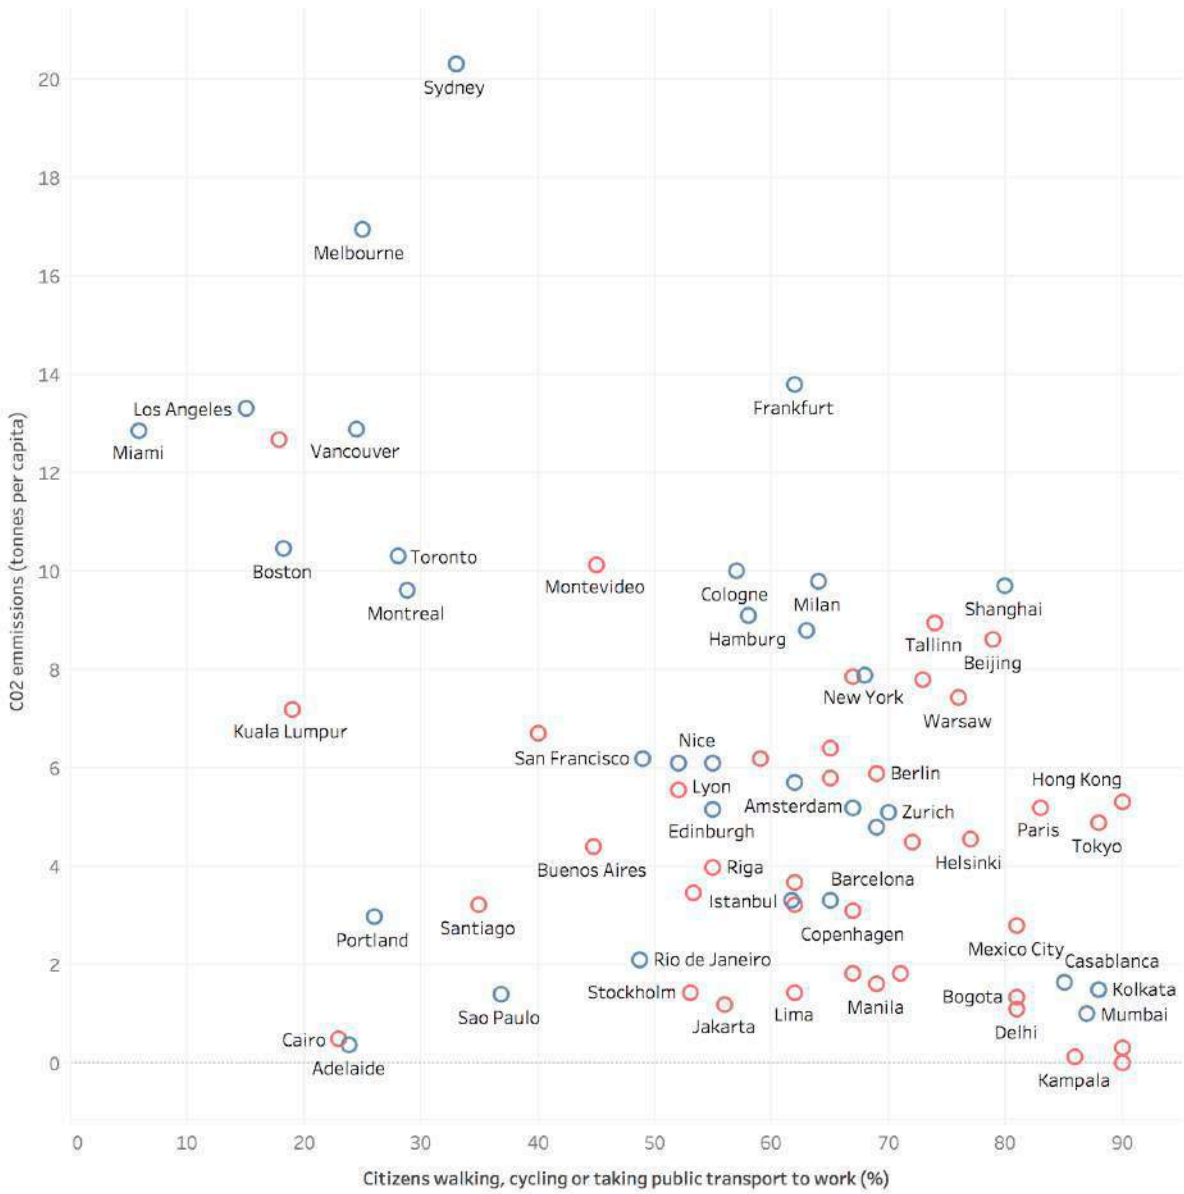

Figure 3. Correlation between CO_2 emissions and the share of trips made by walking, cycling and taking public transport. Source: Environment Europe™ Sustainable Cities Database, 2018

Such cities as Stockholm, Mumbai, Bogota, Delhi, Mexico city, Paris, Amsterdam, Seoul, Barcelona, Sao Paolo, Berlin, Singapore, Moscow have a significant percentage of trips made by walking, cycling and using public transport and are associated with lower per capita CO_2 emissions. On the other hand, such cities as Sydney, Shenzhen, Almaty, Los Angeles, Miami, Kuala Lumpur, Boston, Vancouver, Toronto rely on a private car in a much more pronounced way and therefore have significantly higher CO_2 emissions per capita.

The role of renewable energy in reducing CO_2 emissions in global cities has been confirmed at a very high level of statistical significance (Figure 4). This clearly reinstates the tendency in such cities like Sao Paolo, Bogota, Montreal, Stockholm, Rio de Janeiro, Zurich and Copenhagen that are largely powered by hydro energy to have lower per capita CO_2 emissions. At the same time cities like Sydney, Atlanta, Almaty, Frankfurt, Miami, St Petersburg, Shanghai, Boston, Los Angeles, Vancouver, Shenzhen that tend to have lower levels of renewables in the energy mix, tend to exhibit higher per capita CO_2 emissions.

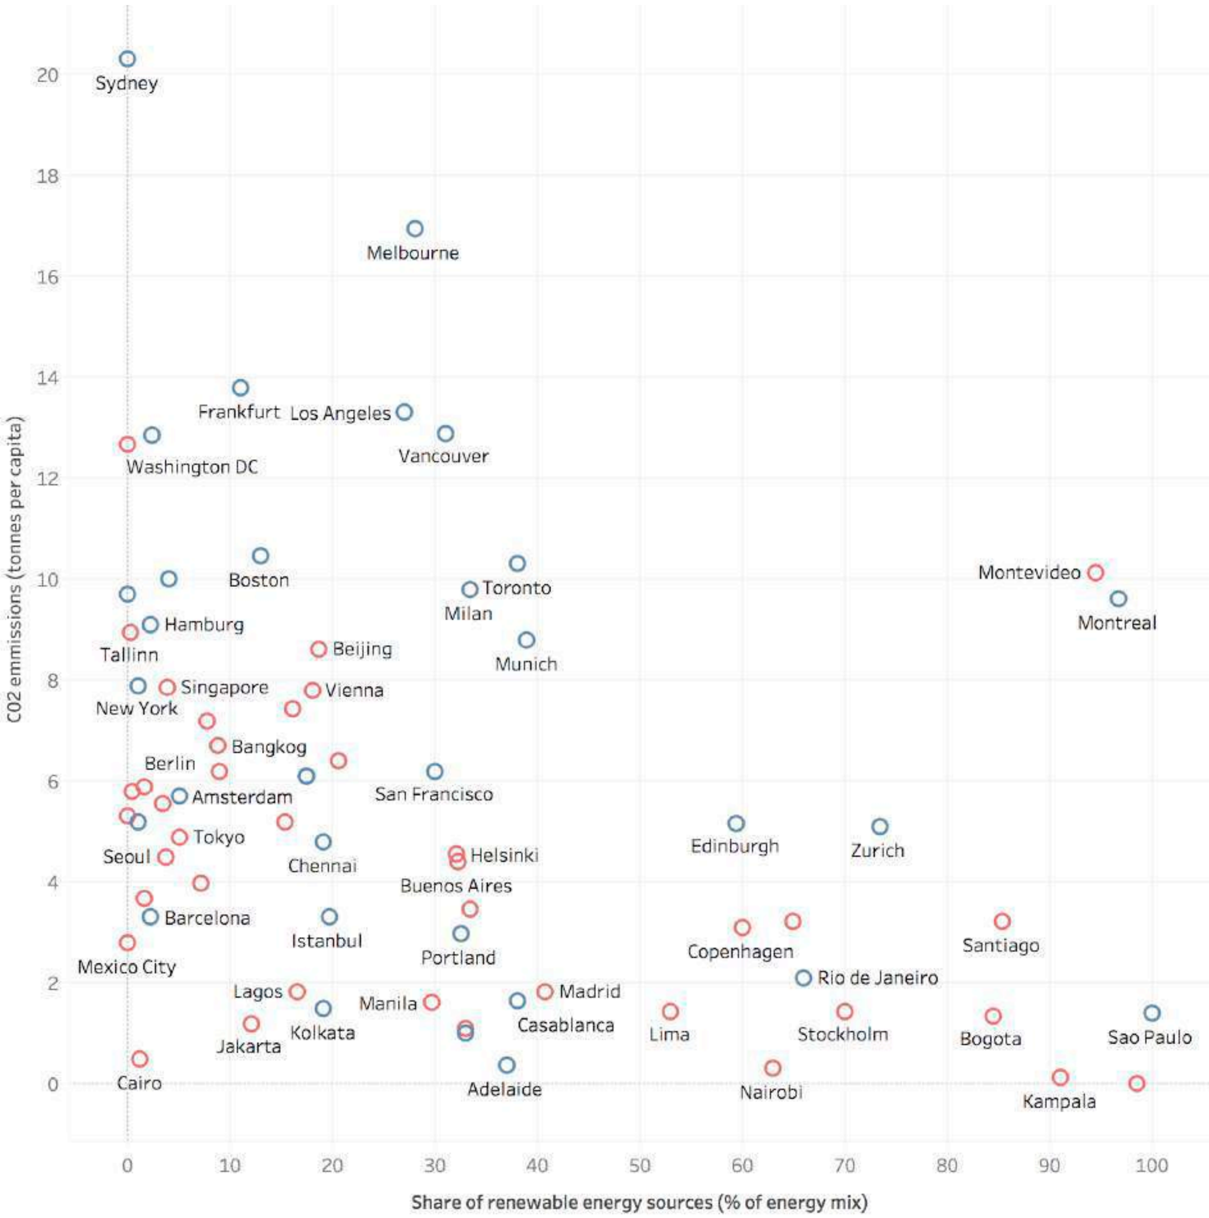

Figure 4. Correlation between CO_2 emissions and the share of the renewable energy for global cities. Source: Environment Europe™ Sustainable Cities Database, 2018

The hypothesis of a strong water-energy nexus, whereby larger CO_2 emissions tend to go hand in hand with higher water consumption has been confirmed. Figure 6 presents an illustration of such phenomenon and shows cities like Los Angeles, Almaty, Atlanta, Miami, Toronto, Kuala Lumpur using larger amounts of water with higher per capita CO_2 emissions. At the same time, cities like Bogota, Lima, Lagos, Madrid, Adelaide, Barcelona, Copenhagen, Seoul, Rome exhibit lower levels of per capita CO_2 emissions accompanied by lower water consumption.

The research outlined above forms an important step in creating multivariate regression models explaining variation in key urban sustainability indicators, such as CO_2.

4. Urban CO_2 function

Based on the global data covering 71 cities, contained in the Environment Europe Cities Database we were able to generate a regression that captured 80% of the variation in urban CO_2 emissions across the whole world (Figure 5). Urban CO_2 emissions tend to decrease with the increasing daily mean temperatures in the city (Table 2). On average, higher temperatures result in reduced need for heating and associated CO_2 emissions. At the moment, we cannot take into the account increased electricity consumption due to air conditioning. Cities with an OECD capital status tend to exhibit significantly lower CO_2 emissions possibly as a result of higher technological development in public transport systems, electric cars and pedestrianisation as a new trend in urban planning and design.

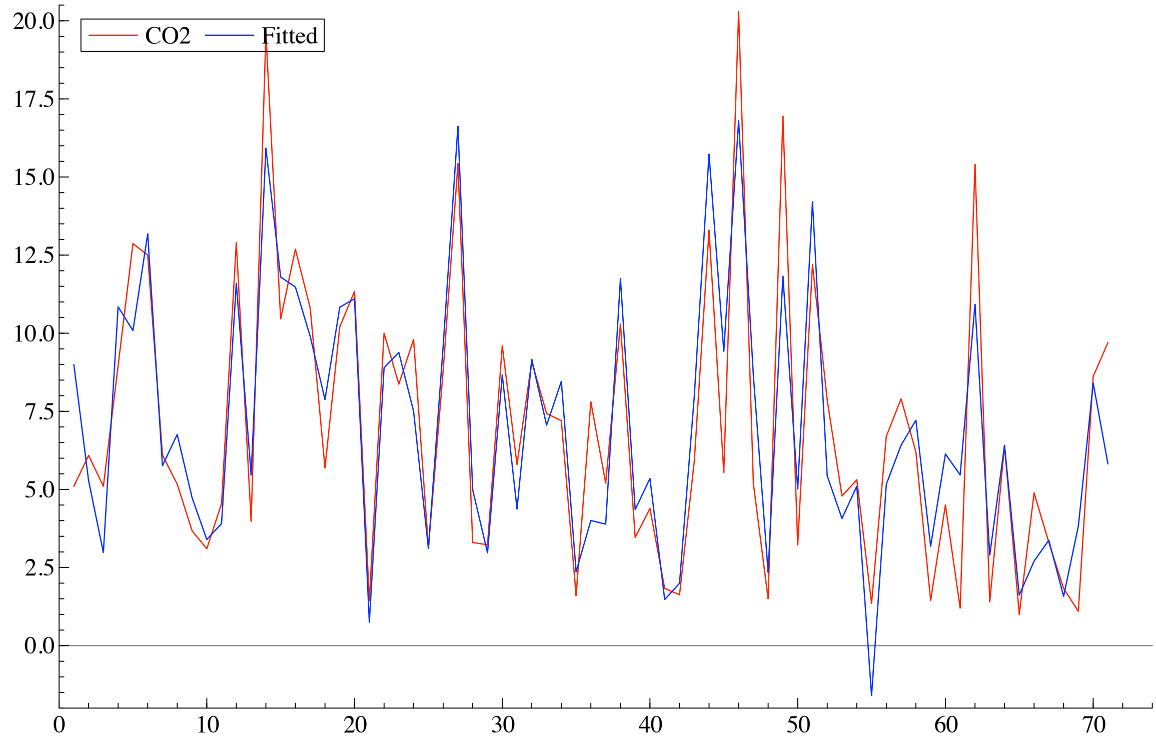

Figure 5. Global Urban CO_2 Emissions Linear Regression, (Environment Europe™ Cities Database, 2014 data).

The large share of renewables in the energy mix tends to reduce urban CO_2 emissions according to our results. On the other hand, the share of coal in the energy mix tends to increase urban CO_2 emissions. And additional behavioural variable, representing the share of trips made by walking, cycling and using public transport is shown to reduce urban CO_2 emissions (Table 1), which compared to petrol-based combustion engine cars generate less harmful GHGs. Paradoxically, higher recycling rates under every else being equal, tend to increase CO_2 emissions as additional amounts of energy are need for complex recycling (statistical significance of this factor is lower, but is it still significant at 10%). The next variable, CO_2 tax is reflecting the existing structure of incentives globally and shows an effect to reduce CO_2 emissions, however statistical significance of this factor is lower.

Table 1. CO_2 regression coefficients in the linear urban regression

Variable	Coefficient	Std.Error	t-value	t-prob	Part.R^2
Constant	15.2640	1.023	14.9	0.0000	0.7794
Daily Mean Temperature	-0.234784	0.04427	-5.30	0.0000	0.3087
OECD Capital Status	-2.29855	0.6474	-3.55	0.0007	0.1667
Share of Renewables in the	-0.0376761	0.01115	-3.38	0.0013	0.1534

Energy Mix					
Share of Coal in the Energy Mix	0.0486420	0.009920	4.90	0.0000	0.2762
Share of Trips made by Walking, Cycling and Public Transport	-0.113082	0.01036	-10.9	0.0000	0.6543
Recycling Rate	0.0692216	0.01286	5.38	0.0000	0.3150
CO_2 Tax	-0.0306765	0.01428	-2.15	0.0355	0.0683

Source: Environment Europe Cities Database, 71 observations, R^2=0.805394

Overall, this equation 'explains' 80% of the variance in the global CO_2 emissions. Such model can be used for out-of-sample forecasting.

5. Most sustainable global cities

Below we will explore some of the most sustainable and smart cities globally trying to explain how they achieved their remarkable success, paying particular attention to climate-related issues. Among the most successful cities are San Francisco, the US high tech and sustainability hub in the most economically successful state of the US, California, which is equivalent to the economy of France in size, as well as two national capitals: Stockholm and Seoul (Figure 6), which stems from our previous research in sustainability benchmarking.

San Francisco

San Francisco leads our ranking in Economic and Environmental Dimensions worldwide, which corresponds to the World Economic Forum ranking. The Strategic Plan of San Francisco for 2016-2020 has a mission 'to provide solutions that advance climate protection and enhance quality of life for all San Franciscans'. The Strategic Plan has five goals: 1) Promoting Healthy Communities and Ecosystems; 2) Leading on Climate Action; 3) Strengthening Community Resilience; 4) Eliminating Waste; 5) Amplifying Community Action.
In particular, Goal 2 uses an active target to reduce greenhouse gas emissions by 40% by 2025 and has the following subgoals: maximize energy efficiency in existing buildings; reduce dependency on single occupancy vehicles by improving access to sustainable and affordable modes of transportation; commit to ambitious carbon reduction targets across city agencies; continue to share San Francisco's practices and lessons to show the world what is possible; decarbonize the energy used for heating and cooling buildings; accelerate shift to 100% renewable grid electricity by 2030 and maximize local on-site generation of renewable electricity through policy development and investment; decarbonize the transport sector by facilitating deployment of electric and zero-emissions vehicles.

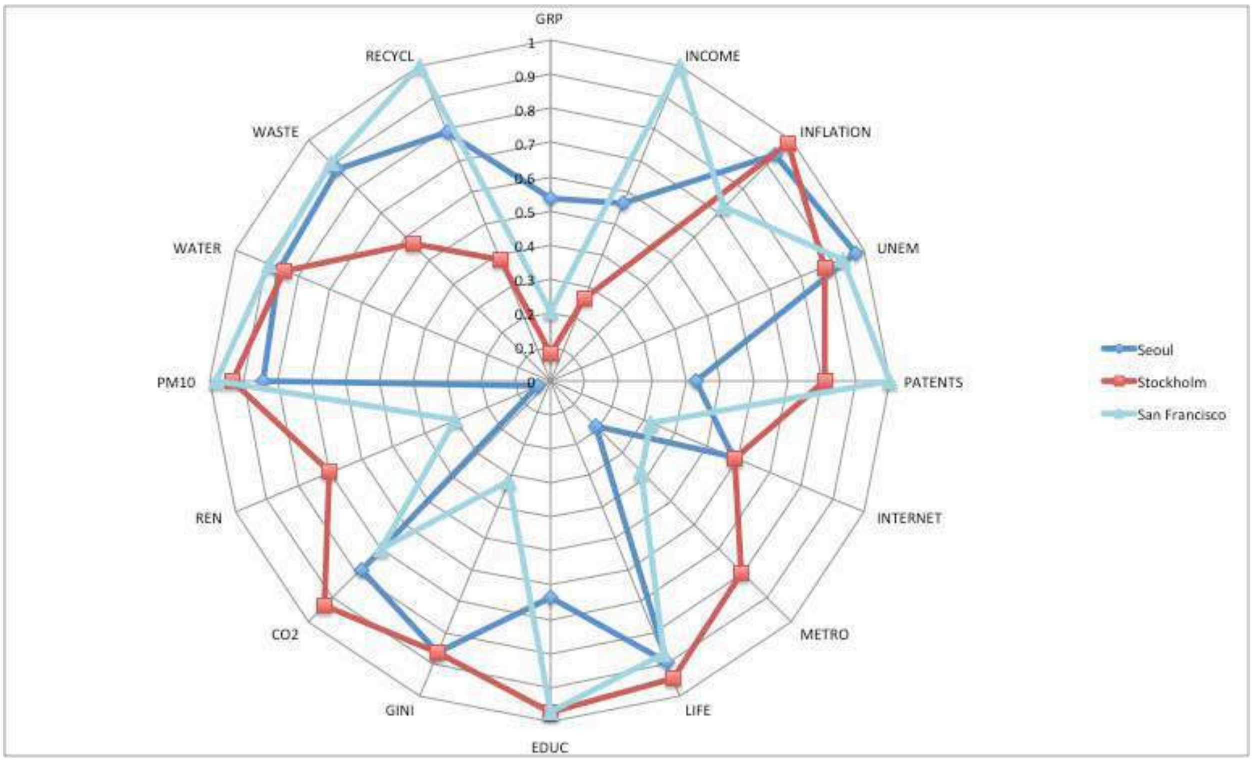

Figure 6. Comparison of the most successful cities globally: San Francisco, Stockholm, Seoul. Further away means better performance on each of the indicators.

San Francisco is one of the world leaders on recycling (80%), generating very small amounts of municipal solid waste per person (195.4 kg per year). 49% of the trips made by citizens are carried out by walking, cycling or using public transport. San Francisco Generates 6.2 tonnes of CO_2 per person per year and generates 30% of its energy through renewable sources. In the field of air quality San Francisco exhibits low levels of PM_{10} pollution at 15.77 $\mu g/m^3$, which is within WHO limit of $20 \mu g/m^3$. It has a reasonably diverse systems of underground public transport.

Economically, San Francisco is one the most vibrant places in the world. With high per capita income of 88518 USD at PPP in 2010 prices, inflation is low at 3.8%, unemployment at 4.4%, which is three times lower than Los Angeles. San Francisco is a world innovation hub with 3.24 patents registered per 1000 inhabitants, which is higher than Boston. Income differentiation in San Francisco is high, illustrated by a Gini index of income inequality of 0.51. Such relatively high income inequality could limit San Franciso's performance in the social dimension.

Stockholm

Stockholm has received a prestigious prize of a 'European Green Capital' in 2010. The city of Stockholm adopted Environmental Program for 2016-2019, based on complementarity between environmental protection and human needs. The six priority areas of this programme include: sustainable energy use, environmentally friendly transport; sustainable land and water use, resource efficient recycling, a non-toxic Stockholm, a healthy indoor environment. Our research shows that along with a serious concern about the environment, Stockholm exhibits extremely strong economic performance. Sweden is consistently ranked high in the World Economic Forum Global Competitiveness Index. Sweden is a very open economy and outperforms USA, Japan and Brazil by attracting approximately 4.7% of GDP in foreign direct investment per annum. At the same time, it invests in the range of 3.7% of GDP in research in development, which considerably higher than the EU average of 1.8%. Sweden and Stockholm managed to decouple economic development from the growth in CO_2 emissions as a result of technological modernisation in the 1970s with the extensive use of hydropower and nuclear energy as well as successful application of environmental taxes since 1991 (Shmelev & Speck, 2018). Stockholm aims to be fossil fuel free by 2050 and is actively involved in new programmes on green urban transport.

The Stockholm economy is largely innovations-based with the number of new patents registered (2.62 per 1000 inhabitants) higher that all other regional European centres including technological giants like Copenhagen, Munich, Zurich. Stockholm outperforms Tokyo. At the same time Stockholm is characterised by very low inflation, in fact deflation at 0.04%. The level of higher education in Stockholm is 58% of all the residents aged 25-64. Stockholm, representing the Nordic governance model, is characterized by high level of taxation as % of GDP and a reasonably low Gini index of income inequality (0.3).

In the environmental dimension Stockholm is characterized by low CO_2 emissions at 1.44 t per capita. One of the possible reasons for such low CO_2 emissions in Stockholm could be its active reliance on renewable energy. Stockholm occupies one of the leading positions in Europe on the share of renewables in the energy mix (70%), following Zurich. Stockholm's performance on renewables is considerably better than other European cities – Copenhagen, Edinburgh, Madrid, Rome, Moscow, Vienna, Paris, London, Amsterdam. On the other hand, according to the data on the share of all trips made by walking, cycling and using public transport, Stockholm is unfortunately not in the lead, following Vienna, Madrid, Moscow, Amsterdam and London at a modest level of 53%.

Another important parameter for 'explaining' low CO_2 emission levels is infrastructure, which gives affordance to use public transport by residents. In this regard Stockholm is characterized by a highly diversified system of underground networks with 108 underground stations per 100.000 inhabitants. This is better than most European cities: Madrid, Amsterdam, London, Rome, Berlin, except Paris. Air quality in Stockholm is at a good European level with an average annual concentration of PM_{10} at 26μg/m^3, which is nevertheless higher than the maximum recommended by the World Health Organization of 20μg/m^3. Better air quality is observed in such European cities as Edinburgh, Madrid, Zurich, Amsterdam and Vienna: it is worse in London and Paris. In the field of circular economy, Stockholm generates rather large amounts of municipal solid waste of 597 kg/person per year, 31% of which is recycled. Other European cities practice less resource-intensive lifestyles: Madrid, Amsterdam, Berlin, London, Paris, Vienna. Recycling rates are lower than Stockholm in Madrid, Rome, Paris, Copenhagen, and higher in Vienna, London, Berlin and Amsterdam

Seoul

In November 2017 Metropolitan Government of Seoul adopted 17 Sustainable Development Goals and 96 targets. Seoul Plan 2030, and urban planning document, covers three central dimensions: environment, society and culture, and the economy and includes 30 urban development indicators. Among Seoul's strategic priorities are reduction of Seoul's reliance on nuclear power, energy efficiency and sustainable energy action plan, increasing female participation in economic activities. Already in 2013, the International Telecommunication

Union issued a Smart Cities report devoted to Seoul's achievements. The Seoul's Smart City programme includes fast optical wire and wireless network, Seoul began distributing second-hand smart devices to low-income families, established a u-Seoul net in 2003, which connected major public buildings, offices and municipalities via a fiber-optic cables arranged along Seoul's underground tunnels. The Smart Work Center was established to allow government employees to work closer to home and 30% of staff were covered by this initiative in 2015. Seoul's open governance model implies a strong system of community mapping, through which citizens could raise concerns about their neighbourhoods and communities. Seoul's smart metering project aims to reduce electricity consumption by 10% and in 2012 a pilot project covered 1000 families with smart meters. The Open Data Square covers information on general administrative work, welfare, culture and tourism, city management, environment, safety, education, health, industry, economy and transportation. Smart solutions are used in Seoul to optimize personal travel of citizens, planning routes, choosing green transport solutions and reducing carbon emissions.

Seoul's metropolitan area maintained a significant share of Korean economy approaching 50% in 2013; at the same time Seoul metropolitan area provided employment for 50% of the country's population. Seoul's unemployment rate of 2.3% in 2014 was at the level of regional leaders like Beijing and Singapore, but lower than that of Tokyo. Seoul has a significant rate of residents with higher education (40.6), which is slightly lower than Singapore but higher than regional centres Beijing, Hong Kong, Shanghai, Shenzhen, and is higher than similar levels in Berlin, Vienna and Rome. The reasonably low Gini index of 0.3 underlines the values of equality in Korean society and is considerably lower than that of regional leaders like Singapore, Beijing, Hong Kong. Inflation in Seoul is low at 0.71%, which is comparable only to Copenhagen, not mentioning deflation in Stockholm. According to our model, which uses the Smart and Sustainable Urban Development Indicator Framework, the number of patents registered per 1000 inhabitants in Seoul is at a very respectable level of 1.4 per year.

In the environmental field, CO_2 emissions per capita measured in Seoul on an annual basis at 4.5 are lower than regional leaders Tokyo, Hong Kong, Singapore, Beijing, Shanghai, Shenzhen. Compared with European cities, Seoul is dominated by Scandinavian cities that traditionally exhibit very high performance: Stockholm, Copenhagen, but is performing better than Paris, Amsterdam, Berlin, London, Vienna, Munich. Seoul also outperforms San Francisco, New York, Montreal, Boston, Washington, Los Angeles.

Recycling is definitely one of the main strengths of Seoul with 63.5% of all collected municipal solid waste being recycled. Green space in Seoul is not particularly abundant at 1.39 m^2/ per person, which is lower than Tokyo, Beijing, Shanghai, Barcelona, London, Paris, Stockholm, Berlin, Rome and Copenhagen.

6. Conclusion

In this article we focused on global cities; the centres for economic activity and the cities that are responsible for a considerable share in global CO_2 emissions and produce substantial volumes of waste. The application of cross-sectional regression allowed us to produce a robust CO_2 emission model for cities. The key factors affecting the CO_2 emissions for cities we identified are: the share of coal in the energy mix, share of renewables, share of trips made by walking, cycling and public transport, mean annual temperature, OECD capital status, recycling rates and CO_2 taxes. All the factors combined contribute to the 80% of the variation in urban CO_2 emissions worldwide. The multidimensional sustainability assessment identified sustainability leaders: San Francisco, Stockholm and Seoul. The results have put the performance of individual cities within the global context and presented the indicator-based sustainable development performance of individual cities within a coherent framework. Learning from best practices and worst cases in this context provides an invaluable insight for policy reform to create smarter, greener, more compact, socially diverse, economically strong and less polluting cities around the world.

The impact of climate change on potential use of vacation homes

Stefansdottir, Harpa; Xue, Jin; Næss, Petter; Steffansen, Rasmus; Richardson, Tim, ÅS, Norway

ABSTRACT:

The aim of the study is to lay out how changing climate may affect the future use pattern of three selected vacation home areas in Norway. This study is mainly based on eleven qualitative in deapth interviews with vacation home owners in Trysil, Oppdal and Kragerø, but also to some degree questionnaire survey among a larger sample of vacation home users in Norway. Climate scenarios were also developed about future conditions in the case study areas. These were compared to the interviewees perception of possible changes the last years and thoughts about climate change influence in the vacation home areas. In the study we have looked at how the current weather conditions influence the current use pattern, mainly frequency of use and time of year, activities performed in the vacation home areas that have relation to weather conditions and the (climatic) motivation for these activities, when relevant. Based on information about the current use pattern, the aim of the study is to present results as an assessment of the potential change due to climate change.

According to the interview interpretation shorter skiing season in the mountain areas and more mild and wet weather in general is likely to influence use pattern in future. If the winter season becomes shorter, this would affect the attractiveness of the cabin negatively for some of the interviewees and likely reduce the number of visits somewhat.The middle period in spring (April-May) can also become longer in the mountain areas. Some interviewees would drop to go to their cabin in this period, where it is not much snow around and not good to go hiking either. However, weather conditions are likely to influence choice of activities but not necessarily the use frequency of the cabins. Vacation home users seem to be most likely to choose the activities made possible by the conditions. Smaller changes in general, eg. more rain, seem to influence time spent on each outdoor recreational trip and choice of place to go to. In case of fewer skiing trips at the cabin users are likely to go more trips on foot instead and the hiking period in the montains is likely to become longer.

The results indicate that only part of the motivation for using mountain vacation homes is related to weather conditions. When important part of the motivation is skiing, less snow is likely to influence use pattern. However, for many of the interviewees the motivation is related to performing recreational activity in the nature and use is connected with love for mountain nature. This explains why the interviewees say they would choose activities made possible by the conditions. Common motivation is also need to change place, family gathering and relaxing, which is indipendent of climate.

Warmer climate may most likely make use more attractive by the coast. In Kragerø, more storms are however likely to make water based activities more difficult. Apart from this, the period for going to none-primary dwelling might get longer because of milder climate. In addition, motivation for use of the cabins in Kragerø is strongly connected to family gathering and place identity and use is therefore not likely to change in spite of warmer climate.

Most often vacation home users are likely to try to adjust their activities to the conditions. The results suggest that sustainable planning of vaction home areas and the nearest towns should take into account the need to meet variety of activities that could be of interest for vacation home users and that are not sensitive to climate.

Vacation home planning, perceptions of nature and climate change

Steffansen, Rasmus; Xue, Jing; Stefansdottir, Harpa; Næss, Petter; Richardson, Tim, ÅS, Norway

ABSTRACT:

This study focuses on perceptions of nature and climate change in relation to Norwegian vacation home planning, ownership and use. The analysis draws on data from planning documents, two survey questionnaires both with respondents from Greater Oslo and in-depth interviews from owners/users of vacation homes in Norway. The data largely reveals an anthropocentric outlook from both the planning side and the user side, resulting in a neglecting of nature and climate changes related impacts and effects.

Vacation home ownership and use in Scandinavia is relatively high and combined with its use pattern and material composition it results in high environmental impact. Different rationales justifying such (not necessarily recognized) detrimental environmental behavior have been promoted throughout time. These are among other recreational motives (including "escape" from urban areas), rural economic development, and social place attachment. However the most prominent and most persistent throughout Norway is a special historical/traditional relatedness to nature. A traditional life *in* nature, which still is part of the national heart and soul. The practice of vacation home use is therefore argued to be part of being "truly" Norwegian. The narrative therefore has both the social and natural dimension of promoting national identities that have great environmental consequences. In the meantime local and national political bodies use vacation home developments to promote a narrative of rural economic growth. For the mainstream economic perspective these combined narratives of traditions and economic growth, therefore provide an optimal opportunity of justification.

However, from an environmental and climate change perspective the phenomenon of vacation home ownership can be seen among others as excessive housing consumption and economic expansion into amenity rich natural areas. A phenomenon, which also include considerable climate impact while itself being vulnerable to climate change. These perspectives have largely been neglected previously in research. This study will remedy this by looking at how planning documents promote the narrative of the "true" Norwegian as vacation home owner. In addition, the study will supply with data from surrey questionnaires and qualitative interview data. This in order to investigate how the common public understanding of climate change impact and behavioral changes, in relation to the narrative are conceived. Illuminating the two sides, of planning and users, will highlight to what extent there exist a neglect on anti-anthropocentric views on climate change and consequences as well as impacts on the natural environment in general. Such knowledge will help inform which measures might be needed if a transition towards a more climate and environmentally friendly vacation home phenomenon is to be planned for.

Conclusions: Planning documents for most parts take a point of view from human recreational and economic needs, arguing that nature is a place for human experience and expression. Such experience and expression is often justified in traditional Norwegian life. Users, i.e. questionnaire and interview participants reveal that there is little concern towards natural harm and climate impacts from vacation home ownership and use. Most interviewees state that their ownership and use of vacation home are most likely not to change due to climate change impacts, while most owners of vacation homes prefer the most environmentally detrimental form of vacation home spatial organization. Still, almost all vacation home uses (both interview and survey data) state that nature experience (including escape motives) are the main motives for engaging in ownership and use. This constitute a dilemma to planning. This study have brought new insights forth and thereby significantly contributed to the body of knowledge within the field of vacation home research as well as climate change planning.

The Effect of Climate Change on Ghana's Cities

Nada TANDOH, Land Use and Spatial Planning Authority - Ghana

Ghana is not isolated from the changes in climate the world over. Impacts of climate changes include floods, drought, heat waves etc. The impacts of climate change have exacerbated the negative issues arising from urbanisation. In reducing these challenges policies and strategies have been developed, and then mainstreamed into governance to ensure implementation. Ghana's perspective of climate change impacts on cities and resilience are discussed.

Introduction

Osman-Elasha, (2009) described climate change as a constraint to development. This is due to impacts generated in the advent of a climate change. The key events due to the change in climate in Africa include severe floods and drought, sea level rise and ocean acidification, increased water demand and reduced water availability, heat waves and spread of disease to new areas (e.g. malaria), more damage from high wind in storms, and disrupted crop calendars, with different pests, diseases and water requirements. As a result of industrialisation in developed countries, unfortunately developing countries however are more susceptible to threats in the changes in climate, thus they cannot be disregarded. This is due to the fact developing countries lack the resources to adapt and mitigate to impacts of climate change. Satterthwaite, (2006) in justifying why the low or middle-income countries cannot be overlooked stated that (i) these nations represent three quarters of the world's urban population, (ii) the world's population growth in twenty years would increase in these countries and will subsequently have a major impact on future greenhouse gas emissions, and (iii) these countries have a large and growing proportion of the world's population at risk from floods, storms and other climate change impacts. Currently, countries at risk are the least responsible for greenhouse gas emissions. Most cities in Africa are at risk from extreme weather events independent of climate change because of the lack of investment in basic infrastructure. It is of the essence that the quality of infrastructure in cities minimises the additional risks, generated by climate change.

In Ghana, the unparalleled population growth, high rate of urbanisation and unplanned spatial expansion have exceeded the capacity of the city services and infrastructure. These challenges have caused the cities to be susceptible to natural and man-made disasters including floods, seal-level rise, building collapse, disease outbreaks, fire etc.

Temperatures in all ecological zones of Africa are rising, while rainfall levels are generally reducing and patterns have become unpredictable. But the focus of this paper is on the climate of Ghana since the country's independence, how its change is impacting the process of urbanisation and the country's infrastructure, and how the nation has been able to withstand the shocks and stresses so far. In addition, we discuss what measures the government has adopted to enhance resilience of cities and to ultimately promote sustainable development.

Climate Patterns in Ghana - From Independence to Date

Ghana's location in the world is affected by tropical storms, and the influence of the Atlantic Ocean and the Sahel. The seasons in the country comprise the dry season (December- March) and the rainy season (April-November). The southern zone of the country is the rainiest, with a precipitation of between 1,500 - 2000 millimetres (60 inches) per year. The northern part is the driest, where rainfall is about 1000 millimetres (40 inches) per year. In regards to temperatures, it is usually about 35°C (95°F). During the dry season, also referred as the Harmattan season, a dry, dust-laden wind blows from the desert. The air is dry and nights are cool.

From the year 1961 to 2000, there has been progressive rise in temperatures and decrease in mean annual rainfall in the country. According to UNEP and UNDP (2010), Climate Change is patent in Ghana through: (i) Rising temperatures, (ii) declining rainfall totals and increased variability, (iii) rising sea levels, and (iv) high incidence of weather extremes and disasters. The country has six (6) agro-ecological zones defined on the basis of climate, reflected by the natural vegetation and influenced by the soils. They include (i) Coastal Savannah, (ii) Rainforest, (iii) Deciduous Rainforest, (iv) Transition (v) Guinea Savannah, and (vi) Sudan Savannah (see figure 1). The average annual temperature has increased to 1°C in the last 30-40 years. It is anticipated that temperatures will continue to rise, while rainfall is also forecasted to decrease in all agro-ecological zones (see tables 1 and 2). Historically, temperatures risen are likely to continue in the future, thus it is predicted that average temperatures are estimated to increase between 0.8°C and 5.4°C for the years 2020 and 2080 respectively. Also, within the same era average rainfall is estimated at decline between 1.1% and 20.5%.

Year	Sudan Savannah	Guinea Savannah	Transition	Deciduous Rainforest	Rainforest	Coastal Savannah
2020	0.8	0.8	0.8	0.8	0.8	0.8
2050	2.6	2.5	2.5	2.5	2.5	2.5
2080	5.8	5.4	5.4	5.4	5.4	5.4

Source: Minia et al. (2004) cited in the National Climate Change Adaptation Strategy 2010

Table 2: Scenarios of Mean annual temperature change for ecological zones

From the above table, it is obvious that the challenges inherent in all zones are extreme weather patterns of flooding, drought and high temperatures. On the other hand, in the transitional zone projected trends that are most likely to pose the major problems are the early termination of rainfall which is likely to convert the current bimodal regime to a unimodal regime.

In respect of sea level rise, Ghana has over the last 40 years experienced an increase of 2.1 percent in sea level. There is also the possible increase to 5.8 cm, 16.5 cm and 34.5 cm by 2020, 2050 and 2080, respectively (MESTI 2012). This is anticipated to affect cities and towns within 30 metre contour of the national coastal zone where about 25% of the population lives. It is of essence that five (5) cities are along this coastal zone of the nation with significant infrastructure including the national capital, Accra and the Metropolitan areas. The coastal areas are already extremely vulnerable to flooding and erosion. Erosion, submergence and sea water intrusion will lead to the loss of economic, ecological, cultural and subsistence values through loss of land, infrastructure, and coastal habitats.

The change in climate affects the nation's economic outputs and livelihoods, and subsequently Ghana's long term development prospects. It is worth noting also that thriving cities are crucial for national economic growth and innovation. On the contrary, an urbanisation process obstructed by climate change-induced hazards and limits, while guided by poor planning or lack of it, burdens the entire national economy.

Ghana's Cities - Urbanisation and Infrastructure

Over the past thirty (30) years, Ghana has experienced significant structural transformations. The total population of the nation has doubled from 1984 to 2013. Urban population has increased from less than four (4) million people to about fourteen (14) million people. In comparing urbanisation in urban areas to the national population, it is observed that there has been an increase from 23 percent in 1960 to 51 percent in 2010 thus exceeding the rural population. It is projected that by 2030 urban population in the country will be 22.6 million (World Bank Group, 2017). Africa in totality has been showing similar trends between years 1975 and 2015 the share of its urban population living in cities of over five (5) million increased from zero (0) to 3.4 percent, whiles the share in cities of five (5) to ten (10) million increased from 1.5 to 2.3 percent. The share in cities of one (1) to five (5) million increased the most from 3.2 to 12.5 percent, while the share in cities of 500,000 to one (1) million increased slightly from 3.3 to 3.5

percent. At the same time, the urban population share in cities of fewer than 500,000 inhabitants has decreased from 17 to 14 percent (LAPII Volume I, 2015).

Ghana's rapid urbanisation is characterised by the concentration of population, investments, economic activities and services in a small number of key cities. Three (3) major cities, including Accra, Kumasi and Sekondi-Takoradi, constitute fifty (50) percent of the total urban population. Due to their economic importance, they have engulfed smaller cities and towns having physically exceeded their administrative boundaries. Consequently, challenges arising from this development include low density expansion at peripheries reaching towns and villages that are about 100 kilometres from the centre (urban and peri-urban sprawl), ribbon development along feeder and trunk roads, and cluster patterns that lack basic services and social amenities including inadequate affordable housing. This in effect puts the expanding urban population at risk from natural and man-made disasters.

The capital of Ghana is Accra which forms part of the Greater Accra Metropolitan Area (GAMA). GAMA has a 2016 projected population of about 4.6 million inhabitants. It is predicted to more than double to 10.5 million people by 2040. It is located in the southern part of Ghana along the coast of West Africa. It occupies a total area of about 3, 245 square kilometres. Its coastline however, is 225 kilometres. Access to services is determined both by their availability and affordability. Due to proximity to infrastructure, access to services is mainly determined by location. On the other hand, affordability is determined by household's ability to pay for available services as a result of cost and income. Also, due to rapid urbanisation, the administrative boundaries at the local government level are experiencing outward expansion and proliferation of informality. This has also resulted in under serviced and infrastructure deficient communities, with increasing congestion, high levels of pollution and limited employment opportunities. Also, the urban sprawl in GAMA has brought about a change in the urban form.

Why Climate Change Matters

Evidence has proved elsewhere the negative effect of climate change on economies of nations. An example is the landslides in Sierra Leone in 2017. It is affecting Ghana's economic outputs and livelihoods too; hence the nation's long term development prospects are threatened. The country is particularly susceptible to climate change and its variability due to reliance on sectors of the economy that depend on stable weather, like agriculture, energy production and forestry. Though it is tricky to forecast, it is anticipated that the nation can look forward to more intense weather events like torrential rains, excessive heat and severe dry winds to challenge national development agenda. The increased occurrence and harshness of the climate conditions for instance, droughts and floods are potential factors to slow, delay, destroy and sternly impair land use activities and the functional qualities of infrastructure developments. It is imperative that the projected annual temperature increase of 2.2° to 3.5°Celsius - which is mostly marked for the dry season - is notably higher than the average (1.5° to 3.0° C) for the African continent. This poses a potential burden for housing design and real estate development, and has already necessitated an increased demand for energy for domestic cooling of homes.

In Ghana, it has been argued that the hot weather conditions experienced in the three northern regions have primarily accounted for “un-liveable” settlements in the dry season and so compelled the increased migration to cities and towns in southern Ghana. These population movements are apt to cause interference in the functioning of the existing energy supply, water supply, sanitation, transport, residential accommodation and communication networks of the newly inhabited areas. The migratory flows influence the running of the affected cities in the southern zone of the nation, most obviously by compounding slum development. In addition, an extremely high temperature due to climate variability is likely to also sway communication infrastructure. For instance, telecommunications data and computer centres with large quantities of heat in electronic circuits could possibly be damaged due to increased temperatures and heat waves.

Some cities in Ghana portray marked sensitivity to drought. The country has one of the lowest conversion factors of precipitation to runoff, at an average of 15 percent. Thus, major rivers basins in the nation pointed out 30 percent decrease in runoff in previous years. The country's hydroelectricity facility obtained from the Akosombo and Kpong dams have experienced critical low water levels in the past years, thus threatening hydroelectricity supply for domestic and industrial services. This has also necessitated the authority in charge (Volta River Authority) to operate below capacity. In the 1990s, the dams were partially shut down and only 85 percent of electricity needed to meet manufacturing sector was generated. This caused the economy to experience impediments such as unemployment, power rationing on factories and processing plants. Most severe impacts of droughts are accounted in the three northern regions on the socio-economic conditions of the residents.

Climate variability is particularly manifested in major changes in the rainfall patterns. Severe droughts may give way to rainfall. However, these are often torrential and apt to cause extensive runoff disruption which leads to damage to houses, bridges and utilities installations. It is worth noting that other parts of the Ghana are naturally flood prone areas. World Bank Group (2017), recorded that over the last 40 years floods have affected four (4) million people in Ghana, mostly river floods (the Volta River System), and urban areas especially Accra. It significant to note the severity of the floods has caused the loss of lives as well. The floods in 1996 record the highest deaths of 411 people to date (ibid). The table below recounts disasters in the country as a result of floods and drought that affected the greatest number of people and caused greatest number of casualties.

Year	Type	Total people affected	Total deaths
1983	Drought	12,500,000	-
1984	Epidemic	-	103
1991	Flood	2,000,000	-
1995	Flood	700,000	145
1996	Epidemic	-	411
1998	Epidemic	-	67
1999	Flood	324,602	52
2001	Flood	144,025	-
2007	Flood	332,600	56
2008	Flood	58,000	-
2009	Flood	139,790	-
2010	Flood	-	45
2011	Flood	81,473	-
2011	Epidemic	-	101
2014	Epidemic	56,469	249
2015	Epidemic	-	85

Table 3: Top Devastating Disasters in Ghana (1983-2015)

Impact on Urban Infrastructure

The impact of floods in Ghana’s cities leads to the temporary or permanent destruction of roads, including highways, bridges, culverts and flyovers. For instance, urban road networks in Accra have experienced near collapse in recent years as a result of bitumen being washed away by floods. Recent torrential rains occurring in the country, though unrecorded, are believed to have caused various degrees of damages to the telecommunication infrastructure like the cell phone masts, internet hubs, transformers and aerial telephone cables. It is observed that as a result of the top soil being washed away due to flooding, the buried copper and optic cable network have been destroyed. The National Disaster Management Organisation (NADMO), the institution responsible for disaster management spends an estimation of 85 percent of its resources and efforts to address issues related to hydro-meteorological disasters. Again, in 2007, the Government of Ghana spent $1,290,644.70 on floods relief victims in the Northern sector, Central and Western regions of Ghana exclusive of the various contributions made by the development partners. In June 2018, the city of Accra experienced some disasters after a heavy rainfall where people were trapped in the homes and vehicles leading to the death of two and four missing people.

It has become vital to address these urban development and resilience challenges. Proactive investment in urban resilience is essential to minimise the risks from recurrent disasters. It is intended not to only mitigate future risks of disasters, but rather protect existing infrastructure and housing, reduce poverty, and promote investments and shared prosperity. The following discussion presents approaches and policies that the country has adopted to reduce the effects of climate change in the nation.

Improving Resilience to the Effects of Climate Change in Ghana’s Cities

In order to enhance Ghana’s current and future development to climate change impacts it is critical to build resilient cities and ecosystems. In 1995, the nation was among other nations who ratified the United Nations Framework Convention on Climate Change (UNFCCC), and therefore have responded to the challenges institutionally and through policies, strategies and actions. The discussions below will review a number of such documents in Ghana, as they illustrate approaches on how the nation plans to withstand future shocks and stresses of cities and continue pursuing sustainable development.

The Ghana National Climate Change Policy (NCCP)

The Ghana National Climate Change Policy (NCCP) was prepared in 2013 and launched in 2014. Its vision is to "ensure a climate resilient and climate compatible economy while achieving sustainable development through equitable low carbon economic growth for Ghana". The government response to climate change is to recognise the policy as a development agenda and to ensure that it is mainstreamed into other policies and all sectoral activities in order to achieve sustainable national growth. The three objectives of the policy are effective adaption, social development and mitigation. However, it gives priority to adaptation over mitigation. Five strategic areas identified are: (i) energy and infrastructure, (ii) natural resources management, (iii) agriculture and food security, (iv) disaster preparedness and response, and (v) equitable social development. NCCP also identifies ten programme areas to address critical issues. Expressed as actions, these are: develop climate-resilient agriculture and food security systems; build climate-resilient infrastructure; increase resilience of vulnerable communities to climate change risks; increase carbon sinks; improve management and resilience of terrestrial, aquatic ad marine ecosystems; address impacts of climate change on human health; minimise impacts on access to water and sanitation; address gender issues in climate change; address migration; and minimise greenhouse gas emissions.

The programme areas also identify towns and communities that the policy themes and strategy would address. To build climate resilient infrastructure Nzulenzu in the Western Region of Ghana is identified as well adapted to annual flooding of the Amanzule wetlands. Flood homes in Buipe in the Northern Region are also targeted as a focus area to increase resilience of vulnerable communities to climate related risks.

National Climate Change Adaptation Strategy

This is a ten-year strategy expected to span from 2010-2020. It is expected to (i) ensure a consistent, comprehensive and a targeted approach to increasing climate resilience and decrease vulnerability of the populace; (ii) deepen awareness and sensitisation for the general populace particularly policy makers about the critical role of adaptation in national development efforts; (iii) position Ghana to draw funding for meeting her national adaptation needs; (iv) strengthen international recognition to facilitate action; (v) facilitate the mainstreaming of climate change and disaster risk reduction into national development. The strategy has been listed in ten (10) priority programmes. Aside the government, the private sector and the civic society organisation have been identified to implement the programmes in the strategy.

Ghana National Climate Change Master Plan Action Programmes for Implementation: 2015–2020

This document is a five-year plan of action focused on the ten policy areas obtained from National Climate Change Policy. These policy areas have underlined programmes and actions expected to be implemented within a specified timeline and an estimated budget. For the purpose of this paper, the second policy area, focused on the need to build climate resilient infrastructure has programmes like (i) Build capacity to design climate-resilient infrastructure (ii) climate–resilient sectoral and local development planning, (iii) ensure that key infrastructure is climate proof, (iv) flood prevention activities, (v) flood prevention activities, (vi) develop climate infrastructure for key services, and (vii) protection of coastal resources and communities.

In conclusion, rapid urbanisation in Ghana appears to be a national change, the unprecedented population growth, unplanned spatial expansions have exceeded the capacity of cities to match up. This has subsequently created housing shortages, urban sprawl, and informal settlements separated from essential city services and infrastructure. These challenges have made cities exposed to natural and man-made disasters and the effects of climate change have also intensified these vulnerabilities. Planners and the populace as a whole have recognised the impact of urban sprawl and poor infrastructure on the changing climatic patterns in country. Thus, climate change actions have been institutionalised and integrated into mainstream development policies, plans and programmes at the national, regional and local levels. Also policies and strategies have been developed as a guideline to be implemented. Institutions responsible for service provision have been decentralised so as to minimise the dependency at the national level and ensure maximum service provision at the local level. The success of all these strategies and actions that have been developed and implemented on climate change need the participation of all stakeholders that will lead to a thriving, competitive and inclusive cities.

Endogenous resilience – integrating urban informality with climate change planning in Pacific Small Island Developing States

Alexei TRUNDLE, Australian-Germany Climate & Energy College, The University of Melbourne, Australia

Synopsis

This paper demonstrates pathways for building on the resources, networks, and latent capacities of urban informality to enhance the climate resilience of urban systems. Post-disaster case study research from two Pacific Small Island Developing States is used to illustrate conceptual and practical opportunities for urban planning to complement endogenous resilience.

1. Introduction

Resilience is a contested and emergent concept that is increasingly being applied to cities (Tyler & Moench 2012). Building on a complex, interdisciplinary discourse that draws on theoretical developments within ecology, engineering, psychology and economics, resilience "now rivals sustainability as a major organizing principle or "buzzword" for urban research and policy" (Meerow et al. 2016, p.12). The concept, however, has sustained substantial criticism from social scientists, with applications to complex social settings – such as cities – being argued to lack mechanisms for assessing subjective sub-system values and frameworks for the consideration of rights, equity and justice (Davoudi et al. 2012; Olsson et al. 2015).

Informal settlements are classified by the United Nations Human Settlements Programme (UN-Habitat) as comprising household dwellings lacking in one or more of five key characteristics: improved drinking water; adequate sanitation; durable housing; adequate living spaces; and secure tenure (UN-Habitat 2016). As such, these areas are defined by their existence outside of the institutional norms and structures that underpin city-scale governance and planning. Nonetheless, analysis of informal settlements – which provide housing for an estimated 880 million urban dwellers globally (ibid) – demonstrates a rich array of informally-derived coping mechanisms, capacities, and non-institutional social structures that are able to be activated during climate-related shock or stress events (Seeliger & Turok 2014; Jones 2016).

Observations of these capacities have resulted in a number of contemporary additions to resilience thinking that articulate 'endogenous' enactments of urban resilience, capable of operating at a sub-city level independently of 'exogenous' impositions such as those driven through top-down, resilience-enhancing interventions and capabilities (for instance disaster management systems and climate adaptation planning processes) (Ziervogel et al. 2017). In attempting to address the inequities and subjective issues referred to above, an understanding of the interface between exogenous and endogenous modes of resilience stands to benefit both the implementation of climate resilient development initiatives, and the conceptual application of resilience thinking to socially contested urban systems.

Following Helmke and Levitsky's Typology of Informal Structures and Systems (2004), this paper draws on observations of these interactions in the capital cities of two Pacific Island Countries: Port Vila, Vanuatu and Honiara, Solomon Islands. These enactments have been identified through household interviews with 6 informal settlement communities, focused on rural-to-urban migrant community members who provide a dialectical understanding of their newly inhabited urban domain (Massey 1990; Lawson 2000). This primary data has been integrated with institutional interviews, the review of policy and development project documentation, and spatial analysis of secondary socio-demographic variables, providing a multi-faceted understanding of how informal climate resilience can be enacted – and interact with – climate resilient development at a city scale.

Section 2 of this paper provides an overview of urbanisation in Pacific Small Island Developing States, setting out a rationale for focusing on these relatively under-studied urban environments as case studies in informal climate resilience. Section 3 outlines the conceptual framework that has been developed iteratively throughout this research project to explore the interplay between institutional and informal enactments of climate resilience, centred upon the aforementioned migrant dialectic. Section 4 demonstrates case study evidence of endogenous resilience, interacting with institutionalised urban functions in differing ways. Section 5 summarises wider reflections on these findings for urban climate resilient development, highlighting the importance of building on endogenous resilience in the process of planning rapidly growing cities through changing climatic shocks and stressors.

2. Pacific Island Cities

Small Island Developing States (SIDS) are a grouping of countries and associate non-UN members that are recognised for their unique development challenges, being characterised by extensive coastal and marine environments that are argued to limit the deployment of mainstream development models (Connell & Corbett 2016). Depicted in Figure 1 below, SIDS merit specific attention in a number of international development processes and agreements, including the Hyogo Framework for Action, the Paris Agreement, the Sustainable Development Goals, and the New Urban Agenda (UN 2005; UNFCCC 2015; UN 2016b; UN 2016a). Much of the rationale for this special attention stems from their high levels of economic and physical exposure to natural disasters and climate change hazards, such as sea level rise, storm surges, cyclones, and ocean acidification (Butcher-Gollach 2015).

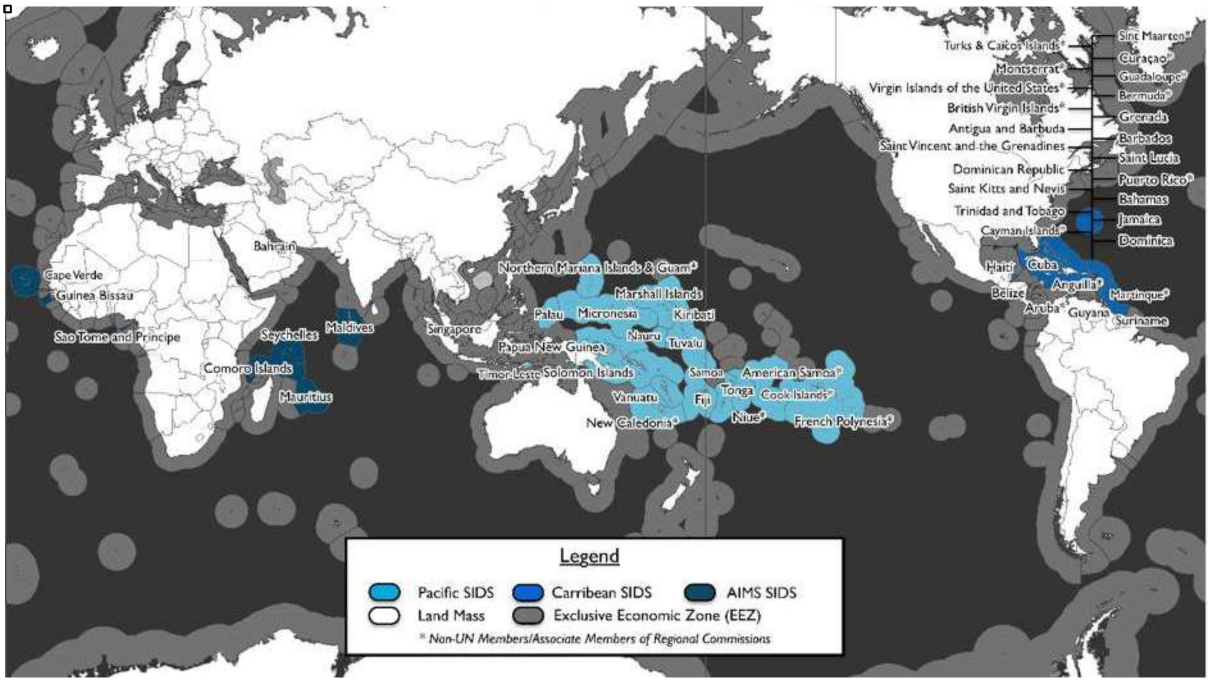

Figure 1: Groupings of Small Island Developing States (SIDS) (Trundle 2016)

Recent disaster events highlight the risks posed to SIDS by climate-related natural disaster events. The impact of Tropical Cyclone Pam on Vanuatu in 2015 was estimated to result in a total economic cost (comprising both damages and losses) of US$449.4 million, equivalent to 64.1% of the country's national gross domestic product (World Bank 2015). Despite being smaller in spatial distribution, severe flash flooding in Honiara in 2014 (known as the 'April Floods') had a similar impact at the city-scale, with damage and loss of US$107.8 million equating to roughly 10% of the more substantive Solomon Islands economy (SIG 2014).

Analysis of a series of annual country-level natural disaster risk assessments by the United Nations University's Institute for Environment and Human Security (UNU-EHS) puts these events in a wider international context. An assessment of risk reporting from 2012-2016 found Vanuatu to be the nation-state facing the most severe level of natural disaster risk globally, with the Solomon Islands ranked 6th over the same period (Mucke 2015). These rankings were determined as a function of both exceptionally high natural disaster exposure on a per capita basis, as well as an observed lack of adaptive and coping capacities at a national scale. The work of UNU-EHS echoes similar findings in urban-focused disaster risk analysis, with a Natural Hazard Risk Atlas developed in 2015 identifying Port Vila as the most at-risk urban environment out of a global sample of 1300 cities (Verisk Maplecroft 2015).

Pacific SIDS are expected to gain another 3.9 million urban inhabitants by 2050, from a 2010 baseline of 1.6 million; a rate of increase 3.5 times greater than the projected global average over the same period (Bedford & Hugo 2011). Within the Pacific SIDS group urbanisation levels and projected rates of change, however, vary substantially. Although more than half of the global population now live in cities, urbanization in the South-Western Pacific has lagged substantially behind the rest of the Asia-Pacific region (see Table 1).

	Share of Population Living in Cities			
Region	**1990**	**2000**	**2010**	***2020 (projected)***
World	42.6 %	46.4 %	50.5 %	*54.4 %*
Asia	31.5 %	36.8 %	42.2 %	*47.2 %*
Pacific (incl. Aust., NZ)	70.7 %	70.4 %	70.2 %	*70.4 %*
Polynesia	40.1 %	41.2 %	42.4 %	*44.7 %*
Melanesia	19.9 %	19.0 %	18.4 %	*19.9 %*
Solomon Islands	**13.7 %**	**15.7 %**	**18.5 %**	***23.0 %***
Vanuatu	**18.7 %**	**21.7 %**	**25.6 %**	***31.0 %***

Table 1: Regional Rates of Urbanisation 1990 – 2010 (UNDESA 2012)

The sub-region of Melanesia in particular has one of the lowest rates of urbanization in the world, with an estimated urban population share of 18.4% in 2010 (UNDESA 2012). However, over the last few decades a step-change in rural-to-urban migration has been observed. The population of Greater Port Vila for instance, grew at an annual rate of 7.7% between 1999-2009, in contrast to Vanuatu's national annual average rate of 2.5% (Trundle 2017). Similarly – and despite the Solomon Islands experiencing prolonged civil unrest and violence driven by informal peri-urban settlement around the capital – Greater Honiara grew at an average annual rate of 5.4% over the same period, compared with an annual rural population growth rate of 1.8% (SINSO 2013).

Despite housing an increasing share of their respective national populations, the presence of critical infrastructure and national institutions, as well as the co-location of most donor and non-government organisation headquarters, Pacific cities have undergone limited critical analysis; many having been isolated from customary land ownership during colonial rule, with urban residents engaged in the cash-economy being functionally disconnected from 'traditional' subsistence-based livelihoods (ADB 2010; Jones 2016). There has therefore been neither detailed consideration of the potential impacts of climate change on Pacific cities, nor analysis of how best to develop climate adaptation plans and policies pertinent to these rapidly growing urban centres (Mitchell et al. 2016).

3. Identifying Informal Climate Resilience: A Research Framework

Resilience is defined here as the ability of a system to cope with, recover from, adapt, or transform in response to a shock or stressor, as measured by an acceptable return to or maintenance of system function. This definition builds on Olsson et al.'s typology of Socio-Ecological Systems (SES) and Ecological Resilience, which identifies a need to differentiate between divergent meanings and attributes of resilience when applied to social and ecological case studies (2015). This ontological approach is reflective of cities being dynamic, non-equilibrium, transformative systems; a characterisation that is consistent with the rapid population growth and urban development processes discussed above (Folke et al. 2010).

Urban climate resilience – that is, applications of resilience thinking to urban systems, specified to climate-related current and future shocks and stressors – is applied through a more nascent body of literature. As part of this research, the use of resilience thinking in relation to urban planning for climate change has been reviewed, with related terms plotted in Figure 2 (analysis based upon a review of full-text, peer-reviewed publications in the *ProQuest* literature database). Notably, although frequency of explicit reference to 'urban climate resilience' is small in comparison with less specified resilience concepts (such as ecological, community or disaster resilience), applications of urban resilience and climate resilience have accelerated over the last decade substantially, with a focus on climate change and cities evident in a substantial number of these respective publications (Sharifi 2016).

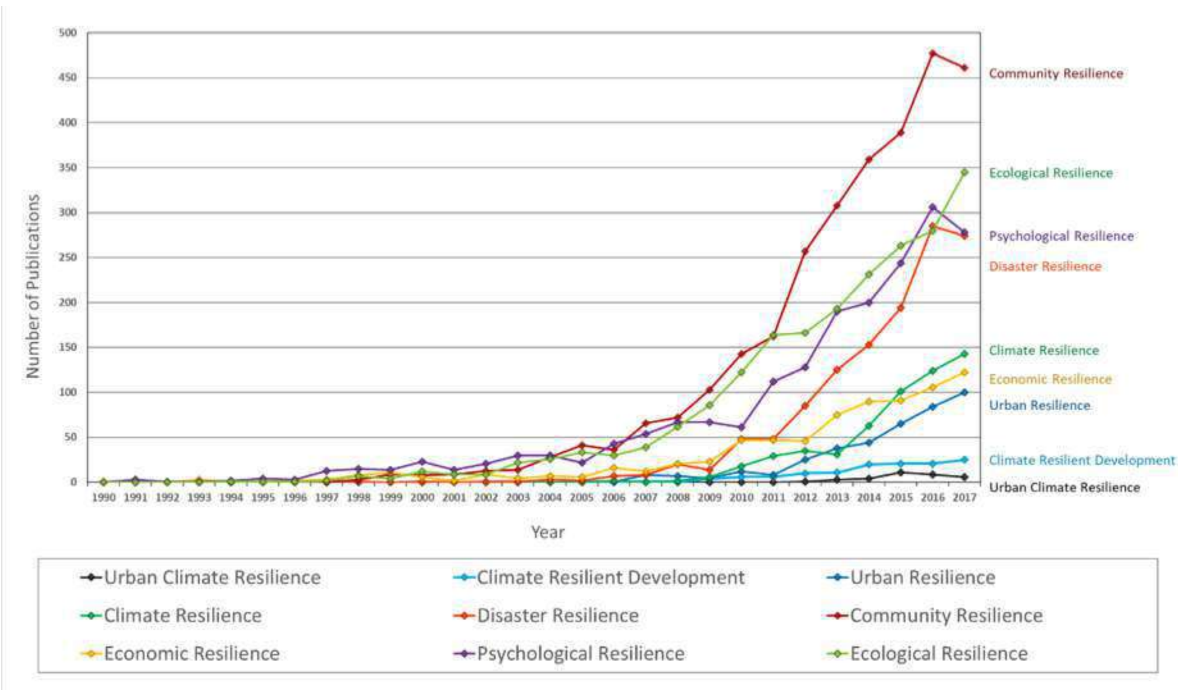

Figure 2: Groupings of Small Island Developing States (SIDS) (source: author)

As noted by Jabareen (2013), Meerow and Stults (2016), and others, the application of resilience within urban contexts is, however, much more prevalent in practice than in theoretical, peer-reviewed sources, having been promoted widely through city networks such as the Asian Cities Climate Change Resilience Network (Tyler & Moench 2012), ICLEI – Local Governments for Sustainability (Meerow et al. 2016), and the Rockefeller Foundation's 100 Resilience Cities Initiative (Da Silva & Moench 2014). Although informed largely by socio-ecological systems based resilience theory, the uptake of conceptual frameworks, such as Gunderson and Holling's Nested Adaptive Cycles 'panarchy' heuristic (2002), and emulation of theoretically espoused resilience characteristics (such as redundancy, inclusivity and predictability) has been varied (Meerow & Stults 2016). This lack of theoretical rigour has reinforced criticisms of the use of resilience thinking in heavily contested, politicised systems such as cities; at best, with these applications being little more than as a 'buzzword' (ibid), and at worst, imposing structural functionalist ideologies to reinforce neoliberal economic paradigms that "depoliticize social change" (Olsson et al. 2015, p.6).

Most critically, as Olsson et al. note, "one person's resilience may be another person's vulnerability" (ibid). This observation is particularly pertinent in reference to informal settlements, a domain where a lack of institutional control is often interpreted as a weakness in the city system (Seeliger & Turok 2014). The occupants of these settlements often represent the poorest urban migrants, with viewpoints, knowledges and resources derived domains beyond the city itself (Lawson 2000). In the Pacific, such migrants draw heavily on experiences of subsistence livelihoods, well beyond the global economic paradigms and urban institutional processes discussed above (Jones 2016).

As an initial output of this doctoral study, a conceptual framework for examining informal climate resilience in rapidly growing cities has been developed, as shown in Figure 3. This framework incorporates the nested institutional frameworks that operate in many of the urban settings within which climate resilient development initiatives are applied – as reflected in the vertical axis, allowing for consideration of Gunderson and Holling's nested adaptive cycles (2002). Enactments of informal climate resilience are then able to be considered in light of these institutional initiatives from the perspective of informal settlement households, embodied in the migrant dialectic shown at the centre of the horizonal axis of the same figure.

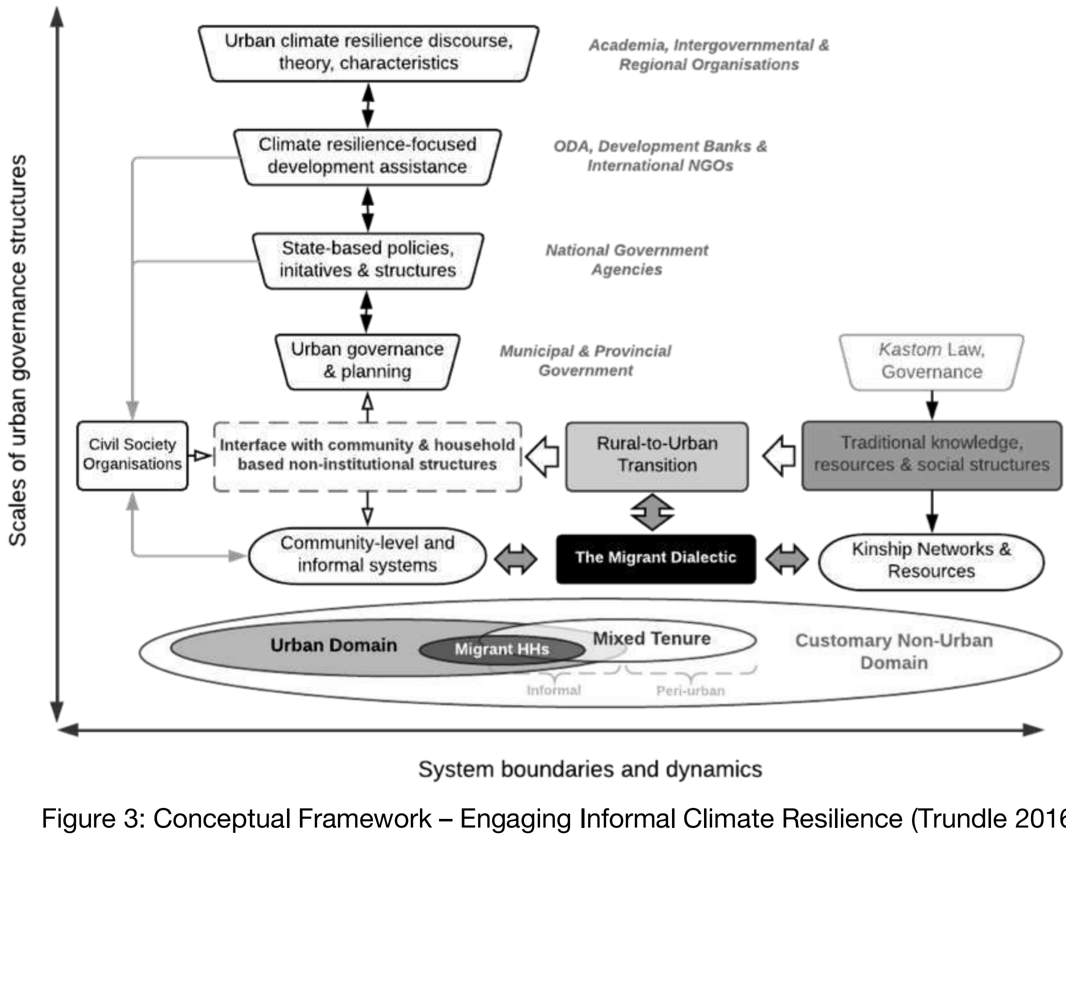

Figure 3: Conceptual Framework – Engaging Informal Climate Resilience (Trundle 2016)

A third 'axis' not able to be depicted in **Error! Reference source not found.** is temporal, rather than spatial or scale-based, but nonetheless underpins the adaptive cycles central to Gunderson and Holling's Panarchy model (Gunderson & Holling 2002). As noted by Holling in his earlier work on the model's adaptive cycle (Holling 2001, p.395):

> "The α phase is the stage that is least examined and the least known. It is the beginning of a process of reorganization that provides the potential for subsequent growth, resource accumulation, and storage. At this stage, ecological resilience is high, as is potential. But connectedness is low and internal regulation is weak. There is a wide stability region, with weak regulation around equilibria, low connectivity among variables, and a substantial amount of potential available for future options. Because of those features, it is a fertile environment for experiments … it is a time of both crisis and opportunity."

This phase provided a focal point in the two case study cities, with the aforementioned April 2014 floods and Tropical Cyclone Pam grounding the enactment of informal climate resilience in two recent and significant climate-related shock events.

4. Enactments of Informal Climate Resilience – Case Study Evidence

A mixed methods case study approach was taken in this doctoral research, centred upon semi-structured, qualitative interviews with migrant households in 6 informal settlements, as well as interviews with institutional representatives. These datasets have been integrated with secondary spatial data and the review of policy and project documentation, as outlined in Section 1. Fieldwork was conducted in mid-2017, with follow up visits to each community conducted in late 2017/early 2018.

Analysis of qualitative findings has been conducted through the thematic coding of interviews, a sample comprising institutional representatives (n=26) across each of the two case studies, as well as informal households grouped by city and community (n=57, 77 participants). Preliminary outputs from these interviews formed the basis of a series of follow-up workshops with each informal settlement community (n=6, 140 participants), as well as one customary land owner group (18 participants), allowing additional feedback and data gathering with a focus on perceived and potential interactions between informal and institutional modes of climate resilience specific to each settlement area.

A complete set of findings is not able to be presented in this paper, however examples of enactments of informal climate resilience have been identified that interact with institutional resilience across each of Helmke and Levitsky's four institutional-informal domains (2004). These domains reflect differing baseline levels of formal institutional functionality, as well as the alignment – or lack thereof – of values between formal and informal actors, and are classified as being: (i) complementary; (ii) substitutive; (iii) accommodating; and (iv) competing. Recurrent themes relating to resilience enactments across each of these domains are described below.

4.1 Complementary Informal Climate Resilience

Examples of enactments of informal climate resilience that addressed formal institutional gaps, or enabled local outcomes within the formal institutional urban framework abounded in the 6 case study communities. Most prevalent were adapted or hybrid applications of traditional disaster management techniques and knowledge, which provided a crucial source of resilience in each of the informal settlements, despite the highly modified urban conditions and limited resources that were accessible to the communities.

Examples included the use of traditional 'thinning' techniques on backyard '*sup sup'* garden crops, where leaves along the trunks of edible plants such as cassava were removed to prevent breaking during cyclonic winds and allow them to rapidly 'bounce back' following the shock event. Other applications included the reinforcement of a traditional 'A-frame' housing structure using vines and bamboo, procured from forested areas adjacent to a peri-urban community. Instances of traditional disaster response knowledge being used to supplement evacuation centres were also evident during Tropical Cyclone Pam, as summarised by one interview respondent from Etas Community in Port Vila:

> "Before Cyclone came last time, a lot of people from Banks they were hiding in caves when the cyclone hit. So we started looking for caves too here like … to me, I felt the cave was much safer. And we didn't hear any effects of like wind, we were just … it was quiet inside. We got solar, we watched laptops, movies. During the big Cyclone Pam. (ETHH3)"

4.2 Substitutive Informal Climate Resilience

Substitutive enactments of informal climate resilience were defined as those that replaced ineffective formal institutional procedures and rules. Most prevalent in this regard were the variety of faith-based community structures and associated organisations, reflective of the high levels of Christian religious xobservance in each country. As summarised by one interview participant:

> "Especially from here you go down [the valley], and it's a community. From here, valley inside lo … community has different churches. The church for one community, so they *controlem olsem* people, how they live. The church pastors, when things, problems, *em* different *lo* every community but you mention at church and they go 'oh, lets meet after prayer', bell, *em* ring and community talk about this, it's good. How we *respectem* every people of the community, *pikinini*, the women, elderly people in the community too." – JBHH4

Variation, however, within these structures reflected differing levels of institutional connectivity. In Blacksands, a peri-urban community to the west of Port Vila, a 'local' church provided a critical support structure for the community, conducting fundraising to support those who lost their homes during Tropical Cyclone Pam. The church structure itself, however, was reduced to a basic A-frame and tarpaulins 2 years after the cyclone hit (having previously been built out of corrugated iron), unable to be rebuilt using more 'permanent' methods due to complex informal land tenure arrangements with customary owners. The lack of connection to international church structures also prevented reconstruction through institutionalised church funds, with international faith-based donors disconnected from the community.

In contrast, the church central to the community of Ontong Java Settlement – at the Mataniko River mouth in central Honiara – provided extensive disaster response structures, staffing, and training to its community. It also housed the city's only early warning system for tsunamis and cyclones, which was connected to the National Disaster Management Office, demonstrating the 'fuzzy' boundaries between informal and formal capabilities in such settings.

4.3 Accommodative Informal Climate Resilience

Informal systems and structures that contradicted the intended function of formal rules – without directly undermining formal institutional authority – also contributed substantial to the resilience of both Port Vila and Honiara. In particular, the misalignment Western, planned understandings of both the household unit, and the shared nature of access to urban services and utilities, undervalued the connectivity and redundancies within informal settlements.

In terms of housing allotments for example, land was not understood to be defined in relation to a single nuclear family, but instead is traditionally occupied by an extended family network, consisting of multiple houses surrounding the head of the extended family network. This arrangement is depicted in Figure 4, which illustrates a representation of the Wind Valley community chief's formal allotment area. Although this arrangement does not comply with formal land use requirements, it does provide a critical basis for community-level resilience, enabling the sharing of resources such as standpipes, kitchens and sanitation facilities across multiple households.

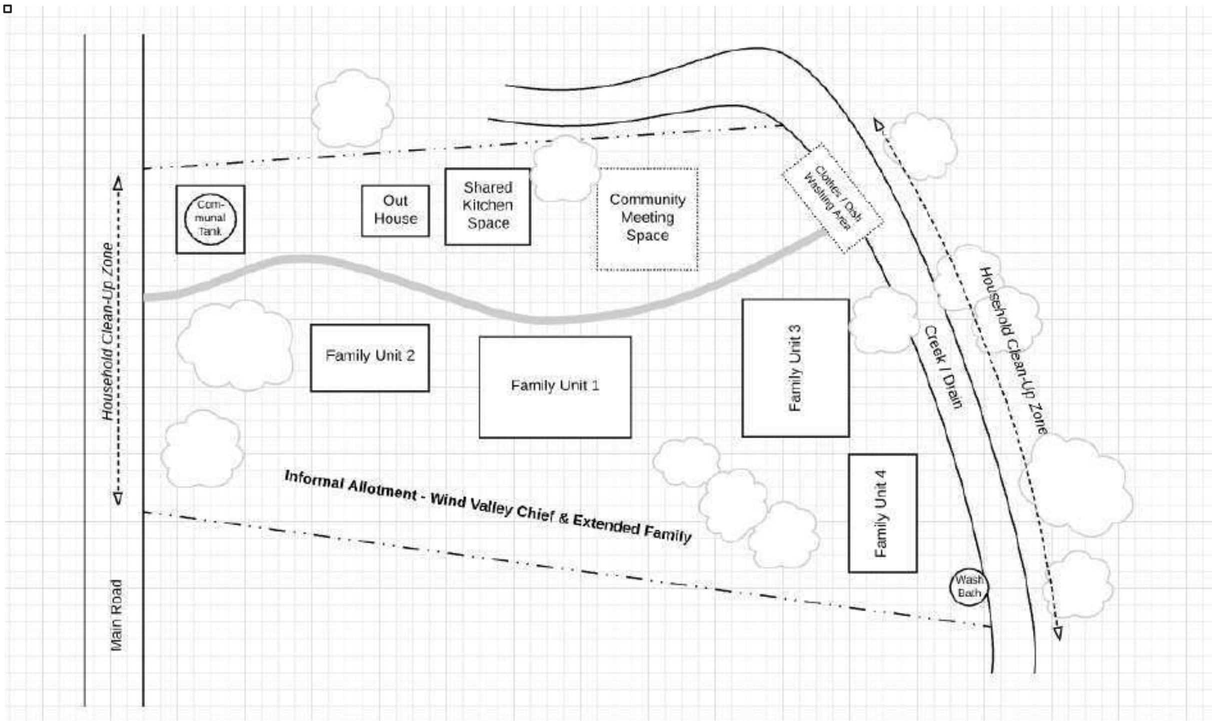

Figure 4: Multi-household allotment use in Wind Valley Community, Honiara

Other critical accommodative tenure arrangements included the use of semi-rural areas at each city's fringe for subsistence food production. As one household respondent reflected:

> "the [land owners] just provide us their land to plant food while they use the land for their project. Plant anything they want … Only families who came here first, and buy big land, acres of land, and so they just ask us to go and plant food. So that's where we now, like we said it is God's blessing, he can help us even though the land where we are staying is not enough, we can get food from the other land." (ETHH2)

4.4 Competitive Informal Climate Resilience

Most problematic were enactments of informal climate resilience that were in direct conflict with formal institutional functions. These often reflected contested or high-value urban assets, no more so than the critical resource of potable water. In the case of Jabros informal settlement, to Honiara's south, this also reflected the potential to transition from 'accommodative' to 'competing' function, as highlighted in the quote below:

> "First, when we first settled here, we have our stream here. And then, the Solomon Water come and then, Solomon Water come and pipe it …when we arrive here we used to use our stream, then they take it from us." JBHH1

Elsewhere, a lack of consideration of informal structures and tenure variation had resulted in conflict over a climate resilient development initiative, with some members of the community of Etas – a large area with mixed tenure and a number of sub-community groupings – actively undermining what they perceived to be inequitable distribution of the initiatives benefits:

> "First time somebody help us with water pipe, but like he put a pipe to each home and then some they used it but they didn't pay. And then, because, this land... people got angry, and they started cutting up the pipes" ETHH3

This lack of understanding of informal structures severely undermined institutional efforts to enhance Etas' climate resilience, with the 6000-strong community instead reliant on a stream estimated to be 2 hours walk from the settlement for drinking water, despite this source being heavily polluted by an upstream landfill site, and running dry during periods of drought.

5. Opportunities & Challenges: Urban Planning for Climate Resilience

As the examples provided in Section 4 demonstrate, informal structures have the potential to contribute to, but also undermine, urban planning for climate resilience. Equally, the lack of effective mechanisms for engaging informality within institutional frameworks is limiting, and in some cases also undermining, a rich array of locally-derived resources, structure and forms of knowledge that contribute to the overall resilience of urban systems. Critically, it is often informal structures that are most effective and defined at household and community scales, with their interface with institutional capacities reflecting the predisposition of urban climate resilience practice to operate at a whole-of-city level. As shown in Figure 5, this can exclude fundamental building blocks of resilience that draw on both non-institutional and non-urban capacities.

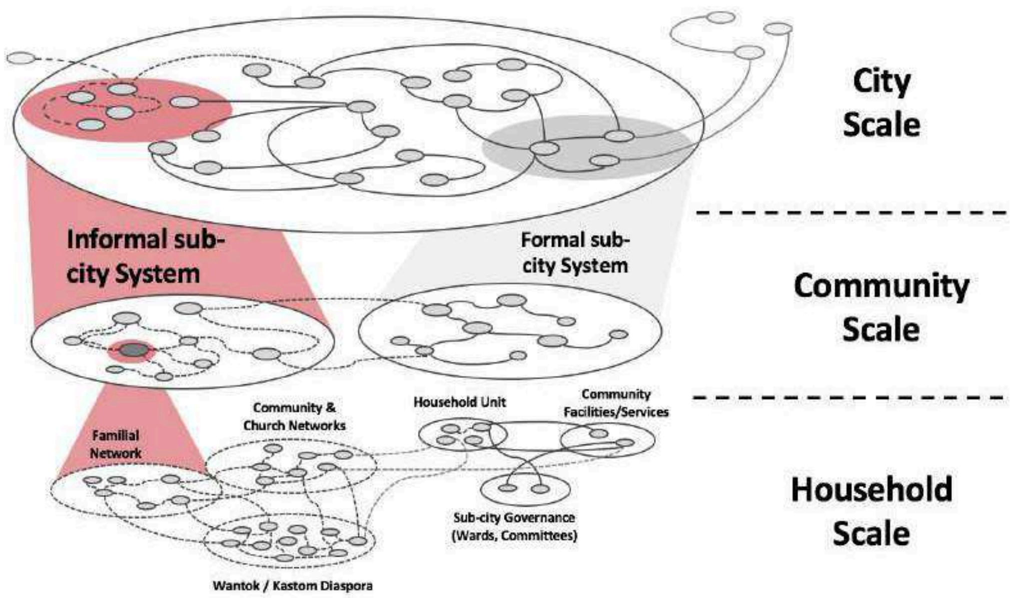

Figure 5: Informal climate resilience across multiple urban system scales

By engaging actively with informal settlements, economies, and systems within urban climate resilience frameworks as a discrete sub-city component of city systems, urban planning has the opportunity to build on a vast array of latent urban resources that are fundamental to the livelihoods of more than 880 million urban inhabitants (UNDESA 2012). With a further 2.5 billion people projected to occupy cities by 2050 (Sassen et al. 2017), there is little doubt that urban informality will continue to increase globally, and will require new mechanisms for adapting to shocks and stressors such as those generated or worsened by anthropogenic climate change.

Ziervogel et al., in their seminal article on endogenous resilience, note that "the concept of "negotiated resilience" might help to account for the situated power and political dynamics that commonly drive risk management and resilience-focused governance approaches (2017, p.9). This approach is predicted on an understanding that resilience is subjective and as such contains assumed values and distributive powers that require safeguards and principles beyond normative characterisations of urban climate resilience properties (Tanner et al. 2015).

These yet-to-be-developed mechanisms represent the most critical challenge to urban focused climate resilient development initiatives, if they are to engage with informal settlements in a systematic, but equitable, manner.

Although Pacific SIDS are in many ways unusual environments for urban analysis, their positioning at the fringe of global urbanisation presents unique insights into alternative modes of urban livelihoods and resilience-building, drawing on subsistence livelihoods, customs and traditional knowledge. While more developed cities try to establish shared community infrastructure, improve urban biodiversity and food production, and enhance local hazard awareness, these qualities are already prevalent in the informal settlements of the South Pacific. Instead of imposing Western frameworks for urban planning into such environments, an opportunity instead exists to exchange planning approaches for mutual benefit.

6. Conclusion

This paper presents some of the outputs of a doctoral study examining how informal social structures, resources and non-institutional networks are contributing to, and being engaged by, efforts to build climate resilience in Port Vila, Vanautu and Honiara, Solomon Islands. Findings were derived from a series of semi-structured interviews conducted across 3 informal settlements in each of the two cities, as well as with institutional representatives involved in climate resilient development initiatives.

By examining the dialectical position of migrant households within informal settlements, a vast inventory of informal climate resilience enactments have been able to be mapped out, both in direct response to two major climate-related shock events, and in relation to generalised resilience qualities. These enactments have then been classified in order to better understand the nature of their interaction with formal institutional objectives and functions, with a number of key themes highlighted in Section 4.

Learnings from both case studies suggest that more can be done to better support endogenous modes of urban climate resilience, with both exogenous climate resilient development programmes and the wider discourse of urban climate resilience lacking effective mechanisms for negotiating the core functions of a city-system through transformative shocks and stressors. Without a strong grounding in rights-based principles of equity and justice, resilience thinking will struggle to maintain conceptual relevance in rapidly growing, climate-vulnerable cities such as Port Vila and Honiara.

Place-based adaptation solutions for South African settlements

Van Niekerk, Willemien; Pieterse, Amy; Du Toit, Jacques, PRETORIA, South Africa

ABSTRACT:

South African settlements were planned and continue to develop in maladaptive ways with the most vulnerable households living on the urban periphery in sprawling settlements, far removed from the formal urban economy, public transport and amenities. The spatial configuration and the ways in which land is used and developed in South African settlements is often unsustainable and place communities and settlements at risk of, among others, the impacts of climate change. Place-based adaptation of the built environment, cognisant of the urbanisation challenges, will protect the development gain, contribute to the resilience of settlements and address their development goals. The objectives of the presentation are to: 1) Briefly present the evidence of the future risk trajectory of South African settlements as the rationale for the type of adaptation options that were selected from good practice examples. 2) Discuss the general urbanisation challenges and development goals of South African settlements in light of climate change adaptation. 3) Explain the process of how place-based adaptation options were linked to each settlement's risk profile. 4) Consider the implications for policy and practice in South Africa as well as other countries with similar development contexts. For this body of work, climate change projections over South Africa were downscaled to an 8x8 km resolution. The projections allowed researchers to model future hazard trends to better understand the impacts of climate changes on settlements. Combined with future vulnerability scenarios, the future risk trajectories of settlements in South Africa could be determined. A menu of adaptation options in the urban planning domain were compiled from examples of good practice. Based on the future risk trajectory, the urbanisation challenges and development goals of South African settlements, specific place-based options were proposed per settlement. The finding include that, based on climate change projections, South African settlements will in future generally become hotter and drier. Risk of future extreme events in settlements include flooding, drought, coastal and inland storms, and heat waves. This complicates the urban context even more. Key challenges include water, food and energy security, poverty, informality, inequality, service and infrastructure backlogs, lack of funding, capacity and political will to implement adaptation options, etc. Adaptation options that are place-based and context-specific will be showcased, while also reflecting on the process of developing these adaptation solutions. This body of work will 1) assist municipalities to adapt urban planning and development practices to climatic changes in line with development goals, 2) influence policy development at the urban planning/climate change adaptation nexus, and 3) identify priorities for mainstreaming climate change adaptation into local development planning. The project findings, methodology and outcomes will be of interest to many other countries with similar development and capacity challenges at the local scale as South Africa.

The role of spatial development in the energy and climate transition

Anneloes VAN NOORDT, Department of Environment & Spatial Development, Belgium

1. Synopsis

This paper is focused on how spatial development can contribute to the energy and climate targets. Focus points will be defined to indicate the role spatial development can play and a research by design exercise will be discussed. To conclude, policy recommendations in general and specifically for Flanders are formulated.

2. Introduction

Themes like nature, housing, mobility and environment have been part of spatial development for many years now. An additional focus which is receiving more and more attention (Sijmons, 2014; S. Stremke, 2017; Sven Stremke & van den Dobbelsteen, 2012; Van Kann, 2015) is the theme of energy. Just like the other themes, a structural link between spatial development and energy is needed according to these authors. Energy policy has consequences regarding the spatial design of our environment and the other way around spatial design and spatial policy also determines the energy systems.

The white paper of the spatial policy plan Flanders (Vlaamse Regering, 2016) acknowledges the challenge of the energy transition and links it to strategic objectives of contributing to a robust European energy network, living environments with a high quality of life generating a surplus of energy, reducing mobility by concentrating new developments near collective transport nodes, safeguarding energy services provided by open spaces and facilitating the generation of renewable energy in every type of land use. The spatial development principles as defined in the whitepaper are based on using less energy by avoiding wasting energy, increasing the energy efficiency by spatially stimulating the exchange of energy, facilitating the localization of renewable energy sources and bundling energy infrastructure.

This paper wants to contribute to already existing knowledge on the role of spatial development in the energy and climate transition. It aims to clarify and illustrate the possibilities and opportunities of spatial planning in Flanders to contribute in reaching the international long term targets regarding energy and climate on different scale levels from neighborhood to region. This is done by analyzing how spatial planning can contribute in an integrated way to the three energy targets: minimizing the energy demand, maximizing the energy efficiency and promoting the generation of renewable energy. At the same time, the overall goal of Flemish spatial development to stop further land take of green fields and even reduce the amount of land take is taken into account. The overall spatial strategies of doing more with less space, reusing space and reversible use of space are used as a framework to formulate concrete policy recommendations regarding space and energy. Its conclusions are based on a research project commissioned by the Spatial Development Department Flanders and the Environment, Nature and Energy Department and executed by Tractebel – Engie (Wauters, Dhondt, Fremault, & Corens, 2017).

3. Energy and space, what are the challenges?

Here, an overview will be given of the most recent insights regarding the relationship between spatial elements on the one hand and energy demand and generation on the other hand, with a specific focus on small scale energy generation, mobility and buildings. Existing literature and good practices are explored and analyzed in order to be able to indicate what the role of spatial development is. By confronting policy intentions concerning the spatial development with the desired developments on climate and energy, we can look further than a mere one-way approach in which spatial development is dependent on the objectives of energy and climate policy. This means we also explore the reverse connection: in what way can climate and energy policy contribute to the objectives of spatial policy. In order to concretely link the energy targets to the spatial context, the most important spatial elements for each sub target is analyzed.

3.1 Reducing the amount of energy used

Following the Trias Energetica (Duijvestein, 1998; Lysen, 1996) and the new step-strategy (Van den Dobbelsteen & van der Grinten, 2008) the first sub target is to reduce the amount of energy used, because the less energy we use, the less (renewable) energy needs to be generated. Within this sub target four elements should be addressed. First of all, the demand for transport should be reduced. In order for spatial policy to contribute to lowering the demand of transport, a location policy focusing on reducing the need for transport by concentrating different types of activities (like logistical centers, office and industrial areas, recreational zones and housing areas) in each other's proximity. The location of these activities influences the number of movements and the distance. The highest gains are achieved when daily activities are located close to each other. A second element would be to stimulate the use of sustainable transport options by either reducing the amount of motorized transport (by walking or biking) or using collective transport. Again location policy is an important factor. If activities are in each other's proximity walking or using a bike would become more attractive, while a smoothly operating collective transport systems relies on enough critical mass to be efficient. Moreover, facilitating sustainable transport options also requires providing the right type of space, like a network of bicycle lanes, parking spaces for car sharing, infrastructure for public transport and multimodal hubs. A third element is reducing the energy use in buildings. Energy use in buildings is mainly determined by the size of the building, the surface volume ratio and insulation. Focusing on smaller and more compact buildings and less detached buildings combined with higher insulation standards would help to reduce the energy use in buildings. In certain cases, renovation of existing buildings will not be possible or wanted. Demolition and new development (with new typologies) will offer a better solution. Moreover, because of the dispersed ownership of buildings in Flanders it is challenging to renovate buildings on a larger scale. Facilitating collective approaches for renovations could offer opportunities. The fourth element, which is also crucial to realize the first three elements, is spatial efficiency. A high spatial efficiency is needed to offer a sufficient amount of services on a short distance to reduce the need for transport. Moreover, transport over short distances is more easily made sustainable. Higher densities facilitate the organization of public transport. Building more compact is an integral part of spatial efficiency. However, each area has its own challenges, therefore a place-based approach is crucial. Using higher densities will however only be accepted if the overall quality of life does not decrease. It is therefore crucial to not only look at the individual building, but also at a district or city level making connections between buildings and green and blue infrastructure (Wauters et al., 2017).

3.2 Increasing the energy efficiency

The second sub target would be to increase the energy efficiency. First of all, the efficiency of buildings could be increased by improving the way energy is produced and transported within and between buildings. Examples are using collective installations both for generating energy (solar panels, geothermal energy) as well as distributing for instance heat (heat networks); replacing outdated installations; recover energy surpluses by introducing heat cascades and generating heat close to the place where it is used (Wauters et al., 2017). When individual energy end users are interlinked their energy need can be brought down to 1/5th of the need of independent users (Posad, 3E, Universiteit Gent, & Resourcedesign, 2016). Secondly, increasing the energy efficiency in transport is mainly a matter of technology and infrastructure. Spatial planning has only a small role to play here (Wauters et al., 2017).

3.3 Increasing the amount of renewable energy

The last sub target is to increase the amount of renewable energy. Two spatial elements within this sub target are put forward. This is first of all the use of renewable energy within buildings. The use of renewable energy can be subdivided into two components. First of all, there is the use of renewable energy generated elsewhere, the large scale renewable energy projects. Switching to renewable energy sources, like wind, sun, water and biomass, would require using more space compared to the conventional sources, because these renewable sources are a lot less energy intensive compared to fossil fuels (Sijmons, 2014; van Noordt, 2016). Moreover, the potentials of these different sources are much more place-based (Posad et al., 2016) with, for instance, the possibility to generate electricity with water power being dependent on the availability of water and a sufficient amount of height difference. On the other hand, renewable energy can also be generated on a smaller scale making it possible to integrate the generation into the built up environment, like solar panels, smaller wind turbines, biomass power plants and CHP. But although these smaller scale energy generating facilities and storage are more easily integrated into the buildup environment, they still need space and an intelligent integration. On the other hand, the great variety of landscapes in Flanders could also offer possibilities for different forms of local energy generation, local energy cycles and connecting producers with consumers (Architecture Workroom, Boeijenga, Vink, LIST/GRAU, & H+N+S Landschapsarchitecten, 2013). These opportunities could contribute to innovative spatial-energy strategies. Local renewable energy generation could also have adverse effects, like creating self-sufficient energy islands or supporting spatial developments in unwanted areas. A collective approach towards this local generation seems to be needed. Generating energy locally should not only be stimulated on the level of a building, but also on different scale levels. Generating, distributing and storing energy locally is however a very complex issue demanding expert knowledge, which is not always locally available. Spatial policy could play a facilitating role in tackling this complexity also paying attention to the three dimensional component. The second spatial element in increasing the amount of renewable energy is the use of renewable energy in transport. Again, transport can use renewable energy generated elsewhere, like explained above. Secondly, clean fuels could be used for transport. Although this is not influencing the direct spatial needs of transport itself, it does influence the location and type of distribution points. At the moment it is still very uncertain which fuel source will break through, whether these are electric vehicles, vehicles on natural or biogas or vehicles on hydrogen or even some other type of fuel. Spatial planning therefore needs to be flexible and able to quickly respond to changing trends to facilitate these new developments. New forms of transport also enable new mobility concepts; this could also have an impact on the spatial configuration. A system where cars are shared would for instance need a different type of parking facilities (Wauters et al., 2017).

4. Focus points for spatial policy

Integrating the energy and climate challenge into spatial development is more than only taking certain specific measures or using specific instruments. Climate and energy goals need to be an integral part of spatial policy. Based on the insights explained above on the relationship between space and energy, and on the analysis of several successful international examples, five aspects are put forward in which spatial policy has a clear role to play and these aspects should therefore become focus points for spatial policy when regarding energy. All of these aspects are illustrated by good practices to elaborate them into more detail and to inspire policy measures.

4.1 Active spatial policy

At the moment spatial planning connected to the theme of energy is mainly following the needs put forward by energy policy, acting merely reactive. But, in order to achieve the ambitious goals of climate policy, it will not be sufficient to only play a facilitating role. Upgrading the existing urban structure and mitigating the adverse effects of previous measures will demand a more pro-active type of policy. Moreover, the actions needed from an energy transition point of view could be used as a lever to realize spatial quality. Examples would be to support large scale renovation projects, actively supporting new housing typologies with a higher spatial efficiency, investigating how the local potential for generating renewable energy could be improved by increasing the spatial efficiency and extending energy networks to enable local energy generation. At the moment most examples of an active spatial policy are connected to mobility projects. Reorganizing (car) mobility plays an important role in both small and large scale projects. The overall goals are twofold: on the one hand an increase of the quality of live is pursuit by reducing noise, enhancing air quality and reducing spatial impact, on the other hand more space is dedicated to alternative forms of transport (Wauters et al., 2017). In Barcelona, for example, so called 'Super Blocks' are created with large car-free zones for bicycles and pedestrians and ring roads with good public transport and other facilities. This project proves that large changes or investments are not always necessary to achieve improvements (Joanneum Research & UNDP, 2017). In a new brownfield development in Amsterdam, Buiksloterham, developers are obliged to take a number of sustainability measures regarding energy, resources, climate and mobility. Only those project proposals that reach a high level of sustainability are selected. Moreover, the municipality of Amsterdam regards geothermal energy as one of the most important renewable energy sources. In order to facilitate the use, an underground energy plan is made. This plan offers a framework for new geothermal systems with the goal to avoid negative interferences and to use the potential available to the fullest (Metabolic, Studioninedots, & DELVA Landscape Architects, 2016).

4.2 Collectivizing interventions

Challenges in both the housing and in the transport sector are asking to be tackled in a more collective way, especially on a lower scale level. Examples could be local energy initiatives, collectively improving the sustainability of the housing stock, extending collective types of transport and providing collective facilities for new sustainable types of fuel. For certain energy projects, collectivizing is essential in order to make the project profitable (Wauters et al., 2017). For other cases, like in the example of Vauban, Freiburg, collectivizing interventions is a way to reach sustainability goals that go beyond the scale of the district itself. In Vauban collectivizing certain measures goes hand in hand with participation. Collectivizing could also be a way to involve larger groups of residents with the energy and climate policy, reducing the resistance towards certain projects at the same time. Executing projects in a collective way can be done on many different scale levels. On the level of one building, on the level of a building block, a district or even a whole city several examples can be put forward like cohousing, exchanging renewable energy, heat networks and so on. An important issue to be able to collectivize projects is a clear framework from the government that facilitates collective action. This could be done by either administrative simplification or active policy. Governance is also needed in order to align different initiatives. When looking at the case of Freiburg, collectivizing, in the form a citizens building assemblies, has proven to be the key to reach higher densities without decreasing the quality of life. On the one hand less space is used by providing collective facilities like collective heat production, collective forms of transport and collective outdoor areas, while at the other hand energy use is reduced and housing becomes more affordable. The revenues and added value are used to finance the greater investments in insulation and energy generation (Salomon, 2009). Another example of a collective project is a new housing development in Naaldwijk, The Netherlands. In this district 146 houses and a nursing home are heated by residual heat from the adjacent green houses in summer. This residual heat is stored underground and used during the winter, while the cooled down water can be used in summer to cool the houses (KAW Architecten, 2017).

4.3 Place-based policy

Demographic and geographical differences need to be taken into account within a place-based approach to be able to use local opportunities and neutralize local obstacles. Rural areas with a shrinking population need other approaches compared to suburban districts with young families. Moreover, the efficiency of renewable energy sources knows important regional differences. Most of the existing energy projects take site specific characteristics into account. Custom made solutions are applied in order to tackle local challenges. A one size fits all solution is not possible regarding energy projects (Wauters et al., 2017). A special example of place based policy is Geneva where planning of energy production and consumption is directly combined with spatial planning. A total integration of energy aspects within spatial development projects is achieved by adjusting the regulations. This approach recognizes the need to not only focus on the individual level of buildings to achieve the climate targets, but instead to focus on the whole territory of Geneva and its land use. In this canton energy concepts are developed at a district level. Based on an analysis of the locally available resources, the needs, the actors and infrastructure a strategy for sustainable energy supply is developed at region, city, district, quarter and neighborhood level. Part of the strategy is also to inform individual residents, based on the above mentioned analysis, about the most suitable heating system like geothermal, heat network and so on (Favey, 2013). Rotterdam as well has a clear place based approach. The Rotterdam Energy Approach and Planning (REAP) offers a scheme with which each neighborhood can sustainably be redeveloped. The REAP methodology is a newly developed practice to become climate neutral for both new developments as well as existing neighborhoods. It is based on the principle already explained above: to first of all reduce the energy demand, secondly to reuse residual energy and lastly to apply sustainable energy sources. Originally there was a fourth step to meet the remaining energy demand by using fossil fuels as efficiently as possible, but the first three steps should make this last step unnecessary. Based on the different types of housing typologies recommendations are made to undertake actions for each of the three steps (Tillie et al., 2009).

4.4 Tuning different policy levels and policy fields

There needs to be a higher degree of alignment between spatial policy at the one hand and other policy fields at the other hand. Prospective studies and investment plans for improvements on existing infrastructure or extension of infrastructure for instance, needs to align spatial opportunities. Connecting energy generation with a clustering of different functions could increase the energy efficiency, while existing heat sources could facilitate development of new functions with a heat demand. When (inter)national good examples are analyzed one of the conclusions is that they do not focus only on the energy- and climate transition. Often these projects also want to realize other goals like city-development. By combining diverse goals, the project also gets interesting for other users or initiators (Wauters et al., 2017). For example, in Gent Dampoort a project on building block renovation took other goals besides reducing the use of energy into account, like security (fire safety, reducing the risk of CO-intoxication), health and the quality of the environment. In the end the project produced a manual in order to inspire and guide other possible projects towards building block renovation. Forging alliances is one of the crucial elements to guarantee success. Existing instruments were integrated into a unique partner cooperation (Canfyn, 2013). The case of 'Hammerby' in Stockholm, Sweden is another good example of how different sectors need to be integrated. In Hammerby the goal is to close all the cycles (of water, waste, materials, etc.) This necessitates the cooperation and adaption between many stakeholders and government institutes. On the other hand, synergies can be achieved by this type of interdisciplinary planning of energy, water and waste flows (Gaffney, Huang, Maravilla, & Soubotin, 2007). At the moment most of the newly developed projects have no relationship with other projects or with their direct environment. In order to facilitate an integrated approach, regarding both energy consumption and energy generation as well as water management, traffic policy and so on, different scale levels need to be included. Moreover, combining or even integrating spatial planning with other sectors, like mobility, housing or energy has also proven to result in more effective policies.

4.5 Awareness & training

Spatial policy only has a limited impact on the way projects are executed. Creating awareness with all the involved actors like architects, therefore remains a crucial aspect in developing climate and energy friendly projects. Good practices are needed in order to show how certain changes can be achieved in the field. Furthermore, a change in attitude and behavior is needed to fully realize the energy transition. A shift from private to collective transport, from dispersed to dense urban areas and from energy wasting to energy saving attitudes is not only a matter of spatial development, people using that space are the most important factor. Communication and direct knowledge support is needed. Many of the cases already mentioned invest a great amount of their attention towards participation and communication. By involving a high number of participants in an early stage knowledge can be exchanged and build up (Wauters et al., 2017). The example of 'Leuven low traffic inner-city' combines participation with awareness raising. The project started with an initiative of local residents wanting to convince people of the advantages of a car free inner-city. Through a website an awareness campaign is being conducted by informing residents, visitors, merchants, restaurants, schools, businesses, service providers and the local government and motivating them to participate (Platform Autoluwe Binnenstad, 2017). One of the most known international examples of climate and energy friendly cities is Copenhagen, it aims to become the world's first CO2 neutral capital by 2025. Although Copenhagen is already scoring high points on mobility (mostly by bike and public transport), housing (space saving apartments) and energy efficiency (using district heating), still more can be done concerning saving energy, the modal split and reuse of waste. This is why one of the six action areas is focused on 'Copenhageners and Climate' in which 9 initiatives are dedicated to information, consulting and training (City of Copenhagen, 2009).

5. Research by design, case of Veurne, Flanders

To further specify and evaluate the role of spatial development within the energy transition a research by design exercise was executed on a concrete case. By applying some of the insights derived from literature and international examples, further insight can be achieved into the possibilities, limitations and conditions of measures in a Flemish context.

The case of Veurne deals with a typical Flemish allotment area from the second half of the 20th century. This neighborhood, 'Voorstad', is an example of the dominant living environments in Flanders in the second half of the 20th century. The neighborhood itself developed between 1970 and 2000 and is characterized by an aging population, low population density and houses which are no longer adjusted to the current living standards. Moreover, the projections for demographic developments predict a shrinking population by 2030. It's location, however is relatively good, with a close proximity to the city center, although the connections towards this center are rather poor, resulting in a high use of the car for all movements. Due to the good location and changing population, it is expected that the neighborhood will enter a period of high dynamics. The goal of the research by design exercise is to analyze how this neighborhood can transform towards a more sustainable neighborhood, keeping the existing local specificities into account, but also the energy challenges and focus points like explained above.

5.1 Using densification as a principle for energy transition in a neighborhood

The first principle that is applied to the neighborhood 'Voorstad' is densification. Densification principles have been investigated from different angles the last years like affordable housing and landscape, but less from the energy and climate point of view. Many new principles regarding densification have been put forward, but at least in Flanders, not much is moving. The different principles regarding densification have been put together in a matrix in figure 1. The x-axis represents the scale of densification and the number of involved owners. Starting with one plot, over several plots to a small building block. The y-axis represents the intensity of the extension. From small extensions using the existing footprint to a complete renewal of a building block.

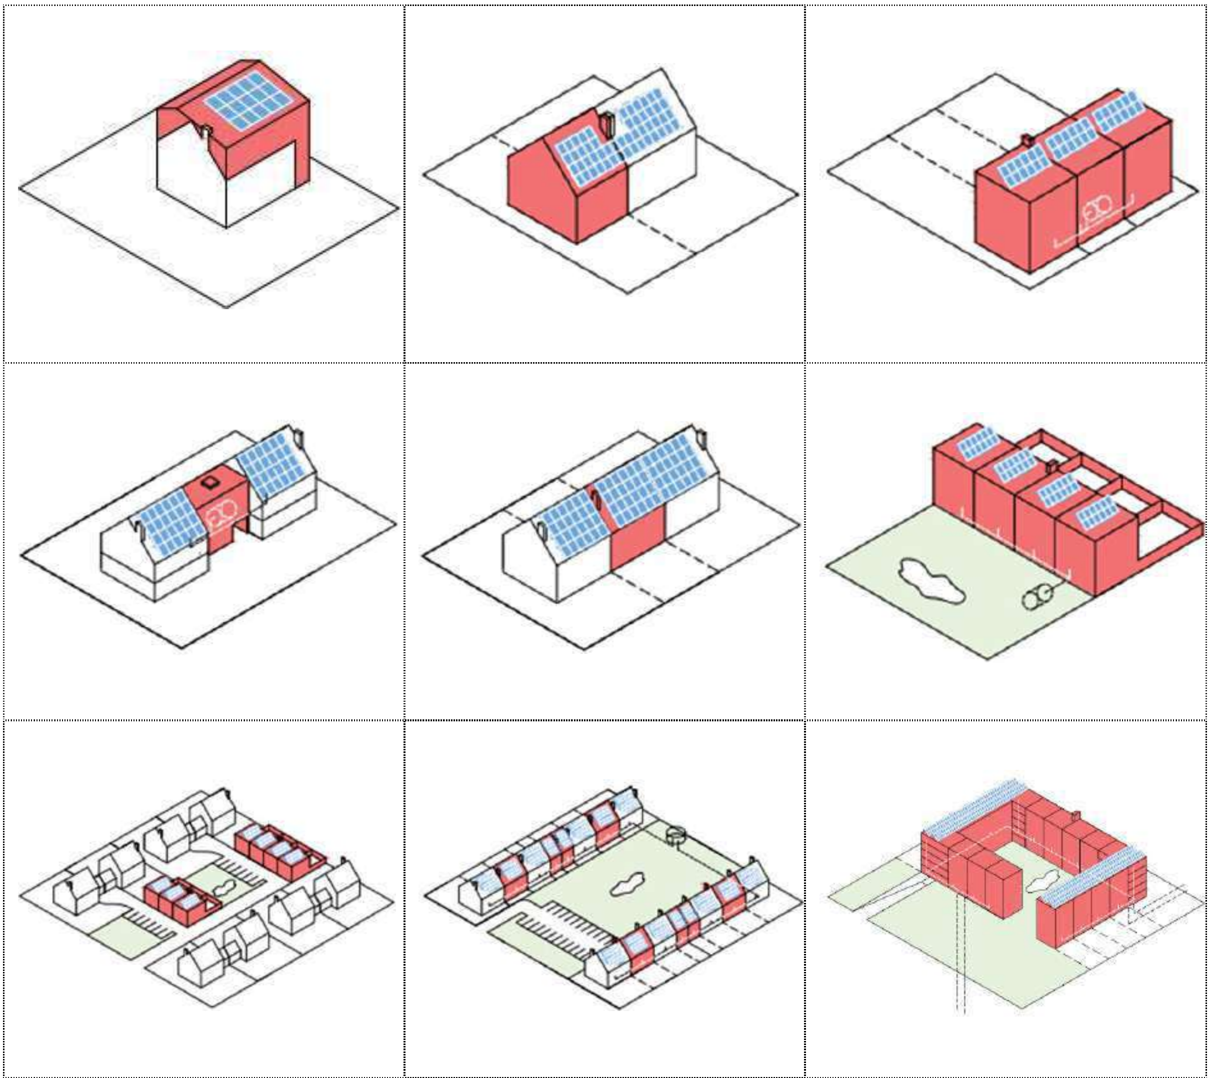

Figure 1: Principles of densification

Based on these principles a scenario exercise has been done that analyzed each individual building on its quality. By using a decision tree choices can be made not only for individual buildings, but also for neighboring houses and the whole block. This analysis made it possible to decide which interventions were needed for each building. Each plot realized progress concerning sustainability. Every densification strategy achieved either higher compactness, a better orientation, higher densities or collective energy production, or a combination of these components. Profits are not achieved by one large investment but by combining several small scale interventions, that enabled residents to take their own initiative.

5.2 Reducing car dependence to minimize energy needs

The second principle is focused on mobility and encouraging walking, cycling and using public transport (in that order) instead of the car. By adding more fine-grained connections for walkers and cyclists and by paying attention to the organization of the infrastructure, for example the width of a footpath, walking and cycling can be encouraged while using the car discouraged. Figure 2 shows the design principles. Most research on applying these principles has been done in newly developed, highly urbanized areas, while there is a lack of research on how to do this in existing allotments, like the neighborhood in Veurne.

Increasing the comfort of pedestrians / cyclists	**Discouraging car-use**	**Improving public transport**
 Fine-grained network for pedestrians and cyclists	 Less parking lots	 Public transport stop next to neighborhood
 Car-free streets	 Collective parking & car sharing	 Public transport stop & amenities next to neighborhood
 Car-free neighborhoods	 Collective parking & car sharing outside neighborhood	 Public transport stop & amenities in neighborhood

Figure 2: Principles for mobility

By analysing and categorizing the existing road network in Veurne a differentiated strategy for each road can be developed based on the above principles. Three main road loops could provide sufficient accessibility, while roads outside these loops could be downgraded to infrastructure for bicycle and pedestrians on which cars are not allowed. Collective car parks farther away from the houses are introduced to further minimize the amount of cars in the neighbourhood. To increase the accessibility by foot and bicycle to the city centre new connections for this type of transport is added.

5.3 Spatial instruments

When analyzing the existing instruments for spatial development in Flanders, it becomes clear that these instruments are adequate to accomplish the measures like indicated above. Most larger and middle sized towns are already using these instruments with success. However, smaller towns and 20th century allotments are not. They could use support in creatively implementing a variety of proposed measures to create more sustainable neighborhoods. When doing this they should first of all examine the location of the neighborhood: does it have enough potential to further develop? A second step is to analyze the urban planning structure: is this robust enough? The third step would be to zoom into the buildings themselves: are they still qualitative enough to keep or adjust? (Wauters et al., 2017).

6. Policy recommandations

An active, place-based approach that takes local specificities into account and makes use of local opportunities seems to be needed to facilitate the energy transition. In this part several recommendations towards spatial planning in Flanders at different policy levels are given.

6.1 Location policy

First of all, a smart location policy is needed (Wauters et al., 2017). Structural improvement of the performance of the urban system is only possible when spatial policy in Flanders drastically changes its course towards reduction of mobility. Allowing developments like housing areas and business parks to take place on sites which are not suitable undermines all other efforts. This issue is also deeply connected to the subject of land take. Flanders has one of the highest built up and sealed up areas of the world, stopping a further increase of land take would therefore greatly facilitate increasing the spatial efficiency and redevelopment of brownfields. Selecting suitable sites for future developments is crucial and could be based on the study recently executed by VITO on the value of nodes (Engelen et al., 2016). This “node-value” is based on accessibility by public transport and the availability of services. Further research however is still needed to elaborate on this ‘node-value’. Should it for instance also need to include aspects of renewable energy availability or other aspects like quality of life, safeguarding flood prone areas and so on. An integral assessment framework is therefore needed.

6.2 Interventions within existing urban fabric

Serious energy reductions can only be achieved when the attention of spatial development is shifted from new green field projects towards transforming the existing built up areas (Wauters et al., 2017). Special attention needs to be given to frequently occurring situations in Flanders like the 19th century belt and the 20th century allotments. Transforming and redeveloping housing types which are difficult to upgrade should not be treated as a sacred cow. For some badly located sites the only solution is to demolish the buildings and relocate them. This strategy is not only beneficial from an energy perspective, but will also have other benefits like creating more open space for other functions like green-blue infrastructure. These type of actions will only be possible if there is a high sense of urgency both within the general population and within policy makers and should mainly be applied within those sites with a low ‘node-value’. This also necessitates the development of policies for shrinking regions, where demographic scenarios are predicting a decreasing population. People are leaving because there are no jobs, low services or a bad connection towards other places. This leads to a downwards spiral, where lower population densities trigger those services which are still there to close down. Shrinking areas could demonstrate important potentials as well to realize the goals towards climate and energy. In these areas the existing spatial structure could be changed by focusing on strengthening the cores, increasing urban densities in those cores and clustering services.

6.3 Urbanize

Although most attention in the last decades has been put on urban areas resulting in many urban interventions, the challenges remain, particularly when focusing on mobility. In Flanders urban areas are regarded with anxiety by most inhabitants as places which are lacking green spaces and privacy. The administrative boundaries of urban areas do not coincide with the functional boundaries, resulting in a suboptimal (collective) transport system and lack of investments in bicycle highways. But besides the transport system, a change in the mindset towards housing typology within the functional urban areas is also needed. Within cities, neighborhoods are mixed and vibrant places where several functions and typologies exist side by side, whereas in the 20th century suburban sprawl a mono-functional organization dominates. Transforming from a mono-functional ‘housing area’ towards a ‘city neighborhood’ will decrease the need for transport, increase the spatial efficiency and reduce depopulation (Wauters et al., 2017). Cities are highly dynamic environments, where innovations are tested, also regarding new energy solutions like new ways of living together (co-housing), exchanging energy or collaboration (circular economy). Facilitating these types of dynamics by giving them space to experiment could support the discovery of new spatial solutions.

6.4 Space for renewable energy

The urban sprawl greatly influences the possibilities to realize larger scale energy projects. Although Flanders has a similar density as Denmark and Germany, the share of renewable energy generated by wind turbines is remarkably lower. Open spaces are scarce, reducing the opportunities for wind turbines and increasing the amount of people negatively affected by wind turbines. The spatial structure of Flanders can however be changed, like examples from the past show. In the SIGMA-plan, large areas were designated as ‘overflow’ areas for rivers, preventing other, more populated areas to be flooded. The new spatial policy plan Flanders also focuses on a structural change within the built up area: by intensifying built up area around well connected nodes and reducing the built up space in other areas, space is opened up for other functions like placing wind turbines. Prioritizing the energy transition, also in spatial policy, needs long term visions and the development of financial instruments to support the already existing instruments (Wauters et al., 2017). Active policy can be supported by mapping renewable energy potentials and using these potentials in a place-based approach.

6.5 Supporting local governments

At the moment many local governments in Flanders are struggling to make the right choices regarding energy and spatial development. The region of Flanders, but also the provinces can play an important role in supporting those governments. First of all, Flanders could serve as a knowledge broker towards local governments. Much research has already been done at the regional and provincial level that could be beneficial for local governments, making sure these insights also reach the lower levels should be one of the tasks. This could be done by supporting the development of concrete projects either by providing ready to use instruments like assessment frameworks or energy potential maps or by providing a pool of experts that could give input. Second of all, the local level can be supported by providing new types of collaboration and financing models, which can be used within new developments. Lastly, there is a need in Flanders to start experiments which can inspire other municipalities. The existing good practices are mainly located in foreign countries, with other spatial specificities and planning practices. Starting innovative experiments which are representative for the Flemish context and take local specificities into account are therefore crucial. Moreover, these experiments should not stop at just providing a masterplan, they should follow the project towards realization and even beyond (Wauters et al., 2017).

The Ground Beneath Our Cities

Guri VENVIK, Geological Survey of Norway, Norway

Abstract:

The subsurface is important for cities. Cities not only expand outward and upward, but also downward. The more use we make of subsurface space, the more surface space we free for the one function that cannot do without daylight and fresh air: living. Increasing urbanisation challenges the sustainability and resilience of cities world-wide. At the same time, often overlooked are the resources and opportunities in the ground beneath our cities. This is one of the reasons why a European network of specialists joined together with the aim of improving the understanding and use of underground space. The participants of COST Action TU1206 Sub-Urban (2013-2017) display a cross-section of skills and knowledge of subsurface issues in 31 European countries and 26 cities. After sharing their experiences, the common pathways (and pitfalls) to improve collective planning of the subsurface became more evident. A key recommendation from this work is improving communication between the urban planners and the subsurface experts.

1 Introduction

Exploitation of underground space is not new, as is well documented (Admiraal & Suri, 2015;Bobylev, 2016; Campbell et al., 2017; Mielby et al., 2016; van der Meulen et al., 2016). Geology plays an important role in how cities develop with regards to the subsurface, as exemplified by Reynolds & Reynolds (2015). However, there is still a lack of usage of geological information: data and knowledge, when it comes to underground space that can reduce risk and increase cost reliability, cost efficiency with re-use of data in projects and build sustainable and resilient cities for the future. Most cities expand on the surface, but this expansion has its limits (Wang, 2015). As Wang (2015) points out, the subsurface is an untapped new frontier for cities. We differentiate between the built environment and the natural environment. To achieve resilient and sustainable urban development the two should go hand-in-hand and not compromise. That is the motivation behind the work of the Sub-Urban network.

This paper will present the collective work of the network COST Action TU 1206 Sub-Urban that was active from 2013 to 2017 with its final action dissemination in April 2018. The aim for the Sub-Urban network was and still is to increase the awareness of the possibilities and challenges that lie in the ground beneath our cities (TU 1206 Sub-Urban, 2012). At present, the subsurface is regarded when it gives an economic possibility, such as mining or other resources, but more commonly when challenges occur, such as unforeseen problems in tunnel building, sink holes, collapsing foundations and many more examples (van der Meulen et al., 2016; De Stefano et al., 2015). During the Actions four years the network increased to 31 participating countries and 26 city partners. The core structure was the Geological Surveys in Europe collaborating on common challenges; how to increase the awareness of the subsurface in urban planning and make the most of the information Geological Surveys collect and manage (Campbell et al., 2017). The principle rule was that each country should bring at least one collaborative city partner into the network, so that the planners' view and understanding of the challenges and possibilities got a strong voice. Other institutes such as Universities etc. were also welcome to join (TU 1206 Sub-Urban, 2012).

2 Underground space in European cities

Although all cities are different in historical and cultural setting, the challenges they experience are surprisingly similar (van der Meulen et. al., 2016). Increasing urbanisation confront the sustainability and resilience of cities world-wide (Admiraal & Suri, 2015). The obstacles of the subsurface are plentiful, such as cavities (De Stefano et al., 2015), and unforeseen ground conditions. At the same time, often overlooked are the resources and opportunities in the ground beneath our cities, with examples from Oslo, Rotterdam, Glasgow, Odense, Ljubljana and Lisbon.

2.1 Oslo – value of the underground

Oslo city, the capital of Norway, is one of the fastest growing cities in Europe. That requires urban planning not only above ground, but also below ground. Especially public transportation is in focus, to enable commuting within reasonable distance and time from the city boarder and surrounding areas. The in-the-making Follo railroad is estimated to 3 billion Euro, while existing subsurface infrastructure has an estimated value of 11 billion Euro with planned constructions at a budget of additional 6.2 billion Euro (Bekkhus et al., 2018 *in prep*; Venvik et al., 2018). Since the underground constructions are out of sight, their value and function is often not appreciated compared to constructions at surface, such as buildings with impressive architecture.

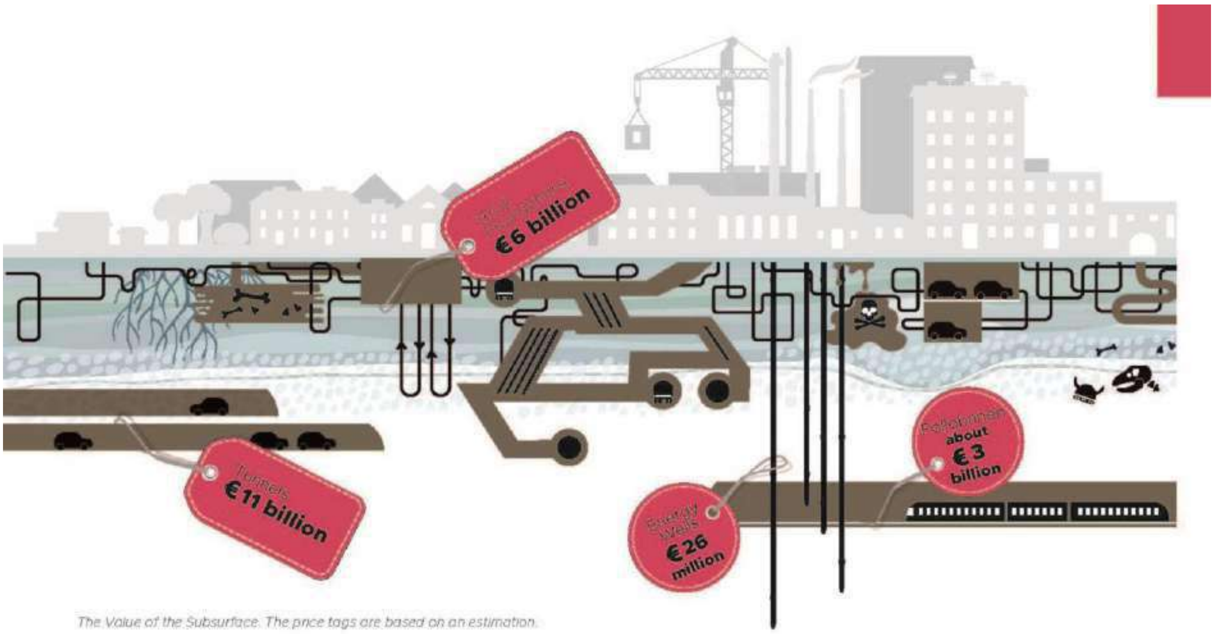

Figure 1: Oslo city has estimated the value of the subsurface, already existing and ongoing contractions. More underground installations are planned, constantly increasing the value.

2.2 Rotterdam – from contaminated ground to holistic urban planning

Rotterdam city, on the western coast of the Netherlands, is one of (few) cities that has achieved a lot regarding resilient and sustainable management of the subsurface in urban planning. In a way, one might say that they are forced to, having a city below sea level or at the riverside and ocean front. The challenges for Rotterdam became evident when re-development of the city began after the second world war (1950-60).

Formerly industrial areas or brownfield were turned into residential areas. That was when polluted ground became a main focus for the municipality and lay the grounds for ground investigations for contaminated soil, and collecting data regarding the subsurface in a public sector. “Soil Protection Act” in 1987 was a result of this work. Re-organization within the public sector lead to merging of urban planners, engineers and urban development into a collaborating team forcing a holistic approach regarding urban development (van Campenhout et al., 2016,). Geological information of the subsurface is implemented into the planning process at an early stage. Contaminated ground is mapped and data is available when decisions of development is executed. Rotterdam is an inspiration of good collaboration across disciplines and a holistic approach to common challenges for the best and most sustainable solutions for urban planning (Rotterdam Resilience Strategy, 2016).

Figure 2: Rotterdam City in 2035 – the other half of Rotterdam. Using the subsurface in a wise manner gives urban development a new dimension to explore. Illustration: Gemeente Rotterdam.

2.3 Glasgow – making the best out of old money-makers – up-cycling old mines into renewable energy

Glasgow is an old mining city, on the western coast of Scotland, UK, which had its victorious time in the late 1800. The mining activity has left the underground penetrated with abandoned mine shafts and cavities that has given challenges regarding the underground. In the recent years up-cycling (or creative reuse) of the city is in focus, from a city with economic and social decline to a turnover in growth and prosperity. To enable such up-cycling ground conditions is central, and it spans from contaminated brownfield turned into residential areas, across developing infrastructure, to abandoned and problematic mines turned into renewable geothermal energy (Whitbread et al., 2016).

To enable the up-cycling of Glasgow, geological knowledge and data about the underground is essential. Glasgow city council is in close collaboration with the British Geological Survey (BGS) to facilitate data for urban planning to reduce time spent, increase data-reuse and avoid future incidences (Bonsor, 2016; Whitbread, et al., 2016). Communication and a common language has been one of the most important building bricks to bridge the gap between disciplines and enable collaboration for a common solution. This involved re-organization within the municipality and exchanging working tasks and focus for BGS. A geological model of the underground is developed to form the basis for development projects, both infrastructure and buildings, where public and private actors and users can contribute to further development (Whitbread et al., 2016).

The main threshold that had to be dealt with was gathering and organizing data about the underground, especially borehole information. Previously, the ownership of the data was spread among private companies that executed the drilling. Throughout the up-cycling

Glasgow council has changed the contracts on their behalf, where all data collected in public projects are of public property and for BGS to manage the data, organized in their databases (Whitbread et al., 2016).

Figure 3: The underground of Glasgow city is full of old mine shafts. Not all are well mapped and accounted for. This drilling machine was mapping the quality of the subsurface when it occasionally found an abandoned mine shaft and fell in. Photo: British Geological Survey.

2.4 Odense – letting citizens take part and find solutions for reoccurring problems

The largest city on the island Fyn in southern Denmark, Odense has it challenges. In historic times, the water source for potable water came from the ground beneath the city and within the city borders. The depletion (abstraction) of groundwater lowered the groundwater level and dried up previous marsh and wetlands, creating new ground for urban development. As the city grew, and with increasing populations the threat of epidemics spread by drinking water, the water source was moved outside the city borders and into the nearby municipality (Laursen & Mielby, 2016).

With time, this change of water source caused the groundwater to rise and return to natural (old) water levels, returning developed land into marsh and wetlands. This change causes flooding of basements, streets and infrastructure. In a residential area that had reoccurring flooding the citizens came up with a sustainable solution that the municipality buys the damaged properties and turns the area into a storm water basin and recreational park (Figure 4; Laursen & Linderberg, 2017).

Figure 4: From problem to solution. Above: re-occurring flooding in residential areas in Odense city. Here from Ejersminde Street. The citizens themselves came with the proposition to turn the most challenged are into a storm water basin that also functions as a recreational area for the neighbourhood (Laursen & Linderberg, 2017). Photo: Ejgil Juul Nielsen.

2.5 Ljubljana – managing two possibilities in the best manner for maximum benefit

For Ljubljana city its most precious resource lies in the ground beneath, clean drinking water of good quality and in large amounts, enough to keep the entire city with potable water. The challenge is to keep the groundwater safe from harm and hazard, such as pollution and bad water management. Groundwater, as underneath Ljubljana, is a natural source of clean, well-protected and naturally purified water ready to drink (Janža et al., 2016 and Janža, 2017).

This jewel is also a resource for renewable energy; shallow geothermal energy for heating and cooling. Ljubljana, as several other cities, are today supplied by fossil fuel for heating and electricity. By using the groundwater for heating and cooling the CO_2 emission can be decreased enormously in short time (Janža, 2017).

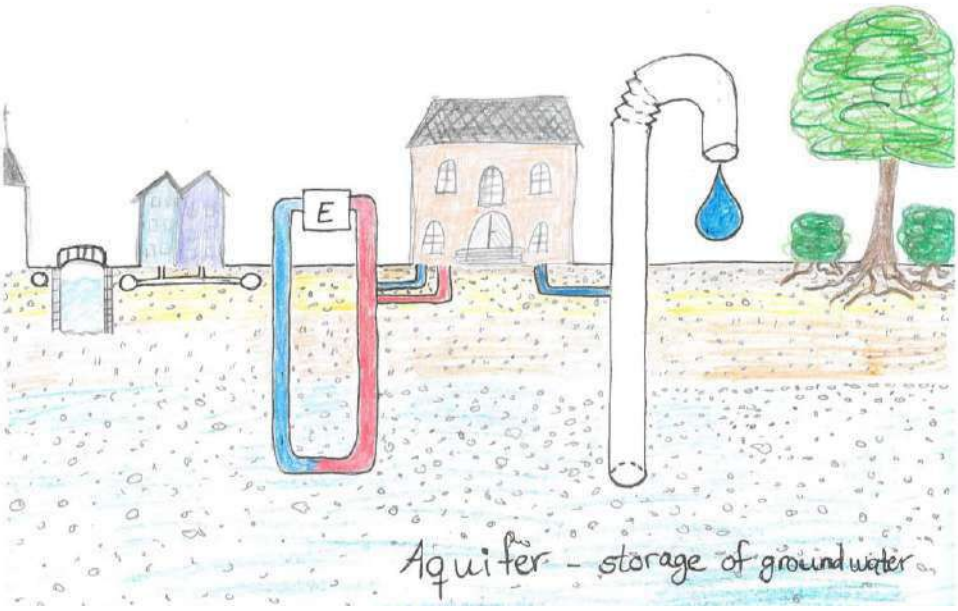

Figure 5: The most important natural resource lies in the ground beneath the city of Ljubljana: pure groundwater as potable water in rich amounts. The same resource can be used as renewable energy source for cooling and heating, reducing the carbon footprint for Ljubljana. E = energy.

2.6 Lisbon –natural disasters on the city planning agenda

Natural disaster is difficult to prevent or hinder, but it is possible to adapt and mitigate. Lisbon city has two major natural threats; re-occurring flooding from the river running through the city and earthquakes. Built along the river shore, the river has given opportunities to prosper in shipping, trade and had a constant supply on fresh water. But as the city grew the river was constrained. Climate change causes the flooding to occur more frequent and intense than previously, causing the river to go over its limits and cause damage to the city (Pinto et al., 2016). To adapt to climate change and the re-occurring flooding the Municipality of Lisbon has mapped the areas prone to flooding and implemented it into their urban planning, management and development plan for the city (Pinto et al., 2016).

Earthquakes is a known hazard for Lisbon, being located in an active area of plate movement, between the African and European plate. Earthquakes in the range of 2.8 to 5.6 in Richter's scale occur up to twice a year (https://www.earthquaketrack.com/p/portugal/lisbon/recent). City planning and development must adapt to such hazards, with respect to building construction, infrastructure and safety of the citizens. Implementing natural hazards into the urban planning makes Lisbon prepared for future events. Both flooding and earth quakes can trigger landslides, therefore Lisbon municipality has mapped areas prone to landslides and incorporated it into the city planning and development (Figure 6; Pinto et al., 2016).

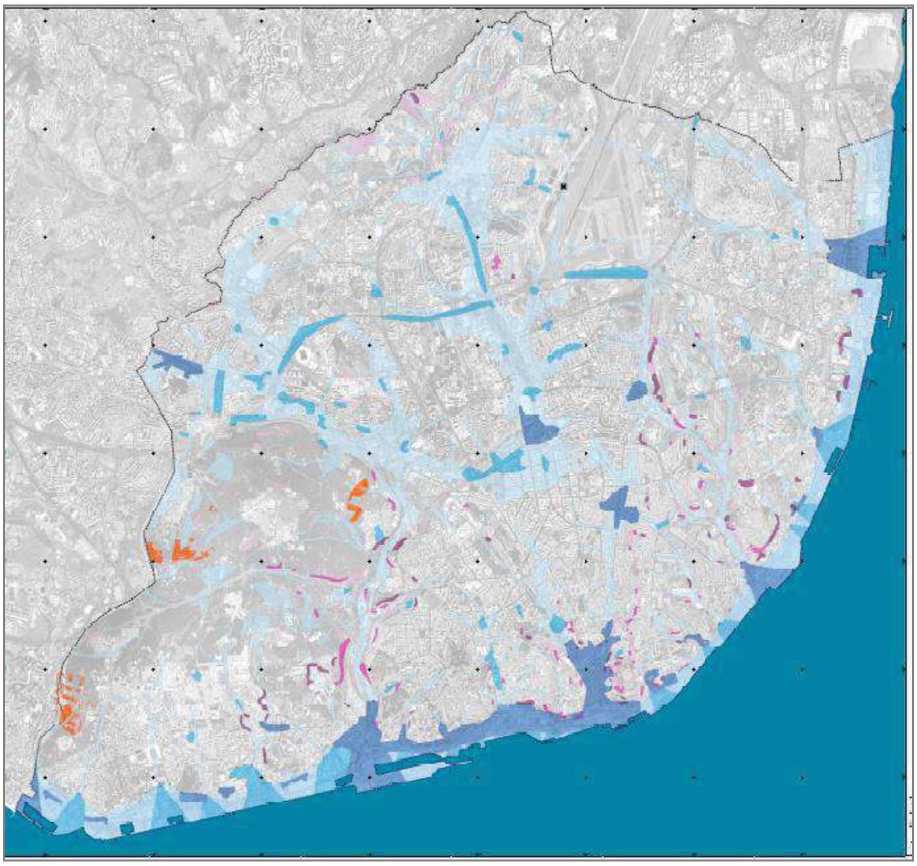

Figure 6: Natural and anthropogenic Hazards (blue – Flood Vulnerability classes; pink – Landslides Susceptibility classes; orange: fire vulnerability classes), Pinto et al., (2016).

3 Tools to incorporate the natural environment with the built environment into planning

Re-use of subsurface data will reduce risk and unforeseen costs as well as increase the resilience of urban development. There are many approaches and tools to implement subsurface data into planning tools. Geological Surveys are collecting subsurface data and organizing the data into databases that are targeted to deliver data to planning tools. Within the Sub-Urban network several approaches and tools were compared, to share experience and knowledge. A common opinion is that subsurface data must be included in the process for future urban development. Whatever tool or approach is chosen the benefits will be great. Here are two approaches presented:

3.1 GeoCIM – Geo City Information Model

3D modelling tools such as BIM (Building Information Model) is a well-known planning and design tool within the building sector. Such tools are also developed for city planning, such as CIM (City Information Model). They both lack the implementation of subsurface data, such as ground condition and geological information, therefore, a further development of these two that includes the subsurface is suggested (Figure 7; Schokker et al., 2017).

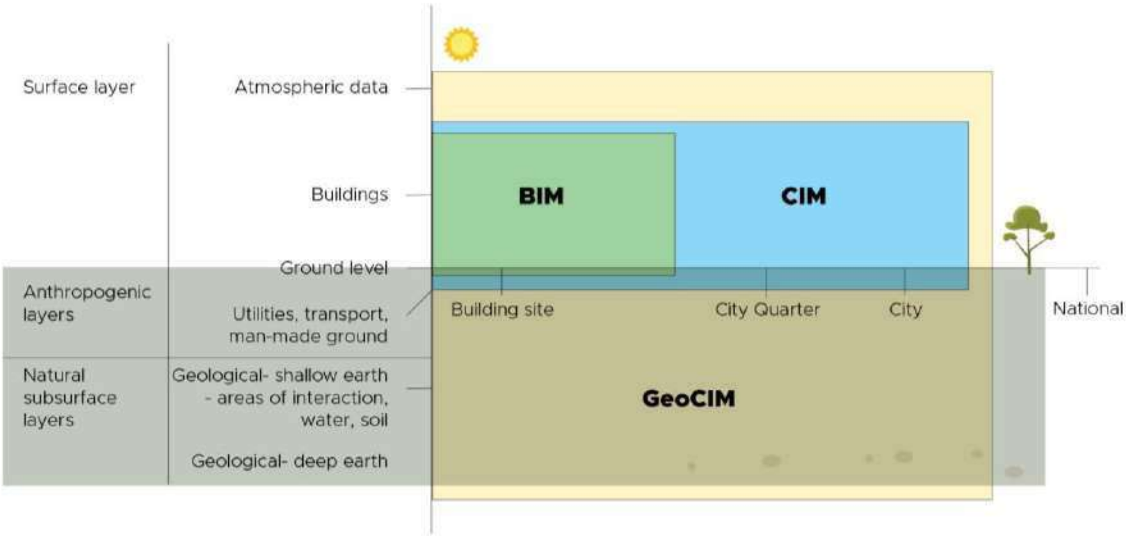

Figure 7: Vertical and horizontal scopes of BIM, CIM and GeoCIM (Geo City Information Model, Schokker et al., 2017).

Re-use of subsurface data will reduce risk and unforeseen costs as well as increase the resilience of the urban development. There are many approaches and tools to implement subsurface data into planning tools (Figure 8; Schokker et al., 2017).

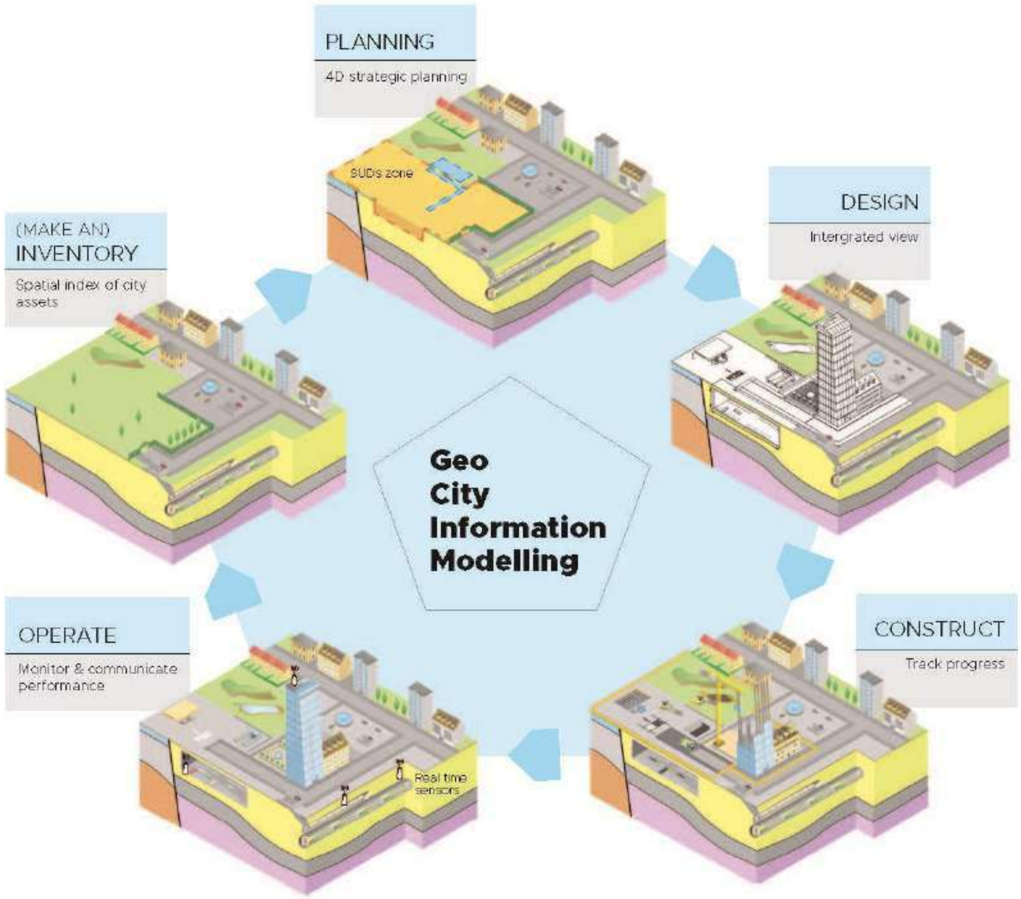

Figure 8: Geo City Information Model (GeoCIM) implementing the natural environment into the built environment by including geological data into construction and planning models. Illustration: British Geological Survey.

3.2 The Sub-Urban toolbox

Following the city case studies (van der Meulen, 2016) a toolbox is developed. It comprise a fit-for-purpose suite of recommended methodologies, good practice, guidance, and case studies to enable the free flow of key subsurface data and knowledge, and can be delivered to all those engaged in subsurface issues to enable improved urban planning and sustainable development. It is a free access source of knowledge, relevant to the needs of both researchers (e.g. Geological Survey Organizations) and urban policy- and decision-makers[1].

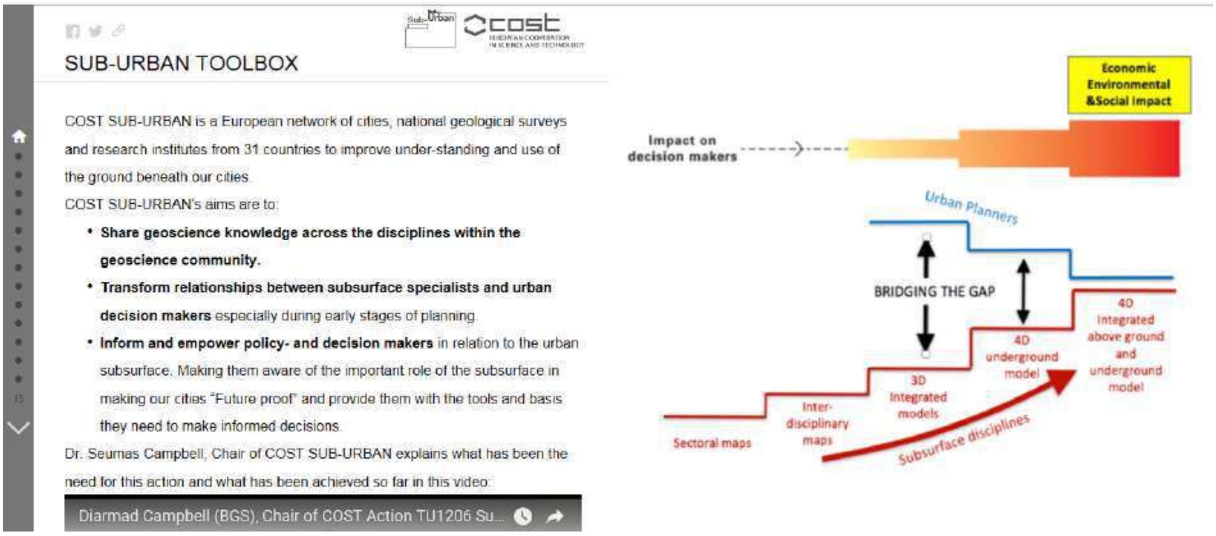

Figure 9: The Sub-Urban TOOLBOX is an open access web platform that gives check list of what to consider when planning in the subsurface, tips to where data is accessible and how to use the data.

To make it easy to navigate through the Toolbox we make use of a metaphor: a bike. In this metaphor our knowledge of urban planning is represented by the front wheel and the knowledge of the subsurface is represented by the back wheel. *Using* this knowledge, translating it into workflows is represented by the crank. Via the crank the bike is put into motion. And the decision-makers, addressing the city needs, sit on the saddle: they decide when the bike moves and in which direction. This bike concept divides the Toolbox into sections or topics. Within the Toolbox you can find 'highlights' like good practices and best efforts as well as gaps in our knowledge.

[1]Toolbox is accessible from :http://sub-urban.squarespace.com/toolbox-1/ or https://rotterdam.maps.arcgis.com/apps/MapJournal/index.html?appid=5f495157aae84a2780b5e7d87dcd66f2

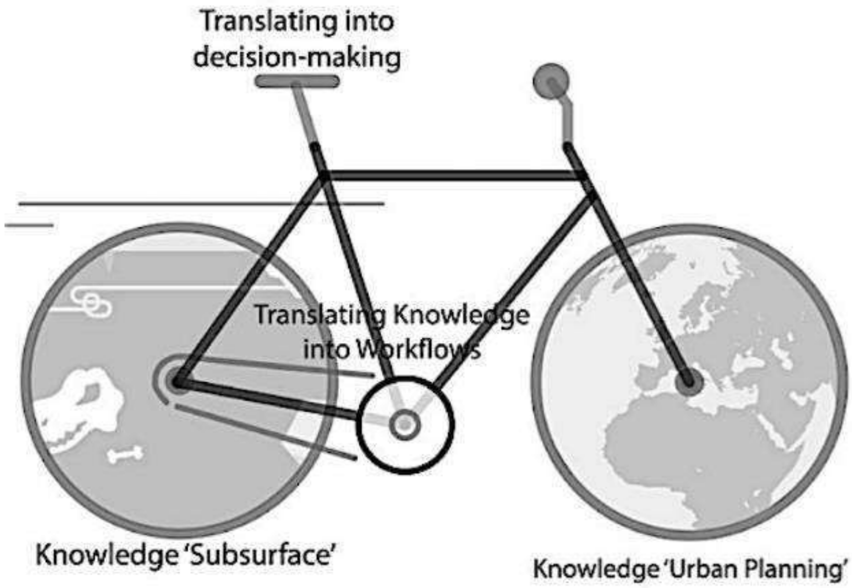

Figure 10: The bike metaphor for the Sub-Urban TOOLBOX.

4 Awareness of potential in using the subsurface in urban planning

The main challenges that became evident during the four years of knowledge sharing is that i) lack of or not specific enough laws and legislation, especially regarding data ownership and sharing of data, are hindering re-use and cost efficiency of data. ii) Communication across disciplines is challenging, and a common language for common understanding is a necessity (Campbell et al., 2017). Even if similar words are used, they often have different definition, meaning, within different fields. An example, the word "subsurface" has a different definition for a city planner than a subsurface expert. iii) For a planner and the planning process there is also the necessity of the right information at the right time and in the correct format / context. This is seldom in focus for the specialist who does not work with the planning process (Mielby et al., 2016).

One of the aims of this work is rising awareness of the subsurface, changing the concept that the subsurface is still in mind even if it is out of sight (Venvik et al., 2018):

Some **Pitfalls** to collective urban subsurface planning:

- Lack of dialogue between parties involved
- Lack of municipal and state subsurface policies and legislation
- Low awareness of subsurface assets and challenges
- Inadequate tools to make relevant information and data accessible

Some **Pathways** to collective urban subsurface planning include:

- Maintaining trust between parties
- Develop a simple common language (mutual understanding)
- Early coordination during planning and construction phases
- Understanding of responsibilities

Multi-dwelling home lifestyle and climate change

Xue, Jin; Næss, Petter; Steffansen, Rasmus; Stefansdottir, Harpa; Richardson, Tim, ÅS, Norway

ABSTRACT:

Cultural heritage sites in northern Norway are manifests of a lifestyle long-lost to industrialization and centralization. Often located between fjords and mountains, many of the sites, such as the fisherman villages in Lofoten and Sjøgata in Mosjøen, consist of wooden buildings that date back to the 18th and 19th century. The buildings are well-kept as they are still in use by the locals; they also serve as important identity markers for the people living in the areas as well as being beloved tourist attractions. The last couple of years climate change has begun to show its presence more than ever in the northern parts of Norway. Heavy rain and unstable winters lead more often to floods, avalanches, and landslides, and the cultural heritage sites that previously were resilient and withstanding are now vulnerable.

In the city of Mosjøen in Vefsn municipality urban planners are trying to develop a new zoning plan for the cultural heritage area Sjøgata. The zoning plan should also function as an adaptive strategy to climate changes so that the historical environment of Sjøgata can be kept for the future. The highest climate risks to Sjøgata are flooding, a rise in the sea level and avalanches, one of the consequences of this is that insurance companies refuse to offer home insurances due of the risk of damage.

The challenge for the urban planners is how to plan for landslides, avalanches and floods, and how to safeguard the historical buildings when this happens. As a part of the work with the zoning plan, the planning department in Vefsn has looked at the possibility to alter the landscape by raising the wooden buildings as well as the terrain up to the future expected sea level. The department also tried to find out if the zoning plan could allow new ways of anchoring and detaching buildings from the foundations so that the buildings could "float" both on water and avalanches without being too damaged.

The new zoning plan for Sjøgata is still is a work in progress. There are several issues due to climate changes that have to be solved in order to complete the plan and whether the strategy will work is yet to be seen.

It is certain that urban planners in northern Norway need more knowledge and research on adaptive strategies to handle climate changes so that the cultural heritage can serve as identity markers, tourist attractions, and homes for another 100 years.

New York City- Environmental Review & Planning for a Sustainable Future

Ingrid YOUNG, NYC Mayor's Office of Environmental Coordination, New York City, USA

Synopsis:

New York City's environmental review and planning are key to creating a sustainable and resilient city. The environmental review process facilitates how our city can appropriately adapt proposed developments to the planet's changing climate. Planning with an environmental review emphasis should function by shaping future development to optimally serve this vast community with an adaptable, sustainable and secure city.

Introduction

New York City, with its five distinct boroughs/neighborhoods totaling approximately 304 square miles (489 km) is large urban mecca. From a planner's perspective, one can imagine that maintaining a vast geographical area with a diverse population (approximately 8.6 million as of 2017) comes with immense challenges. City agencies, including the Planning Department, Department of Environmental Protection and several branches within the Mayor's Office have a great deal of responsibility to usher projects and policies which focus on creating sustainable, resilient, enduring growth while reducing emissions, decreasing waste and inefficiency and preserving natural resources.

1. The Roll of Mayor's Office of Environmental Coordination (MOEC)

Within NYC government the Mayor's Office of Environmental Coordination (MOEC) was established under the New York City Charter (1989 revision). The agency's role is to assist all City agencies in carrying out and fulfilling their environmental review responsibilities. We are an advisory body who provides guidance and technical expertise on environmental procedures and progressing standards. In addition to serving as a liaison to federal, state, and city coordination we also maintain the entire digital catalog of city led environmental reviews.

MOEC and the New York City Planning Department have a partnership in our roles related to environmental review. Both agencies perform environmental reviews according to the City Environmental Quality Review (CEQR) guidance. CEQR is governed by a combination of state and city laws and regulations that specify the various components and procedures under which reviews are conducted.

The following section provides a brief history of the Federal, State and City legislation relative to environmental policy. The evolution of New York City's environmental review framework is evidenced by the series of legislative policies which unfold within larger and more varied municipal agencies.

2. Creation of Environmental Laws and Guidance

National Environmental Policy Act (NEPA)

The National Environmental Policy Act was established in 1970. The development of this policy can be attributed to increased public appreciation and concern for the environment that developed during the 1960's amid increased industrialization and pollution across the United States. The original intent of Congress in the creation of this policy was to "encourage productive and enjoyable harmony between man and his environment; to promote efforts which will prevent or eliminate damage to the environment and biosphere and stimulate the health and welfare of man; to enrich the understanding of the ecological systems and natural resources important to the Nation; and to establish a Council on Environmental Quality." (NEPA,1970). A significant outcome of this policy established the requirement that all federal agencies prepare environmental assessments (EAs) and environmental impact statements (EISs). Shortly after implementation of the Act and in the decades to follow many countries around the world utilized the NEPA model to enact their own policies.

Beginning in June 2018 the Council of Environmental Quality (CEQ) issued a request to take comments on updating the NEPA Guidance. This is a unique opportunity to for cities, states and individual citizens to provide specific recommendations regarding new additions, deletions, or modifications to the text of our current NEPA regulations. Perhaps within the coming year we can anticipate an amended NEPA document which considers the importance of factoring in measures for sustainability with regard to climate change language and guidance.

New York State Environmental Quality Review Act (SEQR)

The New York State Environmental Quality Review Act (SEQR) is the New York statute which became law on August 1975. SEQR is the model which provides guidance to develop regulations to guide New York State and local government agencies in the implementation of environmental reviews. SEQR was intended to change government decision making by requiring agencies to balance the environmental impacts with social and economic factors when deciding to approve or undertake new development.

New York State Department of Environmental Conservation (DEC) recently adopted amendments to SEQRA regulations to streamline and incorporate additional transparency to this permitting process. These changes will take effect starting January 2019. Most relevant to resiliency and sustainability these amendments encourage sustainable development through green infrastructure, incentives for the private sector to install small to medium scale solar arrays, and continued commitment of government implementation of renewable energy sources (DEC, 2018).

New York City Environmental Quality Review (CEQR)

In 1973 the City established Executive Order No. 87 which directed that all major projects need to assess environmental impacts. By 1977 the City had formally developed its own

City Environmental Quality Review (CEQR) process and centralized primary agencies (City Planning) to lead the environmental review functions. In order to expedite review functions and ensure consistency with applicable laws, the City issued an Executive Order by the Mayor to institute a new office of oversight- the Mayor's Office of Environmental Coordination (MOEC).

New York City's Environmental Quality Review (CEQR) is our city's process for implementing and conducting an environmental review for proposed actions associated with new development. The CEQR process requires that agencies identify, analyze and disclose the potential environmental impacts of a proposed project before city approvals are considered. The 2014 CEQR Technical Manual is the guidance document which provides recommendations for specific protections or safety measures regarding development. This manual covers some 20 technical areas for analysis, as outlined in the following section.

MOEC staff are currently undertaking an extensive outreach with City agencies to address pertinent concerns shared by all city stakeholders in order to update the 2014 edition of the CEQR Technical Manual. These updates will most certainly have a central focus on incorporating resiliency strategies, and fine tuning climate related guidelines.

3.0 CEQR Process

The City level environmental review process requires the involvement of multiple New York City agencies and a high level of coordination. The average environmental review of an EAS or EIS will evaluate multiple technical analysis areas, approximately 20 technical areas. Among these CEQR analysis areas are: Land Use, Air Quality, Water and Sewer Infrastructure, Transportation, Noise, Public Health, Community Facilities, Socioeconomic Conditions, Hazardous Materials and several others. The thorough analysis of these environmental reviews requires the input and involvement of technical experts from different city or state agencies.

It should be noted that not all proposed development or proposed legislative measures are subject to CEQR analysis and City Planning Approvals.

There are several stages that unfold when a project begins CEQR environmental review. These are outlined below and graphically portrayed in the flow chart in **Figure 3.0.**

Step 1. A project is introduced, the proposed Actions requiring regulatory approval are identified and any involved City or State agencies are identified for coordination.

Step 2. The proposed Actions required are classified into a "Unlisted" or "Type I" CEQR category.

Step 3. An EAS is prepared. Answering specific project related questions within the EAS form will identify what technical areas are required for analysis.

Step 4. The completed EAS is reviewed by an expert city agency(s).

Step 5. A Determination of Significance is issued. This issuance will identify if the proposed actions result in No Significant Adverse Impacts or Significant Adverse Impacts are possible.

Step 6. If the project is determined to pose No Significant Adverse Impacts, then the Environmental Review process conducted by the City is complete. If the project is determined to pose potential Significant Adverse Impacts, then Project will require the submission of detailed analysis under the Environmental Impact Statement (EIS).

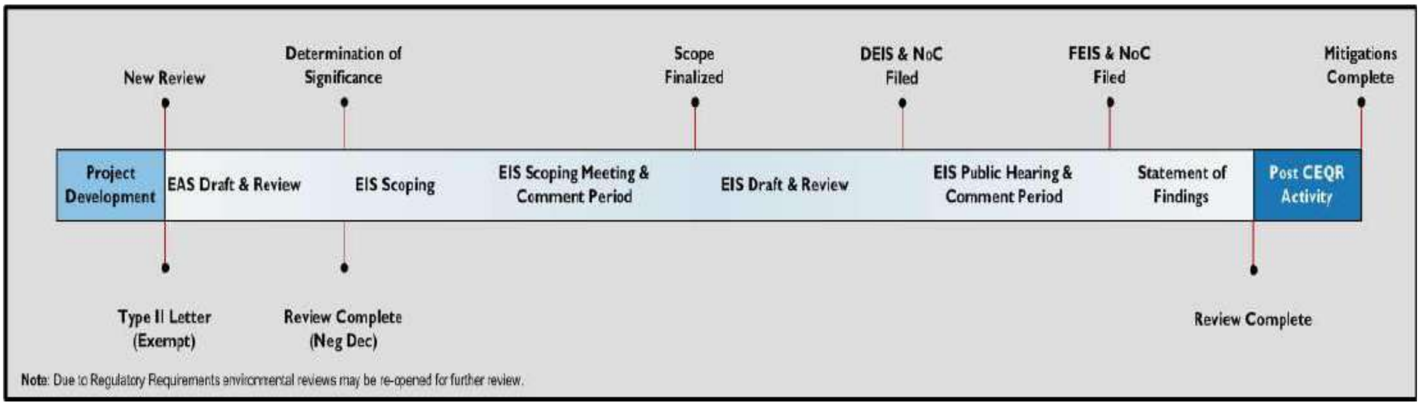
Step 7. With a project requiring more detailed levels of analysis under an EIS, a public involvement period is incorporated into the review, known as a Scoping or Public Hearing. The public are invited to submit comments on the project related to any sections of the environmental analysis.

Step 8. The revised EIS will reflect responses to the public comments and address any potential areas requiring further analysis. The EIS will continue to be reviewed by the expert technical agencies.

Step 9. Once the City agencies reviewing the EIS are satisfied with the completed analysis and any technical detailed studies have identified proposed mitigation for potential impacts resulting from the project the Application will be presented before the City Planning Commission and later to the City Council for a vote.

Step 10. Should the Planning Commission and City Council vote yes on the project then the Environmental Review process conducted by the City will be complete. Should a no vote be issued by either body, then the EIS will undergo further modifications and additional analysis.

Figure 3.0 **CEQR Process Flow Chart**



4. New York Commitments Toward Resiliency and a Sustainability Future

Climate Change

It is apparent for many coastal cities, New York included (with 580 miles of coastline), that our existing and future coastal development depends on the thoughtful, informed collaboration of multiple communities and even neighboring countries. Resolving methods for effectively securing coastal communities can be approached on a regional scale. The work of the United Nations Office for Disaster Risk Reduction developed a "Regional Action Plan for the Americas" to target priorities for action relative to developing public policy around disaster risk reduction (Waddington, 2018). Considering policy level applicable to all coastal areas spanning North and South America is setting an immense standard. However, with climate change acting as an existential threat to all cities and countries (factoring the steady sea level rise resulting from climate change), it seems an efficient method for addressing a contiguous area.

Responding to recent studies conducted under the World Meteorological Organization (WMO), the World Bank and the International Energy Agency which corroborate the relentless pace of climate change, the UN Secretary General António Guterres issued a global call to action to proceed with political decision making and financing to cut global emissions.

Sustainability

In 2017 New York State passed the Climate and Community Protection Act. At that time it was a very progressive state level climate and equity policy, which gained traction, after being passed by the state Assembly last spring. The bill set a mandate of 50 percent renewable energy by 2030 and 100 percent renewable energy in New York by 2050, with 40 percent of investment (whether through carbon pricing or other avenues) targeted for environmentally vulnerable low-income communities (McGhee & Reich, 2016). In response to our current White House administration announcing the forthcoming United States withdrawal from the Paris Climate Agreement, NYC's Mayor de Blasio signed an Executive Order committing the City the principles of the Paris Agreement.

On a local level, in 2006 New York City passed the Climate Protection Act. This Act set a mandate of 30 percent reduction in citywide emissions by 2030 and 80 percent reduction in citywide emissions by 2050. Applicable policies and programs specifically how to fulfill these emission reductions are outlined in former Mayor Michael Bloomberg's 2007 initiative "PlaNYC". The goal of this plan was to focus on better adapting to climate change, conserving city resources, and the reduction of the carbon footprint. Furthering the commitments within PlanNYC, our current Mayor Bill deBlasio introduced "OneNYC" in 2015 which sets forth goals of growth, equity, sustainability and resiliency. The OneNYC plan also provides "New York City's Roadmap to 80X50" which outlines specific steps toward achieving the ambitious GHG reduction target (MOS, 2018).

Resiliency

For city planning and associated environmental review, a common sense approach would involve preparing resiliency measures which factor in anticipated climate change risks. The New York City's Waterfront Revitalization Program (WRP), is a division within City Planning. Key to their role within planning and environmental review is their list of waterfront policies addressing the City's varied coastal conditions.

Primary goals of the WRP's policies include:

- development of waterfront planning and preservation while ensuring consistency with long term city and state waterfront goals,
- minimizing potential conflicts from proposed development while maximizing the benefits derived from economic development, environmental conservation and public use of the waterfront

Significant changes addressed in their 2017 Report "NYC Waterfront Revitalization Program Climate Change Adaptation Guidance", include sea level rise projections, flood damage reduction elements, adaptive measures for flood design and policies to promote climate resilient designs (NYC Planning, 2017).

As previously mentioned *One*NYC is the City's current strategic plan for inclusive growth and climate action. It is also the first resilience strategy released by any city in partnership with 100 Resilient Cities, pioneered by the Rockefeller Foundation. 100 Resilient Cities (100RC) is a nonprofit organization established in 2013, dedicated to incorporating resilience planning into multiple aspects of city growth.

100RC aims to: 1) Facilitate individual cities in becoming more resilient, establishment of a Chief Resiliency Officer.
2) Support of a global practice of collaboration among governments, NGOs, the private sector, and individual citizens.
3) Increased sustainability through shared resiliency strategies.

Resiliency planning includes communities examining their land-use and construction policies in order to avoid rebuilding in harm's way. Governments can incentivize adoption and enforcement of building codes which account for extreme weather scenarios and climate impacts. Additionally, the private sector can incorporate climate risk into insurance policies and incentivize communities for factoring in mitigation (De Souza, 2018). A focus on resiliency planning should ultimately reduce the need for emergency response to increased severe storm incidents and impending sea level rise. While incorporating for extreme conditions in resiliency planning, communities can reduce recovery costs as well as property and infrastructure damages.

In support of New York City's goal to reach an 80% reduction of GHG's by 2050, multiple levels of programmatic changes with respect to sustainability have been initiated.

The list below highlights several programs and steps that have been taken to meet our goal of becoming a more sustainable and resilient city.

• **Community Retrofit NYC**- a program for reducing emissions (GHG) in small buildings. Achieved through the elimination of steam heating systems and the conversion to heat pump systems (Gentric, 2018)

• **NYC Clean Fleet-** The goal of incorporating 2000 electric vehicles (EV) into the City's vehicle fleet. This includes partnering with local utility providers for the installation of over 100 EV chargers citywide.

• **Bills proposed** for banning straws and plastic bags, currently instituted by many countries to completely remove or tax the consumption of single use plastic products.

• **GreenNYC-** Program that provides steps for reducing energy use (both for home & work), eliminating unnecessary consumer waste (providing alternatives to single-use disposable products) and living a sustainable lifestyle (transportation choices, product selection- non-toxics, reduced packaging, and composting.

• **NYC** greatly encourages and supports City Employees to utilize water refilling stations in all City/Federal buildings and discourages the purchase of bottle water and drinks. Sustainable/reusable decanters are provided.

• **NYC CoolRoofs**- City initiative for installing energy-saving reflective rooftops.

- **Zero Waste-** Program geared toward reducing New York City's trash and refuse contributions to landfills. Target aims to have zero trash by 2030.
- **Resiliency Legislation –** Department of Buildings codes which address building moving or raising to secure the lowest above-grade floor property outside of flood zones.

• **NYC Green Infrastructure Program**- Program includes rooftops retrofits with vegetation or rainwater retention/catchment, reduction of storm-water runoff with installation of bioswales and rain garden planting.

• **City Divestment of Funds-** New York has proposed to divest from fossil fuel reserve owner companies- This represents upwards of $5 billion in investments. The City's commitment is among a vastly growing assembly of municipalities, states, countries and corporations to send a worldwide message that their obligations under the Paris Agreement can be fulfilled with the refusal to financially sustain the fossil fuel industry (Paddison, 2018). Approximate total in divested fossil fuels investments has reached 5 Trillion Dollars worldwide (Fossil Free, 2018).

5. Conclusion

Presently the sustainability and resiliency initiatives mentioned in this paper have been steps New York City and any city can take in order to reduce a community's vulnerability to climate change impacts. These initiatives also effectively utilize or conserve resources while reducing waste. With a robust administrative framework incorporating environmental review it's feasible to address the complex evolving nature of social and economic impacts resulting from climate change. The range of analysis incorporated into environmental review on a city, state and federal level is a significant component for guiding future development in creating sustainable and healthier communities.

Track 2

SPOTLIGHT CITIES:
Planning for Coastal Cities, Remote Towns, and High North Cities

Making the most of underground spaces

Moderators: ADMIRAAL, Han (ITACUS/Enprodes); CORNARO, Antonia (ITACUS/ISOCARP Swiss ND/Amberg); REYNOLDS, Elizabeth (URBEN/Think Deep UK)

ABSTRACT:

Many cities have them, and the city of Bodø is not an exception: unused underground spaces in the form and shape of former civil defence or military bunkers. The question often is what to do with these relics of the past. The most obvious answer is to turn them into a museum, preserving the past as a poignant reminder of what we need to avoid in the future. With the advent of decarbonizing our cities, making our cities resilient and develop them sustainably, the question is whether these abandoned spaces can serve a better purpose. Are they just waste spaces or can they be proved to be assets waiting to be given a new lease of life? This session will be led by the authors of two new books on the use of the urban subsurface. Han Admiraal and Antonia Cornaro wrote the book ‘Underground spaces unveiled: planning and creating the cities of the future’ published in March 2018. Elizabeth Reynolds wrote the book ‘Underground urbanism’ which will be published in November 2018. In the introduction, we will look at popular uses ranging from underground agriculture to recreational uses. After introductions by the authors, we would like to turn the session into a workshop with the audience and the authors as well as representatives from the local municipality, the real estate department of the Ministry of Defense, the local aviation museum; and the airport authority will look at possibilities to repurpose these underground spaces. For additional inspiration, this session will be held at either the underground NATO base in Bodø or in one of the many cold-war shelters. The outcome will be a report to be presented to the local representatives at a later date. Also, the event will be the kick-off of a new ISOCARP group on underground urbanism. Because of the specific location where the workshop will be held, the maximum size in term of participants will be 30 people excluding the session moderators and local representatives.

Climate risks and urban drainage: A case of the National Capital Territory (NCT) of Delhi

Mahak AGRAWAL, Urban Planner, Correspondent– ISOCARP (International Society of City and Regional Planners)- Review (mahakagrawal2016@gmail.com, +91-9560560573); India

Cities are victims as well as a primary reason for climate change. They account for over 70% of global greenhouse gas emissions and shelter over 50% of the global population (IPCC 2015). The paper is an attempt to highlight the interplay of urbanisation, natural environment and climate variability for the National Capital Territory (NCT) of Delhi, particularly their implication on the city's mobility. With the help of aerial imagery and meteorological data, the study is grounded in detailed spatial-temporal empirical analysis conducted at macro and micro levels for the period of 1986 to 2016.

Empirical analysis at macro-level notes that during 1986-2016 Delhi lost 94 hectares of its vegetative cover, 6 hectares of water bodies and 14.3 hectares of flood plains for every 100 hectare increase of built up area. Simultaneously, surface run-off increased 3 times leading to increased flooding, travel time and road length under water. The correlation model built from this analysis forecasts city flooding to increase more than 80% by 2041 with 90% of city limits becoming a concrete jungle- thereby, increasing travel time by 43 minutes and clogged road length to 38 kilometres, from urban flooding. Micro-level analysis of the most vulnerable population, including 141 villages with over 2,800,000 inhabitants, indicates increased losses from flooding, burdening the state exchequer with over 20.1 million INR [~0.3 million USD] annually.

This interplay therefore has multi-dimensional implications on urban mobility and makes it imperative for a liveable urban future to conceive the city in a holistic framework of climate resilience, guided by policies of land use-land cover and transport planning.

Keywords: *Urban Development Pattern, Urban Flood, Travel Time, Inundation, Affected Population and Area*

1. INTRODUCTION

Climate change is a global phenomenon and variability of climate over decades is attributed, directly or indirectly, to human activity which alters the composition of the atmosphere, thereby contributing to natural climate variability observed over comparable time periods. Emerging trends of climate change indicate a global rise in human induced warming, higher than the natural warming of the earth which will continue to increase at a much more rapid rate. The Intergovernmental Panel on Climate Change 2014 report (IPCC Fifth Assessment Report. 2014) highlights that while global population grew from 4 billion to 7 billion, a 75 per cent increase since 1970, greenhouse gas emissions increased by 82 per cent, with an annual increase of 2.2 per cent in the last decade alone.

The Paris Climate Agreement 2015 supports the cause of climate change mitigation and shifts it from a global scale issue to one of development at the urban scale. This is not a new finding. In 2008, urban development became central to the international discourse on climate change, when global urban population increased by 50 per cent while total GHG emissions increased by 70 per cent. Four cases for this situation were identified: land use and land cover change, transportation, building construction, and pollution related to industry. These four categories of activities coincide with areas affected by the role of urban planners and urban planning in terms of planned development, adapting to climate change and mitigating future risks. Essentially, cities and climate change are intertwined and urban planning plays a vital role in this equation.

2007-08 also saw the publication of a tremendous amount of literature and research on cities and climate change. In India a plethora of research has been produced which studies the impacts of climate change, the spatial distribution of greenhouse gas emissions, and urban drainage in relation to changing intensities of precipitation. However, only a few try to think beyond these topics and assess climate change in terms of urban development patterns. The need to study climate change and the impact of urban development on climate change becomes more important today since cities cover less than 3 per cent of the earth's surface but contribute over 70 per cent of GHG emissions and account for 75 per cent of global energy consumption (UN-Habitat. 2011). Moreover, this trend of urban growth is forecast to continue as rural population decline.

This paper is an account of a study of climate change and its relationship with urban development and urban mobility in Delhi during the period of 1986 to 2016; with 1986-96 marking the decade of economic reforms and the post-Asiad games construction boom, while 2006-2016 marks ripples of construction boom for the Commonwealth games and the notification of the Master Plan for Delhi-2021. Empirical analysis is conducted for the four time periods- 1986, 1996, 2006 and 2016 using two prime secondary sources, which include meteorological data from the Indian Meteorological Department and raw aerial LandSat imageries from the online portal of the United States Geological Survey, Global Land Cover Facility and Bhuvan India. GIS modelling and analysis of aerial imageries in relation to statistical data indicate a trend of human induced climate variability for the city.

The paper is structured into three broad sections. In the first section, Delhi's urban development trend is described in terms of increase of built up areas and loss of heat sinks. In the second section, climate change is assessed in terms of natural climate variability and reflected through precipitation variables. The third section assesses the implications of urban development and climate change on mobility patterns of the city. The fourth section scales down the assessment to micro level and examines implications on the vulnerable population of the city. In particular, an empirical analysis based on primary surveys and supported by secondary meteorological data is conducted to assess physical, social and economic impacts of climate change on the most vulnerable population in the city, identified as residing in the villages located in the flood plains of Delhi. This includes implications on their mobility patterns.

The last section concludes on a note of dire need of climate resilient urban strategies to achieve a sustainable urban future of the city.

2. URBAN DEVELOPMENT PATTERN OF DELHI, 1986-2016

Delhi, capital city of India, is testimony of numerous changes and cumulative challenges. This section documents the changes which underscores the trend of urban development in the city. The change in land cover of Delhi (as indicated in Table 1) indicates that after 1986 the city spread around its core with infill developments. Moreover, developments from 1986-1996 amounted to 1.3 times the development of the preceding two decades. This may be attributed to the real estate growth that emerged after the 1980s Asiad games and economic liberalisation of the country's economy in 1990. Statistically, the city's developed area increased from 39.2 per cent of the overall city area in 1986 to 58.2 per cent in 2016.

Table1: Change in Land Cover of Delhi, 1986-2016

Land Cover	1986	1996	2006	2016	Decadal Change		
	Area (in sqkm)	Area (in sqkm)	Area (in sqkm)	Area (in sqkm)	1986-1996	1996-2006	2006-2016
Total Built Up	581.45	710.4	783.6	863.5	22.5	11.0	10.8
Forests	176.8	178.1	172.1	176.2	0.8	**-3.8**	2.6
Other Green areas	48.6	66.8	70.2	75.8	36.0	5.5	8.6
Water Bodies	41.9	34.4	29.6	25.4	**-21.7**	**-16.6**	**-16.9**
Agriculture Land	586.0	432.5	368.2	284.6	**-33.2**	**-17.7**	**-28.2**
Wasteland	48.3	60.8	59.3	57.6	25.9	**-2.8**	**-3.2**
TOTAL=	**1483**	**1483**	**1483**	**1483**			

Extracted by the author (2017) from USGS (1986, 1996, 2006 & 2016)

The increases in population and the built-up areas in the city resulted in the conversion of agricultural fields into non-agricultural use like residential, commercial and other non-permeable concrete 'jungles'. The city has witnessed a rise in its density as well. It is conjectured that for a population increase of 12.4 million during these three decades, there is a corresponding increase in developed area from 581.45 square kilometres in 1986 to 86,350 square kilometres in 2016. This is further accompanied by an increase of urban density of 2.6, an increase of developed area density by 1.8 and an increase in gross residential density by 2.14.

These developments have engulfed natural green areas and flood plains of the city, thus disturbing the city's microclimate and ecological balance. Both of these natural areas serve as heat sinks. Empirical analysis indicates that 57.5 per cent of the city's area acted as heat sinks in 1986 which declined to 37 per cent in 2016, with an annual rate of depletion equivalent to 1.4 per cent. Moreover, it is observed that heat sinks are depleting at a much faster rate (equivalent to 1.4 per cent) than the rate at which the built up area is increasing (equivalent to 1.3 per cent). Also, it is found that a 100 hectares increase of built up area corresponds to a loss of 94 hectares of vegetative heat sinks and 6 hectares loss of water based heat sinks.

3. CLIMATE CHANGE OF DELHI

The climate of NCT of Delhi is categorised into four seasons by the Indian Meteorological Department- winter, summer, monsoon and post monsoon. The winter season extends from December to February. Summer includes March, April and May while the monsoon season extends from June to September. The post-monsoon season includes October and November. The paper however assesses this change in climate for Delhi only through precipitation variables using meteorological data obtained from the Indian Meteorological Department, New Delhi and Irrigation and Flood Control Department, Government of NCT of Delhi.

3.1.1 Precipitation variability

The annual precipitation variability is assessed in terms of annual rainfall and annual number of rainy days for a time frame of 115 years, from 1901 to 2016. The trend of annual precipitation post-1901 (as indicated in Figure 1) shows that the average rainfall has increased by 210 millimetres and that the periods of drought have become longer than the periods of heavy rain.

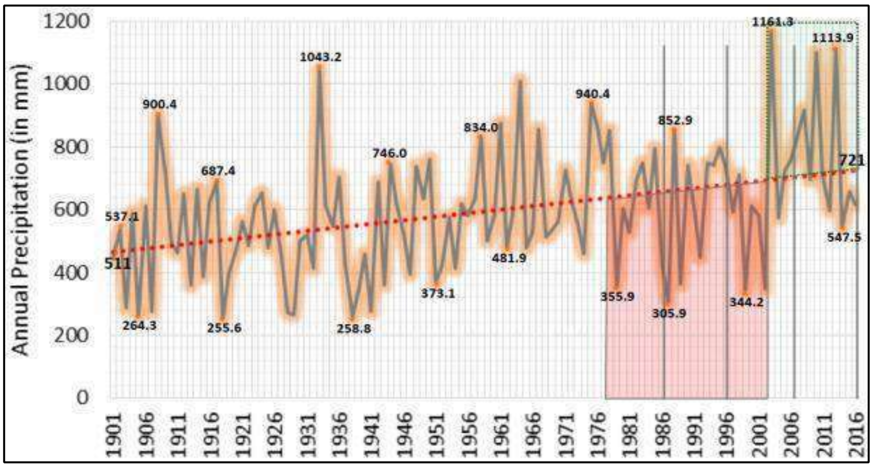

Figure 1: Change in Annual Precipitation for Delhi, 1901-2016
Source: IMD (2016)

Assessing the trend in the number of rainy days for Delhi (as indicated in Figure 2), in the same time period shows that the average number of annual rainy days has increased by 9 rainy days while the average precipitation per rainy day has increased by 2.5 per cent. Since the annual precipitation and number of rainy days are increasing, and given that the actual duration of precipitation has reduced, this resulted in a sharp rise in rainfall intensity from 13.2 mm/hour in 1986 to 22.9 mm/hour in 2016 (the latter leading to flooding of over 50 per cent of the city in three hours in 2016).

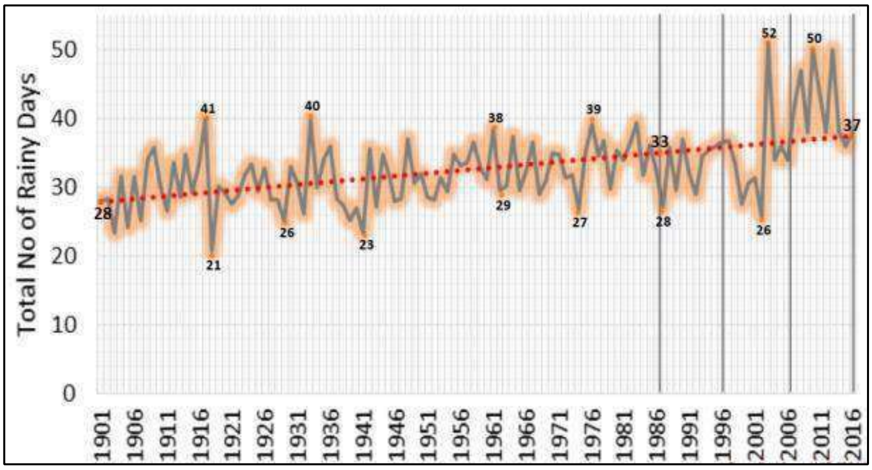

Figure 2: Change in Annual Number of Rainy Days for Delhi, 1901-2016
Source: IMD (2016)

The seasonal precipitation variability is assessed in terms of seasonal share of annual precipitation and rainy days for the timeframe 1901 to 2016. Analysis of the seasonal share of annual precipitation (as indicated in Figure 3) shows a trend of wetter summers and drier post monsoon periods. Rainfall and rainy days are increasing but the actual duration of precipitation is reducing leading to increase in rainfall intensity from 13.2 mm/hour in 1986 to 22.9 mm/hour in 2016. In 2016, 3 hours of rainfall at this intensity flooded over 50 per cent of the city, breaking down the city's mobility and livelihoods.

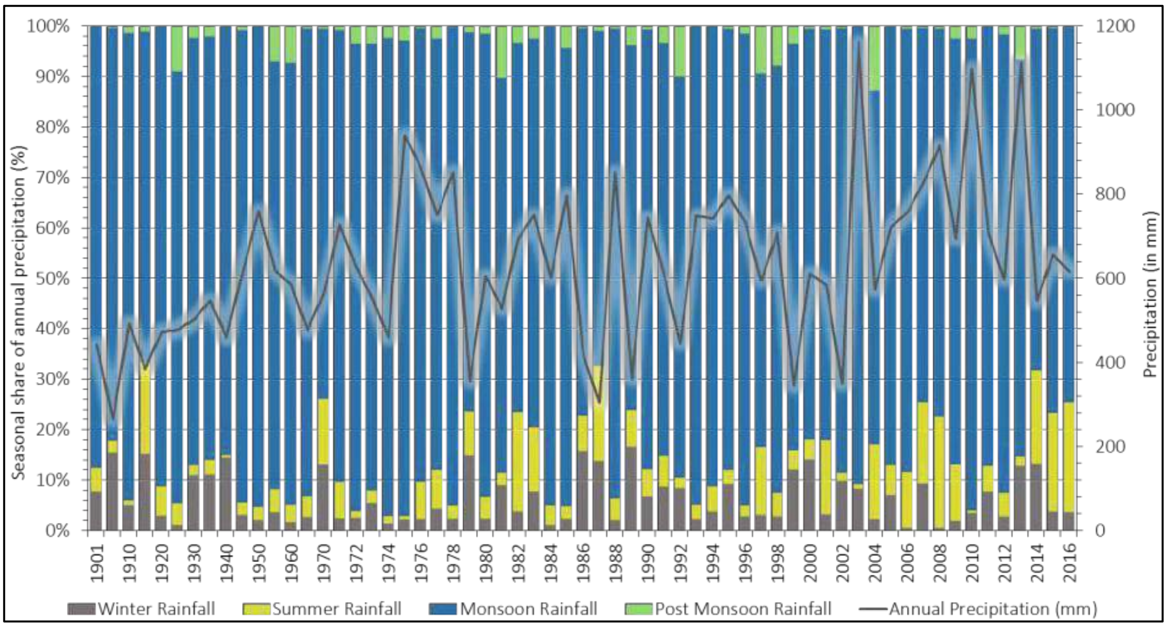

Figure 3: Seasonal share of annual precipitation for Delhi, 1901-2016
Source: IMD (2016)

4. Interplay of Climate Change and Urban Development with the Mobility Pattern of NCT of Delhi- 1986-2016

4.1 Contribution of the Transportation sector in total Green House Gas (GHG) emissions

The increase in GHG emissions for Delhi have been assessed at two levels. First, a spatial distribution of GHG emitters has been identified which included the built up area as well as wasteland. Second, the sectoral contribution of GHG emissions from the sectors of waste, transport, domestic and industries is estimated using the Tier II methodology formulated by the intergovernmental panel on Climate Change in 2007.

In the first case, imageries indicate an increase in the total area of greenhouse gas emitters, which has a direct correlation with the densities of the developed area. Their empirical analysis indicates that the city had 42.5 per cent of its area under greenhouse gas emitters in 1986 which increased to 56.8 per cent in 2016. That is at an annual rate of increase equivalent to 1.3 per cent, with the result that the city's emissions are increasing rapidly. The increase is related to increases in densities of the developed area.

In the second case, GHG emissions from the sectors of waste, domestic, industries and transportation was calculated using the Tier II methodology formulated by IPCC in 2007. The method uses emission factors for energy consumption in each sector. Based on this, emissions for NCT of Delhi have been estimated. This table shows that the city's GHG emissions have increased 4.5 times since 1986. Moreover, the increase has been over 12 times for the transportation sector, 3.5 times for the domestic sector, 3 times for the waste sector and 2.9 times for the industrial sector.

Empirically, for every 100 hectare increase in built-up area between 1986-2016 was leading to an increase of GHG emissions by 0.078 million metric tonnes of CO2 equivalent.

4.2 Urban Floods and implications on urban mobility

The city comprises 24,840 hectares of flood plains of which 68 per cent forms a part of the river Yamuna floodplains. The city has three drainage basins (as indicated in Table 2) based on the watershed that includes the North basin with a basin area of 26,694 hectare; the West basin with an area of 75,633 hectares; and the South and East basins spread over an area of 45,973 hectares.

Assessing the development pattern of Delhi, it is observed that the city has lost over 41 per cent of its flood plains and the loss has increased by 1.4 times since 1986 (as indicated in Figure. 4). The city's flood plains have reduced in width from 800 meters in 1986 to 300 meters in 2016 as a result of construction and developments located in flood plains.

Table 2: Loss of Flood Plains in Delhi, 1986-2016

Basin	Area of Basin (in sqkm)	Area of Flood Plains (in sqkm)	Loss of Flood Plains (in sqkm)				Loss of Flood Plains, 1986-2016 (in sqkm)
			1986	1996	2006	2016	
North Basin	266.94	20.02	3.96	4.91	5.17	5.83	1.86
West Basin	756.33	113.45	33.01	39.48	41.07	44.81	11.80
South and East Basin	459.73	114.93	56.91	72.37	83.03	84.97	28.06
TOTAL=	1824.1	248.4	93.9	116.8	129.3	135.6	41.7

Extracted by the author (2017) from USGS (1986, 1996, 2006 & 2016)

Summing up, the National Capital Territory (NCT) of Delhi witnessed a ~~paradoxical~~ dramatic ecological change over the past three decades. For every 100 hectare increase in its built up area it felt adverse repercussions of corresponding hard coverage of 94 hectares of green sinks and 6 hectare of water bodies.

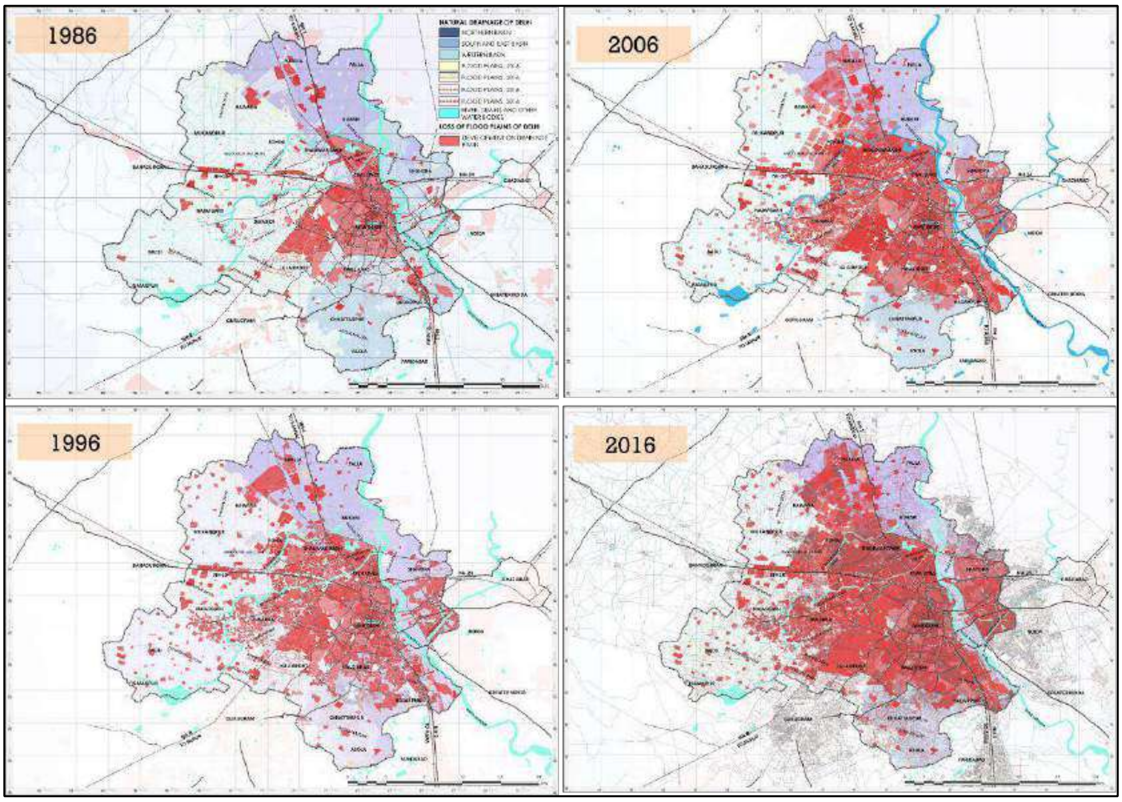

Figure 4: Loss of flood plains in Delhi, 1986-2016
Extracted by the author (2017) from USGS (1986, 1996, 2006 & 2016)

4.2.3 Impact of the built environment on surface run off

Increasing development of drainage basins and the resulting loss of flood plains, coupled with the increase in impermeable surfaces has led to an increase in surface run-off from the city. Due to an interplay of urban development and natural climate variability, the city's surface run-off has increased from 211 million litres per day (MLD) in 1986 to 622 in 2016, that is a 2.9 times increase over the last 30 years. Also, it is observed that with the loss of every 10 hectares of green cover, the surface run off increases by 0.014 MLD. Annually the surface run-off is increasing at 3.7 per cent while the loss of heat sinks is 1.4 per cent. That is, surface run-off is increasing at a much faster rate than the loss of permeable surfaces in the city. The entire chain of events becomes crucial in the light of strong interdependence between loss of heat sinks- both vegetative and drainage basins, increase of impermeable surface, urban expansion and changing precipitation pattern.

5. IMPLICATIONS ON URBAN MOBILITY OF DELHI

5.1 Macro-Level Implications

At the macro level or city level, the empirical study indicates critical linkages between the urban development pattern, climate variability and urban mobility. The two major linkages identified are – first, increasing greenhouse gas emissions with change in urban development which adds to climate change at a regional level, and second, the impact of urban floods on road networks of the city and consequently on the average travel time.

First, in terms of greenhouse gas emissions, recapitulating earlier facts, emissions for NCT of Delhi increased 4.5 times since 1986. However, the increase has been over 12 times in transportation sector alone, owing to rising vehicular traffic and increased congestion on roads. Second, increasing surface run-off and impermeable surface, along with increasing intensity of rainfall has led to increase in the area flooded by precipitation in Delhi (Figure 5).

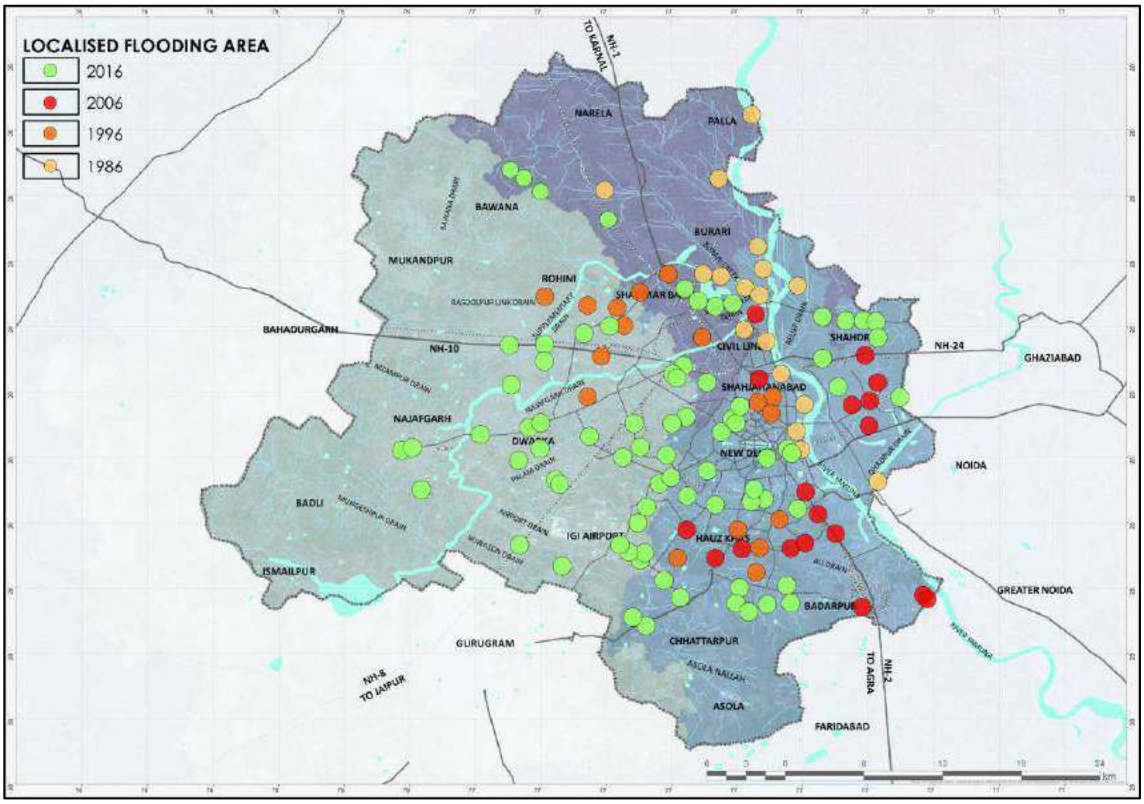

Figure 5: Change in waterlogged/ flooded area in Delhi, 1986-2016
Extracted by Author (2017) from USGS (1986, 1996, 2006 & 2016)

While the period witnessed an annual growth of surface run-off by 3.8 per cent, it led to increase in flooding by 2.5 per cent. Moreover, for every increase in surface run-off by 1 MLD [million litres per day], flooding increased by 85 hectares, the road length affected increased by 68 meters, while vector borne diseases increased by 7.8 per cent. The problem is aggravated by extraction and increasing reliance on groundwater to meet the water demand supply gap.

6. Impact of Climate Change and Urban Development on the Mobility Pattern of Vulnerable population of NCT of Delhi- 1986-2016

Having established the correlation between urban development and climate change at city and spatial levels, this section analyses the impact of climate change on vulnerable population. For this purpose, the flood plain of the river Yamuna is identified and the population at risk recorded. The village population is identified for detailed analysis and surveys among the cohort of climate risk population located in the flood plains, as it has the least adaptive capacity.

4.2.1 Profile of the Flood Plains of the River Yamuna in Delhi

The flood plains of the river Yamuna make up for over 68 per cent of the city's total flood plains. Over a period of time, the river has undergone a change in the course of its flow. Since 1986, studies have indicated that the flood plains have reduced in area and width by 800 metres on either side of the river in 1986 to less than 300 meters in 2016. The land cover on the flood plains of the Yamuna river have undergone major changes in the past three decades.

The land use on the flood plains of the Yamuna river have undergone major changes in the past three decades as well (as indicated in Figure 6). The trend indicates that of the total built up area, residential use has increased by over 200 per cent in the past 3 decades, followed by a 92 per cent increase in commercial and a simultaneous reduction in industrial use. To support the development, utilities and transport infrastructure have grown at the rate of 37 per cent and 14 per cent respectively. That is, the no man's land has become a favourable site for real estate despite the environmental senstivity of the region.

It is because of this increasing built up area alone, that the flood plains and its environmentally sensitive ecosystem have undergone a rapid depletion, accentuating the climate risk as well as frequency and intensity of floods in the river Yamuna.

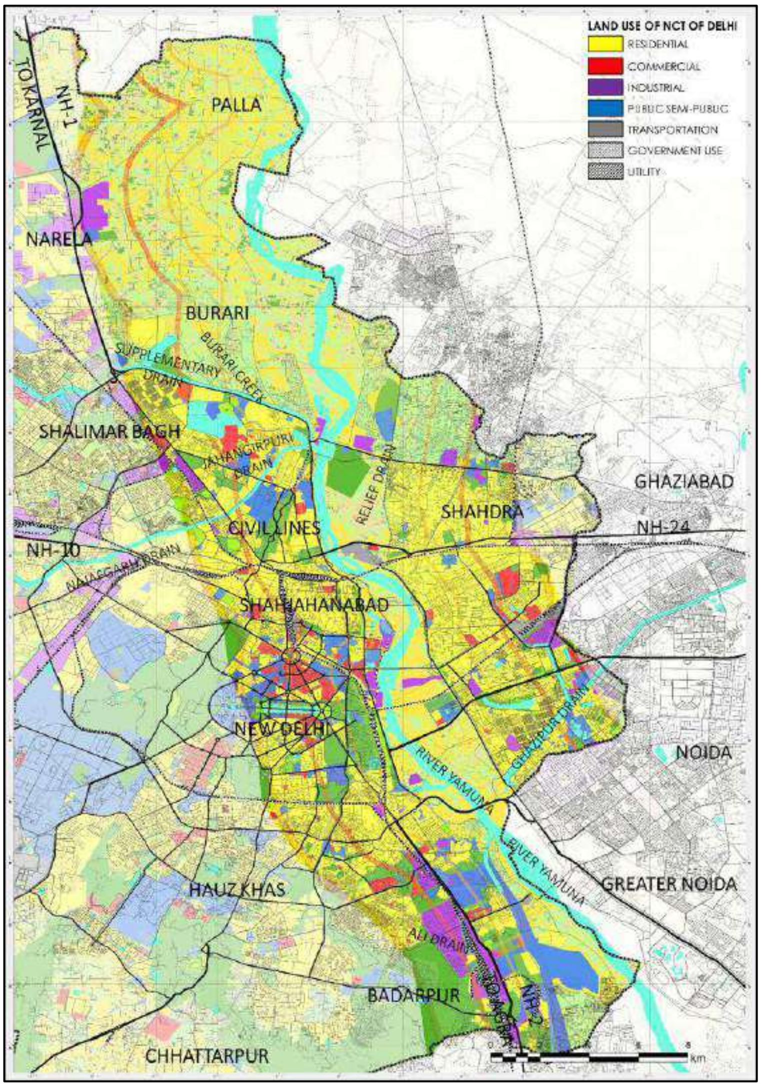

Figure 6: Land Use in flood plain of river Yamuna in Delhi, 1986-2016
Extracted by the author (2017)

5.2.2 Vulnerable Population

Climate resilient urban planning highlights the necessity for assessing the impact of climate on vulnerable population. With increasing developments on the flood plain of the Yamuna river, particularly residential development, the vulnerable population has increased by more than 2.4 times in the last 3 decades. Amongst the three categories of vulnerable population, maximum increase has been in the number and area occupied by unauthorised colonies while villages have reduced in number due to their conversion into census towns but increased in total population due to natural increase. Over time, planned colonies such as the Commonwealth games village have also come up. However, for the purpose of assessing climate risk on vulnerable population, villages are identified separately from the cohort owing to their limited adaptive capacity.

144 villages exist within the flood plains of Delhi that are prone to flooding. These villages are categorised annually by the Irrigation and Flood Control Department of Delhi, Government of National Capital Territory of Delhi into two categories – most vulnerable/totally exposed area villages and moderately vulnerable moderately exposed area villages. However, owing to constraints of time and human resource, only 3 villages (indicated in Figure 7) were selected for impact assessment, which include Badarpur Khadar, Usmanpur and Garhi Mandu in the upstream river Yamuna, north of the Wazirabad barrage.

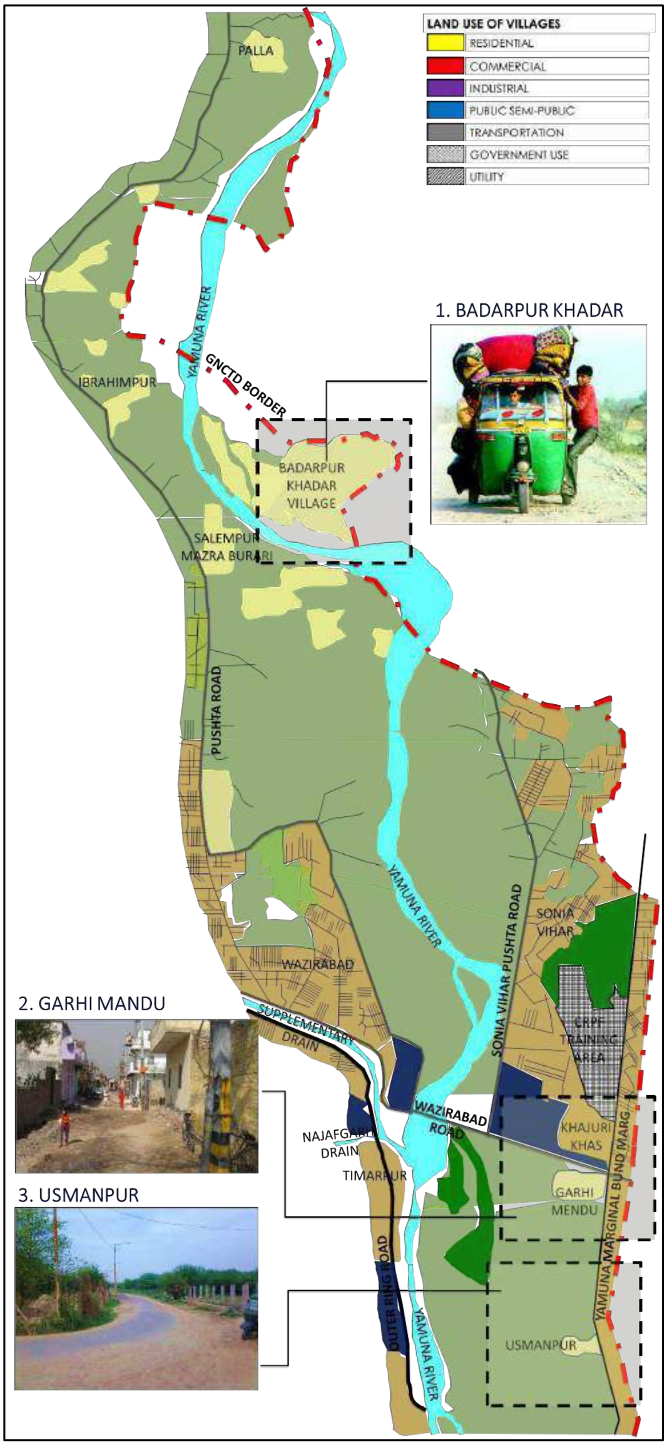

Figure 7: Location of Case villages in the upstream of river Yamuna flood plains, 2017
Compiled by the author (2017) from I&FC (2017)

The impacts were assessed in terms of physical loss, social impact and economic impact.

- **Physical impact -** The physical impact of floods is felt in terms of temporary loss of habitation by way of entry of flood waters into houses and loss of connectivity to the outside world, thus impacting access and connectivity of the settlement with the outside world. To cope with it, prior to flood warnings issuance villagers vacate to higher ground or are resettled to relief camps set up by the Delhi government.
- **Social impact** - Owing to the loss of connectivity and inundation by flood waters, access to education facilities is disrupted for an average of 10 to 12 days. Also, incidences of increasing vector borne diseases, like malaria, dengue, chikungunya and snake bites, have been recorded.

  Economic impact- Due to loss of connectivity to the outside world, a worker loses 10 to 12 working days and tends to lose over 25 per cent to 30 per cent of monthly income. It varies from Rs 250 (~4 USD) per day per capita to Rs 415 (~7 USD) per day per capita.

Summing up the survey findings at micro level, it is found that apart from temporary loss of habitat and connectivity to the outside world or suspension of school and increase in vector borne diseases and snake bites, the average economic impact incurred by the villagers is equivalent to 30 to 35 per cent of their monthly income, equivalent to 10 to 12 working days. Apart from the costs incurred by villagers, government spending on resettlement and relief camps is an annual burden on the state exchequer. The overall monetary loss due to floods in the Yamuna river flood plain is valued at 0.3 million USD per annum which includes 0.23 million USD as the cost incurred by government. Thus, the need to enhance resilience of vulnerable population becomes imperative.

6. Conclusion

The research presented here highlights the interdependence of urban development, climate change and the natural environment, as well as a multiplicity of implications arising from these interdependent phenomena. The need for planners and cities to deal with them in the planning system becomes critical, with cities being guzzlers of over 3/4 of overall resources and generators of about 3/4 of waste and pollution, while accommodating a little over half of the global population. Innovative thinking, planning principles and design within an appropriate framework to set strategies and priorities will be of the essence.

The study underscores the need for a climate resilient urban development for Delhi which means to start envisioning and planning the city according to its carrying capacity. The city's expanse and political as well as socio-economic importance has led to its relentless growth in area, population, vehicles as well as pollution and degradation of natural resources. For that reason, there is a need to put a break on the increasing trend of city development. This requires strong mobilisation of political support for fruitful planning strategies and policies. An example is the recent initiative of *Clean India Mission, famously known as Swachh Bharat Abhiyaan* by Prime Minister Narendra Modi. It has brought about a wave of behavioural change at every level of governance across India and given sanitation a political priority at the centre. Thus, political nexus and push, as well as bureaucratic support play a binding role in ensuring success of planners' efforts.

One of the priority proposals to be rolled out with central support is to initiate decongestion of the city, which can be supplemented by the upcoming Regional Rail Transit System connecting Delhi to surrounding towns of the National Capital Region. Delhi would continue to exist as an employment hub. However, a pressing current need is to start containing the development of the city. create heat sinks at an accelerated rate and redistribute population along more ecological principles. This could take the shape of land use-transport integration, redistribution of population densities and opening up public space, earmarking aquifer and recharging zones for no development among others.

Enhancing the climate resilience of population and infrastructure becomes indispensable to counteract the impacts which have arisen from years of past developments. Moreover, urban planning needs to widen its scope beyond the administrative boundaries of NCT of Delhi and start working at the level of Delhi Metropolitan region. This is particularly important for a climate resilient urban future. This would encompass making it a mandatory provision for all spatial plans to have a chapter on climate change and its implications on urban development. In particular, it should become a statutory requirement for the urban planning processes and plan documents to have a chapter with explicit mention of, and focus on climate change and its relation to urban development in Delhi. It is also proposed that any spatial plan shall have a chapter on climate change and policies for climate resilience, before it can be approved or notified in the official Gazette. The master plan document would have to elaborate climate strategies at city level and provide details at spatial level as well.

It is long overdue that planners start looking beyond the jurisdiction of the National Capital Territory of Delhi and start working and assessing climate and its relation to urban development for a region beyond the state boundary. That is, the urban planning jurisdiction should extend to the Delhi Metropolitan region. This recommendation is further supported by the fact that the predominant climate of the city is determined within 60 kilometres in radius of the city.

Apart from spatial development strategies including transit oriented development, redistribution of population and densities, protection and conservation of the city's drainage pattern, recharging the ground water aquifer and enhancing the green infrastructure, certain other spatial development and planning strategies should be compulsory as well.

Firstly, the master plan of Delhi has to have a comprehensive and clear non-disputable policy for relocation and rehabilitation of climate vulnerable population. Unambiguous provisions for the resettlement of population at risk of climate change have to be included in writing in all spatial plans. Resettlements within the same planning area have to be given priority. In case this is not possible due to space constraints, the resettlement location must not exceed 5 kilometres from the original stay.

Another strategy of paramount importance relates to enhancing the climate resilience for existing immovable infrastructure. There are three approaches to ensure that. First, roads could be aligned according to high flood risk level, or put out of use during the monsoon season. The second approach relates to the 'asset management approach', whereby planners, engineers and professionals from other disciplines would move from road design to planning and maintenance. That is, this approach is a departure from a reactive patch-and-mend approach to a preventive management approach. Lastly, it is necessary to opt for 'user behaviour management', whereby signage will guide users to alternative routes which are less or not affected by climate risk.

In this paper strategies for climate resilient urban development have been proposed for the National Capital Territory of Delhi. New guidelines for climate resilient urban development are also envisaged more generally for any megacity in India with similar attributes and evidence to that of Delhi. They include: land use and urban planning measures; planning for drainage including floods and solid waste management; management of water demand and conservation systems; building and enhancing resilient housing and transport systems; and strengthening of ecosystem services. These five categories of guidelines are directly related to spatial planning and development strategies, that need to be included and comprehensively detailed in spatial planning documents. Beyond that, another 5 categories of guidelines are proposed which are more related to institutional capacities and multiple sectors, affected by climate change and induced risks. They include: diversification and protection of livelihoods; encouraging institutional coordination mechanisms; establishment and strengthening of emergency and warning systems; improved technology and information systems; and enhancing education and capacity building of citizens.

Effects of Urban land use change on Selected Public Utilities for Sustainable Development in Akure, Nigeria

Comfort Opeyemi Aladekoyi, Department of Physical Planning, University of Medical Science, Ondo, Nigeria
Michael Ajide Oyinloye, Department of Urban and Regional Planning, Federal University of Technology, Akure, Nigeria

Abstract

Urban landuse change is one of the main driving forces of global environmental change. It is central to the sustainable development debate. The aim of this research is to examine the effects of urban landuse and its impact on selected public utility services in Akure with a view to improve strategies to protect these utilities for sustainable development. The research was conducted using remote sensing, Geographical information System and questionnaire to collect the required data for the purpose of fulfilling the objectives of this study. In this study of analyzing the urban landuse change, 2010 and 2018 IKONOS are used in a post classification comparison analysis to map the landuse changes and identify the conversion process in Akure. The landuse change statistics results obtained revealed that residential landuse has changed rapidly for the periods (2010-2018). The results also show increase in commercial landuses between the same periods. The results of the analysis reveal that the built-up area has been growing rapidly for the periods (2010-2018). Findings show that, housing provision (residential), business purpose (commercial) and educational (institution) are the major causes of land use change in the study areas. To reduce the effect of land use expansion in the study areas, policy measures were recommended which include regulating the growth and spread of development, regional development programs. In our opinion, the information provided by these technologies could help city planners and policy makers to attain and sustain future urban development.

Keywords: landuse, public utilities, sustainable development, remote sensing, GIS, satellite imageries

INTRODUCTION

Land use refers to the activity, economic purpose, intended use and or management strategy placed on the land-cover type(s) by human agents or land managers. Land cover refers to the characteristics and surface cover of the earth surface as represented by vegetation, water, bare earth, impervious surface and other physical features of the land (John *et al*. 2003). Land use change occurs when the use to which land is put in different from what it was in past. For instance, an open space or forested area could turn into a built –up area. Therefore, land use and landcover changes play an important role in local and regional environment conditionm of a particular territory and they are linked to global environmental change (Adeboyejo and Abolade, 2006). In order to understand 'why' land use changes as well as 'how' the changes occur. It may be necessary to know what is currently going on and the pattern of these activities in general form (Hudson, 1980).

The patterns of land use within different urban areas have different forms due to the factors that are shaping this pattern. Such factors include topographical features, legislation and legal decision from the government, social and religious, even customs (land holding system), government policy on public utilities and social services supply (Adeniyi, 1978).

Several researchers have employed various methods or techniques for landuse and landcover change. In his studies carried out by 2004 in Shaoxing City in China, Peng and Howarth (2004) used Satellite imageries for the year 1984, 1997 and 2000; one of the goals of the study was to produce a land use map of Shaoxing City and its surroundings. The results show that there are undoubtedly a lot of changes that occurred between 1984 and 1997 when compared with those of 2000, due to the sufficient time gap.

Similarly, Zhi-Yong *et al* (2005) used image processing and analysis in a GIS environment to assess spatial change in urban land use patterns and population distributions. Here, unsupervised classification was used to classify the images into land use classes. With Census data in a GIS, census polygon was constructed into various sets of units, and then comparison made with the classified image by proportion in surface.

Elnazir *et al* (2004) analysed the nature, rate and location of urban landuse changes, urban built-up land was extracted from each of the images, overlaid on each other to obtain an urban expansion image. These extractions were done on layers in the vector GIS environment and the result used to identify urban land change to obtain real time information. Musaogwu *et al* (2002) incorporated remote sensing and GIS to create overlays of two or more independently produced classified images· It can be used to detect changes, trend, location and amount of changes that have occurred. Zubair (2006) examined the use of GIS and Remote Sensing in mapping landuse and landcover in Ilorin, Nigeria between 1972 and 2001 to detect the changes that has taken place in this status between these periods.

The objectives of this study include to:

(a) identify the major land use types using remote sensing/ GIS in the study area.
(b) estimate the proportion of land use devoted to these different empirical evidence urban land use types in the study area.
(c) analyse the casual factors responsible for landuse change
(d) determine the planning implications of the urban land use change on these selected public utilities in the study area

THE STUDY AREA

The study area is Akure, the administrative capital of Ondo State. The city is located within Ondo State in the South Western part of Nigeria (see figure1). It lies approximately on latitude 7^0 15^1 North of the Equator and longitude 5^0 15^1 East of the Greenwich Meridian. Akure is a medium- sized urban centre and became the provincial headquarter of Ondo province in 1939. It also became the capital city of Ondo State and a Local Government headquarters in 1976 (see figures 2 and 3). The city's morphology has changed over time to assume its present status with its attendant land use problems, as experienced in similar medium sized urban centres in Nigeria. Akure is located approximately 700 kilometers South West of Abuja, the Federal Capital of Nigeria and about 350 kilometers to Lagos the former capital of Nigeria. The annual average temperatures range between 21.4 and 31.1^{o}C, and its mean annual relative humidity is about 77.1%. It is located within the tropical rain forest region of Nigeria where rainfall is high throughout the year. In 1963, Akure had a population of 71,106 which increased to 109,253 by 1976 (Olotu, 2005). The rapidity of its development within forty two years stemmed from the political status of the city which was initially a provincial headquarters later a state capital thus servicing as the seat of both local and state governments ever since; this accounted for the influx of people into the city for employment. In 1991, the population had risen to 239,124 and by 2006 the population was put at 340,021 (NPC, 2006).

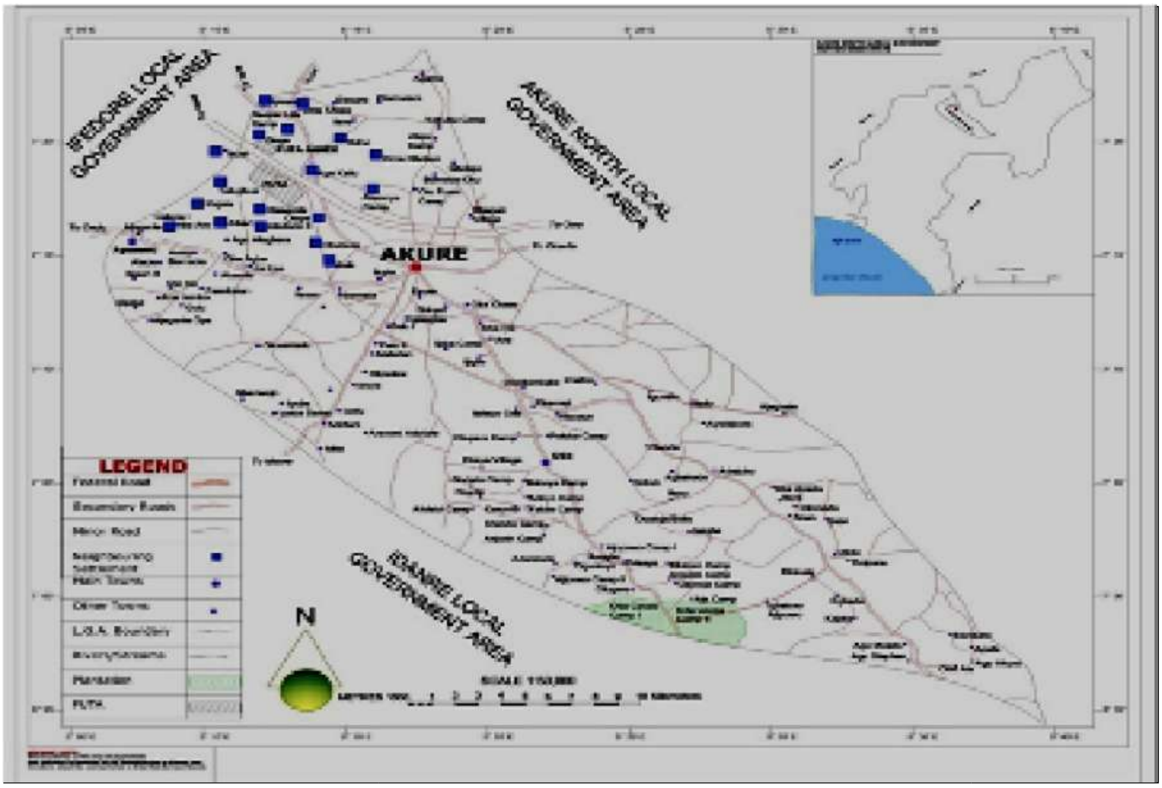

Fig. 3: Map Showing the Location of the Study Area

DATA ACQUISITION AND METHOD

This study was interested in the effect of urban land use change on selected public utilities in Akure. It also seeks to use the capabilities of Geographical Information System and remote sensing techniques to determine the rate of land use change on these utilities in the study area. To achieve this, IKONOS images of Akure were acquired for 2010 and 2018. The images are geometrically corrected and ground control point obtained through intensive ground surveys permitted the co-registration of all images to Universal Transverse Mercator (UTM). The Urban Satellite imageries were made to pass through process of image enhancement, geo referencing, resampling, image classification was performed on false colour composites into the following landuse: residential, commercial and institutional. Information collected during field surveys was combined with the digital topographic map which was developed for the study area was used to assess the accuracy of the classification.

The questionnaire method was used to generate attribute data to further enhance our information on the study. For the purpose of this study, the selected landuse areas are: residential (Obaafunbiowo and Igoba); commercial (Isikan market, shasha and Akure mall) and institutional (Federal university of Technology, Akure and its environs. The questionnaires were allotted based on the number of buildings in the selected landuse in each area.

Two hundred and forty questionnaires (240) were administered in all out which 200 were retrieved in analyzable form given a response rate of 83.3%. By this the exercise is considered successful. Table 1 shows the residential and the number of questionnaires administered per landuse area.

Table 1: Questionnaire Administration Analysis

Landuse Areas	Sampled areas	No. of Buildings in the areas	No. of Questionnaires Administered	Questionnaire Retrieved
Residential	Obaafunbiowo/Igoba	301	60	43
Commercial	Isikan market/shasha Market/Akure mall	298	60	45
Institution	Federal university of Technology and its environs	167	60	55
Sub-total		**766**	**240**	**200**

Source: Author's survey (2018)

The data collected using this medium was processed using Statistical Package for Social Scientists software (SPSS). Results obtained were presented in form of tables and figures. The areas covered by the questionnaire include demographic factors responsible for urban change in the study area. All questions were carefully analysed and considered in addition to spatial information from GIS analysis to arrive at our conclusion.

RESULTS AND DISCUSSION

Three major classifications were used in this study. These are the residential which comprises of the dwelling houses; commercial which include Isikan market, shasha market and Akure mall; and institutional landuse including Federal University of Technology and its environs. However, the total area of each of the landuse was calculated in 2010 and 2018. The total areal extent for each land use type is thus summarized in table 2. On comparing the figures 4 and 5 and table 2, it was observed that the residential landuse (Igoba) covered 7,573,720 square meters (0.03%) in 2010 and increased to 19853,027.32 square meters (78.23%) in 2018, while Obaafunbiowo in figures 6 and 7 decreased gradually from 1502,192.16 (0.25%) in 2010 to 2747,914.12 square meters (0.08) in 2018. The commercial landuse on the other hand in figures 8, 9, 10, 11, 12 and 13 due to massive in population affected the landuse change to various conversion of residential use to commercial. The commercial land use change of Isinkan decreased from 5937.30 (67.13%) in 2010 to 20776.61(0.08%) in 2018 while shasha and Akure mall increased drastically from 28969 square meters (0.10%) and 12100.17 square meters (0.05%) square meters in 2010 to 83299.80 (0.33%) and 31708.78 square meters (0.12%) in 2018 respectively. The institutional land use in figures 14 and 15 as result of massive encroachment, farming activities and various expansions going on, the landuse change decreased from 21161387.69 square meters (19.15%) to 2639.908 square meters (10.41%) in 2018.

Table 2: Selected Land use change in (m^2/year) and (% year) of Akure in 2010 and 2018

Selected area	2010 in square meters	% in 2010	2018 in square meters	% in 2018
Futa	2,161,387.69	19.15	2,639,908.44	10.41
Isinkan	5,937.30	67.13	20,776.61	0.08
Shasha	28,969.61	0.10	83,299.80	0.33
Akure mall	12,100.17	0.05	31,708.78	0.12
Obaafunbiowo	1,502,192.16	13.32	2,747,914.12	10.83
Igoba	7,573,720.03	0.25	19,853,027.32	78.23
Total	11,284,288.96	100	25,376,635.07	100

IMPLICATIONS OF LANDUSE CHANGE IN THE STUDY AREA

A tremendous increase in population as a result of the improved status of Akure from a traditional town to a State capital led to changes in land use pattern, which initially dominated by residential and cultural landuse to a more complex and diversified type of landuse. Institutional, commercial and administrative and social landuses among others were added to the existing landuses. Akure has undergone and is still undergoing many changes in physical form and economic functions in terms of land uses in response to the population growth. There are so many inter-woven factors contributing to this population growth. The creation or establishment of industries created job opportunities which attracted migrants into the town. This has led to changes in residential as well as commercial land use. Furthermore, the creation of higher institution of learning such as The Federal University of Technology has also contributed to population growth which has both directly or indirectly influenced other landuse activities.

However, the impact of the population growth is also seen in the establishment of new markets and development of the old ones. In essence, the establishment of Shasha market and renovation of Isikan market and Akure mall are due to population growth and urban expansion. One can now be able to infer from the above that population growth in Akure leads to the increase in types and areal extent of urban land use.

Other variables that are responsible for land use changes in the study area include: the type of building; use of building; age of building; and building approval plan before construction among others (see Tables 3 7).

Table 3 shows that the bungalow type of building is the most occurring type of building with 36.7%, follow by block of flats also having 25.0%, storey buildings with 20.8%, and lastly followed by duplex with 12.9%, This is an indication that the other building types meant to accommodate large number of people are springing up and this will give rise to population of the study area and other urban problems such as overstretch of infrastructures will then be experienced.

Table 3: Building types

Response	Frequency	%
Bungalow	88	36.7
Storey Building	50	20.8
Duplex	31	12.9
Block of Flats	60	25.0
Others	11	4.6
Total	240	100.0

The result of the survey describes the previous uses of buildings in the study before they were converted into new uses as shown in figure 4. This result is a true reflection of what the area is ought to be in its real nature as planned. The survey conducted shows that residential covers about 50.0%, commercial 22.9%, institutional 16.7%, recreational 5.0% while industrial is 5.4% respectively. This shows the use at which the study is purposely meant for from inception. This is actually turning to a commercial land area from residential area.

Table 4: Former Use of Building

Response	Frequency	%
Residential	120	50.0
Commercial	55	22.9
Institutional	40	16.7
Recreational	12	5.0
Industrial	13	5.4
Total	240	100.0

Table 5 also shows the results of the present uses of building in the study area. The result shows that the most dominant use of land is the residential is 53.3%, with commercial 24.2%, institutional 16.3%, recreational 3.3% and industrial 2.9%. This survey reveals that the extent at which changes have occurred in the study area, this occurrences have not actually stop, so there is possibility that the area will attain another state of commercially developed area in the nearest future. This is an implication that one might not actually be able to ascertain the use of this area in the future to come if the government do not find measure to stop the ongoing change.

Table 5: Present Use of Building

Response	Frequency	%
Residential	128	53.3
Commercial	58	24.2
Institutional	39	16.3
Recreational	8	3.3
Industrial	7	2.9
Total	240	100.0

Table 6 gives an insight on how the buildings are converted from their previous use to their current use. From the survey carried out in Table 6, it is shown that most conversion are actualised by addition of uses to the previous use that is having mixed-use and this accounts for about 40.0%, followed by change in use from their original use which also account for 24.2%, also alteration of buildings also account for about 15.0%, partial demolition and renovation accounts for 10.4% while reconstruction and total demolition accounts for 6.3% and 4.1% respectively. The implications of all these indicate that buildings are being converted at an alarming rate.

Table 6: Present Use of Building

Response	Frequency	%
Mixed use	96	40.0
Change in use	58	24.2
Alteration in buildings	36	15.0
Partial demolition and renovation	25	10.4
Reconstruction	15	6.3
Total demolition	10	4.1
Total	240	100.0

Table 7 shows that over 50% of buildings in the study area did not secure building plan approval before construction. Up till the time of this study, there are no plans for most of the buildings in the study area. The situation reveals that property owners in the syudy area develop their properties without due regard to physical planning rules and regulations.

Table 7: Building plan approval before construction

Approval	Frequency	%
Yes	110	45.8
No	130	54.2
Total	240	100.0

CONCLUSIONS AND RECOMMENDATIONS

The study has revealed on the percentage basis the various landuse categories in the study area. It is clearly seen that residential and commercial are the most extensive landuse found in the study area. The reason for the high proportion of residential land use is the absence of other activities which is present in the large and medium towns, with this, one can easily infer that Akure falls to the categories of medium towns, since it has over 78.23% of its land area occupied by residential units. Furthermore, the study reveals that the total area covered by residential cum commercial is greater than the total area occupied by the remaining landuse activities combined together as shown in table 2. The result of the study shows that public institutions covered an area of 10.41% in 2018 and because of huge land requirement, they were located at the urban outskirts. Example include Federal University of Technology.

The landuse changes done in this study shows what exists in the urban scape of selected areas of Akure has therefore shown that the current landuse situation is such that can lead to ecological disaster. The study therefore advances some recommendations as a way of preventing these problems. First, the urban developer should be in conformity with planning regulations. People should be aware of such regulations to serve as a guide and rule for them in building o their houses both in terms of spacing and distance away from the roads. Second. Land conservation act should emphasis systematic growth of the city. Third, population growth through immigration should be controlled through the policy of regional development programme.

Abstract

The coast is one of the most complex systems on earth as it is the result of the continuous interaction between people, land and water. These physical processes shape the geomorphology of the coast, which sustains specific ecosystems that provide crucial services to human societies to flourish. This paper aims at expanding the understanding on the functioning of the waterfronts, which are crucial factor to increase the awareness regarding the challenges of developing and governing coastal areas and waterfronts. Evidently, climate change represents the major human-induced source of natural risks. Understanding the risks associated to the coast is crucial to provide safe and resilient human environment. Planners must address the challenges of waterfronts and coastal areas' planning approaches. Coastal cities are facing the challenge not only by providing high quality services for its inhabitants but also to integrate specific coastal and waterfront uses that demand a large quantity of space and requires highly specialized services. Ports, dwellings, beaches, promenades, protectorates, industry, logistics, resorts, restaurants, are just few of the uses that characterized most coastal cities and waterfronts and need to be integrated into the urban fabric and smartly diminish the consequences of climate change. This paper provides an analytical narrative of Doha, the capital city of Qatar as a typical city-state in addition to significant coastal cities in Qatar like Al-Khor and Al-Wakra. The Gulf always played a major role in Qatar's economical, social, cultural and political life. Inhabitants of old Doha being fishermen and pearl divers perceived the Gulf not only as source of their prosperity but also considered as a sacred entity.

Selected Congress Track: 2-SPOTLIGHT CITIES: Planning for Coastal Cities, Remote Towns, and High North Cities.
Keywords: Coastal Cities – Waterfronts – Doha, Qatar – Coastal Management – Coastal Development – Climate Change Impact.

1. Introduction

Some cities have long-treasured waterfront promenades, many cities have recently built ones, and others have plans to create them as opportunities arise. Beyond connecting people with urban water bodies, waterfront promenades offer many social and ecological benefits. They are places for social gathering, for physical activity, for relief from the stresses of urban life, and where the unique transition from water to land eco-systems can be nurtured and celebrated (Macdonald, 2017).

> *"The waterfront isn't just something unto itself. It's connected to everything else."* Jane Jacobs.

The Gulf waterbody and the extended coastline are of a great social and cultural significance to the community of Qatar. With more than 600km of continuous waterfront, Qatar is blessed with a great potential which can be vital for its urban and economic future. This natural potential can be also perceived as a great plight if the impacts of climate change particularly the sea level rise are not considered. This paper illustrates a major shift in contemporary urban development in Qatar. The shift stems from a deeper understanding of the vulnerability of Qatar as a peninsula facing the consequences of climate change in an inevitable manner. Evidently, the first cycle of globalizing the waterfronts urbanity in Qatar and particularly Doha the capital city, was characterized with an emphasis on the image of the city on the expenses of being concerned and prepared for the consequences of climate change and global warming. Plenty of skyscrapers were built along the waterfront to generate a global city image for Doha. Additionally, a number of mega real-estate projects resorted to gulf reclamation to gain more land and create fantasy housing and recreational projects.

The paper sheds light on new planning approaches, coastal management strategies, global warming impact assessment, climate change readiness and urban development guidelines which characterize the new waterfronts development paradigm in Qatar. The related outcomes of Qatar Vision 2030 specifically the Integrated Coastal Zone management Plan for Qatar will be assessed to scrutinize its policy making, planning and implementation. More significantly, the paper traces the impact of the declaration of Qatar National Development framework and Qatar National Master plan, as calls for a better planning for the local waterfronts. The paper concludes with a holistic planning matrix which advises the development logic of coastal cities in Qatar to create a balanced relation between Gulf, city and society. It also suggests planning principles, policies, guidelines and regulations for future waterfronts and coastal areas' development in Qatar.

2. Qatari Cities and Water: A Unique Relation, the Past, the Present and the Future.

The relation between Qatari cities and water is historical and influential. The Urban history of Qatari cities was substantially affected by the proximity of the Gulf and the economic dependence on fishing and pearl diving. Studying the urban evolution of Qatar and other Gulf States would reveal two forms of settlements allocated in an adjacency with water. The first form is fishermen villages which were distributed along the waterline in the preferred sites for starting the fishing trips and its proximity to the community Souq. This form or pattern of waterfront development was not limited to Qatar but was repeated in all Gulf States as fishing and pearl diving were the main economic pillars for all pre-oil traditional settlements in the Gulf. The second pattern of waterfront development is the portal cities. These cities grow gradually and organically around a simple port which was used to facilitate trade activities within the Gulf and with neighboring countries particularly Iran, India and other surrounding countries.

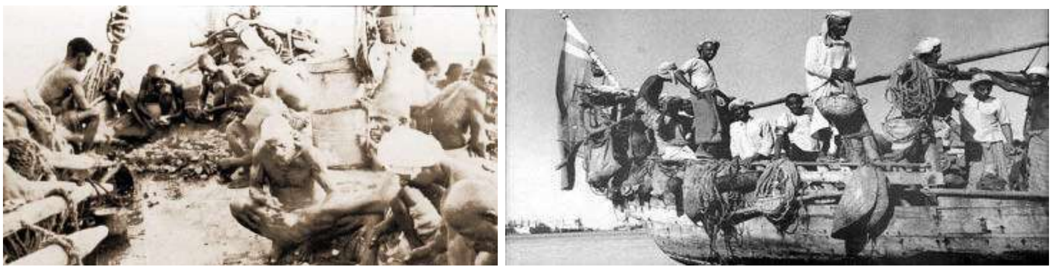

Figure 1: The economic base of the origin of Doha as a fishermen village

2.1. The Impact of the Gulf on Doha's Urban Evolution

The city of Doha is the capital of the State of Qatar and is located on the Persian Gulf. The primary industry in the city was pearl trading through the 1920s, and then collapsed due to the invention of pearl harvesting techniques in Japan. The population peaked at about 27,000 inhabitants in the 1920s (Alraouf, 2017) and consisted of traditional Islamic desert settlement patterns, as described by Hakim(1986).These patterns consisted of a vernacular road networks of cul-de-sacs, which enhanced the privacy of neighborhoods, known as ferej, and the market, located close to the port and constituting the central public realm. After national independence, Doha entered a phase in the 1970s and 80s when the discovery of oil fueled a physical growth of the city's infrastructure. While the old city centers were replaced by commercial buildings and apartment blocks for foreign labor, low-rise housing areas rapidly extended the urban periphery (Al Hathloul 1996). Studying the urbanity of Qatar and particularly Doha, would reveal the significance influence of proximity of the Gulf on the city growth pattern over the past decades. The city of Doha is the largest city and capital of the state of Qatar, and is located on the Persian Gulf. It has one of the fastest growing populations in the Arabic world (World Bank 2014). While the population of Doha was below 500 thousand just 20 years ago, it is now over 1.2 million and expected to continue rising at unprecedented rates. Even if we trace how Doha transformed from a traditional settlement to a cosmopolitan and global city, we can clearly identity the impact of the Gulf on the city morphology, roads development patter and growth directions. In other words, the urban growth dynamics of Doha were substantially relaying on the strong connection between city and water. The overall morphology of the city can also be seen as a reflection of the Gulf waterline geometry. Changes in the composition and configuration of urbanizing Doha were found due to the gradual growth respecting the genesis of the city's development; the Gulf.

Figure 2: The whole process of urban evolution in Doha, the Capital city of Qatar was based on the strong connection with water

2.2. Why Waterfronts are Significant to Qatar's Urban Future?

The Gulf and coastline assets are of great spiritual and cultural significance to the people of Qatar. As all the main cities in Qatar are basically coastal cities, planning for their sustainable future is crucial. All these coastal cities were and still represent the main centers of urbanization in the whole State. The growth of Qatari coastal cities population and the preference for living in coastal areas has resulted in their ever-increasing development. Coastal cities and waterfront areas are the most common destination, which brings in economic growth but implies additional urban development and increases the need for resources, infrastructure and services. Qatar went through different phases of dealing with waterfronts in the last decades. Most of the coastal cities were transformed from humble fishermen settlements to modern cities.

3. State of the Doha's Waterfronts in the Post-Oil Era

Historically a pearl-trading center, Doha has reinvented itself in just two decades into one of the world's busiest business, cultural and tourism centers. The Evolution of Doha's Waterfront if critically analyzed reveals profound conclusions about phases of development. The capital city Doha has witnessed a number of transformations after the discovery of oil. As per the waterfront, specific changes can be concluded as follows:

3.1. From a source of livelihood to a view.

One of the main transformations that can be observed in the post-oil era is the fact that the Gulf was not perceived any more as a source of livelihood. Fishing and pearl diving are no longer the back bone of the State's economic base. Hence, the Gulf's new value, particularly for hotels and real estate developers lies in its ability to provide stunning views for hotels' guests and residential towers dwellers.

*Figure 3: Doha's waterfront in the 1940s and **1960s**.*

Figure 4: **1990s**

3.2. The Port and the Market vs. the Glittery Towers

The post-oil era is also related to the domination of changing the image of the city so it can be easily related to global cities around the world. The waterfront which was historically distinguished with its vibrant port and lively market transformed into a setting for iconic development which constructs the new image of the city as a global urbanity. The result of such process resulted in the lining up of towers overlooking Doha Bay. Parallel to such aggressive development another form of urbanity can be observed. Considerable portions of the waterfront were designated to private entities primarily hotels, restaurants, resorts turning the enjoyment of the Gulf waterfront to private places. This privatization of the waterfront was accompanied with lack of interest in creating spaces for people and reestablishing the strong connection between the city, the community and the waterfront in Doha.

Figure 5: Doha's accelerating waterfront development in the last decade

4. Contextualizing the Waterfronts of Qatari Cities

In addition to Doha, the Capital city, Qatar's cities are all adjacent to water. The main reason can be understood once the urban history of each city is analyzed. All these cities are originally based on fishing or trade small ports. So every Qatari city overlooking the Gulf has its history but also acquired some architecture, urban, cultural and functional roles through the last few decades. Therefore, for planning the future development of Qatari cities' waterfronts, being informed about its history and current status is significant. The idea is using the personality, historical narrative, urban character and assets of every Qatari city to articulate its unique approach to waterfront development. For example if we compare between the other two cities following Doha in the ladder of Qatar's most important and populated cities, interesting conclusions would be revealed. In the case of Al Khor City/Municipality, the fishing port is the origin of the city. Al Khor city is located specifically on the East coast of Qatar, about fifty kilometers from Doha and come third in terms of population with its 200,000 inhabitants. The personality of the city now is weaved around a recreational role which needs to be elaborated and further explored. The future development of the city and particularly its waterfront should consider the city character, function and personality. Hence, invest more in developing the City and its waterfront as a holistic recreational development serving the community, the city and the whole country. The second important case is Al Wakrah City/Municipality. Al Wakrah, a city in Qatar is located south of Doha. The Eastern shore of Al Wakrah faces the Gulf. Originally fishing and pearling village, Al Wakrah has now evolved into a small city with a population of more than 300,000 inhabitants making it one of the largest cities in Qatar. The city has a strong history and evidences of the traditional architecture and urbanism of Qatar. It is also the location of the famous fort and traditional market. Hence, a focus on the historical heritage as a potential for developing the city's waterfront can be a key to its uniqueness within the Qatari context.

Figure 6: Partial attempts to develop parts of Al Wakrah waterfront as a manifestation of local heritage to attract tourism and serve the local community alike.

5. The Main Challenges of Waterfront Development in Qatar

For Qatar to develop its waterfronts and coastal cities in a sustainable manner, a number of challenges need to be confronted. As explained earlier, all the waterfronts and coastal cities in Qatar are part of the country's environmental assets and also contain the most significant urban and architectural heritage due to the fact that all traditional cities in Qatar were historically portal cities connecting Qatar with the rest of the world via trade and other economic activities. Here are the main challenges as prioritized to be confronted in any strategic planning aiming at developing waterfronts and coastal cities in Qatar.

5.1. Waterfronts as a Catalyst for Urban and Economic Development

To mitigate these problems it is necessary to consider coastal cities as dynamic complex systems which need energy, water, food and other resources in order to work and generate diverse activities, with the aim of offering a better socio-economic climate and quality of life. As a consequence, the integrated management and sustainable development of coastal cities is essential, with science, technology, architecture, socio-economics and planning, all contributing to provide support to decision makers. As stated in Qatar National Development Framework: “Although Qatar is a coastal nation, there is a significant under provision of recreational and leisure facilities in coastal locations for the community to enjoy". Qatar National Development Framework (QNDF).

5.2. Environmental Conservation.

The activities common to coastal cities and waterfronts areas require the development of well-planned and managed urban environments, not only for reasons of efficiency and economics, but also to avoid inflicting environmental degradation that causes the deterioration of natural resources, quality of life and human health. Preserving the environmental assets allocated along the extended Qatari coastline including mangrove trees. Qatar should learn from the negative consequences of water reclamation as it negatively affected marine ecosystems. Extensive coastal development in Dubai's artificial islands is a very illustrative example of such negative impact. Another important aspect in planning contemporary waterfronts is dealing with the future consequences of climate change.

Figure 7: The view over a few mangrove trees that grow on the shores of Qatar

5.3. Heritage Conservation.

The second main challenge in developing waterfronts and coastal cities in Qatar is heritage conservation. All the portal cities in Qatar from Doha to Al-Khor or Al-Shamal in the north or Al-Wakra in the south are sites for a valuable architectural and urban heritage. From the fabric of the traditional center of these cities to the unique vocabulary of architectural elements used in houses, mosques and majlises, conservation and preservation of such valuable and irreplaceable heritage should be a priority. Hence, the role of urban planning authorities in Qatar should be articulated around a more sensitive approach to waterfront development. An approach that will allow development and growth but more significantly acknowledge the importance of conserving the nation's heritage and preserve such valuable chapters of Qatar’s history.

5.4. Waterfronts in Qatar as Places for All

Many scholars in the field of urbanism, through their research, have highlighted the importance of the human dimension in urbanism (Jacobs, 1961; Gehl, 2013) and offered insights into systematically studying environmental behavior (Zeisel 2006) through international studies in public life (Whyte, 1980; Gehl, 2013). Studying public life offers immense insights to urban environment professionals by bringing users back into focus when they may be overlooked in design (Gehl, 2013). The expected outcomes could play an essential role in achieving the needs of the whole social spectrum that are considered as community members dwelling within Doha and other cities. People in Qatar could belong to any of the more than 150 nationalities that make Doha and other Qatari cities one of the world's most diverse places. Hence, waterfronts development in Qatar should speak to this diversified human mosaic and take their needs and aspiration into consideration.

6. The Role of the Urban Planning Department in Qatar: Towards an Integrated Coastal Zones Development

The Inevitability of Coastal Protection

Qatar coastline has come under increasing pressure as it continues to attract many new residents and visitors seeking the lifestyle and environment of coastal living. Planning for coastal communities must balance the need to provide jobs, housing, facilities and transport for a growing population while maintaining the coast's unique qualities. It was evident in Qatar National Development Framework (QNDF) that Qatar as a costal nation is not utilizing such a potential to the maximum level desired[1]. Qatar National Development Framework (QNDF) and the generated Qatar national Master plan acknowledged the lack of clear strategy to deal with the waterfront development and coastal growth. Hence, Interim Coastal Development Guidelines (ICDG) was developed with the determination to use it temporarily till the finalization of a comprehensive and integrated study dealing with Costal Zones Management. The main value of ICDG is to guide the assessment and approval of recreational, leisure, tourism and other forms of development and facilities proposed in coastal locations. Additionally, it directs public and private sector development to follow a clear set of development objectives, definitions and regulations to prevent the risk of environmental degradation in the Coastal Zones.

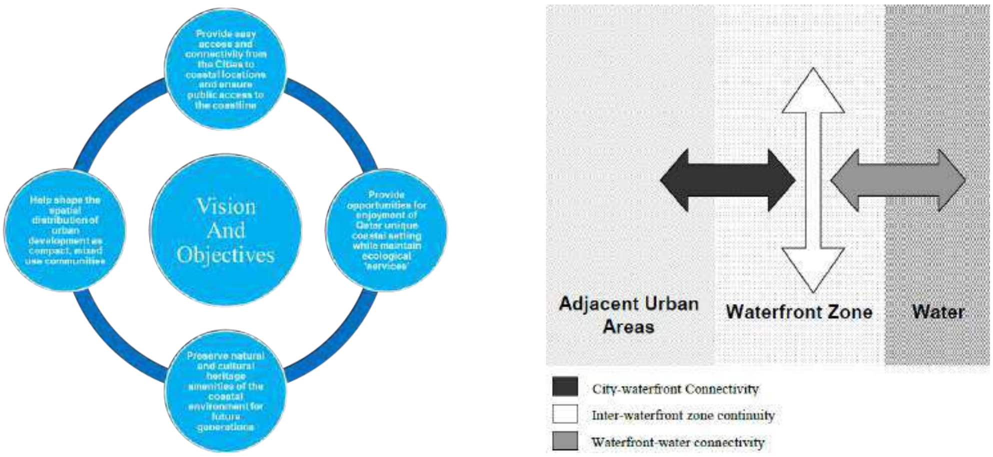

Figure 8: (Source: QNMP, ICZD)

Based on the coastal form of Qatar and the land use sensitivity analysis that has been undertaken and mapped, appropriate forms of land use and occupancy in the four major coastal zones have been identified. The Four Coastal Zone Types are Protected Areas and Aquifer Protection Zone, Developed Areas, Future Development Zone, and QP Jurisdiction Zone boundary and areas that have not been designated in the first the first three types. The third type or zone which is related to future development was also divided into three zones depending on the sensitivity of the development context. Hence, Classification of Future Development Zone was categorized as such The Future development zone with less environmental sensitivity, The Future development zone with medium environmental sensitivity and The Future development zone with high environmental sensitivity.

[1] QNDF has proposed the preparation of a comprehensive Integrated Coastal Zone Management Planning (ICZMP) to help manage and sustain the nation's valuable coastal assets.

Figure 9: The main promenade of Doha and the connected green public spaces.

Figure 10: The interaction between people and the waterfront along the city's active promenade.

7. Global Lessons: The Urban Value of Costal Development

The meaning of a city vibrant waterfront is centered on creating places for all people. Cities seek a waterfront that is a place of public enjoyment. They want a waterfront where there is ample visual and physical public access – all day, all year - to both the water and the land. Cities also want a waterfront that serves more than one purpose: they want it to be a place to work and to live, as well as a place to play. In other words, they want a place that contributes to the quality of life in all of its aspects – economic, social, and cultural". Remaking the Urban Waterfront, the Urban Land Institute (Seattle Department of Planning and Design, 2012)**.** In this section of the paper, a number of global case studies were analyzed in order to draw conclusions regarding the main features of positive and vibrant waterfronts. The selected case studies range from mega city like the Shanghai Bund Waterfront Redevelopment, the Northern Hong Kong Waterfront and Melbourne Waterfront Revitalization. The cases also include examples of small and medium scale interventions like the case of Aker Brygge Wharf, Oslo, Norway and the Cheonggyecheon River in Seoul, South Korea.

Figure 11: The best practice cases of the Shanghai Bund Waterfront Redevelopment and Melbourne Waterfront Revitalization respectively

The cases of Aker Brygge Wharf, Oslo and the Cheonggyecheon River, Seoul illustrated the value of small and medium scale interventions which aim to transform the city water potentials into a source of distinction and force to create new spatial experiences. In the two cases, the waterfronts were planned as social public spaces within the fabric of busy cities.

Particularly, the the Cheonggyecheon River development illustrated the importance of small act and big Impact approach. How the Cheonggyecheon River urban design restored the green heart of Seoul. The project is intended to create a green oasis in a concrete jungle. The large scale cases like The Northern Hong Kong and Waterfront Melbourne Waterfront Revitalization deal with the waterfront not only as a social and recreational edge to the city but rather as a center of holistic development which been infused through the whole waterfront and more significantly penetrated the depth of the city. These projects have been planned in light of a development framework which sees the waterfront as a catalyst for the whole city development. In the case of The Northern Hong Kong Waterfront, the refined urban design framework provides a coherent and legible structure of uses, building forms, open space and connectivity. It is built upon the waterfront promenade and four principal design corridors to create a sense of place.

8. Creating a Great waterfront: The Suggested Strategies
Planning Principles, Guidelines and Recommended Actions for Vibrant Waterfronts

This study involves an initial review of the literature on waterfront developments and urban sustainability to extract a comprehensive set of criteria that can be used to develop a vibrant, sustainable and successful waterfront (Macdonald, 2017; Andersson, 2018). Therefore, in this section, the lessons learned from the selected case studies in addition to the analysis of published literature on the new trends of planning waterfronts would construct the base for suggesting strategies, planning and design concepts which can guarantee the creation of create waterfronts. First of all, the importance of providing a diversity of attractions to create an all-time and all-season waterfront. Also, to provide a continuous waterfront promenade with an extensive greenery. The promenade as an extended spatial experience supported by green spaces would encourage social interactivity and sense of belonging to the waterfront. Such frequent usability can't be attained without allowing for public access and providing for environmentally friendly transport including green buses, bicycles, safe pedestrian routs and even effective water transportation. It was also documented that in all successful waterfronts, the main landmarks were integrated with the waterfront promenade to increase connectivity and vibrancy.

A social approach to urban waterfront regeneration is an important condition too as it will guarantee that the regeneration of the waterfront is actually speaking to all people without any form of rejection, discrimination or neglect. Such an inclusive approach would create bonds between people and place. The social approach to waterfront development would affect the decision making in the planning processes. The role of planners in public space planning is crucial but integrating the views of the community members is equally important. Hence, citizen participation in the planning and design process of any waterfront is not an option as waterfronts are one of the most social places and should by planned and designed by people and for people. Another crucial principle in planning waterfronts is to diversify uses and activities along the waterfront and within the coastal cities to include residential, commercial, cultural, institutional, and mixed uses connected with open and public spaces.

For a waterfront to succeed and attract people and enhance its city, a focus on quality and successful place making is highly recommended. Design-based waterfront developments should attain a number of qualities to accomplish positive planning process which would lead to vibrant and attractive waterfronts. More integrated spatial and planning patterns to guarantee the success of waterfronts can be crystalized as such:

8.1. Waterfront as a Sequence of Public Spaces
Begin by envisioning a network of well-connected, multi-use public spaces that fit with the community's shared goals. Waterfronts should be designed as a sequence of active and vibrant public spaces speaking to the whole city dwellers.

Figure 15: Waterfronts should be designed and planned as a number of connected positive public spaces

8.2. Public Goals are the Primary Objective
Waterfronts everywhere are too valuable to simply allow developers to dictate what happens there. . This is not to say that private development is unwelcome and should be discouraged – on the contrary, it is often necessary to the future of a healthy waterfront. But the best solutions for revamping waterfronts put public goals first, not private short-term financial objective. The viability of a waterfront development is also about how to balance public and private invest to be economically sustainable.

Figure 16: the needs of the different sectors and groups of the community are the primary objectives of a successful waterfront.

8.3. Build on Existing Assets & Context
After establishing the public spaces and public goals, begin the public visioning process with the existing assets and surrounding context. Therefore, it is wise to start small to make big changes. Placemaking is about doing more than planning. Many great plans get bogged down because they are too big, too expensive, and simply take too long to happen.

8.4. Create A Shared Community Vision
Unlike a master plan, a community visioning process does not lock a project into a prescribed solution. It is a citizen-driven initiative that outlines a set of goals--ideals to strive for--that set the stage for people to think boldly, make breakthroughs, and achieve new possibilities for their waterfront.

8.5. Create Multiple-Use Connected Destinations
Create a vibrant mixed-use community affordable and welcoming for all. The value of inserting popular destinations within the waterfront is to create a special place to draw people. The most effective way to propel a visioning process is to set a goal of creating a number of great destinations along a waterfront, an idea will guarantee extensive flow of people in different day times, seasons, weather and conditions. Such destinations along the waterfront should be connected to one another and incorporated into a vision for the waterfront as a whole. The connectivity between the selected and well planned destinations should be achieved via encouraging walkability and design the public realm which would encourage people to walk and reach the different destinations in safe and enjoyable manner. Link: Connect the city and the water. And provide multiple ways to get around and to reach the waterfront include transit, walking and cycling. Additional aspect in terms of suggesting uses for waterfront is to focus also on suggesting water uses. Activities like boating, sailing, fishing, swimming and other related activities add positively to the vibrancy and open up options for different users.

8.6. Open the site with accessible public spaces for all.
A vital dimension in developing waterfronts which would speck to the whole community is maximizing opportunities for public access. It is essential that the waterfront be accessible for everyone to the greatest extent possible. Therefore, facilitating access and enhancing linkage would enhance the overall quality of the development. Waterfronts should be seen as a manifestation of the democratization not privatization of public spaces.

8.7. Create a green, sustainable, innovative model community.
To balance environmental benefits with human needs, waterfront development should consider environmental assets and a healthy blend with it in order to produce a showcase of authentic sustainable development. While a wide variety of uses can flourish on a waterfront, many successful destinations embrace their natural surroundings by creating a close connection between human and natural needs.

8.8. Waterfront's Identity and Image.

Despite all functional aspects of a waterfront but it is also a platform to represent the identity of the city or the state. A waterfront also collectively would construct an image that can be literally printed in the minds of the dwellers or visitors alike. Therefore, the visual qualities of the waterfront is significant as it can be a representation and manifestation of identity and responsible for the city image.

9. Conclusions and Recommendations

Qatar should acknowledge that waterfronts, the unique places where land and water meet, are a finite resource, embodying the special history and character of each city. Qatar's approach towards developing its extended waterfronts should be holistic, comprehensive and sustainable. The suggested urban planning principles, patterns, guidelines and actions are tools to ensure that all coastal cities in Qatar exploit its relation with water in a way which would serve people, attract tourism and promote diversified economic routs. Doha and all Qatari cities should perceive the blessing of being developed along the waterfront as a great potential for a more sustainable and livable urbanism. Towards Looking at the urbanization of Doha and other Qatari cities, waterfronts can act as a medium to achieve City/Waterfront interaction. The urbanity of Qatar needs more effort towards connectivity and continuity. The connections, corridors and vibrant green streets towards the waterfront act as the city veins facilitating the coastal development to connect with the inner parts of the city. Hence, the successful waterfront acts as an interface to connect and link the city with its surrounding waterbody. It's possible that Qatar may end up getting a sparkling, successful new waterfront districts that draws in tourists from the world's four corners. In order to strengthen the waterfront's coherence and connection, this paper pays special attention to the design of waterfronts, ensuring that promenades are maintained as pedestrian and cyclists-friendly zones. But the suggested approach implies a different definition of target groups. A definition which gives priority for the local community and hence calls for a balanced urbanism, community participation and a public and private partnership. Developing waterfronts in Qatar can be seen as physical manifestation of the memory of place. Qatar architectural and urban heritage conservation within Qatari waterfronts commemorates history while creating a new legacy.

A comparison of the utility of urban strategies for small towns: The Cases of Lobatse and Arandis

Simbarashe Hope CHITAPI, South Africa

Synopsis: This paper compares the urban strategies put forward by two small towns in decline. Each town, although somewhat remote is within 100km of a significantly larger town. The paper assesses the plans' resilience and sustainability response, scores utility and implementatibility and proposing an improvement for future strategy formulation processes.

1 Introduction

It seems obvious that that the purpose of planning is to put the plan into action. As the increasingly popular 6 Ps adage goes, Proper prior planning prevents poor performance. Completely unexpectedly, this adage alludes to something that urban planning has long failed at: performance. In a sense, planning too often misses the very reason for its existence. At some point planning must stop and implementation begin.

However, planners have consistently demonstrated a "curious lack of interest in developing methods to evaluate how successfully plans are implemented" and focusing instead on hypothetical assessments of the impacts of alternative proposed plans (Talen, 1996, p. 248). The nett effect is that planning has increasing become a 'tick box' exercise with no real ability to implement. This failure to implement has been a barrier to effective planning so long that it was coined "new plan syndrome" (Calkins, 1979), a term which describes the phenomenon where plans are updated and/or redone with no regard of the extent to which the previous plan (or plans) were executed; it is easier to simply ignore the what come before and to try to conjure a new plan.

But planning "is only defensible as an activity if it [is carried out in the belief] that it will deliver a future that is '*better*'[i] than that which would result without [it]" (Campbell and Marshall, 2008, p. 476 emphasis added). Planning is therefore inherently optimistic and a good plan is necessarily aspirational and transformational without being merely a pipedream: It must be implementable. But how do we know if a plan is even implementable within the specific context? In the small-town context, capacity and governance are the key considerations and as such are the lens through which each of the abovementioned focus areas are viewed.

Implementation evaluation can happen at least two distinct stages: Before implementation (i.e. the planning process) or during/after policy implementation (i.e. the plan implementation) (Talen, 1996). This paper intervenes at the level of the plan itself discussing ways to test a plan's 'implementability' even before the implantation phase—the argument being that only evaluating plan implementation ex post facto is somewhat redundant (although certainly not fruitless). Hence, this attempt to examine 'implementability' rather than the implementation. The premise is that if a plan's implementation is defined and measured in terms of performance (conformance), then the plan itself—specifically its implementability—has an important impact on successful implementation (Tian and Shen, 2011, p. 13).

Thus, the question of plan quality arises: What is a "good" plan? 'Is a plan with high implementation conformance a good one?' (Tian and Shen, 2011, p. 13) or should the substantive contents be examined. Believing that the substantive contents are critical, this paper attempts to address both content quality—with a focus on sustainability and resilience—and implementability. It considers four integration (cross-cutting) themes that impact a town's 'spatial functioning':

- Economic development
- Quality of urban environment
- Optimisation of land use
- Sustainable urban infrastructure

This paper is then a policy evaluation in that it applies evaluation principles and methods to examine the content of urban policy (plans) in a rudimentary attempt to understand the merit, worth, and utility the plan.

2 Approach

The approach is guided by the Centers (sic) for Disease Control and Prevention (CDC) Framework for Evaluation in Public Health (regular implementation reviews are commonplace in the health sector). The Framework outlines an ongoing process comprising six steps for policy evaluation throughout the policy lifecycle from problem identification to policy implementation (Figure 2).

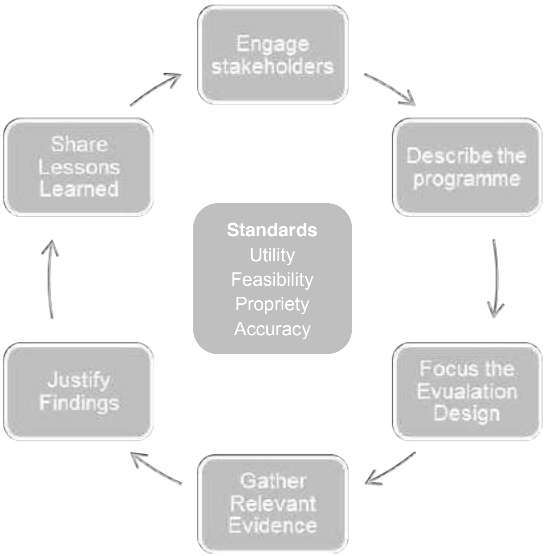

Figure 1: Six-step Policy Evaluation Process
(Adapted from: CDC, 2012a)

This paper constitutes an initial analysis and does not exhaustively adopt the Framework. It does however, follow most of the basic steps. Figure 2 shows the policy lifecycle highlighting the sections which is applicable to this paper.

Figure 2: Policy Development Phases and Types of Evaluation
(Adapted from: CDC, 2012a)

The remainder of the paper is structured as follows: The third section discusses theoretical perspective on the terminology, specifically sustainability, resilience and small towns. Section four determines the evaluation framework. The case study analyses are presented in section five, comprising an assessment of the representations of economic development, quality of urban environment, optimisation of land use, urban infrastructure from a sustainability and resilience perspective. The last part sums up the discussion and proposes next steps which would give the research more relevance.

3 Context and Terminology

The theme of rapid urbanisation is ever present in planning literature and popular culture today. (United Nations figures support this showing that much of about 2/3 of the world's population will be urban in 2050 (UNDESA, 2014). However, much of the discourse focuses on so-called megacities and too often forgotten in the narrative of urbanisation are the myriad of small towns despite the fact that more than 50% of the urban population live in urban areas with under 500,000 inhabitants (UNDESA, 2012). Indeed, even in a completely urbanised world is that there will be many small towns, fewer larger cities and only a few megacities (Batty, 2015 citing Cristelli *et al.*, 2012). So, cities will continue to be the dominant human settlement "regardless of whether the fact is considered positive or negative" (Vaništa Lazarević *et al.*, 2018, p. 1130).

In particular, Sub-Saharan Africa's urbanity is dominated by towns of fewer than 500,000 residents with 26% of such settlements inhabited by fewer than 50,000 people (Tacoli and Agergaard, 2017). Arandis and Lobatse are towns in this latter category with respective populations of about 8,500 and 27,000, respectively. Each is also located in a relatively arid climate zones and need to consider sustainable and resilient development.

The concepts of sustainability and resilience feature prominently in the Sustainable Development Goals (SDGs) particularly through SDG11*: Make cities and human settlements inclusive, safe, resilient and sustainable*. Both Namibia (Arandis) and Botswana (Lobatse) have committed to the integration and implementation of the SDGs.

Each town is located about 80 km from larger, more significant town, Gaborone and Swakopmund, respectively. This location, while somewhat remote is also sufficiently proximate for the pull factors of the larger cities to cause significant decline. Particularly in the developing world, the flow of people to large(r) urban centres has a double negative nett effect—it decreases the quality of service delivery in the receiving centres and decreases the viability of the sending settlement. In the case of these two towns, only Lobatse has suffered depopulation decreasing from about 29,000 in 2011 (LTC, 2018). Meanwhile, Arandis has struggled to attract investment despite a population growth rate of about 10% (RUL, 2018).

Thus, in the "no [place] is left behind" spirit of the SDGs', this paper investigates the regeneration efforts of these two small towns.

3.1 Small town

While 'small town' has no specific definition per se, the most fundamental definitions are based on population size with the United Nations smallest population category being urban agglomerations with "less than 50,000" (UNDESA, 2012). However, population alone is problematic since urban hierarchies vary across the world (Bell and Jayne, 2009). A town's "'cityness', [physical] smallness, 'third-tierness', 'localness'" would be a more justifiable basis for its 'small town' status (Fahmi *et al.*, 2014, p. 2). Thus, the relative importance of a city within its own (country's or region's) urban hierarchy should be of greater relevance rather than its absolute population.

Segueing from this is the economic importance of a settlement. Small towns (however defined) tend to have small, unvaried economies. Economic diversification and development strategies typically fail from an absence of economies of scale. Still, these towns often play an important role serving as service centres which both stimulate and support rural and hinterland economies. In particular cases, small towns are sometimes thought to blur the undefined line between urban and rural since they often include significant agricultural activities (Fahmi *et al.*, 2014).

Accordingly, this paper considers a small town as a tertiary city (in its own countries context) with less than 50,000 inhabitants with a relatively one-dimensional economy. Small towns can be grouped in two categories: those within (relative proximity to) a larger (mega) urban region and those within rural regions (Prabatmodjo, 1993). This this paper deals the former.

3.2 Sustainability

The term "sustainability" implies indefinite continuance and as such is a logical goal of human settlements. *Our Common Future* (also known as the Brundtland report) defines sustainability as "meeting the needs of the present without compromising the ability of future generations to meet their own needs" (WCED, 1987). Some criticise this 'classic' definition for "[resting] heavily on the dubious assumptions of limits to growth" (Bruegmann, 2008, p. 148) since it supposes that the resources used in the future will be those used today. However, it may well be this very prudence that makes the definition so apt. At the same time, this simplistic eschatological conception of sustainability belies the scientific reality[ii] that "'sustainable' cannot mean 'forever'". Moreover, it is immeasurable and reliant on an impossible capacity to bequeath utility on future generations (Daly, 2002, p. 40).

The utility-based[iii] *Our Common Future* definition must therefore be augmented by a more immediate impetus. But, utility as a basis encourages frugal consumption—use less—while throughput is the impetus for efficiency—use wisely. "'Frugality first'…, induces efficiency as a secondary consequence [while] 'efficiency first' does not induce frugality—it makes frugality less necessary" (Daly, 2006, p. 11). Both frugality and efficiency are valid, necessary and inextricable. Thus, this paper looks at sustainability through both the frugality and efficiency lenses and expects strategies to demonstrate an appreciation for cyclical resource flows.

However, sustainable urban development entails more than just environmental concerns and must also focus on economic viability, physical liveability and social equity. The fifth dimension is political sustainability—which will be called governance here (Pieterse, 2011). It holds the sustainability puzzle together and without a focus on governance sustainability, realising urban sustainability becomes that much harder.

3.3 Resilience

Resilience is a related but distinct concept which, has gained traction in urban discourse since the 2008 (economic) crisis, is sometimes used (wrongly) in place of sustainability (Vaništa Lazarević *et al.*, 2018). As climate change increases the frequency and intensity of natural disaster, resilience becomes a more important goal for cities. Resilience asks how well a place can “absorb the presence of an organism or activity” using the health concepts of “immunity and recovery” (Neuman, 2005, p. 18). It has both preventative and reparative dimensions.

Resilience is the capacity to recover quickly from difficulties. The Rockefeller Foundation’s 100 Resilient Cities movement defines urban resilience as “the capacity of individuals, communities, institutions, businesses, and systems within a city to survive, adapt, and grow no matter what kinds of chronic stresses and acute shocks they experience” (Rockefeller Foundation-RF, no date). Most definitions capture this sense of an urban areas ability to withstand both immediate and forecast multi-hazard threats. They tend—more so than the definitions of sustainability—to highlight the individual citizen’s role in constructing and maintaining urban resilience. Resilience, in contradistinction to sustainability, seem to have a more obvious focus on both short- and long-term futures of urban systems (Vaništa Lazarević *et al.*, 2018).

4 Evaluation Framework

Before articulating the evaluation framework, it is important to reiterate the purpose of the evaluation (CDC, 2012a). The aim of this evaluation is two-fold: To establish whether the plan aligns with the targets of SDG 11 and determine the extent to which each town’s strategy embodies sustainability and resilience principles. Effectively, it seeks to see whether the plan is implementation-worthy. Secondly, it seeks to determine whether the policy is implementable—that is whether there is enough guidance so those responsible for it will be able to put it into action.

To this end, specific evaluation questions were identified. Ideally this is done in the policy drafting phase to ensure quality outcome (CDC, 2012b). The following are some policy content evaluation questions used in this evaluation framework (CDC, 2012c):

- Does the policy clearly state the goals or objectives?
- Are the components of the policy consistent with those of model policies?
- Which major stakeholders played a role in the policy’s development?

The evaluation has two stages. The Utility Assessment tests the plans inclusion of principles of sustainability and levels. It further assesses the expected outworking of these by comparing the number of projects planned in each SDG category. The Feasibility Assessment considers the implementability of the plan asking questions about implementation guidance.

4.1 Utility Assessment: Resilience and Sustainability

SDG Goal 11 is developed into ten targets. For this paper’s analysis, these are customised to a small-town level and their assigned to one (or more) of the four focuses of this paper—viz. economic development, quality of urban environment, optimisation of land use and sustainable infrastructure Table 1.

Table 1: Customisation of the SDGs Targets to Small Town Setting with the associated Focuses indicated

No.	10 Targets to Achieve resilient and sustainable cities	Principles within a small-town setting	Applicable focuses
1.	By 2030, ensure access for all to adequate, safe and affordable housing and basic services and upgrade slums	**Housing**: Density that allows increased usage of infrastructure, makes public spaces viable and limits new infrastructure requirements	Economic Development Quality of Urban Environments Optimisation of Land Use
2.	By 2030, provide access to safe, affordable, accessible and sustainable transport systems for all, improving road safety, notably by expanding public transport, with special attention to the needs of those in vulnerable situations, women, children, persons with disabilities and older persons	**Transport**: Support for non-motorised transport (NMT). Linked to land use with a focus on vulnerable people groups	Economic Development Quality of Urban Environments Sustainable Urban Infrastructure
3.	By 2030, enhance inclusive and sustainable urbanization and capacity for participatory, integrated and sustainable human settlement planning and management in all countries	**Participatory Planning**: Adoption of structures that promote citizen inclusion in urban planning and management	Quality of Urban Environments Governance
4.	Strengthen efforts to protect and safeguard the world's cultural and natural heritage	**Heritage**: Promotion and protection of cultural and natural heritage in town's spaces	Quality of Urban Environments Governance
5.	By 2030, significantly reduce the number of deaths and the number of people affected and substantially decrease the direct economic losses relative to global gross domestic product caused by disasters, including water-related disasters, with a focus on protecting the poor and people in vulnerable situations	**Disaster Mitigation**: Development disaster management protocols and mitigate risks through nature-based design and preparedness	Economic Development Quality of Urban Environments Optimisation of Land Use Governance
6.	By 2030, reduce the adverse per capita environmental impact of cities, including by paying special attention to air quality and municipal and other waste management	**Quality Environment**: Focus on cyclic economy and incorporate environmentally regenerative design	Quality of Urban Environments Sustainable Urban Infrastructure
7.	By 2030, provide universal access to safe, inclusive and accessible, green and public spaces, in particular for women and children, older persons and persons with disabilities	**Public Open Space**: Design varied open spaces *networks* that are safe for and accessible to vulnerable people groups	Quality of Urban Environments Optimisation of Land Use Sustainable Urban Infrastructure
8.	Support positive economic, social and environmental links between urban, peri-urban and rural areas by strengthening national and	**Rural-Urban Rapport**: Support rural activity with associated urban functions	Economic Development

	regional development planning		
9.	By 2020, substantially increase the number of cities and human settlements adopting and implementing integrated policies and plans towards inclusion, resource efficiency, mitigation and adaptation to climate change, resilience to disasters, and develop and implement, in line with the Sendai Framework for Disaster Risk Reduction 2015-2030, holistic disaster risk management at all levels	**Urban Governance**: Openness to greater citizen participation by embracing digital platforms, flexible, transparent and consultative decision making	Optimisation of Land Use Sustainable Urban Infrastructure Governance
10.	Support least developed countries, including through financial and technical assistance, in building sustainable and resilient buildings utilizing local materials	**Genius Locii**: Booting local economy by using local / traditional designs, techniques and materials	Economic Development Sustainable Urban Infrastructure Governance

4.2 Feasibility Assessment: Implementability

The feasibility assessment is a series of questions focused on the process, content and guidance offered by each strategy. Since this paper advocates reflection, this assessment includes questions about the previous plan(s). It also attempts to assess the plans flexibility since strict adherence to (the specifics of) the plan is not always useful in a dynamic environment (Tian and Shen, 2011). Adherence to the spirit of the plan (if not the letter of it) is important. It questions the extent to which planners can adjust the plan. This assessment of the implementer's agency further demonstrates the need to assess implementability in the first place.

5 Analysis

The case study compares two towns: Arandis is a small mining town in the Erongo Region of western Namibia and Lobatse, a small—although significantly larger than Arandis—town in the South-East District of southern Botswana.

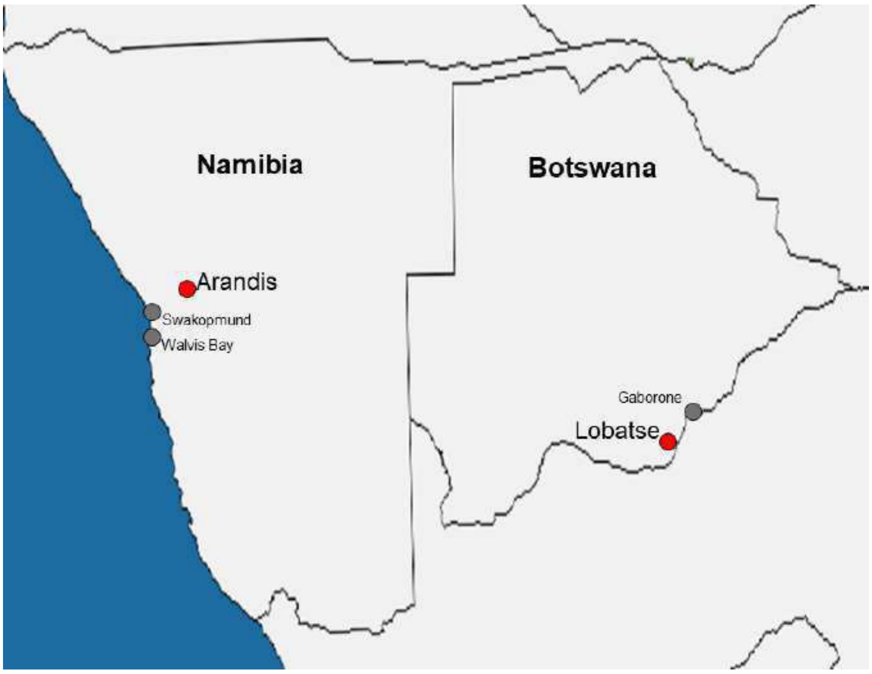

Figure 3: Location of Arandis and Lobatse

The principal reason for the choice of these two towns is the author's familiarity with them. However, the comparison may still be warranted as each is a small town in decline which has put forward strategies to stimulate regeneration. Both are somewhat remote being within 80km of significantly larger urban agglomerations so are susceptible to urban degeneration. Both towns have arid climates and are vulnerable to climate change hence the paper's focus on resilience and sustainability. Additionally, as small towns in proximity to larger urban centres, each town reports capacity constraints particularly with respect to urban management and planning and often seek consultant's assistance with strategy development. Hence this paper also seeks to assess whether the inputs of said consultants are conveyed in an implementable manner. The towns have similarities and some noteworthy differences (although these have not been calibrated for) (Table 2).

Table 2: Key similarities and differences between Arandis and Lobatse

		Arandis	**Lobatse**
Similarities	Proximity to larger settlement	60km from the Walvis Bay-Swakopmund urban agglomeration. These touristic and logistics towns are the country's second and third largest respectively.	75km from Gaborone, the country's largest city and economic and political capital.
	Climate	Hot and arid	Hot and arid
	Political / Administrative Classification	Phase 2 municipality (receives direct financial support from national government)	Receives funding from national government
	Regional impact	Mining activity impacts the town which is very susceptible to resource price fluctuations	Border proximity along SA-Namibia corridor. Some cattle rearing and other agriculture in the area around the town.
Diff	Population	8,500	27,000
	History and	A young town proclaimed in 1994 after	The area of Lobatse has been settled

national relevance	formation as a mining settlement in 1978 for Rössing Uranium Limited employees. It ranks about 25th in Namibia in terms of population.	since the 18th century. Considered around independence as a candidate to be the nation's new capital, Lobatse is seat of the judicial system ranks about 13th in population size in Botswana.
Economy	Single industry: Mining	- Main industry: Beef. - Country's largest concentration of agro-based industries - Limited manufacturing
Climate	Desert with mean annual rainfall of about 45mm and mean annual temperature of 19°C.	Semi-arid with about 550mm mean annual rainfall and mean annual temperature of 20°C.

5.1 Utility Assessment

The following analysis tests if and how the principles of sustainability and resilience are embedded into urban strategies. It seeks occurrences of the terms focusing on parts of the plan where the objectives, vision, aims and conceptual approaches are expounded among others. Terms related to sustainability included *green*, *renewable*, *recycle*, *cyclic*, *reduce*, *efficiency* and variations thereof. Terms related to resilience included *resilient*, *prepared*, *adaptive*, *flexible*. It is followed by an assessment the extent to which the projects in the strategies reflect the SDGs.

Table 3: Instances of Terms Related to Sustainability in the Arandis and Lobatse Urban Strategies

		Sustainable	Green	Renewable	Recycle	Reduce	Efficiency
LOBATSE		Principles; projects; development; regeneration	—	—	—	—	—

5.2 Feasibility Assessment

Table 5: Feasibility Assessment

		Arandis		**Lobatse**	
		Comment	Score	Comment	Score
Contents	**Does the policy clearly state the goals or objectives?**	**Yes**. One of the main objectives of the council is to gain economic independence from the mining activities—i.e. economic resilience. The strategy then outlines thirteen strategic objectives defined within four Strategic Themes, namely cultural capital, community service excellence, stakeholder relations and financial sustainability.	1.0	**Yes**. It seeks to provide the implementers and investors with a quality plan for participatory regeneration of the town focusing on specific precincts. It further provides an implementation framework for Lobatse regeneration efforts.	1.0
	Does the plan highlight its alignment to higher policies?	**Yes**. The strategy reports alignment to Namibia's Vision 2030 and National Development Plan (NDP) 4 (since superseded by NDP5). It further aims to develop a marketing and tourism strategy aligned to the Erongo Regional Tourism Plan. It fails to indicate alignment to the Erongo Region's Strategic Plan and its principal themes of socio-economic development, operational efficiency, good governance despite alignment thereto.	0.75	**Yes**. The plan forms part of the overarching Lobatse Development Plan (2000 - 2024). While any other alignment can be inferred (through its association with the Lobatse Development Plan (2000 - 2024), it fails to specifically indicate alignment such plans.	0.75

Process / Ownership	**Which major stakeholders played a role in the policy's development?**	The strategy was prepared by Council with the support of consultants. However, inputs from other stakeholders were limited.	0.75	The plan was developed by private consultants with regular inputs from Lobatse Town Council and the Department of Town & Country Planning within the Ministry of Land Management, Water and Sanitation Services.	0.5
	Is there any analysis of the previous plans and/or the implementation of such plans?	**No**. The strategy only mentions other sector strategies e.g. LED Strategy (2009) which were current at the time of drafting and which should also be consulted when reading the strategy. Curiously it barely references most these again. Neither does it indicate that it is the first such document.	0.25	**No**. It mentions an older development plan, Lobatse Urban Development Plan (2003 - 2009), but makes no attempt to assess the implementation of this nor any other plan.	0
	Are the implications of such plans (and the assessment of their implementation) for the current plan indicated?	**N/A** (The above was not done well.)	0	**N/A** (The above was not done well.)	0
Implementation guidance	**How flexible is the plan?**	The strategy is flexible in as much as it does not have budget for all its projects. However, it fails to indicate alternative scenarios to help implementers rationalise.	0.5	At times, the plan presents some alternative scenarios and their implications which give implementers good information should they chose / need to deviate.	0.75
	Are the requirements (pre-requisites) for implementation clearly stated in the policy?	Not always. At the project level, the strategy indicates some requirements as "Assumptions and risks". Throughout, it mentions some requirements currently lacking but stops short of clearly identifying general implementation pre-requisites.	0.5	Prerequisites are not specifically presented but the plan indicates that infrastructure upgrades will be required (to stimulate private development) and suggests that special funding be put in place to that end.	0.25
	Are the requirements feasible given available resources? If not, does the policy present a rectification / amelioration action?	The requirements listed are often "availability of funds" and hence it's is difficult to definitively indicate feasibility. As a Phase II town, the Council is dependent on national government.	0.5	The requirements although not specifically listed will likely include funding. Having received budget cuts in recent years from national government, difficult to definitively indicate feasibility. However, the plan calls for some specialist design and capacity may not exist locally.	0.5
	Does the Strategy culminate in projects – that is specific	The strategy presents forty-three strategic initiatives/projects for implementation of over its five-year period. The projects are time-bound with high-level financial requirements indicated	0.75	The presents several projects for each precinct. The projects are not time-bound nor is any attempt to give high-level indicative costs made. Although	0.5

interventions which are **a. Time bound** **b. Budgeted** **c. Prioritised** **d. Geolocated (as required)?**	and where relevant, located. There are not prioritised.		not all prioritised, the plan does give some strategic interventions which should be prioritised for regeneration.	
Does the policy assign responsibility to appropriate implementing and/or monitoring actors?	**Yes**. Each of the strategic initiatives/projects has an associated responsible entity. However, it is explicitly clear who is responsible for **monitoring** implementation progress.	0.75	**Yes**. Each of the strategic precinct has specific intervention high-level actions for the realisation of its projects. Each action has an associated responsible entity. However, the plan only gives a generic overview of monitoring and evaluation indicating that independent evaluators should assess three key evaluation processes (i) at the beginning of the project to establish existing situation; (ii) during implementation and (iii) at the end of the project by external.	0.5
Does the policy articulate the mechanism for monitoring implementation ?	The ATC Strategic Scorecard reflects that the organisation needs to implement, manage and report quarterly on twenty-six (26) Performance Indicators / Measure within the thirteen strategic objectives. It further gives the reporting baseline so that those monitoring have a sense can get a trend immediately.	0.75	**No**.	0
Does the policy identify indicators for assessing program success?	Yes. At the project level, the strategy's scorecard has targets and completion dates for projects.	1.0	**No**.	0
Is there any mention of costing? Where the funds will come from? How to seek funding? And what are the financial operational and maintenance implications?	Yes. Reflected in the ATC Scorecard, is a resource requirement estimate per strategic initiative/project budget across the strategy's horizon. It doesn't propose funding sources or financing mechanisms.	0.5	The plan makes no attempt to cost interventions. It does however highlight the need for a budgeting process to mobilise funding from both private sector and government finances to implement the regeneration plan. Further, it proposes a special fund for all infrastructure and catalytic projects as well as the annual budgets that deal with operational issues. It suggests that a "certain amount be allocated annually (development	0.5

			and re-current) over the next 10 years for the implementation of the Lobatse Regeneration Plan. This budget should include funds for sectoral strategies and detailed design that is essential spur implementation.”	
SCORE (x/11)	**ARANDIS TOTAL**	**8.0 (62%)**	**LOBATSE TOTAL**	**5.25 (40%)**

6 Discussion

This two-step utility analysis of the development urban strategies of Arandis and Lobatse indicate that sustainability is a well-understood concept which features prominently even in small town plans. Resilience, on the other hand is a relatively new concept and is still being adopted into the lexicon and is yet to be embedded broadly into the strategies.

The analysis showed that the most frequently used terms are the sustainability and resilience (and variations) which appear in both strategies. Sustainability features across each of the four integration areas (economic development, quality of urban environments, land use and urban infrastructure) and governance. Associated terms appear less frequently. The Arandis strategy scores poorly with less than 50% the frequency of instances of sustainability (as associated terms) as in the Lobatse strategy.

Resilience and its associated terms, are mentioned significantly fewer times in both strategies. In the Arandis strategy, there were only three instances—across governance and urban infrastructure—while the Lobatse strategy associated resilience with all five integration areas.

The second step in the analysis assessed the conversion of the concepts as expressed in the SDGs into concrete projects. Here exposed the gap between the concepts and their application. In the case of Arandis fewer than 50% of projects clearly express the principles. It must be noted, however that the strategy has several governance-focused projects which align with the sustainability and resilience principles of the SDGs. Lobatse’s strategy fairs significantly better with in the 72% of projects clearly expressing the principles. However, the plan has only one governance-focused project. It is noted with concern that neither town’s strategy makes any mention whatsoever of disaster mitigation and preparedness.

The feasibility analysis indicates that both strategies are well constructed indicating their purpose clearly and aligning themselves to plans on higher levels. However, their scores are mediocre with regards process/ownership. Moreover, each plan perpetuates “new plan syndrome” with no evidence of having consulted, much less assessed the implementation of previous plans.

Overall, the Arandis plan emerges as the more implementable plan. It contains in part all the elements that offer guidance to implementers including an indication of financial requirements, timeframes, pre-requisites and project-specific monitoring and evaluation.

7 Concluding and further remarks

This paper has shown that in the case of small towns, sustainability and resilience are concepts that are not fully embedded in urban strategy. Resilience in particular, has yet to gain traction. It further showed that there is at times a disconnect between the discourse in the strategy and how it manifests as projects. This is especially true for supranational goals and targets which find little expression in the town's projects.

Still, Lobatse's plan emerges as superior with regards to its embedding sustainability and resilience, particularly sustainability. However, from an implementation perspective, Arandis' strategy seems more likely to be implementable. It quantifies time and money and offers measures to monitor progress.

It becomes difficult then to determine which is a good plan—the one that reads well or the one that can be implemented well? In the context of under capacitated municipal officials, it is interesting to note that Arandis' strategy was developed in closer association with the Council which may be a lesson to improve future plan's implementability. The more aspirational/transformational plan was developed by consultants with limited Council involvement. Perhaps a closer association is required to bring aspiration and implementable to a convergence.

This paper was primarily a desktop exercise with minimal engagement with either town's official. The next step is to test the assessment with the implementers (i.e. council officials) to determine whether they feel it is useful as a sort of rubric to assess the work of future consultants (or indeed their own). A following step will be to review in the medium- to long-term whether the implementability index line up with implementation in reality?

Acknowledgements

This paper was done following two projects done by Aurecon South Africa (Pty) Ltd in each of the subject towns. These allowed the author access to information that would otherwise have been difficult to obtain. Furthermore, Aurecon sponsored presentation of this paper.

---

[i] But, for whom must the future be better? That there are scales of better. But in all cases, "better" should represent good value and benefit particularly for the poor. In other words, better refers to a Just City.

[ii] According to the Second Law of Thermodynamics, the entropy of the universe tends to a maximum. In other words, the universe must end and thus nothing can be sustained indefinitely.

[iii] Utility reminds us that societal actions – regardless of intention – can reverberate through time. We are experiencing this today with global warming.

Territory and urban planning: perceptive studies over the south border of the city of Buenos Aires, Argentina

Jennifer Ailen CHOI, Laura CORBALAN VIERO, Mitchell DE SOUSA, Rocío DI CORRADO, Analía FERNANDEZ.
Department of Research on Science and Technology, Faculty of Architecture, Design and Urbanism. University of Buenos Aires. Argentina.

1. Introduction

The city of Buenos Aires and its agglomeration concentrates thirty percent of the Argentine population. (INDEC, 2010) Historically, the political governments focused all the equipment, investment, progress on the north of the city, the place where all the financial, core services, and the main country harbor is. The south part of the town and all the cities around it has been, where lies the most urgent vital unfulfilled needs of the population. The river Matanza-Riachuelo that cross over the urban agglomeration of Buenos Aires, has been significantly a place of urban segregation for being located in the south area of the main town. Since the post-colonial times, the river has been officially a place that separates the jurisdiction of the city of Buenos Aires with some of the towns that were built around the urban agglomeration.

Since its place has never been treated as a whole and has always been treated as a boundary, there is always been a focus for factories to dispose its waste and an attractive place for a large portion of the underclasses to settled down there, occupying illegally the previous terrains that were once from the railway, now abandoned. In addition, the population that inhabits the south side of this limit has few accesses to enter the Capital, with very few points of contact between both margins. This situation frequently generates collapses in public or private vehicular traffic, due to the need to access the area with the greatest range of services found in the capital area. Beyond all the problems listed, the high levels of contamination that the river has make it one of the most critical in the world. (Alonso, 2018) Thus, the inhabitants of the aforementioned settlements fight for their rights of use and appropriation of space, while the State demands intervention in the urban coast, constituting one of the most promising discussions in this urban sector. (Gruschetsky, 2011)

Knowing all of the effects of urban troubles in places of boundaries, it is undebatable that a more species concern of what happens at the local level of population should be done. Urban management until recently does not know how to handle territorially this kinds of places and even by using countless tools for intervention on these they fail to correctly trigger the main concerns. The issue regarding this failure is that they keep on developing the same strategies by the same diagnostic studies and without knowing that such tools are dated or not precise the troubles around those areas will be worsened by time. (Brenner, Marcuse, Mayer, 2017:99)

The study presented here focuses on the perception of those who lives in this boundary through interviews and collective experiences and is a part of a more developed project in the University of Buenos Aires study called URBAN LANDSCAPE AND SUSTAINABLE INTERDESIGN: Guidelines and strategies for landscape interventions in border areas of the city.

The main objective of this work is to propose a methodology of diagnosis on urban territories in a low degree of scale, by the pedestrian view of the city, using the commonly labeled concept of participatory mapping (Diez Tetamanti, 2016) and developing a distinguished theoretical approach to landscape studies on urban areas: The landscape units (Choi, Corbalán, De Sousa, Di Corrado, Larumbe Araujo, 2018). This methodology was developed in order to study places within cities that are surrounded by edges (Lynch, 1960) and/or boundaries (Arriaga Rodriguez, 2012), such as the limits between neighborhoods or cities. We have found that this methodology in development is way more precise and effective for the study of particular scales and cases in the territory rather than the convenied simplistic morphologic ways of studying the territory which is yet an overused trend on urban management policies.

The following paper will show the detailed development and the results of the undergoing work around the stated methodology. To do so, the first part of it will be focused on the theoretical approaches surrounding the main component of it which is the concept of Landscape Units. A representative concept currently developed by the research team that structures the main potential axis for this new methodology. It is by studying and itemizing them in the territory that the process of identifying the particular troublesome areas is more pertinent.

The second part of it will be focused on the methodology of how these Landscape units were detected on the particular case of study and how they were represented. As well, how these are applied into the territory by the inhabitants of it by the use of surveys, audiovisual methods and so on. In the last part, there will be the results of the applied methodology with some successful mapped places in a proposal to counteract the raised hypothesis of the research work.

2. Theoretical Approach

To define some of the further points, it is important to remark our views on the idea of scale. We share the view of the concept of scale as scalar configurations, as Erik Swyngedouw defines: “I conceive scalar configurations as the outcome of socio-spatial processes that regulate and organise social power relations. As a geographical construction, scales become arenas around which socio-spatial power choreographies are enacted and performed” (Swyngedouw, 1997). It is important to note, though, that most of this theoretical support is mostly based on urban landscape areas rather than rural ones.

We rescued the idea of edges from Kevins Lynch and considering the described scale that we studied as a low degree socio territorial scale where these edges are most easy to identify: “Edges are the linear elements not used or considered as paths by the observer. They are boundaries between two phases, linear breaks in continuity: shores, railroad cuts, edges of development, walls. (...) These edge elements, although probably not as dominant as paths, are for many people important organizing features, particularly in the role of holding together generalized areas, as in the outline of a city by water or wall” (Lynch, 1960: 46). Lynch's took for granted the idea of scale which is one huge criticism that the spatial territorial studies gave on him but considering the precision of studying the territories, this idea of edge seems relevant considering this scale of study.

In addition, we differentiate the idea of edges with the one of boundary, sharing the concept that defines Arriaga Rodriguez on “frontier or boundary” as “absolute place” and as a “socially built place” (Arriaga Rodriguez, 2016) being the last one of the elements that will support the idea of Landscape Units. This idea of boundary as an absolute place is how we usually undermine those places that are separated interjurisdictional by the imposing forces of the core elemental powers. “its physical existence is independent from the social phenomenons that happens, since it only answers by its own natural law. The geographic place is transformed by the human action, only by its appearance but not from its essence. (...) the “absolute place” is a mere holder of objects, humans and social activities and the social activities are precisely the main used element to differentiate, classify the geographic space.” As Arraiga Rodriguez says, the commonly imposed boundaries of this “absolute place” is one of the potential issues surrounding segmentation, fragmentation and tension between the social activities that surrounds them.

As the discipline that we are currently working on is mostly based on the main links between the landscape studies, cultural geography and urban areas most of the conceptual basis will be related to these subjects, even though it is deeply influenced by a lot of interdisciplinary areas which is the main key to understand how cities work as a whole (Graham and Marvin, 2001: 33). By that, the central conceptual focus on this work, the Landscape Units, is a very debatable tool currently on development but with some really effective appliance onto territorial crops. Then in this sense, we will follow up to define four of the main core concepts surrounding this idea:

First, the Lynch´s idea about the imaginability of the City “That quality in a physical object which gives it a high probability of evoking a strong image in any given observer. It is that shape, color, or arrangement which facilitates the making of vividly identified, powerfully structured, highly useful mental images of the environment”. (Lynch, 1960: 9) These useful mental images that Lynch evoke in such quote refers to the association of the vividly spaces that people has in their territories. It is a proper tool to define common aspects of the cities that are heavily influenced by the subjectivity of those who remarks the landscape of the cities that they live within.

Second, the idea of cultural landscape which is a theoretical construction that decant over the landscape that we perceive are read by the symbols, meanings and customs each society built over the territory. (Corbalán, Kestelman, Tella, 2018) Such landscapes are not unchangeable, they are constantly converting and it is mostly the local population that modifies, represents and permanently generates new territories that signifies individualized landscape units with their own features. We perceive, understand and build the landscape through the filter of culture.

Then, the relevance on studying landscape by the perspective of urban infrastructures. Specially, Infrastructure Networks. which are the bundle of materially networked, mediating infrastructures. These landscape units aren't statical and they are heavily influenced by the urban intervention of political actions, as well as the own actions of the community. Yet the infrastructure that supplies the commonly shaped community that live within (transportation, water, etc) affects the dynamics of the flows and settlement of the population. (Graham and Marvin, 2001: 10)

Finally, boundaries as “socially built place” such as Juan Carlos Arriaga Rodriguez defines it and inspired by the thesis of David Harvey (Harvey, 1977: 3-6): “This conception of boundary it is an space that could be explained by the production of those who organizes it, by the dominate action and the power that has place and by the representations of which the subjects that lives and also the groups that has the political and economic power to transform it. Boundaries are the fragment of a bigger space -the territory- that has been structured by social relations of dominant production.” (Arriaga Rodriguez, 2012) This is a pretty important concept to understand the boundaries that are drawn by the detection of landscape units. Territorial crops by social dynamics have boundaries even without being as strong as the already defined “absolute place”. Social interactions are constantly building new ways to reproduce themselves in their territory, yet there is a range of such even if they aren't statical. Our proposition by drawing the limits of these landscape units has to do with the common territorial perception that people have in them even if one or two has a wider spread of their territorial belonging.

The Landscape Units are places from the territory characterized by the combination of different elements from diverse sources such as nature, cultural, perspective, symbolic and that recognizes its territorialities that differ them from the other places around essentially beyond the interjurisdictional boundaries and edges (Choi, Corbalán, De Sousa, Di Corrado, Larumbe Araujo, 2018).

3. Methodology and Appliance

Applying such idea into the territory takes the detection and the representation of these Landscape Units which are usually labeled and recognized by four main components that we suggest: the urban structure, the citizen participation, the perceptual or participatory mapping and the environmental images.

For the analysis of the urban structure, we use three definitions of such and we make a comparison between them. Firstly, the arrangement of land use in urban areas by official zoning planning and then, the real usage of the land. Since most of the featured work are in cities with very low regulation it is pretty necessary to do a heavy focused research onto the second point. Such research is usually made by observation or interviews on the field work but it was also made by analysing their conditions on satelital programs. The way of representation of such analysis is basically comparing those two kind of urban structures to identify those places where the informality is way more rounded, and whether that comprises a big territorial dimension it can be identified by itself as a Landscape Unit as well as for those places that are essentially respectful with the official arrangement of land use. As for the last definition, we also study the historical rehearsal of the territory. Understanding how things were settled we tie up the four core concepts that defines the landscape units. This is crucial for building them since most of them are a result from the whereabouts of how the settlement was initially made, how the first population used the land and finally how the main cores of power managed it afterwards. From this point we could detect the potential landscape units and draw a intenting map as an ad-hoc hypothesis of how they could be shaped.

The second step is to apply such potential landscape units into territory by gathering enough participation of the people from the different detected units. Such work focuses on interviewing them by asking sensitive aspects of what they feel regarding the environment that they usually live in their routine. Some of course aren't regular visitors of the places but our focus are mostly those who their reproductive practices are within these places. Once finished we followed up on translating those perceptions and comparing them with the Ad-Hoc landscape units that we made “abstractally” before. Then, we calibrate the subtle differences between these new landscape units maps with the Ad-hoc ones, essentially the spread of the boundaries, or if there is any huge contradiction we would return to the first step to analyse those particularities and so on until we have a more precise map.

The third and final step is participatory mapping and environmental images respectively. The main reason to understand simultaneously both ideas is that they are very similar in execution. Basically it consists on interviewing specific persons from this landscape units with a more severe detailed and try to construct alongside them maps using the references of the imageneabilities ones from Kevin Lynch (Lynch, 1960: 20). After that, we proceed to do something similar by other means of representation such as short films, collages, etc. Indeed we can convey the hard processed information into a more accessible one. It is a way to express the feelings that are associated with these landscape units by representation to other persons. Whether it is effective or not, in terms of social communication, it is yet a nice resource to pull of territorial mapping by other ways aside of the morphologic and geographical one.

By following these steps, we are still developing this alternative methodology tool on urban studies. Even though there is quite a lot that is taken for granted, the idea of this resource is to be used as a complement to other territorial studies. The next step to polish it would be to cross other social statistics to this sensitive representation. It could open a lot of opportunities to think why this landscape units were settled historically and infrastructurally in the first place.

4. The case of study: Nueva Pompeya (City of Buenos Aires) and Valentin Alsina (Lanus) and the appliance of the developed methodology.

Figure 1: Map of Buenos Aires and its agglomerations. Highlighted in black is the Riachuelos River and the two main municipalities where the cases of study are located. Source: Geographic National Institute

The localization of this troublesome area is in the south part of the Buenos Aires City and in the north of the southest part of the Metropolitan area, they are different jurisdictions and on the type of government as well as for the distributed budget by their local centralized management. In the Autonomous City of Buenos Aires, Nueva Pompeya is just a neighborhood within an extensive area of administration while at the other side, Valentin Alsina is a city within a set of cities. Hence, both jurisdictions in every aspect are completely different. Interestingly enough, since the beginning of the settlement of the old harbour in the basin of the Riachuelos River (which is the river that divides both jurisdictions and also the city of Buenos Aires with the rest of the territory) it has been always a place of boundary, as an “absolute place”.

Yet, the main reason of choosing this case of study in particular were two aspects: firstly as a place of boundary by itself and how the river is overlooked by being a place that divides the population. This river, the Riachuelos river has a huge historical fluctuation of treatment by local authorities but in particular by this tense area since it is today the most conflictive part of most of the basin. Secondly, the heterogenization of the qualities of both sides of the river. How this place is looked and associated as pretty different despite being in the same metropolitan area (which it isn't actually truth) and how the connection through the river is just subtle and unison.

This urban river has a huge attach with the development of the country as a whole and in particular with the first growth of the metropolitan Area. Also, it was used back in the first twenty years in the beginning of the twentieth century as a channel of harbor. Simultaneously it was also the place where part of the first railway areas were settled and so the first industries of the country. Altogether the border of the basin in both banks was already, in the beginning of the republic, a place that separated the main capital city with the rest of the country (Gorelik, Silvestri, 1991). Graciela Silvestri, an historian from Argentina, divided the Riachuelo in three different sectors by its actual condition and its historical rehearsal: the first one as the La Boca neighborhood that despite being also a marginalized place there is a huge identity attached to it related to the Tango and the historical harbour; the sector of Villa Lugano and Lomas de Zamora where the project of canalization of the Riachuelo was successfully made and the sector that comprehends the two localities of our case of study, which is a place of historical unfulfiness: “this sector is instead unknown to the inhabitants of the formal city. it constituted an unity of action from a technical point of view for the channeling companies that tried its modification (of the Riachuelo). The inefficiency of these interventions are evident in the territory: the riverbanks continue without being transformed, the abandonment of both shores is in line with works that were never completed.It was a thriving sector at the time of installation of the factories in the country, especially the metallurgical. The building nowadays are ruins from those undertakings. The misery that at the beginning of the century is condensed in the puddles of the dump, multiplies today in informal settlements.” (Silvestri, 2004; 30) It is, however one of the main focus of fluxes of all the metropolitan area of Buenos Aires since it has one of the three bridges of all the river that connect the main city with the south region. By virtue of that, it is clearly remarkable the variety of services of public transportation, the overwhelming automobile traffic and the railroad connections.

After this background it is clearly that the choice of this landmark is mostly based on the urgence of building up an identity that it is mostly obscured by the adjacent landscape identities of this sector. Such imprint will be cleared when applied the methodology already explained before.

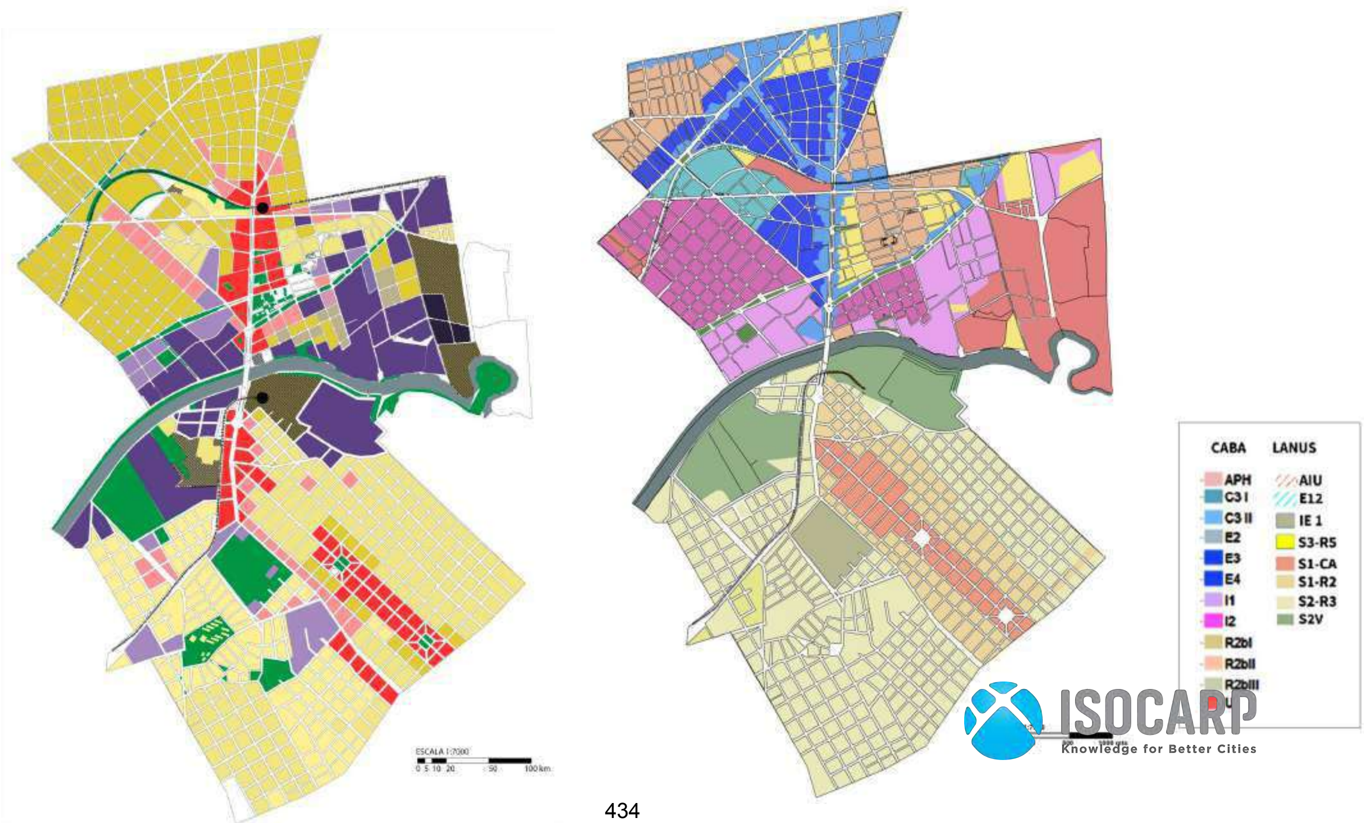

Figure 2 and 3: Cropped territorial fragments of the south axis Nueva Pompeya (City of Buenos Aires) and Valentin Alsina (Buenos Aires Agglomeration) showing the zoning areas (at the right) against the real usage of the land (at the left). It is interesting to see how there is a chromatic diversity from one to another. That means how the usage of the land are mostly illegal on the edge of both places.

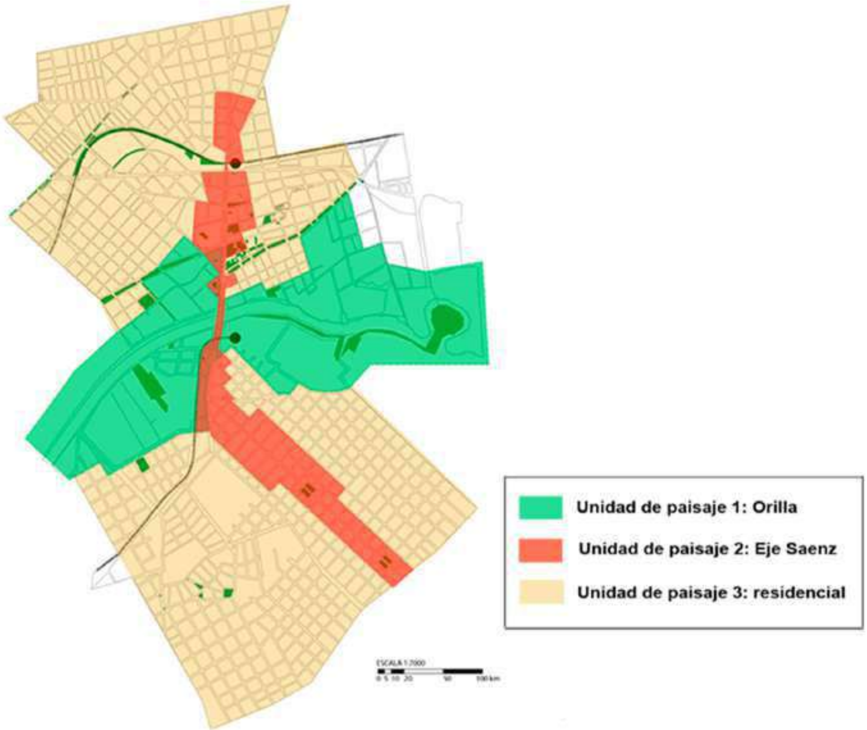

Figure 4. Landscape units detected on the border of the Riachuelo River. South region of Buenos Aires. Source: Urban border mapping: Riachuelo, City and fluxes. Perception of three landscape units in the limit of Nueva Pompeya (CABA) and Valentin Alsina (GBA). (Choi, Corbalán, De Sousa, Di Corrado, Larumbe Araujo, 2017).

Considering the appliance and the comparison between both urban structure (the land uses and the real usage, figure 2 and 3). It is clear to see that the contradictions are pretty evident. While there is a pretty loyal respond to the zoning plan code as it spreads away from the banks, it is evident that the most informal areas are the ones over the shores, as expected. The City of Buenos Aires has a way more diversified zoning meanings which is way more flexible on these kind of places, however the old sites of the abandoned railway system as being a place of uncertain jurisdiction and the illegal occupation within it remains as an huge remnants on the planning code. Synthetically, the cities jurisdiction doesn't know how to handle the growth of this urban issue aside of the fact that most of the people there are informal settlers.

As it can be seen in the figure 4, after the analysis of the factors exposed we have detected three landscape units. The first one related with those who lives by the shores of the river (in green), the second in the commercial corridor (in red) and third the residential homogenous area which both sides share also very strong similarities despite being two different places.

As for the first landscape unit, being both jurisdictions divided and without knowing by the administrative scope of the territory on the Riachuelo, these boundary areas are treated as remnants. However, both shores in the real usage have very strong similarities, mixed with old and new industrial sites that covers quite a big area but with very few constructed space, whether they are new or not. There is an important flux of heavy transport circulation parallel to the river attached to this industrial features. At the same time, it is a place of huge residential profile since in both sides of the banks beneath these industrial sites. There are two slums: Villa Zavaleta in Buenos Aires city and Villa 8 in Alsina, Buenos Aires Province. They are mostly occupying the contradictory site of the railway, as it was explained previously. We have determined that all this common issue with this place, both in political administrative terms and in terms of actual use, allowed us to designate them as a proper landscape unit.

As for the other two that we have made a presumption were: firstly, the mixed usage corridor (in red, figures 2 and 3) through the only bridge of the place (Puente Alsina Bridge). Being one of the few access to Buenos Aires from the south, there is a huge amount of public services as well as a huge corridor for individual transportation. It is a predominantly places of fluxes where most of the commerces depends highly on the intermodal transshipment and also serves as a centrality to people in their surroundings. It is also a place of huge variety of characteristics in the urban structure and it is mostly well respected between the two. As we assumed that most people that reproduce their economies in this place aren't settlers we identify this place as a different landscape unit which, the Riachuelo, is overlooked as a boundary. Finally, the remnant mostly residential with few local commercial sector that has a very homogenous profile in terms of urban structure. It is the place where the urban structure is mostly equivalent and it is usually witnessed by settlers and neighbors of these neighborhoods.

Once the representative work is made, sensitive surveys are carried out to the inhabitants of the detected Landscape Units. This talks represents a recompilation of narrative accounts and heterogeneity of interviews. Allowing one to corroborate the confirmation of Landscape Units Ad-Hoc and to detect also Landscape subunits inside them by the interviews of the key actors. In the case of the study it was a intended, we have identified three kind of inhabitants with three different conceptions surrounding where they usually gather and where they avoid. Essentially, a great deal of the local population were somewhat disappointed with the low permeability that the neighborhood has. For the residential landscape usually their own territorial perception was indeed way self-centered, mostly their reproductions were mostly associated with the neighborhood so a great deal of the subjects that were discussed were more about the problems within the neighborhood, how most of the people avoid going to the slums and how the Riachuelo was a place that was highly influential by the people that lived in the slum (Corbalan, Kestelman, Tella, 2017). Yet, as for the workers of some of the industrial sites and the slums inhabitants in both side they share a common view of the Riachuelo as place of potential subsitency although their reproductions were also territorial, their attachment with their settlements in the first case and the struggle for the right of the city in the second case turned the discussion to be extra-territorial instead of the mentioned Landscape unit. Both don't feel like they belong there even if both have two completely different reasons. However, the shared view of the Riachuelo was enough to break up the common association of this river as a boundary as an absolute place and be a potential tool to give them a place to struggle their rights. One of the gathering interviews with one of the inhabbitants of the slum of the referencing Landscape Unit says in a nostalgic tone that what they could do if the Riachuelo was a usable river for their subsistence “It would have been a great place for living, it would allow us to fish, it would give us food and navigation, anyway…" (Corbalán, De Sousa, Kestelman, Tella 2017: 10).

As for the landscape unit surrounding the accessibility, most of the inhabitants took for granted a big deals of problems of the sector in particular. Most of the workers, the biggest set of the population that we have interviewed, stated that they didn't live near their place of work and that they take the opportunity of the massive influx of people to make a profit out of it. Most of them does avoid places that aren't landscapelly moved. As soon as some doesn't hear a horn or can't see any bus they immediately think that they aren't allowed to be there. To most people the residential area is a set for an uncanny place and knowing that slums are nearby most think that it has direct relation with criminality (Cargnelutti, 2016).

Figure 5. Some footages of the video of different landscape units and the interview with Mario (Inhabbitant of Landscape Unit 1 - Environmental images. Source: https://youtu.be/K70M6c-Q1B0. (Corbalán, De Sousa, Kestelman, Tella, 2017)

This allows one to corroborate the confirmation of Landscape Units Ad-Hoc and to detect also Landscape subunits inside the Landscape Units by the interviews of the actors. Finally we usually use methods of representation, in this case we have used audiovisual productions as a methodology of narrative reconstruction of the landscape: method that allowed us to achieve a common agreement between what was interpreted by the research team and what was represented and the reception of all common questioners. (Jean Nogué, 2014: 15). The next step was, from the construction of this narrative tales around landscape and the finally shaped identified landscape units we have realized a short video with some footages of the commonly associated landscapes of each one of the units. As well, we decided to gather three interviews that represented the most accurate in the common representation of these. This video allowed us to do the final step of this diagnosis which is participatory mapping. In this final step we built, alongside at least this three character, the perceptive social maps , translated by Lynch's representation.

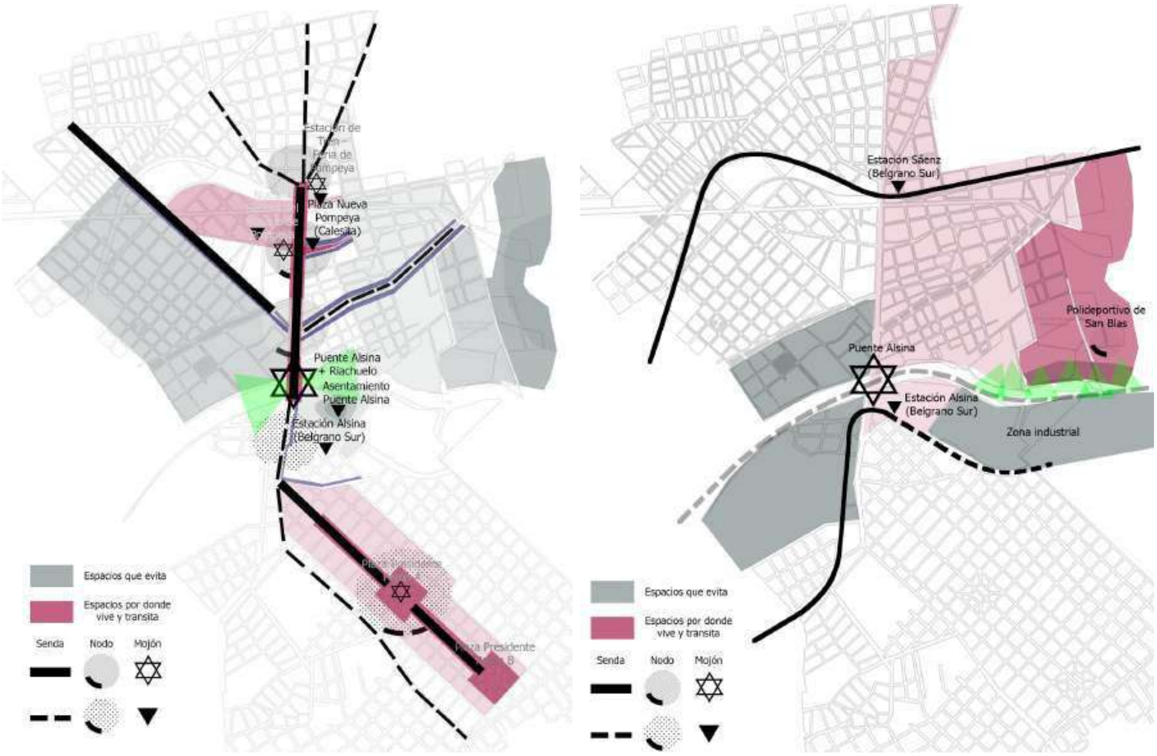

Figure 6 and 7. Perceptive maps from Judith (Landscape Unit 2) and Mario (Landscape Unit 1). The references are based on the imagineability maps from Kevin Lynch (1960). We have added two new factors though, a different grades of places (in grey) that the person in particular does not go because he or she doesn't feel comfortable going to and a pink of which are the places where the person usually goes. Source: Urban border mapping: Riachuelo, City and fluxes. Perception of three landscape units in the limit of Nueva Pompeya (CABA) and Valentin Alsina (GBA). (Choi, Corbalán, De Sousa, Di Corrado, Larumbe Araujo, 2017)..

Conclusion

After explaining our methodology of detection and verifying the landscape units, we undertand that the traditional way of planning it is, usually, based on jurisdictional boundaries to decide and intervene in the territory. Nevertheless, the landscape units as a theoretical construction extrapole those edges and it is successful for creating more complex diagnosis that encompass social problems, economical fluxes, environmental pollution, not only enclosed by a mere jurisdictional area. These landscape units, likewise, turn out to be more dynamic and in constant changes when they are analysed from the collective image of the city and the landscape perception of border.

As stated before, this potential tool should also be treated as a complimentary resource on urban diagnosis. By crossing over hard information of the territory with a more perceptive way, the results are quite precise and more meaningful. Although the steps of this way of study takes a lot of social parameters for granted, it should also reach all kind of interdisciplinary disciplines to continue nourishing the proposed contents.

The following procedure regarding the analysis of territorial frames in places of border proved to be pretty successful on showing more layers of complexity. The daily perceptive landscape of these "Landscape units" of the inhabitants of different parts of the neighborhoods has a more strong bond within themselves rather than with the neighborhood that it is conveniently shaped on.

The success of this diagnostic methodological development demonstrated the validity of studying the territories from the scale of the “landscape units” defined by the identification of the people who inhabit them instead of analyzing them from their official delimitations.

In this context, it would be desirable that this concept arrived can be incorporated in the analysis of future plans of different urban sectors of our country in order to plan cities for they own inhabitants. After all, knowing what people feel towards the environment they belong to is giving the rights of the city to their people.

S.O.S. – Sustainable Open Solutions to climate waterfront

(Insert the Title of your Presentation Here. Do NOT use uppercase letters only)

Pedro Ressano GARCIA, Ana Claudia OLIVEIRA, Laboratory Experimental of Architecture and Urbanism (LEAU) and Lusofona University,Lisbon,Portugal

1. Abstract

Climate change became a fascinating subject to the urban environment. Our scope is to develop a research network, associating architecture schools, urban research laboratories, local authorities and NGOs on architectural solutions to deal with the problem of the consequences of climate change, more focused on Waterfront Cities. Today, and worldwide, are already many entities working directly on issues related to the effects of extreme swings in the climatic conditions. So, why is it urgent to share, systematize and upgrade knowledge on the subject?

The effect of climate change is increasing at an abnormal rhythm which demands adaptation and transformation of vulnerable territories. In the last years, many projects were interrupted when they faced strong opposition coming either from public opinion, the media or lawsuits. Project proposals seem to address sensitive cultural values and consequently meet years of discussion, only to be put aside eventually. Such difficulties bring a loss of competitiveness on all sides, as well as decreasing quality of life for their citizens. The anterior information represents a problem within the European Community. Data related to historical and geographic records of specific waterfronts are used to construct patterns of development, feed algorithms and integrate the support of artificial intelligence to design possible future scenarios. To face the future challenges in managing, adapting and mitigating the effect brought by the increasing number of disasters, Lusofona University ULHT/LEAU has been cooperating with ten partners, from Portugal, The Netherlands, Italy, Greece, Poland and Sweden to share their best practices, including research on waterfront projects that merge equipment as well as public spaces and infrastructures, to produce and disseminate solutions, that enhance resilience. The research is carried out by four schools of architecture and urban planning, and entities working together with the worldwide market. The final result aims to produce Sustainable Operative Solutions.

S.O.S. waterfront mission is to develop affordable research environment and efficient operational tools between educational and non-academic partners by creating a Doctorate Consortium's to face the effects of climate change. The aim is to make use of the existing strategic network to enhance the research carried on in the field of urban waterfronts.

The main question folds upon the need to distinguish our study and show the added value of our project directly with some initial assumptions. The network has the objective to research in different scales such as:

1) Solutions for urban planning (the vast territory),
2) Solutions for urban projects (in a scale of the district or smaller urban facade),
3) Solutions for public spaces,
4) Architectural solutions at the building level,
5) The contribution of new technologies (warning devices or other) and
6) "Social" solutions (organization of the affected populations).

The research network reinforces the dynamic partnerships and increase the quality and technology innovations of the research, to design tools, to face the growing costs imposed by disasters. S.O.S. Climate Waterfront aims to bring excellence in research to a higher level and to improve its international position. To reach excellence requires the call for (1)

interdisciplinary and international research case studies, (2) steady sustainable research structure, (3) dissemination and open access of knowledge covered by different cultures, sciences and communities in each location.

The problem affects the citizens, the environment, and the local economy. Municipalities, stakeholders, Port Authorities and local communities are involved. Some projects that succeed in conquering public support and integrating the signs of the collective identity are included in the research. Climate change solutions can only be successful in ensuring a resilient city if they also engage citizens, educating them about climate change challenges, solutions, and fostering possible changes in lifestyles. The Doctorate Consortium is building up trans-national collaborative events with local Municipalities to produce solutions needed for waterfront cities to face climate change. The research project is supported by a Marie Skłodowska Curie Action, MSCA Grant.

2. Introduction

Urban waterfronts are facing new challenges when dealing with climate change. The problem affects the citizens, the environment and the local economy. Municipalities, stakeholders, Port Authorities and local communities often disagree upon their own needs. S.O.S. – Sustainable Open Solutions for European urban waterfronts aims to develop new solutions that emerge from the present necessities. Why is it urgent to share, systematize and upgrade knowledge on the subject?
The effect of climate change is increasing at an unprecedented rhythm which demands adaptation and transformation of vulnerable territories. In the last years a number of projects were interrupted when they faced strong opposition coming either from public opinion, the media and/or lawsuits. Projects seem to address sensitive cultural values and consequently face years of discussion, only to be put aside eventually. Such difficulties bring a loss of competitiveness on all sides, as well as decreasing quality of life for their citizens thus representing a problem within the European Community. To mitigate climate change impacts, several solutions have been proposed to reduce greenhouse gas emissions, including modern efficient energy alternatives and enhancing the use of sustainable energy sources (HASAN*, [et al.]*, 2018).
The creation of data on the waterfront uses historic and geographic records of specific locations to construct patterns of development, feed algorithms and integrate the support of artificial intelligence to design future possible scenarios. S.O.S. Climate Waterfront project gathers ten partners from Portugal, The Netherlands, Italy, Greece, Poland and Sweden to share their best practices, including research on waterfront projects that merge equipment's as well as public spaces and infrastructures, projects that succeed in conquering public support and integrating the signs of the collective identity. Climate change solutions are more successful when ensuring resilient urban environments. To achieve results are expected to engage citizens, educating them about climate change challenges and solutions, and fostering possible changes in lifestyles.
Transnational examples and the exchange of best practices benefit from special conditions not available in a single city or a single institution. Local experts, municipal representatives, stakeholders and international scholars are requested to work together, exchanging views, gaining new perspectives and discussing new interdisciplinary approaches, expanding and raising the level of the discussion, creating a think tank. The fundamental changes that are expected to take place in the climate system in the next decades are likely to have severe implications for the stability of the financial system (DAFERMOS*, [et al.]*, 2018).
Through an interdisciplinary methodology, the S.O.S. Climate Waterfront fills the gap in the understanding of how the different scales of urban and landscape planning, architectural design and technology are linked in water-related strategies and how they impact each other in the definition of preventive action plans and in the enhancement of

more conscious solutions to inform the community, human welfare and socio-economic activities along those vulnerable territorial settings of the waterfront.

3. Emergency at the waterfront

Nourishing a structured and necessary transfer of know-how and technology at several levels gives the research team to take excellence in research to the next move, enhancing a better position in the national and international research scenario. The relation between climate change and its potential effects on the stability of slopes remains an open issue (PALAZZI*, [et al.]*, 2018).
Improving the innovative nature of research towards a higher quality to reach excellence the research team focus on the urban waterfront to better prepare them to face the challenges posed by climate change. To achieve this, a steady and interdisciplinary research agenda is required, including environmental issues, smart technologies, strategies of resilience in urban design and culture. To reverse the vulnerability of urban waterfront researchers, accomplish skills and know-how towards advancing knowledge and insights on how to produce strategies; by formulating cross international and interdisciplinary solutions for the future.
European urban waterfronts are a subject of growing impact upon the citizens and businesses in terms of economic competitiveness and environmental quality. Sustainable open solutions are in the center of the debate of waterfront searching for resilient strategies in the context of difficulties stemming from environmental constrains brought by climate change. Waterfront brings together a number of different topics since it relates two different worlds: land and water. From the side of the water there are maritime transportation requirements, natural ecosystems, the necessary reduction of carbon emission, control levels of pollution and sensitive ecological areas. In land, the community, stakeholders and political leaders depend on solutions that require the collaboration of different fields of knowledge; physical, economic and social (MELLO, 2002). The community's quality of life, the environmental improvement and the increasing use of renewable energies are often in conflict with the necessary changes.
SOS Climate waterfront combines two strands of vibrant analyses—waterfront research and disaster studies. To examine specific examples of modern urban waterfronts reactions to the disaster and the disruption of urban structures and buildings. To envision how local, regional, national and international actors, both public and private collaborate to mitigate risks and enhance the resistance to face disasters.
The research project is developed from two approaches:
1) Develop research strategies aiming at designing policies and recommendations to meet the needs of urban waterfronts regarding public spaces, water management and selecting European best practices, to introduce researchers in public design and participatory processes on the transformation of waterfronts. The parameters that influence the transformation of the waterfront are shared with others to implement meaningful tools to deal with the production of future scenarios that integrate environmental, social, economic parameters to visualize and that encourage the community towards more participation in decision-making.
2) Develop new means of research based on historic records, geographic data, digital-methods and co-creation with local scholars to engage them actively in research activities (co-research approach). Additionally, the collected data is used to increase the identification of patterns of previous urban development on the waterfront. To visualize future progression of waterfront, depends on the development of the software produced by the team members. The new software identifies patterns of development in the past to predict future scenarios and include parameters directly related to climate change. The hypothesis produced for the future transformation of waterfronts is capable of engaging municipality representatives and especially technical staff to play a noteworthy

role and envision decision-making in the urban agenda.
The novelty of the approach is to overcome the problems that affect urban waterfronts and join efforts of specialists from different disciplines that have a recognized expertise in the subject and develop complementary research in the field of climatic transformation. The vulnerability of the waterfront and the variety of implications require a method of synthesis and to process similar situations that the present institutions do separately, the project demands an active knowledge and know-how exchange among all partners solving specific problems that emerge from each waterfront, via direct and broad discussion between experts:

Objective 1: Recognize gaps in current research, namely at geographical, historical, cultural, political and climatic among partners, to develop approaches for better understanding and enhance systematic means to relate people to the waterfront.
Objective 2: Introduce experienced researchers to foster collaboration and provide a platform where communities, public spaces and technology is addressed, based on new research fields, new forms of collaboration and new networks.
Objective 3: Upgrade the research group through enabling a stronger networking between its research staff and European top researchers.
Objective 4: Progress the cross-fertilization and interaction between researchers from different institutions and with expertise in different fields.
Objective 5: Supply structured opportunities for developing scientific and personal relations, among and beyond the Project.
Objective 6: Provide the involvement of relevant stakeholders, and the dissemination of results to scientific, academic, practitioners and policy-makers at all levels (EU, national, regional and local), media and the general public.
Objective 7: Distribute know-how on aspects of humanities-led, collaborative sustainable urban development and new insights in order to improve urban and social policies.
Objective 8: Promote the exploitation of advancements and Project results.

3.1 State of the Art

Sea level rise, high tides, storms and floods enhance the vulnerability of urban waterfront territories. The necessary transformations face years of discussions and/or lawsuits involving significant losses and costs, before cities adapting to change and effectively adapt waterfronts to climate change. Resilience is transformative and in each transformation, tries to create a stronger, improved city (YAMAGATA, 2018). In the recent years, most research projects have included regional and municipality representatives and they have highlighted the importance of thinking beyond regulations to face the present challenges. The alternative thinking or so called "out of the box", brings the risk to open the Pandora box with all the problems involved.

Cross sectorial and interdisciplinary solutions are successful if dealing with conflict existing in every process of transformation in an environment free from current administrative procedures. However, for the future, waterfronts will need to formulate lasting solutions efficient and imaginative strategies. The necessity to create more resilient cities, increase livable public spaces, promote urban natural environments and support a sustainable urban waterfront is expected to improve healthier communities.
The necessary changes do not represent a problem. Transformation does not by definition compromise resilience. Quite the opposite, according to the Principal Researcher at the National Institute for Environmental Studies in Japan: Resilience is not a static state of a system. It is a process. A city is dynamic and is always changing. (…) Resilience is transformative, and in each transformation, tries to create a stronger, improved city's (YAMAGATA, 2018) that is, resilience itself can be understood as change. According to the United Nations Development Programme the concept of

human development is used in all research actions thus focusing on people, their skills and opportunities rather than depending only on resources or profitable income. The main goal is to expand the realm of possibilities so that urban waterfronts can adapt, transform, develop skills and opportunities to be meaningful areas for the community. It goes therefore beyond economic features, and into reflect cultural, political, environmental and social, characteristics that influence the quality of human life in the context of climate transformation. Planning a waterfront development, require the city officials or a developer to start by envisioning a network of well-connected multi-use public spaces that fit with the community's shared goals (MOSTAFA, 2017).

One of the central challenges is how commit with citizens and waterfront territories where opportunities for educating cities can be offered for everyone. It is directly linked with equality, sustainability inclusiveness cohesion and education for peace. Educative cities promote, policies and democracy, integrated and lifelong learning education based on knowledge on how modern cities recover from disasters (CAMPANELLA, 2005).

The research project is in line with the European Commission proposal for increasing climate-related expenditure. Since 2010 EWWUD (GARCIA, 2017) has produced research, published five books and exhibited results, considering that it is strategically important for waterfront investment to be climate-resilient.

3.2 novelty inter/ multidisciplinary

SOS Climate waterfront builds a new multidisciplinary collaboration network involving top European research institutions in architecture, urban design, regional planning and landscape architecture articulated within existing networks in specific fields of expertise – to better understand the impacts of climate change in urban waterfronts and explore them from social, environmental, educational, technological and urban design perspectives. The research project is innovative by bringing together high profile scholars from complementary disciplines and geographies, academic experts and researches to work with municipalities, local actors and stakeholders, and together develop new concepts, formulate and communicate innovative design proposals (GARCIA, 2017).

Urban waterfronts are challenged by human, educational and urban development that cannot be comprehensively tackled by traditional approaches. The co-creation concept for urban waterfronts is a concept that fundamentally differs from traditional public engagement approach, as it focuses on the collective influence and responsibility of all stakeholders by creating the public good (SMANIOTTO, 2017).

SOS Climate waterfront focuses on the expanding potential of networked society to exchange information, education and spatial related issues, aiming to share strategies, policies and improve civic engagement in cities. It will increase the views on co-creation experiences and step up innovative research methods and techniques supported by exchange of knowledge and digital systems. Due to the nature of the topics, only an interdisciplinary research approach can reinforce staff capabilities and the profile of ULHT and partners. The network will provide an ideal environment to emerge knowledge on co creation and co-research and can be considered itself as a co-creation ecosystem. This will enable the development of approaches to community education programmes with tools, workshops, and publications that explain complex processes and/or policies for specific/targeted audiences.

3.3 knowledge sharing to achieve innovative objectives

The ground-breaking nature of the project comes from the methodology we have been testing since 2010 by bringing together municipality representatives, environmentalist, designers, geographers, cultural agents and researchers to exchange knowledge and cooperate in finding solutions and define strategies. The methodology to meet those established goals includes, in particular for the transfer of knowledge, joint initiatives for capacity building, and trans-national collaborative activities. The selected parameters cover a wide range of data resulting from human activities and environmental conditions. The costs involved to mitigate and adapt are significant and covers a broad range of expertise. To process data from different fields of knowledge and interpret their consequences it is necessary to exchange data and to cross references with other experts. The various developing countries in Asia like China, Malaysia, South Korea, Singapore etc. are developing their infrastructural facilities at an exponential rate (PUROHIT*, [et al.]*, 2015).

The problem of the waterfront has been developed by each partner participating in the project. It has been address from complementary perspectives, economic, cultural, data management, social and environmental. The diversity of themes covered by the partners is crucial for the success of the project. Expertise, exchange of interdisciplinary knowledge with others lead to a broader perception in the field of interest of a particular waterfront. The exchange is oriented to include preliminary research of selected waterfront, following three major guidelines; historical, cultural and geographical records. After the workshop edition, the dissemination of results is able to reach broader audiences, planning and designing adaptation programs and strategies, considering aforementioned variables help to increase the efficiency of efforts (JAMSHIDI*, [et al.]*, 2018).

To imagine the future, it is necessary to understand the past through the historic records available, that provide background on previous conditions. The geographic data is fundamental to relate urban territory with natural territory, as the water currents shape the landscape and the fluvial or/and maritime activities. Waterfront activities are essential for the construction of collective memory and operate as a tool for identity of the community. The cultural influence has a deep influence in the opinion of the communities and the political leaders. Historical urban and geographical research contributes to a rigorous evaluation of particular waterfront potentialities: a way for products distribution, fishing activities or others cultural valences. With climate change it is difficult to predict the impact on waterfront areas as they are vulnerable and their resilience depend on competent but fragmented studies. S.O.S. Climate waterfront methodology allows to strengthen collaboration, to investigate new techniques, to cross references and learn to access to specific instruments and/or methods.

Workshops; the participation in the workshops brings together the interdisciplinary team that integrate permanent staff, scholars and researchers cooperating with the scientific committee. To engage the present debate, the scientific committee invites external consultants and professionals from partner institutions to integrate the research group participating in the workshop. Each workshop addresses one specific waterfront location. A transnational multidisciplinary perspective contributes for the necessary integration of the local waterfront urban environment. The cooperation with experts coming from international partner institutions provides the opportunity to develop a set of local proposals. During the event participants exchange views, gain new perspectives on the researched topic, discuss new approaches of resilience and have the opportunity to test their methods in an international environment.

Conferences gather local experts, municipal representatives, partners and international scholars to share them researches on urban waterfronts. This is useful to exchange mutual visions and common practices, which constitute a relevant tool for future research. Conferences are designed to disseminate the knowledge produced to the wider audience of policy-makers, stakeholders, environmental associations, local communities, media, and the general public and to improve the skills of its staff. The research community promotes the active participation in international science and technology related conferences by providing the framework to include host presentation of papers from external guests previously selected.

This is an important output for the research proposal since communication is oriented towards different audiences.

The overarching methodological framework is backed by the concepts of co-oriented and adaptive and comparative research. The scientific strategy encompasses measures for stepping up and stimulating scientific excellence and innovation capacity. This includes the development of research design and digital tools to playfully engaging companies and communities in research activities and create opportunities to gather with specialist to collect the results of them researches.

- Dissemination and outreach activities - S.O.S. Climate waterfront research community promotes the scientific and public dissemination of the outcomes and findings. A website operating as a knowledge platform will be set at an early stage organized towards providing easy access to knowledge and know-how around the project's key areas and issues detected within the topic. It will also serve as central for social media activities. Further dissemination efforts include publications in relevant/indexed journals, policy briefs, studies reports, booklets and cooperation with other organizations, programs, networks, operating in the areas related to the project. The benefits from creative and innovative solutions contribute for most desirable sustainable development of urban waterfront in Europe. ISOCARP, is expected to list institutions that will continue to provide an international interdisciplinary vehicle for dissemination of results.

Cultural institutions, urban design exhibitions and art festivals have been actively involved in the dissemination of previous results of the waterfront topic. The creation of a body of knowledge on the subject of waterfronts that contribute to the identification of long and short term solutions is sustained by the edition of the web based material, production of documentaries, oriented towards the different audiences and publication of books. Everything is the central outcome of the research. The investment in communicating to reach new audiences through web tools, social networks and local media intends to disseminate and bring for public awareness, solutions that transform the waterfronts and the lives of their communities if local actors converge efforts and collaborate. It plays an important role in this process, because they influence the public opinion to think differently and attract the public interest to support the necessary transformations.

Our previous publications succeed to influence local administrations to take in consideration the results thus the challenges now facing climate change are required to receive feedback from local and international partners and the results of a comprehensive set of field observations, surveys and controlled laboratory experiments demonstrated that the waterfront suction, which remained thus far unexplored in soil mechanics (SASSA*, [et al.]*, 2013).

The activities develop a strategy to maintain the cohesive and sustainable collaborative network beyond the Project S.O.S. Climate waterfront scientific strategy is focused on four main research lines:

1) environmental planning for climate change, the influence of geographic and historical factors on the construction of the new territories over the water. To illustrate the precarious condition and the complexity existing at the waterfront, the analytical cartography will inform several stakeholders and citizens about the artificial landfill and the risks associated with extreme swings in climatic conditions.

2) economic impact. The unsuccessful implementation of the necessary transformation for waterfront sites is simultaneously affected by discontinuous and contradictory decisions lead by politicians. Such situations conduct to by an extensive waste of effort. The economic costs are significant and represent a large percentage of the necessary investments thus highly permeable to political short term decisions. Consultants for this project have been involved technically but not politically at the waterfront transformation process.

3) cultural influence and public space the top-down approach, based on desk-based macroscopic diagnostic and prospective analyses, plans and projects, has prevailed in urban development planning and decision making, thus neglecting the fact that the present city dynamics and future options depend on the changing presence, character and activity of a great number of individual and institutional actors as development stakeholders. This is especially evident in waterfronts, one of the most valuable and indeed unique urban area.

4) data management. The team will collect data to produce visual animations of possible scenarios that envision the vulnerability of waterfronts when exposed to climate change. This has been done by local institutions integrating geographic data. To envision the implications of future projects, management of public spaces that merge equipment's as well as squares, gardens and road structures, data will cover previous projects and future scenarios. The development of possible waterfront urban scenarios using technology spreads a wider understanding regarding waterfront transformations. It is innovative to use material from different fields of knowledge to simulate new outputs. Data related to historic and geographic records will feed the information of specific waterfront development. The information regarding the transformation of the built environment will allow the identification of patterns of development.

Such information will be used to feed algorithms and trace the storyline to speculate on climate change effects. Also, using patterns is useful to integrate the support of artificial intelligence to visualize future possible scenarios. Though speculative this is useful for researchers to be in dialogue with citizens, practitioners, decision makers and engage them in innovative solutions. It is not the cities that can be intelligent, but the societies that inhabit them that must be prepared (OLIVEIRA, 2017).

3.4 participating organizations

The achieved results since 2010 have revealed that the project is innovative by bringing together scholars to conceptualize and formulate design proposals to be brought forward for discussion, some present solutions in a new methodology that engage citizens, and their representatives. The research focus on changes affecting both, the city and the port are neither strictly private (investors 'concern) nor public, but are rather collective responsibility.

Indicators show that the methodology is effective within the local context. The results become a reference to coach the dialogue between residents, governmental institutions and investors. It will be necessary to consolidate the network of exchange knowledge since common topics were found with other partners:

LUSOFONA UNIVERSITY - Portugal

POLITECHNIKA GDANSKA - Poland

ARISTOTELIO PANEPISTIMIO THESSALONIKIS - Greece

UNIVERSITA DEGLI STUDI DI FIRENZE - Italy

INTERCULT PRODUCTIONS EK - Sweden

GDANSK MIASTO NA PRAWACH POWIATU - Poland

CHAMBER OF COMMMERCE - Portugal

FUNDACJA RIVER//CITIES PLATFORM - Poland

INESC ID – INSTITUTE OF COMPUTOR SYSTEMS - Portugal

CPO Noord-Holland (CPONH) – The Netherlands

Conclusion

The working plan of S.O.S Climate Waterfront was discussed and approved by all team leaders. The agreement about the number and dates of visits as well as about visiting persons is established according to their profile (MNG, ER, ESR) and specialization. All the partners agree that the project is feasible regarding both implementation of the tasks formulated and the timeframe. The tasks assigned to each participant are designed according to the work plan in order to meet their expertise and focus in the field of their scientific and scope of interests. Furthermore, the partners welcome knowledge sharing in the structure of the S.O.S. Climate Waterfront project provides a good opportunity to expand their field of research/expertise and enhance scientific innovation of their institutions. The collaboration in the project is profitable for all the members.

A strong consortium with unique combination of expertise will implement the S.O.S. Climate Waterfront (academic and non-academic). All partners work at the forefront of their discipline areas and have well-known scientific and leading reputation, thus ensuring research excellence. The consortium will train new researchers, expand research competencies in innovative design, partner with private sectors in research projects, thus providing substantial opportunities for real world testing of the research and introduce creative/innovative practice research methodologies to a new generation. The project will develop interdisciplinary and multi-sectorial competences that will have significant impact on leading researchers that will be experts in the assessment of waterfronts environmental adaptations and will provide successful water resilient strategies. Beneficiary will also be staff, practitioners, policy makers. S.O.S.'s extensive dissemination (website, media web, books, exhibitions, conferences, scientific articles,) will ensure that the results achieved are open-access and are widely shared.

Between fjords and mountains: Climate changes vs. cultural heritage sites in northern Norway – an example from Mosjøen in Nordland county

Granmo, Ida Marie, MOSJØEN, Norway

ABSTRACT:

Cultural heritage sites in northern Norway are manifests of a lifestyle long-lost to industrialization and centralization. Often located between fjords and mountains, many of the sites, such as the fisherman villages in Lofoten and Sjøgata in Mosjøen, consist of wooden buildings that date back to the 18th and 19th century. The buildings are well-kept as they are still in use by the locals; they also serve as important identity markers for the people living in the areas as well as being beloved tourist attractions. The last couple of years climate change has begun to show its presence more than ever in the northern parts of Norway. Heavy rain and unstable winters lead more often to floods, avalanches, and landslides, and the cultural heritage sites that previously were resilient and withstanding are now vulnerable.

In the city of Mosjøen in Vefsn municipality urban planners are trying to develop a new zoning plan for the cultural heritage area Sjøgata. The zoning plan should also function as an adaptive strategy to climate changes so that the historical environment of Sjøgata can be kept for the future. The highest climate risks to Sjøgata are flooding, a rise in the sea level and avalanches, one of the consequences of this is that insurance companies refuse to offer home insurances due of the risk of damage.

The challenge for the urban planners is how to plan for landslides, avalanches and floods, and how to safeguard the historical buildings when this happens. As a part of the work with the zoning plan, the planning department in Vefsn has looked at the possibility to alter the landscape by raising the wooden buildings as well as the terrain up to the future expected sea level. The department also tried to find out if the zoning plan could allow new ways of anchoring and detaching buildings from the foundations so that the buildings could “float” both on water and avalanches without being too damaged.

The new zoning plan for Sjøgata is still is a work in progress. There are several issues due to climate changes that have to be solved in order to complete the plan and whether the strategy will work is yet to be seen.

It is certain that urban planners in northern Norway need more knowledge and research on adaptive strategies to handle climate changes so that the cultural heritage can serve as identity markers, tourist attractions, and homes for another 100 years.

Adaptive Strategies for Mobility Planning in Remote and Coastal Cities and Towns - "LAST MILE" project case

Lucia ILIEVA, CSDCS, Bulgaria

Short abstract:

Mobility and Accessibility are vital elements for sustainable urbanization with a direct impact on climate change. The INTERREG Europe Project "LAST MILE" is presented with its focus on developing adaptive strategies providing user oriented services for the travel chain's last segment in remote tourism destinations and coastal cities and towns.

Introduction

Mobility and Accessibility are vital elements for sustainable urbanization but there is a need to change the current supply driven approach which gives preference to cars, and adopt a new planning paradigm focusing on people. Transport must remain at the heart of urban planning, providing sustainable solutions to mobility needs through the introduction of transport systems that focus on access, safety and efficiency within the larger context of reducing the need to travel in urban areas. Sustainable transport is included in seven of the 17 SDGs of the 2030 Agenda and is directly covered by 5 targets and indirectly by 7 targets. Four possible goals are considered important: Accessibility, Efficiency; Safety; and Climate respect. From the other hand upholding the right of people to travel safely using efficient and sustainable transport networks is a fundamental human right that is described in the UN Universal Declaration of Human Rights as "freedom of movement". This is why many EU projects aim to connect people to adequate transport services in rural communities, to reduce congestion in cities, and to link urban and rural areas by sustainable means of transport.

1. Project objectives

The LAST MILE project (INTERREG EUROPE, 2016 – 2020) aims to find innovative, flexible solutions for sustainable regional mobility systems. It wants to offer visitors the possibility to travel the 'last mile' of their travel chain sustainably and, at the same time, provide alternatives to car use for residents on their daily trips.

The project sets a concrete focus on the problematic accessibility of the last link of the travel chain from origin to destination (the so called "last mile") and collects and analyses solutions to cover this bottleneck with sustainable modes of transport. The environmental benefit and resource- and cost-efficiency in the long run are considered.

LAST MILE aims, among others, at pointing out how sound institutional framework facilitate the implementation of especially demand-responsive transport (public, sharing, pooling). The project will take on-board lessons learnt here, to further encourage at a later stage of the project partners and regional stakeholders to implement new successful approaches from other regions in Europe when preparing their regional action plans.

Transfer of best practices and innovative approaches to regional policies is also an aim of LAST MILE project. The 6 regional project partners have elaborated a set of regional reports analyzing their territories in relation to the status-quo of sustainable mobility, flexible transport and tourist activity. This exercise is the first step towards building a backbone of the interregional exchange.

Regional reports have been consolidated and summarized in a Synopsis Report that deals with analyses of the institutional frameworks and barriers of each region and the evaluation of good practices, and identifies common opportunities and challenges shared among all regions.

2. **Methodological approach**

The project focuses on user oriented services for the travel chain's last segment in remote destinations offering and promoting door-to-door accessibility. Still, in terms of the full distance to cover between origin and destination, there is often a bottleneck on the last link of the journey, i.e. the distance between the regional railway station and accommodations. This missing link is crucial for deciding what kind of transport to use. Experiences have shown that a demand-responsive transport system combined with regular public transport is a thankful enhancement in many cases. The last-mile problem can be solved by introducing a variety of flexible transport services (FTS) making the transportation multimodal, on-demand, seasonal, shared, and increasing passengers' choice and convenience. The overall transportation system step by step becomes more digital and therefore more efficient by better matching demand and supply.

Last Mile aims at developing adaptive strategies for providing user oriented services for the travel chain's last segment in remote tourism destinations and coastal areas of 6 European countries: Austria, Bulgaria, Luxembourg, Poland, Slovakia and Spain. These countries are situated in different European areas but all have remote tourism destinations with difficult accessibility for visitors. In the Alpine regions of Upper Austria, on the Black sea coast of Bulgaria, in the natural parks of Luxembourg, in West-Pomeranian coastal zone of Poland, in the mountain region near Kosice in Slovakia and High Pyrenees in Spain still major transport systems face difficulties in achieving last-mile connectivity, so people have to travel by car or take a taxi. This missing link is crucial for deciding what kind of transport to use. Experiences have shown that a demand-responsive transport system combined with regular public transport is a thankful enhancement in many cases. The last-mile problem can be solved by introducing a variety of flexible transport services (FTS) making the transportation multimodal, on-demand, seasonal, shared, and increasing passengers' choice and convenience. The overall transportation system step by step becomes more digital and therefore more efficient by better matching demand and supply.

In the frames of the project 7 partners from 6 countries ask for common solutions for the mobility services in the last mile. The major part of activities is dedicated to exchange of experience between the participating regions. Study visits have been performed in every country in order to demonstrate the existing last-mile mobility solutions. The best practices were evaluated in terms of impact on the climate change, sustainability and transferability. Actually they are part of the Good Practices Collection of the IE program thus supporting the International Public–Private Platform named "Global Partnership for Sustainable Transport" which focuses on three main areas:

• Promoting best practices in mobility and accessibility

• Starting dialogues – encouraging governments and businesses to talk about transport sustainability and come up with concrete solutions.

• Working in partnership with other projects and initiatives promoting resilient and sustainable cities and transport.

3. Project implementation

The project is developing on 2 phases. The Phase 1 (April 2016- September 2018) started with a thorough research including 3 different joint analyses, which build the backbone of the INTERREG exchange:

- Analysis of the national legal and institutional frameworks and economic aspects related to sustainable demand-responsive/flexible transport systems and the identification of the barriers that are hindering the implementation of especially small scale systems in remote areas/hinterland
- Analysis of the technical state-of-the-art of sustainable transport, in particular of flexible systems in the different regions
- Analysis and evaluation of existing practices in regional flexible transport policies. This joint research evaluates good practices of and beyond the regions, taking into account former best practice collections of other projects as well. During the study visits the regional approach including the specific framework conditions, financing structures and the concrete mobility systems is discussed and evaluated using two specific questionnaires prepared by CSDCS. In this regard, potentials for optimization or innovation are identified, and if applicable concrete solution approaches are elaborated.

The analyses prepared by each partner region were consolidated and summarized thus allowing the preparation of a **Synthesis and policy recommendations.** Based on the results, it derives recommendations for policy makers at different levels. They were used for elaborating regional adaptive strategies for mobility planning with Action Plans **for implementing flexible transport services** that prepare actions and investments to improve the door-to-door accessibility of peripheral tourist/recreational destinations benefitting also the inhabitants. These strategies will make sure that lessons learned from the research and interregional exchanges are integrated in the regional policies. Actions defined will be put in practice during the Phase 2 of the project (October 2019 – March 2021).

4. Outcomes of the research

For all project partners the project is a real challenge because of the need to introduce the modern concept of Mobility-as-a-Service (MaaS) in the transport schemes of remote and coastal regions where the transport connections are rather scarce and are not a priority to local governments. The Bulgarian case is very indicative, because the Black sea resort region of Varna abounds of attractive tourism landmarks (sand beaches, pictoresque lagoons, roman remains, rain-forest parks, etc.) that can be accessed only by car becaus eof the lack of public transport.

The Bulgarian partner CSDCS analyzed the national legal and institutional frameworks and the economic aspects related to sustainable mobility services and the identification of the barriers hindering their implementation in remote areas. The goal was to elaborate a strategy for implementing flexible transport measures that prepares actions and investments to improve the door-to-door accessibility of remote coastal recreational destinations. It was elaborated with the large collaboration with all levels of decision-makers in the region, tourism and transport experts, as well as a large public participation. A series of awareness raising events and public consultations were conducted for identifying the most appropriate strategic measures for improving the accessibility.

To establish contact with and to sell the last mile idea to players in the fields of tourism, transport, and environment (tourist entrepreneurs, transport authorities, protected area management, local politicians etc.) who might have a vested interest in the policy or project, and whose involvement could have a positive financial or political impact was crucial for the project's success. For the first time the tourism and transport sectors in Bulgaria meet and discuss their common problems and interests having the possibility to exchange experience with more advanced European regions. The project made it possible to bring together all the important subjects involved in people's mobility to try and find points in common and to encourage partnerships both locally and across borders.

5. Conclusions

As a result of the project, adaptive strategies were elaborated and Regional Action Plans were set in all 6 regions. For the Varna coastal area in Bulgaria the strategy was developed with focus on how to bring people and places together by creating relevant flexible transport services rather than simply increasing the length of urban transport infrastructure or increasing the number of movements of visitors.

As Varna coastal region and the other 5 project regions are tourism destinations, the project outcomes would be: improved urban-rural connectivity; improved regional environmental/climate conditions; strengthened institutional capacity for tourism destination management; and effective project implementation and knowledge management. This project represents one more step to the appeal of a seamless, technologically-facilitated transportation ecosystem, universally accessible yet designed for maximum efficiency and site-specificity.

Study on the relationship between urban climate change and urban development construction in severe cold area

Hong LENG; Cunyan JIANG
[1,2] School of Architecture, Harbin Institute of Technology, Harbin 150001, China
[1,2] Hei Longjiang Cold Region Urban-Rural Human Settlements Science Key Laboratory, Harbin 150001, China

Abstract: A sizable majority of researches show that urban climate change has great relationship with urban development construction. However, because of the big climate environment difference in summer and winter, for cities in severe cold area, urban climate environment affected by urban development construction has its own complexity compared with that in warm area.

In order to study the importance of urban development construction in affecting the urban climate environment in severe cold area, this paper takes a typical winter city Harbin in northeast China as the research objective. On the basis of analyzing the climate evolution and urban development from 1988-2017, the paper makes a correlation analysis between urban climate elements and some typical urban development construction indexes in summer and winter separately, finding the underlying mechanisms of the two factors' mutual influence. At last, according to the correlation analysis results, this paper confirms the key urban development construction indicators, and advances some urban planning strategies to avoid the negative effects that urban development construction brings to urban climate environment in severe cold area.

1. Introduction

A sizable majority of researches show that urban climate change has great relationship with urban development construction, especially in recent decades. T.R.Oke is one of the earliest experts who discuss urban size 's influence on urban heat climate[1]. Peter Bosselmann analyzes urban form and climate in 1990s[2]. Some researchers focused on studies of how urban construction affect urban climate environment in different regions. Du Yin and Rohinton Emmanuel discussed the urban climate change under urban expansion and shrinkage respectively in warm areas[3][4]. Bernard Kumi Boateng and S Piketh took Ghana and in Africa as the research object, studying the relationship between urban growth and thermal climate change. Y Shi pays much more attention on microclimate spatial distribution in sub-tropical high-density urban environment[5]. Climate change is also connected to urban planning policy in some developed countries[6][7]8. In addition, some researchers integrates climate change considerations into related urban planning technical specifications and guidelines, as well as some urban planning strategies, in order to make the research results much more effective[9][10][11].

However, because of the big climate environment difference in summer and winter, for cities in severe cold area, urban climate environment affected by urban development construction has its own complexity compared with those cities in warm area. For example, as the urban grows and develops, in summer, heat island effect in winter cities are also noticeable, extreme hot weather often happens; In winter, unreasonable urban design makes the microclimate of partial urban areas very bad, especially big wind velocity and lack of sunshine. In fact, temperatures of winter cities in China are far below those in other countries at similar latitudes; the mean temperature in January is lower than -18°C due to the cold air that comes from Siberia every year[12]. So winter cities in China face much more complicated climatic issues than those in other area.

Related research on cities in severe cold area is rare in the literature. This study took Harbin, a typical Chinese winter city, as the research objective. The main purposes of the study are (1) Analyze the climate evolution and urban development construction in recent 30 years in typical winter cities; (2) Develop the correlation analysis between urban climate and urban development construction in typical winter cities; (3) Advance some planning implication to improve climate environment in winter cities.

2. Methods

2.1 Study site

Harbin is located at 45° latitude N and 128° longitude E, and it is known as a typical winter city in northeast China. Harbin is the capital city of Heilongjiang Province, and also the transportation, political, economic, cultural and financial center of northeast China, with a total population of 9.62 million at the end of 2016. The city of Harbin encompasses approximately 53000 km^2, urban area 10198 km^2, with the GDP of 610 billion. The location map of Harbin is shown in Figure. 1.

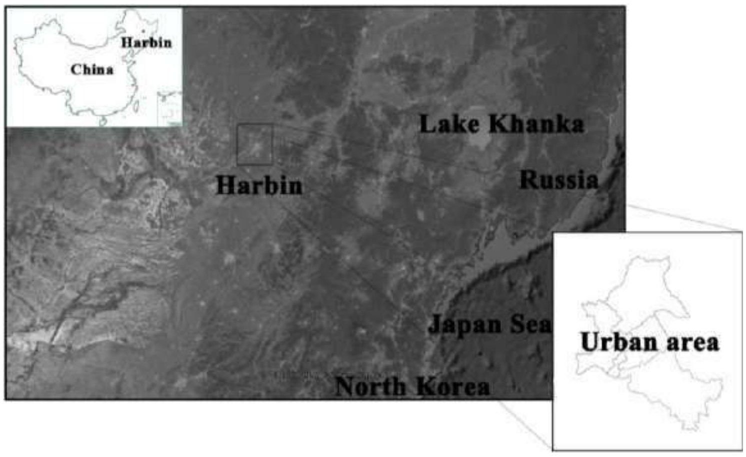

Figure 1: The Location Map of Harbin

Harbin belongs to the temperate continental monsoon climate zone, the annual mean temperature of which was 3.6℃. The mean temperature of the coldest month, January, is approximately -19.5℃, and the lowest temperature of -37.3℃ occurred on Jan 26th, 1985. The mean temperature of the warmest month, July, is approximately 22.8℃, as shown in Figure 2. Usually, summer is from June to August, in which the mean temperature is higher than 20℃; winter is from November to March, in which the mean temperature is lower than 0℃. The heating period in Harbin is from October to April, and only about 140 days in the year are frost-free.

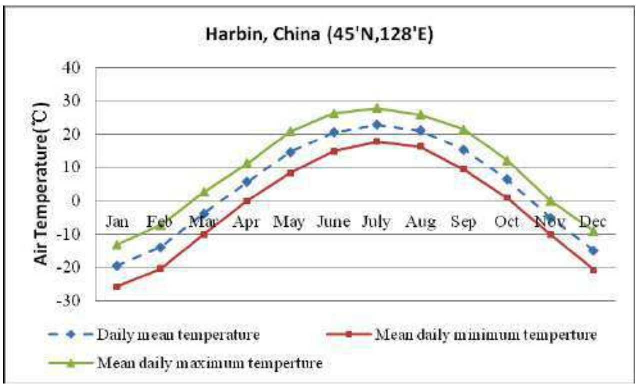

Figure 2: Mean daily mean, maximum, and minimum air temperature in Harbin ,China

2.2 Basic data analysis
Meteorological data for Harbin from the China Meteorological Data Sharing Service System from 1988 to 2017 was used to study the climate environment evolution in Harbin, which offers authoritative meteorological data for scientific research. This study used the average adjacent day or month value instead of using incomplete data in the system. The main climate parameters are temperature, sunshine duration, wind velocity and relative humanity in the 30 years. Temperature parameters contain mean temperature, minimum temperature and maximum temperature; wind velocity parameters contain mean wind velocity and maximum wind velocity; relative humanity parameters contain mean relative humanity and mean precipitation.

Urban development construction data from China City Statistical Yearbook from 1988 to 2017 was used to study the urban development construction in Harbin. The main indexes are population, urban built-up area, land use intensity, green coverage ratio and GDP. In addition, some satellite image maps of Harbin in different typical years are from the website of United States Geological Survey, through which the urban evolution in recent 30 years can be seen clearly.

2.3 Correlation analysis
Based on the meteorological data and urban development data in the 30 years of Harbin, the Person correlation analysis between meteorological data and urban development construction index is discussed. All the indexes in the Person correlation analysis pass through the test of independent. In order to show the specialty of winter cities, the analysis process was performed based on the data in summer and winter respectively. In the analysis, summer meteorological data is the mean value from June to August, winter from November to March.

3. Results

3.1 Climate environment evolution
Figure 3 shows the climate environment evolution from 1988 to 2017 in Harbin. In the 30 years, the annual mean temperature rises up 3.1℃, urban heat island effect begins to come up. The raise range of mean minimum temperature in Harbin is more than the decline range of maximum temperature within the 30 years. In addition, the temperature change characteristics shows the level of warming in winter is higher than that in summer, so the urban heat island's influence on urban temperature mainly focuses on night and winter in Harbin.

The mean sunshine duration in Harbin drops year by year. Harbin was the region of abundant solar energy resources, there was 250 days in which sunshine duration is more than 6 hours[13]. Before the year 2006, the annual sunshine duration hours are 2500, and after that, the numbers are about 2200, with a reduction of 1 hour per day. As the urban development construction advances, air pollutant concentration and total cloud cover increases and direct solar radiation decreases, so the sunshine duration reduces in the past 30 years.

Wind velocity in Harbin has a significant decline in the 30 years, the wind velocity variation slope is about 1.5m/s, and the mean wind velocity is about 2m/s in recent 5 years. The days with strong wind (11m/s) in 1960s are 10.8, but in 1990s they are only 0.6[14]. Annual maximum wind velocity reduces greatly before 1990s, and after that, the reducing speed is lower. The annual maximum wind velocity stays in about 10m/s in the nearly 15 years, which is a similar result as 'the wind energy resource census', the reserve of wind energy resource are shrinking in most region of China[15].

The mean precipitation peaked at the year 1998 with the value of 800mm, and since the year 2000, the value begins to reduce, annual mean precipitation is only about 500mm. Because of the decrease of precipitation, the relative humanity shows a decline in the 30 years in Harbin.

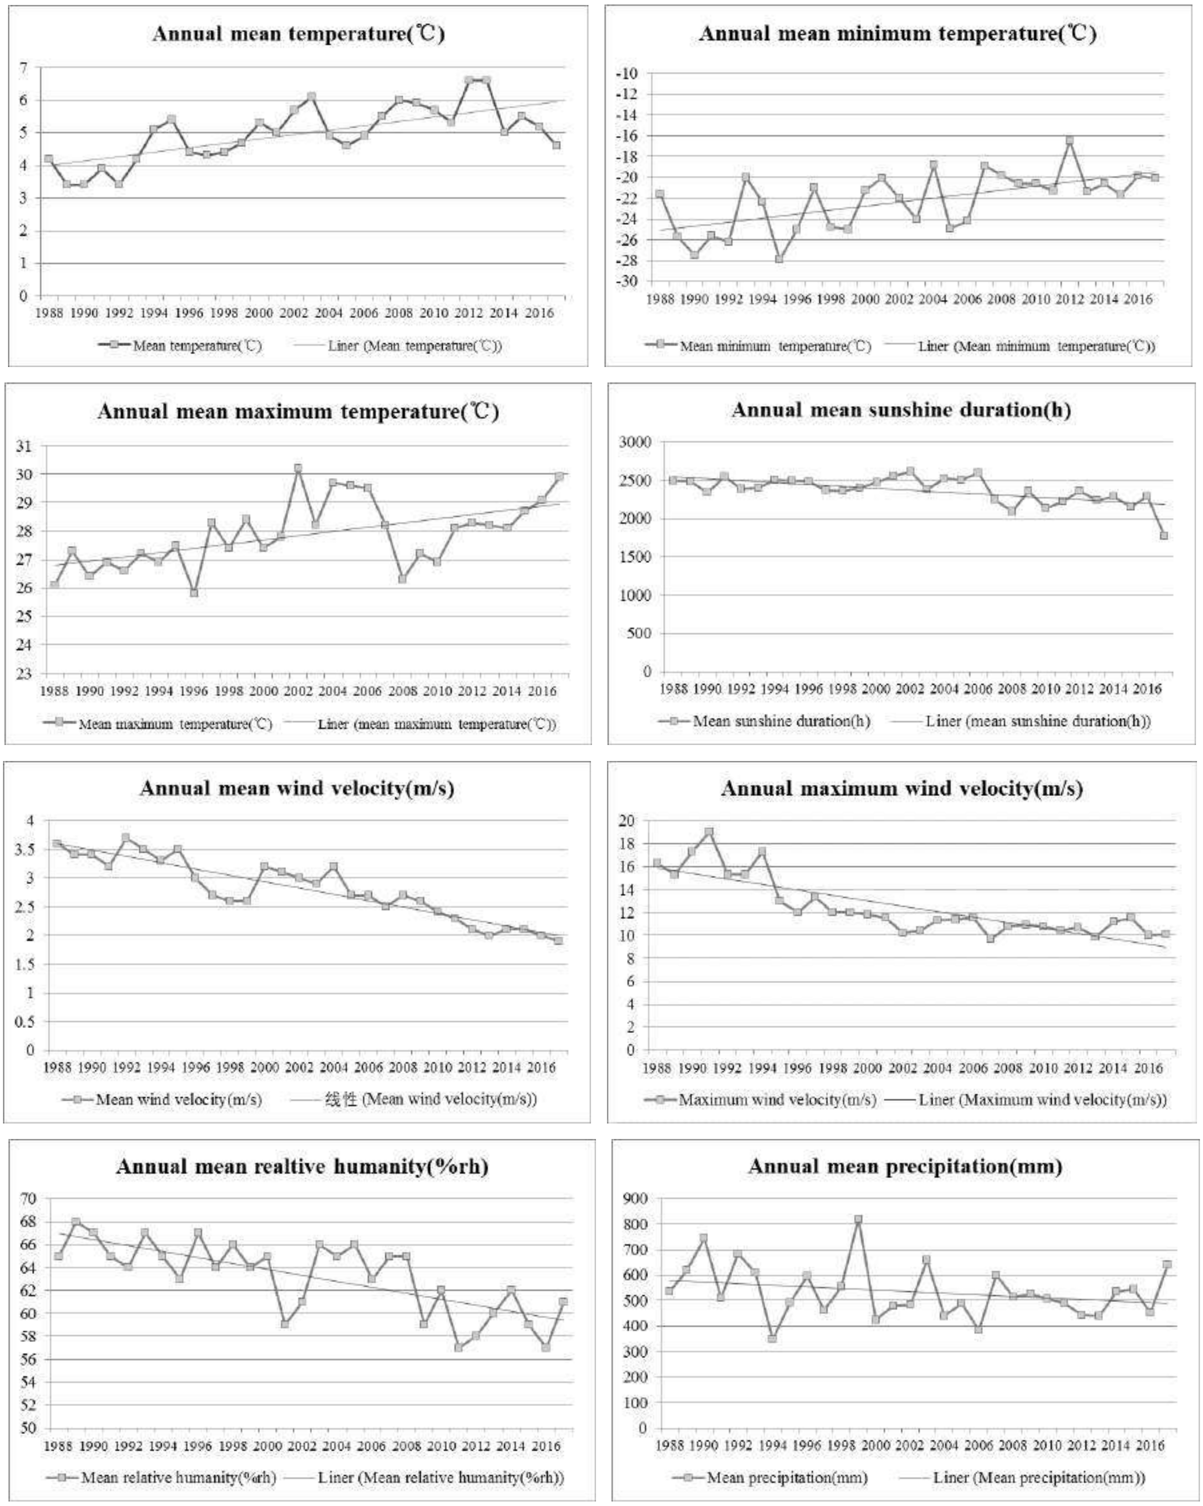

Figure 3: The climate environment evolution in the 30 years in Harbin

3.2 Urban development construction

Figure 4 shows the Harbin main urban area spatial patterns change situation in the year 1988, 1997, 2007 and 2017. Urban construction land in Harbin is expanding within the 30 years, especially in the recent 10 years. The main urban area in Harbin has a significant expansion to the north and south along the Songhua River. Table 1 shows the urban development construction condition of Harbin in typical 5 years, and it has a fastest growing in the recent 10 years, urban built-up area in 2017 is triple the number in 1988, and urban area in 2017 is nearly 6 times as that in 1988.

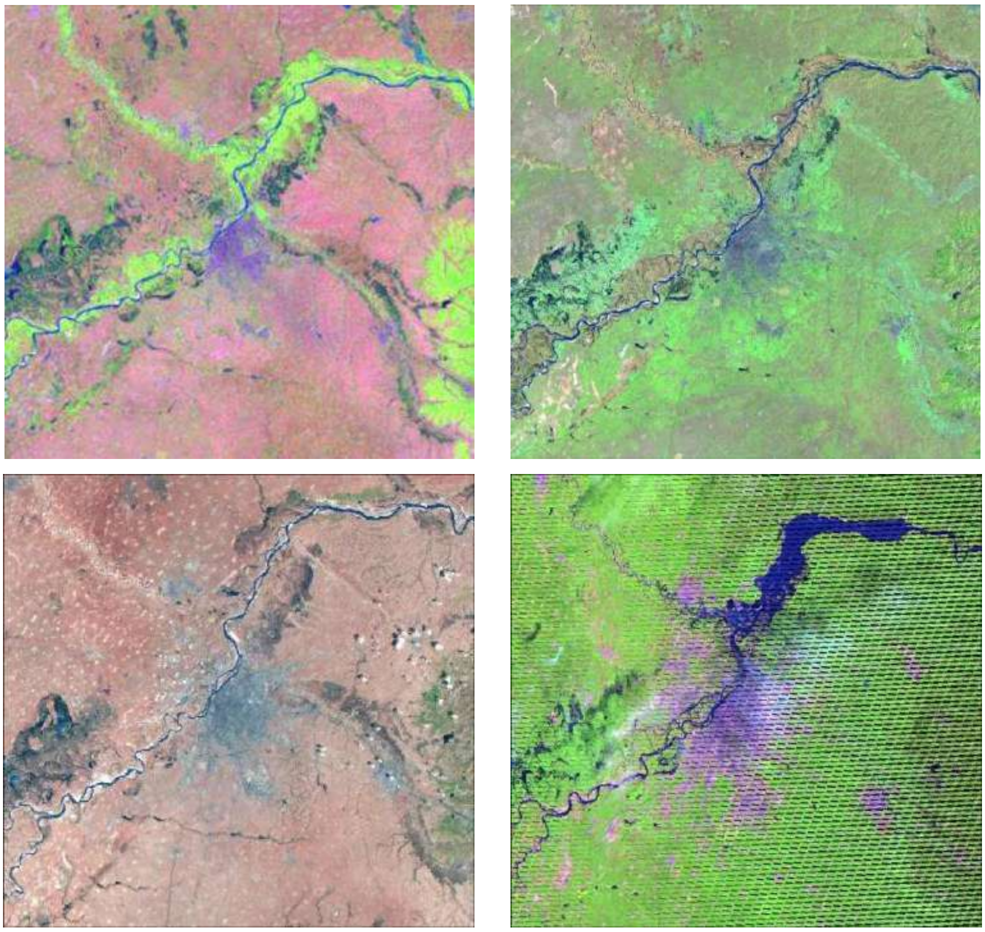

Figure 4: The Urban evolution of Harbin

Table1 Demographic and geographic information of Harbin

Items/ Year	Year 1949	Year 1988	Year 1997	Year 2007	Year 2017
Urban built-up area (km^2)	86.31	153.27	291.09	398.95	428
Urban area (km^2)	930	1637	1637	4275	10098.32
Green coverage ratio (%)	6.34	11.2	19.7	28.87	38.51
Population (Million)	0.76	2.46	2.59	3.99	5.49
GDP (Billion)	0.38	9.68	53.2	183	575

3.3 Correlation analysis

(1) Results in winter

Table 2 shows the correlation index of meteorological data and urban development in Harbin in winter. First, mean minimal temperature has no relationship with urban development, but mean maximum temperature has significant correlation with urban development factors at level 0.01 except urban exploitation, which is similar to the results of mean temperature. Land use intensity has no relationship with any three temperature indexes. Mean sunshine duration in Harbin in winter is influenced greatly by urban development construction factors except land use intensity. Mean sunshine duration declines with urban development, and the correlation coefficient is more than 0.6. Mean wind velocity has a strong relationship with all the urban development construction indexes at level 0.01. Active influence with population, urban built-up area, green coverage ratio and GDP, negative influence with land use intensity. However, urban development construction has little effect on mean relative humanity in Harbin in winter.

(2) Results in summer
Table 3 shows the correlation index of meteorological data and urban development in Harbin in summer. Mean minimum temperature has relationship with all urban development construction indexes except green coverage ratio, and all the correlation coefficients are more than 0.67. However, there is no statistically significant difference between mean maximum temperature and urban development construction indexes. Mean temperature is influenced by population, urban built-area and GDP at level 0.01. Mean sunshine duration in Harbin in summer has a negative relationship with population and urban built-up area, and the correlation coefficients are about -0.5. Mean wind velocity has a strong relationship with all the urban development construction indexes at level 0.01, active influence with population, urban built-up area, green coverage ratio and GDP, negative influence with land use intensity. The more land use intensity is, the more mean wind velocity is, which has the same result as the climate change analysis in the 30 years. However, urban development construction has little effect on relative humanity in Harbin in summer, which has the same results as that in winter.

From the correlation analysis results shown above, it is can be seen that some climate environment evolution indexes have strong relationship with urban development construction indexes except land use intensity in Harbin which is only related to mean wind velocity in both seasons. Land use intensity changes with the urban master planning updates. Land use intensity is the ratio of urban construction area and urban administrative area. In one urban master planning cycle, there is little change in urban administrative area, however urban construction area changes irregularly some time. Therefore, land use intensity in different years and urban master cycles can be similar, which in individual years maybe even smaller than the last year. As a consequence, land use intensity is an index has little effect on climate environment factors.

For showing the specialty in winter cities, there are some certain rules in winter and summer respectively.

First, for winter cities in severe cold area, there is significant difference between urban development construction’s influence on summer and winter temperature. Mean and maximum temperature are the main aspects that urban development construction affect temperature in winter, but mean and minimum temperature are the main influenced objects in summer. Based on the results mentioned above, it is can be seen that as the city grows, maximum temperature in winter is decreasing and minimum temperature in summer in increasing, furthermore, and almost all the correlation coefficients are more than 0.6, which shows a strong relationship. Urban development construction in Harbin has an irreversible influence on urban heating island effect.

Second, mean sunshine duration in Harbin declines with urban development construction in both summer and winter, which validates increasing urban heating island effect in Harbin aggravates air pollution and total cloud cover, as well as its negative effect on urban sunshine environment. In addition, green coverage ratio and GDP is related to sunshine duration only in winter, which indicates cold weather make urban green land have different effects on sunshine duration.

Third, even though the trend of mean relative humanity in Harbin of 30 years is declining, and dry island effect exists, urban development construction has a little influence on relative humanity, no significant difference. Therefore, it is deduced that urban relative humanity has much more relationship with underlying surface patterns and structure. The main precipitation pattern in winter is snowing, so the mean relative humanity in four winter months are similar to each other.

At last, Green coverage ratio has much more influence on winter than that in summer, and that maybe caused by the cold weather, which caused big difference in vegetation forms and patterns in winter compared to summer. In addition, compared with other climate parameters, green coverage ratio has the closest relationship with wind velocity in Harbin in both summer and winter. The correlation coefficients are more than 0.8, and the significances are all at level 0.01.

Table 2: Correlation index of meteorological data and urban development in Harbin in winter

Meteorological data/ Urban development factors		Population	urban built-up area	Land use intensity	Green coverage ratio	GDP

4. Discussion

4.1 Implications for urban planning and design

Previous studies found that urban planning and design has close relationship with urban development construction. However, in different countries and climate region, the correlation analysis results kinds are totally different. Based on the analysis results in Harbin above, population and urban built-up area are the most important influencing factors on climate change, thus for cities in severe cold area, proper urban scale controlling and compact urban form building are available approach to mitigate the climate change. For controlling urban scale, appropriate population size and environment capacity are the main methods. For building proper compact urban form, optimizing land using structure, slowing down the speed of urban construction land expansion, proper multi-functional urban land complex are the main methods. Even though these strategies are also suitable to cities in other climatic zone, it is much more meaningful to winter cities, which can slow down the speed of climate change, meanwhile reduce the problem of urban traffic and energy consumption much more effectively.

According to the results, for optimizing temperature conditions in winter cities, decreasing the minimum and mean temperature in summer, meanwhile increasing the maximum and mean temperature in winter by taking some measures on urban development construction are available, because it has opposite effect on the two seasons. For optimizing sunshine duration and wind velocity conditions in winter cities, taking the same measure on urban development construction would has the same effect on the two seasons. Therefore, further urban planning policy and strategies need to pay attention to the difference in summer and winter.

However, urban development construction is not the only criterion affecting climate in cities. Other factors such as people's behavior, energy consumption, even the movement of the earth and the force from the universe space are also key points[16], so there are lots of measures can be taken to mitigate the climate change in winter cities. Some experts suggest make the urban climatic map to guide the urban planning practices in different seasons and urban scale, in order to ease the conflict between urban development construction and climate changes more intuitively[17][18].

In addition, for cities in severe cold area, at the same time of mitigating the climate change, adapting regional climate condition and improving local microclimate environment are also extremely important[19], as well as studying the relationship between them and urban development construction in different urban scale, through which would enhancing the entire urban climate adaption for winter cities[20]. These should be taken into deep consideration in future design and policy.

4.2 Limitations of the study

There are also some limitations in this study. There are only five urban development construction indexes discussed in this study, some other indexes may also affect climate a lot. In addition, compared with the meteorological data from related official website, in situ measurement in some typical urban area may reflect much more real problems, which should be combined with the official data in the study. Furthermore, for winter cities, there is a particular period in the whole year-marginal season, which are the periods between winter and spring, fall and winter[21]. In sunny days without cold wind, a lot of people go out for outdoor activities in marginal seasons, so the urban climate research in marginal season is also extremely important to winter cities

In further studies, the correlation relationship between climate change and urban development construction in winter cities need to be quantified by studies with more depth. Through more precise calculation and simulation results, it is useful to the cultivation of environmental urban policy in winter cities.

5. Conclusion

Based on the meteorological data and urban development construction data, this study concludes that climate change and urban development construction change a lot within 30 years in Harbin, finding that maximum temperature in winter is decreasing and minimum temperature in summer in increasing as city grows. Besides land use intensity, all four urban development construction indexes have important effects on climate change in summer and winter respectively.

The research results can be used to guide the urban planning and design for cities in severe cold area, as well as providing technical support for urban material space design based on urban climate environment adjustment in the future, enhancing the sustainable development capacity for cities in severe cold area, which are of great significance and the key points in the field of urban climate environment research.

Study on Residential Design and Renovation Planning of Villages in Forest Areas of Severe Cold Region Based on Resilience Theory

LI Han, Harbin Institute of Technology, China
FU Benchen, Harbin Institute of Technology, China

Abstracts: With resilience concepts is increasingly expanded in urban planning and architectural design industry under global climate change, renovation planning and residential design of the resilient village gradually show the key significance in rural areas, as important as urban field. In addition, development of the resilient village has been subject to many restrictions and security risks, especially in forest areas of severe cold region in China, due to the special climatic and ecological characters. In this context, the paper mainly focus on the connotation, characteristics, systematization and application of the resilient village in forest areas of severe cold region, through theoretical research, field research, system modeling and empirical research, based on resilience concepts. From the overall perspective, the paper aims to promote the process of resilient renovation planning and residential design in special climatic and ecological areas, through systematic research of the resilient village, in order to deal with climate change and other adverse factors
Keyword: Resilience concepts; forest areas of severe cold regions; the resilient village; stability landscapes; renovation planning and residential design

1. Introduction

In recent years, more and more researchers in China start to focus on researching the corresponding design strategies to deal with the impact of climate change, and pay great attention to renovation planning and residential design under special climate and ecological conditions. However, villages in the vast forest areas of northeastern China have been neglected by these researchers for a long time, which is the main component of the forest area compared to the cities. At present, the planning and residential design of these villages are lagging behind, due to the particularity of its climate, ecological environment, social economy and other factors. The problems of the forest villages mainly center on the settlement structure, energy utilization, building materials selection and ecological regulation. Furthermore, cause of the large amount and individual small scale, most of the forest villages scattering in the vast forest areas are more vulnerable to climate change and interdependent with the surrounding forest ecosystems. In order to change this situation, it is necessary to introduce resilience concepts in village renovation planning and residential design

Resilience is defined as “the ability of a system or organization to withstand and recover from adversity” (Holling 1973). A resilient organization is one that is still able to achieve its core objectives in the face of adversity through a combination of measures. Resilience concepts is composed of four dimensions: latitude, resistance, precariousness and panarchy, with adaptive cycles, cross-scale effects and transformability (Brian Walker 2004). As resilience concepts is widely applied to urban and regional planning field, the concept of resilient city has been gradually accepted, which is known as the capacity to absorb external disturbances and maintain the primary features, structure and key functions of urban or urban systems (Resilience Alliance 2007). Meanwhile, it has been defined that rural resilience is a new development concept (Heijman 2007). The idea of combining resilience concepts with village panning has also sprouted. For example, there are research on the analysis of rural community resilience (Skerratt 2013), the components of rural resilience (Buikstra 2010), the resilience capacity to a developmental shock (Daisaku 2013), and spatial and productive development of coastal resilience (Diego 2014), However, there is currently a lack of systematic and empirical research focusing on the resilient village under special climate and ecological conditions, and cross-branch resilient research that combine village planning with architectural design.

Therefore, from theoretical and practical perspectives, the paper mainly focuses on renovation planning and residence design of the resilient village in forest areas of severe cold regions in China, based on resilience concepts, in order to deal with climate change, improve integrated adaptability and promote sustainable development. During the research process, the regional characteristics are highlighted, such as special climate and natural resources. Simultaneously, the organic integration of village planning and residential design is emphasized, in order to form a more systematic and interconnected resilient system.

2. Field Research

With case-based reasoning (Aamodt 1994), several typical villages were investigated through field research, and outstanding issues were summarized as original database for modeling.
Specifically based on the research requirement, 10 villages were selected and field surveyed with representative characteristics in terms of scale, age, development and planning, which locates in forest areas of severe cold regions in Northeastern China (Figure 1-3).

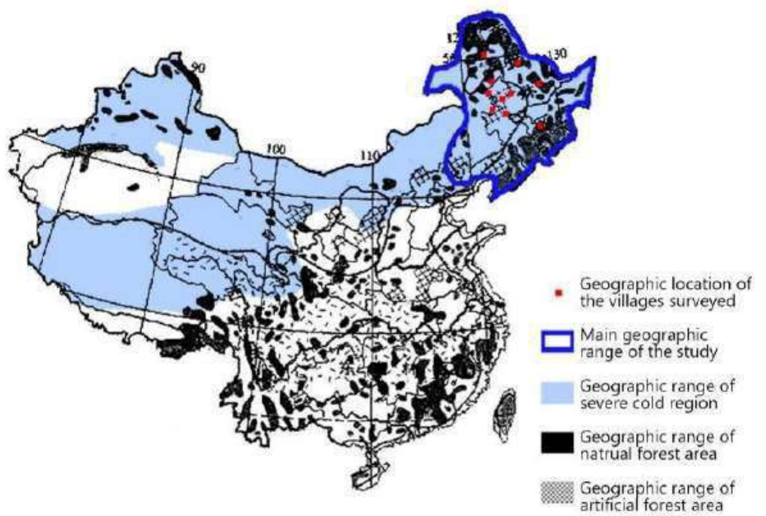

Figure.1 Research ranges and village location on a national scale (Source: Author).

Figure.2 On-site interview (Source: Author).

Figure.3 Field mapping (Source: Author).

In each village, one relatively typical house was selected for detailed surveys, which are mapped and evaluated to analyze plan area, construction status, and average daily energy consumption. Based on the results, basic information and current situation of the villages and residences were compared and analyzed (Table 1, Figure 4-7).

Figure.4 Comparison of village land area (Source: Author).

Figure.5 Comparison of village population (Source: Author).

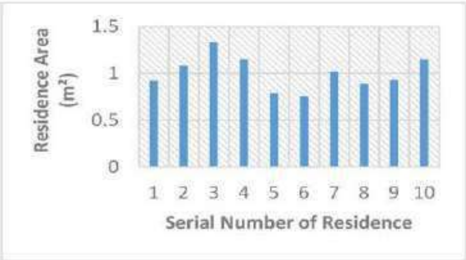

Figure.6 Comparison of typical residential area (Source: Author).

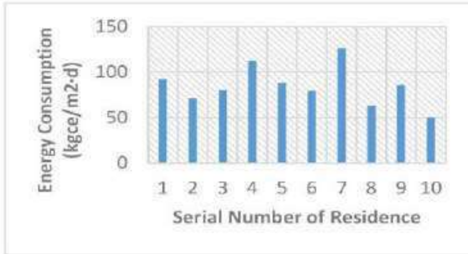

Figure.7 Comparison of average daily energy consumption of typical residence in January (Source: Author).

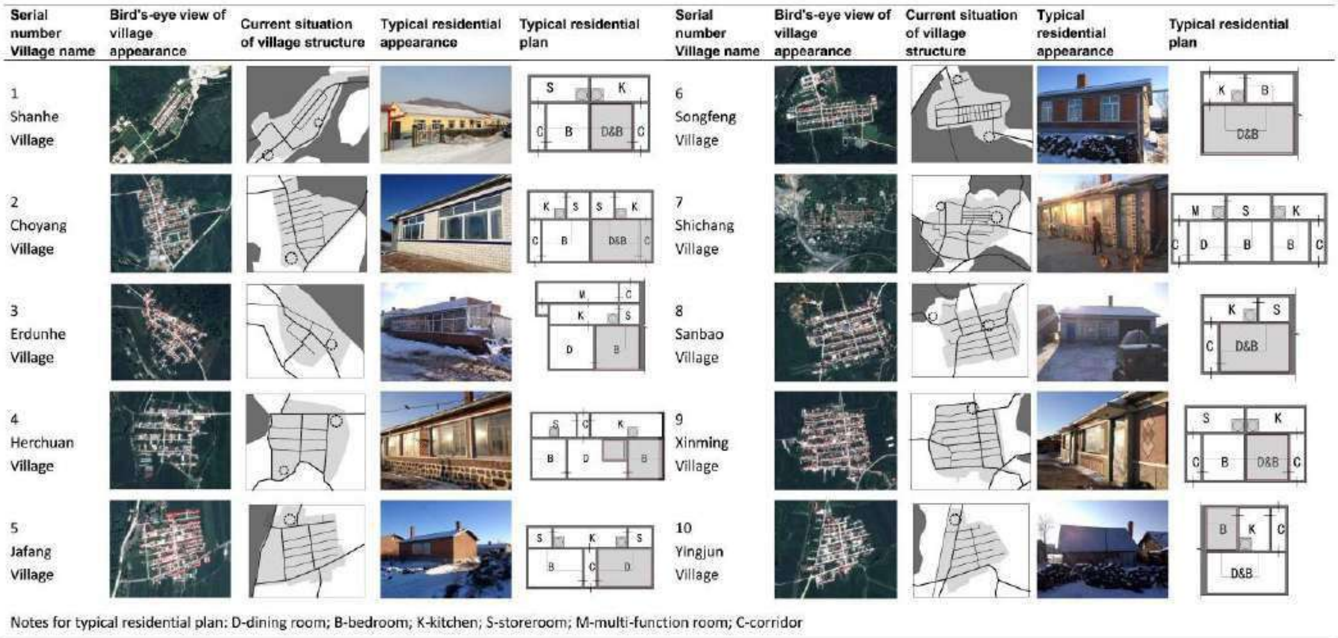

Table.1 Basic information of typical villages and residence (Source: Author).

By analyzing and summarizing the results of field research, many current problems was found in villages of forest areas in severe cold region. Main outstanding issues include the following four aspects:

Firstly, in the social aspect, the problem of “over-dilution” is serious， which was caused by the loss of population and the vacancy of land. With the development of urbanization, the number of residents in the village has continued to decrease, while land wastage and inefficient use have been increasingly severe. To remedy this kind of problem, it is necessary to reconstruct rural areas in a timely manner, however, which is in contradiction with the current urbanization policy pursued by the local government. The gaps between the existing problems and policy preferences poses a great threat to village resilience ability.

Secondly, in the economic aspect, the industrial structure and development model of the villages are relatively rigid. In recent years, as the transformation of traditional centralized forestry management in China, many villages in forest areas have lost their economic status, with external attractiveness declined. At present, the villages are still dominated by traditional planting industries without rational occupational guidance to the residents. Therefore, the local industrial structure needs to be adjusted and diversified.

Thirdly, in the ecological aspect, there is a lack of reasonable forest protection plan and special disaster prevention plan. As most villages in forest areas of severe cold areas are located in the mountainous area, the villages are faced with more disaster challenges compared to other natural areas in China. These challenges, such as winter cold waves, forest fires, and landslides, have posed great security risks for many villages. Otherwise, the existing protection mechanism of forest resources is not sound enough, and the relationship between the villages and the forest is lacking of balance and symbiosis

Fourthly, in the technologic aspect, the village's municipal facilities and building technology are relatively backward. Most villages are lacking in centralized drainage facilities, centralized heating facilities and standby electric generation system. In addition, as the main type of architecture in the villages, residence is generally faced with a series of problems from function design to construction technology, such as unreasonable functional layout, non-recyclable materials, and high energy consumption in winter.

3. System Modeling

3.1 Conception of the Resilient Village

Based on the results of previous investigation and analysis, it is very urgent to carry out resilient village renovation planning for villages in forest areas of severe cold regions, which is an active, nonlinear and complex process. The concept of resilience has important implications for village renovation, which reveals that villages, as an important part of the social-ecosystem, also have resilient characteristics, such as complexity, precariousness and adjustability within certain limits. Through various methods, the resilience concept will play a positive role in promoting village renovation

Compared with other villages in China, the area and population of villages in forest areas of severe cold regions are relatively small. Therefore, in the process of village renovation, the resilience of individual residential units is superimposed, which will form a great synergy in the residential settlement and directly influence the construction of resilience villages. Thus the resilient village construction requires the integration of residence, village and surrounding environment.

3.2 Space-time Characteristics of the Resilient Village

In terms of basic characteristics, the resilient village includes redundancy, flexibility, learning capacity and restructuring capacity (Figure.8).

In terms of spatial situation, the spatial form of the resilient village is dynamic with the resilient capacity. Resistance and precariousness are a set of opposition factors, and the degree of dispersion is determined by the resilient capacity. Thus the spatial situation model of the resilient village is similar to a dynamic cylinder, the section of which expands or contracts with the size of resilient capacity, and the height expands with the influence of social, economic, ecological and technological factors (Figure.9).

In terms of time series, precariousness and resistance of the resilient village system interact with each other over time, and the result determines the resilient capacity of a village. If the resilient capacity gets larger, the system is still in the original stable landscape, or towards a higher level. If the resilient capacity gets smaller, and the threshold also reaches the maximum, then the village will go beyond the threshold into another kind of stable village, or fall into a temporary system collapse (Figure.10).

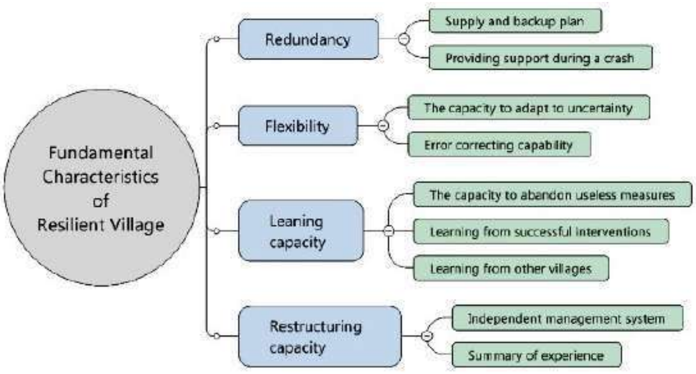

Figure.8 Fundamental characteristics of resilience village (Source: Author, derived from Surjan 2001).

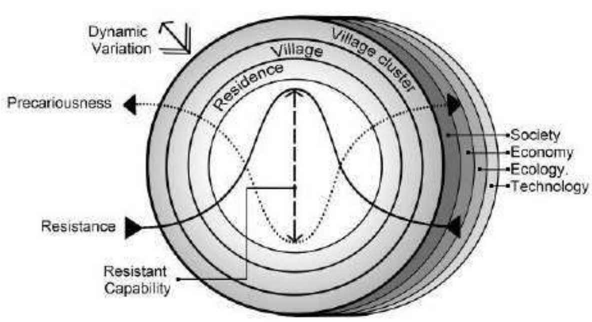

Figure.9 Spatial situation model of the resilient village (Source: Author).

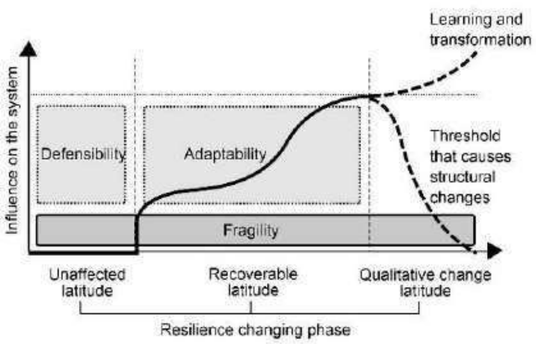

Figure.10 The time series model of the resilient village (Source: Author, derived from Wilhelm 2012).

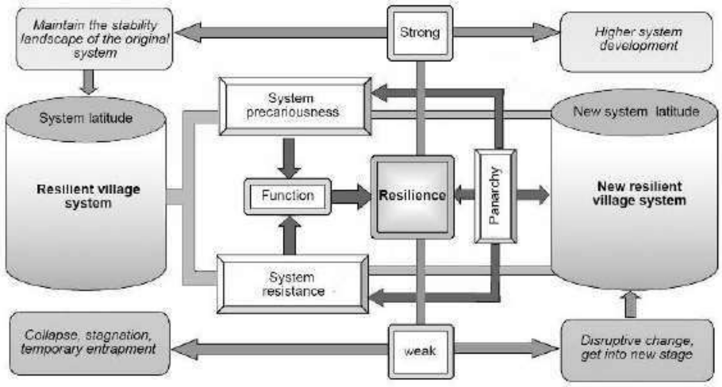

Figure.11 Stability landscapes on the resilient village system (Source: Author, derived from Wilhelm 2012)

3.3 The System Model of Rural Resilient Capacity

According to the research progress of, resilience concepts, Basin Model (Walker 2006) can describe the properties of restorative force in a vivid and accurate way, which includes state space, basin of attraction and stability landscapes. Among them, stability landscapes presents four primary elements that construct the resilience concepts, which are altitude, resistance, precariousness and the distance from the system to the threshold (Figure.11).

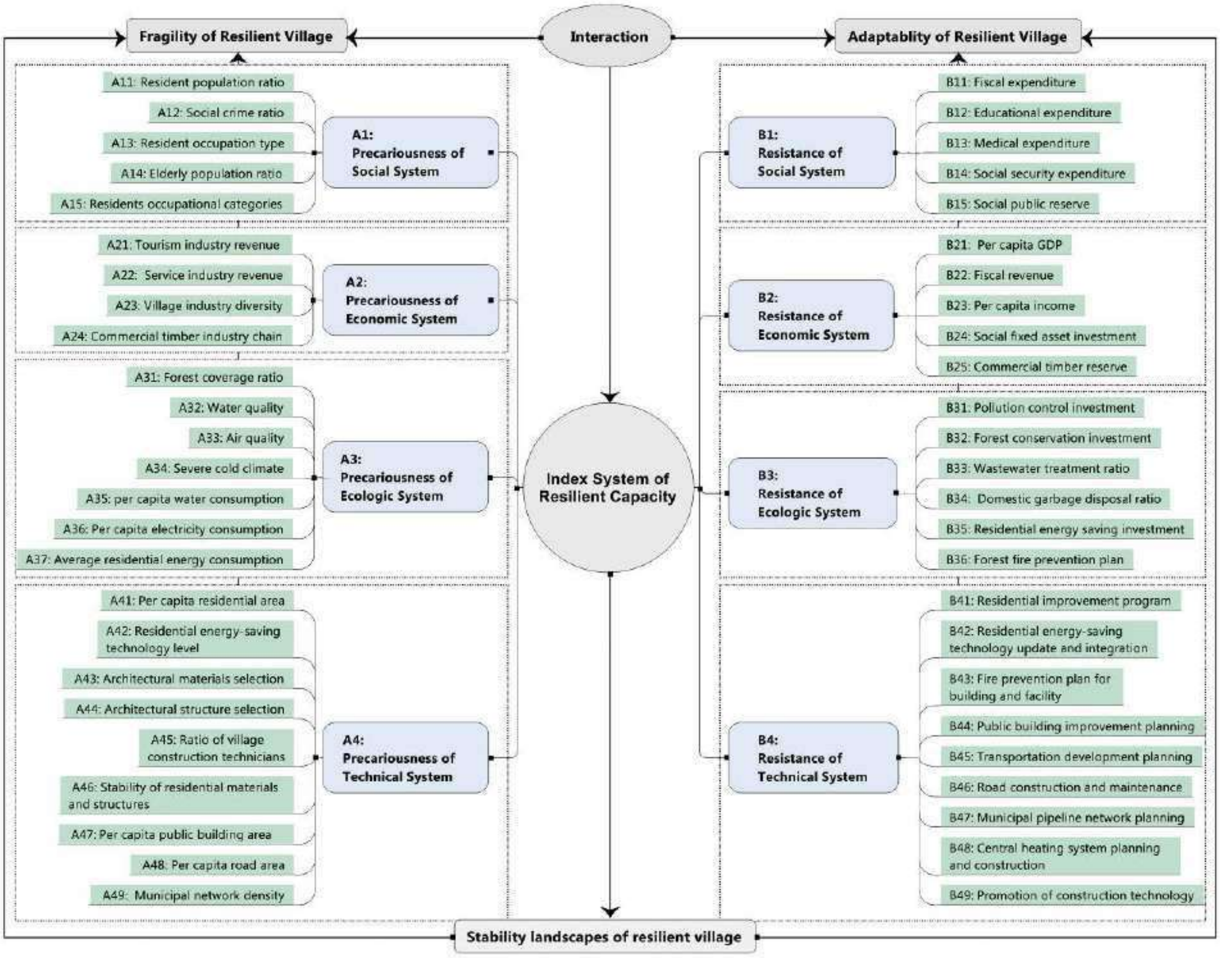

Figure.12 Index system of the resilient capacity for villages in forest areas of severe cold region (Source: Author).

Based on stability landscapes, the rural resilient capacity system has the characteristics of openness, complexity and dynamics, which constructs the basic rudiments of the resilient village. By Delphi method, the impact factors are accurately screened. Then, through Set Pair Analysis (Jingzhong 2004), the active and passive effects of impact factors on the system are calculated in detail. Furthermore, the index system of the rural resilient capacity was constructed to support the village renovation in forest areas of severe cold region, including four sub-systems, including society, economy, ecology and technology, and 50 impact factors (Figure 12). According to different action properties, the impact factors are divided into two categories: precariousness and resistance, forming a dynamic balance of the rural resilient capacity.

4. Empirical Research

Empirical Research is a practice of relevance combining engineering practice with planning theory (Benbasat 1999). Based on the previous research, Shanhe Village was selected for empirical research, for renovation planning and residential design. Shanhe Village is located in in the forest areas of Daxingan Mountain, belonging to Pingshan town, Archen City, Heilongjiang Province. After the disintegration of traditional centralized forestry management in China, Shanhe Village has been faced with slow economic development, while the industry of which has been dominated by traditional agriculture and aquaculture for these years. Compared with the surrounding villages, Shanhe Village has certain typical characteristics, with a wide range of urgent problems to be solved.

4.1 Renovation Planning of the Resilient Village

According to the specific situation of Shanhe Village, comprehensive renovation planning was conducted (Figure 13-16), including the following four aspects:

In the social aspect, the information feedback mechanism should be established so that the system can have good information circulation and self-adjustment ability. At the same time, intergenerational assistance at the community level should be promoted to develop social networks and community leadership. In addition, overlap land use should is allowed, to activate diversified living and production modes. Furthermore, residents are encouraged to participate in the planning work, to reflect their living needs and creative ideas.

In the economic aspect, the development of diversified economic modularity is encouraged to enhance the innovation and utilization of featured resources, reducing economic risk. A modern timber processing factory is planned to replace the original quarry, in order to end the traditional crude exploitation of natural resources and make refined and sustainable utilization of the commercial timber resources. With the theme of featured village experience, the local tourism industry chain is carried out, including guest service facilities, planting experience farm and a forest sightseeing route.

In the ecological aspect, the ecological service system should be constructed to realize the management and evaluation of local environment. To protect the forest, it is necessary to take fire prevention as the first priority, with popularizing fire prevention knowledge and establishing inspection system. The natural stream around the village should be reasonably protected and moderately exploited. In addition, aquaculture ponds can be set up with the topography, to mitigate the risk of rainstorm in combination.

In the technologic aspect, the plan advocates the application of technological innovation and supports the integration and utilization of efficient technologies. To achieve this goal, emphasis is placed on the renovation of energy-saving technology in residence, in order to reduce energy consumption in winter and improve indoor thermal comfort. At the same time, improving the municipal management network has been placed in an important position, including setting up centralized drainage and wastewater treatment facilities. In addition, it is also necessary to carry out technical transformation of central heating facilities.

Up to now, the renovation plan of the resilient village has been partially completed with initial results, due to the active support of local governments and residents (Figure 17). A series of hydrophilic facilities has been built including the dike, platform and bridge, forming an important hydrophilic landscape node. Rare tree species have been recorded and protected, while natural streams nearby has been cleaned to maximize ecological authenticity. The residential square has been built to hold large-scale activities. The forest sightseeing project have been carried out, along with cultivation experience fields, tourist center, tourist hotel and restaurant. In general, the positive function of the resilient village has been beginning to emerge, which has shown certain demonstration effect to the surrounding areas.

4.2 Residential Design of the Resident Village

A demonstration residence has been built in the Shanhe Village. In the process of design, construction and application, enhancing resilient capability is always being an important content, which is mainly embodied in the following stages:

In the functional design phase, the functional pattern of demonstration residence can be converted from the fourfold mode to the double mode or the single mode, based on the diverse family structure and dynamic residential pattern of the residents (Figure 18).

In the structural design stage, a variety of environmental protection materials and energy saving technologies are integrated to construct the structural system. Among them, timber is selected as the main material, to found the prefabricated light-wood structure system. The new EPS module insulation system is selected to realize the integrated construction of insulation, structure and template. The electric geothermal heating system is chosen as the heating system to reduce heating energy consumption in winter (Figure 19).

In the construction organization stage, the construction process consists of three main stages. The construction organization mainly focuses on promoting of building techniques and generalizing of the self-construction model. The self-construction model encourages the local government to be responsible for the organization and promotion, professionals for leading technical support, and residents for participating in construction of their own accord. Finally, it took about 4 months to complete the residential construction (Figure 20).

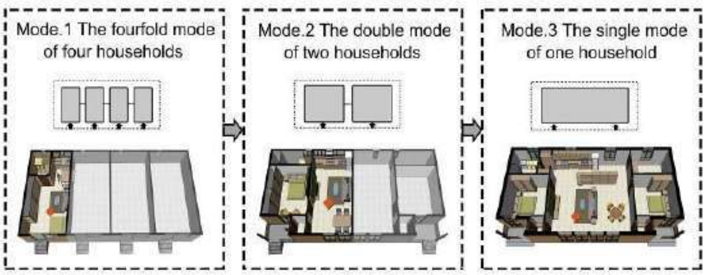

Figure.18 The residential pattern conversion (Source: Author).

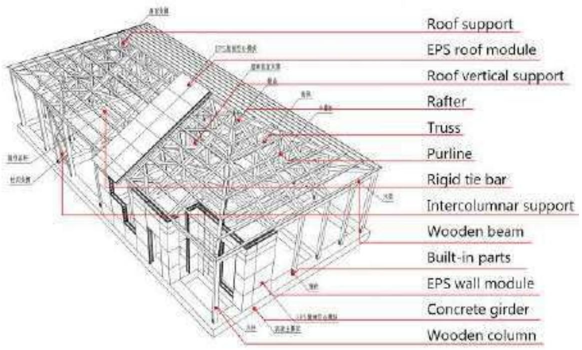

Figure.19 The prefabricated light-wood structure system (Source: Author).

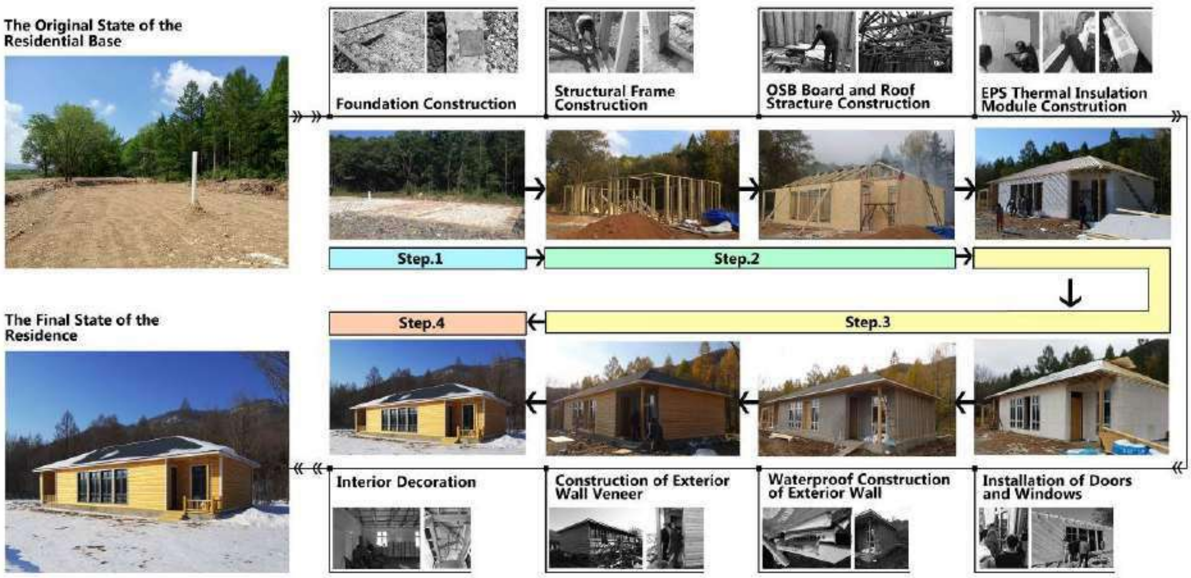

Figure.20 The construction process of demonstration residence (Source: Author).

In the testing stage, one traditional residential house in the same village was selected for comparison. During a seven-day testing in January which is the coldest month of the year, the room temperature and energy consumption were analyzed and compared of the demonstration residence and comparative residence. It is found that the average temperature and thermal stability of the demonstration residence are better than those of the contrast residence (Figure 21). Otherwise, it is confirmed that the energy consumption of the demonstration residence is less than that of the comparison residence, with the total average energy-saving ratio being 35.8% (Figure 22).

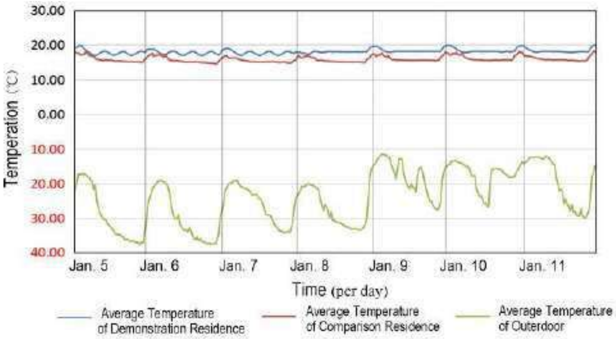

Figure.21 Comparison of average Indoor and outdoor temperature (Source: Author).

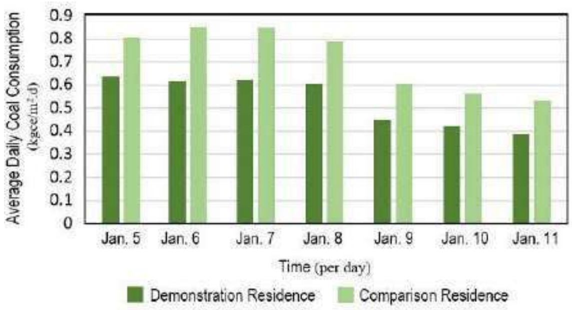

Figure.22 Comparison of daily energy consumption (Source: Author).

5. Discussion and Improvement

Based on the serial process of theoretical research, field investigation, systematic modeling and empirical research, this paper makes a relatively systematic study on the resilient village in forest areas of severe cold regions. The period of empirical research is relatively long, and the procedures are relatively complex and dynamic, according to the construction situation. So far, part of the village renovation plan has been completed, and the demonstration residence has been basically completed. Although there are still some disadvantages, the positive impact of the empirical project to Shanhe Village cannot be ignored, especially in aspects of society, economy, ecology and technology, which has promoted the resilience concept to the surrounding area as a demonstration.

By comparing the results of the empirical research with the system model of the resilient village, it is found that the resilient village system needs to be improved and revised in some aspects. For example, in the ecological aspects, it is found that local residents' awareness of environmental protection needs to be improved through systematic demonstration, and the proportion of science popularization should be increased in the ecological part of the resilient village system. In the social aspect, the system of the resilient villages need to be constantly revised and updated, according to the situation in the construction process. Therefore, the work handover of key participants needs to be properly implemented to prevent deviation from the initial target. In the technical aspect, the demonstration residence have a good guiding role for the reconstruction of endangered residence and the reformation of wooden residence. But the guidance for the reformation of general brick-concrete-structured residence still needs to be improved.

6. Conclusion

From the overall perspective, the resilient village is an systematic and dynamic concept for coping with climate change and improving the comprehensive ability of villages. For the villages in forest areas of severe cold region of China, it is necessary to carry out rational renovation planning and residential design under the guidance of resilient concepts, which also requires multi professional knowledge, support from various sides, and long-term efforts. At present, the resilient village system constructed in this paper is at the initial stage of deepening research, including qualitative research, preliminary quantitative research and empirical research. In the future, it will be a meaningful development direction to quantitative the index and to build a comprehensive evaluation system. Moreover, adhering to the resilient concepts, it is also of theoretical significance and application value to carry out the research on the expansion of the resilient village for other rural areas in special climate and ecological areas

Using Computer Simulation to Plan and Design Traditional Dong Towns & Villages in Mountainous Areas of Tongdao, Hunan, China

Xin LI, Tianjin University, China

Abstract

This paper details the use and outcomes of an automated computer planning and design simulation program, using Dong towns & villages in Tongdao, Hunan as the basis for research. The planning and design program simulates the traditional "site selection" and "expansion" processes for these towns and villages, automatically taking into account the cultural customs, community structures, and spatial characteristics of the Dong people. Encouragingly, the simulation program has successfully reproduced the traditional layout and expansion manner of existing Dong towns & villages. It is considered that the use of this program will help to protect traditions and landscapes as China continues to undergo rural-urbanization.

1 Introduction

The New Rural Construction is accelerating in China (Guo, J. Z. and Li, K. 2006). Therefore, how to protect the towns & villages' traditional cultures and rural landscapes has become a hot topic (Feng, J. C. 2013), in the face of large-scale relocation and resettlement of towns & villages. It is difficult for traditional planning and architectural design institutes to systematically research the traditional cultures, architectural forms and geographic information of varied towns & villages, due to the short design cycle and limited manpower (Figure 1).

Figure 1: Damage to the rural landscape by simple and crude planning and design. Image Source: https://www.worldphoto.org/zh/node/1549

This paper introduces a new rural planning and design program that can computer simulate the traditional "site selection" and "expansion" process of small towns & villages in China (Figure 2). We have used the Dong nationality (Figure 3) in Tongdao, Hunan, as the research basis. The simulation is structured around the traditional cultures, spatial patterns and geographical environment information of Dong towns & villages. The program can be used to assist in the protection of rural cultures and landscapes in light of rapid urbanization of the rural landscape.

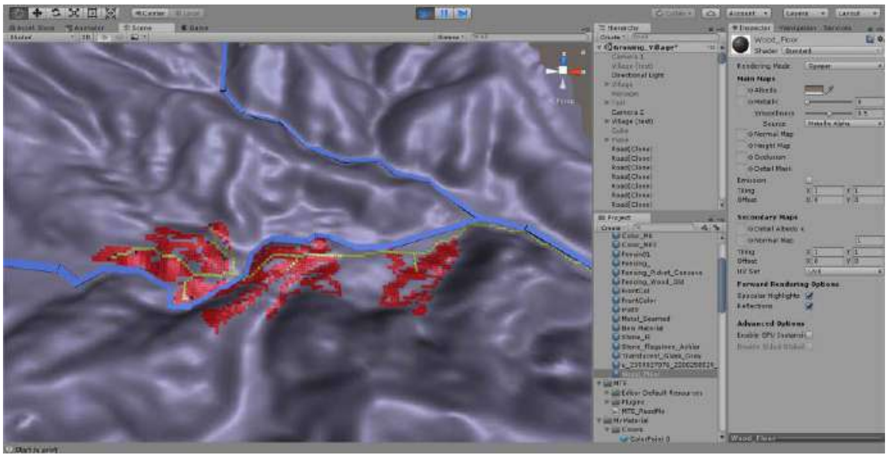

Figure 2: A town pattern created by the simulation program (with the main menu).

Figure 3: Representative examples of Dong towns. Image Source: https://www.gettyimages.co.uk/detail/photo/dong-minority-girl-royalty-free-image/168505385

Tongdao is located in the southwest of Hunan province, China, bordering Guangxi and Guizhou province, and is one of the major settlements of the Dong people. Located in the mountains and physically isolated from major centers of population, Dong towns & villages are less influenced by Han culture and customs. As a result, the traditional culture and ethnic characteristics of the Dong people are well preserved through the distinctive built character and design of their settlements. The Dong nationality is the most "architectural" nation among the ethnic minorities in China (Liu, S. 2008).

The Dong people have a unique social organization and town structure. The traditional Dong society is mainly composed from the bottom up of families, ethnic groups, clans, villages, towns and grand towns (Figure 4). Towns in the same area comply with the same local law "Kuan" to form an alliance. The layout of the Dong towns & villages is significantly affected by this social structure, where clan inhabitants form a clustered layout around a traditional drum tower (further detailed in Section 1.4).

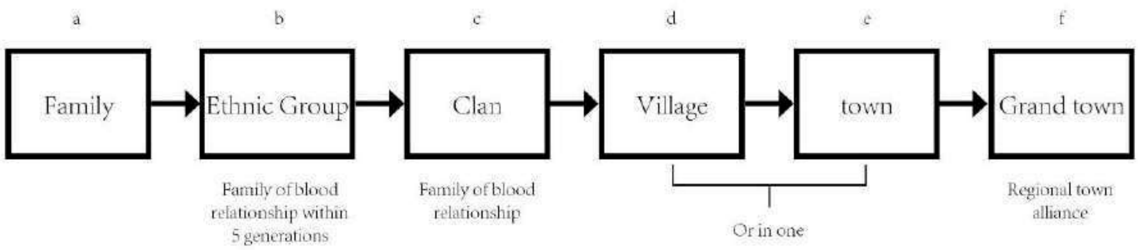

Figure 4: Social structure of Dong nationality. Image Source: Cai, L. 2013 (redrawn)

The cultural characteristics of the Dong towns & villages are unique, well-kept, and clear in organizational structure, which are characteristics that are conducive to being input into a computer simulation.

2 Background

The use of computer simulations in relation to human settlements has become more common in recent years. For example, Parish and Müller proposed a user guided city-generation based on an L-system (2001). Weber et al. developed an interactive geometric simulation of 4D cities (2009). Vanegas et al. presented an interactive dynamic system for the design of urban spaces using geometrical and behavioral modeling (2009). Emilien discussed village growth simulations on arbitrary terrains (2012). Beneš et al. demonstrated procedural modelling of urban road networks (2012). Batty simulated the urban form of a randomly established tree structure (2009). Leach established the concept of "group intelligence" to generate swarm cities (2009). PanahiKazemi and Rossi applied computational strategies for intervention in informal settlements (2014).

The pattern of human settlements are most often related to geographical conditions, nationalities, and cultures. Therefore, a simulation could be meaningful only if it captures the specific local geographical, ethnic characteristics, and cultural customs. By studying the site selection, growth and expansion of Dong towns & villages, the simulation program tries to extract the "genes" of the traditional Dong settlements and simulate it in a way that meets the traditional context and is compatible with the local environment.

3 Simulation Procedures

1.1 Overview

The author conducted a field survey of 13 Dong towns & villages in Tongdao (Figure 5, Table 1). Among them, there are 4 mountain-type towns and 9 riverside-type towns.

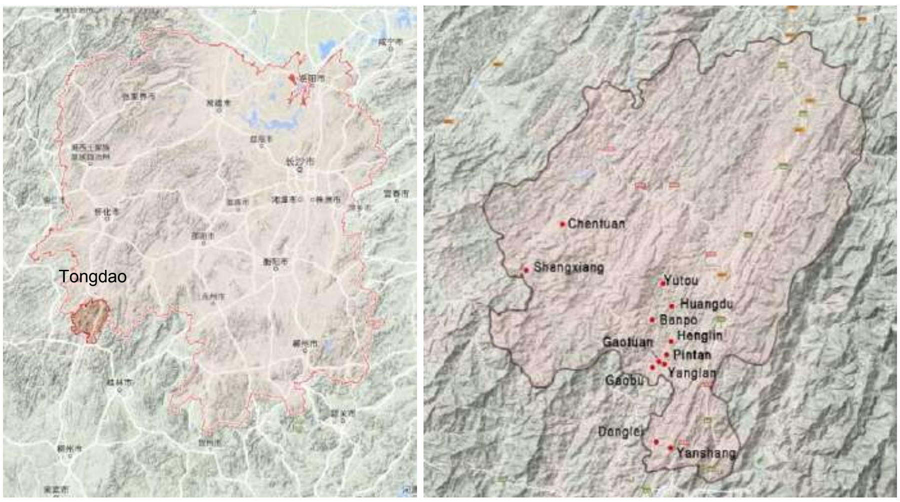

Figure 5: Location of Tongdao in Hunan province (left), distribution of the surveyed towns in Tongdao (right). Image Source: Google map (redrawn)

Table 1: Surveyed villages sorted by type

Mountain-type				Riverside-type				
Yutou	Yanshan	Banpo	Gaobu	Huangdu	Pintan	Gaotuan	Shangxiang	Donglei
				Hengling	Yanglan	Zhongbu	Chentuan	

A comprehensive statistical analysis of the Dong towns in Table 1 is conducted through related paper reading, field investigation, aerial photography, three-dimensional model reconstruction and CAD drawing. The results of this analysis are then used to establish the towns & villages' site selection, growth rule formulation and parameter settings, which can then be input into the computer simulation.

The main contents of the simulation program can be divided into four parts: environmental analysis; site selection & assessment; selection of the first drum tower site; and selection of new drum tower sites and settlement expansion.

1.2 Environmental analysis

1.2.1 Classification

Farmland is an important factor that affects the layout of towns & villages. Farmland located in flat valleys close to a river is a basic principle that forms the foundation of the layout of Dong towns & villages. By observing the layout of farmland and buildings in different types of towns, the author divides the Dong towns & villages into two terrain types: the mountain-type and the riverside-type (Figure 6). In mountain-type towns & villages, all flat valleys close to the river are primarily used as farmland, and housing will traditionally be located on gentle slopes at the foot of the mountain. Riverside-type towns & villages are usually located in wide, flat areas nearby a river. Having abundant flat land for farmland, housing will usually be located in the middle of the plains. Due to flood control considerations, housing is often kept at a distance from the river, and will form a clustered pattern surrounded by farmland.

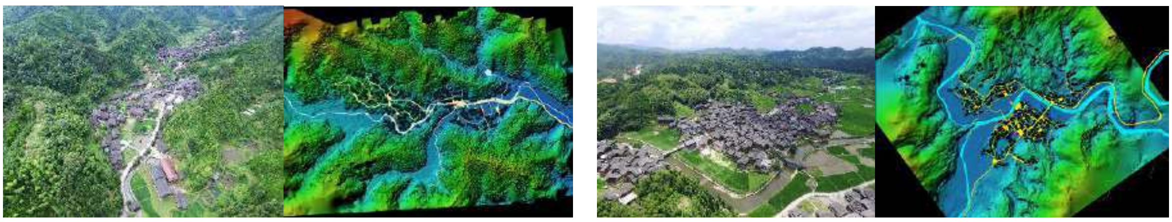

Figure 6: Mountain-type town Yutou (left) and riverside-type town Gaobu (right). Image Source: self-photographed and self-drawn

Therefore, the simulation program will first perform a slope analysis of the terrain to determine its type and will then use different slope and altitude parameters to perform an environmental assessment according to the different terrain types.

1.2.2 Analysis

The Dong people live on rice farming and plantation forestry (Cai 2013), therefore, the basic principle of site selection is being close to a mountain or river. From the cultural point of view, the Dong people inherited the remains of the ancient Baiyue culture, namely the tradition of "being in the valley, among bamboos," and " mountain and water". This is because rice cultivation requires a source of water, and the mountain can provide wood for the construction of houses, while providing space for plantation forests and terraced fields (Cai 2013).

Mountain and water are the most important influence factors for Dong towns & villages. The program simulates the influence of mountains and water resources on the site by analyzing the hydrophilicity, elevation, slope, and geographic dominance of the given terrain (Figure 7).

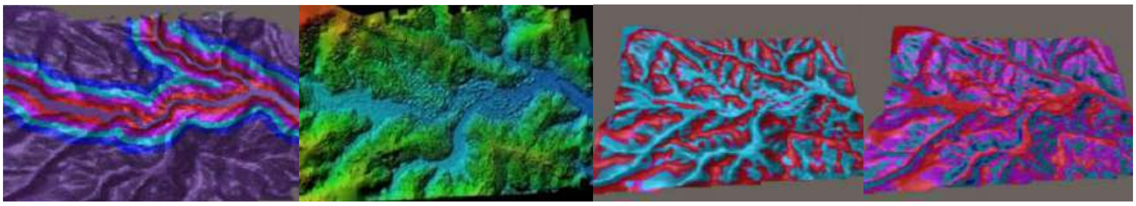

Figure 7: Yutou town's hydrophilicity, elevation, geographic dominance and slope analysis

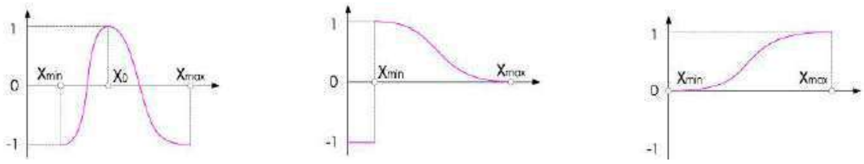

Figure 8: From left to right, function of slope & elevation, hydrophilicity, geographic dominance

The results of the environmental analysis are reflected in a scoring function at each point ("P") of the terrain model. Each point has a score range of -1 to 1. Negative numbers indicate sites undesirable for selection, and positive numbers indicate sites ideal to be selected. There are different functions for different environmental criteria to obtain the corresponding scores (Figure 8). x_{min}, x_0, and x_{max} are parameters set according to different function. x_{min}, x_{max} represent the maximum and minimum values of an environmental factor. The x_0 value represents the ideal value. Finally, the program combines various criteria scores with different weight factors. From these results, we can choose the area ("G_0") that is geographically suitable for the location of the village or town (Figure 4). However, the area obtained at this stage is not the final site selection area, but rather a collection of all possible site selection areas of the terrain model (Figure 9 and Figure 11). In the next step, we need to determine the first village (Figure 4d) that forms part of the town. The area that best suits the Dong culture will be selected from area G_0.

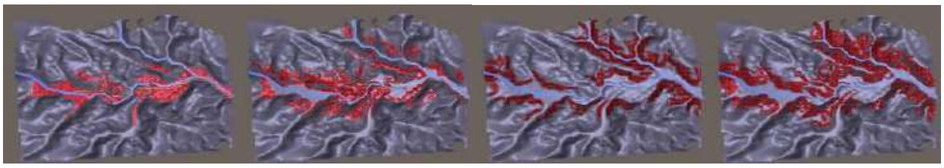

Figure 9: Influence of slope on site selection. x_0 value: 0, 15, 30, 45 degrees (from left to right)

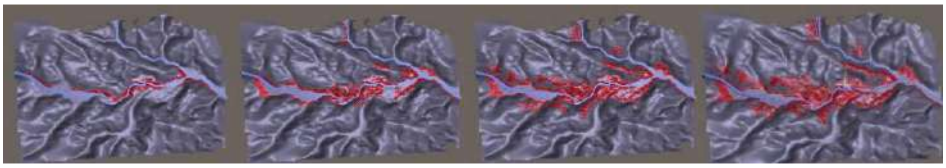

Figure 10: Influence of hydrophilicity on site selection. x_{min} value: 40, 100, 160, 200 meters (from left to right)

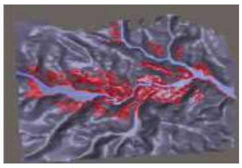

Figure 11: Influence of elevation in site selection. x_0 value: 280, 400, 520, 760 meters (from left to right)

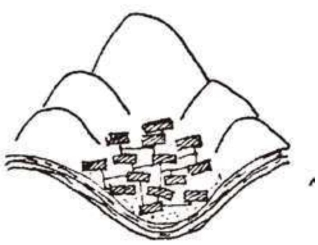
1.3 Site Evaluation

Environmental analysis is objective based on the influence of slope, hydrophilicity and elevation. However site evaluation will also require consideration of emotional and cultural factors. The site selection of Dong towns and villages follows the “Fengshui” concept similar to that of the Han nationality. Song identified (2016) that traditional settlements of the Dong people are mostly built with the characteristics of “sitting west, facing east, leeward to the sun, facing water and backing to the mountain”. As most Dong people live in mountainous areas, with constrained direct sunlight, and little airflow, facing east is conducive to receiving sunlight in the morning for the purpose of heating. Zhou mentions (2008) that ancient towns & villages in west Hunan are usually settled on the side of the mountain that is embraced by a river, which is the “lucky side” in the native “Fengshui” concept, while the opposite side is the “unlucky side”. Flood control is another important factor that influences site selection (Figure 12). Cai summarized (2013) that the ideal site of a town based on the “Fengshui” concept is with its back to the mountains, with “guarding” mountainous areas to the sides, facing a flat and wide plain, embraced by river, and that the downstream of the river should bend.



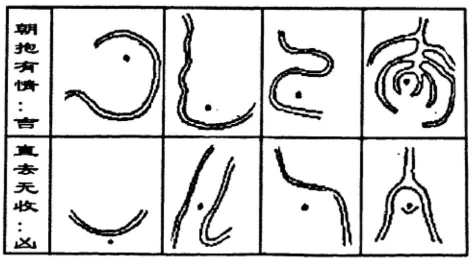


Figure 12: Ideal site selection (left), lucky (right upper) and unlucky (right lower) river side. Image Source: Zhou, T. 2008

In summary, the best site location for the Dong people would be a town located on the south-east side of a mountain, facing a flat and wide plain, embraced by river. At the same time, a large enough site area is necessary for future development. Based on this logic, the program selected the area G_1 from G_0 as the first village site of the town (Figure 13).

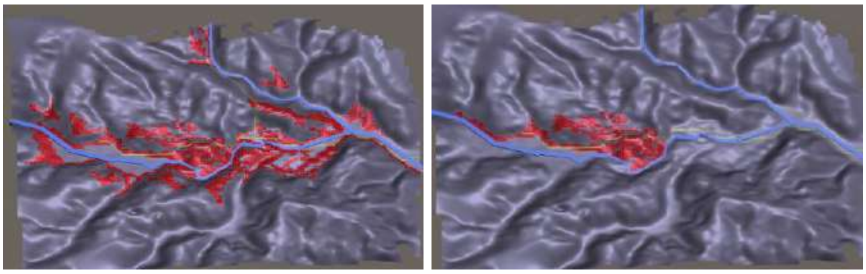

Figure 13: All possible site selection areas G_0 *(left), and the first village site area* G_1 *(right)*

1.4 Organizational Structure of Dong Villages and Towns, and Drum Tower Siting

Several clans (Figure 4c) cluster together around a drum tower to form a village (Figure 4d), and several villages will form a town (Figure 4e). This is the basic organizational structure (Figure 4) followed by the Dong people. Drum towers are a symbol of the political and cultural center of Dong towns & villages, and are an important meeting place, including for festivals and daily life of the Dong people. During times of war, drum towers are also important buildings for defense and transmission of information between nearby Dong villages. Drums placed on the tower would be knocked to summon clan members (Cai, L. 2013).

After the simulation program determines the suitable area for the first village, the next step is to locate a drum tower. Based on the core position of the drum tower, the most common location is at the center of the village. As a defense building, a drum tower needs to be situated in a position that can overlook the village. Therefore, riversides and main entrances are also common site selection locations. Among 32 drum towers the author visited (Table 2), there are 15 located in the village center, 13 located on the riverside, and 12 located at the village's main entrance, with a probability of approximately 4:3:3.

Table 2: Drum tower statistics

*ME: Main Entrance; RS: Riverside; C: Center

1.4.1 Siting the first Drum Tower

We can use the following steps to calculate the position of the first drum tower. 1) Calculate center of mass of G_0 area, to get point A (Figure 14a). Then find the nearest riverside location B from point A (Figure 14a). 2) Generate a path L (Galin et al. 2010) from A to the outside point of the village (predefined). The intersection point C between L and the G_0 area boundary is the main entrance location of the village (Figure 14b). 3) The drum tower location is determined by the probability of 4:3:3 among points A, B, and C. When located at elevation, it will have the advantage of good outlook for purposes of defense. We adjust the location by "geographical domination" analysis (Figure 14c). 4) Based on the results of this analysis, better defensive positions of A_1, B_1 and C_1 are selected within the search radius (Figure 14d).

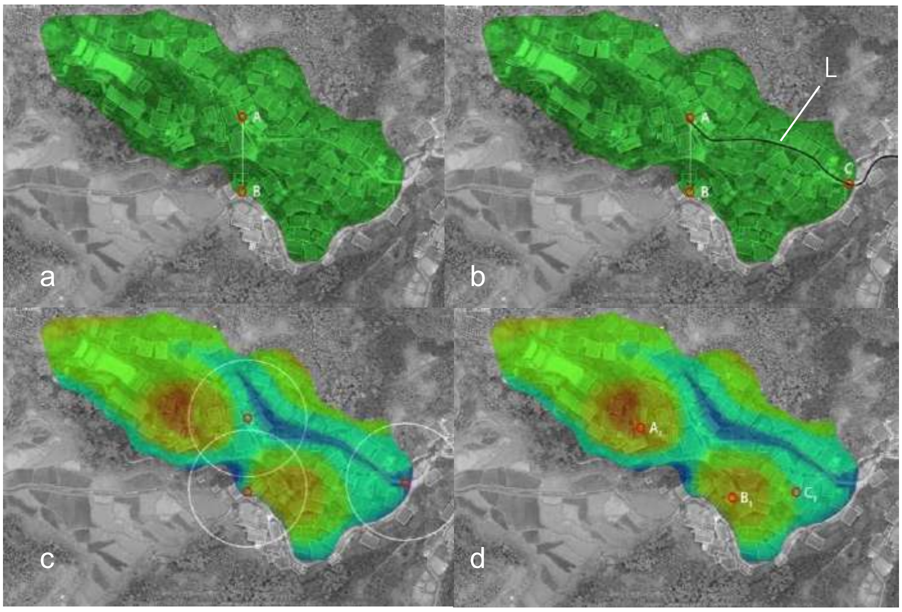

Figure 14: The process for selecting the location of a drum tower

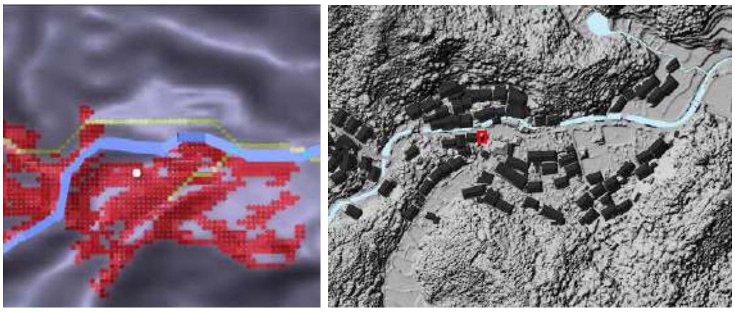

Figure 15: Comparison of simulation result (left) with real position of the drum tower (right)

1.4.2 New Drum Towers & Settlement Expansion

The expansion of a Dong town (Figure 4e) will involve the birth of a new village (Figure 4d) and new drum towers. Culturally, a drum tower is like an invisible magnet, which attracts a cluster of clan (Figure 4c) houses around it. The "magnetism" of a drum tower to attract clan houses weakens as the distance increases. Thus, a Dong village will have a maximum physical area. Any exceedance will eventually lead to an end to v illage expansion. This will usually result in some clans separating from the original village and building a new drum tower nearby, around which a new village will be established (Figure 16).

Figure 16: "Magnetism" radius of drum towers in Yutou town (left), and Gaobu town (right). Image Source: self-drawn

The results in Table 2 show that the “magnetic” radius of a drum tower is fairly regular, being on average 100 meters, and attracting approximately 60 clan houses.

The relationship between Dong villages can also be drawn by analyzing the location of the neighboring drum towers. For the purpose of local alliances, mutual defense and signal transmission, the neighboring drum towers are usually not far from the others, with an average distance of about 100 meters. When villages are located on both sides of the river, a new drum tower is usually sited on the riverside or in highlands for enhanced signal transmission (Figure 17).

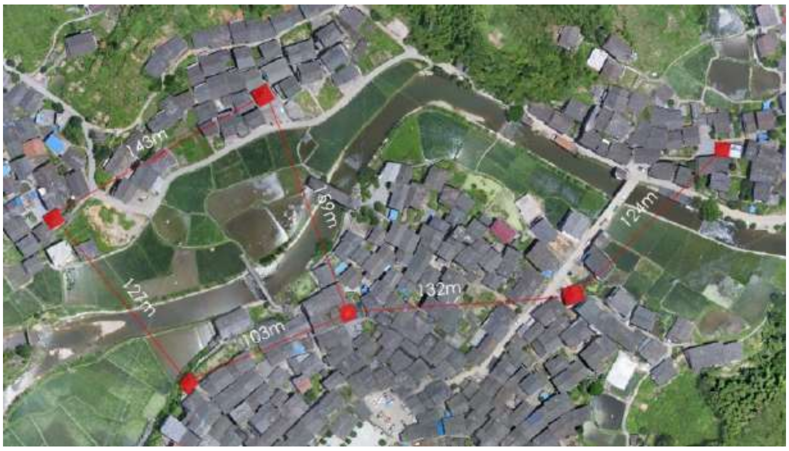

Figure 17: Drum tower network locating on both sides of the river

The program uses a drum tower network-based expansion method, based on the data collected on the “magnetism” of existing Dong village drum towers. The search area for a village is roughly an annular zone centered on the first drum tower (Figure 18a). The program calculates the intersection of this ring-shaped area with the G_0 area and selects the block with the largest area. This will then indicate the initial area of the new village G_{2a} (Figure 18b). We set the center of mass of G_{2a} as the initial position of the new drum tower and calculate the intersection of the G_{2a} region with the tower’s likely influence area. This then allows us to draw the expansion zone of the new village, represented as G_2 (Figure 18c-d).

Using the same site selection principles as the first drum tower, such as center of village, riverside, main entrance and physical elevation, we can determine the final site of the new drum tower from the G_2 area.

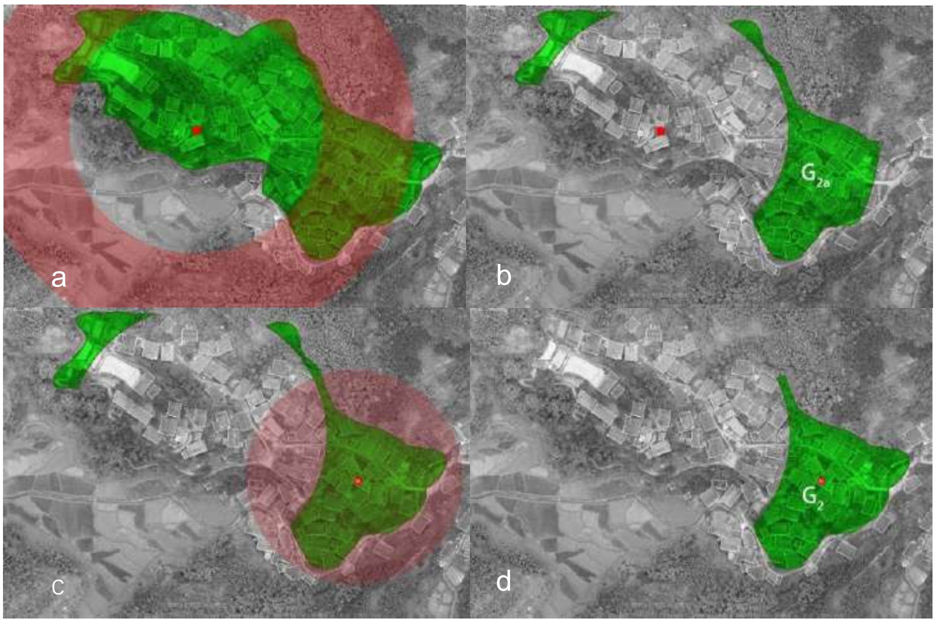

Figure 18: Site selection process of new village.

4 Results

The simulation program introduced in this paper has been used to analyze the site selection and expansion of D ong towns & villages throughout Tongdao, Hunan. The fol lowing functions are implemented:

1. Through a comprehensive analysis of the env ironment, appropriate village and town sites can be selected. Different location strategies can be adopted for different terrain types (Figure 19).

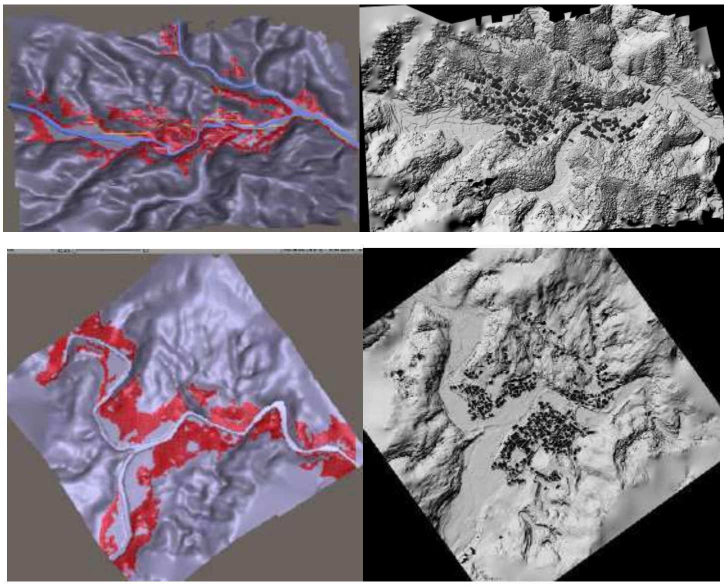

Figure 19: G_0 area of mountain-type town mainly located in sloping land (top-left), while riverside-type mainly in flat land (bottom-left), real layout of Yutou town (top-right), Gaobu town (bottom-right)

2. Cultural factors of Dong site selection can be added to the simulation by applying the traditional “Fengshui” concept to the evaluation process. The site that suits the “Fengshui” concept can be selected from all possible site selection areas to determine the location of the first village (Figure 20).

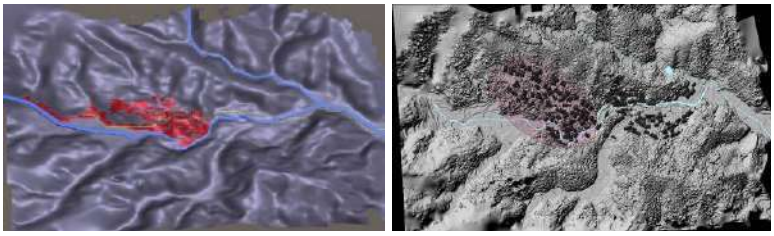

Figure 20: Program selected G1 area (left), first actual village of Yutou town (right, marked in red)

3. The ideal location for a drum tower can be determined through analyzing the village area (Figure 21).

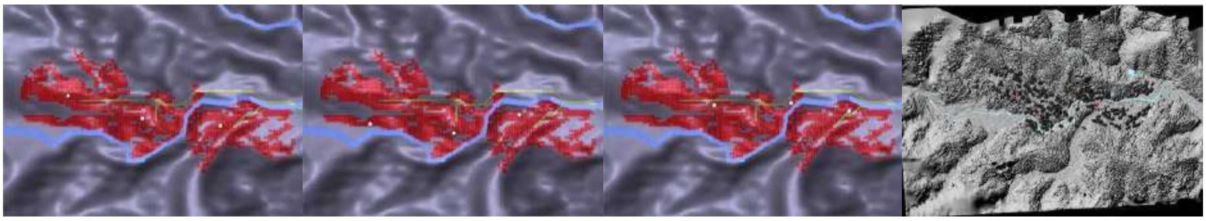

Figure 21, left-to-right: Location of Drum Towers with key factors of center of mass, riverside, main entrance, and the real drum tower’s location (marked in red)

4. The expansion of the Dong towns can be simulated through the growth of new villages and determining the location of the new drum towers (Figure 22).

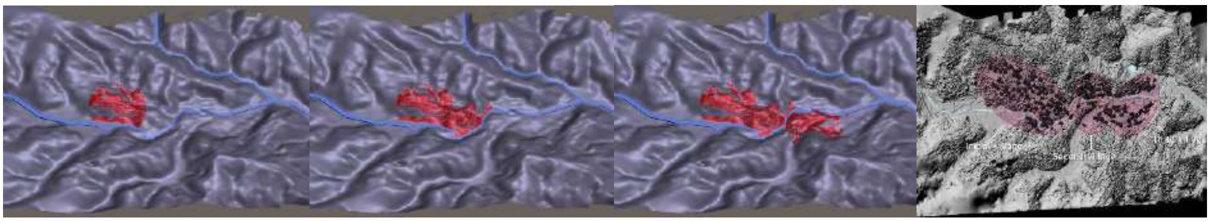

Figure 22, Left-to-right: Simulation of first, second, third villages and the real layout & sequence

5 Conclusions

This paper has detailed a novel planning & design program that can be used to simulate the establishment and growth of Dong towns & villages, through automated “site selection” and “expansion” planning based on varying terrain types. With appropriate inputs based on an analysis of existing, traditional growth patterns, the program can successfully reproduce the layout and expansion sequence of existing Dong towns & villages.

However, the use of this program is not limited to the replica simulation of existing traditional towns and villages, but can be used to guide the planning and design of new rural settlements in China, in a way that captures and preserves culture and history.

Planning for the north-European waterfront cities – issues and strategies

Piotr LORENS, Gdańsk University of Technology, Poland

1. Introduction

Redeveloping urban waterfronts is nowadays a part of planning agenda or already implemented practice in many (if not most) of the cities worldwide. Even in case these projects are not fully implemented yet, a number of the successful examples can be identified [Breen, Rigby, 1994] [Breen, Rigby, 1996]. Since the phenomenon of waterfront redevelopment is a subject of interest of many scholars, a number of the analysis of this was developed. These included such the issues as generation of the waterfront project, various types of those as well as in-depth analyses of the most appealing case studies [Schubert, 2002], [Bruttomesso, 1993].

Within these cases tourism development was identified as one of the major driving forces for many of those projects. But tourism depends to some (if not to large) extend on climate realities and associated with these issues. Therefore, these have to be taken into account while considering the design and functional solutions of these structures. Another issue is associated with the attractiveness of the waterfront itself – and it depends (among others) also on the size and attractiveness of the “host city” itself.

Within this paper the specifics of small-and medium-sized waterfront cities, located outside the “climate comfort zone” are elaborated. Within this group the special attention was paid to the cities located in the northern Europe. Usually these are small and medium –sized municipalities, rarely aspiring to become the leading centers of urban development in their respective countries. At the same time their economy was traditionally based on fishing, small-scale maritime industries and local trade. In addition, in many cases these cities are not extremely attractive for mass tourism and are located aside from major transportation routes. Therefore, it seems necessary to rethink the “urban waterfront development pattern” within these sites, as the strategies based on copying the solutions known from larger cities cannot be effectively used.

2. Waterfront redevelopment as the global success story

Redevelopment of urban waterfronts is one of the leading themes in contemporary planning practice. This issue is a subject of interest to many scholars and practitioners, associated with development of waterfront cities. In literature on this topic one can find a lot of information regarding leading examples of this process, discussion of issues and problems associated with this phenomenon as well as analysis of the results achieved [Lorens, 2013]. In addition, many specialists in this field managed to developed a sort of “guide of good practice” for cities and planners interested in undertaking an effort associated with reshaping the waterfront site [Interreg II-C, 2002]. But one can easily spot that most of the cases discussed are based in climate zones allowing extensive public use of the waterfront sites for the most part of the year. In addition, most of the appraised cases are located in the relatively large cities, which allowed development of the diversified urban program and extensive networks of public spaces. Therefore, the phenomenon of waterfront redevelopment is frequently associated with extensive development of large scale urban structures, in the climate realities allowing extensive public usage of these.

This process has been pioneered by such cities as Baltimore, Boston, London, Liverpool, Oakland, Seattle, and San Francisco. The transformations of water-based areas in these cities began as early as the 1960s. In that period was the building of the famous Sydney Opera in the early 1970s, as well as the Paseo del Rio in San Antonio, Texas. However, it was the Inner Harbour project in Baltimore that played a significant role, being the template for many other ones, e.g. Darling Harbour in Sydney. This similarity goes yet further than the principles for the realization of transformations (in the functional sense), but embraces also the cooperation between public and private sectors that leads to the realization of these projects. Generally speaking, the beginning of the transformations of the former port areas occurred in the United States, (Boston, Baltimore) and blazed trails for other centres [Lorens, 2014].

3. Complexity of urban waterfront regeneration

The revitalization of waterfronts is a complex process of many dimensions, considering the scale of issues it embraces [Brenn, Rigby, 1994] and includes the following:

Economic dimension: the transformation of traditional industrial domains is its main element, realized by such means as the introduction of new technologies and the relocation of factories beyond traditional industrial zones[1]. In effect, changes in the economic structure of cities appear, including the disappearance of traditional forms of production and processing. Hence, the new projects carried out in the areas close to water prove helpful in the economic regeneration of a city thanks to the creation of new domains of entrepreneurial activity and the creation of new work places in the service sector, etc.

Social dimension: social changes – including the growing wealth of societies – foster the interest in tourism and increase the needs for recreation. The notion of *cultural tourism* appears. It denotes the emphasis put firstly on the use of cultural values of a given site, being linked to the raised interest in local colour and the need for learning about a given place, as well as on experiencing different cultures and customs. It is also linked to the increasing sense of identity of local communities, expressed by such things as the cultivation of tradition and local customs, including those concerning water, the port and the sea.[2]

Environmental dimension: Since the 1970s, the urge to protect environmental values of valuable places has been increasing, along with the growing interest in removing pollution from degraded sites. The programs for the purification of reservoirs, also in harbor and industrial areas, are the best examples of this urge. Purity of water is an important factor in the revitalization of waterfronts and can largely determine the success or failure of the whole undertaking. The same pertains to the purity of the soil. If the land is polluted (because of former industrial activity) its purification becomes a prerequisite, which the initiators of the functional and spatial transformation project must undertake;

Cultural dimension: the protection of the historic heritage of cities, including the elements related to their identity has also been enjoying the increased interest of both public sector and urban communities. This is particularly related to the preservation of maritime tradition, expressed by cultural undertakings and a respect for particular sites shown by their refashioning alluding to local history. Of chief importance here is the revitalization of old buildings related to the harbour tradition in such a way that their adaptation to new functions can preserve the basic elements of their former design.[3] These buildings, when suitably incorporated into the new urban structure, can even work as catalysts in the development of new urban programs. The return to tradition and cultural values of former harbours is also expressed by the creation of open-air museums, the development of educational institutions (like museums or marine aquaria), and finally, the creation of new objects that develop relations with the former structures of ports both in their scale and character. They serve not only commercial purposes but are also a specific kind of depository of the collective memory of the local community, encompassing the history of former harbors and people related to them [Edwards, 1992]. These tendencies have provoked a crucial turn in the paradigms of urban planning, previously dominated by a heritage of modernist urban planning from the 1950s and 1960s.

It can be observed from the above examples that water-based areas have been transformed all over the world and that – in each case of the transformation program – an array of issues had to be taken into account. But – at the same time – it seems to be possible to define a number of key types of waterfront redevelopment patters. These may constitute a general typology of waterfront transformation schemes.

4. Key types of waterfront redevelopment patterns

The analysis of regeneration programs introduced in degraded waterfronts in port-cities may include a number of issues. Among the most important ones one may identify such the issues as: role of a project in the city structure, functional program of the project, attitude to the cultural heritage of the city as well as realization strategy adopted. These issues are presented in more detailed way in the following parts of this chapter.

4.1. The role of a project in the city structure

A different definition of a project within the city structure can be formed, depending on the scale and character of a given project:

- **a project of a significant role for the structure and functioning of the city** – this denotes first these ventures which aim at more than the solution of the problems of degraded post-harbour areas and the creation of the new quality of urban environment. Therefore, the basic elements here are the facilitation of city life and the creation of opportunities for the economic development of the city, along with the significant new residential areas and a great concentration of work places. As an example one can quote the **Canary Wharf** in London which has considerably changed the structure of the city causing, among others, shifts in main spatial arrangements;
- **project of minor importance** which do not significantly change the mode in which the city functions. These are small projects, addressing only fragments of degraded urban structures. Among the examples are **Rowes Wharf** in Boston, *South Street Seaport* in New York and particular elements in the revitalisation of the old ports in Barcelona and Genoa.

Certainly, the scheme for a given revitalisation program can be a mixture of different types. Basically, there is a combination of a single or two big projects – called the leading projects – with a series of supporting actions which are only the support and aid for the main one. A classical example of such a program are London Docklands, where the *Canary Wharf* was the main project, realized within the assumed framework and was surrounded by many smaller ones of marginal significance.

However, a slightly different situation happens in many cases. The transformation program is built from a bunch of minor projects. Yet then there is no feeling of the "new quality" being created in the waterfront area of the city and this may affect the success of the venture. The examples of such types of program can be found in Boston, San Francisco, Barcelona, and Genoa. Obviously, sometimes, certain programs became more significant than others, yet they did not gain a clear dominance in the functional and/or spatial structure of the cities.

4.2. Functional program of a project

The projects realized in the framework of waterfront transformations in cities have a very diversified functional program; therefore, some of the projects are determined as to their specific role and location in the entire structure of transformation. The following groups can be enumerated here:

Commercial projects – related to the development of downtown functions, especially service program; these can be divided into two categories:

- ***festival marketplace*** – the introduction of a commercial programme addressed to a wide public, such as shops, restaurants, entertainment, safeguarding the vista to the water, space for artistic appearances and extensive public space, i.e. the combination of places of catering and shopping with opportunities for socialising, all of this being a concentrated enterprise. The superior goal here is the creation of a specific *genius locii* as a magnet attracting people to spend time in a carefully created space. The concept of the "festival marketplace", invented by James Rouse from Rouse Development Corporation and designed, among others, in Baltimore by Benjamin and Jane Thompson, was incorporated especially in American programmes for the transformation of degraded port structures. This is linked to the lack of the European-type public spaces in American urban structures. Thus, the "festival marketplaces" served as the surrogate of such European marketplaces and blazed trails for another phenomenon, namely, artificially created urban spaces.
- ***mixed-use projects*** are multi-function structures, with a large participation of commercial and service functions, alongside a considerable office, hotel and residential programs.

Cultural, educational and environmental projects. Urban waterfronts have always provided unique placement for religious architecture, monuments, public art and big public institutions. This practice is continued today. For instance, the symbol of the post-war Australia is the opera house in Sidney, located on the Bennalog promontory. Similar, contemporary waterfront buildings often become city symbols, as Osaka Aquarium does. Waterfronts are also a logical location for the buildings which testify and document a marine heritage of a city, for example: marine museums (e.g. in Auckland and Stockholm) and historic ships mooring nearby. The buildings of these museums themselves can be significant symbols in these cities' structures as *Suntory Museum* in Osaka is (1994). However, the prerequisite for enterprises like that is the purification of water in the waterfront area. Beside symbolic and aesthetic values, these sites have also an educational value; they inform the public on the importance of water in our life and serve as the source of knowledge

– especially for young people – about environmental interdependencies governing our life. As an example, one can quote here huge marine aquaria the construction of which became the starting point for many revitalisation programs on many post-harbor areas (Boston – 1969, Baltimore – 1981). They have an exceptional power to both fascinate and educate people and are one of the most interesting examples for contemporary port-cities.

Recreational projects, An important role of waterfronts is providing leisure for its users and inhabitants. This is realized in various forms: angling, swimming, sailing, quiet musing, etc. Thus, new parks, public spaces, promenades, marinas, children playgrounds and vantage points are being created. It seems safe to presume that recreational areas with related cultural functions will dominate new waterfront projects, taking into account catering and shopping facilities, addressed to the clients of these recreational areas, aimed at the strengthening of "the waterfront experience".

Residential projects. People have lived on waterside for centuries, both for practical and aesthetic reasons. Living next to water is today so attractive that developers will quite often create artificial little lakes and ponds, to later build new residential houses around them. It is an axiom of the real-estate business that a plot near water is more expensive than a similar one, lacking water in the neighborhood. Despite the threat of hurricanes and floods, people are still building their shelters in waterside areas. The increasing demand for houses near water is an important element of the waterfront phenomenon. However, due to the fact that a house – a private space – is located on water – a public space (in a sense) tensions between these two worlds appear. When a given waterfront object is well-devised and carefully executed, a direct vicinity of water is guaranteed to the wide public and the waterside passages and boulevards become attractive and inviting. Unfortunately, an untoward tendency to separate the area from its surroundings in some residential waterfront projects has appeared, especially considering expensive luxury flats. Consequently, fencing and sentry boxes appear to create an impression that a given waterside area belongs to residents and trespassers are really unwelcome. A demanded effect can be achieved by, e.g. the introduction of a certain number of subsidized social flats, as was done in the *Entrepot West* project. The style of the development of such planes depends on location very much.

Industrial-and-port constructions. Many of the most fascinating waterfronts in cities are related with ports functioning still and operating transportation equipment on their premises. A port view with its huge cranes and ships mooring at quays is very attractive. While many of the port functions are now being carried out on the peripheries of urban structures, some have still remained in the city centres; examples of this are Oakland, San Francisco, Hamburg, Rotterdam. Heavy industrial installations, small factories, sewage processing plants, bridges and passenger terminals – all these institutions are located on waterfront land and sometimes render great influence over the shape of the whole waterside area of a city. Other elements here are small enterprises and firms linked with port sites for years, even centuries, which are situated in the direct vicinity of city centers. These institutions create a more diversified and authentic image of a given waterfront. Looking at this issue from a strictly economic point of view, such functions as marinas, boat building workshops and small shipyards, bases of fishing cutters and other objects may easily be replaced by more intense commercial functions. Therefore, they quite often leave their old location in the search for cheaper land or, even, cease their activity. Industrial users of waterfronts, especially the larger and more significant ones will remain; however, cities enjoy the possibility of making their installations more attractive, making them an attractive element in the project. In case of small marine businesses, the decision is more complicated: should one interfere to preserve these small enterprises or should one let them go. This type of enterprises, although not so spectacular as large commercial ones, offer work places, anyway, employing unqualified people, and retain the maritime character of a given local community.

4.3. Realization strategies adopted

The kind of land use in waterfront areas is based on the type of realization strategies adopted. Although, it may be possible to identify three key approaches: creation of **new physical spaces;** use of **cultural heritage spaces** and revitalization of **the space for a local community**. But – despite the adopted mode of intervention – it appears that revitalization programs for post-harbor areas usually embrace a series of single investment programs, filling the entire structure of the post-harbor area. Quite often, still abandoned and degraded areas can be neighbors to already completed projects. The projects themselves are of a different scale and character and they perform different functions in the structures of their cities. However, the rule is that they complement each other and make defined functional and spatial relations.

Still, one can distinguish certain characteristic modes of behavior:

- The entire regeneration process is based solely **on individual ventures**; in this instance there is no common idea to link them. As a result, we obtain a rather haphazard set of investment projects, often conflicting with each other in function and space. Therefore, the success of such a venture is rather doubtful. A classical example of this is the Manhattan waterfront in New York.
- Comprehensive revitalization programs are prepared and they assume the considered transformation of the entire post-harbor areas. This has a double dimension: the revitalization (in the sense of organizational and financial structures, along with the working mode) and the design. In this particular case, entire districts are subject to an all-embracing design, which tackles the whole of the architectural and urban form. This is the case with Amsterdam.
- The entire process is divided into smaller autonomous investment tasks within the framework of a general concept. This is an intermediate type of regeneration, assuming a common general regeneration scheme, embracing the realization of necessary infrastructure investment within the entire area (financed from public funds) and then, individual schemes are applied to defined projects, financed and designed according to their own schemes. Examples: London, Genoa, and Barcelona.

Considering the utility of the program introduced into post-harbor areas, one can distinguish at least two situations in the world, where:

- The goal of revitalization is to **regenerate degraded spaces into new downtown functions** of a diversified character. Such is the case of, for example, London Docks or Kop van Zuid in Rotterdam
- The revitalization programme delegates a part of the area to various port functions – both cargo handling and passenger service. As examples, one can refer to passenger terminals and ferry terminals in Genoa and Barcelona or the new port structures in the old docks of Antwerp.

One of the prerequisites for the success of revitalization programmes is the **cleaning of the natural environment**, especially water systems; an example is Boston. Usually, the formation **of an autonomous public agency** proves necessary as this body might foster such a process. Example: Baltimore Harbourplace.

The key tools guaranteeing the success of such a transformation process are:

- **Development strategy** – that allows for the avoidance of many spatial and organizational conflicts, guarantees a suitable character for the project, its division into stages and the support of the local community. Its framework should be comprised of, among others, decisions on new roads, public spaces, etc.
- **Emphasis on the adaptation of existing structures** – wharves, etc. to new purposes. This facilitates the elaboration of projects of a unique character and, simultaneously, perfectly suits the context of the given site.
- **Social research and consultations** – initiated by both private developers and public agencies, they facilitate the achievement of the best possible projects and the avoidance of unnecessary social resistance, corresponding to the use of all the advantages of the site (e.g. the use of areas of water, preventing them from being desolate, offering the possibility of a wider view of the situation on the water, etc.).
- **Cooperation with the local community** – this not only helps to avoid conflicts with the community but also, rather, gains community support and cooperation in carrying out the project, thanks to the guaranteeing of defined benefits. This also permits the improvement of the project making it more attractive, for example, by facilitating suitable conditions for the development of local artisans or art

The above comparison proves that the key elements in revitalization programs of post-harbor areas are:

- *Defined operations on infrastructure*, new roads and public spaces, bestowing new areas with a defined new structure
- *Varied scale and character of investment programs*, which will impose a defined structure onto entire areas
- *Coherent financial and organizational modes for the realization of particular tasks*, which guarantees a well-organized, efficient realization of particular programmes and their parts

Public spaces and infrastructure are designed individually so it is difficult to speak about any sort of classification. However, the issues for particular projects in different cities are often of similar character, so their arrangements can be applied appropriately in pre-defined ways in various places. The case of the organizational-financial team is difficult to classify, as are the organizational and financial modes, of which thorough analysis is a necessary supplement to the discussion of strategy and the realization of particular objects.

4.4. Attitude to the cultural heritage of a city

Historic waterfront areas are inseparable from the maritime heritage of local societies and as such are related to the prosperity years of many port cities. Traditionally, waterfront neighbourhoods are counted the most colourful parts of cities, with regard to the medley of historical architecture. In many cases, the option of the purification of architecture from some part of historic structure for preservation and revitalisation is decided upon, instead of cleaning the huge areas from the remains, considering such a choice proceeds a rich (in the cultural sense) milieu. However, the process of "gentrification" and the creation of "false history" are often spoken about. Nevertheless, were the redevelopment of old structures does not go along with the income from selling the exclusive flats located in old warehouses and other structures, these structures, often ancient, would dilapidate as unprofitable.

While a former warehouse shines again, now being i.e. a wine shop, the renewed structure becomes even more interesting in its form and atmosphere than many modern buildings, even if it is no longer received as "authentic" old warehouse. **The atmosphere of a city which has been able to preserve its historic waterfronts is now helping the city face an opportunity to profit from modern tendency to maintain links with the past.** There are many examples of operations, each different in its nature, which result in:

- **the removal of the whole of existing structures and the introduction of a new layout**, no links with the site are developed. This type of activity is only exceptional, e.g. the non-durable character of existing building structure or the lack of any aesthetic values. The glaring examples of this approach are Manhattan waterfront in New York, especially Battery Park City.
- **the preservation of old urban layout and single structures** and the removal of the remains of the to-date existing economy. This type of intervention is the most often rendered because it quite often proves impossible to preserve many of historic buildings of little or no cultural value at all. What is preserved, instead, is the wharf layout, extensive water system, while selected objects of high aesthetic values are being renewed. Examples of this are: a significant portion of London Docklands, especially St. Catherine's Dock and Albert Dock in Liverpool.
- **the full preservation of old structures and filling them with new content.** This type of intervention is rather rare because the condition and structure of development hardly ever permit the preservation of the majority of buildings.

5. Climate and location issues vs waterfront redevelopment schemes

On the basis of the “success stories” of many cities undertaking the waterfront urban redevelopment process also municipalities located in “less privileged” from the climate point of view areas as well as small- and medium-sized cities tend to rethink their water related urban structures. This relates both to cities located in the hot and cold climate zones – which to large extent make the traditional type of waterfront redevelopment patterns unviable, both due to climate conditions and – being the result of those – different economic and cultural realities. In result, the design patterns based on the traditional “success stories” seem to be unsuitable for these locations and the designers and developers of waterfront sites located in such cities have to look for the alternative solutions. Same applies to small- and medium-sized cities, which not necessarily bear potential for implementation of the mixed-use, large-scale urban projects. In these cases also the problem of relations between “global” trends associated with development of mass tourism as well as with implementing the typical mixed-use patterns and specifics of local economy and cultural environment has to be taken into account.

In case of those cities one can identify the following key specific approaches associated with the nature, scope and character of the smaller scale and located within the less-privileged climate realities waterfront redevelopment program. These were developed in relation to an overview of the issues associated with this topic as presented in the previous part of this paper.

5.1. The role of a project in the city structure

One has to note that in this case transformation of the waterfront is associated with the redevelopment of the entire city economy – as it takes place of former fishing industry and small port operation facilities. This means that implementation of such a program is based on the fact that traditional small-scale maritime industries are fading away and that the new type of economic activity – which is associated with spatial transformation – are taking the place of the "old" industries. This is associated with transformation of the fishing industry, diminishing importance of the small-scale cargo shipping etc. Therefore, since the scale of the intervention is usually medium to large (in relation to the scale of the existing city) and also due to the fact that its associated with transformation of the key economic sector of the city, it can be stipulated that the role of the waterfront redevelopment for the entire urban development process is much larger in case of small-and medium-sized cities than in case of large cities and metropolitan areas.

In this case one can state that the new intervention not only aims to solve the site-specific programs of the degraded post-harbor and post-industrial sites, but also can change the entire economic and spatial profile of the city, including introducing its new water-oriented face. This may be associated with diminishing the importance of the historically developed main streets or urban centers, but this depends on the existing spatial structures of the cities. Also, the functional composition of such an intervention depends heavily on above mentioned role. Similarly to other cases, usually the transformation program is built from a bunch of minor projects, but – usually – due to the scale and character of the intervention – these constitute the new "urban quality" not only for the site involved but for the entire city.

5.2. Functional program of a project

The projects realized in the framework these transformation schemes – in line with the typology presented in the previous chapter – may be very much diversified from the functional point of view. But there are two sets of factors, which make the functional profile of these projects different:

- Climate realities – which make the open-air recreation very limited in time throughout the year;
- Realities associated with the scale of the cities – which decide about the different profile of the users – both in terms of tourists, inhabitants and businesses – than in case of the large cities and metropolitan regions.

Therefore, within each of the functional categories (as listed in the previous chapter) the following specifics of the particular types of the projects may be observed:

Commercial projects – are usually associated with more traditional **mixed-use projects**, with a large participation of commercial and service functions. These may include hotel and residential programs, although most of those are focused on tourist industry and – to some extend – on creating the new offer for the inhabitants of the city. Also, the new office spaces may be part of such the developments, but usually these do not constitute the most important part of the intervention.

Cultural, educational and environmental projects – these may become the very important parts of the transformation schemes of the small- and medium-scales waterfront cities. Especially the projects associated with local history, traditions and culture are of great importance for the success of the entire scheme. In case of some of the cities, these projects may draw attention of tourists and visitors, planning to visit these sites just because of these attractions. The best example may be the small Polish city of Hel, which is famous in the country because of two institutions: center for rehabilitation of Baltic seals (the only one in the country) and fishery museum (occupying the old church).

Recreational projects – are usually limited to the public spaces which are used only for the short periods of time (due to climate reasons) as well as marinas and yacht operation facilities (which are also active only for the fraction of the year). Therefore, on the contrary to the many of the world-famous waterfront projects, the recreational facilities do not play the leading role in the structure of the entire scheme. But at the same time one has to note that these elements still constitute the very important part of the overall "waterfront experience".

Residential projects – play a very important role in these schemes, although it has to be noted that usually these are places of the “second apartments” or “holiday places” rather than permanent living areas. This comes from the fact that small-and medium-scale cities are not in need of such the prestigious and posh places to live, and their communities are not interested (in general) in moving to these places. Therefore, the rules which are applied to other residential projects, do not work in these cases.

Industrial-and-port constructions – still are (and probably for long will be) still of great importance to the analyzed waterfront sites. Although many of the small-scale maritime industries are gone (like fishing, food processing, small cargo handling etc) due to major shifts in economic realities and globalization (to name just a few), still there is room for niche type of functions – like pleasure fishing, yacht maintenance / repairing / production etc. It has to be noted that these activities usually are not aimed to compete on the larger markets, but do decide about the local identity of the space and are focused on local customers only. In fact, many of these may – due to these factors – actually decide about the attractiveness of the project and / or the city itself. Of course, many of those may have historic origins and long years of tradition, but also the entirely new businesses within this sector (and spatial constructs associated with these) can be identified [Kautto, 2001].

5.3. Realization strategies adopted

When discussing the realization strategies, all three models described in the preceeding chapter (namely: creation of **new physical spaces;** use of **cultural heritage spaces** and revitalization of **the space for a local community**) can be employed. It also appears that – in the end – revitalization programs for small-and medium-scaled cities usually are based on comprehensive transformation of the infrastructure (public spaces, embankment improvements etc) along with an array of individual small-scale building interventions (in form of individual building projects).

When discussing the utility of the program introduced into post-harbor areas, usually within the regeneration scheme includes both various small-scale port functions (as described above) as well as downtown / city center type of structures. Of course, in each case one of the prerequisites for the success of revitalization programs is the **cleaning of the natural**

environment, especially water systems; but it has to be noted that this usually is not a huge problem and a major obstacle for the regeneration program.

5.4. Attitude to the cultural heritage of a city

As discussed above, historic waterfront areas are inseparable from the maritime heritage of local societies. In addition, these areas usually are home for interesting parts of the maritime heritage, including port cranes, warehouses, embankments etc. But at the same time in case of the small- and medium-sized cities the scope of this heritage is much smaller than in larger cities and ports, and – in addition – the structure and character of these elements are much less important form the architectural and industrial heritage point of view. Therefore, in many cases it is decided to keep a lot of the historic elements, but usually these are reused for the new functions – although keeping their heritage character. This contributes to the outstanding identity of the site as its “unique feature” [Brattberg, 2001].

6. Conclusions

As discussed in this paper, waterfront regeneration is one of the leading themes in contemporary planning agenda. In addition, it can be perceived as a world-wide urban success story. There are many examples of the successful transformation, although usually only the cases from large cities are taken into account.

It was argued in this paper that the small-and medium-sized cities as well as ones located in the “less privileged” climate zones do require slightly different approach due to their specifics and character. But at the same time it seems that transformation of the waterfronts in these cases may be of much greater importance for the city as such than in case of larger urban areas.

In addition, it has to be stated that not only the character of the urban structure in these cases is different but also the economic rationale of this transformation is of different character. In the end, the entire process has to be dealt with in an alternative way than in bigger urban centers.

1. Introduction

In Brazil, the Urban Growth Boundary (UGB), called as “Urban Perimeter” and as part of the Comprehensive Plan, is defined by a specific municipal law. It is a polygon that outlines the urban area of a municipality and, by exclusion, the rural area. The spatial distribution of urban occupation in a municipality territory may produce, and in fact this occurs, a plurality of UGB polygons. For legal effects, only the land inside these polygons are recognized as urban land. These polygons demarcate urban settlements, urban expansion areas and specific urbanization areas (communities in rural areas with urban characteristics).

Urban perimeter is the most used urban planning tool in Brazil - present in 85% of Brazilian municipalities (IBGE, 2015) -, to arrange and control urban growth. Besides that, it is also used for tax purposes, since it delimits the areas where municipal property tax can be applied.

However, it is observed that urban perimeter does not play its role due to: i) its original oversize setting; and, ii) its subsequently progressive enlargement. This is an evidence of poor urban planning and technical fundamentals, used to provide throughout the city social housing, gated communities or other typologies as well (Santoro, 2014). This is also reinforced by municipalities’ legislators, managers and technical staff understanding of urban perimeter as a mere instrument to regulate conversion of rural into urban land, allowing without limits horizontal urban expansion pushed by real estate market dynamics. Thus, this common understanding leads to the annulment of urban perimeter as a technical tool for arranging and controlling urban expansion.

This is a relevant issue for the international debate about sustainable urban growth, considering the opposite models of urban development: compact and continuous vs. fragmented and dispersed. According to the United Nations sustainable development requests the ability to ensure that “it meets the needs of the present without compromising the ability of future generations to meet their own needs” (Brundtland, 1987). The former model better applies to the objectives of sustainable urban development considering the three fundamental principles: economic growth, social equality and environmental protection.

Based on this development model, urban planning should consider urban expansion economic feasibility (where benefits exceed investment costs needed to urbanize new areas); social equality (where all citizens of new urban areas access urban infrastructure, facilities and services) and environmental protection (where natural resources are preserved, environmental fragilities are respected and urban expansion negative impacts are mitigated).

Nevertheless, there are, by innumerous perspectives, opposing theoretical sides in the international debate about the real effectiveness of the UGB, or similar, as an instrument to control urban sprawl and, consequentially, to preserve agricultural and natural areas from uncontrolled urban occupation. It can be mentioned, as examples, the initiatives of: Seoul in South Korea (Bengston & Youn, 2006); Melbourne in Australia (Ball, Cigdem, Taylor & Wood, 2014); Brussels in Belgic (Boussauw, Allaert &Witlox, 2013); besides many others in Portland

and in the State of Oregon, in the United States (Mildner, Dueker & Rufolo, 1996; Weitz & Moore, 1998; Jun, 2004).

In this context, this paper's objective is to contribute to the discussion about urban perimeter adequate shaping and dimensioning towards sustainable development in the state of Parana, Brazil. Thus, the following spatial metrics related to urban perimeter are considered: i) gross demographic density; ii) occupation rate; iii) displacement of its centroid from city center; and iv) shape irregularity degree. To produce the required geostatistical information, considering urban perimeters of Parana state municipalities, it is used the GIS application called "SEDU/PARANACIDADE Interativo".

However, initially, aiming to better understand urban perimeters performance in Parana, it is briefly presented the context of Brazilian municipalities concerning: i) their political and administrative autonomy; ii) their competence to legislate on urban issues; iii) the urban perimeter in the context of Brazilian urban legislation; iv) the relation between the urban perimeter and the Comprehensive Plan; and v) the financing system for urban development in Parana, managed by the Autonomous Social Service PARANACIDADE.

2. Urban perimeter as an urban planning tool in federal legislation

Brazil, located in the subcontinent of South America, is a federative republic composed of the indissoluble union of 26 states, a federal district and, peculiarly, 5.570 municipalities. The latter are also federative entities and are political, administrative and financially autonomous. They share duties with the federal and state governments and have their own as well.

According to 1988 federal Constitution, municipalities are ruled by "organic laws" (leis orgânicas), which act in a similar way to constitutions. Furthermore, they ought to legislate about local issues, in compliance with the state and federal legislations. Likewise, they are responsible for their territorial arrangement, through urban land planning, parceling and, use and occupation control. Municipalities ought to plan and implement the municipal development policy, considered by the Comprehensive Plan, which is itself prescribed as an urban planning tool in municipality's organic law.

Even though the definition of urban perimeter, by a specific law, is a municipal duty, there are general legal requirements to be considered regarding federal legislation. According to Braga (2016), the very first reference to municipalities' requirement to define an urban perimeter is the 1966 National Tax Code (Law 6172/66). As stated by this author, the municipal urban property tax can only be charged to real estate owners whose properties are within urban perimeter. Afterwards, in 1999, an amendment to the federal Urban Land Parceling Act (Law 6766/79) set rules to land parceling restricted to urban areas, urban expansion areas and specific urbanization areas, as defined in the Comprehensive Plan by means of the urban perimeter law.

In 2012, an amendment to the 2001 Brazilian Statute of the City (Law 10257/01), which establishes general guidelines to urban policy, defined criteria to be followed when municipalities change the urban perimeter. By means of a specific urban development plan, it must be considered: i) the delimitation of the new urban perimeter; ii) the definition of areas restricted to urban occupation or subjected to special control due to natural disasters threats; iii) the definition of specific guidelines and areas where infrastructure, transport system, public facilities, either urban or social, will be available; iv) the description of land parceling and use and occupation parameters, so that use diversity, employment opportunities and income generation are enhanced; v) the definition of areas for social housing; vi) the definition of guidelines and specific tools towards environmental protection, and historical and cultural heritage preservation; and vii) the definition of an equitable sharing mechanism considering the benefits and the burden arising from urban growth.

Although the Statute of the City addresses the urban perimeter issue in the context of the Comprehensive Plan Chapter, their relationship is fairly weak, as far as the former is not, in fact, considered neither as an urban policy tool nor as part of the Comprehensive Plan. Besides that, the latter is only mandatory to 30% of the Brazilian municipalities: those with more than 20 thousand inhabitants, that conform metropolitan areas and urban agglomerations, that make part of tourism regions, and those where investments may significantly harm the environment or are vulnerable to natural catastrophes.

2.1 Urban perimeter as an urban planning tool in state legislation

The state of Parana, located in the South region of Brazil, is one entity of the Federative Republic of Brazil and is subdivided into 399 municipalities. In its 1989 state Constitution are established guidelines to urban policy, more specific than those in the federal Constitution. Likewise, the state Constitution also defines that Parana cities with population less than 20 thousand inhabitants will receive technical assistance from an urban development state agency to fix general rules for urban land occupation, aiming to guarantee the city and private property's social function. The state agency created in 1996 by law (11498/96) is the Autonomous Social Service PARANACIDADE.

Replacing an older one founded in 1972, its aim is to foster urban, regional and institutional development in favor of Parana municipalities, following state urban policy guidelines, and to encourage them to participate in the formulation of state urban policy and Parana financing system design to support them.

Since 2002, Parana government has established the State Financing System for Municipal Development (Decree 5631/02), which is managed by PARANACIDADE, aiming to finance urban infrastructure and institutional strengthening actions. Among the latter is the Comprehensive Plan. PARANACIDADE provides to state's municipalities its Terms of Reference and related technical support. The delimitation of the urban perimeter is implied.

PARANACIDADE's Comprehensive Plan Terms of Reference content strictly follows the State Urban Development Act (Law 15229/06). Differently from other Brazilian states, it sets the Comprehensive Plan's scope, to be considered by Parana municipalities, which includes:

i) Collection of data, diagnoses and guidelines regarding both urban and rural as well as regional municipality's reality considering environmental, socioeconomic, socio-spatial, public infrastructure and services and institutional aspects;
ii) Guidelines and proposals, establishing municipal urban and rural development policies and a permanent planning system;
iii) Urban legislation: Comprehensive Plan, urban perimeter, urban land parceling, urban and rural land occupation and use control, street network, building code, code of ordinance, and urban instruments as proposed by the Statute of the City;
iv) Investment Plan, according to Comprehensive Plan's priorities, as a tool for municipal capital budgeting;
v) Monitoring and controlling system of Comprehensive Plan implementation based on indicators;
vi) Urban planning and managing administrative unit within local public administration.

This same state law also prescribes that state government will only lend money from the State Financing System for Municipal Development to those municipalities that have a Comprehensive Plan and therefore an urban perimeter law.

Among 152 municipalities of Parana state that signed financial agreements, in the last two years, 81 did not change urban perimeter polygon after Comprehensive Plan's approval, while other 71 did. Most of these (41) have changed it only once in a 10-year period, although 6 have reached up to 25 amendments in the same period of time. This indicates that urban perimeter changes occur in periods shorter than the maximum time gap established by the Statute of the City as mandatory to Comprehensive Plan updating.

3. A theoretical approach to Urban Perimeter and UGB effectiveness as an urban planning tool

The arranging and controlling urban tools effectiveness, as in the case of urban perimeter in Brazil and the Urban Growth Boundary in other countries, has been a controversial subject of international theoretical debate. In a positive perspective, there are those that defend that urban perimeter sets limits on horizontal expansion, contributing to urbanization costs decrease, by making it more compact and sustainable. On the other hand, some doubt about its effectiveness due to the lack of scientific evidence.

According to Braga (2016), urban perimeter is one of the most important urban tools to urban development policy implementation, since it qualifies municipal land for urban use by recognition of areas suitable for urbanization. The author also reinforces that incorrect urban perimeter delimitation, due to its oversize, contributes to increase environmental, social, urban mobility and infrastructure costs.

In line with the need to control urban sprawl, Silva, Silva & Nome (2016) argue that the lack of instruments to arrange and control urban growth, such as the urban perimeter, contribute to worsen citizens' quality of life. The authors point out that, in a country like Brazil, which presents extreme social inequalities, it is a contradiction to defend dispersed, low population density cities, which is inconsistent with sustainable development. This idea brought by all these authors was already present in Mascaro (1986).

Haughton & Hunter (1994) defend high urban population densities in favor of sustainability, because: i) it maximizes the use of available infrastructure and reduces both the relative cost of its implementation and the need for its extension to distant areas; ii) it contributes for reducing commuting, since concentration of people favors economic activities at the local level; and iii) it tends to favor pedestrianism and the implementation of collective transportation systems.

Although some recognize that urban growth control produces more sustainable cities, there is no agreement on formal UGB effectiveness. Jun (2004) compared the metropolitan area of Portland urban growth, which has an UGB, with other metropolitan regions of the United States that do not have it, between 1980 and 1990. The author's conclusion was that in both cases, the process of urban sprawl was similar.

As in Portland, Boussauw, Allaert & Witlox (2013) pointed out that urban sprawl excessive control and compactness in Brussels, capital of Belgium, increased surrounding cities urbanization, intensifying the suburbanization process. Although this phenomenon usually occurs in metropolitan areas, it cannot be ignored that it may happen in any other smaller urban contexts as well.

Another important aspect, regarding urban delimitation, aiming to increase occupation density and optimize the available infrastructure, is urban land price increase. Ball, Cigdem, Taylor & Wood (2014) suggest, from a study of the metropolitan region of Melbourne, in Australia, that land prices rose within the UGB after its enactment. Land price increase and interference with free real estate market forces are some of the main arguments against UGB as an instrument to arrange and control urban space.

In Brazil, as adequately pointed out by Santoro (2014), urban perimeters are, in general, flexible, responding to local real estate market forces, rather than a restrictive and controlling tool. The author states that urban perimeter laws, in Brazil, are usually modified on a case-by-case basis, without clear urban planning objectives and guidelines.

Although urban perimeter effectiveness to arrange and control urban sprawl can be the subject of important theoretical questionings, the way it has been used in Brazil - flexible and on demand under pressure of real estate market forces – makes it, in fact, an annulled instrument of urban planning.

4. Method of analisys

To achieve this paper's objective, a method, similar to that used by Braga (2016) to the city of Piracicaba – SP, enables Parana municipalities urban perimeter sustainability evaluation through the following 4 spatial metrics: i) gross demographic density; ii) occupation rate; iii) displacement of its centroid from city center; and iv) shape irregularity degree.

The current analysis considers 388 polygons, corresponding to Parana municipalities that have Comprehensive Plan, 97% of the total number. Only the main municipal city urban perimeters are taken into account, although in some municipalities there are more than one urban perimeter that likewise delimit urban occupations within municipal territory.

These 388 municipalities have distinctive features: more than half of them (203) are small (with less than 10 thousand inhabitants) and isolated in the agricultural rural area; some few are located along the Atlantic coast, others conform conurbation areas or belong to metropolitan areas.

For the sake of analysis, Parana municipalities were grouped into 8 populational range sizes, considering 2010 demographic data census, based on the mix of 2 methods of classification: "equal interval" for the 4-lowest population size ranges and "natural breaks" for the other 4-highest ones, taking into account the great population size disparity among Parana municipalities.

The first spatial metrics is gross demographic density. For the sake of its calculation, it is considered 2010 demographic data census relative to main city urban perimeters and urban perimeter areas, as defined by municipal laws, available in SEDU/PARANACIDADE Interativo database. In principle, the higher the gross demographic density, the smaller is urban sprawl.

The second spatial metrics is urban perimeter occupation rate. The urban occupation polygons of Parana municipalities were obtained from the SEDU/PARANACIDADE Interativo, based on 2017 and 2018 satellite images. The indicator value is obtained dividing the total of urban occupation areas within urban perimeter by its total area. In theory, the greater the urban perimeter occupation rate, the greater the arrange and control municipal capacity over urban growth. It should be noted that, high values of urban perimeter occupation rate may also mean that urban perimeter outline is outdated or being disregarded as a tool of local urban growth control.

The third spatial metrics is the displacement of urban perimeter centroid from city center. Its evaluation was done taking into account the distance in a straight line between the urban perimeter polygon centroid and a point considered as the center of the city. Usually, most of urban infrastructure, facilities and services available to population are concentrated in the city center. Therefore, it could be said that the more distant is urban perimeter polygon's centroid from city center, the less equal is urban infrastructure, facilities and services people's access (if its whole area were to be occupied).

At last, the fourth spatial metrics is the urban perimeter shape irregularity degree. It is calculated by the ratio between the length of the current urban perimeter polygon and the length of the circumference of a circle with the very same area, subtracted by one. So zero means perfect regularity. The closer the two measures are, the less irregular the urban perimeter polygon tends to be, near a circle shape, the most regular and compact geometric figure. The less irregular is the urban perimeter polygon shape, the more likely organized tends to be its occupation (if its whole area were to be occupied).

Thus, the four-spatial metrics here considered allow to evaluate urban perimeter performance towards urban sprawl control, as shown by high gross demographic densities, high occupation rate, low urban perimeter centroid displacement from city center and low degree of its shape irregularity, in favor of environment preservation, commuting costs and emission of air pollutants decrease and conversion of rural into urban land decline, as well as, urban infrastructure, facilities and services rational use. Preventing urban perimeter annulment, aiming to control urban sprawl and guarantee sustainability, is one of the main tasks of local administrations towards the correct use of this tool as prescribed by urban legislation.

5. Results and Discussion

Parana municipalities total urban perimeter area is approximately 6,000 km², corresponding to 3% of state total territory, in the same order of magnitude of world's land surface covered with urban areas, according to Schirber (2005). Yet, the state average urban occupation rate of urban perimeter area is only around 50%.

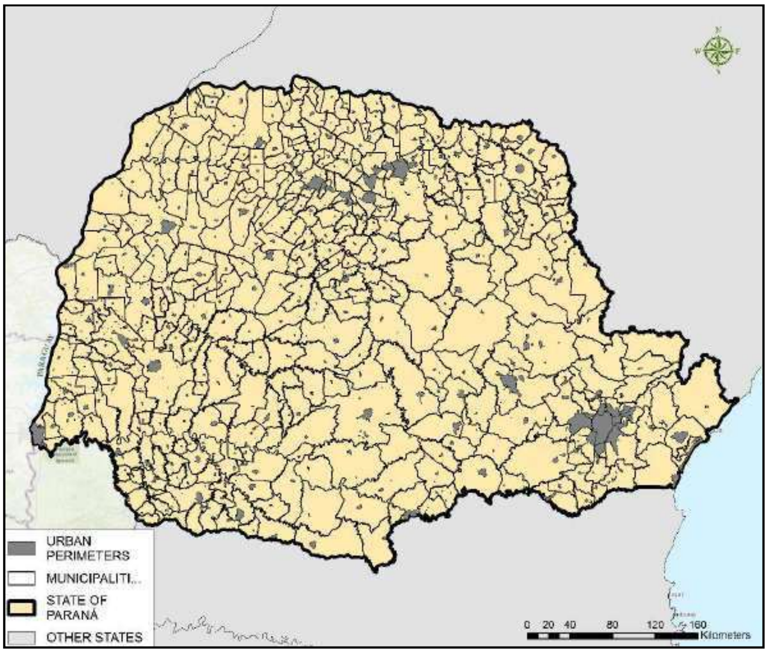

Figure 1 – Parana urban perimeters
Source: SEDU/PARANACIDADE Interativo, 2018

5.1 Gross demographic density

Urban perimeter gross demographic densities observed in Parana municipalities were classified into three ranges, considering the state average gross demographic density (15 people per hectare) and the minimum gross urban demographic density reference postulated by Braga (2016), which is 50 people per hectare. Here it is also considered a state reference value – 20 people per hectare – obtained from average values of urban parcel size (360 sq meters) and number of residents per household (2.9 people). The three ranges defined, within

Parana state context, are: i) very low (less than 15 people per hectare); ii) low (between 15 and 20 people per hectare); and iii) regular (more than 20 people per hectare and less than 50 people per hectare).

None of Parana municipalities present urban perimeter gross demographic density greater than 50 people per hectare, what makes Parana a fairly low densely urban populated area. Curitiba, the state capital, shows the closest value to Braga's parameter, 40 people per hectare. On the other hand, the municipality of Quatro Barras, in the Metropolitan Region of Curitiba, has the lowest urban perimeter gross demographic density, less than 2 people per hectare (Figure 2).

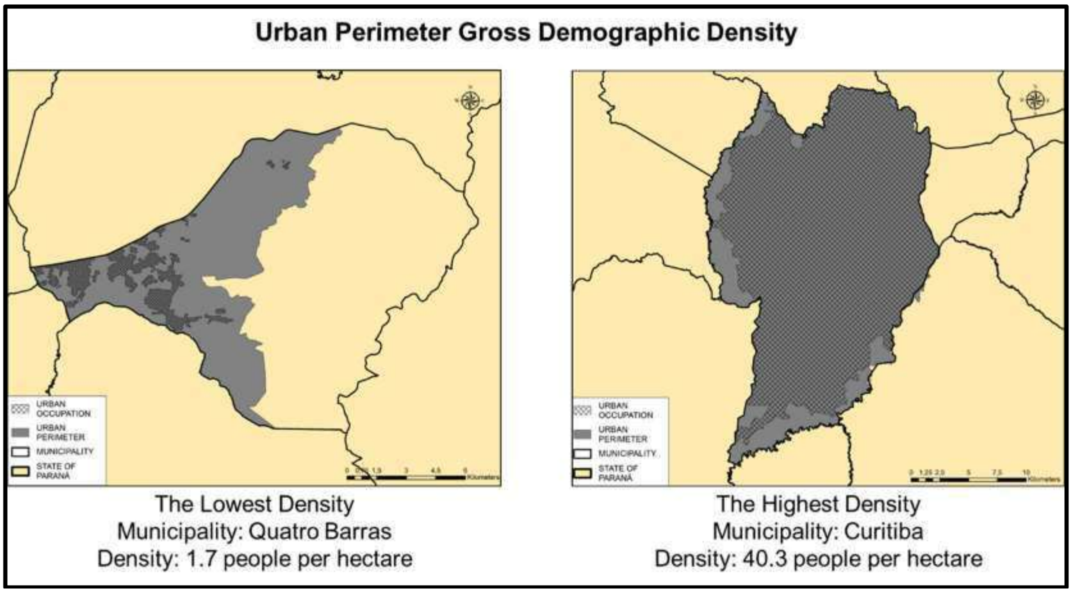

Figure 2 – The lowest and the highest gross demographic densities of Parana urban perimeters
Source: SEDU/PARANACIDADE Interativo, 2018

Table 1 shows the high number of Parana municipalities with densities lower than 15 people per hectare: 242, corresponding to 62.4% of the 388 here considered. The lowest densities predominate in almost all population range sizes, except for the highest, where densities higher than 20 people per hectare prevail. It is possible to assure that, in Parana, the urban development model tends to be of low urban land occupation densities, regardless population size.

Table 1: Number of urban perimeters classified by gross demographic density and population sizes

URBAN POPULATION	GROSS DEMOGRAPHIC DENSITY			TOTAL
	0-14	15-20	>20	
141,958 – 1,751,907	3	0	5	8
68,441 – 141,957	10	4	1	15
31,962 – 68,440	8	5	3	16
16,103 – 31,961	31	5	2	38
7,172 – 16,102	42	21	15	78

TOTAL	**242**	**82**	**64**	**388**

Source: SEDU/PARANACIDADE Interativo, 2018

5.2 Occupation rate

Urban perimeter occupation rates in Parana show high levels of diversity, being classified into 5 ranges: i) very low - between 8% and 25%; ii) low - between 26% and 50%; iii) regular - between 51% and 75%; iv) high - between 76% and 90%; and v) very high - above 90%.

Table 2 shows that most of urban perimeters in Parana (285) have occupation rates between 26% and 75%, averaging 57.5%. Despite being here considered as a regular rate, there are still 42.5%of non-occupied areas within urban perimeters, in average, which indicates an urban perimeter oversize trend vs. effective demand for new urbanized land.

In general, occupation rate extremes (the lowest and the highest ranges) are concentrated in municipalities with less than 16,000 inhabitants. In these municipalities, where continued, strong demand for new urban land can be reasonably expected to be negligible, the urban perimeter seems to be treated as an unimportant control tool as shown both by its oversize or its undersize (where occupation rate reaches far more than 100%).

Table 2: Number of urban perimeters classified by occupation rate and population sizes

URBAN POPULATION	OCCUPATION RATE					TOTAL
	8 – 25%	26 – 50%	51 – 75%	76 – 90%	> 90%	
141,958 – 1,751,907	0	1	4	2	1	8
68,441 – 141,957	1	8	6	0	0	15
31,962 – 68,440	1	6	7	2	0	16
16,103 – 31,961	4	20	11	3	0	38
7,172 – 16,102	2	22	37	13	4	78

524 – 2,437	9	22	31	12	2	76
TOTAL	**20**	**124**	**161**	**65**	**18**	**388**

Source: SEDU/PARANACIDADE Interativo, 2018

Figure 3 demonstrates Parana urban perimeters with the lowest and the highest occupation rates which, in both cases, are inadequate. The urban perimeter of Presidente Castelo Branco Municipality is only 6% occupied, far below Parana state average (57.5%). Even though the real estate market dynamics does not justify such small occupation rate, it can be seen from Figure 3 that there is an urban occupation in the north of urban perimeter, indicating a trend to sprawl into rural areas.

On the other, in Floresta Municipality, the urban occupation maladjustment is characterized by its 158% occupation rate. Here, urban perimeter undersize can be seen as its disregard as an urban control tool.

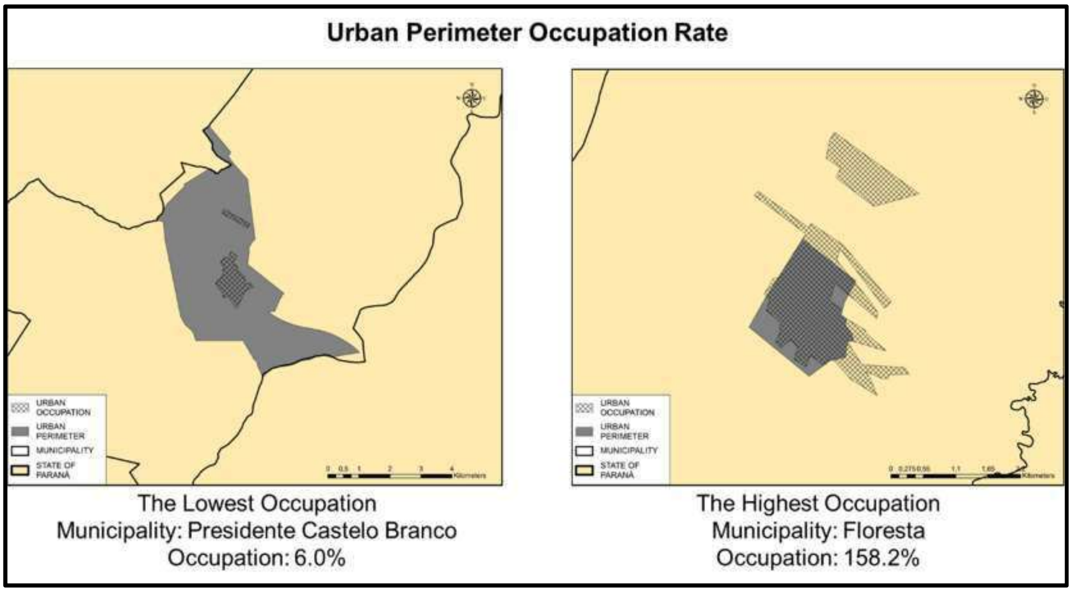

Figure 3: The lowest and the highest occupation rates of Parana urban perimeters
Source: SEDU/PARANACIDADE Interativo, 2018

5.3 Displacement of urban perimeter centroid from city center

Displacement of urban perimeter centroids from city centers were classified into 5 categories: i) very near - between 0 and 0.38 kilometers; ii) near - between 0.39 and 0.89 kilometers; iii) slightly distant - between 0.90 and 2.03 kilometers; iv) distant - between 2.04 and 3.80 kilometers; and v) very distant - between 3.81 and 10.22 kilometers.

Larger municipalities tend to have the greater distances between urban perimeter centroid and city center. Conversely, smaller municipalities usually have the smaller ones (Table 3). Nevertheless, geographical factors that gave rise to some city centers or foster their increase, in Parana, such as maritime foreland and seaside groundwater basin, river borders, conurbation areas, international boundaries, lead to significant displacements.

As examples, it can be mentioned the municipalities of Pontal do Parana (20,920 inhabitants) with 10,221.11 meters of displacement (located along the seacoast); Colombo (212,967 inhabitants) with 6,696.23 meters of displacement (conurbation with Curitiba, the capital state); Paranagua (140,469 inhabitants) with 5,953.16 meters of displacement (located along Paranagua bay); and Foz do Iguaçu (256,088 inhabitants) with 5,531.03 meters (located on an international boundary). In such cases, horizontal urban expansion, within the urban perimeter, tend to make more difficult people's access to urban infrastructure, facilities and services, concentrated in the city center, and therefore cities less sustainable.

Table 3: Number of urban perimeters classified by displacement of urban perimeter centroid from city center and population sizes

URBAN POPULATION	DISPLACEMENT FROM THE CITY CENTER (KM)					TOTAL
	0 – 0.38	0.39 – 0.89	0.90 – 2.03	2.04 – 3.80	3.81 – 10.22	
141,958 – 1,751,907	1	2	1	0	4	8
68,441 – 141,957	4	3	6	2	0	15
31,962 – 68,440	8	4	4	0	0	16
16,103 – 31,961	11	15	6	6	0	38
7,172 – 16,102	31	37	8	2	0	78
4,152 – 7,171	42	27	8	3	0	80
2,438 – 4,151	44	28	4	0	1	77
524 – 2,437	55	12	5	3	1	76
TOTAL	**196**	**128**	**42**	**16**	**6**	**388**

Source: SEDU/PARANACIDADE Interativo, 2018

On the other hand, some municipalities with population over 50,000 inhabitants have very near or near displacement distance values, such as: i) Cianorte (69,958 inhabitants) with 95.70 meters of displacement (isolated city); ii) Paranavai (81,590 inhabitants) with 437.31 meters of displacement (isolated city); iii) Toledo (119,313 inhabitants) with 559.62 meters of displacement (isolated city); and Ponta Grossa (311,611 inhabitants) with 618.18 meters of displacement (regional center). In such cases, urban expansion tends to be fairly well balanced concerning people's access to central urban infrastructure, facilities and services from several regions of the city, optimizing daily city commuting. Figure 4 illustrates two municipalities that belong each to the extreme ranges of urban perimeters centroid displacement in relation to the city center.

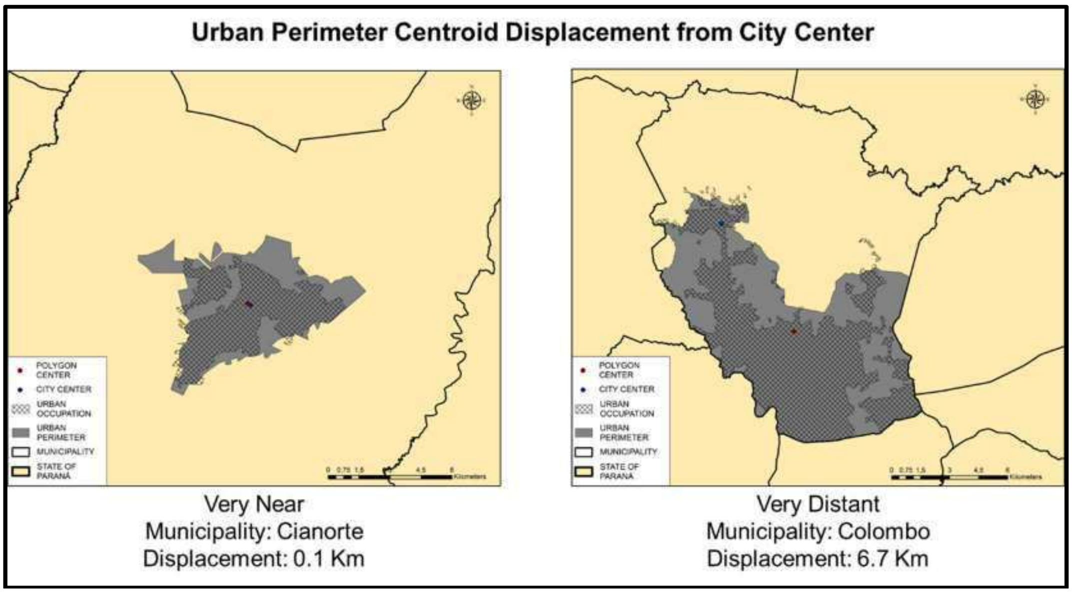

Figure 4: Parana municipalities of the first and fifth range of urban perimeter centroid displacement from city center
Source: SEDU/PARANACIDADE Interativo, 2018

5.4 Urban perimeter shape irregularity degree

Urban perimeter shape irregularity degree aims to identify the level of urban perimeter compactness. If compacted, its shape tends to a circumference; otherwise, the urban perimeter has an irregular form. The proportion of street network extension in relation to urban perimeter area tends to be high, and, consequently, increasing commuting distances and times. The results were classified into 5 ranges: i) regular - between 0 and 0.20; ii) very slightly irregular - between 0.21 and 0.31; iii) slightly irregular - between 0.32 and 0.41; iv) irregular - between 0.41 and 0.52; and v) very irregular - between 0.53 and 0.77.

Table 4 shows that municipalities within the largest population range size have irregular or very irregular urban perimeters, even though it is observed unexpectedly small municipalities classified in this very same category. Most part of the smaller municipalities are equally placed within the other four irregularity range sizes.

Table 4: Number of urban perimeters classified by irregularity shape degree and population sizes

URBAN POPULTATION	**DEGREE OF SHAPE IRREGULARITY**					**TOTAL**
	0 – 0.20	**0.21 – 0.31**	**0.32 – 0.41**	**0.42 – 0.52**	**0.53 – 0.77**	
141,958 – 1,751,907	0	0	0	5	3	8
68,441 – 141,957	0	2	5	4	4	15
31,962 – 68,440	2	2	5	3	4	16
16,103 – 31,961	3	4	12	13	6	38
7,172 – 16,102	5	15	26	21	11	78
4,152 – 7,171	13	12	25	24	6	80
2,438 – 4,151	10	26	21	13	7	77
524 – 2,437	11	21	24	14	6	76
TOTAL	**44**	**82**	**118**	**97**	**47**	**388**

Source: SEDU/PARANACIDADE Interativo, 2018

Urban perimeter irregularity degree may be explained by several factors. Notwithstanding, two prevail: i) federal or state roads (as in Ponta Grossa, Araucaria, Sao Jose dos Pinhais, Carambei municipalities); and ii) land surface irregularity (as in Cerro Azul, Tunas do Parana, Almirante Tamandare municipalities).

Figure 9 illustrates the two Parana urban perimeter extreme irregularity degrees. The most irregular one is Cerro Azul urban perimeter, which adjusts both to land surface irregularity and a federal road. These two aspects lead to the linear shape of Cerro Azul urban land occupation, in north-south direction, limiting street network connections, and the federal road plays the role to link the different regions of the city.

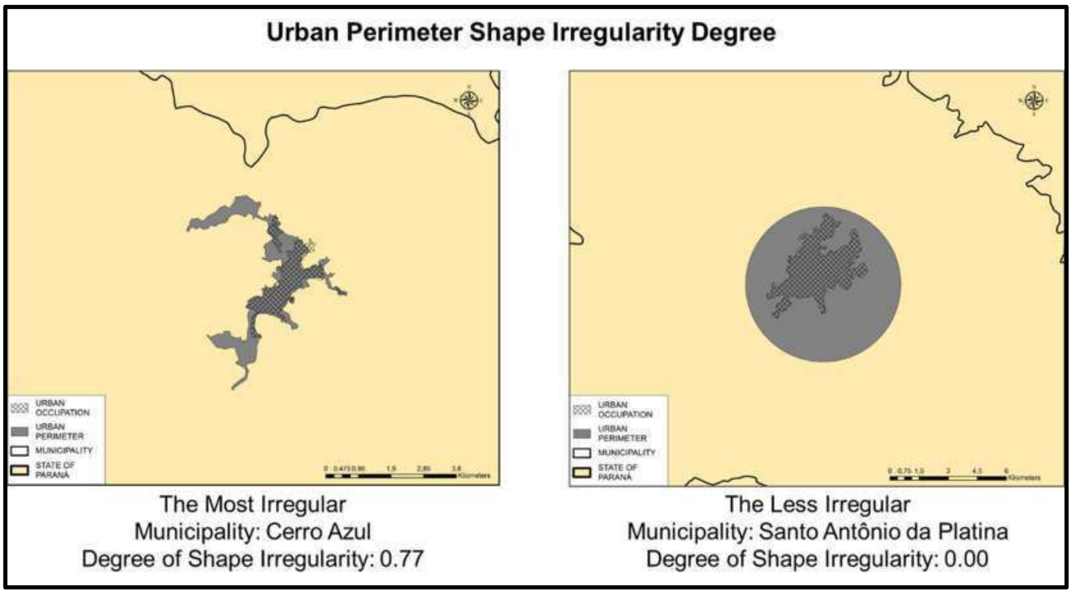

Figure 5: The most very irregular and the most regular Parana urban perimeter shapes
Source: SEDU/PARANACIDADE Interativo, 2018

The urban perimeter of Santo Antonio da Platina Municipality is the opposite case: its shape is a perfect circumference, which, in theory, represents perfect geometric regularity (its shape irregularity degree is zero). However, when comparing the urban perimeter area to the actual occupied area, it is observed that there is no relationship between them, which suggests that this urban perimeter's shape (and oversize) seems to be a pure abstraction, totally disconnected from municipality's reality.

6. Conclusion

Brazilian legislation assigns to urban perimeters, through a specific law, the task of delimiting urban settlements, urban expansion areas and specific urbanization areas, following the Comprehensive Plan guidelines. According to IBGE, urban perimeter is the most used urban planning tool in Brazil. Of the 399 Parana municipalities, 388 have, legally, urban perimeter.

Nevertheless, its effectiveness for arranging and controlling urban occupation may be put into question. This paper evaluates this questioning through 4 spatial metrics: i) gross demographic density; ii) occupation rate; iii) displacement of its centroid from city center; and iv) shape irregularity degree.

The results showed that most of Parana urban perimeters have very low gross demographic density levels, with less than 15 people per hectare. In addition, there is none among Parana municipalities whose urban perimeter gross demographic density exceeds 50 people per hectare, as an evidence of an extensive urban land occupation model, which tends to increase urban costs.

The low urban perimeter gross demographic densities are related, generally, to urban perimeter oversize compared to its actual urban occupied area. In average, Parana urban perimeters are occupied by slightly more than 50%. Considering that Comprehensive Plan, including the urban perimeter, should be updated, at most, every 10 years, the urban perimeter polygons can be considered large enough to comprise urban growth during this period.

Urban perimeter oversize puts at risk urban occupation control, since it contributes to less dense and more fragmented urban occupation. In addition, it also hampers its occupation arrangement as shown both by urban perimeter centroid displacement from city center and shape irregularity degree.

In general, larger municipalities present greater distances between urban perimeter centroid and city center. Furthermore, those municipalities that comprise conurbation areas, located along international boundaries, seacoast or bays show significant distances as well. In such cases, urban growth within urban perimeter tends to intensify these distances, increasing urban commuting in number and in extent to access urban infrastructure, facilities and services concentrated in the city center.

The evaluation of urban perimeter polygon shapes also shows that the smaller municipalities concentrate most of regular or very slightly irregular polygons, which tend to a circumference. Most of Parana urban perimeter polygons are slightly irregular or irregular, due mainly to surface land irregularity and urban growth along federal or state roads. The urban perimeter irregular shape, if followed by urban occupation, tends to limit urban connections and to increase distances between the various city regions.

Parana municipalities urban occupation pattern, based on both low demographic density and low spatial concentration levels, reduces municipal management performance towards urban infrastructure, facilities and services offer, add to local government poor technical and financial capacities. Increasing distances to overcome in order to attend citizen's demands, rises public and private urban costs, and make cities progressively more and more unsustainable.

It is possible to assert that, in Parana, the annulment of urban perimeter as an urban technical tool may be due to legislators and public managers' political clientelism and to local administration staff institutional weakness. Besides that, this may also be an outcome of Brazilian culture, especially in countryside cities, that associates urban quality of life to horizontal and widespread occupation, based on large parcels and single-family housing, aiming to replicate countryside lifestyle into urban areas. Without changing this paradigm, any urban technical tool aiming to control urban sprawl tends to be annulled.

Development of recommendations on the planning structure and street design in the cities with cold climate

Artem NIKOLAEV, Sergei KUDINOV
Institute for Design and Urban Studies, ITMO University, Russia

Abstract

Urban settlements located in cold regions have their own specific features related to climatic conditions. Winter, which can last for several months a year, affects the daily life of the population. Precipitation in the form of snow, low air temperature, short daylight hours, strong wind, ice – all these climatic features accompany the activities of people in cities with such climates and form their habits. Thus, these features compel urban planners to seek solutions that meet the needs of people living in cold climates. In Russia, the climate, namely, the presence of a long and cold winter, strong wind and insolation insufficiency, is almost never taken into account when designing or improving territories. As a result, streets are unsuitable for a comfortable city life in winter.

In this paper, the problem of imperfection of Russian city-planning standards in the field of space management and planting is considered. The purpose of this paper is to analyze the Russian and foreign standards for city design in cold climates. The report contains the results of an analysis of Russian regulatory documents in the field of street design; the results of a comparison of these documents with documents from Finland, Canada, and the USA; a list of recommendations for adding new and improving existing aspects of street design in Russian regulatory documents.

1. Introduction

Creating an urban environment in which it would be comfortable to be outside at any time of the year is an important, yet challenging task. This is especially true for cities located in areas with cold climates. The more time people spend in the open air, the better it influences their mental health (Beyer, Szabo and Nattinger, 2016). Active street life helps residents build new social ties, while the city economy thrives on taxes collected from small businesses and rising real estate prices (Lee, 2014). Moreover, regular physical activity, including walks, positively affects health, reducing the risk of developing a number of diseases. Winter is accompanied by heavy snowfalls, short daylight hours and long periods with temperatures below 0 degrees Celsius. Severe climate in such periods can significantly limit outdoor activity and affect the availability of the urban environment. People spend most of their lives indoors, which makes streets lifeless. In addition, urban transport is limited to the use of motor traction, and a large amount of snow creates numerous problems in ensuring pedestrian motion safety and road maintenance. On the other hand, a prolonged winter in cold regions provides a number of opportunities for organizing leisure activities, for example, holding winter festivals, developing winter sports or other activities related to snow. These benefits can be used in cities of subarctic areas to offer residents a special category of entertainment not typical for cities in temperate regions.

Nevertheless, in the northern latitudes it is quite difficult to make it comfortable to stay outside – in winter people can spend 70-95% of their time indoors (Pressman and Zepic, 1986). In this regard, it is important to make efforts to improve the aspects of urban planning and space management which will make it comfortable for people to stay outdoors even in winter, namely, to walk, organize leisure, communicate, and visit various facilities. It is necessary to effectively use knowledge on the urban climate in the field of street design and improvement.

In Russia, street design and improvement is regulated by federal and local guidelines which were developed back in the 1960s and were called Building Norms and Rules (Russian “SNiP”). Updated revisions of SNiP were called Codes of Rules (Russian “SP”), however, their content remained practically unchanged. Analysis of existing Russian city planning standards showed that they cover improvement superficially; some of the aspects considered are not related to each other and do not provide an integrated approach to space management; many rules and recommendations do not take into account the climatic characteristics of the area. At the same time, more than 60% of the territory of Russia is in the permafrost region, and the average annual air temperature in the country is -5.5 °C. For example, in the eastern part of the Sakha Republic (subarctic climate zone), in Chokurdakh, the temperature is below 0 degrees for more than half of the year. At 93.1% of Russia's area, average temperature of the coldest month of the year is below −10 °C, and at 82% of Russia's area average temperature of the coldest month of the year is below −15 °C. In many cities, average temperature in winter is not lower than −20 °C, for example in Belgorod (−5.9 °C), Veliky Novgorod (−7.7 °C), Vologda (−9.7 °C), Kirov (−11.9 °C), Orenburg (−10.9 °C), Smolensk (−5.9 °C). Thus, improvement of many Russian cities needs to take into account the peculiarities of the cold climate.

The main purpose of this work is to compare Russian and foreign guidelines and regulations on space management and improvement in cities. Comparative analysis will identify gaps in Russian regulations and, in future, help develop specific amendments to city planning legislation based on relevant experience of other countries with a similar climate.

2. Scientific background for urban planning and improvement in cold climates

International scientific community has paid attention to urban design issues considering natural and climatic conditions since the 1980s. For example, N. Pressman and X. Zepic in their work "Planning in Cold Climates: A Critical Overview of Canadian Settlement Patterns and Policies" attempt to identify a range of problems related to the winter season in the urban environment (1986). The main goal of the work was to develop strategic approaches that would be able to minimize the consequences of the winter season for people and urban life in Canada. Professor I. Eliasson in her article "The use of climate knowledge in urban planning" came to the conclusion that, in spite of the availability of information on the local climate for urban planning, in most cases this data is not organized and actually stays uninvolved in city planning (2000).

In the 21st century, thanks to the spread of the Internet, the number of available publications on problems of urban planning in areas with cold climates increased. Studies began to be published on cities and countries that had previously paid no attention to climatic characteristics in urban planning. For example, the article "Climate-Sensitive Urban Design in Cold Climate Zone: The City of Erzurum, Turkey" presents the results of a study of adaptability of urban environment components in the Turkish city of Erzurum (street orientation, typology of building, planting, improvement, etc.) to cold climate conditions. According to the results of the study, the author states a set of decisions and recommendations that, if they are taken into account in city planning processes, can affect the adaptability of streets to the winter season (Dursun, 2015). In addition to expanding the geography of research objects on this topic, research works emerge on specific elements of urban environment and their adaptation to the cold climate. In "Urban Drainage In Specific Climates," C. Maksimovic analyzes and classifies the problems of design and operation of drainage systems in a cold climate in the case of Scandinavia (2000). Among modern studies on problems of urban planning in cold regions, we can mention the work of Saeed Ebrahimabadi on considering climatic factors in urban design (2015). Essi Oikarinen's analysis of concepts in the approach to climate-aware urban planning and design in the northern climate is also noteworthy (2014). Peter Bosselmann, Edward Arens, Klaus Dunker & Robert Wright studied the impact of the current layout of Toronto on the manifestation of weather factors (1995). Patrick J. Coleman in "Pedestrian mobility in winter" explored the problem of pedestrian activity in the winter period and considered a number of approaches and solutions for stimulating walking in the cold season (2001).

In Russia, the problem of climate-aware urban improvement has not been studied, in contrast to construction issues in cold climates, as evidenced by a small number of studies on this topic. For example, A. Klochko, PhD, in "The Impact of Climate Change on Architectural Urban Design and Regulation" focuses on the need for further analysis and revision of building norms and standards, taking into account the climate in Moscow (2013). Another work that can be mentioned here is "Specifics of Design and Construction of Low-Rise Buildings in the Arctic," where Professor Yu. Varfolomeev compiles a list of changes recommended for inclusion in SP 42.1330.2016 in order to improve current legislation in the sphere of urban planning (2014). His conclusions are based on the results of a 30-year study of construction and operation of low-rise buildings in the Arctic zone of Russia.

Despite the fact that scientific interest in the problem of urban planning in cold climates continues to grow, available research is rarely used directly in urban design and improvement. Scientific research in this area is not given due attention. City authorities often face a number of limitations: lack of knowledge and tools, political peculiarities, other priorities in planning practice, economic situation. An analysis of the research background on this issue showed that most publications are aimed at structuring knowledge in the field of urban planning in view of climatic characteristics in order to apply this knowledge in future practice. In other words, setting the principles and rules for urban design in cold regions should serve as the basis for improving official standards and introducing new solutions in the field of planning and improvement.

3. International experience in urban planning in cold climates

The climate in some regions of Canada, USA, Finland, and Russia is similar. In these countries there are many cities with long and cold winters, plenty of snow and wind. In Russia these are Murmansk, Yakutsk, Syktyvkar, in the USA these are cities of Alaska, such as Anchorage and Juneau, in Canada – Edmonton and Fort St. John, in Finland – Helsinki and Oulu. The list is not limited to these cities only. In any of the countries under consideration there are settlements with an average winter temperature from 0 down to −15 °C, with extreme cold, and heavy snowfall. Thus, it is permissible to consider the experience of the USA, Canada and Finland when developing recommendations for improvement of Russian standards. Borrowing experience will make it possible to adapt proven practices and simplify the development of guidelines for Russia.

3.1 Regulations for improvement in cold climates in the USA, Canada, and Finland

Emma Sanborn in her work “Integrating Climate Sensitive Design Principles in Municipal Processes: A Case Study of Edmonton’s Winter Patios” views the development of climate-aware urban planning in the context of Canada (2017). Starting from the 2000s, the focus of urban planning has begun to shift towards climatic characteristics, ecology and cultural diversity. Improvement of the urban environment has become an important aspect of city planning policy at the local level. Various guidelines and recommendations focused on the problem of designing an environment for cities with cold climates have begun to appear. For example, a set of recommendations for improvement to be used in the design of urban areas has been developed for the city of Edmonton. The document covers a wide range of aspects: the location of buildings, the layout of the street grid, the design of facades, creation of public spaces, arrangement of public transport stops, planting. Despite the fact that the document is not an official guide, the recommendations contained in it can be used to resolve various issues in the field of urban planning.

For the city of Fort St. John, a set of recommendations for designing the urban environment has also been developed. The document describes such aspects as the use of materials and colors, planting, improvement of public areas, parking planning. For the cities of Thunder Bay and Vancouver, similar guidelines have been developed, the use of which is recommended when designing an urban environment where the climatic characteristics are of high priority. As can be seen from the above analysis of sources, in Canada there is vast experience in studying the problems of improvement in cold climates, as well as in developing special regulations.

The experience of the USA in climate-aware design and improvement is well reflected in the documents regulating the city-planning activity in Anchorage, Alaska. For example, in the regulations for street improvement and landscape design, attention is paid to greenery planting: plant species should be selected taking into account the characteristics of the climate in the region; evergreen plants that can relieve the winter landscape and offer protection from the wind are recommended for use; in winter it is recommended to use fences protecting trees and shrubs during mechanized cleaning of the site; when planning the territories, planners have to provide zones for storing snow during winter cleaning; in doing this, it is necessary to find a compromise between the convenience of movement for pedestrians and cars and the need to store snow; also, planners are required to provide for possible winter activities that can be organized in popular areas of the city – their size should allow for making a ski track or building an ice rink. As the USA has only a small number of areas with a harsh climate, this country has less experience in developing climate-aware standards and guidelines than Canada.

In Helsinki, Finland, street improvement is regulated by an official guideline. The document contains instructions on how to design, organize and maintain streets to ensure a high-quality urban environment. However, with regard to climate-aware improvement, it only states that outdoor furniture should be located so that the area around it can be mechanically cleaned. The remaining aspects are only covered superficially. Since regulations and official documents in Finland are written in Finnish, it prevented us from analyzing the experience of Finland in climate-aware design and improvement in detail.

Based on the results of the search for studies and standards for improvement in the 3 mentioned countries, it was decided to thoroughly study the experience of Canada and apply it in developing recommendations for enhancing Russian standards for design and improvement. It is in Canada that official and unofficial regulations for different cities are developed with detailed consideration of the basic aspects of improvement. In addition, the largest number of sources found are devoted to the problems and experience of Canada in the field of climate-aware design and improvement. The Canadian climate is characterized by cold winters and cool summers due to the geographic location of the country. In the north of the country, polar climate prevails. On the territory of Canada, there are cities located in subarctic zones with a relatively low average annual temperature and abundant precipitation in winter. For example, in Brandon, Winnipeg, Edmonton or Whitehorse, average monthly temperature in winter can drop down to −15 °C even in the southern part of the country, although you can as well expect temperatures of about −40 °C with strong ice-cold winds. Average annual temperature in some Canadian cities is the same as in many Russian cities.

3.2 Regulations for improvement in cold climates in Russia

According to Russian legislation, city planning regulations (SP and GOST), including ones on improvement, are divided into mandatory and voluntary. The mandatory regulations are mainly technical regulations that set minimum requirements necessary to protect the life and health of citizens, ensure environmental protection, fire safety, etc. In this work, we analyzed the regulations aimed at aspects of improvement and space management. In order to describe the situation more accurately, we divided the aspects found into two groups, depending on the mandatory or voluntary nature of the regulation in question. The mandatory standards for improvement which take the climate into account are listed in Table 1.

Regulatory document	**The statement of the aspect**
SP 34.13330.2012 "Automobile roads"	Climate zoning should be considered in roadway construction
SP 42.13330.2016 "Urban development. Urban and rural planning and development"	The planning pattern should be developed in view of natural and climatic conditions
	For areas north of 58°N, the dimensions of residential areas may be reduced but not more than by 30%
	Distance from pedestrian walkways to the nearest public transport stop should be reduced to 300 m or to 400 m depending on the climatic conditions
SP 52.13330.2016 "Daylighting and artificial lighting"	Lighting of the roadway of streets, roads and squares of urban settlements located in the northern climatic construction zone of the Asian part of Russia and north of 66°N in the European part of Russia should be designed based on the recommendations listed in the document

Table 1: Mandatory regulations for improvement taking into account climatic characteristics

The list must be supplemented with optional regulations, which are presented in Table 2.

Regulatory document	**The statement of the aspect**
SP 42.13330.2016 "Urban development. Urban and rural planning and development"	Public spaces should be provided in residential areas taking into account natural and climatic characteristics
	The density of residential and business buildings should depend on natural and climatic characteristics

Table 2: Non-mandatory regulations for improvement taking into account climatic characteristics

As can be seen in Table 1 and Table 2, there are very few aspects in federal legislation that emphasize special requirements for design in cold climates, and they mainly contain general guidelines without details. There is no systematic approach to the consideration of climatic characteristics in design and improvement either in mandatory or in voluntary regulations.

In addition to federal regulations that control city planning throughout the country, there are local regulations for individual regions or cities. Local regulations are necessary to clarify the federal ones and to cover the missing aspects. In order to identify aspects of climate-aware improvement in local regulations, several cities were selected that belong to the same climatic sub-area of Russia, have similar climatic characteristics, are capitals of their regions and have publicly available documents. The results of identifying such aspects are given in Table 3.

City	**Average winter temperature**	**Local regulatory document**	**A suitable aspect**
Syktyvkar	−12.8 °C	Local standards of city-planning design of Syktyvkar	The following aspects are taken into account in the design of small architectural forms (SAF): Correspondence of SAF materials and design to the climate and the purpose of the SAF
			Protection against frost and snow drift, ensuring water drainage
			Convenient maintenance, as well as mechanized and manual cleaning of the territory near the SAF and under the building
			Cleaning of the territory in winter
Yakutsk	−36.7 °C	City improvement rules for Yakutsk	To protect pedestrians and protruding glass shop windows from snow and icicles falling from the edge of the roof, it is recommended to install special protective nets at the level of the second floor. To prevent icicle formation, the use of an electrical circuit along the outer perimeter of the roof is recommended.
			Cleaning in winter
Murmansk	−9.3 °C	City territory improvement rules for Murmansk	As unfavorable climatic factors affect different parts of the city, protective green areas are formed
Vorkuta	−18.8 °C	City territory improvement rules for Vorkuta	Removal of snow and ice during winter cleaning; snow storage; snow disposal; clearing of icicles
Irkutsk	−16 °C	City territory improvement rules for Irkutsk	Materials for advertising boards should be used in view of climatic characteristics
			Specifics of territory cleaning in winter: cleaning technology, frequency of cleaning, snow storage

Table 3: Results of the analysis of local standards for improvement and space management

As can be seen in Table 3, local regulations complement the overall list of aspects that take into account the climatic factor. Nevertheless, all the listed aspects are mentioned superficially, no recommendations for compliance are given. In order to specify the shortcomings and gaps in the Russian regulations, it is necessary to compare them to foreign documents.

4. Comparison of Russian and international regulations for improvement

In order to determine what aspects of design and improvement in Russian regulatory documents need to be enhanced, it is necessary to highlight the existing aspects in federal and local documents. Such aspects are presented in Figure 1.

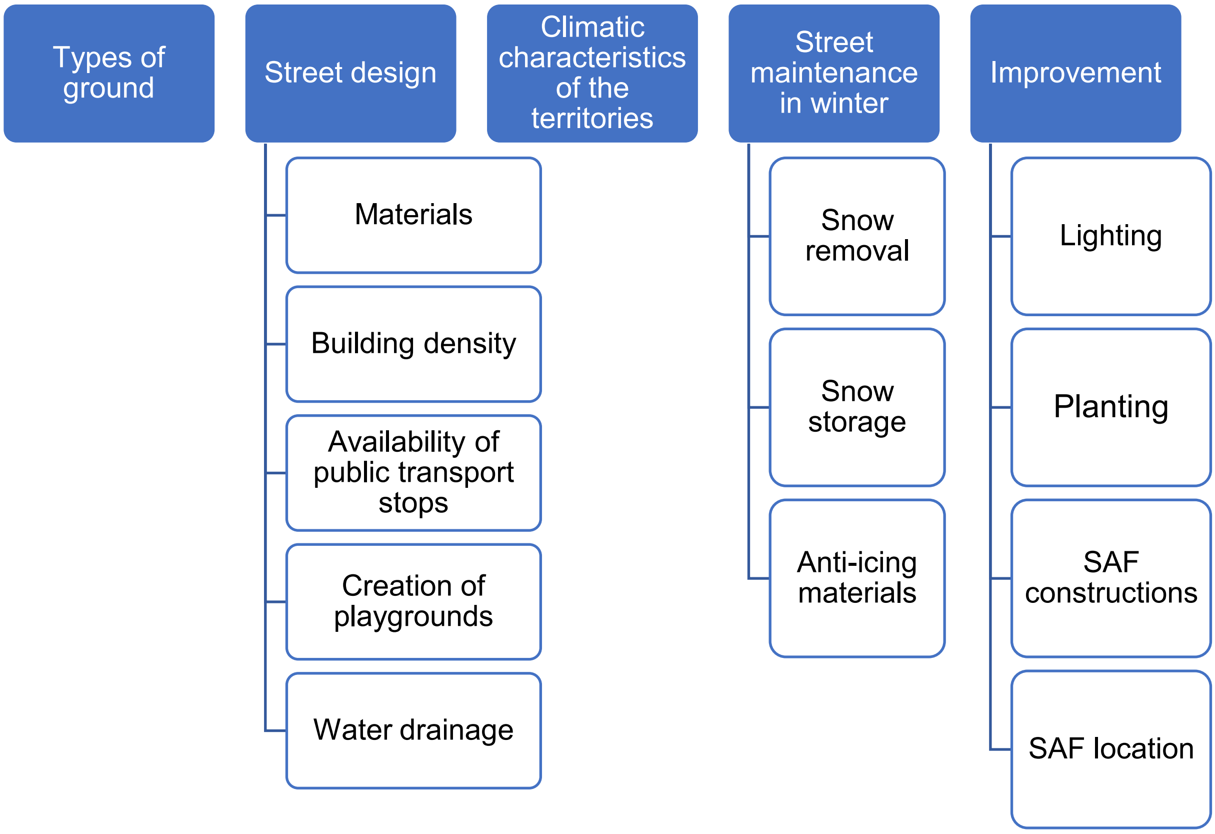

Figure 1: Aspects of improvement and design covered by Russian regulations

Most of the design and improvement aspects listed in Figure 1 need to be enhanced. The aspect of street maintenance and cleaning in winter is covered in most detail, including rules for cleaning frequency, places for storing snow, protection from ice and slippage, cleaning technologies, requirements for mechanized cleaning, protection of pedestrians from falling icicles. For this aspect, a recommendation can bed borrowed from the Anchorage improvement regulations, where it is recommended to fence off greenery in winter in order to prevent it from being damaged during mechanized snow removal. In general, the aspect of cleaning and maintaining streets in winter is covered in detail in the Russian regulations, but the recommended technologies are outdated compared to those used in other countries.

The aspect of street improvement is covered superficially in the Russian regulations, so they can be enhanced by borrowing a number of recommendations from international regulations, namely: Edmonton Winter Design Guidelines; Fort St. John Winter City Design Guidelines; Vancouver Street Restoration Manual; Thunder Bay Urban Design and Landscape Guidelines; Anchorage Design Criteria Manual. The following recommendations can be used to enhance the design and improvement practice:

1. Planting. Recommendations for the use of certain plant species that are suitable for cold climates, including evergreen plants; using greenery to protect streets from the wind; protecting plants from damage during mechanized cleaning.
2. Design of sidewalks. When designing sidewalks, it is important to provide for snow removal in winter. Sidewalks need to be wide enough for mechanized cleaning. In addition, buffer zones should be provided for temporary storage of snow, otherwise snow will accumulate on the sidewalk and reduce its walkability. In addition, it is recommended to use surface materials for roads and sidewalks that are easy to clean from ice and resistant to reagents. Innovative technologies should be used in the field of urban environment design, for example, heated sidewalks can prevent the accumulation of snow and ice.

3. Designing intersections and pedestrian crossings. It is recommended to ensure good visibility of signs and traffic lights at the intersections, so that they are always noticeable in periods of short daylight. It is recommended that the phases of the red traffic signal be shortened so that pedestrians do not have to stand in the cold air for a long time. The roadway in the pedestrian crossing zone must be narrowed to provide pedestrians with the shortest possible trajectory of movement. Elevated pedestrian crossings should be used to avoid the accumulation of snow and water on them.
4. Lighting. In conditions of short daylight hours, it is recommended to use good lighting of sidewalks, motorways, bicycle lanes, public transport stops, pedestrian crossings. At the same time, it is important to develop such a lighting system that electricity is used efficiently and the maximum amount of light is delivered in periods of poor visibility. In winter, additional lighting can be used for trees and facades as part of city decoration.
5. Public spaces. It is recommended to install screens for wind protection, gas heaters and other heating structures in order to make it comfortable to be outdoors. Public spaces, such as parks, should be multifunctional and provide an opportunity to organize winter activities in them.
6. Outdoor furniture. It is important to install outdoor furniture from materials with low heat emission, so that it is comfortable to sit on the furniture at any temperature. It is recommended to place seats and leisure facilities in such a way that the wind blows in the back. In addition, surfaces should preferably be deigned in such a way that accumulated snow is easy to scrape off. Outdoor furniture should not prevent snow removal, so its location is important. It is necessary to provide places for seating with temporary roofs or canopies so that people can stay outdoors during snowfalls. Movable outdoor furniture is suitable, so that people can move it and always be under the sun or stay protected from the wind.
7. Navigation. Urban navigation should be as informative as possible, namely, important directions and an approximate time to the destination should be displayed. It is important to provide an option for changing the content of the signs, so that new directions can be added in winter. By default, signs should be well visible in the dark and during snowfalls, and have such a form that they don't accumulate snow on their surface.
8. Public transport stops. Providing stop shelters with panels displaying transport arrival time will make waiting more comfortable for passengers. In extremely cold regions it is recommended to make enclosed shelters to protect passengers from cold temperatures and wind.
9. Seasonal activity. Winter provides an opportunity to organize seasonal activities, such as festivals and sports events, which will ensure active street life throughout the year.
10. Drainage systems and water removal. In periods of warming after negative temperatures, a large amount of water emerges, which must be removed in a timely manner from streets, sidewalks, roofs and public spaces.
11. Street art. Placing permanent and temporary art objects stimulates traveling around the city and spending time outdoors even in winter.
12. Building. It is recommended to plan the building process in such a way that the distances between residential houses and social objects are minimal. At the same time, the location of buildings should consider the wind chart and insolation. Streets should be protected from the wind and illuminated by the sun as much as possible.

5. Conclusion

In this work, we have managed to analyze the Russian experience and the experience of the USA, Canada, and Finland in improvement and space management. Regulations, official and unofficial guidelines, research works and reports have been studied. A comparative analysis of Russian and foreign regulations has made it possible to identify aspects and directions in improvement that are not currently taken into account in Russia, or require further elaboration and specification. As a result, a list of 12 directions with brief characteristics of each direction has been compiled. At the next stage we plan to work out solutions, technologies, regulations, and rules: a guideline will be drawn up with specific recommendations on street design, space management and improvement. The resulting guideline can be used as a comprehensive manual for architects and planners in Russia and other countries. Based on the recommendations included in it, amendments to official federal and local city planning regulations will be developed.

A Resilient Coastal Mega City, A Resilient People: Flooding as a Climate Change Threat in Lagos, Nigeria

Olufemi, O., PhD, Independent Urban Planner/Researcher, Oakville, Ontario, Canada, solaoluf@yahoo.com;

Ogunmodede, O., PhD Candidate, Department of Urban and Regional Planning, University of Ibadan, Ibadan, Nigeria f.fisayo@yahoo.com ;

Somoye, O, Independent Town Planner/Researcher, Lagos, Nigeria bukiayangbile@yahoo.com

ABSTRACT

With an estimated population of about 11.2 million Lagos popularly referred to as 'Èkó' or 'Lasgidi', is a coastal city vulnerable to recurrent flooding which has progressively modified the shoreline but the residents and city's resilience to recurrent flooding is incomprehensible. With increasing urbanisation, population growth, urbanisation of poverty and daily influx of people from other States of the Federation, various settlements have evolved along the wetlands without supportive infrastructures thus, making neighbourhoods highly vulnerable to flooding. The paper examines residents' vulnerability and resilience to flooding, the coping and mitigating strategies and policies that have been adopted by residents and the State. For a resilient city and a resilient people the paper proposes resilience thinking and adaptive governance through flood mitigation education and awareness programs that eradicates or minimizes refuse or debris dumping in storm-water channels.

INTRODUCTION

Nigerian cities, in low lying terrains like Lagos, are prone to coastal, river or urban flooding. Urban flooding occurs where little or no provision has been made for surface drainage, or where existing drainage has been blocked with municipal waste, refuses and eroded soil sediments (Folorunsho and Awosika, 2001). Urban flooding is a serious disaster in the world, which not only causes serious damage, disturbs normal life and working conditions, but also pollutes the city and causes sanitary problems (Chen, 2004).

Lagos, a vibrant commercial capital is a megacity occupying two main islands in the Atlantic Ocean, separated by creeks and mangrove swamps. Lagos experiences coastal and urban area flooding, high tidal levels, ocean waves, and storm surges. Inadequate infrastructures to contain the run-off, peoples' attitudes and non-compliance to physical planning measures all constitute barriers to proper flood control. The major causes of flooding in these areas include excessive and recurrent rainfall, overflow of water bodies, encroachment of building on flood-plain, poor/faulty/non-functional drainage network and indiscriminate dumping of waste into water channels leading to drainage blockage. Lagosians continue to be vulnerable to flooding and their resilience in addressing the flooding challenges remains unparalleled.

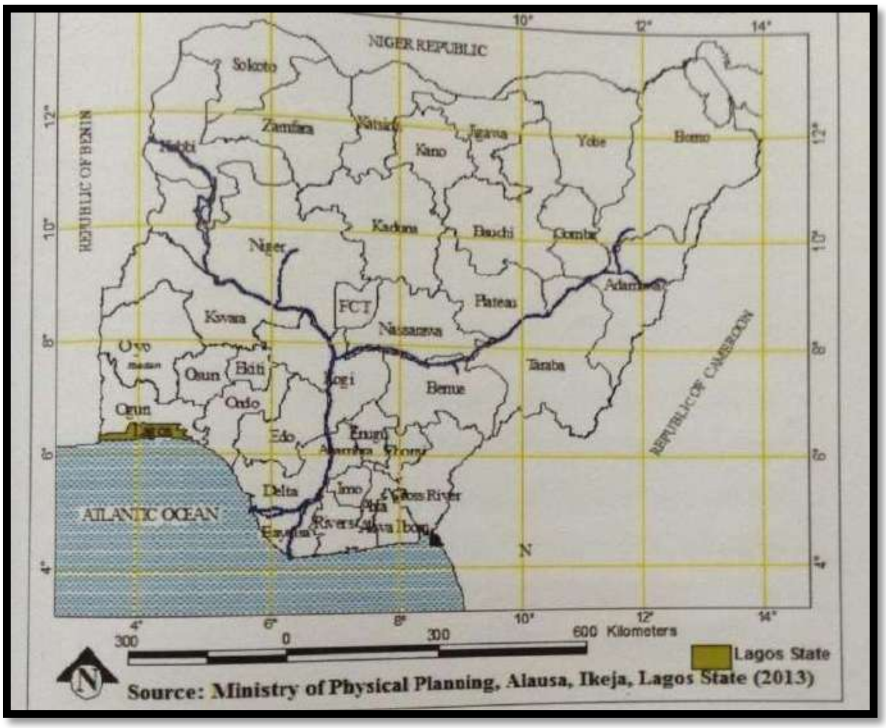
Resilience means "ability to adapt to and through a difficult situation. Resilience is a term that is often used to mean 'bouncing back from a terrible event' or 'having strength to cope', or 'being determined to see things through to the end" (Mowbray, 2011:2). Resilience refers to the process of overcoming the negative effects of risk exposure, coping successfully with traumatic experiences, and avoiding the negative trajectories associated with risks (Fergus and Zimmerman, 2005). Resilience and Resilience thinking enables the system, individual, people, community, city or economy to adapt and embrace shocks arising from a catastrophe though innovative resolutions.

The paper examines residents' vulnerability and resilience to flooding, the policies that have been adopted by residents and the State to cope with flooding. For a resilient city and a resilient people, paper adopts the resilience framework and proposes resilience thinking and adaptive governance (through flood mitigation education and awareness programs well as integration of geo-spatial and remote sensing techniques towards appropriate flood modeling, simulation and forecasting) as an approach to minimize the devastating impact of flooding.

STUDY AREA

Lagos megacity occupies two main islands in the Atlantic Ocean, separated by creeks. Its land area is 153,340 hectares, with 209 km^2 (some 19.6 per cent of its landmass) covered by water and mangrove swamps (Filani, 2012). The seat of Nigeria's government until 1986, Lagos (Figure 1) remains the nation's commercial capital, contributing more to its economic growth than any other city. With an estimated population of 16 million, Lagos is the most populous conurbation in Nigeria with a population density of about 5,000 persons/km2, making it one of the most densely populated cities in Africa (Filani, 2012).

Figure 1: Lagos State in Nigeria context



Source: Ministry of Physical Planning, Alusa, Ikeja, Lagos State, 2013.

Lagos State has 20 Local Government Areas (LGA) (Figure 2), out of which 16 make-up the metropolis. The Local Governments considered in this study include Ojo, Kosofe, Eti-Osa, Lagos Island, Amuwo-Odofin, Ikorodu, Ajeromi-Ifelodun and Agege (Figure 3).

METHODOLOGY

The study utilized both secondary and primary data. The secondary data regarding coping and mitigating policies and its implementation were obtained from the Lagos State Ministry of Environment- Lagos State Waste Management Authority (LAWMA), Office of Drainage Services; and Lagos State Emergency Management Agency (LASEMA). Primary data was collected using informal interviews and structured questionnaires administered in 2014/2015 on 150 residents through purposive sampling to elicit information regarding frequency of flood occurrence and residents coping mechanisms.

RESILIENCE FRAMEWORK

Resilience is the "the ability of a system to absorb disturbances and still retain its basic function and structure" (Walker and Salt, 2006:.1) and "the capacity to change in order to maintain the same identity" (Folke et al., 2010). Resilience is about survival and adaptability. Resilience is "the ability of a system to maintain its structure and patterns of behavior in the face of disturbance" (Holling, 1986:296). Resilience "is the ability to persist and the ability to adapt" (Adger, 2003:1).

Resilience originated in the 1970s in the field of ecology from the research of C.S. Holling (Pisano, 2012). Resilience is defined as "a measure of the persistence of systems and of their ability to absorb change and disturbance and still maintain the same relationships between populations or state variables" (Holling, 1973:14). The concept of resilience in relation to social–

ecological systems incorporates the idea of adaptation, learning and self-organization in addition to the general ability to persist disturbance (Folke, 2006). "Resilience is the capacity of a system be it an individual, a forest, a city or an economy, to deal with change and continue to develop. It is about the capacity to use shocks and disturbances like a financial crisis or climate change to spur renewal and innovative thinking. Resilience thinking embraces learning, diversity… and humans and nature are strongly coupled to the point that they should be conceived as one social-ecological system" (Moberg and Simonsen, 2014:3).

The resilience perspective shifts policies from those that aspire to control change in systems assumed to be stable, to managing the capacity of social–ecological systems to cope with, adapt to, and shape change (Berkes et al., 2003, Smit and Wandel, 2006).
Resilience in the ecological literature reflects different aspects of stability that focuses on efficiency, constancy or persistence, change and unpredictability (Gunderson et al, 2002). He notes "the differences between these two aspects of stability – essentially between a focus on maintaining efficiency of function (engineering resilience) versus a focus on maintaining existence of function (ecological resilience) – are so fundamental that they can become alternative paradigms whose devotees reflect traditions of a discipline or of an attitude more than a reality of nature …"(Gunderson et al, 2002:1).

Resilience Thinking

Resilience thinking on the other hand "is about generating increased knowledge of how we can strengthen the capacity to deal with the stresses caused by climate change and other aspects of global change. It is about finding ways to deal with unexpected events and crises and identifying sustainable ways for humans to live within the Earth's boundaries" (Moberg and Simonsen, 2014:3). "Resilience thinking provides a framework for viewing a social-ecological system as one system operating over many linked scales of time and space [notwithstanding that] its focus is on how the system changes and copes with disturbance" (Walker and Salt, 2006:38). Resilience thinking addresses the dynamics and development of complex social–ecological systems (SES) (Folke et al., 2005)). Three aspects are central: "resilience, adaptability, and transformability" (Pisano, 2012:12). For resilient world the values of diversity, ecological variability, modularity, acknowledging slow variables, tight feedbacks, social capital, innovation, overlap in governance, ecosystem services (Walker and Salt, 2006). Table 1 shows the facets of resilience.

Table 1: Three Facets of Resilience

Resilience concepts	**Characteristics**	**Focus on**	**Context**
Engineering resilience	Return time, efficiency	Recovery, constancy	Vicinity of a stable equilibrium
Ecological resilience	Buffer capacity, withstand shock, maintain function	Persistence, robustness	Multiple equilibria, stability landscapes
Social–ecological resilience	Interplay disturbance and reorganization, sustaining and developing	Adaptive capacity transformability, learning, innovation	Integrated system feedback, cross-scale dynamic interactions

Source: Folke (2006)

Pisano (2012:9) focuses on social-ecological resilience as the best suited for considering governance issues and conceptualises resilience characteristics through the definition of social-ecological resilience that, draws from Carpenter et al (2001) as the:

- Amount of disturbance a system can absorb and still remain within the same state or domain of attraction;
- Degree to which the system is capable of self-organization;
- Ability to build and increase the capacity for learning and adaptation.

Social–ecological resilience is about people and nature as interdependent systems. This is true for local communities and their surrounding ecosystems, but the great acceleration of human activities on earth now also makes it an issue at global scales (Steffen et al, 2007), making it difficult and even irrational to continue to separate the ecological and social and to try to explain them independently, even for analytical purposes (Folke et al, 2010).

Adaptive Governance

The Stockholm Resilience Centre considers adaptive governance as “an evolving research framework for analysing the social, institutional, economical and ecological foundations of multilevel governance modes that are successful in building resilience for the vast challenges posed by global change, and coupled complex adaptive Socio-Ecological Systems” (Pisano, 2012: 25). Adaptive governance deals with the complex issues that socio-ecological systems are confronted with (Pisano, 2012). Adaptive governance is best understood as an approach that unites those environmental and natural resource management approaches that share some or all of the following principles: polycentric and multi-layered institutions, participation and collaboration, self-organization and networks, and learning and innovation (Djalante, Holley and Thomalla, 2011). Four interactive crucial aspects for adaptive governance are suggested by Folke et al (2005) namely: (1) to build knowledge and understanding of resource and ecosystem dynamics; (2) to feed ecological knowledge into adaptive management practices; (3) to support flexible institutions and multilevel governance systems; and,(4) to deal with external perturbations, uncertainty, and surprise. Figure 4 shows an illustrative representation of the links between the crucial characteristics of adaptive governance that will help in building and governing resilience (Pisano, 2012).

Folke et al. (2005) recommends four interactive crucial aspects for adaptive governance:

- Build knowledge and understanding of resource and ecosystem dynamics
- Feed ecological knowledge into adaptive management practices
- Support flexible institutions and multilevel governance systems
- Deal with external perturbations, uncertainty, and surprise

Figure 4: Interlinkages between key characteristics of adaptive governance in relation to building resilience

RESIDENTS PROFILE

The residents profile is shown in Table 2. About 52.7% and 47.3% of respondents were men and women respectively. 62.6% of respondents were above 40 years old while about 37.4% of respondents were above 40 years old. In regards to marital status 37.3% were single, while 50%, 6% and 6.7% of the respondents were married, divorced and separated respectively. 12.7% of respondents had no education while 34.7%, 28.6% and 24% of respondents had primary, secondary and tertiary education respectively. About 60% of respondents earned less than ₦40000 (US$111) per month while 30% earned between ₦ 41000 and N80000 per month (US$114-US$222) and 10% earned above ₦ 80000 (US$222) per month. 21.3% of respondents have stayed in the study area since birth, 27.3% between 1-5 years, 22.7% between 6-10 years, 11.3% between 11-15 years and 17.3% have stayed in the study area for above 15 years. Some of the factors which attracted respondents to the flood prone areas include low rent (28.7%), low rent and proximity to work (13.3%), low rent and market availability (9.3%), availability of cheap land (14.7%), nearness to work place (11.3%), and family ties (12.7%). All the respondents in the areas visited attested to have experienced flooding before.

RESIDENTS VULNERABILITY TO FLOODING

Lagos State is susceptible to recurrent yearly flooding due to its spatial location, topography, urbanization of poverty and crowding. The incidence of flooding is indicated in Table 3.

Table 3: Flood incidence in Lagos State from 2000 to 2014

Year	**Affected locations**	**Rainfall began**	**Duration in days**	**No of deaths**	**Number of displaced persons**	**Main cause**	**Comments**
2000	Most parts of the metropolis	22/5/2000	1		None	Rainfall	Socio-economic activities paralyzed, road blocked
2000	Lagos City	20/5/2000	2	10	None	Rainfall	The flooding was up to a metre (yard) deep

Table 3: Flood incidence in Lagos State from 2000 to 2014

Year	Affected locations	Rainfall began	Duration in days	No of deaths	Number of displaced persons	Main cause	Comments
							in several low-lying areas of the city, tens of thousands of homes all over the city were inundated with water.
2002	Lagos	7/24/2002	3	2	None	Rainfall	A mother and baby drowned
2004	Lagos City	6/17/2004	2	0	None	Rainfall	Ten hours rain floods large areas of Lagos City hyped by locked drains caused by dumping refuse
2007	Lagos area- Ikorodu, Kosofe	8/1/2007	15	6	5000	Rainfall	Ogun river flooding; 4,000 homeless in Lagos. 200 buildings destroyed 6 people dead
2009	Lagos Mainland – Apapa axis	30/6/2009	2		None	Rainfall	
2010	Lagos business districts, Island	7/7/2010	1		1760	Rainfall	Most streets in the city's key business district were swallowed up in flood. Motorists forced out of business.
2010	Lagos mainland and Island	14/6/2010	1		None	Rainfall	Roads were flooded. Canoes constructed to ferry people across 'the river'.
2011	Lagos	10/7/2011	2	Over 25	5393 households	Rainfall	5,393 households were affected in 31 districts/streets. Estimated output loss of ₦100 billion
2012	Lagos mainland and Island	27/06/2012	3	7	None	Rainfall	Houses submerged, one collapsed in Bariga. Community linking bridges washed off; pupils trapped; roads and bridges were submerged by the flood, and many properties were swept away
2013	Lagos Island and Mainland	10/4/2013	1		None	Rainfall	Commuters were stranded as downpour causes flooding, gridlock in Lagos
2013	Lagos Island	9/08/2013	1		None	Tidal waves	Homes were flooded
2014	Lagos Island and Mainland	20/4/2014			None	Rainfall	Roads and Drainages were submerged
2014	Lagos Island and Mainland	10/07/2014	1		None	Rainfall	Roads and Drainages were submerged; movement was impeded.

Source: Informal Research culled from various Newspaper sources in Nigeria (Vanguard, The Punch, Business Day, Daily Champion, Daily Times, Global Flood Register).

The major causes of flooding in the study locations include:

- Flat topography
- Excessive and recurrent rainfall
- Overflow of water bodies
- Encroachment of building on flood-plain
- Absence of building setbacks and construction of houses on drainage or water ways (Photo 1)
- Opening of a dam (Oyan dam) in neighbouring Ogun State
- Poor/faulty/non-functional drainage network (Photo 2) and,
- Indiscriminate dumping of waste into water channels leading to drainage blockage

Most of these factors seemingly are human triggered apart from the topography. In low lying areas like Amuwo- Odofin, Ajegunle, Owode and Ojo, residents said flooding occurs anytime there is a heavy rainfall for several hours.

Photo 1: Inadequate setback of houses

Source: Authors 2015

Photo 2: Clogged drainage between houses

Source: Authors 2015

Incomplete canal dredging and inadequate infrastructures to contain the run-off constitute barriers to proper flood control measures. For example, in Ajegunle, a canal was dredged in 2010 after the flood with the expectation that it would be concretized but up till not completed. Residents complained that flooding effect have heightened after the dredging than it was before the dredging (Photo 3). The unfinished dredged canal accumulates stagnant water and remains a breeding ground for mosquitoes and flies. Residents notes the Lagos State Waste Management Authority (LAWMA) comes around once in a while to spray the water to avoid/minimize flies infestation.

Photo 3: Abandoned dredged canal

Source: Authors 2015

Peoples' attitudes, non-compliance to physical planning measures and high rate of influx of people into the city of Lagos has led to indiscriminate development and construction of different forms of unsustainable and unstable shelter/housing that fail to comply with planning regulations and standards of housing development. These developments impede free flow of water and run-off during and after rainfall thus leading to flooding. Floods have devastated many parts of Lagos leading to loss of several lives and property and the displacement of many people.

RESIDENTS RESILIENCE

The immediate response to flooding by the residents varies. About 23.3% of respondents want to leave the area (flee from area), 22.7% of respondents fill the roads with sand using sandbags, putting wood shavings on roads; 22.7% of respondents use buckets to dispose flood water from their houses; 16.7% of respondents want to relocate temporarily; and 37.3% of the respondents have done nothing during the flooding incidences.

However, over the years, residents of these areas have adopted various coping strategies. These include:

- Clearing and de-silting of drainage,
- Building of embankments and raising of building frontages,
- Use of boats for movement during flooding,
- Building high walls to prevent floodwater from entering the houses, construction of trenches around houses,
- Arrangement of planks and tyres on sandbags to aid movement to their shops/buildings

However, in the low cost housing in Amuwo-Odofin residents who do not live on the ground floor worry less about flooding. With dysfunctional governance structure residents' adaptability is notable in the various methods used to contain flooding (Photos 4-7). The residents self organize to make their community flood resistance by using no or low cost materials like planks or used tyres to construct embankments and keep the community moving.

Photo 4: Sandbags and planks

Source: Authors 2015

Photo 5: Temporary bridges

Source: Authors 2015

Photo 6: Bridge made with planks

Source: Authors 2015

Photo 7: Planks placed on tyres for movement

Source: Authors 2015

Majority of these coping strategies are rudimentary, unsustainable, temporary and inefficient. Government Agencies like Office of Drainage Services, LASEMA and LAWMA have attempted some intervention according to the respondents.

POLICY RESPONSE

Office of Drainage Services

To combat the occurrence and re-occurrence of flooding in Lagos State, the Government through the Office of Drainage service embarked on the dredging of the silted streams and drainage channels in Lagos. In the year 2008, a total of 676,603.55 metric tons of silt were evacuated from existing collector drains and canals and carted away to maintain the hydraulic efficiency of the drains as designed. This is to improve their carrying capacities and enhance the efficiency of the channels to effectively drain storm-water run-offs. The first drainage master plan (Lagos Mainland drainage master plan) was designed and concluded in 1974 in a bid to control urban flooding and inundations (Drainage Department, Lagos State Ministry of Environment, 2014).

Subsequently, drainage master plans for other areas were concluded in 1992 and 1998 respectively. The 1992 master plans were the Apapa Storm water drainage master plan and Lagos Island Storm water drainage master plan. The identified works were divided into two namely Priority 1 works and Priority 2 but only priority 1 works have been implemented to date. The last master plan was Greater Lagos Drainage master plan and it was concluded in 1998.

In Lagos State, between 2007 and 2011 a total of 169 drainages were dredged, while 124 of the waterways were lined with concrete and about 45 channels were also dredged between 2007 and 2011, and proposed to be lined before 2015.

Lagos State Environmental Management Agency (LASEMA)

LASEMA strategies cover 5 main aspects:

- Flood Prevention: The LEMC (Local Emergency Management Committee) was established in 2014 under the Lagos State Environmental Management Agency. The committee consists of 774 local members from all the wards in the State. The members are from all agencies related to the environment, Community Based Organizations, and representatives of communities. The committee was established in accordance with priority 3 of the Disaster Risk Reduction Convention in Kobe, Japan. The goal of the committee is to ensure reduction of risk at local level through knowledge, innovation and education. These three elements would then build the culture of safety and resilience in Lagos Community.

- Flood Preparedness: Identification of flood vulnerable communities through risk mapping and hazard vulnerability mapping. Other agencies working on the environment are also identified for collaborative efforts for example the Nigerian Metrological Agency (NIMET), Lagos State Environmental Management Agency (LAWMA), Lagos State Environmental Protection Agency (LASEPA), Department of Metrological Services, Emergency Flood Abatement Department, an Office of Drainage Services in the Ministry of Environment, and Ministry of Physical Planning and Urban Development (MPPUD).
- Flood Mitigation: This involves the use of early warning systems to sensitize and educate vulnerable communities on how to prepare, respond to and recover from the impact of the disaster; monitoring and enforcement of environmental laws like the Lagos State building code and Lagos State emergency plans.
- Flood Response: Stock piling of necessary equipment to combat flood and ensure easy response, and building of relief camps for rehabilitation for affected persons. Presently, Lagos state has two existing relief camps in Lagos East- Agbowa, Lagos West- Igbodo and an on-going construction in Lagos central-Lekki. For example, the 1760 Internally Displaced Persons during the 2010 flooding were resettled temporarily at these relief camps.
- Flood Recovery: Obtaining the demography and characteristics of the people to ascertain and predict flood victims (so as to prepare relief materials and number of people that would be displaced.

Lagos State Waste Management Authority (LAWMA)

Spatial growth is not the only product of population expansion, but also, waste generation, particularly, municipal solid waste that is impossible to avoid. About 10,000 tons of solid waste is generated each day in Lagos, with GPC of 0.65kg/person/day. The rate at which municipal solid waste is being generated hinders the capabilities, financial and technical, of LAWMA to sanitarily manage waste. Solid waste is left uncollected and dumped indiscriminately in water bodies, air-spaces of buildings, open lands, road verges and public drains. Littered waste becomes permanent feature of urban landscape.

DISCUSSION

Flooding challenges due to the encroachment of buildings on flood-plains, poor/faulty/non-functional and inadequate drainage network; and indiscriminate dumping of waste into water channels have resulted into displacement of people, loss of livelihoods, loss of productive hours, pollution of drinking water, destruction of farm lands, housing and infrastructures, water borne diseases, and death as seen in this study.

Urban sprawl and urbanization of poverty continue to cause overcrowding, and poor quality of housing in Lagos as evidenced in the study locations. Inadequate urban planning, poor infrastructures or lack thereof, poor enforcement existing planning regulation and non-compliance by people continue to cause havoc especially during flooding incidence. With the ever increasing urban population in Lagos, encroachments of wetlands and building of illegal structures, flooding will continue to reoccur unless people and governance structures transform.

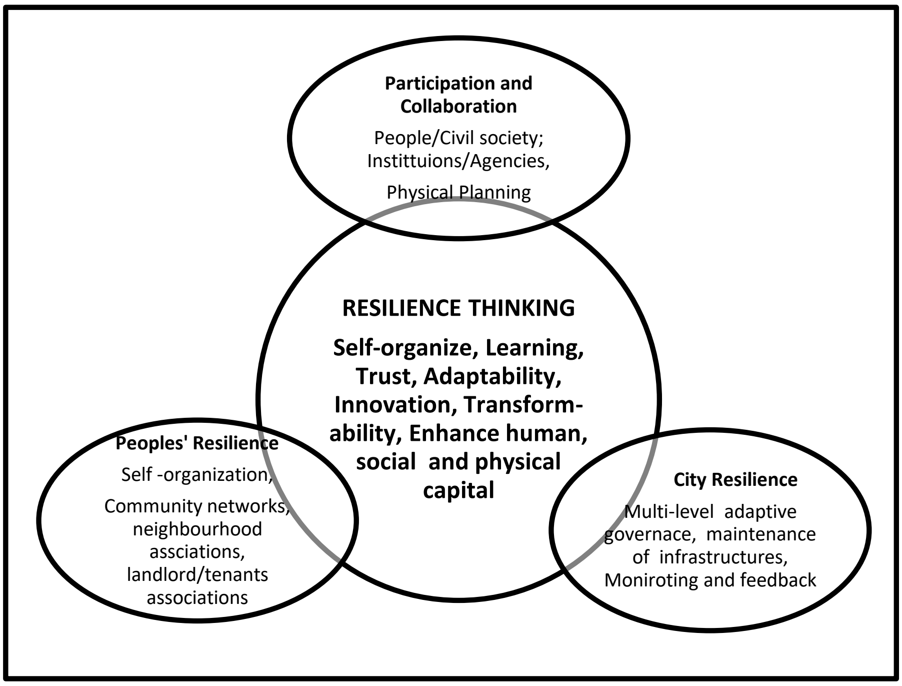
The people and city's resilience will continue to be tested in periods of flooding. Therefore adaptability measures that build resilience and transformability or transform-ability of residents and the governance regimes to self-organize and develop the capacity to learn and adapt is very critical.

Policy, programs, plans and projects by government agencies such as LASEMA, Lagos State Ministry of the Environment-Office of Drainage Services and LAWMA are laudable but have fallen short of people's expectations. Projects are not completed due to bureaucracy, funding inertia or lack of funds. Canal dredging and de-silting of drainages in areas like Ajegunle, Owode, Ojo, Agege, Amuwo Odofin, Lagos Island, Eti-osa were not completed, thus increasing the vulnerability of the people to more flooding disasters. Respondents noted the 'silent' inactivity of The Ministry of Physical Planning and Urban Development.

WAY FORWARD

Resilience thinking is about the capacity to learn, adapt, self-organize, and transform-ability. WEF (2018) notes the failure of urban planning, failure of regional or global governance and increasing urbanization are among the interconnected risks of climate change. Thus, planners have a major role in facilitating resilience thinking and developing tools together with the community (civil society) and policy makers to build resilience especially to avert flooding or any other environmental disaster (Figure 5).

Figure 5: Building Socio-Ecological Resilience in Flood Incidence



Source: Authors Conceptualisaton, 2015

Appropriate feedback and monitoring is also very critical to building resilience and achieving adaptive governance.

Planners

Physical (Community) Planners must ensure the:

- Facilitating participation and collaboration among civil society and policy makers
- Revision and enforcement of planning regulations, building codes, development control measures, zoning by-laws and change of use laws
- Revision and enforcement of Lagos building codes and non-compliance will lead to demolition of structures blocking the flow of drains and canals
- Improved sanitation and proper waste disposal measures
- Flood mitigation education and awareness
- Advice on building materials to be used in flood prone areas and
- Inform citizens about flood prone areas in the city
- Integration of geo-spatial and remote sensing techniques towards appropriate flood modeling, simulation and forecasting

Residents

People would always be at the centre of socio-ecological resilience. Residents should be properly informed and educated in the areas of:

- Utilizing good quality building materials,
- Proper waste disposal methods,
- Refrain from dumping waste indiscriminately or along water channels or in drains/gutter,
- Flood control and the devastating consequences
- Education is key to resilience thinking

Government

Multilevel governance is fundamental to resilience thinking and building resilience. Thus, the State Government through appropriate agencies (private, public, CBOs or NGOs) should:

- Develop awareness mechanisms as to the risk of flooding in communities
- Develop monitoring structures
- Set up effective information and warning systems
- Ensure enforcement and compliance of all environmental laws
- Ensure a budget reform for efficient performance
- Provision and maintenance of infrastructures
- Dredging and de-silting of blocked canals and drainages
- Review periodically flood adaptation and mitigation policies and programs

CONCLUSION

The communities in the study Local Government areas show resilience by the different measures adopted and adapted deal with flooding. These communities have persisted to reoccurring flooding. The utilization of planks/wood and used tyres (wheels) as pathways; and the construction of bridges to facilitate movement of people and goods indicate the extent of adaptability and transform-ability of the residents. For a resilient city and a resilient people, physical/community planners should begin to build resilience (socio-ecological resilience) and incorporate resilience thinking and adaptive governance into plan making, planning policy and practice especially in flood or any emergency and disaster situations.

Challenges and lessons learned after Supertyphoon Haiyan in Tacloban City, Philippines

Paragas, Gerald, PANGASINAN, Philippines

ABSTRACT:

Touted as the world's strongest typhoon on record to make landfall, Haiyan slammed the central Philippines on 8 November 2013 with maximum sustained winds reaching 315 kph (170 knots) with gusts up to 379 kph (205 knots) just before landfall. The Category 5 (based on Saffir-Simpson hurricane scale) super typhoon, known in the Philippines as Yolanda, caused over 6,300 casualties, displaced over 4 million people and destroyed or damaged over one million houses due to high wind speed and storm surges. In total, 171 municipalities in 14 provinces across five regions of the country were affected by the storm. Tacloban, being the Eastern Visayas region's largest urban area and one of hardly hit areas, sustained the worst with damages estimated at Php 7 billion and recorded a death toll of almost 2,700 (Office of Civil Defense, 2014). The scale and nature of the impact of Haiyan created one of the worst humanitarian crises the Philippines has ever faced. To fulfil the overwhelming task for coordination, the cluster system was applied at the City Hall, with perceived parallel coordination efforts from regional and national governments, and international organizations.

In the aftermath of the supertyphoon, the City Government created a task force called *Task Force Tindog Tacloban*to 'coordinate the needs of the public and optimize the communication between the national government and the different international organizations with the local government' (CDRRMC Resolution No. 05, Series of 2015). Then later, the local government, with support from United Nations Human Settlements Program (UN-Habitat) and key agencies, began to conduct a purposive recovery and rehabilitation planning process which led to the creation of Tacloban Recovery and Rehabilitation Plan.

Sharing author's survivor accounts and actual involvement in recovery and rehabilitation efforts, with crucial information from partners in national government and non-government organizations, this study shall describe the experience of the Tacloban City Government, its challenges to include surge of foreign humanitarian workers, successes and lessons learned as the City transitioned from humanitarian response, to recovery and development phases after the disaster. The report will also examine the institutional systems which were set up to coordinate emergency response and recovery and rehabilitation in Tacloban, and reflect on the main achievements and lessons from emergency response to recovery to resilience and sustainable development. Over four years after the mega-disaster, the case of coastal Tacloban remains relevant today, showing the impacts of climate change to urban areas, and providing context to discussions on Philippine polices and international interventions related to disaster risk reduction and climate change adaptation.

THE DEVELOPMENT of JUWANA SETTLEMENT as a NORTHERN JAVA COASTAL CITY in INDONESIA HAS THE POTENSIAL TO SUPPORT GLOBAL MARITIME AXIS

Naniek Widayati Priyomarsono, Rudy Surya, Ninawati, Theresia Budi Jayanti
Master-Architecture, Faculty of Engeneering, University of Tarumanagara
Jakarta, Indonesia
Address: S Parman no. 1 Grogol Jakarta Barat, Indonesia
naniekpriyomarsono@gmail.com, **+628164821799**

Keywords (3-5): *settlement development, coastal city, global maritime axis*

1. THE BACKGROUND

Juwana was a subdistrict town in Java north coastline of Indonesia became a trajectory of post lane (*Daendels*) from Anyer to Panarukan. Juwana was a coastline area and low plain passed by a largest river of Pati district namely Gonggo river. Society on the coastline of Gonggo river as a preliminary society developed Juwana as a town by applying dualistic concept cosmology and expressed in shape of residence, shape of worship building. Besides, concept of religious dualistically cosmology in determination of site of building toward the position of The Creator. Two aspects of dualistic were reflected on spatial form of outside space, spatiality, and shape of its building.

In its development of Dutch colonization, Juwana became Trade Hub a bit hectic and a significant port in Java island. Trade transaction of foreigners buying earth crops, including opium transaction. Therefore Juwana was North lane very significant, as a place for assembling-up ships, and industrial center of brass handicraft, batik, and cigarrette.

Society living in Juwana from generation to generation was a fishery society and milkfish producer whose their yields dominated milkfish market in Indonesia. Besides Juwana area has specific traits namely; a settlement of the beginning existed on the bank of river and coastline, formed liniary settlement. As time went by the Chinese merchants visited Juwana and established settlements with radial forms, there was open space in the midst as orientation center. Juwana developed with the establised axis of Daendels street penetrating liniary settlement, growing to be a town with a building in the architecture of colonialization of the Dutch, *Indisch*, the Chinese and the Java becoming characters of Juwana town.

This town experienced changes and development with the usage of settlement by fishermen, merchants, and handicraftsmen. Information from numerous sources, in the beginning of the fifteenth century the coastline cities in Java island underwent the rapid progress and its peak was at 16th century, due to trade advance of inter-continent.

Condition today Juwana undergoes decline in the businesses of handicrafts, traditional fishermen, and the building-up of ship. This is due to the lack of facilities and facilities of town supporting the town including facilities and diminution in an environmentally significant quality, as well as its usage of news tools for seeking the fish named *cantrang* effecting less favorably on traditional fishermen.

2. PROBLEMS

Problems are how Juwana as a Java North coastline town which location is strategic and potential with power resources and in the past time was trade hub affords to support World Maritime World as initiated by President of Republic of Indonesia, Joko Widodo.

3. THE USED METHODS

Research done qualitatively interpretative with a natural approach in the study of the phenomena at hand for comprehension and interpretation (Norman Denzin, Yvonne Lincoln, 2002:176). A data search with strategy method of *grounded theory research* with an observation, interview on informants pertinent to research objects. Data compared to notes and writing pertinent to problems. Then analized to obtain the accurate findings.

4. DATA IN THE FIELD

Juwana as a subdistrict town with Pati as a district capital city are both located in a lane which was a trait separating Java island with Muria island in the north (it is the present Jepara town), both are trade towns.

4.1 The Colonial Epoch

From the map and historical criteria at hand Juwana since in the Mataram epoch was a significant port hub and reckoned due to eographical site and potencies they hold. Juwana of the colonial epoch was a trade hub a bit hectic. Likewise about port hub dominated by the Dutch usually there was building of fortress as a place for supervising the pace of loading in the port and guarding toward the rebel as it was in Juwana. Juwana in addition was famous as the building-up place for ship as well as brass handicraft industrial center. Also it was a district region. In the administrative period of Governor General Daendels there was a built-up road of post or well known as *Gorte Postweg*, as a great road piece made from Anyer to Panarukan. In the Dutch administration, Juwana was a center of Kawedanan city (*District*). Started on January 1902 up to present, its status became Subdistrict, a part of Pati district. City's profile stretched from South-East to North-West, perpendicular to Gonggo river.

Juwana was a Java coastline area used by Mataram kingdom as a port for selling earth crops and the entry of overseas merchants mainly deriving from the China. Its linear settlement pattern followsed Gonggo river flow and changes to enter into the rural area to form radial pattern with squares as event center. In the 16^{th} century, Juwana is an important port town in Java island. The foreigners bought the earth crop and sold to other places. Opium was one of witnesses how Juwana became a North coasatline lane that was important. *Henri-Louis Charles Te Mechelen*, head of inspector for Regi Opium & Residency Asistant of Juwana in 1882, reckoned that one of twenty Javanese persons had been inhalers of opium during the epoch.

4.2 The Today's Juwana

Juwana, geographically is domiciled 12 kms from Pati district capital city and 87 kms from the capital city of Central Java, Semarang. Juwana is adjacent to Java sea and also passed with Pantura road (Pantura is Java North Coast). Majority of population in Juwana was Javanese and minority was Chinese ethnic dwelling in the area of city center. Juwana as a fisherman city with inhabitants work hectiness starts from about 04.00 in the morning, road of Juwana city starts to be alive, hundreds of mothers and fathers working in the fish landing quay are seemingly busy with bicycle heading to their work places. In the morning at 07.00 o'clock like in the other small cities, Juwana starts to experience hectic hours where hundreds or even thousands of workers from the outside and the inside of Juwana crowds on the roads and it was added with childrens at busy time there in Juwana except Sunday. In the midday, the atmosphere of Juwana city is also busy. In the afternoon at 16.00, streets are again crowded with workers already leaving from the work places. Whilst in the afternoon & evening, the bustle is concentrated on squares and area of Juwana market.

The latest development of Juwana is most of shop-residences as office and mini market shops like Indomart, Alfamart, as well as great number of state banks or either private banks spreads. Besides, Juwana also has ample cooperatives such as; Cooperative of Muria and Cooperative of Pangestu which are both as great cooperatives headquartered in Juwana. This marks an economical cycle and financial cycle in Juwana a bit well. Juwana together with Pati, Jepara, and Kudus categorized into area of integrated economy potency named then as WANARAKUTI (Juwana, Jepara, Kudus and Pati).

Juwana itself has a big role for Pat district. Juwana is an industrial centers for a brass handicraft, furniture handicraft, ship-building, batik handicraft industry, and as district's fishery center with a fish auction place, and cultural center in Pati district. Ample customs, tradition, cultures in Juwana still sustainable up to present and Juwana deserves as "cultural city" from Pati district, street facilities in Juwana itself lacks of sufficiency such as narrows streets in the city, a bit dirty streets and less available sidewalks.

Juwana has ports in Bajomulyo and Pajeksan-Kudukeras, both ports are located on the area of Gonggo river every day, hundreds of ships parks on the bank of river. Gonggo river is a "grace" and also "disaster" for Juwana city. The grace is that due to this river, Jakarta residents are successful to be fisherman. Juwana is exception from fishermen. Fishermen in Juwana mostly have rich houses, cars, and luxurious stuffs. This is seen from fishermen deriving from area of Bendar and Bajomulyo. "Disaster" of Juwana river is about almost every year Juwana undergoes flood mainly in the area of Bumirejo & Doropayung due to overwater of Juwana river unable to accomodate the water.

Figure 5. Situation of Juwana Fisherman's settlement
(Source: Private Document, 2018)

Settlement Spatiality Pattern of Kampong Nelayan Tambak Bendar Bajomulyo Juwana can be identitifed to have a character of fisherman's settlement in the aspect of spaceness (unique) as well as factors taking influence in order to restrict and es tablish reliance (*determine factors*) on spatial pattern. It is seemingly visible that components of space shapers (*spatial space and urban space*) relates to social culture, economy and fisherman's settlement physics having significance on growth of fisherman's settlement also on Juwana city. Through a spatiality pattern significance as a response on dependence/reliance factors will be produced by a parameter going to determine considerative steps, pattern shapers or spatial perspective thus it can be identified so far about the possibility of spatiality problem troubleshooting able to do in fisherman settlement development and Juwana city overall.

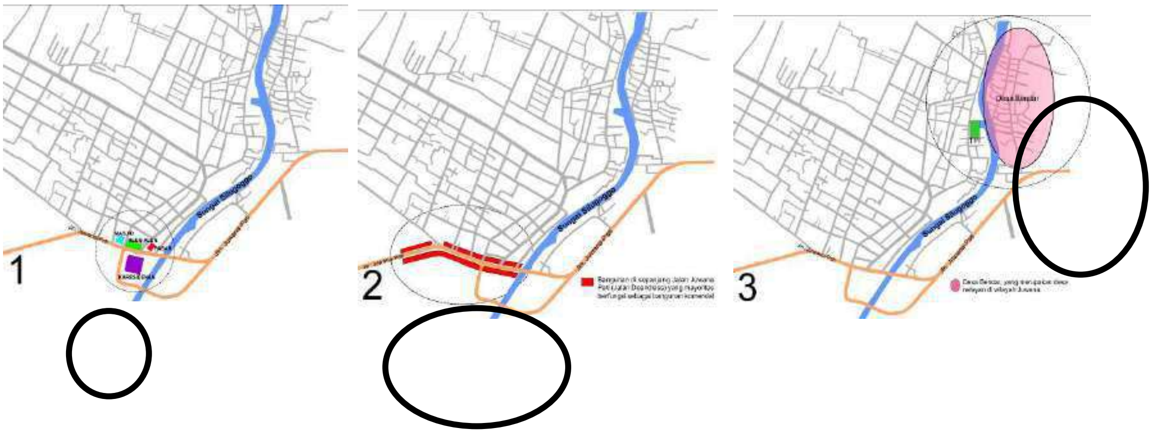

Figure 6. Juwana Room pattern Map with River
(Source: Private Document, 2018)

Pattern of Space 1: Subdistrict Office with City Squares as Juwana city activity
Pattern of Space 2: Commercial center forming the axist on the road of Daendels (PANTURA)
Pattern of Space 3: Location of Bendar village as Fisherman settlement village unique along the Gonggo river. A mosque (green color) as society's activity center

Research event done in steps of formulating research design, conducting comparation and existing region identity, determining variables and measurement parameters, probation and analysis. It is concluded that fisherman settlement spatiality pattern of Bendar village was formed from nature condition as basic form and develops in the frame of economical activity as determinative factors for setting the space in spatial scale or urban structurized in the basic level (*core*), transition and di fusion (separated level). There is access determining mode/mobility from social aspect or economical aspect (*backward-forward linkage*) with *leading sector* of fish capture activity, public space availability has significant meaning in spatiality pattern marked with the importance of quay existence and Fish Auction Place as *core area*. Thus social alteration aspect very relates to society economy increase that cause on city spatiality detail. Therefore it is necessary to have planning integration by placing determinant factor such as ecological humanism which influences on sustainability of fisherman settlement quality increase.

Figure 7. Juwana Beach Area
(Source: Private Document, 2018)

5. DATA STRUCTURE AND ANALYSIS

What's on the mind when thinking about Juwana town ? A fisherman town, a town of folks friendly, successfull and many more....

Juwana is a town on Java north coastline with an area width of about 5.593 ha (55,93 km²). Juwana town is the second largest in the Pati. Geographically, Juwana is adjacent with Java sea, on the north adjacent directly to subdistrict of Batangan, near the South adjacent directly to Jakenan subdistrict and Pati subdistrict, and near the West adjacent to Wedarijaksa subdistrict.

A number of Juwana subdistrict's population was 104.901 inhabitants (District Document; 2017). Majority of Juwana subdistrict has employment as fishermen. Since in Juwana there is fishery port located in a village of Bajomulyo. This fishery port is District's Fishery Port abbreviated or called as PPD, however this port's quality is assumed o equal with *Nusantara* Fishery Port or National Fishery Port. It is a fact from facilities available at around port such as: fish auction place, gasoline filling place, docking work place, ice factory and salt plant. The objective is as a fish ship-support media at sailing time. In this port there are fishery ships from numerous sizes and different types in terms of capture devices s*tarted from purse seine*, *long line*, fish trawling, *bagan apung* and *bagan tetap*.

Juwana fishermen are hard and dilligent in work, due to dilligence of this Juwana fishermen thus almost all inhabitants live prosperously. It can be seen from houses of inhabitants. Juwana can be equalized to big cities at hand in Indonesia.

Village of Bendar, is one of villages in Juwana assumed as most prosperous village. If you visit Bendar village, then you will feel as if being in the elite houses of businessmen and apparatus. You will forget that Bendar is solely a fishery village. How is possible with majority of employment as fisherman, almost all inhabitants of Bendar have luxurious houses with vehicles and motors with assumption that they have more than one. However Bendar is still Bendar and Juwana is still Juwana. Even though it can be said as most prosperous town of fishermen, Juwana inhabitants is still low profile and humble.

This success can be obtained since they use capture device called as *cantrang (purse seine).* That device can capture marine yields up to the bottom of it. Fish capture are at about Java Sea waters. Fish capture area in about Java Sea and Makasar strait is a most proper for ships with capture devices. Since that area has no coral but mud and is still rich of fishery resources. Therefore the condition can put opportunities for fishermen to gain capture yields in maximum. They with big ship can be the in the midst of sea for about 2-3 months. This makes discrepancy toward traditional fish capture which its fish yield is just so.

A governmental policy, in this case it is a Minister of Marine and Fishery as the authority in terms of prohibition of trawling or *cantrang* device receives protests and blasphemy. A policy issued by Minister Susi Pudjiastuti makes ample fishermen into bankruptcy.

A head of association of Lamongan's fish trawl or Pukat Tari Lamongan, affirmed that ample fishermen are jobless since a ban to use capture device of trawl, *payang* and *cantrang* up to the effective date in December 2017. Minister of Marine and Fishermen announced that extension of cantrang usage in six districts like Rembang, Pati, Juwana, and Lamongan with the condition.

Faculty of Law, University of Indonesia (FHUI) held *Focus Group Discussion* (FGD) “Decreasing the Vulnerability of Indonesia’s Fishing Communities: Countering the Threats of Illegal & Unsustainable Fishing” on Friday (3/11/2017) presented a field report of Newton

Fund in Bitung and Dobo by three researchers named Prof. Melda Kamil Ariadno, Ph.D., Prof. Adrianus Meliala, Ph.D and Muhammad Bilahmar before the audience, with outcome; these fishermen conducts traditional capture and aware the importance of keeping-up nature resources in the waters. Society do the warning, and threatening if finding big ship using *trawl, by reason of destroying the marine habitat.*

Figure 8. A meeting of President and accompanied by Minister of Fishery and Marine Susi Pudjiastuti with Association of Indonesian Fishermen 08 May 2018 (Source: Association of Indonesian Fishermen, 2018)

With pro and contra about capture device named *cantrang* it its kind in the field, finally the president Mrs, Joko Widodo (Jokowi) said, Government keeps attempting to suggest fishermen in their green-minded effort of the fishing capture. According to him, effort of Minister of Marine and Fishery, Susi Pudjiastuti forbiding the usage of fishing capture named cantrang is a nature in terms of marine ecosystem is not wrecked thus capture yields of fishermen can be ample.

Jokowi also asks fishermens' understanding that the ban of cantrang has no mean at all to block fishermen doing fishing. Transition of leaving from cantrang usage to devices recommended by KKP shall be done by Indonesian fishermen for the prevention of marine ecosystem destruction.

Besides, another potency held by Juwana is ship production or ship building-up with Marbau wood already famous all around the Indonesian waters. Experts making this ship is Juwana native inhabitants and Bajo ethnic from South Sulawesi. Both are fishing societ. This industry is local genus rarely found in the other places since the needs of experts in capability and special skills.

In order this industry can develop thus Minister of Liaison places order of 100 transport ships in capacity of 35 gross tonnage later to use as logistic transport ships in East Indonesia.

Figure 9. Process of Ship Building-up in Juwana as One of Indonesia's Maritime Axis Establishment (Source: Private Document, 2018)

Figure 10. Prototype of Juwana Traditional House
(Source: Private Document, 2018)

6. SUMMARY

Juwana having marine resources and coastline as well as human resources grants important suppport for Juwana economy in specific and Indonesia in general, as well as holding the interest in the national and in the global since holding a rich nature biodiversity. For the power resource is harmony it takes as follows;

1. Integrated approach for planning and management of coastline zone,
2. It is necessary for availability in information and accurate data for the sake of proper management,
3. Transparency is needed in power resource allocaition,
4. Cooperation is needed between PEMDA (DIstrict Administration) and local societies in resources management.

Juwana can be a prototype for Java North coastline own able to support the establishement of world maritime axis in order to form economy network, culture, and life of all Indonesian societies integrated with numerousi recource potencies.

Resources they have are: ship building-up, fisherman port, milkfish/*tambak* fishery industry, food industry, and town spatial structure aready formed with Gonggo river as a bit large port mainstream for fish with ship-building-up potential to support Indonesia as world marineity axis.

7. THE FUTURE HOPE

Becoming Indonesia as World Marineity Axis is a vision to future relied on reality that in the region of Unity State of Republic of Indonesia, there are potencies of marine resources super indefinite in numbers. This was initiated by Joko Widodo President of Republic of Indonesia in his presidential early period. Thus coastline area becomes development attention necessary to focus on architectural rsearches in order to strengthen marine axis in Indonesia, particularly in Java island. Thus it takes as follows;

1. It is necessary for a sustainable development and marine and coastline resources management as well as human resources with target of "function management of ecology and social economy", and protection toward the production.

2. Capacity increase of local production commensurate with international standard sustainable development management toward coastline resources, marine and human being with work synergy between BAPPEDA (District Planning Institution), and Ministery of Marine and FIshery or KKP

3. It takes as follows: 1. *Art District*, 2. *Financial District*, 3. *MICE Activity*, 4.*Creative Industry District*, 5. *Food, SME* & *Traditional Comercial Center*, 6. *Education, 7. Fishery Center.* With existing completion, it is expected that Juwana can be main destination of PANTURA (*Pantai Utara Jawa* or Java North Beach). It shall be single destination and single management. Therefore it needs new Branding, one of most proper one can be seen from preliminary establishment of the town namely "World Marineity Axis"

Figure 11. Example of Juwana Brand Image
(Source: Private Document, 2018)

4. Presidential Regulation is necessary in the usage of fish capture net based on green environment. Thus no "pro and contra" activities in the fields.

5. From the four points above, it is hope that there will be Juwana prosperousness as world marineity axis held by Indonesia and have a positive impact on marineity Indonesia in the eyes of the International.

What can we do beyond 2050? Long-term adaptation in Boston and New York

Dalia MUNENZON and Mathew STAUDT, One Architecture & Urbanism (ONE)
New York, NY, USA

Synopsis
This session uses case studies of coastal resilience plans in Boston and New York to discuss building long-term adaptive capacity, asking: What comes after the projected benchmark of 2050? What are resilience strategies for the long-long term?

Introduction

According to 100 Resilient Cities (100RC), a Rockefeller Foundation initiative funding the development of resilience strategies in cities around the world, urban resilience is “the capacity of individuals, communities, institutions, businesses, and systems within a city to survive, adapt, and grow no matter what kinds of chronic stresses and acute shocks they experience.”[1]

100RC and many similar initiatives – among others, C40 and the International Council for Local Environmental Initiatives (ICLEI) – have adopted resilience as a steering principle. One of their central directives is organizing cities and communities to cope with the risks of climate change in an era of steadily more extreme superstorms such as Hurricane Sandy in New York (2012) and Typhoon Yolanda or Haiyan (2013). This process has, in turn, triggered a number of urban and regional-scale design competitions and visioning plans for how (especially coastal) cities should be planning long-term adaptation to sea level rise, storm surge, extreme heat, inland flooding, eroding infrastructure, and other climate / urban vulnerabilities.

Many of these plans use mid-century (2050) and end-of-century (2100) projections as benchmarks for risk projections, thus tethering design strategies to finite time periods and goals. In this paper, we will explore what happens when we look beyond these projections to even longer-term goals, imagining forms of resilience able to adapt to changing environmental, social, political, and economic circumstances far after 2100. How will precedents for resilience set by today’s design practices and coalition-building influence decisions made decades later? How can we build adaptive capacity for climate change and related stresses in the long-long term?

Long-term adaptation in Boston and New York

These questions form the backbone of the Dutch design and planning firm One Architecture & Urbanism (ONE), which has honed its expertise in large-scale resilience planning and infrastructure in the United States following its winning proposal for the 2014 Rebuild By Design competition: The BIG U. Since then, ONE has been at the forefront of a vanguard group of resilience planners, many in Boston and New York, using the framework of “flexible adaptation pathways” – an approach acknowledging the uncertainties of future climate conditions and the need for multi-layered, iterative responses in systems as complex as a city or urban watershed.

This approach has been largely informed by the New York City Panel on Climate Change (NPCC1) formed in 2007 by Mayor Bloomberg, which developed guidelines for risk

[1] http://www.100resilientcities.org/resources/#/-_Yz47ODU4NidpPTEocz5j/

management centering the ability of plans to evolve through time to meet changing risk projections, vulnerabilities, as well as physical, environmental, social, and economic circumstances. These guidelines, both in terms of risk projection and design standards (to cope with increasing heat, precipitation, heat level rise, and other stressors) surfaced in the form of reports by the Mayor's Office of Recovery and Resiliency (ORR) and many other city agencies, as well as the ongoing revisions to the City's OneNYC plan.

Through case study examples of flagship projects by ONE in both cities, the opportunities and challenges of long-term adaptation strategies can be illuminated. As a Dutch firm now working primarily in the United States, ONE bring a critical perspective toward water-centric design with an acute focus on process, precedent, and the importance of a robust implementation strategy intimately involving stakeholder interests. Prior to its American work, ONE also initiated a "Deltametropolis" design studio for the Dutch government's Ministry of Planning, and led the visioning process of Randstad 2030, a federal plan for the long-term development of the western region of the Netherlands, and has worked across a wide gamut of sociopolitical contexts from the highest levels of governance to the smallest-scale grassroots urban initiatives and community groups.

In cities like Boston and New York – both of whose urban coasts have been expanded through land reclamation – capitalist frameworks of governance and private interest remain invested in the expansion of shorefront development ignoring common-sense resilience strategies following even the harshest of storms. Today, nearly 12.3 percent of new residential units in New York (one in eight) is built in "a high risk flood zone, up from 10.7 percent in 2014 … last year, 2,362 flood-zone units were completed – nearly double the number delivered in 2014"[2].

This stark disconnect from the ages-old Dutch practice of "controlling nature" and its contemporary emergence as the McHargian philosophy of "designing with nature" has led us to pursue *resilient* design over the *sustainable.* Resilience presents designers, engineers, and policy leaders with a flexible toolkit rather than a goal or quota, and thorough integration with scientific considerations accommodating the certainty of large-scale ecological shifts in years to come. *Sustainability,* defined by Merriam-Webster as "a method of harvesting or using a resource so that the resource is not depleted or permanently damaged," plateaus efforts toward a flatline goal, most commonly associated with finite carbon sequestration, renewable resources, and emission caps. Resilience thinking, while including many of the same priorities, also accounts for unanticipated shifts in climate (SLR and meteorological) projections, the ever-changing context of environmental and social risks.

In the most basic terms, resilience is a narrative that embraces networked relationships (both physical and social) and known unknowns. As Ross Exo Adams elaborates in the article "Scaleless" for *Cultural Anthropology* (2018), resilience urbanism "blurs the boundary between bodies and infrastructure just as it blurs the distinction between the organization of space and the distribution of governance." In a similar vein, ONE has found resilience to be a helpful framework not just in the design context but also in terms of "project risks" and project management: it is a tool to navigate the complexities of governance and the competing interests

[2] https://www.nytimes.com/2018/07/06/realestate/luxury/new-buildings-rise-in-flood-zones.html

of stakeholders, and can be leveraged as a framework to structure collaborative relationships between public and private entities on long-term projects for which there are few priors.

In order to successfully advance resilience projects into implementation, ONE has adopted an ad hoc coordinator / integrator role between city agencies, private contractors (mostly in design and engineering), and public interest groups. In the several decades of this practice, ONE has come to view this highly collaborative planning role as central to any design process geared toward short-term implementation and long (-long) term goals. The consequences of this mediatory role have become clearest in ONE's projects in New York and Boston.

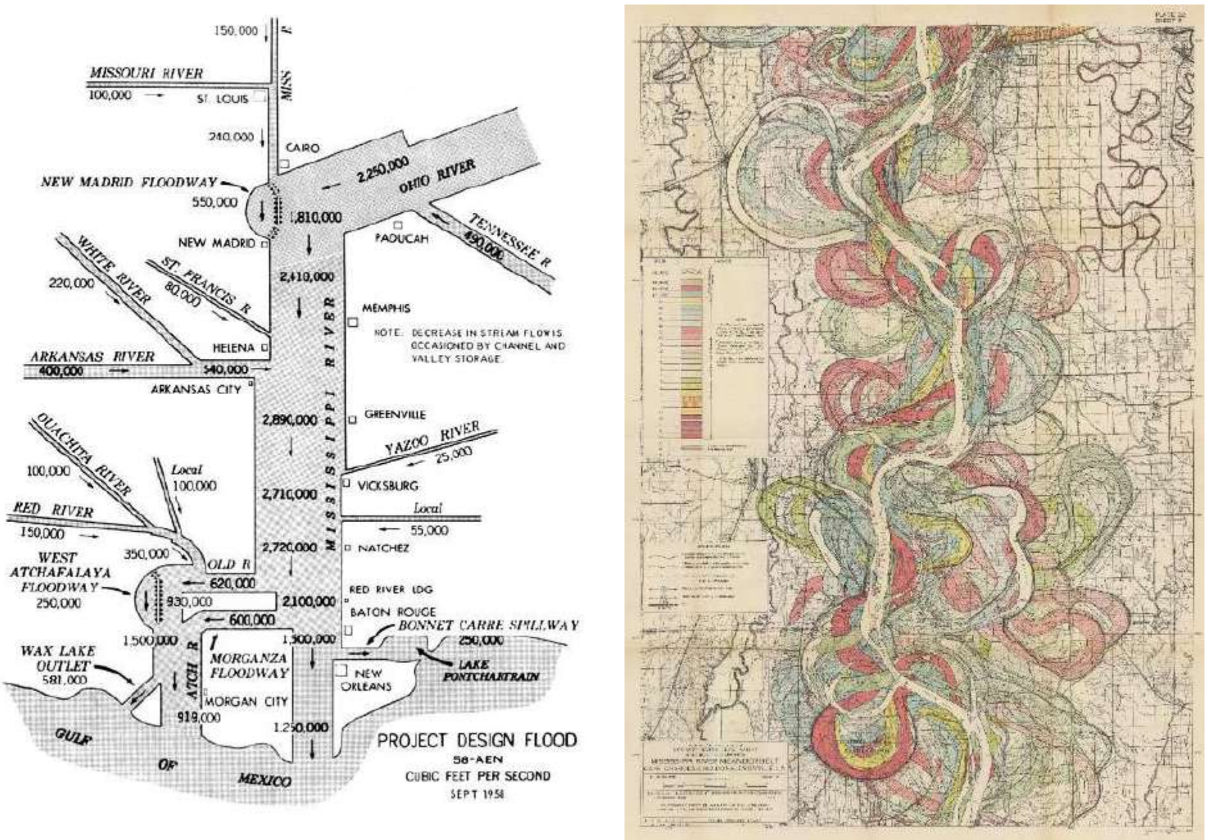

Fig. 1: Visualizing technocratic versus flexible, adaptive resilience thinking: USACE's Project Design Flood (1958) versus Harold Fisk's maps of the historic pathways of the Mississippi River throughout the formation of its delta (1944).

In its first iteration by NPCC1, "flexible adaptation pathways" can be read as a kind of design manifesto in addition to a scientific caveat, and its criteria read as design ideals: *(1) multidimensionality, (2) interdependency, (3) intertemporality, (4) holistic indicators and monitoring,* and *(5) societal processes and transformation.* In ONE's reading of this methodology, we see this as an addendum to the technocratic approaches of reactionary, post-disaster master planning and strict design timelines. In our experience, we have learned that resilience projects, even from a managerial standpoint, must adopt the same principles of flexibility, collaboration, intertemporality, and more of the points above: they must be able to evolve their identities in response to changing conditions, and not respond to the risks (environmental, social, political, urban) posed at a finite moment in time. Rather, they must anticipate and embrace uncertainty, allowing for multiple identities and services to coexist and evolve at the same time. A metaphor from geography might be the disparity between the Army Corps' 1950s-era water management mandates for the Mississippi River, dubbed Project Design Flood, versus the river's historic identity as a highly modular body of water, shifting over the landscape with changes in the pull of gravity. An example from landscape architecture might be the *jardin en mouvement* according to Gilles Clement: anticipating decay, change, and the inherent competition of a restricted number of plant species, allowing this to rule a garden rather than establishing restrictive design rules.

In 2016, the City of Boston opened up a proposal for the first phase of its new Climate Ready Boston initiative, an extension of its Imagine Boston 2030 master plan focused on climate adaptation and coastal resilience. Building on this initiative, the first geographically-specific report focused on the waterfront districts of East Boston and Charlestown. The team of contractors assembled consisted of Kleinfelder, Stoss Landscape Urbanism, One Architecture & Urbanism (ONE), and Woods Hole Group. These two neighborhoods were prioritized due to their relatively higher risk to coastal flooding, dense vulnerable populations, and narrow, well-defined flood pathways, making them optimal for short-term infrastructural interventions to cope with inundation.

In the five years since the conclusion of the Rebuild By Design competition, the ten design teams selected to move forward have advanced at variant speeds, but The BIG U has perhaps developed furthest of all in the shortest time span. In 2015, immediately following the competition's close-out, the BIG team secured $35 million in HUD funding to develop a first compartment of the plan, dubbed the East Side Coastal Resiliency (ESCR) Project. Soon after, a second compartment, the Lower Manhattan Coastal Resiliency (LMCR) Project received funding to advance into a speculative design and feasibility study incorporating the long-term impacts of flood protection systems on existing infrastructural systems and social context of Lower Manhattan, but has not yet moved forward into physical plans. After securing these projects, ONE has also become a central player in the development of the East Harlem Resiliency Study and a similar initiative in Breezy Point, Queens – one of the coastal communities hardest hit by Hurricane Sandy.

From their inception, ESCR and LMCR have illustrated the challenges faced by resilience plans whose continued life depends on the long-term health and strength of public-private partnerships and their ability to manage and prioritize competing interests between agencies without an established framework for collaboration. Liaising between the Mayor's Office of Recovery and Resiliency (ORR), the Department of Parks and Recreation (DPR), the Department of Planning, the Department of Transportation (DOT), and private utilities such as ConEdison, ONE has become a specialist in highly collaborative design processes.

Among the primary lessons learned from these various projects, we have recognized the following principles as integral to the long-term feasibility of resilience projects beyond the century-long checkpoints of risk projections: (1) Planning and design should function as an integrator: collaborative design processes and community engagement are key; (2) Creating dual top-down and bottom-up approaches to implementation, rooted in both technocratic and grassroots planning processes; (3) Looking beyond feasibility to factors such as funding streams, resource chains, carbon sinks, and multiple-benefit services that projects can tie into beyond 2100. It is important to hold both scales in mind at the same time: short-term solutions allowing cities to build public and private support around quick wins and more immediate risk solutions, while also creating a framework for a project's adaptability and phased implementation in the long-long term.

Countering the current paradoxical trend of redeveloping New York City's vulnerable waterfronts

Drs. Gitte SCHREURS, KU Leuven Department of Architecture; Belgium
Prof. Dr. Kris SCHEERLINCK, KU Leuven Department of Architecture; Belgium
Dr. Erik VAN DAELE, KU Leuven Department of Architecture; Belgium
Prof. David BURNEY, Pratt Institute of Architecture and Urban Planning; New York, USA

1. Introduction

The growing impact of changing environmental and economic conditions on a global level, generates an urgent requirement for cities to respond in a resilient way. Therefore, this research aims to gain insights on the physical transformation of vulnerable industrial waterfronts that deal with productive decline and climate change. This paper will illustrate current redevelopment methods that are implemented in (post-)industrial coastal areas in the metropole city of New York (Fig.1) and conduct a critical analysis regarding this paradoxical redevelopment by mega-projects that are favoring exclusive access for rich communities or mere leisure activities. The paper will use the redevelopment of Williamsburg, Brooklyn as an exemplary case of an already redeveloped waterfront where industry is relentlessly replaced by mere residential and recreational facilities. To counter this method of urban planning, the paper will test a novel research strategy at the intermediate scale on the vulnerable waterfront of the Coney Island Creek, more south in Brooklyn, which can be considered as a best example of urgently needed transformation of remaining industrial coastal areas in the city.

This paper questions the profit-based motifs of current real estate developers. How can coastal areas that are in direct threat of storms, rising sea-level and pollution function resiliently in the future, when they are rapidly developed in order to generate the highest possible profit-range?

2. Global awareness of a changing environmental and economic climate.

2.1 Environmental changes

New York City is one of many cities worldwide that is suffering under the consequences of growing environmental issues. Climate change is causing the seas to rise and storms to intensify around New York; inundations of more than two meters are expected to occur every five years by 2030. Changes in climate are generally measured by three parameters: the sea-level, the mean yearly temperature and the mean yearly precipitation.

When we look at these parameters, the numbers don't lie: trends in temperature, precipitation and sea levels have increased overall throughout the century. In New York City, mean annual temperature has increased 2.5°C and mean annual precipitation has increased 19.5cm (a change of 1.4% per decade) from 1900 to 2011. Year-to-year precipitation variability was greater from 1956 to 2011 than from 1900-1955. Sea-level in New York has risen 33.5cm since 1900. (NYPCC, 2013) Temperature, precipitation and sea level are expected to rise even further by 2020 and 2050. The New York City Panel for Climate Change has calculated the estimated increase for each parameter with low-, middle- and high-estimates (for best- and worst-case scenarios) (Fig.2).

Baseline Climate and Mean Annual Changes

Air temperature Baseline (1971 - 2000) 54°F	Low-estimate (10th percentile)	Middle range (25th to 75th percentile)	High-estimate (90th percentile)
2020s	+ 1.5°F	+ 2.0°F to + 3.0°F	+ 3.0°F
2050s	+ 3.0°F	+ 4.0°F to + 5.5°F	+ 6.5°F
Precipitation Baseline (1971 - 2000) 50.1 inches	**Low-estimate (10th percentile)**	**Middle range (25th to 75th percentile)**	**High-estimate (90th percentile)**
2020s	-1 percent	0 to + 10 percent	+ 10 percent
2050s	1 percent	+ 5 to + 10 percent	+ 15 percent
Sea level rise Baseline (2000-2004) 0 inches	**Low-estimate (10th percentile)**	**Middle range (25th to 75th percentile)**	**High-estimate (90th percentile)**
2020s	2 inches	4 to 8 inches	11 inches
2050s	7 inches	11 to 24 inches	31 inches

Based on 35 GCMs (24 for sea level rise) and two Representative Concentration Pathways. Baseline data are from the National Oceanic and Atmospheric Administration (NOAA) National Climatic Data Center (NCDC) United States Historical Climatology Network (USHCN), Version 2 (Menne et al., 2009). Shown are the 10th percentile, 25th percentile, 75th percentile, and 90th percentile 30-year mean values from model-based outcomes.Temperature values are rounded to the nearest 0.5°F, percipitation values are rounded to the nearest 5 percent, and sea level rise values rounded to the nearest inch.

Figure 2: Baseline Climate and Mean Annual Changes by the NYC Panel of Climate Change
Source: NPCC Climate Risk Information Report, 2013

Besides sea-level, temperature and precipitation, there is a fourth important parameter to illustrate the impact of climate change on the urban conditions: the occurrence of extreme weather events. In 2012, super storm Sandy had a devastating impact on New York City and was an eye-opener that the city needs proper risk management and resilient urban planning to answer to future extreme weather events. Even though a storm like Sandy is no direct outcome of climate change, the impact of a storm on the city increases significantly due to the changing environmental parameters. The extent and magnitude of coastal flooding during super storm Sandy increased due to the risen sea level in the New York City area. Also, unusually warm upper ocean temperatures made the hurricane gain additional strength (NYPCC, 2013). Numbers show that there has been a general increase in the overall strength of hurricanes in the North Atlantic since the 1980's (USGCRP, 2013). It is during extreme events like these that the risks and flaws in the current urban planning system are exposed. It is crucial for the future of the city that new coastal developments take into account the devastating consequences of these more regularly occurring events.

Though not only hurricanes are a direct threat to the waterfront of New York City, but also the regular coastal flooding. Rising sea-level increases the impact of coastal flooding and flash floods during heavy rainfall or storms. Several flood maps show the projected impact of floods on the urban fabric.

The New York City Department of City Planning has developed the Flood Hazard Mapper, providing a comprehensive overview of coastal flood hazards that threaten the city today (NYCgov). The mapper also shows how the flood hazards are likely to increase in the future as a consequence of climate change and aims to function as a tool for the making of resilient design decisions by property owners, companies, architects and planners.

FEMA (Federal Emergency Management Agency) has also developed Flood maps, showing projected flood zones for the future of New York City, taking into account sea-level rise from both ocean warming and ice sheet melt. They also factor in local conditions such as vertical land movement and regional climate variations. The maps represent the potential flood extent of the 100-year (1% annual chance) and 500-year (0.2% annual chance) flood areas in the 2020's and 2050's, based on the high-estimate of sea-level rise. This means an estimated sea-level rise of 28 centimeters by 2020 and 78,7 centimeters by 2050, in comparison to the sea-level of 2013 (Fig.3).

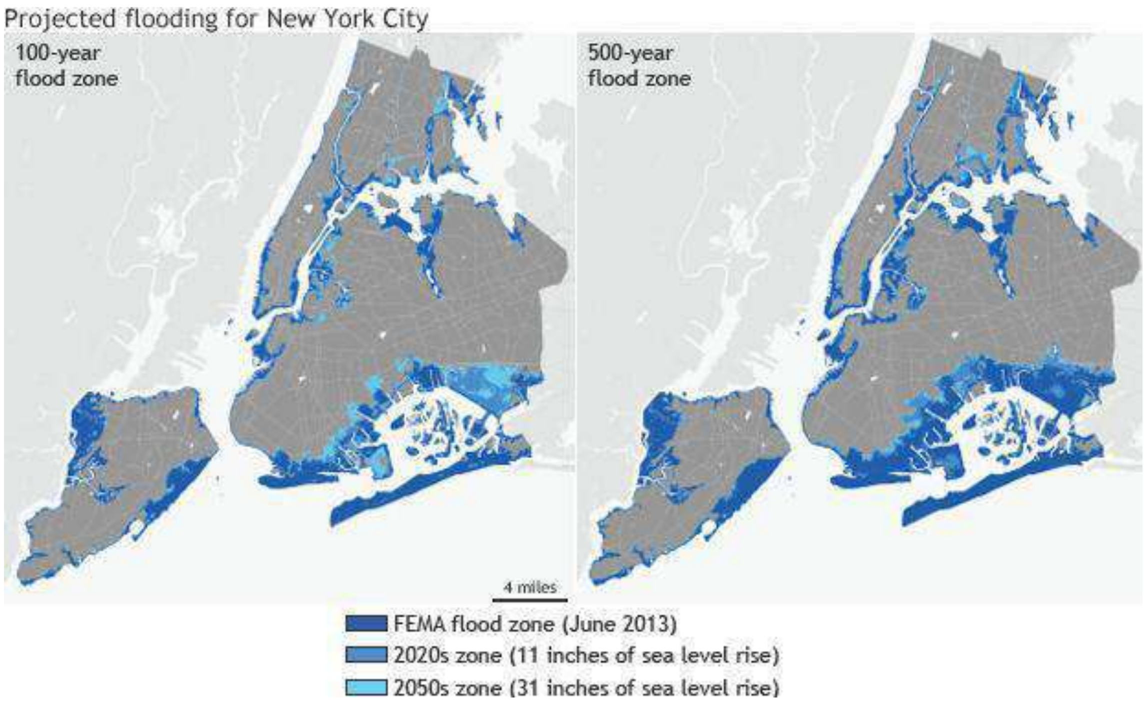

Figure 3: 100-year and 500-year inundation map of FEMA
Source: NPCC Climate Risk Information Report, 2013

After hurricane Katrina (2005) and super storm Sandy (2012), a general awareness for the dangers of climate change and its potential impact on the coastal urban fabric of New York has grown. Yet, we can see a clear paradox in today's city -and especially coastal-development. Despite the awareness for water threat: waterfront property values are rapidly rising, pushing all industrial activity out of the city. There has never been a higher demand for coastal residential development in New York City, while research on how to deal with climate change is still in full progress. The current mindset of city planners and local governments appears to be mainly set on problem-solving after a peak moment, instead of prevention.

2.2 Economic changes

New York City's 930 kilometers of coastline were once indispensable for the growth and prosperity of economy in the city. The city's waterfront has been subject to a vibrant history of industrial development. The first colonial settlements of the 17th century were mostly located at the waterfront. Because of the thriving agriculture that was rapidly developing at the water and the lack of paved roads, ships became the main transportation method between the islands that formed New York City. During the first industrial revolution at the end of the 18th century, industries replaced the agriculture at the waterfronts of New York because of this beneficial transportation by freight ships. At the start of the 19th century, the enormous amount of freight boats was accompanied by ferries to serve commuters between the different boroughs. Waterfronts seemed more important than ever for the economic wealth of the city.

However, when the New York Central Railroad was introduced in the 1850’s, a large part of freight transportation shifted to trains for they were faster than ships and had more possibilities of reaching other cities and states. After the completion of the Brooklyn and Verrazano Bridges, physically connecting the different islands of New York, trains and trucks became the most important sources of freight transportation. Industries adjusted to this shift and started facing the streets instead of the waterfront, entailing the decline of the waterfront’s importance. This inevitably resulted in graduate relocation of many industries to more inland sites. As a consequence of this relocation, New York City of today knows a large stretch of post-industrial waterfront landscapes with underused or even abandoned warehouses and docks.

Today, developers deal with the issue of how to reprogram or revive these locations. Different approaches are tested on the post-industrial coastal landscape. One of the new developments we can witness at coastal areas is the emergence of ‘modern industry’s’ that are partially reclaiming the old industrial sites, trying to sustain the economy in the city. Warehouses are converted into coworking spaces for young entrepreneurs or recreational facilities (parks, playgrounds, etc.) are implemented to provide waterfront access for the community. However well-intended, this change of initial industry to more modern facilities does not only have a positive social impact. Simultaneously with the exodus of larger industries from their prime waterfront locations, employment opportunities for low-educated workers disappear out of the city center. Affordable housing for low-income families and walk-to-work opportunities become non-existent because of the rapidly rising property and land value by gentrification at the coastline. The conversion to ‘modern industries’ inevitably contributes to an elite waterfront accessibility and rise in value of the neighboring properties.

What generates even a larger social and economic impact, is most of the post-industrial waterfronts today being rezoned or reprogrammed to fully non-industrial uses, eliminating all initial productive activities, favoring exclusive waterfront access for tourists and high-income residents.

3. The paradox of property value and resilient waterfront redevelopment

For the first time in the history of New York, the city shows a significant interest in the repurpose of urban coastal areas. Often, adaptation in New York City is implied by transformation of the productive or residential waterfront to natural flood zones with mere natural or recreational purposes (D’Hooghe, MIT CAU, 2014). These parks and piers are implemented by the city on many waterfronts in or within close proximity to Manhattan, to serve inhabitants and tourists by offering leisure activities and magnificent views over the city skyline. Ferries are recently initiated to connect the different boroughs and offer easy access from Manhattan to Brooklyn and Queens. These ferries, as rather minor interventions, generate a huge impact at the area of destination. Comparable to most cities globally, accessibility is key in New York. A direct ferry connection to the touristic and economically thriving Manhattan generates inevitable and rapid gentrification for the receiving end of the ferry line. Waterfront land is bought by large real estate project developers for hallucinatory prices. Existing constructions, dating from the industrial revolution in the 19th century, are ruthlessly demolished and replaced by high-rise, low-cost residential towers, overlooking the Manhattan skyline. To then be sold for millions of dollars to the wealthy few. One of the reference cases to illustrate this phenomenon is Williamsburg, in the north-west of Brooklyn.

3.1 Reference case: Williamsburg, Brooklyn, NY

Williamsburg is a neighborhood in Brooklyn, located east of Manhattan, with the East River as a separation between the two. Since the late 1990's, inland Williamsburg has already been undergoing a form of gentrification by the hipster and artist culture. However, its waterfront fully remained a thriving industrial area, with shipyards and heavy industries characterizing the Williamsburg coastline. The inland area was an easy target for gentrification as it has always been rather easily accessible by metro (L-line) and car (Williamsburg Bridge). Rents in Williamsburg significantly increase when the property is within close proximity of a metro entrance. However, the waterfront recently became more accessible as well for locals and tourists, by the newly initiated East River Ferry line, providing a direct connection to Manhattan and other point in Brooklyn.

During the industrial vitality of the 19th century, employment opportunities were created for many blue-collar workers. This resulted in the development of low-rent residential properties for immigrants and lower-income families, in close proximity to their workplace. However, during the industrial decline of the 20th century, Williamsburg dealt with large unemployment rates, increasing crime and residents relocating to different parts of the city. During the recent revitalization of the 21st century this changed drastically and rents are skyrocketing, pushing out all remaining low- and medium-income residents and families, welcoming an elite, white community. By demolishing the remaining industry that was still operative in the area, walk-to-work opportunities for lower-educated workmen become inexistent in the area.

Until 2005, the waterfront had a land-use of mere manufacturing and industry. Today however, a huge rezoning is initiated as interest for the Williamsburg waterfront has grown rapidly for its stunning views over the Manhattan skyline, improved accessibility and gentrification of the inland areas. Before the rezoning, the waterfront was characterized by active manufacturing, light industrial activity and smaller residential developments. After the rezoning of 2005, the land-use exists primarily out of residential new developments and the designation of old warehouses into expensive lofts. To guarantee a certain social mix in the area, the City Council of New York obliged real estate developers to provide one out of three new developments as affordable housing. However, by loopholes in the regulations, the developers forgo these incentives by creating lower rent apartments at less desired, more inland locations instead of implementing them in the new developments at the waterfront. This generates large-scale residential areas, merely affordable by the elite (Fig. 4).

Figure 4: The redevelopment of the Domino Sugar factory into high-priced apartments and parks
Source: Article in Archdaily: "Domino Sugar Factory Master Plan Development"

The redevelopment of the Williamsburg coastline happened over a very short time span, barely taking into account the environmental issues and economic opportunities that the area has. Inland Williamsburg is safeguarded from the flood zones according to FEMA. However, all of the properties at the Williamsburg waterfront are located within a flood evacuation zone and within the 100-year FEMA Flood inundation zone. During super storm Sandy, Williamsburg was spared from devastation because of low tide. Though power cut-offs, lowered accessibility for emergency services and obstructed escape routes after flooding can generate severe problems for residents living in high-rise towers within flood-zones.

Another major risk in these post-industrial areas during flooding is the pollution. Previous industrial activities have contaminated the soil of the post-industrial sites. The Williamsburg waterfront knows several polluted areas where asthma rates are significantly higher than in non-polluted areas (Fig.5). These areas are particularly risky during flooding, because the contamination in the soil will surface and be transported inland by the floodwater. The contaminated water can enter buildings and mix with sewage water.

Figure 5: Polluted sites in the Williamsburg/Newtown Creek area.
Source: Website greenpointers.com

The rapid redevelopment of the Williamsburg waterfront (and several other waterfronts) is in direct contradiction with the city's current studies on climate change and the aim for resilient development of New York. The speed of the real estate market and profit-based developments seems to outdo the importance of sustainable city-planning that is more than ever necessary for this metropole, surrounded by water.
This makes us question the city's intention for future development: do we want short-term, profit-based projects with rapid gentrification of very vulnerable coastal areas, or do we choose long-term resilient planning of the city's 930 kilometers of coastline?

4. Understanding actual needs and natural adaptation processes of the urban fabric

This research aims to counter this current tabula rasa approach of redeveloping a waterfront from scratch. It is impossible to tackle all post-industrial waterfront areas -with all their complexity- by only one general solution. Instead, this doctoral thesis seeks to provide answers, based on gaining critical insights regarding the daily operation of a specific waterfront and its unique characteristics such as territorial configuration, property structure, appropriation of collective areas, resilience to climate change and a changing economic situation. The hypothesis is that, by fully understanding the conditions of transformation and the everyday operation of a specific coastal area at the intermediate scale; a full understanding of its levels of resilience can be generated. This profound knowledge can then be reflected on similar coastal areas and function as design strategies for architects and urban planners, taking into account an area's full complexity, fragilities and opportunities. In this way, a resilient answer can be offered that enhances the current social and economic structure of the area, while dealing with the threats of climate change.

This research does not limit itself by analyzing the mere urban situation, neither only the architectural scale of the building itself. Instead, the focus lies at the intermediate scale; the scale of the streetscape, how the building relates to the streetscape and how the user can give meaning to them (Scheerlinck, 2010). The method of this research at the intermediate scale, is to analyze the area by the notion of six parameters, which are believed to cover the crucial aspects that are to be understood to enhance the changing urban conditions on economic and environmental levels.

The first parameter covers the *Activities* of the area, this means the analysis of daily, routine operations, as well as more occasional or time-related activities. Comparative analysis of the activities is conducted at several moments in time: during week and week-end days, before and after working hours, during mid-season and in holidays. The second parameter analyzes the *Morphology* of the area. This takes into account the type, style and land-use of the building, its amount of storeys, appearance of the façade and relation of the building to the streetscape. Parameter three shows how the water is related to the adjacent land: the analysis of the *Waterline*. Is the waterfront visibly of physically accessible from the land? How does this waterfront react during a flood or storm? What is the waterfront activity (if any) and does the shoreline exist out of a hard or soft edge? Next, the analysis of the *Infrastructure* and *Accessibility* is conducted. What kinds of infrastructure connects the area to the broader region and how does this impact the ongoing activities? What is the configuration of the streetscape and how are the individual buildings accessible and related to the sidewalk on pedestrian and vehicle level? Finally, an important aspect in order to fully understand an area, is the social structure. Therefore, the last parameter is the *Social participation.* What is the daily use of space by the direct users? How do they find it convenient and what are their annoyances?

4.1 Reference case: Coney Island Creek, Brooklyn, NY

Coney Island is an urban peninsula, located at the southernmost end of Brooklyn. Coney Island is famous for its amusement park and beach and generates a true exodus to escape the city on hot summer days (Koolhaas, 1978). However, as part of this intriguing urban peninsula where amusement, leisure and entertainment attract many tourists and investors; the Coney Island Creek is a subordinate area, lying in the shadow of this urban glamour. The area around the Creek struggles with a complex coexistence between industrial, recreational and residential waterfront conditions and constant threat of storms and urban floods (Fig.6).

Figure 6: The peninsula of Coney Island
Source: Aerial photo from Apple Maps, edited by Drs. Gitte Schreurs

All these vulnerabilities bring along political disinterest and make the local economy entirely dependent on private investments of small shop owners. The political abandonment and lack of individual capital of the small entrepreneurs leaves little space for alternative commercial and urban development processes to assure the resilience of this industrial waterfront.

The area of the Coney Island Creek is considered the best example of a vulnerable industrial waterfront, in urgent need of redevelopment to guarantee proper living standards and prevent severe decline. The aim is to implement and test the previously explained approach of parameter analysis on this area and therefore unveil the island's complex coexistence between industrial, recreational and residential waterfront conditions. The research wants to understand the vulnerabilities, but also the opportunities of the area, to later implement this knowledge during the development of resilient design strategies for this complex area.

In order to fully understand the area at the intermediate scale, the six parameters are analyzed at the scale of the building block. This method of research will be illustrated below by the example of one building block in the Coney Island Creek area, located between W15th and W16th street, north of Neptune Avenue. This method will later in the research be performed on all six types of building blocks that are to be found in the Coney Island Creek area in order to generate a consistent, comparative analysis of all parameters at the intermediate scale, representative for the entire area of the Creek.

- *Activities*: The building block is generally zoned as M1-2, light manufacturing. With the special overlay zoning CO, which allows for residential and industrial activities to take place in adjacent buildings. For each property, the official land-use, defined by ZoLa New York is mapped and compared to the actual land-use at the time of observation, in June 2018 (Fig. 7). However, in order to display the vibrant activities as correct as possible, all occurring activities are drawn on plan at different moments in time: on a weekday, a weekend day, during working hours and after working hours (Fig. 9). By fully understanding the daily operation and formal or informal activities within this building block, we can understand the actual need for novel spatial facilities and adaptations.

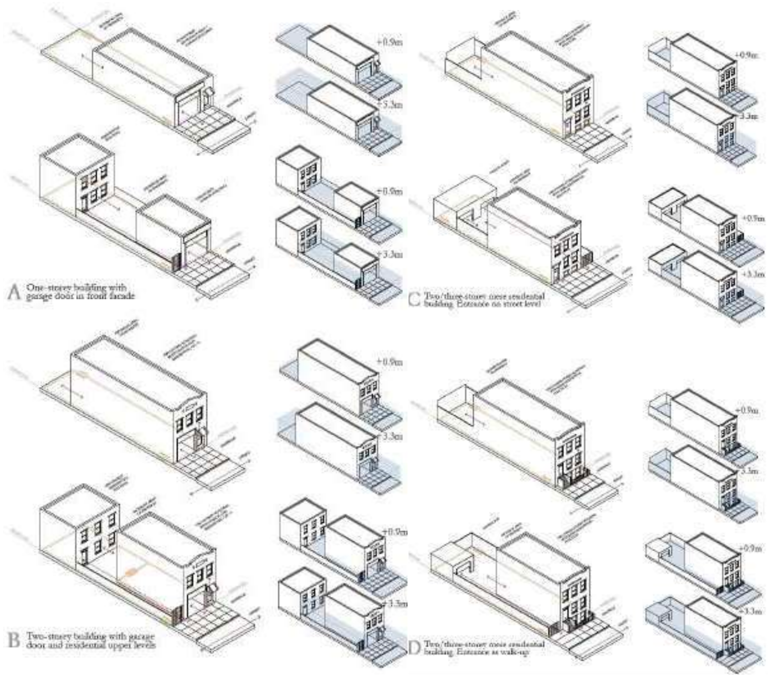

Figure 7 (left): Building block: Official land-use ZoLa NYC vs. actual land-use in June 2018
Source: Maps by Drs. Gitte Schreurs, based on information from ZoLa NYC and observations

Figure 8 (right): Typologies of buildings, located within this building block, by Drs. Gitte Schreurs

- *Morphology*: Analyzing the morphology, means analyzing the typology of the existing buildings, the relation between neighboring constructions and between the building and the streetscape. By analyzing this parameter, we can understand patterns of activities related to types of housing and how the typology of the building is used to benefit the activity. An example within this analyzed building block on Coney Island is typology type B: a two- or three-storey rowhouse, with a garage door on ground-level, providing the opportunity to open up the building and let the territory of the industrial working space extent onto the public sidewalk. Residential facilities can be found on the second (and third) floor of the building, preventing water damage to the house when floods occur (Fig.8). The façade in-between the garage door and the residence windows is used for commercial signages in benefit of the industrial activity on the ground floor. Knowledge on the informal use of indoor-outdoor space and ground floor - upper floor relationships of all building typologies can be used to design more sufficient buildings in similar spatial contexts in the future.

- *Waterline*: The waterline is crucial to investigate when we want to understand how to deal with land-water relationships in urban and architectural planning. In this building block analysis, we analyze two aspects of the waterline. For starters, when applicable, the physical relation between the water of the Creek and the land is drawn in map and section (sea-level vs. ground-floor level, hard or soft edge, natural or landscaped waterfront, etc.). Secondly, the impact of the 100-year and 500-year flood is illustrated per typology, specific for the area. In this example, for every typology is illustrated how a 0.9 meter flood level (1% annual chance) and a 3.3m flood level (0.2% annual chance) would impact the specific building type (Fig.8). This too is important to take into account when new constructions are designed.

- *Infrastructure*: The parameter of infrastructure is most important on the larger scale; the relation of the building block with the surrounding urban fabric. How well accessible is the area by motorized vehicles, public transportation, boats or by foot? How do these connections impact the activities in the area? The analyzed building block is very well-connected to the most important highway of New York City, the Belt Parkway, providing a beneficial accessibility for motorized vehicles. This characteristic triggers car-related entrepreneurs to settle in the area. The main types of land-use in this block -besides residential- are car repair services and parking facilities. Because of the less convenient public transportation, this area is less sought-after for residential purposes, allowing small-scale car-related businesses to remain located in a standard building block. However, if by renewed planning the public transportation would become more beneficial for this area, the land-value would most likely rise rapidly, pushing out all small-scale car-related activities, to replace the industrial activity with residential facilities, generating higher profits from rent.

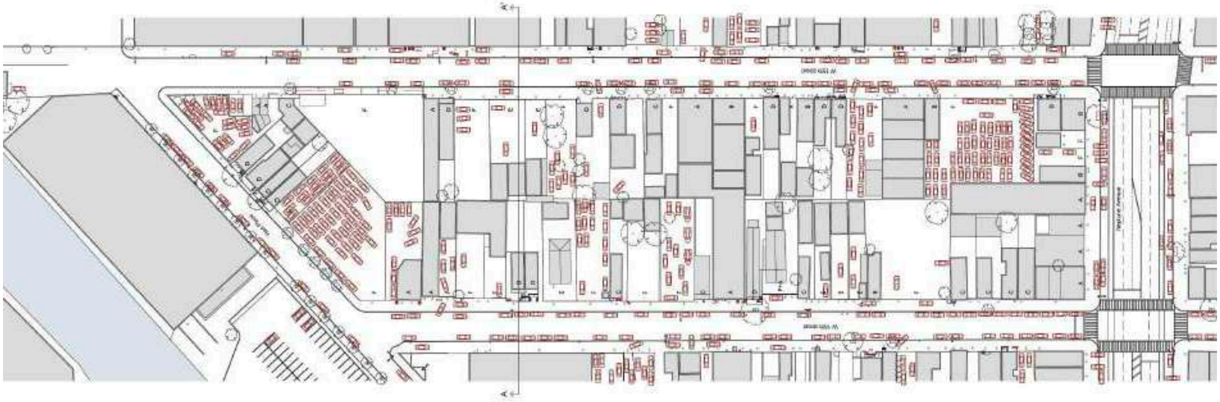

Figure 9: Building block: Activities in June 2018 on a weekday during working hours
Source: Map by Gitte Schreurs

- *Accessibility*: The analysis of the accessibility focuses on the scale of the building. A consistent mapping of all entrances (garage doors and regular doors) within the building block is conducted. The aim is to show the relation between the front door/garage door and the street. Does interior and exterior become one productive territory once the garage door is opened? What are the public/private relationships during informal appropriation of the sidewalk by industrial activities? Is there a direct relation between the sidewalk, the front entrance, the interior and the backyard? Understanding the accessibility of a building in combination with the activities taking place inside and outside can help us to grasp the need of public and private space of these companies or residences.

- *Social participation*: A final and very important parameter is the social participation. Many crucial aspects that contribute to fully understanding the operation of an area are not noticeable by mere spatial analysis. Therefore, for the building block analysis, a survey is taken from several workmen and inhabitants to generate crucial additional information about the daily operation of the area. The aim of the participation process is to understand the social structure of the companies, opinions about the working space or houses, the impact super storm sandy had on personal or property level and gather opinions about spatial and organizational elements they would personally like to change or add to the area.

These six parameters are the research method that resulted out of previously conducted research on this subject. However, they are still subject to change and can be altered as the PhD continues. For now, these six parameters are believed to cover the necessary knowledge to fully understand the aspects of an area at the intermediate scale to conduct the knowledge that is necessary to take into account when designing for this particular, or for similar, areas.

5. Conclusion

New York has 930 kilometers of coastline, of which each area has a very unique character, spatial layout, daily use and social structure. Today, a renewed interest for investing in these coastal areas, seems to generate redevelopments that happen at a fast speed because of profit-based real estate interest for waterfront residences. However, threats from the changing climate have never been more acute than they are today. Therefore, it seems rather paradoxical to develop these billion-dollar projects by a tabula rasa method while research on climate change is still in full progress and the economy is changing rapidly by new technologies. Planners seem to approach the city from a top-down method where demolition is the starting point and profit-based housing is the goal.

Instead, in order to generate a resilient metropole, that can withstand the challenges of the future and answer to today's needs, we must develop proper design and planning strategies. Not from the mere urban or architectural scale, not from the starting point of demolition, but starting from the actual need of the specific area. By analyzing the urban fabric at the intermediate scale, elements will surface that normally stay invisible for the general urban planner or the architect.

This research believes that resilient redevelopment is only possible by fully understanding the existing situation and the natural processes of spatial use and small-scale adaptation. Only then we can provide resilient future-proof planning and designing solutions for coastal areas that are as complex as these in New York City, and reflect this practice towards similar areas globally.

PLANNING FOR COOLER STREETS; FUNCTIONS AND ELEMENTS FOR COOLER COASTAL CITIES. THE CASE OF GOLD COAST, AUSTRALIA.

Key Words

Urban Heat Island (UHI), Urban Cooling Strategies, Cooler Cities, Nerang Street, Australia, Masterplan, Solar Reflectance Index (SRI).

Synopsis

The paper presents the case of Nerang Street in Gold Coast, Australia as an example of integrating Urban Cooling Strategies into the design phase of a masterplan project. With adequate urban planning and design strategies, the aim is to reduce the Urban Heat Island (UHI) in coastal cities of Australia.

Introduction

It has been nearly four years now since diplomats in Paris agreed that the world community should commit together in the fight against global climate change. In addition to this event, summer heatwaves have drastically increased worldwide, becoming more frequent and risky, especially in Australia. Yearly extreme temperatures, are now becoming the number one natural risk to human lives in Australia (Nairn & Fawcett, 2013). Over 1000 people aged 65 years-old and above died mainly in urbanised areas due to extreme heat waves (McMichael et al. 2002). This phenomenon is called Urban Heat Island (UHI) and is a threat to today's cities (Figure 1). The effects of global climate change are palpable and urging to act now.

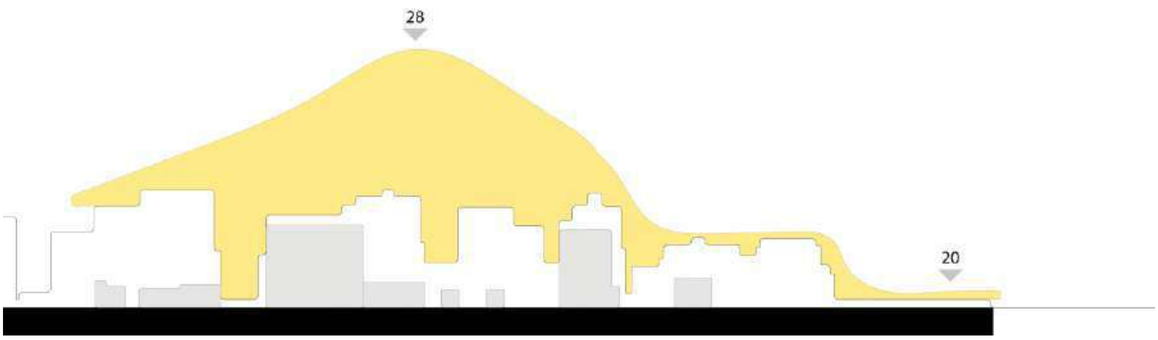

Figure 1 Generalised description of differential cooling rates between urban core and its surrounding. The difference in UHI is given by the difference in urban and rural temperatures.

Studies across the world's major cities demonstrate that, highly urbanised areas have a higher average temperature of 1°C to 12°C than less urbanised areas(EPA, 2014, Hopkins, G. 2014, Lehmann, S. 2014). The Australian Government has dedicated resources and new ways are being developed to reduce UHI in major Australian Cities (202020 Vision, Urban Forest Strategy – City of Melbourne, Pale pavement trial – City of Sydney Australia, Buildings that Breath – City of Brisbane and Urban Cooling Guide). Efforts are focused on moderating the intensity of UHI by changing the vegetation cover, previous surface areas and water availability (Coutts et al. 2009). Practical procedures developed for built environment professionals and cities to manage the effects of UHI in urban centres is a step towards recognizing the UHI phenomenon and mitigating its effects (CRC, 2007, 202020 Vision). However, across new projects, the changing character of streets and public spaces has seen extensive use of building materials causing low evapotranspiration, which triggers higher temperatures therefore creating UHI. Urban designers, Landscape architects and Architects have a major role to play to diminish the risk of UHI. New masterplans have to incorporate into the design process more elements that act as natural cooling mechanisms like vegetation cover, previous surface area and controlled stormwater management, (Stone and Rogers, 2001, Coutts et al. 2009). Every °C in temperature reduction through better design of cities matters. Study shows that 1°C temperature increase requires 1.5million kWh more cooling loads per year, thus generating 1000 tonnes in carbon dioxide emissions (Flinders University, 2015). Therefore reducing UHI will have social, economic and environmental effect on urban-dwellers of coastal cities in Australia.

The aim of this article is to demonstrate the importance of determining the UHI ratios in the early stages of masterplaning process. Nerang Street (700 metres segment from High Street to Marine Parade) in Gold Coast, Australia, is an example that has used desktop and site observation methods to determine UHI that informed the proposed interventions in the masterplan.

METHOD

Three methods were adopted to explore the UHI ratio in Nerang Street in order to generate the urban design tool.

The first method analyses the daily maximum temperature data for a 5-year period from three nearest bureau stations; Gold Coast seaway (2.2 km away from Nerang street), Heinze Dam (4.4 km) and Coolangatta (14.0 km). [1]The daily maximum temperatures from the three stations determines the monthly maximums for the 5-year span. The produced data is compared with the heat stress index table (Table 4), defines the amount of days where possible fatal consequences occur for the life of people aged 65 years-old (National Weather Service Heat Index, NOAA). Next, the monthly maximum from Gold Coast seaway station (being the nearest to Nerang street) is extracted from Heinze Dam station and then Coolangatta station. The mean of the difference between these meteorological stations determines the difference in temperature from Nerang St to its closest surrounding, thus providing the atmospheric UHI difference. In result, the comparison will determine whether Southport (where Nerang Street is located) is warmer or colder than its nearest surroundings. The study recognises that the method reflects the differences in areas rather than the specific street in consideration. For this reason, the second and third methods will provide a more insightful information on the UHI of Nerang Street.

The second method analysis sun-shading process on Nerang Street using *NearMap* and computer aided software (Appendix 1) during the hottest days in every year for the past 10 years. This study captures the areas with the longest sun exposure on the street. The length (d) of the exposed area is divided by the average walking speed (s) and this will determine the amount of time (t) it takes for a person to cross the area, thus, the amount of time a person is exposed to heat stress (t=d/s). Further, the paper observes and considers the amount of crossings regulated with traffic lights and the time required to cross the street.

[1] In absence of temperature data specifically related to Nerang Street, data from local meteorological stations produced by the Australian Bureau of Meteorology were used to demonstrate the difference in UHI between stations. The paper recognises that this data is not accurate to the microclimate existing in Nerang Street. Therefore two other methods where deployed to provide more insightful results.

Lastly, the paper analysis thermal emittance of surface materials of Nerang Street segment. By using the solar reflectance index (SRI) the paper determines the material contribution to UHI (EPA, 2014). Further, referring to 'heat stress index' table, the study determines the stress level a person perceives walking Nerang Street on a hot day. Lastly, urban cooling intervention matrix (CRC, 2007) examines the cooling strategies used by HASSELL's masterplan for Nerang Street.

RESULTS AND DISCUSSION

Comparing 5 year maximum daily temperatures between the nearest meteorological station to Nerang Street (Gold Coast Seaway, 2.4 km) and the closest surrounding station (Heinze Dam 4.4km and Coolangatta 14.0km) shows a contrast of yearly mean ranging from -0.7[2] to 1.0 degrees Celsius (Appendix 1). Respectively the yearly mean between Gold Coast Seaway station and Heinze Dam [3](Table 1) indicate that mainly the area of Southport (where Nerang Street is located) has experienced from 0.6 to 1 degree Celsius warmer temperatures. Results from comparing monthly maximum temperatures for a five-year period between Gold Coast Seaway station and Coolangatta provide a mean that support the fact that Southport experiences warmer temperatures (Table 2).

Table 2 5 Year Monthly Maximum Temperature Difference between Gold Coast Seaway Station and Coolangatta Station (Years 2013-2018)

Data demonstrates that Nerang Street in Southport, experiences yearly higher temperatures than the compared stations. Suggesting that people living and walking outdoors are prone to higher heat stress than the comparing areas.

The spatial variability of UHI in a specific area is controlled by shading cover and the surface characteristics, which determine the evapotranspiration ability of Nerang Street. The result from mapping the shading cover of Nerang Street for a 7 hour Sunrise-Sunset process (Appendix 2) of the hottest day from 2013 to Aug 2018 revel the areas exposed to heat stress in Nerang Street segment under investigation (Figure 2). Three areas present concern about increased UHI. The length of sun-

[2] Negative temperature means that during that year it was hotter in Southport where Nerang street is located than the comparing weather station.
[3] Heinze Dam closed in 2010. Data compared between Gold Coast Seaway and Heinze Dam are from 2005-2010.

exposed area 1 and 2 in figure 2 is about 120 m. Area 3 has a length of 110m of exposed surface (Figure 3). The average crossing time of Nerang Street segment under study for a 65 years old individual walking with a speed of 0.9 m/s (Webber, 2016) is around 12 minutes[4]. During this time, the individual is exposed to the effects of sun for more than 5 minutes. Given that human body temperature takes more to cool down and faster to heat up (Webber, 2016), revels that crossing the segment of Nerang Street can have serious health consequences for people aged over 65 on a hot day during 11 am to 4 pm.

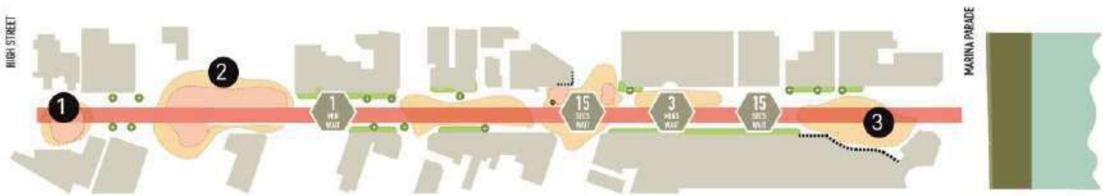

Figure 2: Heat exposure map of Nerang Street Segment under investigation

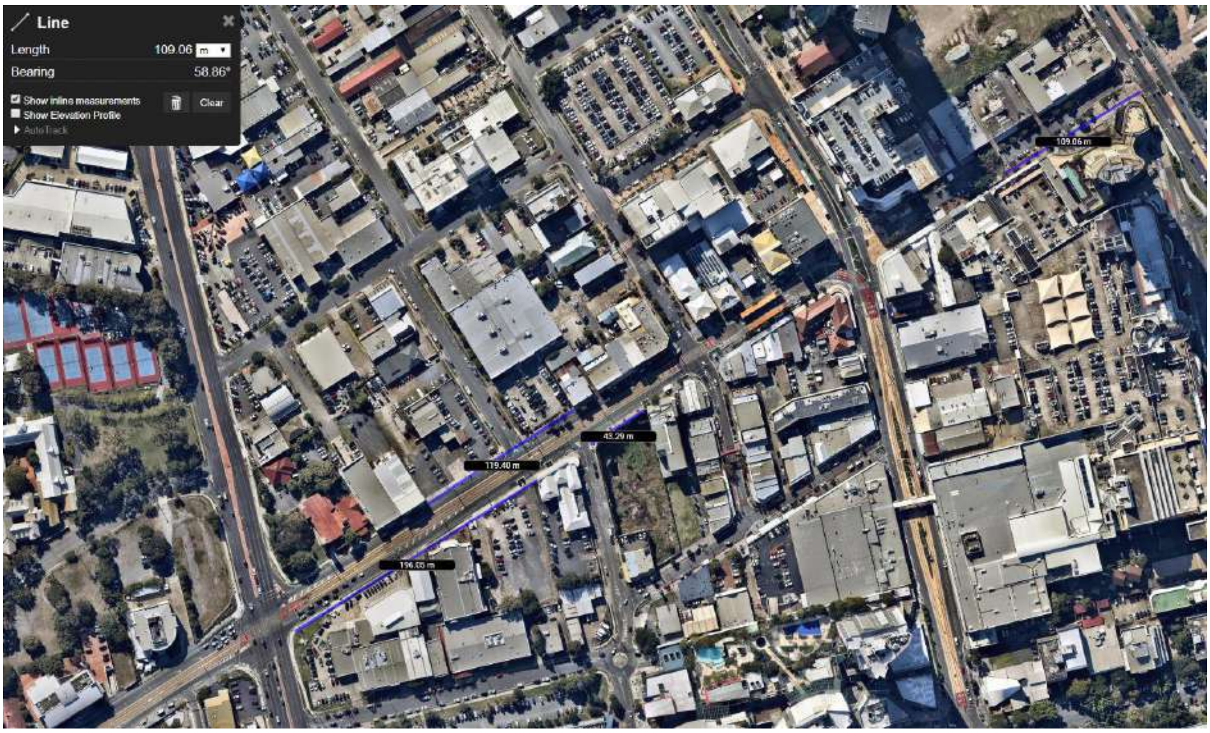

Figure 3: Length most sun-exposed Areas

Generally the surface material of area 1,2 and 3 (figure 2) is made out of coloured concrete (light rail tracks), 40mm asphalt black (carriageway), green verges and concrete at sidewalks (Figure 4).

[4] Referring to Webber (2016) the older the individual the slower is his speed. This study considers the speed of 0.9 m/s as appropriate for measuring the exposure of an individual to UHI while crossing the street from High Street to Marine Parade or vice-versa.

Considering the differences in albedo and SRI of materials, Babic S. (Babic et al., 2012) have demonstrated the surface of the street is in average 16.4 °C for asphalt and 11.0 °C for concrete hotter than air temperature. Indicating that the surface material contributes to a hotter air temperature in sunlight-exposed area.

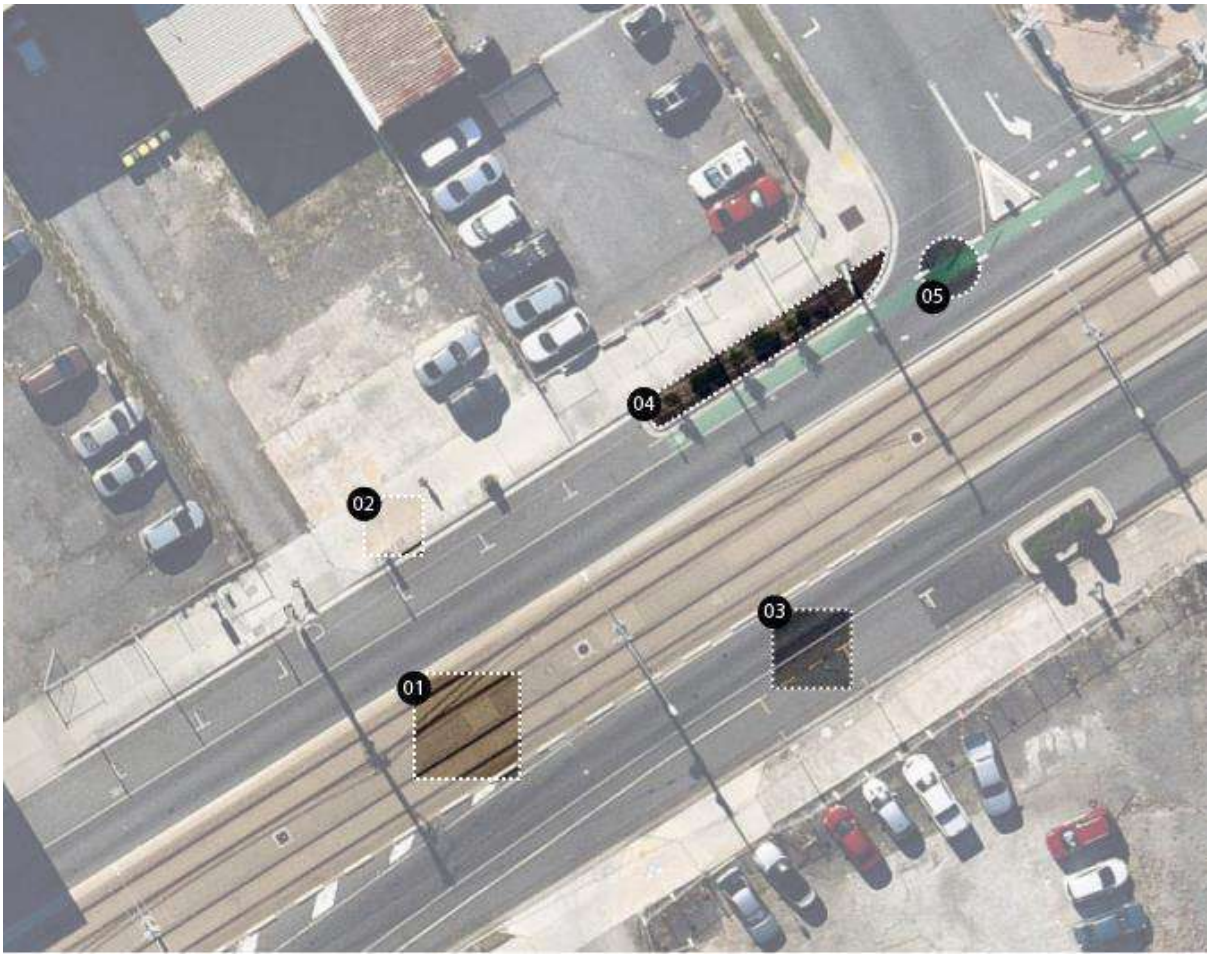

Figure 4: Material Inventory of Nerang Street Section 2 as per Figure 3

Adding 1 °C[5] to the highest recorded temperature experienced in Nerang Street (December 2014, Table 3) results in an overall temperature of 38 °C. This temperature in a 50% humidity is considered dangerous for human life as per heat index table developed by the Australian Bureau of Meteorology (Table 4) and that immediate measures should be taken to prevent heatstroke.

[5] Is the minimum increase in heat that would have occurred in Nerang Street on the hottest day recorded given the surface characteristics of the street.

Table 4:Heat Index Table: Australian Bureau of Meteorology 2009

As the natural landscape is replaced with impervious surfaces, runoff increases as water is rapidly removed through the stormwater network and infiltration is restricted – significantly reducing evaporation, which drives higher UHI (Hopkins, 2014). The results of the third analysis (Table 5) is a very dry urban landscape which means that more energy is partitioned into either heating the atmosphere or into heat storage driving higher night time UHI. Table 5 provides an understanding of the current situation of Nerang Street and in the same time the solution to improving the UHI conditions.

RE-IMAGINING NERANG STREET – CASE STUDY

Gold Coast is known for interactive streets with outdoor activities, public life and thermally comfortable environment. Gold Coast City Council and HASSELL Studio Brisbane have undertaken a transformative master plan for Nerang Street, fostering cooler streets, more welcoming and attractive to the people and investors. To achieve this, the master planning process has undergone a series of urban analysis on factors influencing UHI rates in Nerang Street, and adopted a Street Toolkit (Figure 4) as a response (Gold Coast City Council & HASSELL 2018).

The main factors governing the UHI generation and the amount of energy available for heat storage during day and night relate to the amount of shade and surface characteristics of the street. The urban cooling guideline (2017) provides with a set of strategies to help mitigate the UHI. These measures include water sensitive urban design, increased vegetation, high albedo and thermal emittance surfaces. HASSELL studio adopted the strategies and developed a toolkit (Figure 4) to approach the new masterplan of Nerang Street. In producing the masterplan (Figure 5) it is acknowledged that evapotranspiration rates and surface temperatures are not simply aligned with vegetation cover but rather with water availability (Deilami et al. 2016). Therefore, the masterplan considers integrating water feature along with new shading structures, permeable paving and increased vegetation cover to mitigate UHI.

In response to heat spots in segment 1,2 and 3 from figure 2 (Heat exposure map of Nerang Street Segment under investigation) the new masterplan changes the street design and through water sensitive urban design it introduces water feature that capture and reuse stormwater. Unvegetated areas are transformed into green oasis using local plants and vegetation, providing more shade and promoting safer streets for locals and visitors.

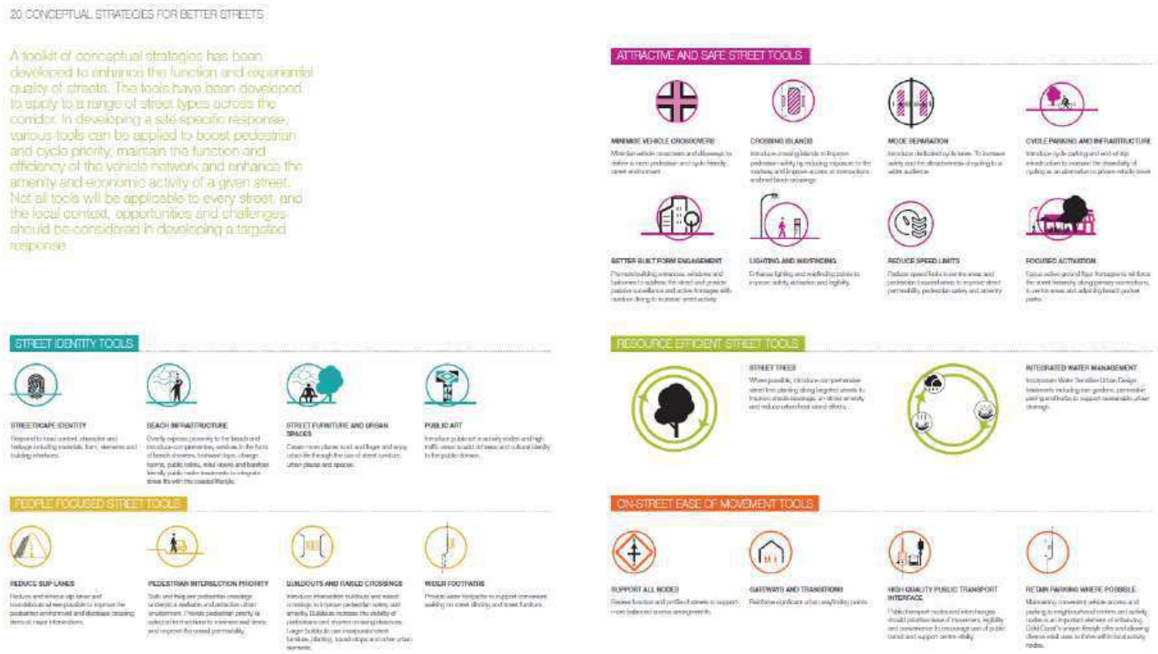

Figure 5: Better Streets Toolkit HASSELL

Figure 6: Nerang Street Concept Masterplan HASSELL

CONCLUSION

UHI is predominantly a phenomenon caused by urbanisation and characteristics of urban surface. Mitigating its risks requires mapping UHI and analysing surface characteristics at the early stages of masterplan. Desktop analysis of weather stations and shadings along with site observations are effective methods for urban planners and designers to foster a cooler city.

Temperature analysis revealed that Nerang Street experiences warmer temperatures than other compering areas. This suggests that there is potential for developing heat islands in parts of the street. Based on the produced data, on the hottest day of the 5-years in analysis, a 65-years old human walking Nerang Street could have experienced possible heatstroke with high life-threatening risk.

The paper recognises that the differences between meteorological stations are not an accurate estimation of UHI in Nerang Street in Southport. The analysed data reveals that in general the area is warmer then the two nearest weather stations. There are many factors influencing the changes in temperature between compared stations. Could be simple climacteric changes between the stations or may be the rapid urbanisation of Southport that drives relatively higher temperatures. Determining the factors influencing the differences in temperature between Gold Coast Seaway, Heinze Dam and Coolangatta stations requires another research.

Mapping and observations done in Nerang Street revealed 3 areas that are exposed to higher temperatures. The new masterplan for Nernag Street developed by HASSELL adopts cooling strategies and toolkits that mitigate UHI, by controlling heat retention of the street using water features, encouraging evaporation and transpiration, keeping previous surfaces cool, and increasing the vegetation capacity in the area. These factors are essential to minimise heat stress from extreme temperatures and manage the Urban Heat Island effect in urbanised areas.

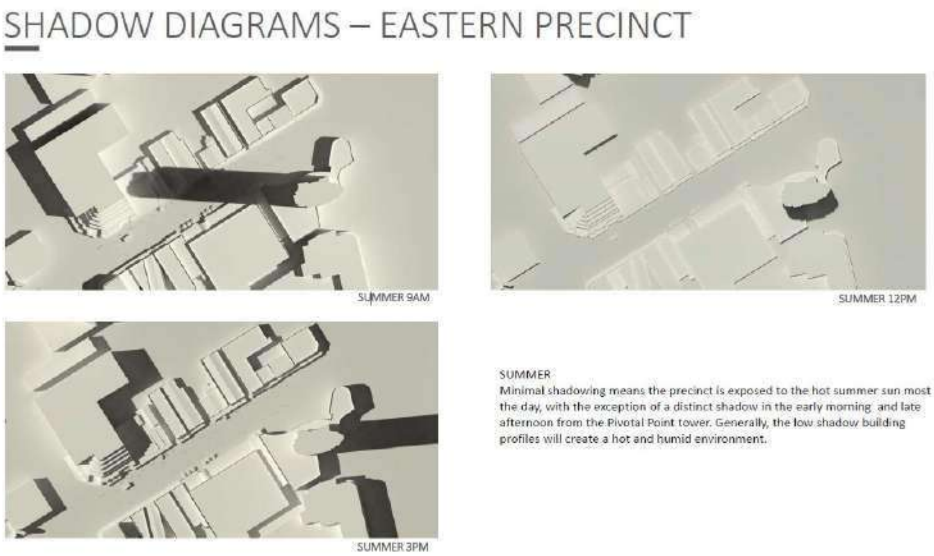
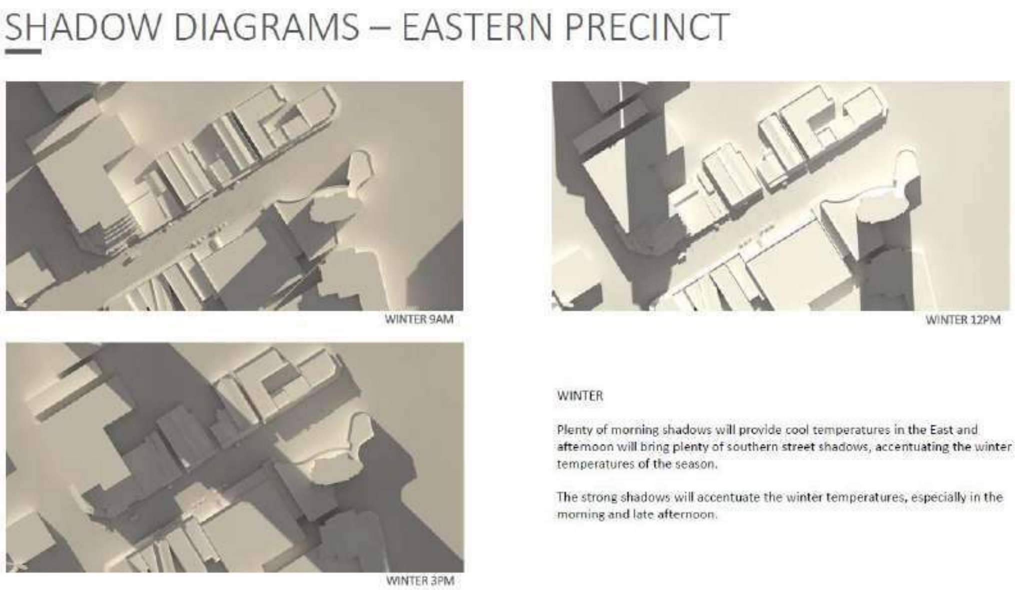
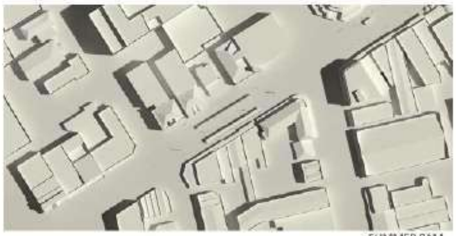
APPENDIX

APPENDIX – 1 – Computer generated shadows of Nerang Street during the warmest day of the year



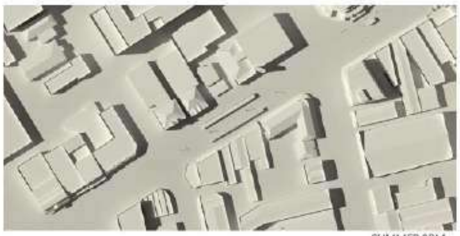


SHADOW DIAGRAMS – CENTRAL PRECINCT



SUMMER 9AM

SUMMER 12PM

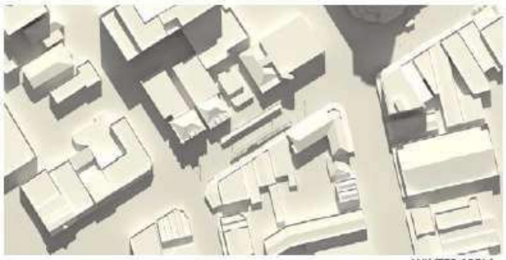


SUMMER 3PM

SUMMER
The central precinct is highly exposed to the summer sun, especially in the middle of the day with the afternoons providing some reprieve. Minimal shadowing during the day will create a hot and humid environment.

SHADOW DIAGRAMS – CENTRAL PRECINCT

WINTER 9AM



WINTER 12PM

WINTER 3PM

WINTER
In the morning hours existing structures cast shadows in a north-west pattern, with higher buildings covering a large distance on the ground. The eastern side of the streetscape remains uncovered in the early afternoon, with most shadows returning in the afternoon, providing a cooler climate.

Climate change adaptation in Hong Kong from urban planning perspective: flood zoning as control mechanism

Wong, Chui Ying Tracy, CAMBRIDGE, UK

ABSTRACT:

With rising sea level and higher intensity of typhoons under climate change, severe storm surge is anticipated and will induce more frequent and extensive coastal flooding in Hong Kong. Notwithstanding, official flooding blackspots were not locations of actual occurrence of major floods because the impact of storm surge was considered difficult to be addressed through land drainage system, resulting in a major loophole of flood adaptation in Hong Kong.

Conventional way of flood adaptation through engineering measures with past design standard could not catch up with the latest flood occurrence and magnitude. Upgrading of infrastructure would be costly, disruptive to local community and not be flexible and timely enough to respond to the growing flooding risk. Site formation level made by the reclamation geotechnical engineering works decades ago was also irreversible, necessitating the need for alternative management measures on flood risks. Flood adaptation from urban planning perspective is therefore pursued to complement and compensate for the design failure of engineering and structural measures.

As land use planning is governed by zoning control, flood zoning is proposed to be the research focus. The analysis would review the literature on flooding risks to Hong Kong and the influence of urban planning on flood adaptation policies. To enable in-depth analysis, a flood-prone community of Heng Fa Chuen and Chai Wan located at the south-eastern coast of the Victoria Harbour was selected for pilot testing of flood zoning. The flood risk exposure and vulnerability of this community were analysed. Through site visit, interviews and desk research, factors affecting effectiveness of flood zoning were discussed, leading to formulation of the flood zoning proposal. Flood zoning aimed to guide and regulate urban development by integrating flood risks with land use vulnerability classification and flood zone compatibility. Certain requirements on planning and building codes, urban design, monetary measures as well as public education through administrative, regulatory and statutory mechanisms were proposed. It was demonstrated that flood zoning could be an alternative and implementable tool for flood adaptation. The research outcome is evident-based and could be scalable to other parts of Hong Kong.

Track 3

CLIMATE-PROOF CITIES:
Planning for Weather, Water, Food and Energy

The contribution of urban underground space to climate-proof and resilient cities

Han ADMIRAAL, Owner and Managing Director, Enprodes Management Consultancy BV, Rotterdam, the Netherlands

Antonia CORNARO, Business Development Manager, Amberg Engineering AG, Zürich, Switzerland

Co-chairs of ITACUS, International Tunnelling and Underground Space Association, Chatelaine-Geneva, Switzerland

Synopsis
Climate proofing our cities is a double-edged sword in that it requires both climate mitigation and climate adaptation to be central to urban policy and planning. With the Paris climate agreement determining national agendas, cities are confronted with the need to prioritise decoupling from fossil sourced energy and replacing it with renewable forms. At the same time the climate is changing and requires cities to adapt to more frequent and intense rain fall events but also to counteract the effects of the urban heat island effect. We are learning that the way we have planned and designed our cities in the past lacked the focus on urban resilience and that we need to catch up fast. At the same time urban populations are evermore increasing and the need for a more inclusive planning becomes more evident each day. It is within this context that urban density, often translated into high rise developments as the final solution, needs to be reviewed. Reaching for the sky is not going to provide the solutions for all the challenges facing the urban environment.

In our paper we discuss how the answer could partly lie below the surface. Integrating underground space into the urban fabric is in our opinion a necessity as part of the climate proofing of our cities. This holds true firstly because underground space is part of the urban metabolism and needs to be appreciated as such. Urban drainage is often inadequate because the natural infiltration of rain water has been severely disrupted through over paving our streets, gardens and parks. The hardened urban surface is making rain water runoff into sewer systems that are becoming overloaded and unable to cope with climate change effects.

Secondly, urban underground space delivers ecosystem services to the city and offers invaluable resources in the form and shape of space, water, energy, and minerals. Safeguarding these services and at the same time utilising the resources, requires a balancing act by policy makers, decision makers and urban planners. Secondly, the premise that we can free up surface space by making more use of underground space is in our opinion too limited. Too often we see surface uses being placed below the surface, resulting in the same mono-functional use of space that is cluttering our cities and is one of the main causes behind the lack of urban space. The balancing act we mentioned also provides the opportunity to go for a more integrated approach that calls for a multi-functional space use. Why build a long tunnel that is only used to carry off rain water when there is rain fall? Isn't it possible, with a little more thought, to use the precious space that is created in a different way? In our paper we will argue that when it comes to seeing urban underground space as part of the urban metabolism, we need to develop an underground urbanism that ensures that the peculiarities but also the inherent advantages of underground space are fully appreciated. If we are able to do this, then creating urban density need not be limited to reaching for the sky, but can include exploring and exploiting the surface below the city. In that way future cities can become resilient and climate proof within the area constraints that exist and without giving way to uncontrolled sprawl.

1. Climate proofing and urban resilience

Climate proofing cities and making them resilient is very much a topic that urban planners need to cope with in the 21st Century. To understand how this relates to the topic of our discussion, namely the use of underground space, we need to have a common understanding what we mean with climate proofing and urban resilience.

Figure 1: The emergency management cycle. Source: Cornell University

One way of doing this is to take the emergency management cycle (see Figure 1) and see where climate proofing fits in. When looking at climate proofing in the context of the Paris agreement, we can distinguish two approaches: climate mitigation and climate adaptation. Climate mitigation is about taking those actions that will limit the overall effect of climate change, that is: what actions do we need to take to limiting the overall impact of climate change. This is often linked to reducing CO_2 emissions, decarbonising our cities and limiting the average global temperature rise to 1°C or 2°C. Most scientific research now confirms that climate change is happening and that there is no way we can reverse the process. What we can do is to limit the impact or the time within which the impact will occur. Given this fact, climate adaptation is concerned with how humankind and indeed our cities can adapt to what is to come. The coming decennia will see more rain, more wind, higher temperatures. We will see rain where there is now drought, and heat where it is now cold. The melting polar caps are a good example of this and the resulting sea level rise is threatening and will impact coastal plains and river deltas. A large part of the world's population live in or near coastal plains (see Figure 2). The World Bank projects that by 2025 at least 65% of the urban population on each continent will live in coastal zones prone to flooding and storms. (Rockefeller Foundation, 2013).

Climate mitigation is very much about prevention and mitigation. What is it we can do to reduce the risks and limit the impact? Climate adaptation goes a step further in that it asks what can be done now to prepare for imminent disasters that could strike urban areas.

Urban resilience in this context looks at the whole picture in terms of stresses and shocks that threaten our cities, whether they are natural or human in origin. Where climate mitigation and climate adaptation is linked to how human activity is causing climate change and with that impacting cities, urban resilience is concerned with the combined effect of stresses and shocks. As such, urban resilience will also look at how to respond and recover through disaster risk management.

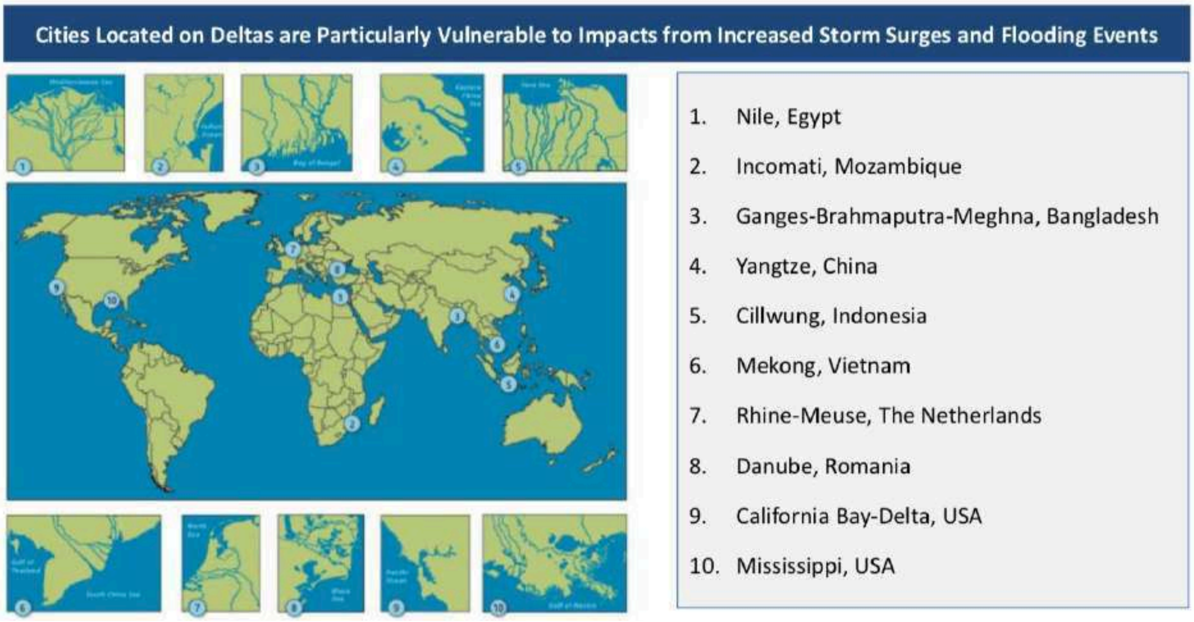

Figure 2: Cities located in Deltas. Source: Rockefeller Foundation.

The relationship between these aspects can be derived from the approach taken in the Netherlands in terms of coastal protection. It is a three-layered approach that considers both ‘hard’ or physical measures and emergency response. It is crucial that urban and territorial planning is seen as an integral part of the approach linking the need for physical measures with disaster risk management (Government of the Netherlands, 2009).

Figure 3: Multi-layer safety; prevention, sustainable spatial planning and disaster management . Source: Government of the Netherlands

The development of cities and especially rapid growing mega-cities has questioned how to maintain the core quality of cities. Cities as places to be, to live, to interact. Cities should be places we want to be in and enjoy, rather than functional places dominated by brutalist architecture where we have to be to survive. For urban planners this constantly requires questioning what it is that determines the urban being, the urban metabolism.

As Hajer and Dassen (2014) consider when writing about Smart Cities: “We have to reconnect the biophysical and social domains in new ways. Our first task is to create a broader awareness of what is required to make a city function. The urban metabolism is hidden. If we could unveil the urban metabolism, it would become clear what contemporary urban life consists of, and we would get an idea of what disconnect requires”. The disconnect they refer to is the question of weaning the city from fossil based and carbon emitting fuels. Their core consideration is however that to achieve this and to create a Smart City, it is vital to reconnect the biophysical and social domains in new ways.

It is our profound belief that this reconnect requires urban planners to consider the urban subsurface (Admiraal & Cornaro, 2018). With the subsurface we literally mean that what is below the surface. It is the unknown and unseen, yet in many ways it is also the foundation of the city and the supporter of life in the city. When looking at climate proofing our cities, at urban resilience or even in the bigger context of the urban being or urban metabolism, we feel that to make any sense of it all, what lies below our feet needs to be considered.

Firstly, we need to understand that the subsurface consists of more than just geology. Certainly, in some cities the support on which they are built consists of hard rock. In many other cities and especially those near the coast, this can vary greatly. This variation is not just in terms of supporting layers, it is a rich environment consisting of water flows and biodiversity in its own right. What we feel we need to consider is that as we discover the sky is not the limit, as we start to look at what opportunities lie below the surface of our cities, we cannot discount the unique properties of the subsurface.

2. Subterranean complexity

The complexity of the subsurface is best illustrated by the vast number of phrases used to denote it: subsurface, soil, below-ground, underground space, subterranean, geology. As discussed, the variety in geology also makes it complex. As the new Spatial Planning Vision for the Subsurface (Government of the Netherlands, 2018) points out, the world below our feet is an ecosystem that delivers services. As such, that ecosystem is vulnerable to interventions. It applies to the ecosystem services, but also to the quality of the soil and the groundwater. As such, we need to strike the right balance between making use of the subsurface, creating underground spaces that enhance the city, and preserving the quality of the same subsurface and the services it delivers. It is the balance between exploiting and preserving.

This should not come as a surprise to urban planners. The whole purpose of planning is to decide on how the use the available space and resources for the greater good of the city and its citizens. The same balance needs to be struck between public space and private space, between open areas and build-up areas. In terms of the subsurface there is however a major difference: the use of space below the surface is in most cases non-reversible and with that non-renewable. It means that physical underground space, once colonised by the urban need for space at the surface, in only a few cases will be returned to its original state.

A good example of this are former mines. In the case of the Netherlands the last coal mines were closed in the 1960s. They left an enormous legacy in terms of the largest industrial complex in the country, invisible below the surface, trapped in underground space for posterity. From a climate proofing point of view, they are interesting in that the Minewater project is now re-using the former shafts. In their own words: “A fully-fledged thermal ‘smart grid’ for delivery of heating and cooling water with a sustainable hybrid energy infrastructure has now been developed. This includes an independent pipe network to deliver both heating and cooling water to the connected clients.” (Minewater, 2018).

At the same time, the former mines are threatening the urban fabric and are a concern in terms of urban resilience in that they are stressing the surface as the water in the mines rises. Although the debate on the effect is still going on, it demonstrates how human intervention below the surface is still impacting us today, as is the way human induced earthquakes are causing social concerns in the North of the Netherlands. These are caused by the vast gas extraction that has taken place over the past 50 years.

These examples illustrate that activities below the surface can impact the surface and therefore need to be considered when bearing in mind urban resilience. There is also an interesting relationship between surface and subsurface in that development of one, often influences the other. Green parks are vital for our cities in that they help with clean air, produce shade and reduce the urban heat island effect. They provide citizens with space to recreate, to sport or to relax. They also provide capture areas for rainfall and natural infiltration into the soil and below. As we build up our cities, less and less space is available for natural infiltration, which in the long term can dry out the soil and alter its composition and thereby the natural processes that lie at the core of the ecosystem services it delivers. Conversely, once we start using the subsurface to create underground spaces, these influence what can still be done on the surface as well. Once an underground mass rapid transit system has been constructed, the ability to create further spaces above or below ground is impacted.

Having established that the subsurface should be part of urban planning practice, if only to fully comprehend the stress and shocks that could affect the city, we will take a closer look at how underground spaces can contribute to climate proofing and urban resilience.

3. Opportunities for underground spaces

To illustrate how underground spaces can contribute to urban resilience and climate adaptation, we will discuss two examples. The first is the Stormwater and Management Tunnel in Kuala Lumpur, Malaysia (see Figure 4). To all intent and purposes this structure was built with only one thing in mind, to rid the city of excess water during heavy rain fall to prevent flooding. It wasn't until someone smart mentioned the fact that for most of the time the tunnel would be empty and unused, as it doesn't rain continuously, that the idea to create a double-deck road tunnel inside the structure came about. The idea became a reality and the toll road now passing through has helped in recovering the cost for the total project in seven years (Admiraal and Cornaro, 2018). It also helped the city deal with notorious congestion. From our point of view this is an excellent example of how use of underground space can help a city with adapting to climate change and make it more resilient. It also is an example of a solution that is multi-use.

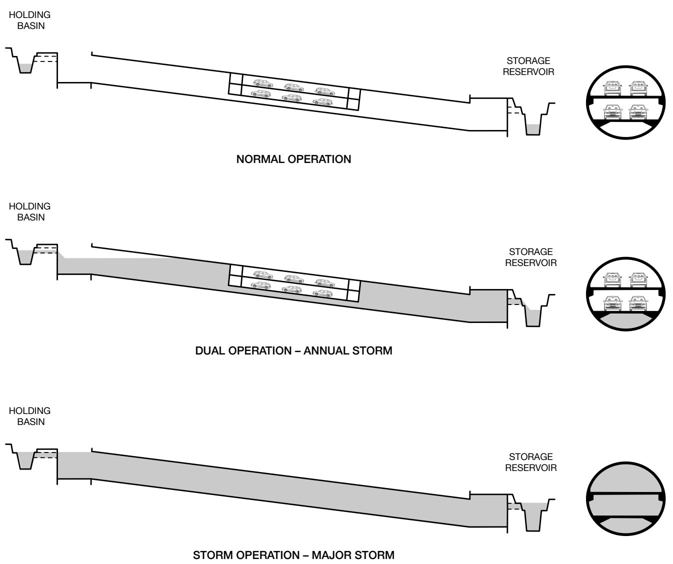

Figure 4: The SMART tunnel operating principle.

This aspect of multi-use is an important one. For decades we have been using up space at an alarming rate for both infrastructures and buildings that only perform one use and even then only part of the time. Think of highways running through cities, think of large office parks that empty at night, or shopping malls that lie at the edge of cities and attract large crowds away from the city core. As land becomes even more scarce as we have to rethink how we use it and even need to consider going below the surface, we need to get better at how we use the available space.

The example of SMART is an interesting case. It is also an example where the multiple uses cannot take place simultaneously. When the water comes, the cars need to be cleared of the road tunnel. So even though it is multi-useable, it can only facilitate one of the uses at a time. A step further is the underground car park in Rotterdam that combines space for parking cars with space for water retention basins. If during heavy rain fall the city sewers and canals cannot cope anymore, the water can be offloaded to the underground water retention basins for temporary storage. Once the rain has passed and water levels settle again, the basins are pumped out using the existing drainage system. This structure houses two uses that can both function at the same time. By combining them both into one project the advantage of lower cost per project and the availability of two combined budgets doubling the funding was used to make the project feasible (Ibid.).

The third example is underground mass rapid transport systems. They are of interest for two reasons. The first is that they are underground. As such they are a lot less susceptible to earthquakes than structures at the surface. This has been proven over time with earthquakes in both Japan and Chile. This advantage means that these networks can play an important role in disaster recovery. They provide an infrastructure that after the event is still available and not blocked by the damage that occurs at the surface. The second reason that they are of interest is that we can expand there under normal conditions by asking ourselves why they should only transport people. The primary use of these systems is rapid transport of people. As cities struggle more and more with inner city logistics, that is how to supply the city centre, couldn't we have the existing systems or the ones yet to be built take on the role of logistical support system as well?. In doing so we turn tunnels constructed for a single use into useful underground spaces that really serve the city by providing multiple services. The tunnel becomes a space that can be used for a variety of uses, including carrying cables and pipes. This is in much the same way as human-made caverns are being developed in Singapore, Hong Kong and Switzerland (see Figure 5). They are first and foremost providers of space. What is placed inside these spaces can vary over time from storage to industrial facilities to recreational facilities. The underground civil defence shelter in Helsinki that now serves as a swimming pool is a good example of the latter.

As Brown (2014) writes: "Today's transportation, waste disposal, water, sewage, and energy distribution systems are necessarily inter-dependent. Power plants require water cooling, water treatment and public transit require electricity, energy generation requires the transport of coal, and so on. And all of these systems rely on information technology (IT). Nevertheless, we continue to disaggregate them physically and jurisdictionally into distinct sectors, and we mentally separate utilities and the natural systems from which nearly all infrastructural services are derived."

We feel that any use of the subsurface should also be seen in the light of unifying the sectors that serve the city. As we do so we may find that we are providing services in a way that don't eat up the remaining space. By looking at underground space in a more appreciative way, but also seeing it as an opportunity for creating multi-use, one structure facilities, we contribute to the needs of the city without impacting land use in the traditional way. In our opinion underground space can play a role in delivering zero-energy projects with zero-land-use as the main advantage.

Figure 5: Human made cavern in Switzerland designed for industrial production. Source: Amberg Engineering AG.

In a yet to be published 'Words-into-Action' document on land-use management, the UN Office for Disaster Risk Reduction states: "The above notwithstanding, urban development and infrastructure projects can build disaster resilience in the following ways: (…) Design large scale underground spaces (e.g. car parking, tunnels, etc.) so they can serve a variety of DRR functions (e.g. as temporary water retention basins, as refuges) while also providing efficient access for servicing dense urban building blocks with water, energy and waste removal services. (Admiraal and Cornaro, 2018).

This is the way underground spaces can contribute to climate proofing cities and making them more resilient: by serving a variety of disaster risk reduction (DRR) functions. We do need to keep in mind that the complexity for the urban planner lies in the fact that it requires a 5D approach. Firstly, we need to move away from the traditional 2D approach to include 'depth' as a third dimension and approach space in 3D. On top of that two other dimensions need to be considered. One of them is time as we saw from the above, the other is geology. Time comes into play in terms of creating non-renewable spaces. It means we need to be clever when it comes to repurposing these structures. They may be non-renewable, but they can certainly be re-useable as we will see next.

4. **Repurposing existing structures**

The cityscape is rapidly changing. But as we move forward the future holds big questions. How will mobility evolve and how will car ownership maintain its social status? Already we are seeing how cars need to be adapted to the decarbonised city. Electrical vehicles are becoming the norm. Notwithstanding the fact that we don't really know where to get all the power from to charge them. Even if we can provide the power, the outdated electricity grids that were never designed with this demand in mind, will struggle to cope. With the advent of automated vehicles, the idea of calling for a pod that arrives at the door and takes you to your destination, might not be such a futuristic concept anymore. Hyperloop sees this as its standard mode of operation. In this way it could prove to be the disruptor that ends our idea of personal car ownership.

In Belgium, this vision made the city of Mechelen think about the future of its inner city underground car parks. What could we do with all this underground space once the demand for temporarily storing cars is no longer there? (Vlaams Bouwmeester, 2018)

Students of the University of Antwerp took on the challenge and started looking at this issue. What surprised one of the authors[1] was the enthusiasm with which the students took on the challenge and how they came up with multiple ideas. For students there was no drawback in the fact that these underground spaces were just that, underground. They all saw major advantages of unused spaces below the streets of the historic city centre that could serve a multitude of uses that would normally not be in reach. They also saw major opportunities to create additions to the urban fabric that would further enhance the city centre. The fact that many cities have historic centres they want to preserve make a strong case for repurposing existing underground spaces, whether they are existing basements, disused underground stations or as is the case in Mechelen future disused car parks. In the same way the Carrousel du Louvre has greatly enhanced the Louvre Museum in Paris, France, without damaging the cultural heritage it represents. Underground spaces can reinvigorate historic city centres and provide them with the services that modern city life requires. Indeed, it can help make these historic centres resilient and adapting them to climate change, again without the need to intervene in the heritage function they perform. (Admiraal, 2018)

The example of the Amfora project, a proposed concept making use of the space below the river Amstel in Amsterdam and its many canals, also aimed to do just that (see Figure 6). Even though this concept has not yet made it past this stage, it does provide a frame how we can see the cities of the future by preserving what we are proud of and providing new space to maintain liveability. Repurposing existing structures whether for storing water, storing data or growing food are all examples of how to achieve this. By combining these uses, that is reusing water, reusing residual heat and using it to grow plants or fish, we achieve a symbiosis beneath the city that will prove to be of immense value and contributes to our aim of decarbonising the city.

Figure 6: AMFORA project beneath river Amstel in Amsterdam. Source: ZJA Zwarts & Jansma Architects.

As we wrote in our book: “And an urban underground future, how will that feature in all this? We believe it offers yet untapped potentials. Not just in terms of spatial development and physical use. Underground space will become vital for survival in that it offers heat for energy

[1] Personal observations by Han Admiraal during workshop at University of Antwerp on 7 May 2018

and storage for water. It offers shelter, and it offers the ability to create connections that bypass obstacles that we have created on the surface. As such, it allows for efficient, straight line networks, minimising distance and maximising connectivity. It does require some imagination, it does require adapting legislation, and it might need some more advanced and faster technologies." (Admiraal and Cornaro, 2018)

5. Conclusions

When we look at our cities in terms of climate proofing and urban resilience we cannot afford to not look at the subsurface. In doing so we need to consider an approach that does justice to the unique environment the subsurface represents. A 5D approach is needed to not only look at the 3D spatial aspect, but also include the dimensions of time and geology.

Before even considering the use of the subsurface, a deeper understanding is required that enables decision makers to strike a balance between exploitation and preservation, that is between extracting resources from the earth and protection ecosystem services. The complexity of the subsurface stems from this, it is not just a physical foundation on which the city is based, it is a supporter of life at the surface as well.

The opportunities to create underground spaces and systems that enable the city to climate proof itself and become more resilient are there for all to see. Underground spaces can provide mobility and access even after major natural disasters. They can provide shelter and storage space. Even when it comes to energy they can play a role in providing heating or cooling or acting as an intermediary for storing wind or solar power.

The dimension time is crucial in our understanding that underground spaces once created cannot be undone the way buildings at the surface can be demolished. In this sense the space created is non-renewable. It is however re-useable as repurposing of existing underground structures is demonstrating. As such we need to look at creating underground spaces that serve multiple uses in the here and now, but also in the future. We need to move from creating mono functional underground structures to multi-use underground spaces.

ABSTRACT

Globally, coastal zones are vulnerable to climate change impact of storm, rising water level, pollution and acidification. Resilience is the ability of a system, community, or society exposed to hazards to resist, absorb, adapt and recover from the effects of a hazard promptly and efficiently by preserving and restoring critical services. Resilience is also acknowledged both explicitly and implicitly in the range of the proposed SDG targets. Peri-urban areas are often seen as attractive places to live and work as it offers a high quality of life as opposed to busy and hectic urban living. The upside of this is a dynamism exemplified by economic success and business growth often clustered around vital nodes and edges: innovation centres, airports and other well-connected transport interchanges located in these Peri-urban communities. These communities eventually develop into urban areas which may be worse of in planning if not properly guided creating imbalances in the built environment.

Ningo Prampram is the interest of study for this paper, specifically Prampram which is its capital. This paper uses a pragmatic, mixed-method and exploratory approach with epistemological underpinnings which investigate the necessary interventions required in developing resilience into Peri-urban settlements. Ningo-Prampram is one of the fastest growing Peri-urban area in Ghana. Although this suburb was once a lightly populated residential area devoid of extensive commercial activities, it has sprung into a bustling and growing commercial spine due to its strategic location to Accra and Tema taking account its waterfront appeal and potential. Recommendations put forth from the study include the redesign of the built environment; towards a more responsive, low impact pattern of buildings and spaces. Also, it proposes that systems and measures which protect critical infrastructure against events which causes vulnerability in these communities must be used in tandem with ecological strategies.

Keywords: Resilience, Peri-urban, Prampram, Vulnerable, Community, SDG

1.0 INTRODUCTION

1.1 Global need for resilience for Coastal Communities

Historically, most cities have survived and thrived at locations with good accessibility (e.g. ports) or with favorable natural endowments such as a neighbouring river, a coastal location, or fertile soils. These topographical areas are often associated with an increased probability of hazard events—floods, cyclones, storm surges amongst many others (Neumann et al., 2015; Stefaniak, 2014). However, low elevation coastal zones (LECZ) cover 2% of the world's land area but contain 10% of global population and 13% of the world's urban population (Shah & Ranghieri, 2012). Moreover, an approximated 23% of the earth's populace (1.2 billion people) settle within 100km of a coastline (World Population Review, 2016; Neumann et al., 2015). By 2030 AD, a projected 50% of the planet's populace will inhabit coastal regions (USAID, 2011). As population density and financial activity within coastal region grows, pressure on littoral ecosystems intensify (UNEP, 2007). This number is only expected to grow in the years to come, as settlements located in coastal low lands continue to grow rapidly, either by necessity or choice (Henrique, 2015). This increases the level of risk within such communities. Currently, more than 70% of the world's coasts are experiencing coastal erosion, flooding, shoreline retreat; indicating the eventual damage and danger to many coastal areas (Addo, et al., 2011).

The principal cause of increase in natural hazards is the phenomenon of climate change, which is affecting communities today as seen with recurrent floods, seasonal drought and increasing land and water temperatures (UNISDR, 2011). Ruijsink et al. (2015) cites the United Nations Framework Convention on Climate Change (UNFCCC, 1992) definition of climate change as: a modification of climate patterns which is directly or indirectly ascribed to human influences which change the makeup of the earth's atmosphere over similar time periods. As temperatures increase, sea levels will continue to rise, and large storms will become more frequent and prolonged, leading to a higher incidence of flooding (Henrique, 2015). The issue of climate change has diverse implications endangering the existence of settlements especially coastal settlements because of their unique contact with the sea. According to Venkataramanan & Smitha (2011), the average global sea level rise primarily is as a result of three factors which include the thermal expansion of warming ocean water. The melting from the ice sheets of Greenland, Antarctica glaciers and ice caps, and the adding up of water from land surface runoff (UNEP, 2009). The Institute for Public Works in Australia (2008) states that for every 20 cm of sea-level rise, the occurrence of any extreme sea level of a given height increases by a factor of about 10. Hunter (2008) expatiates that by this approach, one should expect that in 2100 a rise of sea level of 50 cm would allow that events that occur once a year to occur several times within that same year. It is apparent that drastic and efficient measures are required to respond to the incoming threat that sea-level rise pose (UNEP, 2009). Levine, et al. (2011) opines that responding to climate change and its related uncertainty is a primal development task, stressing that the impact on world and local climate are expected to have considerable implications for biomes and the occupation of the towns that rely on these natural resources. According to UNFCCC (2011), governments, communities and individuals are introducing adaptive measures to minimize the effects of climate change. However, an analytical study of most interventions discloses that these measures in fact are not intended at increasing resilience of affected people rather they are reactionary and eventually costly thus it hardly resolves effectively impacts that are long term anticipated (UNFCCC, 2011).

Now, climate change has become a forefront development agenda jointly of advanced and developing countries. This is possibly influenced by the persuasive proof that buttresses the reality of this happening hence this makes it difficult for nations that are conservative and climate change deniers to unequivocally ignore issues related to climate change (Kankam-Yeboah, et al., 2010). Nevertheless, due to increasing occurrences of natural disasters and impact of climate change there is pressure to design and create resilient buildings, communities and landscapes that can withstand and adapt to changing risks, while being sustainable and creating healthy environments (Wholey, 2015). Resilience provides the capability to minimize distress whilst retaining its usage. When change occurs, resilience offers the structure for regeneration and restructuring (USAID, 2011).

1.2 Importance of resilience to the SDGs and Quality of Life

Resilience is the capacity of a community or society to adapt and react when exposed to a hazard in order to reach or maintain an acceptable level of functioning (Henrique, 2015). A resilient settlement is one that is able to cope with disaster and climate impacts now and in the future, thereby limiting the magnitude and severity of those impacts (ARUP, 2015). Given the close links between disaster risks and climate risks, efforts to build resilience in communities by integrating climate change adaptation with existing efforts in disaster risk management can be beneficial (ibid). Adaptation to climate change requires communities to plan based on current exposure but also on projected future changes that may unfold through gradual increasing changes (e.g., temperature increases) as well as extreme events (e.g., heat waves) (Shah & Ranghieri, 2012). The need for resilience in coastal waterfront communities satisfies portions of the Sustainable Development Goals (SDG). Moreover, resilience is acknowledged both explicitly and implicitly in a range of proposed SDG targets, these include: Goal 1- No poverty, Goal 3-Good health and well-being and Goal 11-industry, innovation and infrastructure, decent work and economic growth, sustainable cities and communities. These goals provide a framework for these specific targets in protecting the environment, people and ensuring prosperity for all (UIA, 2015). In summary, coastal communities by 2030 must strengthen and build resilience to vulnerability from climate related hazards and other economic, social and environmental shocks and disasters to ensure good quality of life for all (ibid). A focus on strengthening resilience can protect development and ensure people have the requisite resources, skill set and capacities to minimize, prevent, anticipate, absorb and adapt to a range of shocks, stresses, risks and uncertainties (Fehrenbacher, 2013). The concept has been applied across a wide variety of disciplines, though largely popular and employed in disaster management and provides a useful operational framework for reducing various risks faced by people and communities, now and in the future (ARUP, 2015).

1.3 Types of contributions built environment professionals can make to facilitate SDG

In this era of population shifts, climate change and unprecedented levels of urbanisation, professional stakeholders of the built environment have an important role in responding to the complex challenges of the built environment. Through the effective planning, designing, construction, development, management and improvement of cities, urbanisation can become a model for sustainable development; embracing the intrinsic link between the built environment and job creation, livelihood opportunities, and quality of life (UIA, 2015).

1.4 The future outlook of coastal communities in Africa and the need for thorough discourse of the Ghanaian case

Climate change is expected to affect coastal communities worldwide over the coming century. Sea Level Rise (SLR), although only one part of climate change phenomenon, will be one of the greatest impact experienced in the coastal zone, with increasing flood risk, coastal erosion and saline intrusion posing a host of socioeconomic and environmental implications. The successful integration of the natural, physical, social and economic implications occurring within coastal communities will be a major challenge (Nicholls and Branson, 1998). This will be key to ensuring the sustainable management of coastal systems. However, building public involvement and understanding for climate change adaptation policy will depend largely on how inhabitants process information and make decisions (Center for Research on Environmental Decisions, 2009). In coastal West Africa, rise in sea levels are linked to melting polar ice caps, consequently working with coastal erosion to eventually plunge coastal settlements (Bokpe, 2015; Goussard & Ducrocq, 2014). Bokpe (2015) cites UNIRIN projections that West Africa's shoreline stretching out from the orange dunes in Mauritania to the thick tropical forests in Cameroon will be under water by the closing of this century, as an apparent outcome of climate change. Other significant urban centers in West Africa which experts have classified as flood-prone include Nigeria’s Lagos, Gambia’s Banjul, Bissau in Guinea Bissau, and Nouakchott in Mauritania (Chukwuocha & Chukwuocha, 2014). Furthermore, the African continent comprise 320 coastal cities and 56 million inhabitants occupying seaside areas less than 10m above sea level and remain at risk in the fight against sea erosion and inundation (Bokpe, 2015). Amongst Ghana’s coastal front, Ghana’s south-eastern coast has suffered more from the negative effects of climate change (Dovie et al., 2014). However, the south-eastern section has been marked out as the most susceptible (Appeaning, 2015: Ly, 1980). Ly (1980) states that the south-eastern section is recognized as the most weathered section with frequencies as alarming as 4m/year before the construction of the Akosombo Dam on Volta River. The dam built in the 1960’s, decreased sediment sock to the coast creating a counterbalance in sediment deposition along the coast (Boateng, 2009). Subsequently the construction of the dam resulted in increased erosion levels, 8m/year around 1970 (Appeaning, 2015: Ly, 1980). Results of a historical shoreline change analysis (in Figure 1.0) from 1974-2005 show that erosion along the Ghanaian coast is widespread, with an average erosion rate of 1.5m/yr in other words 90% percent of the coast is eroding (Ashton, 2012).

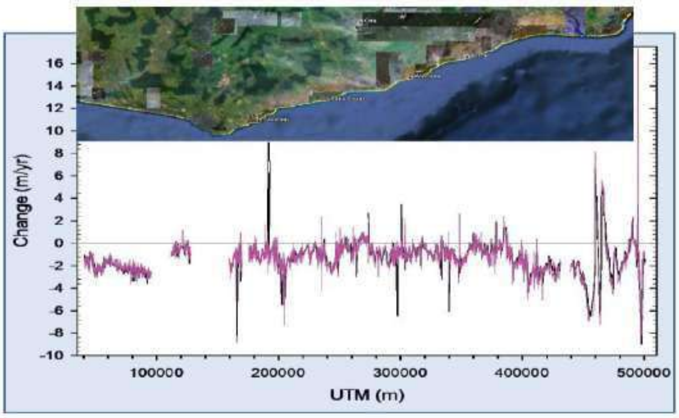

Figure 1.0: Results of historical shoreline analysis (Ashton, 2012).

To worsen the situation, the resettlement of individuals within the coastal areas and ruin of flora like mangrove swamps, extraction of valuable ore near sections of the shore damages the balance of the seaside structure and either starts or aggravates weathering in these areas (Appeaning, 2015). If this situation is unattended to, continuous erosion activities reveal that coastal shield areas are projected to be entirely weathered by 2100 (Bokpe, 2015). The EPA Status of the Ghanaian Coastal Zone Report (2006), indicates that two-thirds of the total land areas along the country's coast are in danger of being consumed by the sea; that for every metre rise in sea level, it is estimated that there would be 1,110 sq. km loss in land to the ocean. Bokpe (2015) citing a study from the Department of Oceanography and Fisheries of the University of Ghana, states that this impending danger is not only limited to coastal communities but also national relics like; the numerous forts and castles such as Osu Castle, one of the antiquities of the slave trade and symbol of political authority along the West Coast of Africa, would be swallowed up in sea's appetite. Also, it is projected that coastal erosion would overtake significant vestige like the Christiansburg Castle, independence square of Ghana and the Densu Ramsar area located in Accra between 2052 and 2082 – all located within the coastal region (Appeaning, 2015). It is expected that 1m sea level rise will engulf a large expanse of the Volta Delta ecosystem (Bokpe, 2015). Thus, there is the call to revise coastal erosion management using a holistic strategy which includes the ecofriendly method of harmonizing with nature and not fighting it (Appeaning, 2015). However, Appeaning (2015) posits that also adopting coastal management plans will permit a comprehensive evaluation of threats related to the shoreline eventually allowing the creation of a long-term policy framework to lessen the threats to the community and its environment.

Unfortunately, Ghana does not have a comprehensive development framework or policy to manage climate-related risks in coastal areas in other words building climate resilience has weak links between the national policy framework and district-level planning thus weak capacity in providing resources to assist climate-vulnerable communities to initiate resilience building by themselves (Dovie, et al., 2014). Neither are there explicit national building regulations (LI 1960) which stipulate how flood prone areas should be dealt with (National building regulation, 2006). Presently, coastal erosion management in Ghana is momentarily responsive, site-tailored and normally includes using stiff engineering methods. The existing strategies utilized by the government are unmaintainable and not sensitive to the environment (Appeaning, 2015; Olympio & Amos-Abanyie, 2013). The Government of Ghana usually proposes groynes and revetments which stabilizes the sections of the coastline of affected communities (Appeaning, 2015). Groynes are a type of coastal guard normally structural in nature, it involves the construction of barricades being built into the sea to minimize erosion. These primarily entrap and restrain the shore sand from relocating from the coast (O'Brien, 2014). Concrete structures used as obstacles are called revetments, these break off the impact of coastal erosion and absorb wave energy to reduce erosion on cliffs (Mangor, 2004). Some interventions include the Keta sea defence, Sakumono sea defence, Ada sea defence and New Takoradi sea defence among others (Appeaning, 2015; Boateng, 2009). Appeaning (2015) observes that the sea defense walls are temporary solutions that shift the problem from one area to another; for instance, the building of the Keta sea defence has led to heightened coastal erosion along the Ghana–Togo frontier by over 50%. The Oceanography and Fisheries Department in the University of Ghana (UG) has mapped the following town's red flags high coastal erosion:

- Greater Accra Region: Kokrobite, Bortianor, Labadi, Teshie, Nungua, Tema, Prampram, Old Ningo and Ada
- Volta Region: Keta, Dzito, Anyanui, and Atorkor
- Central Region: Elmina, Tantuam, Komenda and Senya–Breku
- Western Region: Esamang, Axim, Prince's Town, Dixcove, Adjua, Amanful Kuma, Shama and Atekechi.

Consequently, if the phenomena remains unchecked, it could drive away tourists and culminate in the loss of revenue to the country (Appeaning, 2015). According to Appeaning (2015), the creation of a comprehensive databank of the country's coastal geomorphology information would inform the appropriate authorities about changing trends which can affect the development of coastal tourism in the country (ibid). Bokpe (2015) opines that the sea rampage on the country's shoreline is aggravated by poor land use and poorly planned and designed buildings. With this risk in full glare, several measures would have to be undertaken to ensure the preservation of the Ningo-prampram settlement and other coastal communities. This would include the integration of climate change into local development planning in order to ensure that resources are available for community-based adaptation, and that local development initiatives do not increase vulnerability by overlooking climate risks (Dazé, 2010).

2.0 THEORECTICAL FRAMEWORK

2.1. Resilience and Peri-Urban interfaces

Today's world is rapidly urbanizing, with particularly radical urban growth anticipated in developing countries. This fast paced development has resulted in the creation of Peri-urban areas which are the extension of urban activities beyond existing administrative boundaries in urban regions (Marshall, et al., 2009) .The term 'Peri-urban' has been used to define 'a place, concept or process' (Narain and Nischal 2007: 261). 'Peri-urban' thus refers to the urban fringe and the physical edge of cities as a place, it refers to the movement of goods and services between physical spaces and to the transition from rural to urban contexts as a process and finally, as a concept, it refers to an interface between rural and urban activities, institutions and perspectives (Marshall, et al., 2009). In other words, Peri-urbanisation can be defined as "a process in which rural areas located on the outskirts of established cities become more urban in character, in physical, economic, and social terms, often in piecemeal fashion" (Webster, 2002, p. 5). Most literature has gone beyond defining the Peri-urban as a place where there is a mixture of urban and rural livelihoods being pursued, and rather theorises about the Peri-urban processes (Narain and Nishcal, 2007). However, Friedberg (2001) has argued that the Peri-urban areas are primarily integrated into urban environment. As such, Peri-urban areas occupy unique space which are simultaneously supported and endangered by the dynamics of the urban economy (Marshall, et al., 2009). Urbanization brings the creation of new opportunities, but also a dramatic increase in the concentration of poverty and environmental degradation in Peri-urban zones (UNFPA 2007). Also, the 'colonization' of urban fringes results in changes in land use, new forms of household composition, differential access to urban benefits (such as health infrastructure and employment) and increased pressure on common natural resources. The Peri-urban interface showcases a ''comme si comme ca'' phenomenon, usually characterized by either the loss of "rural" aspects or the lack of "urban" quality. From an environmental perspective, the peri-urban interface can be characterized as a varied montage of "natural" ecosystems, "agro-" ecosystems and "urban" ecosystems affected by the material and energy flows demanded by urban and rural systems (Allen, 2003).

From a socio economic viewpoint, the peri-urban interface also presents several peculiarities. The continuous but uneven process of urbanization taking place in these areas is generally results in land speculation and grabbing, change in economic activities, and the emergence of informal and often illegal activities such as illegal acquisition of land, mining or quarrying activities for the supply of building materials and others (Ianquinta & Drescher, 2000). Consequently, the social composition of peri-urban systems becomes highly heterogeneous because of the 'mixed' range of dwellers which include most often small scale farmers, informal settlers, industrial entrepreneurs and urban middle-class commuters that co-exist but with different and often contending interests, praxis and perceptions. This composition is subject to change over a period (Allen, 2003). In order words, the composition and interests of these groups tend to change over time, in a process characterized by the variable assimilation of new stakeholders (ibid). As a result, Peri-urban interfaces are typified as overlapping institutions in different sectoral units with different spatial and physical responsibilities. This is related to the changing geographical location of the Peri-urban interface or of the process whereby institutional arrangements or areas of remit tend to be either too small or too large, too urban or too rural in their orientation to address impending or unresolved issues (Ianquinta & Drescher, 2000).

2.2 Developmental Dynamics of Coastal Peri-urban interfaces in sub-Saharan Africa

The urban population in West Africa is particularly fast growing in the coastal areas (Hitimana et al., 2011). During colonial times, commercial activities concentrated strategically along the sea coast (Kuper, 1965). During the 1960s and 70s, new bureaucracies, infrastructure, and companies provided employment in coastal urban centres. This resulted in rapid immigration to urban areas in most sub Saharan African countries (Okpala, 2009). This hotspot of commerce became attractive because of the opportunities which would eventually reduce dependency on agriculture, diversify household income, improved social care and/or escape from armed conflicts (AfDB, 2005). In today's world, changing lifestyles and impact of internationalization has advanced urban growth (Cohen, 2006). Additional factors that contributed to the growth of informal processes of urban development in West Africa include governments' low levels of financial capacity, ineffective administrative systems, poor governance, mismanagement of resources, and corruption (Ianquinta & Drescher, 2000).

Ghana can be seen as an example for trends in urban development in West Africa (Otoo et al., 2006). Population densities along the coastline and traditional inland trading area such as Tamale and Kumasi, grew considerably during colonial times and after (Kleemanna, et al., 2017). Between 1960 and 1984, Ghana's population doubled (12.3 million in 1984; GSS, 1989) with an annual growth rate of 2.7%. For urban areas, migration from rural areas remained the main source of growth accumulating in an annual growth rate of 4.7% (Kleemanna et al., 2017; Frazier, 1961). This led to a strong increase in the urban population, which reached 50.9% of the total population in 2012 (GSS, 2012). This population growth was higher than the growth of the total West African population, which increased by about 40% between 1960 and 1980. Also, Ghana's urban population is higher than in West Africa, where in 2010 about 42% of the West African population lived in urban areas as compared to Ghana (OECD, 2015). This higher population pressure in Ghana has led to extreme pressure on natural resources, urban sprawl and creation of Peri-urban settlements which hitherto were small village or town settlements. Land use planning is key to meeting increasing demands for human needs and at the same time maintaining the natural environment. This poses a question as to whether peri-urban settlements cretaed by urbanization in major cities serve as catalysts or are a distraction or an indication of poor urban planning practices (Kleemanna et al., 2017).

2.3 Traditional Conception of Peri-urban Interfaces in sub-Saharan Africa

A key feature of Peri-urban environments is their dynamic nature, wherein social forms and arrangements are created, modified and discarded. It is important to recognize that the spectrum of change from rural to urban is discontinuous, "lumpy", multidimensional and that it arises from underlying social processes (Ianquinta & Drescher, 2000). For a thorough understanding of Peri-urban, one must understand the concept of urban and consider established theoretical definitions of urbanization/urbanism identify the following components: Demographic component (i.e., increasing population size and density), Economic sectoral component (i.e., a primarily non-agricultural labour force), and Social-psychological component (i.e., consciousness of what it means to be urban). Urbanization is a process of concentration and intensification of human life and activity. It is an uneven process that takes place in a physical environment. One consequence of urbanization is the uneven incorporation of a variety of institutional forms into the larger cultural environments, identified as urban, Peri-urban and rural (Mbiba & Huchzermeyer, 2002).

In our pursuit of a definition for Peri-urban, one also has to explore the larger question of the relationship between rural and urban environments. One observation that is well established in the literature is that rural out-migrants generally do not go directly to large cities. Rather, a series of moves are involved, called step migration, wherein rural migrants move first to villages or small towns and successively to more urban environments. Another observation in the literature is that migration does not sever most linkages between the migrant and her/his community of origin and family (Allen, 2003).

Together these points underscore the importance of conceptualizing the Peri-urban environment as a dynamic, transformative, and reciprocal arena linked at the macro level not only by economic activities and geography but also significantly by the social fabric of individual and family networks. Thus, the Peri-urban environment is dynamic exactly because of the flow of migrants and the density and heterogeneity of activities present. It is transformative because it changes the migrants and the migrants change it. It is reciprocal not only because individual migrants and the social environment influence each other, but also because the individual links between donor areas and the receiving areas continue to induce change in both directions at the aggregate and institutional levels (Ianquinta & Drescher, 2000).

2.4 Resilience strategies with respect to Waterfront communities

Communities can assess, manage, and limit the risks of potential disasters and climate change impacts to protect their populations and assets. Managing these risks to build long-term resilience involves understanding the level of exposure and sensitivity to a given set of impacts, developing policies and effective programs to reduce impacts, and identify resources to promote investments and planning that will limit vulnerabilities and enhance adaptive capacity (Shah & Ranghieri, 2012; ARUP,2015). Fehrenbacher (2013) reminds that the resilient design and building means commencing the design process by considering thoroughly the typical use scenarios of the building, frequent points of stress resulting from regular use, in addition to potential disaster situations that could question the integrity of the building and/or jeopardize its occupants within that environment. The local environment determines the features that make a building resilient or not thus a resilient design is always site or area defined (Rettenwender & Spitz, 2009). According to Alfraidi, et al. (2015), a comprehensive resilient strategy includes understanding of site, layout, structure, envelope, system and operation (as summarized in table 2.0).

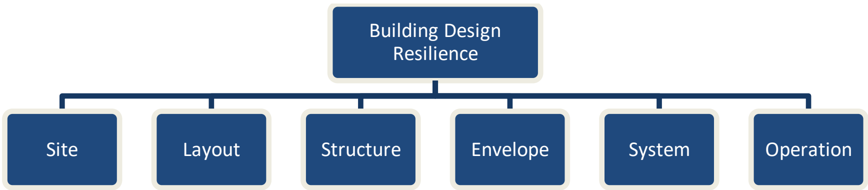

Table 2.0: Classification of Design Resilience Strategies (Alfraidi, et al., 2015).

- Site: Data from the site analysis influence the design process in order to develop a resilient design targeted at tackling the threats of climate change (Alfraidi, et al., 2015). For instance, the determination of the wind properties and the danger of inundation and erosion helps in influencing landscape design (Roy, 2013).
- Layout Design: The design of the layout should be adequately adaptable to permit a space to be reconfigured whilst retaining the use of other adjacent spaces (Alfraidi, et al., 2015).
- Structure: This refers to the ability of a building's structural system, materials and foundations to maintain its function in advent of changes related to climate and to decay graciously when necessary (Alfraidi, et al., 2015). These strategies include elevating floor levels, electrical fittings and equipment in order to stop or reduce with projected flood level (Henrique, 2015).

- Envelope Design: This involves the choices of material, shape and orientation of roofs which are significant influences in deciding on envelope resilience. These key factors must react to variations within the climate and deliver both long life span and robustness (Henrique, 2015).
- Building system: These are designs that include interventions which allow the building (system) to resist distress and disturbance (Alfraidi, et al., 2015).
- Operation: This involves the ability of a system to adopt to unexpected dangers or shocks and recover without causing disruption in routine social activities (Alfraidi, et al., 2015) .

Other resilient considerations would include use of landscapes, blue green infrastructure, land geomorphology, respect of natural landscape patterns (i.e. Fractals) other than using conventional planning methods at all times. NYC Department of City Planning (2013) summarizes a few resilient and adaptive methods for coastal settlements in Fig.3.0

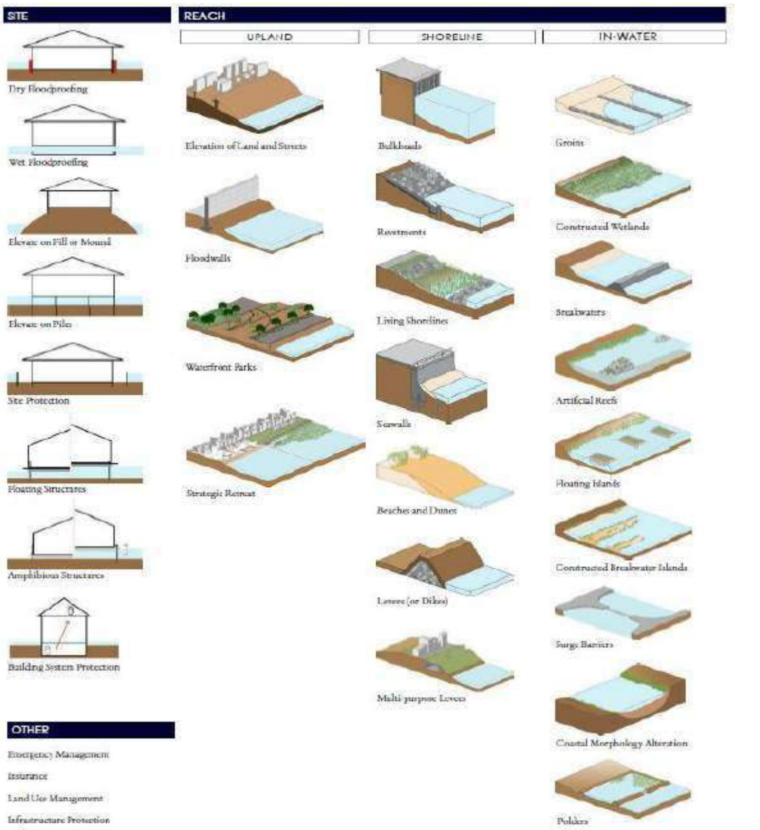

Figure 3.0: Resilient approaches for waterfront (coastal) communities (NYCDCP, 2013)

3.0 CASE STUDY

3.1 Hanoi, Vietnam

Vietnam, one of Southeast Asia's stable economic country is experiencing one of the greatest urban transitions in the world. At the national level, the urban population increased from 23.7% in 1999 to 29.6% in 2009 (with 25.4 million urban residents out of the country's 85.8 million people) (Nong et al., 2015; VSY, 2003). The urban population continues to grow at an unprecedented rate and is projected to increase by 45% by 2020, which translates to more than 30 million urban residents (Nong et al., 2015). Vietnam has a population of nearly 90 million, which makes it the third largest country in Southeast Asia and the 13th largest (by population) in the world. A little less than 30% of the population lives in urban areas, but the urban population is growing rapidly at a rate of 3.4% per year. Many of the country's cities are located along Vietnam's long coastline, rivers, and low-lying areas, rendering them particularly susceptible to hydrometeorological disasters now and into the future (Shah & Ranghieri, 2012). Because of its topography, Vietnam is susceptible to several types of natural disasters thus Disaster risk reduction and climate adaptation clearly has be mainstreamed into Vietnam's urban strategy (ibid).

Hanoi, the second largest city in terms of population and the capital of Vietnam is situated in the fertile Red River Delta, Northern region of the country. Hanoi is bounded by Thai Nguyen province to the north; Bac Ninh and Bac Giang to the east, Ha Tay to the southern west, and Vinh Phuc to the west (see Figure 3.1). The population of Hanoi has increased more than 40 times from the late 1910s to the 2000s. The rate of growth in urban population of Hanoi remained higher than peri-urban, and the difference is increasing overtime. The higher urban population growth of Hanoi is mainly because of the expansion of the urban boundary of the city to the peri-urban periphery and migration from peri-urban and other provinces to urban areas. Therefore, the proportion of total population living in urban Hanoi is continuously increasing. The urban and peri-urban ratio of 31:69 in 1978 has changed to 54:46 in 2001(Vien et al., 2005). By 2002, urban citizens occupied 53.43% in the total population. The average population density was 3,122 people/km^2, but it is quite different from that between urban and peri-urban areas: The urban was 18,220 people/km^2 (especially in Dong Da district: 35,341 people/km^2) while peri-urban area was only 1,600 people/km2 (the highest place-Tu Liem district: only 2,841 people/km^2) (Vien et al., 2005; Vietnam statistical Yearbook, 2002).

Figure 4.0: Geographical location of Vietnam (Vietnam Statistical Yearbook, 2008)

In 2003, two new urban districts named Hoang Mai and Long Bien of Hanoi were established. The two districts are split from parts of Thanh Tri, Gia Lam peri-urban districts, and Hai Ba Trung urban district (Vien et al., 2005). Until recently, the focus on urbanization in Vietnam was mainly placed upon the larger cities, for example Hanoi, Haiphong and Ho Chi Minh City. Nonetheless, intermediate-sized cities will become increasingly important in the coming years like Thua Thien Hue Province, as these cities are seen as new growth areas where opportunities for development are still present (Satterthwaite and Tacoli 2003; UNFPA 2007). The promotion of urbanization in intermediate-sized cities in an attempt to promote economic development across different regions and cities (Nghi 2008). This will also slow down further growth of already large cities such as Hanoi and Ho Chi Minh City. The Vietnamese government regularly opts for the conversion of agricultural land to facilitate further urbanization and industrial growth (Van Suu 2008; Dien et al. 2011). While urbanization is on the rise, at present, 70% of the Vietnamese population remain rural citizens, whose lives are heavily impacted by urban development policies, including agricultural land conversion. However, the Vietnamese government has taken steps in learning from their Dutch counterpart ways of increasing resilience in their region through architectural and engineering methods as discussed in the theoretical framework (Thinh 2009; Dien 2011).

4.0 METHODOLOGY AND PROFILE OF STUDY AREA

4.1 Research Methodology and Data Analysis Strategy

After exploring the main theories and concepts used in academic debates related to the resilience and examining Peri-urban issues, this section highlights the methodological approach used in the research. The study adopted a mixed method approach with a ratio of 80:20 (Qualitative: Quantitative) with underpinning epistemological knowledge about Peri-urban areas and interfaces and resilience strategies for coastal communities employing literature review. The research also employed a case study approach which was exploratory in nature. Desktop analysis of archival documents as well as secondary data from the statutory bodies and institutions in the municipality was relied upon. A visual survey that sought to establish the state of the Prampram community with respect to the current state of infrastructure, community amenities, socio-economic, cultural, ecology and institutional framework was also undertaken. Philological analysis was undertaken using aerial and normal view photos as well as panoramic views of the townscape. Geographic Information System (GIS) Software ARCGIS 10.2 was used to perform spatial analysis and projections after the existing maps were updated through the visual survey. In other to understand the Prampram community ecology, community narratives from key stakeholders was also solicited to appreciate the expansive psychological, cultural and political dynamics that may influence the resilience of the Peri-urban environment. This drew out stakeholders' rich holistic and ecological understanding which aided the research team to paint a contextual picture of Prampram as baseline data. The methodology used drew out community themes in solidarity with its needs, strengths, aspirations, challenges and changes.

5.0 Results and Discussions

5.1 Profile of Prampram

This section summarizes the physical characteristics of the Ningo Prampram community by adopting Kevin Lynch description of urban principles. Lynch (1960) describes an urban environment as comprising edge, node, path, district and landmark. Thus under the visual survey, the following themes were evaluated; natural environment, existing land uses (districts),community services, housing, transportation issues (edges, nodes, path landmark), population and employment, local economy and previous planning interventions employed within the community.

5.2 Ningo Prampram

Ningo Prampram is a Peri-urban community that consists of two main towns Ningo (old and new) and Prampram. Ningo-Prampram covers a total land area of about 622.2 sqkm. The district is located about 15 km to the east of Tema and about 40 km from Accra, the capital of Ghana (GSS, 2010). The district is bounded in the north by Shai-Osudoku district, south by the Gulf of Guinea, in the east by the Ada East district and to the west by Kpone-Katamanso district (MMDA, 2014). The district's proximity to Tema and Accra makes it easy for community members to have access to many social facilities and infrastructure, such as, good roads, water, hospitals and electricity. The district also serves as a dormitory for workers in many industries in Tema and Accra metropolis (GSS, 2010).

Prampram which is the capital of the Ningo Prampram District, is one of the fastest Peri-urban areas amongst Dodowa, Pokuase, Amasaman and Afienya in the Greater Accra Region of Ghana. Although this suburb was once a quiet, lightly populated residential area devoid of extensive commercial activities, it has within the five years sprung into a bustling and growing commercial spine due to its strategic location within the Accra and Tema boarders. Figure 5.0 illustrates a map showing boundary of Prampram.

Figure 5.0: Map showing boundary of Prampram (Google Earth, 2017)

Figure 6.0: Aerial view of Prampram shores with its community in the background (Authors fieldwork, 2017).

5.2.1 Population

The total population of the district is 70,923 out of which 47.3% are males and 52.7% females. Also, 41.7 percent of the population live in urban localities and the remaining 58.3 percent are in rural localities (GSS, 2017). However, the population has a youthful dependency ratio as illustrated in figure 7.0

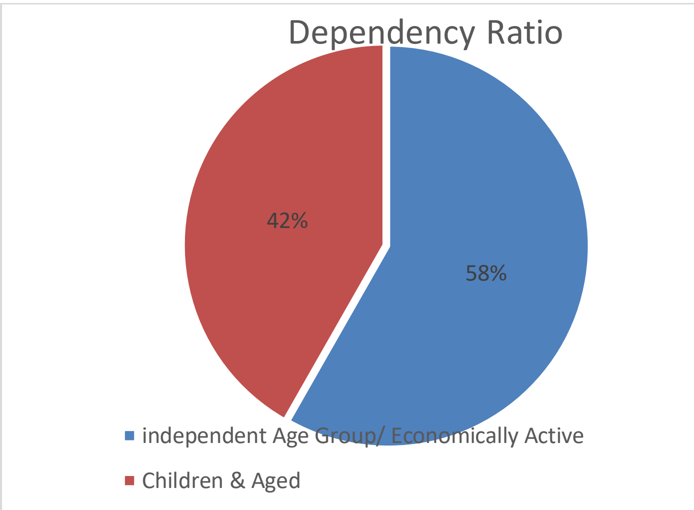

Figure 7.0: Dependency Ratio (representation by Authors, 2018)

5.2.2 Relief and drainage

The district forms the central portion of the Accra plains. The relief is generally gentle and undulating, a low plain with heights not exceeding 70m. The plains are punctuated in isolated areas by a few prominent inselbergs, isolated hills, outliers and knolls scattered erratically over the area (MMDA, 2014).

5.2.3 Climate

The south-eastern coastal plain of Ghana, which encompasses the Ningo-Prampram district, is one of the hottest and driest parts of the country. Temperatures are however subjected to occasional and minimal moderating influences along the coast and altitudinal influences affected by the Akwapim range in the northwest. Temperatures are appreciably high for most parts of the year with the highest during the main dry season (November – March) and lowest during the short dry season (July – August). The maximum temperature is 40 0 C.

The combined effects of high temperatures and high insulation levels, on the other hand, are of invaluable asset to the salt-making industry, as they account for the high and rapid rates of stalinization and crystallization crucial for the winning of salt. They also provide enormous potentials for solar power development (MMDA, 2014).

5.2.4 Local Economy

The local economy of the district is made up agriculture, commerce and services. Other thriving new and lucrative activity includes real estate activities which form the backbone of the economy as the district is largely becoming a dormitory settlement.

5.2.5 Service

The service sector covers a wide range of activities: finance, commerce, real estate and housing development, health, education, sanitation and water, electricity, transport, hospitality and tourism, etc. The District has only two (2) banking facilities (i.e. Dangbe Rural Bank at Prampram and a branch of the Dangbe Rural Bank at Ningo). The real estate and housing development is the fastest growing sector of the district economy. There are nearly twenty (20) different real estate companies developing properties within the District. The district has become an ideal place for such activities because of its proximity to Tema and Accra.

5.2.6 Roads

The total length of roads within the District area is 264.9 km made up of asphaltic concrete, surface dressed and unpaved roads. The District can also boast of two (2) first class roads

(Tema – Akosombo & Tema – Aflao) and a second class road that links Dawhenya to Prampram as illustrated in fig 8.0.

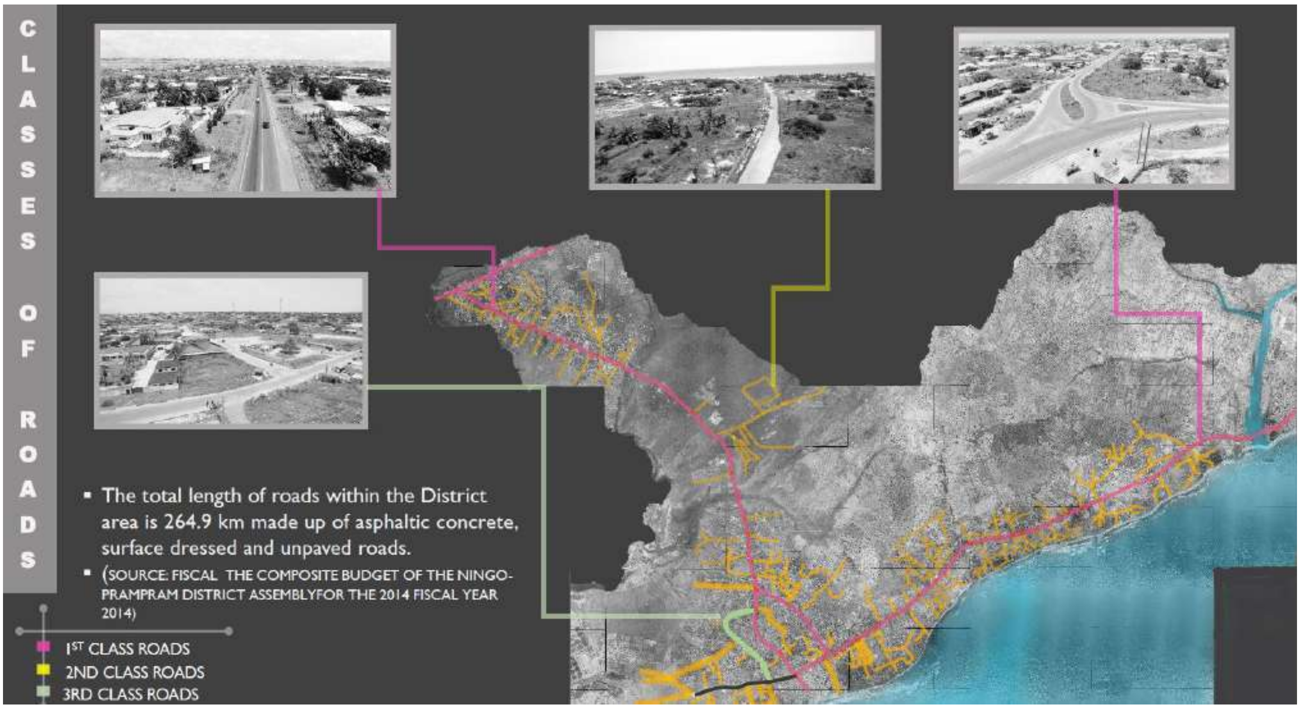

Figure 8.0: Classification of roads in Prampram (KNUST Department of Architecture, 2017).

5.2.6 Education

The District has a total of 199 basic school facilities out of which 47% are private. It also has one (1) privately administered tertiary institution (Central University College) which attracts students from all over the country and beyond resulting increased 'migration' of people from the main city center (Accra) to this peri urban community.

5.2.7 Health

The District has a total of twelve (15) health facilities out of which seven (7) are privately owned. Out of these facilities, there are five (5) CHPS compound constructed at various vantage locations within the district to make health care very accessible to the local people. The private health facilities augment the efforts of that of the public by providing services ranging from midwifery to obstetrics and Gynaecological services (GSS, 2010).

5.2.8 Hospitality Industry

Although this sector does not play a major role in the local economy, the tourism and hospitality sectors in the district have great potential. For instance Prampram and Old Ningo are one of the oldest European coastal settlements in Ghana. Prampram was the site of a small British trading post and fort built in 1742, while Ningo was the site of a Danish fort from 1735 until it was handed to Britain in 1850. However, neither fort survived to this modern day, except for some traces of Prampram's Fort Vernon remains. The main attraction of the area is the beach, particularly the stretch around New Ningo, generally regarded as safe for swimming and dotted with holiday homes. The estuary on the west flank of Old Ningo has natural beauty enhanced by colourful fishing boats moored on the beach. Prampram also boast of the first Police Station built in the country.

5.2.9 Previous Planning Interventions

Due to the strategic location of Prampram to the industry city, Tema and the capital of Ghana, Accra, attempts have been made by local planners to restructure the town from its organic form to western grid pattern. Apart from the local planning interventions, the UN Habitat in 2016 made planning proposals with regards to the master planning of Prampram. This is illustrated in figure 9.0 and Figure 10.0 respectively.

Figure 9.0: Prampram land Use Plan (local interventions) (KNUST Department of Architecture, 2017)

Figure 10.0: UN Habitat masterplan proposal for Prampram (UNHABITAT, 2016)

5.4 SWOT Analysis of Prampram vis-à-vis developmental plans

Analysis	Remarks
Strengths	-Resilience strategies have been integrated in the planning by using blue-green infrastructure in the UN Habitat masterplan proposal
Weaknesses	-Initial Local plans did not consider the incorporation of resilient strategies - Grid pattern adopted may increase vehicular traffic situations within the Peri-urban community -Planning type adopted is not organic to the current lifestyle of the people
Opportunities	-Tourism can be boosted -Coastline can be protected and preserved; lives, properties and livelihoods of fisher folks can be protected -Improve current services and roads within the communities -Alternate routes should be created and improved to reach other parts of the main city without using the current existing roads which cause vehicular traffic especially during the early and late hours of the day due to influx of Peri urban dwellers
Threats	-Tendency to destroy the natural organic form of the settlement which had the semblance of fractals due to the introduction of grid pattern planning

5.4 Discussions

Data obtained from literature and field work conducted in Ningo Prampram illustrates that Peri-urban communities function as satellite towns to main cities due to their proximity. Also, due to the affordability of lands, rent and/or leases in Peri-urban communities. Even though distances to city centres may be further away from their places of dwelling. Many Peri-urban dwellers also prefer the quiet ‘country’ nature of Peri-urban areas but with enough amenities and services to make living in such communities comfortable. The Peri-urban environment must also be viewed as a dynamic, transformative and reciprocal linked at the macro level not only by economic activities and geography but also significantly by the social fabric of individual and family networks.

Ningo Prampram is a Peri-urban community located at the outskirts of Accra and Tema, both important commercial and industrious hub of Ghana, respectively. As a result of urban sprawl and expensive accommodation and land in the main city center, most middle income and poor families are locating their homes to the outskirts of Accra and Tema. Field studies conducted in Prampram revealed that Ningo Prampram has seen an increase in population, provision of services and increased attention from real estate developers seeking to take advantage of the housing market deficit. The introduction of Central University has also influenced the population dynamics and commerce within the area as it attracts businesses both small and medium scale to provide for the university population as experienced with other public universities in the country, as in the case of University of Ghana, Legon and Kwame Nkrumah University of Science and Technology, Kumasi. Further developments prove that the Government of Ghana intends to move the Government Seat to Prampram as a mechanism to decongest the National Capital, Accra. It has been arranged that the headquarters of major Government Institutions, Ministries and other private institutions would be transferred to Prampram. Additionally, Prampram is proposed to host another international airport to compliment the Kotoka International Airport in Accra. This implies that Prampram could be transformed into a government city or an aerotropolis or both hence must consider the issue of resilience both as a waterfront community and in its social and infrastructural system before it expands into a major city center and continues the chain reaction of creating other Peri urban communities which surround it. Consequently, the master plan proposal has been accepted by the UN Habitat lab by the Ningo Prampram district even though by the SWOT analysis conducted, the masterplan is not sympathetic to the culture of the people of Ningo-Prampram. However, it is likely that even though resilient strategies have been integrated into the master plan proposal. The local inhabitants of that area may not adjust properly or the reality and vision of the masterplan may totally be defeated when implemented in spite of the infrastructural measures adopted.

6.0 Recommendations and Conclusions

Based on the culmination of findings from literature and field studies. A visual survey undertaken in the community revealed that there is a high influx of students, workers and families acquiring accommodation within the community. Ningo Prampram like most coastal communities in Ghana, has great potential as a tourist destination away from the bustling nature of Accra and Tema. From literature review and field studies, it can be summarized and concluded that Peri-urban communities requires resilience strategies which include:

- The consideration of coastal geomorphology measures like coastal retreat, waterfront parks and elevation of land and streets
- The incorporation of Architectural and Peri-urban planning approach such as elevation of buildings, wet proofing buildings, complete barricade of site from flooding situations and the use of amphibious building structures.
- The role of 'hard' engineering methods are also required to maintain a resilient waterfront. These would include strategies like building levees, dunes, revetments and surge barriers.
- Also, the Incorporation of blue green infrastructure such as storm water systems and the use of mixed used open spaces can also improve resilience.

The following recommendations were concluded on as relevant for the growth and resilience of a Peri-urban town as a resilient coastal waterfront community. Ningo Prampram requires a masterplan which must embody an increase in the level of protection and minimizes the impact of possible flooding. This master plan should allow for the natural movement of water while integrating safe routes, raised access to the buildings, permeable landscaped surfaces and basins, all without compromising the aesthetic and social aspects of the design. The waterfront must be developed with appropriate facilities to attract tourists (local and foreign) to facilitate tourism in that area. Also, a comprehensive coastal geomorphological information to develop custom solution to safeguard the coastline. In planning Peri-urban settlements, urban planners should consider other organic forms of planning like the use of fractals to develop masterplan or land use plans for Peri-urban communities

For future studies, it is encouraged that simulations should be conducted to investigate the viability of the masterplan proposal and what effective alternative can be used to develop proposals for coastal Peri-urban waterfront communities.

Planners' information need in adaptation to climate-induced floods

Rebecka SNEFUGLLI SONDELL[1], Daniela BAER[2], Nathalie LABONNOTE[2], Terje SKJEGGEDAL[1], Edvard SIVERTSEN[2]

[1]NTNU, Norway
[2]SINTEF, Norway

Abstract

This study investigates urban planners' need for information to adapt to climate change. Interviews with planners in Trondheim and Stavanger disclose gaps in the provision of data and needed tools.

Climate change is increasingly seen as a major challenge within the field of urban planning. Many places will need to adapt to new climatic conditions, resulting in more severe droughts; rising sea levels; increasing precipitation; air pollution; water scarcity and increasing risk of landslides. Despite the growing awareness of the potential consequences of climate change, the process of climate change adaptation remains slow. In Norway, the central role of the local municipalities in the climate change adaptation process was underlined in the White Paper on climate change adaptation and urban planning has been given a central role in the adaptation process.

One of several reasons for the passive approach to climate change adaptation is the lack of relevant information. Although there is an abundance of research about climate change and its consequences, local officials report that the available data is often not relevant or applicable to the adaptation process on local level.

This study explores planners' information needs regarding climate change adaptation. More specifically, the focus is set on adaptation to climate-induced flood events, as a result of increasing precipitation and sea level rise. Two case studies of the Norwegian municipalities of Stavanger and Trondheim are used to shed light on the necessary data and tools to enhance adaptation to flood risk through planning. The study also considers to what extent the expressed information needs can be covered by existing information resources, as well as what data and tools that would be useful but are currently unavailable in the planning process.

1 Introduction

Climate change is a challenge gaining increasing interest and concern within the field of urban planning. Many places will experience more extreme climates with more severe droughts; increasing precipitation; rising sea levels; landslides; air pollution or water scarcity (Field *et al.*, 2016). Despite the rising awareness of the potential consequences of climate change, the process of climate change adaptation remains slow. In Norway, the local municipalities were assigned the main responsibility for the adaptation process, with the White Paper [*Stortingsmelding*] on climate change adaptation (St.meld. 33, 2012-2013), nevertheless many municipalities remain passive actors in the adaptation process.

Previous research finds that one of the reasons for the slow adaptation process in local municipalities is the lack of relevant information. While there is a lot of information available about climate change and its potential effects, officials on municipal level report that they lack information that is locally relevant and useful in the local adaptation process (Aall *et al.*, 2015; Dannevig and Aall, 2015; Hanger *et a*l., 2013; Storbjörk, 2007; Tol *et al.*, 2008). Guidance material specifically targeting adaptation in the municipalities is often dominated by general information about climate change and lacks descriptions of specific adaptation measures that could be implemented (Hauge *et a*l., 2016). A survey conducted among Norwegian municipalities showed that 9 out of 10 municipalities wish to have more information about the local effects of climate change (DSB, 2008). The mismatch between the existing information resources and the local planning practitioners' need for information represents therefore a substantial obstacle to incorporating climate change adaptation in municipal planning processes.

The main motivation for this study is to define which information resources are needed in planning for climate change adaptation within the specific scope of climate-induced floods in Norway. Climate-induced flood risk includes sea level rise and urban runoff.

The research question may be expressed as: What data, tools and guidance material are needed to improve flood adaptation in municipal planning processes?

The methodology is presented in Section 2, together with the chosen case studies. In Section 3, the findings are presented and discussed in relation to relevant planning theory, in order to assess the necessity of information resources for a pro-active approach to flood adaptation in planning. Section 4 summarizes the main findings of the study and gives some suggestions for implementation.

2 Material and Methods

2.1 Case study 1: Stavanger municipality

Stavanger is a coastal municipality in south-western Norway, incorporating the city of Stavanger and its immediate surroundings with a population of 130 000 inhabitant (SSB, 2018). Projections suggest that the region will see a 10 percent increase in the average annual precipitation until the end of the century (Miljødirektoratet, 2015). In addition, the number of days with extreme precipitation could more than double in the worst scenarios (Hanssen-Bauer *et al.*, 2015). The risk for floods will thus increase, especially in urban areas in form of increasing urban runoff (Miljødirektoratet, 2015). Stavanger is also vulnerable to the effects of rising sea levels. Already today, central parts of the city are at flood risk during storm surge events (COWI, 2017) and the sea level is expected to rise by up to 80 centimetres by the end of the century (Simpson *et al.,* 2015). A recent cost-benefit analysis of future flood damage in Stavanger estimates the potential costs to 11 billion NOK by 2090, a cost that could be reduced to 3 billion if adaptive measures were implemented (COWI, 2017).

2.2 Case study 2: Trondheim municipality

Trondheim municipality is, with its 190 000 inhabitants the third biggest municipality in Norway based on population size (SSB, 2018). Historically, about 50 different flood events have been registered in Trondheim, primarily related to spring floods of the nearby rivers and streams, but more recently also due to extreme weather events. Climate projections suggest that the region will face both increasing precipitation and sea levels, resulting in higher flood risk. The total annual precipitation is expected to increase with 17 percent in the coming century in the worst scenario and the number of days with extreme precipitation could increase with up to 77 percent (Hanssen-Bauer *et al.*, 2015). While sea level rise has so far been compensated for by the regional effects of land rise, it is expected a sea level rise of 53 centimetres by the end of the century (Simpson *et al.*, 2015). This will increase the risk of flooding in the coastal areas especially when storm surges and wave effects are considered.

However, in opposition to Stavanger, the possible consequences of sea level rise are not yet seen in Trondheim today.

2.3 Methodology

The study is primarily based on twelve in-depth interviews with public officials at administrative units involved in planning processes in Trondheim and Stavanger municipality. Considering the lack of previous research about the information needs in the planning process with regard to adaptation, the study is intrinsically exploratory in character. As a result, the interviews followed a semi-structured interview design. The interview included a selection of mandatory topics to ensure that key areas were covered, while allowing other (potentially new) topics to be addressed.

The mandatory main questions and topics that have been addressed are detailed in the following:

- Background?
  Topics: task, role, previous experiences.

- How is climate change adaptation to flood risk addressed in the municipal planning processes today?
  Topics: Previous flood events, cause, effect on the society, effect on the planning process, need for adaptation, factors for facilitating adoption, focus area for climate change adaptation, adaptative measures, success, failures.

- Are the available data/tools/knowledge sufficient for enabling climate change adaptation to flood in municipal planning?
  Topics: Accessibility, relevance, success, failures, user-friendliness, capacity building, responsibility, in-house developed tools, communication.

- How could one better accommodate the needs for data/tools/knowledge about climate change adaptation to flood in the municipal planning process?
  Topics: improvement, lack, communication, dissemination, format, capacity building, prospects.

The organisation of the adaption process varies among the municipalities, and it was therefore not clear from the start who the most relevant informants would be. The coordinator for climate change adaptation provided contacts with relevant interview objects. Priority was given to people who had experience of working with flood adaptation. Their input was therefore assumed to be more informative based on their previous experience. In addition, "*snowball sampling*" was used to identify other relevant interview objects.

3 Results and discussion

3.1 Knowledge-status on climate change adaptation in the municipal administration

The interviews suggest that there is a **general lack of knowledge** and competence within the field of climate change adaptation. The competence on flood adaptation, especially concerning sea level rise, is often very limited in the municipal administrations. Several of the interview participants claim that the competence on climate change adaptation varies a lot from person to person and is primarily based on individual engagement and interest in these issues. "Not all 50 people who work at the planning office are fully updated on these issues. Even though the aim is that they will be", says one of the interview participants. When asked to name the most important factor for strengthening climate change adaptation in planning, one of the planners brings up the need for a "general understanding of what climate change adaptation is", which suggests that even a basic understanding of the concept might in some cases be missing. Awareness about the need to adapt, together with knowledge about available adaptive measures, are identified as two of the prerequisites for succeeding with planned adaptation (Füssel, 2007). Thus, the absence of these factors could explain why climate change adaptation often has not come further in the municipalities.

The competence gap is most likely even **larger in smaller municipalities** with fewer resources set aside for climate change adaptation. Trondheim municipality was reported to function as a mentor on climate change adaptation for smaller municipalities in the region of *Trøndelag*, none of them had addressed the need for adaptive measures before.

Although the competence level might not be sufficient, the focus on climate change and adaptation to flood risk was reported to have **increased dramatically** in both Stavanger and Trondheim municipalities. "I have worked here for 25 years now and in the past 5 years it has become a growing focus on these issues" said one respondent in Stavanger. At the same time, another respondent noted that flood adaptation was not a central issue on the planning agenda. "In most plans, this is not the main focus, because there are many other things we need to take into consideration as well".

The interviews also suggest that there have been some **internal competence-building initiatives** on climate change adaptation, such as seminars and thematic meetings. However, these have primarily been singular events. In addition, both Stavanger and Trondheim established an intersectoral working group on climate change adaptation, in order to improve the communication between different disciplines and to ensure a more holistic approach to adaptive measures. Interview participants from Stavanger municipality appeared to be satisfied with the intersectoral working group, especially since it includes not only technical service units but also the planning and building inspection units. "But we are not done yet. There is still some potential for improvement", one person says, pointing to the need for some organisational changes and to strengthen the mandate of the group. The intersectoral working group in Trondheim also showed potential for improvements, among other aspects to overcome lack of engagement and insufficient competence among the members. "We need some restructuring, otherwise we will not move forward", said one of the members of the group. "Not everyone has the time, they are not dedicated and competent enough" said another respondent. Lastly, both municipalities are also members of various cooperation networks on climate change adaptation that provide a platform for exchanging experiences and learning from others. However, for the exchange to be fruitful the knowledge must be brought into the local adaptation process. "The network is meant to provide competence and inspiration, but this has to be included in the documents back home, otherwise it makes no sense. It does not matter if you sit here [in the network] glowing with enthusiasm and interest if you do not bring it back home", said one of the respondents.

As a result of limited competence and capacity within the municipal administration, analyses related to flood adaptation in the planning process are usually conducted by **external consultants**. However, one planner underlined that there are not many experts in this field also among private consultants: “The amount might increase if more municipalities begin demanding these [analyses]” said the planner. While no further assessment of the knowledge status among private consultants has been conducted in this study, the interviews suggested that the competence on adaptation to climate-induced floods is rather limited both in the public and the private sector.

The type of mentioned information resources has also been observed to largely depend on the **type of flood risk**. As shown in Figure 1, the interview references to data and knowledge predominantly address adaptation to sea level rise, whereas references to tools are slightly more directed to adaptation to urban runoff. Two hypotheses might explain this tendency: a) reliable data on urban runoff might be difficult to acquire due to the unpredictable nature of the intensive precipitation; or b) a relative lack of information resources on sea level rise would result in a higher demand.

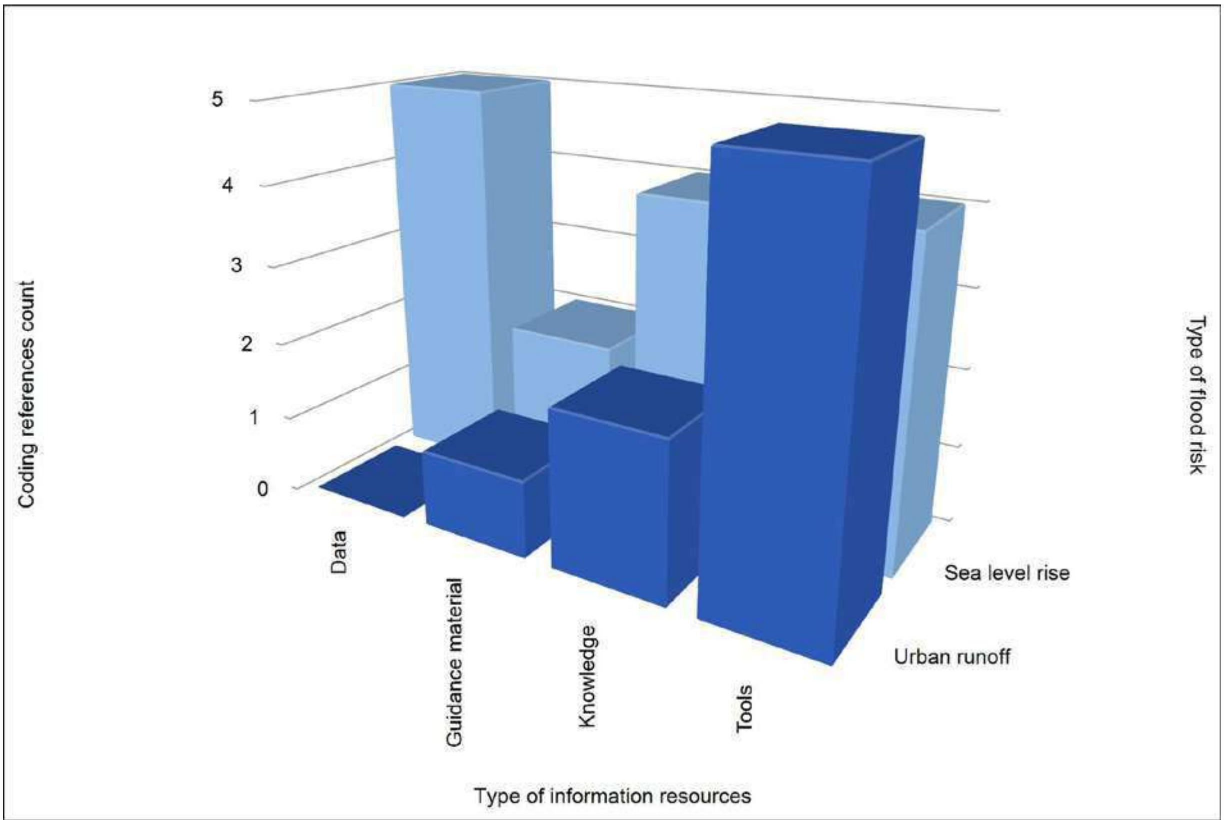

Figure 1: The recurrence of the flood types in relation to the different types of information resources in the interview material.

3.2 Data

Access to data is important in climate change adaptation, both for identifying vulnerabilities and for designing sufficient adaptive measures. **Geographic data** is an important part of the information used to predict and prevent flood risk and is often presented under the form of flood risk maps. One of the key challenges related to geographic data appeared to be the quality of the data sets. "All units try to keep up to date […]. But sometimes we need more precise and more detailed data", said one respondent working with geographic data. Using inadequate data sets in flood risk analyses can result both in that vulnerable spots are missed and that the flood risk zones that require adaptive measures become unnecessarily large. This appeared to represent a critical challenge for mapping waterways. "It is like this with GIS analyses: 'nonsense in, nonsense out'. And this is also the weakness of our old flood way analysis. We see that it does not entirely match with reality [...]. The culverts and streams and such were not sufficiently mapped", said another employee from the geo-data unit. The identification of streams from *Felles Kartdatabase* (FKB) has been based on whether or not the stream is visible on an orthophoto. This approach was reported as problematic in vegetated areas where visibility is low, resulting either in arbitrary mapping or in stream discontinuity.

Laser scanning is mentioned as one of the main solutions for addressing the problems with data resolution, according to NOU 2010:10. "With laser scanning, even in areas with spruce forest, there will be some laser rays reaching the ground, so you get a terrain model also where there is forest", explained one respondent from the geo-data unit. The ongoing nation-wide laser scanning of Norway was therefore observed to be a much-welcomed initiative.

The project began in 2015 and terrain models for large parts of the country are now openly available online. "Previously, the municipalities had to finance and buy this service themselves, but the ongoing laser scanning is actually tax-financed" mentioned a respondent. Hence, in addition to improving the quality of the terrain models, the national laser scan improves the availability of data especially for smaller municipalities that might not have had the resources to conduct mapping projects of their own, thus laying the ground for better flood risk analyses.

Besides geographical data, respondents in both Stavanger and Trondheim municipality noted the importance of **historical data** of flood events. Past flood events were also described as the most reliable source of data for predicting future flood risks. "It is our strongest card in planning, that we prevent [flood risk] based on our previous experiences", said another respondent from the geo-data unit in Stavanger, while agreeing that scenario-based predictions of the future were also important despite their high uncertainty. Both municipalities have records of previous flood events, however the awareness and use of these records seemed to be limited in some of the administrative units, at the same time as being mostly person-dependent. "I have at least not been taught where to look for such information", revealed one respondent from the water management unit. "I know that those who have worked here for a long time know this by heart. But the question is what happens when they leave? Should we then learn it all again?".

The interviews revealed that many of the actors in the planning process have limited or no awareness of the **validity of the data** flood adaptation is based on. "It is a rather simple procedure when I look into the zoning plans", said one respondent at the water management unit. "We just look at the output of these [flood risk] models. But the question is, how well do these results represent reality? I actually don't know that". Only one municipality appeared to actively attempt to verify and validate data used in the planning processes. The verification of data was then primarily based on the engagement of one person at the contingency unit: data could then be verified via the use of external contacts, such as research institutes and national agencies. "I haven't heard about any other [municipalities] that do what I do […] Many just skip this part and hope for the best", said the contingency official. The underlying problem to the lack of data verification is the limited expertise within the municipalities. "It is very specific knowledge that we don't have. There is no one in the municipality [administration] who has expertise on wave impact and such things. And then we are a rather large municipality, so the smaller municipalities don't have a chance to check these things", claimed another informant. As a result, many public officials have no choice but to trust the data provided by external sources.

The inability to verify data also results in the use of **outdated data**. "There were some discussions about what data that would be correct to use for a plan we were working on. You have some [data] [...] and then there was some work […] that was more recent but not approved by the ministry", explained one planner. "We thought we should nonetheless use those that had been approved on a national level [...] even though those numbers were starting to get a bit old". Similarly, one of the respondents from the environmental unit noted that the municipality's flood risk maps, which were made in 2011, were already outdated by newer data. "If you look at the maps on the municipality's website you will see the old sea level estimate from 2011, which says 40 cm sea level rise […]. However, the new guidelines from the Norwegian Directorate for Civil Protection (DSB) [*Direktoratet for Samfunnssikkerhet og Beredskap*] say 70-80 cm, and even more recent research says that we can forget about these small numbers, it will be 100-150 cm". The time lag of acquiring and internalising the most recent data therefore slows down the adaptation process further.

3.3 Tools

GIS software products are one of the key tools in flood adaptation and are used to create flood risk assessments as well as to identify the existing waterways and catchment areas.

GIS tools are often used to generate static 2D maps, however several respondents mentioned **3D-visualisations** as one type of tool that could benefit from further exploration. "If you visualise [flood risk] [...] in 3D […] it becomes understandable to everyone", claimed one respondent from the geo-data unit.

To some extent, the needs for data and tools in the adaptation process was observed to trigger the development of **new functions in the existing simulation software**. Users' needs were in some cases communicated back to the provider, who could then incorporate more customized functionalities. According to one respondent from the geo-data unit, it was easier to influence Norwegian software providers compared to international ones. This was particularly relevant when many municipalities experienced similar problems. "If it is a large company that is based in Europe or the United States, then it is rather difficult to have an impact", described the respondent, who also underlined the importance of educating providers who were not necessarily aware of the challenges regarding flood adaptation.

Quantitative evaluations were also mentioned as important for bringing flood adaptation higher up on the agenda. "Everything you quantify and measure gets prioritised", revealed one of the water management engineers in Trondheim. Although both municipalities implemented regulations and guidelines to enhance flood adaptation through the planning process, neither of them conducted any evaluation of the impact of these measures. The definition of key performance indicators is necessary for identifying both successful examples and problems and would result in a more efficient adaptation process.

Economic analyses of adaptive measures and flood scenarios, when combined to quantitative evaluations, represent not only an opportunity for evaluating a strategy in terms of risk reduction and implementation rate, but would also further inform decision-making and lead to more efficient adaptation. "Transforming it into [monetary value] will allow for comparing, when you are dealing with complex issues involving both 'apples and pears'", said one respondent from the water management unit. Yet the interest in conducting economic assessments was observed to be seemingly low. A cost-benefit analysis of flood damage was developed in one of the municipalities: a GIS-based analysis enabled the estimation of future costs of flood damage to infrastructure as well as possible costs and benefits from adaptive measures. "This is a tool that all municipalities could use if you familiarise yourself with it", said an informant from the contingency unit. "I haven't received many inquiries about it so far, so I suppose there is not so much focus on these matters".

Other key tools used in the planning process today are the various **construction standards**, such as the local water management regulation [*VA-normen*] and regulations on technical requirements for construction work [*Byggteknisk forskrift* (TEK17)]. However, standards are inexistent for more specific solutions such as blue-green solutions, although these are viewed as the preferable and more sustainable way of handling urban runoff. Choosing blue-green solutions therefore becomes a riskier investment, since consultants are not responsible for potential flood damage as long as they act in accordance with the approved practice in many cases the existing construction standards. But when no such standards exist, *e.g.* for blue-green solutions, it is more difficult to claim that sufficient measures were taken if damage were to occur. One water management engineer therefore asked for similar standards for construction and dimensions also for blue-green solutions. "I think it is essential for the implementation of blue-green solutions. Consultants and developers need to feel certain that the solutions they implement are reasonable, and perhaps most importantly, that they will not risk getting responsibility for damage that could happen in the future".

Several of the interview participants claimed that the tools that are available today are generally good. When it comes to **possible improvements** the opinions are more divergent. One informant claimed that there were already rather many tools available, while another was surprised that not more tools had been developed and taken into use. The latter also noted that the main weakness was the quality of the input-data rather than the tools themselves.

Sometime tools exist but are not used by the municipalities. One possible explanation to the **limited use of tools** is the lack of awareness and competence. Toolboxes that collect relevant resources can be found; however, these are not necessarily complete and are often one of many such resources collections. In addition, the employees experience that it is difficult to stay fully updated on developments in the field. "It is a very large organisation and many areas of responsibility and many people, so it is not always easy to keep update on everything that is new", according to a planner.

3.4 Guidance material

A large amount of guidance material on climate change adaptation has been published in recent years. A review of 84 different reports and websites addressing climate change adaptation was published by *Klima 2050* (Hauge *et a*l., 2016) and identified some **general trends** in the existing guidance material. Firstly, it often focuses primarily on general information about climate change, rather than detailed information about implementation of possible solutions. Secondly, much of the guidance material lacks a defined target group, which may reduce the effectiveness of the communication. Moreover, none of the reviewed guidance material focused on decision-making processes and coordination between different sectors in the adaptation process. These findings were also reflected in the interviews.

The guidance material that is available **does not reflect the need** of the users. One respondent described difficulties in finding more technical information in the guidance material. Another one asked for more examples of how adaptive measures could be implemented in practice and for more information about the implementation process. The guidance material was also mentioned to be too much simplified, *e.g.* in regard to the complexity of the impact of waves on sea level rise. At the same time, users reported to experience difficulties when navigating through an overload of information. "If it is like you say that there are more than 80 reports out there, it is rather obvious that it will be difficult to keep track of it all", reflected one planner.

The absence of process-related guidelines was also considered as an opportunity for improvement on adaptation. "There should be [...] guidance material for each phase [in the planning process]", said one informant. "Those who are responsible for the different phases in a project need to get clear guidelines describing that 'here you should watch out for this; and consult these actors and ask about such and such'. Then you can say that this is done; OK, move on to the next phase. [...] There is too much discussion about this [process] in general" observed an informant from the environmental unit.

There is also an **uneven focus** on the different topics covered in the guidance material. The interviews indicated that the available guidance material is more useful for dealing with urban runoff than it is for addressing sea level rise. This is in agreement with the thematic analysis presented by Hauge *et al.* (2016), which showed that 19 percent of the guidelines reviewed focus on urban runoff, compared to merely 1 percent that dealt with sea level rise.

The often **poorly defined target group** is mentioned as another challenge with the current guidance material. "Who is it made for? Is it for someone with a PhD or are they written for [anyone]?" asked one informant from the environmental unit. The unclear target group was also considered to be one possible explanation to the limited usage of the existing guidance material. However, when asked about who primarily uses the guidance material, the general perception was that the resources were used. "Maybe the environmental unit uses it. The building inspection office and the planning office probably also must look into these matters. [...] Guidance material on climate change adaptation should also be something that the water management unit goes though", estimated one planner. Nevertheless, most of the interview participants primarily talked about others using the guidance material, while those that did use it mainly emphasized its deficiencies.

4 Summary and conclusions

To answer the question: what data, tools and guidance material are needed to improve flood adaptation in municipal planning processes? Twelve interviews were conducted with public officials at administrative units involved in planning processes in Trondheim and Stavanger municipalities in Norway.

Adaptation was shown to gain importance within the planning field, mostly via increased efforts to strengthen competence. However, there is still a need for greater knowledge and awareness on adaptation. The engagement was observed to largely vary, both among individuals and depending on the type of flood risk concerned. The main results suggested that adaptation planning is still not fully institutionalised in the planning practice and is given attention on a more ad hoc basis.

Results showed that there is an ongoing and seemingly accelerating process for improving the quality and access to data used for flood adaptation planning. Yet the major challenges were observed to be related not to the data itself but rather to the ability to make use of it. The interviews unveiled weak points in the organisation of data and the competence of its users, suggesting that these could be possible areas for improvements.

The interviews also suggested that there is a potential for improvements, both regarding the use of existing tools and the development of new tools. The development of tools for visualisation, quantification and standardisation could provide better decision-making support. In addition, organisational and educative measures could probably enhance usage of the already available tools.

Finally, the interviews confirmed the previously observed trend: the available information resources on adaptation do not correspond to the information needs in the municipalities. One measure for improving the usefulness of the guidance material would be to better coordinate the content with the needs as expressed by the users. The use of the existing guidance material would also benefit from better organisation and awareness of the existing material and, perhaps foremost, a reduction in the number of reports and documents.

This study is expected to inform the research agenda and thus to contribute to the development of information resources that are better adapted to the planning practitioners' needs. It is hoped that this study will in the long-term increase the resilience to negative effects of climate change.

Sustainable and smart energy transition in cross-border territories. Insights from the European Alpine macro-region

Adriano BISELLO, Eurac Research, Institute for Renewable Energy, Italy
Silvia TOMASI, Eurac Research, Institute for Renewable Energy, Italy
Daniele VETTORATO, Eurac Research, Institute for Renewable Energy, Italy

1. Energy transition in Europe and in the EUSALP macro-region

1.1 The European perspective

Since 2008, the European Commission is pursuing Member States to improve their climate and energy strategies and legislation in order to achieve ambitious goals. Starting from the pioneering “20-20-20 package” (European Commission, 2010) – aiming at a 20% reduction in GHG emissions (on 1990 levels), an increase to 20% of EU energy from renewable sources, and a 20% improvement in energy efficiency by 2020 – medium and long-term targets have become even more challenging.
The European Commission's 2011 Energy Roadmap (European Commission, 2011) defines development routes and priority investments needed to foster renewable energy penetration, energy efficiency increase, and to smarten grid infrastructure. The final aim will be reducing greenhouse gas emissions by 80-95% by 2050, developing a new social and economic model, called “low carbon” (Aiken, 2012). Within this vision, specific areas are mentioned as key points, as the construction sector, striving for their decarbonization (da Graça Carvalho, 2012). For example, the European Strategic Energy Technology Plan 2008 (SET-Plan) (Commission of the European Communities, 2007) supports the overrun of the “nearly zero energy buildings” concept in favor of “positive energy districts” where smart interconnected efficient buildings produce on a yearly basis more primary energy than what they use. Or the EU “winter package” 2016 (European Commission, 2016) proposing new consumer-centered energy rules to smooth the transition and recognizing how “local energy communities can be an efficient way of managing energy at a local community level by consuming the electricity they generate either directly for power or for (district) heating and cooling, with or without a connection to distribution systems”.
In fact, to achieve this smart energy transition in a fast and efficient way, and to metabolize deep cultural-societal changes, a strong international cooperation is needed. On one hand, sustainable-energy strategies and projects, like those developed since 2008 under the framework of the Covenant of Mayors initiative or within specific calls for funding (e.g. Interreg or Horizon 2020) are strongly encouraged. On the other hand, it is crucial that territorial strategies dealing with a more general cross-border coordination incorporate this new energy paradigm into their governance systems (Osuch, Pawlak and Sowińska-Milewska, 2009).
This is the course of action taken by the EUSALP, the European macro-regional strategy for the Alpine region. So far, there are four macro-regional strategies around Europe, and EUSALP is the newest one, it was launched in 2015 and is going to provide a framework for cooperation, coordination and consultation between and within Alpine states facing common challenges (DG Regio, 2015). It is a great opportunity for stronger regional cohesion and coordinated implementation of sectoral policies among nearby territories, including obviously the energy ones.

In this regard, our paper starts to investigate some crucial points related to following questions:

I. How is the EUSALP territory addressing the energy transition through energy planning instruments and strategies?

II. Are neighbor territories already cooperating to achieve coherent and integrated cross-border energy strategies?

The paper begins offering an overview on the EUSALP, its energy figures and ambitions (section 1). Then it proceeds recalling the materials and data used for the analysis (section 2), leaving to the reader the possibility to explore them more in detail. Finally, it provides some preliminary answers to the research questions (section 3) and draws conclusions, also defining possible future research areas (section 4).

1.2 The macro-regional strategy for the Alpine region

The EUSALP embraces seven Countries, of which five EU Member States (Austria, France, Germany, Italy, and Slovenia) and two non-EU countries (Liechtenstein and Switzerland) distributed around the Alps, a 1,200 kilometers long mountain chain. Austria, Slovenia, Liechtenstein, and Switzerland are entirely included in the EUSALP, while remaining countries only participate with some territories. Figure 1 shows the location of the EUSALP region within Europe and highlights the 50 territorial entities that it embraces (half of them are Swiss cantons, whose borders are not drawn in the map).

Figure 1: EUSALP territory overview by countries. Source: Eurac Research.

Looking at the map it is clear how EUSALP not only deals with sparsely populated mountain areas. It includes also flatlands, where large metropolitan areas are located, and even coastal regions. In total it covers near 10% of the EU surface (more than 470,000 km2), encompasses 16% of the population (about 70 million of EU citizens and 8 million of non-EU), and generates the equivalent of the 20% (3,100 trillion €) of the GDP of the EU (Tomasi et al., 2019). In fact, the EUSALP motto says “mountains and plains addressing together common challenges and opportunities”[i]. Therefore, spatial-socio-economic heterogeneity matters in the EUSALP and it must be carefully considered by its governance board in the development of actions within the three thematic policy areas (economic growth and innovation, mobility and connectivity, environment and energy) and in the cross-cutting one (governance).

In particular, there are nine Action Groups (AG) in charge to translate the identified issues and potentials into concrete actions and more specifically the AG9 has the mission to "make the EUSALP territory a model region for energy efficiency and renewable energy" (DG Regio, 2015).

The AG9 has some specific objectives, namely:

I. setting up an Alpine energy efficiency cluster. This cluster should serve as a forum for cooperation and innovation, bring technical solutions for the specific energy needs of the Alpine Region, and develop energy efficiency processes and products particularly adapted to the Alpine Region, especially in the housing and mobility sectors;
II. greening the Alpine infrastructure: focusing on energy efficiency in the building sector and promote harmonized, affordable and operational assessment tools to be used by public authorities in order to boost sustainable and low-carbon buildings in the Alpine Region;
III. setting up an Alpine renewable energy cluster while taking into account ecological, economical and land use issues and considering societal trade-offs;
IV. support energy management systems in the Alpine Region by developing, sharing and installing energy efficiency and decentralized monitoring systems at the local level and by promoting regional energy monitoring;
V. support a better use of local resources and increase energy self-sufficiency while reducing impacts on climate and the environment.

Current energy consumption in the EUSALP amounts to some 2,300 TWh/year. On average, each EUSALP inhabitant has a per capita consumption of 28 MWh/year, which is slightly above the EU-28 average (25 MWh/year). The share of renewable energy sources (RES) in heating needs in the EUSALP territory rounds 21% (slightly better than EU average) mostly thanks to biomass. On the contrary, the share of RES in the electricity generation is quite high (40% against EU average 29%), especially due to a strong and well-rooted hydropower production in the core Alpine territory (Tomasi et al., 2019). Thus, there is room for improvement in several areas, in order to become an "exemplary territory" in energy efficiency and share of renewable energy sources.

2. Research materials and sources

It is clear that to achieve the above-mentioned energy-related objectives it is fundamental to gain knowledge of the status quo of EUSALP energy balances, energy strategies, targets, and expectations expressed by the different territories. To define the overall picture and to better understand peculiarities, the AG9 developed in 2017 an online energy survey. Results of this survey have been summarised into the "EUSALP Energy Survey Report 2017" (Bisello et al., 2017). Integrated by further desk research, they are the basis of this paper and have been used mainly to answer the first question. The second point has been addressed by investigating one fundamental international cooperation programme in the Alps: the Interreg Alpine Space programme. This programme is financed through the European Regional Development Fund (ERDF) as well as through national public and private co-funding of the Partner States. In the current programming period, 2014–2020, the programme is investing €139 million in projects through which key actors develop shared solutions for prevalent Alpine issues (www.alpine-space.eu). These projects have on average 85% EU co-financing rate.

3. Main findings

3.1 Energy strategies and planning instruments of the Alpine territories

In order to shed light on the current energy strategies within the EUSALP, data about existing energy transition visions and their implementation has been retrieved through the "EUSALP Energy Survey 2017". Data entered by the respondents has been checked and integrated by desk research when missing or incomplete. Aiming to draw a broader context of energy planning, national and European energy plans and strategies have been added to local energy transition planning instruments. The final list consists of 125 documents that can be classified as energy laws, programming documents, and planning operational instruments. Among them the broad majority addresses energy transition in general, 11 focus on the expansion of RES, three on energy efficiency and two on air emissions. Each local, national and supranational energy strategy and planning instrument has been then further characterized by its publication year and finally compared. Figure 2 depicts an overview of recent energy strategies and planning instruments developed within the EUSALP area, and compares local instruments to national ones, while Table 1 synthesizes the steps of development of the European energy strategy for the medium as well as the long term.

As predictable, the planning of energy transition in the European member states follows the adoption of the European energy strategies. In fact, Austria, Germany and Italy published their first energy strategies between 2010 and 2011. Moreover, even if Slovenia never succeeded in releasing the new National Energy program, which should replace the old one, it adopted manifold sectoral action plans in the last decade (Ministry of Infrastructure, 2010). Moreover, a new regulatory impulse is taking place, as Austria, Germany, and Italy published new energy plans very recently (2017-2018). Liechtenstein, even if not an EU member State, adopted its medium term energy strategy in 2012, and recently monitored the state of its implementation.

A similar trend also characterizes the energy strategies of the EUSALP territories belonging to EU-member states, except for France. In fact, they generally developed local energy transition programs and planning instruments after the entry into force of national regulation.

On the other hand, Switzerland shows an opposite trend: the majority of cantonal energy strategies are prior to the federal energy strategy, which sets energy transition objectives and principles to be reached by 2050. The Swiss federal energy strategy is characterized by the need for progressive withdrawal from nuclear energy production. Germany too has developed its energy strategy, which stresses the urgency to define a nuclear energy exit, following the dramatic events of Fukushima in 2011. Even if a few local energy strategies of Swiss cantons state the willingness of decreasing and ultimately stop electricity production from nuclear plants in the next future (e.g. Schaffhausen and Thurgau), the majority of cantons released their energy strategies before 2011, and have not renewed them more recently.

	Year	Strategic document / Initiative	Focus

3.2 EUSALP energy targets – increasing RES in the medium term

Increasing the share of RES in gross final energy consumption is one of the three fundamental objectives for climate and sustainable energy identified by the EU (European Commission, 2010). The other two concern the reduction of greenhouse gas emissions and the savings in primary energy consumption. Similarly, in their energy strategies, the EUSALP territories set the goals and commit themselves to reach them within a certain target year, defined in the medium or long term. Although the majority considers the 2020 as medium term target year, a few commit to reach them within the 2025 and some others the 2030. Here the medium term targets of share of RES have been considered; data about such goals has been retrieved via the "EUSALP Energy Survey 2017" and if missing it was integrated by further desk research. Switzerland has been treated as a whole due to generalized lack of data about the cantonal medium term targets of renewable energy penetration in the energy mix.

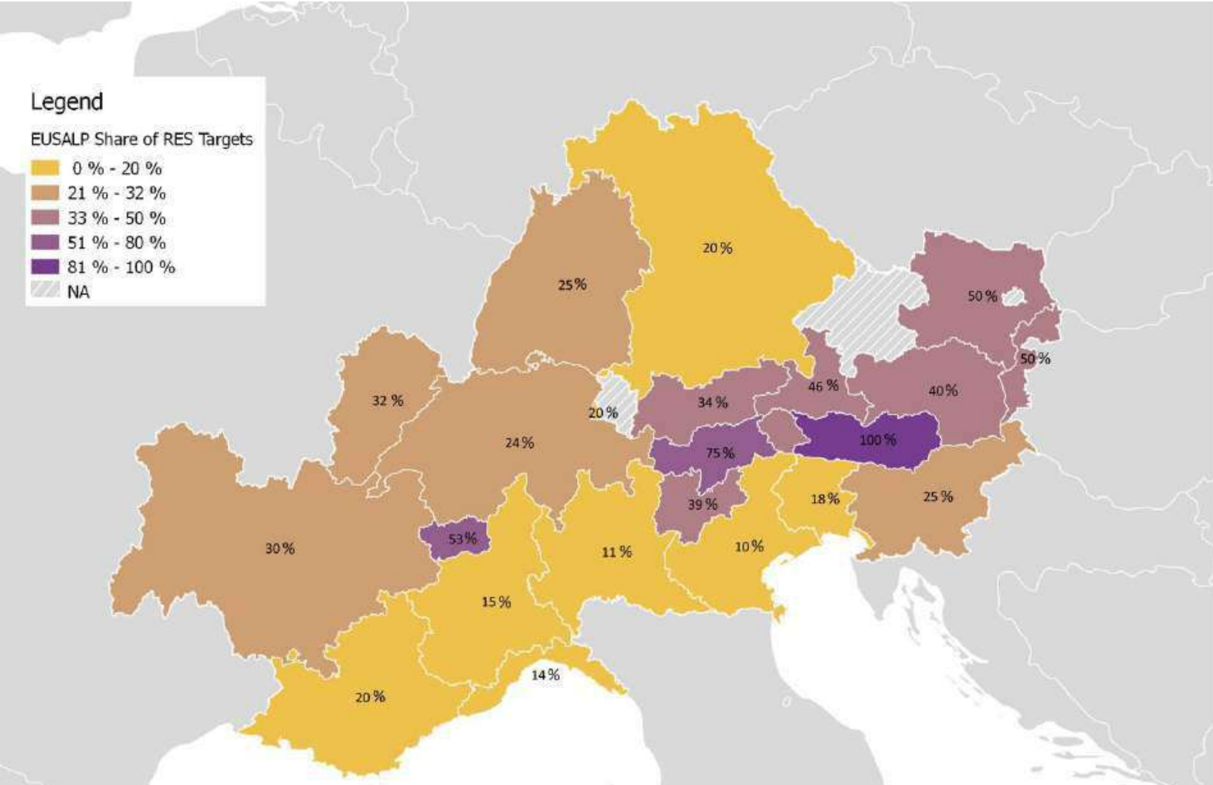

Figure 3: Share of RES in the medium term targets set by the EUSALP territories. Source: EUSALP Energy Survey 2017 and Eurac Research elaborations.

The spatial analysis of the data about the targets returns a heterogeneous picture of the EUSALP area: in general, more extended and industrialized territories show lower RES targets, while the core alpine and less densely inhabited regions seem to be more ambitious in setting their medium term targets, as figures in Table 2 demonstrate. In the specific, as Figure 3 shows, those EUSALP territories that are more peripheral set energy targets below the 20%, as well as Liechtenstein that, although not being an EU member state, appears aligned with the European energy targets. On the other hand, Slovenia committed to go slightly beyond the energy objectives set by the European Commission, as well as Switzerland, even if this latter is not a EU member state. The Austrian regions, at least those providing data, are more ambitious; in fact, they strive to cover up to the 50% of their energy consumption with RES. Two Italian core alpine provinces intend to perform even better in the medium term, namely South Tyrol and Valle d'Aosta. Finally, the Austrian region of Carinthia stands out, aiming to fulfill its energy transition by 2030.

	Population	% EUSALP	Surface	% EUSALP
Group 0% - 20%	39,883,432	50%	182,743	39%
Group 21% - 32%	30,082,001	38%	183,592	39%
Group 33% - 50%	4,948,321	6%	65,597	14%
Group 51% - 80%	646,816	1%	10,653	2%
Group 81% - 100%	557,047	1%	9,542	2%
NA	3,608,309	5%	15,017	3%

3.3 Energy cooperation within neighbor territories in the Alps

Both the management bodies of EUSALP and Interreg Alpine Space (AS) programme foster synergy between the EUSALP AGs and the Interreg Alpine Space projects. AS projects directly contribute to the implementation of the macro regional strategy because the majority of territories eligible for funding are within its borders. As shown in Figure 4 the core Alpine area is also interested by the Alpine Convention, which is an international treaty between the Alpine Countries (Austria, France, Germany, Italy, Liechtenstein, Monaco, Slovenia and Switzerland) as well as the EU, for the sustainable development and protection of the Alps[ii].

Figure 4: Overlapping perimeters of EU Alpine Space Interreg programme (red), EUSALP macroregional strategy (blue) and Alpine Convention international treaty (green).

As Table 3 reports, currently there are ten approved projects in the period 2014-2020 under the priority axis "Low-Carbon Alpine Space": seven addressing the specific objective (1) to establish transnationally integrated low carbon policy instruments, and those remaining the specific objective (2) to increase options for low carbon mobility and transport[iii]. The overall budget allocated for cooperation projects under these topics touches €25 million and projects are working in close cooperation with various EUSALP AGs.

Project acronym	Map Key	Project name	AS Specific Objective	N° of Partners	EUSALP AGs	Project budget
CaSCo	1	Carbon Smart Communities	1	11	2 - 9	€ 2,291,187
CESBA Alps	2	CESBA Alpine Space – Sustainable territories	1	11	9	€ 2,818,739
GREENCYCLE	3	Introducing circular economy system to Alpine Space to achieve low-carbon targets	1	9	2 – 6 – 9	€ 1,946,271
GRETA	4	Near-surface Geothermal Resources in the Territory of the Alpine Space	1	12	9	€ 2,962,952
IMEAS	5	Integrated and Multi-level Energy models for the Alpine Space	1	12	9	€ 2,146,210
PEACE_Alps	6	Pooling Energy ACtion plans and Enhancing their implementation in the Alps	1	10	9	€ 2,148,879
THE4BEES	7	Transnational Holistic Ecosystem 4 Better Energy Efficiency through Social innovation	1	14	9	€ 2,900,412

						€ 24,784,430

Table 3: Co-funded AS projects under the "Low Carbon" priority axis in the period 2014-2020. Data source: Alpine Space project database and Eurac Research elaborations.

The overall number of involved legal entities is 93, lower than the algebraic sum of consortium members, because the majority of them only participates in one project, but a few are involved in multiple initiatives (partners are 36% public authorities and energy agencies, 38%R&D institutions, 13% NGOs, and 6% business entities and SMEs). The most active is in fact the French energy and environmental agency "Auvergne Rhone-Alpes Énergie Environnement", with seven running projects. Far behind are the Slovenian research institute "E-Zavod" and the Italian regions of "Piemonte" and "Lombardia" having four projects each one. Then come another Slovenian institution called "BSC, Business Support Centre, Kranj", the German NGO "Climate Alliance" and the "Liechtenstein Institute for Strategic Development", each with three projects. Seven entities are members of two project consortia.

Considering the amount of different entities, the most represented State is Italy (some 30% of the total partners are Italian), then comes Germany (22%). The two non-EU countries Swiss and Liechtenstein lie at the bottom of the chart, having respectively 5% and 2%. Remaining countries count 13% each. Italy is also the most frequent leader, coordinating four projects, while non-EU countries never appear in this role.

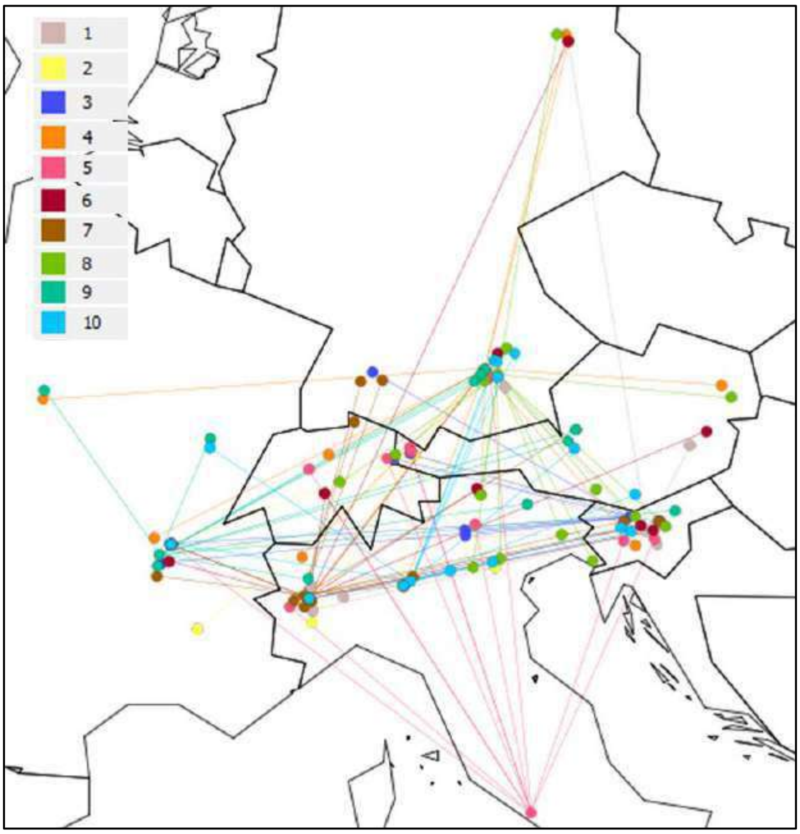

Figure 5: Network of relationships in energy related AS project.
Source: Eurac Research elaborations.

Thanks to the software Gephi (https://gephi.org/) it was possible looking more in details at the geographical distribution of partners and networks defined by projects (see Figure 5). The German state of Bavaria, Slovenia and the Italian region Veneto are the more active (each one 13-14%). Just by adding those coming from the French region Auvergne-Rhône-Alpes (8%) is covered almost half of current partners in the entire Alpine Space Programme (48%) related to low carbon objectives. At the opposite, near four fifth of Swiss cantons, half of Austrian states and one Italian region (Liguria) never provide consortium members. A few partners have the legal seat outside the EUSALP borders.

Partners from Bavaria, Slovenia and the Veneto region actively cooperates in seven out of ten project, forming the stronger territorial relationship in the EUSALP area, which involves only the eastern side, although among non-adjacent territories.

Coming back to the most active single legal entities and cross border international relationships, it comes out that “Auvergne Rhone-Alpes Énergie Environnement” often cooperates with research institute “E-Zavod” and the “Piemonte” region. Inter-regional cooperation within national borders is particularly evident in Italy between “Piemonte” and “Lombardia” regions that join three projects together.

4. Conclusions

The paper discusses the results of recent research on energy issues related to the Alpine Macro-Regional Strategy – EUSALP, and ongoing cross-border cooperation. EUSALP is promoting the idea of a unified and harmonized approach to the energy transition. Even if this aim is highly recommendable, the status quo is quite different for several reasons. Some of them relate to geographical, social and economic characteristics of the territories, while others to historical reasons and different national policies and strategies. Renewable energy targets widely differ in times and ambition, although the general aim is to increase the share of RES replacing fossil fuels or nuclear plants, and some clusters of territories sharing a similar effort in the energy transition can be identified. Further research should explore which features possibly explain such clustering. Once again, different strategies and context define various trajectories. Given that, much more effort is needed to combine them in a rational way and to find synergies. We suggest to repeat this analysis in the next future to monitor if local territories will follow national regulatory momentum. This will help us to answer in a more robust way the question "Is there a regulatory push from the supranational (EU and other transnational initiatives) to the national, and finally the local regulatory level, or are local territories pushed forward in the governance of energy transition by other drivers?". An effective planning and monitoring system for the strategies implementation that allow to harmonize the initiatives and track the progress made would be desirable, as well as assessing the co-benefits that coordinated energy transition strategies can deliver to the society, exceeding the avoided CO_2 emissions (Bisello et al., 2017)

Concerning the second point of our investigation, it results that cross-border regions in the EUSALP are already actively involved in several projects, aiming to share best practices, define guidelines and disseminate insights on specific energy technologies, certification tools and modeling approaches. Some "cooperation patterns" are recognizable, showing attitude of local entities (mainly public administration and NGOs) to interact with nearby and non-adjacent regions. The presence of business players and SMEs should be encouraged, to reinforce the quadruple helix concept (Carayannis and Campbell, 2010), enabling regional innovation ecosystems to properly growth, defining smart specialization strategies (Vettorato, 2017). On the other hand, still too many territorial entities are not involved in energy related Alpine Space projects. Moreover, joint projects aiming to design and implement a coordinated regional energy planning system are still missing. Further projects addressing cross-border energy planning and monitoring should be encouraged through EU funding programs, involving all the EUSALP territories sharing similar ambitions and eager to overcome recurrent problems. To harmonize targets and approaches a voluntary initiative similar to the well-known Covenant of Mayors (addressing the regional dimension in planning for adaptation and mitigation instead of the urban one) could be useful. Insights gained from EUSALP research are replicable in other cross-border regions that promote a sustainable and smart energy transition (e.g. the EU Macro-Regional Strategy on the Baltic Sea Region – EUSBSR, the EU Macro-Regional Strategy on the Danube Region – EUSDR, the EU Macro-Regional Strategy on the Adriatic and Ionian Region – EUSAIR).

5. Acknowledgment

The authors are extremely grateful to the Agency for Energy South Tyrol - CasaClima, and all members of EUSALP Action Group 9 and contact persons involved in filling the EUSALP Energy Survey 2017 for the time and effort dedicated.

The authors would also like to acknowledge the colleagues of the Urban and Regional Energy Systems group of the Institute for Renewable Energy at EURAC Research, who supported and contributed with their expert knowledge to this research, in particular Giulia Garegnani for sharing with us the information on Alpine energy projects.

Usquare.brussels a resilient planning approach

Bonhomme, Geraud, BRUSSELS, Belgium

ABSTRACT:

Brussels-Capital Region acquired former barracks with a remarkable heritage and located in the heart of the city. The purpose is to convert them in an international university resilient district by incorporating the principles of circular economy and sustainability at all stages of the project.

Ambitions: localizing global Agendas for climate-proof and resilient cities

Climate crises, scarcity of resources, urbanization, social dualisation: our societies and our environment are in movement. Planning must anticipate these fluxes. It is no longer possible to underutilize land, waste resources or demolish and rebuild buildings.

It is essential for local authorities to engage in the fight against climate change by adopting resilient planning approaches. The Usquare project propose to tackle this issue.

Programming: combining heritage, circular economy, sustainable development and knowledge

Brussels-Capital Region will set the vision for the site, finance and supervise its conversion. Europe will also co-financed the creation of an inter-university cluster for sustainable development (ERDF program 2014-2020)

Use of the buildings will be maximized to be converted into:

600 housing for international students,

200 affordable housing,

a residence for university researchers,

a student counter,

a fab-lab / incubator for innovative young entrepreneurs

an inter-university research cluster for sustainable development ,

an interpretation center presenting university research on sustainability,

neighborhood facilities,

a cultural center.

Moreover the merry-go-round will be converted into an educational food hall hosting a local and sustainable food market and craft-food activities.

New resilient planning approach: linking spatial planning and circular economy

Brussels-Capital Region has decided to develop a new resilient planning approach by linking two new regional tools:

Spatial planning tool called PAD (Plan d'Amenagement Director / Master Development Plan). The innovativeness of this tool is to combine regulatory components with strategic ones. It is also a flexible planning tool able to evolve with the time and accommodate new uses and needs of residents, inhabitants and universities.

Circular Economy tool called PREC (Plan Regional d'Economy Circulaire- Regional Plan for Circular Economy). This tool has already received two European awards for its innovativeness by combining sectoral actions with territorial ones in order to implement this new economic model.

Strategic components for sustainability:

The Master Development Plan (PAD) defines program of assignments, structuring of roads and public spaces, characteristics of constructions, heritage protection, mobility and parking.

It intends to use this heritage as a factor of identity. The integration of the site in the city will be done via the planning of access from outside and two major public spaces with a social and environmental vocation (rainwater management, temperature regulation, biodiversity and vegetation mesh).

Regulatory components for sustainability:

The PAD requires reconversion to ambitious energy consumption objectives, local water management, and energy or agricultural production of roofs. It drastically restricts the presence of motorized vehicles and encourages active modes (maximized bicycle parkings, internal and external cycling routes).

Circular economy and sustainability approach

The PAD carries in its strategic part the main objectives of sustainability: circular economy of the building sites and the activities to be established, energy performance, integration of the publics, evolution of the buildings and modularity of the public space.

Moreover a project of transitional occupation of the site until all permits are delivered is being studied. Amongst other purposes, it would allow universities to make research on the circular economy model that could be used for the reconversion of the site itself

Conclusion:

We do believe the next ISOCARP Congress will be an appropriate opportunity to present our project and exchange with the participant on how spatial planning could help to fight against climate change.

Study on the Framework of Water Environment Layer in Urban Layer System

1. Lulu CHEN, Harbin Institute of Technology, China.

4. Binxia XUE, Harbin Institute of Technology, China.

Abstract
Many city issues have emerged during city development and environmental changes, which mostly are due to the weak organization among city elements, therefore affecting the city physical spatial morphology. Urban design therefore should comb the relationship among city elements. The contemporary urban design has additionally had the research in elements in recessive ecology, culture and civilization while the traditional urban design focuses on the external elements of city physical space. The era of big data, meanwhile, provides a large amount of data information about them. Urban design, as a kind of graphic language, should combine the graphic information with data information. In this paper, the concept of urban layer is proposed to determine its characteristics and content with an attempt to comb and integrate city elements using urban layer system. And the superposition of urban layers is also applied to analyze how urban elements affect city spatial morphology .
The key of this paper lies in the urban water environment layer in urban layer system with the structure of urban water environment layer. Based on the comb and summary of the existing urban design theories related to urban geography and water, the relevant elements and urban maps, which affect urban design, are selected, extracted and integrated to establish the framework of urban water environment layer and its content and elements.
Beijing, as the capital of China, has drawn worldwide attention in its construction. In this paper, environment layer in urban layer system is initially applied in general urban design projects of Beijing waterfront. The author has tried to guide urban spatial morphology and urban design project of Beijing waterfront through the analysis, comb, superposition and research of waters and waterfront water environment within Beijing downtown area.

Keyword
urban design; urban layer; urban water environment layer; Beijing City; waterfront urban design

1. Introduction

1.1 The focused research of urban connotation in contemporary urban design

The traditional urban design theory focuses on studying the urban spatial form. However, contemporary urban design is not only a study on the dominant urban physical space, and also studies the recessive urban ecological environment, urban cultural connotation and human needs. So that, it can make urban design more comprehensive.
City internal recessive attributes directly or indirectly affect the external urban spatial morphology. Urban design therefore should comprehensively consider the elements in each level, which affects urban development, with the analysis, research and integration. urban layer research framework of urban design is established to clearly comb each level, elements and their inner relationship ,which affect urban design.

1.2 Problems of relationship organization among urban elements

As city develops and environment changes, many city issues and contradictions have appeared. For instance, city construction has led to water depletion and urban ecological environment deterioration has caused microclimate issues. Many city issues are mostly due to the weak organization among city elements, therefore affecting the city physical spatial morphology. Urban design therefore should comb the relationship among city elements. Urban layer system framework is therefore established to analyze the specific content of elements, affecting urban design, and the dominant and recessive relationship between them, as well as the influence on urban physical space from urban elements, single superposition or superposition of multiple layers.

1.3 Combination of graphic and data urban design

As a graphic language, urban design is expressed and controlled through different types levels of diagrams. Because of the era of big data, many scholars from different areas have studied various urban maps by using data and urban geographic map, such as, urban climate map, urban block map, citizen ideology map, urban noise map, and so on. urban layer system is established to integrate all urban data, maps, elements, and layers so that data, information and graphic language can be more used systematically in urban design.

2. Urban design and urban layer system

2.1 urban layer and urban layer system

Urban layer refers to the elements and relationship among them in the city, such as physical space, ecology, economy and humanity. It includes the visual dominant information and hidden information of each urban element, a dynamic information carrier. Each urban layer is composed by certain elements. These layers constitute the entire urban layer system through the superposition. Each layer in layer system is a certain relatively independent variable, which may be relevant to other variables and can be shown in layer groups according to different requirements.

Urban layer system covers all kinds of elements which affect urban spatial morphology, which is controlled by each element of the city through the superposition of layers. In urban design, it's can be found how single urban layer or multiple urban layers affect urban physical space. The influence of urban layers on urban design can be single or overlapped.

2.2 Urban layer and urban subject map

Urban subject map is a graphic language which can perfectly display one or several urban natural or social elements, an map with specific content, such as urban functional zoning map and map of urban underground pipes. In urban design, urban subject map is a visualized urban element or geographical information carrier of a group elements, which express the instantaneous information, static information and visible relationship of this element or groups. It is the geographical identification of this element or groups in urban layer. In additional to the visible relationship from the urban subject map, urban layer also includes the hidden recessive relationship within or among elements, indicating the collection of urban subject map and internal relationship.

Urban subject map, as a collection of one or a group of elements of urban layer, is the graphic expression of its information relationship, which is usually show in urban geographical map for the convenient of analysis, superposition of layers and guidance for urban design project. Urban subject map may be specific only for one certain urban layers, not all urban layers.

2.3 Urban layer system and urban subject atlas

Urban subject atlas, as a kind of information evaluation tool, integrates geographical distribution, analysis and planning recommendation of one urban subject element. The conditions and relevant issues of one urban element are shown on two dimensional map, visualizing urban element information. Urban planners can easily obtain relevant urban element information through urban subject atlas and make right evaluation together with city land use and city development trend. Ultimately urban subject atlas could provide guidance for the practice of urban planning.

Comparing with the existing urban subject maps, urban subject atlas also include the analyzed map and planning recommendation map of the elements. Such as, the existing urban climate atlas contains urban maps of elements related to urban climate, urban climate analysis map, urban climate planning recommendation map. All maps are drawn on the basis of urban geographical maps.

Urban layer system include several urban subject atlas as well as the recessive relationship and dynamic changes among all the urban subject atlas. It's more complex in dimensions and relationships than two dimensional urban subject atlas. Figure 1 shows the relationship among urban elements, urban subject map, urban subject atlas, urban layer and urban layer system.

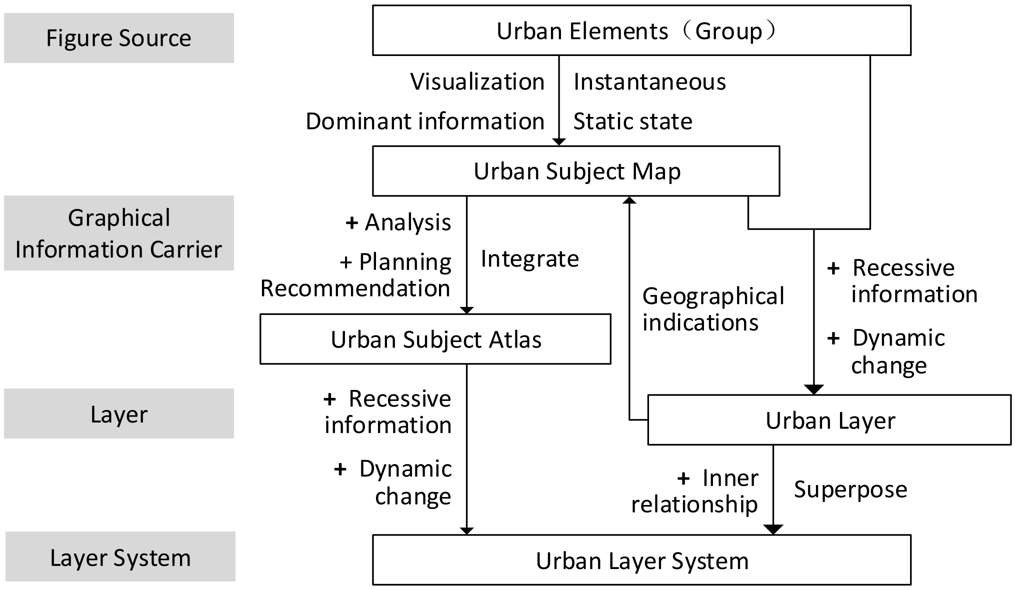

Figure 1: The relationship among urban elements, urban subject map, urban subject atlas, urban layer and urban layer system

Figure sources: drawn by author.

3. Multiple dimensional urban layer system

Most of the urban designs in China are vertically spatial planning and design. The temporal dimension usually takes into account of the construction order, namely phase planning of the future development and construction. But urban design should include more dimensions and contents. Urban layer system firstly should include the visible vertical space, which belongs to horizontal dimension and longitudinal dimension. Additionally, some recessive dimension and content should also be concluded. In temporal dimension, urban layer also should consists of the historical evolution rules except for the future development order. Urban space affords citizen life and spiritual demands, which also should include spatial symbolic dimension. So that, urban layer system should be a four-dimensional system. It contains horizontal dimension and longitudinal dimension, which are dominant. And also contains recessive temporal dimension and symbolic dimension, which are recessive (Figure 2).

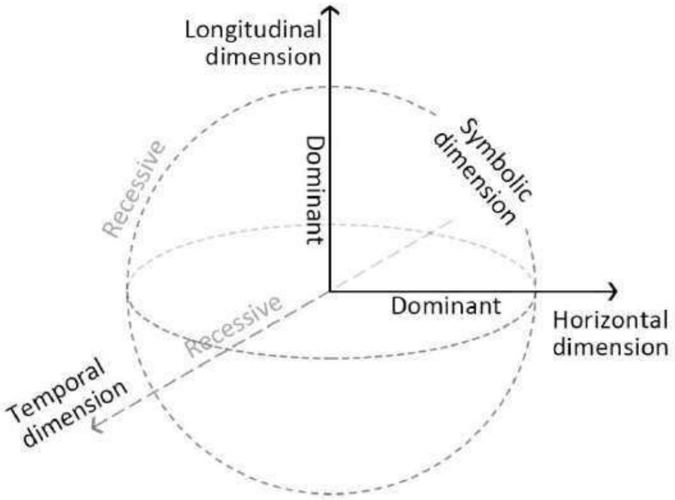

Figure 2: Four-dimensional analysis of urban layer system

Figure sources: drawn by author.

3.1 Horizontal dimension

Urban layer system should corresponds to all kinds of practical urban design projects. In China, urban design is generally divided into 4 levels: comprehensive urban design, district urban design, plot urban design and subject urban design. Urban layer system should consider the macro level, meso level and micro level, so that it can be able to cover all different scales of urban design projects (Figure 3). For different scales of urban design, urban layers and elements are different. Each level of urban layer and elements should have a certain degree of independence, so that they can adapt to the changes of urban design at this level. At the same time, in addition to considering the content of each level separately, it is necessary to link different scales. The layers of each level contain the elements and layers of the next scale, and the layer itself is integrated into a higher level of urban layer system as an element or layer. Urban layer system must be suitable for all types of urban design projects, such as, urban renewal, new district construction, subject urban design and comprehensive urban design, and so on. Every type of urban design project should has targeted selection of urban layers and elements, and they should be selected based on system relationships.

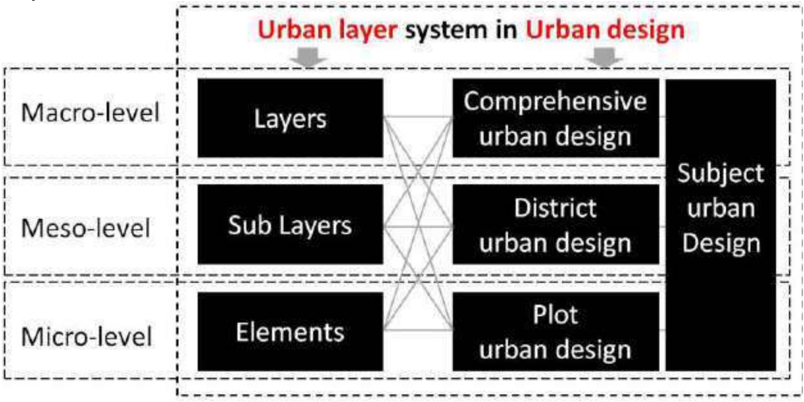

Figure 3: The relationship between urban layer and urban design levels in China
Figure sources: drawn by author.

3.2 Longitudinal dimension

Natural geographical environment of the city is the key aspect to affect urban design, therefore urban layer should consider each longitudinal geosphere, which affects urban design. Within geosphere, earth's crust is mostly close to urban design, which affects urban design through geology, geomorphology, topography, underground resources and geological hazards. Outside geosphere, the close elements include hydrosphere, biosphere and atmosphere (Figure 4). urban layer should consider the relationship between each longitudinal geosphere and urban spatial morphology. In urban layer, hydrosphere should focus on water environment. Biosphere affects urban design through different biological activities. It's emphasized that people's activities are also considered in biosphere in urban layer. The atmosphere should pays attention to the climate conditions in urban layer.

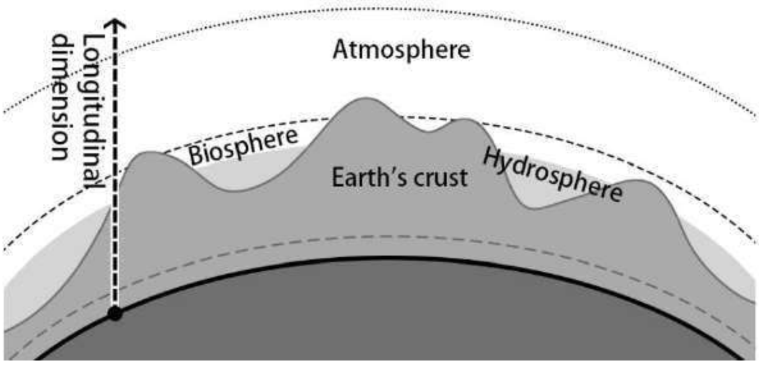

Figure 4: The relationship between the longitudinal dimension of urban layer and geosphere
Figure sources: drawn by author.

3.3 Temporal dimension
City develops gradually and urban layer should be dynamic, which is significantly different from other graphic language of urban design. Without a review to the past, it is impossible to recognize the future. Therefore urban layer should corresponds to the time changes as much as possible. Based on city history, the development rules of the city is combed and analyzed to find out the urban elements and layers with maximized influence on urban physical space as well as determine the dynamic elements. The relationship between single urban layer or element and time changes is discussed. Within several related layers, the changing trend of each layer and changes between layers are also discussed as time changes.
3.4 Symbolic dimension
Urban layer should also consider symbolic dimension besides the common urban physical space, buildings, ecological environment, infrastructure and other entity dimension. The essence of the layer is to express the symbolic information more conveniently through the signs and graphic information. Urban symbolic dimension mainly include sites, citizen's activities and their psychological assessment. Site doesn't develops through city while the city grows up through the site. Site, as meaning space of a city, constitutes most of external space with urban network. Urban layer system physically therefore requires to consider the physical relationship and symbolic connotation of urban sites. Urban design work should include the participants of all the city construction activities beyond the professionals and management staff. Urban design, based on urban geographical images, could express citizen' activities and their psychological assessment more simply, which is convenient to make suggestions to urban design.

4. Establishment of research framework for urban water environment layer
4.1 Idea to build the framework of urban water environment layer
From ancient to modern times, city construction and water are mutually influenced and constrained. Along the timeline of city construction, water is mutually coupled to city siting, development, spatial morphology and function. Urban water environment layer is thus gradually emerged and continuously upgrading as city develops. In urban design, urban water environment layer should be constructed based on the relationship between city and water from ancient to modern times during the city construction period (Figure 5). This paper will starts from city siting, construction and citizen's use and refines corresponding elements. The logic relationship of urban design is applied to integrate urban water environment layers in each period. Beijing waterfront space is taken as an example to further explain urban water environment layer.

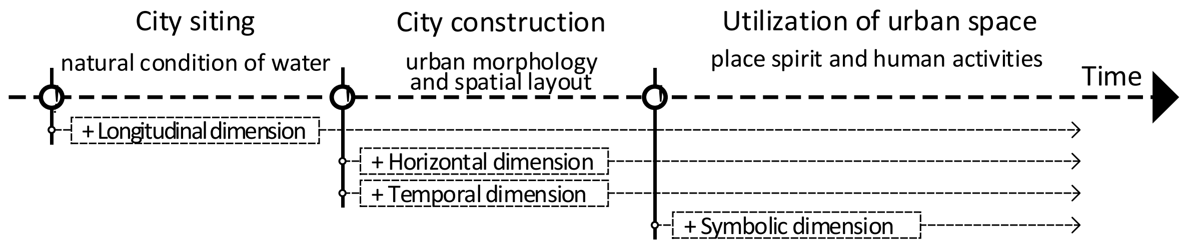

Figure 5: The relationship between urban water layer development and time
Figure sources: drawn by author.

4.2 Water environment layer during city siting period
Water source was undoubtedly the initial consideration when the ancestors decided where to live. Ancient cities almost were built along the water system to use the water conveniently. Water system functions as water source, materials' transportation, farmland irrigation and military defence while also bringing flood disaster and deposition of rivers and lakes. As said in a prose, "Guanzi Chengma", the relationship between water environment and city location is narrated. The capital of a country must be on top of mountain instead of at the foot of it. When living far away from the hills on the high terrain, there is sufficient water and when living far away from the water on the low terrain, there is no need to construct dykes. People

should take advantage of the existing environment and nature, without having to stick to the rules, to further create their own roads. Since humankind's settlement modes and location are related to water source, most of the ancient cities emerged from the water. Water condition will be considered for city siting, which promotes the longitudinal dimension in urban layer (Table 1).

Sphere	**Urban water environment layer**	**Urban design elements**
Earth's crust	Geological conditions	Flood, deposition, freeze and thaw, geological condition for suitable construction
	Terrain and landform	Embankment slope, height, block undulations
Biosphere	Flora and fauna	Vegetation, animals
	People's activities	Water and activities
hydrosphere	Underground water	Location and source of underground water
	Surface water	Water source site, underground basin, flowing direction and water yield
Atmosphere	Water and climate	Temperature, humidity and precipitation

Table 1: Urban water environment layer during the period of city siting
Table sources: drawn by author.

The earliest site for Beijing is Xi, which is the capital of Yan Country (337-370) during the Warring States period. The siting of Beijing City was located on the northwest of the Great Plains of North China, surrounding by mountains on three sides. It's Chexiang River to north and Leishui River to the south, forming a small plains adjacent to the water. Gaoliang River also flowed through the city. This siting mode just accords with the of one water with three mountains in ancient Chinese Fengshui (Figure 6). From the climate environment, Beijing city is one of the areas with most precipitation in North China also with suitable temperature and humidity. In sight of water environment, the underground water reserve of Beijing City is abundant . Water was accessible for digging wells, convenient. The surface water originated from the nearby Yongding River and more distant Chaobai River. All these have affected urban design elements and water environment layer of Beijing City siting.

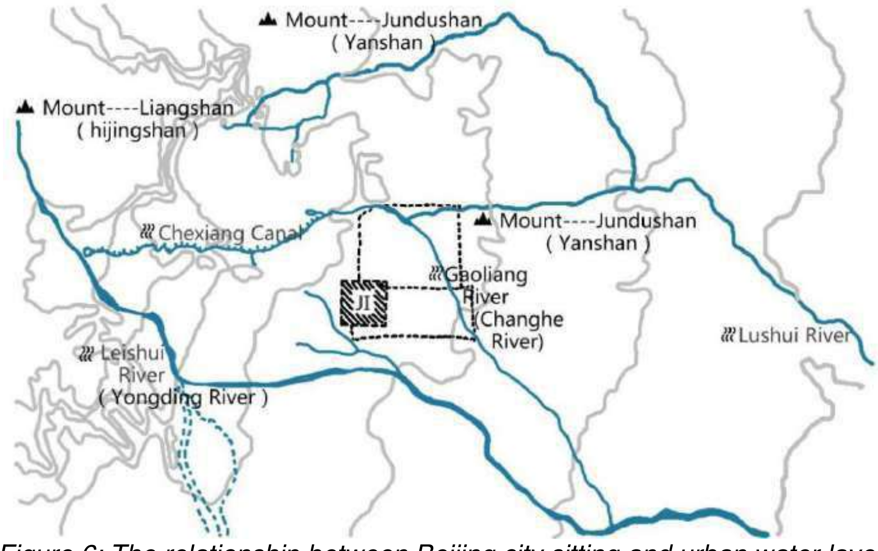

Figure 6: The relationship between Beijing city sitting and urban water layer
Figure sources: drawn by author.

4.3 Water environment layer during city construction period

Comparing with the city siting period, urban water environment has more influence on urban space during the city construction, during which urban water environment layers are mostly related to urban space. In early period, namely the construction process after siting, the influence on urban design from water environment are mainly shown in following aspects. The overall urban pattern is affected from the location of water source, the basin, flowing direction and morphology of the surface water at a macro level. Since urban waters in

different areas function distinctively in the city, the function and morphology layout of urban space surrounding the waters are relatively different as well on the meso level. The morphology pattern of waters and shoreline have affection o the spatial mode and blocks' structure within a certain distance from the waters. Therefore in the urban design of this period, horizontal dimensional urban water environment layers are added.
After city construction, city requirements continuously changes as time proceeds. City will be faced rounds of planning and design and urban renovation. During this long period of urban development, urban water environment will be endowed with corresponding time meaning and historical connotation, namely temporal dimension of urban layer. Therefore urban water system evolution layers and other water environment layers are included in urban design (Table 2).

Dimension	Urban water environment layers	Urban design elements
Horizontal dimension	General urban design The overall urban water pattern	Ecological security pattern of urban water environment , urban surface water basin, urban groundwater distribution, urban water function
	Zoning urban design level Waters and urban space	Water and urban space layout, water and urban ecological landscape space , water and sight
	Plot urban design level Waters and spatial structure	Block's pattern, waterfront space, shoreline and skyline surrounding water
Temporal dimension	Urban water evolution	Urban water function evolution, groundwater distribution evolution, underground water distribution evolution

Table 2: Urban water environment layers during city construction period
Table sources: drawn by author.

Jin Dynasty (1115-1234) moved the capital to now Beijing City from Chang'an City, which is the capital during Tang Dynasty, becoming Jinzhongdu. Starting from Jin Dynasty (618-907), Beijing City began its city construction. During Jin Dynasty, waters in Beijing City functioned as water supply, flood transportation and flood discharge. The water system pattern was set up for Yongding River and Gaoliang River. With the subsequent construction during each periods, the whole urban water pattern was relatively solid during Ming (1368-1644) and Qing Dynasty (1636-1912) for Beijing City, similar to the that of the current Beijing City.
During city construction, Beijing's waterways also have had certain influence on the whole spatial layout and blocks' spatial structure. The most characteristic of planning of imperial palace is that the water surface was taken as the center to determine urban pattern. The following urban planning for Ming and Qing Dynasty also continued this concept that water is taken to determine the city. Therefore Beijing' central axis and natural waters were complemented during Yuan (1271-1368), Ming (1368-1644) and Qing Dynasty (1636-1912), indicating the integration between urban planning and natural water as well as the urban layout with city adapting to the topography (Figure 7).

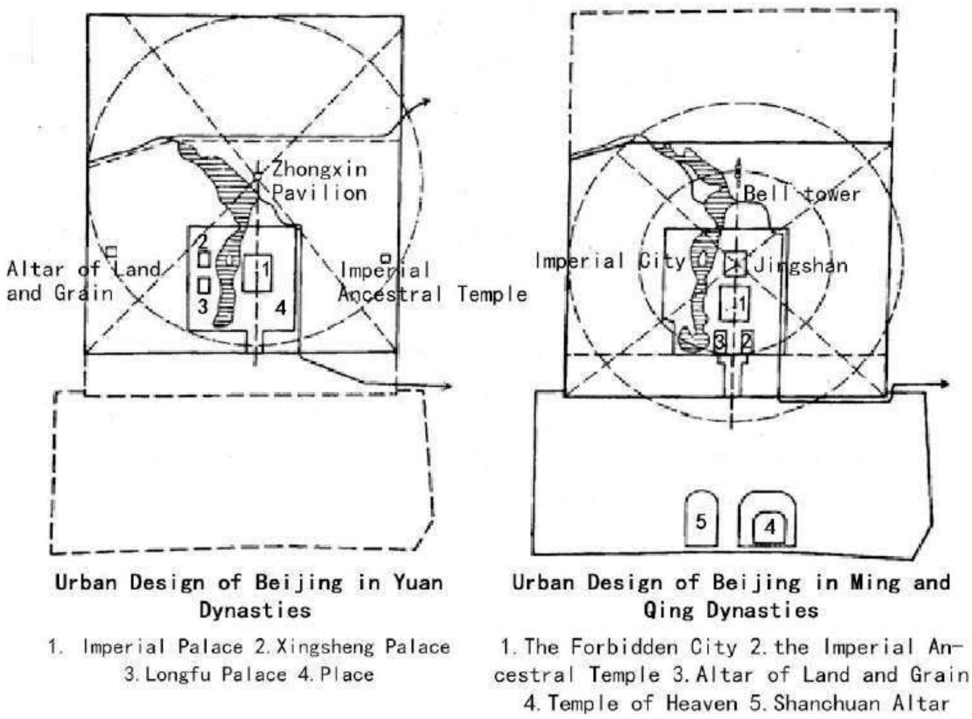

Figure 7: The relationship between the overall spatial layout of Beijing and the water in the Yuan Dynasty and the Ming(1368-1644) and Qing Dynasty (1636-1912)
Figure sources: drawn by author.

The blocks' layout of Beijing City is mostly rectangular in the north-south direction. But to in accordance with shoreline and topography, there are many inclined street in waterfront areas. It's can been the influence of water on urban spatial layout during city construction period (Figure 8). urban water environmental layers for Beijing City have taken urban layout and spatial structure into account.

Figure 8: The inclined street of Shichahai area in Qing Dynasty (1636-1912)
Figure sources: drawn by author.

4.4 Water environment layer during utilization of urban space

After city construction completion, urban space begins to be used by citizens. people and urban water environment interact through citizens' a series of activities in urban water and waterfront space. Then citizen's utilization has endowed urban water environment and its surrounding space with certain meaning of the place. Urban design begins to think out human activities and the spirit of the place in urban water environment. Urban water environmental layer begins to form the symbolic dimension. From the point of human activities, the urban water environmental layer should include urban design elements, such as waterfront activities, activities' facilities and space, service radius of activity space, and so on. The place spirit includes urban design elements, such as urban cultural connotation, historical significance, neighborhood relationship and so on (Table 3).

Urban water environment layer	**Urban design elements**
Human activities	Waterfront activities, activity facilities and space, service radius of activity space
Place spirit	Urban cultural connotation, historical significance, neighborhood relationship

Table 3: Urban water environment layer during utilization of urban space
Table sources: drawn by author.

The initial functions of Beijing's waters were irrigation, water supply and shipping with less activities between people and water. People's activities began to increase after the solid water pattern during Ming (1368-1644) and Qing Dynasty (1636-1912). From the Republic of China, citizens would use frozen rivers to access and make outdoor recreation. As Beijing's waterfront transformation, waterfront space has begun to have the spirit of place with increasing citizen' activities, such as fishing, running and visiting. The current waterfront areas of Beijing can afford the functions of urban cultural connotation, historical significance and neighborhood relationship (Figure 9).

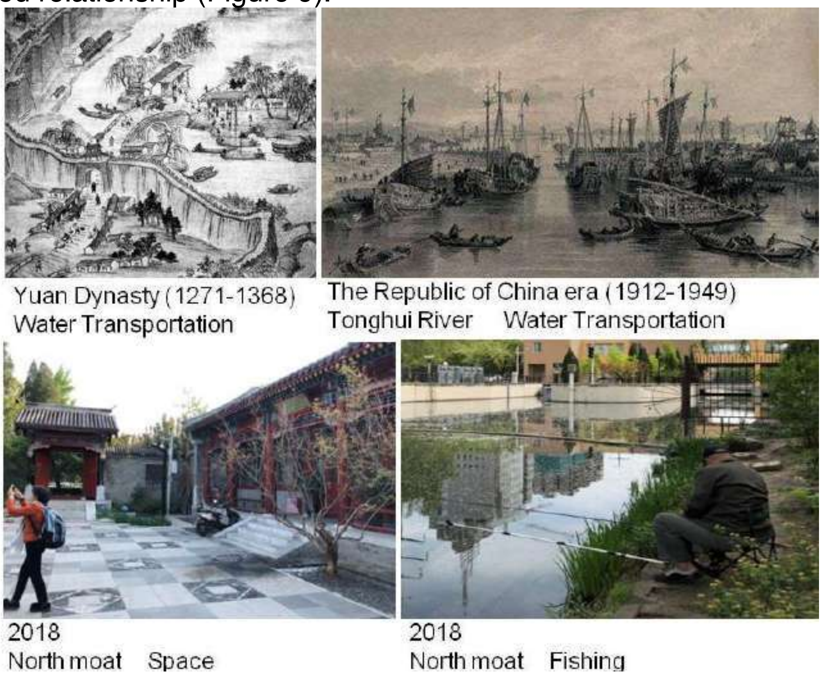

Figure 9: The use of Beijing waterfront in different periods
Figure sources: shoot by author.

5. Conclusion

In this paper, urban layer system is proposed to be set up in urban design, following by the concept interpretation of urban layer, urban layer system, the existing urban subject map, urban subject atlas and others. Meanwhile, the concept of urban layer is explored out from four dimensions: horizontal dimension, longitudinal dimension, temporal dimension and symbolic dimension. Ultimately, the author has attempted to establish the framework of urban water environment layer and Beijing waterfront urban design project is taken as an example to further illustrate the application of urban layer system and water environment layer in urban design from the practice perspective.

Green Warsaw – the future of green vegetation

Karolina CZYZEWSKA, Politecnico di Torino, Italy / Poland

1. Green vegetation on the buildings and its impact on the city

Living in a big, well developed city may be fascinating, but may also lead to a lot of health issues as well as other uncomfortable consequences for the life of its inhabitants.

The city, exposed to a quick, high level development in a very short time is facing problems of Modern civilization, causing around 3000 people dying untimely in Warsaw per year. Trying to solve the problem of the urban heat islands and air pollution taking as example the city of Warsaw I came up with a solution available for new developed buildings as well as a solution easily applicable for already existing buildings. Although green roofs and vertical gardens are artificially created by humans, they can be considered as patches and corridors necessary to achieve landscape continuity in heavily urbanized areas. Vegetation can be used to mask fragments or entire buildings for better correspondence with the surrounding landscape[1]. The research has been focused on 3 main problems in the modern city: How to reduce stress of habitants; How to reduce air pollution in the city; How to solve the problem of urban heat islands.

1.1 How to reduce stress of habitants

Reducing stress of habitants can be achieved by making space not feel overcrowded. Crowding - not density - is the reason of urban stress. With the proper urban planning the space can be designed in such manner that even the most dense areas are not going to feel overcrowded and not being a cause of stress for its inhabitants. Open spaces and park systems applied into the dense area can strongly minimize the stress and raise the livability level. Additionally, green cities equal good health: incite people to practice sport, increasing the possibilities to be close to nature, keep calm, restore the body, mind and soul; incite people to have social interactions. The research proves that green eliminates stress and high level of aggression, soothing the senses[2]. Emotional balance affects employee performance, which is why increasingly green roofs and living walls are used in buildings in which people work.

High density spaces can still remain dense, with the green elements designed on the pieces of architecture, which are not evident and very often forgotten. Top roofs, walls, balconies or terraces should be effectively used as green areas which are able to fulfill at least some of the functions the traditional gardens has.

Figure 1: Overlay on green balconies visualization

Overlay on green balconies have the advantage on green roofs and green walls, that does not necessarily has to be expensive. As an element of a private apartment is extremely easy to implement by independent private customer as much as the building developer. It interacts with the closest environment of the habitant, changing the view but also the air quality and temperature in the apartment. It does make the owner of the balcony feel responsible for his own prosperity and allow him to improve the life quality without necessary contracts, agreements, respecting building law and a structure requirement, which are very often a problem to implement a green walls or green roofs on already existing buildings.

1.2 How to reduce air pollution in the city

Air pollution is an environmental and social issue and, at the same time, it is a complex problem posing multiple challenges in terms of management and mitigation of harmful pollutants. Air pollutants are emitted from anthropogenic and natural sources; they may be either emitted directly (primary pollutants) or formed in the atmosphere (as secondary pollutants). They have a number of impacts on health, ecosystems, the built environment and the climate; they may be transported or formed over long distances; and they may affect large areas. Effective action to reduce the impacts of air pollution requires a good understanding of its causes, how pollutants are transported and transformed in the atmosphere, and how they affect humans, ecosystems, the climate, and subsequently society and the economy[3].

As we can read in the report written by the European Environment Agency (EEA), the air quality in Poland is not very satisfying. Many stations, also in Warsaw are reporting concentration of PM10 and PM2.5 above the EU annual limit value. That means that most of the habitants in big cities are very often exposed to pollutants in and around their homes, which may have very bad effect on their health.

Poland belongs to the countries with the most polluted air. In Europe every year, 45,000 Poles die prematurely due to air pollution, as carcinogenic and mutagenic substances enter the air. Breathing air contaminated with sulfur compounds, dust, benzo (a) pyrene and other harmful substances causes deadly diseases: lung cancer, chronic obstructive pulmonary disease and asthma. Health costs resulting from air pollution estimated for only city of Warsaw is from 6 billion - 18 billion PLN annually.

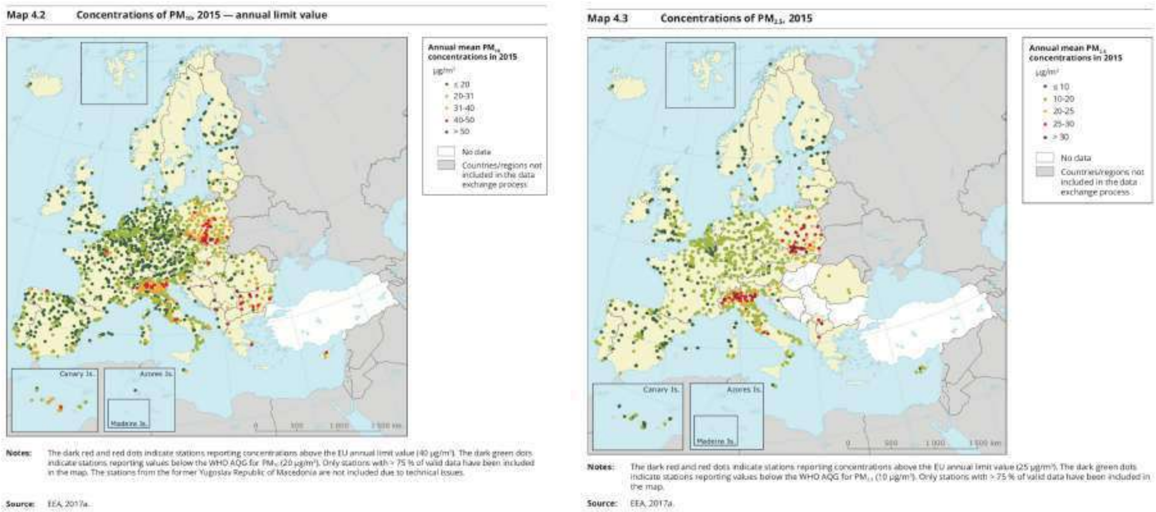

Figure 2: Concentration of PM10 and PM2.5 in Europe[3]

Green areas are not only useful as a space which brings people closer to the nature. It is also a place with plants. And those exact plants may be the solution for the air pollution. The research states that plant leaves as well as certain microbes are able to absorb air pollutants or transform them in less or nontoxic substances.

The average tree produces oxygen of an estimated value of over 30,000 dollars during the 50 years. Depending on the age and species of the tree, these benefits are different - for egzample 60-year-old pine can produce enough oxygen for 3 people, and 100-year-old beech can produce enough oxygen even for 10 people. The work of such a single tree is compared to the work of even 4-5 large air conditioners for 20 hours a day. Therefore, trees can be considered as friends of our wallets - they allow to save up to 30% per year on air conditioning, while in winter they can reduce heating costs by 20-30%[2].

Green infrastructure can directly influence air quality in three main ways: Increase in deposition of pollutants; Altering the wind flow; Emitting biogenic volatile compounds and pollen. Every one of these ways can influence air quality on different scales. The first and the third influence the air quality on a city scale, while the second influences the air quality on a local scale. In addition, there are also indirect side effects.

Studies assume that the deposition of a pollutant depends on the deposition velocity, the well mixed height of the pollutant and the concentration of the pollutant. The deposition velocity of green is in general higher than that of other urban surfaces due to the metabolic uptake by plants, the “stickiness” of the leaf surface, the large surface area of green, and the aerodynamic properties of green. The higher the deposition velocity, the lower the concentration of the pollutant will be and the more deposition.[4]

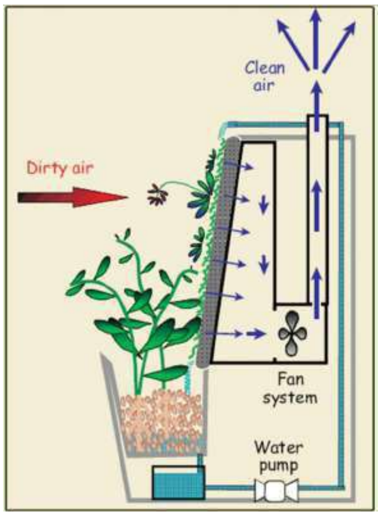

Figure 3: Scheme of cleaning the air by green walls

During past years several studies have been done to understand the impact of plants on the quality of the air. Two different consequences emerged: Phytoremediation and Biofiltration. Phytoremediation can be defined as the use of plants to remove pollutants from the air, water and soil. There are various techniques to do this process. Phytoextraction: the use of plants to clean up pollutants via accumulation in harvestable tissues; phyto(rhizo)filtration: the use of plants in hydroponic set-up for filtering polluted water; phytostabilisation: the use of plants to stabilise pollutants in soil by preventing erosion, leaching, or runoff, or by converting pollutants to less bioavailable forms; phytodegradation: the breakdown of pollutants by plant enzymes, usually inside tissues; rhizodegradation: the degradation of pollutants in the rhizosphere due to microbial activity and phytovolatilisation: the release of pollutants by plants in volatile form.
Biofiltration is defined as the process of drawing air into an organic material, such as soil or plants and removing in that way the gases.[5]

1.3 How to solve the problem of urban heat islands

The Urban Heat Island effect describes the tendency of urban areas to experience higher outdoor air temperature levels compared to their contiguous rural periphery. This phenomenon is mainly attributed to the special characteristics of the urban landscape, including building density, size and orientation, open space configuration, and the use of heat absorbing construction materials, irrespective of global warming. The design of urban landscapes and buildings, including intensive development leading to massive loss of vegetation and pervious surface cover, might increase the intensity of the Urban Heat Islands effect and thus compromise the thermal comfort of people at street level, exacerbate discomfort caused by the overheating of indoor spaces, and increase energy consumption resulting from cooling energy demand in buildings.[6]

Urban Heat Islands are present mostly in metropolitan areas, and are created by energy from people, cars, buses, and trains and other places which have lots of activity and lots of people. It is also connected to the crowding - density problem. Skyscrapers and other high density constructions tends to create a lot of heat which bypasses insulations and having nowhere else to go, ends up between the buildings creating a urban heat island. Again plants are the solution: they help to cool things down. Plants absorb carbon dioxide, a leading pollutant. They also produce a cooling effect on the environment thanks to the process of evapotranspiration: heat energy is lost as water evaporates and transpires from vegetation.

Thanks to the greenery we can lower the temperature in the closest area as a result of the evapotranspiration process in the summer even 2-11oC[7]. In winter, the construction of the vertical garden protects the façade against the impact of wind power, reducing energy consumption for heating. The research shows that green elements installed on the facades of the buildings improves also the microclimate inside the rooms. In rooms with green walls, the temperature is reduced by an average of 5oC, which significantly reduces the energy consumption for cooling by means of air conditioning[8]. Analysis of energy consumption in buildings with green roofs and walls indicates that this type of development allows reducing the cooling load costs in the range of 17-79% per year and 0.6-19.5% in the total energy consumption calculation in the building[9]. A 20 cm layer of soil substrate and 20-40 cm of plant cover has the same insulating properties as 15 cm of mineral wool.[9]

The sources emitting heat radiation are mostly the sun and the surroundings (buildings and ground surface). Some of the sunlight falling on plants and substrate are absorbed and some is reflected and transmitted[10]. The proportion of solar radiation absorbed, reflected, and transmitted varies across type of plants, their different leaf density and colors. Approximately half of solar radiation is absorbed in the plant and the amount of radiation reflection is nearly equal to that of transmission, which mostly ranges from 20 to 30% of solar radiation. The absorptance of plant leaves is strongly dependent on water content, leaf hairs and leaf thickness. Thick and waxy-leaves, such as conifer needles, absorb up to 88% of solar radiation[11]. Plants are an effective reflector and transmitter in long-wave radiation from their ability to reflect 50% of near infrared radiation and they are effective absorbers in the short-wave radiation, particularly photosynthetically active radiation (PAR), which can be absorbed up to 85%.[12] Additionally, heat transfer in the Living Walls is a result of heat exchange by convection between plants and air in the surroundings, plants and air in the canopy, plant and substrate, and substrate and air in the canopy. Conductive heat transfer mainly occurs between plants and substrate and also through the leaf. It is noted that the amount of heat exchanged from leaves to leaves is usually negligible. Apparently, substrate depth is one of the key factors in impeding conductive heat exchange.

Evaporation and transpiration are the important mechanisms to cool down the leaf due to the use of considerable heat absorbed in a leaf[10]. About 60% of the heat accumulated in a leaf can be dissipated by transforming it into latent heat. However, this ratio of latent heat dissipated from the plant to total absorbed radiation by the plant can be highly varied according to wind speed and moisture content of the air. [13]

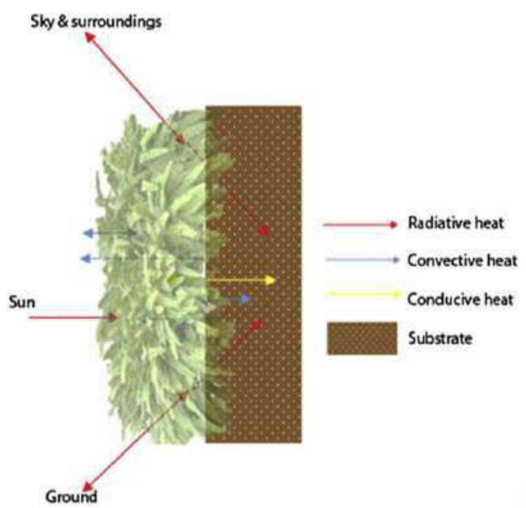

Figure 4: Radiative / Convective / Conductive heat[14]

2. The vision of green balconies as a future of modern cities

Taking into the consideration all the positive impacts of the green walls on the environment but also inhabitants the idea has been proposed to be implemented in some areas of buildings. Green balconies seems to be a great solution independently - or together with green roofs and green walls. It can be implemented by a private investor, which is willing to purchase a plants just for his own balcony, but also by a developer of the building which is willing to implement it to all existing balconies in the building.

Figure 5: Before and After - Ursynów visualisation

2.1 Technological solutions

Currently on the market available are three different systems which can be used for the construction of overlay on green balconies. Each of the solution is different and can be choosen respectively to the expectation of the client and his budget.

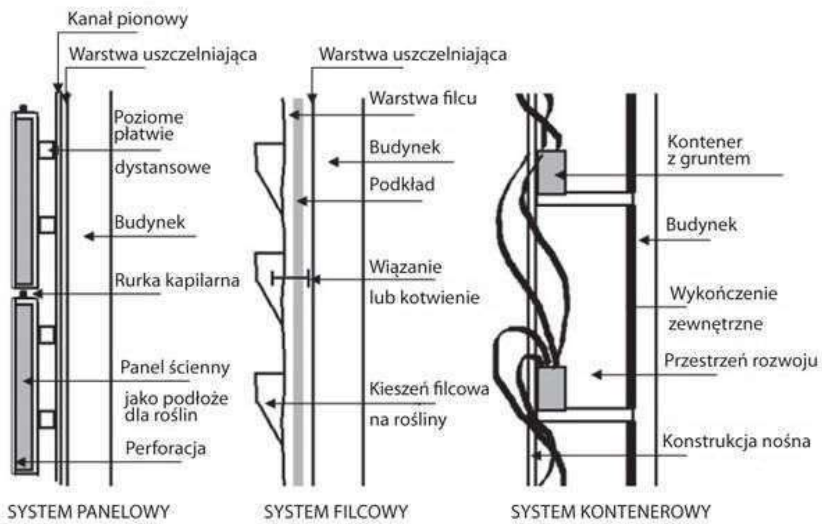

Figure 6: Scheme of three different systems of green walls[15]

Nature based solution, green infrastructure and ecosystem services: a framework for understanding and creating resilient urban ecosystems

Claudia de Luca, Alma Mater Studiorum, University of Bologna, Italy
Elisa Conticelli, Alma Mater Studiorum, University of Bologna, Italy
Simona Tondelli, Alma Mater Studiorum, University of Bologna, Italy

Synoptic:

Climate-proof cities rely on Nature-based solutions, green infrastructures, ecosystem-based adaptation and ecosystem services to create resilient urban ecosystems. Nevertheless, the relation among these concepts is still not completely clear. This paper aims at providing a better understanding of these concepts and of their integration into urban planning, to support cities embedding those within their plans.

1. Introduction

'Everything you can imagine, nature has already created' (Einstein).

It is now widely recognized that human activities have reached a level that could result in abrupt and, in some cases, irreversible environmental changes detrimental to human development (Eggermont, H.et al., 2015). Societies face increasing challenges such as climate change, jeopardized food security and water resource provision, and enhanced climate related risks, such as floods, drought, cloudburst, heat waves, etc. In this regard urban areas, with around 60% of world population living in cities, will face even greater constraints due to overpopulation, social inequities, environmental challenges, and limited available resources. In this context, Nature Based Solutions (NBSs) can provide a valuable answer to environmental and societal challenges, and can contribute to increase urban resilience.

In the last years, NBSs have entered in the scientific and research vocabulary as an appealing term to define solutions that are inspired by nature and that are able to provide multiple benefit in a range of impact categories (water management, climate adaptation, food provision, urban regeneration, social inclusion, etc.). Although the concept of Nature Based Solutions strongly relies on green infrastructures, ecosystem-based solutions and ecosystem services, the relation among these notions is still under debate in current scientific literature. Moreover, the integration and implementation of those concepts within urban areas poses a great challenge to urban planning and policies, even if, at the same time, it provides decision and policy makers with a unique opportunity to shape future resilient urban ecosystems. The transition from traditional urban planning to an ecosystem approach planning process, sometimes called ecological planning, has been recognized in literature (Ygitcanlar, 2015 and Vasishth, 2008) but is still far from being systematically integrated into cities' plans and strategies. The shift from a mere preservation and conservation of urban ecosystems towards an integrated planning and management of nature based services and solutions is slow, but it will be crucial to develop liveable, health and resilient cities.

The aim of this paper is to present an overview of the different concepts (NBSs, green infrastructure and ecosystem services). First, starting from existing literature, the paper will provide a comparative analysis of the different definitions of the analysed concepts. Secondly, it will investigate an example of integration of such concepts within strategic planning (Greenspace quality, Scotland).

2. Definitions

The idea of finding solutions to the increasing societal challenges that are nature-based is gradually spreading into EU cities and regions. Nevertheless, different terminologies and concepts have been used in the last decades to define instruments, tools and solutions that refer to the use of ecosystems and nature to tackle a broad range of challenges and to improve humans' wellbeing and health. Within the scope of this paper, the focus will lie on the definition and integration of such solutions in urban and peri-urban areas.

2.1 Green Infrastructures (GIs)

Green and blue infrastructures have been identified in the last decades as one of the most interesting and promising strategy for achieving sustainability. One of the first definition of GI has been given by the Conservation Fund (2004) delineating them as 'the interconnected network of natural and semi-natural areas, features and green spaces that support native species, maintain natural ecological processes in rural and urban areas, and contribute to the health and quality of life for human beings' (The Conservation Fund, 2004).

The idea of planning those infrastructures in an integrated and interconnected way always support the concept of GI and the same conservation fund in 2006 renamed them as 'a strategically planned and managed network of natural lands, working landscapes, and other open spaces that conserve ecosystem values and functions and provides associated benefits to human populations, in order to link GI concept closely to its implementation'.

With the same vision and objectives in mind, the EU Commission proposes in 2013 the strategy on green infrastructure to enhance Europe natural capital. Within this strategy, GI are defined as 'a strategically planned network of natural and semi-natural areas with other environmental features designed and managed to deliver a wide range of ecosystem services such as water purification, air quality, space for recreation and climate mitigation and adaptation. This network of green (land) and blue (water) spaces can improve environmental conditions and therefore citizens' health and quality of life. It also supports a green economy, creates job opportunities and enhances biodiversity. The Natura 2000 network constitutes the backbone of the EU green infrastructure'.

Compared with the previous ones, this definition strongly connects GI with the ecosystem services they can provide and it includes at the same level green and blue spaces; moreover, by mentioning Natura 2000 network as the main backbone of EU green infrastructure, the urban dimension of GI appears to be less evident than in the Conservation Fund definition, that was focusing on citizens' health and quality of life as the main impacts to be considered. Nevertheless, as also mentioned by Wang et Banzhaf (2018), the scale, the range, the extent and the implementation of such solutions can strongly vary from case to case as well as the benefits and the impacts they can produce on human wellbeing and health and on the environment. Thus, a strategic planning of such solutions is absolutely needed to maximize those benefits.

In the same line, the definition from the German Federal Agency for Nature Conservation in 2017 considers GI as a 'strategically planned network of natural and semi-natural areas with other environmental features designed and managed to deliver a wide range of ecosystem services. It incorporates green spaces (or blue if aquatic ecosystems are concerned) and other physical features in terrestrial (including coastal) and marine areas. On land, GI is present in rural and urban settings'. In this case, the concept of green and blue infrastructures is highlighted and their integration into planning strategies is strongly supported.

GI concept are also often mentioned in Chinese (Wang et Banzhaf, 2018) ad US (EPA, 2008, Fletcher et. Al, 2014, Coutts et Hahn, 2015) literature, being the concept operationalized at worldwide level.

2.2 Ecosystem services

The definition of ecosystem services (ES) and the huge work that has been done so far to evaluate and assess their values already give a clear idea of the power of this concept and definition. ES have reached a worldwide recognition and found their basis in 2005 with the Millennium Ecosystem Assessment (MEA), an impressive work that involved more than 1300 scientists worldwide. The definition that came out from that momentum summarizes the 'anthropocentric' conception of the term, stating that ES 'are the ecological characteristics, functions, or processes that directly or indirectly contribute to human wellbeing: that is, the benefits that people derive from functioning ecosystems (Costanza et al., 1997; Millennium Ecosystem Assessment (MEA), 2005).

ES have been categorized in 4 different types of services such as provisioning, regulating, cultural and supporting services, each of those providing a different kind of benefits to people. To support the relevance of this concept and reach decision and policy making, different approaches in the last decades have focused their attention mostly on the mapping, evaluation and economic assessment of such services. In particular, at EU level, the Biodiversity strategy requests Member States to map and assess the state of ecosystems and their services in their national territory with the assistance of the European Commission. They must also assess the economic value of such services, and promote the integration of these values into accounting and reporting systems at EU and national level by 2020 (Target 2, Action 5, Biodiversity Strategy). Although most of the attention is focused on evaluating and assessing ecosystem services, it is important to mention also the possible trade off generate by ecosystem to human being, called ecosystem disservices. Indeed allergenic pollen, spread of diseases, etc. should be considered whenever an ecosystem is evaluated.

2.3 Nature Based Solutions (NBS)

'Nature based solutions' is the youngest term introduced in this context and, most likely for this reason, currently the one on which there is less consensus. The first reference to the term nature-based solution can be found in the late 2000s in a report of the World Bank focusing on solutions to mitigate and adapt to climate change (MacKinnon et al. 2008). In this report, attention is mostly focus on nature, while biodiversity preservation and urban environment are hardly mentioned, and the proposed concept doesn't differentiate much from the previous definitions of GI.

In 2015, the EU Commission set up an expert group on Nature Based Solutions and re-naturing cities, which set the way towards a dedicated funding stream within the Horizon 2020 funding programme. In that context, NBSs have been analyzed with a strong focus on urban environment and have been defined as 'actions which are inspired by, supported by or copied from nature. Some involve using and enhancing existing natural solutions to challenges, while others are exploring more novel solutions, for example mimicking how non-human organisms and communities cope with environmental extremes. NBSs use the features and complex system processes of nature, such as its ability to store carbon and regulate water flow, in order to achieve desired outcomes, such as reduced disaster risk, improved human well-being and socially inclusive green growth. Maintaining and enhancing natural capital, therefore, is of crucial importance, as it forms the basis for implementing solutions. These nature-based solutions ideally are energy and resource-efficient, and resilient to change, but to be successful they must be adapted to local conditions'. Building on this report, the EU Commission in 2016 adopted the following definition: 'NBSs are solutions that are inspired and supported by nature, which are cost-effective, simultaneously provide environmental, social and economic benefits and help build resilience. Such solutions bring more, and more diverse, nature and natural features and processes into cities, landscapes and seascapes, through locally adapted, resource-efficient and systemic interventions'. Within this definition, the role of NBSs as actual solutions to pre-identified societal challenges within cities assumes a strong relevance, while at the same time, the focus on mimicking, which was clearly mentioned in the expert group report, appear to loose relevance.

The IUCN definition, 2016, built on the idea of nature-based solutions as one of the possible strategies to tackle societal challenges defining them as ‘actions to protect, sustainably manage, and restore natural or modified ecosystems, that address societal challenges effectively and adaptively, simultaneously providing human well-being and biodiversity benefits’. Anyway, also in this case the focus looks broader than the urban scale stating that NBSs are applied at a landscape scale, thus not including punctual solutions implemented at a building level (i.e green roof), for instance. Again, this concept is quite similar to the GI definitions mentioned in the previous paragraph.

This EU Commission definition appears broader than the IUCN one, and could be further developed using a categorization made by DELTARES. In particular, they divided NBSs into two categories:

- The use of existing natural areas as NBS, where we can use one or more ecosystem services in addition to the conservation or promotion of biodiversity, mostly focusing on ecosystem preservation (i.e national and regional parks, earth biosphere, Natura 2000 sites)
- New NBS designed and installed to support one or more ecosystem services and to make a given contribution to biodiversity

The second category has been further subdivided into two groups. This differentiation assumes a great importance when referring to urban environments, since they requires different implementation strategies at the operational level:

- Hybrid NBS: combinations of hard infrastructure with soft or green elements, examples being green walls, green roofs, mobile plant containers, and so on. They often focus on one or two benefits in addition to the contribution they make to biodiversity. Effectively, they cannot exist without the hard structure. They are not connected to the subsurface and therefore not dependent on the nutrient fluxes or hydrological flows in the local system. As a result, their potential for replication is really high.
- Ecosystem-based NBS: re-installations of ecosystems or parts of ecosystems, examples being urban parks, natural embankments, urban wetlands, and so on. They are connected to the subsurface and are therefore highly dependent on local hydrological flows and nutrient fluxes. This consideration, and the fact that we expect them to deliver numerous ecosystem services, thus creating multiple impacts, makes the implementation of these solutions complex.

For the first time, in these definitions it is possible to find the reference to small scale projects, i.e green roofs, vertical walls, etc., which are increasingly spreading around cities. Those solutions provide ecosystem services and can be considered as a component of a broader green infrastructure vision, but that are not included, as such, in none of the other definitions.

3. Relation among the different concepts

Although the definitions of the three considered concepts in some cases appear to overlap and to be separated by vague borders, there is a need for a clearer differentiation.

Assuming that NBS are predominately an EU-based terms, not really spread in extra EU literature and practices, here below some relations among them are delineated.

3.1 Nature based solutions and Green Infrastructures

NBS and GI both represent solutions based on natural (green and blue) features and processes used to tackle clearly identified societal challenges. Both need to be carefully planned and strategically integrated with reference to urban, peri-urban and rural areas, being GI in EU mostly mentioned with reference to peri-urban and rural areas and NBSs for predominantly urban areas. Nevertheless, the main difference between the two, according to the authors' view, stands in the scale and the range of the project themselves. Indeed hybrid NBSs can be implemented in single, punctual and small scale projects (i.e green roofs and walls developed by private households), while ecosystem-based NBSs (i.e urban parks, lakes, floodplain) need much stronger financial, planning and administrative support and should be embedded in a broader vision of green infrastructures connection and network. Moreover, since ecosystem based NBSs are predominately embedded within urban projects and solutions, the social impacts they can create assume, sometimes, stronger relevance in comparison with other generated impacts.

3.2 Nature based solutions, Green Infrastructures and Ecosystem Services

ESs have sometimes been considered as a concept comparable to NBS and GI (Demuzere et. al, 2014, Maes and Jacob, 2015, Eggermont et. al. 2015), not clearly defining the different application of those concepts. In accordance with Pauleit et al, 2017, while NBSs and GI can be considered as more practical and solution oriented approaches, the concept of ESs is more abstract with a very strong focus on evaluation and assessment. Indeed ESs can be used in the evaluation of implemented NBS and GI infrastructure projects, providing decision makers with useful evidences regarding the environmental, social and economic benefit of such solutions. This approach could push forward the implementation and the integration of NBSs and GI within spatial and urban planning, assuming that those kinds of solutions create multiple impacts that traditional grey solutions don't.

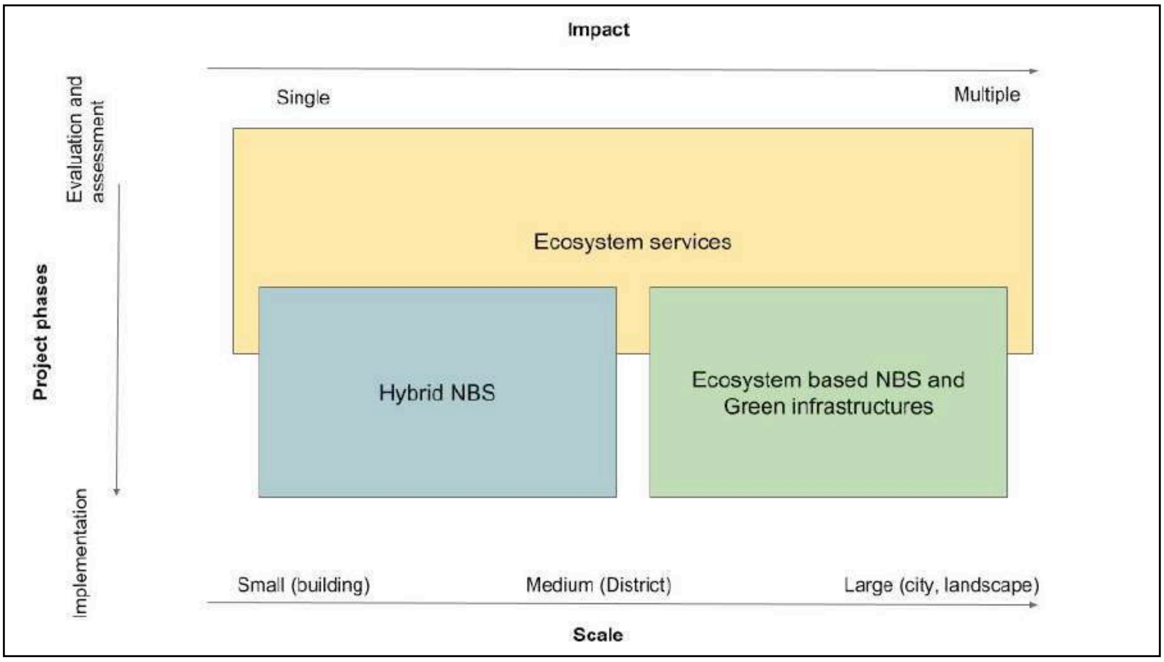

Figure 1 Relation among NBS, GI and ESs (Authors' elaboration)

Building on the conclusion of Pauleit et. al., 2017, Fig.1 summarizes the relations among the three described concepts. ESs can be considered as an assessment methodology while NBSs and GIs works at the implementation level. Hybrid NBS (i.e. green roof, vertical walls) are implemented at a smaller scale (building) and usually produce smaller impacts, if not integrated in a wider plan. On the other side ecosystem-based NBS and GI are implemented at wider scale (district, urban, regional) and produce a wider categories of benefits and impacts.

4. From theoretical definition to practice: challenges and good practices

As illustrated in the previous section, the concept of green infrastructures and NBSs has emerged as a way to secure the provisioning of ecosystem services in human-dominated landscape (Ahern, et al. 2014).

Beside the fact that ecosystems provide benefits to people also very far from the ecosystems themselves (i.e food provision, drinking water), a wide range of benefits (i.e. air quality, climate regulation services, soil permeability, recreation and cultural services) directly affect people living within or very close to a particular ecosystem. By 2050, the world's urban population is expected to nearly double, making urbanization one of the twenty-first century's most transformative trends (UN, 2017); for this reason, urban ecosystems, already established or newly created through NBSs, assume a crucial and fundamental role in improving people health and quality of life. In this sense, the interest of including NBS and GIs into strategic urban planning and ecosystem services as an assessment methodology of urban plans and projects is rapidly growing. Although the definition and the understanding of these concepts and their evaluation in terms of effectiveness and impact assessment is constantly growing in research and practices, their integration into 'business as usual' urban planning process still has to come. This issue is also at the centre of the Urban Agenda for the EU debate, as it is one of the issues tackled by the Sustainable Land Use and NBS partnership. The scope of this paper will be limited to present a good practice implemented in Scotland for the integration of functional and qualitative approach into planning strategies and assessment, even though a wider and deeper discussion on the opportunities and challenges presented by the topic is needed.

4.1 Greenspace quality guide: the case of Scotland

In 2008, Greenspace Scotland published a report "Greenspace quality- a guide to assessment, planning and strategic development", that detailed the steps to be followed to deliver a comprehensive greenspace strategy. In this context, greenspaces correspond to the above-mentioned ecosystem-based NBS and GIs referring mostly to urban parks, green corridors and urban farming.

The key measures of such spaces have been defined through the analysis of 3 different values:

- *Quantity*: "quantity in terms of the overall quantity of greenspace, its distribution spatially and in terms of differing types of greenspace (parks, green corridor, etc.)". The quantity criteria is currently the most used in urban planning standards and minimum requirements, probably due to its easy applicability and monitoring.
- *Accessibility*: "accessibility in terms of how well connected, accessible and inclusive greenspace is to the communities". Accessibility, as well a quantity, is a common indicator used in urban planning and it is easy to monitor and evaluate.
- *Quality*: "quality in terms of how well a greenspace or a wider network of greenspace assets addresses the varied functions need and aspirations of its users and other stakeholders".

This definition of quality recalled the idea of functions and services that a particular ecosystem – greenspace in this report- can provide to the community. The core role of the community in the greenspace planning appears even more relevant in the quality definition; indeed "quality of greenspace is a relative term and is best understood in terms of fitness to purpose". The idea of fitness to purpose implicitly includes the identification of targets to be reached and/ or final consumers to satisfy. The process of quality definition suggested in this guide is indeed built on the customers/users' and the stakeholders/local authorities quality definition. Even though the responsible local authorities should delineate the general plan towards the final targets and requirements, also in line with regional, and national objectives to be reached, quality needs also to be discussed and agreed by local actors. Indeed quality parameters and perceptions are embedded in and dependent on the local and climatic conditions and circumstances, different cultural background and local needs.

5. Conclusion

Social inequalities are likely to increase in our cities in the following years, due to overpopulation, migrations and increasing disparities. At the same time climate change effects will make our settlements more and more prone to extreme events such as drought, floods, fire, etc. Re-naturing cities is one of the most promising solutions to tackle social and environmental challenges and to make urban ecosystem more livable and resilient.

NBSs and Green Infrastructures, through the ecosystem services they provide, will strongly support the creation of climate proof cities, improving, at the same time, wellbeing and quality of life of citizens. In this context, this paper reviewed 3 concepts -Nature Based Solutions, Green Infrastructures and Ecosystems Services - to compare and relate those with current planning approaches. In this sense, ESs can be considered an assessment methodology while NBSs and GIs are operational solutions at strategic and implementation level. A further differentiation of NBS has been discussed: hybrid NBS (i.e. green roof, vertical walls) as solutions implemented at small scale (building) provide narrow impacts, if not integrated in a wider plan. On the other side ecosystem-based NBS and GI are implemented at wider scale (district, urban, regional) and can generate a wider categories of benefits and impacts. In both cases, that to be as effective as possible both NBSs and GI should be carefully and strategically integrated into urban regional and national plans and strategies.

To generate multiple impacts and benefits NBSs and GI have to be carefully planned and designed. Indeed the services that a particular solution can provide strongly depend on how this solution has been planned and designed (i.e type of vegetation used, interconnection with other NBSs, etc.), and are not directly related with the extension of the implemented solution. In this sense the quality of those solutions assume a great value, criteria which is not included in minimum planning requirement so far.

This concept of quality and performance indicators can push forward the integration of NBS and GI into urban environment. In this sense this paper mentioned an interesting case in Scotland where a shift towards a more qualitative approach in planning is being performed. Through this case the authors wanted to focus the attention of one of the possible approaches to relate NBSs and ESs with urban strategic planning, but further research on the topic is needed.

Abstract

Urbanization as a global transition process of socio-economic dynamics has been the burning issue of spatial science related disciplines for the last few decades. The complex system of urban mechanisms and the changes in population patterns have provided scientists from various domains a multi-dimensional research lab where land use and land cover change (LULCC) has become one of the most important issues affecting natural systems at different scales (Bajocco et al., 2012). All among the problems caused by anthropogenic activities and ongoing urbanization process, climate change came into prominence as one of the most critical environmental concerns due to its widespread effects threatening species, ecological systems and the sustainability of urbanizing landscapes. The relationship between urbanization and climate change has been most notably articulated by the greenhouse gases emit due to human activities and fossil fuel consumption. Herein, the study presented in this paper intends to focus on another variable that was not highlighted clearly in the process of fighting and adapting to climate change, yet, play an important role in climate regulation on surface and subsurface layers. Soil, as a defining component of ancient and recent cultures provides critical ecosystem services (ES) that enables life on Earth. Its role in climate and water regulation systems has tremendous effects on ensuring the equilibrium between surface and subsurface interactions. However, likewise other natural systems in urban areas, soil has been exposed to critical human intervention and lost its characteristics temporarily or irreversibly. This paper, at that point, aims to reveal the significance of soil ecosystem services (SoES) in adaptation and mitigation to emerging environmental challenges on the basis of climate change and stormwater management in urban areas. In accordance with this purpose, the scientific literature examining the relationships between urban planning, LULCC and SoES will thoroughly be analyzed to identify the research gaps and develop strategy options for making the integration of SoES into urban planning mechanisms possible.

1. Introduction

'Land, then, is not merely soil; it is a fountain of energy flowing through a circuit of soils, plants, and animals' (Aldo Leopold, A Sand County Almanac, 1949).

Soil is a vital part of the natural environment and it is essential for the continuity of life. The United Nations Food and Agriculture Organization (FAO) has declared 2015 as the International Year of Soils, "paying tribute to the life-giving ground beneath our feet" (Pantsios, 2014). Similarly, United Nations Sustainable Development Goals (2030 Agenda) has highlighted the importance of land, soil and water relationship through land and soil degradation, flood risk and integrating ecosystem values into national and local planning processes under the Goal-15: Life on land. Soils are also given an earlier emphasis in the Millennium Ecosystem Assessment (MEA) Report (MEA, 2005a), which popularized the term 'ecosystem services' and inspired by a number of researchers. The report provides a clear nomenclature for ES framework under 4 major function groups (provisioning, regulating, supporting and cultural) and assesses the consequences of ecosystem change on human well-being. Divergences of opinions regarding the most suitable classification of ES has brought some revisions made by the 'Economics of Ecosystems and Biodiversity (TEEB)' committee and 'European Environment Agency (EEA)' under 'Common International Classification of Ecosystem Services (CICES)' in 2009. However, both in the MEA Report and the studies in literature regarding the definition and classification of ES, very little attention was devoted to soils and insofar they often left out many of their common uses and services (Baveye et al., 2016). As Dominati et al. (2010) mentioned, a large-scale ecosystem approach was adopted by the MEA Report in which soil received little or no attention (Figure 1) apart from its role in soil formation. From this point of view, this research aims to emphasize the significance of 'below-ground mechanisms' as much as the services provided by above-ground systems and it particularly focuses on the SoES with a special attention to stormwater management and climate regulation in urban areas.

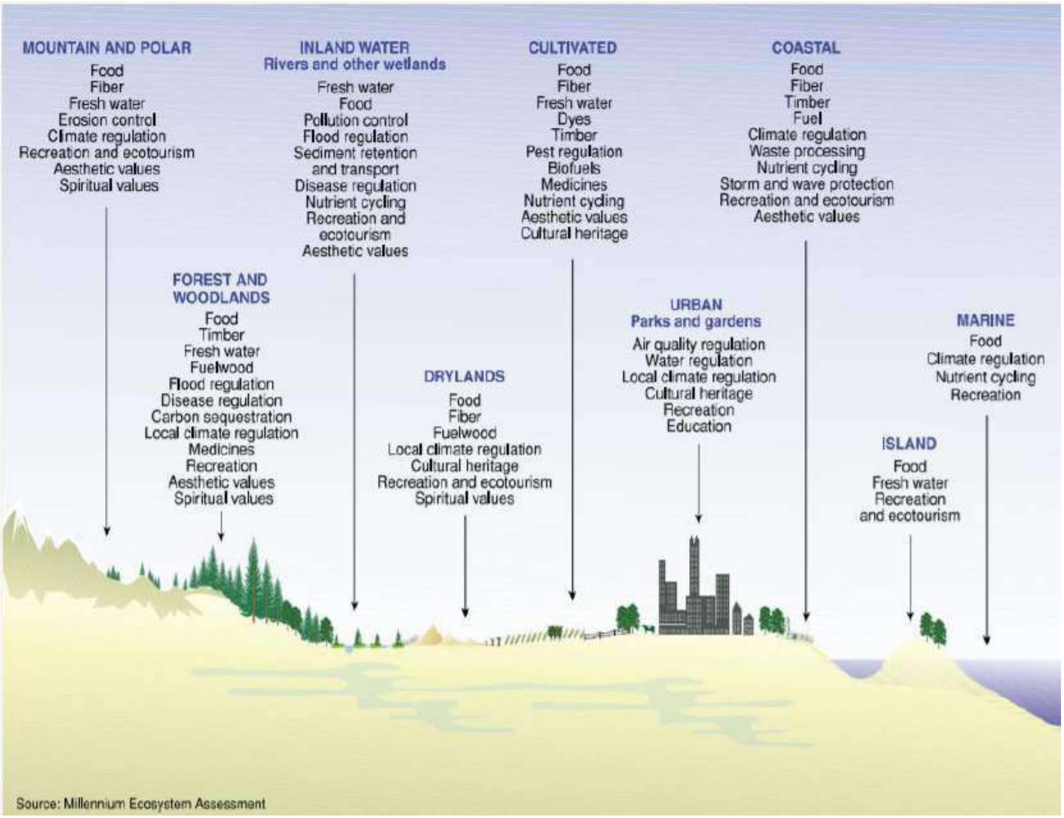

Figure 1: Multi-contexts of Ecosystems and Their Basic Services (MEA, 2005b)

2. Human-dominated Landscapes

We are living in a rapidly urbanising world. This has been revealed once again by the findings of United Nations indicating the rate of urban population which was 30 % in 1950 has reached 55 % of the world population today and it is expected to increase 68 % by 2050 (UN, 2018).

Urban areas are innovative catalysts and frontrunners of development. They provide greater access to social, educational and medical services, commerce and economic activity, public transportation network and enhanced opportunities for cultural and political participation for their citizens. However, at the same time, they are the hubs for environmental conflicts where natural hazard risks and environmental disturbances have accelerated. The process of urbanisation is defined by Mosel et al. (2016, p. 9) as:

> the increase in the proportion of the population living in urban centers that is overwhelmingly the result of net rural to urban migration caused by economic growth and industrialisation, political and social conflicts, rural impoverishment, and natural disasters

which stimulates dramatic changes on land. The expansion of urban areas due to rise in population and economic growth increases the additional demand on natural resources thereby causing land transformations especially in megacities and peri-urban areas. According to CBD Report (2012), the land area occupied by cities increases at a higher rate than the increase in urban population. Likewise, a global sample of 120 cities observed between 1990 and 2000 shows that while the population grew at a rate of 17 %, the built-up area grew by 28 % (NYU, 2015). Rapid urbanization and inadequately managed urban expansion lead to urban sprawl and unplanned urban patterns (UN, 2014), where the communities become more vulnerable to water and climate-based problems (Tezer et al., 2012).

2.1. Transitions in Land use and Land Cover; A Growing Threat for Natural Capital

Land use and land cover (LULC) are one of the key determinants of landscape's structure, functions, and dynamics in all around the world (Wu and Hobbs, 2002). Land cover defines the '*biophysical state of the earth's surface and immediate subsurface, including the soil material, vegetation, and water status*' while the land use differs from land cover as a result of anthropogenic behavior to change land cover to their benefit (Verheye, 2006, p. 337). The Food and Agriculture Organization (FAO, 1995, p. 21) describes land use as *'the human activities which are directly related to land, making use of its resources, or having an impact on them*'.

The negative environmental impacts associated with urbanization, such as loss of cultivated land, habitat degradation, biodiversity loss and urban flooding are linked to the unplanned changes in LULC caused by poorly designed and coordinated urban sprawl (Pauleit et al., 2005). Today, urbanization is among the most important land-use change trends globally and the conversion of land to built-up is often considered as one of the most problematic trajectories of LULCC (Elmqvist et al., 2013) due to its distinct impacts. The urban-growth driven changes in LULC have direct or indirect impacts on urban ecosystems including air quality, habitat and landscape fragmentation (Sala et al., 2000), soil degradation (Tolba et al., 1992), flood/drought risk (Carlson and Arthur, 2000), surface runoff and consequently the hydrological cycle with an influence on climate processes at local, regional and global levels (Chase et al., 2000). The interactions between urban ES and the response of ES bundles to the changes in LULC are complicated and variable. Therefore, the research intends to highlight the services provided by soil and the consequences of LULC on the regulative (climate and water regulation) soil services in rapidly urbanizing landscapes.

2.2. Soil in Urban Landscape

Soils are complex mixtures of minerals, water, air, organic matter, and countless organisms (FAO, 1985) which interact and contribute to the global cycles that make all life possible (Govers, 2015). However, due to changing consumption patterns, global demographical dynamics, population growth and urbanization, soil is coming under increasing pressure resulting in physically, chemically and biologically altered characteristics in comparison to nonurbanized soils (Pavao-Zuckerman, 2008).

Soil as a dynamic and multifaceted life support system is affected by five major factors (climate, organisms, relief, parent material and time) interact to create different soil types (Brady and Weil, 1996). Recently, human activity is accepted as the sixth factor has an influence on soil formation (Pickett and Cadenasso, 2009) due to direct anthropogenic disturbance and indirect impacts of urbanization. Previously, Jenny (1941), described soil formation in the absence of humans, while Effland and Pouyat (1997) and Pickett and Cadenasso (2009) considered the anthropic factor influence to modify natural soil formation processes (Figure 2). Indeed, the term 'Urban Soil' can be defined as:

> a soil material having a non-agricultural, man-made surface layer more than 50 cm thick, that has been produced by mixing, filling, or by contamination of land surfaces in urban and suburban areas (Craul, 1992, p. 86)

which indicates a disturbed soil structure by human interference. Jim (1998) identifies the characteristics of urban soil as: modified soil structure (compaction), presence of a surface crust on bare soil, restricted aeration and water drainage, interrupted nutrient cycling, modified soil organism activity, anthropic materials and other contaminants and modified soil temperature regimes. According to BIO Intelligence Service Report (2014), soils in urban system are mostly compacted, sealed, and modified. Their characteristics are temporarily or irreversibly lost and their biophysical properties such as structure, soil temprature and organism activity are partially or completely interrupted due to critical human intervention.

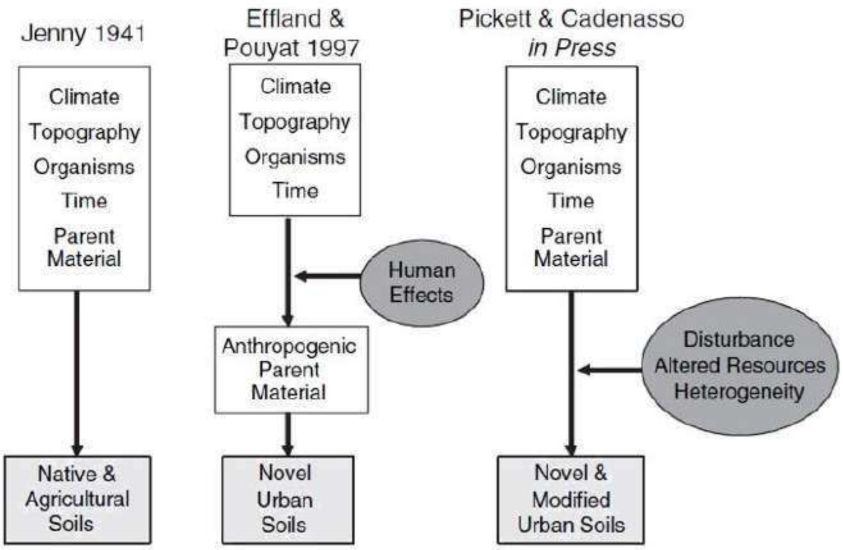

Figure 2: Factors Effecting the Modification of the Soil Formation Process (Pickett and Cadenasso, 2009).

Although soils in urban landscapes are predominately altered, they still can provide many of the same ES as unaltered soils (Pouyat et al., 2010). The potential of ES provision by modified urban soil has been confirmed by the studies conducted under Baltimore Ecosystem Study (BES) (2010) as well. The study revealed that urban effects on soils occur at multiple scales. Yet, urban landscapes are biologically active in pervious areas and still have a high potential for water filtration, carbon storage, and nitrogen retention which are significant for, thus climate and water flow regulation.

3. Ecosystem Services (ES) Provided by Soil

Ecosystem services are defined as '*the benefits people obtain from ecosystems*' in the Millennium Ecosystem Assessment Report (MEA, 2005a) with an emphasis on the dependency of human well-being to the Earth's natural capital (Costanza et al., 1997) including the most biologically active zones of soil (Barrios, 2007).

Soils are one of the species-rich habitats and the foundation off all terrestrial ecosystems (Finvers, 2008; Jónsson and Davíðsdóttir, 2016). They moderate the majority of ecosystem processes while providing a range of ecosystem goods and services mostly driven by the soils biotic community. Healthy soil contains a myriad of organisms (microbes, fungi, bacteria, invertebrates), whose activity in soil is central to support and moderate nutrient balance, biogeochemical recycling, primary production, water regulation and biomass production (Brady and Weil, 1996; McKinney, 2002; Jónsson and Davíðsdóttir, 2016). Soil Thematic Strategy (EC, 2012) identifies soil biodiversity as the key component of soil quality and sustainability. Although soil microbial diversity has a critical role in ecosystem processes, key functions of soil are not limited with the services provided by its microbial community. Due to environmental interactions take place among the surface and sub-surface layers of the land, soil serve as a gene pool and source for food and other biomass production. It constitutes a physical support for man-made structures while regulating Earth's fundamental processes (retaining carbon, water and nutrients, regulating greenhouse gas emissions, global and local climate, hydrological cycle, air purification etc.) and contributing to cultural heritage (Barrios, 2007; Dominati et al., 2010; Pereira et al., 2017).

The role of soil in providing these crucial services is mostly neglected in ES framework, which has been formed in various classifications (Costanza et al., 1997; de Grooth et al., 2002; MEA, 2005a; CICES, 2009; TEEB, 2010) and still could not formulate a consensus regarding the classification and valuation of SoES (Robinson et al., 2009). In Figure 3, the services provided by soil is illustrated based on the categories defined by MEA (2005a).

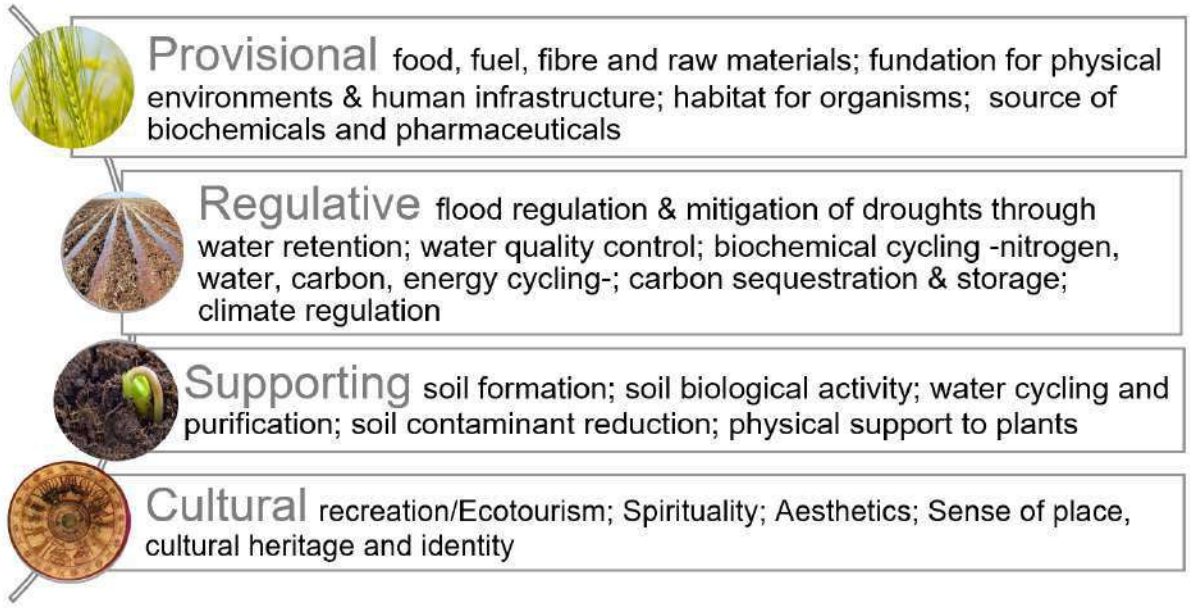

Figure 3: ES Provided by Soil (compiled from Daily et al., 1997; Dominati, 2013)

According to Jónsson and Davíðsdóttir (2016), recent developments have underpinned the importance to include multiple aspects of SoES in ES framework due to their critical role in to climate change mitigation and flood risk management in urban areas. As such, soils can function in urban landscapes by reducing the bioavailability of pollutants, storing carbon and nutrients and moderating the hydrologic cycle through absorption, storage, and supply of stormwater (Pouyat et al., 2010)

3.1. Soil in Hydrological (Water) Cycle

Soil and water system are inherently connected. They directly or indirectly affect each other and contribute to the continuity of life. The continuous and vital movement of water on, above, and below the surface of the Earth is defined as hydrological cycle (USGS, 2017), where soil play a critical role.

Soil is responsible for the infiltration, transpiration, storage, percolation and distribution of water flow in the hydrological cycle. According to BIO Report (2014), soil retains 67 000 km^3 of water globally that is mostly used for root uptake, plant growth, groundwater recharge and soil organisms (Quinton, 2015). Altough infiltration and storage of water in soil media mainly associated with gravity, precipitation, hydrological characteristics (saturation level, moisture content, capillarity etc.), soil texture and structure (particle size, porosity etc.) (FAO, 1985), the condition of soil surface regarding the land cover, vegetation type and human activities is one of the primary determinants of water-soil relationship (Mangala et al., 2016). In the context of the natural flow of hydrological cycle, water naturally seeps down by gravity during the precipitation/irrigation while there are no physical barriers such as impermeable layers at soil surface. In urban landscapes, however, sealing of soil and the conversion of land pattern from permeable surface to impermeable cover surfaces (roads, pavements, buildings, asphalts etc.) is closely associated to soil's capacity to store and infiltrate water (Veerbeek et al., 2011; Quinton, 2015), which increase the surface runoff and flash-flood risk.

The causes of antropogenic interventions on soil can be summarised as: decrease of water infiltration and chemical activity; reduced storage of water and carbon; cut down of soil evaporation; increase in local temprature (surface and sub-surface) and water erosion; biomass and organic matter loss; pollution; impeding soil water and atmosphere exchanges (biochemical cycling) together with the negative affects on the functions of soil organims, groundwater replenishment and natural water balance in urban areas (BIO, 2014; Pouyat et al., 2010; Scalenghea and Marsan, 2009; Pavao-Zuckerman, 2008; Grimm et al., 2008). In natural systems, permeable surfaces prevent or limit runoff by capturing part of the rainwater, while reduction of this ability (soil sealing, compaction, saturation) and the existance of impervious surfaces reduce the amount of water infiltrates into soil (Figure 4). This can lead to high levels of stormwater runoff resulting in fluvial (river overflowing) or pluvial (urban) flooding with higher magnitude and frequency (Rambaldini, 2009; Bacchin et al., 2013) mostly in poorly planned urban settlements.

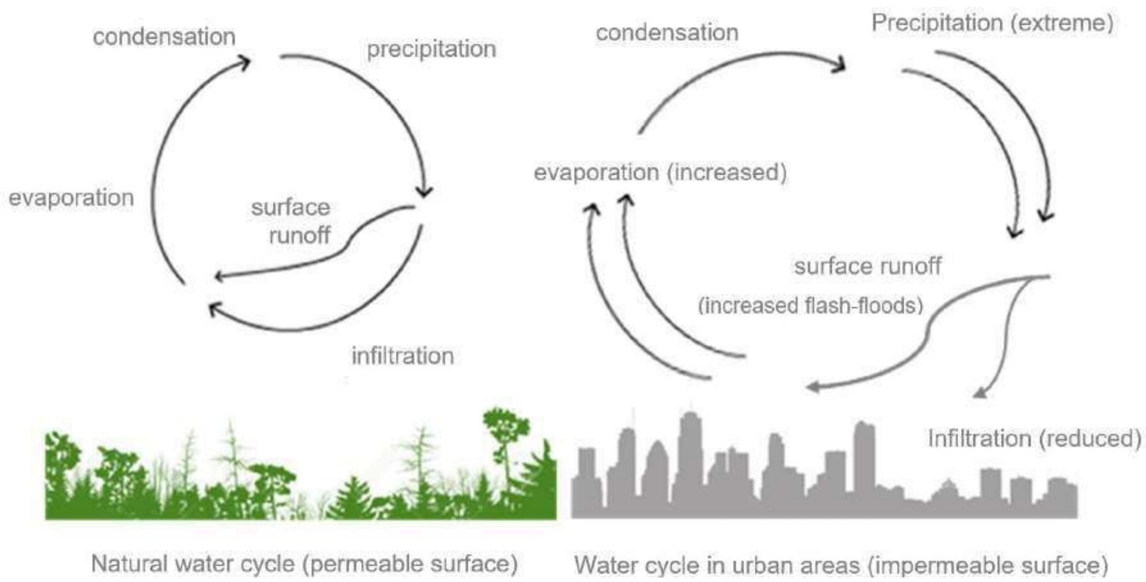

Figure 4: Hydrological Cycle in Natural and Urbanized Areas (adapted from Bacchin et al., 2014)

3.2. Soil in Climate Regulation

According to UNEP (2012), urban areas comprise only around 3% of the land surface of the earth, but they use approximately 75% of the earth's natural resources and emit 60% to 80% of greenhouse gas emissions. Greenhouse gases (GHGs) play a vital role by trapping the solar energy in the atmosphere and influence the climate of the planet; known as 'greenhouse gas effect' (EPA, 2017). This naturally occurring process is vital and provides higher and livable temperature ranges on the Earth. However, the increase of atmospheric GHGs in exponential ratios intensifies GHG effect, alters the energy balance and cause an increase in Earth's temperature, which threatens the continuity of human welfare and ecosystems health.

The Intergovernmental Panel on Climate Change (IPCC) defines climate change as *"statistically significant variation in either the mean state of the climate or in its variability, persisting for an extended period (typically decades or longer)'* and it emphasizes the distinct influence of human on climate change (IPCC, 2013). Due to greater amounts of GHGs emissions mainly caused by energy generation, vehicles, industry, biomass use and human alteration on LULC (EPA, 2017), the global surface temperature in the past decade was detected 0.8 °C higher than the beginning of the 20th century (Carter et al., 2015). According to NOAA (2018), carbon dioxide (CO_2) is of greatest concern in all of the GHGs, since it contributes the most to the climate change. Atmospheric CO_2 levels in 2009 were measured higher than at any time in the past 800,000 years and currently, it is continuing to increase at an accelerating rate (EPA, 2017). Scharlemann et al. (2014) indicated that carbon emissions resulting from changes in LULC are the second largest source of human-caused carbon emissions to the atmosphere after emissions from fossil fuel combustion. Researches conducted under the Global Carbon Project (GCP) (Le Quéré et al., 2016) also revealed that the global CO_2 emission sources have grown in the industrial era primarily from fossil fuel combustion, cement manufacturing, and land-use change from activities such as deforestation (Figure 5).

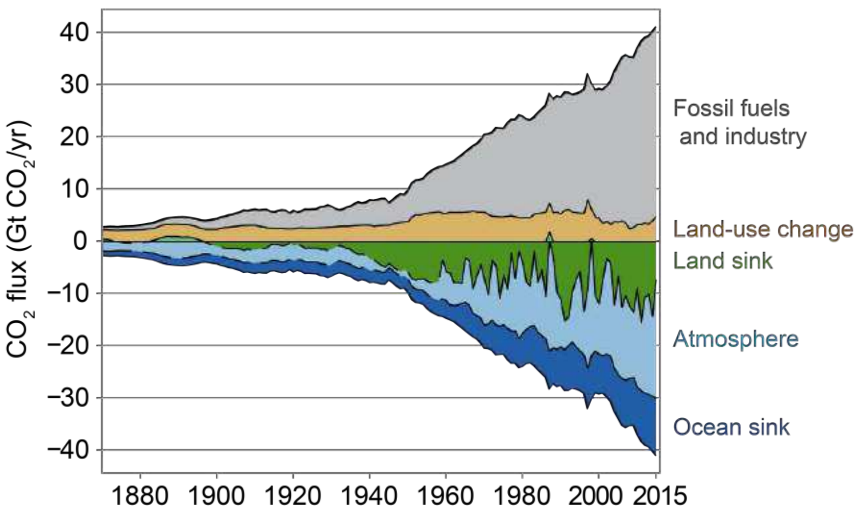

Figure 5: The Global Carbon Budget (Sources & Sinks) (Le Quéré et al., 2016)

CO_2 naturally emitted by the oceans, plants and land, where 80 % of the total carbon in the terrestrial ecosystem is found in soil (Lal, 2008). Soil as the second largest carbon reservoir after oceans (EPA, 2017) captures and stores the carbon in the form of soil organic carbon (SOC). Sequestration of carbon by healthy soils and vegetation is an important part of continual (exchange) cycle of CO_2, and crucial for key soil functions such as stabilization of soil structure (erosion control), flow of plant nutrients (productivity) and water infiltration and storage in soil (Pereira et al., 2017). SOC supports soil organisms to perform in biogeochemical cycles and help soil to regulate the microclimate (surface and sub-surface) as well (FAO, 1995).

The significant role of soil in climate regulation could be a critical link to mitigate climate change particularly in urban areas, where the transition of land cover in the form of built-up or paved-over areas leads to modifications in surface microclimatic and hydological conditions including urban heat island effect and changes in surface runoff pattern (Jiang et al., 2015). Currently, unsustainable land management practices and increase of urbanization-driven LULCC alter soil carbon balance while endangering the capability of soil to store and sequestrate carbon (FAO, 1995). Nevertheless, in addition to the strategies imposing to reduce the dependencies on fossil fuels, it is also critical to contribute to carbon dioxide-driven climate change mitigation efforts by increasing the carbon stocks in urban areas.

4. Discussion: Considering SoES in Urban Spatial Planning

Traditionally SoES have not been thoroughly studied in urban planning. Hence, tools are needed to incorporate SoES into urban land management and spatial planning processes.
The purpose of this paper is to reveal the significance of SoES in urban planning and spatial decision-making process through the following objectives: (1) analyzing the effects of urban growth-driven LULCC on soil; (2) identifying the role of urban soil in climate change mitigation and urban stormwater management; (3) proposing a conceptual framework illustrates the basic stages for building SoES-friendly urban planning and design strategies.

In accordance with this purpose, scientific literature examining the relationships between urban planning, LULCC and SoESs is systematically analyzed. The results obtained illustrate that although subsurface system has not been fully incorporated into ES framework, recent studies (e.g., Pavao-Zuckerman, 2008; Robinson et al., 2009; Pouyat et al., 2010; Dominati, 2013; Baveye et al., 2016; Silva et al., 2018) several international organizations (e.g., United States Environmental Protection Agency, United Nations Environment Programme and Food and Agriculture Organization) and some relevant policies (e.g., United Nations Sustainable Development Goals, European Commission Soil Thematic Strategy) have pointed out the great influence of SoES on urban sustainability. Particularly, the critical role of soil in urban climate regulation and flood risk is explicitly underlined with an urgent need for adaptive, comprehensive and multi-disciplinary spatial planning process. From this point of view, a ‘multi-layered’ approach has been adopted in this study (Figure 6) based on the ‘Dutch Traditional Layer Approach’ introduced in 1998 (Van Schaick, 2011). The perspective classifies the land basically under three layers; substratum, networks and occupation patterns, where the natural subsurface systems are incorporated with aboveground urban development as a part of ‘human’ and ‘natural’ system connections. The framework proposes to understand the status quo at the first stage. Following studies investigate the ES potentials of the area and reveals the critical zones of selected SoES provision. Herein, the permeability of the surface (soil) and subsurface (geology/hydrogeology) layers are crucial for water infiltration -and accordingly circular movement of stormwater- while the areas with high capability to store carbon are critical for carbon sequestration to combat climate change. At the last stage, the critical zones of substratum are overlapped with the occupation and network layers (spatial configuration and the changes in LULC) to detect the areas necessitates protection and/or improvement.

The framework illustrates a generic perspective and necessitates tailor-made strategies for the area/region to be studied. Accordingly, the results obtained need to be translated into spatial planning practices with an overall aim to integrate SoES-friendly measures into current urban planning processes at different scales. Thus, the framework can provide normative principles guiding for future studies, which intends to increase the resilience of urban environments to emerging environmental problems. Considering the functions of soil in climate and surface runoff regulation within the constructed environments should be taken into account in planning processes of both existing or future developments. Developing and implementing SoES-based urban spatial planning approach is significant to enhance (i) functioning of SoES in urban landscapes; (ii) resilience of urban areas to climate change and storm water runoff problems; (iii) sustainability of urban ecosystems and related services in long-term.

Green Infrastructure for Metropolitan Areas in Mexico

Juan Ángel DEMERUTIS-ARENAS; Jesús ESCOBOSA-BURGARA
University of Guadalajara
Mexico

Abstract
Mexicans have decided to live in large metropolitan areas, this is a fact since the year 2000, when most of the country's population lives in one of them. However, this change in population distribution was not paired with key components for sustainable development, such as large green areas which could define metropolitan level green infrastructure (GI). Metropolitan areas should include a network of strategically planned and managed natural areas to preserve living ecosystems, build resilience for climate change and at the same time provide the population with the benefits associated to living near GI.
This study aims at defining the main features of Metropolitan GI, how it should look like and what criteria should be considered in order to face climate change. Although neighborhood and urban green areas are well specified in planning literature, there are no references for the metropolitan scale; therefore, to address this gap the article elaborates an inventory of the GI in place in one actual Metropolitan Area. The selected case study is the second largest city in Mexico with 4.8 million inhabitants, but with little information about its GI: the Guadalajara Metropolitan Area (GMA). In order to understand how the existing GI helps climate change mitigation and adaptation, the urban ecosystem services actually provided are highlighted. This services include provisioning (urban agriculture and water sources), regulating (climate regulation, water infiltration, erosion control), cultural (tourism and recreation), and supporting and habitat (habitat for species and diversity).
The study uses existing plans, images and local sources as inputs for spatial analyses, which are complemented with field visits to monitor and calibrate the information. By assessing the services provided by existing GI, as well as conducting a suitability analysis of the metropolitan territory, this article also shows the potential areas which could help enhancing/ building a comprehensive GI system for the GMA.
The article concludes with recommendations that could help consolidate and enhance the Green Infrastructure of the GMA. These recommendations could be considered for future cool Metropolitan planning and resilience.

Key words: Green Infrastructure – Metropolitan Planning – Guadalajara.

1. Mexican Metropolization

Mexico has gone through an urbanization process of several stages (Unikel, Ruiz Chiapetto, & Garza Villarreal, 1976) which has led the population of the country to live predominantly in cities since 1980. Within this process, it is required to point out the phenomenon of metropolization: a tendency to the physical articulation of localities that formerly operated independently, but that now are integrated forming a single unit, in such a manner that they add up to a population of 50,000 inhabitants, whether they are localities of a single municipality or, alternatively, localities that are based in two or more municipalities that show a degree of physical and functional integration (SEDESOL - CONAPO - INEGI, 2012).
Large metropolitan areas became the predominant form of population concentration in Mexico from the year 2000 on, when more than 50% of the population was already settled in 55 metropolises (idem, 2012). This phenomenon continues to be a trend and will probably last for a few more years (see Table 1).
In 1980, there were already 26 Metropolitan Areas (MAs) in the country, of which Mexico City, Guadalajara and Monterrey stood out; by the year 2010 there were 56.8 million inhabitants in 59 MAs.
The substantial concentration of people in MAs -mainly due to migration from other cities, has caused the territory to be occupied without regard for the most sensitive natural areas that represent the potentiality of bringing nature to the metropolis, leaving the environment out of the urban structure and therefore, failing to reach the global target of a sustainable urban

development (UN-Habitat, 2009, United Nations, 2015). It is even possible to affirm that the system of open green spaces has yet to be recognized in the metropolises as a fundamental element of the networks/infrastructure systems of a city.

Indicator	1980	1990	2000	2010
Metropolitan areas	26	37	55	59
Districts and metropolitan municipalities	131	155	309	367
States	20	25	29	29
Total population (millions)	26.1	31.5	51.5	63.8
National Population Percentage (%)	39.1	38.8	52.8	56.8

Table 1. Indicators of the metropolization process 1980-2010. Adapted from SEDESOL - CONAPO - INEGI, 2012.

The environment thus, is a fundamental system that has been affected by the urbanization process, and which is necessary to attend given that all the changes made by the human being in metropolitan territories have ecological and socioeconomic effects. Among the first, we count the loss of natural areas that are replaced by the development of housing, roads and other city needs; this development has also caused the fragmentation of natural spaces, which in terms of biodiversity limits the possibility to preserve existing resources; as well as the degradation of water resources when rivers are erased with earthworks and when aquifers are overexploited; overall, nature's ability to respond to changes is diminished. Among the latter, it stands out the loss of "free" natural services such as flood control and at the same time, the risk of floods increases, which leads to great economic losses as well as the loss of human lives; additionally, the uncontrolled urban growth in the distant peripheries of the cities causes disproportionate expenses for the introduction of infrastructure for mobility, water and electricity (Benedict & McMahon, 2001).
Despite this situation, when reviewing the metropolitan public agenda it is evident the great concern that exists to know and to plan the infrastructure for mobility, for the supply of electricity, for the provision and treatment of water, or even for rainwater (gray infrastructure); but it is also evident the lack of a commitment to understanding and planning for a system of metropolitan green spaces to support the natural environment, particularly to increase environmental sustainability (Benedict & McMahon, 2001, Vásquez, 2016, IMEPLAN, 2016).
Just as in other urban/ metropolitan infrastructures systems, a multi-scaled approach is necessary in which a specific recognition of the relationship between patterns and processes carried out in the territory can be accomplished. This approach implies the establishment of main and secondary systems in order to achieve an efficiency at a regional / metropolitan level but also at a local, intra-urban level. The observance of an order of hierarchy as established in the planning of the most recognized urban systems (roads, water, sewers, electricity, among others) must also exist in the way we plan green spaces; namely, green infrastructure.
Like any system, existing and potential nodes and links should be identified where there are important connections in order to interrelate the different hierarchical levels, which in urban contexts are multiple scales such as the regional / metropolitan, the districts / neighborhoods and the plots or individual sites (Ahern, 2007).
These elements are present in the territory through a spatial language that according to Ahern (2007), is distinguished as a "Mosaic Model". This model uses the following three elements of the landscape to define its structure: patches, corridors and the matrix. Patches are homogeneous polygons of the territory that differ from their surroundings (they provide multiple functions, including wildlife habitat, aquifer recharge areas, or sources and sinks of species and nutrients). Corridors are areas with an elongated shape such as pathways for the flow of animals, nutrients, and wind. The matrix refers to the dominant land cover in terms of area, degree of connectivity and continuity (see Table 2).

Urban Patches	Urban Corridors	Urban Matrix
Parks	Rivers	Residential Neighborhoods
Sportsfields	Canals	Industrial Districts
Wetlands	Drainageways	Waste Disposal Areas
Community Gardens	Riverways	Commercial Areas
Cemeteries	Roads	Mixed Use Districts
Campuses	Powerlines	
Vacant Lots	Poliducts	

Table 2. Elements of the urban landscape as classified in the model Patch - Corridor Matrix. Adapted from Ahern, 2007.

2. Biophilic Cities: Between Sustainability and Resilience

Sustainability has already been extensively addressed by the existing urban planning literature. It is appointed as a holistic frame of reference to guide the development of cities, and to simultaneously improve their performance among the three dimensions of sustainable development: economic development, social equity and the protection of the environment (Campbell, 1996, Farr, 2007, UN-Habitat, 2009).
In addition to sustainability, another concept that has been incorporated into theoretical discussions about cities is that of resilience. The impacts of global climate change (i.e., an increasingly volatile climate and the large number of disasters and the consequent damages that have occurred around the world) have turned resilience into an urban and metropolitan aspiration (Metropolis Observatory, 2017). What started as adaptation to disasters and damages, has currently expanded to discussions about resilient cities, which take into account in a wide range the potential impacts and stress that cities will most likely face in the future: water scarcity, rise in food prices, and increasingly high temperatures during the summer, among others (Newman, Beatley, & Boyer, 2008). Resilience can be defined in several ways; in this study it is understood as the ability to successfully adapt and to respond to those impacts. The word resilience is derived from Latin *resiliere*, which means to spring back or to rebound. Godschalk (2003) describes resilient cities as ones "capable of withstanding severe shock without either immediate chaos or permanent harm... While they might bend from hazard forces, they would be able to adapt and would not break. Composed of networked social communities and lifeline systems, resilient cities would become stronger by adapting and learning from disasters”.
Resilience does not imply a return to dysfunctional or unsustainable conditions, but adaptation to dynamic social and ecological conditions in ways that protect and enhance quality of life, long-term ecological productivity, as well as public and personal health of the inhabitants of the MAs. Resilience is not only a matter for cities and metropolises, but has important implications for both individuals and families, which is precisely at the level where the stresses, pressures and shocks of modern life will come to bear (Beatley & Newman, 2013).
In order to improve sustainability, but above all to increase resilience, cities may become biophilic, and there are several paths through which biophilic urbanism can make it happen. Some of them have already been thoroughly studied, but others are still experimental and require extensive analyses (see Table 3).
One of the clearest paths is biophysical, the resilience benefits provided through the protection and enhancement of the natural systems and features in and around a city (Beatley & Newman, 2013). The natural systems in a city and region provide essential services that help cities and urban regions respond to and spring back from climatic and natural events. Cities with large natural wetland systems will be better able to absorb flood waters from hurricanes and storms, for instance. Protecting and restoring these great ecological systems is a key strategy that allows cities to be more resilient in the face of disasters.

Biophilic Conditions and Infrastructure
-Percentage of population within a few hundred feet or meters of a park or greenspace; -Percentage of city land area covered by trees or other vegetation; -Number of green design features (e.g., green rooftops, green walls, rain gardens); -Extent of natural images, shapes, forms employed in architecture and seen in the city; -Extent of flora and fauna (e.g., species) found within the city.
Biophilic Behaviors, Patterns, Practices, Lifestyles
-Average portion of the day spent outside; -Visiting rates for city parks; -Percent of trips made by walking; -Extent of membership and participation in local nature clubs and organizations.
Biophilic Attitudes and Knowledge
-Percent of residents who express care and concern for nature; -Percent of residents who can identify common species of flora and fauna.
Biophilic Institutions and Governance
-Priority given to nature conservation by local government; percent of municipal budget dedicated to biophilic programs; -Existence of design and planning regulations that promote biophilic conditions (e.g., mandatory green rooftop requirement, bird-friendly building design guidelines); -Presence and importance of institutions, from aquaria to natural history museums, that promote education and awareness of nature; -Number/extent of educational programs in local schools aimed at teaching about nature; -Number of nature organizations and clubs of various sorts in the city, from advocacy to social groups.

Table 3. Important elements (indicators) of a biophilic city. Adapted from Beatley, 2011.

Large wooded areas provide ecological benefits that will make cities more resilient -including effects such as moderation of air pollutants, cooling through evapo-transpiration and shading as well as flooding reduction.
Protection and restoration of rivers and urban streams reduce the vulnerability to floods, provides important cooling benefits and helps to moderate the weather and temperature changes predicted as a result of climate change. That is why cities with extensive networks of parks and green spaces are also likely to fare better in the face of long term climate change (idem, 2013).
Biophilic urbanism can help to protect or strengthen favorable climatic and micro-climate conditions in cities, which also helps them become more resilient in the face of a host of emerging resource scarcities likely in the decades ahead (idem, 2013).
“Greening” cities can significantly reduce energy consumption for heating and cooling by the function of trees as climate regulators. In promoting modes of urban mobility other than automobiles (walking, bicycling) there is the possibility of greater resilience in the diminished oil supplies. Additionally, the principles of biophilic urbanism can achieve significant water conservation, but also, through the protection of peri-urban farms and agriculture and by promoting urban agriculture, might help to ensure the food security of a city (idem, 2013).
A biophilic city is one with abundant biodiversity, full of nature, a place where residents see, feel and experience the richness of plants, trees and animals in the course of their lives, and do so in their homes, in their jobs, in the spaces where they perform recreational activities, as well as they commute. The components of nature, large and small, from the tops of trees to the invertebrates and even microorganisms that are part of larger natural elements and ecosystems, define a city and provide it with character and meaning (Beatley, 2011).Biophilic
