Synopsis - This paper seeks to investigate the case city of Singapore. In particular, it examines the planning and development of the Punggol eco-town through documentary research and onsite observation. The paper will interrogate the key strategies, results, lessons learned and replicability of Singapore's eco-city planning. The analytical lens is on illuminating the strengths and weaknesses of eco-city planning.

1. Introduction

Against the speed of urban expansion and the global push for sustainability, making existing cities and new urban development more ecologically based and livable has become a priority in an expanding number of countries around the world (Joss, 2012; UN-HABITAT, 2009). A similar growth trajectory is emerging across Asia, from China to India, Indonesia, Japan, Korea, Malaysia, the Philippines, Singapore and Vietnam even though the challenge is to mainstream sustainability in development plans and policies. Among Asian countries, Singapore seems to have assiduously promoted ecological modernization, which seeks to promote economic growth with environmental improvement.

As encapsulated in a series of government documents (especially after Singapore has committed itself to becoming a party to the Kyoto Protocol in late 2006), for example, in the 2009 Inter-ministerial Sustainable Singapore Blueprint and 2011 long-term Concept Plan, the aim is to plan for a sustainable Singapore. This will be effected through an environmentally responsible and sustainable approach to development where future development balances economic growth with environmental stewardship and social harmony. Sustainable development is not an after-thought in Singapore. It is an integral aspect of the urban planning process where the inherent circularity of the physical processes of resources, activities and residuals must be managed effectively while providing wellbeing and quality living. Towards this end, Singapore is developing the Punggol eco-town (2011) as a prototype for its future public housing development.

Even though the notion of eco-city planning is not new in international urban planning literature, it is being applied to the whole of government and all the actors of Singapore's community including households and businesses. Sustainable development is promoted as a way to grow Singapore more efficiently (to develop with less resources and waste), cleanly (to develop without polluting the environment), and green (to develop while preserving greenery, waterways and natural heritage). The approach is to introduce effective *planning and design* concepts to make it conducive for residents to adopt eco-lifestyles, exploit *urban solutions* to achieve stretched environmental targets, and engage, educate and enable *people* to be an integral part of the 'go green' efforts.

This urban planning paradigm shift can have far reaching effect at several levels. At the local level, public housing, at least in the Singapore context, is where the majority (over 80%) of

Singaporeans live. At the regional and international levels, Singapore's urban planning and development has been increasingly regarded as an inspiring model for many developing countries (Yeung, 1987; Yuen, 2011). In recent decades, Singapore has been exporting this urban knowledge. It is building eco-cities in the region in collaboration with local partners (e.g. Tianjin eco-city in China) while emphasizing that Singapore acts as a 'living laboratory' aimed at incubating and displaying new 'smart' environmental technologies and sustainable development urban solutions. Using the case study of Punggol eco-town, this paper will interrogate the key strategies, results, lessons learned and replicability of Singapore's eco-city planning. The analytical lens is on illuminating the strengths and weaknesses of eco-city planning.

2. The Basic Ideas of an Eco-city

An eco-city is developed as an aid to mainstreaming sustainability in urban development at the neighbourhood level (Kulshrestha, 2007). Its goals are to maximise (e.g. respect for nature) or minimise an attribute of urban planning (e.g. demand for land, transport or energy consumption). Its roots can be traced to the early work of the 19th and 20th century planning pioneers such as Lewis Mumford, Frederick Law Olmsted, Patrick Geddes and Ebenezer Howard who have variously argued for planning and building cities more sustainably while preserving nature and ecological surroundings (Mumford, 2004; Hall 1996).

As early as 1898, Ebenezer Howard has promoted the concept of developing 'garden cities' with carefully balanced areas of agriculture, industry and residences, surrounded by greenbelts. Patrick Geddes and Lewis Mumford, for example, have advocated the idea of an organic city where cities as living organisms evolve as they adapt to a changing environment while Ian McHarg developed the concept of ecological planning and a multi-layered approach on the regional scale with an ecological orientation to explicitly connect ecology theory to planning and design practice, thus laying yet another integration of human and natural environments in urban development, especially in Europe.

In the USA, since the mid-1970s post-oil crisis, the importance of compact urban structure, building with nature and other city planning approaches in saving energy and resources has been emphasized by Urban Ecology, a Berkeley-based non-profit organization, which later went on to coin the term 'eco-city' to address the sustainability of city development (Register, 2002). The advocacy is to 'rebuild cities in balance with nature'. In recent years, as urbanization deepens and greening urban growth becomes ever more urgent, there is renewed attention on the eco-city concept and practices (Susuki et al, 2010). The vision of eco-city is no longer a city architect's imagination but increasingly grounded in research and science of sustainability (Wong and Yuen, 2011).

Eco-cities are being built in different parts of the world, from North America and Europe to the Middle East and Asia. In the United Kingdom, the proposal is to build 10 new eco-towns by 2020 (Morris, 2011). The intention is to offer an opportunity to promote sustainable living and zero-carbon development while also maximising the provision of green space and potential for affordable housing. In the Middle East, Abu Dhabi is developing the world's first carbon neutral city, Masdar (US\$22 billion project). Masdar (6 sq km) is planned for a population of 45,000 to 50,000 with standards in green living that include clean power, desalination plant run on solar power, magnetic trains for transportation (cars are not welcome) and 100% waste recycling.

In Asia, China is embarking on a programme of building eco-communities. Eco-city building is proposed for not just the big cities like Beijing, Shanghai and Tianjin but also the small- and

medium-sized cities of Yuxi, Weihai, Rizhao and Changshu, among others. Many countries have offered to help China develop eco-cities. The most advanced of these developments is the 30 sq km eco-city at Tianjin for 350,000 residents, which started in 2007 as a joint collaboration between the governments of China and Singapore. The aim is to achieve harmonious living with man, economy and environment and on a wider scale, for the Tianjin eco-city to become a development model for other Chinese cities.

Eco-cities would characteristically comprise compact, pedestrian-oriented, mixed-use neighbourhoods that give priority to public transport and re-use of land (Roseland, 1997; Engwicht, 1992). They are designed with the consideration of socio-economic and ecological requirements dedicated to minimizing the inputs of energy, water and food, and waste output of heat, air pollution, etc so as to create an attractive place to live and work. It is not uncommon for eco-cities to have goals such as to minimize demand for land, particularly for greenfield sites, to minimize primary material and energy consumption, to optimize interaction with municipal and regional material flows, to minimize impairment of the natural environment, to maximize respect for natural context and to minimize transport demand, among others.

But, building eco-city also implies building a culture for change that is based on ethical behavior, social responsibility and clean capital so as to maintain a harmonious and non-exploitative relationship with the biosphere. The UK Sustainable Development Commission (2011), for example, has reported that the concept of sustainable lives is as yet not well understood among UK government officials and experts interviewed. The lack of definition, direction and vision for sustainable lives is a major challenge, especially when coupled with an overwhelming predominance of consumerism within present society and the mixed messages from inconsistent or contradictory policy decisions that create confusion and worse, undermine existing buy-in towards more sustainable behaviours.

3. Punggol Eco-town

Singapore, located 1° north of the equator in Southeast Asia, is an island-state with a land area of 714 km and a population of 5.3 million. Since 1960, its resident population has been progressively resettled from the once pervasive slums and squatter settlements to live in high-rise, high-density self-contained public housing new towns. By the 1990s, the city is almost slum-free. Still, as with many other fast growing coastal cities, Singapore faces several potential vulnerabilities including coastal land loss, increased flooding, water resource scarcity, increased energy demand, urban heat stress and public health threats (e.g. dengue, haze). Many parts of Singapore are less than 15m above sea level.

Recognizing that the environment is critical to economic growth and long-term development, Singapore has adopted an action-oriented approach to sustainable development with emphasis on long-term vision, integrated urban planning, sound environmental policies and high regulatory standards. For instance, in the transport sector, private vehicle ownership and usage are controlled to reduce energy consumption and traffic congestion. The Inter-Ministerial Committee for Sustainable Development (2009) formulated a blueprint with extensive public inputs, setting targets in several priority areas:

- Improving resource efficiency (e.g. to achieve a 35% improvement in energy efficiency from 2005 levels by 2030, attain a recycling rate of 70% by 2030, reduce domestic water consumption to 140L per person per day by 2030);

- Improving quality of the urban environment (e.g. to reduce level of fine particles in the air to 12 $\mu\text{g}/\text{m}^3$ and cap SO₂ levels at 15 $\mu\text{g}/\text{m}^3$ by 2020 and maintain same levels up to 2030, have 0.8 ha of green space for every 1000 persons and increase greenery in high-rise buildings to 50ha by 2030, improve accessibility for pedestrians and cyclists and have 70 per cent of all journeys made by public transport);
- Developing knowledge (to build key capabilities and technologies, especially in resource efficiency and urban planning and design and to develop Singapore as a knowledge hub and provider of services relating to environmentally sustainable urban development); and
- Encouraging community ownership and participation (to make environmental responsibility a part of Singapore's people and business culture, e.g. schools to step up their efforts in promoting environmental education, public sector to adopt more environmental sustainability practices).

The government has committed to invest S\$1 billion over five years to support these efforts including helping businesses reduce the upfront costs of investing in resource efficient buildings, systems and processes. Buildings will be made more energy efficient. Developers are encouraged to build green buildings and since 2005, their efforts are recognized through the Green Mark Scheme. The goal is to have 80% of buildings certified with Green Mark by 2030. For existing buildings, an S\$100 million Green Mark Incentive Scheme has been introduced to help owners undertake energy efficiency retrofitting. The government will take the lead by developing eco-friendly public housing. Solar technology will be piloted at 30 public housing precincts across the country. The Housing and Development Board (HDB) as Singapore's public housing authority and largest residential developer will reduce energy use of common areas in public housing buildings by 20-30% and build more eco-friendly public housing starting with development along Punggol Waterway in Punggol New Town.

Since its establishment in 1960, the HDB has constructed 23 new towns and more than 1 million residential units and a substantial volume of related commercial, industrial and institutional facilities. As early as 2004, the HDB has established a Committee on Environmental Sustainability, comprising representatives from public and private sectors, to formulate a long-term strategic direction and forward planning for the development of environmentally sustainable public housing towns. It has committed to having all its new projects Green Mark certified since 2007. A review of the HDB Green Housing Book (2007) revealed a combination of passive and active approaches towards creating a sustainable environment including:

- Creating a better environmental quality through design in retrospect to the site (taking account of the locality, existing topography and accessibility), design for comfort living (through passive design and facilities provision, e.g. greenery, pneumatic refuse collection system, low volatile organic compound paints to achieve acceptable air and noise quality) and earth control measures at development sites (through erosion control and sediment control);
- Achieving energy efficiency largely through the use of zero-energy and low-energy systems in every possible areas, e.g. designing in relation to nature, greenery provision (e.g. vertical greening), building elements such as building form and orientation with the windows facing North-South and gable ends facing the East-West direction, façade articulation, wall design (e.g. cool wall) and effective exterior envelopes, maximization of natural lighting and ventilation, monitoring of energy usage, low energy consumption systems and alternative energy;
- Promoting water conservation and reuse in view of Singapore's water resource shortage, starting from the design of water distribution system to the water fittings installed and more recently, the introduction of water sensitive urban design;

- Improving resource materials in the construction of buildings through design consideration (e.g. standardization of doors and windows), alternative construction, alternative materials, recycled materials and construction modularization by testing green technologies and innovations in its building developments.

On 28 March 2007, it started building an eco-precinct - Treelodge@Punggol (completed on 19 December 2010) as a pilot project to demonstrate that innovation and sustainable development can be both practical and cost-effective. The precinct comprises 7 16-storey apartment blocks with 712 units of 3- (98), 4-(600) and 5-room (14) flats. As with earlier developments, the basic unit of planning is the neighbourhood where the daily needs of life are accessible within 5 minutes' walk but with a strong urban design focus on public spaces, making the neighbourhood not only walkable and liveable but also improving human scale and the sense of place.

3.1 Starting with Eco-precinct

Treelodge@Punggol, a build-to-order public housing scheme, is designed with triple aims - to lower maintenance cost, to meet environmental targets in energy, water, etc and to enable the community to experience eco-lifestyle. The precinct is designed to harness the elements of nature (e.g. daylight, rainfall and wind) and technologies to promote sustainable green living. It incorporates passive design as well as a range of green technologies and innovations for effective energy, water and waste management. The 7 residential blocks are designed with a podium car park across their 1st storey where the roof of the car park is landscaped into an eco-deck, transforming it into an activity centre, a connector with a green spine connecting all precinct amenities and to public transport nodes and a large green footprint. The latter has enabled maximization of greenery in the eco-precinct, achieving a greenery provision of more than 4.0. The introduction of the podium car park-eco-deck has actualized several benefits:

- Allowing residential blocks to be spaced further apart, thereby providing larger inter-block spacing;
- Facilitating the introduction of a vehicle-free eco-deck on the roof of the podium car park, thereby allowing more greenery (a hybrid green roof system, vertical greening and large trees are grown at the car park level through air wells) to be introduced and creating a landscaped environment for residents to rest, relax and socialize while helping to absorb environmental noise;
- Providing direct car parking facilities at the immediate ground level of the blocks for residents, thereby increasing convenience to residents.

As part of the green living, the precinct is, however, designed with a reduced number of car parking spaces and co-location of land uses and facilities to reduce travel demand. The eco-precinct is located in proximity to the existing Punggol mass rapid transit station and Damai light rail station. Aside from public transport, residents are encouraged to car share; a car-sharing scheme is planned including hybrid cars. Other design strategies to improve residential environmental quality, energy, water and resource efficiency include:

- Strategic positioning of all residential blocks with facade windows to face the prevailing north-eastern winds and maximize natural lighting and ventilation;
- Use of cool building walls with enhanced thermal insulation to mitigate heat and radiation from the tropical sun;
- Solar panels on rooftop to power lighting of common areas;
- Energy saving light fittings in common corridors and car park deck, energy-saving machine roomless lifts that use 10% less energy than conventional lifts;

- Dedicated recycling refuse chutes within the flats;
- Rainwater harvesting system to support use of rainwater for washing common corridors and landscape irrigation;
- Integrated wash basin-toilet pedestal system to allow water used for hand washing to be redirected and recycled to the pedestal cistern for the next flush.

Another prime feature is the intensified greenery, which is expected to lower the surrounding temperature by as much as 4° Celsius while beautifying the precinct environment. Greenery takes several forms - the eco-deck above the car park, skyrise greening on building roofs, facade greenery and community gardens. To enhance site ecology and the green experience, lift lobbies at the car park level are also designed as landscaped courtyards while a green spine (with a tree-lined 650m jogging path, exercise stations, community pavilions, children's playground made from recycled materials) provides additional recreation spaces for all ages and connectivity within the precinct.

According to the HDB, the eco-features have increased overall construction costs by about 5-8% but the total estimated energy savings is about 2 gigawatt hours that could power some 400 four-room households for 1 year. Treelodge@Punggol has since received several sustainable development awards. It is Singapore's first BCA Green Mark Platinum Award public housing project, the highest rating given to promote energy savings, water savings, healthier indoor environments and adoption of more extensive greenery in the design and construction of green, sustainable buildings. In 2010, Treelodge@Punggol has also received the Chicago Athenaeum's Green GOOD Design Award, recognizing the importance of sustainable design. Initial reaction from the potential residents has been positive, with many looking forward to 'moving in to our own place and we are very pleased with the specially designed ecofriendly features here at Treelodge' (HDB Corporate Newsletter Jan/Feb 2011: Breaking Ground).

Following the Green Mark award of Treelodge@Punggol, in 2010, the HDB has announced plans to further promote the notion of sustainable township development, extending the notion of the eco-precinct to the entire new town, designating Punggol as Singapore's first model eco-town. Punggol, to be developed in two phases (phase 1: 2011-2015, phase 2: beyond 2015), will be designed to promote sustainable living based on three key principles - to introduce effective planning and design concepts to make it conducive for residents to adopt eco-lifestyles, to exploit urban solutions to achieve stretched environmental targets and to engage, educate and enable people to go green. It has recently launched an e-book to help residents learn more about the green features found in Treelodge@Punggol and a series of e-games to help residents keep the environment clean and green and make recycling their way of life.

A crucial aspect of the Punggol eco-town project is that it will serve as a 'living laboratory' to identify and test cost-effective new ideas and technologies in sustainable development, integrating urban solutions to create a green living environment and build local capacity to replicate these solutions in other HDB new towns (Table 1). A two-tiered test-bedding strategy is adopted - emerging technologies are test-bedded at one or two precincts within the Punggol eco-town, e.g. Treelodge@Punggol to prove their feasibility before they are implemented on a larger extent across the town. A multi-agency collaboration led by the HDB has been established to spearhead the development. The intent is to provide all participating partners with the planning insights and experience to replicate successful sustainable features of Punggol eco-town in other public housing towns and ultimately, the entire Singapore.

Table 1: Eco-urban Solutions in Punggol New Town

Area	Eco-urban solutions	Target over next 5 years
Energy	Solar photovoltaic system	To reduce energy consumption for the common areas by 20%.
	Elevator energy regeneration system	
	Energy efficient lighting in common areas	
	Smart grid/meters	
Urban mobility	Use of electric vehicles through the car-sharing scheme. Charging points for the electric vehicles to be located at strategic points to enhance the convenience to residents of using an electric vehicle.	
	E-bicycles to provide an environment-friendly alternative for residents to commute within the eco-town or simply just for leisure.	
Water	Water efficient fittings	To bring about a net water reduction of about 10%.
	Rainwater harvesting	
	Smart water meters	
	Water quality monitoring	
Resources and waste	Recycling points at every level in the residential blocks by building a second centralized refuse chute dedicated for recyclables to enhance convenience for residents to dispose their recyclable waste but also raise collection efficiency for waste collectors.	Three times increase in recyclables.
Maintenance	Fuel cell emergency power supply	To reduce maintenance costs.
	Self-cleansing paint

When examined against climate change actions, the various eco-features of the Treelodge@Punggol eco-precinct appear relevant to addressing climate change (Table 2). Some of them are mitigation measures and others are adaptation to climate change.

Table 2: Assessing Treelodge@Punggol Eco-precinct

Urban function	Eco-urban features	Relevance to climate change
Land	High-rise city living - a room with a view (compact city): 7 16-storey apartment blocks with 712 units of 3, 4 and 5-room flats. There are 98 units of 3-room flats, 600 units of 4-room flats and 14 units of 5-room loft units.	Increase green coverage and hence lower ambient temperature and reduce energy used for air-conditioning.
	Podium car park.	
	Accessibility to amenities and public transport: Located in Punggol New Town, at the junction of Punggol Road, Punggol Drive and Punggol Place, Treelodge@Punggol is just a few minutes' walk from the future Town Centre, Punggol MRT/LRT Station and the Punggol Bus Interchange.	Reduce need for travel and hence energy used for transport.
Water	Green Mark Platinum Award for water efficient buildings.	Reduce fresh water usage.
	Rainwater collection system: the building roof has 400 sq m of space to collect rainwater. Rain falling on the roof is first drained into a tank situated on the 16th storey of the block, and then treated using a chemical free system before stored in a tank for common area (common corridors) washing and irrigation. The water tank can store up to 7,000 litres of water, which is sufficient for a month's washing.	
	An integrated washbasin and toilet pedestal system in the flats for water used to wash hands to be recycled for the next flush.	
Energy	Green Mark Platinum Award for energy efficient buildings	Reduce energy usage and hence less greenhouse gas emission.
	Solar panels on the rooftop to tap on clean energy to power the lighting for the common areas, e.g. common corridors of the estates as well as the eco-deck. This will save 80 percent of energy used.	
	Units are designed with larger windows to allow more natural light.	
	Motion sensors for multi-storey and podium car parks to provide on-demand lighting.	
	LED Lighting.	
	A 'Car Sharing Scheme' will be introduced to provide residents with access to a fleet of cars, which also include hybrid cars.	
Environment	Unique to this eco-precinct is the 5-room loft unit that features a double-volume living room and an open terrace that can be converted into a sky garden.	Increase green coverage and hence lower ambient temperature and reduce energy used for air-conditioning. These features are expected to lower the surrounding
	Intensified greenery with an eco-deck above the car park, skyrise greening on roof decks and a community garden. Vertical greening along the columns	

Urban function	Eco-urban features	Relevance to climate change
	<p>of the residential blocks.</p> <p>Enhanced landscaping to intensify greenery.</p> <p>North-south orientation of the buildings.</p> <p>The buildings are designed to face the prevailing wind direction for cross ventilation.</p> <p>Designed to reduce noise transmission between rooms, the flats will be fitted with the patented FerroLite partition wall system. The wall is essentially non-load bearing and made of ferrocement. As compared to other cement-based partition walls, the hollow core of the FerroLite wall reduces the need for raw materials like cement (by 30%) and sand (by 20%), yielding overall savings of up to S\$1.5m per year. In addition, services can be installed and concealed within the wall with minimal wet works and without the need for hacking.</p>	<p>temperature by as much as 4° Celsius.</p> <p>Cool down the ambient temperature in the flats and hence reduces the need for air-conditioning.</p> <p>Reduced use of cement helps to reduce greenhouse gas emission in cement production. Hollow walls also help to insulate tropical heat.</p>
Health	<p>A 650m long tree-lined pathway that circles the eco-precinct to cater residents for jogging or taking leisurely walks in a lush environment.</p> <p>Exercise stations for the elderly.</p> <p>A children’s playground made from recycled materials.</p>	Encourage healthy lifestyle to improve resilience to climate change.
Waste	A dedicated recyclable refuse chute at each block to encourage recycling.	Reduce inclination of recyclable waste and hence reduce GHG emission.

4. Conclusion

In contrast to many other Asian countries, Singapore has realized and fully accepted that unsustainable development will undermine long-term economic wellbeing. That is, economic growth and sustainability need not be mutually exclusive. A proactive approach is adopted to address sustainable development comprehensively and to mainstream sustainable development in its urban plans. Singapore has started to develop an eco-precinct and scaling up to an entire eco-town. Even though the eco-town is very much work in progress and also not the only smart growth solution, the development experience demonstrates how new neighbourhoods can be designed to be more sustainable. Urban planning strategies can play a critical role in improving environmental quality and addressing climate change by providing such housing and public infrastructure that minimizes transport and energy demands, maximizes respect for nature while satisfying basic needs. It can be a game changer. An integrated planning approach not only coordinates the spatial development of quality core living and working sectors with transport development but also unlocks sustainable living opportunities.

Though early days yet, through its eco-precinct and eco-town planning, Singapore is seeking to transform its current highly energy-intensive urban economic system into much less energy intensive and much less carbon intensive processes. Critical to the transition to lower carbon development is vision, supportive institutional framework and understanding of cross-sectoral issues as well as participation of the population whose lifestyle will eventually determine the extent of sustainable development achievement. In other words, while government commitment is crucial, sustainable development is not the lone action of government. So, it is imperative that every opportunity is made to engage the people, from policymaking (e.g. in the inter-ministerial sustainable development blueprint making) to planning and design of the eco-town and community education to raise awareness and promote a more sustainable way of living as the everyday 'default' way of life.

A key lesson for other fast growing Asian cities is that cities must and can be planned to develop more sustainably. Admittedly, this is not an easy task. As illustrated by the Singapore eco-town development, it will take time and costs. Even as we acknowledge that green development may be more costly than conventional development, its benefits in terms of longer-term energy and resource savings could align and better support the delivery of more productive and resilient built environment. Given the long gestation, the development is perhaps best approached in an incremental way, building up local knowledge and capability as well as the confidence in finding urban solutions that are suited to local conditions. But, crucially, underpinning the incrementalism would be the necessary requisite to look at the urban area as a whole to grasp the full meaning of sustainable urban development, having appropriate scale (start with a smaller area and test-bedding before scaling up), connectedness (to the community and cross-sectoral interests) and the fundamental principle of thinking and acting sustainably now, rather than later. Eco-city planning is a learning process. It should, therefore, also be monitored and reported upon to better understand how the settlement is functioning and where changes might be needed.

The Evaluation and Improvement Method of Waterfront Urban Landscape: the Case of Urban Landscape Planning for West Lake in Hangzhou, China

Ye ZHAO, School of Architecture and Planning, Southeast University, China

Jianguo WANG, School of Architecture and Planning, Southeast University, China

Abstract

Urban landscape usually contains two layers of meaning: landscape and viewing, especially in waterfront zone. Traditional design focuses on landscape design which purely improve the quality of objects in static, passive way much more than noticing the initiative viewer as subject. Actually, landscape and viewing are dialectic. Interactive design using reasonable visual evaluation methods, integrated with “positive” human activity optimization as well as “passive” landscape improvement, can be helpful to enhance the quality and controllability.

West Lake in Hangzhou is the famous cultural heritage in China with humanities and nature fitting each other perfectly, which also represents the model of blending natural scenery and modern city. However, it faces some urgent problems in modern urban development, the relationship between West Lake and the city has become extremely uncoordinated, as it suffered very serious “pressure” from the city.

This paper takes West Lake as example, basing on lots of survey, analyzes the visual effect from every grid viewpoint on the lake (using GPS to locate), and tries to find out the both way of adjustment from the respects of viewer and landscape, and finally proposes some thinking of the design method.

Being water-adjacent is one of the critical principles for ancient cities. In contemporary city, although the functional factor has gradually declined, the landscape meaning is getting greater. People are enabled to comprehend a city in a panoramic way at an open waterfront zone, which can improve the quality of the city. As so, the relationship between the urban and the water landscape is a fundamental issue for the urban construction.

When considering urban and landscape, people usually treat them as two separate objects simply collaged. Researchers seldom focus on the interaction of the two parts as well as the value based on this, and the following strategy is hence ignored. This paper takes West Lake in Hangzhou as example, tries to find reasonable, simple, universal methods to solve the “landscape oriented” urban design issues.

1. Background

1.1 Urban Waterfront Landscape

Urban waterfront can be divided into two types: one is inside the urban area as a planar

element, like West Lake in Hangzhou, Xuanwu Lake in Nanjing, while the other goes through the urban as a linear element, like Qinhuai River in Nanjing, Grand Canal through many cities. The former one can form a panoramic view of the city; the latter one is more tend to be landscape belt. In comparison, the open water body is more valuable for urban landscape.

Though there are mature principles for the waterfront space design, like building setback distance, height and massing control of the buildings near the shore, have guaranteed the basic quality of the environment, the shape and scale of the water vary as well as the relationship between city and water, that can deeply influence the viewer. If open waterfront zone boasts multiple public sight-seeing points, people can read the city's skyline from different places, at different angles, it would be easy to establish the impression of the whole city.

Due to the integration of the architecture and landscape discipline, architects began to draw the overall thinking into detailed architecture design: the impact of new construction in the built environment, the way of coexisting, the design strategy in visually sensitive zones, the use of computer technologies to simulate the building volume, the visual sequences and landscape effect at key viewpoints. A series of analysis on the massing, height, façade, top and the whole outfit have accelerate the rational of the design.

Overall thinking is good for architecture design in some levels, but not enough for the large scale of the city, especially at panoramic waterfront zone, which might emerge the problem of "entirely mess, partially ordered". So, besides discussing possibilities of the design, the evaluation should get rid of architect's personal preference, judge objectively through scientific method and public participation, and finally achieve the adjustment and control.

1.2 Evaluation Methods

Hangzhou is outstanding among cities boast large-scaled waterfront in China, and so is West Lake in Hangzhou. It has experienced both natural and man-made evolution through thousands of years, with great crystallization of mild temperament and cultural allusions, which is the best representation of Hangzhou. But, this characteristic has faced some challenges in modern development. The lake opens up to the city so straightforwardly that increasing high-rise buildings and rising height expose directly without any cover. The well-proportioned skyline has turned into a stiff wall rapidly, and has replaced the lakeside kind of feeling. West Lake has suffered the pressure coming from the city, very seriously.

The landscape planning contains two processes: evaluation as approach and control as result. Both of them will divide the landscape into initiative viewing and passive objects. Initiative viewing focuses on the variety and sensibility, while passive objects emphasize on reality. According to the difference of the evaluation and control, evaluation mainly discusses people's initial feeling as visual subject, while control prefers improving the quality of the landscape based on the conclusion from people.

2. Evaluation methods

According to general rules of landscape viewing behavior, the viewer and landscape are two basic elements. The viewer stresses the viewpoints, route and the psychological feeling, the landscape stresses the value and significance of every constitute unit of the landscape.

2.1 Evaluation of the Viewer

Chinese researchers have proposed many analysis modes: aesthetic mode, ecological mode and so on. So far, researches are normally qualitative description, lack detailed method for some special condition.

1. Categories of viewpoints

West Lake is famous of “being surrounded by hill at three sides and city at one side”. It’s 3200 meters from south to north and 2700 meters from east to west, with 5.6 square kilometers of water area, surrounded by hill at south, west, north direction, and city at east. The Baoshi Hill (BaoChu Pagoda) and Wu Hill (ChengHuang temple) are the borders of the “stage”, the distance between them are the visible urban landscape. The Su Causeway, the Bai Causeway, Gu Hill, Isle Mid-lake Pavilion, Ruan-gong Isle are the most important public space and viewpoints. (Figure 1)

Figure 1: Visible Area from West Lake

We classified the viewpoints into three types according to the sightseeing activity: spots, linear and planar. Spots are usually at dominant height or can get special experience, there are two spots in West Lake: BaoChu Pagoda and ChengHuang Temple. Linear points are a series of points along people’s route, which can provide continuous visual experience and change with people’s movement. Su Causeway and Bai Causeway are typical linear points. Planar points are multiple ones in a larger area yet have little difference. Since the lake locates on one side to the city, people’s activity on the lake can be divided into several large areas.

On the other hand, people’s activity has two types of static and mobile. When people stand still at some relatively stable point, the feeling is independent and unique. Good static viewpoint is favorable for landmark buildings. Mobile viewing means people formed the perception during the moving, overlaid multiple urban landscape façades and finally got the whole impression. It is always related to the linear and planar points, continuous movement and visual overlying is the basic feature. During the route, special spot in mobile process equals static spot.

2. Evaluation methods

We took many ways to collect the performance of urban landscape as follows:

1) Questionnaire. We collected opinions of different groups (ages, nationalities, education levels) by questionnaires and interviews randomly along the Su Causeway, at “Ten Scenes”

and boat docks. The questions involve selection of viewpoints and route, landscape nature and feelings, architectural features and details, the overall impression and evaluations. All withdraw 100 valid questionnaires, of which 80 were Chinese, and 20 were English copies.

2) Viewpoint marking. During the continuous scene, mark out the best, the worst, sudden change spots with explanation and illustrations. We chose the Su Causeway and the Bai Causeway as the route, started from the south of the Su Causeway, walked forward north, bypassed Gu Hill, until the east end of the Bai Causeway, marked out 22 spots with photos and writing.

3) Pictures and records. This is the most direct way to record the real situation of the landscape at every special spot. The broad lake is a typical planar spots assembled, on which paddleboats can cruise randomly. We put a grid on the lake, which is 250 by 250 meters in north-south direction, numbered every intersection point, then used the GPS to locate, took multi shots at every point that can merge into a panoramic view of the city from this angle. We got 130 valid photos, 120 of which were used. (Figure 2) Through the methods above, most of the viewpoints have been covered, around and in the lake.

Figure 2: Photos from Three Viewpoints

2.2 Evaluation of Landscape

The evaluate object is the elements that form the urban landscape, such as buildings, trees and so on. Although visual effect is a subjective concept, there are some general aesthetic standards and common sense that can be quantified.

1. Single element

Urban landscape is formed by many elements, which contain manmade elements like architectures, sculptures, bridges, and natural elements like mountain, water and trees. For West Lake, manmade elements are dominant and important for the visual effect, especially when the buildings are continuous background. Since high-rise buildings determine the quality of the skyline, we defined the visible area in depth of 9 km, evaluate every high-rise building in this area from the aspects of height, scale, façade, top feature, material and distance from lake shore. According to the principle of coordination with the surrounding, we picked the best 5 buildings from the total 70 ones: West Lake culture center, Xinqiao Hotel, China Bank, Hangzhou Friendship Hotel and ZJCOF (Zhejiang Cereals, Oils & Foodstuffs Import & Export Co., Ltd).

2. Group elements

The skyline and layers mainly show the group performance. Since the center of the city keeps changing, land developing intensity increasing rapidly, the quantity and height of the buildings

being break, the overlap situation has been serious in recent years, the vacant has been gradually filled into a “wall”.

The rigid surface and the same height result in the monotonous façade, and the variety and value have been weakened. So, in order to get good visual effect, the skyline and subjective experience are the key points.

The skyline is one kind of special impression of the whole city, formed by the high-rise buildings. A good skyline needs appropriate fluctuation, landmarks at exact position, and natural link between city and nature. We graded from the unit density, unit area range and unit First height Difference. The higher density is, the less obvious rhythm; the greater area range is, the better identifiable is; the higher difference is, the more obvious fluctuation is.

The subjective experience judgment is from the buildings’ layers, color and visual patch, in detail, the substantial degree of layers, area proportion of manmade and nature, and color coordination. The variety and color coordination are correlative to the quality, the higher the better, while the area proportion of manmade and nature is inverse correlative, the less the better. (Figure 3)

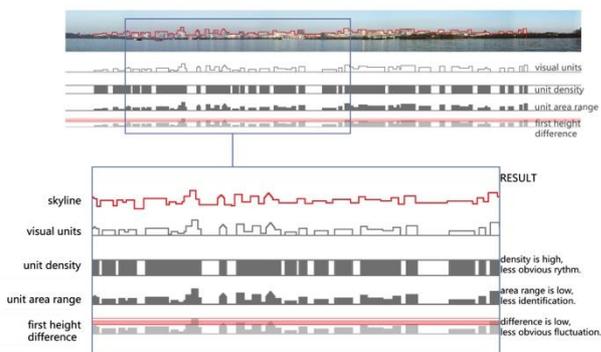

Figure 3: Skyline Analysis

2.3 Relationship between viewer and landscape

In the actual process, the evaluations of the two parts happen simultaneously. People are subject; landscape is object, by the medium of viewer. A complete process can be described like: people stand at some point (or along some route), use the methods of viewing judgment, make evaluations of the landscape. So, they are not isolated but relying on each other. If analyses “point” without “landscape”, it’s prone to over-emphasize the subjective choice, if judge the “landscape” without “point”, it will be unpractical in built environment.

The comprehensive evaluation is based on the data synthesis and screening, the evaluation of the landscape is quantities, hence treated as the basic conclusion, while the evaluation of viewer is qualitative, and treated as the adjustment suggestion.

But the conclusion is not a precise score, especially when the viewpoint’s choice is quite subjective, so we add the questionnaire some descriptive expression, such as “ the visual quality at the YaDi Bridge is pretty good, 85 score”, “ when I row a paddleboat moving from north to south, the whole landscape is getting better”, “I think the landscape west to the ‘Three Pools Mirroring the Moon’ is much better than the east part”.

3. Methods of control

3.1 Improvement of viewpoints

During the process, we graded 102 photos and classified them into 4 levels: the first class is the best 23 viewpoints, scored 80-90, the second level is 13 points which are 60-79, third is common points, 48 ones, which are 30-60, the fourth is the worst 18 ones scored 10-30. All these points are scattered in three types (spot, linear, planar). Among “Ten Scenes”, “Spring Dawn at Su Causeway”, “Orioles Singing in the Willows” and “Leifeng Pagoda in Evening Glow” are better than “Autumn Moon Over Calm Lake” and “Lingering Snow on the Broken Bridge” that are closer to the urban façade. Respectively, Su Causeway is far from the façade, with “Isle Mid-lake Pavilion” in between adding the layers of the landscape, is much better than the Bai Causeway. On the lake plan, the area east to the Isle Mid-lake Pavilion is the worst at all, for there is no any block or landmark. (Figure 4)

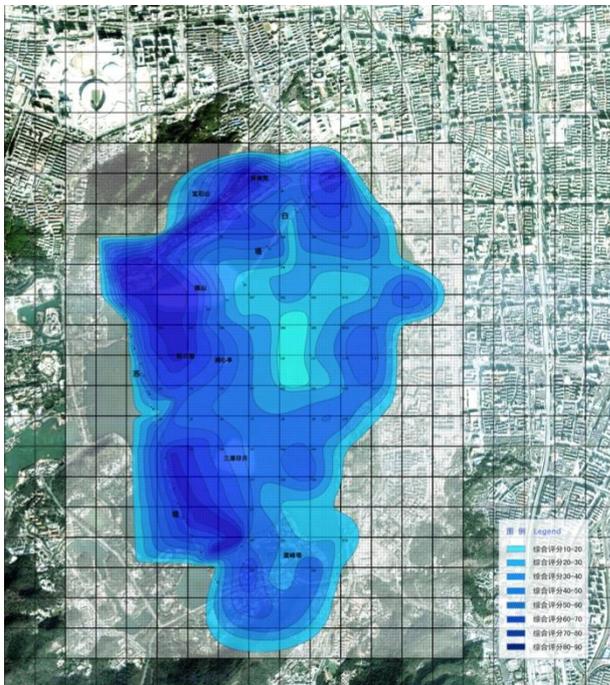

Figure 4: Scores of all Viewpoints on the Lake

Through the analysis, we proposed the improvement strategies:

1. Avoid negative viewpoints (spot aspect). Viewpoint is unit of the system, numerous points form routes. The quality of the points decides the whole effect. In fact, most of the “Ten Scenes” face the urban façade directly, so when the façade is not good enough at some spot, the spot should be avoided. For example, “Lingering Snow on the Broken Bridge” should increase the probability of XiLi Lake on the other side of the bridge. “Leifeng Pagoda in Evening Glow” should guide people to overlook the Su Causeway. “Orioles Singing in the Willows” could shift the focus to the “inland” activities like jogging. “Breeze-ruffled Lotus at Quyuan Garden”, “Three Pools Mirroring the Moon” and “Viewing Fish at Flower Pond” should improve the tour line and environment inside the scenic area rather than outside.

The viewpoints along the shore need different approaches to optimize: poor ones could take advantage of adjacent landscape to attract and transfer people’s interest, such as willow

shadow effect can block the lake and city landscape but emphasize the depth of the shoreline, while excellent viewpoints should increase opportunities and space for tourists to stay.

2. Update cruises on the lake (linear aspect). There are 4 terminal docks located at the south and north end, and 1 transfer dock at the “Three Pools Mirroring the Moon”. The exist cruise are 5 lines: “Three Pools Mirroring the Moon” – Su Causeway, “Three Pools Mirroring the Moon” – Lake Shore park, Lake Center Islands – Gu Hill, “Three Pools Mirroring the Moon” – YongJin Dock, HuaGang Dock – “Three Pools Mirroring the Moon”. This means 60% of the cruises go across the worst area. So, under the premise of not changing docks and sight attractions, we change the shape of the cruise line to avoid the worst area: in regard to the cruises via central islands, move the stops from the east side to the west, in regard to the cruises toward the eastern shore, move the stops towards natural section of the bank, where trees can cover the high-rise building far away. (Figure 5)

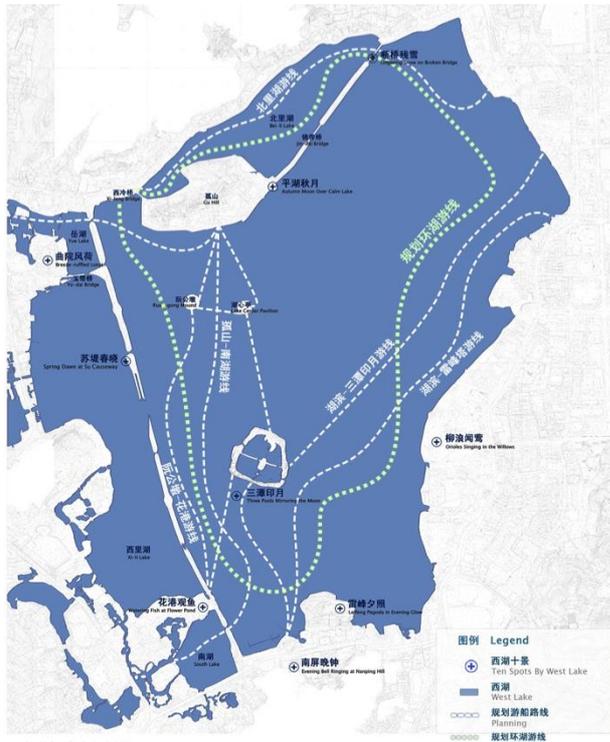

Figure 5: Adjustment of Cruises on the Lake

3. Choose good view surface (planar aspect). On the lake, the area east to the Isle Mid-lake Pavilion is the worst, followed by northern part, and the southern is the best. The visual quality is related to the shape of lake itself and relative position with the urban façade. Medium and close landscape are very effective in improving the panoramic scene, so, marking out the best surface is also a positive countermeasure. According to the questionnaire and photo scoring, the Su Causeway and “Orioles Singing in the Willows” section are the best surface for panorama.

3.2 Improvement of the urban landscape

Since the urban landscape is the appearance of the buildings' organization, improvement should pay attention to the spatial structure and form.

1. Urban center system adjustment and overall layout planning

This strategy is based on the overall planning of the urban structure. High-rise buildings are mainly distributed in Wulin Square, Qinchun Road, Station District, Qianjiang New District, Binjiang New District. In the next 20 years, Qianjiang New District is the direction of the development, which means more high-rise buildings will appear in the façade. According to the data calculation, Hangzhou's urban center system would become a continuous one connecting five sub-systems into one. But this doesn't allow the random grow. High-rise buildings should be well placed, not only in plan, but also in elevation, not only in new district, but also in old area. From the perspective of "viewing city from lake", if the buildings perpendicular to the façade can "form skyline fluctuate in rhythm and combine landmarks at multipoint, the façade would be worth viewing. So, we prefer the "two cores and four sub-cores" spatial system: Wulin Square as traditional commercial core and Qianjiang New District, each represents the north and south develop center of the city, four sub-cores locate around and between. When people see the urban façade at any point from the lake, the skyline will appear multi combinations. (Figure 6)

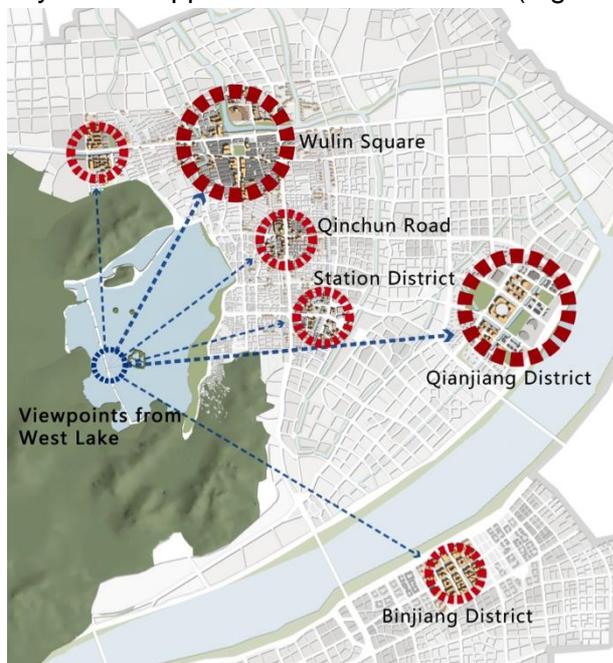

Figure 6: Urban Center System Structure

Besides the adjustment of the layout, the height control is another critical method. We numbered every block in the visible area, picked out the buildings higher than 8 floors and 32 meters, established corresponding data files (property, location, floors, color, material, top, photo), overlaid the atmospheric visibility that reduce along the distance, finally got the lake-centered visible cambered area data base. The concentric spheres are circled with the Su Causeway, radius as 2 km, 3.5 km, 6 km, 9 km separately, corresponding to lakeside house, Qinchun Road, Station District, Qianjiang New District. Ideal skyline shape helps us decide the height upper limit for each stage: 32 m, 100 m, 150 m, 200 m. 70% buildings must be within the height, between 50%-70% of the figure, in order to attain the safe pattern of the spatial structure and landscape (basic requirement), afterwards, the buildings in "two cores and four sub-cores" need some adjustments according to the whole three dimension effect. The entire east coast city is divided into 18 control zones by this mode, with the urban plots

fully covered. Buildings' height limitation within different plots provides the basic framework and platform for the future management and control, and connects with the next level of urban design work well. (Figure 7, Figure 8)

Figure 7: Safe Pattern of the Urban Spatial Structure

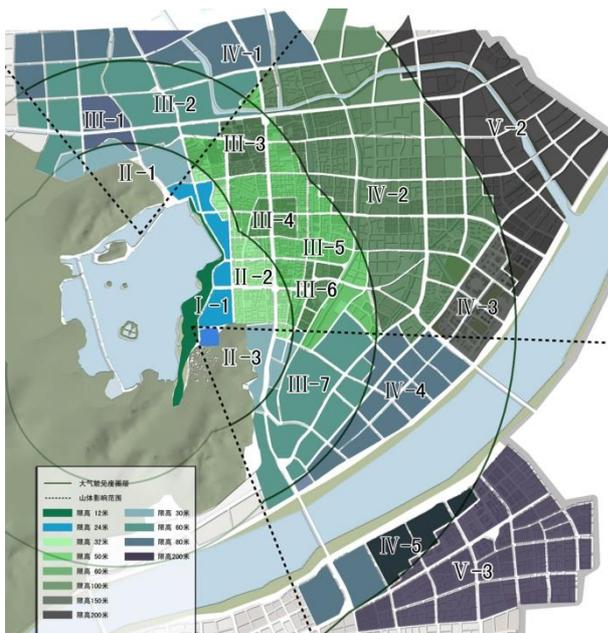

Figure 8: Height Control of 18 Plots of the Visible Area

2. Improvement of single buildings

Improvement of buildings is mainly on the exterior. We chose the feasible aspects of top improvement, façade improvement and greening: rectification of the "temporary shape" and advertising boards at the high-rise buildings' top, reduction of conflict with the built environment by choosing materials and colors according to the building's status in the whole façade, greening on the annex platform for increasing the variety of the base level. Then, we picked 25 single buildings to carry out the plan.

3. landscape supplement in lakeside

Lakeside space has special value for it can provide a relative separate surface for landscape viewing yet blends the lake and shore into one, the design of the space can not be neglected. Among the photos, we found that all the points where photos contain Isle Mid-lake Pavilion, Gu-Hill or tortuous shorelines, the point must be above second level. Because of these natural elements attract people's interests, the urban landscape easily get blurred and out of focus. For its property as the boundaries of urban landscape and as the edge of the lake landscape, we proposed two ways of supplement: urban interface fix and lakeside landscape construction.

As the start of the landscape, lakeside should link with the urban in a natural way, from the height, massing, shape, style. Buildings should lower than 12 meters, in simple style and small scale, just for adorning the shore.

In tourists' opinion, the lake is broad lacking of focus, but the shore is rich of all kinds of plants and furniture, so they prefer the pavilions and trees to the lake. In so, the arrangement of the plant should correspond to the landscape, tall trees at surface needs shelter, low shrubs at surface needs opened up.

4. Conclusion

1. Characteristics of the city need to be shown by representative of culture or landscape, commonly referred to as "special culture" or "characteristic landscape". In the context of urban landscape increasingly following the same pattern, protection and inheritance of landscape, publicity and highlighting of cultural characteristics, is an important measure in enhancing the quality and content of the city. But more important is to find a balance between conservation and construction, to seek reasonable remodeling methods, to create a dynamic, competitive environment full of human temperament.

2. "Landscape + View" two-way adjustment for urban landscape visual evaluation has multiple effects. Conduct reasonable route guidance and viewpoint choice from the "View" perspective is what urban design has done: closely integrated design with people's feelings. While actively respond to the plight of urban construction, and reflect on foresight idea, which is helpful to establish scientific platform enables the control and management of urban landscape operate more rationally.

3. Visual evaluation remains some deficiencies. First, landscape planning based on visual assessment can not independently solve all problems, let alone replace the overall urban planning, but needs support from other assessment methods and planning results. Secondly, "visual evaluation" as the name suggests, is landscape environment evaluation in accordance with personal visual aesthetic standards. We followed the planimetry perspective rule, but when groups of people work together, because of the difference of standard and personal preferences, may cause bias in terms of accuracy and scientific aspects, to be further improved. Thirdly, the interviews have a strong "personal touch", the number and the level of participants directly influent the accuracy and objectivity of the "conclusion", therefore, the set of the interview questions, organization of programs are particularly important.

Track 3: Community and Stakeholder Engagement

49th ISOCARP Congress Proceedings

Planning for Age-Friendly Neighbourhoods

Claudia BALDWIN, University of the Sunshine Coast*

Caroline OSBORNE, University of the Sunshine Coast

Phil SMITH, Deicke Richards Architects

Conference Theme: *Frontiers of Planning: Community and stakeholder engagement*

Abstract

Traditional models of retirement living provide low to high care options derived from care or leisure oriented models that generally result in the segregation of seniors from the rest of the community. Research investigating international aged care provision uncovered innovative models of senior living that have 'unbundled' care and accommodation, providing for greater choice and independence as seniors' needs change. Many of the case studies examined, support not only seniors' preference to age-in-place (Quinn & Judd, 2010), but also foster their engagement in activities or with others, including multiple generations. This affects mobility and reduces social isolation, major contributors to seniors' health and wellbeing (Productivity Commission, 2011). From a design perspective, this trend also liberates the way housing and care options can be conceptualised and designed for seniors, to allow for more innovative approaches. Whilst the WHO (1997) Age-Friendly Cities Guidelines suggests that seniors should be included in decisions that affect them, there are few examples in the academic literature where seniors were asked about their preferences for neighbourhoods or housing.

This gap in the literature inspired a consortium of non-profit, private and public sector partners led by the University of the Sunshine Coast to investigate the neighbourhood and housing preferences of seniors in South East Queensland, Australia. Conducted over one year in 2011, the participative research methodology using PhotoVoice and Design Charrettes allowed seniors to critically inform a brief with detailed design principles and to oversee and advise a design team on suitable housing options. The research culminated in a number of housing typologies that were designed in active collaboration with seniors in design charrettes (Baldwin et al., 2012).

The findings of these two pieces of research clearly converge to provide key lessons in the housing, neighbourhood and care preferences of seniors. A significant outcome was the development of the "Ageing in Neighbourhood" concept, which demonstrates how a range of housing typologies suitable to seniors might fit together in an urban neighbourhood to increase housing choice for seniors. The participatory approach of this research was instrumental in exploring the contribution that planning can make and the trade-offs that seniors are willing to make to achieve acceptable design solutions. This research has broader implications: it demonstrates the value of using innovative methods of engagement to capture the future that seniors envision as they age; and provides insight into planning and delivering inclusive neighbourhoods.

Introduction

Global trends in health care have increased longevity and are foreshadowed to skew demographics in favour of a greater percentage of older people. The World Health Organisation (2007) estimates the number of people aged 60 and over as a proportion of the global population will double from 11% in 2006 to 22% by 2050. Older people typically express a strong desire to preserve their sense of self, maintain their independence, retain control and exercise choice. Baby boomers in particular have experienced much greater

capacity than previous generations to fulfil their desire to remain active and independent and satisfy their preferences (Productivity Commission 2011:51). This has implications for the kind of community that seniors want to live in and the kind of accommodation that will suit their needs as they age.

In general, seniors prefer to 'age in place', that is, to remain in their home and neighbourhood. Government aging policy encourages this to reduce pressure on service delivery systems. The consequences are that as people age, the suitability of their accommodation may not match changes in their mobility needs, partly because of a lack of housing options for those wanting to stay in their community, but not in their home. As communities are seldom designed for mobility issues of older people, the lack for community preparedness can result in social isolation and inactivity with consequent effects on health and well-being.

The alternative is the traditional model of retirement living which provides low to high care options derived from care or leisure oriented models that generally result in the segregation of seniors from the rest of the community. Evidence from the literature and the findings of our research suggest that traditional models of retirement living are a 'last resort' for people as they age, with transition to this model of care often associated with higher care needs. A 'third way' is required that enables other living options for people who wish to continue to live independently in the community they call home. This paper presents insights gained from two research projects, one exploring innovative options for aged care communities; the other, examining characteristics of a community that would enable older people to 'age-in-neighbourhood'.

Methods

1) Desk-top study – International Examples of Innovation in Age-Friendly Environments (Baldwin and Osborne, 2010)

The first research project was completed in 2010 as a desktop exercise investigating international examples of innovation in the delivery of age friendly environments which involved co-location, integrated design, and service provision. The investigation of current developments was initiated in late 2010 through telephone and email interviews with five industry executives and eight key industry associations (including seniors, retirement and aged care, childcare and student associations) in Australia. This 'snowball' technique led to identification of, and email exchange with, ten providers across the globe who were adopting innovative integrated practices.

A concurrent literature search included Australian and international technical reports, academic journal articles, and web sourced information. Although a number of potential case studies reviewed through websites and literature illustrated good practice, they were not included in the assessment as they provided a fairly traditional approach. An example of a sound but traditional approach was considered to be integrated graduated aged care within a facility or site where a resident could move from independent living, to assisted living, to full care equivalent of a nursing home.

While the study was limited by a short timeframe and resources, the findings are sufficiently thought-provoking to warrant sharing with the wider professional community.

2) Photovoice and charrettes – Infill Development for Older Australians in South East Queensland (Baldwin et al, 2012)

The second research project was conducted over one year in 2011. Whilst the WHO (1997) Age-Friendly Cities Guidelines suggests that seniors should be included in decisions that affect them, there are few examples in the academic literature where seniors were asked about their preferences for neighbourhoods or housing. As a result, University of the Sunshine Coast led a consortium of non-profit, private and public sector partners to ask seniors in South East Queensland, Australia about their preferences for neighbourhoods and housing. As a sea change location, the Sunshine Coast is already home to a larger than average older population: 17% in 2010, compared to Brisbane's 11%, and the trend is expected to continue.

The research involved two stages with a different method used at each stage:

1. PhotoVoice was used to gain understanding of older peoples' perspectives and develop principles to guide design, during May and June 2011. Participants were asked to take photos of what makes a neighbourhood and accommodation a good place to live as one ages, and what are the barriers. They shared their photos in groups and developed a narrative using their own words and pictures. These were then synthesised into 15 design principles and presented to a professional urban design team in phase 2.
2. A two-phase design charrette process was used to apply the principles and embed participants' perspectives in design typologies during August and September 2011. Participants worked with the design team in groups to develop innovative housing designs for four selected sites in each city. The research culminated in a number of housing typologies that were designed in active collaboration with seniors (Baldwin et al., 2012).

Figure 1: Designer Phil with seniors at the Sunshine Coast Charrette 2

Findings

1. Desk-top study - International Examples of Innovation in Age-Friendly Environments (Baldwin and Osborne 2010)

While the search identified a number of innovative practices around the world, in this paper we focus on ways that enabled older people to remain integrated into a community: one is home-based; the other facility-based. We give a couple of examples of each.

a) Home-based

The Wesley Homeshare program in Melbourne, Australia facilitates elderly or disabled people to remain in their own home with live-in support in exchange for free rent. Wesley Homeshare matches householders with people of integrity to provide companionship and help around the home through interviewing applicants and assessing needs. Homeshare Coordinators draw up and negotiate agreements detailing the arrangements for living together including specific tasks, sharing or managing living costs. Every agreement is different and designed to suit the circumstances of the match. Homeshare monitors the arrangement.

The MedCottage Relocatable Senior Cottages, USA is designed for frailer people who need assistance. The 12-by-24-foot MedCottage is a state-of-the-art, tastefully decorated transportable hospital standard room, which can be located on a caregivers' property. It features:

- A self contained kitchen with a washer-dryer combination and medication dispenser.
- Bedroom with a hospital standard bed and additional accommodation for a caregiver.
- Universally designed, including a handicapped accessible bathroom
- A communication centre provides telemetry, environmental control and dynamic interaction to off-site caregivers through smart and remote monitoring throughout the modular home eg relays health-related messages (such as medication reminders); a video system that monitors the floor at ankle level, so the patient has privacy but caregiver knows if there is a fall; and among other things, a lift attached to a built-in track in the ceiling that can move a patient from bed to bathroom so the caregiver could avoid heavy lifting.

b) Facility-based

Some of the more innovative models of senior living have 'unbundled' care and accommodation, providing for greater choice and independence for people as their needs change. One of the better-known examples is the Humanitas Foundation Apartments for Life in Rotterdam, the Netherlands, comprised of 200 universally designed apartments housed in high density buildings centred around a village square which includes recreation, medical and shopping facilities as well as gardens and studios. People can organise the care they need while being part of a multi-generational community.

Somewhat similar is the Ocean Street Bondi Development, Sydney, Australia being developed by The Benevolent Society with 128 universally designed apartments housed in two medium rise buildings and one existing building. Housing and care provisions are separate to facilitate individualised care from low to high care needs onsite. While the facility

is for seniors, it enables locals to stay in their multi-generational neighbourhood but in more suitable accommodation with care tailored to their needs as they age.

The Pike Place Market, Seattle USA provides affordable housing for elderly, low income and disabled people in 300 apartments in the historic district, accessible to facilities, employment opportunities, fresh food and public transport.

Other facilities deliberately fostered seniors' engagement in activities with external others, including multiple generations. Ebenezer and Fairview Health Services, Minnesota, USA features a 'campus' with a range of independent living units, assisted living, and dementia care plus an adult day care and child day. Its Inter-generational Day Program includes interaction between children and seniors in a purpose-built intergenerational space featuring a kitchen area, computer centre, arts and crafts and outdoor play area. Other partnerships in the USA are between the care facility and nursing or medical schools, which provide mutual benefits of internships and additional healthcare. At Ithacare Longview, NY activities include an intergenerational choir, theatre and university lectures and tutorials in conjunction with the adjoining University.

2) Photovoice and Charrettes - Infill Development for Older Australians in South East Queensland (Baldwin et al., 2012)

An outcome of the PhotoVoice exercise was development of 15 principles (Table 1), derived from participants' photos, to guide design of neighbourhood and accommodation environments for older people. The highest number of photos were about issues of residence accessibility as one ages, revealing real concerns about lack of universal design in dwellings: for example staircases and narrow steps and non-adaptable kitchens and bathrooms.

Table 1: Principles for Neighbourhood and Dwelling Environments for Older People

Neighbourhood Scale	Dwelling Scale
1) Walking Paths and Walkways	9) Density and Visual Amenity of the built form
2) Proximity to Services and Facilities	10) Universal Design
3) Outdoor Environment and Use of Green Space	11) Sustainable Design Features
4) Public Transport and Connectivity	12) Private and Shared Outdoor Space
5) Pedestrian Safety in Neighbourhoods and Towns	13) Versatile Spaces
6) Safety for Older Motorists in Neighbourhoods and Towns	14) Maintenance
7) Sense of Community	15) Security in the Home
8) Perceptions of Personal Safety	

While many of these principles are consistent with WHO's Age-friendly Cities Guidelines (2007), a significant outcome of the research is the importance to our participants of some additional features: private space for hobbies, private outdoor space (patio), shaded outdoor spaces, sustainable design and visual amenity. Providing living space of adequate size and design that is safe and accessible to outdoor areas such as patios and balconies, can be an economical way of providing useable space and desired visual and practical amenity.

In addition, the design charrettes provided an opportunity for seniors to interact with urban designers and planners, with mutual learning about the challenges of meeting the design principles. Seniors expressed concerns about density and a clear preference for medium rise buildings rather than high rise. However, this may be as much about aversion to aspects often associated with high rise, such as contemporary minimalist concrete apartment designs. Seniors demonstrated a clear preference for visual amenity and the physiological benefits of being able to control the temperature and climate in the residence through accessing natural sunlight and ventilation enabled by thoughtful design. Concerns were also expressed about privacy, noise, and safety in case of electricity failure resulting in need to use stairwells to access the ground rather elevators in multi-dwelling environments. As a result, designs that appeal to seniors (and no doubt other potential residents) are those dwellings that efficiently mitigate the challenges of multi-dwelling living through their design.

Figure 2: Intergenerational interaction adjacent to a university

Some residents expressed an interest in designs that also enabled the opportunity for social exchange. For example, one design that appealed reflected the potential for intergenerational interaction in a multi-building complex adjacent to a university (Figure 2). Seniors liked the idea of one building being for seniors; the other for international or post-graduate students, with the view to social exchange between different age groups and cultures.

Discussion

From a design perspective, this trend also liberates the way housing and care options can be conceptualised and designed for seniors, to allow for more innovative approaches. The findings of these two research projects clearly converge to provide key lessons in the housing, neighbourhood and care preferences of seniors. At the dwelling scale, universal design and unbundled care and accommodation are critical facilitators of enabling seniors to

age in place. Whether living independently or in a seniors' only community, older people value opportunities to be physically and mentally active, involved in work, hobbies, and volunteer work within the broader community. What is required, according to international trends and the preferences of seniors in a South East Queensland context are additional choices beyond staying at home (ageing-in-place) or segregated retirement living. A third way, universally designed dwellings, can provide the opportunity for residents to stay in their home regardless of how their needs, or that of their family, change over the life course.

However, universally designed dwellings are not a panacea for social isolation among senior cohorts. Age-friendly neighbourhoods also need to be incorporated into planning strategies, with safe shaded walking paths, and dwellings accessible to services, facilities and transport as essential components to support seniors' mobility and reduce social isolation. Such active ageing is strongly associated with better health and wellbeing outcomes for seniors (Golding et al., 2010:9). This suggests that age-friendly neighbourhoods and universally designed dwellings unbundled from care will provide more sustainable options that will afford seniors with greater choice and independence.

A significant outcome of the research was a demonstration of how a range of housing typologies suitable to seniors might fit together in an urban neighbourhood to increase housing choice for seniors, allowing "Ageing in Neighbourhood". The dwelling typologies ranged from 2 storey townhouses in a complex of 12 dwelling units, to 3-5 storey options. All typologies were prefaced on the design brief developed in collaboration with the senior participants through the PhotoVoice and design charrette process: incorporating universal design, through ventilation and natural sunlight for each dwelling and communal spaces. While lifestyle and dwelling preferences of the participants dictated that different typologies appealed to different participants, one typology in particular met with considerable approval from residents in both case study locations.

A 2 storey, 12 dwelling complex (in 2 blocks of 6) appealed to seniors firstly due the size of the 'community', and secondly due to the orientation to maximise opportunities for natural light, through ventilation and a sense of privacy and individuality. Of particular interest in a planning context was that in this typology, seniors traded off car parking spaces for a communal area and to reduce the cost of dwellings. The complex was designed to include half of the normal code requirement for car parks (6), separately titled. It could be argued that in moving towards more sustainable urban forms, dwellings in close proximity to public transport and facilities should be eligible for planning code exemptions to reduce the number of car parks, not only to reduce the cost of dwellings but also to provide incentives to developers to incur the marginal expense of incorporating universal design into the development.

Conclusion

The Desk-top study investigating models of care and accommodation for seniors overseas and Australia provides insight into innovative responses to the global trend of population growth and ageing which could be more widely adopted in the Australian context. Of particular merit is the concept of unbundling care and accommodation options for seniors so that choice and independence are at the forefront of planning and policy options. The PhotoVoice and Design Charrette research project demonstrated that seniors in South East Queensland welcomed not only the concepts of the international examples that unbundled

care and accommodation, but also had clear preferences for universal design and other physiological aspects that are important in the South East Queensland climate and culture.

The participatory approach of the PhotoVoice and Design Charrette research was instrumental in exploring the contribution that planning can make and the trade-offs that seniors are willing to make to achieve suitable design solutions. It also identified barriers to innovation in contemporary housing challenges.

Further, the research outcomes illustrate the significance of the participative research approaches used to inform innovative, sustainable approaches to urban planning. Whilst seniors may immediately benefit from these innovative planning approaches, people of all ages benefit from accessible homes and neighbourhoods including young children, parents and persons with physical challenges from every life stage. If planning is to provide places that are for 'the greater good', our challenge then as planning and design practitioners is to genuinely listen and to authentically respond.

Harnessing Social Media for Urban Planning: An Overview

Matija BRKOVIĆ, Višnja SRETOVIĆ BRKOVIĆ, Faculty of Architecture, University of Belgrade, Serbia

The widespread adoption of the Internet dramatically altered whole segments of our society. Considering the increasing demand for participation in planning practice and new communication possibilities offered by the Web 2.0 and social media, this paper asks how these two add up. How can planners make use of social web?

1. The Rise of the Social Media

In 2004, O'Reilly Media Web 2.0 conference marked the beginning of the Web 2.0. The term did not indicate a new version of the World Wide Web ("Web"), nor an official specification; instead, it marked a certain point in the evolution of the Web, in which the static web pages became a thing of the past, whereas the interactive web pages filled with the user-generated content became a point of reference. This opened new opportunities and paved the way for the new kinds of the Web applications.

While the term "Web 2.0" has a broad meaning and incorporates different kinds of interactive and user generated content, in this paper solely on Social Media as one of the most prominent applications on Web 2.0. As defined by Kaplan and Haenlein (Kaplan & Haenlein 2010), "Social Media is a group of Internet-based applications that build on the ideological and technological foundations of Web 2.0, and that allow the creation and exchange of User Generated Content". Kaplan and Haenlein further differentiate Social Media on Blogs, Collaborative projects (e.g., Wikipedia), Social networking sites (e.g., Facebook), Content communities (e.g., YouTube) and virtual social and game worlds. Among these, virtual worlds are still not as popular as other types of Social Media and for this particular reason are omitted from this paper.

Beginning with the 21st century, the Social Media literally changed the way we interact socially and provided a platform for communication and exchange of ideas and information. Number of active Facebook users surpassed 1.15 billion in 2013 (Ref. ad. 1)—that is more than 3.6 times the population of US, or almost as the population of India; in 2013 Twitter users generated on average 400 million messages (tweets) each day (Ref. ad. 2); the image below illustrates a trend by depicting 500 million "check-ins" on Foursquare over the period of three months only. The Social Media dramatically altered our personal communication, and many segments of our society—businesses, sciences, arts and governments.

Figure 1: 500 million “check-ins” on Foursquare (source: <https://foursquare.com/infographics/500million>)

2. Social Media from the Planning Perspective—the Application Scenarios

Parallel to the evolution of the Internet, the planning practice evolved too. We witnessed a shift from the traditional, technical, top-down planning paradigm, to a more collaborative (even bottom-up) approach to city planning. Communication between different actors and bodies, and involvement of public throughout the planning process and decision-making, has become a standard component of planning practice.

Bearing in mind the increasing demand for participation in planning and easier than ever communication possibilities offered by the Social Media, the current challenge is to link the two. The crucial question thus is—how can planners and planning itself benefit by using the Social Media?

Social media provide different opportunities, like:

- Population sampling and data mining (non-participatory);
- Providing/delivering one way information or making announcements,
- Communicating, surveying, asking questions, asking for opinions, requesting feedback;
- Civic engagement, community empowerment and collaboration.

There are many ways planners can use social networking services in their everyday planning practice. Different approaches can be roughly divided into the following groups:

- Using existing (vertical) social networking services;
- Using services built for the specific planning purpose/tasks;
 - Establishing a new service, built from the ground up;
 - Opting into the existing state-level service;
- Adding new (horizontal) layer atop of already established services;
 - Starting a new service, built from ground up;
 - Using existing service;

Each approach has its benefits and shortcomings, which have been explored and the results are summarized in the next passages. Different cases or examples from the world practice have been taken to illustrate these approaches. The list of the used examples is not meant to be conclusive, nor does it necessary represent the best ones.

Using existing social networking services

Social networking services such as Facebook, Twitter, or Foursquare can be used to expand the outreach capabilities of the government agencies, including the planning related ones, and to broaden the abilities to interact with public. The typical use case scenarios are sharing information, plan mock-ups, making announcements, conducting polls, asking and answering questions, brainstorming, etc.

This approach is widely used. For example, in 2013 the Victorian government used Facebook, Twitter and YouTube to share ideas and engage citizens in a consultation process for the preparation of the New Metropolitan Planning Strategy for Melbourne.

Figure 2: Plan Melbourne Facebook page (source: <https://www.facebook.com/PlanMelbourne>)

Similarly, the city of Louisville is currently using Twitter as a platform to gather ideas and visions about the future of Louisville and to enable public to comment and discuss issues with community leaders.

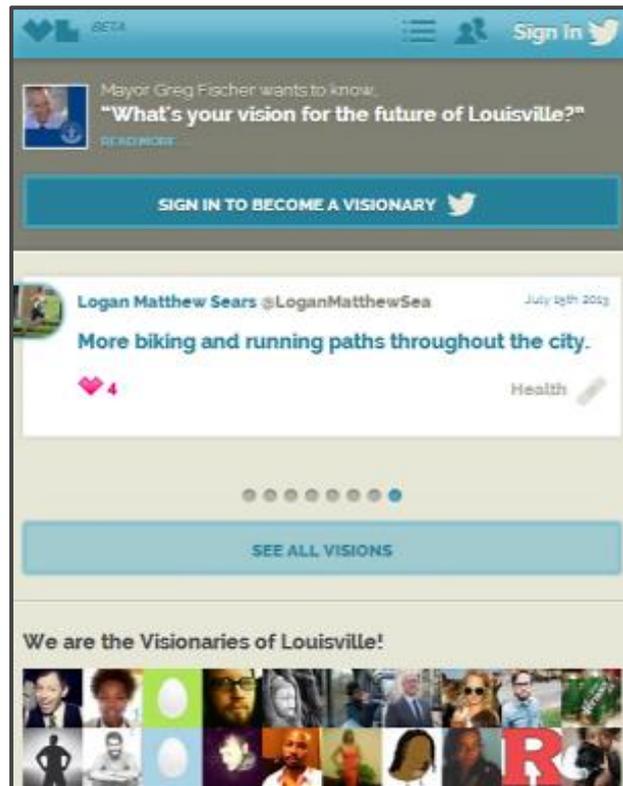

Figure 3: VizLou web page showing its Twitter feed (source: <http://www.vizlou.org/>)

Social networking services can be used for data mining too, without the explicit permission from the users. Even a simple query “New York parks” at Foursquare.com provides a map indicating a “rank” of each park, together with the users’ comments that may contain some valuable information. However, this method does not fall in the domain of citizen participation, and generates some ethical questions that should not be overlooked.

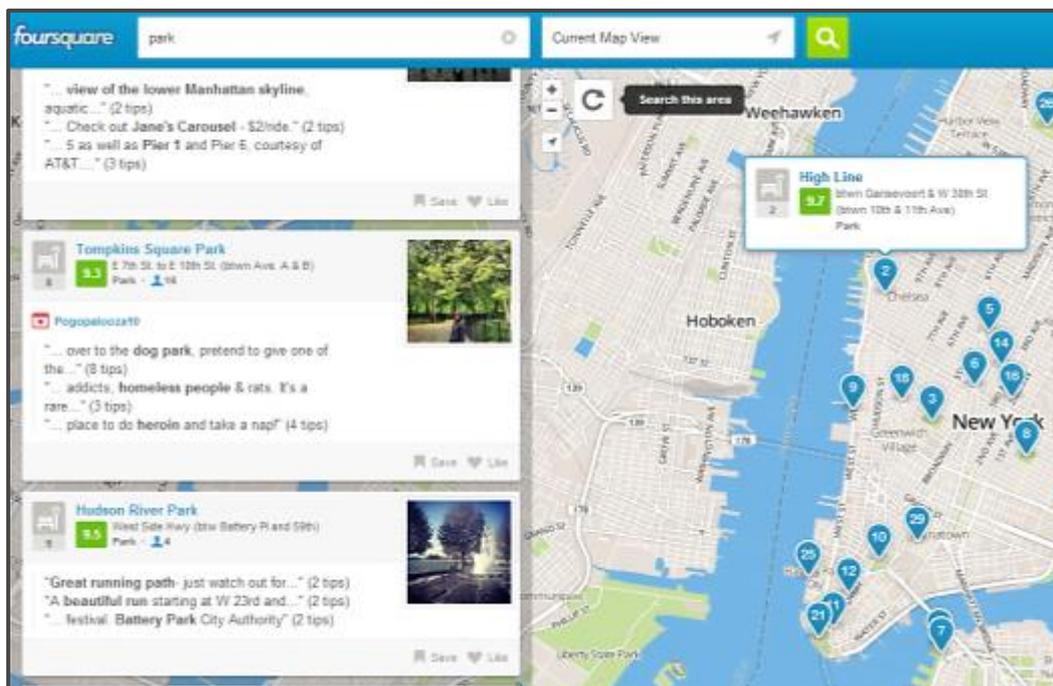

Figure 4: New York parks—Foursquare (source: <http://www.foursquare.com/>)

There are some advantages by using the existing social networking service as compared to the others, conventional approaches, such as:

- There is already the existing user base,
- They are easy to implement,
- There are no maintenance costs.

However, when deciding for, or using this approach there are issues that are to be considered:

- These are privately owned services
 - Privacy issues
 - Who owns information?
 - Specific service policies may limit the scope of their use
- They are not fit for every need
 - User interface is often not appropriate for planning purposes, which may limit the scope of its use
 - Social networks tend to reinforce a positive approach (e.g., there is a “Like” button, but not “Dislike” etc.)
- User bias—careful research is needed to determine the user profile;

The existing social networking services require planners to adapt to the specifics of the service, instead the other way round. Taking into account the advantages mentioned above, this approach could be used as an excellent supplementary way for informing the public, conducting polls, or communicating and discussing the planning issues with the citizens.

Using purposely built service

On the other end of the spectrum, the second most common approach to the use of Social Media are the services that are specifically built to enable e-participation in planning. We can differentiate the two subtypes of these solutions: first are the state-level services that municipalities can opt into; second are the stand-alone custom-built solution.

Services such as System48 in Inđija (Serbia) (Brković & Sretović 2012) or MansfieldTomorrow are examples of this approach. System48 city service is designed to improve cooperation between the local government, municipal departments, and public utility enterprises on one hand, and service recipients on the other. It allows citizens to report different issues easily. The value of the system for planning purposes rests within the stage of the on-going and post-project monitoring, as well as a means of securing relevant information on vulnerable sites, environmental quality, specific issues that require immediate planning responses, etc.

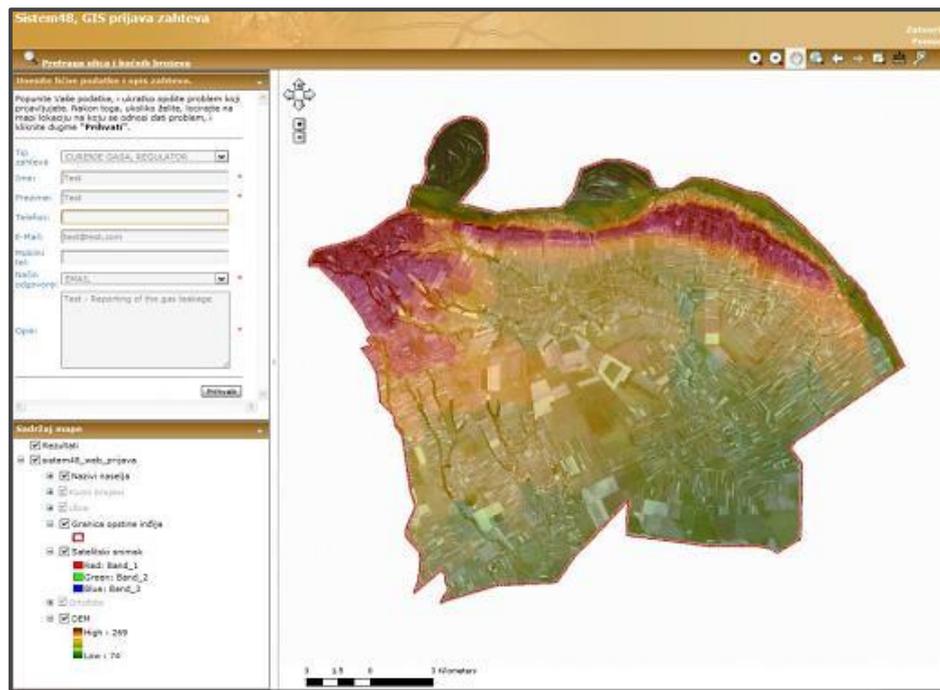

Figure 5: Reporting an issue and pinpointing its location on the web-based map (Source: http://gis.indjija.net:7777/sistem_web_prijava/)

MansfieldTomorrow is a website based on Shareabouts framework (Ref. ad. 3) created with the aim to allow public to “address issues such as where new development should occur, what that development should look like, how to promote local businesses and support farms ... make living in Mansfield more affordable for working families, and ... preserve the essential characteristics of our town.” (Ref. ad. 4)

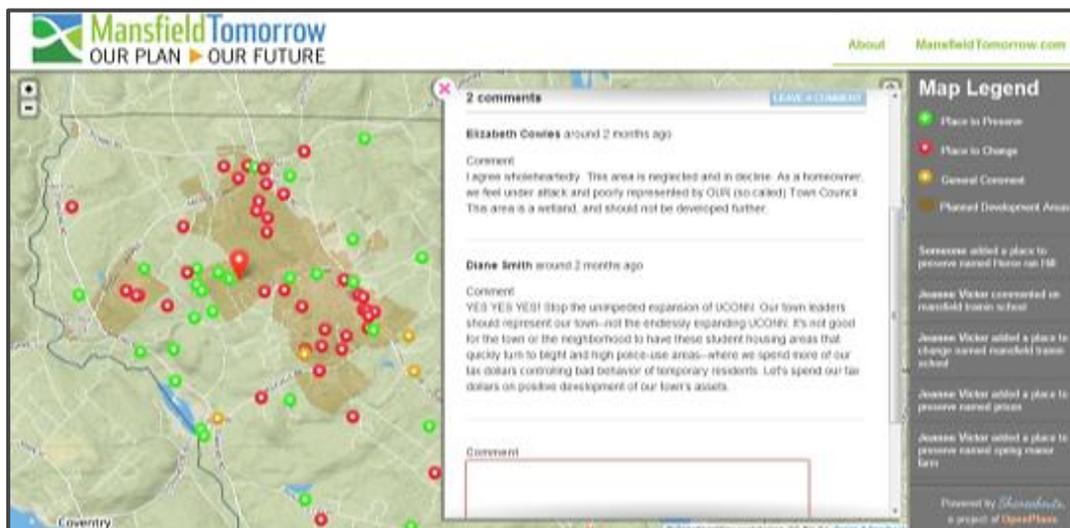

Figure 6: MansfieldTomorrow web app (source: map.mansfieldtomorrow.com)

The benefits of this approach are:

- Allows flexibility and custom tailoring to the specific needs for planning purposes;
- Complete control and ownership of data;
- Allows tight integration with city GIS;
- Allows tight integration with city services and/or municipal departments;

However, whilst it does have its advantages, this approach also has the shortcomings. The degree to which these shortcomings come across depends on whether the service is created

from scratch, or is it a state-level service that municipalities can opt in. The shortcomings fall into one or more of the following:

- Effort, time, money and people needed to build the service;
- Maintenance costs;
- In order to function, it is necessary to attract users first;
- User bias—careful research is needed to determine users' profiles;

Adding horizontal layer atop of the already established social networking services

This is a somewhat novel approach taken by services such as SeeClickFix from US, or Urbanias from Brazil. It tries to combine the benefits of using the existing social networking services (particularly its established user base), with flexibility of custom/purposely build solutions. Furthermore, it tries to traverse across the multiple social networks, further extending the user base and the ways it can be interacted with. Similar to the purposely-built solutions mention above, this approach also can include privately owned services that municipalities can opt into or stand-alone custom-built applications.

SeeClickFix is a mobile phone and a web tool that allows citizens to report non-emergency issues, communicate with public officials, add comments, suggest resolutions, or add pictorial documentation. It also connects with other social networks, allowing the reports to be made via Facebook application or Instagram. Likewise, Urbanias from Brazil uses a Facebook app and a mobile app with similar functions.

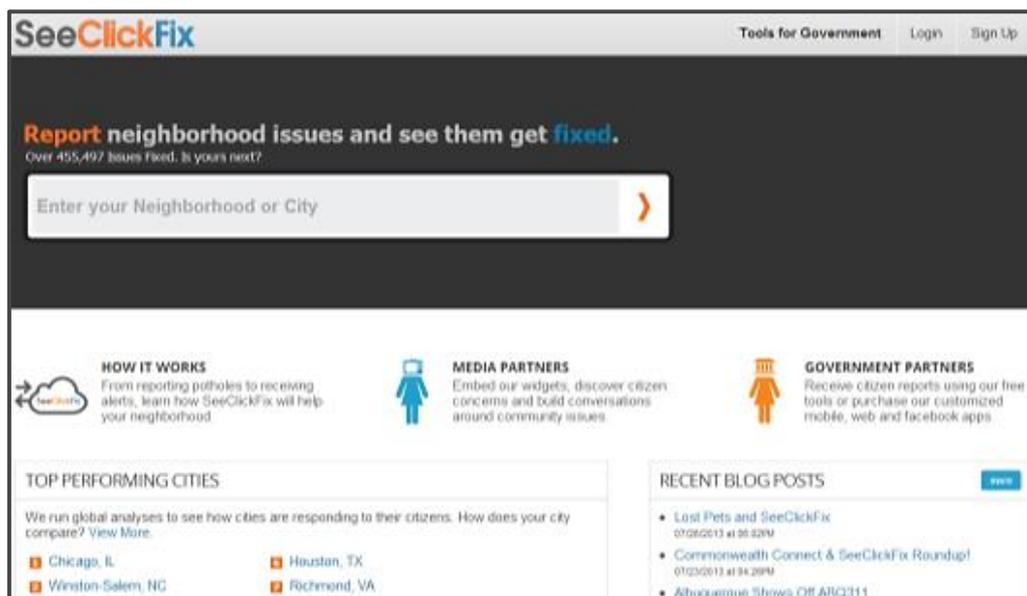

Figure 7: SeeClickFix web reporting (source: www.seeclickfix.com)

Figure 8: Urbanias Facebook app (source: <https://www.facebook.com/Urbanias>)

Whilst somewhat more difficult to implement, this approach does indeed combine best of the both worlds. Likewise, it also inherits some of their weaknesses, such as building and maintenance costs and a possible user bias. In addition, even though it does start with an existing pool of users, it still needs to attract them to actually use the service, though this is somewhat easier than starting with a no user pool at all.

3. Concluding remarks

The assessed capacity of the Social Media as applied to planning is shown in the following table:

Service	Flexibility (more is better)	Costs (less is better)	Ease of attracting users (more is better)	Achievable/likely participation (more is better)
Existing services	■	■	■■■■■	■
New service	■■■■/■■■■■ (opt into/new)	■■/■■■■■ (opt into/new)	■■/■ (opt into/new)	■■■/■■■■■ (opt into/new)
Horizontal layer	■■■/■■■■■ (opt into/new)	■■/■■■■■ (opt into/new)	■■■■/■ (opt into/new)	■■■/■■■■■ (opt into/new)

Figure 9: Comparison of different approaches to the use of Social Media in planning

One can observe that the flexibility is directly proportional to the achievable/likely participation levels, and approximates cost of the service. The users are easiest to attract when a service is based on the existing social network, which is already in use and to which the users are accustomed to and know how to use it.

With regards to the participation ladder as defined by Weidemann and Femers (Carver & Peckham 1999), the Social Media are in the domain of limited participation. This stage of the ladder implies deployment of the particular modes of public involvement and the ways of acquiring their responsiveness. Participants are usually required to obey the timeframes as defined by planning authorities, and have to comply with existing laws and institutional

arrangements. Rarely does the public have a genuine power in starting the planning process or carry it out. Finally, it is only in the domain of purely theoretical study that the possibility there is for what Shirky (Shirky 2005) describes as collaboration instead of institutions.

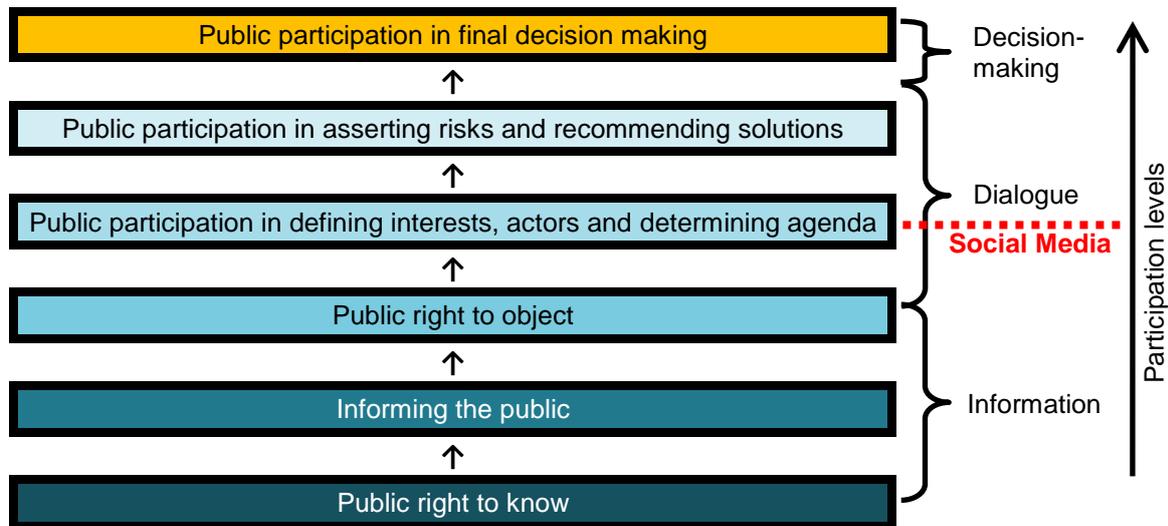

Figure 10: Participation ladder, taken and adapted from (Carver & Peckham 1999)

The Social Media should be understood and taken as a medium that support the participatory process, while they do not generate it by themselves. In order to make them functional and operational, the adequate legal, technical and administrative support is necessary. The legal component is of a particular importance and it presents the key factor in making the socially responsive environment within which the citizens are given a prominent role, together with a workable model of interaction between local governments and their citizens. Only there where the citizens' involvement in public affairs is guaranteed, the Social Media may play an important role throughout the planning process.

Notwithstanding the above, the successful application depends on the citizens' readiness to use them, and their willingness to become the active constituents of the planning process. Thus, one of the challenges planners and all those who are involved in making Social Media usable for planning purposes are faced with, is to create the user-friendly and easy to approach modes of their use.

The level of e-participation depends on the complexity and refinement of the technology in question. As a rule, the complex and high-tech technologies are used by rather a limited poll of users, while the more simple ones are available to a much larger audience. „The effects of use correlate to the level of sophistication of the instrument; the more sophisticated the instrument is the better results are obtained, while their accessibility and use adversely correspond, the simpler they are the wider their use there is“ (Bajić Brković 2006). Furthermore, „in reaching a wider audience there is a trade-off between making it as simple as possible for any user to be able to participate and knowing exactly who it is.“ (Macintosh 2004)

In order to use Social Media efficiently for planning practice, it is necessary to:

- Encourage inclusion of all groups, through the promotion of systems, rising public awareness, and enabling an access to modern technology;
- Choose a right tool, or multiple tools, in addition to the traditional ones;
- Acknowledge the fact that the acquired data or input do not represent public in general nor the entire population, but only its subset, and:
 - carefully study users of the system in order to determine exactly which group it does represent, and use the output accordingly,
 - do not use these systems as a sole or a main source of data, instead, use them to supplement or verify data obtained in other ways;

The Social Media should not exclude the established ways of public participation; instead, they offer the complementary modes for doing things, and present a promising alternative for those who choose to use them. The Social Media and conventional or already existing e-based modes are not mutually exclusive—they complement each other and provide an option for better planning.

4. Acknowledgments

Research and writing of this paper was done under the project: *Spatial, environmental, energy and social aspects of urban development and climate change—mutual influence; PP1: Climate change as a factor of spatial development of settlements, natural scenery and landscape; Project no. TP36035* funded by the Ministry of Education and Science, Government of the Republic of Serbia.

Still climbing the stairway to heaven: public participation in planning

Paul BURTON, Griffith University, Australia

1. Introduction

Arnstein's famous conceptualization of public participation in planning as a ladder helped to illustrate the broad range of possibilities that exist when engaging the public in matters to do with the development or implementation of plans. While this conceptual ladder has been extended, turned into a loop and subject to other geometrical contortions, it has also been used in a way that Arnstein did not perhaps fully intend when she first proposed it: the ladder has been given a moral dimension in which joint decision making between planners and the public and the co-production of plans is the best imaginable form of public participation in planning (Collins & Ison, 2009). The manipulative and therapeutic lower rungs are often used to describe participatory exercises which are taken to be insincere or not genuine and which are a long way from the ideal of co-production. In this sense the ladder has come to serve as a stairway to what many would see as participatory heaven.

This paper challenges this moral dimension to Arnstein's ladder and its derivatives, whether it was her intention or not, and proposes an alternative approach based on a more systematic consideration of different possibilities of participation in practice as well as in theory. It reflects broader debates in political theory in which representative forms of democracy have developed in response to theoretical and practical concerns with more direct and participatory forms and suggests that in judging our participatory endeavours we should recognise the contingent nature of fitness for purpose and beware of applying universalist notions of democratic value.

2. Democratic theory and participation

While the various forms of public participation in politics developed by Pericles and described by Aristotle that emerged in Athens in the 5th century BC are often taken by contemporary advocates as the epitome of democracy, there is a tendency to forget that other notions of democracy exist and indeed developed in response to a substantial and significant critique of participatory democracy (Pennington, 2010). This is somewhat surprising as representative democracy is easily the most popular form chosen by institutions that consider themselves democratic as the basis of their organization of day to day government, even though critics speak of a crisis of legitimacy affecting many representative forms of government.

The Athenian principle of government in which 'the people' govern themselves begs a number of questions: what constitutes 'the people'; are all matters of government subject to popular rule; and does the scale or extent of 'the people' have any influence on the practicalities of popular government? While 'the people' is sometimes taken superficially to mean every member of a particular institution (citizens of a nation state for example, or residents of particular neighbourhood), any scrutiny of the term usually reveals a number of caveats and exclusions. In Periclean Athens the *demos* comprised property-owning males and women and slaves were excluded. In many contemporary nation state democracies the right to participate in elections is limited to citizens over a certain age, but excludes certain other groups including (in Australia) prisoners serving sentences of three years or more, people of unsound mind and convicted traitors. The extent to which other groups of people are considered suitable for participation is discussed in more detail later in the paper. The second question raised above concerns the scope of popular politics: is it sensible or indeed possible to subject each and every matter of day-to-day governance to the direct will of the people? It is not too difficult to imagine a somewhat Pythonesque scenario in which the people spend all of their time in the agora (or its contemporary equivalent) deciding what is to be done and as a consequence have no time to actually do anything!

Democratic theory has long wrestled with the problem of how and where to define a sensible boundary between matters of broad policy direction that can usefully be determined directly by the public and more prosaic matters of day-to-day governance which may be better left to some combination of political representatives and public officials skilled in implementing policies and programs. The final question relates to scale and to the suggestion that at some point the size or scale of a body of people becomes too large to be able to cope with direct participation in all forms of public decision making. While Periclean Athens is sometimes taken to represent the ideal or even the maximum scale at which direct democracy is possible, scholars have shown that not all citizens did in fact fulfill their civic obligation to participate and that active participation was in fact becoming even then the preserve of a particular class of political enthusiasts.

The fact that all kinds of institutions (including universities, clubs and societies, companies and charities) tend to delegate responsibility for the day to day running of the institution to a small number of members (including some employed specifically to carry out these tasks) suggests an innate recognition of the practical difficulties of involving everyone in every decision that has to be taken. Of course the way that those delegates are then chosen, held to account for their behaviour and subject to censure or recall is the very stuff of representative political theory. But there are arguments other than the purely practical for assuming that the active participation of everyone in everything is less than ideal and that limiting the power of the whole or the majority of members of any particular institution may be beneficial. Majorities sometimes (perhaps often) choose to behave badly towards minorities. Rawls' notion of justice as fairness suggests a set of principles including the promotion of liberty and equality and the recognition of difference that most people would agree to if they did not know at the time what their social position was, with these serving to limit the power of majorities to persecute minorities.

But if we are to avoid the problems of polarization in which participatory and representative forms of democracy are treated as mutually exclusive, then we should consider the circumstances in which different forms are more or less appropriate and in which they might mutually support each other. And of course this is what happens in practice as participatory forms of politics are developed alongside representative forms. Representative forms are often best for determining broad political direction and overall rules or policies, while more participatory forms can be more effective in deciding particular applications. The interface between these two forms and practices often reveals tensions and questions to be answered: how should differences between participants be resolved; can formal responsibility for a decision be delegated to others; is the right to be heard the same as the right to have your way, and so on. In concluding this section I would simply say that these questions must be answered on a case by case basis and not by resorting to an *a priori* claim that one form of democracy is inherently and self-evidently superior to another.

These relatively abstract arguments about the nature of democracy and the participation of citizens in democratic politics provide the context for a more focused consideration of the nature of public participation in planning.

3. Public participation in planning

Public participation has been an accepted feature of planning for almost as long as planning has existed as a statutory responsibility of local or metropolitan governments. But in the UK in the 1960s the publication of a report, *People and Planning*, into public participation in planning by the Skeffington Committee marked its elevation into a matter of considerable professional interest and public debate. Broadly speaking there was support for the idea that many of the perceived problems of planning could be alleviated by promoting greater public participation, although as many critics observed the nature of participation varied from the right to inspect and comment on draft plans through to some rather vague notion of engagement in the process of preparing plans. Not all critics saw greater participation as necessarily entirely beneficial and Lewis Keeble (1961), then of the University of London, spoke of giving planners a freer hand from 'month by month lay dabbling', while Colin Buchanan (1969) suggested that if planners performed to a higher professional standard then the demands for greater participation would dissipate or even disappear.

Damer and Hague (1971) in their critical review of public participation in the UK, note the importance of a number of factors in explaining its growing prominence. These include American planning experience and Kennedy's promotion of 'maximum feasible participation' as a key principle in his war on poverty; increasing interest in participatory rather than representative forms of democracy; clear evidence of bottlenecks in the operation of most planning regimes and an emerging concern to promote new values in planning. However, they are especially critical of Skeffington for a number of reasons. First, they claim it has no theoretical context which might explain how greater public participation and what might now be termed planning performance are causally connected. This leads, secondly, to a tendency to see participation as a way of increasing public knowledge of planning which would in turn lead to a more consensual and productive form of planning. As they note, this simplistic and naïve view of the nature of planning obscures the fundamental social and political conflicts that underpin much planning and other forms of state intervention. It was in this environment, albeit on the other side of the Atlantic, that Sherry Arnstein developed and promoted her ladder of participation.

To a great extent this lack of theoretical groundedness and a degree of political naïveté continues to characterize much writing about public participation in planning (Innes & Booher, 2004). The most up to date statement on public participation from the Planning Institute of Australia (PIA) begins by noting that we are all part of many communities (of interest, affiliation and place for example) and suggesting that members of these

communities 'reasonably seek to participate' in decisions that affect them. The PIA statement goes on to say that 'careful consideration of many points of view and competing interests is an essential part of good professional practice' and that 'good planning practice involves maximizing opportunities for participation in planning'. However, there is no consideration in detail of what constitutes 'good planning practice' or 'good professional practice' other than this procedural claim that it entails a degree of participation. Nor is there any calibration of the relationship between the two, so that we might be able to anticipate how much more participation might be needed in order to achieve a certain improvement in 'good planning practice'.

In the next section I propose and describe three questions that should be considered by anyone responsible for organizing and managing any participatory exercise in planning. The contention is that by contemplating these questions and coming to a view that is suitable for the particular circumstances, the exercise will be more likely to satisfy the expectations of both organizers and participants.

4. Principles of participation

In this section I present briefly three questions that should be considered by anyone organizing any program of public participation in planning. The questions relate to three important principles of participation, namely: the right and the obligation to participate; the scale or extent of the participatory exercise; and the nature of the participatory relationship.

Who should participate?

In relation to the question of who should participate, it is worth beginning with the most extreme case and considering why it should be anything other than everyone. However, we might propose that everyone in practice means everyone with the status of citizen, in other words we might feel justified in excluding those without the right to vote in local, regional or national elections. But there might be other grounds for restricting the right to participate, for example to those who are knowledgeable about an issue or to those who are enthusiastic about participating. In other words, various criteria could be applied in selecting from among a large group with a formal entitlement to participate. The value of organising around enthusiasms described by Bishop and Hoggett (1986) suggests we should select only those who are sufficiently motivated and interested to put themselves forward and avoid trying to cajole the uninterested, while remaining conscious of Michael Waltzer's warning of the dangers of rule 'by men with most evenings to spare' (1970: 235). The capacity and willingness to listen to a variety of alternative positions before coming to a view might also be used to exclude those with existing unalterable viewpoints in the same way that biased or prejudiced citizens might be excluded from a trial jury. One might select only those with a certain level of knowledge or experience of an issue. Opinions on the significance of this are divided: for example Arblaster describes an optimistic view of civic capacity in saying, '...political wisdom is not a matter of specialised knowledge, but something in which everyone has a share...' (1987: 21), while on the other hand referring to Schumpeter's less flattering view of the 'proven ignorance, irrationality and apathy of the people' (1987: 53). Thomas Jefferson proposed a fine resolution to this apparent dilemma when writing to William C Jarvis in 1820 (Peterson, 1984) saying,

"I know of no safe depository of the ultimate powers of society but the people themselves; and if we think them not enlightened enough to exercise their control with a wholesome discretion, the remedy is not to take it from them, but to inform their discretion by education."

Finally, the principle of random selection might be adopted on the grounds that it is inherently fair in avoiding bias during selection. It was used as one of the criteria in filling positions of public office in ancient Athens and has long been used in the selection of jurors for criminal trials. It serves as the basis for distributing substantial sums of money through national

lottery schemes and has also been used for over half a century in drawing unbiased and representative samples for social survey research. Moreover, more than one criterion might be applied, so that participants had not only to be interested but also knowledgeable in order to qualify for selection.

This discussion illustrates that a number of legitimate positions can be taken when thinking about who should be encouraged or allowed to participate in planning exercises. No one is self evidently superior and to some extent the most appropriate selection criteria will depend on the nature and scale of the exercise. But before considering this, we should think about the inclination and the obligation of citizens to participate?

Some may not be interested in participating in a particular debate, feeling that it is of no great consequence to their lives, while others may feel they know so little about an issue that their contribution to any public debate would be worthless. Others may simply be too busy going about their lives to have any time for such activities. Whether citizens have a more formal obligation to be active and to participate is another matter and as noted above the legal obligation on Australian citizens to vote in elections is somewhat peculiar in comparison with most other democracies. A more nuanced position might therefore acknowledge that not every citizen will choose to participate in every, or indeed any public decision making process that is open to them and that there are valid reasons for choosing not to do so. It is worth noting that for some, the disinclination to participate (in politics generally rather than in planning in particular) is evidence of underlying feelings of powerlessness or disempowerment that require positive strategies to remedy them. The assumption is that active citizenship is the norm, but if it is not the case in practice then there must be forces at work that are undermining this norm.

In summary, it is perhaps most important to recognise that reasonable and respectable arguments can be put forward for a variety of different selection principles. These principles can entail anything from the selection of all members of a particular constituency, through many to only a few. Thus when it comes to evaluating the success of participatory initiatives we must ensure that we are applying the relevant criteria of success rather than assuming a greater number of participants is always better than fewer.

Scope of decision and scale of participation

Decisions vary in terms of the extent of their impact and we can conceive of this variation as a continuum. At one end of the continuum are decisions that affect everyone in a particular constituency or jurisdiction, while at the other end are those affecting only a few. We can label these extremes as strategic (affecting all) and individual (affecting few) and perhaps define a point in between as programmatic where the impact of a decision is felt by an intermediate grouping somewhere between the many and the few. This continuum can exist both within and across spatially nested constituencies so that a strategic decision could apply to a neighbourhood, a city of which it is a part, a region of which it is a part and a country of which it is a part and so on. A similar way of conceiving this continuum is to distinguish between decisions about constitutional matters (eg who to include and the broad terms of engagement), about policy matters (eg principles of entitlement) and about the application of constitutional or policy decisions to specific cases (eg should I be granted a particular welfare benefit?).

The significance of this conceptual continuum is three-fold. First, as the number of people affected by a decision increases, so there is a corresponding increase in the number who can claim a right to participate in the making of that decision on the basis of being affected by it. Other things being equal this increases the likelihood that not everyone will choose to exercise this right if it is granted and, more significantly, that a smaller sample of people will be selected to participate. The political challenge is to be able to justify the criteria for selection and hence cases of non-selection, in other words, why was I not selected?

Second, strategic level decisions affecting the many often serve to constrain lower level decisions. In this sense they help set the rules or priorities applied at lower levels and may

therefore be important in influencing the outcomes of subsequent participatory exercises. For example, regional land use plans typically determine the total requirement of land for new housing developments and identify areas for growth. District level plans then identify particular sites and finally individual planning applications are determined on the basis of specific residential patterns and house designs. While an individual application may be rejected on the basis of design, the case for growth will already have been accepted at a prior and more strategic stage.

Third, the actual significance of strategic level decisions can appear to be inversely related to popular perceptions of their impact and hence to the propensity to participate. Thus, people are often more inclined to participate, whether by unfettered choice or following an invitation, in small scale and parochial decision making exercises than in broader and more strategic arenas. Managers of participatory exercises have long struggled to present strategic choices in ways that are meaningful and comprehensible to the large populations affected and stimulate popular interest and excitement. In contrast, very localised proposals (to close a school or post office or to open a residential home for recovering drug addicts, for example) often generate intense local interest and demands for participation through attending public meetings and signing petitions.

The nature of participatory relationships

The third question refers to the nature of the participatory relationship, or the relationship between those people who choose to, or are invited to, participate and those who retain formal responsibility for making the decision in question. At one end of the spectrum of possibilities, formal responsibility for taking a decision is handed to all participants, for example in a referendum, while at the other end participants are allowed only the most cursory degree of involvement and in ways that have no meaningful impact on the decision taken. Arnstein's ladder may have been the first and most well known conceptual representation of this spectrum, but others have offered variations on this theme including the International Association for Public Participation (IAP2) public participation spectrum (IAP2, no date), which serves also as the basis of PIA's position on public participation in planning.

The problem with Arnstein's ladder and subsequent variations is that it embodies a set of normative assumptions about the relative merits of the ends of the spectrum, without fully articulating and justifying them. Thus it is assumed that delegating the power of decision making to the people (however defined and delineated) is not only a good thing, but a better thing than simply asking 'the people' to choose between a predetermined set of options. This assumption only holds for certain models of democracy, typically those rooted in the participatory conceptions of Barber, Pateman and Hirst or further back in the work of Mill or Rousseau. In alternative conceptions, seen in the work of Schumpeter or Sartori and in Burke's notion of representation, popular participation does not serve as a yardstick for democracy and if anything signifies the potential for wasteful or even oppressive political activity. Unless we take the debate between representative and participatory forms of democracy to be settled in favour of the latter, we cannot accept that involving more people in co-decision making is necessarily and always for the best.

From this it follows that there may be situations in which simply presenting information, clearly and concisely, is the most appropriate. For example, regardless of how it was arrived at, presenting information about the composition and powers of a new state planning agency may be entirely appropriate and need not (indeed should not) invite comment on whether or not the decision to do so was good one. On the other hand, when asking for input to a long term plan for the pursuit and management of growth in a jurisdiction, it is sensible to include as many people as possible and be as clear as possible about the scope and parameters of the plan. Depending on the nature (ie the scope and scale) of the activity, judgments can be made about who it is best to invite to participate and the terms on which they might do so. These judgments have, of course, to be defended and some may be unconvinced by the

arguments and chose not to participate or may indeed choose to establish alternative channels and forms of participation.

In the next section we look in more detail at the application of some of these principles in the practice of public participation in planning.

5. Applications

It has become increasingly common in planning regimes in Australia and other developed countries to follow what is often described as a neoliberal agenda of reform in which lighter touch regulation accompanies a more streamlined and expeditious process of planning. As part of these processes the costs of more extensive programs of public participation and engagement often receive more attention than the benefits and streamlining tends to result in participation focusing on processes of plan making rather than on implementation and the assessment of development proposals.

The logic of this approach rests on the not unreasonable assumption that plans, in whatever form they take, serve as the basis for any subsequent assessment of development applications and so it is sensible to invest time, expertise and effort, including the time, expertise and effort of the public, in preparing plans that are as good as possible, however that may be judged. This is not to say that public participation in development assessment ceases or is reduced to an entirely tokenistic process (although this is often how unsatisfied opponents of particular development proposals feel), but the argument is made that it is better to focus participatory effort in developing a plan that has broadscale applicability than on a large number of specific development applications that would otherwise have to be assessed without an overarching plan or set of assessment principles. It is important to remember that these arguments are more about the relative balance of effort than about more absolute positions, although they are sometimes conducted in these terms.

A second notable aspect of this argument is that it reinforces a technocratic notion of planning in which it is possible to differentiate without too much difficulty between the legitimately political and the properly technical aspects of decision. This has of course has been the subject of intense debate among planning theorists and practitioners for many years and shows little sign of either abating or being resolved to the satisfaction of all. In brief the argument is that the process of plan making is necessarily political, both in the sense that it involves elected politicians and that the public at large have an acknowledged role to play in making choices about (for example) the desired pace and pattern of growth, the extent to which zones should be used to regulate land uses and the scope of aesthetic judgments about urban design. The argument continues that the assessment of development applications against the criteria and principles of an agreed plan can then be treated more as a process of professional and technical judgment with more limited opportunities for public participation. The opportunity for third parties, in other words neither the proponent nor the assessor, to lodge legitimate appeals against planning decisions is clearly a significant factor in the way the assessment of development applications is conducted in any particular planning jurisdiction.

In his recent memoir on life as a Minister in the New South Wales government, including time as Planning Minister, Frank Sartor reflects on reforms he introduced in an attempt to improve the planning system of that state (Sartor, 2011). Among measures to strengthen the metropolitan scale of planning, especially around Sydney, and to make state-wide investment in urban infrastructure more secure, he advocates the 'depoliticisation' of local government level development assessment. While this may appear to reveal a surprising degree of political naïveté in someone whose book describes decades of political manoeuvring within the New South Wales Labor Party, it reflects the practical experience of

contemporary planning in many Australian cities. His comments on public participation are especially noteworthy,

Current processes for public consultation have not engendered a culture of constructive debate, problem solving, mutual respect or consensus building. Rather, we have developed a culture of confrontation, mistrust and sloganeering by competing interest groups.' (2011:204)

It is unlikely that this description is limited to planning in New South Wales, but applies much more widely and could be taken to describe the norm rather than the exception. It is certainly a long way from the Habermasian ideal speech situation sometimes envisaged for planning (MacCallum, 2009) and even from the nuanced conceptions collaborative planning described by Patsy Healey (1997). But it does serve to illustrate the persistent gap that exists between our views of how we would like public participation in planning to operate and the stubborn reality of it in practice.

6. Conclusions

Debates in planning sometimes descend rather too quickly into polarized arguments in which absolutist positions are taken. Thus we can find ourselves arguing for or against participation *per se*, rather than treating it as a variable that we can engage in to a greater or lesser extent. Similarly, we can find ourselves driven by the moral imperative associated with many conceptualizations of participation and feel obliged to move towards the apparent heaven in which everyone affected by a decision is actively involved in preemptory debates and indeed in taking the decision itself.

If we are to continue to devote time and effort to encouraging and enabling public participation in planning in its various forms, then we should be reasonably clear about the potential benefits to be obtained in doing so and perhaps even more clear about whether these benefits are achieved in practice. We might expect that after at least fifty years of advocacy for greater public participation in planning we would have achieved a reasonable degree of clarity about these impacts from a series of research projects and evaluation studies. Unfortunately this is not the case. While there are some well designed and robust studies of the impact of participation, they are not yet commonplace and not all are in the field of planning whether we define this in terms of land use planning, urban and regional planning, spatial planning or strategic planning. There are more studies that take the form of practice stories and while these are perfectly legitimate research designs in themselves, they do not always allow a more comprehensive assessment of the value of public participation in planning.

In this respect it is not easy to answer the question: does participation in planning make a difference and is the difference we hope for? In part this is a methodological or research design challenge, but also an ideological one in that for some (perhaps many) the benefits of participation or rather of more than less participation can be taken for granted. Echoing another statement of democratic principle, advocates of participation hold these truths to be self evident. For the more skeptical, there is however a substantial methodological challenge in measuring the beneficial impacts of participation or in comparing its costs and benefits, but the challenge can be met (Burton, 2009; Burton, Goodlad & Croft, 2006; Lane, 2005; Williamson & Scicchitano, 2013). This is due mainly to the fact that participation is a variable rather than an absolute. We can do more or less participation and what we do under the banner of participation can and does vary substantially. Given the wide range of potential benefits described above this makes the design of robust research difficult and helps explain why focused practice stories are more commonplace when it comes to researching participation.

The critical stance taken in this paper is not intended to diminish the importance of public participation in planning. Any planning regime that systematically excluded the public from

processes of plan making and of implementation in the form of development assessment would probably not be effective, nor would it be seen as a legitimate part of a democratic system of local or regional governance. But we know from experience that many participatory exercises do not meet their own ambitions: there is no obvious connection with 'better planning outcomes', whatever they may be and both organizers and participants feel dissatisfaction with the process. I have suggested that by answering three key questions about any participatory exercise there is a greater chance that these shortcomings will be overcome. This represents a more productive way forward than using as a generic yardstick a set of principles derived only from models of participatory democracy, in which implausible notions of mass participation are used. Rather than seeing Arnstein's ladder as a stairway to participatory heaven, we would do better to abandon the moral dimension to her conceptual framework and rely on more contingent criteria for judging the success of participatory episodes.

Community Engagement in Trinidad and Tobago: Theory or Practice. Case Study of Neighbourhood Upgrading Programme, Waterhole, Cocorite.

21

The University of the West Indies, St. Augustine

Abstract

Community Engagement is a buzz term used by academics, International development Organizations and planning and development practitioners. All RFPs, TORs and Technical proposals make mention of having community engagement in the development of the plans. Experience shows that it makes for a good technical proposal etc., but is it just rhetoric? Can community engagement be effectively achieved as outlined in the literature?

In recent times in Trinidad and Tobago the issue of community engagement made international headlines as there was protest action taken over the start of construction of a controversial section of a highway. Some were angered as they highlighted that their voices and concerns were not being heard and addressed.

What are the factors affecting effective community engagement in Trinidad and Tobago? To answer the question the case study of Waterhole was used as it is a microcosm of community engagement issues in Trinidad and Tobago.

This paper identifies theoretical and practical approaches to community engagement in land use planning and compares them with the practice in the case study Waterhole. On site interviews were done with the residents of the Waterhole Community as well as officials from the Land Settlement Agency in order to collect the data to answer the question posed.

It was found that, amongst others, ethnicity, power distances, violence, attitude of the state, limited budgets affect community engagement in Trinidad and Tobago. Suggestions for addressing these and other issues are highlighted.

Introduction

Trinidad and Tobago is a developing country and as such it undertakes many social and physical developmental projects in an effort to reach developed status. These projects are mainly funded by UNDP, IDB or other International donor agencies or organizations. These donor institutions usually have terms and conditions on how the projects are to be administered. One of these terms and conditions is community engagement. Despite stipulating the need for community engagement most people only become aware of the

plans or projects during the actual implementation phase of the project or those who are aware are not effectively engaged.

In 2010, a stop was made to the construction of a smelter plant in Cedros, Trinidad and Tobago after numerous protests showed that the residents of Cedros did not accept the plan that the government had made for the country and that they were not engaging the local residents.

In 2012, an IDB funded highway project made international headlines as a group called the Highway Re-route Movement protested on the site daily, one individual an environmentalist and activist carried out a hunger strike for 21 days in order that a review be undertaken, however, work still continues on the highway.

This shows that development if it is to be sustainable, successfully implemented and accepted must be people centred. Plans must not just be made for the people, the people must help to make and shape the plans. How to achieve this people centred approach is through effective community and stakeholder engagement.

Having examined the two scenarios above, there appears to be a disconnect between what is stipulated by development agencies through TOR's and policy guidelines. and how the projects are being implemented with respect to community engagement- its role and its importance. This leads to the question, is community engagement being effectively implemented or achieved in Trinidad and Tobago in order to achieve development? The question is important, as development can only occur through the implementation of plans. If plans and projects are rejected or stopped over protest action then development will be delayed or will not occur. If the government still goes ahead with a development plan that is not of the people the benefits of the plan will not be realized and development will not occur.

To answer the question, the Case Study of NUP of Waterhole Cocorite is used. The paper will highlight the challenges to community engagement in Trinidad and Tobago, and .factors affecting community engagement in Trinidad and Tobago. It also outlines the approach taken for the Waterhole project in order to compare it to best practice management approach for community engagement.

Methodology

On March 13th 2013, a survey in the form of a questionnaire was conducted in the Waterhole community. A total of 16 free response questions were asked to 10 randomly selected persons in the community. The sample included both men and women both young and old. The survey was to find out whether the community knows what squatter regularization is, what they see as the benefits of it, what community engagement means to them and whether or not they were satisfied with the approach to community engagement and how the engagement was done to facilitate the NUP in the Waterhole community.

Community Engagement

In order to answer the question fairly an understanding and definition of community engagement is necessary as community engagement means different things to different people and many people use the term loosely to describe very different approaches.

In order to investigate the question: “community engagement theory or practice?” This paper reviews the theory or approaches behind current engagement practices, examines international best practice and compares this with a local case study.

Community engagement is a term that is easily and repeatedly used in the area of sustainable development, but exactly what are the philosophies and ideologies that influences community engagement (how and who to engage)? Community engagement is a critical and indispensable component in any neighbourhood upgrading project. In a squatter settlement upgrading project unlike a conventional housing scheme or a sites and services project, the beneficiary population is already living on the site thus it is mandatory to involve the community in the preparation of the regularization and upgrading plans. (UNCHS/HABITAT 1985).

In the context of squatter regularization, community engagement can be defined as the voluntary and democratic involvement of beneficiaries in contributing to the execution of the project, in sharing the benefits derived from the project and in making decisions with respect to setting goals, formulating the project and preparing and implementing the plan. (UNCHS/HABITAT 1985).

Boles et al (2000) notes that community engagement is hardly understood though often used in developing countries without a serious attempt to critically analyse the different forms that engagement could take.

Community Engagement Theory and Practice

Collaborative Planning

The discipline of planning over time has developed approaches to engagement to land use planning and development. Theoretical approaches to engagement in planning have evolved to become known as Collaborative Planning in the UK and as Communicative Planning in the US. This type or method of planning has become extremely popular internationally in an effort to develop plans based on consensus.

Collaborative Planning evolved from a criticism of the technocratic model of planning where it was limited in application as it failed to recognize that planning was based on diverse values that could not be derived from science and that there was no optimal or correct plan that could be implemented without incorporating the interest of stakeholders (Guton et al. 2006). As such planning theory responded to the criticisms by acknowledging the role of goals and objectives identified through democratic political processes to set the framework in which plans were prepared. The challenge was to develop optimal means and structure to achieve citizen participation in the planning process (Guton et al. 2000).

Healey (2006) contends that all planning activity involves some interactive relation and some kind of governance process. She indicates that the metaphor “collaborative planning” was used and mis-used by politicians and policy makers in the UK from mid 1990’s onwards to describe their ambition for a new form of governance.

Collaborative Planning was first inspired by the perception of planning as an interactive process (Healey 2006). Planning is a governance activity occurring in a complex and dynamic institutional environment shaped by wider economic, social and environmental forces that structure but do not determine specific interactions. Healey (2006) defines governance as the process by which societies and social groups manage their collective affairs. Planning and policy initiatives are concerned with maintaining and enhancing the qualities of places and territories. Collaborative Planning was motivated by a moral commitment to social justice, especially as realized in the fine grain of life experiences in the context of culturally diverse ideas about local environments and ways of life (Healey, 2006)

Collaborative planning is described as a logical extension of alternative dispute resolution (Gunton and Day 2003). The approach is such that no one is excluded from the planning discourse and decisions are arrived at collaboratively.

In practice, the planner’s role in achieving the collaborative approach to planning is to use their technical knowledge to produce a strategy as “knowledge brokers and mediators” who play the role of critical friends. (Abu-Orf, 2005) For the planner to do this, the planning process should have inbuilt in it a two-way communication process in order that true collaboration can occur. Communication is an essential part of collaborative planning. It sounds simple but more often than not it is difficult to achieve for a multiplicity of reasons.

Bessette (2004) has identified how community engagement can be achieved using the communication model.

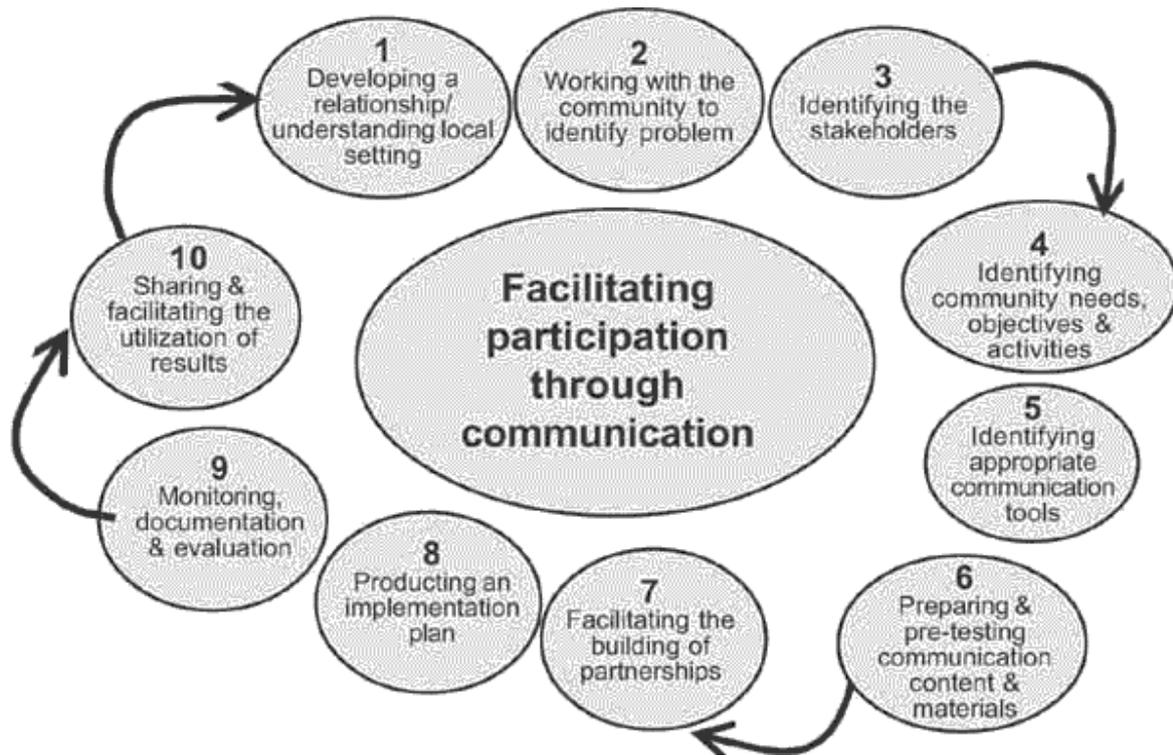

Figure 1 The PDC process (Bessette 2004)

He notes that the Participatory Development Communication Process (PDC) is about building mutual understanding and collaboration, facilitating a partnership and accompanying a development dynamic.

The ten (10) steps that make up the PDC model are:

1. Developing a relationship with the community
2. Working with the community to identify problems
3. Identify the stakeholders
4. Identify community needs, objectives and activities
5. Identify appropriate communication tools
6. Preparing and pretesting communication contents and materials
7. Facilitating the building of partnerships
8. Producing an implementation plan
9. Monitoring, documentation and evaluation
10. Sharing and facilitating the utilizations of results

Bessette (2004) notes that the PDC process is not sequential; some of the steps can be implemented in parallel or in a different order. The process is a continuous one not a linear one.

Collaborative Planning as a theory has become accepted. However advocates and critics are unanimous in their call for more research to evaluate the strengths and weaknesses of Collaborative Planning and to identify best practices guidelines for effective use of the collaborative model (Conley and Moote, 2000).

Planning For Real

A lot has been said and written about collaborative planning, about the need for inclusion and communication, but does not really show how community engagement can be attained and more often than not collaborative planning efforts because of the focus on communication can end up as talk-shops.

Gibson (1989) presents and offers a practical how-to of how collaborative planning can work.

This approach by John Gibson has been used since the 1970's as a means of giving local people a "voice" and professionals a clear idea of local people's needs in order to bring about an improvement to their own neighbourhood or community (MIT, 2013). The approach is an evolving style of community planning that does more than accept local knowledge but it integrates the search for local knowledge with community- building and capacity-building (Forester, 2005). It is based on an "Eyes down, hands on, rubbing shoulders, a lot less by mouth" approach (Forester, 2005). Planning for Real uses simple 3- dimensional models as a focus for people to put forward and prioritise ideas on how their area can be improved. It is a highly visible, hands-on community development and empowerment tool, which people of all abilities and backgrounds find easy and enjoyable to engage in. The problems and improvements are identified through pictorial "option" cards. This is to overcome the difficulties of verbal communicating by providing an "alternative currency" to words as a means of exchanging views and information (MIT, 2013). This highly participatory approach to planning appears to be especially effective in engaging citizens who avoid processes that require written comments and public presentations before large gatherings.

Planning For Real is designed to catch the eye and tempt the hand of everyone involved- residents, planners etc. together around a model, home-made by the residents themselves with planners joining in as time allows. This creates a working not just a talking relationship, based on a mutually rewarding experience and not just a statutory requirement for engagement. The Planning For Real tool comes in a kit and can be purchased. In recent years the Planning For Real Kit has become popular in some developing countries and has been used in the Caribbean (MIT, 2013). This approach is highly recommended for urban upgrading projects due to the underlying philosophies. However, there is danger in using this technique as in any other participation technique, where planners will adopt a top-down approach rather than using it to facilitate a community building process (MIT, 2013).

The PDC by Bessete and the Planning for Real by John Gibson represent the ideal models of community engagement as outlined earlier represent the approaches that should be

applied to the Neighbourhood Upgrading Project context. This is because of their effective practical approaches to community engagement in a logical and room for iteration.

These models show not how any government or consultants will engage the community, but rather it shows what steps must be done to say that real engagement has taken place. At times the engagement approach taken by the government or consultants can be skewed for their benefits. These accepted models remove this potential bias for example, in the PDC model by the fact that sharing and utilization of information is necessary in the engagement process.

The approach to community engagement carried out in the Waterhole NUP is compared against the accepted models presented earlier to make the case of community engagement: theory or practice?

Background

Trinidad and Tobago is a twin island republic nation located to the south in the Caribbean region. Just like many countries in the West Indies, it was under colonial legacy. It gained Independence in 1962 and since then had started on a quest of development through western ideologies such as urbanization and industrialization. This led to significant rural-urban migration as people were moving away from the plantations into the urban areas in search for other types of jobs. Today 73% of Trinidad and Tobago's population lives in urban areas, the second highest figure after the Bahamas. Data shows that there is a steady growth in urbanization as an annual change rate of 2.9% from 2005 to 2010. This increase in the urban population has significantly increased the demand for housing and urban services, thereby distorting the housing and land markets

As Trinidad and Tobago was a colony, the resident population was brought primarily to work as slaves or indentured servants on the plantation for production purposes only, the masses were therefore deprived of access to wealth and assets such as land. This is so as of today, 47% of households have inadequate or lacked documentation of the land they have built their houses on.

It is estimated that there are 328 squatter sites in Trinidad and Tobago and as time goes on as the issue of access to affordable housing and land as well as overall social and economic policies are not tackled new squatter sites will spring up adding to this figure.

Urban squatting in the country is significant and chronic. Urban squatting occurs along the Western coastal areas and along the foothills of the Northern Range. Urban squatting in Trinidad is characterized by physical, social, and economic problems. Problems include sites being located in vulnerable areas, poor road and drainage infrastructure, lack of solid waste and waste water disposal systems, poor and sub-standard housing quality, non-conformity to planning standards, high levels of crime and violence, juvenile delinquency, high levels of poverty and unemployment coupled with lack of skills and lack of access to basic social services.

Squatter Regularization in Trinidad and Tobago

The Land Settlement Agency (LSA) is the state agency under the Land Tenure Regularization Act of 1998 to legalize irregular squatters on public lands. The Act has identified those sites which are to be regularized.

The IDB through the LSA embarked on the Neighbourhood Upgrading Programme (NUP) where component 1 deals with Squatter Regularization.

Under the NUP the LSA seeks to improve the living conditions of beneficiaries in selected squatter sites by regularizing the layout, allocating lands for non-residential use to provide necessary services, upgrading the physical infrastructure and providing security of tenure.

Waterhole

Waterhole is an urban hillside squatter site located in the Greater Port of Spain region. The site is located north of the Western Main Road in close proximity to a major shopping mall, West Mall.

The Waterhole Community just like all the other Squatter sites is the visual and physical sign of state neglect. They represent the state's inability to provide access to land and housing to the low-income brackets. However, these communities also represent the pride of the residents who were able to upgrade the area through their own self-help approach in order to incrementally develop the area to what it is today; from the make shift drains to the wooden footpaths are all what was done by the community over time. There is a pride there that is so deep that it can affect the way the state intends to address the issue of urban squatters in Trinidad and Tobago. Many residents say "here was nothing before; it is I who developed here through toil and sweat." Mangin (1967) describes this as where "The squatters can boast of a major accomplishment where planners and governments have failed."

Community Engagement in Trinidad and Tobago Overview

Trinidad and Tobago has a strong civil society movement, including NGOs and academic institutions such as UWI.

Reports indicate that there is a view that using participatory processes is not yet seen as an integral part of planning and management, but as a separate add-on activity. It is noted that while some participatory approaches have taken place, the general consensus is that they have been ad hoc, small scale local initiatives that have not given an equitable role in decision-making to key stakeholders.

It is felt that there is need to institutionalize participatory approaches in policy and practice. As it stands the Town and Country Planning Act and the Squatter Regularization Act do not speak of community engagement. The Environmental Management Act speaks about a Social Impact Assessment which is very limited in scope.

In Trinidad and Tobago there is an extremely strong perception that while government agencies and key decision makers speak the language of participation, there is no true understanding of what participation means and its true potential value in management of

livelihoods (CANARI, 2000) . This has manifested itself in the low levels of commitment to participatory approaches and decision-making power and authority (CANARI, 2000) .

Participation for material incentives is an increasing common model in the country with government and externally funded projects. In some cases community organizations and members are increasingly unwilling to become involved in engagement initiatives unless there are direct financial benefits. There is little focus by both government and civil society to adopt the wider and more complex benefits of community engagement (CANARI, 2000) .

Approach to community Engagement NUP Waterhole

The following information was derived from interviews and questionnaires conducted with the people in the community. In November 2011 the Neighbourhood Upgrading Project Waterhole, Cocorite was started. The community engagement for the project primarily was:

- A community presentation at the end of each phase. The consultants would present the final output of each phase to the community.
- The hiring of a community liaison officer whose role was reduced to escorting the consultants throughout the site, which was necessary due to the increased levels of crime and violence in the Trinidad and Tobago society and to prevent any negative actions related to how the community typically views outsiders.

The NUP project was broken down into three phases:

- Land Use Concept
- Land Use Plan
- Sub-division Plan

The Community of Cocorite, Waterhole did not know officially that the NUP had started, at the Land Use Concept stage. The community was only aware of the project after the LSA had already accepted the Land Use Concept Plan and the Consultants had to present the concept plan to the community on March 28 2012. Actually, work had already started on the next phase of the project, all without real community input, as there was a lag between acceptance of the concept plan and the community presentation.

Community Presentation

The LSA only planned for 3 community meetings and this highlights the low level of importance placed on community engagement as viewed by state agencies. This approach, in theory, is ineffective. In practice, the community engagement was not effective as the project came to a stop after the first community presentation.

The execution of squatter regularization projects should be examined with an aim of trying to spread the limited resources evenly. This can be done by developing cost-effective solutions for each component of the process including data capture and engagement, as practice shows that without proper engagement the project will not be accepted by the community and may therefore fail.

The presentation took the form of a power point presentation with maps, and text. The officials and consultants were seated at a head table emphasizing the power divide. Neither leaflets nor print-outs were made for the community to review before or during the presentation. The presentation was not interactive, the residents indicated, that interactive secessions are more effective. Questions had to be asked at the end of the presentation as to not distract the presenter. Residents indicated that during the presentation, they wanted to ask questions but having to wait until the end they forgot or were not interested anymore in raising them. A controlled interactive delivery setting would have been preferred by the community.

The community expressed concern, anger and resentment that such a detailed presentation was made to them, without any input from them. Questions were asked, who told you to draw that line there, who told you what roads we need, who did you consult in the community? The community evidently wanted to be involved in foundational aspects of the plan for example, the land use designations and the determination of relocation as was evidenced in the infield surveys.

Residents indicated that racial derogatory remarks were made to the presenter based on ethnicity. The Waterhole community is predominantly of African descent whilst the presenter is of East Indian descent, expressions like “why you don’t go back to Caroni” (predominantly Indian community) and “we do not want your plan” were hurled at the presenter. In Trinidad and Tobago the ethnicity factor stars in all aspects of the society and as it stands sensitivity to ethnicity issues in development and planning have to be considered in order to inform effective community engagement practices when the issue of ethnicity can be problematic.

The community indicated that the day of the community presentation was poorly scheduled as the Waterhole community had already planned their community football tournament in the same venue and on the same day as the presentation. Some residents indicated that the LSA had no respect for their community spirit and that the LSA was wasting their time with the presentation. This fuelled aggression throughout the community presentation. The LSA was threatened, and then were asked to leave. Some residents indicated they do not agree with the threats, but the football was planned first. A good approach to community engagement should have consulted the community about a proposed date and then it would have been found that the date by the LSA should have been shifted.

At the presentation some critical questions were asked but the community found that they were not answered clearly, for example, the issue of relocation, the issue of compensation, and the issue of not being able as a resident to contribute financially to the regularization exercise. The poor response to these questions made the residents uninterested in the exercise stating that it is just a usual waste of tax payers’ money. Some indicated that when the LSA is willing to answer those questions they could come back to the community.

The Waterhole community appears to be suffering from “engagement” fatigue as many plans are presented with no implementation. The community is an ideal representation of neglect. Some residents indicated that they listened intently to the presentation despite what was happening and were actually looking forward to the LSA coming back in 2 weeks’ time to discuss and decide on conclusions with the community. But the residents say this never happened and now they are tired of “talk-shops” and false promises. Residents say they will be willing to participate but presentations alone cannot suffice as engagement. The residents indicate that after the big presentations, meetings must be held to capture the community’s ideas and to incorporate them in the final plan.

Community Liaison Officer

It was accepted by the LSA that the need for a Community Liaison Officer is critical; however the definition of the role was not clear from the onset and therefore the benefits of having community liaising as an engagement tool was not realized.

The selection of the community liaison officer proved to be an unpopular one with the community. He was selected because he was known to the consultants. From the interviews it was gleaned, that having understood the need for a community liaison officer, at the initial stage of the project, the community should have been aware of the project in order that the community themselves could select a person or a group of persons that will be best suited with the necessary skills and knowledge to represent the community. This would lead to them being accepted and having consensus with the residents in the community.

The community liaison officer was deemed to be too political in order to be able to speak objectively for the community as a whole. Residents, who indicated they were opposed to him, said they will not participate in the process and do not want to be part of the project.

It was revealed that the Local Government Councillor should have had a major role on the project; he should be the one taking all the concerns and engaging the various stakeholders on behalf of the community. However, some residents indicated that the councillor does not do his job. A Guardian Newspaper report highlights that the councillor along with the Minister of Social Development were touring the community and they were pelted with rolls of toilet paper months after the community presentation. Incidents like these show that community representation is a very sensitive one and as such the person or persons must be able to be effective at it.

The heckling by the community towards community officers, officials illustrate the extent to which the community will go to express their concern, non-acceptance and disapproval of a project or programme. How they respond to this power difference is in an aggressive and disrespectful way, which will act as a deterrent to other agencies, other interested community liaison officers to be eager to effectively engage as they fear they will be attacked in a similar manner.

The comparison of the case study with the best practice selected will lead to a conclusion about how to correct the local process.

Analysis

The PDC model identifies ten (10) steps necessary for successful engagement, however the NUP approach was limited as it only focused on presenting the final output. In this respect the approach can be defined as consultative as opposed to engaging. Consultation is defined as when one decides on what they want to achieve and ask others what they think of it, whether the persons respond or not is insignificant as those being consulted have no real say in the final decision.

Urban squatter sites in Trinidad and Tobago are known to be socially volatile, hence the need for security in order to ensure safety whilst carrying out community work in such areas. There seems to be a view that the community liaison officer role is to be the security. It is however important to note, that the roles of security officer and community liaison officer should not be mixed up. These are separate distinct roles, security has a purpose and community liaising has its purpose. At times one person can fill the roles, but both roles must be fulfilled, not one at the expense of the other. Acceptance of the person or persons to fulfill these roles by the community is paramount to the success of an overall engagement strategy and hence for the success of the NUP.

The approach to engagement by the LSA assumed that the consultants along with the LSA already knew what the community wanted, but this was far from the case. Institutionally in Trinidad and Tobago, the culture towards development is a top-down approach where the government or consultants selected by the government select a development problem, in this case squatter sites, identify potential problems, make decisions, present decisions and implement all without community engagement. This top-down approach is one where the government thinks that it is doing the squatters a favour and therefore the community is seen as a mere beneficiary and not central to the decision making process. The concept that beggars cannot be choosers come into play in the top-down approach to development. This top-down approach cannot work in urban squatter communities as it intensifies the power divide and its consequences between the community and the technocrats deciding on and implementing the plan.

For successful development, communities like Waterhole must be involved in identifying their own development problems, in seeking solutions and making decisions about how to implement them.

From the data collection exercise, it was revealed that the community needs a more participative approach to NUP. As such Planning For Real should be used. If planning for Real is utilised, the community could be certain that having invested time for such an approach the government is serious about the project. Residents do not feel to be engaged as they deem the government as not serious about squatter regularization. Planning for Real serves as a psychological incentive to participate where the community and planners work hand in hand with each other.

The name Planning For Real alone speaks volumes, as the community sees planning as a waste of time, they do not understand the process. The community indicated most times the planning exercise end up as a written report with no implementation and more often than not, the community is excluded from the process. Planning for Real would bring awareness

to the community about the different factors planners have to consider in developing the best plans for a community.

With Planning For Real, where residents are actually involved in shaping their community, the community's attitude towards planning will change. In addition it will create a neutral environment where sharing of knowledge would occur as well as easing tensions. With this approach, the issues of race and power differences will take a back seat as the community will be able to determine for themselves that progress is being made with true community input. The community will have no time for exaggerating the differences; focus will be placed on building community models and shaping their own space. This high degree of empowerment will be greater than causing conflict that is synonymous with consultative approaches.

With respect to the community presentation approach adopted by the LSA, according to Tony Gibson, having community presentation is very limiting. This is so because he states that presentations tend to privilege the more highly educated and professionally trained members of the community while marginalizing others. This is indeed true, as residents indicated that they were confused when the maps and "big words" were presented on the slides. Planning For Real is ideal and effective in engaging citizens who avoid processes that require written communication and public presentations before large gatherings.

As was identified from the survey, that the liaison officer was deemed too political to represent the community, it is paramount that engagement activities and its objectives do not become politicized or used for political party purposes. This is a general trend with respect to community engagement in Trinidad and Tobago.

The community engagement approach by the LSA failed to develop a harmonious relationship with the community, an antagonistic relationship between the community and the LSA developed after the community presentations. the approach failed to have mechanisms in place where residents can come to the consultants with concerns as well as to help them identify their own problems. There was a need to ascertain what the community sees as critical in the NUP, was it the deed of lease, was it contracts to upgrade the community, was it the need to be involved in every step of the way?

The approach further failed to utilise other stakeholders necessary for the success of such a project. the LSA is the only agency responsible for squatter regularization in Trinidad and Tobago. However squatter regularization is complex and requires the expertise that one agency alone can realistically have. The LSA does not have the administrative, financial and technical resources to truly operate like a specialised agency, therefore, the need to involve other stakeholders for support and to capitalize on their different strengths. For e.g. the Citizen Security Programme an organization whose objective is to reduce crime and violence operate in the Waterhole community but it was not involved in the NUP.

The approach failed to pretest their engagement approach. No preliminary community engagement meetings formal or formal were held at the start of the project to gauge how the community reacts to project in order to develop the best engagement plan based on how the first meetings went. If this was done the LSA would have realised that public presentations after decisions have been made would not have sufficed. these kick- off meetings could be used to "test the waters" and offer the opportunity to see what the community wants explain, how to explain it, identify the best ways to incorporate community ideas and inputs into the

plan , all in order that it can be analysed and presented back to them. if you have a pre-planned approach, by testing it, one will be able to see how the community responds and then continue with the approach or make necessary changes to improve the engagement process.

Finally, community engagement can cease to be meaningful if it is undertaken purely for the sake of having to be seen to engage. This is important to note as there are consequences to flawed participation as the case study highlights. Community engagement must be well thought out and implemented properly, success is not measured in theory but in practice. If the practice is of community engagement is not effective it can lead to community ill-will, aggression, violence and stop to development projects at the expense of those who need development to happen.

Conclusion

Community engagement in Trinidad and Tobago is not in line with the desired practice. The approach needs to be more collaborative as opposed to consultative in approach. It is all ideal to have community engagement as a foundational principle but if the community itself is not the centre of the development, that is, if the models presented are not effectively utilized in Trinidad and Tobago, it is just pure rhetoric.

Bottom-up Urban Development in Action

Marija CVETINOVIC, EPFL, Switzerland
Ivan KUCINA, AF-BU, Serbia
Jean-Claude BOLAY, EPFL, Switzerland

1. Introduction

The conceptual framework explained herein examines the blurred and askew structure of neglected urban neighbourhoods in post-socialist cities. This requires innovative, small-scale, dynamic proposals in order to overcome the rigid administrative procedure of urban development and to transform the negative side effects of imitating and lagging behind the conventional urbanisation model and those of the accelerating globalisation into a development impetus suited to these environments. In this highly competitive international economic and political arena, transitional countries experience severe consequences due to the paucity of practical experience within this new context of a market economy and decentralised political and administrative powers, a lack of resources, the scarcity of general international investment and scant interest in seeing dramatic shifts in all aspects of social organisation and urban transformations. The alternative strategy could be put forth through bottom-up spatial production of all the urban actors and stakeholders involved as a common denominator of a non-intrusive platform for the active representation, assessment and management of urban conflicts as a range of iterative “inter-states”.

Belgrade, with its one and a half million inhabitants, is the capital of Serbia. It is the only large European city situated on the confluence of two great rivers, the Sava and the Danube, waterways that throughout history marked a border between two of the most powerful European empires - Ottoman and Habsburg. Its picturesque position and historical mixture endowed Belgrade with vast spatial potential for creative urban development. In fact, as the former capital of the socialist state, it underwent remarkable economic, social and cultural damage during the nineties, a decade of wars and national turmoil in the former Yugoslavia and which had insurmountable consequences as regards uncontrolled urban growth. The expansion of bottom-up informal building that followed the explosion of a grey economy has taken over all its free spaces as well as the existing buildings both in the centre and on the periphery of the city. Conversely infrastructure inherited from the socialist period, but with its low institutional capacity, with the Belgrade has continued to be the centre of economic growth with a variety of services' expansion, building innovations and urban conflicts.

Beside the effects of the war economy, the urban growth of the Serbian capital has been determined by dramatic social, economic and political deterioration, as has been the case with the other post-socialist transitional cities in Central and Eastern Europe. The abrupt shift from a communist regime to that of a neo-liberal economy hindered urban development in Serbia and led to political instability, convergent socio-economic forces and inconsistent planning systems. Inherited from the communist era, top-down urban planning procedures and strategies, were rendered inefficient in addressing urban conflicts at all spatial levels. In addition, the failure to successfully replicate more advanced models of western neo-liberal economies made it clear that a fragmented, small-scale approach to spatial and social conflict could achieve more long-term consistent and far-reaching results. For this reason, the focus of the study presented here evolves from individual informal development to citizen participatory practices, which are both an essential prerequisite of social integration and an inter-medium for addressing urban issues in a broader context.

A case study of Savamala, a devastated urban quarter of Belgrade, represents the research and action that has been identified as an exploratory analysis of the interactional process involving the various urban actors in a socially and spatially constrained urban environment.

It is taken as a testing ground for the implementation of an innovative tool for “action and learning by doing”(Lydon 2012) in the urban planning of transitional post -socialist cities.

The first part of this paper provides an overview of spatial and historical circumstances and their transposition which designate Savamala neighbourhood as a suitable environment for instigating efficient bottom-up urban transformation. Then, we will present how an experimental learning tool for bottom-up urbanism is adjusted and applied to the context of Savamala. Its alternative urban development model is based on the combination of a participatory approach within the principles of tactical urbanism through the transposition of obvious urban conflicts and clandestine social potential and spatial capacities in urban development opportunities. Participatory activities are rounded up in an urban transformation programme named Savamala Civic District and in the Urban Incubator project activities. Finally, the aim of this paper is to indicate a chance for urban change through an iterative process of small-scale citizen interventions. The resulting urban state of Savamala will eventually expose economic, political, cultural and spatial transformations elicited therefrom and explicate the initial step in building an urban development model appropriate for urban environments in post-socialist cities.

2. Savamala neighbourhood

2.1 Location

Savamala is a neighbourhood in Belgrade situated on the southern bank of the Sava River and belongs to the central city zone known as the Savski Amphitheatre. Its name translated into English means “Sava neighbourhood”, and intrinsically, its name is derived from the Turkish word for neighbourhood “mahala”, combined with the name of the river whose bank it is situated on, which testifies the resolution of city authorities about 100 years ago to spread the urban structures to the river in order to set forward its urban development.

The neighbourhood of Savamala is among the most important landmarks of the city of Belgrade (apart from The Kalemegdan Fortress, Knez Mihailova Street and Kosancicev Venac urban neighbourhood) and it justifies such a role as it is a unique area in Belgrade with such a plausible collision between traditional and modern and past and present, rich in tradition, history and heritage. But world wars, authoritarian rule and the current economic crisis have left their marks.

Savamala today is stuck in a long-term process of decay. It is also a transit area that permits heavy traffic (trucks, trams, cars) to bypass the city centre; this aggravates its already alarming traffic jam. Therefore, this neighbourhood, endowed with an extraordinary spatial and economic potential and rich urban history, is now a traffic bottleneck with intense pollution and urban noise whose obvious spatial conflicts are neglected by both the authorities and professionals (“Urban Incubator Belgrade” 2013). Moreover, Savamala is economically underdeveloped and socially disadvantaged, and has a reputation as a home to outcasts, prostitution and criminality, while its citizens are continuously fighting for better living standards, only one kilometre away of the city centre that does not lag behind other European metropolises in terms of its architecture and urban design quality.

2.2 History

Savamala is the first Belgrade city quarter to be erected in the 18th century for the Christian population outside the Kalemegdan fortress during the reign of Austro-Hungarian Empire. Urbanisation in the manner of a European city started after 1833, when Serbian authorities gained control over Belgrade and decided to make the Savamala neighbourhood an elite commercial and cultural urban quarter. Therefore, Savamala exhibits a rich heritage of valuable historical buildings from the 19th and early 20th centuries and a few relics from the Ottoman period.

Over the centuries, the river Sava was the border between the Hapsburgs and the Ottomans. As they fought for the domination over the city, it consequently suffered continual instability, shifting from demolition to rebuilding. During the short peaceful periods, Savamala grew up as a trading centre adjacent to the river ferry border-crossing. During the late 19th and early 20th century, following the pace of modernisation of the independent Serbian Kingdom, new national cultural institutions were established next to the trading services. For a short time, Savamala became the site for massive building projects, considered to be of the greatest cultural and historical significance. However, in the course of the destruction during World War I and the subsequent establishment of the Yugoslav Kingdom that shifted the border far from the riverbanks and focused the development of the city centre in uptown Belgrade, Savamala lost its attractiveness and fell largely into a state of decay. The streets were not maintained, inconspicuous warehouses were stuffed into empty plots, buildings were partly abandoned and occupied by the urban poor, and the area repeatedly suffered major floods.

Beside the damages from bombardments during World War II which led to the intense deterioration of the area, after the war, Savamala was disregarded as the legacy of the capitalist era, and its main transversal street Karadjordjeva – once among the most beautiful city avenues – was turned into a crowded, noisy and polluted transit roadway surrounded by poor warehouses and manufactories that replaced the bombed palaces. Furthermore, Savamala also hosted the enlargement of the state major traffic infrastructure, including the nearby main train station, the bus terminal, the river terminal and two of the city's main bridges connecting the city centre to New Belgrade, newly constructed capital of a socialist Yugoslavia that projected its high collective ideals onto urban development by appropriating the concept of modernist urban development.

2.3 Contemporary

After the major political shift in the year 2000, post-socialist transition has started opening up the possibility for private capital to enter the privatisation process and to dispose of property. In such an economic constellation, Savamala has a potential to become an attractive urban area for investments. The situation has also been recognised by a combination of corrupted public authorities and powerful private developers, who have been aiming to maximize their profit by usurping public spaces and built infrastructure. Consequently, very little room would be left for any other form of urban development (such as socially and culturally sustainable development would be) apart from seeing it as an asset for gaining political influence and as an abundant source of profit.

Despite the ownership change, Savamala has been saved from this newest development trend mostly because of its long-term decay that is making it a far too complicated case for the limited investments with short-term turnovers that are dominating in Serbia. In addition, the recent European debt crisis that has been largely created by speculation in the real estate business is postponing any financial injection to the construction industry in Belgrade until the distant future.

In the meantime, taking advantage of this long gap in development, a number of small-scale public initiatives, as well as creative services, have found their place in Savamala, infusing sparks of new life into the area. In the absence of an overall urban development strategy, independent cultural entrepreneurs supported by the local municipality Savski Venac have started to transform unused warehouses and craft shops into spaces that are open for public participation and social production. What today might seem not more than a sum of ephemeral activities has a potential to become a driving force for a possible urban future of Savamala. For example, KC Grad – an independent cultural centre, Magacin – an NGO culture cluster, Mikser House – a creative association, Nova Iskra – a young designers incubator, and “Urban Incubator” – a Goethe Institute initiative, all of which have finally introduced the opportunity for an alternative strategic gateway to influence the future development of this devastated but promising neighbourhood (“Mikser Festival” 2012).

3. Strategic Gateway

The alternative model for urban development of Savamala is based on the conceptual idea of extending the urban life of Belgrade down to its riverbanks by infusing small-scale cultural practices and crowdsourcing activities, creative industries, urban manufactories, and cooperative economies. This conglomerate of individual initiatives strives to physically transform the Savamala neighbourhood and to influence the long-term process of urban transformations that are based on social interest rather than on real estate speculations. In the long-run it will change its urban image in these ways: converting abandoned warehouses into socially productive facilities, activating riverfront usage, encouraging local community participation, attracting new visitors to the neighbourhood (professionals and general public, both local and global) and finally revalorizing and repositioning the Savamala neighbourhood within the physical and functional scheme of the whole city of Belgrade.

<i>Social potentials and spatial capacities</i>			
<i>Economic</i>	<i>Political</i>	<i>Cultural</i>	<i>Spatial</i>
<ul style="list-style-type: none"> • Trade and artisanal area • Location: close to city centre 	Participative and self-organisational initiatives (KC Grad, Mikser, etc.)	<ul style="list-style-type: none"> • Heritage • Tradition: crafts 	<ul style="list-style-type: none"> • Location: river bank close to the confluence Sava-Danube • Spatial resources: abandoned buildings and empty plots

Figure 1: Categories of social potentials and spatial capacities in Savamala

This model of urban development combines such an approach of tactical urbanism with participatory actions in order to set forth urban transformations. According to Mike Lydon's paradigm of tactical urbanism, pop up projects operate with local ideas and respond to local challenges in such a manner that they bring positive changes and develop social capital and organisational capacity through low-risk, iterative approach (Lydon 2012). In terms of an urban development model, the process of urban change for Savamala is to be built through 4 phases:

1. Identify urban conflicts and brainstorm capacities of Savamala neighbourhood – explanation of an urban context, a deliberate, iterative approach to instigating change
2. Congregate ideas and set up a common vision for Savamala's urban transformation – focus on local ideas as a response to local challenges
3. Try to resolve urban conflicts by instant actions – agility and value of short-term projects based on the development of social capital and the building of organisational capacity
4. Build low-risk scenarios and introduce a non-intrusive, bottom-up strategy of urban development for Savamala neighbourhood

3.1 Urban Conflicts, Social Potentials and Spatial Capacities

In order to identify and elaborate how participatory activities influence urban development in Savamala, it is essential to transpose the current state of its urban environment into factors which could denote such positive impetus. Namely, contemporary urban development aims to correlate all of the elements of a modern urban environment (urban actors, social practices, space, built environment, infrastructures) which are influenced by economic, political and cultural factors in order to improve living conditions and facilitate positive social interactions. However, the interaction and interconnections among these key agents in an urban environment not only incite and develop social potentials and spatial capacities, but also evidence production and the challenge of urban conflict.

<i>Urban conflicts</i>				
<i>Economic</i>	<i>Political</i>	<i>Cultural</i>	<i>Spatial</i>	<i>Technical</i>
<ul style="list-style-type: none"> • Attractive location for private investments • Lack of systematic investments in constructing industry (debt crisis) • Poor population in the area • Criminal activities present in the area 	<ul style="list-style-type: none"> • Lack of regulatory framework • Powerful economic actors with strong political influence 	<ul style="list-style-type: none"> • Marginalised groups living in the area • Disintegration of heritage (fragmented approach to renovation and revitalisation projects) 	<ul style="list-style-type: none"> • Transition area (heavy transport) • Abandoned and ruined buildings and empty plots • Deteriorating industrial area • Noise and pollution 	<ul style="list-style-type: none"> • Lack of data about the state of physical structures • Lack of data on social structure in the neighbourhood

Figure 2: Urban conflicts in Savamala categorized according to defined factors

Benefitting from these social potentials and spatial capacities (Figure 1), as well as addressing urban conflicts (Figure 2), involve the continuous reviewing of how the collision among these positive and negative influences actually produces a variety of contextual resources. In this case, the conceived locational, spatial and cultural resources of Savamala are those that aspire to generate a set of actions for building a model of urban development that achieves common viewpoints, goals and priorities among all urban actors and stakeholders (Figure 3). Knowing that this urban development model renders qualitative urban change, it is crucial to determine the beginning and end state of factors that indicate such a change, i.e. economic, political, cultural and spatial characteristics re-imagined in terms of urban conflicts, social potentials and spatial capacities.

<i>Contextual resources</i>		
<i>Locational</i>	<i>Spatial</i>	<i>Cultural</i>
<ul style="list-style-type: none"> • Accessible, • Close to city centre • Close to the river 	<ul style="list-style-type: none"> • Abandoned buildings and empty plots currently without interest from powerful economic actors because of financial crisis 	<ul style="list-style-type: none"> • Rich in tradition and cultural heritage • Aroused interest for this neighbourhood from cultural and artistic groups, individuals and organisations

Figure 3: Contextual resources in Savamala indentified after the analysis of urban conflicts, social potentials and spatial capacities

3.2 Urban Transformation Programme: Savamala Civic District

Savamala Civic District was originally envisioned as a set of participatory activities supported by the Mikser Festival, common denominator of which was building a platform for all urban actors and stakeholders to engage in changing their immediate surroundings, even though neither the wide variety of these actors, nor exact steps end state in this process, were to a great extent clarified beforehand. Therefore, the priority goal of the project was to create a sort of civic district as a long-term participatory realm for taking the most of a range of opportunities for non-institutionalised, flexible and dynamic urban transformation programme through various levels of sharing:

- *Knowledge-sharing* (Hess and Ostrom 2007) – the educational aspect of an urban transformation process

1. Capacity-building – regenerate community and strengthen the exchange of creative ideas where everybody needs to have an understanding of the personal and public relevance of urban transformation and then make their contributions irrespective of social status. Urban transformation offers an incentive to invert any negative feelings into collaboration in order to generate new standards of living and working.

2. Knowledge-building - continual production of new knowledge through knowledge exchange. Interaction between devastated places and advanced practical and academic professional knowledge plants sparks of a new life in people's minds that could be injected into the paralysed urban body, suggesting the way for the new approach to urban development

- *Experience-sharing* – an interactive system for continuous social exchanges

3. Collaboration-building - in an innovative and inspiring manner, encourage a wide variety of urban actors to join the network and contribute their talents, and to present and incorporate their social and cultural particularities to the emphatic culture of exchange

4. Reality-building - a serial of civic activities should work as a booster for social exchange in order to enlarge production of urban energy needed for running community services and cultural practices in the course of future development.

- *Vision-sharing* (Meroni 2007) – creative participation to instigate qualitative urban change

5. Facility-building - inauguration of diverse minuscule public spaces (urban bundles) for group gathering, meetings, debates and collaborative work. These small public spaces represent a kind of hot spot, buzzing with energy, exchange, invention, and dedication to a better life,

6. Vision-building – a series of common projects develop a vision of urban transformation by adding up sequences and unfolding the experiences of the community that is using and building it - plot by plot, building by building, and street by street. Collaboration among different actors produces a diversity of projects and increases opportunities for a variety of proposals.

In order to test this program an international group of experts who work on innovative models for bottom-up synergies among the social, cultural, infrastructural, ecological and economical aspects of an urban development gathered in Savamala during the Mikser Festival in 2012. The event included a series of meetings, debates, collaborative works and public space installations taking place in Savamala neighbourhood. The intention was to explore how the urban transformation programme could be triggered through cultural activities and creative interventions. In order to meet this goal seven parallel workshops addressed the status and development of Savamala from different perspectives, such as:

- Unheard Stories of Savamala (SIMKA and Ana Ulfstrand, Stockholm)

This artistic workshop promoted an ethnological approach towards research that could interpret the urban devastation – from collected documentation, interviews, and observations.

- Urban Body (Alexander Vollebregt, Rotterdam)

While struggling to find a true resilience and prosperity in the contemporary condition of Savamala, participants have to learn to use the full potential of their minds and bodies to develop an enhanced urban comprehension.

- 5 Obstructions for Urbanism (Todd Rouhe and Lars Fischer, Common Room, New York)

Several onsite installations have been built according to creative methodology articulated by the Five Obstructions: 1. Appropriate the everyday: elevate the ordinary 2. Never finish: making and using architecture are interconnected 3. Share space: negotiate and overlap. 4. Include differences: redefine boundaries and be inclusive. 5. Don't be new: don't be new for the sake of the new.

- Butong Installation (Lars Høglund, Stockholm and Benjamin Levy, Paris)

Installation made of Butong, material that was created in 2009, served as a convertible eco barrier in order to protect the public space from the aggressions of heavy traffic.

- Urban Bundle (James Stodgel, Santa Fe)

A temporary public space installation that provides an initial condition for citizen gathering, meeting, debating, and collaborating in the process of creating and maintaining their social and urban environment.

- A Sense of Place (Ljubo Georgiev, Maja Popovic, Failed Architecture, Amsterdam)

The workshop took place in one of the courtyards of Karadjordjeva Street transforming it from a place of conflict into a place where neighbours gathered together. The habits of local people were learned in order to find out how to reinforce their sense of belonging to the place and to upgrade the space they are forced to share.

- City COOP Web Platform (Ana Lalic, Vancouver)

Students were designing a wireframe storyboard that will serve as a draft plan for creating the website platform that will build a social network of citizens, experts, developers and institutions to exchange ideas and opinions related to the urban transformation of Savamala.

3.3 Project Urban Incubator

Generating Savamala Civic District from the bottom up becomes apparently feasible through the enabling of direct interaction between urban space and civic life. Hence, the revitalisation project Urban Incubator, supported by the Goethe Institute Belgrade, aims at visualising the urban future of Savamala as a network of places where all urban actors and stakeholders can meet to share their respective cultural merits and urban experiences. All the actions inside this project rely on communication among individuals, self-organised associations, public services and private enterprises as equal participants in the societal realm which will demonstrate its influence by performing spatial changes as social exchange and eventually boost urban transformation.

Figure 4: Spatial distribution of Urban Incubator activities in Savamala neighbourhood

Urban Incubator reflects the urban future of Savamala through ten site-specific parallel project activities (Figure 4). These activities are divided into three groups depending on what they address: the developing infrastructure for social change, systematic collaboration within the network of civic engagement and pop-up events and instant actions for the reconstruction of everyday life:

3.3.1 Building ICT infrastructure for social exchange

Based on the fact that new technologies and mass-media are an omnipresent reality-builder and an essential social glue in a modern networked society that extends spatial essence of urbanity via technical resources (Amin 2006), the idea was to use online social media and web 2.0 technologies as informational, communicational and educational tools to first assemble and then spread around perceptions of space, time, lifestyles and a sense of

community among urban actors and stakeholders of Savamala and further expose them to the criticisms and influences of the general public. In this way, intellectual and social networks are created, that stretch from obvious spatial proximity, constitute a synergy on the basis of knowledge and information and represent the core stimulus of applied creativity, all of which are essential structural elements of qualitative urban change.

Nextsavamala – Crowdsourcing a City Vision

This activity is based on its successful application in Hamburg, where these instruments have been developed and tested. It represents a web-based public forum and workshops for collecting and filtering citizens' visions and discussing, developing and pitching ideas that can be later on implemented in actual planning processes for Savamala neighbourhood.

It incorporates two manners of networking: online (not only for urban actors and stakeholders from Savamala, but for all interested in urban planning and development topics) ("Nextsavamala" 2013) and offline communication (workshops, conversations, and a post-box for residents of Savamala). So, the online platform and social network serve for recognising urban conflicts (input data) as well as gathering and discussing ideas for urban transformation and implementation (projects, scenarios).

In its essence, it is a sort of citizens' agenda which contains the practical answers of how citizens envisage the future of Savamala. Moreover, through a careful decoding and mapping process this agenda could also provide us also with possible manuals of how to organise participation if there is a lack of adequate structures and traditions, as it is the case in post-socialist countries, where there is no practical experience of public participation, but a recent trend of promoting involvement in the public realm.

3.3.2 Network of civic engagement

It encompasses systematic collaboration for building and disseminating knowledge about the urban situation, providing data, gathering information according to these data and informing the public on current urban conflicts, promoting urban development, and setting up modules for active participation in articulating urban development strategy for Savamala. This set of activities considers accumulating social capital through non-intrusive, sequential small step initiatives within an overall interactive and educational process of forming a critical society – trained populace, dynamic interdependence and mutual development of both city and citizens. Human capacity within such a society is able to produce its own space with a strong impact of and on culture and ideology.

Spanish House

This is a temporary pavilion made inside the ruined building of an old captaincy which forms part of the cultural heritage of Savamala. The building is almost completely devastated; only the outside walls have resisted the ravages of time. A set of actions inside Urban Incubator aimed firstly at symbolic revitalisation of the building by crowdsourced human and social resources and then made it a communication venue for accessing general information about the project and all events organised within the project. It serves functionally and programmatically as a "space of enablement" that symbolises "a public space to be" in Savamala, where its emptiness emphasises the importance of spaciousness of public spaces, freely grown weeds envision the need for public greenery and sculptural residual concrete elements invigorate the urge for public art ("Spanish House" 2013).

Bureau Savamala

This symbolic institution figures as the critical commentator of the whole "Urban Incubator" project. It focuses on critically monitoring and analysing the contribution of artists, any creative projects and creative capital in general on the socially sustainable development of Savamala as a venue for social niches allowing alternative lifestyles which are very attractive to creative individuals. The result of this activity is a sort of record on mapping how this

neighbourhood changes and how the perception of locals and the broader public has changed accordingly (“Bureau Savamala” 2013).

We Also Love The Art of Others

This symbolic name denotes fostering a network among the artistic scene of Belgrade and beyond, whose members are all of different origins. These artists enter into dialogue in this neighbourhood and are motivated as a group to engage in artistic research and interventions in a forgotten place, where all the artistic work is adjusted to the current context. In other words, artists become socially active; they are projecting their vision of the world in a particular social context, investigating the meaning of the “utopian space” of their imagination as an enclave inside a social discourse today. The goal is to re-vitalise the traditional role of Savamala (as a place for trade, international exchange & encounters) through site-specific artistic work with the emphasis on the use of new media in order to best combine networking and innovation as basic engines of contemporary progressive society (“We Also Love the Art of Others” 2013).

Model for Savamala

This component comes from an architectural practice that has set itself a goal of building an 1:200 model of Savamala on the basis of collected local knowledge (“Model for Savamala” 2013). This 3D representation of physical structure will incorporate soft data, namely the social structure of this neighbourhood, which is not based on aesthetics, but on information. So, the information implies the tracing of all urban spaces and structures by creating a passport for each and every structure inside this area. This will comprise two parts (Lee, Yaniya 2013):

- Objective: fact-finding (i.e. height of building, type of roof, façade, number of units, age of the building)
- Subjective: the historical layers, social structure and general impression of the structures

The initial idea is to put these valuable pieces of information next to one another and form a certain sort of knowledge base. Henceforth, it will serve as a core common element of a platform for participation and collaboration. Such exhaustive database is an inexhaustible source of new appreciation and the creation of a new awareness that will continuously attract different people, stakeholders or developers to gather around so as to talk and search for the solutions of – in such a model – well represented and acknowledged urban conflicts.

3.3.3 Energizing everyday life

This line of activities envisions pop-up events and instant actions for clarifying common threads and differences of the socio-spatial model of Savamala which incorporates local knowledge, integrates the customs and needs of citizens, and activates their cultural identities. All the incorporated activities exemplify a strong tie-in between theory, practice, arts and crafts in order to indicate provisory, flexible and dynamic milestones of an urban policy for guiding the urban transformation of Savamala through the practice of social activism and an experimental learning approach.

Listen Savamala

This sound-art project traces urban changes through sound recording in order to justify that it is not only a visual phenomenon. A challenging concept behind it is that an urban change is not only a visual phenomenon and that it is also stimulating to hear the change in a city. The basic work consists of collecting sounds and feeding newly generated ones back into urban spaces in formats such as installations, concerts and radio programmes (“Slušaj Savamala” 2013).

Camenzind

This is a Serbian edition of the Swiss magazine with the same name. It is an outcome of the exchange of Serbian-Swiss-German knowledge on the built environment through four issues of this new Serbian journal covering architectural issues and urban public events, and report collected local knowledge in and about Savamala. It involves critically and creatively reporting on the progress in Savamala and on the Urban Incubator project through printed material (Camenzind magazine) and radio coverage ("Radio Savamala") ("Camenzind" 2013). In a truly participatory tradition, this activity motivates all urban actors to write and read about architecture and urbanism in Savamala. Gaining such knowledge will also give them confidence to be more actively involved in the urban transformation process through an open platform for debates, lectures, discussions, workshops, and salons.

3.3.4 Upgrading the Urban Environment

Designing the urban environment does not only improve its aesthetic qualities, but it also involves a social dimension and creates social value. In other words, its high priority is giving the residents a voice in development as well as teaching them to participate and become politically active.

Savamala Design Studio

In this manner, the aim of the Savamala design studio is to establish a participatory design practice that creates new relationships among various urban actors and stakeholders with an emphasis on encouraging Savamala residents to join to find advice and active support for their own design and construction demands and requirements. The two main parts of this practice are ("Savamala Design Studio" 2013):

- Creation of a toolbox, toolkit (toolbox = toolkit) and a manual of local knowledge, practices and cultural values: through a series of workshops with residents, other urban actors will learn from them and map their everyday practices (i.e. preserving food, recycling waste, barter economy, illegal building construction)
- Establishment of a "Public design support" agency: Experts, practitioners, artists and young professionals will work together in attempting to identify Savamala's own design, construction demands and requirements and to promote new intercultural exchange concerning construction and aesthetical principles of architecture, urbanism, arts and crafts.

School of Urban Practice

The School of Urban Practice conducts advanced educational, research and activist work that redefines design, architecture and urbanism as a field of transformative activities ("School of Urban Practice" 2013). Participants seek the way to improve the everyday environment of Savamala, whether through creating public policy, mediation, urban planning and architecture design, or any other form of design that involves citizens from the very beginning of the designing process. By working for the public interest on the site and by exchanging aspirations with local community entrepreneurs, the School of Urban Practices develops innovative concepts based on critical engagement with contemporary issues of urban commons ("Weblog Project Basement C5" 2013).

Micro factories

These small and new production facilities in Savamala, as the name says, strive to identify small suitable spaces in Savamala and attract participants in order to define and tap into a creative production process that transforms local knowledge, capacities and ideas into innovative design products. Participants collect local materials (usually from abandoned apartments or other places) and work on the design of products that reflects what they find in Savamala and its tradition of small craft workshops (i.e. carpentry). The aim is to make a social network and technical support, and re-connect the talent and experience of locals to their living environment. These new small production facilities are intended to be

microeconomic structures which shape the intense street life of a vivid neighbourhood with local pride and identity through the established relationship between urban space and industrial production (“Micro Factories” 2013).

4. Pillars of the Bottom-up Urban Development Model

<i>Urban Incubator activities</i>	<i>What these activities address</i>	<i>What these activities offer</i>	<i>What they produce</i>
Nextsavamala	Lack of an urban planning strategy and urban development actions for Savamala	<ul style="list-style-type: none"> • Use modern technology (adjustment of urban development strategies to the modern context) • Enlarge participatory body (more resources, more ideas) • Promotion (new urban actors) 	Mobilise available human capacities (locally and globally) to boost urban development in Savamala
Spanish house	Deteriorating cultural heritage and empty plots in Savamala	<ul style="list-style-type: none"> • Promote small-scale, low-budget revitalisation as beautiful, useful, productive • Spatial actualisation of sharing, collaboration, participation through the public space reserved for these activities 	<ul style="list-style-type: none"> • Promoting capacities, quality and beauty of Savamala’s cultural heritage • Integrating the local community in urban development
Bureau Savamala	Forming “creative capital”	<ul style="list-style-type: none"> • Critical approach to changes • Flexibility and dynamics of concepts for activities addressing urban development 	Mapping urban change for a sustainable urban development model
We also love the art of others	Deteriorating public spaces in Savamala	<ul style="list-style-type: none"> • New urban actors - artists • Merging of concepts for urban development in Savamala among various national and international artists • New activities (artistic events) that bring new visitors to this neighbourhood 	<ul style="list-style-type: none"> • New groups of urban actors (artists and new visitors) • New artistic activities
Model for Savamala	Lack of data on physical environment and social structure in Savamala	<ul style="list-style-type: none"> • Low-budget collection of data on social structure and built environment • Brainstorming the data through their incorporation in a spatial model • Engage motivation and capacities of young professionals 	Up-to-date soft data about this neighbourhood and its built environment and cultural heritage
Listen Savamala	Sound identity a noisy neighbourhood	A new perception and approach to the modern city - new layer of auditory data	A layer of soft data about Savamala
Camenzind	Abandoned and ruined buildings and empty plots	Glocalisation – translations of global trends and concepts in local environment of Savamala and vice versa	Representation and interpretation of collected data
Savamala design studio	Disintegration of tradition and heritage	Work on the definition of local knowledge, capacities, values, options and demands as well as building principles	Practical knowledge on culture, tradition and heritage in Savamala
School of urban practices	Weakness of regulatory framework	<ul style="list-style-type: none"> • Transfer academic knowledge into tacit knowledge • Practice based on participative bottom up projects 	New, efficient and effective approach to step by step urban transformation
Micro factories	Disappearing traditions and crafts	<ul style="list-style-type: none"> • Possibility of new production and job creation • Dissemination of knowledge and information • Improving the quality of life of local residents through production and creativity • Education through practice – real life context for young designers and craftsmen 	New activities and new urban functions

Figure 5: Analysis of Urban Incubator activities

The goal of the Savamala Civic District programme and the Urban Incubator project is to instigate qualitative urban change in Savamala that involves dealing with growing urban conflicts, fostering social potentials and benefitting from spatial capacities. In this sense, the

influence of this project is measured according to the extent it adequately answers to the current situation through the new horizons of possibilities offered by the strategy and series of activities (Figure 5). The actual results that they aim at producing in this neighbourhood are:

- Locally mobilise all available human resources to transform a crisis of aggregated urban conflicts into an opportunity for urban development: Teach the local community to benefit from the lack of institutional and financial resources for controlling and governing the exploitation of obvious locational, spatial and cultural resources in Savamala
- Globally mobilise all available human resources for a creative experiment of how the global knowledge could alter the context of Savamala and what it will bring to all the participants of this process in return: use modern mass media and ICTs as a constitutional element of urban reality in contemporary cities
- Show the efficiency and effectiveness of participation through knowledge exchange – emphasise the importance of the local community level in urban development
- Small-scale, low-budget revitalisation of public spaces and buildings – promote the transformation capacities of cultural heritage in Savamala through shared creativity of all urban actors mediated by professionals
- Build the new identity of Savamala, a new network of public spaces and a new layer of urban functions that redefine its urban structure and foster bottom-up, step-by-step urban development – a new set of cultural and artistic activities, a new group of urban actors, new pathways, and a new network of small public spaces
- Establish a strategy interpreting knowledge in flux and in context through constructing a database of up-to-date soft data about the social structure in this neighbourhood and its built environment
- Set an urban practice of “action and learning by doing” for all urban actors, stakeholders and professionals through a continuous critical reviewing of the process of urban development by the local community.

5. Model of Urban Development

Bearing in mind all the facts about the context of Savamala building an urban development model on these data implies analysing in which manner contextual resources (separated into urban conflicts, social potentials and spatial capacities) are treated inside the model, and what economic, political, spatial and cultural transformations result from these actions and how brainstorming such a procedure induces building a database on an urban environment (Figure 4). This procedure is based on principles of tactical urbanism, imagined as a cycle of step-by-step change through phases of ideation, building, measuring and learning that feeds back into itself to foster continuous improvement.

From the approximation of these results, it must be remembered that it is just a step in the process of urban development of Savamala, and that just as it brings forth conspicuous positive changes, so it also gives rise to a new and different set of urban conflicts (for example, gentrification). This pragmatic view combined with an experimental learning approach, will lead to envisioning such an urban development model as a helix. This spiral concept symbolises the idea of “bouncing back and forth” in the sense that solutions simultaneously initiate the generation of new urban conflicts that urge for not only different solutions but also new, advanced sort of knowledge and urban intelligence in general (Figure 6).

The model breaks down into three levels (local community, institutional and global), each of which conceptually repeats the core methodological procedure based on principles of tactical urbanism. The horizontal lines that connect the same phases of this procedure, albeit on

different levels, point out how urban development is actually happening, how it could be merged with urban planning and how urban intelligence could be eventually generated through this process (Figure 6).

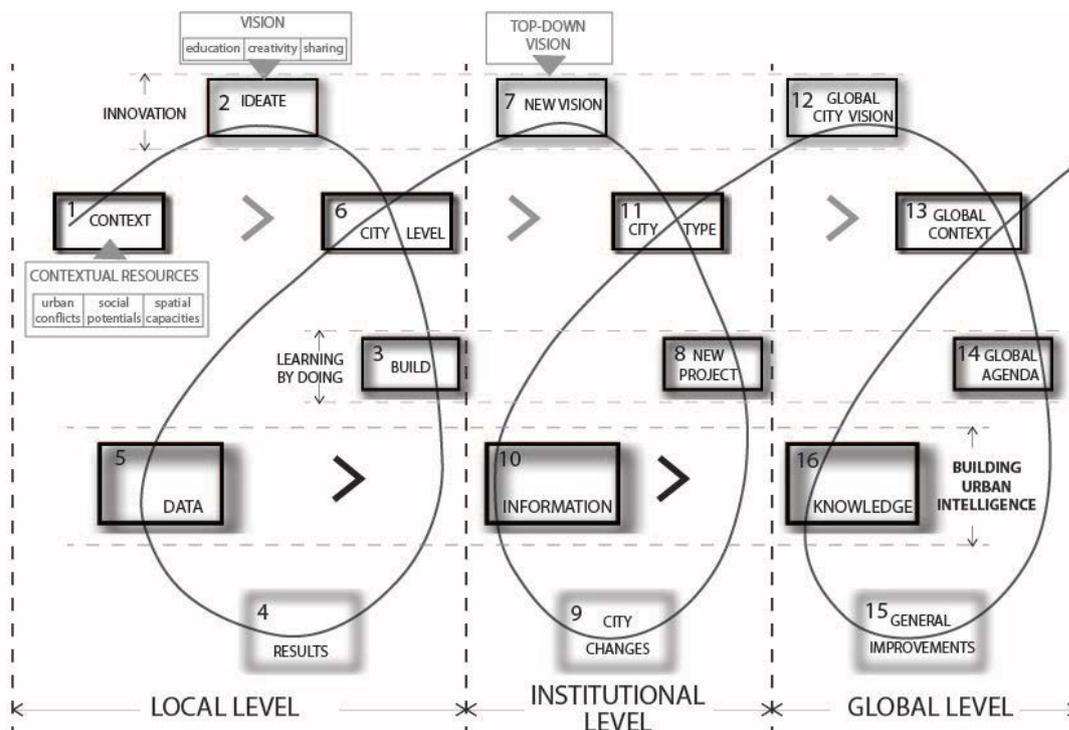

Figure 6: Model of urban development based on bottom-up activities in Savamala

6. Conclusion

The development of related activities in Savamala presents a gradually and spontaneously built intuitive bottom-up urban development model that will correspond to the needs, demands and resources of contemporary urban context in post-socialist city. A forward-thinking overview of the discrepancy between aggregated urban conflicts, on one side, and social potentials and spatial capacities, on the other, has shown that, being liberated from the economic and bureaucratic restraints of a prospering real estate market, Savamala has offered ideal conditions to put such alternative forms and approaches of city quarter development to the test.

The elaborated analysis of these activities set in the context of Savamala explains how times of crises are times of opportunity too. The spaces of obvious urban conflicts could be the polygons for changes, if we take the appropriate approach to instigate urban change. Combined with the exchange of knowledge and creative participation, these spaces could become the places for individuals, self-organised associations, public services and private entrepreneurs to congregate and display their productivity, their facility to be politically active and their ability to learn and act in a societal realm.

It has been conspicuous that although this new network of provisional public spaces and the creative impulse that made Savamala a very lively environment spread almost unstoppably, its urban essence within the image of the whole city of Belgrade stays the same with its run-down buildings, derelict empty plots and open spaces; plus its lack of a sustainable, clear, long-term economic model. Moreover, while the presence of activists in the neighbourhood contributes to the re-vitalisation of urban space and forms “creative capital”, it is at the same time the precondition for gentrification.

However, such new context comes as a result of this first phase of bottom-up urban development and craves for the next round of actions that will more actively involve the authorities, official planning institutions, and powerful economic actors in order to link these

bottom-up changes in the urban systems of the city to the top-down challenges and strategies by emphasising diversity and reciprocity in the nature of the on-going transformations through an overlay of different urban scenarios (according to different urban actors and stakeholders).

To sum up, it is this spiral of relations and influences between different levels and layers of bottom-up urban development and top-down planning through a kind of cross-pollination transfer of concepts and frameworks that initiates the creation of novelty and solutions that are well-adjusted not only to the local context but to global trends as well. An interactive system with an unlimited potential to originate diverse opportunities for new rounds of exchanges generates vibrant and fluid context open to permanent transformation. Therefore, this economy of social exchange is continually contributing to progressive urban development.

The danger of community engagement as an exclusion tool: four case studies in four different scales in Brasilia, Brazil

Gabriela DE SOUZA TENORIO, Universidade de Brasilia, Brasil

1. Introduction

Community engagement in the urban planning process, despite being essential, must always be put into perspective. This is because most citizens have difficulty in thinking in a systemic, comprehensive way while seeking to help their cities carry out planning. In any intervention scale, it is difficult to achieve a kind of public participation that will be inclusive, unless there can be a form of education that can anticipate what will be the implications for the city as a whole, of the local wishes of individuals and groups. Education introduces a collective spirit to the realm of decisions, clarifies the role and nature of the public domain, showing its value to the city and society. Although democratic representation is structured from the relationship of the citizen with a spatial basis, it is necessary to emphasize that places do not belong to its residents, but to the city. The paper illustrates how citizen involvement may show intolerance and segregation desires with four case studies that took place in the capital of Brazil recently and discusses attitudes desirable to obtain a conscious and responsible community engagement.

2. Brasília and community engagement

Brasilia is one of the most sprawling cities in the world, and its population density increases further away from the center. The Central Business District/CBD, where most of the formal jobs are, is situated in the heart of the Pilot Plan, the area where the original design of the city - created by architect Lucio Costa - is materialized, and which has been regarded as World Heritage Site, thirty years later. In 2010, the estimated population was 2,570,160, but less than 10% lives in the Pilot Plan. The rest lives farther away, either in neighborhoods with suburban characteristics, dormitory-neighborhoods or gated communities.

The city's original modernist design brings unfavorable features for its inhabitants' socialization. These have been aggravated by the kind of political decisions made throughout its history, such as those that currently determine its metropolitan structure. With rare exceptions, social classes are separated territorially in 'niches' of homogeneous communities that are not used to share their interests with others. Besides, there are very few public spaces that are suited to bringing them together and allowing them to overcome their differences. Unfortunately, new endeavors coming to CBD, as *Setor Noroeste* (Northwest Sector, discussed in Tenorio & Germano, 2010), perpetuate this exclusionary posture, since they are designed to shelter only a portion of the population, offering only one - expensive - type of housing.

As a result, especially within the heritage area and other upscale adjacent neighborhoods, people use to live, as Freitas, 2010, stated, in a "state of excessive welfare". "The residents of the Pilot Plan and other noble areas have lost the tolerance and flexibility one must have to confront a metropolis like any other in the world".

Not surprisingly, the affected community generally rejects the changes needed to meet the challenges that the city growth imposes, whenever it means to bring into "their" space people

other than those who they are accustomed to live with. As an aggravating factor comes the view of many residents who believe that any action will violate the protection laws regarding Brasília as World Heritage Site, and will make it loses its designation by the United Nations Educational, Scientific and Cultural Organization/UNESCO. Thus, things must remain as they are, even though this means that the city will become increasingly non inclusive.

Four situations in different scales - from local to metropolitan – that occurred recently show how community engagement can reflect exclusion actions. *Figure 1* shows Brasília, understood here as the whole Federal District/FD, and highlights the locations studied.

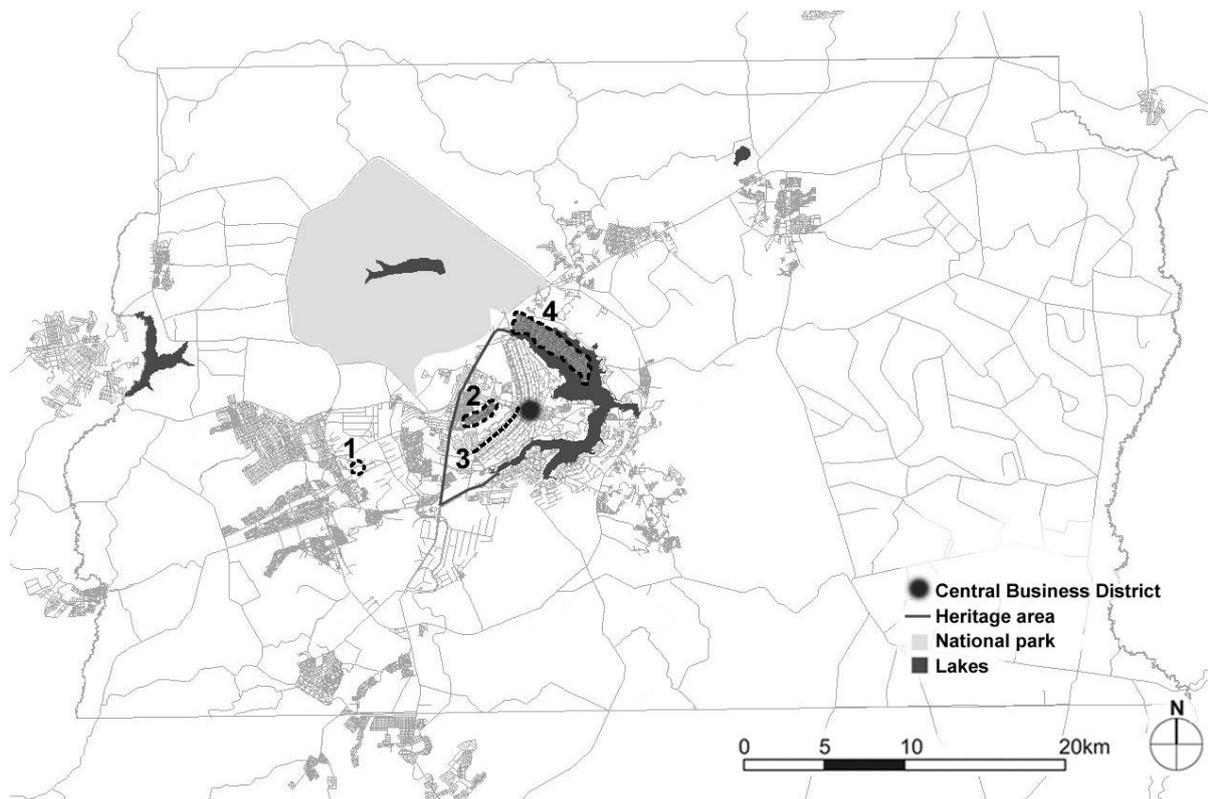

Figure 1: Distrito Federal: axial map. The nuclei outside the polygon belong to another State but depend on Brasília. Numbered, the location of the case studies: 1. Jandaia Square in Aguas Claras; 2. Setor Sudoeste; 3. South W3 Avenue; 4. Lago Norte

3. Four case studies in four different scales

3.1 Jandaia Square, block 205, Aguas Claras - local scale

In 2008, Jandaia Square was built on a plot surrounded by the buildings of block 205 in Aguas Claras, a middle-class district of DF. According to the newspaper *Correio Braziliense*, the residents gathered together and requested authorization from the local administration to carry out a design, and the company responsible for constructing most of the local buildings, built it without any burden on the authorities. Thus, on the initiative and community engagement, a public space was born, with lawns, palm trees, pavements, benches, a fountain and an amphitheatre.

In a dense borough with very poor public realm like Aguas Claras, any attempt to offer a public place has great chances of working at a local level and even being extended across the borders of the immediate neighborhood and attracting residents from other places. This is what in fact happened. The Jandaia Square proved to be a success. This was because it started to be used by a reasonable number of people who were to some extent quite varied (with a good proportion of women and children) and included both people from the nearby

buildings and from other locations, who carried out various activities there. However, among these, there were some activities that caused trouble to the residents and, as a result, they began to think that the establishment of the square had been a mistake.

Less than two years later, the local administration destroyed the fountain and buried the amphitheatre at the request of the residents themselves. (Calcagno, 2009) They made the square less attractive, damaging it, since this was the solution put forward by the majority (Figure 2)

Figure 2: Brasilia, Brasil. Aguas Claras. Jandaia Square as it was originally constructed (on the left) and its current state (on the right). Source: Google Earth.

Although the space has been created on the initiative of the community, it does not belong to it: it belongs to the city. That is why the local administration behavior is so questionable: it was only concerned with the anxieties of the neighboring residents and overlooked the wider context. Besides, when it comes to a place used by human beings (any place, whether public or not), it is no surprise that problematic activities can also occur. This is not to suggest that the maintenance of the square should be discouraged so that it can be kept in the original condition in which it was found, but rather useful information for how to deal with it.

It would be appropriate if the local administration, when was first made aware of the request of the residents, had carried out a full investigation of the place. Public money was used on destroying the fountain and burying the ampitheatre (and this is not any less serious because they had been built with private funds), when it could have been spent (at a much lower cost) in studying the square itself: what activities took place, their frequency, which was involved, exact places and circumstances. On the basis of this information, they could have circumvented the problem by drawing up a list of possible courses of action that could be put into effect while they were monitoring the results. Together with this, they could have sought to make the community fully aware of the benefits of public life and the need for tolerance, while taking the necessary steps to suggest and support events that could strengthen the relationship of the community with that particular space. Ans, of course, if necessary, they could involve the local police.

Clearly it is disturbing that some people who frequent the square intimidate others, as well as the fact that some of the activities witnessed by the residents of block 205 are reprehensible, but is it the case that there are just “offending people” doing “things wrong”? Are there not also “decent people” doing “things right”? Of course there are. And if they were compared, what would be the proportion of those who were “right” or “wrong”? To find this out, it would be necessary to observe, study and get to know the square so that an intervention could be made in a constructive way. Thus, the children would not have to see the destruction of the amphitheatre where they used to play during the morning simply because undesirable activities took place there on Friday and Saturday nights. Admittedly, it would be hard work but it would be worthwhile: a public space is an invaluable asset.

It may be that the residents' expectations have been that the square would fill only their requirements, and that would be intended only to support the uses they have imagined. After all, the square is the outcome of their own design and initiative, and spaces created based on this dynamic tend to reflect the community with which they are situated. So, it is natural that the residents look after them as if they were theirs, and is common the belief that, if any misuse was made of the place, it was probably caused by someone from outside. Thus, when the square began to "cause problems" (or rather, it was so successful that it led to being a mistake), it was no accident that these were attributed to "undesirable visitors", even though there was no evidence to show that it was not local residents who were responsible for the loud music, heavy drinking, drug-taking or acts of obscenity.

3.2 The Public School, Setor Sudoeste - neighborhood scale

The Setor Sudoeste (Southwest Sector) is a borough near to the Pilot Plan that was created in the late 80's. Despite having mixed-use buildings and a major shopping street, the neighborhood is mainly divided into "noble" Sudoeste, where more than 90% of the residents belong to the upper-middle and upper classes, and "economic" Sudoeste, where this number falls to a little less than 80%. As can be observed, people in the borough show little variation of income levels, which makes it a homogenous community.

A few years ago, two episodes demonstrated the frame of mind of some residents of the "noble" part of the neighborhood. In the first, they adopted a stance against the construction of sports courts "to avoid the gathering of yokels" (Alves, 2009). The label of yokel ('*peao*' in Portuguese) has pejorative connotations since it is used to describe farm labourers, people in general who have little education. The fact that it was attached to the potential users of public sports grounds makes it clear that this would not be applicable to the and, thus, would not be an activity they would wish to carry out. This situation resembles, on a similar scale, what was discussed previously.

In the second episode, the residents lined up against the construction of a public school, even though it had been embodied in the original project of the *superquadras* (superblocks) of Brasilia: a spatial pattern followed by the "noble" Sudoeste. According to the Report on the Pilot Plan (document with the city's design principles) "within these *superquadras*, the residential buildings can be arranged in the most varied way and in compliance with two general principles: a maximum uniform building high, perhaps six floors and *pilotis*, and separation of road and pedestrian traffic, especially by allowing access to primary schools and the facilities that exist within each block" (Costa, 1991). Lucio Costa had a utopian ideal of equity, citizen dignity and efficiency of public services, in his proposal for Brasilia.

The members of the Regional Administration were in a state of perplexity when a group of people claim that the public school was not necessary because all their children studied in private schools and this would only be "for the children of domestic servants" (Alves, 2009). It should be made clear that Brazilian society is profoundly unequal, and there is a huge number of people with little education and few qualifications. Thus, domestic servants are readily available to the middle class. This means that a building with 48 apartments is very likely able to offer work to 48 domestic employees either on a monthly or daily basis.

Apart from the depressing fact that the residents' request confirms the prevailing skepticism about the value of public education in Brazil, this attitude reflects a view that, at the very least, is mean-spirited about our society. They ignore the fact that these workers would be able to leave their children close to their place of work (which is at a distance of at least 20km from their houses). And what would be the problem if the children of these domestic servants – or rather children in general who are at a different socio-economic and cultural level than the residents' children – attended a school close to the residential area? A bad

influence? Degeneration? The prejudiced and non inclusive view lingers on. Even today, Setor Sudoeste does not have a public school.

3.3 Change of use in W3 South Avenue - city scale

W3 Avenue is one of the city's main public transport routes and runs along the entire Pilot Plan. According to the original conception of the city, it was intended to be a bordering service highway, which would allow the supply of wholesale goods. This would be located on the east side, while on the west side there would be gardens and orchards.

The original plan was never implemented. Even before the inauguration of the city, where there would be gardens and orchards, single-family row houses were built to serve the first skilled workers who came to the city with their families (Figure 3).

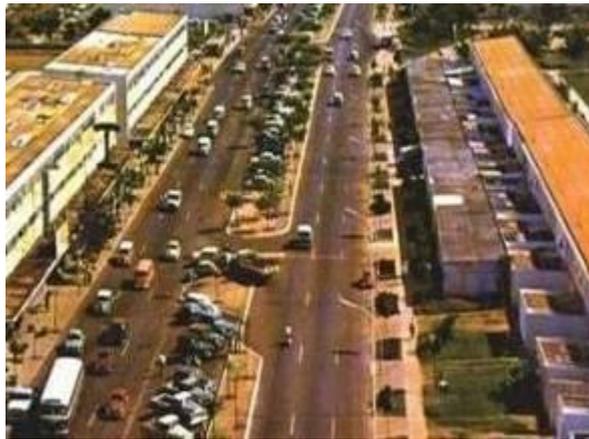

Figure 3: W3 South Avenue in 1969. Businesses, services and dwellings on the East side ("500" blocks on the left) and residences on the West side ("700" blocks, on the right). Source: Arquivo Público do Distrito Federal.

As a result of the delay in establishing the central sectors of the city, which were intended to offer commercial and entertainment sectors, the southern stretch of the W3 began to become the real cultural and commercial heart of the city until the 1970s. According to Holanda et al, 2003, this was the 'golden era', and from then onwards, the avenue entered a period of decadence and deterioration. Among the various reasons for this decline, such as the consolidation of activities in the city center, is the avenue profile. The fact that it only has commerce and services on one side, and residential dwellings on the other, makes it ineffective in becoming a real "pole of attraction", as it had before. However, since some years ago a trend can be observed in which the residential dwellings adjoining - or close to - the avenue began to offer a wide range of services such as beauty parlours, lawyer's offices, esoteric consultancies and guest houses. These were a symptom of the need to take advantage of the infrastructure facilities and attractive sites in Brasília.

The residents complain about these changes, especially the guest houses, which, for them, are apparently places that host the worst of the human species: "They take in criminals, drug dealers and prostitutes", one resident declared (MADER, 2011). According to Holanda, 2012, it is necessary "to distinguish between *urban codes* and *posture codes*. The first regulates building shape and land use, the latter regulates behaviour - desirable practices of urbanity that allows good coexistence. If there are noise, prostitution, drug traffic etc., anywhere in the city, in the adjoining houses of W3 avenue or in the internal houses of the "700" blocks, it is up to the government to repress them. They are not urban problems, but police ones."

Putting aside what statements like the resident's (and they are not unusual) reveal about prejudice, misinformation and generalization, some thought should be given to the real nature of the citizens who actually come to visit the city. It should be taken into account that

the "official" places for accommodation in the Pilot Plan are the expensive ones that exist in the south and north hotel sectors. Although they are not far away from public transport stops, they are not well connected to them. Nonetheless, it must be admitted that accommodation on the W3 can be very convenient and practical for tourists who are less well-off and not in a position to pay for taxis or rent cars.

At the end of 2009, the Federal District Government/FDG issued an official order for drawing up PPCUB (Plan for the Preservation of the Urban System of Brasilia), the purpose of which was to create a master plan for the heritage area aiming to recommend ways for development and for solving problems without spoiling the essential character of the city as originally conceived. After carrying out some studies, the appointed team came up with the suggestion that there should be a change in the land use of the houses in the west limit of W3 avenue, but there was a negative reaction. "We are not going to put up with traders here" stated the community mayor of block 705.

It is clear the residents' partial and exclusionary attitude. As puts Holanda, 2012: "The existence of services in residential area buildings is not necessarily a problem, in Brasilia or in any other city. Moreover, the current discussion is fraught with 'make believe'. For example, make believe there are no offices operating in homes within blocks '700'. Nobody argues against that - and nobody should. They do not bother anyone. But the residents argue against the *popular* services ranging close to the avenue, exactly for this reason: because they are *popular* and do not correspond to the highest income levels prevailing inside the '700' residential blocks".

At the end, PPCUB has retreated and left the '700' land use the way it has always been - single family houses. A lost opportunity. A change like this would be the first step in legalize irregular activities and revitalize the avenue, by making use of its full potential for business and services. The whole city would benefit.

3.4 Lago Norte's second bridge - metropolitan scale

Lago Norte (North Lake) is a borough with suburban features that is situated on a peninsula. Its main residential model consists of single family houses on plots of 1,200 sq. m (the value of a sq m of land is currently around USD 690) which makes its residents the holders of the second highest average monthly domestic income of Brasilia. There is an extremely low supply of trading activities, services or employment, thus the borough depends on the Pilot Plan. Its population is highly motorized and reliant on private cars, and it is common to find a proportion of one car per resident able to drive.

In this area, the only connection to the city center – Bragueto bridge – is becoming increasingly inadequate since it experiences serious congestion at peak hours, day by day. Some redesigning of its access has been carried out, but there has always been an idea of building a second bridge. The supporters of this scheme argue for better links with the city, so that alternative routes can be established to improve traffic in different ways and reduce the time people spend moving around. However, the residents have never welcomed the idea.

For several years the subject lay dormant and seemed to be insoluble, until it was officially again brought up in 2008 by the FDG. It introduced the Estrada Parque Universidade de Brasilia (EPUB) scheme - which consisted of two bridges and a highway. As well as providing more alternatives for the population Lago Norte itself, it would be a choice for the residents of districts located further away, such as Sobradinho, Planaltina, Varjao and Paranoa. In addition, the residents of the gated communities in the north section of the city could go to Asa Norte without necessarily having to cross the existing bridge (Figure 4).

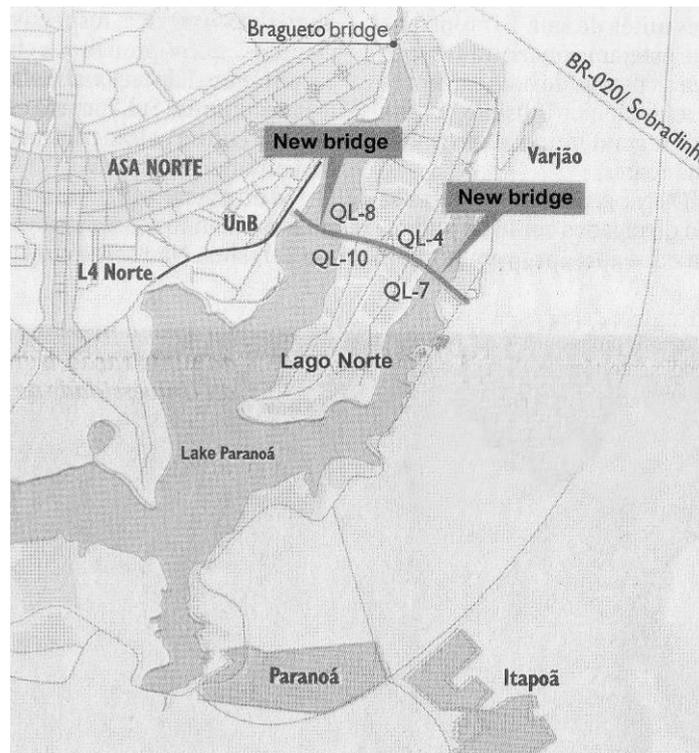

Figure 4: Brasília, Brasil. New bridges for Lago Norte. Fonte: Rodrigues, 2008.

There was less resistance: when the residents were faced with the problems of congestion at their only outlet, they were more willing to accept the idea of being connected to Asa Norte. However, they are reluctant to agree to the connection with Paranoá. One common charge is that this will spoil the character of the place by turning it into a place of through traffic.

The administrator of the borough at that time stated that he was against adding the section of the bridge that would forge a link with Paranoá. "The exit is really necessary for the [Pilot] Plan. However, there is still no need to carry it out on the other side" (Rodrigues, 2008). So... the connection to the Pilot Plan is necessary for the population of Lago Norte, which in 2010 consisted of 41,627 people, but is it not needed for those 453,047 inhabitants (a population more than 10 times higher) living in the north portion of the Federal District?

No fundo, não há como negar que há, sim, outra razão para a recusa. A opinião de um morador a deixa transparecer: "Moro no lago norte há 26 anos e gostaria de ver esta ponte feita, pois só temos uma saída. Mas fazer a perna que liga ao Paranoá não tem razão de ser, pois já tem a saída para o Varjão. Mas não é por segurança, porque se o cara quiser vir até o Lago Norte, vem até remando" (Rodrigues, 2008). Claro está que esse "cara" a que se refere o morador é um ladrão. A população do Lago Norte, isolada em sua península, funciona como um grande condomínio fechado, um grande grupo homogêneo, que tem tão mais receio de outros grupos quanto mais diferentes de si eles forem. Então ladrões só podem vir das bandas do Paranoá? Não há ladrões na Asa Norte ou no próprio Lago Norte? O posicionamento preconceituoso e excludente vem adiando uma solução que proporcionaria um melhor ir e vir para uma parte grande da metrópole.

It cannot be denied that there is, indeed, another reason for the rejection. The opinion of one resident makes this clear: "I have been living at Lago Norte for 26 years and I would like to see this bridge built because we only have one outlet. But to add the 'leg' that links to Paranoá does not make sense because we already have an outlet to Varjão. But it's not for safety reasons because if a guy wants to come to Lago Norte, he can come here by rowing a boat" (Rodrigues, 2008). It is clear that this "guy" is a thief. The people of Lago Norte are isolated on their peninsula and operate like a large gated community, a big homogeneous

group which is very afraid of other groups that are different from themselves. So thieves can only come from Paranoa? Are there no thieves in Asa Norte or Lago Norte? The prejudice is given precedence over a solution that can allow a better means of going to and from a large part of the metropolis.

4. Conclusion

Brazilian law states that urban policy should aim at the full development of the social functions of the city through the democratic management, which popular participation is an integral part (Brazil, 2001). Gomes, 2012, remembering the birth of democracy, states that the reforms of Cleisthenes, in Ancient Greece, essentially replaced "political representation based on tribes, by a space-based representation, established by a territorial division". The democratic governance is so grounded in the concept that the citizen is bound to a spatial component and, therefore, in their engagement, has responsibilities to the territory it occupies and represents, as well as has needs and desires related to it.

Planners need the vision and experience of this community member. According to the Project for Public Spaces/PPS, an American organization that deals with public spaces on the basis of public participation, this community member "is anybody who plays a role in the participation of a specific place": resident, owner of business, worker, member of institutions, official representative, member of some group etc. In short, anyone that has ties to the area is useful and indispensable to the planning process, in any of its levels, regardless of their involvement.

The relation between citizen and place or, in a broader way, between society and space, is explained, for instance, by the Space Syntax Theory. According to its authors, Bill Hillier and Julienne Hanson: "We read space and anticipate a lifestyle". The theory states that there is a social logic of space, as well as there is a spatial logic of societies. Its main axiom is: "spatial organisation is a function of the form of social solidarity" (Hillier & Hanson, 2003), social solidarity being the way people meet in public spaces: in a random way, in diverse groups; or in a programmed way, in homogeneous groups. The authors explain that most societies show, in all levels, both types of solidarity.

Configurational attributes of places (also called spatial patterns by the theory) are in harmony with social expectations that are based on people's cultural standards, of which Holanda, 2002 draws "two millennial socio spatial paradigms": the paradigm of formality and the paradigm of urbanity. The first one is aligned to the social structure that Durkheim called "mechanical solidarity" (terms found in the book *The division of labour in society*, 1893), for which the city is organized through hierarchy, dispersion, specialization and segregation; its parts having well-defined and controlled borders. The latter is aligned to the Durkheim's "organic solidarity" that historically emerged with the social division of labour and complementarity of activities and roles. Implies low hierarchy among its parts, which must be complementary, interdependent and integrated.

Holanda, by studying ancient cultures and their social structures, states that, historically, more democratic societies have their cities designed according to the paradigm of urbanity (2002, p. 130). The reverse is also true: less democratic societies, which feature large social inequalities, have cities designed according to the paradigm of formality.

This finding makes it desirable to search for the establishment, in addressing urban problems, of solutions that undergo spatial patterns more conducive to the shelter of a democratic society. They would be those that minimize distances, smooth borders, integrate parts, extend possibilities of use, favor diversity etc. This requires an ever-expanding vision that often exceeds the limits of the neighborhood and considers the urban system as a

whole. However, people will not always be prepared to - or interested in - take into account the broader impacts of their local choices. And the more homogeneous the community involved, the more it tends to resist changing.

Here is where education plays a main role in community engagement process. Interviews, discussion groups and meetings are the most widely used activities to allow people closely involved in the situation in question, to express their feelings and become involved in the process of creation, by stating their needs and desires. But these occasions for gathering input for the preparation of normative instruments relative to the city or endorsing proposals, cannot take place without a dynamic that allows information to be transmitted. Nor is it possible only to have the residents or homogeneous groups as representatives. The residents surrounding the Jandaia Square were listened to, but what about those who came from other places to make use of it? The residents of Setor Sudoeste were listened to, but was this the case with the domestic employees? The residents of the "700" blocks were listened to, but was any attention paid to those that use the area, though living in other districts or the users – "respectable" and law-abiding people – of the guest houses? The residents of Lago Norte were listened to, but how far does this apply to those who live further away from the Brageto bridge?

The case studies show how attitudes of homogeneous groups in the process of community engagement can be extremely exclusive. The voice of the people is not necessarily the voice of God, in contrast to what is stated in this proverb. The support and involvement of citizens in urban issues should act in a way that improves the city and makes it more inclusive and fair. Planners and urban designers must be aware to this.

WILMA VAN DER BRUGGEN

From top down to bottom up – a somersault?

HelenaChaja Heyning, Wilma van der Bruggen, The Netherlands¹

*Faced with the aftermath of the financial and economic crisis in The Netherlands and the financial repercussions of the ongoing decentralisation process, many municipal authorities have great difficulties to cope with the demands, needs and expectations of citizens. Land development (houses, offices) a major source of municipal income, has come to an almost complete standstill and so do the much needed revenues: the 'old' money has gone and no new profits are in view. 'Future today is not what is has been in the past.'*²

What came to flourish is civic action in all shapes and sizes, from community to single stakeholder's engagement, from energy corporation and care trust to a build-your-own-home movement. The Dutch Big Society and Civic Economy are in the centre of 'let's do it ourselves'. A paradigm shift or a temporary revival of old bygone good neighbourliness and citizenship never really forgotten?

How do authorities, used to top down governance, handle the message of the bottom up movement: con amore or grumbling, is it a tiny step or a somersault, how does it affect their position of power, do they trust citizens?

And how about the city planner? Is he/she dancing and pitching along with the waves of power, is he/she fully engaging the stakeholders in our communities, what tools does he/she need to assist citizens in their self organisation processes? What techniques and strategies exist to address competing interests and reduce conflict? Key question: is a turnaround in planner's education and/or specific training needed?

1. The Times They Are a-Changing³

Until recently spatial development in The Netherlands was for the major part the prerogative of the government (state, provinces) or the local authorities (municipalities), in their slipstream the well-known housing corporations and the almighty private property and real estate companies/contractors. Buying farmland and selling plots for houses, offices etc. was an important component of the municipalities budget revenues, needed for expensive urban renewal elsewhere, parking garages, village library etc. The crisis put these revenues at serious risk: the 'fleshpots of Egypt' are empty and many municipalities groan under heavy financial losses of land bought but not developed as the house and office market collapsed. The 'old' money has gone, the 'new' generation of value is not yet clear. We are in the middle of the downward Kondratiev wave.⁴

Fig. 1: Property and Real Estate companies want to get out but are told 'the next bus stop takes another 7 or 8 years...' (FD)

2. Dutch Big Society and Civic Economy

In the wake of the financial crisis and ailing economy a mixture of the UK's 'Big Society'⁵ and 'Civic Economy'⁶ began to flourish in The Netherlands. The Government's Policy Scientist Council (WRR) occupied centre stage with the report 'Trust in Civilians' asking for more trust between democratic institutions and citizens 'because they need one another to accomplish shared goals'.⁷ Central government started to push the idea of the *sustainable society* taking care of itself 'as 'the state can't take care of everybody and everything anymore'.⁸ It is said that 'citizens are expected to display more self-sufficiency and responsibility and less reliance on subsidies and state-paid care'.

In the past years the Civic Economy became a steady under-current of societal initiatives and business cases based on the mostly local economy. Some city Platforms of Creativity & Innovation were set up and attracted a wide range of 'change-makers' finding ways to a new economy and a new bottom up city planning. Something similar can be said of the Eo Wijers Foundation⁹ promoting residents initiatives and new modes of profit in their 9th and upcoming 10th planning competition.

The old warehouse 'The Taciturn' ('De Zwijger', the nickname of prince William of Orange [1533-1584], the progenitor of the Dutch royal family) is the hotspot of community and stakeholder engagement in Amsterdam: the Platform of Creativity and Innovation's credo is 'what inspires you and how do you get there'. Inspiration cross-pollinates: the Platform is multifaceted and embraces all kinds of professionals. Some deal with city planning or photography, some with design or gaming, some are analogue some go digital, some are entrepreneurial housewives and others Gyro Geerlose.¹⁰ Well known scientists and politicians are regular visitors and/or keynote speakers. The Platform is a forum and also a beehive for professionals from entirely different backgrounds and many, many eager youngsters who meet and discuss, perform pitches, consult, explain, inspire each other, explore the 'in between spaces' and rising the occasion to team up. An increasing number and great diversity of these change-makers are getting on with the job of re-making the local economy and places.

Facts & figures Pakhuis: Visitors: ca 35.000/year; Meetings: ca 250-300/year

3. Paradigm shift or major transition?

'There is nothing new under the Dutch sun' one could say as practical neighbourly help has always existed in some way; farmers had their own cooperative bank and the country's present 5,5 million volunteers are a big asset (2011, 44% of the Dutch population). However the present bottom up movement looks like leading more than before, rumour has it that it asks for more power for people to take decisions.¹¹ Scientists and Advisory Councils talk about a paradigm shift and a major transition. The fundamental drivers of this shift might be 1) a growing recognition that we need a different economic development model and 2) a fundamental transformation in how people and organisations can communicate and collaborate.¹² The great thing is that it shows the type of 'entrepreneurship' that generates civic action and what it can achieve measured by profit and social progress. Prudence is called especially in situations where initiatives are new born and fragile –it is one thing to be willing but quite another to be able. This is even more critical as many authorities clearly extol and overestimate the virtue of their residents and their potentials to address the upcoming social and cultural issues (e.g. taking over the care of the elderly or handicapped).

There are many civic actions and ventures in The Netherlands: from the single resident's 'build your own house' to co-productions and social enterprises like the community energy corporation (wind

farm, bio-burner), urban agriculture on empty building plots, babies-and-mothers-meeting places, 'care' trusts and neighbourhood-banks and the innovating 'daring designs' or social designs (e.g. container) or the gaming industry (look for the game-tool-for-pigs). Some initiatives go regional like the farmers nature associations¹³ treasuring their property and identity and alongside preserving the local landscape and nature. The notion of the 'circular city' and 'circular economy' pops up and outlines the bigger picture.

Some initiatives are shared (public-private), others are 100% private using modern co-investment and co-information techniques: crowd funding, crowd sourcing, open source, serious gaming, etc.

4. Shift of power: a somersault?

Quite a few Dutch authorities are confused and daunted. They don't know how to handle the situation: stay in the familiar top down position or join the bottom up movement? Can we trust the citizens? How about their abilities? How to stay in control and powerful enough to pull a lot of strings? These policymakers often 'oppose', resist, grumble and cling to their 'pocket veto' driven by self-interest –plenty of idea-killers. They are in the middle of a 'perfect storm'. However some authorities count themselves fortunate to share the power and energy with their residents. E.g. the experiment in the Amsterdam East borough (112.000 residents)¹⁴ where the yearly budget in a preliminary draft including the imperative policy, projects and actions, is made transparent, and in a collaborative approach shared with the local residents and entrepreneurs. Next, borough council and residents agree upon what residents/ entrepreneurs pick up and what authorities accomplish. The process is two-way: facilitating (↓) and boosting (↑). Another example is Almere New Town where thousands of families (even low income) can buy a plot of land and build their own house to their own taste¹⁵ –an example of large-scale micro-entrepreneurship unprecedented in The Netherlands (fig. 2).

Fig. 2: Almere New Town – Almere Poort: small scale entrepreneurship

5. From state domination to joint business case: win – win

The present financial situation in Holland is an impetus for a new planning approach.¹⁶ Municipalities might be poor however some private parties, e.g. local entrepreneurs or a (group of) resident(s), are often quite willing to invest in their property if it augments the value or is otherwise rewarding. Local authorities must put this kind of citizens' action/private initiative into the perspective of e.g. urban renewal (regeneration) and place-shaping.

Changing a private run down industrial site in the middle of a town into a green residential area upgrades the surrounding neighbourhood socially, physically and financially (raising value of nearby estates). Previously, the municipality would have bought the premises and redeveloped them, but money lacking the initiative of a private owner should be cheered. The return on capital and investment is for the private owner(s), in due time the municipality will receive the benefits of local tax levying (property tax etc.). In a period of a weak economy this is a window of opportunity with a mutually beneficial outcome and added value. The private investment might even create much spin off and undo an unprecedented multiplier effect.¹⁷

We have seen that the local investors want to control the process, after all it's their property, their money and effort (and risk!). Much asked questions are: is it financially rewarding, how long does it take to get a building permit, how to keep out endless bureaucracy, can I do it on an individual basis or is collective action needed (with neighbouring landowners), will local authorities help, how about other landowners and local action groups? Policy makers in turn should trust the private investors and provide them with scope for involvement: authorities' greater vision and message (framing) should be one of a steadfast ally and facilitator as well as a partner of local society -thus sharing the traditional one-sided power. 'To recognize when they are needed and to stay away when they are not' is a precondition for success.

6. Must the city planner reinvent him-/herself?

'The Times They Are a-Changing': how about the city planner? Many will work on both sides including the interface of institutions¹⁸: the traditional 'indoor-world' of the well known 'old client' e.g. the authorities/property & real estate companies, and the new 'outdoor-world' e.g. the civic stakeholders who take the initiative. What skills, tools and expertise does the planner need to work on that interface and/or to assist citizens in their bottom up actions and self organisation?

In 'old' times (upward Kondratieff wave) planning the city was the exclusive property of the authorities, proficient in policy, procedures, etc.; there was some obligatory 'citizens participation' (most lowest steps Arnstein ladder¹⁹). Most developments, e.g. new housing and industrial estates, proceeded on a pragmatic project-based approach: one client, phases clearly cut/described and an ever narrowing fish-trapped/fyke approach > it's the result that counts within a short well defined period minimising the risks (fig. 3+4).

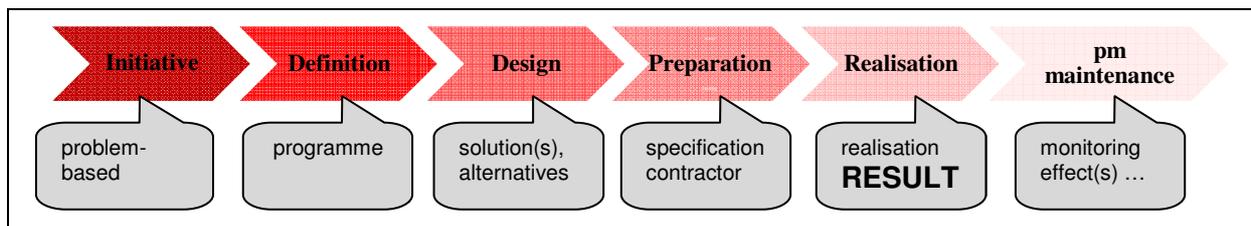

Fig. 3: Phases project-based development

Fig. 4 The pyramid builder (Kor, R. Werken aan projecten, R. Kor)

Given the nature of this case study only a fraction of the several dozens ready-to-use process-oriented instruments can be described briefly. Of course this doesn't do justice to their scientific background, their consistency and comprehensiveness –an apology is appropriate. Do note: some instruments are simple to handle, some tools need the assistance of experts to implement them properly.

8. Ready-to-use process-oriented tools

We start with (1) the Mutual Gains Approach (MGA) being the philosophical basis how to deal with the stakeholders and the cooperation/partnership between the stakeholders in a change process. We will move forward from there to the other tools: (2) Story-telling as a valuable component in really understanding each other, (3) Communication Skills as a prerequisite to make headway with the process, complemented with (4) the Colours of Change to get insight into the different ways of thinking (and acting) in processes of change, (5) Mediation Skills for those – inevitably- moments the process is brought to a boil, and (6) Belbin to check the balance in the team: is it adequately balanced to tackle the problems. Digital techniques (7) might be very convenient to accelerate the process of generating and prioritizing ideas and to create a certain amount of anonymity helpful in (the beginning of) the process so everybody involved gets his/her fair share in the brainstorm.

8.1. Mutual Gains Approach (MGA)²²

The aim of the Mutual Gains Approach is to look to maximise opportunities through consensus building between all the participants in a process. How? By focusing above all on the interests (needs) instead of the positions and by separating the people (stakeholders) from the problem (what's at stake). And in addition to invent options for mutual gain as it can make all the difference between deadlock, i.e. failure, or convergence of views, i.e. success.²³ Furthermore MGA takes care of an early dialogue in the process in order to detect right from the beginning the 'pain' in the proposals for a changing environment and to assure that all parties take their share and responsibility throughout the process (fig. 6).

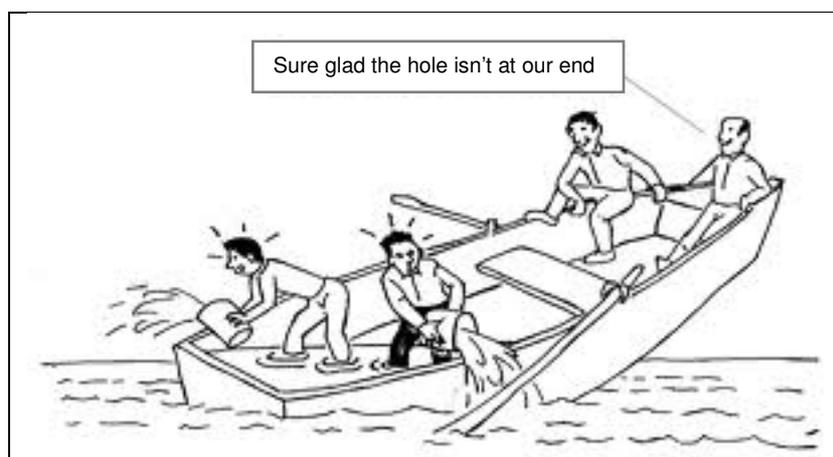

Fig. 6: You're More Connected Than You Think²⁴

The approach should not be mistaken for the Dutch 'polderen' or mediation.

MGA is running (operational) in many Dutch mega-projects difficult to handle due to complex techniques and/or bureaucratic government. It can accordingly be applied in complex situations with many and various stakeholders.

MGA's four steps are:

1. Analysing issues and stakeholders (instrument: matrix);
2. Bringing order in issues and stakeholders: which issues are outstanding, which need

- more attention (instrument e.g. participation ladder);
- 3. Dialogue with the parties involved: problems and possible solutions ('negotiations');
- 4. Monitoring the agreements, evaluation and communication in order to create sustainable relations (monitor).

Together they form the well known 'Plan-Do-Check-Act' circle (fig. 7). Its cyclical character guarantees continuous improvement.

Fig. 7

The method developed by advisors of Twynstra Gudde is very successful to structure a bulk of information and to keep it up-to-date. The instruments are helpful to assure the much needed transparency and reliability (key elements of MGA) towards the stakeholders and the decision-makers involved in the change process. However never underestimate how much effort is needed to arrange for the necessary preparations in order to enter a valid dialogue, nor how many effort is needed to keep the information relevant/up-to-date during the MGA process. It highly depends on the skills, ability and personality of the advisor (or urban planner) how effective the MGA process is.

8.2. Story-telling (cultural anthropology, social psychology)

Stories or narratives are being shared in every culture as a means of cultural preservation (history), to instil moral values (Bible, Qur'an, Torá), education and entertainment. Homer is a famous storyteller, so are the Aboriginals who navigate through the outback by their Tom-Tom-like 'song lines' and the Kung San, the Kalahari Bushmen (fig.8).

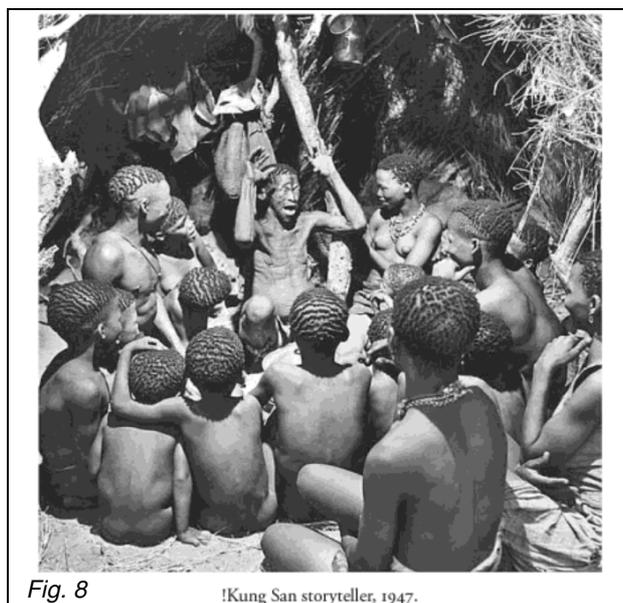

Fig. 8 !Kung San storyteller, 1947.

Modern-day storytelling can be applied as a stimulating intervention, as a means for sharing and interpreting experiences and possibilities of change and development. The local authorities might want to share their 'corporate' vision on the wanted development in a narrative way with the local residents using a metaphor - bold and imaginative like 'garden city' - or a vision (greater scope story). Local realities e.g. the stories and experiences of the residents and users, can be very informative as well as surprising and delightful –creating places that tell stories.

The planner assisting a group of residents would be well advised to invite them to discuss the *genius loci* of the place: its history, its identity, why they are proud of or devoted to the place ('meaning-making'), the people that were important, the impact of future development and what kind of development fits best. Knowledge and pride are a perfect basis for the development strategy. It is imagination creating a reality, using the narrative to interpret the past, shape the future and solve maybe existing or future problems.

Storytelling can also be a means to explicit ones personal or business-like dreams and longings –'I want a big family so I need a five bedroom house' or 'I want to give my hotel business a boost so I need room for extension'. It is then used as a bridge for knowledge and understanding of future projects and programmes.

Storytelling can also help in mediating conflicts and values (*viz. 8.3. Communication and 8.5. Mediation*).

8.3. Communication (*group behaviour, coalition planning*)

Civilians-civilians and civilians-authorities often have different views or speak a different language. That might create misunderstandings and irritation, even clashes -emotions can run very high. The tensions between both parties often arise from too little or no communication at all and a different view of roles, contribution and influence and of what is important for whom, what has to have priority etc. E.g. authorities often think and act in 'policies' (meta level), residents in terms of 'when do I get my permit so I can start to build my house' (micro level). The tensions might endanger the partnership or coalition and bring the position of the city planner in jeopardy.

In bottom up processes a good communication strategy is of utmost importance: who communicates when with whom and about what (do note the aspect of 'deliverance' [Belbin] and 'Rose of Leary'²⁵). Next: is the communication about decisions or about creating a wider support, the timing to implement measures, etc.

The experience shows that the irritation mostly regards (confusion over) the position of the parties involved: 'who is in power', the planning: 'too tight/loose time schedule', the communication (see above), the policy: 'too much policy/procedures, too little implementing/realisation', the finances: 'who pays what, how to share the profit', the organisation on both sides: 'separate, partly merged, point of contact etc.', and the decision making: 'who, when, what'.

In a partnership/coalition good communication is essential for:

- *mutual trust/confidence;*
- *partnership/respect/responsibility and prudence;*
- *win – win (mutual gain);*
- *preventing to be played off against one another.*

Don't forget the communication with the residents not directly involved in the change process. Do inform them on a regular base, create a wider support in order to avoid pressure from unexpected (and unwanted) 'action groups'.

8.4. Colours of change (*change management, action-learning-theories, characters of organisational life, X/Y- theory/ management and motivation, theory of human motivation etc.*)²⁶

Urban (re)development can be looked upon as a ‘change process’. People’s notion of change and how to get there varies. The way people express themselves talking about change and the words they use ‘betray’ their way of thinking and their preferences of the change process. Abstracting: some people believe change can be guided/induced best by general consensus and coalitions, others advocate to plan it in a SMART²⁷ way, some say that incentives and rewards are essential to bring about a process of change, others think change can best be dealt with in a (joint) learning action, others still say ‘let’s go with the flow’. Depending on the various notions five patterns (stereotypes) can be distinguished. Each stereotype is given a colour: yellow, blue, red green or white (fig. 9). Note that nobody is a 100% ‘red’ or ‘blue’ person, nevertheless everybody has a (dominating) mainstream colour –although it might change during one’s lifetime. Every colour has its strength, e.g. talents ... and its weaknesses (pitfalls).

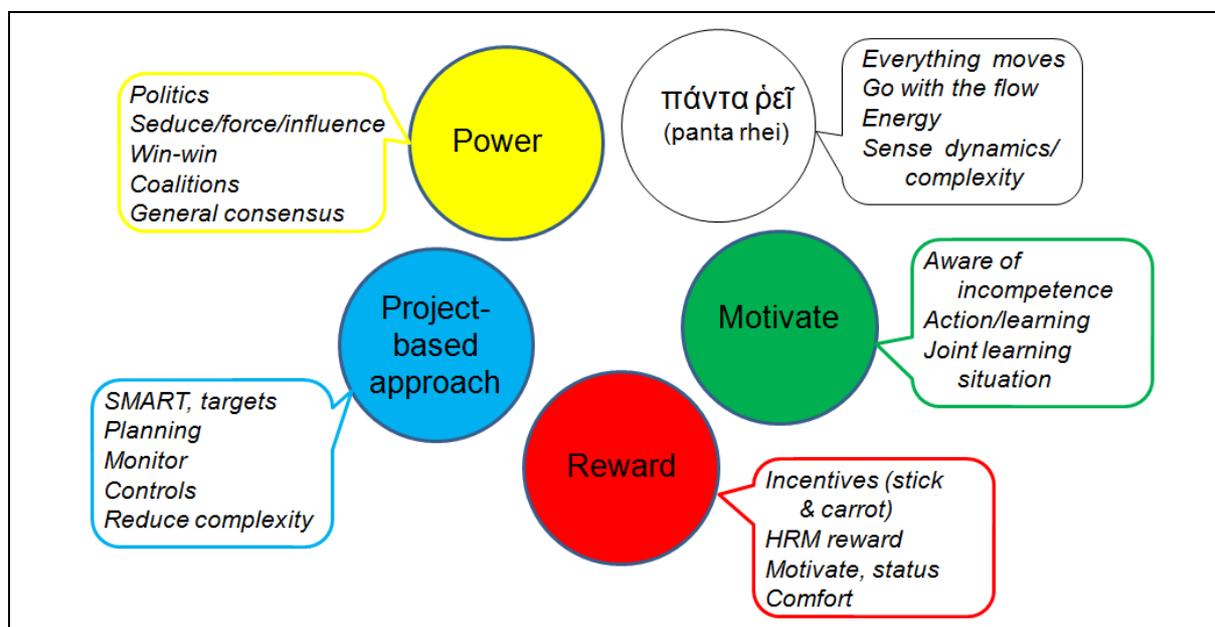

Fig. 9: Colours of change

An example: depending a person’s colour he/she describes the wanted ‘result’ of a change process at best as: a complicated game of power politics –this is obviously a yellow person; a blue person will say that the ‘result’ is clear and can be predicted, a red person can definitely outline the ‘result’ but can’t guarantee it, the green person will sketch it but neither can guarantee the outcome, and the white person won’t predict the result (it’s irrelevant) as ‘the present is important for the next step’.

There are some small tests available to give a person a first insight in his/her ‘colour’, i.e. how he/she thinks and acts in a change process. As in the Belbin test knowing your partner in a joint process might be convenient and speed the process.

The colour theory provides a tool to identify individuals, how they think, act and react in a group during the ongoing process of urban change ([re]development). His or her ‘colour’ also gives a cue how to respond/advise the person concerned. During negotiations every ‘colour’ needs its specific approach.

8.5. Mediation (*group behaviour, coalition planning*)

Talking about irritations (viz. 8.3. Communication): if tensions arise and the process risks to be brought to a boil the planner must asap consider two mediation-like steps:

1. Take stock of:
 - What is the irritation, why and where does it come from;
 - What is really behind the reproach and irritation ('the question behind the question')
 - What is going well and why.

This must be done by personal interviews.

2. Draw upon a mediation-trajectory:
 - Depersonalise/translate reproaches/irritations in notions of 'policy', 'organisation' etc.;
 - inform parties in a combined meeting about their reciprocal understandings and misunderstandings;
 - ask parties to discuss an agenda of 'how to continue the development' and 'how to share the tasks' the next 3 or 6 months.

Depending the situation the city planner can be the mediator, provided all parties trust him/her as a neutral person; sometimes (heavy case) it is better to appoint an independent mediator. If needed the mediation can be repeated several times; in a *light mediation* version it can be part of an iterated 'tuning of the reciprocal expectations for the next period'.

8.6. *Belbin (group behaviour/social psychology)*²⁸

Helping a group of citizens to help themselves get's easier when the participants know each other so they can rely on the other person's contribution and also better understand the 'deliverance' of that contribution. The Belbin Team Role Model is designed to use the talents and personalities of team members to their full potential (fig. 10) and to judge whether a team is sufficiently balanced to fulfill all necessary roles in the process. Filling in a simple questionnaire is enough to identify people's (behavioural) strength in the workplace and to bring the psychological diversity in the group in sharp focus. The nine Belbin roles are complementary, every role has its talent e.g. strengths (and weaknesses). Different roles in a group complete each other and the group thus achieves the maximum performance!

<i>Action Oriented Roles</i>	<i>Shaper</i>	<i>Challenges the team to improve</i>
	<i>Implementer</i>	<i>Puts ideas into action.</i>
	<i>Completer Finisher</i>	<i>Ensures thorough, timely completion</i>
<i>People Oriented Roles</i>	<i>Coordinator</i>	<i>Acts as a chairperson.</i>
	<i>Team Worker</i>	<i>Encourages cooperation</i>
	<i>Resource Investigator</i>	<i>Explores outside opportunities.</i>
<i>Thought Oriented Roles</i>	<i>Plant ('generator')</i>	<i>Presents new ideas and approaches</i>
	<i>Monitor-Evaluator</i>	<i>Analyzes the options</i>
	<i>Specialist</i>	<i>Provides specialized skills.</i>

Fig. 10: Belbin Roles

8.7. *Group Decision Room (GDR) (group behavior , action-learning-theories + ICT)*

A Group Decision Room supports the different steps of a problem solving or decision making process such as the generation of new ideas (brainstorming), the convergence of ideas, the organizing and structuring of ideas, the evaluation of ideas on different criteria, and consensus building. GDR is a digital technique that enables to assess the answers from all participants parallel and anonymous thus saving a considerable amount of time (app. 50%) giving the communication a boost. The anonymity supports a free exchange of thoughts and positive criticism, ideas are only valued on content, independent of who contributed them. In the Decision Room all participants have a computer connected to the central facilitators' one who assembles the (anonymous) information instantly, projects it on a screen for all to see and if necessary collates the data e.g. on priority and make the differences clear in order

to guide the discussion and eventually the voting. In this way a massive proportionate input is assembled in a very short time²⁹ to be discussed and if needed elaborated and/or voted upon in the next tranches.

Fig. 11

The GBR inspires, is effective (one day or half day suffices) and a great way of exchanging opinions, sharing positions and generating ideas and solutions. The GDR is also useful to create an overview of opinions and relations within a group which outcome can help to focus on the evaluation of a product or take stock of the guidelines for the future (consensus, strategic vision).

9. Step into the future!

To sum up: the heart of the matter is the expertise and ability of the urban planner to team up with citizens in the ultimate processes of public participation, i.e. the highest step(s) of the Arnstein ladder, and to create the context wherein real win-win situations won't be a dream. Engaging citizens and actively supporting them in their task requires new standards of planning education, above all process skills in order to be effective in the process of co-creation next to the well-known 'technical' urban toolkit – there can't be a bigger contrast. The gamma sciences like social psychology, sociology, change management etc. offer a wealth of ready-to-use instruments –the new toolkit of the city planner.

- ⁵ The notion of Dutch Big Society can be misinterpreted as the explanation of Dutch Big Society – or ‘Do-Democracy’ as it is called nowadays in Holland, is ambiguous. Some relate it to the UK Big Society (Blond, 2010; flagship policy idea of the 2010 UK Conservative Party general election manifesto), others focus strongly on the local social sector i.e. welfare system and social security (care, amenities, etc.). In the UK the concept Big Society has received criticism from all sides of the political spectrum (too much related to financial cuts, rhetoric) and in practice seems to have gone out of the window. Dutch politicians try to evade this criticism/negative connotation but can’t ignore that many people connect their message of self-help and self-reliance to the financial cuts and reduced budget expenditures due to the financial crisis.
- In the context of this case study we hold on to the international well known notion of ‘Big Society’ with the added important ‘Dutch’ in the sense of civic initiatives and involvement (residents as well as entrepreneurs) in both the local or regional social sector and other societal sectors like the economy, recreation etc. Citizens are not only involved when policymakers invite them to do so, but increasingly on their own initiative. The change-over to the Civic Economy is a small step.

Collaborative Planning: An Evolving Model Of Practice *Phil HEYWOOD, Queensland University of Technology, Australia*

Abstract.

New models of planning are needed that can incorporate the expanding capacities of rapidly developing global communications and social media. Universal internet access and the instantaneous responses of social media combine to expand the bounds of communities, bringing previously separate groups and activities into immediate contact and potential conflict. Both opportunities and demands for collaboration are consequently being dramatically expanded and beneficial change is becoming increasingly dependent on establishing sensitive links between formerly independent fields. Three of these fields of particular interest to planners are explored: they are community development, economic sectors, and scales of governance. Because consensus and mutual understanding within and between them is essential, collaboration becomes both a necessary method and a valuable outcome in the planning of settlements and their major activities.

Collaborative methods within the planning of the major activities of housing, public space and natural environment have been selected to illustrate examples and achievements of good developing practice. Some methods of collaboration are common to all activities: they include comprehensive and innovative consultation; inclusive objective setting; exploratory action research; multiple criteria policy formulation & evaluation; and composite, participatory implementation (Heywood, 2011). This paper considers these techniques by making reference to international and local Brisbane examples of collaborative successes in each of the fields of housing, public space, and natural environment.

The paper concludes that collaboration is already spreading widely to transform brittle and narrow structures of command and control. Cooperative methods can be extended to recognise not only the need for sustainable relations of mutual care and concern among different groups of people, but also the inter-dependence of species and habitats (Midgley, 2006).

Conference delegates may choose to visit some of the local examples cited in the paper themselves if they are staying in Brisbane for a few days after the Congress: South Bank Gardens provide one interesting example adjacent to the conference venue and the Norman Creek Common and conservation corridor at Stones Corner is also within ten minutes travel by Brisbane's excellent Eastern Busway.

CONTEMPORARY CHALLENGES OF CHANGE

Traditional collaborative practices are often so embedded in institutions like churches, madrasahs, universities and cultural associations promoting music and dance, that we tend to take them for granted. Now that the extent and pace of change is challenging the boundaries of human control, conscious collaboration becomes essential. Simultaneous and mounting volatility is affecting physical, social and political climates (Stiglitz, 2002; Flannery, 2010, Vidal 2012) and may result in instability akin to the "Punctuated Equilibrium" which Stephen Jay Gould (1988) identified as a defining feature of geological time. If not well managed, such sudden and interacting events as those, which marked the end of the Carboniferous era, could create conditions as fatal for today's species as those earlier ones were for the dinosaurs. Collaboration therefore assumes great survival value.

Jarred Diamond (2005) has recently argued that such social collaboration, combined with scientific inquiry and intellectual honesty, is required if societies are to manage such threatening changes. In the last two millennia, numerous societies failed and collapsed

through lack of these essentials, including medieval Greenland Vikings facing rapid cooling, Mayan and Anasazi Indians confronted by disease and drought, Easter Island Polynesians destroying their own woodlands to help construct massive monuments to propitiate their gods. The competitive deforestation of ancient Greece, a civilisation that demonstrates the height of competitive individualism, may have also contributed to its trading, economic and ultimate military decline.

Contemporary societies face a similar combination of such challenges. Steep physical rises in atmospheric carbon levels generate rapid rises in climatic volatility and sea levels. The economic and political effects of the collapse of soviet communism coincide with the implosion of capitalism's competitive self-regulation to threaten international economic chaos. Increased risk-taking resulting from the depletion of fossil fuel sources threatens environmental disasters in the Gulfs of Mexico and Benin and the North American Prairies. Meanwhile, the communication revolution is rapidly replacing hierarchical control of global information systems by networks of six billion cell phones. In the face of these challenges, Diamond's proposals to combine scientific inquiry and social cooperation appear very convincing and suggest that collaboration is now even more essential to sustainability and to survival than it was in Neolithic or Medieval times.

THREE ARENAS OF COLLABORATION.

In order to illustrate the roles that collaborative planning needs to play to manage and maintain our current "freedom in a rocking boat" (Vickers, 1972), it is possible to identify three arenas where the activity already plays significant roles- those of community development, economic sectors and institutional governance.

Community development, involving individuals and groups

Collaboration makes possible pleasures of contact and sociability whereas isolated life renders individuals psychologically and physically vulnerable. At the simplest level, mutual grooming removes infestations and promotes feelings of reciprocity. More complex behaviours such as grand parenting and "allomothering" or nurturing the young of relatives or neighbours apply altruism within and between families to bestow both material and psychological benefits bridging and bonding generations, genders and family groups (Hrady, 2009). Team sports teach collaboration and channel conflict to mirror, and train participants for, such social activities as the communal hunt and teamwork for such activities as constructing and maintaining irrigation and drainage systems and securing the communal harvest. By such means, we also learn to manage combative but productive group meetings, whether in Homer's *Odyssey* or the modern boardroom.

Examples of such interpersonal and community collaboration include the flourishing traditions of street parties, urban farms and neighbourhood networks, which enrich civic life throughout the contemporary world. They are equally evident in the Hindu Puja festivals of India, the social activities of Highline Park of New York and the inner city urban farms of London (Heywood, 2011: 11, 214). The instantaneous and convenient links provided by the Internet enhance, rather than supplant people's initiation of, and engagement in, local life. Virtual reality empowers rather than replaces personal contact and comradeship.

Collaboration among economic sectors

The great advantages of collaboration between the three interdependent sectors of government, business and social enterprises are increasingly being recognised -explicitly or implicitly - in the western and developing worlds, and to some extent in Russia and China. "Third way" politics have been associated with the rise of community planning throughout the EU and in particular in the UK, and in Australia's Economic Stimulus program of 2007-2010, which saw almost equal roles taken by each of the three sectors. The extensive National

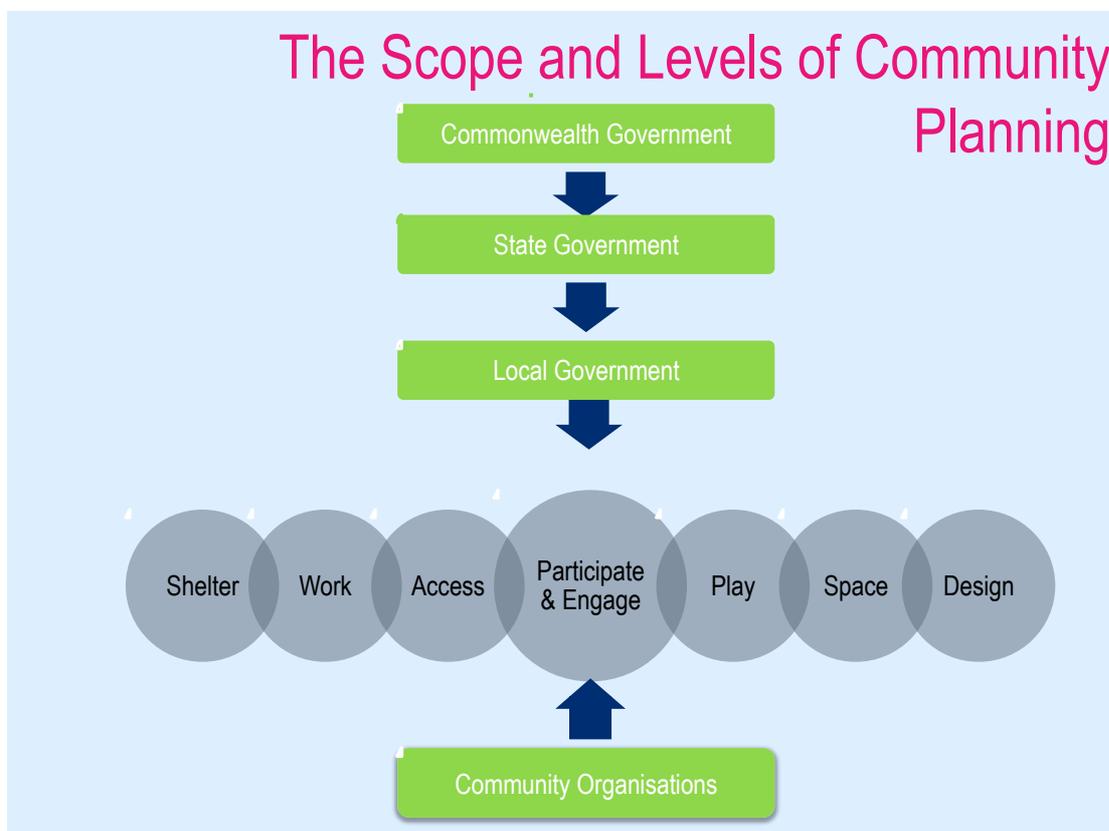

Housing Affordability Fund (HAF) and National Rent Affordability scheme (NRAS), for instance, were taken up primarily by the Not for Profit sector, while national and state governments invested heavily in infrastructure, including school grounds and buildings and broadband communications; and the private sector concentrated on investment in the mining boom, which also contributed to the maintenance of full employment and consumer confidence (Commonwealth Government, Department of Families, Housing, Community Services and Indigenous Affairs (FAHCSIA), 2012). The health of national, as much as that of local and regional, life depends upon such energetic collaboration.

Collaboration in Institutional Governance

Finally, collaboration among and between different levels of governance is essential in a contracting world whose links are daily demonstrated by instantaneous and virtually free communications. The spreading impacts of technological power require adjacent local governments to cooperate in their regulation. Global markets and direct foreign investment compound these environmental impacts, spreading them across out-dated boundaries.

Equally imperative is the need for collaboration among at least six levels of governance in the contemporary world - local, urban/district, metropolitan/ regional, national, supra national and global. In the course of a single day each one of us is likely to encounter strong impacts from many of these levels- neighbourly contact and recreation in the local park, public transport provided or regulated by the city council, travel to work in a regional location, impacts of national benefits and controls, purchase of goods produced in an international free trade or regional economic cooperation area, and the enjoyment of health, work or environmental standards produced and guaranteed by such global organisations as the UN, the World Health or International Labour Organisation.

Figure 3 The Scope and Levels of Community Planning in Australia

Source: Heywood, 2011

In these circumstances, traditions of sturdy independence have been developed into opportunities for collaboration not only across boundaries but also among differing levels of community. A community activist's membership of an international NGO may open a window onto the planning of her local environment, which ultimately gives rise to the designation of a new regional or national park. In the contemporary cyber world we can flit between scales and collaborate with many people whom we shall never meet.

FIELDS OF COOPERATION

Organised activities among practitioners and specialists.

Although collaboration may often start at the most local level of working with one's neighbours, the need soon emerges for links between different specialists concerned with managing activities as diverse as housing, resource management, production, transport, learning, health and play. Categorising human activities into such specialisms to promote economies of scale and support mass production and consumption, may also result in segregated and soul-less places with impoverished community life. Having so recently had too few plans; we now have too many unrelated ones. In order to retain responsive integrated communities supporting rich human experiences, we need to promote routine collaboration among such practitioners and experts as demographers; housing providers; economic, transport and environmental planners; and community development practitioners. Integrated and synoptic Community Plans based on agreement on overall political goals and priorities should frame and precede detailed operational plans for such activities. Within this framework, sectoral plans can then highlight how each activity will support each other's objectives and contributions. Nowhere are the virtues of such collaboration more significant than in the four fields of human shelter; communal spaces; community life; and natural environments. In each of these, effective programs depend on collective action.

Human shelter.

Safe, secure and accessible shelter forms a major part of the fabric of human settlements, generally occupying more third of their total area (Kaiser, Godschalk and Chapin, 1995: 341). It is also crucial to the development of health, learning and productive skills, and these roles combine to make the form, quality and location of housing a major interest of both urban and national governments. They have often been motivated to regulate and prescribe housing rights and enact restrictions that prevent individuals and families from providing their own shelter, where they need it, and using whatever materials they can afford (Thoreau, 2000; Cullingworth, 2006; Turner, 1976). This has two implications: because governments who call the tune should expect to pay the piper, they need to ensure that all their citizens are provided with access to decent and affordable housing; the second is that people need to be involved consultatively and collaboratively in the provision and design of the dwellings and residential areas which will intimately and decisively shape their lives and those of their children and dependents.

Large scale public provision of housing by governments, voluntary agencies and social enterprises intended to meet these needs has often deteriorated into standardised and stigmatised public housing ghettos and sink estates giving rise to demands for more responsive and collaborative forms of delivery (Heywood, 2011). No less than a tenth of all British housing is now provided by Housing Associations funded by the Housing Corporation (now part of the Homes and Communities Agency). In Sweden such bodies provide almost half of all housing and they are also significant providers in France. Until recently they were less significant in Australia; only the South Australian Housing Trust (now Housing South Australia) played a leading role in mid twentieth century planning and provision of dwellings and residential areas, being responsible for a little more than 10% of all accommodation in the state, including the two new towns of Elizabeth and Noarlunga (Marsden, 1986), and

later sharing as a collaborative partner with the commercial developers Delfin in the successful mixed public /private development of Golden Grove, in north east Adelaide.

This collaborative approach linking different sectors and levels of government has recently been applied within 2009- 2013 Commonwealth Government Economic Stimulus package. The Commonwealth Government's \$6 billion National Rent Affordability Scheme (NRAS) and \$500 million Housing Affordability Fund guaranteed start up grants and tax reductions for business and social enterprise providers who agreed to produce suitable housing at levels up to 25% below market rates and levels (Commonwealth of Australia, 2012). Initially, this program was mainly taken up by social enterprise organisations such as Canberra Community Housing in the ACT and the Brisbane, Gold Coast and other Housing Companies in Queensland, but the response to Round 4 applications in 2011 indicates that the business sector is now taking up a substantial proportion of the 20,000 approvals, especially in NSW and Victoria.

Initially the Brisbane Housing Company saw itself as collaborating laterally with governments, professional practitioners and market investors, intending to avoid housing management and involvement with tenants, purchasers or local residents. However experience of provision and need soon drew them into these fields, including extensive tenant consultation and collaboration with the residents and advocates of their award winning apartment blocks and mixed housing estates. If it was experience which generated the establishment of their Tenant Participation Service, it was collaborative links with government departments, community associations and professional colleagues which give rise to such interesting schemes as the Columba Street conversion of an old school block on Richlands High School site in the south western suburb of Inala for 26 affordable rental dwellings, each with small front and back gardens. The simple act of devolving governments responsibilities for affordable housing does not solve the problem of standardised housing and stigmatised estates: that requires the application of collaborative planning and management of the sort which BHC is now practicing.

Figures 4 & 5: Back and Front views of Columba Street conversions of Richlands High School teaching block with small front and back gardens, Brisbane Housing Company

Figures 6 & 7, Attached dwellings Earnshaw Terrace and Barbara and George, residents, Brisbane Housing Company

These issues are at their most acute where housing conditions are most severe, in the overcrowded, under-serviced and legally insecure slum housing and spontaneous settlements that make up a sizeable proportion of the total housing stock in many of the most rapidly growing cities of South Asia, South America and Africa. The first response of central governments is often to plan to clear the squatter's shacks with the intention of relocating them elsewhere, irrespective of the social and economic networks, which are needed to sustain the family and social lives of their occupants. Motivations may vary from preparing the way for modernisation and urban development as in Lima, Rangoon and parts of Mumbai, through intentions to modernise the city's housing stock in Singapore and parts of Seoul, Manila and Rio de Janeiro, to simply creating free space for land speculation as is current happening in Phnom Penh (Australian Broadcasting Commission, 2012).

A more collaborative approach can avoid these conflictual and socially destructive approaches. The deeply entrenched desire of humans to provide and shape their own shelters- going back at least 400,000 years to the wicker work shelters of the Homo Erectus builders of the structures of Terra Amata on the slopes above the modern city of Nice - can be supported rather than repressed (Leakey,1981:123-5). The public sector can concentrate on the necessarily public goods of sewerage; water and power supply and guaranteed public rights of access. The collaborative improvement of over 100,000 of such locally constructed and often spontaneous dwellings in the bustees of inner Kolkata in the nineteen eighties demonstrated natural advantages of working with local residents rather than against them in ways advocated a decade earlier for Peru by John Turner (1976). In Kolkata the Metropolitan Development Authority, using World Bank funds, confined itself to sewerage the slums and providing connections to a huge new treatment plant in the Bay of Bengal, introducing good surfacing and street lighting for the existing network of urban pathways and stimulating the local economy by investing in locally produced drain pipes and sanitary ware (Heywood 1986).

Figure

8. Puja Festival of renewal and cleansing in a Bustee area of inner Kolkata after introduction of public services improvement program.

Figure 9. Inner city water space during Puja festival in Kolkata following removal of sewage by installation of metropolitan waste treatment plant

By comparison, the current crony capitalism that is driving inner city dwellers from one temporary refuge to another in Phnom Penh, using armed police to clear protesters and escort bulldozers is neither socially productive nor politically acceptable (Australian Broadcasting Commission, 2012). In such situations, collaboration should outbid and outlast coercion.

Communal Spaces

Welcoming and sociable public spaces are also hallmarks of healthy societies, allowing people to gather to discuss their hopes and concerns and to celebrate their senses of place and belonging. Italian piazzas, like Siena's Campo and Venice's St Mark's Square, English squares, village greens and town commons and Buddhist stupas and surrounding assembly areas, like that at Boddhnath in Kathmandu all fulfil these functions.

Figures 10 & 11, The Campo in Siena, Site of the annual Palio horse race between Contrade, showing the Palazzo Pubblico and the many engaging open air cafes and restaurants which bring together residents tourists and local entertainers and performers. Photos by author

They both express and generate possibilities of further collaboration, as in the Agora and Stoa of classical Athens, where Socrates stumped around 2.400 years ago, challenging the youth of the city to question the nature of truth and the meaning of citizenship. Further east, one can dine in the open air in Florence's Piazza della Signoria, under the ever-youthful gaze of Michelangelo's David and the safely severed head of Benvenuto Cellini's Medusa. The mix of architecture, art, food and travel still promotes collaboration within and between Tuscan cities, as it does in Brisbane's Post Office Square, depicted below in Figure 13

Figure 12, Lunchtime in the Piazza Signore in Florence, with Michelangelo's *David* and Pitti Palace. Photos by author

Figure 13. Lunchtime in Brisbane's Post Office Square showing happy collaboration of uses, spaces, scales, times and styles. Photos by author

Another example is provided by Brisbane 's Southbank Gardens. Originally slated for totally privatised and commercial redevelopment after the closing of the Bicentennial Expo, they have instead been developed as a metropolitan focus of play, pleasure, exercise, weekend markets and public access. This resulted from collaboration among the three professions of architecture, landscape architecture and planning and between city politicians and community activists in the face of a lucrative fait accompli announced by state politicians (Heywood 1995).

New Zealand's system of Marae - designated open spaces dedicated to Maori cultural purposes - protect them from development and reserve their control for the Iwi or Maori governance body; they offer a fertile example for other countries of a good way to link planning controls to community collaboration and cultural and public space conservation (New Zealand Government, 1991). Community gardens and urban farms can perform similar though less symbolic roles in drawing people together and providing much needed respite from the intensity of urban life. Without collaboration neither Marae not community gardens would long survive, but the remarkable flowering of the latter throughout the great cities of the contemporary world indicates how highly valued are their contributions to urban life. There is no better expression of the role of physical development in prompting social cooperation than these reclaimed urban spaces. Hilary Peters, the moving spirit behind the establishment of Surrey Docks Urban Farm in southeast London writes of "the dreadful alienation of people in the abandoned docks that wasn't just the result of unemployment. They were alienated from themselves, each other and their surroundings." Now the small two hectares farm is a focus for community activists, local craftspeople, human resource development programs, long distance walkers and cyclists and people of all ages looking for worthwhile activities (Peters, 2009; Heywood 2011:11)

Enriching as such re-naturalised spaces are, the great designed set pieces and their modern successors in street malls and city squares remain the classical magnets for social life and collaboration as they have been for over 2,000 years. They need a balance of public, commercial and community activities. Where designed or re-designed without collaboration, as in the recent refashioning of Brisbane's venerable King George's Square with hard surfaces, unsympathetic materials, and intrusive commercial functions breaking up the symmetry of the classical old spaces, they can lose all capacity to delight or even detain their users. Nearby another long established urban space in Post Office Square continues to provides exactly the embracing open textured and welcoming space that the city needs to promote contact and a sense of ownership of the city.

Figures 20 and 21. Brisbane's King George's Square, undergoing reconstruction and resurfacing with a minimum of public consultation and the unwelcoming outcome, contrasted with the sociable space of the nearby Post Office Square. Photos by author

Community Life

Festivals and artistic activities are potent sources of the collaborative stimuli that go to produce the social and cultural capital to bond, bridge and link people to each other and underwrite the social and economic success of the city (Putnam, 1993). Festivals perform amazingly diverse roles, spanning the social inclusion of minority groups and the commercial promotion of culture, tourism and creative industries (Landry, 2008). At one end of the spectrum international Expos and sporting competitions can transform the land uses, self image and tourist trade of great cities like London, Seoul and Sydney while at the other they can bring together fragmented communities needing to recover a sense of self worth. Street parties, too, are a form of festival, as are the parties in the park that are increasingly common in metropolitan suburbs.

Performing skills play a major role in the building of social and cultural capital. Putnam's definitive study of the roles of social capital in the regional development of Northern Italy, *Making Democracy Work* (1993), focussed on choral and other such communal activities as traditional pageantry and folk dancing, and showed how these correlated with mutual trust and capacity to work together even when national and regional politics produced volatile and unstable leadership. Later in the 1990s, Cooke and Morgan (1998) showed that one of Putnam core regions of Emilia Romagna was a European leader in developing an associational economy using strong bonds of contact and trust to link extensive networks of small producers into energetically productive chains. These proved capable of responding rapidly to changing conditions in global markets (in this case in the production of high fashion knitwear) resulting in unusual economic resilience in a decade of uncertainty and contraction

Similar systems of formation of social capital are at work in Australia. Brisbane's month-long annual *Music Fest* every October brings groups of school children from over 500 schools, totalling more than 20,000 participants from all parts and school systems of Queensland and draws in others from Northern New South Wales and the Australian Capital Territory. The Fest, which builds creatively on long standing traditions of regional Eisteddfods, includes choral, orchestral, string, piano and jazz competitions, and has done so for over 30 years. Performances occupy three separate venues running in parallel for 5- 10 hours every day, and involve children from both state and independent systems (Houghton, 2012, pers. com.) It is clear that this extraordinary feat of collaboration between the business, state and community sectors (the Fest was started by the Australian Academy of Music and is now actually run by the commercial Prestige Music Ltd who produce sheet music for schools) is proof against cyclical cut backs in government expenditure on the arts. Participation of teachers is uncontroversially supported out of leave and travel entitlements; and the young people who are competing are financed by their parents and from within their communities. Accommodation in Brisbane is in cheap hotels, back packers and with friends and relations. It is clear that this remarkable annual festival is a rich source of bonding within schools and among the members of their orchestras and bands; that it builds bridges between different

communities and educational sectors who meet each year in Brisbane; and that it links local aspiring young musicians with members of the musical establishment who act as MCs and adjudicators.

Collaboration and cultural development go hand in hand. The Aboriginal Dance troupe of Yuli Burri Bah on Minjerribah (North Stradbroke Island) for instance, conserve and enact the cultural traditions of the Quandamooka peoples at the same time that they maintain their personal fitness and build both bonding and bridging links with each other and with visiting tourist groups from all parts of Australia and worldwide. On an even wider stage, the Tjapukai dance troupe of the Kuranda area of the Barron River uplands of North Queensland now tour the world and reap a rich harvest of acclaim and professional self-respect. Singing, dancing, painting drawing, and designing are all activities that can be powerful vehicles for collaboration. It is also significant that there are several instances where courts of law have confirmed Native Title rights on the basis of songs and dances that traditional owners have preserved to record associations with that country. The courts are leading public opinion in recognising the significance of creative collaboration

Natural environments are the most ancient and perhaps the most widely embraced and acknowledged arenas for collaboration. The preservation of universal rights of access to river banks and woodlands is enshrined in the Common Laws of England which stipulate that as long as public rights of way are traversed once a year they must remain open to all. It was on this basis that throughout the 1930s Tom Stephenson and his associates in the Ramblers Association broke down fences erected across customary paths in England's Peak District and southern Pennines, facing and embracing imprisonment by local landowning magistrates and challenging the courts to defy egalitarian legal traditions. One of the most significant planning acts of UK's Post War Labour government was to establish in 1949 a National Parks Commission (now "Natural England"), responsible for running ten large National Parks in collaboration with County Planning departments with a total extent of nearly 10% of the country's total land area (Cullingworth, 2006; Natural England, 2012) and an even larger proportion in Wales and Scotland. These national parks are designed not only to ensure public access, but also to safeguard natural species and habitats in Areas of Outstanding Natural Beauty (AONBs). They also include a number of much loved long distance footpaths, the first of which, the 256 mile Pennine way, was officially opened by Tom Stephenson in 1965.

Similar collaborative protection of valuable and vulnerable habitats and species is practiced by Australian Aboriginal communities with their setting aside of "Poison Lands" and use of totems to protect vulnerable species like koalas, wombats and even possums. Scientific champions of the spirit of "Gaya" the Greek goddess of nature like James Lovelock (1979), Rupert Sheldrake (1990) and Tim Flannery (2010) extend the idea of the collaboration beyond cooperation for the protection of nature to embrace belief in a deep seated harmony among species which is necessary to maintain the health of the global ecosystem we all share.

Recognition of this kind of reciprocal responsibility leads environmentalists to seek to safeguard important natural features in both rural and urban areas. The Yorkshire Wildlife Trust (YWT) in England, for instance, assists landowners to maintain woodlands and farm buildings in good condition and runs camps to introduce young people to conservation activities and a better understanding of natural environments. The YWT simultaneously protect and present moor, valley and woodland environments. In urban areas in many countries local conservation groups who oppose the destruction of critical creek corridors to make way for new roads and residential developments also collaborate to maintain their health by weekend working bees. In Greater Brisbane, for instance, there are now eleven such groups cooperating in the Brisbane Catchments Network with two local governments

and three other collaborative associations to promote regional scale creek corridor conservation (Brisbane Catchments Network, 2012).

Over the last twenty years, this network has grown rapidly from the pioneering work of such local groups as the N4C (Norman Creek Catchment Coordinating Committee). In the 1980s N4C had joined with other Community groups to protect the short but significant Norman Creek valley from massive industrial and road development (Heywood, 2011). As the City Council found it stage by stage forced to adopt the community's alternative recreational and conservation strategies, they moved into a partnership with N4C and with other such groups, now extending to embrace eight creek corridor conservation groups who are consulted, informed and supported by the council.

Figures 23 and 24, Working Bee along Norman Creek & Imagining the Future of the Norman Creek Catchment (Brisbane City Council 2012)

Similar situations were earlier developed and applied in the USA's northwestern corner where the State of Oregon enshrined riparian rights of conservation and access in its trail blazing 1974 Land Use Act. Five of Oregon's legally binding 19 State-wide Planning Goals, dealing with natural resources of air, land, water, estuaries, coasts, beaches and the Willamette waterway protect and guarantee access to the state's water courses and coastal spaces, and provide an example to other jurisdictions in America and worldwide (State of Oregon, 2012) .

Collaboration is also beginning to supplant competition in the management of the extensive coastal and offshore ocean habitats of the world's largest island of Australia, where many fish, bird and mammal populations are threatened with devastation and in some cases extinction by competitive over fishing and careless conduct of trawlers and tankers. In November 2012, scientists and activists combined to achieve the promise of the world's largest array of marine reserve, when the Commonwealth Government announced the establishment of 40 new reserves adding more than 2.3 million square kilometres to Australia's marine reserve estate (Australian Government, 2012) . This will result in a total area of 3.1 million square kilometres of ocean being managed primarily for biodiversity conservation, fulfilling the Australian Government's part in the creation of a new national system.

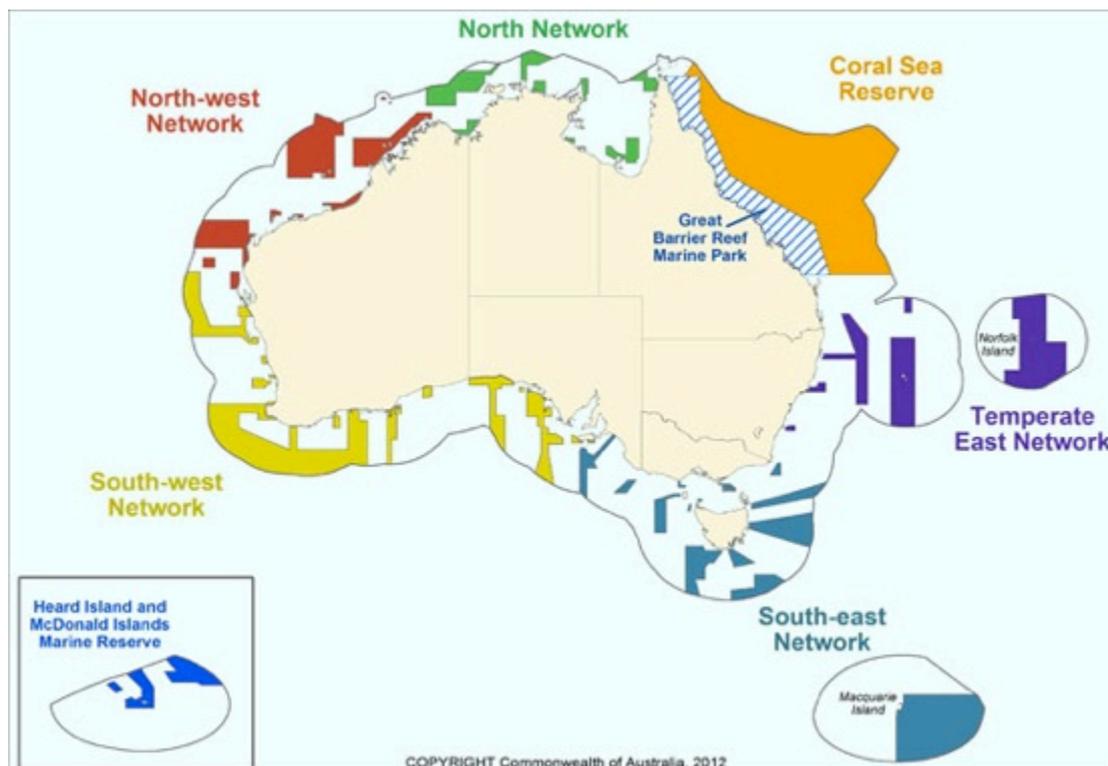

Figure 22. Australia's New Network of Marine Reserves

Conclusions

In conclusion, it is now possible to identify the strong patterns of association and collaboration within and among the three arenas of community development, economy and governance in each of the four selected fields of housing, public space, community life and natural environment, and these are summarised in Table 1 below

Table 1 Arenas and selected activities of Collaborative Planning

Planning Arena	Shelter	Public space	Community Life	Natural Environment
Sphere of concern				
Community Development	Tenants Associations. Housing Coops. Housing mix policies.	Urban Farms, Shows Fairs & Exhibitions. Public spaces like Brisbane's South Bank Gardens	Community Festivals. Performances & exhibitions of music, drama, culture & sport	Creek Catchment Coordinating Committees. Communal spaces like Norman Creek Common
Economic Sectors (Public, Private, Commercial and Community)	Government investment & infrastructure support Brisbane Housing Company's mixed investment streams and	Public Squares. Commercial and Community Craft and Farmers Markets. Community Gardens	Economic Associations & networks/ Creative arts industries Cultural tourism Mentoring &	Ramblers Associations & National Park Associations. Nature England Environmental Protection Agencies.

	tenures		sponsorships	Envt. tourism
Governance (Global, Continental, National, Regional, Urban, Local, Commercial and Voluntary)	Building Standards and Planning provisions Commercial Master Planned Communities Housing Associations and Trust Developments.	National Parks Civic Squares Neighbourhood Parks Private, school and community sports fields Commercial halls and fitness clubs	Residents & Tenants Associations. Delegated powers and partnerships. Land & Watercare. Wildlife Trusts & Funds. Custodianship of Country	Creek Catchment Conservation committees World Wildlife Fund and Wildlife Trusts Societies for the Prevention of Cruelty to Animals. World Heritage Listings of UN & ICOMOS

An interesting aspect of these welcome links is the role collaboration is playing not only as part of the *process* of planning, but also as one of its motivating *goals*. If other widely adopted goals such as prosperity, choice, justice and sustainability are to be pursued and achieved, then there will inevitable conflicts that will arise between aspects of each which can best be managed by acknowledging the importance of collaboration as a value in its own right. Such collaboration should ultimately extend not only within and between communities, but also extend to our relations with other species to help nurture a sustainable world where people consciously aim to live in harmony with each other and with the rest of the global habitat.

These aims no longer appear utopian- they run a greater danger of being regarded as conventional wisdom. Nevertheless, it is essential to recognise that their widespread acceptance would prove to be a great advantage to all. Collaboration can spread like groundwater, percolating upwards and sideways to irrigate and transform brittle structures of command and control. Cooperative swarms and ecologies of mixed uses can replace rigid zones based on promotion of competing activities. Street gardens and creek corridors can transform regimented open space provisions. As the Internet and mobile phones combine to reduce the scale of the contemporary world, collaboration has become simultaneously easier and more effective; Planners have nothing to lose but their chains of command. And we stand to gain a world of initiative, energy and harmony.

Afterword

Congress delegates may choose to visit some of these local examples themselves if they are staying in Brisbane for a few days after the congress: South Bank Gardens provide one interesting example adjacent to the Conference venue; the Norman Creek Common and conservation corridor at Stone Corner is also within ten minutes travel by Brisbane's excellent South Eastern Busway.

Societal Paradigm Shift and Community

KARAKIEWICZ JUSTYNA University of Melbourne, Australia

1 Introduction

Thomas Kuhn (1970) observed that science does not progress linearly through a gradual extension of knowledge within one framework; his proposition was a progression through periodic revolutionary upheavals which he called paradigm shifts. He suggested that the discovery of irreconcilable shortcomings in an established framework produces a crisis that may lead to overturning the paradigm and ushering in a new one. Revolutions are never an easy experience and most of us prefer to engage in evolution, where changes happen gradually, often unnoticed, and no-one is unsettled.

Sometimes, revolutions are needed. For years now, we have been responding to the discovery of the profoundly disturbing evolutionary consequences of climate change. It is clear that collective behavioural change is needed, yet little has changed in popular behaviours. Many of us have been made efforts to be more sustainable. Some of us have forgone our cars for bicycles, some installed photovoltaic panels, most now sort our waste for recycling; however, all of this together has a relatively small impact on our environment and we recognise that we need to do something more substantive and soon. But how do we identify substantive actions that will bring the larger public to embrace such change and result in a societal paradigm shift?

The change must start with a gripping idea. We must find inspirational ideas that allow us to dream about better future and not be paralysed by doom and gloom. Renzo Piano noted in an interview with Peter Buchanan:

What architecture and planning suffer from is a desperate lack of imagination. We need to think about more alternatives and where we might be going, and of new paradigms. We have all sorts of possibilities open to us, and we don't have the imagination to conceive of and use them. What we need now is brainstorm and dream: to stop trashing the world we need culture that is more deeply satisfying. [...] There's terrible dearth of real imagination in thinking about the environment. Most ideas are not exciting. And we are not going to stop people trashing the world unless they are exciting about the alternative. That's the problem. People are not dreaming up sufficiently exciting alternatives." (Piano, 2001 pp 71-72)

Profound societal change *has* happened in recent history. At the beginning of the twentieth century, when the effects of the Industrial Revolution were choking cities and the solution was identified of encouraging people to move out of cities, into the new idea of suburbs, London Underground came up with series of posters advertising all the advantages of suburban life. Ebenezer Howard's Hampstead Garden Suburb offered people the luxury of dreaming about better futures away from pollution of the industrial city. Railways offered a means to move easily back and forth from suburb to workplace. Yet the public had to be introduced to the idea and convinced of its benefit. This was not easy at all. The railway lines and the areas around them were not places associated with dreams or desires. Most of the population saw them as evil distractions, bringing pollution and degradation.

Advertising too was not perceived positively. While we might use advertising today to sell an idea, then advertising was novel and considered vulgar and distracting. It was far from easy, therefore, to sell the idea of something that was unknown and untested. Howard idea's proposition ran counter to many prejudices and preconceptions about city and rural life, about railways, including stations and lines, and about advertising itself. Ultimately, though, it was advertising that made Garden Cities an object of desire.

2 Advertising

Advertising can be defined as a form of communication, primarily used today for marketing purposes. The word comes from Latin *ad vertere*, which means, “to turn the mind towards”. Advertising persuades, manipulates and drives consumer behavior, or ideological beliefs and can be broadly categorized into two types: commercial and non commercial, where commercial advertising will be focused on increasing of consumption of advertised product or services, and non commercial advertising could include promotion of a point of view by political parties, religious organizations, or driving changes towards more sustainable living.

Advertising existed long before the Industrial Revolution. While commercial messages and records of political campaigns have been found in the ruins of Pompeii, it is generally agreed that first formal advertising started together with first newspapers. The first newspaper advertisements began in France in the early seventeenth century. Theophraste Renaudot, Louis XIII's official physician, placed notices offering jobs and goods for sale on the office notice board on Ile de la Cite, but in order to promote these notices to the bigger audience, he create La Gazette, in 1631, which became the first French newspaper. However there was no real need for advertising goods since all goods were hand made and sellers knew each other personally. Packaging and branding were unknown and unnecessary. The Industrial Revolution broke the personal links between seller and buyer, mass production required mass consumption. Manufacturers then needed to explain their new products to their new customers. Competition between different manufacturers introduced brand loyalty and thus branding. It was not good enough to promote a new product, you need to make sure that customers will understand the difference between your product and product offered by your competitor. The same applied to the selling of a “better life quality” in suburban houses. Cheap labor, cheap land prices, and cheap materials, made it possible to create cheaper housing on the periphery. Cheaper housing became another commodity that needed to be sold and therefore to be advertised.

This paper looks at successes and failures of advertising of housing and identifies the factors that motivate people to aspire towards types of residential accommodation, examining the role of communications in persuading people of the benefits of sustainable living.

We suggest that the campaign to sell the idea of suburban living, as exemplified by Ebenezer Howard's Garden City movement, is one of the most successful advertising campaigns of the twentieth century. The idea remains today an “the object of desire”. Yet, we know today that Ebenezer's ideas need to be rethought and adapted to the twenty first century. This form of suburban living cannot be considered sustainable, but neither is the high-rise tower. Therefore the question that we need now to ask is what alternative we can offer to allow people to dream again but now to dream about sustainable living?

To do this requires an understanding of current impediments to sustainable living. While we are aware that many people have positive attitudes towards the environment, these are rarely translated into behavioural change. This is often attributed to the lack of information, and choice for consumers in sustainable living alternatives. Indeed we are not short of ideas, but we are unsuccessful at communicating them to achieve broad public commitment. It is these exciting alternatives that this paper will try to identify and work to communicate.

3 How Garden Cities Became “Objects of Desire”

The Industrial Revolution made cities as desirable places to be. People were eager to move from rural areas to the city because life outside the city was seen as worse. Poverty, hunger and lack of employment or social mobility encouraged significant numbers to move to the city. This is the same scenario observed today in Asia and Africa where urban populations are growing significantly. In many cases there was no choice, the city offered the only possibility to survive. But life in the city was far from being desirable. As early as the 18 century William Hogarth portrayed London's city life in “Gin Lane and “Beer Lane”. Where the

latter depicts a happy and prosperous community, nourished by the native English Beer, the evils of consumption of foreign gin in the former is seem to lead to starvation, decay, madness and suicide. But the prosperity of Beer Lane, which thrived on the consequences of industry, is the cause of misery found in Gin Lane (Fig.1).

Figure 1: Beer Lane by William Hogarth, 1751

The allegory applies to all industrial cities; their wealth and expansion had significant social consequences. The Charles Dickens provides clear descriptions in “Oliver Twist” (1838), and “Hard Times” (1854). In Oliver twist we find this powerful description of life in London during the Industrial Revolution:

“So they established the rule that all poor people should have the alternative (for they would compel nobody, not they) of being starved by a gradual process in the house, or by a quick one out of it. With this view, they contracted with the waterworks to lay on an unlimited supply of water, and with a corn-factor to supply periodically small quantities of oatmeal, and issued three meals of thin gruel a day, with an onion twice a week and half a roll on Sundays. They made a great many other wise and humane regulations . . . kindly undertook to divorce poor married people . . . instead of compelling a man to support his family, as they had theretofore done, took his family away from him, and made him a bachelor! There is no saying how many applicants for relief, under these last two heads, might have started up in all classes of society, if it had not been coupled with the workhouse; but the board were long-headed men, and had provided for this difficulty. The relief was inseparable from the workhouse and the gruel, and that frightened people.” (Dickens, 1838)

“Hard Times” (1854), set in a mythical Coketown, can be identified with Manchester or Preston, and illustrates the dangers of allowing humans to become like machines, suggesting that without compassion and imagination, life would be unbearable.

Nevertheless, new technologies of the time were thought to hold solutions to social problems. The provision of infrastructure, such as sewage, electricity and gas, offered hope of a better future. Misery could be suffered if there was hope for a better future and better quality of life. Although the Victorian city of slums was polluted, overcrowded, and unhealthy, it offered social and economic opportunities to the poorest. Most had escaped rural areas and unemployment in search of opportunities offered in industrial cities. For these, Howard’s

vision of a peaceful life in the country site did not have much appeal; the countryside was not full of promise of clean air, nature, and peace, it was rather wrought by economic depression, without work and wages, and with inadequate social life, it was a place to be avoided, not desired.

3.1 *The opportunity*

Ebenezer's idea was also premised on new technologies and infrastructures and, although the infrastructure enabled city expansion, sprawl and commuting, Howard's ideas looked beyond that. He was promoting was a sustainable way of life not in the suburbs but in discrete and separate Garden Cities. Garden Cities consisted of short distances, employment, entertainment and a range of services accessible by foot. The railway allowed for easy access to a nearby city center and other Garden Cities, but commuters were always pedestrians at both ends of their journey. The land surrounding Garden Cities feed the inhabitants and provided the employment. These principles are recognized today as those of sustainable communities. These principles included return to the community of any land value increases. All residents would pay a modest rate-rent for their accommodation, factories or farms. The rate-rent was calculated to be sufficient enough to repay interest on money originally borrowed. As debt was reduced, more of the income was directed to support community needs and to provide welfare, where needed. Howard's ideas were not as much concerned with physical planning as they were focused on reconstruction of capitalist society into co-operative commonwealths. Howard was more interested in social processes than physical forms of development. These rural communities were conceived to address urban sprawl by creating self-sufficient developments interconnected and connected to big metropolis. In 1884 the economist Alfred Marshall interpreted Ebenezer's ideas:

The general plan would be for a committee, whether specifically formed for the purpose or not, to interest themselves in formation of colony in some place well beyond the range of London smoke. After seeing their way to buying or building suitable cottages there, they would enter into communication with some of the employees of low-wages labor" (Marshall, 1884, p.224)

Eight month after the book was published, in June 1899, the garden City Association was established. At first it was a small group of six friends, which included Alexander Payne, Treasurer of Land Nationalization Society. The aim of the society was to promote Howard's ideas, and to set in motion plans to create the first Garden City. Letchworth, and later Welwyn, demonstrated the practical application of principles described in Ebenezer Howard's "Garden cities of To-morrow". Letchworth was built in the area of severely depressed agriculture land, 34 miles away from London. Howard's idea was to create a garden city with population of no more than 32,000, living on 1,000 acres of land and surrounded by further 5,000 acres of land designated to farms and urban institutions such as reformatories, convalesces homes, hospitals, etc, which could benefit from such settings. If the number of residents reached the limit of 32,000, another city will be created near by and connect to it.

In practice what Ebenezer Howard was proposing was a formation of a trust to purchase and maintain on behalf of the community the land and the buildings. The freehold was to be retained by the trust in order to make sure that community would be able to enjoy benefits resulting from increase in land value and rental values. All of this required capital sufficient enough to be able to purchase the land and buildings. The first Garden City Company was established and registered on 1st September 1903. It took the company over a year to raise 148, 000 Pound Sterling towards the cost of site purchase. The company needed to wait until 1912 for its first profit. Although Letchworth was initially designed to accommodate 32,000 inhabitants, only 1,000 moved in in the first two years. First inhabitants were mostly middle class idealists and artists. It proved difficult to attract industry to the area; nearly ten years passed before the first industry, a printing and binding works, provided employment.

3.2 The challenge

The promise in Letchworth was a better quality of life, better accommodation away from overcrowding, congestion, noise and pollution. It offered life closer to nature and it offered opportunities for people to get out of landlord tenant relationships and being able to become owners of their own homes. Nevertheless it was still extremely hard to attract people to move to garden cities. By assumption, life outside the city was the sub-urban, that is, not as good as urban/ Memories of the poverty and hardship of the life in the countryside and therefore, the idea of rural life was something to be avoided by all costs.

Beyond this initial assumption, however, there were problems associated with railways. Railway for the very long time was being seen as destructive element, not only to the urban structure and the countryside but also as destruction of communities, social structures and culture.

Without any doubt the railway was the most profound transformative innovation of the Industrial Revolution in the 19th century. Some believe that the

“...railway tracks marked the divide between old, rural, small-town, slow-moving Britain and the modern industrial nation of great towns and cities, factories, and constant rapid travel and communication” (Harrington, 1877)

But railway lines also destroyed the stability, the tradition and permanence, of the British countryside and replace it with uncertainty, based on innovation and a transience of life. Nothing like that was seen before and nothing caused the same degree of disturbance and disruption. Installing the infrastructure involved the demolition of neighborhoods and communities through land acquisition. In the 1860s, railway development started to have a significant impact on the pattern of development in cities. Railways needed large areas of space for tracks, stations and storage. The railway tracks often divided old neighborhoods and reduced access across the line caused congestion in places where access was provided. It also caused severe congestions around the stations.

In 1861, railways employed around 23,000 people and by 1891 this figure was almost 70,000. In addition to this, another 48,000 people were employed in ancillary transport industries. If one adds to it families and dependents the total number of people benefiting and depending on railways could have been as much as 250,000. But although there were obvious benefits from railways developments there were also endless problems associated with it.

The terminal station buildings were very imposing and located at the beginning at the edge of the city. They housed hotels, restaurants and other services related to the station and although they provided luxury, they were also surrounded by rundown and undesirable development. This was a consequence of the railway's dependence on steam engines, rendering areas around stations and tracks sooty from the engine emissions and the location of frequent fires from burning embers. Therefore the poorest population often inhabited the land around stations and railways tracks.

At the same time, housing prices in London kept increasing. Most of the population lived in rental accommodation without control. Constant population increases and a lack of inexpensive housing generated demand for affordable housing outside London. New transport infrastructure facilitated the trend but perceptions of the undesirability of land adjacent to the infrastructure strengthened. Dickens captures progression in “Dombey and Son”, published in 1848, only 18 years later, after the first railway construction has begun in London. He describes the construction of the railway through Camden Town and portrays the railway as a transforming force, able to provoke dramatic changes, even improvement but, in the process, creating significant disruption and depravation. Thousands of people were evicted or made homeless; 37,000 people were displaced in London between 1859 and 1867, the period of railway boom; through this, railway construction contributed greatly to increased overcrowding, poverty and misery. John Ruskin also portrays railway as a new

barbarian invasion, destroying the great-civilized European culture. In 1849 he wrote about the destruction of European cities:

“...the railroad and the iron wheel have done their work, and characters of Venice, Florence, and Rouen are yielding day by day to lifeless extension of those of Paris and Birmingham” (Ruskin, 1849)

With the undesirable proximity to rails, the arches and viaducts of railway lines attracted the poorest and the most venerable in society. Alcoholics, prostitutes, criminals, and homeless were drawn to these areas and railway lines and arches became symbol of human degradation. Ruskin observed, in 1876, of the *“... deterioration of moral character in the inhabitants of every district penetrated by railway” (Ruskin, 1876)*

This perception was widely held. In George Eliot’s “Middlemarch”, we find a description of the alarm and anxiety of residents of the town when the construction of the railway lines begins.

“...woman both young and old regarded travelling by steam as presumptuous and dangerous” (Eliot, 1870)

3.3 The role of advertising

The difference between those in the trains traversing the arches and those resident below was symbolic and perhaps contributed to the perception of railways as desirable way of transport to escape squalor. Proximity to railway lines and stations was to be avoided and rural life had only recently been left behind. How then could the promoters lure people into suburbs in adequate numbers?

It is therefore not surprising that the railway companies were fighting for survival and that the first proposal by Howard for Letchworth Garden City was not a great success initially. The railway companies promoting these new suburban or exurban life styles were driven to try something new, to employ an advertising campaign to promote their product and products associated with it, but advertising itself was a novel and not broadly accepted medium Gissing (1894) describes King’s Cross underground station polluted by advertisements.

“...the visual hubbub, which they create acting as an appropriate counterpart to the noise of trains and people, which fills the station, and echoing the chaos and turmoil of the city streets above.”

His description continues, describing the station not as progress but rather as regression to an era of formless chaos:

“...high and low, on every available yard of wall, advertisements clamored to the eye: theatres, journals, soaps, medicines, concerts, furniture, wines, prayer-meetings-all the produce and refuse of civilization announced in staring letters, in daubed effigies, base, paltry, grotesque. A battle-ground of advertisements, fitly chosen amid the subterranean din and reek; symbol to the gaze of relentless warfare, which ceases not, night and day, in the world above”. (Gissing, 1894)

The most famous advert in this campaign for suburban lifestyles comes from 1908 and depicts Golders Green (Fig.2). The artist of the poster is unknown, but the poster was published by the Underground Electric Company Ltd, and printed by Johnson Riddle and Company. The poster represents the aspirations of an alternative life, with people taking walks along tree lined roads, a family enjoying the tranquility of nature in the back garden, with the wife looking after children, relaxing in the deckchair while engaged in domestic reward by mending clothing. In the distance, we can see a railway station and, beyond, the smoke of the city (“the big smoke”). The label underneath aptly promotes: “A Place of Delightful Prospects”.

Figure 2: Golders Green, Underground Electric Railways Company, 1908

Middle classes saw this image, and many of us still do, as an advertisement for a Garden City but this poster, as many others in the campaign, was promoting not a Garden City but a Garden Suburb, borrowing from the efforts of Howard to define a new urban paradigm. It was part of a railway advertising campaign to encourage regular, daily rail usage, but it was not the railway that this campaign was promoting. If you look carefully at the image, you can see the railway station, but the station was not central to this message. The underground rail company was selling a dream, not a service, by encouraging people to dream about a better quality of life previously only accessible to the upper classes.

The campaign worked well; home owners and renters soon started to move to the suburbs in significant numbers. Slowly, the fear of the railways was dissipated and replaced with a form of snobbery. Those on the train were those who could afford it, secure in their employment and, not harnessed to unreasonable employers, blessed with the time to spend on the train travelling along ever longer railway lines. With industrialization, salaries increased, the working day became shorter and spare funds made available to purchase the cheaper products of industrialization.

The impact of railways was extensive. Family lives were scheduled according to train timetables. The gender division was reinforced. Railway stations and train carriages became the domain of suburban male; women stayed in secure houses with gates and walls, protected from the evil of the city centers. Owning a house with a garden had three symbolic values: it could have been seen as a miniature of country house, as a homestead or smallholding, or as a domestic sanctuary in the Garden of Eden. All these were previously available only to the upper classes. Until 1880s, commuting was available only to people who could afford horse-drawn carriages, later, horse-drawn omnibuses and second homes in villas outside the city. The affluent had houses and cottages in the country to which they could retreat on weekends, when on holiday or in retirement. To the newly created middle class, the idea of living a portion of an upper class life style was desirable and therefore powerful advertising technique.

3.4 *The villa redux*

Railway lines and underground produced posters promoting the speed and efficiency of the train, comparing them with walking speed, speed of horse-drawn carriage or omnibus. Efficiency was succinctly illustrated in a poster from 1912 where egg timers showed how

much time commuters saved on a single journey and how much in one week. Other posters communicated the investment made in the interests of the commuters: "What does it takes to move one passenger: 234,000 tons of coal, 71,000 of oil, 10,000 of staff, 6,000 tons of steel and iron, 200 tons of tickets, 184,000 Pound Sterling of taxes". At the bottom of the poster, a short sentence has been added: "306, 000 000 travelled in 1923". Other posters promoted travelling during off peak hours and on Sundays: "Book to Perivale, Sudbury or Harrow, for field, path, rambles in old fashioned country". Garden suburbs were advertised in posters promoting "health of the country and comforts of the town". Slogans such as: "Sunshine is the Brightest where it Falls on Your Own House", or "380 feet above the Thames, therefore out of valley fogs", lured people into the suburbs. The paradise could be found d at the outer edge of the city where the air was clean and healthy lives awaited people away from polluted slums, away from overcrowding, and socially undesirable environments.

The posters portrayed idyllic life in the suburbs and productive employment in the city. In support of this, they guaranteed rail passengers service at least during peak hours cheap fares and "special train services on Sunday". Perhaps off message, one poster from 1915 is particularly disturbing: "why bother about German invading the country? Invade it yourself by underground or motor bus". Advertising used all messages to encourage people to move out of the city to their own paradise on earth.

In the London Transport Museum, we can find 27 posters advertising Golders Green. Some project images of a natural landscape and parks, an idyllic life with children relaxing by the water. Others deploy plans to show the extent of the greenery. There also pictures advertising low cost of tickets and ease of access to events and activities that take place in the area. There is even a poster suggesting time can be saved when travel by train. None of the other 26 posters had the same impact as that of the villa in a garden. The dream was sold not by the nature, peaceful life, time or money saved on public transport that attracted people to the suburbs, but the possibility to dream of a better life, one approximating life of the upper class.

Look again at the poster for Golders Green above, the most successful and often repeated of the images, for closer inspection is revealing. The paradise villa, apparently in the Garden of Eden, is nothing but a typical semi-detached house, the typology very popular in the British Isles but nowhere else in the world. Showing only half of the semi-detached house implied that you would be living in detached villa surrounded by garden. A scaled down version of a manor house in the countryside, this was a perfect image to persuade new middle class that the villas in the countryside were no longer accessible only to the upper classes; they could be affordable for many. Something that previously was impossible dream could now become reality, but it could only become reality with the development of railways.

There was a clear class distinction implicit in the dwelling type and therefore it was not surprising that, when depicting ideal living, the artist of the Golders Green poster has chosen not to show the other half of the structure. The ideal house with the ideal family is carefully depicted as implicitly living in a detached dwelling. While the fiscal reality was a need to share a party wall, the aspiration was of isolation.

3.5 *Paradise tarnished*

The stations and the train became proxy social centers for suburban males. The value of the traditional city was presented as depleted, even problematic, and needed to be exchange for new values now promoted by railways companies as a way to enable people to increase their quality of life, by separating work from domestic life, bread winners from home makers, children from busy streets of cities into secure backyards. The isolation of women inside the home and away from full participation in the society was seen by many as stabilization of society as the whole (Beecher, 1849). Suburbs for a long time were associated predominantly with the middle class but, over time, allowed for a distancing between the upper middle class and the lower middle class with their own suburbs. Places like Surbiton, Ealing or Sidcup were at the top of the social order. In these suburbs the roads were lined

with trees and houses had substantial gardens. Lower middle classes were located in suburbs such as Bowes Park, Palmers Green, Wood Green, or New Southgate. All were safely distant from the city-locked working classes.

Whether upper middle or lower middle class, suburbs shared characteristics of isolation, difficult access to services, schools, hospitals, or even basic provision of shops or more local employment, although the promise of paradise dominated the message. Not everyone was lured by the suburbs. Early on, alternative views were presented of life in the suburbs such as by Arnold Bennett in "Hilda Lessways" (1911) where Hilda offered the following description of her journey from Central London to suburban "paradise" of Hornsey:

"...the train almost empty, waited forlornly in forlorn and empty part of the huge, resounding ochreish station. Then, without warning or signal, it slipped off, as though casually towards an undetermined goal. Often it ran level with the roofs of vague, far stretching acres of houses-houses vile and frowsy, and smoking like pyres in the dank air. And always it travelled on a platform of brick arches. Now and then the walled road received a tributary that rounded subtly into it, and this tributary could be seen curving away, on innumerable brick arches, through chimneypots, and losing itself in a dim horizon of gloom. At intervals a large, lifeless station brought the train to a halt for a moment, and the march was resumed. A clock on the station said a quarter to two." (Quoted in Railways and Victorian Imagination, Bennett, 2004)

Figure 3: Golders Green interpretation, 2013

This book presciently describes the emerging truth of suburban sprawl as manifested in the monotonous landscape seen from the railway. As the middle classes were escaping from inner suburbs in search of better quality of life, the poorer population was moving in to areas left over. New suburbs did not really deliver that which they promised. Stations were deserted except during rush hours. The passage reiterates the dictate of the train schedule in the life of the suburb, governed by the clock. But if the life in the suburbs in 1911 could have already showed some reason to be concerned, the real problem came evident in the late 1930s. Private car ownership in 1919 in England was 109,000; the majority of the population still used public transport to commute and the majority of housing in suburbs was located within walking distance to the station. By 1939, car ownership had increased to 2,000,000 and the location of suburban housing was freed from the constraints of public transportation. With the move to commuting by car came a new set of challenges. but the promise of a "paradise" in suburbia continued to be promoted. Created on the principles and promises of

Garden Cities, Garden Suburbs and suburban living transformed into a reality that has little to do with sustainable living and the aspirations of the Garden City movement.

With this understanding, the question posed here is whether we can once again run an advertising campaign for sustainability as successful as the one that promoted Golders Green.

4 Advertising objects of desire

Today advertising once again has a bad name. Sustainability advertising has taken a turn to promote a message by scaring us, painting terrifying or unsettling futures. The message is one of a pervasive gloom. Polar bears are losing their habitat, the desert is encroaching many of our cities, the water level is rising, aquifers are falling, and some of our cities are going to disappear under water. All in all, there is very little to make us happy today, little to help us imagine a better quality of life. We are so scared that we cannot be scared any more by messages portraying yet another disaster.

Sustainability has lost its image as an object of desire. Recalling the strategy of the Underground Electric Company in 1908, we need a message that calls us to a sense of purpose and hope in taking action. It is time for something new, innovated, exciting and very desirable, an object of desire of “sustainable living”.

Integrating community Participation in Urban Redevelopment Projects: The case of Makongo in Dar es Salaam Tanzania

Joseph Paulo LAYSON, Tongji University, China

Prof Xia Nankai, Tongji University, China

1. Introduction

Many studies have been done about urban planning, but there are no studies done looking at the opportunities and challenges of implementing community initiated urban redevelopment projects. Time and again, development projects initiated by dominant “outsiders” have failed to translate “insiders’ expectations” into equitable, enduring, and sustainable benefits (Bae, 2006). ‘Community’ is a notoriously slippery concept and carries with it a variety of connotations (Cochrane, 2003). It may be conceived as groups of people defined by geography, identity or interest, or even viewed as an aspirational model.

Community participation is a proven approach to addressing urban environmental issues and has been long utilized in various development projects in Tanzania internationally. Thus bottom up approach and community involvement in improving housing and living condition has been a best alternative. Community participation has been rarely discussed, however, in the context of urban regeneration.

However, the quality of participation varies from project to project. Moreover, in spite of the failure of many urban planning programs designed *without* the participation of target communities, some professionals continue to question the value of community members' participating in program design, implementation, and evaluation.

This research brings highlights and suggestions on how to overcome these challenges and use the opportunities for development. This study explores the opportunities and challenges in implementing community initiated urban Development Projects. Many government and nongovernmental development projects and programs put much emphasis on community involvement in development processes (Wema, 2010). These efforts are due to a belief that participatory planning can help development planners and policy makers address community needs and sustainable development.

This paper therefore, critically examines the application of the concept of community participation in the urban redevelopment process in Makongo juu and Tianzifang in Shanghai China. Comparative achievements are given; problems faced examined and possible solutions are put forward. Challenges and opportunities for replication in similar environments are discussed. Preliminary findings revealed that willingness of residents to release part of their plots for improving public infrastructure has made the projects successful.

1.1 Research Objectives

1.1.1 General Objective

The overall research objective was to explore opportunities and challenges in implementing community initiated urban redevelopment projects.

1.1.2 Specific Objectives

1. To identify opportunities in implementing community initiated urban redevelopment projects
2. To identify Challenges in implementing community initiated urban redevelopment projects
3. To recommend the best implementation strategies for community initiated urban redevelopment projects

1.2 Significance of the study

The need for this study came from ongoing remedial efforts of improving environmental challenges to meet Millennium Development Goals (MDGs) in 2015. More over Challenges facing local government in providing public infrastructure and service made a turning to the community that they can organize themselves and initiate redevelopment and infrastructure improvement projects in order to improve their wellbeing. Therefore, knowledge generated from this research will further contribute in identifying challenges and opportunities in implementing community initiated urban redevelopment projects. It will also help policy makers, as well as planners in scaling up successful projects.

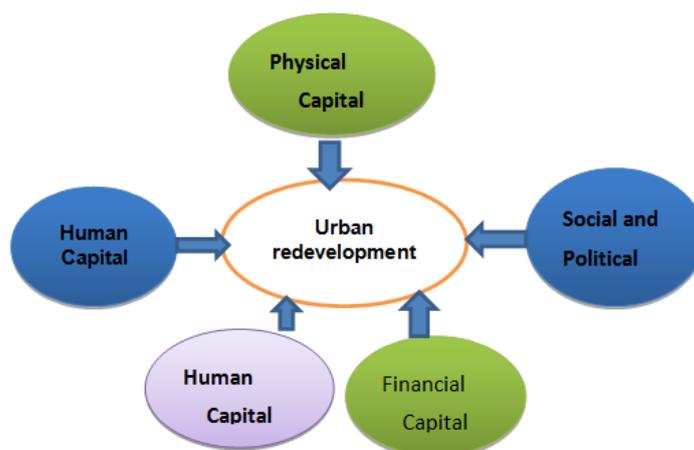

Figure 1: Categories of participation in urban redevelopment

Human: level of education and skills, personal capacity and abilities, health status, number of household members (productive, non-productive), age, household conditions (family background and problems), life philosophy

Social and political: social stratification and hierarchy (vertical), networks (horizontal), social and political contacts, relationships of trust and reciprocity, religion, gender, traditions, access to information, bureaucracy, civil and political rights, memberships

Physical: basic infrastructure (transport, shelters, water, sanitation, energy, communications), provision of public services (access to health care, education, electricity, garbage collection, access to assistance and crime protection)

Financial: income generating activities, savings, credits and loans, remittances, expenditures and costs (consumption)

Natural: land (especially security and stability of tenure), other common natural resources, vulnerability (level of threats of natural disaster)

2. The Study area and Methodology

Urbanization and Urban expansion in less developed country like is an issue given due attention by scholars and state administration for various reasons. One of the reasons is the need to minimize negative impacts of urban expansion in economic, social and environmental impacts, to bring mutual development and symbiotic integration of the rural and urban life that foster social and economic development.

Figure 2: Location Map of Tanzania and Dar es salaam City

Taking Dar es salaam, the largest local authority in Tanzania, its size has grown to more than 4 million people in less than 50 years

Land Area	881,289 Km²
Water Area	61,495 Km²
Total Area	945087 Km²
Total Population	44,928,923
Population Density	51people per Km²
Population Growth per year	2.7%
Average Household size	4.8
Urbanized population	27%

Figure 3: Tanzania Country Basic Information

Total area	3133Km²
Total population	4360000 people
Population Density	2872 people per Km²
Population growth per year	5.6%
Average household size	4.8

Figure 4: Dar es Salaam City Basic Information

Makongo is located in the north-western, peri-urban zone of Dar es Salaam city, about 17 Kilometres from the centre of the city. And approximately 2 kilometers from Mlimani City, and

2 Kilometers from Bagamoyo Road. The area is the fast growing residential and commercial hub of the city.

Historically in before 1960s, the area was covered with Sisal Plantation. Gradually, the peasants and sisal workers transformed the agricultural land into residential plots through subdivision. During the Villagization Programme (1974–76) Makongo was designated a resettlement area, to accommodate people from other areas of the city (Burra, 2004). Later, it saw an accelerated influx of individual home seekers from adjacent institutions and from other parts of the city. One category of landowners evolved during the national campaign of “Human Resources Deployment” from the late 1970s and onwards, which aimed at resettling the urban unemployed, particularly youth, to engage in (agricultural) productive activities. Under this programme, land was distributed to the newcomers by the government. The 1979 City Master Plan incorporated Makongo within the city planning boundary and designated the settlement a green belt area, and later, in the 1985 version, it included both a green belt and institutional uses. However, development of the settlement has continued through informal acquisition and subdivision of the original customary and plantation land. In contrast to the original farming residents, the new landowners or land right holders in the settlement mainly comprise the elite class; well educated public servants, retired civil servants and executives, most of them coming from other parts of the city. Low-income residents occupy the older, consolidated part of the settlement that evolved through customary land tenure and subsequent informal subdivisions. Many of the original landholders have left or have been bought out by new plot buyers.

Currently the settlement occupies an area of 1500 acres, is a densely-settled residential area with an estimated 17,000 inhabitants with an average of 5-6 persons per household, showing that there are between 2840-3400 households.

Makongo is rapidly undergoing both physical form and social structure transformations. Proximity to Mlimani City and two Universities namely Ardhi University and University of Dar es Salaam has promoted land values within the locality.

Dar es Salaam residents are facing unprecedented development pressure as the city's population and economic growth continue. These pressures are exacerbated by environmental damages to residential areas in the past and by potential future stresses. Many communities lack the resources to hire the technical expertise necessary to influence development activities in their areas. They find themselves overwhelmed by the resources that developers can devote to developing plans and proposals. Planning and implementation of urban redevelopment projects based on public funds has been facing challenges.

Most initiatives taken by the residents of Dar es Salaam's unplanned settlements over the last two decades are directed at improving the environment or securing rights to land they already occupy. Another important dimension is to mobilize resources for the provision of facilities and services that have been lacking for many years (Mhamba and Titus 2001)

As a challenge of failure of official system for planning and allocation of land for various uses, Makongo residents made an initiative for the settlement's improvement having concentrated on service provision particularly water supply, road access, land use planning and, more prominently, formation of a community-based organization in order to deal with these issues.

2.1 Methodology

The findings which follow are based on selection of a case study purposely and not in random selection. Case study of Makongo in Dar es Salaam Tanzania was selected to represent some of the diverse contextual variables theorized to affect collective action, and to

represent the different conditions in which the projects was implemented, for comparative purpose. Simply defined, action research is a “bottom-up approach to inquiry which is aimed at producing more equitable policy outcomes” (Silverman,Taylor, and Crawford 2008, 73). Its core principles include reflexive inquiry, local knowledge, collaboration, case orientation, and social action goals (Greenwood, Whyte, and Harkavy 1993). As a “paradigm of praxis,” action research utilizes social science methodologies to understand lived socioeconomic and political conditions in order to solve real problems (O’ Brien 1998). Data were collected by trained field research teams. The data presented in this paper were sourced from field-work enquiries and the author’s involvement in town Planning practice in the last few years.

The research also is based on the data of various focus group discussion and community awareness meetings with government during initiation of the redevelopment in Makongo and updated data for Makongo settlement, However this involved also interviews with Makongo residents on the their views on the projects and their expectations.. Background data on interview respondents were gathered using structured household and individual questionnaires. In addition, a greater number of unstructured interviews were conducted. These consisted of conversations between the researchers and residents.

3. FINDINGS

Findings from this case study are discussed below.

Characteristics of respondents	No. of respondents	percentage
High income class	16	15.094%
Middle (Upper) income class	26	24.53%
Middle (Lower) income class	28	26.412%
Low-income class	36	33.96%
Male	50	47.17%
Female	56	52.83%

Figure 5: Respondents profiles

A total of 106 people we interviewed in Makongo juu in which 47% were females, and 53% were males. In which 16% are high income earners while 51% are medium income earners and 34% are low income earners

Reasons for residency

In regard for the question of reason for the residency, majority responded that they decided to reside in Makongo juu due to location; it is near other places like institutions and public service. The results also revealed that 15% of interviewed responded that they decided to reside there due to the fact that is near their working place. 26% of inter viwed responded that they decided to reside there due to the fact that their family is there while others 17% decided to reside in Makongo due to thet fact that they rent a house in Makongo.

Figure 6: Reasons for residency

3.1 The need of the redevelopment

Makongo is an important area of the Hill socially, economically, nationally and internationally. The area in its built form is unable to cater for the present and future population and its impact on the urban environment and demand for infrastructure services commercial and office spaces. Even though Makongo area is planned, but the areas face problems of poor infrastructure such as access roads, water supply. Internal circulation is problematic. The narrow tracks that serve both motorized and non motorized traffic are not paved and have no side drains. Onsite sanitation is the only method available and offers two options, either a pit latrine or septic tank system. Despite Makongo being a potential area for real estate development; it has been experiencing environmental deterioration for quiet sometime. Inadequate services such as water supply, accesses roads have being constraints in developing the areas as it is supposed to be. Unique location of Makongo makes it a respectable competitor for real estate development. Potential developers, business owners, and residents must be able to accommodate their own needs as well as modern zoning and building code requirements while respecting the form of the community. Makongo Layout Review Plan will enable communities to retain greater control in implementing their Plan. It provides Makongo residents with enhanced ability to negotiate with developers and provide economic incentives for projects that fulfill the community vision.

In our fast-paced, modern lifestyles in a fast growing city of Dar es Salaam where people have multiple options as to where they can live, work, and shop, convenience and accessibility are considered essential for a successful Makongo. Parking, pedestrian and vehicular circulation must be designed in a predictable, logical manner, providing multiple routes in a highly interconnected network. At the same time, density and a flexible mix of uses are vital for creating the critical mass to ensure that Makongo is vibrant, walkable, safe, and sustainable. Section 15(7) gives the mandate to review detailed planning schemes where needs arise and Section 22(2), which gives mandate the director of Town and Rural Planning to direct the review of Details Plans within five years or at an extended time as the director may determine. Due to above mentioned reasons; there is a need for reviewing Makongo Layouts for better development of Makongo

3.2 Vision:

To have a well-planned area for sustainable economic and social development.

3.3 Objectives:

The specific objectives to be achieved by the Redevelopment plan for Makongo Juu area are:

- (i) To create an orderly hierarchy of roads within the entire sub ward and linkage to neighboring sub wards.
- (ii) To develop a series of residential clusters in the undulating settled and unsettled areas
- (iii) To reserve land for appropriate social facilities and civic amenities such as schools, health centres, fire stations, shopping areas and community centres.
- (iv) To improve accessibility to commercial facilities by creating commercial centres at localities
- (v) To provide various recreational areas and parks in the vicinity of or within residential areas.
- (vi) Accessibility for people from home to work, shops, schools, industry and recreational areas is central to the employment of resources and should be fostered to achieve the greatest possible measure of improvement within limited means/resources.
- (vii) To resolve land conflicts.

3.4 Existing Situation

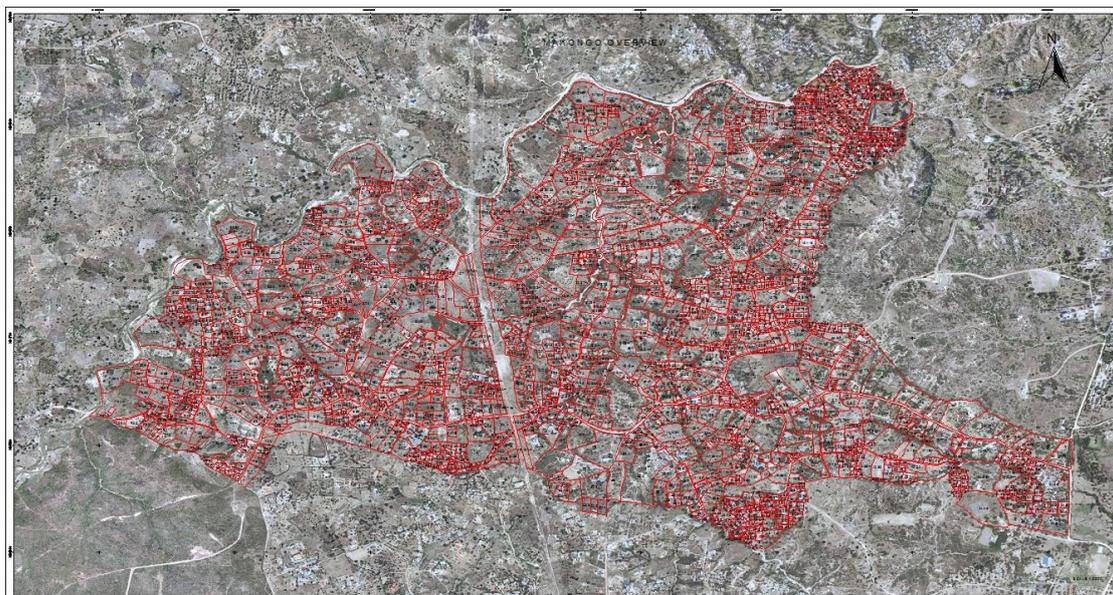

Figure 7: Makongo Overview , existing situation (source: Ministry of Lands)

3.4.1 Previous Plan: Makongo Juu land Use Plan 1985 – 2011

Makongo juu area was declared a planning area in 1985, which implied that land developers and residents in the area could not carry out construction or improvements without getting consent from the City (planning) authority. Town planning schemes to that effect were prepared between 1991 to 1993 and were adopted as official documents to facilitate cadastral surveys and issuance of rights of occupancy. It is more than 20 years now that schemes have not been implemented to achieve the desired outcome. On 22 May 2011, Makongo Juu residents accepted a proposal to adopt and implement the comprehensive development plans. If this area is planned it will be productive and will also contribute to social and economic gains.

3.4.2 Topography

The topography of Makongo is undulating with gentle slopes and plateau. It also has big valleys and streams which drain water in to Mbezi river. These valleys inhibit close movement and increase the cost of transportation. Other valleys provide access where people can pass through and others are wider in the extent that they hinder crossing to other side. So far there are few culverts and no bridges.

3.4.3 Population aspect

Makongo area has approximately 17,000 people with an average of 5-6 persons per household, showing that there are between 2840-3400 households.

3.4.4 Infrastructure

i. Water

Makongo Juu area is benefited by long water distribution network by the Government, in a project popularly known as Chinese water pipes. Most of the Makongo area has been provided with water network but enough water is not available till today. Most of the people depend on buying water from Sinza and Mwenge areas. Treatment of waste water is through soak pits and septic tanks, there is no existing waste water treatment facility.

ii. Roads

Makongo roads are earth surfaced with widths ranging from 2-8 meters. The main road has 8m width and starts from Ardhi University to Goba area. There is a 6m wide road starting from C.C.M office area to Londa Secondary School. Other roads are of 4, 3 and 2m width which are within residential areas. Most developed areas lack access roads particularly where there is congestion of informal development.

iii. Electricity

About 75% of the electricity poles are haphazardly erected within the roads.

iv. Buildings

About 75% of buildings are in good condition, built of sand and cement bricks, iron sheets, and roofing tiles, having good appearance, but incidentally built in unplanned/un-surveyed plots

v. Economic base

Most of Makongo residents are employed in various sectors but others are self employed . There are several large shops and local shops available in the area.

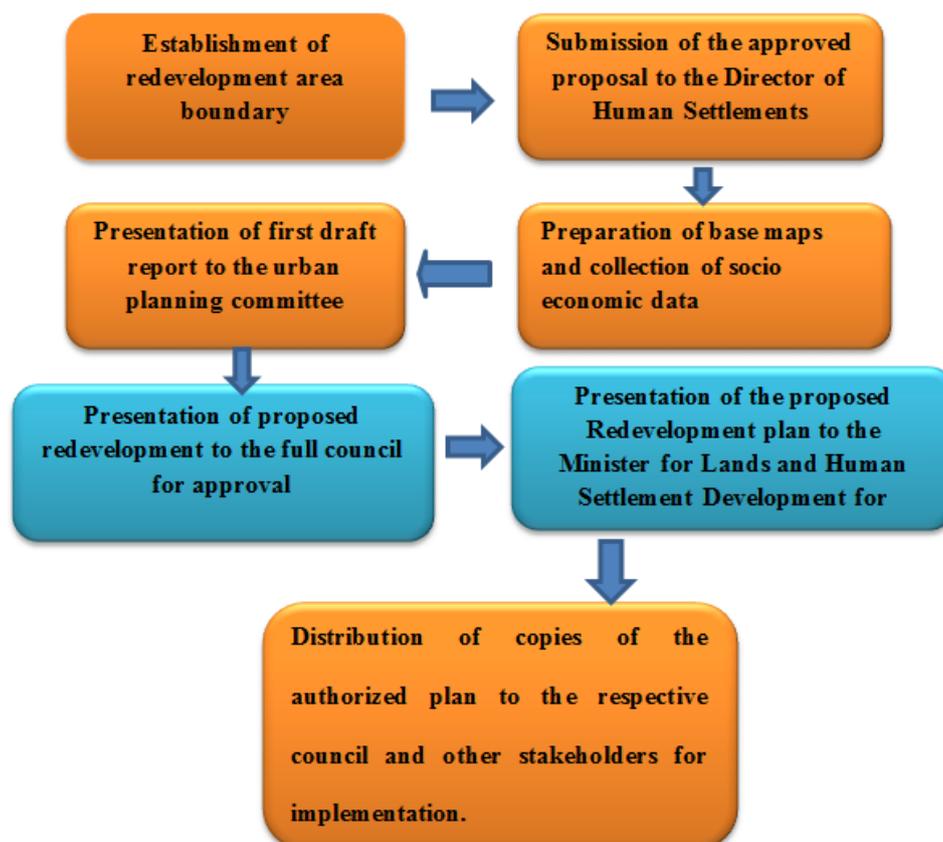

Figure 8: preparation process of redevelopment plan

3.5 Opportunities for implementing the Project

3.5.1 Willingness of the Makongo residents:

Makongo residents, especial property owners, are highly aware and needy of the development. They wish to see their settlements are improved with infrastructures and have the qualities it deserves. This is evidenced by their initiatives over two decades ago.

With the increase in demands for development in the 1990s, Makongo residents realized that many projects in the settlement could not be implemented through normal government funds nor could they be maintained from individual contributions and the community's own resources locally. Thus in 1994, a group of Makongo juu residents formed an organization known as Makongo Juu Development Association (MAJUDEA). The Organization aiming at improving their environment, despite the challenges faced by organization in accessing funds, but dream of Makongo juu residents are coming true as recently in 2011, they reinitiated their ideas of redeveloping their settlement, but at this time this involved the whole Makongo Juu community and the government supported their initiatives. This is evidenced by several meetings held at Makongo Juu between the residents and the Minister for Lands, Housing and Human settlements development and teams of experts from the Ministry and Kinondoni Municipality. More over the study revealed that people are satisfied being involved in the redevelopment process. The study revealed that 58% of respondents are satisfied by the redevelopment process while 15% are dissatisfied and 18% are neutral. 3% are very dissatisfied, and majority of them claimed that they are worry on the compensations' amounts for their lands taken for public use that may be might not be in current market price

Variable	frequency	percent
very dissatisfied	3	3%
dissatisfied	16	15%
Neutral	19	18%
Satisfied	62	58%
very satisfied	6	6%
	106	100%

Figure 9: community satisfaction in participation in the redevelopment process

Willingness of the residents to release part of their plots for allowing provision of public service

This is among the opportunities which helped the project to take off. Residents are ready to release part of their land for provision of public infrastructures such as roads, water service, electricity, drainage, public offices etc. People are ready as they were promised to be compensated according to the current market price.

3.5.2 Political will

In any development project, if it gets support from decision makers, there is a greater chance for the project to succeed. In Makongo project a positive support pioneered by the Ministry of Lands, Housing and Human settlement development, and Kawe member of Parliament is among the reasons for successful of Makongo project.

3.5.3 Community Capacity

There was a challenge of the capacity of the Makongo residents involved in redevelopment process. As reviewed in last two decades of their initiatives in redeveloping their area, most people were unable or unwilling to spend their time in a seemingly never-ending series of meetings trying to make sense of bureaucratic jargon and procedures. The study revealed that despite of having some residents who were having knowledge of the profession, the bureaucratic process of following legal procedures made them give up before achieving their goals. Different people may have very different ideas about what is important and desirable to make life better (even if they appear to belong to the same 'community of interest' and live in the same area or neighbourhood). This has been a challenge to Makongo residents, some of them didn't see the importance of joining in the initiatives. But intervention of the Ministry of Lands, Housing and Human Settlement development in supporting Makong Residents and building Capacity to the residents, and creating awareness, has highlighted that there is a bright future ahead.

3.5 Challenges for implementing the Project

The key challenges to engaging Makongo Juu residents and stakeholders in Makongo juu processes are

- *Socio-economic circumstances of people living in renewal neighbourhoods*

Makongo juu Residents' negative experiences with Government Authorities decrease their levels of trust and willingness to get involved in Urban redevelopment process. This is due to the fact that the cash compensation has been a challenge as majority of land owners claims that they are in worry whether they will be compensated according to market price. However this issue was clearly sorted by Minister of Lands

Prof Tibajuika who assured Makongo juu residents that, the development in Makongo juu is not aiming to make others poor, but to make all progress.

- *Maintaining engagement over several years across a range of community issues*

Unlike most government agencies which engage the community in one-off or issue specific policy areas, Community Renewal is tasked with engaging the community across all issues that could lead to improved quality of life and well-being. Furthermore, urban redevelopment requires intensive engagement to achieve outcomes.

- *Balancing bottom-up with top-down priorities*

Balancing whole-of-government priorities, resource limitations and the aspirations of local communities is a continuing challenge for place-based programs urban redevelopment. Managing people's expectations and encouraging government agencies to realign their core business and budgeting processes are key strategies adopted by Makongo juu urban redevelopment Task Force to address this challenge.

- *Imperative to 'get stuff done'*

A further challenge to the program's community engagement success arises from balancing the need to get projects on the ground while taking a systematic approach to ensure the underlying issues of neighbourhood disadvantage are addressed. Extensive periods of planning and analysis can alienate community members who just want to see positive action in their neighbourhoods.

Conclusion

African cities are growing at 3.9 percent annually, the highest in the world. As Africa urbanizes at a faster rate than any other region in the world, a more integrated approach in urban redevelopment is needed to face these Challenges. More Comprehensive, Innovative & implementable redevelopment approaches are needed in this fast growing continent. Capacity Building to land use Planning Professions is highly needed. Makongo represents a case of an urban community taking land use planning and settlement management initiatives to address their problems, to promote their livelihood and to safeguard their rights to land and to a democratic space in planning. The case portrays the potentials and ingenuity of popular, community initiatives in their responses to the growing deficiencies in settlement management and provision of urban services by the public sector. The other factor that facilitated the participation process of Makongo was the intensive public consultation conducted with the different groups of the residents. These forums had played an important role in bridging the perception of the public and the government about the Makongo juu project. In addition, the public forums falls in the *consultation* level of (Arnstein 1969) *Ladder of Citizen Participation* whereby the public was able to forward their concerns with no guarantee of being considered as it was evidenced by the 3% dissatisfaction with the public consultation of the study's informants and failure to consider some of the public's demand. However, the establishment of the representative committee has increased the level of participation since they were advising the Task force which comprise the Ward, Ministry and Municipal officials whereby the decision making power were still in the hands of the officials, thus there is a need for involving private sectors in detailed planning and implementation of redevelopment plans for sustainability.

The participatory planning paradigm shift: Comparing disciplines and methods

Jan-Hendrik LE ROUX, Elizelle Juaneé CILLIERS, North West University, South Africa

ID Number: 167

Public participation is a process where the public is involved in decision-making, regarding planning aspects that interests and affects them. There are various benefits for Town Planners and other professions when increasing the inclusion of the public in the decision-making process, especially in terms of development issues and creative thinking. Advantages include the improvement of the effectiveness of plans, the resolving of conflict by enhancing consensus between stakeholders and the building of social capital. Along with the advantages are also certain challenges and limitations, regarding public participation, Town Planners have to deal with the choice of participants, practical implementation of theoretical ideas and in certain cases dealing with the unrealistic expectations of the communities.

This study firstly focuses on the paradigm shift public participation has experienced over time and the contrasting approaches that emerged from it. This study further focussed on how public participation is defined and executed in different professions and disciplines. The opinions, methods and problems, regarding public participation, as used in Planning, Health Sciences and Geography in South Africa, was evaluated and compared.

The research concluded with recommendations to enhance the successfulness and effectiveness with regards to the current public participation approaches in South Africa, based on the collective results and findings from the various perspectives and disciplines, as well as the findings regarding the effect of computerised methods on participatory processes.

Introduction

South Africa is a very unique country due to its history and heritage and as a result requires a unique approach to planning, accommodating the different cultures in the country, whilst still improving the country as a unit in terms of its economic, environmental and social status. This poses a huge challenge to unite all the citizens of the country, regardless of the differences in race, culture or belief system.

Public participation is one method which, if implemented correctly, can provide valuable assistance in the search of unity in South Africa, whilst simultaneously enhancing the success of future urban and rural planning. Public participation has many benefits, which will be mentioned later in the paper. It has the ability to help citizens reach a consensus regarding a certain matter, improve decision-making processes and ultimately to help a country move forward and improving its structures. This is exactly what a country, such as South Africa needs in order to experience progression and improvement.

Public participation in South Africa therefore needs to be critically evaluated to generate best-practice methods. In this study the current state of public participation in South Africa will be evaluated. The study will conclude by providing recommendations to enhance the effectiveness with regards to the current public participation approaches in South Africa, based on the results and findings made in this study.

1. Defining public participation

Ordinary citizens, who form part of the general society, want to be informed in detail about decisions that affect them before these decisions are taken (Arbter *et al.*, 2007:6). They want to be able to have a say in potential developments and have direct involvement in current projects and all the development decisions that go with it. Public participation basically comprises all of this. It is a basic principle of democracy. Voting in elections and supporting petitions, are other examples/forms of public participation (Toth, 2010:296).

Public participation can be described as the process where the ideas, opinions and concerns of local communities are collected and analyzed to be used as resources to improve plans and projects that interests and affects them (Ferguson & Low, 2005:7). It is a tool which Town and Regional Planners use to give them a better knowledge of a specific site, as well as an insight to the needs of the community residing in the specific area. This knowledge can then be used by the Planner and other experts (i.e. Developers, Architects and Quantity surveyors) to develop better, more sustainable projects.

Currently in South Africa there is not much emphasis placed on comprehensive public participation. Although policies provide support for participatory processes (i.e. Environmental Impact Assessments (EIA), Integrated Development Plans (IDP), Environmental Management Frameworks (EMF)) these theoretical ideas are not always implemented to their fullest extent.

1.1 Benefit of involving the public

The benefits of public participation include, but are not limited to the following:

- Improve effectiveness (Smith, 2003:25):
 - Decisions can be complex and therefore all relevant information, views, interests and needs should be included and understood;
 - Public participation results in higher quality decisions.
- Meet a growing demand for public participation:
 - The public has a desire to be involved in making decisions that will affect them;
 - There is a need for greater openness of decision-making processes;
 - The public doesn't always trust only expert advice.
- Resolve conflicts:
 - Negotiate tradeoffs;
 - Seek consensus between public and developers.
- Enhance public knowledge, understanding, and awareness (Ferguson & Low, 2005:9):
 - Share information with the public;
 - Opportunities for stakeholders to hear each other and better understand the range of views on an issue.
- Allocate scarce resources (Ferguson & Low, 2005:9).
- Empowerment of the local community (Petermann & Troell, 2007).
- Improving decision-making (Petermann & Troell, 2007):
 - Develop a consensus among key role players to improve performance;
 - Determine the impact of the project in question.
- Understand the needs of the actual users of the space:
 - Build social capital (Cilliers *et al.*, 2012).

Apart from the advantages that public participation has to offer, it is also important to note that the negligence of participatory planning processes as part of any future development plan, may hold many repercussions which are negative for society and also for the remainder

of the specific project. Public participation is however, not a simple and easy task. It has various challenges and limitations as explained accordingly.

1.2 Challenges and limitations of public participation

One of the main challenges when considering public participation is the issue of culture and ethnic differences (Beebejaun, 2006:4). In South Africa this is especially true, because of the multi-cultural population and segregated urban form.

Petermann and Troell mention the following challenges which Town planners are confronted with:

- The choice of participants: For the best results all possible participants should be included, but due to time and budgetary constraints this is not always possible. Stakeholder identification is thus a crucial issue to ensure successful public participation.
- From theory to practical implementation: Petermann & Troell (2007) states that it is not easy to implement theories during the participatory process. It is easy to be creative and jot a few notes down on paper, but to implement these ideas is very difficult. Creative approaches are needed to facilitate the involvement of stakeholders and ensure comprehensive public participation.
- Life span: One of the key words in Planning is “sustainability.” It is therefore important to sustain the benefits of public participation beyond the life span of a specific project. Public participation should keep the future vision in mind, while addressing current needs.
- Unrealistic expectations of communities: It is extremely important to get communities involved in decision-making processes, but communities should be aware of their role and level of involvement in the process. If expectations can't be met by Planners and other experts in the same field, it may result in an unhappy and rebellious community which in turn can lead to more damage being done (Ferguson & Low, 2005:9).

1.3 Paradigm shift

It is important to mention and discuss the fact that public participation approaches have changed a lot during the past couple of decades. These changes can be seen in South Africa, as well as in the rest of the world. Over time the idea of public participation and its role in development has climbed up and down the “importance ladder.” Through all this shifting two basic paradigms has surfaced namely the top-down approach and the bottom-up planning-approach, as captured in Table 1.

Top-down	Bottom-up
No real public involvement	Public involvement
Special interests	Public interests
Capitalistic	Democratic

Table 1: Two different paradigms in public participation

Source: Own Creation (2012)

Smith (2003:22) refers respectively to these approaches as favouring “special interests” (referring to the top-down approach) and “public interests” (referring to the bottom-up approach).

The top-down approach in terms of public participation basically implies that the public is not the main focus group or decision-maker, but rather the local authorities and policy-makers. The public is mainly “informed” about decisions, and communities don’t have an advisory or co-planning role in the process.

The bottom-up approach with respect to public participation is nearly just the opposite. The public is the main focus group and decision-maker. More detailed procedures are taken to involve the community and more community members are interviewed to get a more holistic view of the current situation (Smith, 2003:22).

This “more sustainable” bottom-up approach is starting to get increasingly important for Planners as well as for other disciplines, in South Africa and the rest of the world. However, from research conducted it was evident that different disciplines approach public participation in different ways, and the bottom-up approaches of participatory planning varies among the disciplines.

2. Comparing participatory processes

In an attempt to create a best-practice approach to comprehensive public participation, various disciplines in South Africa were compared. The empirical investigation of this study focused on three different professions (or disciplines) in South Africa, namely Town and Regional Planning, the Health Science Department and Geography/Environmental Science Department. The goal was to analyse the following form each discipline:

- 1) Views regarding public participation?
- 2) How public participation is executed in the specific profession (methods)?
- 3) In their own opinion, what part of the public participation process needs to be revised and improved?

The results obtained gave an indication of the current state of public participation in South Africa and between the different disciplines.

2.1 South Africa: Town and Regional planning approach

South Africa (2012:7) defines Land use management as “regulating and managing land use and conferring land use rights through the use of schemes and land development procedures.”

Planning in South Africa is regulated by the Municipal Structures Act [\[No. 117 of 1998\]](#). It functions under the authority of the IDP (Integrated Development Plan) and SDF (Spatial Development Framework) of each district in the country. The IDP clearly acknowledges the public participation process. However, there is no legislation guiding the quality or quantity of public participation needed, and public participation is thus (although compulsory for most development applications) not monitored or measured.

2.1.1 Methods

Some of the public participation methods which are used in Town and Regional Planning are guided by specific legislation: The Town-Planning and Townships Ordinance (15 of 1986) mentions the advertising of applications in newspapers {Article 56(b)(i)} and by placing informative notice boards at the site of the applicant {Article 56(b)(ii)}.

The public can respond to these advertisements by objecting to an application. Article 56(2)(a) of the Ordinance states that the local authority may give further notice of an application by “posting a notice in such a form as may be prescribed in a conspicuous place on its notice board...”.

According to Article 59(1) of the Ordinance “An applicant or objector who is aggrieved by a decision of an authorized local authority...may within a period of 28 days from the date of the publication of the notice...appeal by lodging a notice of appeal...” This is also where the public can let their concerns be heard.

Lastly, according to the Town-Planning and Townships Ordinance (15 of 1986), if someone in the public objects a hearing will have to be scheduled according to Article 59(5)(a) of the Ordinance. A Board shall determine when such a hearing will take place. Article 59(6)(b) states that the public can state their case and provide his/her reasons why an application should not go through.

2.1.2 Problems – Needs revision

As stated earlier there are a lot of processes involved in land use management. These processes are all being “guided” by the Town-Planning and Townships Ordinance (15 of 1986).

There are no clear objectives and measurements for successful participation processes. According to the Ordinance, a site notice and two advertisements (one in the local newspaper and one in the provincial paper) are adequate notice and involvement of the public. “An objector may appeal within a period of 28 days from the date of the publication of the notice” – Article 59(1) of the Town-Planning and Townships Ordinance (15 of 1986).

Furthermore the Ordinance does not recognize the adjacent house owners of a specific terrain, and therefore they (the people that will be most affected by a new development or rezoned erf) are not even directly approached.

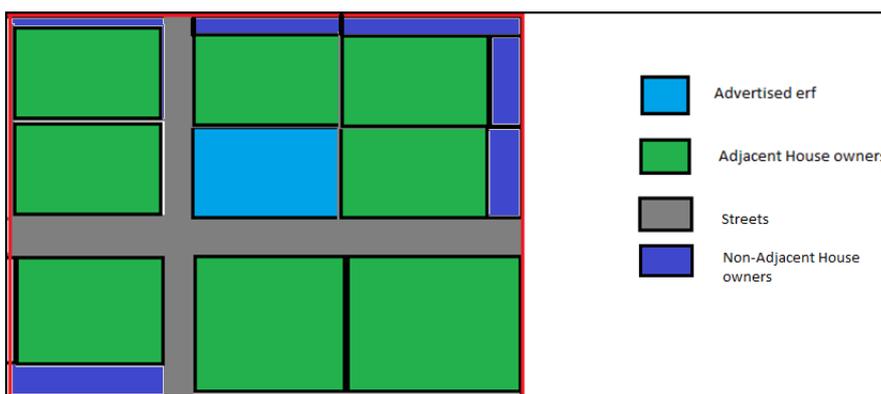

Figure 1: Adjacent land house owners
Source: Own creation (2013)

The level of vocabulary used in the newspaper articles and on the notice boards are extremely high. Excellent vocabulary with difficult terminology is definitely beneficial when working with professionals in the corporate world, but for public participation it is not always necessary. The general citizen (especially in South Africa, with the high levels of poverty and the low levels of education) can't always understand what is being said on the notice boards

and in the advertisements. The ordinance assumes that the public has the necessary knowledge about land use management processes, but in reality it is not true.

2.2 South Africa: Health Sciences approach

"We can do this and that, but what is it that YOU want?" It's a summary of exactly how the Health Sciences discipline approaches public participation. They work using grass roots approach, implying using a bottom-up approach.

Here the focus is on working with the community, not for them. It is viewed as a more sustainable approach – human driven, making sure that the local community understands exactly what it is they are doing at a specific terrain when they are working on a project. The objective is not only to improve the health of the people, as other parties might think, but rather to enhance and equip communities with skills and education.

By working this way in creates a sense of identity and ownership among community members as well as pride and passion.

2.2.1 Methods

The public participation methods used in the Health Science discipline is approached from a bottom-up perspective.

Before a project or initiative is started, a meeting is scheduled for all the relevant stakeholders where the vision of the project is shared. It is important to mention that the stakeholders do not only involve the local community, but according to Sequeira & Warner (2007:10) stakeholders include all the "persons or groups who are directly or indirectly affected by a project, as well as those who may have interests in a project and/or the ability to influence its outcome, either positively or negatively. Stakeholders may include locally affected communities or individuals and their formal and informal representatives, national or local government authorities, politicians, religious leaders, civil society organizations and groups with special interests, the academic community or other businesses." At these meetings each stakeholder can state his/her case and say what problems he/she sees by tackling this project. The aim of the meeting is to reach a consensus between all the stakeholders.

Another method is by doing an ABCD needs assessment. "A growing community-organizing movement, asset-based community development (ABCD), posits that the glass is half full rather than half empty. Rather than focussing on community deficits like crime, vandalism, unemployment or drugs, ABCD aims to identify and mobilize the positive attributes inherent in local government, businesses, nonprofits, voluntary associations and individuals." (Walker, 2006). The ABCD Institute spreads its findings on capacity-building community development in two ways: Firstly through extensive and substantial interactions with community builders, and secondly by producing practical resources and tools for community builders to identify, nurture and mobilize neighbourhood assets (Assessnow, 2009).

2.2.2 Problems – Needs revision

Comprehensive public participation would require the public to also be included in the processes, and not just the selected stakeholders. Another problem that were identified were the issue of different cultures, beliefs and backgrounds, as interacting and communicating with the local community itself is a challenging issue.

2.3 South Africa: Geography & Environmental management approach

Geography- and Environmental management disciplines are probably the disciplines with the most public participation in practice in South Africa. These disciplines are however very

sceptic to use the term “public participation” (DEAT, 2002:6). They say it can be misleading in a number of ways. Every citizen is important, but the term “may be misinterpreted as excluding the private sector and non-decision making authorities.” (DEAT, 2002:6). These groups may perhaps feel excluded from the public participation process. Geography- and Environmental management disciplines therefore prefer to use the term “stakeholder engagement” when talking about participatory processes.

Environmental management defines stakeholders as “a sub-group of the public whose interests may be positively or negatively affected by a proposal or activity and/or who are concerned with a proposal or activity and its consequences. The term therefore includes the proponent, authorities (both the lead authority and other authorities) and all interested and affected parties.” (DEAT, 2002:6).

2.3.1 Methods

The Geography and Environmental management discipline uses a significant variety of methods to get the local communities actively involved in decision-making processes. Some of the methods they use include (DEAT, 2002:15):

1. **Legal Notices** - Notices which informs stakeholders and the rest of the public of a certain project or proposal. These notices are required by law (South Africa, 2010:59).
2. **Advertisements** - Advertisements in newspapers or magazines to inform stakeholders and the rest of the public of a certain project or proposal. It is important that these advertisements should not be hidden in sections in the newspaper where they are generally overlooked.
3. **Websites** - Websites are created that conveys project information as well as announcements regarding the project or proposal. Readers can provide their opinions from their homes via the internet.
4. **Field trips** - Tours to the specific site where stakeholders can see for themselves what’s going on at the site and what the proposed plans are going to look like.
5. **Public meetings** – The proponent meets with the stakeholders in a public place. Anybody can join these meetings. At these meetings the proponent gives a presentation to state the situation, which is then followed by a question and answer session.
6. **Central information contact** – Designated contact persons are chosen to be communicators for stakeholders and the public.
7. **Surveys** – Surveys for collecting information from a percentage of the population. Surveys can be telephonically or through questionnaires.

2.3.2 Problems – Needs revision

A few problems or challenges has been identified in this discipline which needs to be revised in order to make the public participation process, or “stakeholder engagement process”, more significant and sustainable.

According to DEAT (2002:16) the public participation process is only undertaken during the environmental assessment stage. The problem with this is that many planning- and strategic decisions have already been made at this stage, which means that the public could not give any insights or raise concerns of the specific project.

Furthermore, low levels of literacy, low language education and financial constraints are all challenges that are faced. These challenges lead to capacity constraints – it’s difficult to get a mass amount of citizens to engage effectively and equitably in the participation process (DEAT, 2002:17).

When it comes to environmental issues there is generally a lack of interest and concern among local communities. The level of public participation regarding environmental issues thus faces a huge challenge. If the community don't show any interests or express their concerns, environmentalists cannot execute their projects as accurately as they would have wanted to (DEAT, 2002:17).

3. Conclusions

It is evident that public participation is crucial when development decisions have to be made, no matter what type of decision it is or in what discipline or profession it emerges. It forms part of any decision-making process and is necessary for effective and successful decisions to be made in terms of future development options and possibilities.

From the theoretical findings made regarding public participation, it is clear that participatory processes provides various advantages for Planners and communities, but it also comes with various challenges.

A SWOT-analysis of the current state of public participation in South Africa was done showing the following results:

- Strengths:
 - Improve effectiveness - The public can also be creative and innovative.
 - Empower the local community by providing opportunities and information.
 - Conflicts can be resolved by negotiating tradeoffs.
- Weaknesses:
 - It is difficult to implement theoretical ideas in the business-environment.
 - Unrealistic expectations of communities which can't be met.
 - Decisions made through participatory processes are not always sustainable.
- Opportunities:
 - By involving the public, better and more creative plans can be developed.
 - Public can develop a sense of ownership and identity though participation.
 - Public can enhance their knowledge, understanding and awareness.
- Threats:
 - Do not give a community false hope - it could lead to rebellious communities.
 - Make sure that the participatory regulations given in certain policies, such as the EIA, are strictly followed.
 - Always be consistent and fair when working with community members

The main objective of the empirical study was to compare the public participation approaches between different disciplines in South Africa. By comparing these disciplines an accurate picture could be formulated regarding the current state of public participation in South Africa. **Error! Reference source not found.** summarises these approaches between the Town Planning-, Health Sciences- and Geography/Environmental disciplines in South Africa.

Table 2: Comparing approaches towards public participation from different disciplines

	Town and Regional Planning	Health Sciences	Geography
Method	<ul style="list-style-type: none"> • The Town-Planning and Townships Ordinance (15 of 	<ul style="list-style-type: none"> • Bottom-up approach • Before project is initiated – 	<ul style="list-style-type: none"> • Combination of Town Planners and Health

	<p>1986) act as a guideline for public participation.</p> <ul style="list-style-type: none"> • It states that the public should be given notice when there is an application (notice boards and newspaper article). • A member of the community can appeal within 28 days from the publication of the notice. • If there are objections, a hearing will take place where community members can state their opinions or feelings. A Board shall then make a final decision. 	<p>meeting is scheduled for all relevant stakeholders to discuss the vision of a proposal of plan. Each stakeholder can state his/her case at this meeting and compromises are made until a consensus is reached.</p> <ul style="list-style-type: none"> • Involve the public by going into the community and asking exactly what it is they want. • ABCD needs assessment – What are the needs of the community. 	<p>Sciences.</p> <ul style="list-style-type: none"> • Also a bottom-up approach to public participation, but with necessary legislation in place to guide some aspects of the process (NEMA). • Similarities with Town Planning – Also uses notice boards and newspaper articles. • Public meetings may be held where all stakeholders are informed of proposals and projects.
Positive	<ul style="list-style-type: none"> • Every Planner follows the same guidelines (Ordinance), therefore the format of notices and the application processes stays the same in every part of the country. • Other policies (IDP and SDF) within the Planning discipline support participatory processes. 	<ul style="list-style-type: none"> • By getting all relevant stakeholders to reach a consensus, a lot of conflict is avoided. • Bottom-up – Follow a grass root approach. Makes the community very optimistic by talking directly to them and making them feel valued – gives ownership and identity. • Sustainable approach – human driven. Not only to improve health, but also equip communities with skills and education. 	<ul style="list-style-type: none"> • The public are better informed when there are decisions to be made, while the necessary legislation is still taken into consideration. • Notice to adjacent house owners should be given.
Negative	<ul style="list-style-type: none"> • The Ordinance is limited in terms of its approach solely to public participation. It does not accommodate participatory processes as well as it should. • Notice boards and newspaper articles are the only way of notifying community members about applications. • Realistically, most of the community members don't even see the newspaper article, which is published for only 2 consecutive weeks. • Adjacent house owners not taken into consideration. • Level of vocabulary in notices is too high for most normal community members to understand. 	<ul style="list-style-type: none"> • Different cultures and ethnic groups in South Africa. Difficult to accommodate and communicate with all the different cultures. • Communities may tend to complain about other "less relevant" issues and if you don't look into those issues they may get demanding. 	<ul style="list-style-type: none"> • A lot of legislation to support public participation, but it exists on paper and has not yet been implemented in practice. • Participation process is undertaken during the environmental assessment stage, where many strategic decisions have already been made. Therefore the public can't influence those decisions. • Different cultures and ethnic groups in South Africa. Difficult to accommodate and communicate with all the different cultures.

Source: Own creation (2013)

It can be concluded that in South Africa there are positive and negative aspects regarding public participation. Although basic participatory processes is in place and captured in legislation, the issue of comprehensive and qualitative participation should be evaluated and enhanced.

South African town planning disciplines can learn from other disciplines and thus equip itself with better tools and “formulas” to enhance creative and inclusive participation processes. Table 3 indicates the ideas and initiatives Town Planning in South Africa can “borrow” from other disciplines to enhance its current approach to public participation.

Table 3: *Initiatives from other disciplines to enhance the current approach of public participation in Town Planning*

Health Sciences	Geography	International approaches
<p>1) Bottom-up approach – take the local communities into consideration. Reach them at their level, connect with them, and find out exactly what their needs are (not necessarily money, but perhaps education or ownership).</p> <p>2) Sustainable approach – Human driven, by making the community understand exactly what the mission is of a certain project. Objective is not only to improve health, but also to equip communities with skills and education.</p> <p>3) Balance between legislation and reality – legislation more simple in the sense that community members understand it.</p> <p>4) Before a proposal of project is initiated – meeting is scheduled for all relevant stakeholders. Stakeholders are informed of the proposed project. Compromises are made and a solution is found where and all stakeholders walk away satisfied.</p>	<p>1) “Stakeholder engagement” rather than “public participation” – participatory processes include the public, but also authorities, municipalities and other interested and affected parties.</p> <p>2) Bigger variety of methods to inform the public of proposals and projects e.g. websites and field trips. Through these methods the public can also ask questions, raise their concerns and give their opinions with respect to a certain project.</p> <p>3) Notice to adjacent house owners should be given (South Africa, 2010:60).</p> <p>4) Uses reasonable methods when a person wants to, but can't, participate in the process, because of disability, illiteracy of any other disadvantages.</p>	<p>1) Don't only use traditional methods, but also more creative participatory methods to intrigue and involve community members even further.</p> <p>2) Holistic approach – seeks to improve social capital and to enhance place-making within public spaces through public participation.</p>

Source: Own creation (2013)

These positive contributions of the various disciplines can be used to improve the participatory planning approaches used within the town planning scope.

3.1 Improving public participation in Town Planning in South Africa

The Town-Planning and Townships Ordinance is one of the key documents that guide the participatory process in South Africa. Other policies that play a cardinal role in determining these processes within the Town Planning arena are IDP's and SDF's. These documents all address public participation, but there are still a few problems with these policies which

undermine public participation and should be rectified to improve participatory processes in Town Planning:

- 1) Definition – It is necessary to define public participation in terms of a planning context. The definition should state the importance, scope and measurable of successful participation.
Town Planning can in this situation learn from the Geography department, who rather uses the term “stakeholder engagement” than public participation. Stakeholder engagement is defined in section 2.3 by DEAT (2002:6). If public participation can be redefined and structured as something like the above mentioned definition it will provide more clarity and better goals can be set.
- 2) Vocabulary – The vocabulary of a document is a very accurate reflection of the professionalism of a document. It is however true that the higher the level of vocabulary, the higher level of education you need to understand the language. South Africa has a very low level of education throughout large parts of the population, which means that the general man/woman on the street doesn’t necessarily have the education to fully understand extremely high vocabulary. Therefore the policies and other relevant legislation, which Town Planners use for public participation, cannot fully be understood by local community members. Newspaper articles and notice boards speak a “language” that can’t be understood by the uneducated.
Policy-makers don’t have to lower their standards and decrease the level of vocabulary of the policies itself, but any documentation or advertisement that can be viewed by the public should be composed with a level of vocabulary that is still correct and professional, but which is readable and can be understood by a local community member.
- 3) The IDP and SDF make provision for participatory processes, but current guidelines within these policies should be revised and improved. More guidelines should be added to accommodate public participation even further. There should be some form of measurement to determine successful participation processes, stating outcomes and specific guidelines to conduct inclusive participatory planning processes.

Public participation is extremely important and the benefits one can gain by executing it in practice are incomparable with what would happen if public participation was excluded. There are certain barriers currently prohibiting participatory processes to develop to its fullest extent, but with the correct management and structures in place, participatory processes in South Africa can improve. Best-practice approaches from various disciplines can be used to guide the Town Planning approaches to be more inclusive, creative and successful. This will lead to major improvements in terms of sustainable development and future town planning.

The “Three-Old” Policy of Community Renewals in China:

Based on Cases in the Pearl River Delta Region

Fengqing Li , Ph.D. Candidate of Tongji University, China

Huang Huang, Engineer of Guangzhou Urban Planning& Design& Survey Research Institute, China

Synopsis: The wide-ranged community renewals in the PRD Region

The Pearl River Delta (PRD) Region , with an area of 41.7 thousand km² and a population of 430 millions, is an important global manufacturing base lies in the South coast of China. Encouraged by a regional policy named “Three old”, which is specially permitted by Chinese central government as a compromise to the reality, this region has been undergoing a wide-ranged community renewal since 2009. According to the statistics from Department of Land and Resource of Guangdong Province, these renewals have covered more than 600 km² urban and rural built-up area by 2013, which is 3.5 times of the total built-up area in Hongkong.

What caused the wide-ranged community renewals in this region recently and why the authoritarian government compromised? What was the mechanism for policy implementation and why these renewals regarded as the origin of community engagement in China ? These questions will be further discussed in this paper.

Figure 1: The Pearl River Delta (PRD) region in south China.

1. Fundamentals of the “Three-old” Policy for community renewal and engagement

1.1 Regional background :renewal as the only way out from the dilemma for local governments.

According to the building life limit and the economic life limit, community renewal is inevitable after a period of urban development (Arthur O'Sullivan, 2011). After World War II, western countries had gone through wide-ranged community renewals from the manufacture era to the post-industrial era. However, these renewals had not occurred in China until 1990s. As the expansion of urban population in PRD, a large number of industrial lands had been replaced by residential area. Moreover a upsurge in community renewal was in the making for the “land quota” was put into operation in 2006.

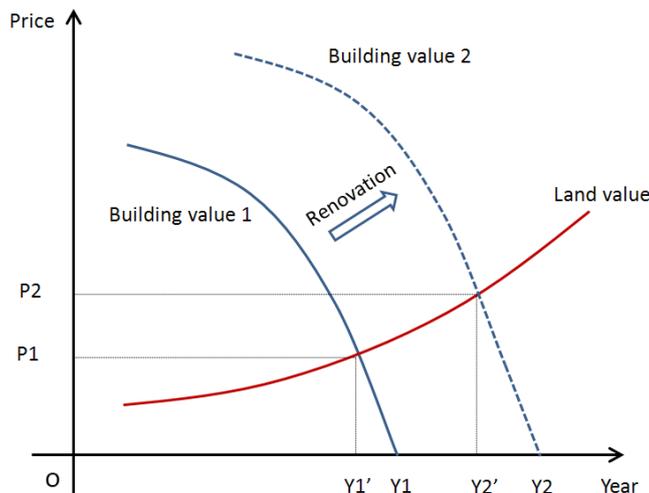

Figure 2: building life limit and the economic life limit

(Y1: building life, Y1': economy life, Y2: building life after renovation, Y2': economy life after renovation. According to Arthur O'Sullivan, 2011)

The “land quota” was addressed by the Central Government of China who hold a tense attitude towards massive consumption of farmland during rapid urbanization, as Chinese written history shows that riots of starving refugees were the main reason of 24 dynasties fell in the past thousands of years. By publishing the Planning Framework of National Land Use(2006-2020) , the Ministry of Land and Resource stipulated the bottom line of farmland with an amount of 1.8 Billion MUs (300 million Acres), and the remaining land quota will be distributed to provinces and municipalities as construction land year by year. Though the quota itself is highly questioned as the food supply has been guaranteed by modern agriculture and international trade today, this policy implement strictly. By such means, the constraint of urban expansion named “construction quota” is founded. No one, including the local government, could occupy any extra farmland without the distributed quota.

As the earliest industrialized region of China, the GDP of the PRD Region soared from 6.5 billion US dollars in 1978 to 757.9 billion US dollars in2012. Meanwhile, urban built-up area expands from 1765km² into 6671km² during past two decades according to the figures of National Bureau of Statistics. The quota for major cities in the PRD Region was nearly exhausted. Take Guangzhou, the capital city of Guangdong for instance, 41 km² of farmland was constructed annually by average from 1996 to 2009, and if this continues, the land quota 2020 for Guangzhou will be spent out before 2014. Community renewal (reconstruction for built-up area needs no quota) is the only way to cope with the dilemma between quota shortage and rapid development.

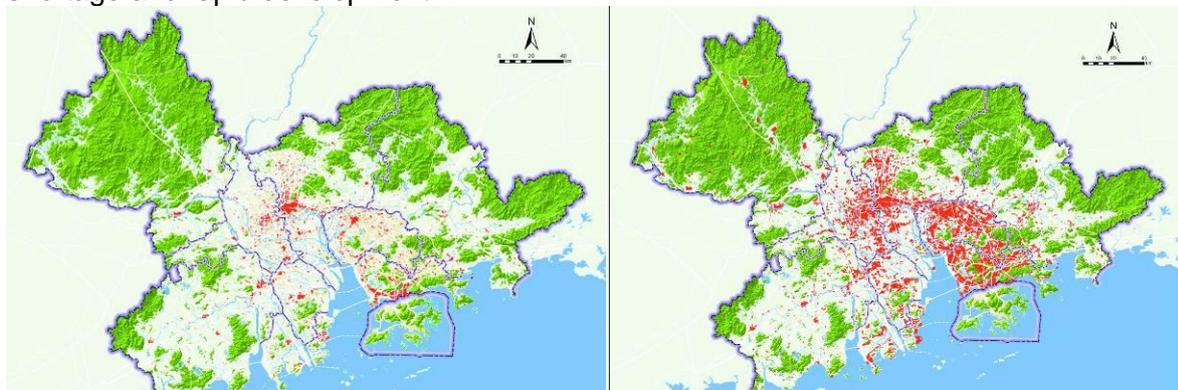

Figure 3:Rapid expansion of constructed land in the PRD Region from 1990 to 2005

1.2 Legislative Background: the “Three-old” policy as a compromise to the reality

According to the Land Administration Law of the PRC (2004), all land in city belongs to the nation as a whole. Any organization, enterprise or individual can rent the state-owned land from the local government for profit-making development through auction. The lease time differs from planning functions: 70 years for housing, 40 years for commerce and 30 years for industry. According to the statistics published by the National Bureau of Statistics in 2010, land rental revenue summed up to 300 billion US dollars by 120 major cities in China which contributed more than 50% of local financial revenue. Chinese local government is becoming land-running enterprise in reality. On the other hand, the law defines that land in rural area (except for mines, meadows, forests, waters, deserts) belongs to village collectives. All rural land are divided evenly and rent to all villagers for free. In order to maintain monopolistic revenue for state-owned land the law also defines that rural land can only be constructed for villagers' dwellings or other agriculture structures. If a real estate program (housing program, commercial program) or a factory needs to be constructed on rural land, the land must be sold to the local government as state-owned land at first in low price, and then it can be sold to developers through auction in remarkable monopolistic price. That is the biggest “commercial confidentiality” of Chinese urban economy.

During the past 30 years, numerous factories had been established on rural land in the PRD Region as “village-ship factories” which belong to rural structures in the name of serving agriculture. At the beginning, these factories were founded by village collectives to deal with agricultural product indeed, which were sanctioned, but more rural land was rented to small enterprises for profit making after a period of time. The local mercantilism governments often took laissez-faire attitude to these illegal factories for two reasons: first, their contribution of tax and GDP; second, the price of land to be developed into industry area was very low so it seemed to be no damage to government benefits. These illegal constructions did not touch the bottom line of the local governments until the local governments realized that the land quota was largely occupied by these factories. Thus the local governments felt obligated to deal with these factories, illegal dwellings and factories should be torn down according to the law. However, there were too many to deal with after a long term of acquiesced attitude from local governments and demolish all illegal constructions was no longer an option at all.

To break the deadlock and encourage community renewals, Chinese central government proposed the “Three-old” Policy (policy of renewal for old towns, old factories and old villages) in 2008 in the name of “encouraging intensive land use”. It is actually a compromise to regional reality. Accordingly, illegal construction land before June 30, 2007 can be exempted and registered as legal property only if the owner willing to pay a certain amount of fine and reconstruct the land following the zoning ordinance. Otherwise if the owner choose to sell the land, he will get a compensation with an amount of 60% of the land revenue through auction organized by local government. The policy is only permitted in the Guangdong province, which is always considered as “traditional pioneer” of reform and opening-up area of China. Encouraged by such compromise, wide-ranged community renewals started in the PRD Region since 2009.

2. Community engagement based on the “Three-old” Policy

As situation mentioned above, the policy is no longer dealing with simple technical issue of land-intensive use, but a redistribution of land vested interest. However, the land fit for renewal are mainly owned by the village collective, which make the villagers as important as the powerful government and wealthy investors. Though the constitution and land law of China define no individual owns any land, the policy implies that villagers had the rights of profit-making through land ownership, just like the local governments.

Based on Muller's theory of public choice (Mueller, Dennis C, 2003), the human society is composed of economic market and political market. Subjects of economic market are consumer (demander) and vendor (supplier). While subjects of political market are electorate,

interest group (demander) and politician (supplier). People has to make decisions on both economic market and political market. The theory further claims that, people always try their best to maximize their benefits on both markets.

In renewal projects, the local government, social investors and land owners (such as the village collective, etc.) constitute a benefits triangle. The government concerns not only economic profits but also political performance, prestige, fame and other political benefits. Based on perspective of the Development Economics (Yujiro Hayami et al, 2005), the government can be regarded as economic organization with public authority. Through renewal projects, the government seek public support for their governance and economic benefits as well. Therefore, the bottom line for local government is the benefits from politics and economy exceed the costs from political and economic risks. It also means the government trends to approve unprofitable program sometimes for political reasons.

The motivations of social investors and land owners in renewal cases are much simpler than local government. From the perspective of "Economic Man", both of them just seek maximum profits and minimum risks in the economic market. Social investors such as capital stakeholders willing to obtain reasonable return on their investment and to avoid potential risks like policy inconsistency, conflict in renewal projects, capital chain fracture and project cycle extension. Land owners such as village collectives are willing to accept the benefits like increasing of land incomes and improvement of living condition but to avoid losing their land rights easily. Land owners like village collectives always trend to choose lower risk plan in the game for their lack of information compared with the other two sides of the triangle.

Based on motivations analyzed above, the game in this triangle is the procedure of redistribution for land vested interest. The transfer of land ownership (if any), compensation for vested interest, demolition-resettlement plan and the FAR are the main issues to be negotiated in the game. If the agreement can be reached in tripartite negotiation among local government, social investors and land owners, a local development union will be formed in a renewal program (Chen Chen, Min Zhao, 2013). Then the renewal plan can be carried out for implementation, otherwise the renewal plan will have to be discarded. Moreover, if there are many "land owners", such as old village dwellings owned by villagers and factories owned by all villagers in one collective, involved in one piece of land, people should vote to decide whether a renewal will take place and which kind of renewal (or compensation) they will accept. Accordingly, the policy stipulates that if 90% of the "land owners" vote for renewal, and meanwhile the owners who vote for renewal got possession of more than 90% of the buildings on the land, the negotiation starts and renewal planning can be made. It called the "double 90" principle in the "Three-old" policy. Besides, other important decision like the type of renewal or compensation, should not implement until it pass the "double 90". So the community engagement is the most important process in every renewal case.

	ROLE	IMFORMATION	ANTICIPATION	BOTTOM LINE
Local government	Public authority	Complete	Political fame Economic Returns	political-economic risks
Capital stakeholders	Social Investors	Well-informed	Maximum Returns	Economic Cost
Village Collective	Land Owner	Incomplete	Maximum Compensation	Land Ownership

Table 1: The benefits triangle of the game for renewal projects in the PRD Region

According to the Ladder of Citizen Participation Theory (Arnstein, Sherry R, 1969), the benefits triangle has constituted a partnership when each side has the power of veto. It represents the senior phase of the citizen power in renewal projects. Therefore traditional

technical renewal planning promoted by powerful authority of government in other places of China is not suitable in this region. Renewal plan should not only propose a technical solution but also respond to all the parties of the vested interest. The voices from villagers should be considered as crucial as voices from powerful government and wealthy investors during implementation of community renewal projects. Therefore the community renewal in the PRD Region guided by the "Three-Old" Policy is widely considered as the origin of community engagement in China.

In following renewal cases of Guangzhou and Foshan, partner engagement and role of planning in policy implement will be further studied.

3. Renewal Project of Lianjiao District, Foshan

3.1 The Event of Emma Maersk

Lianjiao district became world famous for the event of international garbage shipping. According to British Sky Broadcasting Co.(BSY) In November, 2006, the Emma Maersk, one of the biggest container ship in the world, carried 15,000 TEU of garbage back to China after she shipped Christmas presents to Europe. All the garbage was shipped to Lianjiao, a small village in Dali town seated between Guangzhou and Foshan. The event was broadcasted on the SKY TV called "toxic shocked China" which described the garbage collection industry in Lianjiao. As the report had gained widespread concern at home and abroad, China Central Television(CCTV) broadcasted another program to report the situation in Lianjiao. According the report from CCTV, this district had been dealing with garbage sorting, especially plastics, for years and involving nearly a thousand small garbage companies. The annual garbage sorting capacity of Lianjiao exceeded 200,000 tons with poor technique of waste disposal. Therefore, Lianjiao was heavily polluted with toxic smoke in the air and black water in the rivers.

Figure 5: photo of garbage sorting industry in Lianjiao(2006)

3.2 The developing process of Lianjiao district

The situation in Lianjiao is a microcosm of typical rural industrialization in the PRD Region in the past 30 years. According to the research literature (Yang Lian, Yuan Qifeng, 2010), since 1980s, taking advantage of convenient transportation between Guangzhou and Foshan, the village collective gathered farmland from villagers for rent after certain land readjustment and infrastructure construction. In 1992, An industry park for garbage sorting was founded, which covered an area of 112.5ha, 70% of which belonged to Lianjiao village and the rest came from another 4 villages (Lizhong, Lidong, Yayao and Pingdi). The land was all rent by small plastic garbage collection enterprises in shabby bungalows. The total amount of rent from the park was 4 million US dollars in 2006, with an ratio increased by 20% every 3 years. Villagers were satisfied with long term incomes from the rent though they had to suffer from severe pollution. However, the local government could only get 640 thousand dollars from plastics garbage industry as the annual tax, which is one-tenth of the total from Lianjiao district. As the "Emma Maersk" incident exposed, local government considered that community renewal is imperative.

3.3 The plan of community renewal in Lianjiao district

As the fundamental of negotiation, renewal plan for Lianjiao district was proposed by the local government. It provided a future vision for the villagers and investors. According to the planning, trade business was suitable in Lianjiao district for it lies in the joint of Guangzhou and Foshan. In addition, the newly developing business center of Foshan, situated to the south of Lianjiao, trended to extend northwards. The renewal plan concluded that Lianjiao district would be a new part of Foshan city, and the renewal function would include professional trade center, wholesale markets, industry headquarters office, hotel, public services, as well as residential and leisure program.

Figure 6: Renewal planning for Lianjiao district

3.3 The negotiation and engagement for implementation of renewal

The view of renewal plan would undoubtedly bring more profit and the pollution would be controlled. Villagers also expected for more profit and better environment but they always put their ownership of the land at first place. In order to implement the renewal plan, negotiations got started and the process was noted by scholars (Yang Lian, Yuan Qifeng, 2010).

As the land rent was the income source for the villagers of Lianjiao district, villagers in Lianjiao and other 4 villagers mainly opposed to sell the land as "state-owned land". Even the estimate land value may reach 2.75 billion yuan (350 million US dollars in 2006) though auction and the villagers could get 60% (around 200 million dollars) at one time according to the "Three-old" policy. Villagers insisted on maintenance of the land ownership for long-term income. Then three models for development were further discussed with such fundamental.

- (1) MODE 1: Local government control. The local government rent all the land of 112.5 ha for 40 years (which is equal to the rental period of commercial use on state-owned land), and run all programs planned with social investors. The villagers get paid each year as rental and the land, including all buildings above will return to villagers after the rent expired in 40 years.
- (2) MODE 2: Village collective control. The village collectives carry out land readjustment according to the plan and found an incorporated company with social investors to run all programs.
- (3) MODE 3: Local government-Village collective cooperation: The government and the village collectives cooperate found an incorporated company together and share all the incomes and risks.

	MODE 1	MODE 2	MODE 3
Implement the Goal of Planning	GOOD	NORMAL	GOOD
Financial Risk of the Government	HIGH	LOW	NORMAL

Financial Risk of the Collective	LOW	HIGH	NORMAL
Possibility to Pass the "double 90" voting	HIGH	HIGH	LOW
Convenience for loan	NORMAL	NORMAL	HIGH
Convenience for Attracting investors	NORMAL	NORMAL	HIGH

Table 2: Pros and Cons of each mode.

According to the notes from scholars (Yang Lian, Yuan Qifeng, 2010)

There were pros and cons in each mode. Without the participation of the government like Mode1 and Mode3, it is less guaranteed in the Mode 2 as decisions made by villagers are relatively short-sighted and changeable. Compared with Mode 1 and 3, local government trends to choose the latter as there were some obvious defects in the former. In Mode 1, the land is rent by the government but still belonged to the collective as rural land, which means it is not easy for the government to get loan from banks without land mortgage. Moreover, real estate programs such as hotels and residencies are strictly forbidden on the rural land, which is hard to attract big investors and risk rises.

While in the Mode 3, everything seems much better. The collectives offer the land and the local government offers the finance support for construction, all the villagers and the government become stockholders in one land developing incorporated company. Meanwhile, as the land ownership transfers to the company from the collective, it is convenient for applying loan to boost cash flow. And if there is any need of converting some part of the land into state-owned in order to attract a big investor, the government can negotiate with all stockholders, the land fee through auction can flow back as investment for the company. The only need to implement the Mode 3 is pass the "double 90" voting through community engagement.

However, the Mode 3, though attractive, failed to pass the voting for two reasons. Firstly, as 70% of the land belongs to Lianjiao village, villagers in Lianjiao claims 51% of stock ownership, while villager from the other 4 villages opposed strongly against it for fear of losing voting power in the company. Two medium plans were addressed in the process of community engagement as follows: (1) Stripping the voting rights and bonus share rights from stock ownership, which allows Lianjiao village collective owns 64% of the bonus share but 49% of the voting power; (2) The government share more stockownership with more finance investment, until the stock ownership ratio of Lianjiao drop below 50%. Nevertheless, neither of the medium plans approved, villagers reached an impasse for majority ownership. Secondly, founding a company and mortgage the land for loan imply a risk of losing the land if the business runs badly to bankruptcy, which challenges the bottom line of villagers, especially villagers in Lianjiao.

The consensus was finally reached on model 1 though obvious defects can be concluded: the local government obtained the usufruct by rent the rural land, which is strictly forbidden for housing estate. Thus the government took all the risks with limited develop program. But villagers gained 4 million US dollars every year and increased by 10% every 3 years without any risk. What's more, the village collectives can get back all land and buildings above after 40 years without a cent, which seems unfair. It is not hard to come to a conclusion that the government had compromise much during the negotiation because the construction land quota is rare and the village collectives had taken the initiative. The villagers gain incomes without any efforts or risks, which would become a considerable social problem in the coming future.

Anyway, as the consensus was reached, the local development alliance was founded. The renewal project started as planned. When the first phase of the trade center was finished in 2012, the old perspective of Lianjiao district with heavy pollution and garbage everywhere was refreshed like the rebirth of phoenix.

Figure 7: The photos of implemented renewal planning in Lianjiao

4. Renewal Project of Hailongwei District , Guangzhou

4.1 The dispute of farm land quota

Hailongwei is a small island in the Pearl River, seated on the border between Guangzhou and Foshan. There are five villages on the island, with a total area of 20.5km². In a long time ,the traffic was inconvenient of Hailongwei so its development did not follow the typical rural industrialization process of the PRD Region. There were only few enterprises on rural land for manufacture. As there were many brooks on the island, it is suitable for flowers planting industry. Statistics shows that in 2010, the flower trade business in Hailongwei exceeded 2 billion yuan(300 million US dollars in 2010). Because of more incomes from planting industry than manufactures, villagers on the island were satisfied. The flower farmland and brooks were well maintained compared with nearby regions. For this reason. Guangzhou government distributed most of the farmland quota in Hailongwei Island as well, in order to exchange more constructed quota for industrial development in other places.

However, as the traffic barrier of the river was broken by tunnels and metro line, together with the sub-centers of Guangzhou and Foshan had been under construction across the river, land rent in Hailongwei rose sharply and many farmlands for flower planting were replaced by factories and housing estate. In 2012, 55% of the rural land was taken and the land quota almost ran out. There was no more farmland for rent, which means villagers' anticipation for increasing income was shattered by the quota. Of course, they were unsatisfied and even kept building illegal constructions and petitioning constantly. The government felt huge pressure from the protest against quota which can be anywhere but "NOT IN MY BACK YARD".

4.2 The renewal plan for problem solving

In order to solve the problem between land quota and explore a better way of development than rural industrialization as well, renewal plan for Hailongwei Island was proposed by local government. According to the scheme of the plan, all the farmland on the island were arranged together in space without virtually exchange of quota between farmland and construction land. The farmland quota were gathered and arranged as a whole on the southwest of the island, covered an area of 3.2 km². This farmland was planned to be the site of the World Horticultural Exposition of Guangzhou and the biggest flower trade market in Asia after the exposition. Besides, the plan further explained the whole picture of the community renewal for the island. The five villages and industry land would be renovated as a "flower island" with new functions planted in, which include flower exhibition& trade& research, ecological conservation, business office, low carbon industry and waterfront residential program.

Figure 7: The renewal planning for Hailongwei island

Figure 8: Farm land at present(L), in territorial planning(M) and readjustment by renewal planning(R)

According to the renewal plan of Hailongwei, farmland on the island were better conserved and its new role of big events brought better scenery with promising economic feedbacks. Both local government and villagers were glad to see the implementation of the plan and started to negotiate.

4.3 The negotiation for implementation and engagement of the renewal

As Hailongwei is quite near to the sub-centers of Guangzhou and Foshan, the land value is much higher than it is in Lianjiao. Based on statistics, the housing price of Hailongwei area was as high as 250 thousand yuan (4000 US dollars) per square meter in 2012. The social investors was glad to buy constructed rural land and buildings above in this area in order to exchange tremendous profit from redevelopment. Moreover, according to the "Three-old" policy, all constructions including land and buildings constructed before June 30th, 2007, are accepted as a fait accompli and villagers can get compensation through renewal projects. Some village dwellings were more than a thousand square meters and the owners can get millions of US dollars as compensation, or replaced with several new apartment as big as 100-150 m², which can be rented for long term incomes. Under such circumstance, rational villagers would sell their rural constructed land to local government, as the land became state-owned land it can be developed into real estate. The negotiations for renewal plan on the constructed rural land were mainly between villagers and investors; the government only played as supervisor to guarantee the public interest.

The farmland on Hailongwei Island, which can only be constructed as flower & exhibition & trade & research park, on the other hand, attracted no interest of social investors, the negotiation for implementation of 3.2 km² flower land is mainly between the local government and the villagers. Just like the agreements of Lianjiao Project, there were 3 models for renewal implementation: (1) government control, (2) village collective control, (3) government-village collective cooperation. Based on the factors of renewal intention, common profits, joint risks, finance convenience, the model 3 was undoubtedly the ideal choice. However, even though the villagers were eager to get higher profit from the project, they were reluctant to share risks and afraid of losing their ownership of the land through bad management of land mortgage.

Just like the renewal project of Lianjiao, the consensus was reached on model 1, the local government rent all the farmland for 20 years with a payment as much as the manufacture rent. The villagers get the incomes and take no risks at all. After the rent expired in 20 years, all the farmland and facilities above will be return to the villagers. As we concluded in former project, there was no good for the villagers to gain without any risks or efforts, however, the government had no choice but compromised to the villagers who had control of the remaining land and veto to the renewal project.

5. Summary

Extraordinary phenomenon often occurs in Chinese urban development, which western planning theories can hardly explain, such as a small fishing village named Shenzhen had developed into a metropolis with tens of millions of people just in one decade. It is rather difficult to explain the huge power of community renewals in the PRD Region when the present land law was slightly released by the "Three-old" policy. On one hand, if the value of the rural land is fully liberalized, local government in China, who rely on the revenue of state-owned land will be bankrupted. On the other hand, local government feel forced to release some of the rural land value to deal with the shortage of construction land quota. The "Three-old" policy is a compromised and progressive reform to the dilemma. Its implementation in the PRD Region as a successful experiment implies a further implementation for the whole nation in the coming future. The central government has realized defects of the land law are the reason for massive illegal constructions and no one could benefit from the deadlock, therefore the policy implies an amendment of the law in the future.

According to the renewal projects, the construction land quota is one of the rarest resource for regional development in China, so land owners such as villagers have the initiative in renewal negotiations. In order to guarantee the implementation of the renewal policy, a tripartite local development alliance including local government, social inventors and landowners should be found. The alliance reflects the three parties are peers in renewal projects rather than the government monopoly. To sum up, community renewals guided by the "Three-old" policy in the PRD Region is widely considered as the origin of community engagement in China for the power of the government is weakened and the power of village collectives is enhanced. Renewal plan should not only propose a technical solution but also respond to all the parties of the vested interest, which represents the future direction of urban planning development in China.

Abstract: Social capital is a non-economic concept of regional development. This concept emerged out of the thinking about the role of more intangible development factors such as institutions, networks and trust. Is it possible in China to mobilize the social capital to promote the local development and to solve public issues? The present paper is based on the investigation in the village N. The contribution presents the difficulty to mobilize the social capital and the difficulty of the participation in low developed rural China. In the end, the paper suggests that the issue to mobilize the social capital and the enthusiasm of the social members to participate the local development should be considered more in the future in China.

1. Introduction

Over the last three decades, the approaches of regional development have been experiencing profound reform. In discussions and literatures about regional development during that period, social capital is an important concept of endogenous regional growth and development (vgl. Beugelsdijk et al., 2005; Garlick et al., 2006; Elbe, 2008; Miguélez et al., 2011; Stimson et al., 2011). The most influential contribution to the discussion on the relation between social capital and economic development is the publication of Putnam et al.'s *Making Democracy Work* (1993). Putnam et al. (1993: 167) defined social capital as those, "features of social organization, such as trust, norms, and networks that can improve the efficiency of society by facilitating coordinated actions".

Recently, Endogenous development is characterized by the use and enhancement of the local and regional potential through local stakeholders to solve economic and social problems. In regions where social relationships between local stakeholders are based on trust and shared values, participation in social organizations is higher and social capital is higher (Beugelsdijk 2005: 1056; vgl. Putnam 1993). Today, a number of overview papers on social capital and endogenous regional development can be found. Beugelsdijk et al. (2005: 1053) studied the development of social capital of 54 regions in Western Europe and believed: "A positive relationship exists between social capital and regional economic development". After investigation in part of the regions in Spain, Miguélez et al. (2011: 1019) confirmed that social capital correlates positively with technological innovation.

Is it possible in China to mobilize the social capital and to arouse the enthusiasm of the social members to promote the local development and to solve public issues? And is it possible based on trust and shared values to build regional networks, to promote the accomplishment of the sustainability plans in the area of economics, society and ecology?

Since the 80s of the last century, the whole society in China was experiencing a deep structural change. The policy of reform and the economic transformation were the driving forces. During this period, resources continuously gathered in urban areas. The urban territory, urban economical production mode and urban culture expanded dramatically. The population was unceasingly gathering from the rural region to the city or its neighboring region. The disparity between the urban and rural areas is getting bigger. According to the sample investigation from the Chinese National Bureau of Statistics in May of 2013, the

amount of migrant workers was beyond 262 millions (People`s Newspaper: 28.05.2013). The 12th five-year plan issued in 2011 has expressed the development plan of the Chinese economics and the society from 2011 to 2015. In 2015 the gross domestic product (GDP) of China is expected to be 55,800 billion Chinese yuan. The urbanization rate will be 51.5% with the annual growth rate of 0.8%. In addition, in 2015 the expect average per-capita disposable income of the urban residents^[1] will be 26,810 Chinese yuan, and the expect average per-capita net income of the rural communities^[2] will be 8,310 Chinese yuan, both are increased by 7% based on the amount in 2010. (People`s Newspaper: 14.03.2011)

This work is based on a four-year study between China and Germany. Within this period, network resources of the several major literature centers were retrieved, government officers and experts from academic institutes^[3] were interviewed, 18 administrative villages in Yunnan Province were visited. Based on investigation in village N and communication with local residents, the article presents the difficulty in mobilizing social capital to participate in local area development and public affairs in low developed rural China. All the evidence in the present paper is based on the field works by the authors during the period of October 2008 to July 2012.

2. Methodology

The method of the present investigation in N village is the concept of action research. Action research originated from the study in social psychology. After several generations of researchers, the methods of action research are fanned out into a variety of research areas. Today, it is used especially in the interdisciplinary projects to study the social spaces. Hart and Bond (2001: 33) emphasized: The revival of the interest in action research derive from the criticism for positivist approaches in social sciences area, as well as the defects in a large part of organization theories in solving practical problems.

The location to accomplish the investigation is the village N. The village N is one political village, located in the southwestern part of China. In terms of the administrative division, the village N belongs to the H xiang (town) in Z xian (county), which is located in the Da Li Zhou (region) of Yunan Province^[4].

According to the information from the government in 2008, it is a total of 592 poverty counties in China. Among them, 257 poverty counties are located in minority areas. The Yunnan Province has the most poverty counties (73 poverty counties). Z County is a poverty county in China. The disposable income of the county government is merely 120 to 130 million Chinese yuan. In history, the village N was flourishing because of the well rock salt. Today lots of historic buildings including one salt well are kept in the village. The government of the Z County is planning to promote tourism of the village N in the following years. In an interview in the April of 2010, the director of the County tourism bureau said that there was little interest in supporting county government plan to promote the development of tourism in village N.

The main tools to communicate with residents in the investigation were interview, questionnaire and residents meeting. The significant meaning of the investigation is to support the development plan of the local government and try to arouse the enthusiasm of the village members; On the other hand, it provides the empirical data to extend the further researches.

3. The investigation in the village N

Based on the visit to 18 administrative villages, village N was chosen for the investigation. The residents in the village N are Bai nationality with the population of 2,190. According to the publicity from the village committee (at 13.03.2011), the per-capita net income in 2009

was 2,087 Chinese yuan (around 240 Euro). The village N was formed because of salt 2100 years ago in the Han-Dynasty. Currently a great amount historic buildings are kept, which belong to the residents in the village. Those buildings are today the personal property of the villagers in law. On 09.06.2007, the village N was awarded the “Chinese Historic Culture Village^[5]”. The government of Z County is planning to build the village N as the tourist destination in the following years, in order to promote the tourism development in the whole region.

3.1 Difficulty in protecting historic buildings

During the visit in that county, the leader of the local Communist Party Committee (at 23.04.2011) and the director of the county tourism bureau (at 02.05.2011) said that: “The Z County is located in the southwestern of China. Under bad economical situation its government has limited ability. Since the village N is a minority village and has a great amount of historic buildings, the county government decides to concentrate the limited financial resource to develop the village N as one tourism one. In this case, it can build on the one hand a development driver of the tourism in the region; On the other hand, it can promote the economical development of the Z County and improve the income of the people.” In 09.06.2007, the village N won the award of “Chinese Historic Culture Village”.

In order to protect the historic buildings and maintain the village appearance, the local government decided that the historic buildings have to be repaired and maintained complying with the rule 'Xiu Jiu Ru Jiu'. Therefore, the residents in the village must use the original construction material to repair and maintain the buildings. The original materials are clay soil and woods of Pinus trees.

Currently, the interest of the villagers to develop the tourism is little, which results in the difficulty to protect the historic buildings and the village appearance. A part of residents are applying the modern construction materials to rebuild the original buildings. According to the statistics of the authors, there are already 27 buildings which are rebuilt or finished repairing. In order to restrict the rebuilding behavior of residents, one working group is set up by the local government. However, the buildings are personal property of residents, the working group failed.

3.2 Results of questionnaire

The questionnaire is one important part of the investigation. The questions are closed questions. The planned distribution of questionnaires is the free distribution. Theoretically every villager should be able to get one questionnaire. After filling in the questionnaire, the villagers should send back it voluntarily. However, the practice in village N showed that the free distribution and collection can't get a trustworthy results. The villagers do not answer the questions from the questionnaire voluntarily.

Therefore, the final manner is to visit every family and ask the questions from the questionnaire. Since it is random to choose the family, some residents were outside and can not answer it. In the end, the total amount of families who received the questionnaire is 307. That is 71.1% of all village families. The total amount of respondents is 1483. That is 67.7% of all residents. The age of the respondents distributes mainly between 31 to 60 years old. That is 73% of all respondents.

There are 29 questions in the list. Among those questions, 9 questions relate to the social live situation of villagers, 8 questions have the connection with the economical problems and 10 questions are about the joint activities and social development. In addition, there are two supplementary questions.

Question content	Selection sorts	Percent on the total respondents
Level of education	primary	43.0%
	junior middle	39.9%
	high school	14.2%
	higher	2.9%
Medical insurance		100% insured
Pension insurance		0% insured
Migrant worker in family		75.2% (at least one member of the family)
Economic tasks from government		0%
Help each other in village		93.1% help each other

Table 1: Some basic situations in the village N

Table 1 describes some results in the village N. Most of residents in the village N accept the primary and junior middle educations. In the 75.2% surveyed families, at least one family member was working outside as migrant worker. As talking about this problem, the villager head (at 02.05.2011) said that 185 villagers have been working outside for a long time (more than one year). In addition, 93.1% of the villagers often help each other. The relatives and friends are the main source of the help.

In the village N, the annual gross income less than 4000 Chinese yuan (about 480 Euro) of the family denotes the lowest level (22%, 63 from 287 interviewed families). There are 98 families with the percent of 34.1% whose gross income of one year is from 8001 to 15000 Chinese yuan. 23 families with the percent of 8% have the highest gross income which is over 25001 Chinese yuan. In addition to agricultural production, the most village families engaged more activities in variety productions. The Production activities are comprised of forestry (227 families), livestock farming (156 families), transportation (34 families), tourism (17 families) and guesthouse (6 families) etc.

As discussing the attitude to the tourism development, 16.7% interviewed villagers though that they can benefit from this activity; 36.1% stated that they are not benefiting from it. 22.3% indicated they will not benefit from it. During the questionnaire, the villagers H1, H2, H3, H4, H5, X1, X2, Y1, Y2 and Y3 supplement that: "The tourism development is the business of the government. Only the government can benefit it from the tourism development."

3.3 Results of the residents meeting and interview

The residents meeting and interview are another part of the investigation in the village N. During the investigation, one found that it is so difficult to hold the residents meeting. The enthusiasm of the villagers to participate the meeting is low. According to the document of the investigation, 69 residents (inclusive the head of villager) proposed the doubt: "whether participating the residents meeting can solve the current problems of villagers and in the village". During the interview, the villager Y2 talked about his troubles (at 27.04.2011): Y2 had very active attitude to plant the walnut and initialized the work four years ago. Two years later, the local government has ever organized the villagers to plant the walnut and provide 260 Chinese yuan pro mu^[6] each year to every family as the financial support. However, Y2 could not get the financial support, because he planted the walnut outside the assigned area of the government. Therefore, Y2 did not satisfy with it and thought that the local government should give award to the villagers who are good at planting, rather than simply setting the area. Y2 stated that he will participate it if the residents meeting can solve his problem.

In the past two years, 7 meetings were hold in the N village. Five meetings in seven were hold for the particular group of residents. Only two meetings were carried out for all villagers.

During the interview, the head of villager (at 02.05.2011) believed that: “It is so hard to communicate with villagers in the residents meeting. Most villagers do not believe that it is possible to solve the problems through the residents meeting.” He suggests: “10 Chinese yuan should be given to each resident as the manner of the economic reward, if it is very necessary to take the residents meeting in the investigation, so that the residents will come happily.” In the end, the head of villager emphasized that: “It is not straightforward to carry out the work in the village. We have to consider both the task from the government and the real needs from the villagers.”

In terms of the situation that a part of villagers repair the buildings with modern material, some villagers said that: “Since the old buildings were not repaired for a long time, so that it affect the living function of those buildings.” In the viewpoint of the villagers, the buildings must be repaired and the living function must be recovered. The original construction materials, such as woods, are easily degraded. They should be changed in 10 to 20 years. In addition, the forest protection strategy of the government results in the increase of the price of woods. Compared with tile and brick, the woods are cost higher.

As saying the plan of tourism development, the villager H7 said that: “I can borrow 20,000 Chinese yuan to improve the quality of guest rooms in my house. However the reality in Z County is that only the government can decide how to develop the tourism. After all, borrowing money from the bank is something to undertake risk. If the government changes the idea, my loss will be very large. Therefore, it is the wise decision to wait and see.” This idea is supported by the residents H8 and Y4, who are managing restaurants in the village.

4. Important results from index works and expert interviews

This work is based on a four-year study. Within this period, network resources of the several major literature centers were retrieved, government officers and experts from academic institutes were interviewed. In this part of the paper, two important results from index works and expert interviews are shown.

Firstly, in current international discussions and literatures about regional development, social capital is an important concept of endogenous regional development (vgl. Beugelsdijk et al. 2005, Garlick et al. 2006, Miguélez et al. 2011, Stimson et al. 2011). Stimson et al. (2006:35) pointed out: “*Structural agglomeration, regional innovation systems, institutional thickness, organization power and control, enterprise segmentation and social capital are the key concepts of the contemporary regional development literature.*” Additionally the authors emphasized: “... and which are embedded in the increasingly important discussion of institutions and endogenous regional growth and development...”

By analyzing the index results from the network resources of several important academic literature centers^[7] in China, a number of papers on participation can be found. Between 2001 and 2010 Chinese scholars have carried out a great amount of investigations on the participation, but fewer contributions to the endogenous development. Moreover, the similar results according to the index results from the network resources of National Science and Technology Library (NSTL) can be obtained. Among the obtained index results, one can get 37,711 items about “Participation”, 4,402 items about “Social Capital” and only 11 items about “Endogenous Development”.

The results from index works are shown that the most Chinese scholars do not understand the significance of the “Endogenous Development”. In the obtained Chinese literatures, “Endogenous Development” is a new development model in comparison with the exogenous development model (vgl. Zhang et al., 2008; Wang et al., 2009; Zhou et al., 2009). Some scholars (Zhang et al., 2007: 65) beliefs that “Endogenous Development” is a new theory in the field of sociology and compared it with endogenous growth theory in the field of economics (see Table 2).

	Endogenous development Theory	Endogenous growth Theory
Use areas	low developed regions, especially rural areas	developed regions
Disciplines	sociology, anthropology, cultural studies	economics
Focus	sustainable development	promote economic development by endogenous technical improvement

Table 2: The comparison between the “endogenous development theory” and endogenous growth theory (Be translated from Zhang et al., 2007: 65).

Secondly, in the planned economy era, the power of the politics, the finance and the decision-making was in China highly concentrated. With the transformation from the planned economy to the market economy, the power of the financial payment and decision-making regarding local affairs was transferred from the central government to the local government (vgl. Chung, 1999; Qi, 1999; Liu et al., 2006). It formed a Center-Local-Government-Relationship, which indicates that the power of politics and financial incoming is controlled by the central government, and the local affairs and financial payment can be managed by the local governments. In this period, the difficulty of improving local governance in China has aroused a great deal of attention from academics. On the one hand, in order to obtain more the political and financial support from the central government, local governments need accomplishing the “top down” plans and tasks from the central. On the other hand, following the decentralization of the financial and decision-making structure, the local governments have more responsibilities and play a significant role in the solution of the local needs.

After the study of the local governance reform in China, Liu et al. (2006: 29) pointed out: *“local government official have tended to be more responsive to the party and to higher-level government policies than they are to local needs. There officials are, after all, controlled from above both by tight hierarchical personnel arrangements and by fiscal transfer arrangements. Local governments in many regions are usually more interested in various show case projects that cater to upper-level governments rather than local tastes.”*

Additionally, Liu et al (2006.29) analyzed the current problems and emphasized: *“On the one hand, the center understands that local government officials, who are appointed from above and lack accountability to local people, have a tendency to stray from good governance practices; on the other hand, fearing that uncontrolled elections could gravely weaken the center’s ability to enforce its policies and even destroy the Party’s power base, the center has no strong desire to promote popular elections at local levels.”*

5. Conclusions

This paper was initialized by arguing the issue in the period of the reform and opening-up in China. In such a period, the plan economics was transferred to the market economics. The disparity between the rural and urban areas was increased and the residents were gathering from the rural to the urban areas. Accompanied by the transformation of power from the central government to local governments, the difficulty of improving local governance has aroused a great deal of attentions in China. Under this condition, the question is whether it can be mobilized the social capital, aroused the enthusiasm of the social members and based on trust and shared values to build regional networks in China? Based on the index works to several main literature center, the interviews with several experts in government department and academic institutes, the visits to 18 villages and the deep investigation in the

village N, the paper presents the difficulty to mobilize the social capital and the difficulty of the participation in low developed rural China.

Finally three points are concluded to predict the difficulty that China is confronting in this contribution:

- a) The index results of the network resources of some important academic literature centers in China described that there are more researches to “Participation” and “Social Capital”, but rare researches to “Endogenous Development”. Among the obtained index results from the network resources of National Science and Technology Library (NSTL), only 11 items about “Endogenous Development” could be found. Therefore, the contribution suggests that the significance to mobilize the social capital and to arouse the enthusiasm of the social members can't be understood in China, if the people do not understand the significance of the “Endogenous Development”.
- b) It is more difficult in China to improve the local governance especially in the low developed regions due to the existing Center-Local-Government-Relationship. The case in the village N showed that the decentralization is not just about the mechanics of government structures and funding, but also about changing relationships and norms.
- c) Combining above two reasons, the governments in low developed rural China have neither enough understandings, nor enough enthusiasm to mobilize the social members in participating local development and in solving public issues. They also do not have enough enthusiasm based on trust and shared values to build the social relationships. Taking the investigation in the N village as an example, the local government is applying for the award “Chinese culture village.” Only the local government made the effort to apply for it, rather than encouraging the villagers to be involved it. After that, the local government announced the rule of “xiu jiu ru jiu” to keep the village appearance, without the negotiation with the villagers. Eventually, the villagers have the negative attitude to the tourism development of the government. Some villagers said that the tourism development is the business of the government and only the government can benefit from the tourism development. In all, without the support and understanding of the government, it is pretty hard to mobilize the social capital and to arouse the enthusiasm of the social members.

Through the investigation it also shows that some villagers are willing to loan the money from the bank to support the tourism development in the village N. However, taking the consideration of the personal risk, they take the wait-and-see attitude. Those potentials from the public members should be mobilized. In the end, the paper suggests that the issue to mobilize the social capital and the enthusiasm of the social members to participate the local development and public issues should be considered more in the future in China.

Spurring the community involvement in planning - lessons from post-socialist cities

Piotr Lorens*, Dorota Kamrowska-Zaluska*

*Gdansk University of Technology, Poland

Community involvement in planning in the case of post-socialist cities was until recently almost non-existent. But in recent years the development of demand more public participation is dramatically increasing. This phenomenon creates a need for new types of planning tools, as well as an introduction of innovative techniques of conducting the community dialogue.

"Cities have the capability of providing something for everybody, only because, and only when, they are created by everybody." - Jane Jacobs

Introduction

Public participation and community involvement in planning processes is – in general – not a new topic for contemporary planners. But in many parts of the world – including the post-socialist countries– we can still face the lack of understanding of importance of proper community involvement in planning and development processes. The situation in these countries is significantly different from both the highly-developed countries (where we can observe many forms of participation and the need for this is in principle commonly accepted by all stakeholders) and the developing ones (where the key issues are frequently associated with providing basic infrastructure or upgrading the very unprivileged areas).

Post-socialist countries

The post-socialist countries are frequently regarded as relatively well developed and can be characterized as “rich” from the perspective of many others, but in fact they are still on the fast track on the way towards redevelopment of their urban structures. This is accompanied by rapid and frequently disordered urbanization, which is happening in the realities of “liberal model” of spatial development.

In the last few years Poland has gone a long way from centrally planned economy to decentralized governance, where the planning power stays within communities. This is also the case of public participation, in the 80-ies the process was nearly non-existent. It is the law of 1994 on Spatial Planning, which gave residents not only an opportunity to articulate their legitimate interests, but also a number of legal institutions to claim settlement and solve conflicts caused by different interest of the stakeholders. It was an important step towards legal sanction in the field of planning and land use planning typical of a developing democracy. It also gave the basis for the participation of citizens in making public decisions (Siemiński 2007).

In 2004, with the new Law on Spatial Planning, real development of participation procedures begun in Poland. The participation process requirements accelerated due to adaption to the

requirements of European Union, starting with environmental procedures such as environmental impact assessments and then spreading into other aspects of urban development e.g. urban regeneration.

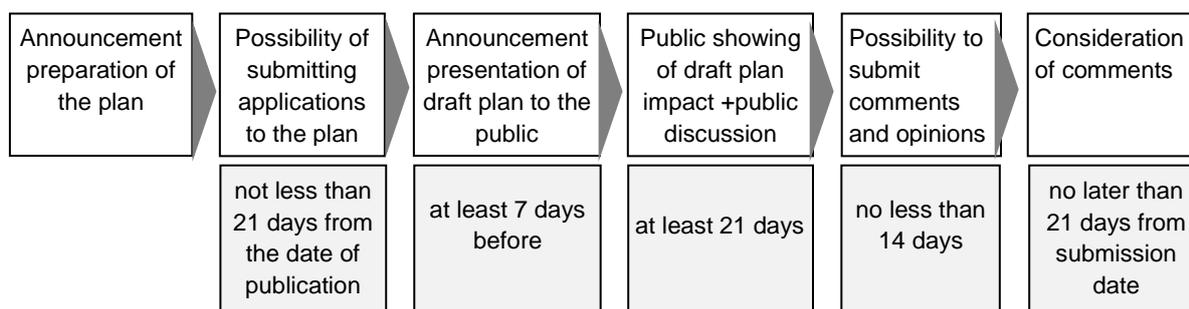

Fig. 1 Phases of participation in preparation of local development plan in Poland

Public participation in the planning procedure is one of the key elements of planning and public consultation, which could effectively support the process of making the right decisions. According to the Polish Law on Spatial Planning and Development the main purpose of public participation in the planning procedure is: to inform about the preparation of the new development plans or the revision of existing ones, to receive proposals or comments from all the actors of the process, to take them into account or to reject them. This process, if conducted properly, should also prevent conflicts and protests. The main steps of this process are:

- submission of proposals for a masterplan and a local development plan (two main tools of spatial planning in Poland)
- public hearing and discussion on the solutions adopted by the draft masterplan or development plan;
- possibility to submit comments and opinions to the draft masterplan or development plan;

This process, though a big step forward, does not always work. Possibility of public intervention happens too late. All the actors of the development process can submit their comments and opinions only after the plan is already approved by all administrative bodies, such as environmental and health departments, as well as heritage conservation office on both local and regional level. As this process is lengthy (takes at least 3 month) it's not surprising that authors of the plan are not willing to incorporate changes proposed by the public and go through the approval procedure again. At the beginning of the process participation possibility is limited only to the submission of proposals, which could be taken into account or not without any explanation, while it would be much more useful to introduce the public discussion at the stage of programming and setting project objectives. This tool was introduced for example in France, by new Law in year 2000. At the stage of setting project objectives for planning documents such as *schéma de cohérence territoriale* and *plan local d'urbanisme* there is a whole process of public consultation, which often includes workshops, public hearing surveys etc.

Beyond the statutory process of participation in Poland

At the same time the local communities are becoming interested in the development process and are looking forward to being accepted as equal or even key partners by other stakeholders. This does not advance the ability of discussing the problems and dilemmas of

spatial development - and this is both the problem of local municipalities, interested in local communities and other stakeholders –i.e. developers and investors. Therefore, we have to face the situation in which the partners are not ready to discuss the development and planning issues, which partly stems from the present liberal paradigm and partly from the lack of conducting the public discourse in general.

In this case planners have to take the leading role in the process and come forth with the innovative – at least in post-soviet realities – planning tools and techniques, allowing the introduction of public participation process in a way acceptable for all key stakeholders. One of these tools are the “planning workshops”, similar to known in the highly developed countries “charrettes”, which allow for the discussion of the PROBLEM and which prevents jumping directly to the discussion of pros and cons of some proposed solutions (which usually are unacceptable for some of the partners/stakeholders) and – in result – prevent unnecessary miscommunication and sometimes even public quarrels.

Participation in praxis

This part of paper shows two examples of non-statutory participation process in Poland. The first one took place in 2008 and the second just finished last year. These two cases show evolution in the public participation in planning in Poland. The first was initiated by local authorities, though there was deep involvement of the majority of key actors of the process. The second is a bottom–up initiative led by local NGO, where public authorities were invited to take part in the process. Of course in both cases the situation is different and there are still such participation processes led by the public sector, but this kind of activity of urban movement is a new phenomenon in Poland. Local neighborhood associations were always present, but their organizational skills and capacities to conduct participatory planning process increased significantly in the last decade. It is partly caused by the development of further forms of grants for NGO financed by European Union or private foundations (like in a case of second project described below), which is new for post-soviet countries.

The first project is revitalization of the downtown of city of Starogard. In 2008 the Local Regeneration Program for Starogard for the years 2008-2013 was introduced. The aim of the Program was a comprehensive transformation of the historic center of Starogard. At the same time, the program define overarching objectives and specific actions to be undertaken for each of the analyzed areas. Even though this general document was very important, it was not the end of the planning process. Consequently, after the acceptance of the document the city decided to continue its planning efforts to prepare the first actions of the implementation phase. The most important part was comprehensive preparation of the revitalization of the main market square in downtown.

The work formula for this project was a mixture of expert and collaborative approach. This kind of approach was needed while end result of the project was a comprehensive design documentation, which could be presented to the regional authorities, as part of a revitalization grant documentation. Because of the nature of the task, most of the work was carried out by a design team. However, due to the large community of interest in the shape of system of public spaces and development of the main plaza, an extended part of this work was done during public workshop prepared and carried out by a team from the Department of Architecture of Gdansk University of Technology.

Finally, four workshop meetings were scheduled, followed by a final presentation of the development of the proposed solution for the Market Square. In September 2008, there was a first workshop on selection of variant of road communication, followed by a discussion about the system of public spaces. At the beginning of October 2008, the next workshop focused on discussion on system of public spaces and the functional structure of the Old Town. During that month, there was a third workshop, where a physical plan of public space was being discussed, as well as the formulation of proposals for the project. The last workshop meeting was focused on details of the revitalization of downtown of Starogard. A presentation of the final version of the study took place in December 2008. A study fully adopted the findings of the workshop meetings. A strong point of this study was the participatory method, with the direct engagement of local communities and most of key institutional partners. All decisions were made by consensus during the meetings, where nearly 60 representatives of different stakeholder were present.

The second project is Centrum Reaktywacja, defined by its authors as “an attempt to develop in participatory mode a coherent and comprehensive vision of the historic city center of Gdansk”. It was implemented in 2012 by the Gdansk Agglomeration Development Forum (local NGO) in collaboration with the Institute for Urban Culture, Gdansk University of Technology and the Society Polish Town Planners. Preparation and implementation of the project was supported by the Stefan Batory Foundation.

Fig. 2 A photography from one of the workshops of Centrum Reaktywacja project

The project aimed to develop common vision for the area, both for the local community and all other stakeholders, which would allow the achievement of social consensus for downtown developments in Gdansk. This project should help to minimize conflicts between the actors of development and to increase public participation in the planning process. The project team

also hopes that proposals developed during workshop meeting could be incorporated into local development plans and be used in the formulation of other urban policies for the area. Their wish is that the success of the project will encourage municipal authorities to open public discussion on directions development of other areas of Gdansk. The third goal is to develop know-how for local officials and local NGO to conduct similar projects in the future.

The project was implemented through building a platform for discussion of shaping present directions of city development. Invited inhabitants of the city formed a civil forum for dialogue. By taking part in a series of workshops with other stakeholder of development process as well as specialists in the field of urban planning, architecture, landscape architecture, social sciences, they developed the key elements of the final document - the study of the development of the district

Fig. 3 A photography from the final conference Centrum Reaktywacja

Using the method of "charrette" allows for a dialogue between different interest groups before creating the situation of conflict, thereby minimizing the risk of its occurrence at a later stage of the development processes. It was based on the preparation, carrying out and conclusions of a series of workshops. Each of them had a clearly defined goal, a method of conducting and expected results. All the work has been prepared so as to achieve the aforementioned objective (Lorens, Nowik 2013).

While the project was prepared, organizers expected between 50-70 participants, whereas in reality more than 140 people attended the workshops. In the case of high-frequency workshops, they were carried out in subgroups and then the results synthesized during plenary sessions. Due to the open nature of the meetings, there was a natural rotation of the

participants, especially during the meetings related to the various specific areas in downtown.

Conclusions

The changes in the relationship between rulers and ruled that the Polish society underwent (and other post soviet-countries – authors comment) are very rapid (Pawłowska 2012). With time a development of community involvement can be observed. In the last twenty years public participation evolved from individual avant-garde actions to becoming a part of statutory process of planning. Today's approach still has some weaknesses, such as involving the community into real discussion only at the end of the planning procedure. It is also not applicable for all the situations, as not all of the development is limited to drawing up a development plan. This is the case of both processes analyzed in this paper. Both of them also use the method of "planning workshops", similar to "charrettes", used in participation practice of many developed countries, a tool so far applied only to a small extent to the construction of urban development policy in Poland.

The abovementioned evolution of approach can also be seen as a stronger involvement of urban movements. Though public bodies, specially local authorities with their planning power, are still important actors of the development, there are more and more cases where public involvement process is led by third sector organizations. This situation is possible due to new ways of financing and increasing organizational capacity of local NGOs. Very often, the planning process is just the first step of using participatory methods, but with time they are applied to other forms of participatory democracy, such as participatory budgeting which is a rising concept in many post-socialistic cities.

Main Title

`Insurgent Planning` in Durban; An investigation on the proliferation of religious sites for the Nazareth Baptist Church

Koyi MCHUNU, University of Natal (Durban), South Africa

Abstract

This paper discusses `insurgent planning` as relevant approach to planning practice, then applies it to the city of Durban in an attempt to shed light on the proliferation of religious sites of the Nazareth Baptist Church. The paper seeks to make a contribution to a growing body of literature on critical urban studies by drawing attention to other ways of conceiving and engaging space in the city. Arguing that predominant planning theories are inadequate to account for the diversity of urban experiences, the paper explores alternative theoretical frameworks that speak more eloquently to contemporary issues, more especially in contexts that are increasingly marked by diversity, difference, informality, marginality, and `otherness`. These theoretical frameworks foreground these issues as constitutive of being (in the city), and as contributions to the collective reimagining of the city. The paper discusses how such a planning approach could improve theory, pedagogy, and planning practice.

1. Introduction

Cities in South African are going through a process of unprecedented social and spatial transformation following the ushering of a more democratic political dispensation almost two decades ago. Urban Planners and other built environment professionals are at the forefront of trying to generate an understanding of the processes that continue to shape current cities in Africa, and to use that understanding to inform Planning Theory and meaningful practice (Dewar et al 2013, Murray 2004, Harrison 1996, Simone 2004, Mangcu et al 2003). This research represents an endeavor at contributing to this rejuvenated theoretical space of critical Urban Studies.

The paper investigates and documents an instance of `insurgent planning` in the city of Durban involving the proliferation of religious sites that belongs to the Shembe Church. `Insurgent planning` ingrains existing but hitherto officially unacknowledged land uses, and/or introduces new identities and practices into the city's urban-scape. While this serves to empower ordinary citizens, it also parodies the official disciplining rational use of space. Such urban narratives are too often ignored in the process of official space making and therefore suggest other ways of being in the city.

The research draws inspiration from a well-trodden path of researchers on `unconventional` uses of space that challenges the predominant notions of space-making. It is foreshadowed, for example, in the pioneering work of de Certeau's (1984) flaneurism along Parisian street; Sandercock's (1998) writings on the challenge of multiculturalism to the (Australian) planning system, and perhaps more recently, Ameel et al's (2012) research on Parkour in Finnish cities, to name a few.

The purpose of the paper is to make a contribution to a growing body of literature on critical urban studies by drawing attention to other ways of conceiving and engaging space in the city. The paper investigates and documents the extent of the Shembe religious sites; describes the process involved with `establishing` the sites; discusses site design and maintenance; and deliberates on how the site is utilized; all with the view to informing public policy/practice, planning theory, and pedagogy. Concepts such as mis-use of space (Mchunu 2006) and loose space (Franck et al, 2007) are deployed as tools for analysis. Both concepts describe the pervasive phenomenon concerning the use of urban spaces contrary to what they were intended or against their zoning designations.

The research relied on both primary and secondary sources of data. In-depth interviews were conducted with key informants. Photographs, and site visits were also sources of primary data. Secondary sources concerning the historical and recent media reports were obtained from the internet.

To begin to think of ways and means of addressing this and perhaps similar challenges, it may be necessary to situate the discussion within the broader political, social, and economic forces that are shaping Durban as a city. Equally important is to try and shed some light on the Shembe Church, including their cosmology.

2. Reimagining Spaces in the City

Around the world new ways of being in the city are emerging, instances of `insurgent planning` abound. Ameel and Tani's (2012:17) discussion of the phenomenon of Parkour in Finnish cities as `new way of movement that challenges conceptions of acceptable or appropriate behavior in urban public space` provides another case in point. They argue that the practice does not `follow the conventional regulations of space and its intended use....they are able to draw their own maps, imposing them on the normal restrictions and codes of behavior' (ibid, 19).

In 2005, I documented the need for spaces to practice initiation among the Xhosa speaking peoples in Cape Town, South Africa. Upon reaching a certain age, boys undergo a process of initiation into manhood which involves prolonged stays in the bush during which, among other things, they are circumcised as a rite of passage into manhood. Communities were forced to improvise as a way out of the impasse as these spaces were not provided for in official plans.

There is also the phenomenon of `street memorials` (Ojo-Aromokudu and Mchunu 2013), which involves the laying of wreaths and crucifixes on sites of fatal road accidents. Franck and Stevens' (2007) introduced the concept of `loose space` as a framework for analyzing such practices.

These studies echo Lefebvre's (1991) notion of space as socially produced through and from the human body. They are also anticipated in de Certeau's (1984) ground-breaking work on flaneurism, which through relaxed strolling along the Parisian streets made the tightly controlled rhythms of the city visible. In a sense flaneurs provided a critique of the strict rules of urban life. The use of space by the Sheme Church needs to be also understood in this

context of this increasing phenomenon of informal use of urban space for activities other than what it was intended.

3. The Legacy of Past Planning

Faced with the demands for diversity and difference, the fabric of the modern city continues to lose its relevance and meaning to the lived experiences of many urban dwellers. Its ensemble of buildings and spaces are confronted with an amalgam of aspirations, imaginations, and social practices that transcend current paradigms that informed its conception. It seems as though from inception, the socio-economic arrangements and the logistics of `belonging` and becoming have proven to be difficult to read for modern planners and decision makers.

It is also becoming increasingly doubtful that local government is a legitimate locus for decision-making and implementation of an inclusive vision of the city. This stems from the perceived halting intervention of the local authority in shaping the city. The means may not yet be at hand to respond to the challenges of a postmodern present (Mabin 1995), whose pace and character of developments demand new and innovative methods.

There is also the issue with past planning practice that has also been discussed extensively in planning literature (Muller 1982 and 1995, Laburn-Pearl 1991 and 1998, Parnell 1993, Mabin 1991, Harrison 1996). These authors highlighted among other issues, the discriminatory nature of apartheid planning, the marginalization based on racial, ethnic and other markers of difference.

The challenges of the Shembe spatial practice to planning intervention have to be seen in terms of the broader social processes that are responsible for persisting inequality; what Mbembe (2013) described as the `lust for our lost segregation`; the deep tensions along racial lines; the proliferation of enclaves of affluence and degradation; and the ubiquitous informality; all of which characterize the current city-form.

There is also the halting intervention of local authorities in shaping the city, resulting in what Peattie (1991:36) described as the `splendid entrepreneurial disorder and hustling boosterism`, and `a functioning order that seems messy on the ground` (ibid: 39). The pace with which development takes place and its character poses additional challenges for meaning government intervention in terms of setting the agenda.

Equally powerful is the ascendancy of a market-driven consumerist culture that revolves around the buying and selling of goods and services, which pervades all aspects of contemporary city life. This has contributed to the pervasive spiritual malaise. The combination of these factors contributes and shapes the current form of the city of Durban.

4. Spontaneous Self-Diversification

In Lefebvre terms (1987), the city of Durban may be characterized as a `spatial practice` produced between `spatial representation` of professionals and city officials, and `representational spaces` as lived and imagined by inhabitants of the city. `Spatial representation` refers to those spaces produced by professionals and officials, and `representational spaces` refers to those spaces that result from people's interaction with the built environment that is produced by professionals.

`Representational spaces` oftentimes are instances of cultural conflict and change, which activates spaces in ways hitherto not imagined, and as such, bring excitement and stimulation that transforms cities beyond the imaginations of officials and academic theory. The numerous siting of these `religious sites` by the Shembe Church predominantly on public/municipal land in and around the city represent instances of `insurgent planning`, which results in `representational spaces.`

In the context of South Africa, planning challenges presented by `representational spaces` cannot be understood without reference to both the colonial and apartheid pasts, which, with the aid of modern planning techniques, marginalized groups in society and other ways of being in the city. Overcoming this legacy is the single most defining aspect of current state planning initiatives in South Africa. Opportunities for `spontaneous self-diversification` emanate, in part, from a more inclusive post-apartheid political dispensation that is more tolerant of difference.

The discussion now turns briefly to focus on the historical background of the Shembe Church and their cosmology with the view to assisting with the reformulating of informative policies and plans. If these sites are to be accommodated in official plans and policies instead of the prevailing polite acquiescence, a better understanding of the practice may be necessary.

5. The Nazareth Baptist Church/ Shembe Church

The Nazareth Baptist Church (Ibandla lamaNazarites or Shembe Church) is the oldest African Independent/Indigenous Church in South Africa. It was founded by Inkosi Isaiah

Shembe (1860's-1935) in 1910. The church forms part of African Initiated Churches that date back to the 4th century Ethiopian Orthodox Church.

The Shembe religion is a combination of Zulu culture and Christianity. The main church is located on a sacred site north of Durban called Ekuphakameni, which is translated to mean 'Place of Spiritual Upliftment'. Recently, there has been a marked proliferation in the number of sites of different shapes and dimensions in and around the city, which bear the hallmark of the Nazareth Baptist Church.

The mere sight of the Shembe religious gathering in seemingly awkward shaped and random spaces in and around the city, especially on Saturdays, is enough to arouse curiosity from tourist and locals alike. White stones arranged in a semi-circle preferably under a tree have become a common sight not only in Durban, but can be seen in other cities as well.

According to the informants, the `founding` of the site follows a well-established ritual of prayer, weeding as part of cleaning process, planting of trees for shade usually at the centre, the placement of white stones, and finally another prayer to `open` the site for service. The penultimate blessing of the site takes place after all the above and this involves what seems from the descriptions, like a more elaborate affair involving a number of priests and invited guests.

Trees are planted where none exists to provide shade. Church members volunteer their time for the upkeep of the site. The size of the space is dictated by the number of the congregation on each particular site, which can be extended depending on the physical extent of the site.

To the uninitiated there appears to be no logic behind the selection of sites, size and orientation, if any, but according a guided `tour` of one site revealed that men sit separate from women, who in turn sit separate from girls and the priesthood. Furthermore, entrances are also separated in similar fashion, with each entrance oriented towards the center, which serves as the focal point for all who enter the space.

Figure 1: A recent site on private property. It illustrates an arrangement of white stones with 4 entrances and a marked centre, typical of all similar sites by Shembe Church. Photograph: K Mchunu, 2013

Every Saturday these `ordinary` urban spaces, majority of which are the postscripts of planning, are activated and come alive as worshippers all dressed in a combination of white and black garb with pieces of traditional Zulu jewelry could be seen gathering together for a service. In addition to Saturdays, specials services are held every 14, 23, and 25th of the month for women, men, and girls respectively. Upon further probing, the significance of these dates did could not be readily explained by the informants.

However, it is noteworthy that once permission has been granted, the site is altered, albeit lightly, to the specific requirements of the Shembe Church. Following a specified set of rituals to mark the site as a worshipping space, strict rules governing entrance into the space are introduced, including removing ones shoes. Although all are welcome for prayers, and the site alterations slight, there is an implicit assumption that these spaces are now to be regarded as religious sites (and `belong` to the Shembe church), to the exclusion of other uses.

6. Implications for Planning Theory and Practice

This practice by the Shembe Church poses numerous challenges for planning as to the appropriate response. What should planners and policy makers do in the face of such a practice? Are such `spontaneous self-diversification among urban population`, as Jacobs (1961) dubbed similar acts of difference and diversity in the city, to be nurtured and embraced in the formulation of policies and plans? A decision of some sort has to be made and action taken as about every facet of urban infrastructure.

Part of the way forward may be found in that dog-eared, well-thumbed copy of Jane Jacobs (ibid), her argument for the need to embrace such practices; Young's (1990) conception of justice, the notion of cultural imperialism in particular; Sandercock's (1998, 2000) and Qadeer's (1994) discussions on the limitations of modern planning in contexts that are increasingly marked by multiculturalism and the need to transcend the limitations through inter alia, a process of inclusion; Harvey's (1992) concept of Social Justice as universal meta-narrative that transcends issues of otherness; and a host of writers concerned with issues of diversity and difference. Also, Schon's (1993) reflective practitioner is also relevant in this context of contested meanings and diverse value systems.

Armed with these perspectives, we could try to `decode` the seemingly random and indiscriminate siting of these spaces in order to celebrate difference, perhaps develop empathies for `otherness` in the city; or allow such practices to `...stand forth with their difference acknowledged and respected, though perhaps not completely understood, by others` (Young, 1990:108).

Identifying relevant sites involves an element of flaneurism by church members may be necessary to discover potential sites. With this ability to navigate urban terrain and to identify suitable spaces, the Shembes seem not bothered to follow conventional planning regulations for space and its designated purpose. They seem to stake a claim on the urban environment without demanding legal ownership, and with a rather uncanny ability to transform the mundane into the transcendental, and in the process reshape urban space.

Once a site has been identified, and a process of negotiation with owners concluded, sites are then transformed into sacred spaces following the process alluded earlier. It is therefore not surprising that thus far, the uses have not turned out to be conflictual, and the forces of law have not yet decided to impose some authoritarian solution. Instead there seems to be a polite nod on the part of the municipality, which may suffice in the short-term.

There is a sense in which it could be argued, and rather convincingly, that this practice by spatial practice by the Shembe Church is posing a question as to who has a right to decide on the correct way to use public space? Through a combination of negotiation with relevant owners, and a rather footloose use of space, the Church introduces a less onerous method for land use management. The Shembe Church is, in a sense, creating a parallel city, a city with a different tempo, value system, and character, utilizing the fabric of the current city. Their city registers on a different scale and answers a different set of needs. The Church of Nazareth is creating islands of tranquility, serene spaces amidst the hustle and haggling, where, according to the informants all are welcome for a pause, a moment of reflection, and prayer irrespective of one's religious persuasion.

7. Diversity and the Modernity

The foregoing raises epistemological challenges around the limitations of modern planning, much about which has been written in planning literature (some refs). Modernism and other fashionable meta-paradigms (Global Cities, World Cities) have come under criticism for failing to adequately account for the diversity of urban practices (Murray 2004, Baum 1996, Sandercock, 1998; Dear 1986, Verma 1996). This diversity is a product of historically specific practices that connect with local circumstances in particular ways (Murray 2004).

The privileging of mainly western epistemology that does not adequately account for this diversity of urban experiences is regarded as problematic. The deconstruction of these predominantly western universal narratives is one of the major achievements of the radical critique of the past couple of decades. But the ground had already been laid long before as Harvey (Op cit.) rightfully noted.

This meant that all forms of meta-theories are either misplaced or illegitimate. Instead, alternative epistemologies, which speak to particular contexts, are touted as more relevant. These fragmented discourses were regarded as more grounded because they articulated particular local circumstances in which individuals and groups found themselves. But fragmented discourses could never go beyond challenging particular issues affecting their groups or members. This fails to address the broader system in which the particular issues are embedded.

Similarly, the spatial practice by Shembe and other similar uses articulate particular issues, advocate for the rights of their constituencies whose ignored needs are symptoms of a much

broader issue of marginalisation and discrimination in society. Although it may be hard to fault the sentiment for embracing the Shembe practice by acquiescing to the request for space as an act of `spontaneous self-diversification` of which Jacobs (Op cit.) speak, its operationalization is fraught with difficulties, especially in the South African context where apartheid perverted and manipulated group differences for political ends` (Mchunu, 2005:223).

The deconstruction of all meta-narratives as a universal basis for action although significant, left in its wake a plethora of fragmented discourses whose legitimacy obtains from being grounded in the particularities of their contexts. This either drains the legitimacy of state policy in the face of such a multitude of voices all clamouring to be heard and accommodated, or at worst attribute such policies to serving the sole interest of the ruling class that Plato's Republic admonished about and the history of South Africa suggest.

Also, group identity may provide an opportunistic launching pad for the redistributive claim on public resources (Mchunu, *ibid*), such as the appropriation of these spaces in this instance. This may be problematic, particularly if the claim is perceived not to be in proportion to the size of the group concerned, and in the context of limited resources (*ibid*). Yet freedom of city life encourages diversity, `the openness to unassimilated otherness` (Young, Op cit.).

Figure 2: A well-maintained site by city council in the suburb of Morningside. Photograph: K Mchunu, 2013

The suggestion to engage as Jacobs (op cit.) advocated also raises other concerns that Harvey (op cit.) highlights as problematic: in what ways can for example informality (shantytowns, street vendors), homelessness, gang turf-warfare's and the like be understood as `spontaneous self-diversification`?

8. Conflicting Uses of Space

The sites are usually located in urban areas in and around the Central Business District (CBD), in spaces officially designated for other land uses. It is to be expected that worshippers will meet other people who have different opinions about how best to utilise the space, or those who preferred the original use for which the plot was designated.

Although these sites are a result of negotiation with the owners for temporal use by the church, this becomes problematic if the land is publicly owned and the municipality has granted permission to occupy without consulting the public. By law, any change in land use requires comment by the public.

The potential conflict that might arise through such appropriation of public spaces by certain groups has been highlighted before. Mchunu (2006) describes a similar phenomenon involving `street monuments` that mark the sites of fatal road accidents. Wreaths and crucifixes are placed on these spots for indefinite periods of time in memory of those who perished. The sentiment is hard to fault, inasmuch as it is hard to challenge the rather benign uses by the Shembe Church. But there is a sense in which public spaces are usurped by particular groups to the exclusion of others without any due processes being followed.

Franck and Stevens (2007) also popularised a somewhat similar notion with their concepts of `tight and loose` spaces. Loose spaces occur where the designated use seems no longer relevant, or where different land uses are tolerated simultaneously. These also tend to be spaces that seem superfluous, or `leftover spaces that are free of official planning and commodification` (ibid, 8), as exemplified in figure 2 above. According to Franck and Stevens (ibid), loose spaces are central to the production of a healthy urban texture. What happens when loose space is appropriated and no longer becomes loose by nature of the use being introduced?

These practices activate spaces in unconventional manners, appropriating public open spaces for their activities. In the case of Shembe, they negotiate their right to use these

spaces with owners, be they private or local authorities. According to the one informant, such uses are always temporal, subject to the agreement with the owner. They also pointed to the lack of physical structures to indicate the non-permanent nature of the use, and that all denominations are welcome to pray.

9. Informality and Marginality

The Shembe practice is representative of instances of marginality and informality that are constitutive of life in the cities. One of the characteristics of contemporary cities, more especially in Africa, is the pervasive informality and marginality as manifested among other examples in street trading, the predominant modes of public transport involving privately operated vehicles, and the infamous squatter settlements or slums, cross-border and rural migrants, (see AlSayyad and Roy 2004). Both marginality and informality thrive on loose spaces of the crumbling urban fabric of the modern city.

Informality and marginality speaks to notions of temporality, ephemerality, uncertainty, and ambiguity. But also inherent in the discussions around informality and marginality are notions of movement and lightness. It is no coincidence that the predominant metaphor of airport cities (aero-polis) is popular in planning and government circles, the emphasis being on speed and lightness. Public transport terminals (airports, bus and taxi ranks, highways, fast-speed rail networks) have become dominant land uses and landmarks. The point being made is that the idea of movement, which has captured official imaginations, resonates with the experience of informality and marginality as other equally important ways of life in the city.

Living on the borderlands as Sandercock (2000) dubs life on the margins or living with informality, is a reality for some of the urban dwellers who have embraced them as positive spaces that are full of potential. She suggests that planners could learn from these marginalised groups by listening to their stories in order to improve not only planning theory and practice, but their lives as well.

Witness how the negative connotations associated with marginal spaces like the infamous townships have been gradually subverted, through popular imagination, by a much more positive narrative of townships as hip spaces. This popular view has been reinforced lately by both private and public sector investments in shopping atria and public infrastructure respectively.

10. Implications for Theory and Planning Practice

Sandercock (2000:6) began spelling out some of the elements required for planning practice to engage more meaningfully with this practice:

`Dialogue and negotiation across the gulf of cultural difference requires its practitioners to be fluent in a range of ways of knowing and communicating. Something more than the tool-kit of negotiation and mediation is needed, some `method`, which complements but also transcends the highly rational process typical of the communicative action model`.

Similar to other expressions of `spontaneous self-diversification` in the city, the official response could either be characterized as respectful, or as providing, as suggested by Jacobs (op cit.), in the sense that there has never been any violent confrontation by the city or members of the public.

In another sense the official response has been uninspiringly halting and at best acquiescing irrespective of where these religious sites may be occurring. This polite `openness to unassimilated otherness` (Young, Op cit.) may be all that planners could do yet, liberating public space for the heterogeneity that comes with the mixing of religions and other expressions of diversity in public space.

To this view I also bring her notion of cultural imperialism as one of what she describes as the `five faces` of oppression, which `the dominant meanings of a society render the particular perspective of one's own group invisible at the same time as they stereotype one's group and mark it out as the Other`. However, this is not to suggest the rest of her views on justice are not relevant, cultural imperialism speaks more to the issue at hand.

Schon (1993:18) called to attention the `mismatch of traditional patterns of practice and knowledge to features of the practice situation – complexity, uncertainty, instability, uniqueness and value conflict`. He proposed substitute the idea of reflection in action for the knowledge and application model of positivism and epistemology based on the idea of reflection in action.

Such approaches should be underpinned by a higher-order unified discourse, one that transcends the postmodern fragmentation that paralyses policy formulation. While acknowledging that justice and rationality as unifying discourses take on different meanings across space and time, Harvey (1991:598) also argues that `the existence of everyday

meanings to which people do attach importance and which to them appear unproblematic, gives the terms a political and mobilizing power that can never be neglected`.

Flyvbjerg (1990, 2001) and Peattie (2001) draw attention to Aristotle's distinction of three forms of knowing; Episteme, which refers to science or knowledge that is fixed and universal; Techne or Technique, what is distinguished as art and craft; and Phronesis, which is defined as knowing what to do in particular circumstances, not generalizable but context-dependent. Phronesis is preferred as the appropriate mode of knowledge for Planning. It is knowledge that is largely experientially determined. This is likely to entail Schon's (Op cit.) reflection in action on a wide repertoire of similar instances.

In conclusion, a context such as obtainable in South Africa, issues of exclusion and inclusion, domination and marginalization remain relevant owing largely to the colonial and apartheid pasts. Sensitivity to Young's notion of justice as discussed above, in particular her idea of cultural imperialism is relevant and inescapable in dealing with instances such as the Shembe practice. The appeal to a unifying discourse as alluded above as demonstrated by Harvey serves as the bedrock upon which the operationalization of the above rests.

The writers cited above are all grappling progressively about the challenges at hand. They all embody the positive aspects of postmodernism as opportunity to rethink and re-energise planning theory and practice.

If cities are a result of collective creation (Peattie 1991), `voices from borderlands` that Sandercock (1995) speaks about have become increasingly vociferous in their challenge for planners to re-envision theory and practice to be more inclusive. They show us what is wrong with our cities and suggest ways for addressing some of these challenges. She elaborates further (ibid: 85) that they:

`...describe the state of living on/in the borderlands, living in between, living on the margins....living with uncertainty, living without universals. But they do not live without hope or without meaning. They embrace uncertainty as a potential space of radical openness which nourishes the vision of a more experimental culture, a more tolerant and multifocal one.

The building and sustenance of more inclusive and tolerant cities demands no less than a practice and a pedagogy that embraces the inherent diversity of city-life. Planning is still relevant in assisting to direct the form and scale of mainly government but also private sector

investment in cities. It also remains relevant in facilitating a much broader envisioning of the city.

Effective Community Engagement Tools in Watershed Plans: Examples from the USA

Mahbubur Meenar, Temple University, USA

Jeffrey Featherstone, Ph.D., Temple University, USA

Lynn Mandarano, Ph.D., Temple University

Brian Olszak, Temple University, USA

1. Introduction

The purpose of this paper is to explore, understand, and document various community engagement (CE) tools or instruments that have been used in the watershed planning process within the United States (USA). By “watershed plans”, we mean two types of plans: (i) watershed management, protection, or restoration plans, and (ii) flood management or stormwater management plans at the watershed level. This paper aims to find out a few exploratory questions. Does the nature of CE tools vary for watersheds of various scales or geographic regions? What are the most commonly used CE tools across the USA and why or how are they used in watershed plans? Have digital civic engagement tools, in recent times, become as popular as in-person engagement practices? What are the primary concerns or constraints of using CE tools effectively in developing USA-based watershed plans? What CE tools have been proved effective in the watershed planning process?

In order to answer the questions, we use qualitative methods such as document reviews and case study research. In the next section, we provide a literature review highlighting evaluations of the use of CE tools in the watershed planning process. In the following section, we develop a typology of various CE tools used in watershed plans of various scales. This typology is based on our review of 23 watershed plans, including watershed management, protection, or restoration plans and green infrastructure plans, selected from various regions of the USA. We document the use of in-person CE practices such as public information meetings, stakeholders outreach meetings, focus groups, and workshops, and digital CE practices such as emails, web sites, and social media. In the following section, we present seven brief case studies, selected from those initial 23 plans, discussing in detail the nature and types of CE techniques used in the watershed planning process. Finally, we discuss the major constraints of using CE tools and provide an outline of lessons learned from the USA that may be applicable to watershed planning in other counties.

2. Literature Review

The late American author and planner Sherry Arnstein (1969) developed a “ladder of public participation” that posits nine steps of participation ranging from “manipulation” at the bottom of the ladder to “delegated control” and “citizen control” at the top. Modern planners are familiar with these CE steps and realize that securing the support of important stakeholders can be the critical step in making a plan a reality (ISOCARP 2013).

Effective CE tools promote participatory decision making, an age-old process where people deliberate together over issues affecting their future and make appropriate decisions (Toker 2012). So, what does it mean in the world of planning? Throughout the decision making process, the planners work with stakeholders, help them reach decisions about planning issues, and translate the process and decisions into planning language (Toker 2012). The

CE process promotes two types of actions: making *for* people and making *with* people. Communities throughout the USA use participatory decision making tools in their planning and development processes in order to fulfill two primary objectives: understanding people's needs and practicing good design and management (Toker 2012).

The process of creating watershed plans can be highly technical. As such, public outreach and education programs are typical to most watershed planning processes. The more advanced forms of CE where citizens participate as decision makers are not as common because some professionals perceive this level of citizen input may undermine the value of the "experts." To address such concerns, watershed planners have developed methods and tools that not only address such concerns but also make this highly technical process inherently democratic.

Evaluation of effectiveness of participation and participation exercises

While much work has been done on evaluating partnerships and public engagement campaigns overall, very little research exists on the effectiveness of CE tools used within the context of watershed planning and management. Carr et al. (2012) conducted a meta-analysis of published research on any form of participation, from passively receiving information to actively engaging in decision-making in water resources management and planning, resulting in a categorization of three types of evaluation and corresponding criteria. The types of evaluations included quality of the participation process, intermediary outcomes, and resource management outcomes. The key findings indicate that only a few studies show watershed management benefits from participation, but no studies reveal negative impacts of participation. An earlier study by Mandarano (2008) reported the results of comprehensive evaluation of a National Estuary Program, a watershed management process, using all three tiers of evaluation noted by Carr et al. (2012). In this study participation was defined by the routine participation by individuals in the formal collaborative planning process. The findings indicate that the collaborative process produced learning, social capital, political capital, institutional changes and on-the-ground outcomes.

More conventional, ubiquitous and formal means of public engagement tools such as public hearings and public comment periods tend to emphasize the existing opposing sides while reinforcing existing power inequalities (Innes & Booher 2004). Kingsley (2008) found in a study of several public information meetings geared towards water management that, while public meetings served as a good source of information about watershed issues, they were not effective at increasing public participation for watershed planning. On the other hand, disseminating public information by utilizing technology-based learning (such as GIS) participants expressed a better presentation experience and enhanced understanding of the relationship between watershed management policies and water quality (Conroy & Gordon 2004).

Conroy (2011) evaluated the specific elements of the participation process in a water-quality planning process that encourage or discourage effective participation. The meeting and participation format (e.g. participating in an advisory board, a mail or telephone survey, an email solicitation, among others) had a significant influence on whether an individual was likely to participate (Conroy 2011). The effect many other elements of the participation process had on participants, including whether the topic was personally significant and whether meeting times were convenient, were also discussed.

Moorehouse & Elliff (2002) concluded from a study of a Texas water resource planning process that focus groups can "help facilitate communication and lessen frustration." Konisky & Beierle (2001) have qualitatively described and discussed the strengths and weakness of what were at the time "innovative" CE mechanisms—such as study circles, citizen juries, and collaborative watershed management—but called for more evaluation of these processes.

Some of these processes are aimed specifically at those who typically do not or would not participate in the more conventional or formal exercises.

Systematic study of the effectiveness of particular tools or mechanisms used for CE has been difficult due to a number of factors, as enumerated by Rowe & Frewer (2004; 2005). Various and overlapping definitions of tools and mechanisms exist, as there is no central authority or universally-agreed-upon definitions for these tools. While the usage of focus groups or interviews is widespread, many forms of workshops and other group-based interactions are often customized to the users.

Constraints to using CE tools effectively in watershed planning

Constraints to effective public participation throughout the process of watershed planning come in many forms. An incoherent leadership structure or failed problem identification can be serious constraints (Floress et al. 2009). The threat of the public seeing issues as being “studied to death” can also be a barrier to effective participation (Larson & Lach 2008), or that the process is seen as being more important to the project sponsors than “getting results” or “doing something.” Larson & Lach (2008) also found that different kinds of participants in a planning process (i.e. whether they are members of place-based or non-place-based organizations) affects the environmental attitudes of the participants, their expectations of the participation process, and how likely they will be satisfied with the results.

3. Review of CE Methods in Watershed Plans

We have reviewed 35 watershed plans, selected randomly through a Google search. After initial reviews, 23 plans that incorporated and described CE methods – either briefly or elaborately – were selected for further analysis. These plans were prepared by government agencies or nonprofit organizations from various regions across the USA, between 1999 and 2012. The CE methods or tools used in these plans were grouped into several categories, described below. Table 1 provides a matrix of PP methods used.

In-person CE practices:

- Public Meetings (public information meetings, citizen meetings, and stakeholder meetings)
- Group Interactions (advisory committees, citizen advisory committees, core work groups, technical work groups/ steering committees, focus groups, and youth outreach)
- Surveys and/or Questionnaires
- Events (workshops, charrettes, open houses, tours, speakers bureau, and major public events)
- Print (press/news releases, newsletter articles, brochures/handouts, and direct mailing)

Digital CE practices:

- Email
- Websites and Social Media
- Open Access Documents (public access to draft plans and document repositories)

Table 1: CE Methods used in watershed plans across the USA

Year	Title	Study Area (sq mi)	In-person CE practices					Digital CE practices		
			Public Meetings	Group Interactions	Survey/ Questionnaire	Events	Print Media	Email	Websites & Social Media	Open Access Documents
1999	Petaluma Watershed Enhancement Plan	146	X	X		X				
2000	Gwinnett County Watershed Protection Plan	437	X	X					X	
2002	Public Participation Plan for Carlsbad Watershed Management Plan	210	X	X	X	X				
2005	WRIA 1 Watershed Management Project	1280	X	X	X		X		X	
2006	St. Clair County Northeastern Watersheds Management Plan	219	X	X	X	X	X		X	
2006	Southern Washington County Watershed Protection Plan	56	X	X	X		X			
2004; 2008	Flint River Watershed Management Plan	568	X							
2008	Plum Creek Watershed Protection Plan	397	X	X	X	X	X	X		
2008	Pebble Creek Watershed Protection Plan	18		X						
2009	Metro North Georgia Watershed Management Plan	4941		X						
2010	Anacostia River Watershed Restoration Plan and Report	176	X	X	X	X			X	
2010	Duck Creek Watershed Management Plan	63	X	X	X	X	X	X		
2010	Mill Creek Watershed Management Plan	25	X	X						
2011	Blackberry Creek Watershed Action Plan	75		X						
2011	Middle Huron River Subwatershed Management Plan	217	X	X		X	X	X	X	X
2011	Norwalk River Watershed Action Plan	64	X	X						
2011	Prairie Dog Creek Watershed Plan	360	X	X			X			

Year	Title	Study Area (sq mi)	In-person CE practices					Digital CE practices		
			Public Meetings	Group Interactions	Survey/ Questionnaire	Events	Print Media	Email	Websites & Social Media	Open Access Documents
2011	San Marcos Master Water Quality & Hydromodification Plan	20								
2012	Antelope Creek Watershed Basin Management Plan	8	X	X		X	X		X	
2012	Barrington-Palmer-Warren Rivers Watershed Plan	68	X		X			X	X	X
2012	San Francisco and Blue Rivers Watershed Improvement Plan	2700	X	X						
2012	Santa Rosa Creek Watershed Management Plan	48	X	X	X	X				
2012	Lower Sonoma Creek Flood Management and Ecosystem Enhancement	166	X							

Based on initial reviews, we have found that the vast majority of plans (80%) reported incorporating the more conventional practices of in-person strategies, including public meetings and group or committee interactions to foster community engagement. Less than half (40%) included a description of any public events other than meetings. These public events could include more interactive processes that might attract a larger subset of the target population, such as workshops, design charrettes, and watershed tours and festivals. Far fewer plans included mention of any digital civic engagement practices: 32% of plans mentioned having a website or social media presence as an outreach tool, while only 20% of plans explicitly mentioned using email. No plans surveyed explicitly mentioned using social media as a part of the planning process, although one (Antelope Creek WBMP) indicated use of a social media strategy for one of their recommendations, focusing on homeowner outreach and education.

4. Brief Case Studies

The seven case studies presented herein highlight the CE tools used to support watershed management planning. In each case study CE tools were used for a range of public education and outreach to decision making practices to inform the formal decision-making body, which are a range of collaborative partnerships and coalitions responsible for developing and implementing the resulting watershed management plan.

Anacostia River Watershed Restoration Plan¹, 2010, Washington DC metro, size 176 sq miles

This watershed restoration plan was prepared by the Anacostia Watershed Restoration Partnership (AWRP), but the CE process was primarily handled by a citizen advisory committee—the Anacostia Watershed Citizens Advisory Committee (AWCAC). The AWCAC was formed and used by the project team to solicit comment and feedback during the plan's development. Additional discussions and meetings with the committee members and representatives of other community and watershed groups were held.

A public meeting open to all citizens was held during the beginning of the planning process to outline the study objectives, the proposed methods to be used and the products to be completed for the plan. Several interim “working” meetings were held primarily with the constituent watershed groups of the study area to brief group members on study progress and solicit feedback on the prioritization and support for proposed or provisional restoration projects in their respective subwatersheds.

Interim reports and fact sheets on the progress and status of the study were posted on the web site *anacostia.net*, with a 45-day open public comment period following the release of interim reports. Final draft reports were posted on the internet for a 60-day public review and comment period, specifically to solicit feedback from community watershed organizations and other interested parties.

Antelope Creek Watershed Basin Management Plan², 2012, City of Lincoln, NE, size 8 sq miles

The City of Lincoln and Lower Platte South Natural Resources District (NRD) worked with a project team of scientists and engineers to establish this watershed basin management plan and oversee the CE process. The CE process included both group interactions and public events. There were two main group interactions: the Core Work Group – professional and technical staff from various agencies, who met 11 times; and an Advisory Council – 12 member council comprised of resident, business and institutional stakeholders, whose members were proposed by the Core Work Group and appointed by Mayor. The council met three times. Two open house events were also held for the public at large: one at the beginning (in which approximately 90 people attended) and one toward the end of the process (in which approximately 40 people attended). In advance of the open houses, 11,000 postcard invitations were sent to property owners, and representatives of special interest groups and resource agencies. The first Open House used a large map of the Basin area, on which stakeholders and other participants could point to their houses and to the associated problem areas. The second Open House featured different stations at which people could stop and learn about the recommendations. More thorough stakeholder meetings were held with six stakeholder groups, which were identified by the Advisory Committee.

Four editions of newsletters were composed and mailed to 1,100 individual stakeholders, including individuals, businesses, non-profit agencies, community organizations and government agencies. The first two newsletters outlined the general watershed management process and the typical stormwater and pollution issues facing a watershed, while the last two presented the watershed modeling and testing conclusions, as well as the stormwater best management practices (BMP) recommendations for the plan. Press releases and news articles were utilized to publicize the open house events, while also keeping the public abreast on plan activities. The City of Lincoln Watershed Department website was also used to keep the public abreast on the details of the planning process. Information on the website included a project description, frequently asked questions, Core Work Group and Advisory Council descriptions and membership, as well as descriptions of the CE processes. The site was regularly updated and included an interactive glossary and several images.

Barrington-Palmer-Warren Rivers Watershed Plan³, 2012, East RI/West MA, size 68 sq miles

The FB Environmental Associates of Portland, ME, was the US Environmental Protection Agency (USEPA) contractor responsible for working with Rhode Island Department of Environmental Management (RIDEM) in the development of this watershed plan and oversee the CE process. The plan encompassed a broad array of stakeholders from Rhode Island and Massachusetts, including municipalities, non-profit and conservation organizations, Massachusetts Department of Environmental Protection (MADEP), and local citizens.

To introduce the planning process to stakeholders, two kick-off meetings were held attracting 27 and 17 attendees, respectively. Stakeholders included municipal elected officials, town/regional planners, watershed association members, natural resource professionals, representatives from non-profit organizations, and landowners in the watershed. Flyers were used to publicize the meetings, and follow-up phone calls were made to invited stakeholders in advance of the meetings. All meeting documents and maps were posted on the project website.

In addition, municipal meetings were held in individual watershed towns. Attendees were identified during the kick-off meetings and included municipal employees and other stakeholders. Similarly, follow-up email and phone calls were used to confirm attendees. In total five municipal meetings were held. Draft summaries of meetings were sent to municipal officials for review and comment before submitting the final draft to the RIDEM and USEPA.

A draft watershed plan was posted on website for approximately 2 months for public review and comment before being finalized. A public meeting was also held to solicit public comment on the draft report.

Duck Creek Watershed Management Plan⁴, 2010, Southeast Iowa, Size 63 sq miles

This watershed management plan was created by Scott County Soil and Water Conservation District (SCSWCD), in collaboration with Duck Creek Watershed Management Plan Advisory Council, Iowa Department of Natural Resources, and other partners from local government agencies. A local nonprofit, River Action, Inc. facilitated a planning committee, which met monthly for one year. The committee consisted of representatives of federal, state, county and municipal agencies, corporate stakeholders, local professionals, environmental organizations and concerned landowners and citizens, and created an initial watershed plan in 2008-2009. This second plan, sponsored by the Scott County Soil and Water Conservation District (SCSWCD), continues the work of the initial plan.

As part of the CE process, the SCSWCD and Partners of Scott County Watersheds, among other local partners, conducted a series of public meetings, with approximately 40 people on average attending each, including the local media, which resulted in press coverage. The plan's description of this process noted that more meetings should be held because they are "an effective means of providing information, receiving input, and attracting press." A direct mailing was sent to land owners and key agricultural operators. This mailing included a request to respond if interested in receiving additional cost-share programs and incentives on manure management planning. There was little to no response. A meeting in which the SCSWCD specifically reached out to livestock producers was organized, with mailed postcard invitations with follow-up phone calls – 25 attended, 14 of which were livestock producers. Surveys were distributed at beginning of meeting, and 7 were returned.

Surveys and questionnaires were sent to the youth in the watershed area specifically soliciting their views. An online Survey was emailed to 400 young people, with 83 individuals completing the survey. The youth survey also was distributed during an environmental fair, and 194 surveys were completed.

The SCSWCD found that there was little enthusiasm for serving on the SCSWCD committee to determine future projects in Duck Creek Watershed. The agency concluded that more enticing, exciting, interactive tactics will be researched and used to engage the public in the planning process.

Plum Creek Watershed Protection Plan⁵, 2008, TX, Size 397 sq miles

The Plum Creek Watershed Partnership and the Watershed Coordination Steering Committee (WCSC) of the Texas State Soil and Water Conservation Board chose Plum Creek to develop a watershed protection plan as a voluntary alternative to more regulatory approaches water quality management. Several initial public meetings were held to advertise and inform the public about the watershed planning process, and participants were openly invited to join the resulting Plum Creek Watershed Partnership, which would be the main vehicle for the planning and CE process. From this partnership, a steering committee, work groups, and a technical advisory group were formed, composed of extension and conservation district representatives, local and regional governments, and citizens and volunteers.

This process had many informational and more passive venues for outreach. A plan website included information on the watershed and partnership, a regional watershed coordination newsletter, press releases, an online discussion forum, links to project partners, access to the Watershed Protection Plan, water quality data, a meeting schedule, and information presented at previous meetings. Fact sheets were distributed in the watershed via direct and electronic mail, at stakeholder meetings, and at other area events, and were made available at various public offices and community organizations; updated versions are made available on the project website. Ten news releases were sent out to over 100 media outlets. Newsletter articles were written and distributed bi-monthly and via email to watershed groups and several other additional outlets such as community organizations, extension officers, master gardeners, master naturalists, and homeowners groups. These articles were also posted on the website.

The partnership steering committee sponsored events such as a watershed tour, which was a full-day event with 64 participants. Its goal was to provide an overview of the current conditions and challenges the watershed faced. An outreach and education work group of the Plum Creek Watershed Partnership, in order to create a logo and branding identity for the watershed planning effort, surveyed stakeholders to solicit ideas. When used with project-related document and marketing materials the logo and associated branding were intended to stimulate more public awareness and program recognition.

WRIA 1 Watershed Management Project⁶, Long-Range Plan for Public Involvement and Education, 2001, Bellingham, WA, Area: 1,280 sq miles

A collaborative partnership among federal, state, and local agencies was in charge of the overall decision-making process of this watershed management plan. In addition, the Planning Unit of a regional coalition of county, city, state and tribal governments created a separate CE plan. This CE plan includes a series of proposals intended to integrate public involvement and education into the ensuing watershed planning process. The plan included the participatory elements for both the planning and the implementation phases of the watershed management plan, with the intent to both inform and solicit involvement and input. When soliciting input the three general strategies were to solicit direct input, stay attuned through “temperature taking” by monitoring the understanding and feelings of citizens in general, and to close the loop by having citizens see how their input was being incorporated into the planning and implementation process.

Several CE tools were used to inform citizens of the issues and of the planning process in general. They included broadcast and print media activities (television, a newsletter insert in local newspapers and radio), a project website, bi-weekly/monthly updates via website, email, fax, and articles in existing newsletters. Project information and updates were included in other governmental outreach efforts as well. In the rural parts of the watershed that did not have established community organizations, informal community leaders are being recruited to help educate the local public during the ongoing planning process. This effort will also

include maintaining a presence at local festivals and events, with tables, information distribution, and displays.

Venues to gather and solicit feedback and comments included quarterly public meetings that included Q & A surveys that followed meetings, a speaker's bureau to attend meetings of community groups and organizations and solicit input, and disseminating information and questionnaires at coffee shops, laundromats and other informal gathering places. A technical team was created to translate scientific and technical information and surveys to an average lay person. An evaluation of the CE process and individual methods will be undertaken by the Planning Unit staff.

Middle Huron Watershed Management Plan – Public Participation Document⁷, 2011, Ann Arbor-Ypsilanti Metropolitan Area, MI, Area: 217 sq miles

The Huron River Watershed Council (HRWC) was responsible for the overall collaborative watershed planning process. A separate public participation plan (PPP) was developed for the Middle Huron Watershed Management Plan. This PPP was submitted by the HRWC, and it included two main categories of participation: Public Notices and Outreach and a Citizen Advisory Committee or CAC. The CAC was made up of local stakeholders that met on a regular basis to provide feedback on the plan as it was being developed. The HRWC, in conjunction with the Middle Huron River Stormwater Advisory Group (SAD) implemented the PPP. Public meetings were held at various stages of the process as well, one of which was in collaboration with the CAC.

Media and press releases and articles in local newsletters were used to alert the public about plan progress and solicit feedback from citizens on the plan development. Announcements to local boards and other interested groups were also made, including email listservs for two adjoining watershed councils. Announcements, flyer distribution were handed out and on display at major public events in watershed communities soliciting citizens' involvement in the planning process and initiative. The project website shared information on the status of the plan's development, as well as the planning process in general—the websites hits were tracked as well.

Throughout the CE process, the HRWC evaluated the various tools. An evaluation survey form was handed out to all participants after each meeting or event, with special attention given to finding out how each participant found out about the meeting or event.

5. Lessons Learned from the USA Experience

Our paper set out to explore how CE tools are being used in the watershed planning process in the USA. We sought to understand the effective use of CE tools from several perspectives. First, our aim was to reveal which CE tools have been proven effective in the watershed planning process. The planning documents reviewed indicate that agencies and nonprofit organizations employ a large number of in-person and digital CE tools. While Sherry Arnstein (1969) would describe many of these tools as “tokenism” in her ladder of participation as most only involve consultation and information exchange, they seem to be legitimate attempts by organizations to inform and engage the public, particularly the important stakeholders in the watersheds. Unfortunately, the descriptions of civic engagement processes in the watershed plans and related documents do not include information relative to assessing the effectiveness of such efforts.

With respect to the variability of CE tools employed and most common tools used, the paper indicates processes across the US are making use of a broad array of CE tools. The most commonly used tools are traditional CE practices such as public meetings, group

interactions, events, and surveys. Digital CE technologies are increasing in usage. There does not appear to be a relationship between the size or geography of the watershed or complexity of the issues and the types of CE tools used. This lack of variability is likely due to the organizers' familiarity with traditional forms of CE and reliance on using the practices already in their tool box.

The most interesting findings are related to the primary concerns and constraints of using CE tools in watershed planning processes. While the efforts appears to target improving the public's education and awareness of the planning process, a handful also appear to include serious attempts to create partnerships and provide some degree of delegated power to plan stakeholders. This limitation is likely linked to the inherent constraints associated with watershed management and planning. Watersheds almost always transcend political jurisdictions and involve fragmentation of authority and involve complex scientific concerns, thus seeking citizen control or delegating decision-making powers to the general public is simply not feasible.

Our paper also describes the complexities associated with conducting CE. Some organizations directly conduct CE processes, while others use existing councils and citizens' advisory committees or create new ones to support the development of a watershed plan. In our analysis of watershed planning we found that it was often difficult to discern the degrees of autonomy and authority provided these councils and committees, and whether or not these functions were important to the success of the formal decision-making process or implementation.

The case studies do not provide clear answer to the question about which CE tools have proved most successful. As noted early, the documents reviewed provided descriptive information of the CE process but not assessments of their impacts. What is needed to answer the question regarding the effectiveness of CE tools and their correlation to successful decision making and implementation is rigorous third party assessments. For example, in his analysis of the planning and management activities of Delaware River Basin Commission (DRBC), a four-state, federal-interstate compact agency, Featherstone (1999) sought to link actions taken by the agency to achieving stated goals and positive outcomes through a program evaluation methodology. Through use of multiple analytical techniques including statistics and surveys, Featherstone was able to document positive outcomes achieved by the DRBC. This level of research was beyond the scope of this paper.

Synopsis

This contribution highlights the role of public, private and non-profit actors in urban regeneration processes reconsidering the leading role of municipal governments. The objective is to investigate which reasons drive local authorities to support PPP, and to understand how partnership models work and which conditions make them effective.

1. Urban Regeneration and Partnership dynamics

In OECD Countries - particularly in United States as well as in Western Europe.- since the last decades Urban Regeneration strategies have been representing a major goal for urban policies. Major cities have been supporting significant efforts to renovate public spaces and improve the attractiveness and accessibility of deprived urban areas, while reinforcing the sense of community and confronting with discouraging economic performances, deteriorating physical conditions, crime and safety concerns, social exclusion, environmental degradation.

The evolutionary path from the obsolete "renewal" rationale in the fifties of the last century to the more recent "regeneration" dimension can be identified in the transition from "place-oriented" to "people-oriented" strategies in which, through the strengthening of the social vector, the idea of physical, economic, environmental regeneration is enriched by new opportunities in order to pursue an authentic holistic dimension of the city and its enlarged community.

As the scientific literature has showed, it is a complex and multifaceted evolution, starting with the "urban renewal" approach and developing through the second part of the XX century with the maturation of specific models labelled by different definitions (Berg, Braun, Meer 1998), going from the so called "Urban Revitalization", mainly connected to the North American domain (Sutton 2008), to the properly called "Urban Regeneration" policies, mostly referred to the European context, despite its deep inner cultural diversity.

In the different styles of success regeneration policies and actions, the common "dna" can be identified in the integration concept: programs and projects show virtuous mix of activities, services, infrastructures, financing, and - "last but not least" - forms of governance with flexible partnerships among actors as representative as possible of the richness and vitality of the urban communities.

The issue of innovative partnerships within the contemporary crisis has become critical for governments, called to promote and implement effective transformations of urban and natural contexts through a virtuous cooperative vision, involving not only the traditional privileged subjects of the private domain, but also the small businesses, the community associations, other molecular, recessive stakeholders.

Agreeing that Urban Regeneration may be defined as a comprehensive and integrated vision which leads to the resolution of urban problems and aims at achieving improvements in the economic, physical, social and environmental conditions of the area that is being transformed (Roberts and Sykes, 2006), it is evident that its success is in most cases strongly influenced by the ability to face the challenge and “invent” and test innovative forms of partnerships ensuring and enhancing broader participation and inclusion in the whole project cycle.

Therefore, it is important to argue on the nature of some specific tools of Public-Private Partnership (PPP) in USA – particularly belonging to the non-profit dimension – trying to figure out their evolution since their introduction some decades ago and their present role in order to pursue virtuous scenarios and define innovative models in Urban Regeneration policies.

In the United States, PPP has a long tradition as national and state-government tool to regenerate urban communities (Osborne, 2000): since the 50s, several US federal programs were approved to support public-private cooperation – Urban Renewal Program (1949-1974), Community Development Block Grants (CDBG, since 1974), Urban Development Action Grants (UDAG- terminated) – and in the last 70s PPP was directly supported by the Carter Administration and its National Urban Policy (1978).

As highlighted by many authors, in the 1990s PPP has been established as a key tool of public policy across the world (Osborne, 2000). With respect to Europe, in general, there is an increasing political consensus about the importance of encouraging and implementing PPP models, although looking at the other side of the Atlantic ocean, different cultures, models and styles are evident. Concerning the “Common law” Country domain, for instance, over the last decades the UK Government has promoted multisectoral partnerships as a key factor to achieve urban regeneration and as an important way of dealing with the most severe urban problems (Lawless, 1991; Bailey, 1995). Indeed, particularly in the “Civil law” juridical culture Countries (Italy, France, partly Spain), the connection between non-profit organizations and private investors remains comparatively fragile (Jacobs, 1987) and in most cases those European non-profits show a high degree of economic dependency from the public authorities, since they represent an organizational tool for providing social services.

The importance of involving multiple stakeholders in urban regeneration processes has been widely investigated (Healey, 1996, 1997, 2007; Osborne, 2000; Reuschke, 2001) and some authors already highlighted how public-private interactions can support urban competitiveness and cohesion. Residents and community organizations have long sought out new formulas in order to guarantee wider participation in urban redevelopment initiatives and new forms of cooperation with the public sector.

Such an effort has to be considered even more important because of the increasing scarcity of public financial resources, which have driven local authorities to enhance a general partnership approach and to support strong relationship with non-profit organizations including the complex reality of local and external stakeholders.

On these premises, the main objective of this paper is to argue the role of public and private subjects in the partnerships supporting Urban Regeneration and the structure of the relationship among them, with a specific focus on the innovative role of non-profit organizations in progress in US. The investigation, based on the analysis of four case-studies, aims at highlighting the issue of the “flexible geometry” in roles of public, private and non-profit actors and the different approaches that might be adopted to reconsider the

leading role of municipal governments while proposing community-based solutions to public problems.

The case-study exploration is not limited to underline the traditional features of some good practices – quality performance in delivering community and social infrastructures, services and facilities, in supporting local community involvement and empowerment in decision making processes – but it also shows some of the problems connected with partnership involving community and public sector organizations – such as the leading (and sometimes meddling) role of public authorities supporting specific interests.

Moreover, the selected case-studies show the significance of PPP in overcoming divisions that previously undermined the urban regeneration process, illustrate different economic implications as for the involvement of the private and the public sectors, point out the decisive role of non-profit organizations when social issues are the main weakness and at the same time the major driving force for the regeneration process.

2. Understanding Public-Private Partnership: a brief background

In the United States the tradition of PPP is well established. As briefly mentioned in the introduction, its first applications date back to the 50s, but it found a wider use, which arrives to nowadays, especially from the 70s with the spread of downtown redevelopments projects (Osborne, 2000).

PPP can be described as a «contractual arrangement between a public sector agency and private sector concern, whereby resources and risks are shared for the purpose of delivering a public service, or for developing public infrastructure. (...) The intent, in any case, is to combine the resources of the public and private sectors, in the quest of providing services at optimal levels to the public» (Akintoye et al., 2008, p. 31). Actors involved in PPP are usually seeking for ambitions «they could not complete alone», which means that a «true» venture is the one in which mutually risk-sharing and mutually beneficial goals drive to jointly owned products (Sagalyn, 2007). In other words, the PPP approach aims at bringing resources and skills of the private sector in a number of different development projects which the public sector could not afford in a stand-alone position (Sagalyn, 2007).

The theoretical background of the PPP approach, especially in the US, is extremely wide as it gets to the very bottom of the same American economic and political tradition (Barnekov, *et al*, 1989), and is furthermore very controversial (Newman, 2001). Focusing our view just on the last decades, and according to many authors, PPP can be read as an opportunity to deepen democracy because of its potential to develop new forms of community participation in the affairs that directly concern the community itself (Coaffe and Healy 2003; Newman 2005). In fact, through both participation of different actors and cooperative practice the effort for a composition of pluralistic views typical of modern societies can find an optimal resolution, which also reflects a more effective and adequate governance (Kooiman, 1993; Rhodes, 1996).

Referring the last concept to the urban studies, PPP supporting urban regeneration operates as a strategic factor in the empowerment of individuals, communities and organizations in the provision of public services, thus transforming them into «self-sufficient, active, productive, and participatory citizens» (Cruikshank, 1994, p. 35), namely “active subjects” influencing and helping to shape government practice (Taylor, 2007).

Moreover, the rationale at the bottom of the PPP approach can be also related to the same origin of the communicative approach, in which «a communicative conception of rationality (...) replaces that of the self-conscious autonomous subject using principles of logic and

scientifically formulated empirical knowledge to guide actions. This new conception of reasoning is arrived at by an intersubjective effort at mutual understanding. This refocuses the practices of planning to enable purposes to be communicatively discovered» (Healey, 1996, p. 239).

Despite an optimistic view, some controversial topics about PPP have been highlighted by a critical literature which points out threats and weaknesses that may afflict the composition process.

On one hand, some authors point out how the benefits coming from the interaction between different actors and different concerns need an appropriate managing in order to translate the intervention of private actors in a proper social benefit (Fainstein, 2001; Sagalyn, 2007; Kokx, 2011).

On the other hand, other authors watch at the topic with a more skeptical view, basically underlining the incompatibility between market-oriented forces and public interests. In the most recent experiences of composition and relationships of different actors Swyngedouw (2005) reads the affirmation of neoliberal policies able to produce social disparities more than social benefits. Newman (2001) and Clarke (2004) focus on the difference of horizons between short-term pragmatism and public governance, pointing out that a performance-driven rationale might not be always appropriate with long-term sustainable goals.

As mentioned in the introduction, this paper intends to contribute to the literature about PPP focusing on the composition of varied concerns and on the interaction between different actors, especially with respect to the role of non-profit organizations.

In the United States non-profits are part of an extensive network involving non-governmental institutions in the integration of local activist organizations and other groups into “traditional” processes (Jacobs, 1987). The strategic role of non-profit organizations in the United States have been increasing following the urban uprisings of the mid-1960s and early 1970s, around a «notion of “corporate responsibility” [which] allowed companies to pursue their quest for profit while at the same time being “responsible” within the urban communities (...)» (Jacobs, 1987, p. 31). As it is pointed out (Ward and Imbroscio, 2011), non-profit organizations have become a new form of governance which institutionalizes the role of a range of actors in shaping the city through formal and informal politics. The same authors recognize the role of these organizations in expanding the definition of planning practice «including informal practices of urban dwellers and poor citizens, and recognize the role of citizens in constructing their neighborhoods, cities and livelihoods».

As the broader topic of PPP is, the literature about non-profit organizations and their role in defining spatial policies and practices is controversial. In fact, as argued by Rathgeb Smith (2000), a lacunae in actual theory still exists and the role of non-profits in enhancing social welfare has been probably overemphasized, especially with respect to explicitly politically significant functions that non-profits are fulfilling in urban areas.

3. Learning from US: Boston and San Diego case studies

As mentioned in the introduction, the main goal of the research this paper is dealing with was to explore diverse model of PPP within the general framework of urban redevelopment strategies. The investigation was conducted within a broader research¹ on urban regeneration tools and strategies in the United States, with a specific focus on economic and social aspects.

Considering the adopted inductive approach and to thoroughly analyse the multifaceted nature of PPP supporting urban regeneration processes, both at theoretical and empirical level, a “grounded theory” approach was adopted.

In order to avoid basing hypothesis on theoretical grounds – therefore in order not to allow for unexpected results to emerge from the investigation itself – quantitative and qualitative data were collected through several methods and different sources. First of all, the analysis of statistics from the Census Bureau was carried out to identify useful data on the demographic, social and economic features of the selected neighbourhoods. A review of community plans, redevelopment initiatives, zoning and land use was useful to identify the planning perspective and the most significant changes in the case-study areas. At the same time, critical overviews on related literature and press were carried out to find out connections, outcomes and possible weaknesses about the interventions and the PPP supporting the redevelopment process. Finally, qualitative data were gathered from interviews with selected stakeholders in order to identify and fully understand the different driving forces involved in the process and in the PPP itself.

More in detail, three different urban redevelopment-oriented models of non-profit organizations in the US were investigated (Business Improvement Districts², Main Street Organizations³ and Community Development Corporations⁴) in different contexts – Boston (Massachusetts) and San Diego (California).

The four cases studies described in the following paragraphs (*Downtown Boston Improvement District* plus the *Washington Gateway Main Street Program* in Boston; *North Park BID/Main Street* in San Diego; *Dudley Street Neighbourhood Initiative* in Boston) were selected in order to analyse differences in partnership composition, in urban regeneration models and in the role played by the involved stakeholders.

3.1 Downtown Boston Improvement District (Boston)

The *Downtown Boston Business Improvement District (BID)* was established in 2011 after 15 challenging years and it represents the strength of a solid finally achieved partnership.

As a non-profit development initiative, it is committed to offer supplemental services to support long-term maintenance while encouraging a general economic revitalization of Boston Downtown, where the mix of commercial, hospitality, institutional and residential properties demanded a higher level of elementary yet consequential public services that the City of Boston provided.

While the *BID* management entity is a non-profit organization of private property owners located in the district, the whole initiative is a solid and long-pursued partnership between local authorities and quasi-governmental entities, private owners and local stakeholders. Actually, as any other BID, the *Downtown Boston BID* is publicly authorized and privately managed, but it has been unusually promoted and supported in the start-up process and in its early stages: the City of Boston and the *Boston Redevelopment Authority (BRA)* played a leading and strategic role during the start-up, strongly championing the initiative and supporting the creation of the partnership.

Undoubtedly, the *Downtown Boston BID* is a successful PPP and it represents an important turning point for the area. A wide range of stakeholders were involved at all stages and the strong public leadership encouraged the dialogue between the actors involved: public meetings, official discussions with local stakeholders, face-to-face persuading campaign were necessary to overcome short and long term problems and to decrease tension. Therefore, since this BID exists in deep relation with local authorities and public actors, it may be considered part of the collective action determining urban policies.

Moreover, since Boston Downtown was facing more demanding issues – the decline affecting the area had causes and implications a BID hardly manages – the public involvement was crucial to support the non-profit in its challenging goal of transforming Downtown Boston into a cleaner, safer and more attractive place.

However, it may be questioned if such an involvement of the public authorities might compromise the BID's self-government and the non-profit autonomy. Actually, this initiative is continuing the positive development trend started by previous redevelopment initiatives promoted by the public authority, but it is hard to distinguish these previous initiatives and the good outcomes they produced from the BID's general strategy.

3.2 *Washington Gateway Main Street (Boston)*

Washington Gateway Main Street is a non-profit organization implementing the Boston Main Streets Program. Set up in 1997 as an outgrowth of the intense work of a 40-members Task Force appointed by Mayor Menino, it aims at revitalizing the neighbourhood from decades of decline while sustaining the economic vitality of its commercial and residential areas.

In more than 15 years, many results have been achieved and the initiative has been supported by an intense volunteer work and by a strong partnership – guided by the *Boston Redevelopment Authority (BRA)* – public sector), a pool of private developers and diverse local communities, in a joint effort to revitalize the whole neighbourhood starting from commerce but giving great importance to social and infrastructural issues. At the same time, *Washington Gateway* initiative was strongly supported by the community, with a wide involvement of diverse representatives and committees – business associations, religious leaders, artists, retailers, bank representatives and residents.

Thanks to the strong connection among all the stakeholders involved in the process, *Washington Gateway* has been really successful in the implementation of the regeneration strategy.

Probably the most remarkable factor has been the cooperation between the public sector and the non-profit organization itself. Since the initiative is part of the *Boston Main Streets Program*, the role of *BRA* has been definitely crucial. Nevertheless, the Main Street itself had a significant role in the decision making process, developing a strong and comprehensive vision with the involvement of the community and the main stakeholders. This “visioning” process has been assured thanks to a wide participation and a broad consensus, both made possible by the creation of an *ad hoc* Volunteer Committee – significantly, more than 22.600 hours of volunteered work helped to the accomplishments of the program.

Figure 1: *Downtown Boston and Washington Street before the urban redevelopment*
(Source: Brown, 2012; *Washington Gateway Main Street*)

Moreover, the special composition of the Board of Directors, with its high skilled staff also working in local organizations and in the City, was very important for partnership building.

It has to be highlighted the strategic role of public and private foundations and committees, helping in the redevelopment process. Once the interests of the private sector increased, *Washington Gateway's* Design Committee worked with developers to review proposals and to preserve historical, social and economic aspects of the area, matching different needs and solutions.

3.3 North Park Main Street and BID (San Diego)

North Park Main Street is an interesting case of different associations and varied initiatives in the same area; indeed, it is a BID – established in 1985 by the City of San Diego – and a Main Street affiliated with the National Trust for Historic Preservation – established in 1996, when the City selected the existing BID to be the pilot project for the national Main Street program. As a volunteer-based non-profit organization, *North Park Main Street* administers the BID (a non-profit organization itself) and promotes the development of the area while preserving its integrity and encouraging an urban pedestrian-friendly environment.

The reasons behind the public and private partners collaborating on the initiative are the diversified strategy promoted by the Main Street itself, the lack of adequate financial resources, the varied social and economic demands of one of the oldest community in San Diego, with a clear historical and cultural character, a strong vocation to become a vibrant and attractive area for young people, an on-going commercial decline.

Actually, *North Park Main Street* has been supported by an intense volunteer work, a strong involvement of the community and a solid partnership – involving the City of San Diego and the *Redevelopment Agency*⁵, almost 500 business and retailers, private developers and local organizations – in a joint effort to revitalize the whole neighbourhood starting from commerce but giving great importance to cultural issues.

A distinctive feature of the initiative is the strong connection between two non-profits (the BID and the Main Street) with different missions and tools but sharing the same Board of Directors. Indeed, while the BID was crucial for the involvement of local businesses paying an annual fee to support the enhancement of services, infrastructure, security, etc., the Main Street played the major role in involving the community, in supporting projects and programs in the area, in finding funds and grants for implementing the regeneration strategy.

On the other hand, the public sector was deeply involved in the physical redevelopment, while the community strongly supported the redevelopment process in its starting stage, also taking advantage from many professionals living in North Park (architects, planners, artists).

Figure 2: Some redevelopment interventions carried out by North Park Main Street

A significant role was also played by the *Community Planning Group*, a quasi-autonomous non-governmental organization – strategic in expressing the demands of the local community and acting as a go-between among the community, the private sector and the public authorities.

3.4 Dudley Street Neighbourhood Initiative

Dudley Street Neighborhood Initiative (DSNI) is a non-profit community planning and intergenerational organizing entity operating in the neighbourhood of Roxbury (Boston). One of the most famous initiatives of its kind in the United States, DSNI was formed in 1984 when elders as well as youth joined together in an effort to claim back their neighbourhood after a period of abandonment and despair. Ever since, it has been operating in the neighbourhood with social and economic targets.

At the basis of the actions and initiatives undertaken by DSNI is a close partnership with different actors and subjects that range from non-profit organizations to governmental agencies and other private subjects.

The rationale behind the various partners collaborating is that DSNI does not have enough financial resources to carry out all the initiatives proposed and needs collaboration and support from different actors. Thus, DSNI partners with different actors on the basis of the initiatives undertaken and promoted and does not set up privileged or specific partnerships.

It can be claimed therefore that its role is mainly to propose, put forward and support new initiatives which are carried out by other agencies.

Dudley Street Neighbourhood Initiative represents a unique case, under different points of view. Although it is a community-based organization and even though it has all the characteristics proper to a CDC, it is not a Community Development Corporation. This has certain advantages on the actions and initiatives proposed by the organization, especially in housing development schemes and in the achievement of the public good. Such characteristic of great flexibility allows DSNI to select the best partner on the basis of different criteria, goals to be achieved and human resources to involve.

Evidently, it can be claimed that DSNI as a community-based organization plays a crucial

Figure 3: The Triangle, main project area for DSNI Boston, in 1995 and 2010

role in urban planning and regeneration initiatives within the area. Its special status of eminent domain authority organization represents a unique case which can hardly be compared to any other case where a private organization is granted such a fundamental power for the planning activity. Its role within the community is very active and its involvement in almost all of the planning and urban regeneration projects undertaken within the neighbourhood ensures that the community interest is taken into consideration and it is a good example of non-profit community planning and organizing entities which reflect the general role that such organizations have within the USA.

4 Perspectives and open problems

As highlighted in the case-studies, within urban redevelopment policies and practices, innovation in PPP models has become increasingly important; the significance of partnerships between the public and the private sectors lies in the possibility to overcome dialectics that previously conditioned virtuous interpretations of the Urban Regeneration idea. In emerging scenarios, non-profit organizations may play a strategic role, when being able to achieve a balance between public and private interests and demands of the community. So, within the general framework of urban redevelopment strategies in US, reflections and case studies have been focused on the exploration of diverse “PPP architectures” re-considering the role of public and private stakeholders involved in the process.

It has been seen that a well-established PPP may support the redevelopment process strongly affecting its success, above all with respect to quality performance in providing social services and community facilities and in supporting local community involvement and empowerment in decision making processes.

Nevertheless, the investigation shows that in some cases strong partnerships and successful redevelopment processes have been possible when the central government and the public authorities promoted, encouraged and financially supported “ad hoc” non-profit organizations.

However, the leading role of public authorities supporting specific interests might be somewhat meddling. If a strong partnership has the potential to be a key factor for the redevelopment processes, this potential may be undermined by an institutional framework that hinders the ability of the involved stakeholders to make choices and to address the main challenges. In other words, under certain circumstances PPP may be highly restrictive, representing a narrow composition or being opaque in its dynamics.

The role of the public sector was crucial for *Downtown Boston BID* where the PPP championed by the public authorities was the decisive condition to overcome long-standing difficulties and repeated failed attempts; but such an institutional involvement was also responsible for an incomplete support by the private sector. Indeed, when in 2010 the BID petition was presented to the City Council, it was signed by at least 60% of the property owners in the district, but some of the most important stakeholders and owners refused to join the non-profit organization – therefore they represent a significant drawback for the BID’s strategy and an important restriction in the PPP itself.

On the other hand, as far as the involvement of the private and the public sectors, case studies illustrate different economic implications.

As pointed out in the literature, often private stakeholders are the key factor for providing substantial levels of funding to non-profits. In *Washington Gateway Main Street*, economic interests in constructing and restoring commercial and residential buildings called for the

involvement of the private sector - relevant since the very beginning of the project both financially and operationally -, while the public authorities were in charge of convincing private stakeholders to invest in the neighbourhood and of deciding about publicly owned vacant land and parcels to be restored.

On the contrary, *North Park Main Street* shows a completely different dynamic. Indeed, the public sector was the financial leader in the physical redevelopment – the City of San Diego and the *Redevelopment Agency* funded most of the interventions carried out in the area – but the public involvement was just a consequence of the community strongly supporting the redevelopment process and overcoming the initial resistance of the City of San Diego.

Finally, it has been seen that in some cases the non-profit organization is the real driving force for the regeneration process, exceeding the role of private and public actors and decisively affecting the PPP.

In the *Dudley Street Neighborhood Initiative (DSNI)*, the fragile balance between public and private sectors was managed by the “leading” role of the non-profit organization and the success of the redevelopment process was based on the involvement of multiple and varied stakeholders, with a scarce presence of public authorities. The latter did not take part in the decision-making process and they were not proactive, while being involved in the initiatives depending on the general goals, on the general financial conditions, on the specific contribution the public sector may produce for the non-profit strategy.

In such cases, when social problems are both the critical issues and the major driving force for the regeneration process, the possibility of adopting a flexible partnership model – with a partnership composition depending on the specific project, with varied stakeholders bringing different expectations to the process and different emphases to their conceptions of how the process should work – may be crucial.

Interesting exception to the ordinary Community Development Corporation model, DSNI is a “variable geometry” non-profit organization, a particular “hub” which identifies from time to time different partners for implementing single projects. A sort of horizontal platform with a stimulating role for endogenous and exogenous stakeholders and agencies.

The Main Street (MS) model represents a significant contribution for “integrated area-based PPP” as well. Its effectiveness is closely linked to the critical mass of available budget as the Boston Washington Gateway and the San Diego North Park experiences show.

Both in CDC and MS models sometimes the hybridization of the original “Civic law” model with the “Common law” one, can allow the Public sector to be seen in a mutating role, from a “resource provider” to a “resource broker”, a facilitator of investments and general involvement of plenty of actors potentially interested in the regeneration process. In this sense, CDC and MS projects cannot do without the direct and active involvement and cooperation of the whole local community in a flexible context of regeneration strategies.

Notes

- 1 This paper is related to the dissemination of the EU research project "CLUDs" (Commercial Local Urban Districts), Seventh Framework Programme, Marie Curie Actions People IRSES, 2011-2014 (www.cluds-7fp.unirc.it). The general goal of the CLUDs research project is focused on exploring the potential of new tools for urban regeneration through the strategic role of small retails - handcraft and typical food - in reinforcing the sense of community, reducing transportation costs and contributing to the creation of attractive urban environment, thus increasing private investments. The main axes of the research program deal with the evolution of innovative "Public Private Partnership" forms and "Urban-rural" relationships for regenerating urban deprived areas and their "territorial milieu". The program implementation is based on networking four EU universities (Mediterranea Reggio Calabria, "Sapienza" Roma, Aalto Helsinki, Salford Manchester) and two USA universities (Northeastern University Boston and San Diego State University).
- 2 Business Improvement Districts (BIDs) belong to the wide range of policies internationally implemented to improve the economic vibrancy of urban communities and to foster revitalization in urban areas while promoting an innovative approach to the delivery of elementary yet consequential public services (Mac Donald et. al, 2010; Mitchell, 2001).
- 3 Launched in 1977 by the National Trust of Historic Preservation, *Main Street Approach* is «a preservation-based economic development tool that enables communities to revitalize downtown and neighbourhood business districts by leveraging local assets – from historic, cultural, and architectural resources to local enterprises and community pride» [National Trust of Historic Preservation].
- 4 *Community Development Corporations* (CDCs) are known throughout the United States as non-profit organizations which aim at community social and economic development in low income and distressed communities. The use of CDCs function as «a strategy designed to solve many of the problems of discrimination, poverty, lack of citizen participation, and the failure of governmental institutions» (Goodpaster, 1968, p. 645).
- 5 The *Redevelopment Agencies* of the City of San Diego (Centre City Development Corporation CCDC, and Southeastern Economic Development Corporation, SEDC) have been dissolved in 2012 by the Governor of California and the City of San Diego, serving as their successor agency, has assumed the former assets, rights, and obligations under the California Community Redevelopment Law. At the moment, the former Agency's affairs and actions are carried on by *Civic San Diego*, a city-owned non-profit that is the entrepreneurial development partner for targeted urban neighborhoods.

Online engagement – linking their digital world to ours

Marissa POWELL, Arup, Australia

1 Introduction

People who attend stakeholder and community engagement activities often fit into one of three categories – retirees and people with time of their hands, people who stand to lose something of value to them and people who are passionate about a cause or issue (and your project just happens to fit into this category). They are the ultra-motivated, the people who turn up to meetings and displays and unfortunately the people who skew our engagement data as they are not representative of the broader population.

The rest of us sit in the “I should get involved but I’m too busy”, the “that’s kind of interesting, but not enough to make me do anything”, the “I planned to go but I forgot” or the oblivious to the entire situation category. It’s this larger group of people that we’re missing through traditional approaches to engagement and they are the most important to ensuring representative input is fed into our planning processes. To engage these people we have to understand how to make it easy for them to participate in the discussion especially when they are usually time poor, they want to give and get information quickly and they now carry their digital life with them wherever they go.

The other side of the story is that it’s time consuming, and often difficult, to translate rafts of qualitative data gained through engagement processes into something meaningful that we can use to inform planning decisions.

To address both these issues, an online e-engagement tool named Collaborative Community Map was developed to give stakeholders the opportunity to provide meaningful input into spatial planning processes. It was borne out of a desire to gather a more representative data set from stakeholders by allowing people to participate in engagement activities at a time and place that suits them. It is a light weight mapping application that is viewed in a standard internet browser and uses the Google Maps interface as its source of mapping data. It allows people to participate in engagement activities and provide information from their own computers, thus broadening the reach of engagement programs. It gathers spatially located data to assist project teams in mapping constraints and concerns associated with planning and design proposals by enabling stakeholder comments and their associated locations to be mapped. These can then be drawn into a GIS environment for further analysis and visualisation.

This paper explores a number of case studies where the Collaborative Community Map was used during planning processes. It shows how by linking their digital world to ours we have gathered more representative datasets, made the engagement process more transparent, broadened the reach of our engagement program and gained valuable spatial data which has helped us to better understand the places and spaces we are planning. This approach is applicable to any spatial planning process.

Visit www.collaborativemap.org to view the mapping tool.

2 Engaging with stakeholders and the community

We plan places for people, so it makes sense that the people we are planning for are given the opportunity to input into the planning process. As society evolves we are becoming more interested in and able to make our voices heard. As planners it is important that we harness this non-technical expertise to improve our projects as we progress planning, rather than just standing and defending our expert choices against public opposition once the planning process is complete.

We operate in planning systems that usually have some form of legislated stakeholder and/or community consultation process wrapped around them. In my experience, most of these legislated processes occur at the end of the planning process and by only doing what is required we are missing the opportunity to improve our planning.

Arnstein's seminal paper 'A ladder of citizen participation' (1969) has shaped the practice of modern public participation. Her approach showed a spectrum of citizen involvement from manipulation through to citizen control. This ladder has further evolved in recent years and still forms the basis of the International Association for Public Participation's (IAP2) Public Participation spectrum (www.iap2.org) as shown in Figure 1. The IAP2 spectrum is the current dominant framework for public participation. The relationship between the two engagement outlines is shown in Table 1.

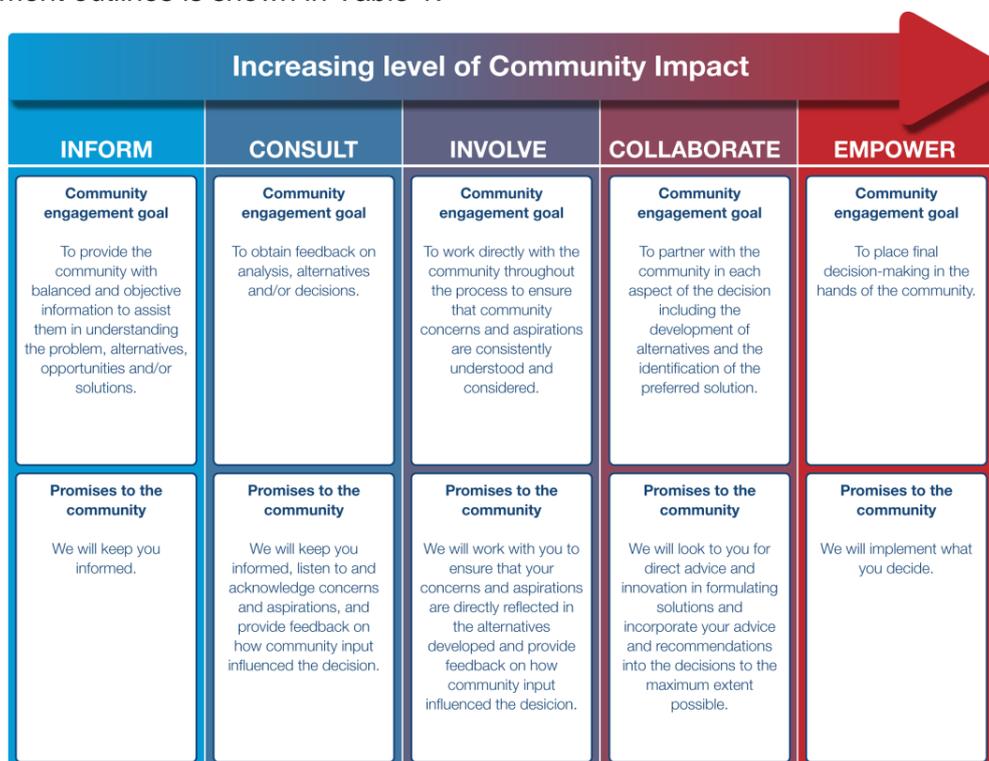

Figure 1: IAP2 Public Participation Spectrum ©

Ladder of citizen participation (1969)	IAP2 Public Participation Spectrum (2004)
Citizen control	n/a
Delegated power	Empower
Partnership	Collaborate
Placation	Involve
Consultation	Consult
Informing	Inform
Therapy	n/a
Manipulation	n/a

Table 1 Ladder vs. spectrum

We've moved on from a time where people could be manipulated into thinking in certain ways or just allowed to vent as a form of therapy, into a space where those who are interested and willing to get involved can have a more meaningful discussion about the issues at hand. It could even be argued that the 'inform' level of the IAP2 spectrum is no longer accepted as a suitable means of engaging with people about planning projects.

At the same time that people's expectations are changing about how they should be able to participate in planning processes, people's access to information via the internet and their constant connectedness to social media presents opportunities to engage in new ways.

Engaging people online could fit into any level of the IAP2 spectrum, it just depends how it is undertaken. Collaborative Map is often used as a *consult* or *involve* level engagement tool to gather information from people about what they need/want prior to planning starting or to gather feedback on plans once they have commenced. That said, it is one tool in the overall engagement toolkit and does not replace face-to-face engagement methods.

3 About Collaborative Community Map

Collaborative Map is an online engagement tool and enables us to gather a more representative data set from stakeholders by allowing people to participate at a time and place that suits them. Through using Google Maps, the familiar interface allow people to engage quickly with the tool and use Google Map's features such as street view as part of the engagement process. More information such as design options or planning layers can be loaded on to the map depending on the level and type of engagement required. The comments that are placed with the tool can also be linked with social media such as Facebook and Twitter to further broaden the reach of stakeholders.

The data that is gathered is spatially referenced and directly assists project teams with mapping the constraints and concerns associated with the planning and design proposals from the stakeholder comments. These comments can be drawn into a GIS environment for further analysis and visualisation.

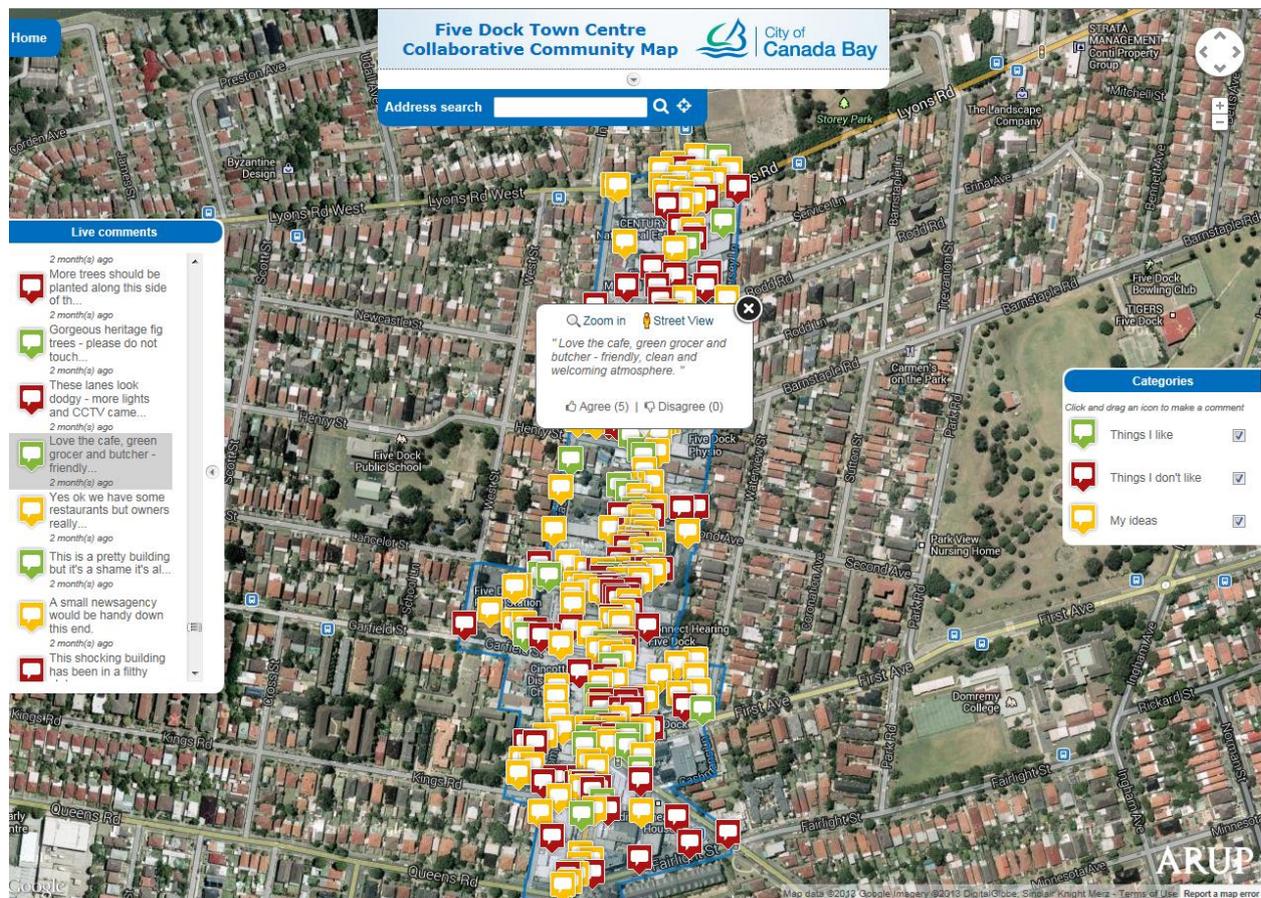

Figure 2: Screen shot of Collaborative Community Map

4 Collaborative Community Map case studies

The mapping tool has been used for a number of applications including master planning, landscape master plans, initial information gathering during preliminary design phases, parking, traffic and pedestrian studies as well as for the display of concept designs for linear infrastructure.

4.1 Master planning / urban design / landscape master planning

For this type of project the tool is used multiple times throughout the design process. It is first used to gather broad feedback about the area that is being planned, for example what people like, don't like and any ideas they may have for the area. This information helps planners to better understand the space from the perspective of users and to understand what will and won't be accepted in relation to changes to the space.

Initial options for the design of the space are then uploaded into the tool to show people what could be done. Comments can be collected on all comments and analysed spatially to understand what people liked and didn't like about the options.

Once a final option has been decided, this can again be displayed for final comments.

An example of this process is shown below for the Bald Hill Reserve Landscape Masterplan. Community engagement began by asking people to tell us what needed improving, what was important and what their ideas were. This information was used as an input into the overall site analysis process to help shape options for the masterplan. Three options were displayed to the community for the site and comments related to each option were gathered and analysed. The final option was a mix of aspects from the three options. The final draft Landscape Masterplan was again uploaded to the tool for final comments from the community. This stage of engagement was the formal 'public notification period' for the project.

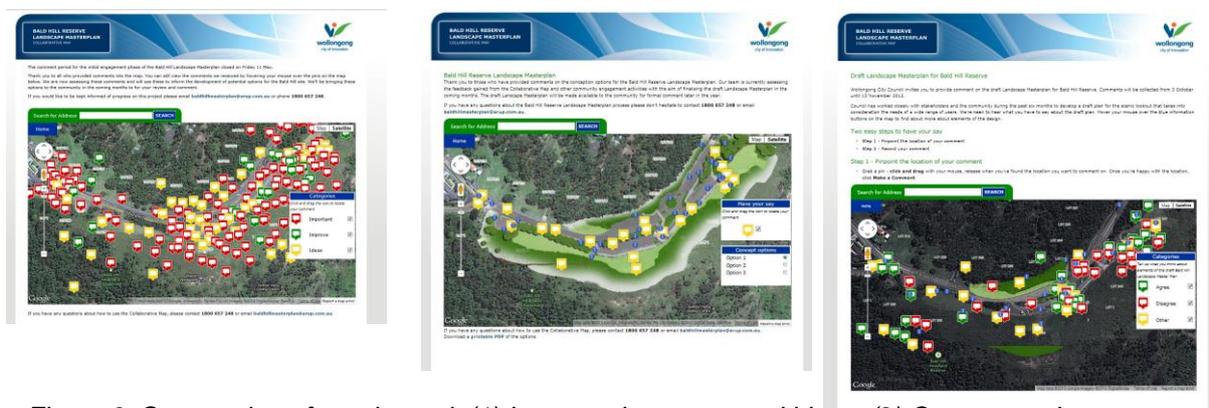

Figure 3: Screen shots from the tool: (1) Improve, important and ideas, (2) Concept options, (3) Final draft Landscape Masterplan

4.2 Parking and transport studies

The tool has been used on a number of transport related studies. For these projects it is interesting to gather users' perceptions of the transport environment in a spatial format and compare this with actual speed, accident and congestion data. The comparison shows areas where perception doesn't match the data which shows the team that they need to gather more (or more up-to-date) data or work with the community to understand this perception.

An example (as shown in Figure 3) of this is a traffic study where there was a perception of speeding occurring on a local street, but the data was not showing this as a fact. It was determined that additional data collection was required to ensure that the data was accurate for this location.

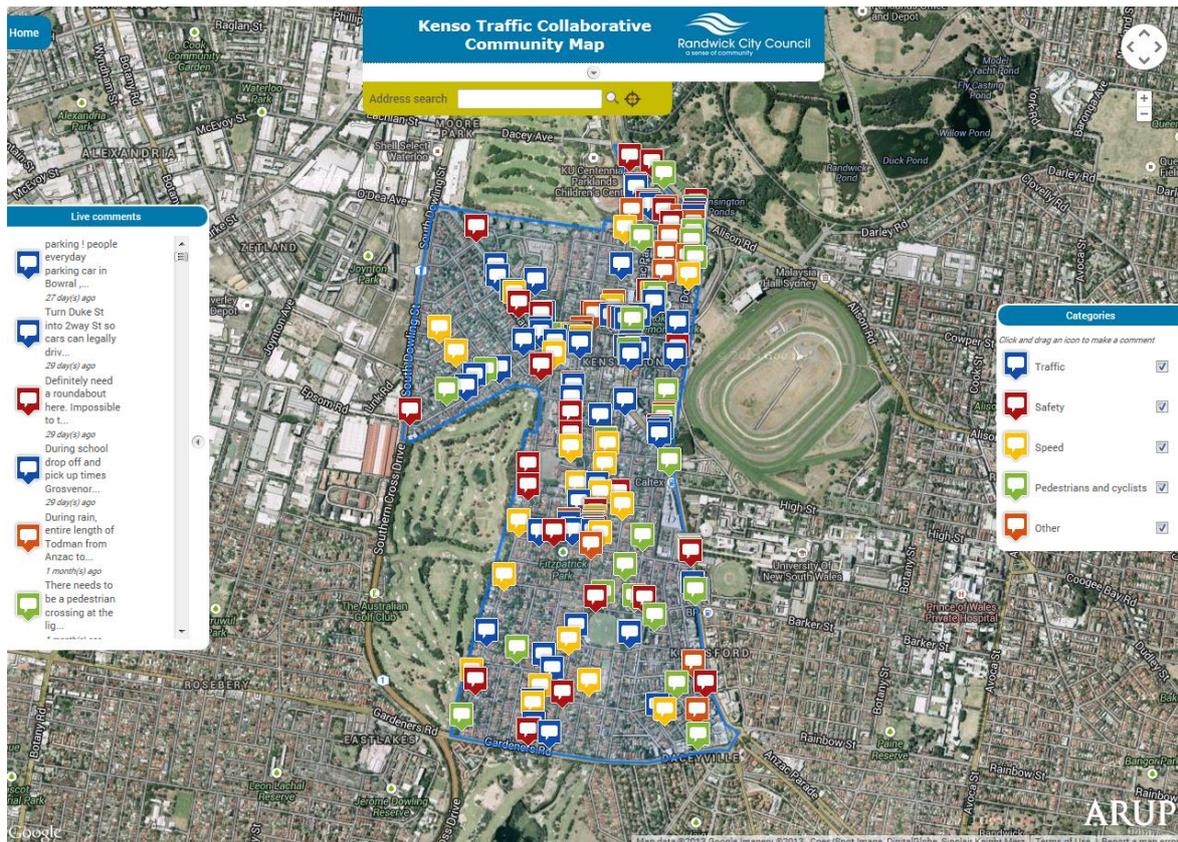

Figure 3: Screen shot of a transport study Collaborative Community Map

Another example (shown in Figure 4) is of a parking study which utilises the collaborative map and analysis to display the conflicting opinions of user groups, in this case paying for parking. These diagrams were used in workshops to work with different users to understand the different needs come to an equitable solution.

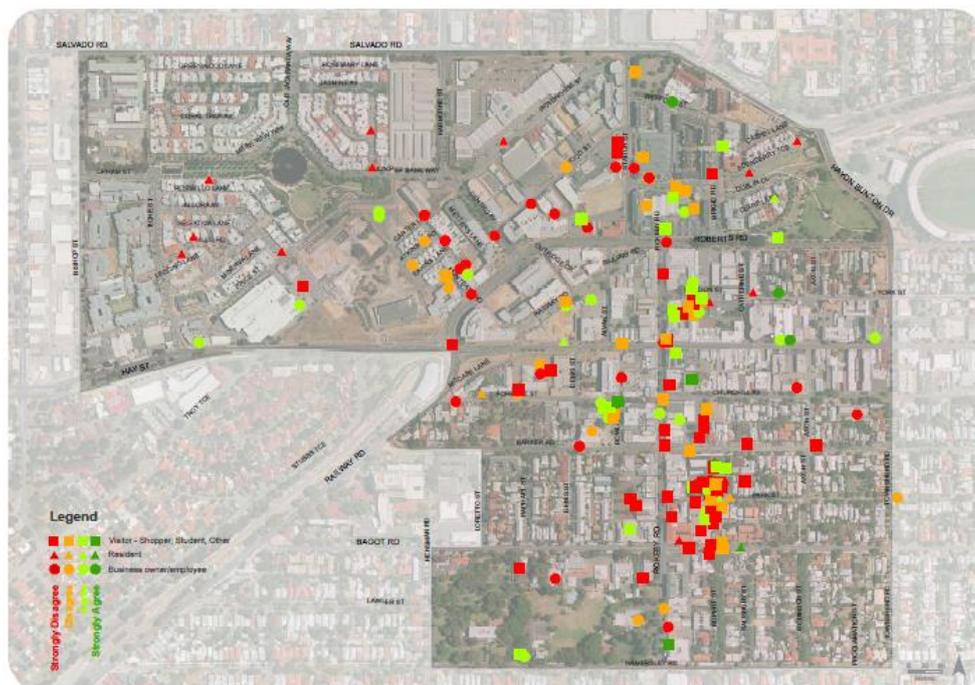

Figure 4: Screen shot of a transport study Collaborative Community Map

4.3 Infrastructure design

The tool has also been used to show infrastructure design to the community. This has been achieved by bringing CAD designs into a GIS format and uploading these into the tool as shown in Figure 5. This allows people to see and comment on proposed designs. These comments can then be used to refine design as it progresses.

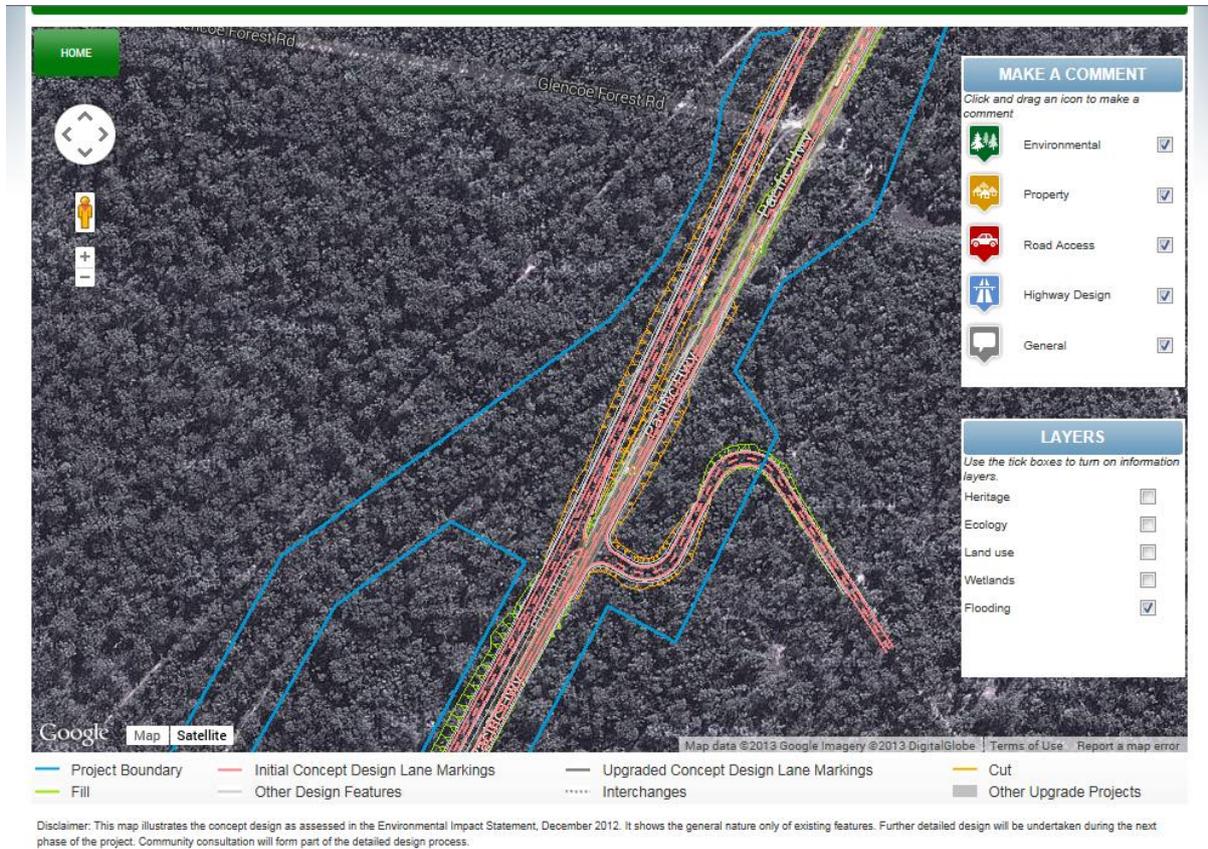

Figure 5: Screen shot of an infrastructure design Collaborative Community Map

5 Reporting from Collaborative Community Map

The key benefit of the mapping tool to the planning practice is the ability to spatially map community comments to see trends and compare this information with other spatial datasets. Figure 6 shows comments input by the community on a road planning project. Figure 7 shows these comments mapped in GIS.

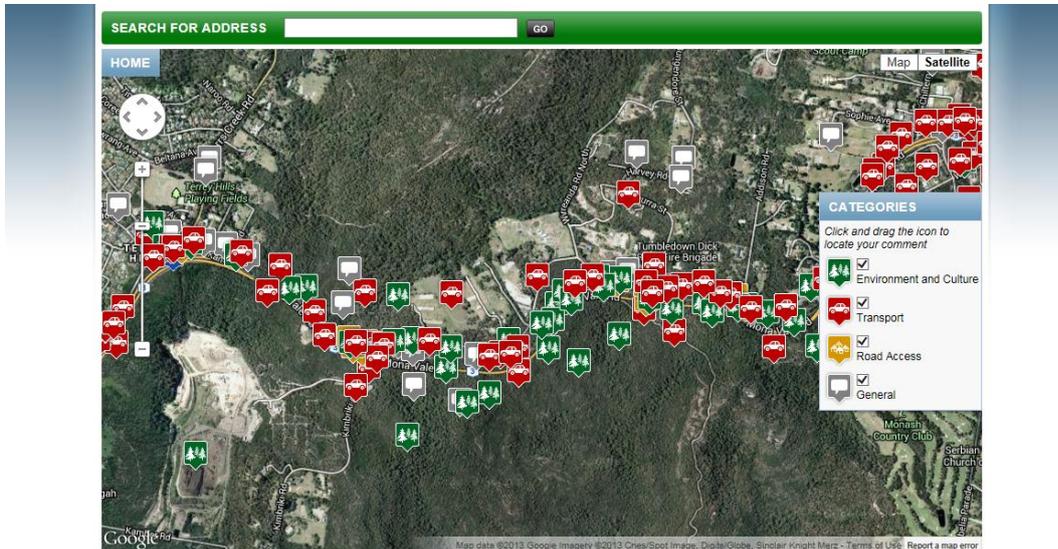

Figure 6: Data input by the community

Figure 7: Comments mapped in GIS

By mapping these comments spatial clusters can be seen. Figure 8 shows a 'hot spot' analysis of 'environment and culture' comments. These comments align will with heavily vegetated areas of the corridor.

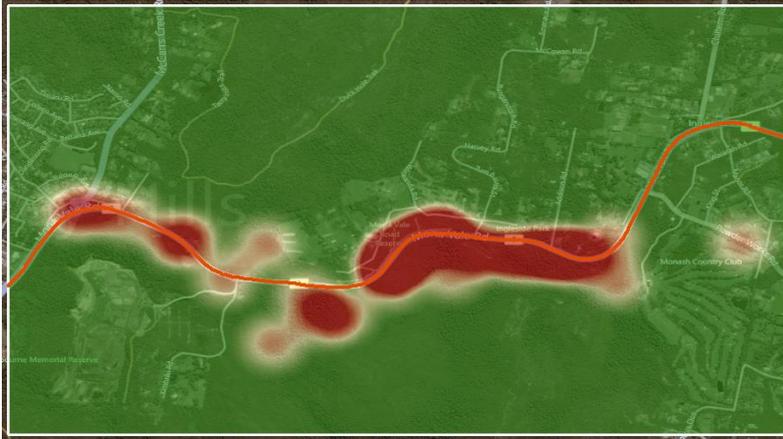

Figure 8: Hot spot analysis of 'Environment and Culture' comments from Figure 2 map.

Figure 9 shows a 'hot spot' analysis of 'transport' comments. These comments align will with steeper areas of the corridor where trucks climbing at slow speeds are considered to be a significant traffic problem.

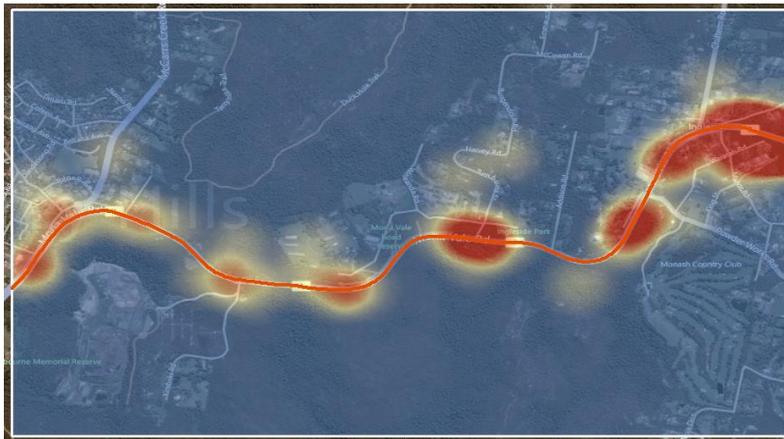

Figure 9: Hot spot analysis of 'Transport' comments from Figure 2 map.

Figure 10 shows a 'hot spot' analysis of 'road access' comments. These comments align will intersections throughout the corridor.

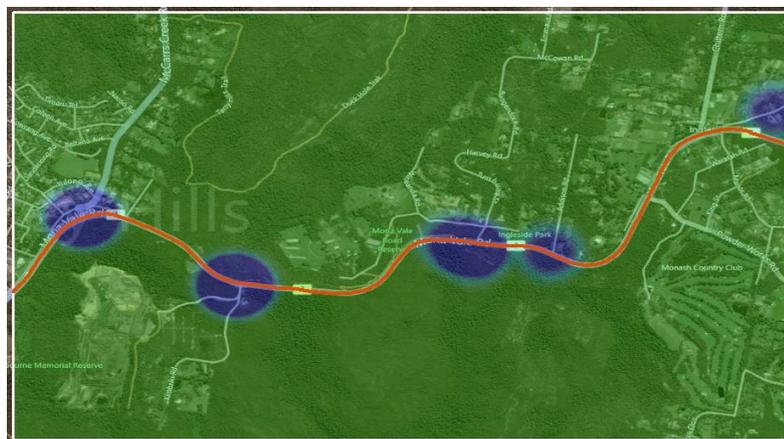

Figure 10: Hot spot analysis of 'Road Access' comments from Figure 2 map.

The analysis of comments from the community for this map deployment showed that community comments were very much in line with the technical analysis of the corridor. This is important as it shows that people who use the corridor are experiencing the issues that from a technical analysis perspective we would expect.

6 How this is advancing the planning practice

As planners we need to better understand the places we are planning for. By seeking information from the people who live/work/use these places we are reducing our assumptions and therefore the risk that we miss something that would mean our plans aren't accepted by stakeholders and the community.

Utilising online engagement tools not only allows us to broaden the reach of engagement activities and involve more people in the process, but allows us to output this information in ways that assist the technical analysis and planning process.

The ways that tools like Collaborative Community Map are benefitting the planning practice:

- *Engagement is more efficient* – online engagement is cost effective and efficient. Setting up and analysing the output of online tools is much cheaper than trying to reach the same number of people via traditional face-to-face means.
- *Engagement activity is more transparent* – people can see what others are saying and that there may be different positions on the issue. Often we see an action group form around an issue and their voice is the only one picked up in media reports and heard in public forums.
- *Engagement outputs are easier to 'sell' to technical colleagues* – It is much easier to 'sell' the benefits of an engagement process when the outputs can be viewed in a format compatible with other technical data. It gives this information more credibility in the process.
- *Engagement can happen at any time* – people can use online engagement tools at any time, from any place. Online engagement allows them to participate as they please instead of us dictating when they can participate in the process.
- *Engagement outcomes can be shown spatially* – engagement inputs and how they have helped to shape planning outcomes can be fed back to stakeholders and the community in a spatial format. This clearly shows where their inputs have / have not been adopted and we can explain why this has occurred.
- *Engagement outcomes show us the areas people are most interested in* – the spatial outputs will show areas that people are most interested in. This helps us to focus our attention on these areas as required.

7 Conclusion

The use of spatial mapping for stakeholder and community engagement activities is an emerging trend that enhances our ability to integrate engagement inputs into planning processes. By using these tools we have gathered more representative datasets, made the engagement process more transparent, broadened the reach of our engagement program and gained valuable spatial data which has helped us to better understand the places and spaces we are planning.

Legitimising Politics of Influence through Participatory Planning Practices in Delhi

Poonam PRAKASH, School of Planning and Architecture- Delhi, India

1. Introduction

Participation has become the buzzword currently. Every policy, programme and scheme calls for participation. Public participation is considered to produce better decisions and improved project outcomes. It is a first step to influence decisions. Notion of power and conflict therefore, is inherent to the concept of participation. Arnstein (1969) sees it as a process of redistribution of power amongst the have-nots. It also is linked to the idea of an empowered citizen who can contribute more meaningfully in the society. Benefits of participation can include create a possibility of co-creating learning and shared control, a sense of ownership and thereby better implementation and lesser conflict over the long term (Cohen and Uphoff, 1980, Healey, 1997)

In the present context of reforms, with efficiency of outcomes as primary concern, the World Bank sees it as a process of 'stakeholder participation' (World Bank, 2000). Stakeholder as a term was initially more closely associated with corporate or business entity. Slowly this replaces the term citizen in which the perception of political and power is embedded. Participation has been sanitized into stakeholder participation where 'user participation and marketisation of service delivery' will ensure better outcomes (Kamath and Vijayabaskar, 2013). Next section of the paper explores the idea of stakeholder participation in two interventions by the international agencies in the forms of local area and city development plans.

It is generally agreed that any meaningful participation requires at the least, availability and accessibility of information, some prescribed form of responding to the information and an equal opportunity to all individuals for their views to be considered. It is also vital to understand the process of who participates, in what and for whose benefit (Cornwall, A., 2008)

Authors have pointed to the downside of participation (Cooke, B. and Kothari, U., 2001, Kaza, 2006). There is a huge gap between the universally accepted rhetoric of participation and empowerment and unjust practices of participatory government. It is also seen a highly contested concept, since the idea of singular public interest is a myth and the dynamics of local interests display uneven power dynamics. Individual rationalities in most cases are unlikely to produce a collective outcome which is rational. The answers to the issue of representation, power and process of decision making continue to remain elusive in participatory practices.

In planning, provision for participation has existed in town planning laws in some form. Its practice though has been untidy one (Day, 1997). In India, too the town planning acts provide for citizen participation in plan preparation and its modification. Third section and fourth section of the paper examine the process of participation plan preparation and modification and tries to show that stakeholder participation is not supplementing but gradually substituting rational comprehensive mode of planning. Stakeholder consultation in planning, in its current form, is more prone and open to legitimizing powerful interests rather than creating conditions for deliberation, conflict resolution and consensus building.

2. Mainstreaming 'Stakeholder Participation' - Role of International Agencies

As part of the reforms agenda pushed by the international agencies, one of the main focus areas is the reforms in regulatory mechanisms. This is also seen in propagating amendments in planning and development laws in India. In 2003, the USAID through the Indo-US Financial Institutions Reforms and Expansion Project-Debt Market Component (FIRE(D)), prepared a 'consensus paper' to simplify building byelaws in Delhi. It was based on the premise that illegal developments in Delhi were mainly due to inadequate building and planning regulations, which do not match the 'market potential' of the area. These inadequacies were also due to lack of 'local stakeholder participation' in the plan preparation (FIRE(D), 2009). This consensus paper for more 'flexible planning and building byelaws' recommended amendment to the Delhi Municipal Corporation Act, governing the Municipal Corporation of Delhi (MCD). One of the main amendments was inclusion of provision to prepare local area plans through participationⁱ.

No such amendments has been made till date. FIRE(D), however, was able to develop the local area plan guidelines and supposedly pilot them in five different parts of Delhi for preparation of 'Local Area Plans' in 2005. Out of three phases of the project, one of the phase of the plans required participation for the purpose of developing a vision and feedback. The Project Note (2009) providing an example of one of the areas out of five piloted areas, acknowledged the resistance faced by the consultants during this consultation and phase. However, without examining or documenting the manner of identification of stakeholders, nature of participation, and process of conflict resolution in the pilot projects, it continues with enthusiasm about participation; "Local Area Planning is a FIRE(D) innovation for addressing the unplanned and illegal urban development rampant in India cities. By combining neighbourhood level data with stakeholder participation, a Local Area Plan proposes a more realistic and cohesive development alternatives. (FIRE(D), 2009)".

Efforts to mainstream stakeholder participation were not restricted only to local level. Simultaneous to the agenda of local level participation through 'stakeholders', a major reform agenda in mission mode called Jawaharlal Nehru Urban Renewal mission (JnNURM) at the national level was launched by the Prime Minister of India in December 2005 for sixty three cities with a budget of Rupees 500 billion over a period of seven years. (Government of India, undated). There were various components of the mission but one that is of particular relevance here is the preparation of 'City Development Plans'. City Development Plans (CDP) were to be prepared for all the sixty five cities through stakeholder consultations.

City Development Plans were very similar to City Development Strategies (CDS) promoted by the World Bank and UN Habitat with strong focus on stakeholder analysis and stakeholder workshops (Grant thronton,2011).ⁱⁱ According to the mission guidelines, the CDP was to be a comprehensive document for 'urban perspective framework' for twenty to twenty five years within which detail projects were to be prepared. The guidelines made no reference to the fact that in all the states in India town planning and or Development Acts were in existence for preparation of statutory plans providing urban framework for twenty to twenty five years. City Development Plans for all the sixty five cities were prepared through stakeholder workshops and hardly any reference was made to the statutory plans already in existence in most of these cities.

An appraisal of the JnNURM by Grant Thronton, India (2011) appointed as an appraisal agency has criticised the consultations while preparing the CDPs. According to the report, consultations with the poor were limited even though the reforms were targeted at them. No consultations were held at pre-plan finalisation stage even though the purpose of the consultation was to develop the vision for the city through participation. The report

goes on to state that “the stakeholders had to accept the plan without consultation.” The reports were available only in English and even then it was difficult to comprehend the proposals by whosoever participated. It further highlights the disconnect between master plans which are statutory plans and the CDPs which were seen only as investment plans. The process of these workshops in the form of information made available, identification of stakeholders and who all attended the workshops has been mostly missed in preparation of the city development plans.

From the appraisal of the consultation mechanism, it would seem that each of the CDP report included a chapter on consultation as a requirement and presented the process as neat and depoliticized process without any conflicting and contested interests, providing a unanimous vision of city. Review of the chapter on Community Consultation in the City Development Plan of Delhi shows organization of half day workshops on two days as stakeholder consultation with various technical persons including government officials in which total of one hour each day was spent on sectoral discussions and forty five minutes for open house discussions as inputs to the vision for a city of 15-16 million population. What is more revealing is the identification of issues from the focus group discussions held with selected few of the ‘communities’ like slums, JJ cluster etc. All the issues documented in these discussions relate to service provision. There is no discussion regarding the tenure status, rehabilitation or implementation of their entitlements according to housing provisions in the statutory plan (Department of Urban Development, 2006).

City Development Plans have by now lost their sheen, but the stakeholder consultations have persisted. International organizations like the World Bank, UN-Habitat, USAID etc. have played instrumental role in mainstreaming ‘stakeholder consultation’ form of participation which appear neat and depoliticized. Following sections provide a snapshot of the increasing focus on participatory planning through stakeholder consultation mode. It would seem that this mode is slowly substituting conventional mode of planning in which opportunities for citizen participation were included by law raising some uncomfortable questions. These examples indicate benefits of this mode of participation accrue more to the powerful groups rather than achieving any redistribution of resources or increase in influence of the disadvantaged groups.

3. Statutory Planning Process in Delhi – Provision for Mandated Citizen Participation

Planning in Delhi is currently governed by Delhi Development Act, 1957. Under the DDA Act, the Delhi Development Authority (DDA) is required to prepare master and zonal plans to ‘secure planned development of Delhi’. The first Plan prepared for twenty-year perspective up till 1981 was subsequently revised two times for the perspective year 2001 and 2021. Currently, review of the Master Plan 2021 is ongoing in Delhi. Any modifications to the plan requires a statutory process of issuing of public notice inviting objections/suggestions for a stipulated period of time. All the objections/suggestions are required to be considered. It is only after this process of public participation, modifications to the plan can be made.

Draft Master Plan for Delhi for the perspective 2021 was notified and placed in public domain for a period of ninety days in the first quarter of 2005, inviting objections/suggestions by the public. It received about seven thousand objections/suggestions. A Board of Enquiry and Hearing was constituted for dealing with objections and suggestions received. It held four meeting to hear around six hundred objections/suggestions and held eighteen internal meetings to prepare the report. In April 2007, Delhi Master Plan for 2021 was notified. Example of manner of participation in modification of mix use provisions in the Master Plan 2021 provides interesting insights in the participatory planning process.

3.1. ***Subversion of statutory provisions for participation – Case of Mix Land Use Provisions in Delhi***

Permissibility of commercial activities in residential premises was introduced in restricted manner in the plan of 2001 for the first time. Its intention was to allow particularly low income families to supplement their incomes through limited commercial activity (Government of India, 1990) The draft master plan for 2021 continued with the provisions of mix use for restricted commercial use in residential premises subject to certain conditions. These provisions were to change dramatically within few months of the plan being placed in public domain in early 2005.

In December 2005, on a public interest litigation filed in 1985, Supreme Court ordered sealing of all those commercial activities in residential premises that were in violation of the master plan of 2001. This led to all round protests by trader associations, representatives of political parties and others (The Hindu, 2005). In response to these protests by the traders and amidst the process of finalisation of the MPD 2021, the Ministry of Urban Development, central ministry, announced formation of a committee known as 'Tejinder Khanna Committee' in February 2006 to comprehensively review the issue of mix use. Composition of the committee included two members as experts and both were also consultants in the preparation of the draft master plan for 2021 already in the public domain, thus creating a very interesting situation whereby same experts would be taking two different positions on a same issue.

The terms of reference of the committee were to make an assessment of the magnitude and types of violations and suggest a feasible strategy for the same including changes in the structure and accountability of existing enforcement machinery (Ministry of Urban Development, 2006a). The report in its findings stated that large scale percentage of residential area is under misuse without actually providing data. Details of surveys or sources for various conclusions were missing. Without evaluation of the implementation of earlier mix use provisions in the master plan of 2001 the report recommended up-scaling of mix use provisions on various roads in the city.

'Stakeholder participation' had by now become fashionable and Tejinder Khanna Committee also took recourse to such participation. The committee issued a so called public notice inviting members of the public with special invitation to representative bodies/interest groups/non-governmental organisations in Delhi to share their views on the issues contained in the terms of reference. It received representations of approximately 490 Non-governmental organisations/interest groups/VIPs/Government agencies. Amongst this the committee chose to invite only eighty six persons due to lack of availability of time (Ministry of Urban Development, 2006b). Selection criteria of these representatives were not stated and individual representations were not considered. The report was also silent on methodology adopted for analyzing these suggestions or the manner of consideration.

This created two parallel processes of participation; one through the statutory process under the Delhi Development Act and another in response to the pressure groups of various trader associations and non-governmental organizations In the meanwhile, sealings and demolitions continued. This also set in motion a process where so called representative participation through NGOs and trader groups to an extra constitutional committee resulted in modification of law.

By now, traders and residents were both protesting; traders because of the closure of shops and residents through resident welfare associations for protecting their residential amenity which was being lost to the commercialization of residential areas.

Since process of hearing of objections/suggestions for the MPD 2021 was continuing and would take some time, the Ministry of Urban Development to hasten the process, decided to notify in March 2006 modifications to the 2001 master plan. This modification included the proposed chapter on mix use in the draft MPD 2021. The notification stated that it had considered all objections/suggestions in the matter (MoUD, 2006c).

Apparently this was not the case, because, on the basis of Tejinder Khanna Report, which had recommended something drastically different from the March notification based on representations from groups, the DDA issued two more public notices inviting objection/suggestions for modification of 2001 Plan for development control norms and mix use provisions in July 2006. The notice said that while master plan was modified on 28 March 2006 for mix use provisions, it has since then received several representations and to implement the Tejinder Khanna Committee report it was decided to issue this public notice for inviting objections/suggestions (DDA, 2006). This was despite the fact that the March notification of four months ago had considered all objections/suggestions.

This proposed modification was primarily the outcome of the 'Tejinder Khanna Committee' report, suggesting more permissibility in the residential premises. Localities, which were already stressed for infrastructure and were dense were given more flexibility for commercial activities. It was pointed out at that time that the option of regularization through plan modification was a result of the 'myths' being created about poor traders, fear of lawlessness etc. (Kumar, 2007). This report further paved the way for increased commercialization pointed out in response to an earlier public notice in 2002.

The public notice for proposed modification started with an acknowledgement for the "need for permitting use of land for purposes other than for which it is planned". In the DD Act there existed provisions for consideration on case by case basis for activities not permitted by the Plan. Instead of considering misuse as an aberration, the proposal sought to regularize majority of violations through this notification. More importantly it sought to make as part of the notification of mix use streets consultation with resident welfare associations mandatory. Public hearing for this notice was carried out at frantic pace and within two weeks after the time for filing objections, final notification was issued. Above sequence of fast paced events should be seen not as a simple policy modification but as a part of larger urban reforms agenda that demands 'flexible' land use laws. Participatory planning through 'stakeholder participation' becomes an instrumentality to allow for this 'flexibility'.

Setting up of expert committee at the level of the Central ministry to hear selected representative groups and consequent modifications to the plan (not necessarily based on the survey data) set aside the statutory process in which citizens had participated. A process was set in motion where citizen was replaced with stakeholder and stakeholders were primarily representatives of groups or associations who could lobby at the central level to an extent of getting the laws amended.ⁱⁱⁱ

3.2. Up-scaling Participatory Planning - second round of Local Area Plans

Neither the Delhi Development Act nor Delhi Municipal Corporation Act provide for preparation of Local Area Plans as yet despite the push for the idea in 2003. In 2007,

however, the Delhi Master Plan 2021 introduced preparation of local area plans for a subzone/ward by the local bodies within three years. It also proposed constitution of local level participatory planning group to frame guidelines for participation at the local level and legal framework review group for framing of local planning regulations.

The legal context of the local area plans continues to be ambiguous and so is its scope, interpretation and manner of participation. In January 2009, Municipal Corporation of Delhi was pushed to invite Expression of Interest from consultants for preparation of Local Area Plans through participatory approach. In April 2010, it was decided to re-pilot thirty three wards^{iv} for preparation of local area plans through public sector institutions. The scope of work prepared by the corporation included stages of base map preparation, mapping of master plan and zonal plan data, draft local area plan and final local area plan. A monitoring committee was set up and the scope identified participation through the ward councilor at each stage of the preparation. The work was to be completed within nine months. The work is at present in the final stages of finalisation with very little participation. In a survey conducted of the ward councilors of the thirty wards in September 2010, four months after the award of the pilot projects, majority of them were unaware of the project for their ward (SPA, 2010).

At the beginning of 2012, MCD issued an advertisement inviting comments on the proposals uploaded on the website related to the local area plan. Less than fifty responses were received. There were, of course, various reasons for lack of response. It also seemed that no one really had much clarity about the central idea of the local area plan preparation i.e. participatory planning. Some of the consultants did make a presentation to the ward councilors after so called third stage of the project. So far participation has been very limited. Moreover, the nature of proposals placed in the public domain for some of the wards seem seem arbitrary in proposing removal or retention of an activity and people. (MCD, 2012). The story of local area plans at the moment is moving at a slow pace due to trifurcation of the municipal corporation and lack of clarity about the process, however, it did introduce as part of the statutory planning process, an idea which as of now is an extra statutory participatory mechanism. These participatory mechanisms and their substitution of other technical processes unfold rather interestingly in the next stage

4. Disconcerting tendencies of 'participatory planning' processes - Master Plan Review

The MPD 2021 provided for plan monitoring and review. With monitoring targets and phases of review identified, the document also proposed ten management action groups on different aspects for the purpose of participatory planning. The review was to be based on monitoring data and processed through management action groups. In October 2011, public notice inviting suggestions for the master plan review were invited within forty five days (Fig.1).

In November 2012, most of the newspapers reported, the central minister's declaration that sixty percent of the plan was irrelevant and asked for major changes. This plan was notified by his ministry five years ago. One could argue this as a positive step of keeping pace with the changes but the only problem was there was very little data, on the changes or the monitoring of the plan, available. Population figures for Delhi by Census 2011 were less than the projected population for 2011 in the MPD 2021. There was significant reduction in migrant population, which would perhaps reduce the requirement of land to some extent. But the media continued to report the need for increase in floor

area ratio and densities to meet the housing requirements particularly the poor. No studies of land requirements were available.

In 2012, the DDA announced through advertisement four open house sessions in different parts of the city, where people could come and submit their suggestions. Public was invited to participate without any monitoring data. Most of the suggestions that came in were from property owners and majority of them suggested increase in floor area ration, inclusion of their street in notified mix use street or regularization of their areas. There were very few street vendors or slum residents or villagers.

Fig. 1 Invitation for suggestions for Master Plan Review

The management action groups constituted in 2008 for the purpose of preparing action plans based on monitoring data for different planning indicators never held any meetings. These were reconstituted in 2011 with a transformed purpose. All the suggestions received were now being sent to management action groups. In a truly participatory style, the objections/suggestions were uploaded on the website along with the minutes of the management action groups.

From May 2013, the public notices for modification to the plan are being issued at a rapid pace. The minister has set a target of hundred modifications to be notified by August 2013. The only problem is that the connection between the proposed modifications and suggestions made by the public could not be seen either in the minutes of the management action groups or in the proposed modification. The basis of these modifications are not the suggestions but most of the times representations made to the minister by groups and associations like PHD Chamber of Commerce, real estate developers association, Federation of Indian Chamber of Commerce and Industry. They pushed for more commercialization, lesser housing for economically weaker section, unrestricted mixing of residential in industrial areas, higher floor area ratio etc. Since majority of the proposals are pre-decided, the process of participation remains more of a formality.

5. Conclusions

Idea of stakeholder participation promoted by international agencies is mostly projected as a apolitical process and is documented as such in the city development plans or initial local

area plans. The agenda setting of these workshops is directed towards service delivery and management issues rather than rights or entitlements issues.

From the example of Delhi, it appears that there is very little understanding of participatory planning process and instead of empowering less advantaged groups, planning decisions are steered towards more powerful interests and the role of participatory planning in redistribution of power and resources is not visible.

Participatory planning practices in its current form in Delhi do not fulfill the very basic requirements for participation; availability of relevant information and procedure for consideration of view/suggestions as well as equal opportunity. Moreover, in the absence of explicit criteria for priority setting, stakeholder consultation mode of participation becomes more prone to favor agendas of powerful interests demanding liberal regulations as well as regularization of existing violations through plan modifications while maintaining the façade of participation.

Personal Note

I was part of a group called Master Plan Implementation Support Group that engaged with the Master Plan process from 2002 to 2007. It was started by Gita Dewan Verma, planner who also advised residents of old settlements, slums, group housing residents, street vendors and others. Many of us in the group responded to various public notices for plan modification and have personal experience of participating in many of the hearings as part of the statutory participation process. Many of the details and nuances not captured in this paper can be accessed at the <http://plan.architexturez.org/site/mpisg>.

Endnotes

ⁱ For a detailed critique of the proposal see Verma, Gita.D.(2005) , The Delhi Municipal Corporation (Amendment) Bill, 2005, <http://plan.architexturez.org/site/mpisg/p/051116>.

ⁱⁱ UN-Habitat prepared a 'Toolkit of Participatory Urban Decision Making' as one of the 'flagship products' of Global Campaign on Urban Governance. City Development Strategies (CDS) in several cities in different parts of the world were to improve the capacity of municipal authorities to implement participatory management mechanisms and upscale 'city consultation mechanism'. CDS approach was stated to be based on three important principles of 'enablement, participation and capacity building'. The Good Governance Campaign was launched in India in 2002.

ⁱⁱⁱ In order to avoid implementation of the court order, the parliament enacted "the Delhi Special Law" in 2006 under which no sealings or demolitions could be carried out for an year. Every year, this Act gets extended for another year.

^{iv} Delhi is divided into 272 municipal wards. Last year Municipal Corporation of Delhi was trifurcated into three corporations.

Geo-social networks and the understanding of the dynamics of the city: the case of Rio de Janeiro's boundaries of formal and informal neighborhoods

Yuri Q.A. TORRES, PROURB-FAU- Universidade Federal do Rio de Janeiro, Brazil
Lucia M.S.A. COSTA, PROURB-FAU- Universidade Federal do Rio de Janeiro, Brazil

1. Mapping as strategy

What use is a map?

This was the title of an exhibition at the British Museum in London, on the late 1980s. The idea was, through the display of different sort of maps, open up a discussion of the different roles played by maps across centuries. In fact, this question has been answered through different approaches and disciplines along time. Earlier in the 1970s, the French geographer Yves Lacoste argued that geography served, first and foremost, to wage war – stressing here one of the interests of the discipline, which is mapping the world and therefore bringing information that could be used to control people and territories. In other words, mapping is knowing.

It is already acknowledged that the act of knowing through mapping means the making of choices: spatial, temporal, physical and even emotional choices – among many others. The graphic recording of this information in a map brings new possibilities of reading and involvement with territories. As argued by Cosgrove (1999, p.1-2): “to map is in one way or another to take the measure of a world, and more than merely take it, to figure the measure so taken in such a way that it may be communicated between people, places or times”.

Here lies the main objective of this paper: having digital information and geo-social networking systems as the main tools of mapping, to explore a social cartography of the city of Rio de Janeiro concerning the relations between boundaries of formal and informal neighbourhoods. These digital network systems have a spatiality that is yet to be further explored. This paper is thus an attempt to contribute to academic studies that look at digital information as a strategy to mapping and understanding urban territories.

2. Geosocial networking systems and the complex contemporary city

The dynamics of a contemporary city are shaped by very diverse and complex factors. Recently ubiquitous experiences towards the city have dramatically changed our concepts and perceptions of its territory. As earlier advocated by Castells (1996) the vertiginous popularization of new ways of communication has collaborated to sharpen urban life through new dynamics and flows. Serra (2010) later addressed the strengthened role of citizens as innovative actors in this environment, affording immediate impact in public spaces. New medias are somehow reinforcing the value of place instead of eliminating it.

In more recent years, new spatial means have been developed on social networks, some of which seem less tied to traditional perception of the surrounding environment. Widespread geo-social networking systems have been playing an important role in shaping a parallel digital space based on the real interactions between citizens and the urban landscape. These networks have opened up new possibilities of exploring the city combining the preciseness of mobile location estimation services with personalized content, full of cognitive and perceptive clues. It has since been producing a new geography characterized by decentralization and horizontality, and people are yearning to some extent to move beyond Cartesian representation.

Connected citizens, touchscreen swiping their latest smartphone while out experiencing the city is a growing tendency on mature and emerging societies. Levels of connectivity and dataflow have starkly increased in the past decade, while both citizens and government are

bound to consider those platforms as a vessel for and a product of urbanity. Those networks also enrich the concept of social and collaborative creation, important for the local identity and community engagement. Recent mobilization through social networks, for example, transcends traditional hierarchies- as recently seen in Turkey and Brazil- and millions go to street demonstrations projecting social structure onto space.

Moreover, the physical dimension of cities has historically referred to people's access to resources, infrastructure and especially the interactions between them through the space. The new urban dynamics, driven by the connected citizens, is subsumed by timely encompassing narratives. Consequently, cities have since become increasingly hard to understand and map. This difficulty has been already noted by Cosgrove (1999, p.5): "Culturally, at every scale, connections between phenomena formerly considered distinct and relatively fixed, rooted in space (...) have been shown to be contingent and unstable (...). An implicit claim of mapping has conventionally been to represent spatial stability, at times to act as a tool to achieve it. In a world of radically unstable spaces and structures, it is unsurprising that the idea of mapping should require rethinking." From this perspective, cities digital counterparts can furnish it at some extension, adding a valuable contemporary case for urban analysis.

It is important to stress that the manner and degree to which is possible the interaction or isolation between citizens also shape the digital world and vice versa. Like digital segregation, spatial segregation is a persisting debate in most contemporary cities. Particularly in emerging economies, where a considerable percentage of urban population lives in precarious informal settlements, spatially segregated and socially excluded from the surrounding formal city, digital inclusion and digital visibility can become an important instrument to tackle inequality and improve quality of life.

Those informal urban spaces, once disconnected and set apart to the emerging digital sphere, do not operate in isolation. On the contrary, they complement and juxtapose with cities' formal circuits, forming a complex web of different morphological and typological patterns, added by cultural singularities, which cannot be disregarded whatsoever.

3. The case of Rio's formal and informal neighborhoods

Roughly 20% of Rio de Janeiro's population live in slum areas (IBGE, 2010), despite the country's considerable economic growth in the past decade and the fact that the city has been put into the spotlight again hosting mega-events such as 2007 Pan American Games, 2014 World Cup and 2016 Olympics.

Large redbrick favelas – as slums are often referred to in Brazil– sitting atop the city's steep and verdant hills, contrasting with adjoining best real estate and sharing together a thin strip between the tropical forest and the Atlantic Ocean, is a memorable portrayal of Rio's social exclusion's reflection in the landscape. Those informal communities that have sprung up unplanned, have been historically regarded as eyesores, unworthy form of urban developments, blighted by poverty, low access to services and widely renowned as lawlessness no-go zones plagued by shoot-outs between rival drug gangs (Neate and Platt, 2006; Leite 2008).

Favelas in the south zone are commonly very compacted settlements wedged between tony beachfront areas like Copacabana and Ipanema, and are historically the cheap workforce for the nearby formal city. The borderline between them has been always clearly defined by the topography. Once ending a road and beginning stairways, there starts a favela. Favelas in the north and west zones are commonly located in sparse hills, fringes of previous industrial sites and wetlands, more fragmented settled.

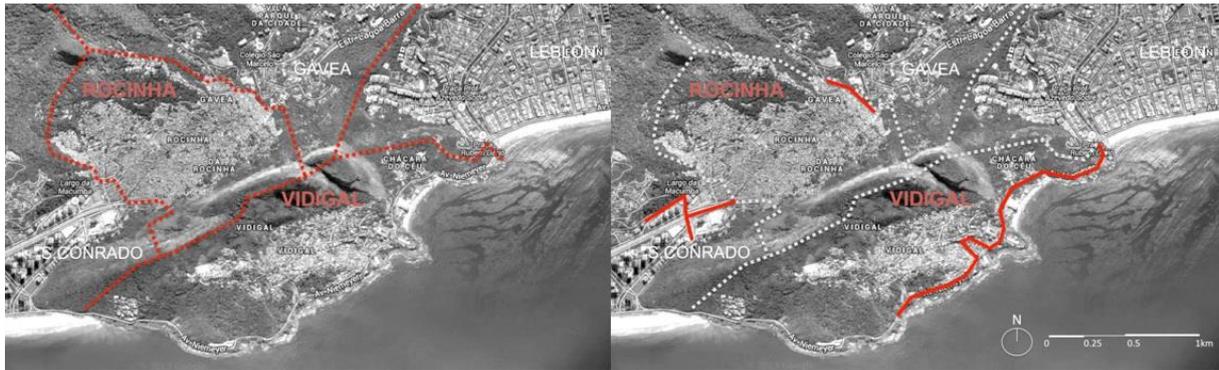

Figure 1: Geographical-relation between neighbourhoods' boundaries and topography in Rio's southern favelas (left) and borderline between formal and informal city (right).

More recently, Rio de Janeiro seems to be compelled to cope with the matter and considerably steps towards a better territorial integration have been perceived. Joined initiatives from municipal, state and federal spheres have unveiled massive investments to recover the historical absence of the state, tackling infrastructure shortage, halting violence and therefore paving the way for better socio-economic opportunities. New housing developments within the favelas for those living in risky areas, water supply, extensive sewage connections and local transportation are among the basic services under provision, addressing most of spatial deficiency. The efforts to strengthen police presence, to seize control and consolidate peace by large community-based police pacification programme, have also taken back territories where drug lords of heavily armed factions previously laid down (Henriques and Ramos, 2011). As an immediate result, these actions has sparked interest from the private sector and encouraged local entrepreneurs to settle down business. Services previously inexistent in those communities and mostly accessed in the nearby formal city started to pop up in the boundaries and within the favelas since then.

Whilst it has collaborated to better integrate once marginalized favelas with the wider city, the complexity of these highly fragmented territories entails much more than any response given. That is, the simplistic and dismissive way in which informal settlements have previously been perceived no longer match the current favela dynamics within the bounds, but still come up against the yet materialized mental borderlines that for decades overlooked inequality. Unlikely other cities where the boundaries of neighborhoods are not clearly defined by their morphological patterns or topoceptive dimension, Rio highlights a more on-the-ground and practical definition of limits and urban identities, a perfect patchwork quilt where formal and informal territories hardly overlapped.

Nevertheless, favela dwellers still commute everyday to the outside city in search of jobs, services, as well as recreation and leisure. Moreover, a certain territorial tolerance has long been a cultural symbol of Rio, meshed by both what is usually considered the formal and the informal parts of urban life. Despite some uncertainty and criticism concerning the rising cost of living among residents, there's a growing sense of belonging and activism issued from the latest developments and somehow the persistent stigma of exclusion and invisibility seems to have lessened. But greater and long-term efforts are needed to push favelas to articulate firstly with its adjoining neighborhood and later with the rest of the city.

Digital platforms and technology democratization are one of the considerable gateways to promote social, economic integration and approach both realities. Where once affordable Internet cafés met an important role in connecting the favelas residents to the world – computer possession and broadband connection were very scarce comparable to the neighboring wealthier districts – now affordable ubiquitous and mobile gears have allowed the rise of freelancer opportunities, access to information, education, and therefore an increase in the digital paths inside the communities. Following the development plans, the government has launched a policy to set up free wireless Internet networks in the most dense populated favelas as part of a broader plan for digital insertion to achieve computer literacy, foster cultural interchange and professionally qualify low incomers (Secretaria de

Ciência e Tecnologia - Rio Estado Digital; Ministério da Cultura- Pontos de Cultura). This may also bring up significant discussions on citizenship awareness and the right to the city through the visibility and legitimacy of these spaces.

4. Mapping the boundaries

For decades, general cartographies of Rio de Janeiro simply did not portray its nearly 1,000 favelas on the slopes of the rich south and the city's poor north and west zones (Peteranderl, 2013). Nevertheless they were easily identifiable on maps by either green or blank swaths with no streets, landmarks or other signs of settlements. Along with the previous cited movement towards the increase of visibility of these communities and their insertion in the planning practices, an intriguing question on how to represent their shapes and dynamics has arisen. Contradictorily, in a more polemic attempt to reduce the prominence of the negative connotation of the favelas, an important map server was formally asked by the city's tourism secretary to ditch the word 'favela' from its database, replacing it by the single name of the settlement, an example of the ambiguous official posture concerning the issue. In the meantime, where map data is scarce and official acknowledgment is pending, the engagement of these communities is a crucial step towards the real citizenship and a symbolic takeover of their historical stigma of abandonment.

Few mapping projects, initially tackled by grassroots organizations aiming to promote social progress within their communities and engaging volunteer youth from poor communities, have harnessed geo-social medias to create a collaborative platform relying on geocoded data of nearby points of interest (Viva Favela ; Wikimapa; Redes da Maré; Lucas, P., 2012). Since the mapping purpose was not simply to cull data and present it objectively, but rather represent the perspective of the cartographers, young correspondents could contribute not only outlining objectively the labyrinthine alleyways, stairs, dead-end roads and other passageway of their communities, but also including vast forms of multimedia such as videos and audio recordings, detailed information on local shops, foodies, bars and other local buzz. Enlarging the discussion, it is feasible that any connect residents could contribute to the making of a comprehensive collective map, even if unintentionally. Virtual performances ranging from messages, social media posts and other possible open generated data – especially geo-tagged ones– culled from the Internet may subsidize the information necessary to feed those maps. Local meaningful spots and identity always left on the wayside of digital platforms may enable a further step to their recognition as part of the wider city.

Traditional maps are blank canvas with nothing on them other than streets and sometimes the most remarkable buildings or touristic venues. The understanding of this new cartography with abundant amount of sensitive information is an emerging research field to address problems and solutions to the planning practices, especially in rapid growth contexts like metropolis in the developing world, where formal and informal settlements are a distinguishing feature and live side by side.

This study stands on the fields of social sciences and urbanism, aligned to traditional theories of citizens perceptions over the territory and their interactions (Jacobs 1992; Milgram 1977) and more recent investigations on the effects of mobile technologies over the physical boundaries of the city (Schwartz 2012; Rainie and Wellman 2012). This study aims to analyze the shaping of the digital urban territory through geo-social networking systems, ultimately Foursquare and Twitter, mining their open data and mapping what it may denotes the interconnected flows of public services and commercial activities, additionally with relevant open spaces.

This study foster what appears to be a potential tool and growing methodology of contemporary urban studies, especially in the field of urban planning. Targeting Rio's most representative slums that are recently emerging to formalization, it methodologically proposes tracking geo-coded information that suggests access to these activities within the boundaries of formal and informal city, anticipating discussion on the yet some degree of dependence of favelas out of their physical boundaries. In this case specifically, the analysis of geo-social networking activity in the boundaries of those neighborhoods delineates the extension of existing formal-informal overlapping services. Using the open digital data generated by citizens of both sides may exemplify the relation of formality and informality in Rio de Janeiro. Case studies in four different zones, the bounds of Rocinha, Vidigal, Maré and Alemão are conducted as paradoxical examples of how digital paths can be taken into consideration while analyzing and re-conceptualizing the dynamics between neighborhoods within a near distance.

4.1 Outlining services

Geo-tagging a message, picture or tweet is based on the coordinates of the user's location by the time of the message, which is typically provided via GPS, wireless or cellular triangulation. It is reported that the majority of geo-social networkers are not location-based influencers, and those who are, aggregate, for instance, place names and personal pictures or tagged messages including other users. The amount of data produced a day counts on quintillion of bytes (IBM, 2012), and the expansive glut of news, shopping, games, music, forums and the like have gone hand-in-hand. Despite social medias playing such a prominent role in citizens' lives, recent studies estimate, for example, that on a typical day, roughly 2 to 3% of total tweets (as Twitter 140-character messages are called) contain any location name or location positioning added (Kalev et al), which is still irrelevant to conduct extensive studies that cannot count on statistical biases. Despite this, about 15 % of geo-tagged tweets contain URLs links to multimedia content, including here Foursquare, Instagram, and Facebook accounts, a wealth of data being generated that may open up future possibilities of researches on social sciences and behavioral studies.

The popular micro-blog Twitter offers releases a publicly available, spatially embedded network dataset that can be fruitful for any territorial analysis (Butts and Acton, 2010). Accessing the totality its tweets requires access to a special service - Twitter's Firehose : the unfiltered deluge of 1 billion tweets produced in the lapse of a couple of days - that has limited access to non-cooperators and can be restrictive in terms of cost for academic researches.

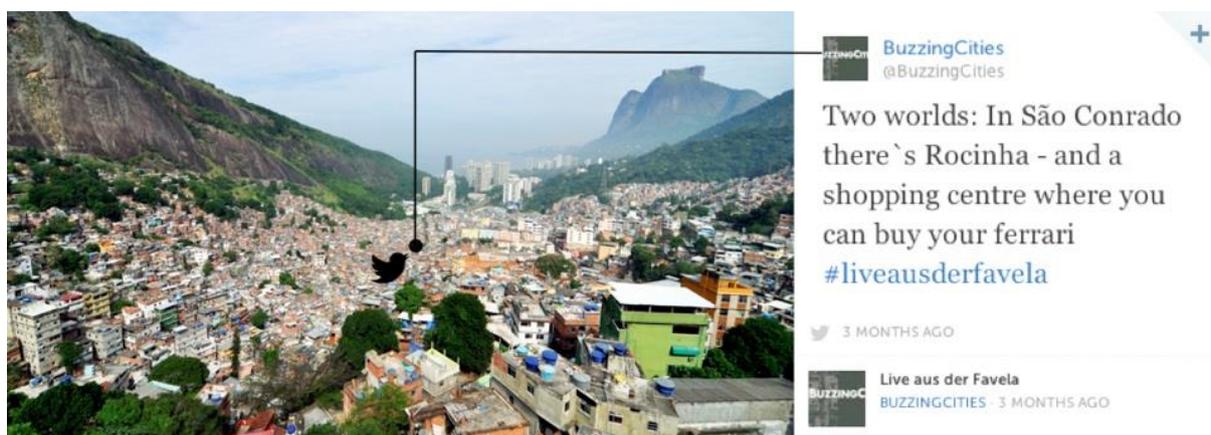

Figure 2: An example of geo-tagged tweet referring to some qualitative information about Rocinha.

The location-based social network Foursquare works like a social recommendation engine, giving its users a chance to timely check-in to places, share their location, search and add place recommendations, contact another nearby user. It is also very business-oriented and the tools are developed to improve personalized content to its users. A recently path towards a more public interface was the deployment of interactive map showing the 500 million check-ins made by its users in the past three months, making it possible to visualize human activity in big cities with considerable accuracy, so that it could become a useful tool to analyze citizens' behaviors and mobility. Foursquare check-in data contains context, has some structure and is short and many Foursquare and Twitter accounts are linked, providing public access to check-ins and posted information even if the account is private.

This study geographically filters this data, relying on the already released information from both servers. In the following pieces, this information is arranged in nodes connected by narrative threads, based on few themes captured from the geo-tagged information. These pathways create networks of meaning, blanketing the terrain and connecting individual action to a broader and collective context. Predictably, favelas show very sparse Foursquare and Twitter activity to subsidize an accurate analysis, whilst most of tagged information is observed in business districts and middle-class neighborhoods. Highly dense tagged areas depict locations where most probably have more access to Internet, that being infrastructural or income related, or most popular places within a city. Middle and upper classes neighborhoods are normally known as a hotbed of social networking activity. In Rio this is even more emphasized due to high concentration of shopping, leisure and cultural activities within those formal grid. Foursquare maps zoomed in the cited favelas show a scattering of small local business such as groceries, bars, gyms and foodies, rather than public spaces and recreational spots frequently identified in other neighborhoods. These activities are based located close to the communities' main accesses and along the few broader traffic routes connecting lower and upper regions (Figure 3).

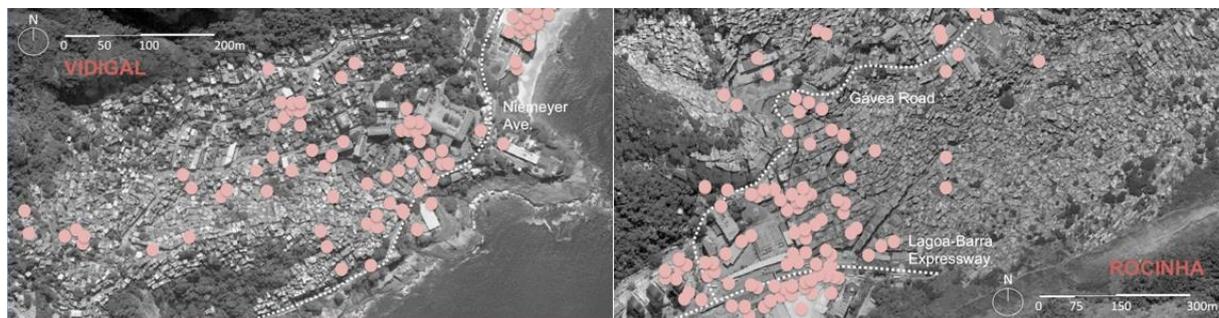

Figure 3: Foursquare check-ins within 500m distance from the community main access: Vidigal (left) and Rocinha (right).

Nevertheless, services target to the tourism sector are some evidence of the new values and uses added to the informal hilly communities in the south zone after pacification. Vidigal and Rocinha crawl up the once hilly forest above within a short distance to city's wealthiest and touristic beachside districts and have postcard views over the city. The increasing number of youth hostels and guesthouses venturing up the steep roads, for instance, related to its geographic proximity to the main touristic venues and landmarks evidences the tourism-related vocation of pacified communities (Figure 4). Some ocean-view properties perched on top of Vidigal are also turning into trendy foodies and terrace restaurants, as described by pictures and comments.

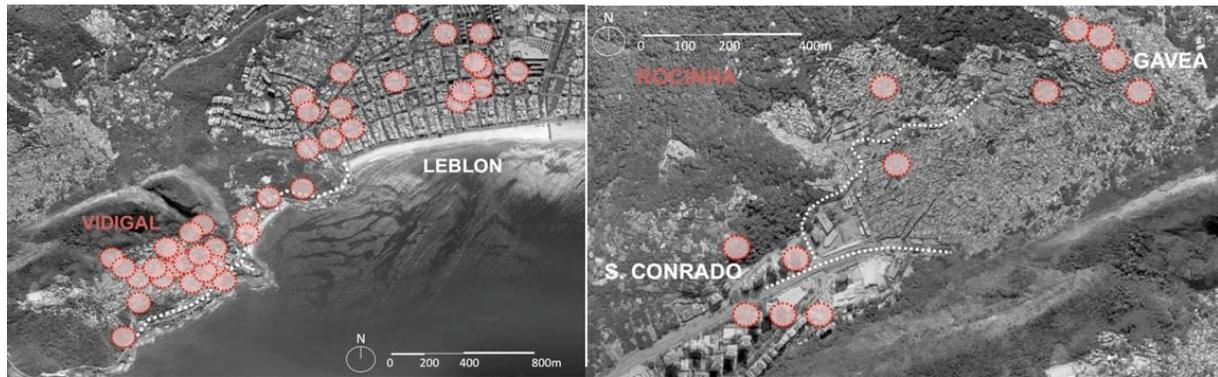

Figure 4: Foursquare check-ins in youth hostels and guesthouses in the neighborhoods of Vidigal/Leblon (left) and Rocinha/S. Conrado (right).

Very far from the tourist-friendly south zone, Complexo da Maré's 16 favelas- which some 130,000 people call home- stretch between two of Rio's main highways (Avenida Brasil and Linha Vermelha- highlighted in red line in Figure 5). Far from being just a dormitory district that serves as cheap labor force to the city, the strip formed by local business and services along Avenida Brasil, Rio's longest transportation hub, configures a lively alley also in the digital world, with considerable concentration of check-ins and tweets (Figure 5-left). Throughout its extension, Avenida Brasil was one of the first public spaces to be wireless-connected (Secretaria de Ciência e Tecnologia- Rio Estado Digital), empowering the construction of a digital datascape in the borders of at least 28 neighborhoods, home of over 1 million people.

Local businesses existing within Maré are more homogeneously spread throughout the zone and more commonly found in the core of the communities. Check-ins in immediate services such as eateries, foodies and cafés, for instance, are well distributed. On the other hand, the nearest formal district, Bonsucesso, historically served the communities with public services. Taking the example of educational services, check-ins in nurseries, schools and technical courses are observed in transversal movements outwards, crossing the borderline to the district (Figure 5-right).

Additionally, health services, such as clinics and hospitals are seemly in the same situation. Local businesses existing within Maré are more homogeneously spread throughout the zone and more commonly found in the core of the communities. Check-ins in immediate services such as eateries, foodies and cafés, for instance, are well distributed. On the other hand, the nearest formal district, Bonsucesso, historically served the communities with public services. Taking the example of educational services, check-ins in nurseries, schools and technical courses are observed in transversal movements outwards, crossing the borderline to the district (Figure 5-right). Additionally, health services, such as clinics and hospitals are seemly in the same situation.

Network of geo-tagged information on local eateries and foodies (light red circle) and schools (red circle) in Maré and nearby Bonsucesso (right image).

4.2 Outlining public spaces

An overall view of geo-coded messages suggests a discrepant concentration of leisure and recreational activities in the formal rather than in the informal neighborhoods. Despite the increasing investments to promote open public spaces within the limits of the favelas, due to its urban plot, very few non-built areas are possible. When existing, such as the case of soccer playing fields, they still do not count on a digital counterpart. In the south zone the beaches have always played the most important role in promoting outdoor sports and leisure, even for the nearby favela dwellers.

Repeated Foursquare check-ins and social circles influence over opting for a place rather than others. This may influence the choice regarding commercial and leisure-related activities. As for the tourism sector it may be useful orienting visitors and relating nearby landmarks. An interesting feature observed while mapping out the districts of Vidigal and nearby Leblon and Ipanema, was the sequence of outdoors activities and observation spots climbing up the hill and drawing a clear line of touristic and leisure continuity (Figure 6).

Figure 6: Foursquare check-ins around Rocinha and Vidigal in places related to outdoor sports (left) and indoor sports/fitness centers (right), suggesting the lack of open public spaces within the favela limits.

The Complexo do Alemão is one of the most deprived and underdeveloped corners of northern Rio de Janeiro and home of around 70,000 people. Made by the haphazard conurbation of 15 different favelas over several decades, urbanization developments have physically integrated the complex with nearby districts: housing programme in strategic vacant lots, new paved routes and Brazil's first mass transit aerial lift passenger system, consisting in cable cars stopping at the top of hills allied with educational and social-related buildings around the stations. It has since been noticed a notable tourism growth inside the community, verified by the concentration of check-ins and tweets suggesting the new vocation for scenic view. Sequential check-ins from the same users are observed, denoting a clear displacement from the first point- the train station, within the district of Bonsucesso towards inner points of the favela (Figure 7).

Figure 7: Sequential theme-related Foursquare check-ins in the aerial tram system of Complexo do Alemão (red circles), with comments and pictures shared in Instagram.

The nearby districts of Bonsucesso and Inhaúma have historically provided public and private services for Alemão's dwellers. The traditional borderline between the districts and the favelas used to be the railway line in the eastern limits of the complex and the main roads sketching its valleys. The recent digital footprints observed in both Twitter and Foursquare suggest a rearrange of services and other activities towards previous impenetrable and economically neglected regions inside the community, notably small regulated and brisk business. As suggested in Figure 8, new centralities around the cable stations promoted by programmatic combinations, establish continuum spaces that take part of the topography and shrink territorial segregation. Along with the delivery of basic social services, these centralities enabled, most of all, the knowledge of the landscape, improving orientations, adaptations and definition of spaces where the previous immense maze-like configuration reigned. The idea of improvement of public spaces as promotion of social and economic changes is therefore reinforced.

Figure 8: Observed check-ins (light red) within and out of 200m-radius distance from the new cable stations (red circles).

The analyzed maps reinforce the extent to which boundaries of formal and informal are still remarkable in the digital world. The findings suggest that the tendency of more cross-social tolerance in some cases, mostly among more consolidated boundaries, stage of some advances in social and security issues. Beyond the placement of text and photos by individuals in the diverse universe of social networks, it should be further discussed the potentiality of crowdsourcing map as a tool of urban analysis and a future referential platform to integrated discussions on the policies and planning practices.

The increasing API integration with other applications and web services may enhance this theory, allowing users to indirectly cooperate. However, there is an increasing concern on the vulnerabilities and privacy risks that can be exploited to violate users' location privacy in geo-social networks. Such vulnerabilities and privacy risks are actually caused by both system's design flaws and users' incautious activities.

5. Concluding remarks

Favelas shelter over one billion people in impoverished contexts all over the world. Territorial solutions are far from being resolved, while local strategies of urban intervention or public policies are aiming at improving their living standards. It has been proved the positive effect of recent urbanization and pacification plans in Rio's main favelas and it may emerge as a gateway to future achievement of full citizenship.

The purpose of mapping the emerging activities observed after those plans is two-fold. Firstly, information democratization, that is to portray favelas from the perspective of citizens and visitors, free of the stigma that often appears in related stories by mainstream media. Synchronized with upcoming events, it is an accompanied opportunity to shed light on life in the Brazilian favelas for the rest of the world. Secondly, pointed evidences of the creative and economic potentials that exist touching the boundaries of formal and informal city. The legitimacy of these potentials has not been properly recognized yet. Many are skeptical, however, arguing that innovative practices of governance go beyond the expected roles of digital platforms in the fields of planning and managing cities' land use regulation.

Regardless, to develop a holistic understanding of the ways in which our digital relationships to territory govern everyday life in urban morphology is a burning issue. Despite the access to the Internet and especially portable connectivity has skyrocketed, few local content is produced by slum residents in comparison with their neighboring districts. To encourage connected residents to take part more fully in the construction of digital space and to instill a technological interest of those still not connected are challenges existing grassroots organizations might bear at first.

This study needs a more profound and comprehensive analysis, which right now highlights the most important and relevant findings counting on the available data. Concluding, it is still anticipated to suggest, counting on mapping biased geo-coded information, a radical change in the urban land use emerging from the dynamics of citizen's digital lives. Meanwhile, as argued by Corner (1999, p. 213), "the function of mapping is less to mirror reality than to engender the re-shaping of the worlds in which people lives".

Abstract

This study evaluates the thesis that planning is a government strategy aimed at 'governing' urban populations. To discuss this statement the paper takes as a reference point the post-structuralist discussion of power, the state and government in contemporary societies. By taking planning as a practice of government the text assesses the Brazilian experience of planning over the last ten years, and shows how planning as a practice of urban regulation has become a legitimation strategy of government.

Introduction

Post-structuralist propositions on power sustain that power is not something concrete or objectified from which one can take possession or maintain ownership, but instead it is a social relation that is established between individuals, and takes the form of webs or networks that exist in the social environment (Foucault, 2008, Laclau and Mouffe 1985, Lemke 2007, Veiga-Neto 2005, Rose 1992). These networks of relationships involve varied combinations and multiple connections between the agents targeting the government of people's consciousness and the conduct of individuals. In these networks the individual is not only an object of the power relations, but he is also subject to these relationships. In the context of democracy, individual autonomy is not opposed to political power, but rather it is the foundation for its exercise, to the extent that individuals are not only objects of power, but they also constitute themselves as subjects of power relations.

The focus is directed to political power, that power generally related to the sphere of the state and which, in a Marxist analysis, means the endorsement and guaranteeing of the reproduction of the social relations of production. Here political power is understood as a system of forces which is concentrated and monopolized by the state and whose function is to exercise power and influence on other spheres of society. Based on the ideas of Foucault, Laclau and Mouffe, this study deals with state action as an object of analysis and examines it as a constitutive element of the government's *problematique*. This analysis is developed by evaluating those strategies of government that are carried out through the various institutions that make up the sphere of governance (public and private). This study takes as its specific objects of analysis those tactics and strategies of government designed to regulate social conduct and individual behavior.

The study investigates the strategies of government that are carried out through the practices of planning and urban management. Particular attention is given to how technologies of power work to control and regulate human actions within cities. It also discusses the mechanisms that make urban planning, a technology of power, while also examining how planning becomes a technology of resistance and social emancipation.

The text covers the strategies of urban government by building on the concept of governmentality developed by Foucault, and investigates the power relations that are established between the agents within the microcosm of urban planning policies. The concept of governmentality draws attention to the kind of rationality embedded in the actions aimed at

understanding and controlling the various aspects of people's lives. This rationality involves manipulating crucial dimensions of people's lives and they include issues such as health, housing, work, leisure, happiness and wealth. Governmentality is an idea designed to capture a form of power that becomes predominant in the modern world – called political power – that emerges from the historical process of institutionalization of power and its concentration in the dispersed state. This form of power is characterized first, by the proliferation of government devices, and second, by the consolidation of a system of knowledge about who, when and how to govern. This knowledge will provide, on the one hand, the expertise for defining the means for the exercise of the art of governing and, on the other, the appropriate techniques for revealing the nature and idiosyncrasies of those upon whom government will be exercised.

The above framework underpins the analysis of the following sections. The working hypothesis starts with Foucault's concept of government which denotes a “historically constituted matrix within which the tactics, strategies and maneuvers of governance agents are articulated in order to manipulate the beliefs and behaviors of people and drive them to certain directions” (Foucault, 1991: 87-104). These maneuvers intercept the perceptions, interests and understandings that people develop regarding the world they live in and affect their behavior and their ways of organizing the physical space. It is in the context of these relationships that the different forms of government emerge and become hegemonic. According to this view the historical process by which governing strategies are constituted is a necessary condition for the formation of different societies throughout history. According to this view, the state is not an autonomous institution, which is outside and disconnected from society, but a structure that is formed alongside and via the same processes that constitute the society itself. Therefore, the state cannot be a central institution which occupies a privileged position within society, with unique and deterministic capabilities for exercising structural functions of social and economic reproduction, because the state itself is a product of relations of reproduction. For Foucault the key issue of modern societies, in addition to the power and domination exercised by the state, is its governmentalization itself.

The contemporary changes in the ways of acting of the state that occurred through the neo-liberal turn of the late twentieth century are examples of the governmentalization of the state. The shrinking of the state and the consequent cooling of its active power in society, are not seen as degrading the sovereignty of the nation-state, but as the emergence of new forms of governance. This type of government produces a new matrix of relations that favors autonomy, free will and individual responsibility. This new form of governance transfers to the private sphere the risk of social reproduction and turns market rules into ubiquitous and immanent rules. In this formulation the government is a concept that goes beyond the idea of government as the management or administration of the state to include other forms of government, such as individual management, family orientation, the administration of the house, the orientation of the soul, etc. Within this approach government is defined as the conduct or management of others' conduct and seeks to synthesize both, i.e. government of the self and government of the other. This work is divided into two parts. The first discusses the concepts of state, government, and governmentality, and assesses the changes in the logic of government that led to the governmentalization of the modern state. In the second part, planning is considered as an instrument of the process of governmentalization. It discusses five propositions about planning as a practice of government by focusing on Brazilian experiences with planning after 1984.

The genealogy of governmentality

The concept of governmentality refers to a set of practices of government that "has the population as their object, the economy as their most important knowledge and the safety devices as their basic mechanisms" (Machado, 2008, p. xxiii). Governmentality is understood as a strategy of governance directed to create docile citizens and governable subjects and which

uses various techniques to control, normalize and shape the individual's behavior. The concept, governmentality, identifies, on the one hand, the relationship between the state's government (politics) and the government of the self (morality), and, on the other, the construction of the subject (genealogy of the subject) with the formation of the state (genealogy of the state).

The term governmentality as proposed by Foucault is constituted by three different but interconnected approaches. The first describes governmentality as a structured mechanism, consisting of institutions, strategies and tactics of action. In this approach, governmentality is defined as the set of devices, procedures and calculations directed to exert a rather specific and complex power, which has the population as its target, proposes political economy as knowledge and safety devices as an essential technical instrument. The second describes governmentality as a trend. In Foucault's own words, by 'governmentality' he understood "the trend, the line of force which in the West led to the supremacy of such power that we call 'government' over all others – sovereignty, discipline – and that led to the formation of a set of specific devices of government and the development of a series of knowledge" (Foucault, 2008a). The third approach describes governmentality as a process: "by 'governmentality', I believe that we should understand the process, or rather the result of the process by which the state of justice of the Middle Ages, was converted into the administrative state in the XV and XVI centuries, and which little by little became 'governmentalized'" (Foucault, 2008).

In short, the word governmentality highlights four aspects of the historical processes behind the constitution of power: (1) its embodiment in the form of an object, i.e. a structured mechanism consisting of institutions, strategies and tactics of action; (2) the hegemony of government as a modern kind of power; (3) the emergence of government apparatuses and of specialized knowledge; (4) the historical process by which the state has become governmentalized (Foucault 1992).

Foucault argues that governmentalization is a historical process by which "the law society and the State of Justice of the Middle Ages was transformed into discipline society under the command of the administrative state and then, to the society of police, controlled by the safety devices that constituted the state government" (Foucault 2008). This process is termed rationalizing the policies and practices of government and became the primary mechanism of change, or the engine behind modern history. Such political rationality is not derived from a larger reason, either transcendental or universal, but is the product of historical developments that, in the case of modernity, produced "this fundamental phenomenon in Western history: the governmentalization of the state" (Foucault, 1991).

The governmentalization of the state means the historical process of "rationalization of government practices in the exercise of political sovereignty" (Foucault, 2008a). From this formulation Foucault develops the concept of governmentality as a guide for constructing the genealogy of the modern state as a category of analysis and then demonstrates his working hypothesis. The concept of governmentality serves to illustrate the multiple relationships between the institutionalization of the state's apparatus and the historical forms of the subjectivity of the individual. The intent is to capture the various processes of mutual determination between the modern sovereign state and the individual in contemporary societies. In this conception, government policies undertaken through state agencies are understood as a contingent and singular political process – a historical event that needs to be explained since it is not a given fact. If the state does not exist as a concrete form of data, but as a historical and contingent constitution of policies that are implemented through government institutions, how does the state act as a coherent political force? Does a multiplicity of institutions and the articulation of disconnected processes combine to form the state?

The State and the Problematic of Government

In the poststructuralist view (Laclau and Moufe, 1985; Foucault, 2008; Lemke, 2007) the state does not have an essential need or functionality inherent within society, but it must be understood as: (1) a 'medium' through which the government problem is discursively codified; (2) a way to separate the political from non-political spheres; (3) an institutional support by which the technologies of government are carried out in mutual coordination. In this approach the problem of government is not limited to the issue of 'state power' but involves verification of how and to what extent the state is linked to the activities of government including: (a) the relationships established between the political authorities and other authorities, (b) those funds, forces, people, knowledge and legal instruments used; (c) the devices, techniques, tactics or political actions that are operationalized. In the context of governmentality the state is not seen as the central institution or the social superstructure, but as another product of a complex and changing system of the discourses, regulatory techniques and power that emerge from the process of government. For Foucault the government is the central issue because it determines a system of thinking – by which the authorities specify the problems – and a system of action – through which government is carried out.

In this conception, the government is not a technique to be used by public authorities or a strategy of state, but instead the state is seen as a tactic of government and a historical dynamic for stabilizing power relations in society. This shift in focus is what Foucault calls governmentalization. In this perspective both the governmentality and the tactics of government are internal and external to the state, and this makes it possible to generate a continuous redefinition of what concerns the state, as well as what is public or private. The state is understood – both in terms of its existence and its limits – as a general tactic of governmentality. For Foucault, what is important for our modernity, our present, is not the growth of the state in society, but the governmentalization of the state because, according to him, since the eighteenth century we live in the era of governmentality.

It is through the analytics of government that Foucault aims to contribute to a theory of the state, because he believes that the formation of the state in contemporary capitalist societies is a crucial event for society's governmentalization. This analysis emerges from the history of governmentality and produces three approaches of the state in the age of governmentalization. The first stresses the importance of knowledge and political discourses for the constitution of the state. In this line the state is defined as a transactional/temporary reality given that it emerges from a dynamic set of relationships that produces simultaneously the institutional structure and the knowledge of the state. In the second dimension Foucault deploys the concept of technology – which incorporates both political and symbolic devices – and specifies the political technologies and the technologies of self. The state in this dimension is seen as a mode of articulation in which certain technologies of government emerge, and create temporary institutional validities by interacting with each other in particular ways.

The third dimension illustrates the state as an instrument and as an effect of the political strategies that will define the boundary between public and private, and between the state and civil society. State action is an effect of the political strategies, because that action cannot be assigned to a single and coherent actor, but is the result of conflicting, contradictory and competitive governance practices that emerge from a number of specialized sources of public government. This explains the relational and temporary character of 'state plans'. To think of the state as part of a network of governance does not mean to consider it a secondary category of analysis, but on the contrary, the state is a strategic instrument for sustaining the differentiation between public and private spheres, for subsidizing the idea of nation and for supporting the creation of sovereign (or territorial) limits. The state is also the instrument that shall determine the conditions of access to public assets and resources. In addition to its status as an instrument, the state is seen as a strategic field – the locus – which is defined as the general

guidelines of social government and where decisions are taken, benefiting certain actors and excluding others. This is the so-called the strategic selectivity of the state

Governmentalization and Planning

The following text discusses four hypotheses extracted from the poststructuralist analytical context and, in particular, from Foucault's propositions on the governmentalization of modern societies. The goal is to analyze the historical relevance of some poststructuralist philosophical conceptions and their implications for urban and regional planning. Each hypothesis addresses a specific issue and opens up the debate on the ontological and epistemological implications of Foucault's approach to the nature of knowledge and the practice of what we call planning in today's world.

Hypothesis 1: In modern forms of government, the main device for social reproduction is the association between the 'political' authorities and the authorities of 'knowledge' (economic, legal, spiritual, medical, technical). This association is established in an attempt to regulate social life and govern the collective affairs based on conceptions of what is good, healthy, virtuous, efficient or profitable.

In the context of Foucault's reflections there is no direct reference to planning as a technology linked to government practices. However, it is possible to understand public policies and urban planning as manifestations of the governmentalization of the modern state, in so far as they seek to organize life, regulate the space and control the actions of the urban citizen. In general, these policies are involved in the search for greater efficiency in the use and deployment of resources (power) aiming to control human conduct. As in cost-benefit analysis, the goal is to "achieve maximum result from a minimum application of power" (Goldstein, 1994, p. 198). The object of public policies is 'the citizen's conduct' and their objectives are to preserve and promote life and their guidelines are based on the concept of 'bio-power'. In this sense, policies seeking to organize the urban space can be seen as planning of the individual's conduct in relation the use of land, in order to promote and preserve the citizen's life in the city.

For Foucault 'bio-power' means those projects directed at individuals in their spatial and temporal characteristics, aiming to promote that community life of which the individual is a part. Foucault observes that the invention of the concept of bio-power, in the mid-eighteenth century, was related to the invention of the concept of population, which since then came to mean a collectivity of individuals who are thought of as a unit that can be describable, measurable, knowable and therefore governable. Bio-power creates the object of public policy in the era of governmentality: population. The population is understood as a collective of individuals that must be preserved through government policies, or as Foucault called 'biopolitics'. Since then, the population is understood as a living body, a body-species that should be governed in order to promote life. It is up to the state – also an eighteenth-century invention – to assume the role of coordinating the policies that will promote the life of the population.

For Foucault the idea of promoting life means to consider two dimensions of biological life. Promoting life first involves caring in such a manner that each individual remains alive and productive; and, secondly, seeks to avoid the human species' extinction. These changes in relation to the concept of life, as well as the invention of population control technologies, serve as generators of the so-called bio political-turn of the seventeenth century, by which the aphorism "to let live – to make die" during the reign of the sovereign is replaced by the guideline "to make live – to let die" of modern times.

In summary, strategies to govern populations were formed from biopolitics, and the latter was based on bio power. As we know, that does not mean the disappearance of power as a

discipline, but involves an interweaving between disciplinary and bio power: a rearrangement of complementarity by which one acts to enhance the other.

Hypothesis 2: Governmentality is the product of political rationality. It defines what is governable and promotes the means to govern. Planning as a mode of governance can only be analyzed in terms of their political rationalities. These rationales are constituted by: (1) discursive fields within which the exercise of power is scientifically delimited; (2) moral justifications for particular ways of exercising power by diverse authorities; (3) notions about what are the means, objects and appropriate limits of the policy; and (4) ways to distribute the driving tasks among different sectors of society.

In the case of planning policies that are designed to guide and discipline urban growth it is not difficult to perceive the political rationality that emerges from the discourse of planning and citizen education campaigns. The state intervenes by means of plans (master) in order to regulate how the individual can use and occupy the urban space, which also involves where and when citizens can move around the city. Utilizing a discourse of competency, founded in technical and scientific knowledge, the state uses the city as an environment for the implementation and dissemination of technologies directed to control citizens' actions, for the purpose of minimizing inefficiencies and to reproduce life and capital.

Public campaigns are meant to act as cultural pedagogies as they use the discourse of mobilization as a technology of government. Public campaigns seek to inculcate appropriate behaviors, rational attitudes and appropriate ways of acting. The rationality manifested through public campaigns, consists of a set of statements that put into circulation certain regimes of truth supported by technical knowledge. What is always at stake in these campaigns is the government process and those power relations associated with this, both underpinned by the discourse of rationality.

Technologies of governance manifested through planning policies should articulate two main mechanisms in order to achieve their goals. First, they must rely on the discourse of persuasion and cultural pedagogies in order to teach and persuade the population concerning their goals. In these cases planning policies and public campaigns work side by side to create awareness and specific worldviews. Second, in order to consolidate strategies of governance, urban planning policies must be put into practice, that is they only hold if and when fully implemented materially, and this means allocating all bodies – normalized or not – in the same space and effectively lend them a purpose.

For Foucault there is no pure rationality that has a universal character and stands outside the world of practice. Rationality is only attained at the level of everyday practice and not at the level of utopias. In the case of government planning policies, rationality is always contingent, permeated by power and dependent on specific interests in each spatial and temporal context. Therefore, all the forms of rationality that orbit around public policy can be understood as a discursive strategy aimed at the governing of populations.

Since the goal of public policy is to perform the best (the most effective, economical and permanent) government of the people, it is necessary to promote the highest possible ranking of the elements that compose them. In such an ordering the logic of planning policies is based on the idea of the deployment of 'rational' planning, the provision of 'proper' uses of the urban space and in some cases the pursuit of the universal right of access to the city.

In the case of public housing policy, the governance logic (or rationality) aims to provide access to 'ownership' (house property) and the ordering occurs through operations whereby the population is compared and classified in terms of poverty, shelter (or lack of) and life conditions. Thus, institutions that seek to ensure access to housing aim toward the principle of inclusion, even if, during the process of comparison and classification, they have to promote exclusion, by choosing a certain criterion and excluding others. Thus, it can be stated that policies that create

spaces for inclusion are also the same ones that create spaces of exclusion. It follows, therefore, that equal access does not guarantee inclusion, in the same measure that it does not remove the shadow of exclusion.

In the case of urban planning policies the rationality underlying governance practices work by creating, ordering and selecting the realities by which they intend to intervene. The problems that are chosen to be the objects of political action are carefully defined, specified and 'technically' delimited, and the solutions that follow will obviously be the technical elimination of those problems. By strategically creating the object of the action and convincing people of the existence of a problem, the government also creates a sense of what is 'appropriate', 'desirable' and truthful. Thus, in seeking to meet the needs and desires created (by the manipulation techniques of bio power) policies end up reproducing or recreating the same problems that they seek to reduce since they are not able to universalize the realization of the promised truth. The logic that creates problems of government, also recreates them as new problems of government.

Hypothesis 3: Knowledge is the foundation of government and therefore the essence of planning practice. As government is the domain of cognition, calculation and experimentation, planning as part of the government involves the knowledge of urban life in order to be able to govern it.

Government is a problem-solving activity, in that it represents the obligations of governments in terms of the problems they seek to solve. The agenda of the government and consequently of the planning process is closely linked to the problems it intends to govern, that is, the 'errors' to be corrected and the 'deficiencies' to be eliminated. The analysis of government throughout history suggests a sequence of *problematizations*, in which experts (politicians, scientists, philosophers, military, etc.) assess what is real and what is ideal, and then seek to reduce or eliminate the distance between them. The concepts thus formulated define what we understand by, for example, poverty, urban problems, productivity, competitiveness, social crises, educational deficits etc. Through this process, needs are identified, proposals for action are drawn up and then linked to the instruments of government available.

As part of the process of government, plans are drawn up and within them strategies of action and techniques of intervention are organized to confront those specific situations defined as deficient or problematic. It is within the realm of plans, policies and proposals prepared by experts (philosophers, politicians, physiocrats, etc.) that it is decided what is desirable, viable or sustainable and what goals should be pursued and when, how and why. This is the domain of strategic plans, programmatic actions and dogmatic justifications. This is the locus of norms and controls; the place where the decisions are made, policies formulated and targets set and, ultimately, who benefits from them.

The transformation of political rationality into plans and government programs does not occur by a deterministic or mechanical process, but through a subtle objectification that translates moral values, knowledge and languages of political power into a technical language of action. This translation involves moving from one space to another, whereby definitions of government, political priorities and strategic concerns are transformed into intervention technologies.

In the context of governance practices, government programs are not only a statement of desires or intentions, but they are also assertions of power grounded in knowledge and competence. First, whoever is in power arrogates competence over society's issues (the economy, nature, health, poverty) and gives to the experts a mandate to deal with them. Second, the knowledge embedded in government programs is essential for legitimating the strategic exercise of power on such problems. Knowledge, in this case, is intertwined with power and thus in turn with the action effected. Third, the political management of an issue requires specific knowledge to represent and describe it in order to expose its truth and allow its reframing in terms of political calculations.

An essential practice for production and consolidation of expertise are the technologies of government that are linked to the activities of registration and calculation that are monopolized by the state. In Foucault's conception the state is not the central apparatus of government, and nor does it represent a class in power, but is an extensive institutional complex where several centralities are constituted and organized to make up the process of government. This complex consists of several scattered apparatuses of government, where multiple centers of government work at producing information and knowledge, raising and evaluating the data and facts of reality in order to maintain appropriate control over the various contexts of government.

The kind of government that emerges in the seventeenth century is closely linked to the notion of statistical data – called the science of the state – because it becomes clear that government as the conduct of conducts is only possible with the accumulation and organization of data related to the object to be governed. This practice progresses over time and since then broadens the range of information that is made available to government in order to guide the behavior of others. The goal is to control all aspects of everyday life, monitor the social accounts, and manage people's desires by using market researches, censuses, economic polls, school surveys, etc. Increasingly 'government' means to analyze, judge and decide based on information and records collected in the real world.

The representation of the object of government is a permanent technical activity that is carried out systematically by government institutions. The effective operation of government requires putting into action an extensive network of research and a meticulous documentation system with the aim of turning the events and phenomena of reality in systematic information: births, deaths, diseases, marriages and divorces, income levels, types of diet, employment, unemployment etc. These recording practices turn reality into something stable, comparable and combinable. The real world is then converted into an object to be examined and diagnosed or modeled. Evidently the information produced in this production line is not neutral, since the action of recording is, in itself, a way of interfering in the real world. In fact, the procedures for collecting and recording information, as well as techniques for evaluation, measurement and modeling, make the object of investigation (the real world) susceptible to different interpretations.

The recording of reality made through procedures of data collection, makes room for the establishment of centers of planning and applied research with the goal of providing profiles or elaborate scenarios of urban social processes it is intended to intervene in. Therefore information collected in a decentralized way must be transported and accumulated in specific locations (planning institutions, research agencies, centers of intelligence, logistics) in order to facilitate undertaking comprehensive diagnoses and effective policies. The concentration of data in specific places gives individuals or groups who run such sites exceptional powers, as these positions allow them to control the calculations and actions to be undertaken. With a privileged knowledge of the object to be ruled, such groups or individuals accumulate power and authority in order to claim legitimacy for their plans and policies. It is in this sense that the production and control of information plays a key role in power relations within society, in that it contributes to the empowerment of certain agents, and this enables them to exert power over those whose only role is to be the objects of such information.

The calculations also have the ability to transform the object of government to the extent that they enable, aggregate or disaggregate phenomena in time and space, revealing regularities, patterns or deviations that will support and enable interventions on a specific reality. The calculations, by themselves, are only mechanical manipulations designed to reveal trends and justify relationships between different phenomena, however, they make entities such as population, economic data or public opinion, thereby they become calculable and predictable variables.

Government is a process intrinsically linked to technical expertise, to the extent that the determination of government targets depends on cognition, calculation and experimentation which are the domains of expertise, par excellence. In planning, the role of expertise is not limited to developing a network of rules aimed at controlling urban life, but also to support the various efforts to consolidate a calculated administration of various aspects of citizens' conduct in cities. Expertise is the key element of policies that seek to drive the behavior of the citizen in urban areas, it is through it that government seeks to educate, persuade, induce and incite people's lives in cities.

Technical knowledge, as we know it today, comes about in the seventeenth century, with the transformation of rationalities and technologies of governance, seen as a solution to the impasse of the liberal conceptions about the role of government. The problem was to reconcile the liberal idea of politics as a field restricted to the public sphere, with the recognition of the political implications of the activities of private companies. It is the spread of technical expertise across the public and private spheres which will allow for the construction of a new rationality of government, one capable of connecting the issues of public and private life. This new rationality will make the private company an object vital for controlling the economic life of the nation, and the family an agent for the control of social life.

In this scenario the task of sewing together the overall objectives of macro political governance, with the detail of everyday governance (corporate or familial) is essentially performed by the expert. Here the expert becomes engaged in a dual role. On the one hand, he acts as a member of the government by seeking to translate the problems of the economy and society into technical language. On the other hand, he acts as an independent expert, and seeks to provide solutions to the everyday concerns of the ordinary citizen (investment, work, children, health, etc.).

Throughout this historical process, various social sciences are created (economics, sociology, psychology) and they gradually construct a repertoire of intellectual visions, versions and justifications that will provide the necessary technological instruments for government action. These new insights provide explanations that make the world something thinkable and intelligible and are expressed in the form of procedures for taming intractable realities, subjugating them to the logical analysis of rational thought. Thus, for example, the management of urban problems involves defining, a priori, all the elements, processes, and relationships targeted for government intervention. In the case of urban public policy, problems are reset through a technical language, and then transformed into laws, processes, and urban features, in order to provide the necessary elements for the city to be understood, designed and managed with a view to increasing efficiencies or reducing dysfunctions.

Government plans assume the world as a mechanical device, consisting of fixed rules, recurring processes and predictable behaviors, which can be programmed and controlled. Such plans turn citizens into objects of government, 'things' to be manipulated, susceptible to diagnoses and prescriptions by means of calculations and normalizing interventions.

In short, knowledge defines and shapes every aspect of social life and, by doing so, makes social life something liable to be governed, that is an object to be managed, planned and disciplined. The city – as we perceive it with its features, peculiarities and problems – can be understood as a product of rational knowledge, which makes it an object of intervention, i.e. a governable entity. The city, seen through the concepts of the social sciences (such as public policy and planning), is but a device that builds on the ideology of scientific rationality and which aims to create an image of the real world that allows us to think about and understand it so as to make the issues of everyday life in the cities something liable to be planned.

Hypothesis 4: The government of social life is expressed through technologies of governance. Such technologies reveal an intricate complex of plans, policies, programs, calculations,

documents and procedures. It is through these practices that the public authorities seek to carry out government aspirations. The technologies of urban governance are manifested in four types: (1) technologies aimed at disciplining the body of the individual; (2) the technologies that aim to regulate population processes; (3) technologies that seek to encourage self-control (technology of self); and (4) political technologies of individuals.

As explained earlier, the government is a process by which plans are formulated and government strategies designed. Both plans and strategies are formed by a web of programs, procedures and tactics by which different political forces seek to operationalize the actions of government so as to allow the establishment of connections between the aspirations of government and the activities of individuals and groups. This set of techniques, plans and procedures is termed 'government technologies'. It is through technologies (and the plans that operationalize them) that the government carries out its political rationality in order to achieve social control. The implementation of such rationality does not only mean the replacement of the real world by the ideal world. It also involves the assembly of a complex system of forces and values (legal, moral, architectural, administrative) that functions as official criteria, regulating and shaping the actions of individuals, groups and organizations.

By focusing on the techniques and strategies of government, the analytics of government examines how the government operates in everyday practice, in order to understand the transformations taking place in the state and public policy. In this methodological maneuver Foucault proposes the concept of technology to grasp the four different strategic modes designed to control society's conduct. The first is related to the techniques of observation and recording. The aim is to control the actions and behaviors of individuals, in order to discipline their body. The strategy is to create docile and responsible individuals able to live in dense communities, such as cities. The discipline as a technology of government begins to be used in the seventeenth century, with the intention of organizing the process of urbanization and to promote the concentration of populations. The target is to ensure the appropriate supply of a tamed population according to the needs of the nascent industrial revolution.

A second group of technologies is linked to those forms of regulation of the population, particularly those living in cities. Here the techniques aim, not only curb undesirable actions, but also to create knowledge of collective behaviors in order to predict and control future events. The systematic observation of urban phenomena is the key elements of the practice of town planning. They allow you to accumulate knowledge about social behaviors, migratory movements, and forms of use and settlement of individuals in urban territory. These skills are crucial for planners, since they allow diagnosing, predicting and even anticipating emerging social problems in urban areas. The purpose of policies for social discipline is to create healthy and functional urban environments which are able to meet the needs of industrial capital.

A third kind of technology refers to the technology of self. Such technologies address the processes by which individuals exert self-control and the ways they see themselves as ethical beings. These are forms of self-imposed control and are derived from broader processes of control and social discipline. The technology of self-control involves a process of curtailment of consciousness, focusing on parameters of normality and proper conduct that are inculcated through laws, public campaigns, education, etc. Here individual experiences that deviate from the standard behavior can become social problems (moral, political, legal, public health). In the case of urban areas, behaviors conceived as deviant from normal, worthy or appropriate, are considered social problems to be removed – as in the case of urban slums.

A fourth group of technologies, termed the political technologies of individuals, act on how we recognize ourselves as members of a social body, and strengthen our sense of belonging as members of a community, participants in a society, inhabitants of a city or citizens of a country. These technologies also act on the level of consciousness, constituting identities, perceptions and creating an intelligible world that will be seen as natural. These sensitivities will

produce an idea of 'we' that will be different from the 'other'. Such technologies are also essential for practices of urban government, because they require collective involvement in situations of social exceptionalism (epidemics, floods, disasters, etc.).

Conclusion

Foucault's theory of power does not start with oppression or domination schemes in order to identify mechanisms that affect and/or constrain freedom. Instead it is a research project that aims to provide analytic tools for understanding the origins and regimes of power and its relations with rationality and knowledge. His theory is designed primarily to produce knowledge that can provide assistance to promote change.

It is worth noting the normative attitude that, throughout the history of planning, has been dominant both in theory and in practice, has not contributed or has been of little help for social development and to advance planning. The ideals of modernity, democracy and social justice are, in general, distant and sometimes unreachable, and may be seized by a shift in the epistemological focus of the discipline. This means that rather than continuing to follow the path of normative rationality, it may be worthwhile to pursue a practical rationality in order to guide planning actions. If, on the one hand, the normative rationality offers noble ideals of struggle, on the other, it does not provide any indication of the routes to be followed in order to achieve those ideals. The analysis developed here explores the dilemma of idealistic planners who strive to formulate coherent plans and magnificent proposals: they know what they want to achieve and where to go, but do not know how to get there, because in most cases the normative ideals are oblivious to the world of the real city.

Idealistic-normative planning concentrates on questions such as 'what is the goal we want to achieve' and 'what is necessary to achieve it.' This study proposes a reversal of such and suggests that planning should concentrate on questions such as 'what are the strategies of the everyday' and 'how they are carried out in the real world'. By focusing on the real city and not the utopia of the ideal city, planners will understand the city as an object-subject with which planning will share actions that aim to change it and to turn it into something better

Foucault develops a kind of analysis that can be useful to construct an idea of planning as a social practice aimed at promoting social change through democratic means. In this formulation the conflict of interest is not something destructive or socially dangerous, but rather is seen as the foundation of freedom. In this sense the possibility of conflict is an opportunity to build a more just world.

Therefore, theories that ignore or marginalize the conflict are potentially oppressive. The idealism of the plans and planning policies seeking utopias, and disregard the conflicts of everyday life, are seen as authoritarian and sectarian, since they advocate the pursuit of a 'single' truth. Political and social life in the real world is made up of diverse views and conflicting interests, and it is these differences that should guide the practice of planning, and not the idealistic models based on fundamentalist ideologies and absolute truths.

The advanced democratic societies tend to value diversity and encourage autonomous groups to constitute their own ways of life, thus legitimizing the differences and conflicts of interest that emerge from them. In this sense, the political consensus is seen as oppressive. The consensus should never suppress or neutralize the interests, commitments, or beliefs of a particular group. In this view, consensus is only possible inside the group, where there is no exclusion.

Every democratic society must guarantee the permanence of the conflict. The role of planning as a democratic practice should be to support the understanding that power and conflict are always at the center of social processes, as suggested by Foucault. As part of this argument, this paper argues that the practice of planning committed to dialogue and open to

conflicts provides a more realistic and rational basis for planning than the idealistic paradigms based on utopias insensitive to the real world and built on oppressive consensuses.

By exploring the counter-face of planning, we found that beyond the oppressive aspect of planning as a rational-idealist activity there is also our failure as planners in making a difference through planning. This study proposed to investigate the practice of planning, in order to assess how it is done in the context of everyday practice. By directing attention to the intricacies of the hidden practice and not to what planning should do, we intended to shed some light on what planning really does in practice. The research also sought to provide an explanation of how power is structured and how it involves us. This helped to elucidate some mechanisms involved in the planning process as a steering device. This study is part of an effort directed at providing an understanding of planning in the context of general government practice. The intent was to contribute to specifying the paths to a more effective planning thereby suggesting how to make a difference.

Creating Vibrant Streetscapes

Holly Williams, University of Oregon, Eugene, U.S.A.

Intro

Streets play a vital role in the health, happiness, and livability of a community. Creating vibrant streetscapes in Old Town Portland will revitalize the area and improve the quality of life for residents and visitors alike. As the city of Portland continues to gain recognition for outstanding planning aspects, it becomes essential to transcend traditional streetscapes and implement design that supports a thriving urban lifestyle. Improving existing streets in the Old Town area can be achieved by: widening sidewalks, implementing multimodal access, using permeable pavement, and creating bioswales. Results of these improvements would include: creation of sense of place, increased pedestrian traffic, improved urban sustainability, and an overall exemplary downtown district.

Body

Active sidewalks

The revitalization of this area depends heavily upon attracting pedestrian traffic. Creating space for pedestrians that is safe, inviting and functional is the ideal way to draw foot traffic to the district (Metro, 2002). By updating the design of sidewalks in Old Town, pedestrians will have a realm in which they can easily move about or simply sit and watch the world pass by.

Wide Sidewalks

Building a sidewalk that is wide enough to incorporate both transportation and open space is a critical part of not only an active sidewalk, but of a vibrant streetscape. A recommended width of 12 feet or more is suggested for sidewalks that include a variety of amenities. Within this 12 foot sidewalk there are multiple zones of activity including a storefront zone, a walkway zone, and a furnishing zone (Metro, 2002). The width of each zone may vary depending on the overall width of the sidewalk, but the walking zone should be the widest, with the furnishing zone and storefront zone approximately one and two feet narrower respectively (The Downtown Alliance Streetscape Steering Committee, 2006). The streets in Old Town that would most benefit from wider sidewalks are Pine Street, Ankeny Street, and 1st Street.

Social Spaces

Creating space within the sidewalk to make a street welcoming is an important part of a vibrant streetscape. Social spaces should create an atmosphere that draws people to the area and allows them to interact with others or simply sit back and relax (The Downtown Alliance Streetscape Steering Committee, 2006). In this study area, creating open space would be a catalyst to attract people into the neighborhood. While people might stroll through Old Town before shopping at Saturday market or after a trip to Voodoo Doughnuts, there is no social space to keep them in the area.

Physical Comfort and Safety

A successful streetscape not only needs to be beautiful and functional, it must also make pedestrians feel safe. Physical comforts such as parked cars and landscaped planters create a buffer from the street traffic and noise (City of Berkeley 2012). The sidewalks should remain well kept and in good repair in order to meet the needs of all aged people. The sidewalks should also be well lit. Pedestrian scaled lighting not only gives the feel of comfort and sense of place, but also provides important safety aspects (City of Berkeley 2012). In Old Town, cast iron street lights and gas lamps could provide light as well as historical context and sense of place. A safe sidewalk does not allow fast moving vehicles at the curb and may have extended sidewalk space near crosswalks to shorten crossing distance.

Ambiance

Streets are among the most important determinants of an area's character and can be essential in creating a sense of place. One of the best ways to add to and enhance the character of a street is with various types of street furniture. Street furniture can include a wide range of elements including street lights, public art, benches and tables, planters, trees and other foliage, trash cans, street vending, restrooms, and signage (Kost & Nohn, 2011). These furnishings make streets a place where people want to spend their time and where they can converse with others. Benches and tables should be placed where they are not obstructing transportation and where trees provide some protection from the elements. They should be placed close to public restrooms, in front of accessible entrances and exits, and outside the main circulation path. Trash cans should be placed at regular intervals to encourage proper disposal of waste. They may also be painted a contrasting color or decorated in an interesting fashion to draw attention to them and create a unique characteristic. (Kost & Nohn, 2011) In Old Town, the incorporation of cast iron street furniture could be used to tie the area to its historic roots and create a sense of place. This photograph of a cast iron bench is one example of iron work that is functional, exquisite and would work well in the district. Public art might also be used to create ambience and give the district a distinct feel. One recommendation for this area would be adding a few pieces of simple, yet bright art that come from a series and are placed through Old Town. For example, painted bikes, like the one pictured here, could be scattered throughout the district. The bikes could vary in color and each one might have a basket located in a different spot that is planted with flowers. For more on street art, please see the section Public Art.

Multimodal

Portland is known as one of America's great bike cities. With huge portions of the population who commute by bike, it is essential to assure their safety and provide them with abundant routes. Part of creating vibrant streets includes access for all forms of transportation. Creating cycle tracks in this area that allow two way bike traffic would greatly improve the flow of transportation for bikers. Having designated cycle tracks in this area would not only provide easy transportation for commuters, it would also attract those people who wish to bike in a more leisurely fashion. More information about the implementation of cycle tracks can be found in the section Active Living.

Bioswales

Bioswales are storm water runoff systems that provide an alternative to storm sewers. They can filter water runoff from rain and snowmelt to improve water quality and remove harmful toxins. Bioswales would be especially important in this area because of the high water table. With the groundwater being less than two stories under surface level, having bioswales could improve the water quality of rain and runoff before it enters the groundwater and then Willamette river (City of Portland Environmental Services). These swales are easy to maintain. According to the US department of agriculture, bioswales require less maintenance than turf grass because they need less water and no fertilizer. Bioswales are also a great way to add green space to an urban environment. They can be landscaped in a variety of ways and become a beautiful part of the natural culture of a city (City of Portland Environmental Services).

Permeable pavement

Permeable surfaces are infrastructure that both provide storm-water infiltration and surface structure. Similar to a bioswale, they filter water through sand and other porous material that lie under the surface (City of Portland Environmental Services). There are a wide range of places that permeable pavement can be used. In Old Town a great place to add permeable pavement would be in the many surface parking lots. This would be an environmentally friendly and creative way to add green space to what is traditionally a solid block of concrete. Permeable pavement can also be used on low traffic streets. First Street, in the Old Town District, would be a prime place to add permeable pavers. It would help to lessen the harsh, stoney feel of the street and be a great way to attract pedestrians. And finally, these permeable pavement surfaces can be used on walkways. There are many environmental benefits to permeable pavement, including surface water management, appearance and they also serve as groundwater and aquifers are replenishers.

Recommendations:

1. Expansion of sidewalks to a minimum of 12 feet
2. Creation of multiple zones within the sidewalk space
3. Addition of cast iron lights to aid pedestrians and reduce light pollution
4. Implementation of grass sidewalks
5. Implementation of grass-lined Max tracks
6. The use of permeable pavement on all surfaces
7. Landscape planters added to a minimum of three main streets

8. Addition of street furniture which includes: public art, benches and tables, planters, trees and other foliage, trash cans, street vending, restrooms, and signage.
9. Implementation of a cycle track
10. Addition of bioswales wherever possible

Track 4: International Planning Exchange

49th ISOCARP Congress Proceedings

Istanbul's Changing Skyline: The Effects of Landmark Projects

Kerem Yavuz ARSLANLI, Istanbul Technical University, Institute of Social Sciences.
Turkey

Abstract

After 2002 economic crisis in Turkey real estate market is evolved with respect to international globalization agenda. Between the years 2002 and 2006, Turkish economy has grown by 7.5%. Consequently, private consumption expenditure have increased by 8% annually, by 6% per capita and private sector investments in fixed assets have increased by 23%. In parallel, the housing and commercial real estate sectors have also demonstrated a considerable growth. Foreign capital investments and the shares of international investors in commercial real estate's have also increased (PwC, 2012). In this paper multi-centre development of Istanbul is investigated with respect to Office, Retail and Residential markets. The Central Business District of Istanbul begins with the Barbaros Boulevard, continues along the Büyükdere Avenue and reaches to Maslak. The high-rise plaza type offices on the Esentepe-Zincirlikuyu-Levent-Maslak direction have contributed to the development of this central business district. Istanbul as the biggest city of Turkey affected with much severe planning problems within last decade. This paper investigates the possible outcomes of changing skyline of Istanbul with respect to planning future of the city.

1. Introduction

Rapid and unplanned growth after 1950 in Istanbul, including heavy industrialization, valuable city land and identity has been lost. Today, population growth and economic development of the service sector and as well as the growth and development of telecommunication technologies has encouraged the development of many sub-centres. After the 1980s, the developments of a multi-center of major cities are found in many countries in Europe and in the United States (Gordon and Richardson, 1996) (Hall and Pain, 2006). McMillen and Lester (2003) had predicted in Chicago, the number of sub-centres in 1970, from 9 to reach 24 at 2040. In particular their model showed the centres to be evolved along the highways. In Canada, Coffey and Shearmur (2001) examined the development of a multi-centre, especially in Montreal. Rowland and Gorbon (1996) as an example to developing countries in Mexico City and Dökmeci and Berköz (1994) in Istanbul demonstrated improvement in a multi-centre development. In addition, Richardson and Bae (2005) examined multi-centre developments in large number of developing countries.

The multi-centre development of Istanbul, has led to the collapse of the historic centre structural form. In addition, since the needs of modern office buildings, transportation network, and parks, and historic preservation district is unable to meet the needs of increased traffic due to the restructuring and growth control has encouraged the development of the new centres around the city (Dökmeci and Çıracı, 1990; 1999).

New sub-centres, along the highways, close to the university and large public housing projects developed in such a large investment in socio-economic and physical environment has encouraged the restructuring. Meanwhile, for the revival of the historic centre and the historic neighbourhoods economic development projects have been started (Ergun, 2003). In 1990, the pedestrianization of Istiklal Street, the development of trade, and functional change has encouraged the restoration of the buildings.

The last 10 years there has been 10 to 15 times increase in the real estate market of Beyoğlu by national and international real estate investors (Dökmeci and Özus, 2005). The historical peninsula, in the municipality of Fener and Balat UNESCO Funds investments in infrastructure and functional restoration of the buildings has encouraged the exchange of population and gentrification. As a result of this development, the increases in prices, local and foreign investors are attracted to this region (Ergun and Dundar, 2004).

In the Golden Horn, the investments made for the cleaning of the surrounding encouraged a revival of important historical buildings (Baycan and Seda, 2003). For example, Kadir Has University in Cibali Tobacco Factory, Eyüp Feshane Fairgrounds, Golden Horn Congress and Culture Centre, Silahtar Ağa Power Plant, Bilgi University Museum of Industry and Shipyards has been some examples of these important revitalizations.

And functional transformation of these buildings started economic development around the neighbourhood. As a result, sub-centres around Istanbul, re-triggering the recovery to economic development by investment in the city's historic neighbourhoods. The internal dynamics of the city's major economic opportunities mobilized for real estate investors.

In this study, the land and housing values in Istanbul, office and retail trade, real estate prices in the city such as the distribution of rental values were examined.

2. Multi-Centre Development of Istanbul

There are many factors that affect the real estate prices in Istanbul, for example, history, quality, and socio-economic characteristics, the location in the city, transportation facilities, natural beauty and views, (Özus and other, 2007). Istanbul, the development of a multi-centre circles around them, affect the functional restructuring of real estate values, and in particular to promote the restructuring of slums and the actual value of land in the city to redevelop a very precious opportunity created indirectly.

Distribution of Land Values

Examining the distribution of land values in Istanbul, as a port city in history, places of work to take place immediately behind the port and the transportation system to be developed as a centre of high land values in the centre and near seaside. In addition, recently-built highway intersections, and their paths along the sub-centres, land values increase in a stepwise fashion according to their importance. Meanwhile, despite being advantageous in terms of accessibility, which is still low value land areas will be investigated in the model.

Distribution of Housing Values

In this study, the distribution of housing values compared to that of 1990 and 2010. Istanbul's population to grow rapidly after the 1950s and 1980s due to the economic development and globalization, urban socio-economic and physical structure has led to undergo a wide range of transformation (Dökmeci and Berköz, 1994).

This transformation in the city, providing new business opportunities and revenue growth, has led to changes in the internal dynamics of housing prices (Dökmeci et al., 2003). In addition, inflation is higher than in previous years, as well as in other developing countries with similar conditions as Istanbul, safe and efficient as an investment in the real estate market has developed rapidly (Önder, 2000).

Socio-economic differences between the districts of the city, has caused the 3 focal points with high housing prices.

(1) With the world-renowned natural beauty and rich mansions and also important companies, the three universities and the second biggest shopping centre, close to the Bosphorus coast

(2) Situated on the west of Istanbul, such as the three largest shopping centre in Istanbul Ataköy and the establishment of a housing estate, which started life in the modern city with easy access to the centre and the ring roads Bakırköy

(3) In the countryside and the sea coast with luxury homes, 10 km. long street in Baghdad, including the luxury shops and entertainment facilities around the neighbourhoods with enhanced luxury, Kadıköy (Dökmeci et.al., 1996).

three common characteristics of these high-demand residential areas are; geographical located on the seaside, once the summer resort for high-income families, Istanbul's richest income layer regions are preferred to locate, commercial shopping centres contain the most luxurious styles, that they have a highly acclaimed modern apartment buildings and villas. In 2010, the city-wide distribution of housing prices is not only beaches but also the luxuries of sites around the city have also seen that the high housing price.

These new residential units, close to the new sub-centres in the surrounding area, a high level of socio-economic environment, social facilities, and the physical environment on a regular basis to present a new way of life plays a role in the increase in housing demand and prices. In these examples, an international award winning and low density residential unit, Istanbul Istanbul project, and on the Anatolian side of Istanbul, a very luxurious life with a high level of density "Up-Hill" project.

With newly emerging sub-centres of these settlements have a mutual interaction in terms of rent, the prices that provide dynamic and productive investment opportunities. In addition, to overcome the deterioration of the historic centre, investment in infrastructure has increased the house prices. Cihangir and Asmalı Mescit are given as an example for economic developments.

These developments are become opportunity to invest at the level of districts, but many neighbourhoods are not yet developed. Municipalities of Fener and Balat districts improved infrastructure in order to attract investors and accelerate urban transformations In addition, residential areas of Istanbul, which is surrounded by the sea on three sides of city, offers the opportunity to urban transformations.

For example, Salacak and Harem Coasts, world-renowned view of the famous Topkapi palace, real estate prices highly effected. In addition, the planned development of the socio-economic environment is the most important factor affecting the prices. For example, in the areas of slum housing prices, there are major differences between the prices of housing sites developed and planned.:

Spatial Distribution of Office Rent Values

Economic accumulation of real estate investments is an important part of the people in Turkey (Onder, 2000), and this rate of investments in the office is increasing. After the 1980s, economic restructuring and globalization, international trade relations, the increase in per capita income and a strategic location between Asia and Europe in Istanbul, has led the size of the increase in the number of companies and therefore has encouraged the growth of the demand for office space. Istanbul office areas, in parallel with the development of the commercial potential of the city since 1970, with the support of the Bosphorus bridges and roads grow to the north of the city.

In particular, banks and insurance companies need a new and larger office spaces, between the years of 1960-1985, Karaköy-Salıpazarı-Fındıklı were satisfied with the built office buildings during this period, Turkey's largest corporate groups and foreign companies settled in these regions.

On the other hand, during the same period office needs of small and medium-sized firms, find their place formerly Taksim-Sisli, and later in Şişli-Gayrettepe axis obtained by converting housing into office space (DTZ Pamir and Soyuer, 1996). Since 1985, a significant increase in the flow of foreign capital, consequently opening of the financial sector under the leadership of Turkey's economy booming emerging needs of modern office building, which was built Barbaros Boulevard and Büyükdere axes, were met with Class A office buildings (DTZ Pamir & Soyuer, 1996).

Istanbul's main office areas that make up the new sub-centres are described below:

Levent Region

The presence of the ring road links to the Bosphorus bridges, with old industrial plants have large plots of Istanbul, the due to its proximity and easy access to other sub-centres (Maslak, Mecidiyeköy, Zincirlikuyu) Istanbul's developed a prestigious office buildings, multi-national companies, became the centre of a preferred business holdings. In 2000, the opening of the subway, and Levent and Etiler shopping areas, restaurants, cafes, social and cultural facilities, the presence of the attractiveness of the social demand for the region is become higher (Aksoy, 2005). Therefore, this region is the region of at least the vacancy ratio and the highest rent values.

Maslak Region

Development axis from south to north in the Central Business area of Istanbul represents the most northern point. In Maslak, surrounded by forest areas, it is impossible for CBD further enlargement Maslak business development centre, has pioneered by Alarko Company which had built new office buildings across ITU campus.

Istanbul's most luxurious office buildings and hotels built with high precedent for this has been the most important business centre. In 1995, the Istanbul Stock Exchange moved to new premises in İstinye, banks and brokerage firms were effective for the demand office space near Maslak. As Levent, Maslak, the presence of a wide range of suitable land and the accompanying high building permits, have allowed for the construction of high-rise office buildings.

Airport Region

Airport, the surrounding low-rise office buildings are being developed on the E-5 and TEM motorways. Completed in 2001, the World Trade Centre of Istanbul, the largest office park in the region is an important investment increases the stock of office (Kuzeybatı, 2004). The development of this region, the large press and broadcasting organizations "Press Express

Way" that centres on the support organizations that want to be close to them, as well as buildings in the area close to the factories tend to move factories are effective in the management units (Aksoy, 2005). In the region vacancy rates are more than the other centres and rental values are significantly low.

Kozyatağı Region

The richest region in terms of office stock in the Anatolian side is equipped with a combination of many different land uses. This region began to develop after 1995, and the presence of empty land, to be the intersection point and the surrounding commercial uses due to features such as luxury housing settlements primarily been a point of attraction for large shopping centres.

Besides regional commercial developments (Metro, Carrefour and Bauhaus) as well as the majority of this period, there has been a Class A office space development took place. (Çelen Valuation, 2003). In particular, the demands from multinational and foreign company's plazas began construction in 1997; the majority of office was put into service in 1998-2000.

The main reasons for foreign companies to choose this area are, accessibility, proximity to E-5 and TEM motorways and white-collar workers employed in these companies, the vast majority (65%) has the Anatolian side residence. In addition, the upper-middle income group experienced Kozyatağı residential areas (such as Ataşehir) office in certain areas not separated by a boundary, office space provides integration with other urban areas of activity. Residential, office and other commercial uses of the coexistence of urban scale, enabling the region to be active at any time of the day, although a certain degree of synergy between land uses (Çelen Valuation, 2003).

Altunizade Region

Altunizade zone, starting with Koç Group and its companies have started to develop with a combination of administrative centres. Altunizade region that requirement when being closer to the city, the majority of which is classified as B, the occupancy rate varies according to economic conditions, mainly the structure of the company has an office administrative centres are located. Altunizade, suitable for the establishment of a new regional centres TEM connection with the company, but the height of the buildings limited due to prevent the negative effect on silhouette Camlica, the stock of the building cannot fully meet the needs of the market (Aksoy, 2005). Although one of the least vacant office stock, the rental value of the lowest in the city.

Kavacık Zone

Kavacık Zone is recently evolving office market as an alternative in the Asian side. Because of being near to Fatih Sultan Mehmet Bridge and close to Maslak region, Kavacık played a role in the development of the business centre. However, residential buildings, particularly the lack of permits, as well as the region's transport, energy, telecommunications, infrastructure and social facilities, such as a number of deficiencies and have lower standards of office in this region prevents the formation of high-quality tenant profile (Aksoy, 2005). Office market rents rising on the European side, as well as the emerging demand for central of operations began for a new offices, and residential areas.

Still, Uskudar district, converted to industrial areas, large office buildings, with lower rental rates, especially banks and retail companies settles operations centres (Çelen Valuation, 2003). However, the planned new centres are needed and unplanned developments cause the loss of customers and revenue.

Distribution shopping centres in Istanbul

Istanbul, Turkey's largest and richest city due to a very lively and has a variety of types of retail trade. This commercial wealth of traditional trade routes between continents for centuries on the extremely important due to the fact that having a strategic position. In addition, the economic restructuring of the 1980s in Turkey as a result of displacement of resources and trade in the city of Istanbul has increased the participation of the world capitalist economy (Tokat and Boyacı, 1999).

As a result, consumer culture, these changes due to the rapid increase in population and income, which has great potential for the development of retail trade in the city of Istanbul, the restructuring of commercially viable form, and encouraged the formation of new sub-centres and shopping centres (Terzi et al., 2006).

Retail trade constitutes 40 to 45% of the consumption of families and consumer spending rose from 8.8% in 2005, to 9.6% in 2006. 19th Middle of the century, department stores, has created an evolution in the development of trade. Shopping, entertainment an enjoyable way to spend time became the new bourgeois aims (Bowlby, 1985).

At the same time, large stores in major cities, the people as a symbol of prestige, prepared an environment plays a role in the creation of the national middle class culture. New community of people in big cities to impose themselves from clothing, upholstery homes until every issue became a focal point of directing their lives (Miller, 1981).

Today this trend, with the effect of globalization on the international level, in the form of mega-markets, and increasingly continue. Recently, the mega-markets opened in Istanbul and their great potential in this area reveals that the interest. Increase in the level of income and car ownership, a new way of life and consumption met through the internet and TV people that require large investments in order to meet the demand for a wide variety of shopping centres have been established (Erkip, 2003). Istanbul for the first mega mall, Galeria, was founded in 1988 Bakirköy. Then the numbers began to increase rapidly, and today has reached 56.

In particular, the mixed-used, i.e. in the form of land use, commercial, office, residential and shopping centres are planned in the form of (Akmerkez, Kanyon and Metrocity, etc.) seems to be very successful. The highest rental values, it is a successful shopping malls. Be explained by the spatial distribution of shopping centres in Istanbul rings. 1 Radius of 10 km from the centre. 1, which is ring, shopping centres, there are 46% and 50% of leasable area. This region represents 44.32% of GDP. 2 positioned around the first ring in the ring, shopping centres, and 54% of the leasable area is 50%. This area represents the 41.93% of the GDP. Although, leasable area is divided equally among the regions, shopping centres clustered particularly in rich districts. 12 units are not currently shopping centre located in the county. Their commercial potential is calculated, which are close to high-income neighbourhoods inhabited districts of the layers was found to have more potential (Terzi et al., 2005).

Alternative Methodology for Istanbul Land use Pattern

A city consists of different functions that serve different purposes and affect each other. Spatial layout of the city includes a wide range of elements in a network of relationships. Individuals, private firms, public sector, they all want to be close to the sources of labour and services. Therefore, based on a wide variety of purposes cities complex planning system according to one aspect is not possible. One of the most important tasks of urban planners is to determine the places, a variety of functions related to each other in an effective manner by objectives. Planning of these functions independently of each other is not possible. An error

on one objective, not only for that functions, but may also be related to an effect on the other functions of the city in terms of functional and economic development. At the same time, the city may lead to an increase in operating costs. In contrast, the selection of a function itself to be successful in the right place, as well as the development tool environment can be, for example, have the tool, such as the conservation of Historical Peninsula City Gardens surroundings.

A wide range of multi-purpose land use models are available for site selection. Carver (1991) on the selection of land-use in the multi-purpose assessment techniques, contrary to each other, according to the criteria and objectives for the evaluation of alternatives, combined with the use of GIS technique. In another study, solve the traffic congestion in an area, or if there is congestion and housing to solve the balanced distribution of work force planning technique is developed to describe in a multi-purpose modelling (Horner and Muray, 2003).

Location models previously developed a wide range of multi-purpose land use objectives to take into consideration, but ignore the impact of different land uses. Whereas this purpose, a number of functions play a major role in the selection of, for example, the minimum distance to a residential site and to benefit from the increase in value and as well as a proximity to a large shopping centre. Hence, in this model, two objectives are to evaluate alternative land use scenarios have been considered in the choice of: (1) the maximum of profit, and (2) to be the minimum distance between the inter-related functions (Dökmeci, et al 1993).

The first goal in the selection of an area of land use to do is to get the maximum profit. According to this purpose, the value of a plot of land in the surrounding environment due to the use of the land as it depends on the value of investments in the plot. For example, some of the other more suitable for the selection of land plots in residential, commercial and entertainment facilities of the place because they are more likely to. Therefore, this objective is being determined by the land use, so as to make maximum profit will be assigned based on the settlement.

Earlier Alonso (1964) and Mills (1972) studies, showed that a plot of land value changes according to the distance from the city centre. This assumption is valid for a single-centre city. However, the development of multi-centre cities, as a result of a plot of land in the vicinity of the city around the type of land use, these variables can affect more than the value of the land. For example, the value of a plot of land around the trade may vary according to whether residential or industrial. As a result, the structure of the city, urban functions arising in the competition for the selection of the most efficient in the use of land formed by the selection. Therefore, the purpose, the proceeds from a plot, it and the surrounding land to be a result of the interaction between land-use types have been formulated by the adoption. For example, the luxury residential as well as commercial area next to the park is located next to or higher than the rest of the district (Dökmeci, et al 1993).

On the other hand, creating some of the industry as well as environmental pollution, land-use types have been caused a decrease in the relative values of the surrounding land. Therefore, the effect of any kind from the environment must be taken into consideration. Based on this purpose, the maximum was based on an investor's profit. This objective has been formulated as follows:

$$Max z = \sum_{i=1}^r \sum_{j=1}^r \frac{V_{ij}}{1 + d_{ij}^{\alpha}}$$

Z: The total revenue from land use in the region,

V_{ij} : i and j are the interaction of land use types in terms of value,

d_{ij}^{α} : the distance between i and j types of land use. α is taken as 2

As a secondary aim, functions as an important factor influencing land use decisions has been considered to be the minimum distance. In the city, more or less of each land use type has a link with the other. Thus, each unit of land use creates a harness around the relationships between units of transport. Thus, every unit is, relative to the location of each unit, so tightly bound to the other units. This is the minimum movement of goods and people between the units; the second purpose of this model is formulated as follows:

$$\text{Min } T = \sum_{i=1}^r \sum_{j=1}^r u_{ij} d_{ij} b_{ij}$$

Wherein,

T: total transport in the region,

u_{ij} : transportation between units i and j, the amount of land use,

b_{ij} : i and j $b_{ij} = 1$ if land use transport link between the units, or $b_{ij} = 0$

The choice of two very different purpose of land use, exposes two very different outcomes. For example, the use of land in a way that accessibility priority, residential areas gathered around and business centres and industry. If we choose to use the land in a way that the maximum gains, residential areas, gathered around commercial activities, parks and water elements. Therefore, the aim of balancing the conclusion that both arrive, a multi-purpose decision-making method is needed. This multi-use decision making method can be as follows:

$$E(a) = \sum_{k=1}^n u_k e_k(a)$$

Wherein,

$E(a)$: (a) the total activity of the alternative,

u_k : k coefficient indicating the importance of the purpose,

Additive (a): (a) the alternative of k according to the intended activity,

n: Number of goals

Indicating the importance of the objectives coefficients were determined by sensitivity analysis. Accordingly, the first goal and the second goal weight coefficient 0.25 and 0.75 respectively. These coefficients are within reach of the investments made and the different types of land use, value of time lost in traffic will vary depending on the time according to the coefficients. According to an alternative with the highest total efficiency of both purposes, is considered to be the best choice in the land use.

Alternative for Istanbul Sub-Centre Silivri:

A multi-purpose land use, site selection model applied to Silivri, the newly designated sub-Centre for Istanbul. Consists of housing development, including university-industry-trade

areas, recent development plan are taken as reference. The main function is planned to be placed in 4 different areas of transportation and value for interaction was prepared for. University, Industry, Trade and residential areas were evaluated according to the model of the fourth alternative. 250 meters of grid is taken as basis for cell size, the proposed plan is 5 km wide on seaside. Average lot size in the region is from 225 to 275 meters.

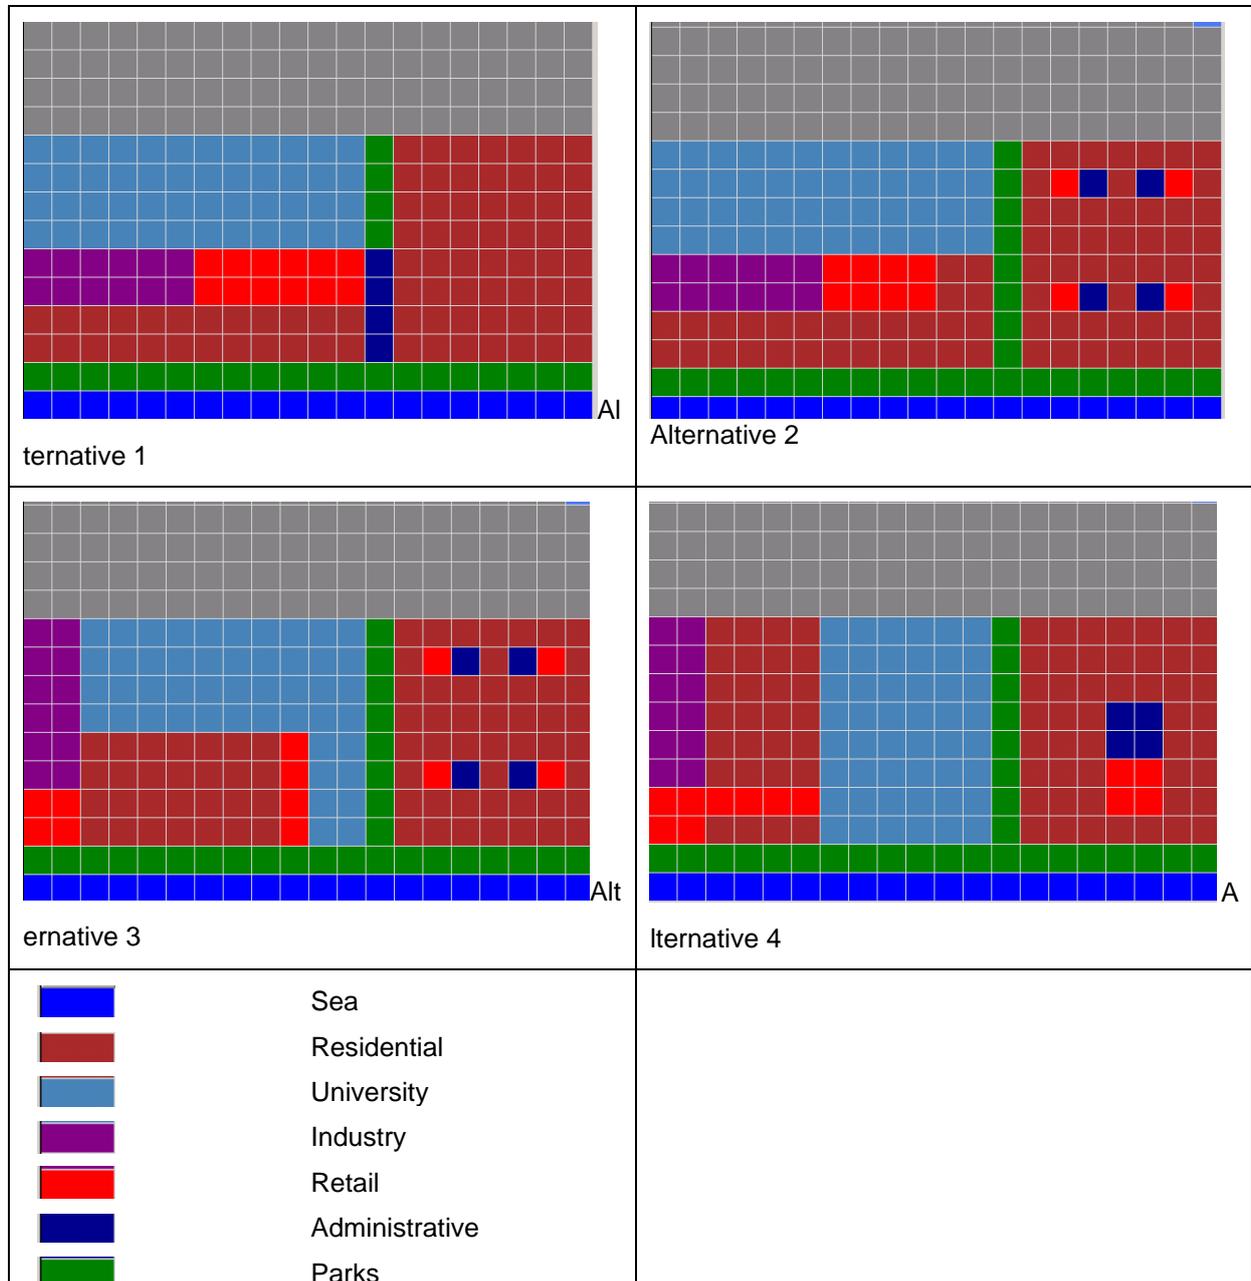

Figure 1 Different Land Use Model for Istanbul Silivri Sub-Centre

Table1: The amount of transportation between the types of land use matrix

	Sea	Residential	University	Industry	Retail	Administrative	Parks
Sea	1	1	1	1	1	1	1
Residential	1	2	3	7	5	3	4
University	1	3	1	3	2	2	1
Industry	1	7	3	4	5	2	2

Retail	1	5	2	5	3	3	2
Administrative	1	3	2	2	3	2	1
Parks	1	4	1	2	2	1	1

Table 2: Value Interaction between Different Types of Land Use

	Sea	Residentia	University	Industry	Retail	Administrativ	Parks
Sea	0	10	10	10	10	10	10
Residential	0	5	3	10	2	6	8
University	0	3	5	1	6	5	7
Industry	0	-7	6	10	6	5	6
Retail	0	8	5	-1	10	8	7
Administrativ	0	10	5	-3	8	10	8
Parks	0	8	6	3	6	6	10

Table 3: Total Values of Different Landuse Alternatives

Land Use Values	1. Alternative	2. Alternative	3. Alternative	4. Alternative
Accessibility Value	0,0837	0,0819	0,0840	0,0847
Revenue Value	0,9990	0,9805	1,0932	1,1874
Total	1,0827	9,8870	1,1772	1,2721

Different from each other in different land use choices by considering four alternative land use evaluation method was developed and evaluated, and the results for each lot are given in Table 5. A single centre, two sub-centres and a large number of land-use alternatives developed by the sub-centre activity was calculated. According to these results, based on the centre second and forth alternatives are higher than the current plan. Other second and third alternatives; expansion of trade, although with increased accessibility weakens the effect of the increase in value. In contrast, the effect of the increase in value as a single centre; decreased availability and are limited to only around the centre. Therefore, an alternative to the settlement with the two sub-centres, it can establish the best balance between the two objectives for the activity is the highest.

Although here, only two main objectives, land based location problems formulated, the purpose is based on the development of multi-criteria modelling. Balancing the conflicting interests of the various groups of land use objectives in the presence of solutions to the problem of selection, the goal is difficult as their numbers grow. For example, the slum transformation project varies according to each individual purpose. Decisions on this issue in accordance with the principles of democratic decision-making procedures are required to submit a multi-purpose (Kigtenberg et al., 2001). In this case, the model results, needs to be adapted according to other purposes.

Furthermore, we examine here only in models of land use, land-use in the selection of the most efficient in order to meet the demand has been developed. However, nowadays, the choice of a town in the land use of a region, a country, or with the effect of globalization on the international level need to be determined in response to society needs. It will be for the creation of a new landuse, as can be in the form of conversion of existing landuse.

In addition, by evaluating alternative land uses; density, transportation, energy consumption and environmental pollution, on the one hand, increase better economic development, on the other hand site selection models are better for the development of sustainable land use patterns. At the same time, the decision of the density of residential, private and public facilities, schools, recreational facilities, fire brigade is also important for the determination of effective site selection. Over time, emerging technologies can be adapted to the requirements of land use systems have the flexibility to provide the efficient use of resources. Advances in transportation and communication; caused large-scale changes in the land use at the 19th century. In this context, developed 'smart growth' concept aims to reduce the negative impact of the spread of a city (Holcombe and Stanley, 2001), and a wide range of land-use in the future will affect the choice of the cities.

However, the choice of land-use patterns in the results of the decision-making process should be considered initially for solid economic fundamentals, and then fit the model taken into consideration social, political and other conditions should be adapted. Land-use patterns in the selection of design, economic, sociological, and research and evaluation of the results of the traffic load as the subject of the proposed research to be conducted in the future.

Distribution of Population in Istanbul

One of the most important goals of planners is, taking into account the connection between the elements that make up the space within the city. Residential areas and business districts are considered as the most important elements that make up that structure (Dokmeci, 2005).

There are a wide variety of variables that influence the choice of location of residential areas. Supply and demand for housing depends on the development of residential areas in the city (Green et al., 2005). Housing supply: is effected by, vacant land, land, and the price of housing, housing types, distance to work places, social facilities, socio-economic status, and the status of the buildings (Malpezzi and Mayo 1997). Demographic and social characteristics of the population of a country are based on the demand for housing as well as economic factors. Variables related to the demand for housing, population growth, birth rate, marriage rate, age at marriage, family size, income, tax, interest rate, inflation rate, unemployment rate, (Arimah, 1992) .

In order to predict future land use and density in a precise way, the past and the present land use and transportation system, depending on the density of the collected data must be evaluated. For the modelling of the whole urban area, each containing homogeneous function areas are divided into small areas, for example, residential, office, park, such as commercial and industrial areas. Therefore, the appropriate unit of area on the census can be considered as the basic units of the neighbourhood (Dokmeci, 2005).

While there are many variables that influence the choice in residential areas, often models on this issue, using a small number of variables that have the greatest impact. Increase the cost of a very large number of variables, such as the use of the calculation process is also difficult. In this regard, based on the models of gravity theory, for a small number but they are formulated according to the data strongly preferred. Hansen is one of the models of this type of model. According to this model, the development of a residential unit, is inversely proportional to the distance from the business center, business center and the surrounding empty fields is proportional to the number of employees. The distance between the place of business of housing, especially in western countries, research, housing is emerging as an important factor in the choice of location (Levinson, 1997; Cervero, 2006).

Hansen Model formula given below:

$$G_j = G_r \left[\frac{L_j A_j}{\sum_{j=1}^n L_j A_j} \right]$$

wherein,

G_j: j district population to settle

G_t: City population growth

L_j: j district vacant land

A_j: Attractiveness Index

Of J Attractiveness index is formulated as follows.

$$A_j = \sum_{i=1}^n \frac{E_i}{D_{ij}^\lambda}$$

wherein,

E_j: j district, the number of employees

D_{ij} ^ λ: the distance between i and j districts

This model, as a result, increasing the population of the city districts that have empty fields, business opportunity, and how other districts will be divided according to the distance. Here the number of houses in general, can be calculated by dividing the number of households, the average number of population in the district. More specifically, the residential neighbourhoods to choose different types of families of different sizes for the calculation of the distribution must be taken into consideration, for example, unmarried and childless families, neighbourhoods close to the centre, garden houses or sites to choose the environment, such as families with children (Kim et al., 2005 Hoshino 2011). In addition, the income level of families to settle in the new districts and the distribution of both types of residential neighbourhoods, the distribution must be taken into consideration. Therefore, the demographic and socio-economic characteristics of families preferred neighbourhood characteristics are needed to be investigated (Dökmeçi and Berköz, 2000).

The results obtained with the model of Hansen residential areas are in need of social, cultural, economic, and recreational areas can also be used in the planning. Establishment of new settlements and the growing population of the city of new centres to be built in these areas can lead to the restructuring of the business relationship of housing all over the city. This model could be run as sequentially until, residential and business areas as a result of the implementation of certain land-use change obtained.

In addition, the scope of the variables in this model can be expanded or different aspects can be addressed. For example, the space used to refer to the 'L' variable does not exist or is empty in less dense areas, the density to be increased at any time, the difference between the target density and current density can be expressed in the formula (Dokmeçi, 2005).

Model adjustment (calibration), coefficient α by giving different values, different times as a result of the model by comparing the value detection are carried out as the best expression of the real trend. The distance can be expressed as the Euclidian or time of commute (Dokmeçi, 2005). Generally, individuals seek a balance between the theoretical cost of land and transportation (Alonso1964). But the key to this, as well as other features that relatives and the social environment (Dokmeçi and Berköz 2000), school quality, commercial facilities, green spaces, leisure facilities, prestige zones (such as Baghdad street) and revitalization projects (in Beyoğlu etc.) may influence the choice of residential location.

Population Distribution Model

TURKSTAT employment data is used in the model for 32 district of Istanbul. Assumed to be 3 million people added to the population and employment in the total population of 15 million will be allocated according to Istanbul (Table 1). Districts with more free space available in the European side are one of the most highly populated districts. Küçükçekmece the second largest free space (14.4%), and the third largest in the labour force (6.39%) will have the highest population (26.56%). In the meantime, Eyüp, both empty fields (2.19%) as well as labour force (1.76%), the second largest population group, although more (24.54%) allowed to produce its own due to its central location. Eyup district to the free space (2.4%) as well as labour force (3.8%) due to its central location, although it is less than the third largest population group (12.12%) will attract. Nevertheless, the Silivri district of Istanbul, the largest free space (38.5%), although with the lack of employment opportunities (1.0%) due to its distance from the city centre much less population (2.77%) be allowed to produce its own.

The model considered to have a more balanced distribution on the Anatolian side. Tuzla (3.52%) and the Maltepe (3.27%) counties circles break, even if a higher proportion of the population, ranking sixth and seventh are required on the European side. Uskudar and the effect of the precedent raised to increase the space and tries to give the new sub-centre.

As a result, this model calculates empty areas in the districts, the potential labour force, and taking into account the distances to the centre of Istanbul's growing population. Among them, particularly, Kucukcekmece, Eyüp and Gaziosmanpaşa have great potential in the future development of the districts. Then the model reveals their potential for transformation in slum areas. Therefore, the model results, investors, planners and managers of great importance for the city and the region.

Conclusion

Istanbul, population and income growth, the service sector, based in the city's development as a result of advances in transportation and telecommunications, the restructuring of the city, and this encourages residential, commercial and office create opportunities for investments. Land-use decision-making process is a very complex includes site selection. Estimates of population growth, starting from the development potential on the one hand, depending on the location of the settlements, and the physical, socio-economic, legal and political characteristics of the functional needs of the city overlaps with each other to create the most effective form is required.

Hansen model applied to Istanbul districts and increasing the distribution of the population of 3 million were calculated. Küçükçekmece district attracts largest population due to its workforce and empty land. Eyup and Gaziosmanpaşa become second and third, although have small empty land and business areas because of closeness to the center. However, with the most available space Silivri, labour, and far from the center because of the potential to be less able to attract population. On the Asian side, in order to create a new sub-centers, Ümraniye and Atasehir population increased.

Multi-purpose land use, site selection model, applied to a portion of the of Silivri district. Developed four different alternative land use. These alternatives are developed, one in the center, the two sub-center and calculated in two different activities according to the purpose of each alternative. As results being evaluated, including two sub-center was the highest efficiency alternative. single center alternative is not satisfactory in terms of accessibility. Thus, settlement plan with two sub-center has a satisfactory result in terms of both purposes.

In studied together these models can be used to complete each other. At the same time, it is possible to use these models as a dynamic, new development areas designated for the city-wide appeal to all business centers, taking into account new population density of each sub-region, centers and essential services, and this process can be calculated as a result of any

change. Thus, when the size of a city-wide alternative settlement proposals, taking into account all the most effective results can be achieved as a result of the evaluation.

In addition, the sub-centers produced a gradual effect of the interaction and the environment as a result of a lot of alternatives for the purpose of evaluating the size of the new centers and, instead, may be decided taking into account the dimension of time. Thus, the development of the whole city and the economic development of the system to provide the most effective when planned. By investing just as it is today, at certain points, and the creation of high-quality urban services bringing the speculation, raising the quality of life of city-wide, but can provide a healthy socio-economic development.

Furthermore, we examine here only in models of land use, land-use in the selection of the most efficient in order to meet the demand has been developed. However, nowadays, the choice of a town in the land use of a region, a country, or with the effect of globalization on the international level need to be determined in response to a need. It will be for the creation of a new space, as can be in the form of conversion of existing space.

The green economy: a strategic approach to sustainable urban development in Caribbean Small Island Developing States (SIDS)

Martha Jillyan ARTHUR, The University of the West Indies, Trinidad and Tobago

Synopsis

Adopting a green economy approach in the Caribbean could provide a framework whereby decisions and strategies regarding cities and urban centres can promote resource efficiency, effective environmental management and a better standard of living for urban residents.

1. Introduction

Two major development issues currently facing Caribbean Small Island Developing States (SIDS) are the challenges associated with urban growth and the economic, environmental and social impacts of climate change related hazards. It is estimated that the Caribbean region is now 75% urbanised with variations in urban growth patterns across countries (Cohen 2004). Urban growth and development in Caribbean is often marred by growing informal settlements, urban sprawl, inefficient resource use and increasing demands on services such as water and sanitation. These urban issues are further exacerbated by climate change related threats such as sea level rise, increase intensity of storms and hurricanes. These associated hydrometeorological risks are detrimental to vulnerable coastal populations, since more than half the region's population live within 1.5km of the shoreline (Mimura et al. 2007). As a result it is critical that Caribbean policy makers address these development issues by identifying strategies that promote economically, socially and environmentally sustainable cities and urban centres.

The recently concluded Rio+20 United Nations Conference on Sustainable Development addressed the concept of the green economy as a mechanism for achieving the goals of sustainable development. The outcome document "The future we want" expressed the importance of utilising green economy initiatives as an important tool for achieving the overarching goal of sustainable development by means of informing policies that reconcile the economic, social and environmental dimensions of development. In this regard it was recognised that it is necessary to change unsustainable patterns of consumption and production and manage and protect natural resources while taking steps to alleviate poverty. It was also noted that countries can move towards a sustainable development path by addressing issues that are pertinent to their development needs. In the case of Caribbean SIDS, a green economy should adopt approaches that are in accordance with national development needs and priorities. Therefore this paper attempts to focus on the urban specificity of the green economy and to highlight the potential for achieving sustainable development goals through the greening of cities in the Caribbean.

The paper proposes strategies for greening the urban sector based on selected priorities from the Caribbean Urban Agenda in the area of natural hazard management and the cross cutting thematic areas of sustainability planning, climate change vulnerabilities. The paper discusses avenues for 'greening' the urban sector in the areas of water, waste and sanitation, transportation, urban form and the built environment and addresses the cross cutting issue of energy use and efficiency in the Caribbean. For the purpose of this discussion the 'urban sector' refers to the combination of essential service sectors that facilitate the efficient functioning of an urban area. This paper¹ is an abridged version of a discussion paper that was produced through an internship programme funded by the European Union (EU) under the EU MEAs project executed by the Caribbean Community (CARICOM) Secretariat. For the purpose of this paper the Caribbean refers to CARICOM member and associate member states.

The Caribbean Community (CARICOM) is an organisation of 15 Caribbean nations with member status and 5 Associate member states. Member states are Antigua and Barbuda, The Bahamas, Barbados, Belize, Dominica, Grenada, Guyana, Haiti, Jamaica, Montserrat, Saint Lucia, St. Kitts and Nevis, St. Vincent and the Grenadines, Suriname and Trinidad and Tobago. Associate members are Anguilla, Bermuda, British Virgin Islands, Cayman Islands and Turks and Caicos Islands. The Caribbean Community and Common Market (CARICOM) was established by the Treaty of Chaguaramas, which was signed by Barbados, Jamaica, Guyana and Trinidad & Tobago and came into effect on August 1, 1973. In 2001 Heads of Governments signed the Revised Treaty of Chaguaramas which transformed the Common Market to a CARICOM Single Market and Economy. CARICOM's objectives include improving standards of living and work; enhancing co-ordination of Member States' foreign and foreign economic policies and coordinated and sustained economic development.

Through the Council for Trade and Economic Development (COTED), Ministers designated by member states are responsible for promotion of trade and economic development of the Community. In particular COTED is responsible for i. promoting measures for the development of energy and natural resources on a sustainable basis; ii. establishing and promoting measures for the accelerated development of science and technology; iii. promoting and developing policies for the protection of and preservation of the environment and for sustainable development. It is at this regional level that specific Caribbean priorities can be addressed and advanced.

2. Caribbean Context

Myers et al (cited in ECLAC 2010) views the Caribbean as a biodiversity hot spot, meriting global priority for conservation purposes. This is attributable to the fact that Caribbean islands have less than 30% of primary vegetation remaining (11.3%) and more than 0.5% of the World's known vascular plant species (2.3%). The region is also home to 2.9% of the World's endemic vertebrate species. The Caribbean region mainly consists of island states, with the exceptions of Belize in Central America, and Guyana and Suriname, situated on the South American continent (UNEP 2008). Territories are surrounded by the Caribbean Sea and the Gulf of Mexico totalling a combined area of approximately 5 326 000 km² (UNEP 2008).

Figure 1: The Caribbean Region and CARICOM Member countries

Caribbean economies are highly resource dependent and are usually reliant on a single economic resource resulting in a lack of economic resilience. The tourism and agricultural industries is the mainstay of several Caribbean economies and the in case of

Trinidad and Tobago oil and gas is the key foreign exchange earner. According to 2012 World Travel and Tourism Council (WTTC) statistics, the economic contribution of tourism in the Caribbean was greater than all other regions in the world. Several Caribbean countries recorded above world average contributions to GDP from Travel and Tourism. The total contribution of travel and tourism to GDP in Antigua and Barbuda totalled 77.4%, The Bahamas (48.4%), Barbados (39.4%) and St. Lucia (39%). One exception is Trinidad and Tobago where the energy sector is the largest contributor to GDP, figures from the Central Bank of Trinidad and Tobago Annual economic survey show that the energy sector accounted for 43.7% of GDP and 54.3% of government revenue in 2012.

Some of the countries in the region are also among the most indebted. St. Kitts and Nevis and Jamaica are the top two indebted countries in the region where 21.94% and 17.2% of exported goods and services is used to service debt. (ECLAC 2013) Added to this, poverty and unemployment are high in some Caribbean countries. In 2010 St. Lucia recorded an unemployment rate of 20.6%, whereas in Barbados and Jamaica unemployment statistics was estimated at 10.4 % and 12.3% respectively. (ECLAC 2013) Urban development in the Caribbean is often dominated by challenges of urban sprawl, informal settlements, peri-urbanism and increasing demands on services such as water and sanitation. It is worth noting that the Caribbean has a unique urban growth pattern characterised by a "... discontinuous, scattered, low density form of urbanisation" (UN-HABITAT 2012). Caribbean cities are usually capital cities dominated by high levels of primacy and intense urbanisation along coastal strips (Jaffe 2008). Owing to this many capital cities in the Caribbean continue to be the primary hub of administrative and economic activity, resulting in a skewed concentration of labour, political systems and administrative services. Urban and rural boundaries are often blurred due to extensive sprawl and as a result urban areas may include small administrative areas where human settlements and economic activity are concentrated.

3.1 Caribbean Vulnerabilities

As SIDS, Caribbean countries' economic and environmental vulnerabilities are exacerbated by challenges associated with urban growth and climate change related hazards. Most Caribbean cities, settlements, critical infrastructure, economic and social activities are located along the coast.

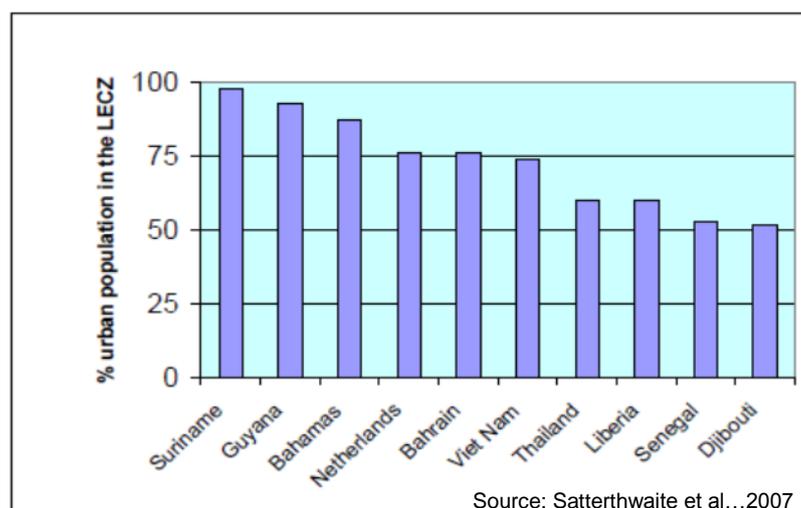

Figure 2: Nations with the highest urban populations in the Low Elevation Coastal Zone

Figure 2 show that three Caribbean territories possess the highest percentage of urban populations in the Low Elevation Coastal Zone. This increases vulnerabilities to climate change related threats such as sea level rise. Risks from extreme weather events that lead to storm surges can be detrimental to the Caribbean leading to inundation of

coastal cities and settlements, loss and damage to coastal infrastructure, flooding, loss of natural defences and aesthetic appeal due to beach erosion and loss of coral species. For instance in 1999, eight Eastern Caribbean states (Anguilla, Antigua and Barbuda, British Virgin Islands, Dominica, Grenada, Saint Lucia, St Vincent and the Grenadines and St Kitts and Nevis) reported estimated damages of EC \$712.5 million or US \$268.8 million due to Hurricane Lenny. Most of the damages reported related to coastal infrastructure, coastal communities and businesses (E. Nurse 2013 pers. comm. June 6th). In some instances losses from a single hydrometeorological event such as a hurricane can devastate an already under resourced Caribbean economy.

According to the World Bank the financial cost of damages to Grenada from Hurricane Ivan in Sept 2004 was estimated at more than US\$900 million, (more than double the country's GDP) (World Bank 2009). Similarly in 2010 St. Lucia recorded US\$334 million in damages due to Hurricane Tomas. Within a single year, economic losses due to the 2004 hurricane season cost Caribbean countries over US\$4 billion. The Intergovernmental Panel on Climate Change Fourth Assessment Report (IPCC-FAR) estimated that climate change is likely to heavily impact coral reefs, fisheries and other marine-based resources in the Caribbean. This increases the potential impacts on critical livelihoods such as subsistence and commercial agriculture. (IPCC 2007). The IPCC-FAR further states that the Caribbean region experienced "on average a mean relative sea level rise (SLR) of 1mm/ yr during the 20th century".(IPCC 2007). The Caribbean Sea has warmed by 1.5°C over the last century and data from the late 1950s to 2000 shows an increase in the number of very warm days and nights. Changes in rainfall patterns are also evident with an increase in the frequency of heavy rainfall events. (UNFCCC 2007)

Climate change impacts on key economic sectors in the region			
Issue or resource vulnerable to climate change	Potential effects of climate change	Sectors at greatest risk	Economic relevance
Freshwater availability	Reduced precipitation; increased evaporation Saline intrusion from SLR	Multi-sectoral	Insufficient supply to boost economic activity and for domestic purposes
Degradation of marine and coastal ecosystems	SLR and changes in sea temperature can affect important ecosystems such as mangroves, fishing grounds and coral reefs.	Tourism Agriculture Fisheries	Most tourism activities are located in the coastal zone. Significant capital investment assets and infrastructure could be affected.
Coastal flooding	Sea level rise will result in flooding of low-lying Coastal areas.	Tourism, Agriculture, Forestry	<i>Same as degradation of marine and coastal ecosystems</i>
Climate	Climate change may increase extreme events such as precipitation intensity, tropical storms and hurricanes	Multi-sectoral	The cost of hurricanes and other natural disasters in the Caribbean region, estimated at several hundred million dollars during the last decade, may increase.

Adapted from UNEP ROLAC, 2008.

Table 1: Climate change related impacts in the Caribbean

The climate related impacts outlined in Table 1 poses significant risk to livelihoods and already volatile economic sectors such as tourism and fisheries. Further to this, devastation from hurricane activity is also a recurring threat to many Caribbean islands, with some islands, suffering frequent damage e.g. The Bahamas, Cayman Islands and Cuba (Bueno et al. 2008). As a result environmental degradation and loss of livelihoods have

continued to hinder the region's progress towards achieving development goals. Since resources allocated for development initiatives are often diverted to finance recovery and reconstruction. (Trotz 2002, CDERA and CDB 2003, Howard 2009). In a business as usual scenario Bueno et al (2008) estimates that the cost of climate change in-action can reach 20.3%, 30.5% and 19% of current GDP by 2025 in Grenada, Haiti and Turks & Caicos respectively. This highlights the importance of implementing strategies to address these challenges.

3.2 The Regional Response to Climate Change

<p>Caribbean Planning for Adaptation to Climate Change Project (CPACC) 1997-2001</p> <p>Institution involved: Implemented by The World Bank, executed by the OAS and overseen by CARICOM.</p> <p>Goal: To build capacity in the Caribbean region for the adaptation to climate change impacts, particularly sea level rise.</p> <p>Activities: vulnerability assessments, adaptation planning, and capacity building activities.</p> <p>Main Achievements: Establishment of coral reef monitoring protocols; Establishment of a sea level and climate monitoring system; Improved access and availability of climate change related data.</p>	<p>The Adaptation to Climate Change in the Caribbean Project (ACCC) 2001-2004</p> <p>Institutions involved: funded by the Canadian Climate Change Development Fund of CIDA, overseen by the World Bank, supported CARICOM</p> <p>Goal: To continue activities initiated under CPACC and to address issues of adaptation and capacity building not undertaken by CPACC.</p> <p>Activities: Public education and outreach Project design and implementation of a business plan for a regional climate change centre; technical capacity, strategies for food, agriculture and water sectors; integration of adaptation planning in development projects.</p> <p>Main Achievements: Development and distribution of risk management guidelines; A draft regional public education and outreach strategy; Implementation of pilot projects on adaptation studies in the water health and agricultural sectors.</p>
<p>Mainstreaming Adaptation to Climate Change Project (MACC) 2004- 2007</p> <p>Institution involved: Implemented by The World Bank, funded by GEF, executed by CARICOM.</p> <p>Goal: Mainstream climate change adaptation strategies into the sustainable development agendas of the Small Island and low-lying states of CARICOM.</p> <p>Activities: Furthering institutional capacity building, strengthening the knowledge base, and deepening awareness and participation.</p> <p>Main Achievements: Integrating climate change adaptation into national & sectoral policies; Strong public education & outreach</p>	<p>Special Programme on Adaptation to Climate Change (SPACC) Project 2007 – 2011</p> <p>Institution involved: Implemented by the World Bank Funded by GEF, executed by the CCCCC</p> <p>Goal: To support, St. Lucia, Dominica & St. Vincent and the Grenadines to implement specific (integrated) pilot adaptation measures to address the impacts of climate change on natural resources, biodiversity & land degradation along coastal areas.</p> <p>Activities: Design of measures to reduce the adverse impact of climate change on the marine & terrestrial environment.</p> <p>Main Achievements: To be evaluated</p>

Table 2: Regional Climate Change related projects

Cruickshank et al. (2012) notes that despite numerous 'institutions, instruments and processes' addressing sustainable development practices, environmental problems continue to increase and have intensified globally. It is argued that since the region's contribution to global warming is insignificant and there is clear evidence of the consequences for Caribbean SIDS, focus should be placed on adaptation strategies that build resilience in these territories. Regionally, CARICOM have been advancing development initiatives in member states that are geared towards adaptation and capacity building. Several projects sought to further these objectives i.e. The Caribbean Planning for Adaptation to Climate Change project (CPACC) 1997-2001, The Adaptation to Climate Change in the Caribbean Project (ACCC) 2001 to 2004, the Mainstreaming Adaptation to Climate Change project (MACC) 2004- 2007. Table 3 highlights the projects' activities and achievements. These projects eventually led to the establishment of the Caribbean Community Climate Change Centre (CCCC).

The Caribbean Community Climate Change Centre (CCCC) was endorsed in July 2002 and became fully functional in July 2005. The Centre is registered under the UN System as a CARICOM Specialised Agency with a mission to "*coordinate the regional response to climate change and its efforts to manage and adapt to its projected impacts*". The Centre is recognised by the UNFCCC, the United Nations Environment Programme (UNEP), and other international agencies as the focal point for climate change issues in the Caribbean (CCCC 2011). The CCCC further provides climate change related policy support and capacity building to manage climate risks related vulnerabilities in CARICOM member countries. In 2009, CARICOM Heads of Government highlighted the regions' commitment to strengthening the response to climate change adaptation by approving "The Regional framework for achieving development resilient to climate change".

The framework provides a plan of action for achieving the goals outlined over the period 2009-2015. An implementation plan was later adopted which places primary responsibility for coordinating the implementation of the key strategic elements of the framework with the CCCC. The main strategic elements of the framework are as follows:

- I. Mainstreaming climate change adaptation strategies into the sustainable development agendas of CARICOM states.
- II. Promote the implementation of specific adaptation measures to address key vulnerabilities in the CARICOM region.
- III. Promote actions to reduce greenhouse gas emissions through energy efficiency, conservation, and switching to renewable energy sources.
- IV. Encouraging action to reduce the vulnerability of natural and human systems in CARICOM countries to the impacts of a changing climate.
- V. Promoting action to derive social, economic, and environmental benefits through the prudent management of standing forests in CARICOM countries (CCCC 2009).

3. Caribbean Urban Agenda

Current literature on urbanisation highlights the city as providing opportunities to collectively address developmental challenges. From a regional perspective well managed cities and urban areas can address challenges such as environmental degradation, resource depletion, vulnerability to the effects of climate change and increasing demands on urban infrastructure due to urban growth and sprawl. Well-designed urban areas with large population concentrations and dense urban settlements can present opportunities for efficient provision of adequate services such as water and electricity. In the Caribbean context, this can place the most vulnerable urban dwellers (people living along the coast and hazard prone areas) at the centre of shifts towards sustainable urban management.

It is argued that a region specific urban agenda should be advanced to address the unique challenges of the Caribbean and to deal with specific urban challenges. There are several global initiatives implemented in Caribbean cities that focused on urban issues albeit from an international standpoint. Some projects that addressed urban issues were the Urban Management Program (Port of Spain, Trinidad), Local Agenda 21 and Sustainable cities programme (Bayamo City, Cuba), the Safer City Program (Kingston, Jamaica) and

Participatory Slum Upgrading Program (Jamaica, Antigua and Barbuda, Trinidad and Tobago and Haiti). More recently the IDB Emerging and Sustainable Cities Initiative (Port of Spain, Trinidad and Tobago and Montego Bay, Jamaica) However; global urban agendas do not sufficiently address the inherent vulnerabilities of cities in the Caribbean.

4.1 CARICOM Policy Framework

Although CARICOM does not have a specific focus on urban issues, specific priority areas such as climate change, renewable energy, safety and crime, and economic vulnerability can be seen as cross cutting urban relevant priorities. Adopting an urban focus to development can promote and advance a Caribbean agenda that deals with sustainable energy, natural resource use and protection and preservation of the environment. In April 2011 the first annual policy meeting for the *Network for the Application of Science and Technology to the Urban Sector (NSUS)* projectⁱⁱ was convened in Guyana. The meeting was focused on “reassessing strategic priorities related to urban and land management in the Caribbean...”ⁱⁱⁱ This represented the first Caribbean Urban Forum which recommended the development of a Caribbean Urban Agenda (CUA) to address urban issues that were of a more Caribbean nature. The meeting recommended that a “holistic and comprehensive framework” be developed that includes high and low thematic priority programmes, a research agenda, a knowledge management facility and capacity building.

Priorities for a Caribbean Urban Agenda (CUA) 2012		
	Thematic Areas	Issues
Climate change vulnerability to: LECZ, Adaptation at local community level Sustainable planning urban form (compact), holistic, Comprehensive Coastal zone settlements planning land management/use, rural/urban integrated planning	Local economic development and poverty eradication	Unemployment Strengthening diversified local opportunities for economic development, provision of housing and basic services
	Enabling mechanisms for government and professional Governance	Research, communication, training, education, financing etc. implementation, communication and legislation, municipal governance, awareness component, co-governance inclusive governance, partnerships, coordination
	Informal sector	tenure security, informal settlements, informal economy
	Natural hazards and disaster management	climate change, built environment resilience, response capacity
	Physical human security	Crime, safety, freedom from fear
	Physical Living Conditions	housing, basic services (water, sanitation, energy use, transportation etc.)
	Inequality	social, economic inequality based on gender, age
	Climate Change contribution to:	energy, emission, transportation, green economy

Table 3: Priorities for a Caribbean Urban Agenda

As a result of the NSUS project the urban sector is now being addressed at the regional level. Subsequently at the Thirty- Seventh Special Meeting of the Council for Trade and Economic Development (COTED) in September 2011, the papers “Development of a Caribbean urban agenda in the context of sustainable development”^{iv} and “Urban Development and the Green Economy”^v was presented by the Caribbean Network for Urban and Land Management (CNULM) and the CARICOM Secretariat. The papers made a case for the adoption of green initiatives in key priorities areas and suggested a revision of the proposed CUA to include the cross cutting issues of climate change vulnerability and

sustainability planning. Arising out of the meeting it was agreed that the Caribbean region should determine its own understanding of the green economy and show how these initiatives can be translated into a regional context. It was also recognised that the urban sector can be a key driver of green economy initiatives

The CUA was again discussed at the Caribbean Urban Forum held in March 2012 and at the Thirty-Ninth Special Meeting of the COTED in April 2012 in a paper entitled "*The role of cities in the green economy*"^{vi}. The CUA currently comprises 11 thematic areas of region specific importance, that include the cross cutting issues of climate change and sustainable planning. See Table 3. The adoption of a CUA can now adequately inform policy at a regional level and provide urban specific inputs for policies currently in draft form (i.e. regional energy policy, climate change and implementation strategy policy and the tourism policy)

4. The Green Economy in the Caribbean

The most widely used and recognised definition of the green economy was posited by the UNEP, which states that a "...*green economy is one that results in improved human well-being and social equity, while significantly reducing environmental risks and ecological scarcities...*" In this regard the concept of green economy and sustainable development is somewhat linked since both ideas embody the principles of integrating economic growth with environmental protection and social improvement. This reinforces the notion that "a green economy can be an enabling component of the overarching goals of sustainable development" (UNCTAD 2011). The recent Rio+20 conference suggests that a green economy should provide a roadmap to achieving development goals and objectives. In this regard the concept is viewed as a framework that enables decision making in key priority areas such as resource efficiency, sustainable cities, sustainable consumption and production patterns, and low-carbon development.

It is important to note that a green economy should not be considered as a wholesale set of rules to be adopted, but a framework whereby countries can address specific development needs and priorities. The Caribbean stands to benefit from adopting green economy initiatives with respect to achieving overarching sustainable development goals. Specific to the Caribbean region green economy initiatives should:

- I. Provide effective environmental management- the Green economy can enable the transition to low carbon sustainable urban development in the Caribbean, which efficiently protects vulnerable ecological resources;
- II. Build economic resilience to promote self-sufficiency through greening of key economic sectors such as fisheries, tourism and agriculture;
- III. Mitigate and adapt to climate change induced hazards such as sea level rise, inundation of coastal cities and settlements, loss and damage to coastal infrastructure such as roads bridges airports; flooding, loss of natural defences and aesthetic appeal due to beach erosion and loss of coral species;
- IV. Job creation and poverty reduction can be addressed through investments in key sectors that promote low carbon development such as transportation;
- V. Provide avenues for promoting sustainable built form since well-designed urban areas and compact urban form can provide opportunities for more efficient urban infrastructure and service delivery.

In that regard, a green urban economy provides a framework to promote low carbon resource efficient cities, which provide a better quality of life for urban residents through growth and investment in key urban sectors such as transportation and infrastructure.

5. Strategies for greening the Urban Sector in the Caribbean

Energy use and efficiency-The global energy debate is inextricably linked to reducing greenhouse gas emissions (GHGs) and mitigating climate change. The UNFCCC recognises that while there is an inherent need for energy consumption to grow along with economic and social development, there is a possibility to be energy efficient and control

GHG emissions. Within urban areas the use of energy is a cross cutting issue, from managing fossil fuel dependent transportation sectors to efficiently managing urban spaces and resource consumption in buildings. The urban environment presents a great opportunity to utilise non-renewable energy resources more efficiently while promoting the use of alternative energy sources such as solar power. Although Caribbean territories are in an advantageous position to harness renewable energy, there is still a heavy reliance on fossil fuels to meet energy demands.

For instance Jamaica's petroleum product imports for the period January to August 2012 totalled US\$1.6 billion; US\$500 million more than the country's exports for the same period^{vii}. According to the draft Jamaica National Renewable Energy Policy 2009-2030, the nation is characterized by an almost complete dependence on imported petroleum and high rates of energy consumption. It was estimated that 87% of Jamaica's foreign exchange revenue is used to buy imported oil. This is attributed mainly to the transport sector that accounted for 37% of petroleum consumption in 2008. Similarly, through the development of a Sustainable Energy framework^{viii} Barbados is taking steps to promote renewable energy and energy efficiency in a bid to reduce the country's heavy dependence on imported fossil fuels and to improve the environmental sustainability of the country. The region's high dependence on imported fossil fuels, rising fuels prices and projected increase GHG emissions solidifies the need to work towards developing renewable and cleaner energy sources. The following sections highlights strategies to promote low carbon transportation, manage basic urban services and promote resource efficiency in the built environment

Water- Ecosystem management and restoration are an intrinsic component of transitioning to a green economy especially in the Caribbean. Efficient water management is critical to the very livelihoods of many Caribbean countries that are heavily dependent on the resource for key economies such as agriculture, industry and tourism. Inefficient management often results in losses and irregular supplies in some areas. For instance although Trinidad and Tobago is not considered a water scarce country; it is plagued by an irregular water supply in some areas. According to the Trinidad and Tobago, Ministry of Planning and the Economy (2012) water use statistics reflect a staggering 40% of demand is unaccounted for, highlighting the pressing need to manage water resources more efficiently.

In response to the Regional framework for achieving development resilient to climate change, the Global Water Partnership-Caribbean (GWP-C) was identified as a key partner in working for water security in the region. Through the Water, Climate and Development Programme and the promotion of an Integrated Water Resources Management (IWRM) approach the GWP-C is making strides in promoting water security and climate resilience. Countries such as Barbados, Dominica, Grenada, Jamaica, The Bahamas and Trinidad and Tobago; have developed or drafted IWRM roadmaps and action plans to ensure better resource management. Therefore greening the water sector within the Caribbean calls for the protection of groundwater and surface water resources through policy reform and regulatory frameworks, efficient watershed management, through effective land use planning (as in the case of Barbados strict zoning policy), urban growth boundaries, investments in adequate infrastructure, appropriate pricing mechanisms, public education.

Waste and sanitation- It is argued that solid waste such as garbage and chemicals from domestic use are often associated with growing affluence and are generated in tandem with population size and urbanisation. One of the primary dangers of ineffective waste management is human exposure to hazardous substances through contaminated drinking water (where contaminants are often leached into surface and groundwater). Waste in the form of pesticides can also contaminate food both inland and as effluent in coastal waters. According to UNEP (2011) solid waste services consume up to 2% of GDP in developing countries. Coupled with this, UN-HABITAT (2012) estimates that emissions from waste represent 3% of total global GHG emissions.

Waste management has become a critical component of thriving cities and thus human well-being hinges on solid waste management and pollution control. Waste generated

by human activity, agricultural and industrial processes can negatively impact ecosystems. Added to threats to human health, environmental degradation and loss of biodiversity can further result in economic losses which can affect important sectors such as fisheries and tourism. Another area of concern is methane emissions from landfills that contribute to overall GHGs. The key strategy for greening the waste sector is to reduce the amount of waste going into landfills. Satterthwaite (2002) argues that cities have the advantage of reducing resource use and waste due to the mere concentration of large groups in close proximity. In this regard, encouraging re-use and recycling presents an avenue for progression towards decoupling waste generation from increased economic growth in the region. However, Greening the waste sector requires a strong regulatory framework and incentives must be present in order to ensure buy-in by all stakeholders.

Transportation- The Latin America and the Caribbean (LAC) region possesses the highest level of motorisation in the developing world. The region has twice as many cars as the Middle East and North Africa and five times more cars than Sub-Saharan Africa and Asia. UN-HABITAT (2012). Continued car oriented development and infrastructure planning and low cost/subsidised fuel may be attributable to the growth of the private car market. In Trinidad and Tobago, the Ministry of Planning and the Economy (2012) estimated that there were 630,000 vehicles in the country, with a projected increase of 30,000 annually. Likewise the Barbados Licensing Authority showed that in 2009 the total vehicle stock on the island was 131,680, suggesting one vehicle for every two persons on the island (UNEP, UWI and The Government of Barbados 2012). Along with private vehicle ownership comes an increase in GHG emissions namely CO₂. The IPCC (2007) estimates that the global transport sector accounted for 13% of total GHG emissions. The IEA 2012 Statistics show that Jamaica and Trinidad and Tobago are the highest emitters of CO₂ among CARICOM members. IEA estimates that from fuel combustion Jamaica emits 8.0 million tonnes of CO₂ (2.8 million tonnes from the transport sector) while Trinidad produces 42.8 million tonnes CO₂ (3.1 million tonnes from the transport sector). Therefore, any greening strategy for the transportation sector in the Caribbean should be geared towards adopting sustainable transport solutions which combine a mix of multi-modal mobility options; complementary land use practices and a strict regulatory framework.

Central to the concept of sustainable low carbon transportation sector is the Avoid-Shift-Improve strategy. The Avoid-Shift-Improve strategy not only attempts to provide environmentally conscious low carbon mobility options but the concept also addresses social and economic sustainability (Dalkmann and Brannigan 2007). The strategy hinges on

- i. **Avoiding** or reducing the need to travel, through more integrated land use planning i.e. creating high density, mixed use developments and integrating transport options along key nodes of activity;
- ii. **Shifting** to more environmentally conscious modes of transportation; refers to the option of alternative low carbon transportation modes, for instance shifting from using private cars towards non-motorised options such as walking and cycling or mass transit;
- iii. **Improving** the energy efficiency of private motor vehicles and in some cases public transport which in turn has a direct effect on the amount of CO₂ emissions. Strategies can include introduction of electric and hybrid vehicles into the Caribbean market. Substituting fossil fuel for cleaner Compressed Natural Gas as in the case of Trinidad.

Urban form and the built environment- Density and compact urban form is a critical component of managing energy consumption (UN-HABITAT 2011). Tackling CO₂ emissions must be collectively addressed by combining effective transport management strategies with utilising energy alternatives and applying the principles of compact urban

form. According to UNEP (2011), dense cities that employ mixed uses are more resource efficient than other settlement patterns. Compact urban form presents an avenue to achieve resource efficiency in the utilisation and management of urban land. This in turn results in less reliance on motorised modes of transport, lower energy consumption and better access to services in cities. Unlike the characteristic low density outward expansion of several Caribbean cities, compact urban form can be realised through adopting smart growth principles that mitigate sprawl and encourage walking, cycling and transit oriented development by

- i. Urban growth boundaries- An officially mapped boundary that is used to separate open space and sensitive watersheds;
- ii. Land use regulation- Zoning can ensure that focus is placed on developing brownfield sites versus greenfield;
- iii. Increasing density- Setting clear density standards for new development projects especially in areas close to transit;
- iv. Infill development- Focusing on developing and regenerating underutilised or derelict sites;
- v. Mixed used developments- Provide a mix of residential, commercial and recreational options where people can live, work and play in one place
- vi. Design standards- establishing strict building codes and standards can translate into increased energy efficiency of buildings and multiple use of urban space (parks, green roofs etc.)
- vii. Street layout and design- urban design standards that promote the use of non-motorised transport such as tree lined streets, walking and jogging paths, building setbacks can encourage alternative modes of transport.

So far this paper has highlighted the benefits of implementing a green economy in the Caribbean. While there is a strong case for this transition, certain factors can hinder the uptake of green economy initiatives. Some of these include:

- i. uncoordinated governance that does not provide an integrated framework for the effective management of green initiatives;
- ii. negative consumer attitudes towards alternative green strategies, such as high density living and alternative modes of transport;
- iii. vested business interest in current unsustainable consumption and production patterns;
- iv. lack of investment by the public and private sectors and
- v. lack of cost effectiveness/ affordability of green products.

6. Recommendations

Policy, regulatory and Institutional framework- the transition toward a green urban economy should be facilitated by a strong regulatory and institutional framework. The proposed Caribbean Urban Agenda can be a good starting point to inform policy on areas that are of critical importance to the Caribbean i.e. energy and climate change. This offers policy makers a framework for streamlining development action to address the common vulnerabilities in the region.

Development strategies- Planning regulations and standards make up a critical component of sustainable urban development planning. Without strict enforcement of planning standards and regulations, efforts to green the environment and change behaviour would be short lived. Key policy instruments can focus on land use regulations that promote infill development and limit the amount of new or greenfield development within urban areas. Promoting high densities, compact urban form and mixed use development is an efficient policy strategy that affords some of the benefits discussed in this paper. Additional building standards and codes can also allow government to ensure best practices in the construction sector by promoting energy efficient certification.

Capacity building and Training- Capacity building and training (including Science Technology and Innovation STI) is critical for the effective deployment of green economy initiatives. Many ideas and best practices can be shared across countries and regions. However, new technologies and best practices used elsewhere require capacity building and re-tooling of locals to ensure a green transition in certain sectors. This would in turn ensure 'green jobs' are created and a market that is supported by innovative green enterprise is facilitated.

Stimulate green investment in technology- There is a central role of technology in the transition to a green economy. Hence government policies should encourage investment in green technologies. For instance technology in landfill gas capture is not highly developed in the Caribbean therefore training and capacity building is needed in this priority area. This can encourage buy-in by the private sector since investment in 'greening' certain sector (which holds high upfront cost) can be justified in the long term.

Fiscal incentives, disincentives and market mechanism- The importance of public and private investment as an enabling condition for the green economy is also critical. For a green economy to work it is imperative that fiscal incentives are tied in with other policy directives. The creation of markets for green products can also stimulate demand and further investment in green technologies.

7. Conclusion

It is now imperative that Caribbean SIDS adopt a framework for development that is driven by social equity, environmental sustainability and inclusive economic growth. It is important to highlight that cities and urban areas in the Caribbean are now facing an urban future marked by increased demands on essential services such as transportation, water, waste and sanitation. Coupled with these urban challenges is the issue of the upward trajectory of climate change related hazards, due in large part to anthropogenic factors.

A business as usual scenario presents a worrying picture for Caribbean SIDS if strides are not made to mainstream sustainability strategies into development planning. Though the region's contribution to climate change may be considerably less than developed countries, there is still a responsibility to lessen the deleterious activities that contribute to overall GHG emissions. A main point of contention is the region's heavy reliance on imported fossil fuels and the ever expanding private car market. Additionally, inefficient resource consumption and lack of energy efficient built form is also adding to the region's contribution to global climate change. To deal with these issues Caribbean governments would have to adopt approaches that effectively use urban planning and resource management approaches as means to achieving sustainable cities and building resilient economies.

A green economy approach provides a framework whereby decisions and strategies regarding cities and urban centres can promote resource efficiency, effective environmental management and a better standard of living for urban residents. Ultimately building economically resilient, well managed socially inclusive Caribbean societies. Although these opportunities can be realised, uncoordinated governance, vested business interest in unsustainable practices and negative consumer attitudes can hinder the shift to a green economy. Added to this, capacity building, effective regulatory instruments and financing options are needed to advance the transition in the Caribbean. While Caribbean regions have demonstrated their willingness to implement sustainability strategies, progress have been uneven. Therefore employing green economy strategies can provide a pathway to sustainable urban development in Caribbean cities.

Endnotes

ⁱ The research that informed the preparation of this paper was supported by the Caribbean Community (CARICOM) Secretariat, under a joint EU-UNEP-CARICOM project, with the financial assistance of the European Union. The views expressed herein can therefore in no way be taken to reflect the official opinion of the CARICOM Secretariat, the European Commission or the United Nations Environment Programme.

The Trilogy of Power, Politics and Planning

Eda Beyazit, Istanbul Technical University, Turkey

1. Introduction

Power and politics are deeply embedded in planning. The idea of controlling cities and nations via planning is as old as the city-states. According to Foucault (1976) every political debate in the eighteenth century onwards included discussions on urbanism, architecture and facilities of common life. Yet, it is not only through planning or infrastructure that power becomes tangible but also through a range of political techniques (Castells, 1997). Therefore, instead of speaking of the influence of power and politics in planning, it is important to refer to the mutual relationship between these three notions, thus, discuss the trilogy of power, politics and planning.

In this paper, such an approach to power, politics and planning is used in order to understand socio-spatial inequalities. Although empirical examples that assess the relationship between these notions can be found in the literature, their use in understanding of socio-spatial inequalities is not very common. Having stated the mutuality of these notions, in this paper power is also acknowledged as a plural term, and power of politics, planning and economy are taken as important determinants of socio-spatial inequalities. For instance, according to Harvey (2006) the clash of different powers, e.g. economic and political, generates uneven geographic development. In this sense, socio-spatial inequalities are explored through the relationship of these powers and the paper is grounded within the urban land rent theory, theories of uneven geographies, geometries of power as well as discussions on participatory planning and right to the city. Planning process and infrastructure development in Istanbul are used in order to explain socio-spatial inequalities.

In Istanbul, plan amendment process has become a major issue especially within the last decade. The Municipal Council of the Istanbul Metropolitan Municipality makes decisions on the future of the development of the city in limited time, with limited participation and regardless of the approved Urban Master Plan decisions. In this sense, the municipality (re)distributes the wealth and urban rent and yet, no regular scheme is applied for the participation of different interest groups to this process. Therefore, tension between different interest groups has climbed in recent years. For instance, professional chambers such as the chamber of urban planners and chamber of architects have sued the municipality on a number of occasions. Recently, public will to protect an urban park (Gezi Park) in its current form against government's plans of demolishing it and resurrecting old army barracks to be used as a shopping mall/hotel complex, has triggered a country-wide resistance. Government's intervention to public space at different scale and forms has become a general practice especially within the last ten years and a way to generate economic surplus. In this paper these interventions are discussed with regard to urban transformation and socio-spatial inequalities attached to this process.

The first section of this paper analyses the plan amendment process in Istanbul. Having acknowledged that the Istanbul Municipal Council approves more than a thousand plan amendments a year (personal interview, Representative of Chamber of Urban Planners 2011), the scope of this research has been limited to a defined area, that is the surroundings of the Istanbul Metro (subway). In doing so, it has been possible to assess the impacts of an important transport infrastructure in the city. In the second section of the paper, one of the emerging terms related to socio-spatial inequalities generated by transport infrastructures, the accumulation of physical capital, is examined with regard to the Istanbul Metro. This

paper uses a series of qualitative data, i.e. expert interviews, newspaper articles and adverts and analyses them with reference to political agency and structure of socio-spatial processes. This method is based on Jager's (2003) analysis of the urban land rent.

2. Conflicts: Adopting the plan or adapting it

Urban land rent theory as well as the notion of commodity, its use and exchange values, is based on a Marxist analysis of economy and economic relationships and draws mainly on Marx's explanation of the agricultural production in the third volume of the *Capital* (Marx, 1990). David Harvey has largely used Marxist land rent theory in order to explain the urban phenomena like socio-spatial inequalities in his early writings in *Social Justice and the City* (1973) as well as in his later work in order to understand the recent economic crises which he believes to have generated in urban areas due to excessive capital accumulation (Harvey, 2006; 2012; Soja, 2010). According to Harvey, use of land, the regulation on land, thus land rent, is a necessary condition for capitalism (Harvey, 1990) which has also been discussed by many others in terms of the production of space (Lefebvre, 1976; Castells, 1996; Soja, 2010).

Improvements on land such as improved infrastructure, increased accessibility and additional construction rights create urban land rent. If we need to specify the form of this rent, it can be described as Differential Rent II (DRII) (Marx, 1990). The Istanbul Metro creates DR II not only directly, based on increased property prices, diversified business sectors and increased CBD activities around the stations as discussed in a previous study (Beyazit, 2013), but also indirectly, as the Metro is used as an additional tool to increase the attractiveness of building blocks and single plots. Planning decisions given by the Istanbul Municipal Council are important determinants of this process and are evaluated in this section. Three examples of residential and commercial buildings are used to explain this process.

After the opening of the Istanbul Metro in September 2000, surroundings of its stations have become attractive areas for investment. Although a number of shopping malls opened within close proximity to the Büyükdere axis regardless of the Metro connection before the Metro was built, some investments have been made considering this advantage (Figure 1). Metrocity, a shopping mall, office and residence complex comprised of three buildings with 24-26 floors, opened in 2003 at the Levent Metro station. Later on in 2005, Cevahir Shopping Mall, the biggest shopping mall in Europe and the second biggest in the world (in 2007) opened at the Şişli/Mecidiyeköy station. In 2006, Istanbul gained an extraordinary building structured like a canyon, comprised of four floors of shopping mall and separate buildings for offices and flats. Kanyon combined the features of street-shopping and shopping in a mall with its peculiar design (Kanyon AVM, 2011). All three buildings have direct access to the Metro stations and passengers can access the shopping malls without going over ground.

In a personal interview with a real estate developer (2011) it has been mentioned that investors see the metro link to the shopping malls as an advantage, likewise, customers prefer shopping malls with connection to the Metro. Therefore, it is possible to state that the Metro creates additional urban rent by offering direct access to and from the shopping malls. Recent developments such as the Diamond of Istanbul, Dubai Towers, Trump Towers, Zorlu Center and other residential and office buildings are shown in Figure 1. These projects have been subject to legal actions as a result of the ways in which they were authorised by the Municipal Council despite not being a part of the local development plans. As a result of exclusive construction rights given to these plots, values increase and the economic gain for the investors of these buildings becomes larger compared to the other investors in the area. Therefore, inequalities occur. Following paragraphs discuss the structure of the process of the generation of differential rent and agencies involved in this process.

Figure 1 Stars point out the residential and commercial developments that the Chamber of Urban Planners has appealed to the Administrative Court about. Numbers mark the shopping malls/residential and office complexes that have direct connections to the Metro stations. 1: Cevahir Shopping Mall; 2: Astoria; 3: Metrocity; 4: Kanyon

Having stated the importance of the connection to the Istanbul Metro for developers, it is crucial to assess this issue from the stand point of decision-makers. Even though the planning process in Istanbul follows a formal path that consists of various stages of urban planning, the final products, i.e. the master plans, are diverted from their aims and objectives due to interventions from national and local authorities. Therefore, the knowledge produced and shared by academics, planners, decision-makers and other stake-holders in the process of preparing master plans is disregarded in order to implement new decisions via plan

amendments, changed construction rights and new urban design projects¹. This section analyses the plan amendment process in order to define the *structure* and the *actors* taking part in the generation of the differential rent based on Jager's (2003) analysis of the urban land rent.

In a personal interview with one of the members of the Municipal Assembly (also a member of the opposition party) the plan amendment process has been discussed. Based on the interview, it can be stated that this process is very straightforward and includes eight steps from the proposal to the consultation and approval of the project (Figure 2). However, when this process is evaluated in depth, it is far more complicated and involves various actors especially in cases where a decision on an individual plot may have effects at a larger scale such as in the construction of shopping malls and office buildings that affect transport, density and economic gain.

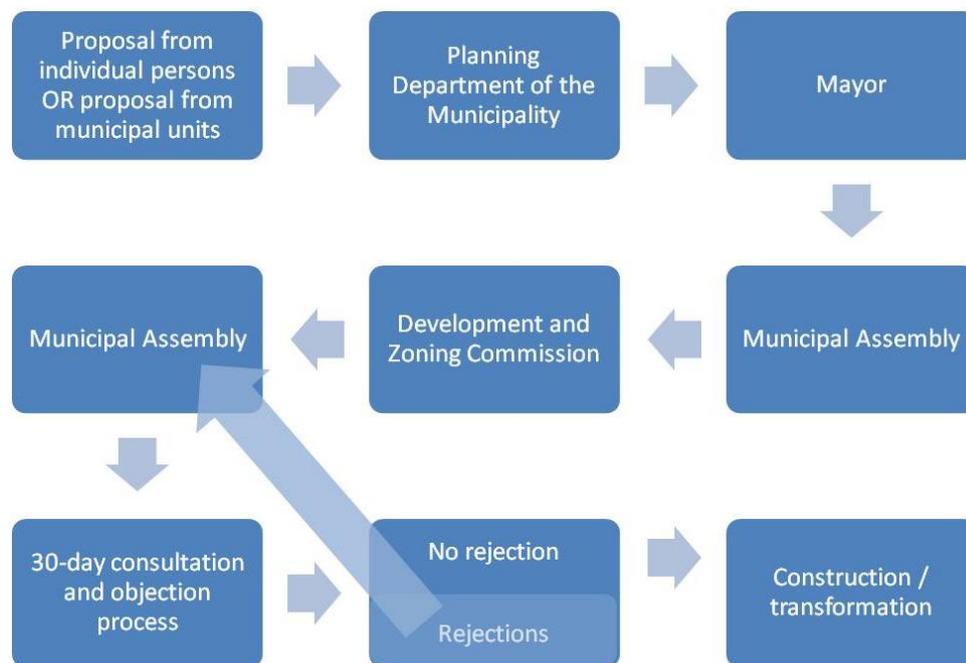

Figure 2 Plan amendment process (source: author's own elaboration)

First of all, differential rent is generated in two ways in Istanbul and is based on the changes of the ownership of the land. Figure 3 demonstrates this structure and the actors involved in various steps of this process. The figure is based on personal interviews with the representative of the Chamber of Urban Planners and one of the members of the Municipal Assembly, decisions of the Municipal Assembly, court documents, national newspapers and non-academic journals on internet.

The first mechanism operates through the declaration of the publicly owned land or partially private land as a "transfer centre" or a "tourism and commerce area/centre" by the Istanbul Municipal Assembly. Following this, the assembly decides (based on the opinion of related

¹ For instance, 2009 Master Plan of Istanbul, a comprehensive study based on four years of data collection, analysis and a wide spectrum of expertise, proposes polycentric development for Istanbul in the East-West direction. However, soon after the plan was published, three major projects were suggested by the Prime Minister himself prior to the National Elections. These projects are; Third Road Bridge over the Bosphorus at the Northern end of the city, a road tunnel connecting the city from south and a new 50m wide canal connecting south to north. First two projects have been included in the latest Transport Master Plan (2012).

municipal units) upon new construction rules on these transfer centres. According to the Istanbul Municipal Assembly's decision number 1985 on Ayazağa Transfer Centre on 16.09.2010, a "transfer centre" may include:

2. Park and ride facilities, parking space, shopping mall and/or cultural centre and/or congress centre and/or education centre and/or hospital and/or tourism centre, office, apart-hotel (residence) functions.

And the plan should be implemented according to the avant (pre) project:

3. [...] Avant project will be prepared by the coordination between the Transport Planning Department and the interest groups (for spatial use, pedestrian-private and transit vehicles connectivity, parking capacity and entrances and exits, connection to the rail system, management plan for the building, parking space and protocol for the usage of the transfer centre) and will be implemented by the approval of the Greater Municipality of Istanbul.

The council defines the tourism and commerce centre as (taken from the amended plan notes of 1/5000 Sisli District Plan decided on 07.11.2010);

3. Tourism and commerce centre may include; hotels, business centres, residences, offices, shopping malls, cinema, theatre, entertainment centre, multi-storey shops, museum, exhibition hall, cultural centre, restaurant, cafes and financial institutions.

The council also suggests for this particular place that;

11. A connection to the metro station can be made.

Second mechanism operates as follows. First, the planning conditions on a publicly owned land are changed by the Municipal Assembly to a "tourism and commerce centre" or a "transfer centre". Later on this land is sold in an auction to the highest bidder. The main difference between two processes is the transformation of the ownership of the land from private to private or from public to private. However, in both cases the construction rights are increased before privatisation (if needed) in order to increase the value of the land before transactions. Therefore, the land is sold by the municipality or by a national institution (such as the Housing Administration and the General Directorate of Highways) after a rise is given to its value by the Municipal Assembly. Despite slight differences between two mechanisms the result is the same: generating differential rent over urban land.

Secondly, agency constitutes an important part of this process. Actors are involved at different stages in the process and make different contributions (Figure 3). While the Metropolitan Municipality, Municipal Assembly, the Mayor, Ministers of the ruling party and National government's units such as the Housing Administration (TOKI) have encouraging roles in the process in collaboration with developers and investors; professional chambers and some individuals (experts, members of the council or the opposition party) may have opposing roles. After the decision is made, individuals or professional chambers may address to the court in order to change the decisions. Administrative courts and court experts consulted by the court may or may not approve the decisions which may lead to either revisions of the decision by the Municipal Assembly or the case to be taken to a higher court, Council of State, by the Assembly.

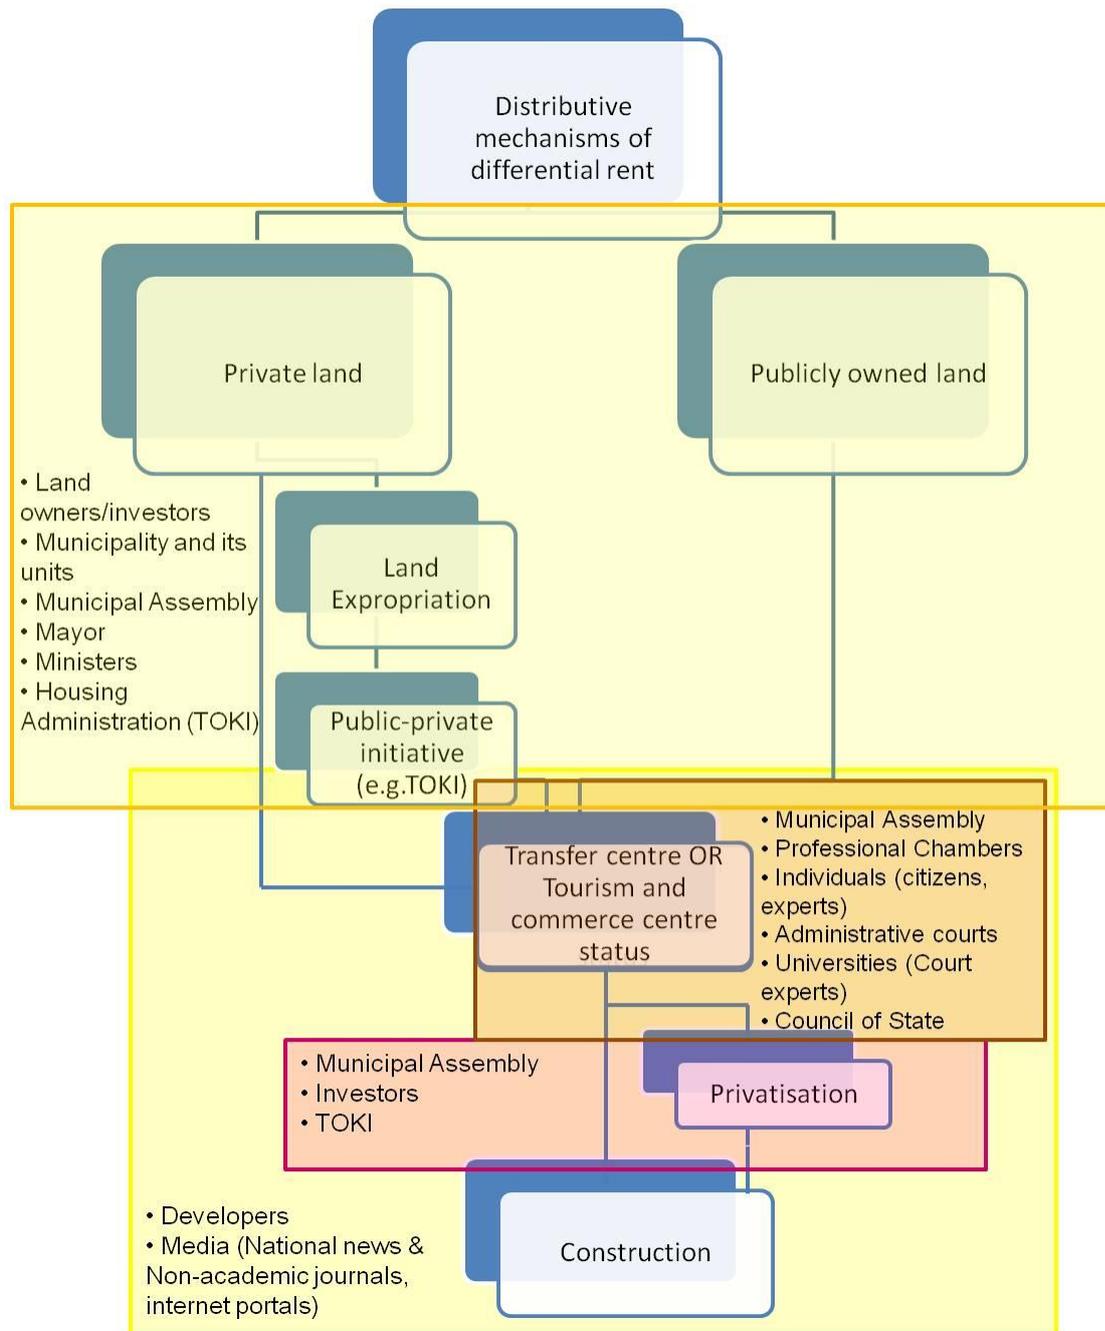

Figure 3 Distribution mechanisms of the differential rent on the Büyükdere Axis, the case of Metro (source: author’s own elaboration)

In this sense, the plan amendment process looks like it is democratically structured. However, power relationships between different actors in the process are likely to influence the decision-making process.

In terms of democracy... it is based on pluralism (*not on consensus*). Decisions (*proposals*) are brought to the agenda of the Council² based on Mayor’s or ruling party’s will. Council decide to say yes or no to these decisions (*mentions that the ruling party would have the majority anyway, therefore, they would have the final word*). Meanwhile, people who are opposing to the decision can present their positive or negative views. They may mention that they do not

² Municipal Assembly or City Council.

agree with the decision. If they are in the *planning* commission, they can place declaratory clause to the decision; if they are not powerful enough in the commission they can address to the council in their party groups and reason their objections.... Have they got other alternatives? Well, they can take the decision to the court, object (*further*) or address to the media. That is how the system works. [...] In any case, if the Mayor does not want *the decision to be made*, he would not send it to the Council. Even if he does send it, he would ask the ruling party to object the proposal.

Politician, 2011 interview (words in italic, my notes)

It can be understood from this statement that the Mayor and therefore, the members of the Municipal Assembly from ruling party, are the most powerful actors in the decision making process. Thus, these groups are the drivers of the agenda on plan amendments. Yet, it is arguable to what extent the members of the Municipal Assembly engage with these planning decisions. Based on an observation of the decision making process in a district municipality during the fieldwork, it is possible to state that the decisions are made in a very short time and without much discussion. The number of plan amendments in a year supports this argument as one of the interviewees mention.

Istanbul Metropolitan Municipality approves about 1000 plan amendments in a year. How does the Municipal Assembly work? Members of the Assembly redistribute large (*economic*) surplus from one place to another just by raising and dropping their hands and create an enormous rent in Istanbul. This rent is never taxed in Turkey, urban rent is not taxed.

Representative of the Chamber of Urban Planners, 2011 interview (words in italic, my notes)

The above quote also suggests that as the urban rent generated through plan amendment processes is not taxed, it is not beneficial for the state, therefore, the public. Although the Municipality usually gains from the transaction of municipal land, it uses its initial gain by bringing physical infrastructure to those areas that accommodate new functions. There are cases in which the municipality negotiates with developers for new environment design or pedestrian crossings, however, it is not clear how much of developers' gain is passed on to such projects concerning public good.

Moving on with the attitudes of the actors in the plan amendment process, it is also possible to discuss that, even though ministries do not have a say in this process, they show their support to the municipalities ruled by the same party. Moreover, the Mass Housing Administration (TOKI) has the power to declare any area or a building plot as an urban transformation area and can purchase and sell land. Being a part of the national government, it has slightly more power than other investors.

Professional chambers, NGOs and individuals (citizens, academics, council members etc.) have the power to object the decisions by informing the Municipality and if they do not receive positive response they can take these decisions to Administrative Courts. However, legal cases *occasionally* result in their favour³. Moreover, they can generate public awareness via the channels of the media and try to create a greater objection to these decisions. However, the media can also be used by the municipality to legitimise their decisions. Therefore, these groups are less likely to have a significant impact on these

³ For instance, in the case of plan amendments on the plot that Zorlu Centre has been built, Chambers of Urban Planners, Architects, Civil Engineers and Cartographers-Cadastral Engineers sued the Ministry of Public Works (currently, Ministry of Environment and Urban Planning), Istanbul Metropolitan Municipality and Prime Minister's Office Privatisation Administration as well as Zorlu Holding based on the decision being against public good and planning principles. Even though decisions by the court were in favour of these chambers in 2008, the situation has turned in favour of investors and national and local authorities in 2009.

issues. Having said that, previous (e.g. the Park Hotel) and recent (e.g. the Transfer Centre planned in the plot abandoned by the Galatasaray Stadium, Figure 1) success stories exist.

Although the Istanbul Metro is not directly related to the decision making process in terms of plan amendments, it has an important part in the decision itself and a crucial role in the construction process. According to Municipal Assembly's description of Transfer Centres and Tourism/Commercial Centres discussed above, direct connections to the Metro can be made from the plots that are given such status. Yet, many new developments that offer mixed uses with shopping malls, office buildings and residential areas mentioned earlier, have benefited from the existence of the Metro stations in the area by gaining excessive construction rights compared to the neighbouring plots. As it is discussed in the next section in the case of the Zorlu Holding, even the developments with no direct access to the Metro are seeking to establish these links. In this sense, the Istanbul Metro can be described as an important spatio-political tool in the generation of differential rent in Istanbul.

3. Distribution of capital

Based on the discussions in the previous section and in a previous work (Beyazit, 2013), it is possible to comment on the Istanbul Metro's impacts on the accumulation of capital. Changing planning and construction rights encourage connection to the Metro stations from tourism and commerce centres. Even though changes in building allowance and planning rules cannot be attributed solely to the Metro, the ways in which the Metro is used in Municipal Council's decisions point out to the importance of connection between the Metro and such functions.

Rights for higher densities are supplied under Transfer Centre status. What is done through these rights for high density?: Only allowing a connection to the Metro.

Especially, these rail systems (*Istanbul Metro, Kadikoy-Kartal Metro, Marmaray*) will create further consequences in Istanbul, maybe we will see that all shopping malls will move to the surroundings of these (*rail*) stations.

Representative of the Chamber of Urban Planners, 2011 interview (words in italic, my notes)

Spatial inequalities arise as the Büyükdere Avenue and its surroundings become favourable investment areas as a result of combination of local and national politics and the existence of the Metro. The Istanbul Metro, with the help of a series of planning amendments, has fostered the functional changes in the area and has influenced the land prices.

You can see plan amendments in every station, the public buildings are sold at very high prices. Metro has affected and is affecting the functional space. There is no empty lot for sale in the area; the building density is very high; road traffic is tangled but the Metro has not reached its capacity yet.

Representative of the Chamber of Urban Planners, 2011 interview (words in italic, my notes)

As a consequence of high values captured through new connections made with the Metro stations, and yet the existence of limited empty lots in the area, new connections emerge between the Metro and Tourism/Commerce Centres even in cases where the plot is not within close proximity to the Metro stations. These situations occur as since investors consider such connection as an advantage (real estate developer, 2011 interview). For instance, based on an agreement between Zorlu Holding⁴ and the Mayor of Istanbul, a

⁴ Zorlu Group purchased the land of the Directorate of Highways after the plans for this plot were changed to include tourism and commercial function. Zorlu Centre is being built on this plot.

pedestrian underground crossing between the Gayrettepe Metro station and the BRT stop in Zincirlikuyu is being built by the investors of Zorlu Centre (Figure 1). The 717m long pedestrian tunnel with moving walkways will not only connect these two stations with each other but also provide seamless transfer between these transport systems and the Zorlu Centre where shopping malls, office buildings and residences can be found. Even though such agreements are made between municipalities and developers in order to capture the 'public good' in exchange for exclusive construction rights given to the developers, private gain becomes more important than the public good as seen in this example since the pedestrian tunnel will also connect these transport modes with the Zorlu Centre. More importantly, since it is the local authority agreeing for such a connection to be made between a private investment and two major transport links, it is possible to state that the Municipality and the Municipal Assembly act as contractors.

In terms of transport and urban planning, the role of Transfer Centres in transport network requires greater attention. In 2009, Istanbul Metropolitan Municipality had sixty-nine Transfer Centres planned for the entire city (IBB, 2009) and fifty-nine of these were included in 2011 Transport Master Plan (IBB, 2011). The location and number of these centres bring up questions on whether they are actually needed and if so, whether the construction rights given to these areas will shift the demand in the transport system. More importantly, the question of whether these centres are planned in order to facilitate the transport network still remains as discussions with experts demonstrate.

In a modern city, you cannot have transfer centres everywhere. Here (*in Istanbul*), since transfer centre means giving exclusive construction rights, it is a preferred function over shopping malls. In terms of function, transfer centre status is preferred because it brings mixed-uses. For instance, there are 5-6 transfer centres only in Mecidiyeköy. [...] In a way, it is a nice thing (*idea*) as it creates a public function with public uses in the ground floor and (*private*) ownership (*through construction rights*) in the upper floors, but this situation is gone out of control.

Representative of the Chamber of Urban Planners, 2011 interview (words in italic, my notes)

The above discussions suggest that the Istanbul Metro is a fixed capital (Harvey, 2005) that produces other fixed capitals such as shopping malls, residences, offices and transfer centres. Yet, such development generates in certain parts of the city and not distributed to the wider community, therefore, creates uneven spatial development. Changing regulations and plan amendments also have crucial role in this process and the role of politicians is very distinctive.

4. Concluding remarks

One can discuss that the ideal planning that advocates comprehensiveness and egalitarianism has lost its powerful image even as early as 1960s when criticisms towards it started to emerge (e.g. Jacobs, 1961). As cities maintain their power in the political arena and their importance continue to increase, urban planning has changed its focus from comprehensive and strategic plans to partial projects in practice (Graham and Marvin, 2001). This transformation can, to a certain degree, be explained through changes in world economy and the deconstruction of the idea of state and entanglement of cities autonomously to the global economy and therefore, through the clash of political and economic powers. In this debate, the plan amendment process in Istanbul demonstrates crucial points on the consequences of drifting away from comprehensive approaches to planning.

First of all, following an approach based on the analysis of structure and agency of various political processes, this paper has shown that the plan amendment process is not

straight forward but rather very complicated. This complexity generates as a result of many actors participating the process one way or another at different levels, in different time periods and changing the course of events. Therefore, such process can be regarded as a multi-dimensional political platform and can be evaluated within the debates of power geometries where some actors are more powerful than others. Some actors, especially from the members of the ruling party in the Municipal Council, get more say in this process and they use plans as a direct (and a powerful) tool to apply their decisions. Others, on the other hand, are restricted mainly by the law and lack the ability to manoeuvre. Therefore, it is possible to suggest the existence of the hegemony of the most powerful actors over less powerful ones in terms of urban planning in Istanbul.

Second, one of the main consequences of partial planning is the accumulation of physical capital in certain areas and the lack of distributive mechanisms concerning the economic and social benefits obtained from new projects. Exclusive construction rights given to certain plots add economic value to the land and differentiate them from nearby areas. The owner of the land or the new buyer/developer gains extra land rent which is not taxed and therefore, the public do not gain from it. Moreover, additional projects offered by the developers to the municipality, such as the pedestrian tunnel constructed by the Zorlu Company bring more private gain than public gain as they propose connections between public transport and their shopping/residence/office units. Therefore, through the analysis of the plan amendment process it is possible to comment on the uneven geographic development in urban areas.

Third, even though the Istanbul Metro is not the main concern of plan amendments, the ways in which it is used by the Municipal Council makes it significant to the process in two ways. First, the Istanbul Metro creates the conditions for an area to become a Transfer Centre and helps the area gain additional construction rights. Second, it increases the value of the property which is constructed with a direct access to one of its stations. As a result of the Municipal Council's decisions, differential rent is generated in the city over the existence of the Istanbul Metro and distributed unevenly to certain groups in the society, allotting spaces based on which company or companies provide the highest tender. Furthermore, the access to the Metro stations is important for investors as it makes the investment in these areas (e.g. shopping mall) preferable for customers. The Istanbul Metro, therefore, facilitates the circulation of capital as well as the accumulation of it in certain areas. The use of the Istanbul Metro as a case study has demonstrated the importance of fixed investments such as transport investment in creating accumulation of capital and therefore, contributing to the generation of uneven geographies.

Despite the growing trend on focusing on partial projects in urban planning, this paper has demonstrated that in order to overcome socio-spatial inequalities and establish democratic decision making mechanisms, comprehensive approach to planning is crucial. Yet, this approach, as we know of it in the planning discipline, should be reformulated with the aim of inclusiveness, participation and "just" distribution of benefits. It should propose a democratic structure that is not based on pluralism but based on consensus. Recent events in Istanbul have provided important lessons for the transformation of urban planning discipline. The protests against the demolition of Gezi Park in Istanbul have been followed-up a country-wide unrest due to the excessive force used by the police and lack of anticipation by the government. More recently, park/neighbourhood forums have demonstrated how the public and different actors can come together, share their opinions and decide on various actions concerning public good and common interests. Such examples may shed light to the ways in which urban planners may overcome the conflicts and clashes between the notions of power, politics and planning in transforming cities.

2 West Masterplan: A New Paradigm in Urban Planning

Bij Borja, JTC Corporation, Singapore

INTRODUCTION

“Urban density spurs innovation”

With just approximately 730 square kilometres of land area, the competition for land and labour in the small island state of Singapore has increasingly heightened. To tackle such issue, new urban planning approaches and innovative strategies have been developed to further optimize land and increase productivity in Singapore. As the nation's leading industrial developer and master planner, JTC Corporation (JTC), a statutory board under the Ministry of Trade and Industry has progressively positioned itself as one of the key drivers of land intensification by constantly innovating and thinking of out of the box solutions while staying true to its vision of creating a dynamic and integrated industrial landscape.

By 2030, the population of Singapore is expected to be at 6.9 million which will result to a denser built environment. Inevitably, industrial land will be in close proximity to other land uses such as residential and commercial areas. Thus, the challenge will be how to integrate the different land uses while maintaining the liveability of the estates in Singapore. Hence, as the primary developer of the nations' industrial estates, JTC has started to masterplan its future estates to become sustainable and liveable environments where both industrial and other non industrial uses co-exist.

This paper will share one of JTC's newest developments, the 2 West Masterplan, and will discuss the future ready and innovative planning concepts in structuring and strategizing the master plan's overall framework. It will also discuss the planning approaches adopted in addressing the concerns over land scarcity, better distribution of good jobs and urban liveability through mixed-use integration and through the development of a new urban infrastructure.

1. The 2 West Conceptual Masterplan

After JTC's highly successful one North, a 200 hectare work-live-play-learn development which is home to clusters of world-class research facilities and business park spaces, the corporation has now embarked on shaping another integrated development, the up-and-coming 2 West. A conceptual masterplan has just been developed to transform this 700 hectare site consisting of CleanTech Park, Nanyang Technological University (NTU), Wenya Industrial Estate and part of Tengah New Town into a mixed use development with work-live-play-learn and make elements. Located in the western area of Singapore, 2 West derived its name as it is the 2nd integrated development with work-live-play-learn components developed by JTC after the one north development.

The main objectives of the master plan is to intensify land use, to enhance the connectivity, liveability and vibrancy of an industrial township and to increase the potential synergies between NTU, Cleantech Park, Wenya, Jurong West and Tengah New Town developments. 2 West is envisaged to bridge the gap between research & development and manufacturing with prototyping, pilot testing and process optimisation while industry focus includes Clean Technology, Materials Science and Manufacturing Technology (3D Printing, Robotics, Advanced Manufacturing).

1.1 Challenges of Conventional Planning

In order to conceptualize new urban planning concepts for this integrated development, conventional planning norms have been reviewed to address its existing issues and challenges. Thus, in structuring the master plan's overall framework, the few questions below have been formulated with the intention to come up with innovative planning resolutions.

- Can we rethink some of our current policies to adapt to a new way of masterplanning and developing JTC's estates?
- How do we make use of limited resources in an environmentally sustainable manner?
- What is the most suitable developmental or business model in creating cost effective working and living environments?
- With the growing population in Singapore, how can we accommodate various uses within a dense yet liveable urban space?
- How can we tap on new methods & technologies in construction as well as IT technologies to enhance the built environment within a Smart city and making it future ready?

1.2 Championing New Concepts

In response to the challenges posed above, a number of strategies for the 2 West masterplan have been developed which aim to champion new concepts in the following 5 areas:

- **Policies**
We aim to review current policies and regulations to facilitate innovative development models and breakthrough infrastructural solutions.
- **Environmental**
To save and optimize land as it has become a scarce resource and be environmentally sustainable in our masterplanning and development efforts.
- **Economic**
To explore potential developmental models and partnerships that can be formed from integrating various uses within single developments.
- **Social**
To develop eco-districts that shall encourage interaction within communities as well as walkable mixed use districts.
- **Technology**
To bridge the gap between the academic research and industrial manufacturing, so as to encourage and facilitate 'prototyping' that would enhance the test-bedding possibilities in the area. Moreover, to integrate sustainable estate-wide goods mover systems and people mover systems to improve on the last mile logistical and transport issues of the flow of goods and people.

2. Key Planning Principles

To address the concerns over land scarcity, better distribution of good jobs and urban liveability, the following four key planning principles were adopted to strategize the planning framework for 2 West.

Source: JTC Corporation

Figure 1 : The key planning principles adopted for 2 West include (Left) integrated development with seamless connectivity, (Center) liveable and walkable urbanism, and (Right) environmental sustainability.

2.1 Integrated Development with Seamless Connectivity

2 West is envisaged as a sustainable integrated mixed-use development wherein various land uses such as commercial, residential, industrial and institutional harmoniously merge. Within this development, industries and companies are clustered together to share common facilities and services. Seamless connectivity is achieved through the development of an efficient infrastructure that facilitates effective flow of goods and services as well as people.

2.2 Liveable and Walkable Urbanism

The 2 West development shall heavily promote pedestrian mobility and encourage walking. Residential homes, recreational facilities and amenities are within walking distances from places of work to reduce travel time and reduce strain on the public transport system. Increased walkability shall bring forth not just health benefits to many individuals but also social benefits to the entire community as it brings about opportunities for social interaction. Hence, a sound pedestrian network shall be developed within 2 West with strong considerations for accessibility, good street designs and creative placemaking.

2.3 Vibrant and Compact Mixed-use Setting

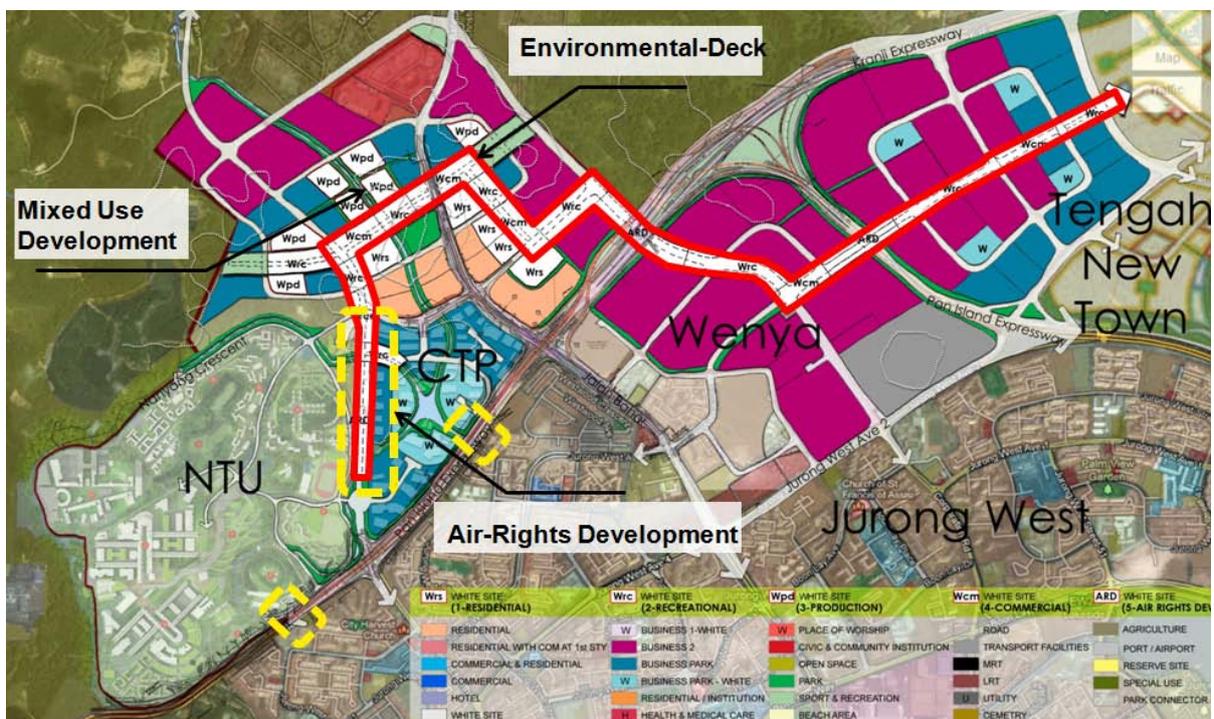

The planning of 2 West shall adhere to high-density and compact planning strategies thereby reducing urban sprawl and creating efficient land-use synergies. The various nodes within 2 West shall be anchored with transit oriented developments. These areas shall offer mixed-use settings along mass transit corridors so that a variety of urban functions are densely located making it very accessible to people.

Vibrancy is another urban characteristic envisaged for 2 West. Although compact developments are planned, lively street life and dynamic public spaces shall be designed to create a vibrant setting. These urban design considerations shall help build a distinctive neighbourhood character and shall help foster attractive communities with a strong sense of place that reflect the values and culture of the modern Singaporean society.

2.4 Environmental Sustainability

As land is a valuable commodity, the overall planning framework for 2 West warrants environmental sustainability efforts as one of its primary objective is to improve the quality of life of its users. The urban framework is set not just to resolve how land should be properly used but also how the environment should be well safeguarded.

Although JTC drives the development of 2 West, the corporation also collaborates with various government agencies in harnessing state-of-the-art green technologies to respond to environmental protection issues, climate change, energy conservation and resource optimization. In addition, to ensure sustainable urban growth for 2 West, proper urban management shall be adhered through the formulation and implementation of innovative policies. Through this, businesses, industries and the whole community become responsible in reducing negative impacts to their environment.

Source: JTC Corporation

Figure 2: The masterplan for 2 West creates synergies between the districts of NTU, Cleantech Park, Wenya, Jurong West and Tengah New Town

3. Key Urban Features at 2 West

The 2 West masterplan focuses on the following three (3) key features conceptualized in response to the issue of land scarcity and increase in productivity:

3.1 Mixed Used Developments

With the adoption of smart growth principles, mixed-use developments shall constitute the key district nodes of 2 West to facilitate work-live-play-learn and make activities. Industrial buildings, business parks, offices, retail shops, residential homes, recreational facilities, communal amenities and a university shall intermix in this vibrant and compact yet liveable setting. Vertical mixed-use developments are also encouraged within 2 West to hinder mono-use of a single plot and to amplify a building's efficiency.

To suffice the residential demands in 2 West, affordable housing and rental housing models are considered for the residential quantum so as to meet the accommodation needs of the workers in 2 West including researchers on short-term visits and foreign students attending short-term courses. As 2 West upholds compact planning, various essential facilities and amenities that support the different housing estates shall be of easy access by the residences.

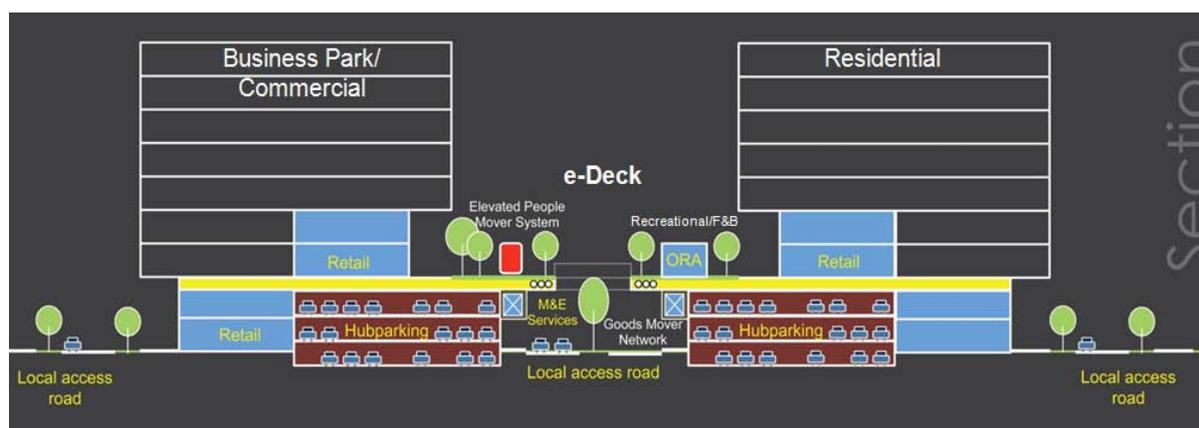

3.2 Environmental Deck

One of the key planning principles for this development is to create seamless connectivity and integration between the districts of 2 West and their surrounding communities supported by the cutting edge economy and technology. The enabler of such strategy is the Environmental Deck (or e-Deck for short), an innovative system of multiple functions that redefines the concept of urban infrastructure. Considered as the highlight feature of this development, the e-Deck is an innovative urban infrastructure envisaged to link up the various elements in 2 West and span approximately 5 kilometres across the entire site. It is an efficient form of a synergistic relationship between public facilities such as public open spaces, amenities and hub parking, the environmental and micro climatic medium such as urban greeneries, storm water management, a state-of-the-art logistics system such as the Estate-wide Goods Mover System (eGMS) as well as common services tunnels providing plug & play utilities options for companies such as electricity cables, water pipelines, sewer pipelines, gas pipelines and telecommunication lines.

Source: JTC Corporation

Figure 3: An aerial view of the 2 West development showing the e-deck that connects the various mixed use developments - industrial, business park, commercial, institutional and residential. Recreational facilities, amenities and the people mover system will be provided at the e-deck, whilst goods mover system, utilities, services, hub parking and roads will be located under the deck.

Source: JTC Corporation

Figure 4: A sectional view of the e-Deck illustrating the people mover system, recreational, landscaping, and F&B spaces above the e-Deck with the retail shops and amenities on the 1st two floors of the buildings next to the e-Deck and the public roads, hub parking and goods mover system under the e-Deck.

Elevated Green Core

Although the concept of environmental deck is not new, this is the first time that such concept will be implemented in a very large scale. As a green artery, the e-Deck will first and foremost serve as an elevated communal green space acting as the main activity spine, providing shared amenities, F&B spaces and public gathering spaces for residents and workers to congregate and interact 24/7, thereby enhancing liveability and vibrancy at 2 West. There is also a continuous space for a variety of recreational activities along the e-Deck that promotes healthy lifestyle and improves quality of life such as running paths, fitness corners and cycling routes.

People Mover System

The deck level will also be integrated with a green Transport System that provides efficient public transportation and strengthens the development's accessibility by linking up the various districts within 2 West. The people mover system will possibly be connected to the main Rail system and there shall be provision for smaller people mover system and cycling paths outside the e-Deck to further establish a good transportation network.

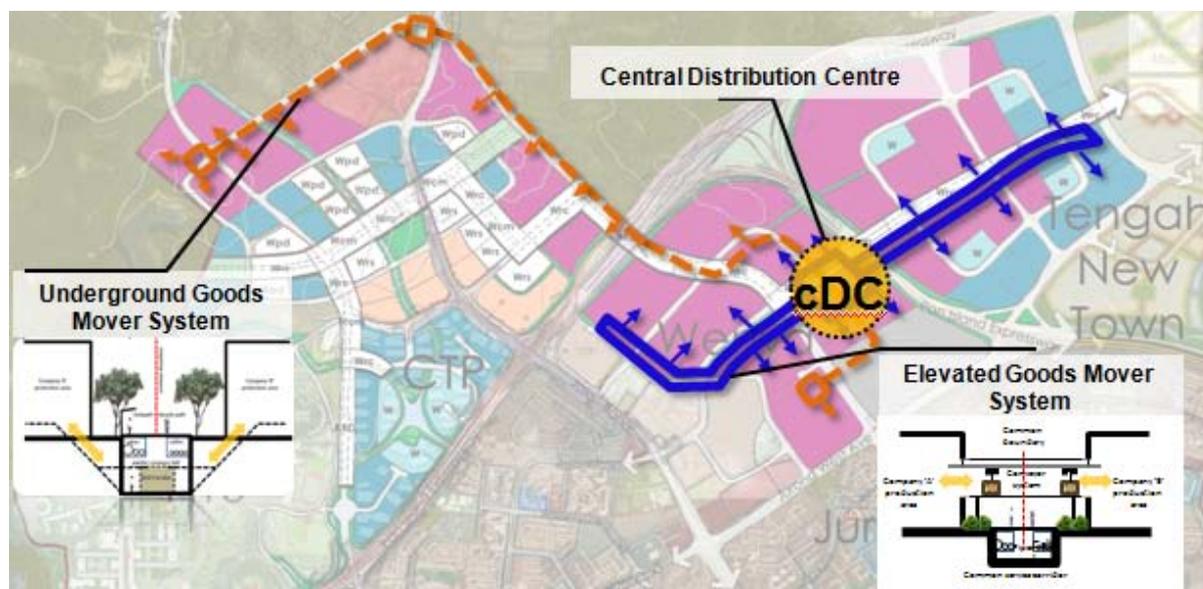

Hub Parking

Housed underneath the e-Deck are two other major components that make up the shared infrastructure system. First is the hub parking, a network of multi-storey car parking facilities catering to the various industrial, commercial and vertical mixed used developments along the stretch. Accessed via the public local road, the hub parking facilities are very accessible to the nearby buildings as most of the surrounding developments are planned within 10 minutes walking distance from the e-Deck. The hub parking aims to reduce the requirement of providing individual car parks for each of the buildings as well as to reduce congestion. Consolidation of the parking spaces not only warrants land savings but also highlights walkability and the inclusiveness of the e-Deck to pedestrians as these facilities are well segregated from people.

Estate Goods Mover System (eGMS)

The other major component under the e-Deck is the estate wide goods mover system (e-GMS), an automated smart logistic system for the distribution of goods to the various industrial developments within the estate. The system is connected to the Centralized Distribution Centre which is eventually linked up to the sea port, the centralized underground warehouse facilities and other industrial estates along its corridor. After arriving at the port,

raw materials and goods are sent to the centralized distribution center (CDC), the main warehouse distribution and sorting hub functioning as the heart of this state-of-the-art goods delivery system. From the CDC, pallets of goods travel via an automated track and delivered to individual industrial companies. Finished products from the industries are then sent back to the CDC via the eGMS for distribution to the companies' various customers.

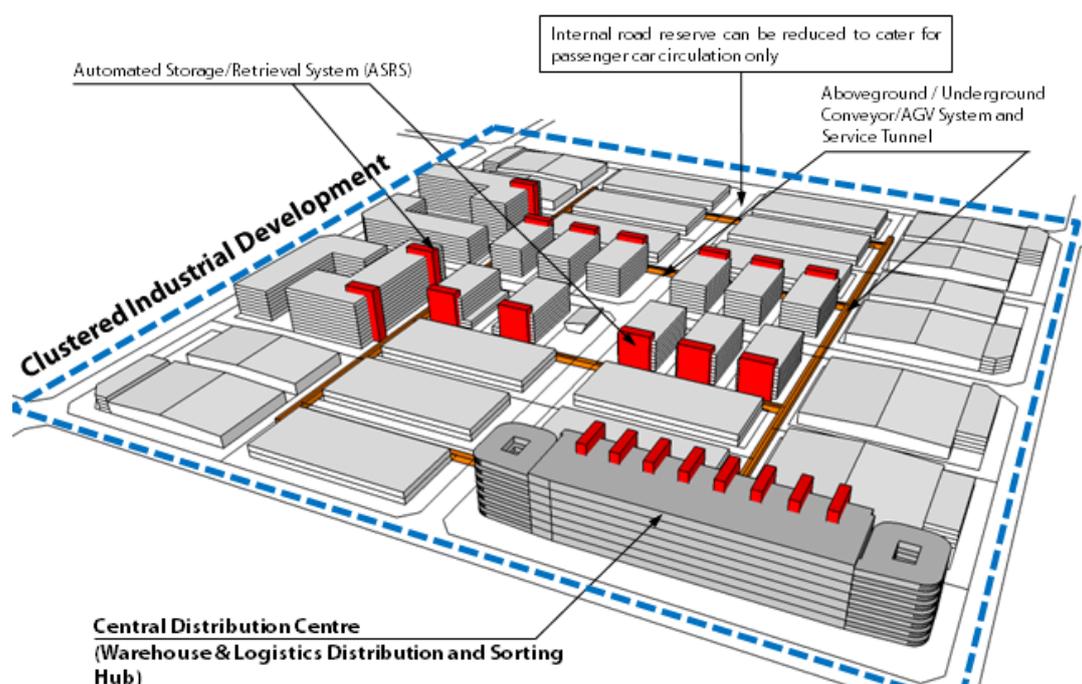

Source: JTC Corporation

Figure 5: The estate wide goods mover system corridor at 2 West with an elevated goods mover system located along the e-Deck and an underground goods mover system provided outside the alignment.

The eGMS aims to facilitate the movement of goods from point to point without relying on highways and roads, potentially relieving traffic congestion. Current typical industrial developments have individual warehouses and loading/unloading zones dedicated to each industrialist's needs and through outsourcing of each industrial development's goods storage, loading and unloading processes to a centralized third-party logistics solution provider, land taken up by these large roads, internal driveways, warehouses and loading/unloading zones shall be heavily reduced. Additionally, the eGMS can assist in curbing the vehicle population growth and help in freeing up additional land for other productive uses as well as mitigate the health and safety buffers imposed by the movement of hazardous goods.

From the end-user's point of view, clear predictability of suppliers' movements and delivery schedules can also bring about cost savings, and facilitate an increasingly just-in-time production model across an industrial park. Freight movement along the e-Deck via eGMS shall be elevated while goods movement running outside the e-Deck alignment is proposed to be underground. The eGMS is envisioned not just to serve 2 West but also the other industrial estates in Singapore thereby creating an island-wide automated goods system.

Figure 6: A conceptual simulation of the eGMS showing how the centralized distribution centre serves a cluster of industrial developments with the aid of technological systems such as the aboveground/underground conveyor system and automated storage retrieval system.

3.3 Air Rights Development

As a land creation initiative, air rights developments are also planned for 2 West so as to make full use of typically unused air space above roads for new developments. The overall objective is to create elevated structures that can span across existing thoroughfares with the intent of supporting a range of different land uses such as commercial, institution, industry and transport. Exploring air rights development can further contribute to significant land savings and could potentially improve connectivity between spaces previously inaccessible as well as facilitate better movement of people and goods.

Source: JTC Corporation

Figure 7: The conceptual air-right development decking over Ayer Rajah Expressway will create more land and synergize one-north's mixed-use development with Science Park which has been separated by the expressway.

4. Moving Forward

In order to ensure that JTC's visions for 2 West shall be implemented and turned into reality, the next step to be taken is to focus on research and development. Through R & D, the micro details of the proposed elements including technical feasibility, financial viability, operational costs and system limitations shall all be carefully studied and investigated assuring successful execution in the future. The results of the studies will definitely aid and guide the planners in developing the detailed design of the masterplan and in finalizing the details of the various urban elements within 2 West.

The conceptual masterplan has generated a number of R & D opportunities in various areas relating to the 2 West development. For the environmental deck, modular, prefab and large span structure design including construction for multi-phase development can be further explored. The details on how to effectively incorporate the people mover system, common services tunnel, recreational facilities, green and blue features, storm water management as well as biodiversity shall also be carefully analyzed to ensure synergy. For the air rights development, JTC is exploring new construction materials and building technologies for long span and heavy loading. Cost effective M&E systems for ventilation, health and safety, evacuation management as well as cost effective system for fire safety & protection are also being thoroughly examined.

JTC will be collaborating with the National University of Singapore (NUS) to embark on the feasibility study for the estate wide goods mover system with the objective of developing the detailed design of this smart logistic system. The study shall look into the potential goods mover corridor alignment, ideal speed, safety & security, mode of goods movement, potential scalability and applicability to other industrial parks. The research also aims to identify the most suitable business model, to resolve last mile issues as well as to develop a software for the effective automation of the eGMS.

CONCLUSION

With limited land supply, increase in population and rapid industrial evolution, Singapore's urban landscape is constantly transforming. As the country's industrial landscape custodian, JTC is also constantly keeping up with the change of times and with the fast transition of industrial and economic demands. The 2 West development is a fine reflection of how JTC responds to urban concerns through creative advanced solutions. Indeed, 2 West can be considered as a new paradigm in urban planning as the master plan made use of innovation and technology as the key enablers in resolving the challenges of urbanization, hence bringing forth sustainable growth in Singapore's urban planning milieu.

Figure 8: This is another artist impression of the potential 2 West development showing the seamless connectivity between NTU and CleanTech Park. It will be a vibrant meeting place and collaborative environment for industrialists, researchers, academics and students to come together to imagine, create and testbed the next disruptive technologies and groundbreaking innovations.

1. Introduction

In recent years there has been increasing emphasis across the world on decentralisation of planning processes¹. The old form of regulatory planning by the state agencies is being replaced by more inclusionary practices through co-option of the non-state actors in the civil society and the market in the decision making process. Such inclusionary processes are considered particularly vital under the rubrics of sustainable livelihood approach, adapted by the international funding agencies, to ensure that developmental outcomes meet the needs of the local communities in developing countries. However, emergence of bottom-up planning does not lead to erosion in the role of the state agencies in the planning process. Rather, newer demands are being placed on the state agencies, in coordinating and balancing competing claims between multiple stakeholders. However,, the role of the planning government agencies in mitigating the conflicting demands of the global economy and local livelihood, are under investigated – particularly in the context of the natural resource rich regions in the developing countries.

This paper compares and contrasts the role of the local government planning agencies in two mining regions of Colombia. Heightened global demand for natural resources is leading to escalation of mining operations in Colombia, by multinational and local mining companies. However, there are growing discontents amongst the local communities, who feel left out of this economic boom, and are stuck in poverty. Under these circumstances, the need for greater involvement of the mining companies to carry out developmental works at the local level, are recognized by the higher levels of the Colombian government; by local civil society activists as well as by the mining companies. However, operationalisation of this concept, this research shows, is to a large degree, handicapped due to capacity constraints of the local planning agencies. The local governments are unable to respond to demands regarding infrastructure development, employment generation, land-use regulation and social and environmental impacts of mining. The research draws attention to specific institutional deficiencies, in political and technological terms, which come in the way of the local agencies playing stronger role in a multi-stakeholder scenario in planning for mining regions and suggests certain remedial measures. The research is based on qualitative research

¹ We acknowledge the contribution of our PhD supervisor, Professor John Minnery, in the development of this paper.

involving, field observations and interviews of local government officials, mining company executives and community activists.

The rest of the paper is organized as follows: Section-2 provides a literature review about capacity building in planning at the local government level in the context of multi-stakeholder governance framework. Section-3 then provides a brief overview about the two case study areas. Following that, Section-4 compares and contrasts the role of the local governments in each of the case study areas, about their engagement with the mining industry. Section-5 concludes the paper through a summary.

2. Capacity Building in Planning and Multi-stake holder Governance

This research demonstrates how greater planning capacity at the local government level can empower the local communities to engage more effectively with powerful external stake holders, (like global mining companies) and gain from the extraction of mineral resources in remote natural-resource dependent regions in developing countries. Conversely, inadequate planning capacities, disadvantages the local communities in the local economic development process.

This is an area of research that had remained relatively less explored. Rather, most of the literatures dealing with planning issues in mining regions explore the decline of local governments' accountability (to respond to community's demands) after the arrival of global mining companies - a situation that intensified after the implementation of the state decentralisation processes (Fiszbein, 1997). Since 1980, decentralisation of the national-state in Latin America increased the responsibilities of local public administrations. However, this increased administrative responsibility had not translated into building capacities at the local level on planning issues.

Capacity-building is an evolving term that has been subject to multiple definitions. The term was first coined by the United Nations Development Program (UNDP) in 1990 and defined as a "long-term process by which individuals, organisations, networks, and societies increase their abilities to solve problems and achieve objectives" (UNDP, 1997). Since then it began to be introduced in developing countries as part of technical assistance programs to help communities cope with the changes caused by globalisation and economic restructuring (Amin & Thrift, 1992).

As defined by the United Nations, capacity-building is a long-term process that involves the commitment of multiple actors. Veiga et al (2001), for instance, state that "the first step to community sustainability ... may relate to local capacity-building and local governance". Similarly, the Institute for Environment and Development (IED, (2001) argues that capacity-building needs to be understood as a multi-stakeholder collaboration process that lasts before and after mining operations, intended to enhance existing skills in local communities. In addition, Loza (2004) defines capacity-building as an ongoing process that improves existing conditions in local communities and that requires the building of partnerships between corporations and communities. Indeed, capacity-building cannot be considered as a reactive response from mining corporations to tackle community problems but as a long-term process that takes into consideration community aspirations (Alizar & Scott, 2009).

Although the notion of community capacity-building is widely acknowledged in the scholarship, there is lack of understanding of existing capacity-building gaps within government organizations to effectively plan developmental strategies and implement good planning practices in mining regions. Lack of governmental expertise to negotiate global economic pressures and their implications on local livelihoods has also resulted in critical

poverty conditions of communities adjacent to mine-sites operating in the north of Colombia, the case study area.

In recent times, there are increasing thrusts on the mining companies to practice good corporate practices, which include building capacities of the local communities, in areas, where mining operations take place. Such practices are bracketed under corporate social responsibility. The Guidance on Social Responsibility, ISO 26000 (2010), defines capacity-building as a process that assists communities to achieve social and economic development standards. Moreover, it is stated that capacity-building is one of the most sustainable legacies that mining companies can deliver to local communities (International Council of Mining and Minerals ICMM, 2005). This notion is also regarded as a valuable legacy that fosters community development (Rio Tinto, 2011) and engagement (BHP Billiton, 2009) and forges sustainable communities (Barrick Peru, 2008).

Following global concerns regarding government capacity-building, a few scholars embarked on research that highlighted institutional capacity gaps. There is a general agreement amongst scholars from diverse streams like natural resource management and mining studies that governments need to strengthen their capacities in the development of policy frameworks for land-use and land-rehabilitation. Particularly, the need for up-skilling of the state agencies in areas such as mining projects monitoring and evaluation, transparency and mining revenues management are emphasised (Alizar & Scott, 2009; Bridge, 1999; Lahiri-Dutt et al, 2009; Mate, 2001). Inadequate expertise in planning issues had forced the local governments to secede leading role in the developmental agenda to the non-state actors in the corporate sector and civil society organizations, in a multi-stakeholder governance framework.

Discussions about of multi-stakeholder collaboration is frequently based on the assumption that governments, corporations and other stakeholders participate on an equal basis in decision-making processes and collaborate in the achievement of common goals (Clarkson, 1995; Gibson, 2000; Tracey et al, 2005). However, this simplistic multi-stakeholder collaboration approach can be challenged due to the idea that the relationships amongst actors are very often driven by factors such as unequal power relations, lack of clarity of roles and responsibilities, and tensions that limit the possibilities of effective collaboration. In Colombian mining regions, these multi-stakeholder relationships are becoming more complex as corporations are very often placed at the centre of development agendas (Cardenas, 2011).

These governance shifts have also allowed communities to become active rather than passive stakeholders and encouraged closer relationships between the community and other stakeholders like governments, NGOs and corporations. In the public sector recent public administration theories like new public management (Hood, 1991; 1995, pp. 3-4) gave more importance to citizens and their participation in public administration practices. The new public management approach led to the creation of participation mechanisms intended to legitimise public administration decisions and to help citizens make sure that public administration met social needs. Similarly, NGOs are gradually becoming integral to governance processes (Bell & Hindmoor, 2009, p. 5; Cashore, 2002, p. 503) which not only increased NGOs' responsibilities at the global and the local level in terms of public goods and services provision for community well-being but also in terms of assistance to governments to govern natural resources and to demand corporate accountability (Bell & Hindmoor, 2009, p. 5; Edwards et al, 1999).

Recent shifts in governance processes in mining regions have also led to a widening of the relationships between mining corporations and their stakeholders (Hamann et al, 2005, pp. 61-63; Mate, 2001, p. 18; Veiga, et al., 2001, p. 462). However, there are major challenges in practice. Scholars from schools of thought like corporate social responsibility, development

and environmental management argue that in reality, corporations engage with their stakeholders to pursue their own interests rather than in an effort to achieve sustainable initiatives for communities (Bebbington et al, 2008, p. 900; Hilson, 2006, p. 44; Jenkins & Yakovleva, 2006, p. 272). And weak state agency capacity exacerbates the problem.

Moreover, collaboration is posited as a win-win relationship based on permanent consensus. However, the tensions that might arise amongst stakeholders in governance scenarios have not been seriously explored. In the Colombian context, these tensions are manifested in lack of communication between mining corporations and their external stakeholders; low levels of trust amongst stakeholders; knowledge gap about stakeholders' roles and responsibilities; and lack of infrastructure and financial resources that prevent stakeholders, particularly governments from negotiating the developmental processes (Fiszbein, 1997).

This existing scenario in which the mining company is the 'star' and the stakeholders are the 'supporting cast' (Minnery, 2007) not only reveals the potential for collaboration but also the possibilities of resistance and conflict. Following Healey (2006, p. 314) and Minnery (2007, p. 341) the notion of conflict in this analysis does not necessarily imply a negative connotation. On the contrary, it is seen here as a resistance to change rather than an explicit confrontation between the parties. The following section discusses the lack of planning capacity of state agencies in a multi-stakeholder scenario and associated conflicting factors.

3. Case Study Areas

This section discusses the role of the state agencies in planning for mining regions through case studies in Antioquia and Risaralda, two mining districts of Colombia.

The state of Antioquia is located on the north Pacific coast of Colombia. It holds the largest reserves of gold, silver, coal, platinum and construction materials in Colombia. (Camara de Comercio de Medellin para Antioquia, 2010, p. 14; Sistema de Informacion Minero Energetico Colombiano, 2010, pp. 16-17). The region is going through a mining boom in recent years, which has increased the responsibilities of state agencies at the local level to deal with mining impacts.

Antioquia is also one of the largest administrative regions in Colombia. Census shows that Antioquia had an urban population of 4.340.744 inhabitants and 1.260.763 people inhabiting non-urban areas in 2005. Despite Antioquia's state agencies' active engagement in planning mining regions, there is a lack of capacity to deal with some of the most critical issues in this arena, such as employment generation, social and environmental impacts and land-use regulation. The local government's weak institutional capacity comes in the way to actively collaborate with other stakeholders to compensate locals for natural resource extraction and forge sustainable livelihood options.

The second case study area, Risaralda is a State located in the Colombian Andes mountain range. With the escalation of mining operations state agencies along with mining companies and civil society actors have collaborated to maximise social benefits in the mining boom. . Strong institutional capacity of the state agencies and active involvement of the local communities had enabled successful implementation of good planning practices in Risaralda's mining regions.

Although mining and exploration projects operating in Risaralda have major impacts on local communities, strong planning practices at the state level have helped communities benefit from mining and forge alternative and more sustainable livelihoods. According to census Risaralda has a population of 859.666 people by 2005. Out of the total population 665.104 people inhabited urban areas whereas 194.562 were located in peri-urban and rural areas. Evidence indicates that Risaralda's local public administrations hold stronger institutional

capacity than Antioquia’s local governments. This situation has allowed Risaralda’s government agencies to mitigate and better respond to mining impacts. The crucial differences between both case studies are shown in Table-1 below.

Table.1: Comparison of the Case Study Areas

	Risaralda Case Study	Antioquia Case Study
Population	859.666 inhabitants by 2005	4.340.744 inhabitants by 2005
Institutional Capacity	Strong institutional capacity	Weak institutional capacity
Developmental Outcomes	Strong planning practices that have led to: <ul style="list-style-type: none"> - Active community engagement - Active state agencies engagement 	Poor planning practices that have led to: <ul style="list-style-type: none"> - Lack of articulation between corporate and government agendas - Gaps between corporate agendas and regional development aspirations
		Capacity-building gaps: Multi-stakeholder collaboration (Corporate-government) Community engagement

4. Discussion

Empirical observations indicate that certain key factors have prevented the government from implementing effective planning practices, particularly in Antioquia case study. These limitations include lack of articulation between corporate and government agendas, gaps between corporate agendas and regional development aspirations and lack of governments’ capacity to foster community engagement.. However, other aspects such as effective communication and information governance are aspects that have to an extent enabled successful government’s interventions in planning for mining regions.

Antioquia case shows that there is little or no relationship between existing development agendas and local aspirations. Neither, there is coordination amongst stakeholders in the implementation of regional initiatives. Weak state agencies’ capacity to deal with mining related issues has major implications for Antioquia’s community development. Local public administrations struggle to effectively allocate mining royalties to tackle local issues and address community’s expectations. Similarly, they lack skills to formulate accurate community investment programs and development plans. This has resulted in a waste of resources and the implementation of initiatives that rarely meet community’s development aspirations. Instead, the implementation of irrelevant initiatives at the local level has further exacerbated the problem, creating discontent amongst locals. A case in the point is artisanal mining in Colombia. Local governments have shown inexperience to handle artisanal mining-related issues which has also had adverse impacts on communities. A group of local miners informed that

“ We want the government to support local miners. However, the government is good at giving orders but unable to come up with sustainable solutions for us. At the present time there are critical issues around artisanal mining. The government has ordered artisanal mines’ closure as part of the solution...but... What are the artisanal miners’ families going to do after closure? In addition, the government has not been able to provide us with meaningful education so that we can sustain ourselves in the long-term. Governments implement mining safety training and other initiatives that do not take into account our expectations (Interview, October 26th, 2012 Focus Group Local Miners)

Employment generation and education are two key elements of Antioquia’s development plan; however, due to lack of local governments’ capacity, the implementation of education programs keeps experiencing major challenges. Former education and employment generation initiatives have failed due lack of coordination amongst stakeholders but mostly due to the gap between these initiatives and existing regional development plans. Hence,

more articulation between these developmental agendas and existing regional needs is imperative to make them more effective. A prominent civil society activist informed when interviewed on 7 November 2012.

Late in the 90s, we thought that there was a skill shortage in the region and we embarked on up-skilling communities in mining. Out of 60 students, just 2 of them are currently working in mining; the rest of them became taxi drivers and bartenders... Similarly, high school students can hardly access tertiary education due to lack of economic resources. Indeed, there is a proliferation of educational initiatives, however, the quality of these actions and their effectiveness to meet regional needs are aspects that need major attention..

The lack of connection between local aspirations and existing development agendas, government's lack of capacity to make companies more accountable, on account of factors such as the proliferation of informal mining are factors that have exceeded local state agencies' capacity. Increase in mining activities by multinational companies in the region is causing resentment amongst locals whose livelihood options are mining-oriented. For some community members mining is considered as cultural heritage whereas for those who depend on it, this activity is seen as the only employment opportunity and therefore the only livelihood option. Most of the interviewees at the community level, in both case studies, were somehow related to informal mining. They are active informal miners, former informal miners or informal miners' family members. Although informal mining is not the focus of this paper is a case in the point to underline Antioquia's administration's lack of expertise to deal with mining-related issues.

Some informal miners and community members in Antioquia perceive large scale mining and exploration projects as a threat. The expansion of mining operations and the opening of new projects have partially occupied land that previously belonged to folk miners. Inconformity coming from community members led the government and other stakeholders in the region to take part in this issue. Governments and corporations are joining efforts to formalise artisanal miners, either providing jobs at large scale mining projects or implementing initiatives intended to compensate communities for the loss of their traditional livelihoods.

According to the community relations practitioner of a multinational company operating in Antioquia, had engaged with countrymen and miners and have carried out several agreements with these groups. These have led to sustainable projects and other types of compensation" (Community relations practitioner, interview, October, 26th, 2012). Corporate policies also reinforce this statement:

As we advance our activities in Colombia, with our joint venture partners and in some cases on our own, we look forward to engaging with legitimate activists and groups to visit our sites to form their opinions about what we are doing well and where we can do better. It is through such interventions that we can improve our interactions with the communities in which we work (AngloGold Ashanti, 2008).

The mining companies operating in the region and the state government are working in partnership to develop a community development initiative for artisanal miners. The strategy consists of four components, which are: employment generation, forging sustainable livelihoods, donations and other types of compensation. So far, 62 people have been trained in mining and have been offered a position at the mine. Others are currently participating in training initiatives in key areas relevant for the company. In accordance with the community relations practitioner this training might provide them with "alternative livelihoods and productive projects" (Community relations practitioner, interview, October, 26th, 2012). Additionally, the company is delivering money and/or negotiating other kind of compensation for natural resource exploration and extraction operations.

The state government claims that the outcomes of this initiative, particularly those based on training and education for employment generation, are tangible and communities are already experiencing the benefits of these initiatives: “Small businesses around mining such as restaurants, laundries and transport agencies have been created... (The) purpose (of these initiatives) is to help community members get organised and stop working in the informal sector” (Senior State Government Representative from Antioquia, interview, October 24th, 2012). The community practitioner of a multinational mining company operating in Antioquia, however, states that these small businesses are part of a shared agenda but they have not materialised yet (Community relations practitioner, interview, October, 26th, 2012). Interestingly, corporate and government’s statements regarding development plans implementation differs substantially.

Lack of coordination in multi-stakeholder agendas for planning mining regions is a persisting issue in most initiatives, at least in the Antioquia case. This is a factor that limits effective governance processes and prevents governments from meeting local expectations. This also demonstrates stakeholders’ unawareness of their roles and responsibilities, particularly governments’. These factors diminish stakeholders’ possibilities to better respond to issues relevant for the community. In addition, these barriers have resulted in a waste of resources when it comes to development plans implementation as governments not only lack the capacity but the resources to implement shared development agendas. Hence, multi-stakeholder agendas need to be developed on the basis of stronger governance practices and robust state agencies. On the contrary, existing limitations might not only compromise local development aspirations but also governments’ role in forging sustainable livelihoods and meet global economic expectations.

As stated above it is not only governments’ responsibility as there are contextual factors also associated with informal mining that have hindered governments capacity to meet stakeholders’ expectations. Although folk mining formalisation is a key theme in government and corporate agendas, community’s discontent remains which has resulted in major issues such as illegal groups involvement and therefore the escalation of armed conflict. These groups have permeated civil society organisations making difficult multi-stakeholder collaboration governance dynamics for planning mining regions. Although there are some governance arrangements in place, governments feel incapable to deal with and negotiate with these groups. A situation that has also compromised community engagement and local livelihoods.

Antioquia’s communities have become passive actors and cannot actively engage with other stakeholders as they feel threatened by the influence of these illegal groups. This has not only exacerbated violence in remote mining areas, but has also diminished community’s possibilities to benefit from corporate-government collaboration and therefore build sustainable livelihoods. “These illegal bands have found mining as a way to financially support their groups and are interested in controlling our territories rich in minerals and metals” (Community member from Antioquia, interview, October, 26th, 2012). Scarce community engagement mainly driven by global-local conflict dynamics and governments’ lack of capacity to deal with local tensions have also become limiting factors for planning regions in a multi-stakeholder collaboration governance scenario.

Despite existing limitations and governments’ lack of capacity to govern Antioquia mining region there are factors that could strengthen state agencies’ capacities. Identifying these factors and assist governments to enhance them in the frame of multi-stakeholder collaboration processes could potentially help stakeholders but particularly governments to overcome aforementioned barriers. The State government is currently developing alliances with tertiary institutions to implement development plans. A case in the point is a recent employment generation and infrastructure initiative that have elicited positive reactions

amongst locals (Complejo Tecnológico Minero Agroempresarial, 2012). Governance arrangements in place, specifically regular communication between involved parties and information sharing procedures to implement of these initiatives have been elicited positive outcomes for the region:

“The way we work is the following: We meet with 16 majors and formulate employment generation and infrastructure initiatives intended to respond to the region’s development plan. In doing so, we work closely with governments, companies and mining communities to agree on the initiative’s impact. We try to develop initiatives relevant for communities... However, all cases are different. There are times when those agreements are not very productive; however, when they take place, these initiatives have a positive impact on communities (Government Tertiary Institution Senior Representative, Interview, November 19th, 2012).

In fact, Antioquia’s stakeholders have strategies in place to facilitate the effective implementation of development plans, however, good governance and planning practices need to be further developed so that governments can enhance their capacity and overcome the factors that limit effective multi-stakeholder engagement which at the moment is preventing communities from meaningfully benefiting from mining.

On the other hand, Risaralda’s state agencies’ capacity and multi-stakeholder collaboration governance processes in place for planning mining regions show better outcomes. This has resulted in more sustainable legacies and livelihoods for communities. Effective governance processes have been the key drivers for development plans implementation and shared agendas in Risaralda. Amongst the factors that are currently fostering local development include existing clear public policies in place that oblige corporations to take part in local development and active community engagement:

“We do not want mining and exploration companies operating in Risaralda to extract our resources and leave the town without any legacies for the communities. We do not ask them for money apart from the royalties and taxes they are obliged to pay-. Instead, we want them to build communities’ capacity so that they can export their local goods internationally. This does not cost much to the company but benefits substantially the community” (Risaralda’s Senior State Government Representative (October 16th, 2012).

Indeed, the state government is playing a strong role in overseeing corporate social performance and supporting communities. This approach has become advantageous for locals as companies have become more accountable. Strong government’s capacity to support local communities has also resulted in more active community engagement and participation in public decisions. This has made Risaralda’s communities more capable to express their development expectations and demand corporate accountability:

“I have been working in mining since I was 7 years old. The company has provided us with some resources to participate in employment generation initiatives. I asked the company for an initiative in which we women could get some knowledge to sustain ourselves in the long-term. The company in partnership with a government VET institution implemented an employment generation strategy for women. However, we need more of these actions in Risaralda. Hopefully there are more coming” (Risaralda’s community leader, November, 23rd, 2013)

Active community engagement and stronger government capacity are factors that foster multi-stakeholder collaboration for Risaralda’s development. More importantly these factors have mainly been driven by state agencies. Hence, corporations and governments need to engage more often in collaborative approaches to build state agencies’ capacities, forge

sustainable communities and foster good planning practices in mining regions. Otherwise, existing limitations like lack of coordination amongst stakeholders, governments' capacity-building gaps to respond to local development aspirations and contextual factors will end up having adverse implications for planning mining regions impacting livelihoods of the local people.

5. Conclusions

This paper discussed the challenges of existing government capacity-building gaps and their implications for planning in Antioquia and Risaralda, two mining dependent regions of Colombia. Expansion of mining operations in natural resource-rich regions in Latin America has significantly stretched governments' capacity to respond to the demands of the local communities for sustainable livelihood opportunities by engaging with the multinational mining companies. Lack of skills in planning weakened the role of the local governments to negotiate effectively with the mining industry to shape the local developmental agenda. Shared agendas worked only for short-term due to the lack of coordination amongst stakeholders, but mostly due to weak institutional capacity at the government level.

In Antioquia case, government-led initiatives are irrelevant for locals, causing discontent and resentment. However, in regions like Risaralda in which local governments' capacity is stronger and there is evidence of good governance and planning practices those initiatives have elicited positive results for communities. This has increased the possibilities to forge sustainable livelihoods in the region.

Weak institutional capacity of the Antioquia government has come in the way to transform mining outcomes into sustainable livelihood opportunities. Inadequate infrastructure and lack of employment generation is the fostering of discontent and resentment amongst communities. The compensation for natural resources has not meaningfully achieved mining communities' development aspirations in Antioquia case due to poor planning practices and procedures in place.

On the other hand, Risaralda case differs substantially from Antioquia. The state government and other stakeholders, including mining companies and civil society actors have been able to develop adequate planning approaches to tackle mining-related issues in the region. This multi-stakeholder scenario for planning mining towns has enhanced state agencies' role in forging sustainable livelihoods in local communities, delivering infrastructure and employment opportunities. Lessons from Risaralda highlight the importance of multi-stakeholder collaboration to help governments extend the reach of its role and responsibilities. Governments alone cannot cope with existing mining impacts and mining companies and other civil society actors should provide them with support when necessary.

Finally, this paper showed the importance of planning in providing sustainable livelihood for local population in remote natural resource dependent regions of the developing countries. More than ever there is a need to take government capacity-building more seriously to adequately compensate communities for natural resource extraction and increase the possibilities to forge sustainable livelihoods for locals. Otherwise, the gains of administrative decentralization from centralized national agencies to the local government would not be able to translate into sustainable livelihood outcome at the local level.

What's Arabic for 'Charette'? Public Participation in the Baniyas neighborhood of Abu Dhabi

Surajit CHAKRAVARTY, Alhosn University, UAE

Meera MANSOORI, Alhosn University, UAE

Meera SHEHADEH, Alhosn University, UAE

1. Introduction

Public participation is a necessary part of due process in planning exercises in the United States and most liberal-democratic countries. In recent times public participation has become a part of the strategy of urban local governments in the United Arab Emirates. Abu Dhabi's Urban Planning Council (UPC), for example, has started using public participation in most of its projects. The reason for this sudden spurt of interest in high-visibility participation workshops is a matter of speculation. This paper examines the meaning of participation in Abu Dhabi, the processes involved in conducting participation, people's attitudes towards it, and the way it is constructed in a non-democratic context.

The United Arab Emirates was formed in 1971 with Abu Dhabi (city) as its capital. The country is a federal union of seven Emirates, with Abu Dhabi (Emirate, which includes the city of the same name) in a leadership role since it dwarves the others in size and resources. The local planning agency – Urban Planning Council (UPC) was formed as recently as 2004. Before that planning was carried out entirely by the Abu Dhabi Municipality (ADM) in collaboration with consultants, as needed. After the formation of the UPC, the functions of the ADM were restricted to plan implementation and enforcement.

The economy of Abu Dhabi is based primarily on oil and natural gas exports. Real estate, retail, financial services and tourism also play important roles. Over 80% of the residents of Abu

Dhabi are expatriate workers with no route to permanent residence or citizenship. Construction of the city began after independence. Some of the older areas, now about four decades old, and having been subjected to extreme weather conditions during that time, are in a state of disrepair. One such suburb is the Bani Yas neighborhood.

In recent times, local agencies involved with urban planning, have begun incorporating public participation into their process. It is remarkable that this is happening within Abu Dhabi's political context. It also raises questions regarding the purpose and nature of participation, and how it is reconciled with the local political culture.

Research questions

This research project is guided by the following questions. (i) What is the nature and role of public participation in Abu Dhabi? (ii) How is the idea of "participation" framed within a non-democratic political context? (iii) What can be done to improve the effectiveness of public participation in Abu Dhabi?

Public participation in Abu Dhabi

Abu Dhabi Citizens and the Sheikh

The Abu Dhabi government has allowed public participation at various scales. The ruler generally is sensitive to the needs of the people. Representatives of the government interact with the public in various forums. In Abu Dhabi, Sheikh Khalifa bin Zayed is represented by the Executive Council of Abu Dhabi. The council lays down public policies and development plans. It also ensures that these policies and plans are effectively implemented. In order to ensure that this is achieved, the council listens to the views of the citizens and incorporates them into the

final decisions it makes. The council is chaired by Abu Dhabi's Crown Prince (Abu Dhabi Government, 2013 b).

Abu Dhabi Urban Planning Council (UPC)

The Abu Dhabi Urban Planning Council (UPC) has begun using the idea of *majlis* to collect public opinion regarding planning. The Majlis is basically founded on tribal customs. UPC, under the leadership of Sheikh Mohammed bin Zayed, usually comes to the Majlis in order to meet the citizens. The Majlis provides a platform through which the citizens freely interact with their leaders. This ensures that the government enjoys the support of the citizens. In the Majlis, the citizens are normally allowed to raise their concerns to the government. These can be concerns of both personal and broader interests. The citizens are also allowed to give their views concerning what they think should be done in order for their interests to be met. It brings about a certain degree of consensus concerning the planning decisions to be adopted by the government planners. The needs of the citizens end up being incorporated into the planning and development decisions made by UPC. This way, the public participates in the planning and development of their emirate (Abu Dhabi Government, 2013 a).

Shahama Majlis

One such *majlis* was held in the suburban area of Shahama in June 2008. The *majlis* was held inside a tent. This particular *majlis* brought together the residents of the Shahama and Bahia. This region is a collection of four neighborhoods. These are: New Shahama, Old Shahama, New Bahia and Old Bahia. These places are inhabited by Emirati Nationals who live on residential plots granted to them by the UAE government. About 25,000 people live in these neighborhoods. During the Majlis, the residents of Shahama and Bahia engaged with both local and international planners in order to determine an effective future vision for the region. Men,

women, youth, children, the elderly, shopkeepers, teachers, widows, widowers, and other citizens of different socioeconomic and political categories all participated in the meeting. They voiced their issues and went as far as giving possible solutions to the issues. After lunch break, the local residents and the planners who had attended the meeting joined hands in coming up with a master plan for the planning of the region. They shared, prioritized and changed various ideas. Some of the ideas which were deliberated during this particular Majlis included provision of affordable housing, lighting of streets and improvement of transportation, provision of recreation facilities and among others. Both local assets and local issues were taken into consideration by the planners and the local residents. At the end of the Majlis, the planners came up with a “consensus plan” which could be used in guiding the planning of the Shahama and Bahia region (Gudaitis, 2010).

Al Ain Majlis

Another Majlis which was held recently in Abu Dhabi was the one which took place on May 2011 at Al Ain’s Al Hil. The residents of this region signed an allegiance document which was presented to the Presidential Court and the UAE government. Although this particular Majlis tends to differ from the one which was held at Shahama, it needs to be pointed out that the demonstration of loyalty to the leader of the UAE shows that the residents of Al Ain are supportive to the governance of their emirate. As a result, they feel represented in the development plans adopted by their government. This is unlike in a case where the citizens are disloyal to their leadership. Under such circumstances, the citizens feel that the government has left them out of crucial planning and development decisions it adopts (Raafat & Hoath, 2011).

2. Case background

The Bani Yas neighborhood

Baniyas area is an old area that has houses that were built in the first wave of construction after independence in the 1970s. Many of the neighborhoods and houses retain their old configurations, even though large parts of the surrounding areas have been redeveloped. The area also maintains original demographic composition, which was brought about by the system of land distribution, allowing each (extended) family to occupy an entire compound for all the members of the family. All families of the tribe were able to occupy their own compounds, allowing close ties both within families and within the tribe. Since its construction the area has not been improved and many parts have fallen into disrepair.

During the 1960s Bani Yas used to be the resting area of the Sheikh when travelling between Abu Dhabi and Al Ain. Highway E22 happened to be the first asphalted roads constructed in the Emirates in the 1960s. The revitalization master plan of the Baniyas started in the 1970 and had gone through many phases. Community facilities and retail were built in 1970s and later in 1989 public buildings were constructed for the use and service of the general public. Recently the Government of Abu Dhabi officially introduced a land marking initiative to build an infrastructure one of its kind that encompasses everything the general public has been waiting for a long time (Baniyas Revitalization Master Plan 2011).

The People (Bedouin)

The word or term Bedouin or Badaw is an Arabic word and it means desert dweller or dwellers or settlers. The word Badaw could also mean plain or nothing meaning there is nothing in the desert. But the Bedouin people who are proud and masters of desert proudly had lived in what is today called United Arab Emirates for centuries (Baniyas Revitalization Master Plan 2011). The Bedouin people are Arab and are found in the United Arab Emirates, Kuwait, Qatar,

Saudi Arabia, Oman, Yemen, Eritrea, Sudan, Egypt, Libya and other Middle Eastern countries. As elsewhere in the UAE, the social composition of Baniyas is composed of the so-called local people or the Arab Bedouin, Indians, Middle Eastern and African. According to a 2005 report the population of the city of Baniyas comprises 79% UAE or Arabs, 15% Asian born Asians, 5% of an African origin (Baniyas Revitalization Master Plan 2011 p.1).

The 2011 Revitalization Master Plan shows that at the moment the population of the city of Baniyas is 68,200. Furthermore, the document shows that there are 2,779 vacant residential plots and if the total occupancy capacity added together the population of the City of Baniyas would have been 85,900 people. The Revitalization Master Plan of 2011 once again stratified the age group of the City of Baniyas in which 71% are less than 30 years of age—which again 47% of the stated percentage are less than 20 years of age or younger. Therefore according to this calculation, the population of the Baniyas is less than 25 years. Furthermore, 36,000 of the city population which is equal 58% are from the UAE. As far as labor force goes, 63% of Baniyas are working people and age working age is stratified between 16 to 65 years old. In addition, the document shows 31,200 of the city population are engaged in active work. Meanwhile, 11% or 4,700 of the city population are school age residents (Revitalization Master Plan 2011 p.4).

Land Use

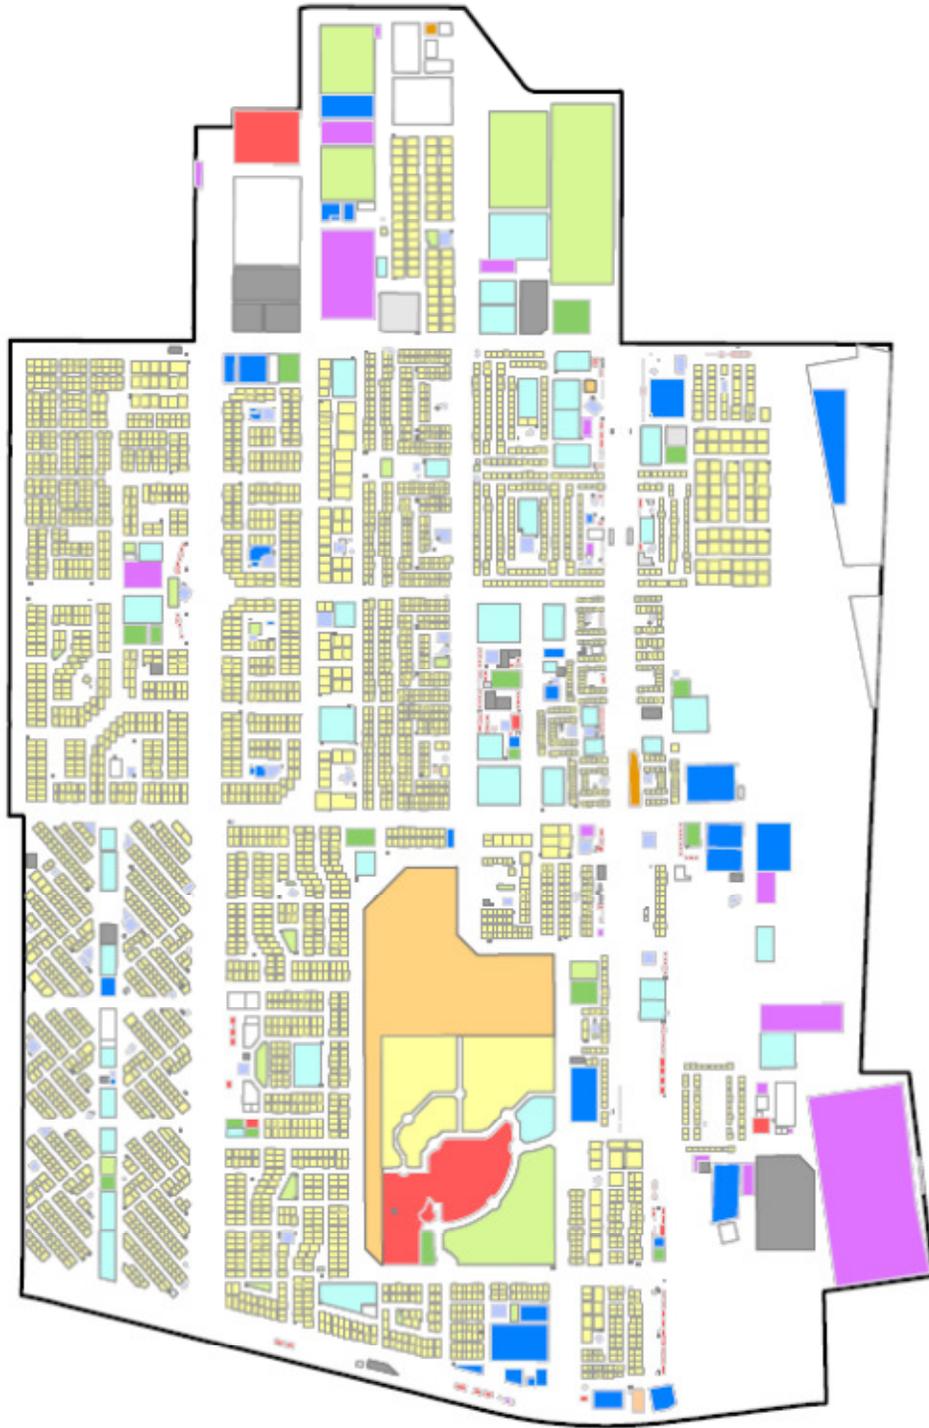

Figure 3: Bani Yas Land use map. Source: Abu Dhabi Municipality, 2012.

Baniyas area is mainly emirate neighborhood that has 6 types of land use such as, residential, commercial, mix use, governmental, school, and community center as shown in the figure below. Baniyas has old houses that are in a bad condition as shown in figure 13, and these houses are called traditional houses and they are only 1 floor but the government had allowed them to add Ground plus 2 floors—which refers to a second story level building. The commercial are located in the two sides of the main roads as shown in figure 13, and it has multi types of uses such as clinic, restaurants, trailer, and car shops.

Baniyas has a center place which is called Souq Al Baladiya where people gather to get their needs and wants such as going to restaurants, printing shops, salons and much more. These areas are mainly mixed with commercial and mix use land use, which are 3 floors. There are schools which are distributed all among Baniyas neighborhoods with different categories primary and secondary. In addition there are private and public schools.

Figure 3: Old Emirate House

Figure 4: Commercial building that on main street (Abu Dhabi Al Ain Street)

In addition, there are multi governmental uses in Baniyas such as Baniyas municipality, Baniyas police station, etc as shown in the figures below. Baniyas have community centers such as, lulu hyper market, Yas market, Baniyas co-operation, two malls (Mafraq Mall & Bawabat Al Sharq Mall), and green market.

As can clearly be seen from the above map, the Baniyas Streetscape are not designed for pedestrian friendly, to the contrary they are designed for vehicles uses. Once again, as shown in the map below the sidewalks are disconnected and there is no clear path. The streets are not safe to move from one block to another because there are a lack of sidewalks and connections.

Bani Yas parks

Baniyas areas have one main park which is divided into two areas one is designated for family and the other one is for ladies and between them there is a wall as a buffer. This park is located at the main entrance to Baniyas Abu Dhabi Al Ain road. There is one park in Baniyas which is divided into two family parks and Ladies Park. The entrance to the park is by payment for

both parks. In Ladies Park, male are allowed to enter the park but they should be less than 8 years old to enter the park. While entering to the parks the direction is clear and the view is clear from the top while walking. They have foundations, and the games are been spread randomly and there are two kinds of games swings and a slider in which such size is not enough to fit a number of people which is usually designated for one to five persons per a game. There are benches that are distributed all around the walking path, and beside it is a basket pin but there are some benches that are randomly distributed on the green space without the basket pin. The parks have two types of lighting one with one bulb and the other one with four bulbs, and they had been distributed among the park in a good way which makes the view clear.

The parks size is good for the human scale, the stairs in ladies park is unsafe because it sharp and unsafe for old ladies. The parks design is grass and tress which looks like a natural design, and there is lack of landscape, and shaded area. The design of the benches is so simple that it doesn't encourage people to use it, and the games as we had mention is small and doesn't encourage children to play and stay a long time playing because children might get bored from it quickly. In addition, the games don't encourage the child to be excited and they are not usually helpful in thinking. The games are not designed for all ages it usually is for 3- 5 years; the swing is unsafe for the young kids because it doesn't have any belt safety. Some of the games are old and damaged and might be harmful for kids. The foundation it's not modern design and it doesn't attract children's, family and ladies. The design had a walkable path that is all around the area and usually it is been used for walking as an exercise for the ladies.

Banias Park lacks essential public services such as the bathroom, mosque, and shops. They have one bathroom but it is in a bad condition, it is located far away in the buffer area beside the park and the location is unclear. There are only two water machines and the designs

are in a bad conditions. The design of the park is simple there is no attraction in the landscape. Usually people gather at the first part of the park, because it's easy access. Because the other parts of the park are all similar and nothing special to encourage people to move from one point to another. The spirit of the park is usually a quiet place. The park lacks electronic games, which doesn't encourage or attract children to use the games.

The buffer that surrounding the park on the right side is unsafe, this buffer is close to the bathrooms, which is dark and has no lighting and no any clear direction leading to the bathroom. From winter to spring—it is the season which attracts the citizens to visit the park, especially if the weather is good. In normally days if the weather was normal usually weekend's people would come to the park, which make the park active.

3. Fieldwork

We started off our research after receiving an official letter to the senior management in the Strategic Planning division of Abu Dhabi Municipality. We were then directed to the Head of Research and Studies Section. They proposed a public participation study for the redevelopment of Baniyas Park. We had meetings with them to discuss preparation of promotional materials, advertisements, and scheduling necessary tools and props. To continue the workshop in a legal way we had to get permission from BaniYas Police Station. We received this permission by writing official letters explaining the purpose of the exercise.

During the course of several meetings with Abu Dhabi Municipality we discussed the locations where the workshops would be held. It was decided that Bawabat Al Sharq Mall, Al Mafraq Public School, Baream Private School, and Bani Yas Parks would be the best locations. The Municipality also approved on our survey, poster, and consent form.

Our next step was to get approval from the mall managers for setting up the workshop. We met with the manager, Mr. Ahmad and discussed the tools and materials that would be used during the workshop. They provided some materials for us to use such as tables, chair, and an appropriate location for our workshop which would be ideal for us to use.

The next step was to contact the school. To do this, we had to get permission from Abu Dhabi Education Council. We contacted them directly, in February, 2013. They requested us to provide them with a copy of our survey, schedule, CV, passport, report for our project, and official letter from Abu Dhabi municipality. This took too long which inevitably delayed the set-up of our workshop. After approximately two months, we finally received the approval on 21st April, 2013.

We carried out extensive interviews, survey and workshop across Bani yas and collected key information and data through statistic and maps, surveys, interviews, drawings, workshops, photographs and observation. We then compiled the information and analyzed it and according to it we wrote the recommendation. The analysis gave us an idea of what the majority of people would like to have in the park and the way it should be designed. We observed that there are a lot of people giving positive response. Almost everyone liked the idea of public participation and believed that it must be carried out in their area for every development. Public participation, as we noticed is very important for every development. It provides vital information to the planner in regards to public feedback and reviews. Since the public is the end-user, they must be included in the planning as it provides key information about what they would like to change in the plan.

Workshop at Bawabat Al Sharq Mall

Workshop Day 1

The workshop has started on 14th February 2013 in Bawabat Al Sharq Mall, It included two durations, the noon duration which included two sessions. The first session from (1.30 – 2.00) and the second session from (2.30 – 3.00). As for the evening duration it included four sessions, where the first session started from (4.30 – 5.00), the second session from (5.30 – 6.00), the third session from (7.00 – 7.30) and the last session from (8.00 – 8.30).

The first session:

Was opened with few number of people; three individuals during the first half hour. The first person was as follows: he expressed his admiration for the project and his support to the idea of development and that it is worth to consider it. His suggestion was a root development of the park through: 1) Improve the appearance of the park; trees, increase the number of games, variation in the form of games, and the quality of usage. That is the games should be varied in terms of shape and size for different age groups: one year old games and older children games. 2) To improve the services of the park in terms of hygiene of public facilities; like toilets or praying room by employing a competent employee for cleaning throughout all the working hours of the park. Restaurants 3) Provide restaurants in both the family park and the ladies park to facilitate the matter for the visitor, as an order delivery from an outside restaurant consume long period. 4) The park should be divided by placing electronic games in one area and another area for smaller children. 5) There should be specialized places set for the barbeque and other places to enjoy the nature, in addition to other quiet places.

The second person was an Emirati woman who was excited for the subject and was very encouraged to participate, where she started by introducing herself and how she has a trading license "The creative women" (to explain this kind of business we must refer that the Emirate of Abu Dhabi in coordination with Abu Dhabi Chamber of Commerce has provided unique trading license for The creative women who has a heritage business or small trading business as support from the country to help women in the trading business). Later she started spotting the light on Abu Dhabi Park and the ideas for (Al Mushref Park Abu Dhabi) for its spacious area and how they go to it when having small parties, birthdays, and family gatherings. In addition, she called on the importance of taking care of providing services that help people especially women in the ladies park and to be concerned in fulfilling their desires through the provision of sports walkway in the park to assist the woman in practicing sport, especially the Muslim woman who needs a unique special place for women only and the park is a good place to do sports and to practice it.

Furthermore, it spotted the light on providing sports club in the park as there is currently no women sport club in Baniyas area, which would in turn help the woman in practicing sport. Nevertheless, she also asked for the provision of a salon for women to save time. 1) Provide a small supermarket and provide a swimming pool for children and adults and have a facility to teach them swimming. And make the park suitable for all ages. From their perspective: through the provision of initial things for woman of such Gym, Salon and a place to care for children them in a place like the park would stimulate the woman to come and visit the park, for it facilitates doing everything in one place- the park, which can be a park and a secured place and a place dedicated to women which will not keep the woman away from shopping, entertainment and exercise her hobby. Also, she praised the presence of restaurants in the form of booths in the

park in a beautifully heritage shape of food and drinks to support woman in performing her work inside the park through giving the opportunity to the "The creative women" to perform their business inside the park in an orderly manner by putting the unified logo of the park which represents the region. The logo should be distinctive and even restaurants should be using the same logo. Through the provision of Heritage Club which collaborates with the "The creative women" with the cooperation of Abu Dhabi Chamber of Commerce to support businesswomen in participating their business in this place dedicated to women and families; which encourage people to visit the park.

Provide manpower for Henna through "The creative women" who can provide the ladies who do henna or any other service. 2) Provide working women in the park .3) provide security in circumstance of lost child or thing through the development of the trust funds 4) Participation of the school in the events of the park. 5) Providing events throughout the months with cultural and heritage diversity 6) Providing educational games specialized in children's education and educational places, led by specialized guides; such as swimming 7) Provide Gulf and Arabic restaurants at reasonable prices 8) Having coffee shops but prevent smoking cigarette and anything detrimental to health. 9) Provide a special logo for the Park 10) Give a special feature for a garden. 11) Maintain the cleaning operation through the distribution of trash baskets in the park 12) Provide special places to have parties.

Third person: called for the need for development and expressed his appeal to the idea of development. 1) Attention to the hygiene of public utilities in the park. 2) Attention to the provision of different games. 3) Expansion in the facilities of the park.

The Second session:

Included two people, starting with the British woman who has never visited the park but was interested to participate to have an idea about the matter as she was interested in residing in BaniYas residential project. 1) She has seen that the project was important and necessary to be developed and stressed on the importance of having events for children and adults. 2) She has also said that the existing components in the questionnaire were excellent and encouraging to visit the park. The second person was a resident of Khalifa B: he had visited the park and thinks that it is important to maintain the park in terms of hygiene facilities and games. 3) The need to have water games. 4) Provide swimming pools. 5) Increase labor working times in the garden. 6) Lack of labors in the toilets. 7) The importance of the presence of restaurants in the middle of the park. 8) The presence of gym in the park and to be safely open. 9) Provide places for barbeque. 10) Provide a praying area for women in the family section. 11) Provide various restaurants. 12) Provide shaded places. 13) Put safety features in fountains. 14) Provide water coolers in the park and to distribute them inside the park.

The third session:

It started with one person only who lived in Baniyas suburbs. He thought that the importance of the development of the park is through: 1) Provide necessary games for the entertainment of children of various shapes to encourage the children to play and that there are not enough games currently in the park and they are not enough for the number of children especially at the weekends. The park is considered as one of the kind in the region. 2) To provide praying area for women in the family section, and to provide cleaning labors in the park around the working hours of the park. 3) Extend the working hours of the park especially at the

weekends and holidays period with the facility of opening the park at the noon time in the holiday period. 4) The park lack cleaning labors in the toilets. 5) There is no maintenance facility in the park for the games which are very old and not secure for children. 6) Expand the area of the park. 7) Provide water games like Yas water park to earn an income for the park.

The fourth session:

The session included four people of one family and the addressing of people was in the form of group discussion. They all called for the importance of maintaining the park and providing all services in the park. They started with the things that is lacking in the park. They have also called for the importance of prohibiting unauthorized food, where there are some people who sell food outside the park-which is not authorized by the official authorities. The food is exposed to the sun and might be expired. This poses danger on the children. They have also mentioned the unavailability of a cafeteria inside the park which facilitates the presence of those type people who take e of the situation to sell food. The other issue is the random selling operation inside the park by unauthorized women which is offensive to the general appearance of the park and is un civilized. They stressed on the importance of preventing them to do such thing for the public safety and that it is important that the municipality should monitor such activities of this category of people. To avoid this problem, it is importance to have restaurants inside the park, and the importance of providing booths for snacks under the monitoring of the municipality with relatively low prices that everyone can afford supported by the municipality.

The selling operation of "clothing" and other things should be prohibited in the park, as it is not suitable for the park appearance as it is a picnic and entertainment area. The park does not have enough games. In addition, there are no safety elements in the Games for the children.

The lighting in the park is very poor, which lacks the new civilization elements in the process of distribution of the games. The park does not contain the elements of civilization and progress. The natural look in the garden does not attract the individual and lack the presence of flowers and different types of landscapes that calms a person's psyche. The entry gate park is very small, so there is a need for expansion for the same, as the current situation does not help in realizing how many people are in the park and it allows people to enter without paying the fee of the park; which is not fair. The administration is not tuned on the mechanism of working in the park. The toilets are very remote and there are no cleaners in the women park which exists on the edge of the park and which is not used and the place is not clear to all. The lack of toilets tissue, hands soap and other necessary things. The lack of places for the elderly and people with special needs. There is no security in the park in the event of any accident or the loss of a child or a thing. The presence of an area right end of the park for women which is unused and the area is isolated, abandoned and planted with high altitude trees, which contains insects and snakes and it is an unsafe area and scary for the children, and it is isolated from the park by trees. There are two fountains in the park of large area and not secured for children, where lots of accidents have occurred. One of the most unfortunate events is when a small child fell in the fountain and died. There are no places for families to sit and no shaded areas in the park. There is no regular maintenance for the games in the park. The administration ignored many issued in the park is due to the reasons that they are unable to control people in the park and they are difficult people to deal with.

It is important to develop the park, and this project is a good project and important in the region. Among the improvements that we would like to stress are: 1) To prevent sales of Food & Beverages from the outside. Prevent sales inside the park in a randomly, uncivilized,

uncontrolled, and unauthorized by the municipality. 2) To provide places for the sale of food and beverages in the park which is authorized by official authorities at acceptable prices with the provision of restaurants in the park and provide machinery for drinks in various areas in the park with the provision of water coolers. 3) Provide toys for children at various ages with paintings that is loveable and entertaining and educational for children, which enhances the child to search, innovate and discover and this will take long time in playing instead of playing for few minutes only. 4) Provide practical games for children to motivate them to play. 5) Provide electronic games and other games that aim for the participation of parents in playing with children, which in turns the park to be a playing area for the whole family. 6) To divide the playing area in the park for ages of one year old to four years old, and an area for children of the age group five to ten years of age.

In addition to area for children above ten years old. So that the games would be targeted by different age groups. 7) Improve the appearance of the park through maintaining the landscape; flowers, small fountains that add nice voice in the park in addition to innovative decorations with modern and new ideas. 8) Distribute seats in the park in a nice and various designs. 9) The necessity to have security personnel to maintain security inside the park. 10) Provide security units in an event of emergency accidents. 11) To provide places for women like gyms in the open air and to distribute sports equipment in the park. 12) To provide new and secure electronic games for everyone. 13) To take care of having parties in the park and having shows all over the year to activate the park and to make a change and entertainment; such as the child day, mother's day, national and religious days, and drawing educational and heritage contests. 14) Encourage schools to have trips to the park and to participate the children in the entertainment activities by having visits to the park by the school. 15) Extend the working time of

the park in public holidays and weekends. 16) Use the alert equipments in the park in a civilized and non disturbing way in case of alert for a specific thing . 17) Put guiding plates in the park to facilitate the direction of people. 18) Taking care of environmental issues through having weekly care for trees and plants by spraying pesticides regularly. 19) Address the social issues in the park which is not accepted by lots of people. 20) Place plates in the park for the prohibited things by official authorities in a clear way, to avoid any complaints by individuals for prohibiting bicycles and playing with the ball in the park. In this way if the prohibition is by the municipality then there will be a sign for the penalties and the violation fees.

21) Have a uniform for labors. 22) Have a food court in an assigned area in the park that will not affect the appearance and the calm of the park. 23) Have games for special needs people and assign people to care for them. 24) Provide places to encourage the creative woman to do her business; like handicrafts, cooking, and painting. 25) The prices should be reasonable for everyone. 26) The development should be based on the priorities of everyone and serve different categories of individuals in the society. 27) The park should be in line with high criteria and standards for games, public facilities, landscapes, in secure and high quality standards that aim for the safety of everyone especially the children. 28) Proper lighting in the park. 29) Motivate the children to participate in the awareness operation in the park and how to maintain the hygiene in the park and help through the operation. 30) Provide a walking path for women and places for practicing sport, jogging, and running. 31) Provide events for the elderly in the park to share their experiences with children. 32) Provide relaxation sports like yoga and other exercises in the open air. 33) To have a specialized committee to extract the opinion of visitors regularly and meet with them in the park to take their opinion about improvements and complaints 34) the path

of the park should be clear and unconfusing for people through providing simple information about games.

The fifth session:

Included two people; one who lives in suburbs of Baniyas (Al Shamkha) which is fifteen minutes far from Baniyas. He said that the park is the only entertainment place in the region which he visits at the weekend. He also thinks that the development is a good initiative in terms of expanding and developing the park, and that our participation is a good thing. 1) The park lacks games, improper games, and the quality of the games is not good. 2) Maintain the hygiene of public facilities- toilets and praying areas. 3) Provide restaurants in the park to avoid buying from outside restaurants. 4) Monitor the administration to improve their work. 5) Provide shaded places with umbrellas and provide seating areas for families. 6) Improve the lighting system of the park. 7) Provide and improve games and electronic games 8) Extend the visiting hours. 9) Provide football field in the park in addition to various fields and playing areas. 10) Provide a gym in the park. And taking care of the general appearance of the park.

The second person: lives also in Baniyas suburbs and visits the park in the weekends as it is the closest park in the region. He said the park lacks football games and good games. The games are only for children at very young ages and not good for children over ten years of age, and even if they bring a ball to the park they are not allowed to play with it in the park, as it disturbs the people who are in the park. Therefore there should be special area assigned for playing football. Provide electronic games in the park. Provide restaurants and coffee shops in the park. Distribute machineries for selling beverages inside the park. Assign places for barbeque. Assign places for families. Provide places for games and seating areas.

The sixth session:

Included a group of young men of the age group 13- 16, some of them participated in the discussion and gave their opinion and answered the poll and others gave their opinion only. They were very eager for the idea and their priority was to have a football field in the park. Because playing football in the park is not allowed. They also stressed on the importance of changing the administration in the family section, who do not respect young men and they think of them as children who wants to foul around and create problems. They complained of the treatment of the guard who swears with bad words and yell at them and threaten them with the police. Their opinions includes: providing water games, contests inside the park. Extend the working hours of the park. Encourage the schools to have trips to the park. Provide seats in the park. Improve the parking areas around the park. Improve the lighting system in the park. Provide games like train, and rental bicycles in the park. Provide a swimming pool for the adults and children. Provide events in the park.

The number of participants was 18 people of different ages, nationalities, residents of Baniyas and its suburbs. The beginning was very encouraging for our project, there were various ideas and opinions about the subject and we have seen that this subject was a main concern for the residents and nonresidents of Baniyas area, which encouraged us to improve our performance and encourage them to participate. It is true that there were some session which did not include lots of people, but this is not a sign of their lack of concern about the subject, it is rather a beginning that requires more time for the people to understand the idea and participate.

The workshop continued for two more days yielding rich information in the form of quantitative and qualitative data.

6.2 Workshop at Bani Yas Ladies Park

6.2.1 Workshop Day 1

The second place we have done the workshop is Baniyas Ladies Park for two days during the weekend, Thursday and Friday. During the preparation for the workshop in the park on Thursday, there was also a workshop and awareness program by the municipality in the department of community service in the Municipality of Abu Dhabi. Their campaign was interested in raising awareness about the importance of maintaining the park and services in several parks in the emirate of Abu Dhabi, including Baniyas Ladies Park. We thought it was good to participate with them to avoid any contradiction in the workshops. After conversation with workers in the program and knowing what the campaign is about, including that they have time to talk with parents about Baniyas Park and their opinion about improving the park. So we agreed to participate with them in the workshop and to participate in the workshop with parents in polling their opinions about Baniyas Park and the ways for its improvement.

The duration of the program lasted for two hours; a TV show for children and parents as an awareness program to maintain the cleanliness and safety of parks in the emirate through the identifying the children's top priority in the park then had questions for the participation of children, then they moved to the free Atelier to express their opinion about parks through drawing. The third session was for the parents and their participation in the development of the park. We participated in this workshop by introducing ourselves to the parents and identifying the mechanism of our park and our study. The audience was large and enthusiastic to participate. The workshop included a group of women who expressed their opinions and debate about the priorities that should be present in the park and things which must be avoided. The number of

people varied between twenty to thirty people, of who participated and presented their views while others participated in the questionnaire only and others did both things.

6.2.2 Workshop Day 2

This day was accomplished with the help of the municipality, as we participated with them in the workshop session which was assigned to poll the opinions and participation of the public, in regards to their vision about the development and improvement operation of Baniyas park. The second day was different, as we made a field round to poll people's opinions for the large unexpected number of people. Controlling people today was more difficult than yesterday. Therefore, it was hard to hear them. We decided to make the field round to take the opinions on group basis.

Workshop at Bani Yas Family Park

Workshop Day 1

First group:

The first group encompassed four people- three women and one man, and their individual opinions were as follows:-

First person: of course we want to develop the park, first by providing games in the park, especially that the current games are old and few and with no change or maintenance. Improve the performance of the administration for the bad treatment of young men. Provide electrical games and provide football stadium to avoid prohibition by the administrator, especially that it is a family park-for now we are prohibited to play ball in the park. Provide restaurant in the park, as

the current one is not a part of the park. As for the hygiene, it needs improvement in terms of toilets cleanliness.

Second person: women in the family park are suffering from the unavailability of a prayer area in the park. We need the provision of praying room in the park. The hygiene of the toilets is bad as they are not clean and does not have proper ventilation. Female manpower should undertake the cleaning process. As for the entertainment element in the park it is lacked for the number of games are few and not proper for usage in terms of safety which is in bad condition and rusted. There should be new games in the park and electrical games and places dedicated for barbeque.

Third person: take care of the hygiene of toilets and provide manpower to do the cleaning process of the park and toilets around the working hours of the park, the games are old and noisy which is scary for children and annoying for people. There is no place dedicated for barbeque, therefore we need places for barbeque, and vendor machines. Set up a radio station to alarm in case of missing thing or person.

The fourth person: provide games and electrical games in the park, to be new and of various use and appropriate for all ages. Maintain the hygiene operation in the park and different facilities. Provide events like parties- educational and entertainment- in the park to improve it.

6.4 Workshop at Schools

6.4.1 The Mechanism of Workshop in Schools:

An introduction about the project and clarify the aims in ten minutes, then divide the students into groups and distribute maps to start the workshop in regards to everything needed by the workshop; park maps, transparent papers, pencils and papers for the opinion poll to start

expressing their opinions about the park for 15 minutes. Then every person start to express the ideas and discuss them in groups, then a discussion panel will be open for everyone to share ideas and opinions. Finally we conclude by the opinion poll and thank the participants and take photos if they allow us.

6.4.2 Workshop Day 1 at Al Mafraq School: Day one 29th April 2013

The workshop consisted of 25 female students who were divided into five groups and we distributed the workshop tools on them for one hour.

The first group: the students did a preliminary drawing about their visions and demands about Baniyas Ladies Park. The plan illustrated providing a walk way in the center of the park. Put entertainment games in the right side as illustrated in the drawing. Provide regular games like max flight, scissor, death train, plate. The section contained an entrance gate and in the left part also water games and theater with gate. Provide a restaurant in the park as illustrated in the planning drawing. As for the second plan, it was about the problems that they suffer from like banning older children from entering the ladies park and no discrimination among people, there should be more gates and there should be a sprayer and supervisors in the park to avoid problems and accidents in the park. As illustrated in the plan (as shown in figure 23).

Second group: the students put two plans one for the family park and one for the ladies park, the first plan included dividing the park into different sections: kids section, elder children section, with space between them, there should be ice rink in the left side and prayer area and place for parties and events. As for the right side, divide the place into three regions. The first region to be allocated for barbeque, second region for ladies gathering with coffee shop, third

region is the food court in the center of the other sections, and a fish tank in the center of the park. Provide train to transport people between sections in the park. As illustrated in the planning diagram. The second plan is for the family park, in the center of the park, there should be restaurants and coffee shops, and a train to transport people between sections to the games section, birds section, water games, and provide Sheesha for men, as illustrated in the plan. (as shown in figure 24).

Third group: the plan illustrated the division of the park and distributing services: entertainment games for children, games for elder children, modern games and a fountain with high dividers in the center of the park as illustrated in the plan. They also wished to have safety element and regulations boards and to take care for the hygiene of the toilets and expand the entrance gate. (as shown in figure 25).

Fourth group: the diagram illustrated the ideas of the students about Baniyas Ladies Park by placing security office close to the entrance and clear direction of the park, by providing clear lightings and landscape by providing more trees and flowers. Provide prayer room and restaurant section and coffee shop and games sections. Provide parking spaces outside the park as illustrated in the plan: (as shown in figure 26).

Fifth group: the students illustrated their ideas about Baniyas Ladies Park; we should have more water games, ice rink, public market, electronic games, food court, and swimming pool in the center of the park. Walk way and flowers around the park. Expand the entrance gate (two gates) as illustrated in the plan. (as shown in figure 27).

All groups shared their ideas and discussed them while focusing on certain ideas and they all shared the entertainment element for children and adults in separate sections. Provide the

safety element and female supervisors in the park. Expand the entrance gate. Attention to the hygiene of the facilities of the park. Have more services like coffee shops and restaurants. The workshop was concluded by active participation of all students and polling their opinions about our project.

School Workshops Day 2 at Al Mafraq Public School and Al Baraem Private School

The second day of the workshop in Al Mafraq School:

The workshop included twenty-five students, who were divided into groups, each group of five students and then they were given tools. The workshop started with a power point presentation for ten minutes introduction about the topic.

Workshop at AL Baraem Private School:

The workshop was for two hours in one day and included a number of female high school students and attended by faculty members. The workshop was first introduced by PowerPoint presentation about the project and about the mechanism of the workshop for students then were distributed students into groups to be discussing their opinions and discuss the opinions between students and faculty members.

4. Analysis

Analysis of quantitative data from surveys:

	Male	Female	
Q7 a	4.21	3.69	0.52
Q7 b	3.92	3	0.92
Q7 c	3.87	3.56	0.31

Q7 l	3.21	2.36	0.85
Q7 m	3.53	2.64	0.89

Table 1: Difference between opinions of genders regarding the different elements in the park.

The total is N= 303 surveys as it's shown in the table above. There are differences between the male and female opinion, in Q7(f) the males are happy and satisfied with the shaded areas but the females are not because the ladies park does not have any kind of shaded areas as there is lack of trees that help provide shade to them. In Q7(g), the males are satisfied with the games that are provided in the family park but the ladies are not because they have fewer games and some even have been removed or damaged. Q7(h) is about the prayer room in the park as there is only one provided for the males only. In Q7(j) and Q7 (k) the females are not happy with the current services the hygiene and cleanliness in the bathrooms in the ladies park.

Answers to open-ended question on suggestion for improvement

Suggestions
Located nearby mosque, and arrange the facilities
Improve the games and clean the bathrooms
Restaurants, electronic games, clean bathrooms and a cleaner and place for "Abayas"
No
Allow children to play football
Place for children for football
football stadium, skate
I suggest that the expansion of the park there are many places is important can be used for women's sports
Entertainment programs and competitions for children, Fireworks, Dances (popular arts), al yola (tradition dance)
Provide workers to clean the park to maintain the utilities
develop the entertainment, taking care of the cleanliness, and provide restaurants and café shop
electronic games, events for special needs, Cleanliness
Improved facilities such as bathrooms, locate the mosque in a near place, improving the children's games, allocation of places for barbecue
Mosque , and repair the games
The guards behavior is unacceptable and unwelcome the visitors
Build a mosque for women

full awareness to the visitors in terms of the cleanliness and maintain beautiful places
No suggestion
Please allow playing football, and provide BBQ area
make use of each part of the park
New restaurant
I suggest to have a Special theater festivals , café shop, gym, and expand the park
Mosque, and electronic games
Cultural events, fireworks, and an orderly entry Visitors
Repair the games and increase the number of games, and provide a mosque for women's, and clean bathrooms
to be in the park café shop, mosque, fire walks, and gym
All the things listed
improve the children games And attention on the safety and security
a mosque nearby in the centre of the park, and a special day for families
Please make a train without a fee, remove the swing
Clean bathrooms and provide a supervision cleaner, and make the mosque closer and put water sprinklers to moisten the atmosphere
Upscale cafes, jogging track, security, time dedicated to women
Security, time dedicated for men and family, cleanness, upscale café
Provide First Aid shop in simple cases (child injured during playing, fainting, etc.)
Music, football, cricket
Security, entertainment games , place for praying
More attention to the existing facilities within the park, Impose financial penalties on those who do not abide by the rules of hygiene especially women's bathrooms, Increase the number of workers, Barbecue places.
Lighting is not enough, BBQ area, develop the games, Attention to cleanliness of facilities
Please make a mosque, train, electronic games with free fees
we want Coffee Shop
New Games
Football stadium
Football Stadium , water land, prayer room , bathrooms, and formula 1
Grocery 24 hour
Increase the games, increase the timing , and increase the Recycle Bin
All had been mention above, only please make the entrance free and distribute water while there are visitors.
Wonderful just need to add more lighting
Clean bathrooms, mosque, horses, and emphasis on boys do not enter the park
Fees free for entrance, Security, worker cleaner
Cars train
develop the electronic games
Electronic games - Cultural events and concerts and educational events
Football stadium only for young people
Small trains, electronic recycle bin, electronic device for lost children
May Allah give you wellness everything is very good
the guards gate are not friendly dealing with visitors hope so that they be more friendly

we hope that the administration park improve the level of treatment with the visitors at the gate
The Guard don't care about the children and they deal roughly with visitors
Fireworks, contests, and festivals
Attention to the cleanliness of toilets and cleanliness of the park, set up a mosque for women
Games, BBQ area , gym
it's a pretty garden just need system and cleaning from kids and some care
Mosque for ladies, BBQ area, football and bicycles area, kids games.
the guard doesn't deal friendly with the visitors
Provide security cameras and improve the area especially the entrance
change the public announcement
Games, BBQ area , gym, restaurants
Kids games, women's mosque , cleaning services
Kids games at the center of the garden only, the voice of the gate is annoying, too many rubbish
Please cancel the guard at the door of the garden because its uncivilized view
Please pay attention to the bathrooms, Remove of the game that made a sound at entrance of the park, change the public announcement because the sound is not clear, there is no space or place for bbq.
Change the public announcement because the sound is not clear and securing better water
Plays
Cultural
Bowling
Give each visitor a map of the garden
A space for bikes ride
No suggestion
Swimming pool and games
Volleyball games
Flowers
Support the park awareness programs to serve the masses to take care of this program
Increase the electronic games
Expand the park to enjoy the park
Expand the entrance door, Cafeteria and restaurants
Please have a library corner
Sabouni Stadium
expand the park, put many restaurants
provide mosques for prayers, water games and electric, Cafeteria (McDonald's)
Swimming pool, water games, restaurants , old souq , entertainment games for adults
entertainment games for adults, Cafeteria and restaurants
Give wellness
improve the park
water games, Ice Skating Rink, entertainment games, Tomboys are not allowed to enter the park
Restaurants, electronic games and water games, clan bathrooms, festivals, prayer room, expand the parking, police women
games and clean bathrooms, souq for famous brands and change the name in to bani yas land and provide

restaurants and coffee shop and lots of games and flowers similar to Flower Garden in Dubai
clean bathroom and improve, a train that goes around the park, expand the park, provide buses for ladies with free fees, and Pest Control
Restaurants, global village, and an area for party (close area)
Sports fields and recreational games, restaurants and cafes, develop Cleanliness and bathrooms, improve the appearance of the garden
provide sport fields, improve the cleanliness of the park and take care of the park and work on it and provide games for summer and spring
clean bathroom, attention on the appearance of the park, the Women tighten security
Expand the park, park cleanliness, and provide restaurants and prayer room.
make the outside place safer for children and adults and improve the appearance of bani yas garden
Improve the bathrooms, a mosque, increase number of parking, and increase the number of security.
amendment the facilities and clean bathroom and increase the games in the park
In addition to the clinic the garden, put more security in the
Ladies Saloon
Electronic games, bicycles, expand the park, provide buses for ladies.
No Suggestion
Restaurants, Football stadium, cinema, parking, and water games
Security, entertainment games
to have in the park mosque, electronic games, and gym
don't switch off the lights earlier
cleaner bathrooms, Area for stuff, and restaurants inside the park
Restaurants, electronic games, and prayer room
Construct a gym for ladies or a club that provide all important centers, construct a " souq sha3bi" old souq
Change the games and provide or put tents for families in case of having a nap.
signification games compared to the global village
I hope that there will be a nursery building
Contests for children
Air-conditioned room
Games
New games, Entertainment competitions
Maintains the park and all what it contains
zoo, Hyde park
Fully developed
TV screen
Circus Show
Change the games and replaced with new ones
The development of games for children and perform the necessary maintenance
Increase recreational Games
Please remove the coffee shop in order to preserve the public health
Add new lighting in all parts of the park
Mosque

No suggestion
Cut the grass Regularly
No suggestion
Bring all restaurants such as, KFC, pizza huts, etc.
a specify a part of the park for ladies, and Development educational games for kids
Sort and trimming the trees of the garden and do not leave the water open
a management the follow up the requirements and the public needs, ads on TV and newspaper about the events that are going to be held in the park, the Offers for companies to do their offers in the garden
Renewal the games and replace the old pieces for safety, An area for nursery ,increase Offers for Children and Families.
expand the parking area at the family section
Repair places that are interest for tourists, a special place for sport
no signs for remembering God "Allah"
workers who have experience in dealing with the Visitors
I suggested that they repair the games and provide a train and make the place like the global village
Divide the park in to four part because its large size section for skate, Sandstone, marine, and park
Festivals and tents for sales and music event to make the park famous
No Suggestion
they should build playgrounds such as football and basketball, and they should build a skate
electronic games and sport field such as football and basketball etc. and train death
Department for animals, pedestrian corridors and sports, increase lighting, heritage
I think it would be nice if restaurants were added and perhaps have different festivals held in there as well.
Increasing the lighting in the garden
No Suggestion
Increase landscape
presents of workers clearers
Dealing with specialized companies to make new games, workers and labors, area for tradition foods and heritage stuff
I would like it to be like the other parks in terms of games
Thank you for the park
I hope that it will be implemented and give some attention
Enlarge the garden, concert halls
Change the time and extended
expand the park timing
expand the park timing
Café shop and swimming pool
Place as global village
the suggest is taking care and the system
improve the services such as the prayer room and Clearness
Games for all ages and ladies, control, provide a space for football, A small concert hall for children, gym, bathroom, Women workers for cleaning, Renal bikes, restaurant with reasonable price for all, increase the timing
rental bikes, Grocery market price, remove the trees to make the view clear, concert hall, games for all ages,

payment control while entering, provide space for football
increase the timing during the holidays, games for all ages, café, restaurant, bathrooms, prayer room, payment control while entering, allow children to bring the ball and provide a space for football
there should be a small parks in each area that serve the children daily and a Walk particular for sport
Increase the timing, games for all ages, bicycles for ladies, football, Price controls either in the restaurant or enter the park.
we support all ideas, but must take into account the entry fee, games and eating all appropriate and not expensive and misuse and The importance of the female element to be a labor Women, Attention to entertainment and diversify services, multi events for kids and ladies and serve all women ages and we want an open cinema
weekly entertainment such as (birds - plays)
a prayer room and a gym for ladies
restaurants, prayer room, new games, grocery
Children pool, Flower garden
Please pay attention to the nature in the garden
increase the games and expand the park
Regulate the entry of visitors
A special walk path for exercise, change some trees that have no useful, put a series of diverse restaurants
Safety, increase games, repair all utilities at the park
library for family, internet (wifi), theater, workshop + skills education (drawing, drawing on sand, Painted / drawing on glass and other , AC conditioner in summer, snowstorm games in summer, a Work camp for schools with the cooperation of the Scouts
Please don't allow the shisha in the garden cafeteria - please make the entrance free - please make the garden only for families because the workers make a pressure on the park.
Have BBQ area, improve the games, shaded area
No Suggestion
a special day for families and another day for ladies
A day for family and day for youth
I hope they control all around the park
swimming pool for women and men , Bicycles, Café, Beauty salon for ladies, restaurant, Grocery with a reasonable price, family visit only , space for football, Payment control while entering
provide securities all around the park , services, clearness, and facilities such as prayer room and restaurant
Adjust the bathrooms and workers for cleaning, canteen with reasonable price for all, a place for football at bani yas family park, games for adults and children, cut down the trees, order the park and lighting , a day for tradition food and yola
Development of services and the provision of services
Increase the games and distribute them all among the park and taking care of the green and the cleanliness of the park
Bani yas water world
The need for a water sports and swimming pool
Games such as, swimming pool, bicycles, roller coaster, and trumelena
Games similar to yas world and amusement games
electronic games, swimming pool for ladies and mans
Taking care for the sport tools
Section for electronics games and sections for small games. And the park should be divided for a Bbq area, games, and an area to enjoy nature and silence.

family park in which all family (father and mother) share in games and activities and have culture and education programmers, taking care of the restaurant and prayer room, small parks that will serve the area (fareej)
Develop the utilities and electronic games
God grant you success and give wellness
Provide prayer room for women's, games, and ladies saloon.
You need to improve too much and put flowers.
Put rules and electronic Recycle Bin
Every citizen or visitor have to maintain the cleanliness of the park
a private space to play football and bikes
expand the park and provide a football stadium
no comment and suggest
Improving Lighting for Al Wathba Park, Insects and soil treatment, open Bani yas park morning until 12 noon, Booth for sale
the guards doesn't deal friendly with visitors
Please put people who have experience in dealing with the public and have uniform
I suggested the most important things are safety and children games, the park is very nice but it only lack some development and safety rules.
Booth for women's cloth, perfumes, and kids toys with reasonable prices. Please lasting insecticide spraying
Expand the park
Football stadium only for young people
Large screen display to watch movies, sabouni stadium.
Display screen for matches, games, improve the bathrooms and prayer room, restaurants, coffee shop, and beautiful view
Supply of some electronic devices
In addition to the clinic the garden, put more security in the park in order to avoid problems
Build a small hotel
seed flowers and clean the mosque and bathrooms, and take the fountains for the children safety, provide water cooler to make it easier to buy
Restaurant - BBQ area - gym - games for all ages.
exclusion the café popular content in the garden immediately, re-dye the color of the garden, Access is an electronic ticket and not in manual from the park keeper, department for dangers games for older people
Taking care of the park
The park need football - volleyball - basketball, you need to increase the games and improve their level, provide bathrooms
football stadium
Enjoy
Build a mosque for women is very important
Improve the games and clean the bathrooms and build a mosque for mans and women's
a special corner for events , and a corner for shops and restaurants
I hope that they repair the electric games, A place for barbecue

Thematic Map of Qualitative Data

Opinions collected at the Family Park

Opinions collected at the Ladies Park

Recommendations based on opinions collected

Based on the data collected from the workshops and surveys we find that the following improvements are most desired by those visiting the park.

- Providing games:

The majority of users prefer to have many and different types of games that serves all age groups and genders such as electronic games like in Theme parks and arcades; these are especially popular amongst the teenagers. Also other entertaining games and play grounds for the very young ones. The games should be distributed along and around the park and in sections, for example a separate area for playing football and another for kid's playgrounds. In addition, the games should adopt the modern style that provide higher standards of safety and entertainment at the same time.

- Provide cleaners

The park visitors/users have suffered from the lack of cleanliness of the public bathrooms, the mosque and also some areas in the park; and so they had the suggestion to have cleaning hours during the visiting hours and not only when the park's closed.

- Offer more and better services

The park visitors claimed that there is no designated rooms or places for the ladies to pray in. In addition, a food court is very much needed in the park and in both (family and ladies area) also a coffee shop/café and some vending machines (snacks & drinks) that could be distributed along some areas of the park.

- Health Club

Requests that a swimming pool located at the side of the park with providing some instructors and trainers and a gymnasium located in the right side of the park which

is would be very useful as there are some unused areas/plots. In addition, the ladies requested a saloon.

- Instruction and guidance

Abu Dhabi Municipality should provide some instruction and rules by using signage (what's allowed and what's not) - fees, costs & expenses, behaviours, types of facilities available and directions.

- Awareness

Spread awareness by advertising events that help preserve public property (games, vending machines, bathrooms cleanliness and mosques). In addition, help protect the environment and how to conform to the instructions of the garden.

- Management supervision

Supervision of property and behaviours of the visitors, fair and unbiased attitude and equality between visitors. As some of the visitors have complained from such mistreatment and have asked for nothing but pleasing results.

- Accessibility

Access to the park should be easy and clear, by developing a better street system and by providing proper sidewalks. Providing special areas for the drop offs and pickups and also areas for bus stops and parking; in order to avoid traffic jams and crowd.

- Landscape

The landscape needs improvement in the type and design, to attract visitors. Using flowers, shrubs, landscape shaded areas, lighting, and the addition of fountains.

- Events

There should be an agenda for events in the park such as cultural events, national events, children and family; these different events can come off monthly or annually.

- Emirati culture awareness

The culture can be revived and shown through hosting several events and providing information booths and kiosks to display the different traditional materials used, food consumed and history lived.

- Neighborhood pocket parks

The residents of Bani Yas have suggested that small parks and green pockets in their neighborhood is necessary very useful. This way the neighborhoods get a unique and environment friendly look and also people can use them on a daily basis.

Conclusions

In the concluding section we attempt to answer the three questions with which we started the project. (i) What is the nature and role of public participation in Abu Dhabi? The Municipality of Abu Dhabi deserves credit for embracing the idea of public participation and supporting research on the topic. There is no doubt that organizing charrettes will make planning endeavours more sensitive to people's needs. Our research also shows that there is an appetite, amongst the city's residents – both locals and expatriates – for telling their story and having their opinions heard. The people who participated in our workshops, for example, were highly appreciative of the fact that the Municipality was involving them in plan-making. If, however, the participation process is not extended to include non-citizens of all socio-economic classes, it runs the risk of appearing exclusionary.

(ii) How is the idea of “participation” framed within a non-democratic political context? Islam stresses the importance of consultation – known as *shura*. This is not really a version of

“democracy” as some have argued. But it is certainly considered a way for the government (or any decision-maker) to make better decisions, consider all perspectives, and create consent, thereby earning legitimacy for the decision. The Qur’an dedicates a whole chapter to *shura*. According to Al Raysuni (2011) *shura* serves the following purposes: (1) determining a correct or the most correct course of action, (2) release from the tyranny of subjectivity and selfish whims, (3) preventing high-handedness and tyranny, (4) teaching humility, (5) giving everyone his due, (6) promoting an atmosphere of freedom and initiative, (7) developing the capacity for thinking and planning, (8) increased readiness for action and support, (9) promoting goodwill and unity, and (10) willingness to endure undesirable consequences. Thus *shura* provides a bridge between planning theory emanating from the liberal-democratic tradition and Islamic thought on representation and consultation.

(iii) What can be done to improve the effectiveness of public participation in Abu Dhabi?

Currently the process of conducting a public participation event is complicated, involving a series of permissions. It can be simplified through enabling legislation that allows the UPC, ADM, DOT (and other relevant agencies) to sanction participation exercises. It is strongly recommended that the participation process be sanctioned by a decree and institutionalized in plan-making and implementation procedures of all agencies involved in urban planning. Further, the participation process should be expanded to include all residents of the city. The participation process ought to return to the community at least once to report how the suggestions were incorporated in the plan, and to get another round of comments. Finally, participation has the potential to become proactive. Communities can be encouraged to envision their parks, streets, markets etc. on an ongoing basis.

4	Events for parents & kids			11	Events for females	
5	Special need and/or orphans			12	Events for Senior citizen	
6	Entertainment Events			13	Health awareness programs	
7	Cooking Events			14	National themed events	

Q5. Write your opinion and suggestions that can help to develop the park:

Additional comments / suggestions

Q6. Do you have a suggestion for a name that this new park could be known as?

Suggested name for New Park

THANK AND CLOSE INTERVIEW

Village Community: A Planning Practice of Local Urbanization in Countryside Areas in Southwestern China

Shang CHENG ¹, Nankai XIA ¹²

¹College Of Architecture And Urban Planning, Tongji University, Shanghai, China

e-mail:12csbwb@tongji.edu.cn

² Tongji Urban Planning & Design Institute, Shanghai, China

Abstract

Introduction and objective: in countryside areas in Southwestern China, especially in Sichuan province, a large amount of villagers are still residing in the small, dispersed villages. These villagers are not able to lead the equal quality of lives as the citizens in Chengdu, the central city in Sichuan province. To solve this problem, this paper introduces a typical planning practice in Chengdu, which is called “village community”. Village community aims to realize local urbanization, by constructing the new-style village in the countryside, which still locals in the countryside areas, but has fulfilled the same functions of the urban communities. Two typical village communities in Chengdu are presented. **Material and methods:** key variables to improve the inclination of villagers to immigrate to village communities are interpreted. These variables are set up as the independent variable, and the rate of villagers residing in village communities (the number of villagers residing in village community divided by the number of the total villagers in the town) is set up as the dependent variable. These data are analyzed by using the statistic methods of correlation analysis and multiple regression analysis, in the SPSS software environment. **Results and Discussion:** the main factors that motivate villagers to immigrate to village communities are number of new village communities and Proximity to enterprises, which imply that housing condition and occupation are the first two important things for villagers.

Keywords: village community, Southwestern China, local urbanization

1 Research Background and Objective

Up to 2012, the rate of urbanization in China has exceeded 50%, nevertheless in countryside areas in Southwestern China, especially in Sichuan province, a large amount of agricultural people are still residing in the small, dispersed villages. These villagers are not able to lead the equal quality of urban lives, which contain the opportunities of jobs, education, medical treatment, and the agreeable infrastructures such as sewage factories, roadways, for instance. However, it's not realistic to push the villagers into cities, which have limited capacity of inhabitants. As a result, Chinese government intends to fulfill the urbanization of these villagers locally, which is defined as *local urbanization*. Local urbanization means that the villagers are still residing in the villages, but their life quality is as high as that of citizens. The villagers can

also work in the enterprises running in villages. This type of urbanization prevents villagers from rushing into cities, without occupation and housing, as the tragedies staging in the cities of Latin America.

A typical planning practice aiming at local urbanization is presented in this paper, which is defined as *village community*. Village community aims to fulfill *local urbanization*, by planning and building a new village, which still locals in the countryside areas, but has the whole urban functions, as apartments, primary schools, medical service centers, roadways, sewage factories. Village community is also close to enterprises, where the villagers work in. As a result, villagers who live in village communities are able to lead an urban life. These villagers can be named as *countryside citizens*.

As the strict land policy is running in China, farmland is forbidden to converse to built land, which can be used to construct buildings. But each villager possesses the private housing land, the area of which is so great, approximately 50-80m² by person. If villagers are willing to immigrate to village community, their housing lands can be collected and conversed to build the new village. Because villagers will be residing in the apartments, which means that the land area of residing is approximately 30-50 m² by person. The residual land can be used to build enterprises, infrastructures, public services, and so forth. In other words, village community does not need extra land, but has satisfied the land demand of urban functions. As the policy of land converse is allowed in China countryside area, the planning and building of village community is feasible, without offending the land policy.

2 Case Studies

The case of village community is selected from Chengdu, the center city of Sichuan Province, over 60% population of which is still residing in the country area in 2011. The problem is that most of the villagers who give up the agricultural work want to enter the center city to get higher-salary jobs, while there are not as much as the number of occupations as they need. As a result, they have to be engaged in some lower-salary and unstable jobs, such as carriers of burdens, waiters in small restaurants, and so on. They also cannot live in the center city, as the rent of housing is so high. Since that, they have to return to their home at villages every night, which are several miles far from the center city. This problem increases the commute cost of villagers, and results in heavier traffic jams on the roads connecting the urban area and the country area. Conclusively, local urbanization of villagers is what Chengdu needs right now. Therefore, the planning and construction of village community has been fulfilled in Chengdu in recent years. By 2011, 1,633 village communities are planned, and 1502 village communities are constructed; where over one million of villagers are already residing.

Two village communities in Chengdu are presented. The first one is *Taiping Village Community*, located in Xinping Town, Xinjin County. This village community is built on the local site, close to the urban area of Xinjin County. The total size of the village community is

about 8hm², and the number of villager about 3000. All of the villagers have immigrated to the new apartments of six floors, and the personal housing area is about 40m². All of the work force are occupied, 85% of which occupy in the enterprises of secondary and tertiary industry. Besides, all the farm land of villagers is centralized to be running together by an agricultural cooperation founded by the villager themselves. The cooperation hires the 15% of the local work force who are still anticipate the agricultural work, and skilled farm workers from the outside. In order to raise the revenue, the economic crop is cultivated, such as organic vegetable and fruits. As a result, each villager does not need to anticipate the agricultural work, but enjoy the rent of land yearly paid by the cooperation. The personal revenue of villagers is over 7000 rmb in 2011.

Figure 1: bird-eye view and Google satellite map of Taiping village community^j

The second one is *Heming Village Community*, located in Liujie Town, Dujiangyan County. According to the unique landscape, this village community is not centralized to a single site, but is divided into seventeen clusters. Several buildings of two or three floors with traditional style are built, instead of apartments with modern style. About 86% of the villagers have immigrated to the new buildings. A license of the land property confirmation is certificated to each villager, which assurance the right of villager to use the farm land. As a result, villagers can rent their lands to the cooperation, or do the agricultural work themselves. In fact, almost all the farm land is centralized to the cooperation, which cultivates flowers and develops country tourism.

Figure 2: bird-eye view and the building picture of Heming village community^{jj}

3 Methods and Material

Village community contains various urban functions, but what are the most important ones to help improve the life quality of villagers, and which factors mostly impact the willing of villagers to immigrate to village communities? In order to know that, some related variables are selected to check and interpret. As most of village communities are located in towns which almost have small size, and village communities and towns have some conditions in common, some factors are based on towns. The factors include:

(1) **Number of new village community in town:** it explains how number of village communities influences the willing of villagers to immigrate to village community. In common sense, villagers incline to immigrate to new communities.

(2) **Proximity of town to central city:** it explains how proximity of town to center city influences the willing of villagers to immigrate to village community. It is represented by linear distance from town to central city. The higher distance it is, the lower the proximity is. As Chengdu is a radial city, and also has a radial road system, linear distance represents proximity of town to center city. In Chengdu, towns close to center city often develop better than the ones far from center city, and villagers in these towns often lead a better life.

(3) **Proximity of village community to roads:** it explains how condition of transportation of village community influences the willing of villagers to immigrate to village community. If village community is closer to roads, villagers can travel more conveniently. It is represented by linear distance from town to various levels of roads, including highway exit, province road, town road, and country road. If the distance is no more than 500m, then it is defined to close to roads, otherwise it is defined to be far from roads. This proximity is been quantified by given an estimation index.

(4) **Economic level of town:** it explains how economic level of town influences the willing of villagers to immigrate to village community. It is represented by GDP of town yearly.

(5) **Revenue level of villagers in town:** it explains how revenue level of villagers influences in town influence the willing of villagers to immigrate to village community. It is represented by personal revenue yearly.

(6) **Size of town center:** it explains how size of town center, which in other side means the developing level of town center, influences the willing of villagers to immigrate to village community. It is represented by the size of built area of town center.

(7) **Proximity to enterprises:** it explains how proximity to enterprises influences in town influence the willing of villagers to immigrate to village community. If village community is closer to enterprises, villagers can commute to enterprises more conveniently. It is represented by linear distance from town to various enterprises, including industry sites, tourism sites and agricultural sites. If the distance to these sites is no more than 500m, then it is defined to close to enterprises, otherwise it is defined to be far from enterprises. This proximity is been quantified by given an estimation index.

(8)Capacity of primary schools in town: it explains how capacity of primary schools in town influences the willing of villagers to immigrate to village community. It belongs to public service facilities. It is represented by the number of student positions in primary schools.

(9)Capacity of medical service centers in town: it explains how capacity of capacity of medical service centers in town influences the willing of villagers to immigrate to village community. It belongs to public service facilities. It is represented by the number of medical care beds in hospitals and clinics.

(10)Capacity of sewage factories in town: it explains how capacity of sewage factories in town influences the willing of villagers to immigrate to village community. It belongs to public infrastructure. It is represented by the daily ability of sewage factories dealing with sewage.

These variables are set up as the independent, and the factor **inclination of villagers immigrate to village communities** (the number of villagers already residing in village communities divided by the number of the total villagers in town) is set up as the dependent variable. 169 towns of Chengdu (which has 223 towns in total) are selected to be the samplings, so the sampling rate is 75.8%.

The data of these variables are collected from Bureau of Planning in Chengdu, in 2010. These data are analyzed by using the statistic methods of correlation analysis and multiple regression analysis, in the SPSS software environment.

Table 1 Variables and their contents

Variables	Estimation index	Variable Abbreviations
Number of new village community in town	Number of villager community constructed in town	Cq
Proximity of town to central city	Linear distance from town to central city (km)	Cd
Proximity of village community to roads	Close to highway exit: 9 Close to province road: 7 Close to town road: 5 Close to country road: 3 Far from roads 1	Tr
Economic level of the town	GDP of the town (million RMB)	Ec
Revenue level of villagers in town	Personal revenue per villager by year	Pi
Size of town center	Size of built area of town center(km ²)	Ua

Proximity to enterprises,	Close to industry sites: 8 Close to tourism sites: 6 Close to agriculture sites: 4 Far from enterprises: 2	ln
Capacity of primary schools	Number of student positions in primary schools	Ei
Capacity of the medical service centers	Number of medical care beds in hospitals and clinics	Hi
Capacity of sewage factories in the village community	Daily ability of sewage factories dealing with the sewage(ton/d)	Wi
Dependent variable: inclination of villagers immigrate to village communities	Number of villagers residing in village community divided by number of total villagers in town (%)	Pc

4 Analysis and Results

The analysis model is:

$$Pc = f(Cq, Cd, Ec, Pi, Ua, ln, Ei, Hi, Wi, Tr) \quad (1)$$

As the independent variables have different dimensions, they are standardized by converting to the natural logistic form, and then the model can be demonstrated as the linear from:

$$\ln Pc = \beta_0 + \beta_1 \ln Cq + \beta_2 \ln Cd + \beta_3 \ln Ec + \beta_4 \ln Pi + \beta_5 \ln Ua + \beta_6 \ln ln + \beta_7 \ln Ei + \beta_8 \ln Hi + \beta_9 \ln Wi + \beta_{10} \ln Tr \quad (2)$$

$\beta_0 - \beta_{10}$ are the constant.

These variables are input into the SPSS software environment and seven independent variables are finally reserved: Revenue level of villagers in town(Pi), Number of new village community in town(Cq), Proximity to enterprises(ln), Capacity of primary schools(Ei), Proximity of town to central city(Cd), Size of town center(Ua), Proximity of village community to roads(Tr).

The result of the multiple regression analysis is that:

$\ln pc = -0.263 \ln Pi + 0.599 \ln Cq + 0.570 \ln ln - 0.362 \ln Ei - 0.193 \ln Cd + 0.167 \ln Ua + 0.447 \ln Tr$ (3) the relation coefficient value $r^2 = 0.890$, and the results passes the student's t test, under the 95% confident interval. It indicates that this equation has an excellent linear relation. Besides that, the result nearly fits the normal distribution.

The result of coefficient correlation check shows that these variables do not have the correlation, except Cd and Pi (0.659). This verifies the hypothesis that in Chengdu, towns close to center city often develop better than the ones far from center city, and villagers in these towns often lead a better life.

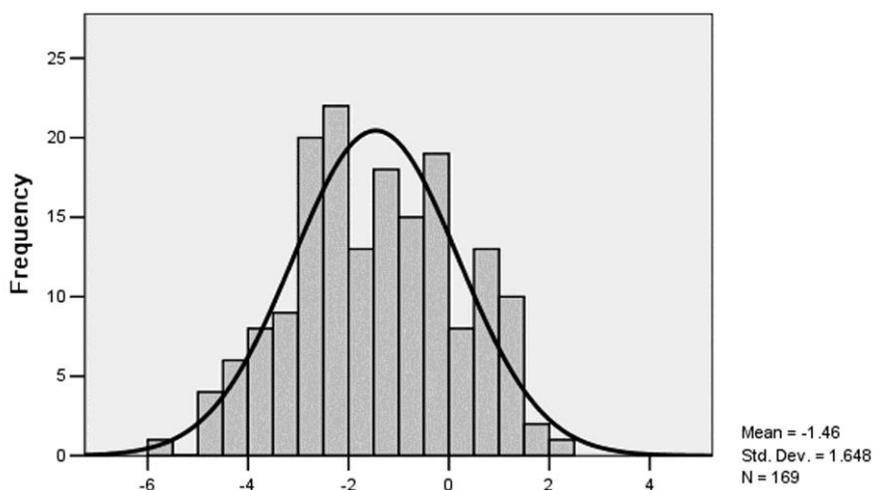

Table 2 the coefficient result

Name	Unstandardized Coefficients		Standardized Coefficients	t	Sig.
	B	Std.Error	Beta		
(Pi)	-.263	.074	-.903	-3.2540	.001
(Cq)	.599	.070	.425	8.555	.000
(In)	.570	.162	.333	3.511	.001
(Ei)	-.362	.060	-1.073	-6.050	.000
(Cd)	-.193	.074	-.248	-2.612	.010
(Ua)	.167	.072	.337	2.301	.023

5 Discussion

The result indicates the weights of each independent variable, which imply its importance to the willing of villagers to immigrate to village community. Among these factors selected, Cq, In,

Tr, Ua have positive impact, and Cd, Pi, Ei have negative impact.

The variable of Number of new village community in town (Cq) has the most positive impact (0.559), which indicates that the planning and construction has a great impact on the willing of villagers to immigrate to village community. It is proved that villagers have great inclination to the new communities, because new communities always have good housing condition.

The variable of Proximity to enterprises (In) has also the high positive impact (0.570), which indicates that proximity to enterprises is also very important for the villagers residing in village communities. As most of villagers occupy in enterprises, as a result, the closer village communities are to enterprises, the more villagers are willing to immigrate to village communities, as it's more convenient for them to commute.

The variable of Proximity of village community to roads (Tr) has a positive impact of 0.447, which is also reasonable. If proximity of village community to roads is poor, villagers incline to still live in the ancient house, where it is closer to farmland, and still occupy in agricultural work. If proximity of village community to roads is poor is better, then villagers are able to travel to other places to work, like enterprises of secondary and tertiary industry, even to town center or the center city.

The variable of Size of town center (Ua) has a positive impact of 0.167, which indicates the influential of size of town center on village communities. As plenty of village communities are close to town center, and the size of town center represents the developing level of town center, the greater the town center is, the more inclination of villagers immigrate to village communities, aiming to work at town center and share the town facilities.

The variable of Revenue level of villagers in town (Pi) has a negative impact of -0.263. The reason is that, according to the census of Chengdu (2011)ⁱⁱⁱ, among the average total revenue of villager per year, the fractions of salary revenue, family commercial revenue(including farming revenue) and property revenue are 31.2%, 56.3%, 12.5%; and the fraction of farming revenue is 41.3%. This structure of personal revenue indicates that farming revenue is still the most important revenue for villagers. Because only 43.7% of farm land in Chengdu has been conversed and centralized, 56.3% of farm land in Chengdu is still cultivated by villagers themselves, individually. As a result, villagers incline to live in ancient houses in order to cultivate their farm land more easily, but not to immigrate to new village communities.

The variable of Proximity of town to central city (CD) has a negative impact of -0.193, which means that villagers residing close to the center city incline to immigrate to village communities. The reason is that villagers residing close to the center city usually do not occupy in agricultural work, but in secondary and tertiary industry. As a result, residing in new village communities is more convenient as their lives are totally urbanized. Oppositely, villagers residing far from the center city still occupy in agricultural work, as there are not as many enterprise as they need in towns. Therefore, they still prefer to reside in their ancient houses.

The variable of Capacity of primary schools in town (EI) has a negative impact of -0.362. That means the higher capacity of primary schools; the fewer villagers incline to immigrate to village communities. The reason is that there are still plenty of primary schools located in villages, which close to villagers' houses but commonly have small size and low quality. If these primary schools are merged into greater ones, the new primary schools will have greater size and higher quality, and villagers prefer to reside in village communities, as the new primary schools are usually close to village communities.

The variables excluded by SPSS are Capacity of medical service centers in town (Hi), Capacity of sewage factories in town (Wi) and Economic level of town (Ec). It indicates that these variables have no relationship with the dependant variable of Inclination of villagers immigrate to village communities (PC). The reason why Capacity of medical service centers in town is excluded is that almost all villages have their own media centers or clinics with small size and low level, that means villagers can share the basic medical service neighbor to their houses. As a result, they do not need to immigrate to village communities which are often located beside high-level hospitals. The reason why Capacity of sewage factories in town is excluded is that sewage factories in town mainly deal with the sewage in town center, while the sewage from villagers is treated by themselves, by pouring the sewage into rivers, pools and farm land directly, or treated by small sewage stations simply. The reason why Economic level of town is excluded is that most of the GDP of town is from the industrial parks, which do not hire many local villagers.

6 Conclusion

The main factors that motivate villagers to immigrate to village communities are number of new village communities and Proximity to enterprises, which imply that housing condition and occupation are the first two important things for villagers. These two factors are also the fundamental urban functions that a city provides to citizens. Villagers incline to immigrate to village communities mainly because these village communities have good housing condition and close to the enterprise where they can work. As a result, a feasible way to improve local urbanization is to plan and build high standard village communities, especially with good housing conditions. The surplus land after land conversion and centralization can be used to build enterprises, which can provide more suitable jobs for villagers, especially in secondary and tertiary industry, which helps improve the salary revenue of villagers. This also helps villagers to leave from farm lands, and improve their property revenue.

Besides that, village communities would better be close to roads and town centers, which improve the commute of villagers, and help villagers to share the urban facilities in town centers. The public facilities and infrastructures in villages as primary schools, media centers or clinics, small sewage stations, should be centralized and merged into something of greater size and higher level, and moved beside to village communities. As a result, villagers can

share the better public service and infrastructures.

Synopsis

This paper compares the urbanization and planning in the two sunshine states of Florida and Queensland highlighting the similarities and differences, evaluates how effective the growth management programs have been, and examines the recent changes and the challenges they bring to the respective states.

1. Introduction

The states of Queensland, Australia and Florida, U.S. have distinct similarities in terms of physical characteristics such as geography and climate as well as population growth trends, development history and structure. In fact, some parts of South Florida such as Fort Lauderdale and South East Queensland (SEQ) such as the Gold Coast are virtually indistinguishable. Both states are late bloomers and both are experiencing higher than average growth rates within their respective countries as a result of being desirable tourism and retirement destinations, both of them have very fragile environments and potentially growing vulnerability to climate change, and both try to cope with the development pressures they are facing by using growth management programs. However, they are different in terms of the planning regimes, central-local government relations, and patterns of urban/local politics.

In Florida, historically the 1985 Florida Growth Management Act (GMA) governed the growth management process whereas in SEQ, Australia's fastest growing region, the latest successor of the Regional Growth Management Framework started in the 1990s, the 2009 SEQ Regional Plan provides the framework for managing the expected growth. On June 1, 2009 Governor Charlie Crist signed the Community Renewal Act as Florida's new growth management legislation despite widespread opposition from environmentalists and local governments. At the same time the Queensland state election in March 2012 ended fourteen years of Labor government and brought to power the Liberal National Party (LNP) and major changes in planning regulations was set in motion. Freestone (2004) observes that historically transpacific exchanges of ideas have been more pronounced in times of prosperity. This may be about to change. These simultaneous developments arising during the aftermath of a global financial crisis make the evaluation and comparison of the planning regimes of these two states very pertinent and timely.

In this paper we first examine the relationship of urban development patterns of Australia and the U.S. and highlight the similarities and differences between the characteristics, development histories, planning regimes and growth management programs of the states of Florida and Queensland. Then we examine the latest developments in the planning frameworks and set up a framework for further evaluation and comparison of the two states.

2. Urbanization and Planning in the United States and Australia

Physical similarities aside, political structures and planning regimes of Australia and the U.S. are so different from each other that it is amazing they can produce so similar urban areas that are sometimes virtually indistinguishable. It makes one wonder whether planning regimes and political structures make a difference at all. A somewhat related question raised by the similarities is whether these similar outcomes are coincidental or intentional due to taking American cities as a model for newer developments in Australia. Most of these questions are beyond the scope of this paper, but they provide a framework for the comparisons we present.

There are many basic similarities between the two countries such as comparative size and isolation, new world colonial history, subsequent common cultural background and language, democratic-capitalist political and economic structure, and highly urbanized developed economies (Freestone 2000: 302) with large percentage of foreign born populations¹ (U.S. Census Bureau 2009a) that make the earlier developed U.S. the ideal model for Australia (see Table 1). The land area of the continental U.S. (48 contiguous states) is almost equivalent to the land area of Australia. However, population of the U.S. is over 13 times and density is over 10 times that of Australia. Furthermore, population distribution is more uneven in Australia (Margerum 1995). Gross Domestic Product in the U.S. is more than 10 times, Gross National Income in Purchasing Power Parity is 30 % and median household income is almost 32 % higher than Australia. Given these similarities Bell and Bell (1993: 82) state that “the model that seemed to be ‘natural’, given Australia’s geography and its relative wealth, was the American, or, at least, the Californian city.”

Table 1. Australia and the United States in Numbers

	United States	Australia
Area (km ²)	9,809,155 (total) (3,537,421 sq. miles ¹) 8,080,464 (continental) (3,119,059 sq. miles)	7,682,300 (2,941,285 sq. miles ¹)
Population (2012) ²	313,900,000	22,000,000
Density (people per km ²) ²	33 (89 per sq. mile ¹)	3 (7 per sq. mile ¹)

Looking up to the “other” new world in addition to or instead of the United Kingdom is a long standing tendency in Australia. According to leading Sydney planning propagandist George Taylor in 1914 “America was ‘indisputably the land of the up-to-date’... America was a nation ... ‘inspired by the same motives as inspire us, and [it] is doing things generally in almost every sphere of activity as we would do them. It is the great university in which we should receive our schooling on how to prosper and progress’” (Freestone 2000: 306). Freestone (2004: 195) reports that “[b]y the 1920s ... informed planning commentators were actively promoting American and Australian cities as comparable “new world” environments.” Facing similar problems of sprawl, uncoordinated infrastructure provision and traffic congestion in the 1920s leading planning advocates in Australian cities “turned away from small area planning schemes based on British precedents towards an American-style master planning approach” (Freestone 2000: 301).

Post-war period witnessed conscious examination of the U.S. as a model. Visits from American professionals to Australia and visits of Australian planners to the States advanced

transfer of ideas. After visiting the U.S. on a Fulbright Scholarship Melbourne planner-economist George Connor concluded that “American technical know-how, optimism, and vision could assist in the resolution of the main problems facing Australian cities—traffic congestion, inner-city redevelopment, suburban infrastructure, and better planning systems” (Freestone 2004: 199). He wrote:

It is in the United States that we find civic problems more akin to those facing Australian cities and it is here where we have most to learn. One cannot but realise that America’s civic problems today are ours tomorrow. Many are, in fact, already comparable. Our traffic problems and general mode of living have so much in common (Connor 1955: 28).

Despite warnings by planners such as Rod Fraser against “an uncritical embrace of American solutions for a country of smaller population and resources” Australian urban development followed the model of freestanding malls and freeways along with the rest of the developed world (Freestone 2004: 200). By 1960s British planning influence in Australia was making further way for American ideas (Freestone 2004). Wright (2001: 49) mentions the urban freeway and corridor development ideas of the late 1950s and the 1960s, exported from the U.S. as the “solution to the problems of the cities.”

This trend continued in the 1970s. Among exported American influences in this period Freestone (2004: 204) counts “environmental management, landscape planning, public participation, transference of development rights, and human-scaled place-sensitive planning.” This was followed by “metropolitan area planning through urban redevelopment, systems planning and corporate planning techniques, the new urbanism, land use–transport integration, and growth management” (Freestone 2004: 205). Ward (2002: 384-385) claims that “given so much common ground between Australian and American suburbs, it was inevitable that the new urbanist philosophy would provide the design underpinning for urban consolidation.” Minnery and Bajracharya (1999: 36) note that “The initial visions for master-planned communities (MPCs) in the SEQ have been influenced by those in the U.S. particularly from Florida and California. Many developers and designers made trips to the United States to gain ideas. Some developers saw parallels between canal estates in Florida and the potential to develop such estates on the Gold Coast... In addition, like the growth of MPCs in sunbelt areas of the U.S., interstate migration to South East Queensland contributed to the planning and development of MPCs here.” Freestone (2004: 207) points to “the resort town ‘with old-fashioned neighbourhood values’ of Seaside near Coolumb on Queensland’s Sunshine Coast, with the architecture a fusion of the American Seaside and traditional Queensland homes” as “a direct American inspiration.”

The brief history presented above shows that urbanization and planning in Australia have been influenced by American ideas and models for a long time. However, this does not mean that Australia borrowed everything “as is” from the U.S. Even by 1920s some planners such as Saxil Tuxen warned that Australia could learn from “America’s good examples without falling prey to . . . its many faults” such as “its relatively laissez faire organization of utilities” and the “ugly face of commercialism” (Nichols 1998: 667). After examining Sydney’s suburban employment centers, extending Mees’s (1994) argument Freestone (1997: 256) concludes that “American development trends, even in the large-scale decentralization of retailing, have still not reshaped metropolitan form and structure in a radical way since the turn of the century.” Freestone (2004: 190) agrees that “American ideas have been demonstrably assimilated into Australian planning theory, ideology, and practice over an extended period” however “Australian responses were not uncritical, deferential, undiscretionary forms of ‘undiluted borrowing’” (209) as Ward (2002) suggests. Thus he (2004: 210) concludes “[w]hat has ultimately been documented is arguably less the Americanization of Australian planning and more the Australianization of American planning.”

Whether coincidental or intentional, uncritically borrowed or adapted, the similarities are gaining attention from researchers. Freestone and Murphy (1998: 295) note “[a]n emerging theme in Australian urban studies in the 1990s has been the relative convergence and divergence of the urban development paths of Australian cities compared to those overseas, notably North American.”

Several underlying factors between the countries and cultures may explain the observed differences in urban structures. Australia has much smaller population and economy. Both have federal systems but even these are different as the U.S. has a federal republican system whereas Australia is governed by a parliamentary system (Margerum 1995). Australia is quite close in geographic size to the continental U.S. (see Table 1) but compared to its 48 states Australia has 6 states and two territories. This means each Australian state covers much larger areas with lot smaller populations. State populations in Australia are close to the smaller states in the U.S. In fact, population of Florida (18,328,34ⁱⁱ), the fourth most populous American state, is very close to the population of Australia (see Table 1). A closer examination reveals further differences in state-local government relationships and transportation and land use patterns.

2.1. State-Local Government Relationships

While both countries have federal systems states have more power in the Australian system (Margerum 1995, Freestone 2000, Worthington and Dollery 2000) which makes stronger metropolitan and local growth controls, existence of special purpose metropolitan planning agencies or state agencies with metropolitan jurisdictionsⁱⁱⁱ, statutory controls and supra-local laws and guidelines reflecting more growth control planning goals, i.e. higher level of state intervention, possible (Freestone 1997). Behind the power states hold in Australia lies the fact that many services provided by local governments in the U.S. such as education, health, police, utility (water, sewerage), (Freestone 1997), fire protection (Margerum 1995), public transport and social housing (Freestone 2000) are provided by state governments in Australia. Freestone (1997) remarks that this resulted in greater equality of service provision, lesser socio-economic balkanization and Parkin (1982 cited in Freestone and Murphy 1998) claims less local competition. Furthermore, states have primary responsibility for environmental and natural resource management in Australia while in the U.S. this authority held by the federal government is often delegated to the states by federal agencies under legislative authority (Margerum 1995). This results in more involvement of federal agencies at the state and regional level in both direct and oversight roles.

In Australia from the mid-1950s, urban development was under the control of state governments through special purpose metropolitan planning agencies or state agencies with metropolitan jurisdictions whereas local governments dealt with day-to-day development and zoning control and strong central authorities oversee their work and have the right of final approval of all local plans (Freestone and Murphy 1998). In contrast, planning systems are more fragmented and regional planning powers are weak or nonexistent in many American metropolitan regions. State oversight of local government plans brought by Florida’s Growth Management Act is one of the exceptions to this.

There are also differences in the local government structure and roles between the two countries. The U.S. has “a two-tiered system of local government, with counties performing functions as agents of state government and municipalities in the form of cities, boroughs, villages and towns” (Margerum 1995: 37). In Australia a single tiered structure exists. “Urban governance was therefore split between the state government and a mosaic of local authorities, with the central (state) government holding the ultimate mandate in metropolitan affairs” (Freestone 2000: 302). Furthermore, due to consolidation, the number of local governments is much fewer in Australia (Margerum 1995).

Different from the governance systems of many other comparable economies, local governments in Australia are responsible for relatively fewer functions. This is apparent even when contrasted with a federal system like the U.S. Worthington and Dollery (2000: 351) note that the services provided by local governments in Australia “are largely orientated towards ‘services to property’ and include roads, drainage, waste management, sewerage and water supplies, footpaths and flood mitigation works. By contrast, local governments in the U.S. generally bear responsibility for a large number of major social policy services, including social security, hospitals and health care, schools and police.”

2.2. Transportation Systems and Land Use

Australian cities have a similar land use to that of the U.S. cities. Both have sprawled extensively during postwar suburban boom (Newman and Kenworthy 1989). Kenworthy and Laube’s 1996 international comparison of automobile dependence reveals that among the developed and wealthy countries examined Australian cities are the next most automobile dependant after American cities and have either very similar values to them in the dependency factors, or are next closest to the American cities. The study includes six large Australian cities (Perth, Brisbane, Melbourne, Adelaide, Sydney, Canberra) and 13 large U.S. cities (Houston, Phoenix, Detroit, Denver, Los Angeles, San Francisco, Boston, Washington, Chicago, New York, Portland, Sacramento, San Diego) among others. The results of the study show that, in spite of the fact that Australian cities are less dependent on freeways and Central Business Districts (CBD) are still accessible by public transit (Freestone 1997) in transportation and land use patterns Australian cities are closest to American cities having similar levels of overall metropolitan densities, per capita metropolitan road provision, parking spaces per 1000 CBD jobs, and percentage of workers getting to work on foot and bicycle (Kenworthy and Laube 1996). In other factors of auto dependence such as the per capita auto use, transit service, vehicle ownership Australia is the next closest to the US.

Kenworthy and Laube’s (1996) study show that in 1990:

- *Overall metropolitan densities* in the U.S. (14 people/ha) and Australia (13 people/ha) are the lowest among all cities examined by a factor of three even compared to the next lowest, Metro Toronto.
- *Per capita metropolitan road provision* shows that U.S. (6.7 meters) and Australian (8.3 meters) cities provide most for the automobile. These are 3 to 4 times the roads in European cities, 6 to 8 times in the wealthy Asian cities, and 9 to 12 times in the developing Asian cities.
- In *parking spaces per 1000 CBD jobs* Australian cities lead the world with 489 spaces, followed closely by U.S. cities with 462. The numbers drop dramatically in Toronto and the European cities and reach very low levels in the Asian cities.
- U.S. cities, Toronto, and Australian cities have the lowest *percentage of workers getting to work on foot and bicycle* at only 5 %.
- The U.S. cities generally have the highest overall *vehicle ownership* with 602 vehicles per 1000 for passenger cars and 755 for total vehicles. Australian cities are next after Toronto with 491 cars per 1000 and 595 total vehicles. These figures also drop dramatically in European and Asian cities. The small gap between the two countries is narrowing. According to the Population Reference Bureau (2008) motor vehicles per 1,000 population between 2000–2005 is 787 for the U.S. and 663 for Australia.
- U.S. cities have 1.7 times *per capita auto use* of Australian cities with 11,113 kilometers per person compared to 6571 kilometers in Australian cities.
- With only 28 kilometers of *transit service per person each year* U.S. cities have the lowest level of service among the cities examined, whereas the Australian cities provide more than double this level (60 kilometers). In *service kilometers* U.S. cities

are again the lowest internationally with 63 trips per person annually, while Australian cities are a little better with 92 trips.

In 1980

- *Average gasoline consumption* in U.S. cities was nearly twice as high as in Australian cities with 446 gallons per capita compared to 227 gallons and much higher than European and Asia cities (Newman and Kenworthy 1989). The authors conclude that this difference is only partially explained by gasoline prices, income and vehicle efficiency. What is significant is urban structure.

Mees (1994 cited in Freestone 1997: 256) identifies the underlying differences between the cities of two countries as the Australian city's "long history of suburban diffusion, good public transportation systems, 'paucity of urban freeways', local government and planning systems promoting less 'open slather' development, and widespread gentrification and retention of status by inner and middle distance suburbs". Central cities maintained their status as the most important employment center in Australian cities. The socio-spatial structure of privilege is the "reverse of the American donut" (Freestone 1997: 255).

3. A Comparison of the States of Florida and Queensland

In addition to the above highlighted similarities there are parts of the two countries that particularly resemble each other. Particularly the southern parts of the states of Florida and Queensland have similar physical characteristics that led to the similarities in their development histories and structures in spite of their different planning regimes.

3.1. Physical and Demographic Characteristics

The two states are similar in terms of physical characteristics such as geography and climate as well as population growth trends. The state of Queensland covers an area of 1,732,934 km² (669,090 square miles) and the SEQ region covers 22,310 km² (8,613 square miles) (Wyeth et al. 2000). Florida covers 151,670 km² (58,560 square miles) (State of Florida 2009). South Florida Regional Planning Council is the closest to a defined planning region in Florida that could be compared to SEQ. It covers a total area of 17,840 km² (6,888 square miles) and has a population of close to 4 million people (South Florida Regional Planning Council 2004). This is comparable to SEQ in population.

Both states are dubbed the Sunshine State in their respective countries. Climate of Queensland ranges from tropical in the north to subtropical in the south. The only subtropical climate in the continental U.S. is in Southern Florida and it is also located within a high-velocity cyclone zone (Abbate 2006). Queensland is also subject to cyclones. The Queensland coastal zone extends more than 9500 kilometers (5900 miles). Florida has 3363 kilometers (2276 miles) of coastline. Both have fragile environments and subject to more floods and droughts. Furthermore, both South Florida and SEQ have greater population pressure and older than average populations than the rest of their states and countries. The move from rustbelt to sunbelt in the U.S. was paralleled in Australia.

3.2. Development Histories and Structure

Similarities are also seen in the development history and structure of the two states. In fact, some parts of South Florida such as Fort Lauderdale and SEQ such as the Gold Coast are virtually indistinguishable. Both states are late bloomers and both are experiencing higher than average growth rates within their respective countries as a result of being desirable tourism and retirement destinations, both of them have very fragile environments and

potentially growing vulnerability to climate change, and both try to cope with the development pressures they are facing by using growth management programs.

Both states started developing later than the rest of their respective countries. The hot and humid climate and mosquito infested swamps were not habitable until the swamps were drained and air conditioning became widespread in Florida. Florida was the least populated and most impoverished state in the South at the beginning of the 19th century (Nelson 1989). By the end of the century, it was South's largest and most affluent state, 4th largest in the nation in population size and among the ten fastest growing states (U.S. Bureau of the Census 2000). Florida was the 4th fastest growing state in the U.S. between 1980-1990 and 7th between 1990-2007 (U.S. Census Bureau 2009a). There were no growth controls for a long time at the beginning of these fast developments. Troxler (2009) claims Florida choked on wild, sprawling construction from World War II until the 1980s when the growth management laws were put in place. Ben-Zadok (2005: 2169) explains that "Florida's massive growth from 2.7 million in 1950 to 9.5 million people in 1980 has precipitated state acts in 1972 and 1975. The legislation aimed to balance growth with the protection of natural resources."

Queensland is the growth state of Australia, and SEQ is still the growth region of the nation. With 18.2 percent of Australia's population in 1996, Queensland accounted for 36.8 percent of the nation's population growth between 1991 and 1996 (Minnery and Barker 1998). Over the same period, SEQ accounted for 25.3 percent of the growth with 11.7 percent of the national population and 77 percent of the State's total growth. SEQ is attracting both interstate and intrastate migration as part of the sunbelt phenomenon. Nine of the ten fastest growing local government areas in the State are near or along SEQ coastline.

Population growth in SEQ has taken place primarily along the coast or eastern corridor (referred to as the 'seachange' phenomenon) e.g. Gold Coast City, Brisbane, Maroochy Shire (see Figure 1). The region overall is characterised by low housing densities, typical in the Australian context. Finally, the region has experienced a significant fragmentation of rural lands and bushlands for rural residential development on the fringes of urban areas and in rural areas (Office of Urban Management 2005: 8).

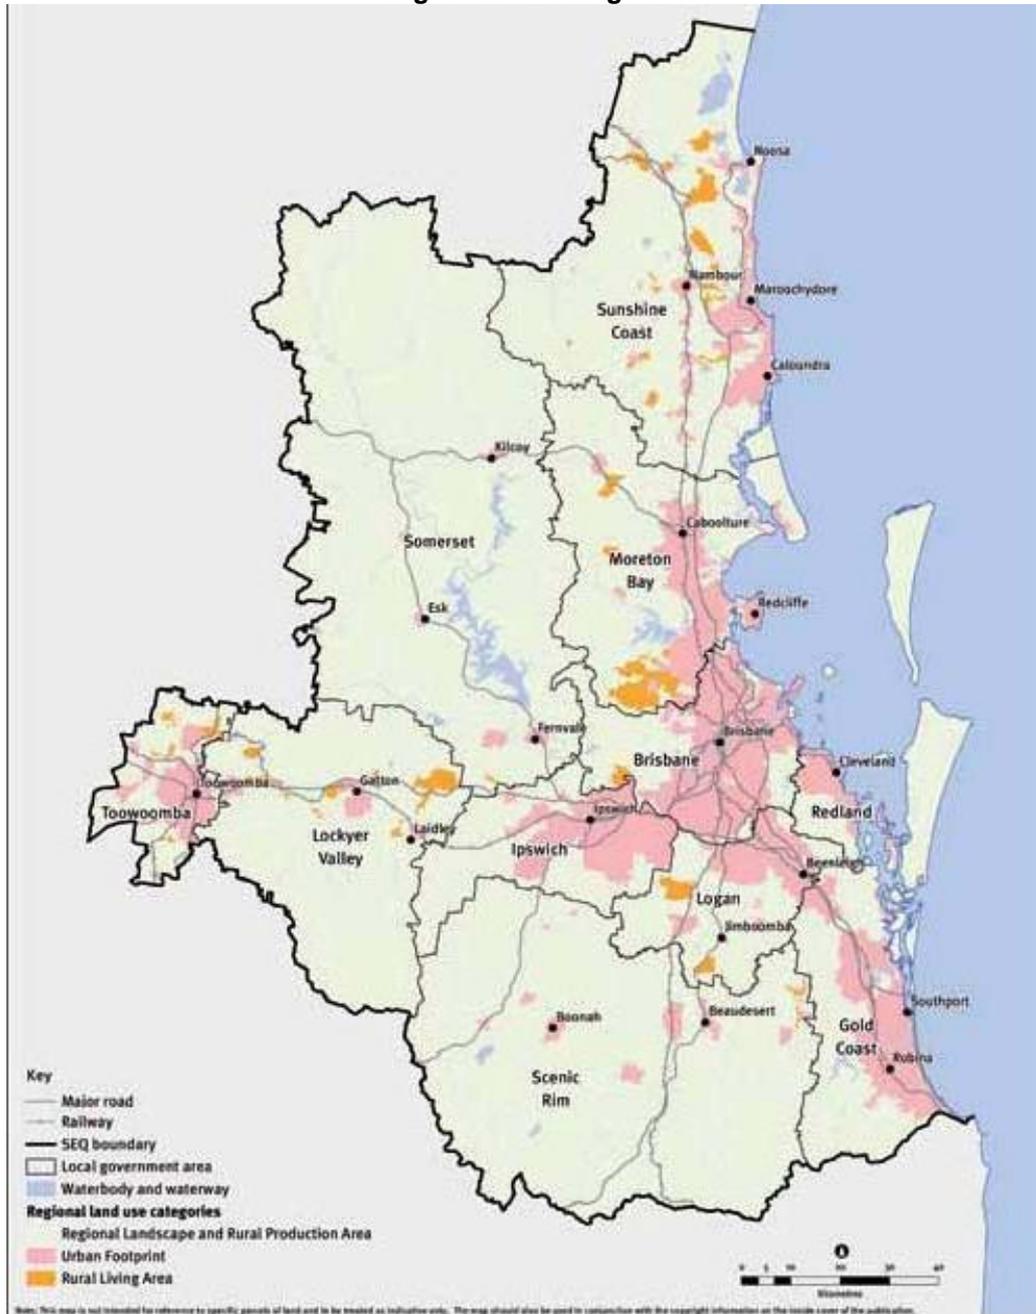

Queensland is the only Australian state that has more than one large city. Unlike other capital cities in the country Brisbane accounts for a relatively low proportion of the State's population (45.5 percent in 1996). Minnery and Barker (1998) diagnose the low-density settlement across a vast area that created a poly-centric urban form as one key feature which distinguishes growth in this region from other metropolitan areas. This low-density sprawling urban growth created difficulties for public sector managers in planning for and providing infrastructure and services (Roberts et al, 1996; Stimson et al, 1997). Furthermore, as Margerum (2002: 181) indicates "this rapid growth and urban sprawl have threatened the very amenities that attract people to the region."

3.3. Planning Regimes and Growth Management Programs

While the states in Australia have more power than in the U.S. including planning authority Queensland historically had a free market approach to development under conservative rule (McKenzie 1997). Collie (1996) reports that unlike other states which used State Planning Authorities/Commissions as a fourth tier of government for land-use and infrastructure planning, development and co-ordination urban and regional planning in Queensland was essentially devoid of any significant direction at state level until 1995. This is not that different from Florida which has a history of promoting growth through land grants (Kelly, 1993).

McKenzie (1997) indicates that the change to a Labor Government in 1989 was instrumental in the State Government intervention in urban and regional development in addition to fast growth not only in urban growth centres such as Brisbane and the Gold Coast, but also in rural and semi-rural shires in the region.

Figure 1. SEQ Region

Source: Queensland Government (2009)

“Local governments in Queensland are creatures of the state government and have contiguous boundaries without any overlapping authority. Although the state government must approve local government plans, state intervention has historically been limited, except to ensure that local governments recognize state issues such as regional transport or issues affecting state land. This has created a culture of strong local government control” (Margerum 2002: 181). The lack of state involvement in planning issues resulted in Queensland local governments holding principal responsibility for planning and local

authorities are politically much more significant than elsewhere in the country (Wyeth et al. 2000).

The potential costs of unplanned, uncoordinated development to the community and the release of new population projections for SEQ prompted the state government to organize the SEQ2001 Growth Management Conference in December 1990. More than 250 representatives of Commonwealth, State and Local Governments, business and industry, the trade unions, professional groups, and community organizations were involved. Abbott (1996 cited in Wyeth et al. 2000: 112) writes that the conference showed:

that people feared that growth and development were out of control . . . the loss of valued agricultural areas, of bushland and coastal environment areas, of the relaxed Brisbane lifestyle, and (of) the region turning into a Los Angeles type urban sprawl from Noosa to Coolangatta.

The conference led to an agreement to develop a cooperative model for growth management in the region. In 1994, a draft regional framework for managing growth was produced, and was adopted in 1995. But issues such as limited commonwealth involvement, failure to coordinate state infrastructure funding, limited resourcing and implementation depending on voluntary agreement created major obstacles, primarily due to a somewhat variable willingness to participate in the process on the part of individual local governments. The SEQ Regional Framework for Growth Management was developed as a governance partnership involving the Queensland state government, the South East Queensland Regional Organisation of Councils and the Commonwealth. The approach was lacking directive powers needed for efficient urban management, but it pointed to the possibilities for cooperative urban regional governance, involving all three tiers of government, and politically was arguably a necessary precursor to the more directive statutory based system that was to follow (Gleeson 2007: 79). In February 2004, the state government announced the creation of a new office of urban management (OUM), followed by an Integrated Planning Act (IPA) amendment to establish the SEQ Regional Plan as a statutory instrument. The Integrated Planning Act 1997 provided a comprehensive framework for managing growth and change within Queensland. It included several elements: the performance based Integrated Development Assessment System (IDAS), local government planning schemes, state planning policies, regional planning schemes, and State department infrastructure planning.

The SEQ Regional Plan 2005-2026 was defined as both a statutory and a planning instrument under different pieces of legislation^{iv}. It had direct effects on infrastructure provision, urban growth boundaries, and resource allocation, and indirect effects through the amendment and alignment of local government planning schemes and state plans and policies (Office of Urban Management 2005: 2) e.g. local planning schemes contradicting the Regional Plan had to be amended. Additional key components of regional planning in SEQ included until 2009 the SEQ Infrastructure Plan and Program (SEQIPP), local growth management strategies demonstrating how local councils would accommodate the projected increase in the number of new dwellings in terms of housing, employment, infrastructure and open space, prepared by local governments, local priority infrastructure plans, and a monitoring system through sustainability indicators.

Among its key strategic directions, the SEQ Regional Plan proposed an alternative to low density residential development by supporting a move towards more compact forms of urban development with higher densities in selected areas (major development areas), by creating an urban footprint (in essence an urban growth boundary) and its bounding Regional Landscape and Rural Production Area (representing 80% of the SEQ region), by using regulatory provisions to ensure that developments are consistent with the regional plan and by linking the regional plan with state infrastructure and service delivery programs and budgetary processes.

The SEQ Regional Plan's main strength has been identified as its statutory force and focus on key issues of environmental and rural conservation, access and transport and urban form. The parallel production of the SEQIPP for transport, power, water and social infrastructure of hospitals and schools with a 20-year time span and provision for annual review, also contributed to its success. Local Growth Management Strategies have also been highly effective. Because the SEQIPP provides local governments with the necessary funded support to fulfil these implementation plans, local governments have had more incentives to meet the requirements to accommodate their allocated share of dwelling increases within the Urban Footprint, protect the Regional Landscape and Rural Production Zone and encourage transit orientated development (Margerum et al. 2008). However, the regional plan has been criticised for its lack of clear objectives and performance indicators, but also for the absence of a strong and inclusive accountability framework involving local actors and the lack of effective channels of public engagement.

During 2008 and 2009, the Queensland Government undertook a review of the SEQ Regional Plan 2005-26 to respond to important growth management issues that have emerged since its release, including continued high population growth, housing affordability pressures, transport congestion, and climate change (Queensland Government 2009). The new regional plan was released in July 2009. Since its release, the new plan was considered by some as a step back from the previous plan and has been criticised for its loss of statutory power.

Florida's growth management program was famous for the three Cs of concurrency (the requirement from local governments to ensure that funds and plans are in place to satisfy the demand for recreation, transportation, sewer, solid waste, drainage and potable water services created by any new development they approve), consistency (the requirement that state, regional and local plans be consistent with the goals and policies of the growth management program), and containment (to prevent urban sprawl) (DeGrove and Metzger 1993). In SEQ the SEQIPP parallels the concurrency element. While Florida's GMA required local plans to be consistent with its objectives, SEQ Regional Plan requires "any plans, policies and codes that relate to the SEQ region being prepared or amended by state agencies must reflect and align with the Regional Plan" and local growth management strategies to be prepared (Queensland Government 2009) providing consistency. The SEQRPs urban footprint is an urban growth boundary that contains development.

4. An Overview of the Latest Developments in the Planning Frameworks

On June 1st 2009 the *Community Renewal Act* replaced Florida's 1985 Growth Management Act. Opponents of the act, including some local governments which sued the state, argue that the act is a violation of the state constitution and label it as "a developer relief act" (Caputo, 2009). The law, which largely exempts builders from building infrastructure to accommodate the needs of new construction - an elimination of the much praised concurrency requirement - and eliminates the review process for some large developments is welcomed by the development industry who argued these changes were "needed to spur the state's development-based economy." Legislature views the act as the jump start the state economy needs after the global financial crisis and expect long-time shelved projects to start. Opponents who point to Florida's oversupply of residential and office space argue the state of the economy is an excuse to weaken the laws and transfer the burden of paying for infrastructure costs from the developers to the taxpayers (Hiassen 2009, Editorial 2009) Furthermore, environmentalists and local governments claim the new law will "exacerbate Florida's housing glut, increase traffic delays and allow uncontrolled development in rural areas" (Klas 2009). "It's a recipe for more reckless sprawl" (Hiassen, 2009). Even the change

in the name of the act governing development in the state of Florida is indicative of the shift in its focus from managing growth to community renewal (development?)

Similar to Florida in Queensland the *Sustainable Planning Act (SPA) 2009* was opposed with claims that this is another hallmark of the government's "mantra of growth at all costs" (McCarthy 2009). Again, similar to Florida the development interests (Property Council of Australia) gave unequivocal and glowing support. One purpose of the Act is to streamline land use planning and development framework to achieve more timely approvals. However the new amendments may result in avoiding the necessary evaluation of applications that give rise to detailed ecological assessments, sustainability principles and subsequent recommendations.

SPA was not the only change in the planning framework of Queensland. After the change of government in March 2012 a series of new policies started reshaping the planning system of the state.

While the new government is continuing the statutory regional planning tradition of its predecessor their objectives are somewhat different. Department of Local Government and Planning has been renamed Department of State Development, Infrastructure and Planning (DSDIP) and its website which was 'actively reviewed and updated to align with new state government priorities' makes clear that the new government's focus is on economic development and re-empowering local government is among its priorities (DSDIP 2012b). The new generation of statutory regional plans are given priority to 'aim to foster diverse and strong economic growth; plan and prioritise infrastructure; manage impacts on the environment; and where necessary, plan for urban growth and resolve land use conflicts such as those arising between agricultural and mining activities' (DSDIP 2012c).

In August 2012 the new government released *Temporary State Planning Policy 2/12 Planning for Prosperity*. The document highlights that the planning system will facilitate economic growth in Queensland through focusing on tourism, agriculture, resources and construction and by cutting red tape and regulation (DSDIP 2012a). The purpose of the Policy is to ensure that economic growth is facilitated by local and state plans, and is not adversely impacted by planning processes. The Policy will guide the amendment and preparation of regional plans. LNP's pre-election policy on 'Protecting the Scenic Rim' was critical of the South East Queensland Regional Plan and a review was promised within three years of taking government (LNP 2012).

In September the Deputy Premier and Minister for State Development, Infrastructure and Planning, Jeff Seeney, introduced the *Sustainable Planning and Other Legislation Amendment Bill (2012)* into parliament, which included specific amendments designed to cut 'green tape' in environmental protection legislation (Part 4), changes to coastal protection legislation (Part 3), and alterations to the Sustainable Planning Act (Part 7). In his speech to parliament the Minister pointed out that:

The state government is committed to restoring efficiency and consistency to the planning and development assessment system to get the property and construction industries back on track. As promised, our government is well underway in reforming and simplifying the planning framework through removing unnecessary regulation from the system and fixing the Sustainable Planning Act 2009 (Queensland Parliament 2012: 1945).

In October 2012 Department of State Development, Infrastructure and Planning released the *Draft Coastal Protection State Planning Regulatory Provision: Protecting the Coastal Environment (the Draft SPRP)* (DSDIP 2012d). This new policy suspended parts of the Queensland Coastal Plan and some of the regional plans. Queensland Coastal Plan

prepared by the previous Labor government was composed of two policies: State Policy for Coastal Management and State Planning Policy 3/11: Coastal Protection. The new Draft SPRP suspended the operation of the State Planning Policy 3/11: Coastal Protection which required coastal development to consider the projected effects of climate change such as a sea-level rise and an increase in the maximum cyclone intensity. It also suspends the operation of parts 1.4.3 and 2.4 of the SEQ Regional Plan which required consistency with the Coastal Plan in general as well potential sea level rise projections specifically.

In April 2013 Newman government released the *Draft State Planning Policy* (DSDIP 2013) which sets out the state interests and related policies that should be used in preparing or amending local planning instruments and regional plans. It identifies a series of principles to support and guide the development of efficient and effective planning instruments. While the principles mention sustainability and protection of natural environment the implementation strategies are clearly focused on facilitating development. The government is currently preparing the *Queensland Plan*, a 30-year vision for the state.

These developments suggest that there has been a significant shift in state-level planning and climate change adaption policies which affect not only South East Queensland but the whole state. Neither climate change nor adaptation has been a priority in any of the LNP's policies, either before or after the election, and it does not appear in any of the legislative changes outlined above. The party has been consistent in its pursuit of its 'four pillar' policy of economic development, with environmental and planning laws being streamlined if they are considered as inhibiting development. Further, there has been a deliberate move to hand back more responsibilities to the local level of government.

5. Conclusions

Growth Management programs of both states have been praised for being pioneers but also criticized for ineffectiveness (Chapin et al. 2007). Their subsequent weakening/removal reframes the situation. In spite of the striking similarities between the states of Queensland and Florida no comparisons have been made to date. At a time when the two states are facing similar problems, trying similar methods to deal with them and changing economic conditions forcing a setback on growth controls they can learn from each other to deal with their problems more effectively. This paper sets up a framework and proposes such a comparison.

ⁱⁱ 2008 estimate (U.S. Census Bureau 2009b)

ⁱⁱⁱ These may have their roots at the planning commissions of the 1920s which were metropolitan-wide rather than confined to the central city as their American counterparts (Freestone 2004). "With local government uniformly weak and fragmented, state governments were the only authorities capable of taking a synoptic approach to metropolitan questions. Their tentative interest in town planning matters in the 1920s came on top of established major responsibilities in the provision of metropolitanwide public services (water, sewerage, public transport, education etc). The political obstacles to adoption of a cross-jurisdictional regional planning commission concept were thus less formidable than in American urban government" (Freestone 2000: 317).

Using spatial modelling to develop flood risk and climate adaptation capacity metrics for vulnerability assessments of urban community and critical water supply infrastructure

Rodolfo ESPADA JR., Armando APAN, and Kevin MCDOUGALL
School of Civil Engineering and Surveying and Australian Centre for Sustainable Catchments, University of Southern Queensland, Australia

1. Introduction

The application of vulnerability assessment in the water supply network takes into account several elements which include the characterisation of the water system, determination of critical assets, analysis of current risk (i.e. flood risk), and evaluation of existing countermeasures (EPA 2002). As a highly significant tool, vulnerability assessment of water supply network provides information to guide and prioritise plans for water supply security and mitigating measures against operational damages from destructive events such as floods.

A series of damaging floods during December 2010 to January 2011 hit the State of Queensland, in Australia. Consequently, over 200,000 people were affected (McDougall 2012), 29,000 homes and businesses were damaged and 37 people were killed (QRA 2011 and QFCI 2012). The damage was expected to cost the Australian economy triple the original estimate of AU\$10 billion (ABC 2011). Specifically, in January 2011, the city of Brisbane has experienced a major flood event inundating more than 14,000 properties (McDougall 2012). The government spent almost AU\$7 billion rebuilding and upgrading the State's infrastructures (QFCI 2012, QRA 2011) due to flooding.

In this study, the vulnerability of water supply infrastructure to flood hazard was examined. During the January 2011 flood, water supply was lost to few suburbs in the Brisbane local government area (QUU 2011) with Queensland Urban Utilities (QUU) provided alternative water supplies to water-deficient communities (QFCI 2011). In general, the daily drinking water requirements of Brisbane area were significantly available during the flood event; however, water supply was constrained by a major challenge caused by the interruption of water treatment operations at Mt. Crosby and North Pine dam due to water turbidity and other problems (QFCI 2011). This situation created a potentially serious water supply shortage in Brisbane not only during the January 2011 flood but was also realised during the January 2013 flood (Keller 2013). This "dirty water" event reached turbidity levels up to four times more than it was during the January 2011 flood and reduced the quality of drinking water for several days (Keller 2013, News Limited 2013).

To enquire into matters arising out of the 2010/2011 floods, the Queensland Floods Commission of Inquiry (QFCI) was established pursuant to the *Commission of Inquiry Act 1950* (QFCI 2012). Investigations and recommendations were made as to how future flood damage can be minimised across essential infrastructures such as electricity, water supply, sewerage, storm water, telecommunications, and roads and rails.

The development of flood risk and adaptation capacity metrics is of considerable importance considering the urgency and relevancy of the issues at hand. However, doing so offers a great challenge due to a wide variety of adaptations as well as the dynamic nature of various environmental and socio-economic factors (Szlafsztein 2008). This research problem is further exacerbated by inductive argumentation which particularly pertains to the sufficiency of indicating variables and availability of statistical models in climate risk assessment. Hinkel (2011) emphasised that when these indicating variables are aggregated with deductive approach (e.g. expert judgment) or by normative approach (e.g. equal weighting), the

delivery of robust results is an issue due to subjective judgments in the former case and the multi-dimensionality of variables to different stakeholders in the latter case. Another challenge that further aggravates the issue is the process of selecting the indicating variables to indicate flood risk and its application to adaptation capacity assessment.

Furthermore, there is a limited research consideration on the geographical interdependency of critical infrastructure protection modelling. In a research survey of U.S. and international research on critical infrastructure interdependency modeling conducted by Pederson *et al.* (2006), modeling and simulation that provide geospatial relationships were excluded in their analysis. Because floods exert spatially correlated disturbances to water supply infrastructures and consequently disrupt water supply services to community, a research question arises as to how geographic interdependency and spatial autocorrelation operate in flood risk assessment.

To sum up, this study was conducted to address the following research questions:

1. How can indicating variables (i.e. hazard, physical and social vulnerability, and exposure) be better use in the integrated flood risk and climate adaptation capacity assessment model for assessing the vulnerability of urban community and critical water supply infrastructure?
2. Despite advances in water engineering, how can spatial technology be of help to reduce the massive flood impacts on urban community and critical water supply infrastructure and mitigate the potential spread of water-borne health problems?
3. What are the possible applications and implications of the generated modelling technique to flood insurance and land-use planning policies?

Specifically, the objectives of this study were:

1. To evaluate indicating variables in generating flood risk and climate adaptation capacity metrics of an urban area which had been exposed to flood hazard; and
2. To generate spatially-explicit flood risk and climate adaptation capacity metrics that will aid to address flood risk management and climate resiliency issues of an urban area and critical water supply infrastructure.

2. Study Area

Comprising an area of 2,200 ha, the study area is located within the 22 core suburbs of Brisbane City, the Queensland's capital in Australia (Figure 1). The City is traversed by the 345-kilometer long Brisbane River, which is the longest river in South East Queensland and flows down from Mount Stanley to Moreton Bay (Middelman 2002). Including the Lockyer Creek and Bremer River catchments, around 6,500 km² (approximately 50%) of the Brisbane River catchment is below Wivenhoe and Somerset Dams (Robinson 2011). Completed in 1984, the Wivenhoe Dam was built as a dual-purpose storage for both drinking water (which supplies water to the City) and flood mitigation (SEQ Water 2012).

Brisbane City had an \$85 billion economy in 2011. However, the City's economic progress together with more than a million estimated residents, had been hampered and devastated recently by 2010/2011 floods. Flood waters in Brisbane peaked at 4.46 metres with significant damage to transport, infrastructure, and residential properties (Queensland Museum 2011).

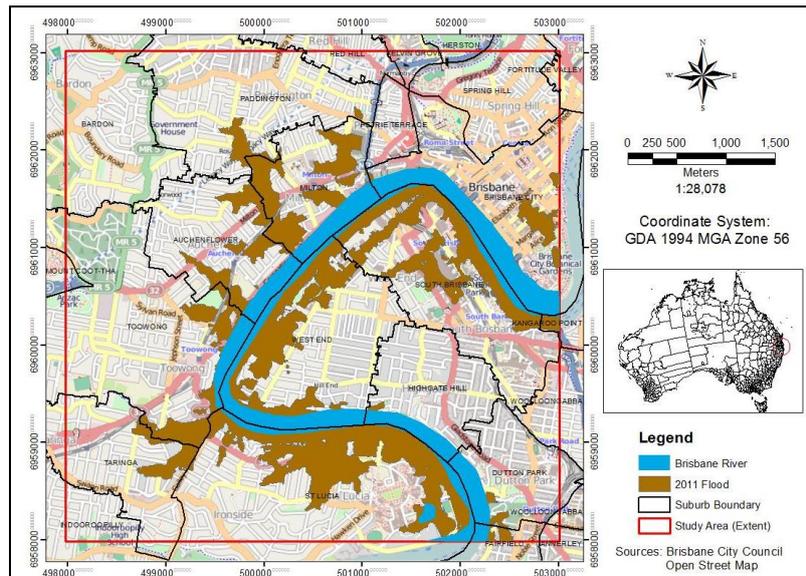

Figure 1. The extent of study area

3. Research Methods

This study is part of an ongoing research project which attempts to develop an integrated approach of formulating adaptation strategies to reduce vulnerability of an urban community and infrastructure assets from floods and the long-term effects of climate change. Figure 2 is the input-process-output (IPO) model specifically used in this study.

Under the input component, the flood hazard, social and physical vulnerability, and exposure indicators were identified based on the availability of datasets and assessed following the flood risk framework. Under the process component, four main spatial analytical challenges were addressed to generate the flood risk and adaptation capacity metrics and assess water supply vulnerability: 1) transformation and standardisation of indicating variables; 2) topological cluster analysis using the self-organising neural network (SONN); 3) quantification of risk and adaptation capacity metrics; and 4) network analysis (Figure 2) (Espada *et al.* 2012, 2013).

This study was also challenged to apply the concept of geographical interdependency using the spatial autocorrelation techniques with emphasis on Global Moran's I and Cluster and Outlier Analysis of Anselin Local Moran's I. Summarising the initial outputs using the Inverse Distance Weight (IDW) method of point data interpolation, the generated raster maps were then carefully analysed to assign categorised values for each indicating variable that generally explain perceived level of flood risk.

To identify which indicating variables can be potentially included in the weighted overlay analysis, the pattern of similarity of these variables was analysed by using the self-organising neural network (SONN) mapping tool in MATLAB version R2011b program (The Mathworks, Inc. 2013). With the Bayesian joint conditional probable weights assigned to selected indicating variables, the flood risk metrics were quantified by using the modified fuzzy gamma function to resolve the mathematical issues (i.e. increasing or decreasing effects) of implementing Equations 1 and 2. Applying Equation 6, the climate adaptation capacity metrics were generated.

The final outputs (i.e. flood risk and adaptation capacity metrics) were then applied in assessing the vulnerability of urban community in general and critical water supply infrastructure in particular.

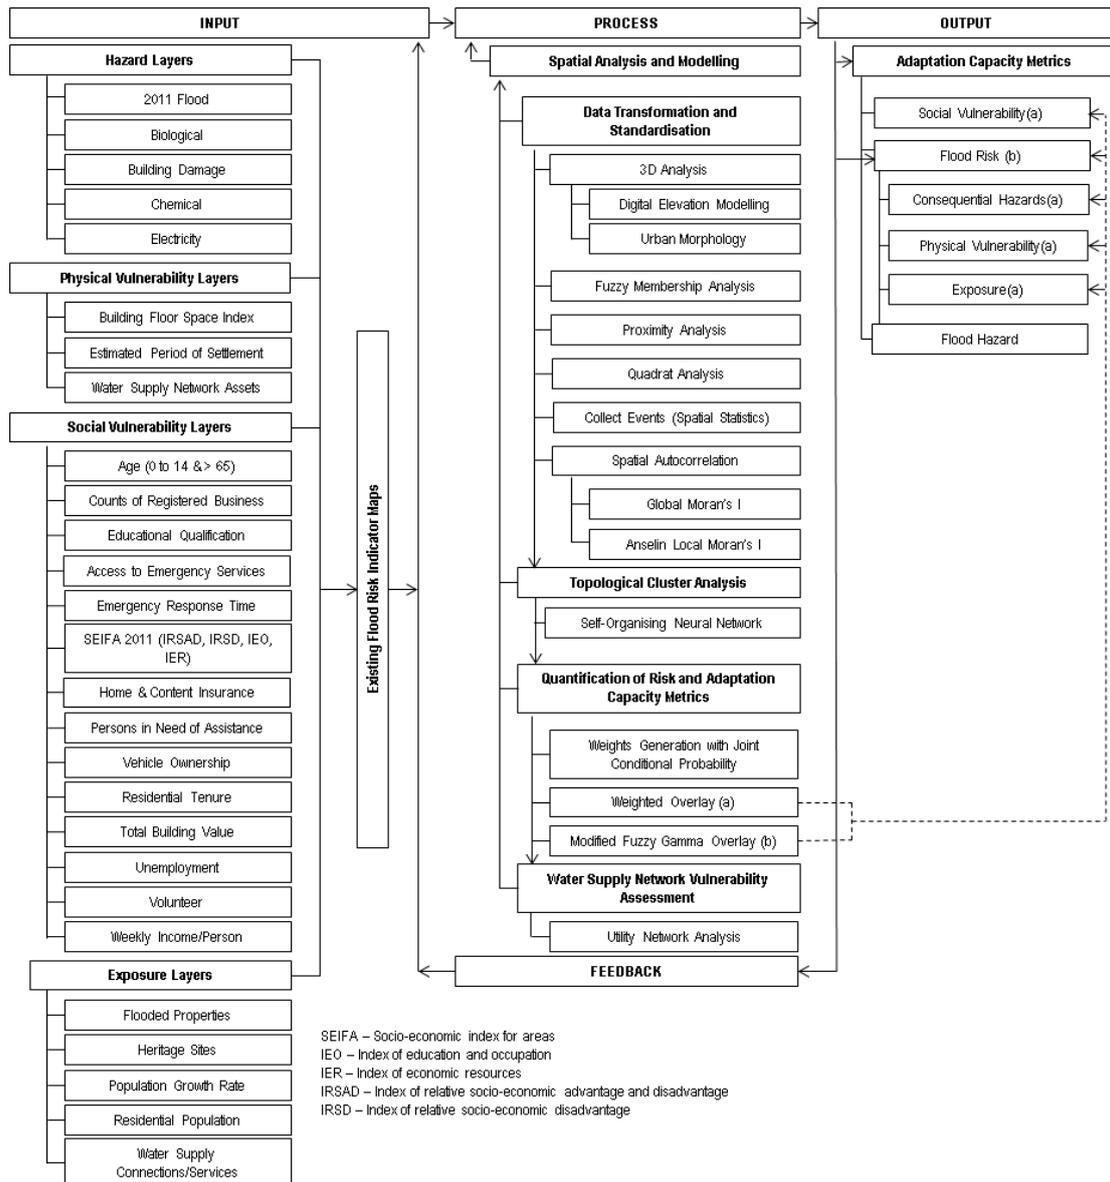

Figure 2. The input-process-output (IPO) model used in the study (Espada et al. 2012, 2013)

4. Flood Risk and Adaptation Capacity Modelling

4.1. Key Concepts and Data Inputs

Expressed in mathematical forms, risk can be stated as (Mirfenderesk and Corkill 2009; Downing 2002; Hughey and Bell 2010):

$$\text{Risk} = \text{Hazard} * \text{Vulnerability} * \text{Exposure} \quad \text{Eq. 1.}$$

$$\text{Risk} = \text{Hazard} + \text{Vulnerability} \quad \text{Eq. 2.}$$

$$\text{Risk} = \text{Hazard} + \text{Vulnerability} - \text{Adaptation Capacity} \quad \text{Eq. 3.}$$

As shown in these equations, the terms hazard, vulnerability, exposure, adaptation capacity are significantly associated to each other and can influence the flood risk assessment process.

Hazard is defined as a “dangerous phenomenon, substance, human activity or condition that may cause loss of life, injury or other health impacts, property damage, loss of livelihoods

and services, social and economic disruption, or environmental damage”. From Geoscience Australia’s (2010) perspective, *vulnerability* is “the impact a hazard has on the people, infrastructure, and the economy”. The term *vulnerability* has been introduced to consider the extent to which people suffer from calamities which depend on the likelihood of being exposed to hazards and their capacity to withstand them, which relates to their socio-economic circumstances (Schneiderbauer and Ehrlich 2004). When talking about the number of assets such as “people, property, systems or other elements present in hazard zones that are thereby subject to potential losses”, that is the way how *exposure* is defined by UNISDR (2009). Going further specific, the term *infrastructure assets* is described as “interrelated built, institutional and environmental systems and services” (Jollands *et al.* 2006).

Looking back to Equation 3, the term *adaptation capacity* has been viewed as a system response to perturbations or stress that are sufficient to make fundamental changes in the system itself, shifting the system to a new state or how the system responds (Gallopín 2006; Preston and Stafford-Smith 2009); hence, may also be referred to as *response capacity* (Preston and Stafford-Smith 2009). And by transforming this equation, adaptation capacity can be expressed as follows (Espada *et al.* 2012):

$$\text{Adaptation Capacity (AC)} = \text{Vulnerability} - (\text{Risk} + \text{Hazard}) \quad \text{Eq. 4}$$

To operationalise Equation 4, it has been further expressed in Equations 5 and 6.

$$\text{AC} = \text{Social Vulnerability} - (\text{Risk} + \text{Flood Hazard}) \quad \text{Eq. 5}$$

$$\text{AC} = \text{Social Vulnerability} - [(\text{Fuzzy Gamma Function \{Consequential Hazards, Physical Vulnerability, and Exposure\}} + \text{Flood Hazard})] \quad \text{Eq. 6}$$

Figure 2 and Table 1 show the thematic layers/indicating variables used to analyse the components of flood risk and adaptation capacity.

4.2 Topological Cluster Analysis with Self-Organising Neural Network (SONN)

This study used 30 indicating variables: 5 for hazards, 20 for vulnerability, and 5 for exposure (Figure 2). Challenged by the selection of the most appropriate indicating variables for inclusion in the flood risk and climate adaptation capacity assessments, the Artificial Neural Network (ANN) particularly the Kohonen self-organising map (KSOM) was explored in this study. A self-organising map consists of a competitive layer that allows classification of datasets with any number of dimensions into as many classes as the layer has neurons, which are arranged in a 2D topology (The Mathworks, Inc. 2011). In this study, the SOM was operationalised with the input layer where the inputs refer to the indicating variables (e.g. flood hazard, water supply assets, etc.), neuron computation, and output layer, and a map of clustered variables as shown in Figure 3 (Mele and Crowley 2008).

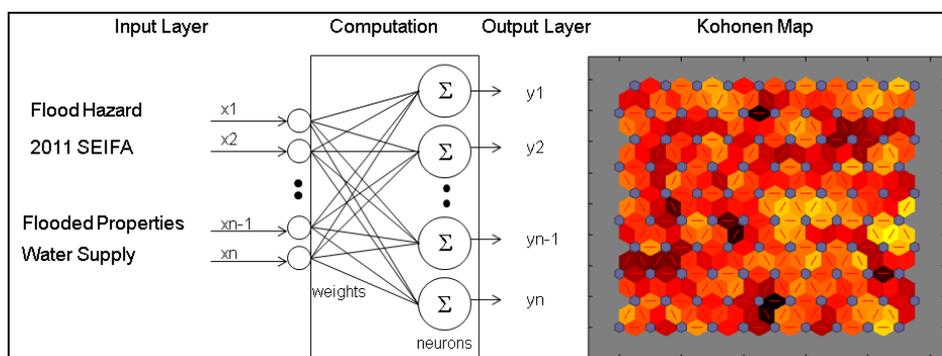

Figure 3. The conceptual self-organising neural network of the study

Processed with MATLAB version R2011b program, the indicating variables were structured to create 907266 x 5 hazard, 907266 x 20 vulnerability, and 907266 x 5 exposure matrices. Utilising the Neural Network Clustering Tool, the indicating variables were grouped or clustered by similarity through the process of classifying a 2–dimension layer of 100 neurons arranged in a 10x10 hexagonal grids. To learn the topology and distribution of indicating variables, the network was trained four times using the batch SOM algorithm with 200 epochs/iterations.

The similarity pattern of indicating variables was then analysed using the SOM planes by taking flood hazard as the basis in the pair-wise comparison. The result revealed a general pattern for two (2) variables (i.e. access to emergency services and emergency services response time) with lower weights concentrate at the centre of the SOM plane. This pattern is intuitively and visually in reverse to the general pattern showcased by flood hazard; hence these two variables were removed from further analysis.

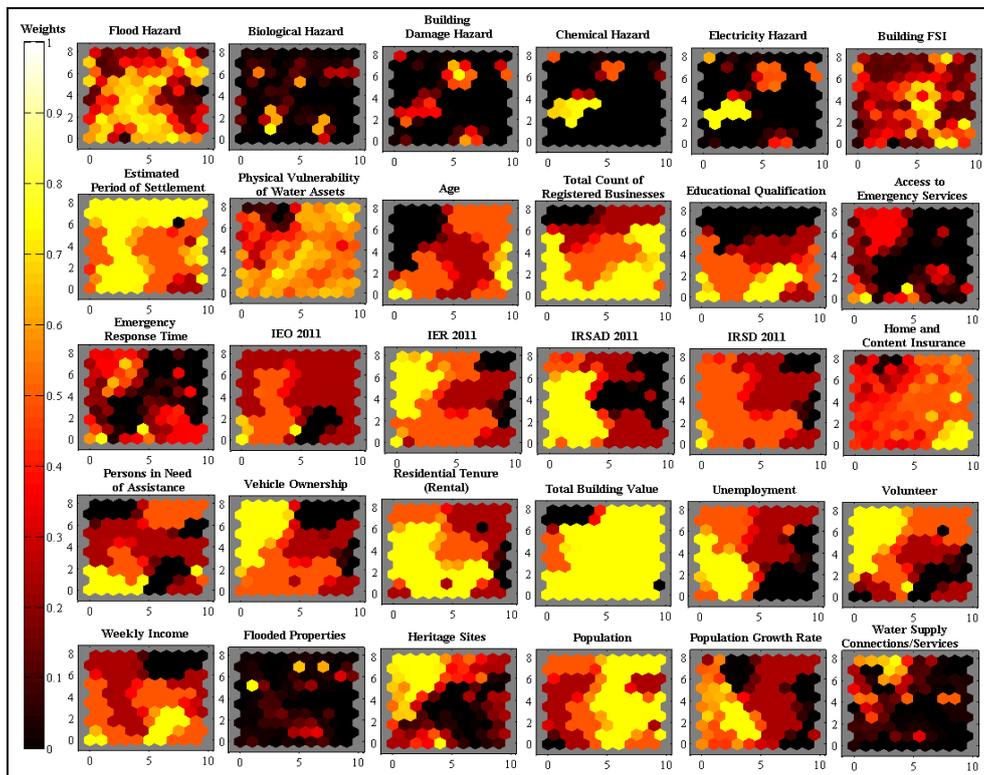

Figure 4. The SOM planes of flood risk and climate adaptation capacity indicating variables

4.3 Quantification of Flood Risk and Adaptation Capacity Metrics

From SOM analysis, the final 28 indicating variables which were selected to include in quantifying the flood risk and adaptation capacity metrics are summarised in Table 1.

The weights column from the Table indicates the unequal Bayesian joint conditional probable weight values used in aggregating the indicating variables of hazard, vulnerability, and exposure. This method of assigning weights is significant because in community vulnerability assessment, for example, people affected by floods, wetlands lost, damage cost, and adaptation cost are important dimensions to consider (Hinkel 2011), which are of unequal importance.

Using the probable weights given in Table 1, the aggregation of indicating variables for hazard, vulnerability, and exposure was performed with the weighted overlay process of Spatial Analyst Tool in ArcGIS 10. Applying Equations 1 and 6, flood risk metrics and

adaptation capacity metrics were calculated with the results as summarised in Table 2 and shown in Figure 4 (map background).

Table 1. The selected indicating variables from SOM analysis and corresponding Bayesian joint conditional probable weights

Flood Risk/ Adaptation Capacity Component	Selected Indicating Variable	Joint Conditional Probable Weight
Hazard	Biological	0.19
	Building Damage	0.19
	Chemical	0.21
	Electricity	0.19
	Flood	0.22
Social Vulnerability	Age	0.07
	Educational Qualification	0.05
	Home and Content Insurance	0.08
	IEO 2011	0.07
	IER 2011	0.06
	IRSAD 2011	0.05
	IRSD 2011	0.07
	No Vehicle	0.05
	Persons in Need of Assistance	0.06
	Residential Tenure (Rental)	0.07
	Total Building Value	0.13
	Total Count of Registered Business	0.08
	Unemployment	0.05
	Volunteer	0.05
	Weekly Income	0.06
Physical Vulnerability	Building Floor Space Index	0.30
	Period of Settlement	0.31
	Water Supply Network Assets	0.39
Exposure	2011 Flooded Properties	0.31
	2011 Population	0.16
	Heritage Sites	0.12
	Population Growth Rate	0.14
	Water Supply Connections/Services	0.27

4.3.1 Applications and Implications of Flood Risk and Adaptation Capacity Metrics to Insurance and Land-use Planning

Table 2 shows that 186 ha (8%) of the study area were exposed to very high flood risk due to the January 2011 flood event. Furthermore, 221 ha (10%) were characterised of having very low climate adaptation capacity.

Also shown in Table 2, majority of the study area (90%) revealed negative adaptation capacity metrics (-31 to <0). This significant finding would imply that vulnerability as a resource-oriented factor determines the strength or weakness of the study area; such that the generated negative values for adaptation capacity meant that the resources are not enough to increase climate resiliency of the urban community and critical infrastructures (Espada *et al.* 2012). The result also signifies that the resources of the community are outbalanced by 31 units taking zero as the break-even metric. The outcome of the analysis further indicates that the capacity of the urban community requires further deliberation as how climate adaptation is intrinsically inseparable to the physical and social vulnerability of a system. If vulnerability takes the definition in this study as the capacity of the people, community, or system to withstand flood risk, it follows then that vulnerability is inherently associated with the general economy of resources, wealth, social well-being, governance, and political will of the people and community, and the capacity to increase climate resiliency of critical infrastructure assets (Espada *et al.* 2012).

Also important to further examine are the physical and socio-economic characteristics of the study area (the remaining 10%) that indicates positive adaptation capacity metrics (>0 to 1)

(Table 2). This signifies that the resources within those areas are one unit above the zero break-even or just enough to alleviate climate risk. However, extra caution should be taken into account considering that some areas are positioned in a highly favourable physical condition (e.g. higher elevation) but the socio-economic resources inhibit the adaptation to climate risk. This finding further implies that the study area requires a range of adaptation strategies that would increase community and critical infrastructure resiliency as specified in Table 1. Adopted from Queensland Reconstruction Authority's (QRA) (2011) four phases of disaster risk reduction, the broad adaptation strategies identified in this study to increase community resiliency include mitigation, preparedness, response, and recovery.

Table 2. Summary of flood risk and adaptation capacity metrics with corresponding adaptation strategies

Flood Risk				Adaptation				
Description	Metrics	Area (ha)	%	Description	Capacity Metrics	Area (ha)	%	Strategy/Measure
Low	1 – 1.02	0.6	0.03	High	0 – 0.93	218	10	Mitigation
Moderate	1.02 – 1.21	1895	84	Moderate	-1.23 – 0	1053	46	Mitigation to Preparedness
High	1.21 – 3.52	181	8	Low	-3.24 – -1.23	771	34	Mitigation to Response
Very High	3.52-30.41	186	8	Very Low	-31.41 - -3.24	221	10	Mitigation to Recovery
Total		2263	100			2263	100	

To recap, Table 2 is the summary of a methodology identified as *flood risk-adaptation capacity index-adaptation strategies* (FRACIAS) linkage model (Espada *et al.* 2012) that allows the integration of a range of spatially explicit analytical techniques used in the flood risk assessment, quantification of adaptation capacity metrics, and identification of adaptation strategies. This model addresses the issue of integrating disaster risk reduction-climate change adaptation framework, which had been treated separately for the past years (Joshi *et al.* 2011).

The insurance and land-use planning sectors can generate a variety of significant insights from this study. For example, while risk-based premium pricing of insurance is an actuarial practice, the basis of such pricing should not heavily rely on the geographic location of risk but significantly consider the adaptation capacity of intended policy holders to pay the premiums and maintain insurability for a long-term. The government can play an important role in maintaining a private insurance market with risk-based premiums (LeBlanc and Linkin 2010) by providing financial subsidies to homeowners in areas at very high flood risk with very low adaptation capacity (e.g. low income, severe disability, significantly flooded properties, etc.). Through this approach, public-private partnership is enhanced and allows the comprehensive planning for disaster risk reduction and climate adaptation.

Whilst insurance policies offer an opportunity of transferring risk, these should not be used as a tool to encourage urban development on areas with highest risk. However, Brisbane City has the legacy of past poor land uses planning leaving homeowners in locations at high risk (van den Honert and McAneney 2011). At the time when the flood hit the region, the Queensland Development Code does not even regulate the construction of building in areas at risk of flooding (QFCI 2012); hence, amendment is recommended to consider not only the risk for flooding but also the climate adaptation capacity of the area/region. To improve the urban development in the City, the Queensland Flood Commission of Inquiry (QFCI) recommended strategies to “flood proof” the City. These include specification of flood immunity level, redesign of residential houses and commercial buildings with water resistant materials, setting minimum freeboard level, operations of “property buy-back” and “land swap” programs, and amendment of the Queensland Development Code to regulate the construction of buildings in areas at high risk to flooding.

4.3.2 Critical Water Supply Network Vulnerability Assessment

Considering that water supply problem during the January 2011 flood, which had been also experienced during the January 2013 flood, was more on water turbidity (Keller 2013 and News Limited 2013), this study examined the vulnerability of water supply by identifying the potential flow of turbid water along the trunk-reticulation mains. Using the results from the flood risk and adaptation capacity assessments in the water supply network vulnerability assessment, eight (8) out of 107 trunk-reticulation main connection points (as potential entry points of turbid water) were assessed as highly vulnerable critical water supply assets being found within areas of very high flood risk and very low adaptation capacity (Table 3).

Using the highly vulnerable critical electricity assets as flag junctions (see brown square dots in Figure 4) in the Utility Network Analysis of ArcGIS 10, the potential path of turbid water through the trunk-reticulation mains was traced and the total linear kilometer was then calculated. Results of the analysis revealed that turbid water may flow along 246 km water distribution lines in the North East and North West using the January 2011 flood event. These comprise 56% of the water pressure main within the study area may potentially affected by supply of turbid water.

Table 3. Counts of highly to very highly vulnerable critical water supply network assets

Water Supply Network Asset	Total	Highly to Very Highly Vulnerable	Percent of Total
Pressure Gauge (No.)	13	0	0
Flow Meter (No.)	61	11	18
Booster Pump (No.)	1	0	0
Control Valve (No.)	1990	268	13
Fitting (No.)	2011	205	10
System Valve (No.)	5010	636	13
Trunk-Reticulation Main Connections (No.)	107	8	7
Pressure Main (Length in Km.)	435	246	56

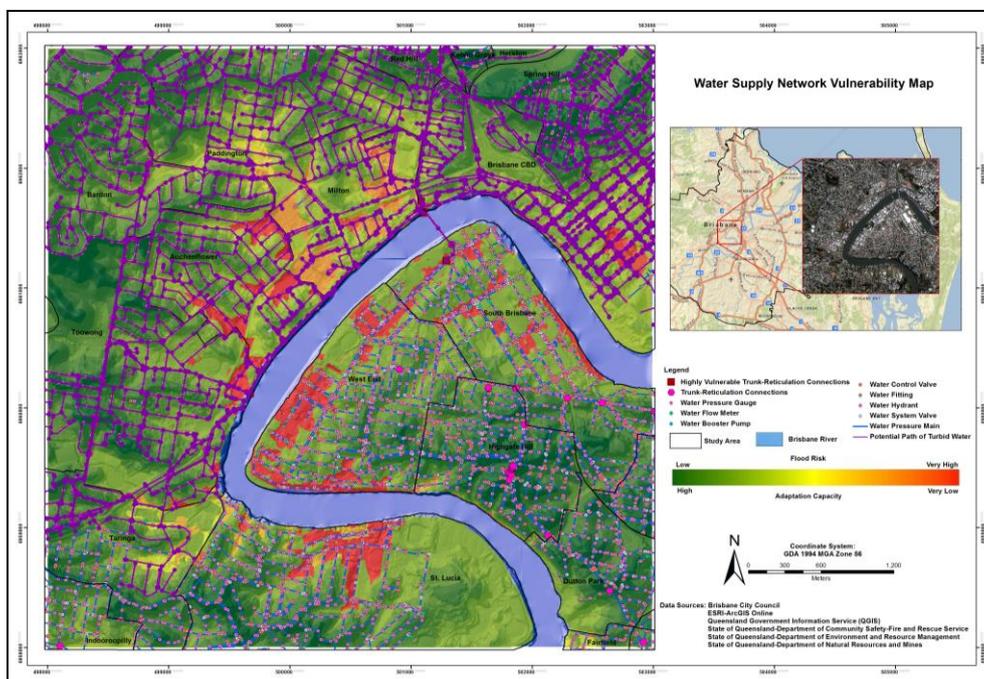

Figure 4. The generated water supply network vulnerability map of the study area

The results from these analyses can assist water supply industry to evaluate the susceptibility of water system to “dirty water” event. The analytical tool and the information generated from this study can help alleviate ranges of consequences or impacts such as

water-borne diseases from any flood event. During the January 2011 flood, no report has been made regarding any breakdown of water supply infrastructure and water shortage except for the quality of drinking water in some areas. Nonetheless, it is noteworthy to take into account the potential flood impacts that may disrupt the entire water supply system. Table 3 identified the highly and very highly vulnerable water supply network assets that can be potentially harmed in the future floods. Without the mitigation measures, the possible implications for water supply infrastructure include reduced security of supply and increased risk of fluvial flooding to water supply/treatment infrastructure (DEFRA 2011). As such, climate threats to water supply should be managed according to some lessons learned such as (The Royal Academy of Engineering 2011):

- To focus on new inter-disciplinary approaches by integrating social and economic solutions with the current engineering solutions;
- To implement distributed water systems rather than centralised water systems;
- Water recycling with conscious on energy implications of recycling water;
- Use of smart meters and intelligent pipework to reduce leakage, monitor turbid water, among others.

During the 2010/2011 floods, the supply of drinking waters was maintained to meet the demands of consumers in south-east Queensland. However, this was constrained by the suspension of water treatment operations at Mt. Crosby and North Pine dam (QFCI 2011). To improve the quality of water during flood events specifically in the South East Queensland and Brisbane areas, Keller (2013) recommended an engineering modification by adding high quality water from the Advanced Water Treatment Plants (also known as water recycling plants) directly into the water treatment plant (i.e. Mt. Crosby Plant) rather than the Wivenhoe Dam. Accordingly, the advantages of this significant change include the following (Keller 2013):

- Generating up to 50% of its usual water production directly from the recycled water;
- “Dirty” river water could have been taken in and treated with the dilution from the purified recycled water;
- Pumping energy would be substantially less by not going to the dam, the high water quality could be maintained, and it would avoid losses through evaporation and infiltration from the dam.

5. Conclusions and Recommendations

In the aftermath of the devastating 2010/2011 floods in Queensland, the Australian governments and the Queensland Reconstruction Authority (QRA) sought to plan and build stronger, more resilient communities in the future.

Linking flood risk assessment with adaptation capacity assessment was the innovative technique developed in this study. Generated from complex spatially-explicit analytical methods, the flood risk-adaptation capacity index-adaptation strategies (FRACIAS) linkage model was then discussed on how it can help to address issues on insurance and land-use planning. This includes the role of the government in the maintenance of private insurance market through the provision of financial and urban development support to areas with very high flood risk and very low adaptation capacity.

This study also examined the vulnerability of critical water supply network to climate risk and the implications if services are disrupted. Although the January 2011 flood in Brisbane did not significantly damage the water supply system, there is still need to improve the quality of water supply. Extreme weather event may cause significant disruption of water supply on

areas with very high flood risk and very low adaptation capacity. This study explored different adaptation strategies to reduce future risk both to the quality of water supply and the physical conditions of critical water supply network.

To improve this study, the following are some factors recommended to consider in the future research works:

1. Integration of hydrologic/hydraulic components and climate change factors in analysing flood hazards;
2. Vulnerability assessment of all critical water network assets (not only the trunk-reticulation connections) that might be subject to flood damages that could result in undesirable consequences; and
3. Vulnerability assessment of electricity supply, roads and rails, communication, sewerage, and storm water infrastructures.

Acknowledgments

The authors sincerely thanks the Australian Government – Department of Industry, Innovation, Science, Research and Tertiary Education (DIISRTE) for the Endeavour Postgraduate Award; and Brisbane City Council, ENERGEX, Queensland Department DERM, Queensland DNRM, and QFRS for the spatial datasets used in this study.

The Role of Social Innovations in a Revised Urban Metabolism Concept Framed by Sustainable Development Paradigms

Peter GEZIK, Slovak University of Technology in Bratislava, Slovakia

Synopsis

This paper presents the outputs of the research focused on a revision of urban metabolism conceptual framework, and a suggestion for a new approach considering social innovations as a key component shaping and redirecting metabolic processes and determining a city's sustainability.

1. Introduction

This article is focused on the role of social innovations in a revised urban metabolism concept. Urban metabolism is a concept utilized for quantifying energy and material consumption and tracing use patterns in urban environments (Pincetl et al. 2012, p. 193). This concept emerged in the mid-sixties when Wholman (1965) compared urban processes of material, energy and water transformation to those occurring in metabolisms of living organisms. Since its first emergence, the emphasis has been mainly placed on the efficiency with which resources are used, and the theory of urban metabolism has not been widely developed (Golubiewski 2012). The vagueness of the concept and lack of studies, which could provide a comprehensive quantification of urban metabolism, (Minx et al. 2011) resulted in urban metabolism failing to become a widely applicable system-based approach. Since the last decade, many authors (Newman 2008; Minx et al. 2010; Goonetilleke et al. 2011; Pincetl 2012, Pincetl et al. 2012) continue to struggle to expand the concept, and define missing components which can transform the urban metabolism concept into a widely applicable system-based approach. In their scholarly articles they outline various urban drivers and factors which need to be considered as lifestyles (Minx et al. 2010), knowledge, information, technology, culture (Goonetilleke et al. 2011), and cultural priorities (Newman 2008). Scholars also highlight site-specific impacts on the character of urban metabolism and its correlation to locations, activities, or people (Pincetl et al. 2012). This article focuses on social innovations which utilize information, technology (Mulgan 2006), and shared knowledge via social networks, and shape cultural priorities and needs as their development and character determine characteristics of a respective community. Social innovations also characterize the lifestyle of a specific community because they are "generated by a social movement, defined as a group of actors sharing the same conditions, interests, visions, objectives or ideas, who are determined to undertake one or more actions designed to tackle some sort of social need" (Oliveira & Breda-Vázquez 2012, p. 524).

By the end of 2008, increasing urbanization achieved its magical milestone with more than a half of world's populations living in urban areas. More than ever before cities are becoming key habitats for humans and thus also placing increasing pressure on the environment, resources, and energy demands. A better understanding of the processes within the city system can reflect the interlinkages between the different drivers of urbanization, arising pressures and impacts, and can identify appropriate response measures (Minx et al., 2010). Negative impacts bounded with expanded human activities necessitates new planning approaches which may mitigate the impact and deliver sustainable development. Pincetl et al. (2012) advocate that expanded urban metabolism can address these negative impacts and outline possible pathways to sustain the quality of life for humans without permanently exhausting planetary resources or altering the planetary dynamics that support civilization.

Urban metabolism, when utilized as a system-based approach to understand urban metabolic processes and impacts, has the potential to integrate sustainable development measures into the management framework for urban development and growth. Goonetilleke et al. (2011) perceive the integration and adaptation of sustainable development into the management framework for urban growth as one of the most critical challenges facing modern urban settlements. Sustainable development paradigms also represent a framework for the research within this article.

The aim of this article is to challenge the urban metabolism concept and outline possible paths for its further extensions, which can overcome the inconsistencies in the theory and allow the concept to be utilized as a widely applicable system-based approach to understand urban metabolic processes. The key research question addressed is how social innovation determines and shapes "technical and socio-economic processes that occur in cities, resulting in growth, production of energy, and elimination of waste" (Kennedy et al. 2007, p. 44). This article is limited to a generally applicable theoretical background for further studies and experiments regarding the interplay between social innovations and material, and energy flows in urban metabolism. The methodology was based on a wide literature review utilizing comparative methods. This article is structured into five sections and a conclusion. The first section describes the current state of the urban metabolism concept, knowledge gaps, and looking closer at the ecosystem perspective. The second section familiarizes the reader with the nature of social innovations, which are exhaustively linked to the concept of urban metabolism in the third section. The fourth section relates the findings to sustainable urban metabolism and demonstrates them with numerous examples. The following discussion is summarizing the results in relation to the research objectives and discusses directions or opportunities for implementation of the findings.

2. Urban Metabolism Concept

Urban metabolism (UM) constitutes a concept addressing challenges associated with energy and material consumption in urban areas which focuses on accounting material and energy inputs and outputs into cities. Based on this concept, which emerged almost half a century ago, researchers have been struggling to develop a better understanding of energy and material flows in urban areas, and between them and the surrounding environment, with a special focus on their environmental impacts. Kennedy et al. (2007, p.44) defined UM as "the sum total of the technical and socioeconomic processes that occur in cities, resulting in growth, production of energy, and elimination of waste". Since the late twentieth century, output measures from UM analyses have been utilized for indicating urban sustainability and livability. This analysis provides a metaphorical framework within which we can examine the interactions of natural-human systems, and also provides a basis upon which to consider sustainability implications (Pincetl et al. 2012).

Despite its various possible applications UM has never been widely utilized in practice. Only a few UM studies exist, and none give more than a cursory explanation and justification of the analogy (Golubiewski 2012). There are numerous inconsistencies and unanswered questions raised by various authors. They argue (Minx et al. 2010; Golubiewski 2012; Pincetl et al. 2012) that further expansion of the concept necessitates a more interdisciplinary approach, which can better face challenges rising from such a complex system of a city. There is also a knowledge gap in understanding how site-specific issues impact sustainability measures for energy and material flows determining urban sustainability. Pincetl et al. (2012) pointed out that UM analysis necessitates matching energy and waste flows to land uses and social-demographic variables, in evaluation of the socioeconomic and policy drivers that govern the flows and patterns. There are insufficient studies explaining which components determine a distinct metabolism of a respective city, and how these specifics should be taken into account in the analytical and regulatory processes. Minx et al. (2010) pointed out that

existing studies provide very little information in terms of the amount of resources extracted or the amount of pollution generated, and how this might change aspects of environmental quality, or how this might relate to basic concepts of environmental sustainability. Insufficient attention has been paid to how changes in the metabolism modify spatial and functional structure of complex and dynamic urban areas, how to manage these changes, and what the drivers of these changes are.

2.1 Ecosystem Perspective

Some authors (Marshall 2009; Pataki 2010; Golubiewski 2012) argue that the analogies described by Wholman (1965) and his followers (Huang and Hsu 2003; Sahely et al. 2003) fail in many dimensions, arguing instead that the metabolic flows of a city should be compared to the processes in an ecosystem rather than those in an organic body. Marshall (2009) suggests that a city is a complex, dynamic, collective entity: a super-unit, made up of components that are themselves units, rather than a corporate unit composing sub-units. He emphasizes the distinction between central intelligence characterizing living organisms and collective or distributed intelligence typical for ecosystems. Whereas an organism is a single individual, an ecosystem encompasses a complex assemblage of multiple individuals located within their environment (Golubiewski 2012), who do not rigorously rely on an overall decision-making executive. Unlike organisms, a city has competing as well as cooperating components, which often behave in a self-interested and selfish way regardless of the interests of a whole (Marshall 2009). An ecosystem is not equivalent to an organism because it is not under direct genetic control (Patten and Odum 1981), and all its components, their functions and unchangeable layout are not predicted before its genesis. Rather, they emerge, develop and cease to exist during one lifetime. Ecosystems are understood as complex systems which are continuously evolving and changing, though this change is at times either slow and gradual, or large and rapid (Biggs et al. 2010). Ecological succession does not operate unidirectionally toward a predetermined climax community and thus the ecosystem does not have a predetermined structure or morphology (Golubiewski 2012). Therefore, Biggs et al. (2010) suggest shifting the focus of ecosystem management away from attempting to maintain ecosystems in some fixed optimal state and instead focusing on guiding ecological change along desirable trajectories.

Buildings, people or infrastructure are components of a more comprehensive system tied together by tangible and intangible bonds (Marshall 2009). Positioning in the city determines the performance of each component and its further development or decline, depending on the mutual interaction between a component and the superior system. A distinguishing feature of complex systems is that they are defined more by the interactions among their constituent parts than by the parts themselves (Biggs et al. 2010). Compared to a city, urban components interact via metabolic flows of energy, materials producing various technical and socio-economic processes represented by UM. Character and extent of these processes determine the transformative change of an urban component. The existence of these processes depends not only on the presence of energy or materials in the system, but on the inclusion of innovations, another element which can impact character, extent and direction. Innovations form the development of an urban component, and their presence and attributes determine the extent and character of needs for certain material and energy flows. Compared to an ecosystem, Biggs et al. (2010) also suggest a social-innovation framework for the analysis of transformative change in ecosystem management because it not only describes processes of change, but also emphasizes the factors and leverage points that may foster their emergence.

3. Nature of Social Innovations

Innovation is a concept studied in many disciplinary contexts, leading to a multiplicity of definitions, including psychological, sociological, and economic ones (Wineman et al. 2009). Innovation differs from invention in that it does not only refer to the creation of new ideas or products, but also to the processes of diffusion or adoption that make promising ideas useful in meeting social needs (Biggs et al. 2010). Social innovation refers to innovative activities and services that are motivated by the goal of meeting a social need and that are predominantly diffused through organizations whose primary purposes are social (Mulgan 2006). They mean the application of creativity to social purposes (Moulaert and Nussbaumer 2005; Mulgan 2006, Oliveira & Breda-Vázquez 2012), introducing changes in a social landscape (Moulaert et al. 2005). Innovations have to cross the chasm as they pass from being promising pilot ideas to becoming mainstream products or services (Mulgan 2006). "Every successful social innovator or movement has succeeded because it has planted the seeds of an idea into many minds" (Mulgan 2006, p. 149).

Social innovations are not easily replicable; it may take decades to create the environmental conditions for growth, and the organizational challenges are no less severe (Mulgan 2006). Places and spaces are highly relevant for the emergence and thriving of social innovations because they are simultaneously dependent on both path and context. (Oliveira & Breda-Vázquez 2012). These dependencies stem from the nature of urban system from which they emerge, as each system has its own specificities, including the mix of resource use and social organization, governance and position in larger systems (Pincetl et al. 2012), quality of communications (Keller 2008), system scale and diversity of actors (Drewe et al. 2008). These factors may contribute decisively, while diversity of actors is considered a key factor in sustaining social innovations and promoting their diffusion across different territories, policy sectors and segments of society (Oliveira & Breda-Vázquez 2012).

4. The role of social innovations in urban metabolism

There is an assumption that different cities have different metabolic processes even though they may use approximately the same amounts of energy and materials because they depend largely on site-specific conditions (Minx et al. 2010; Pincetl et al. 2012). In the last decade many authors (Gandy 2004; Kennedy et al. 2007, Newman, 2008; Minx et al. 2010; Goonetilleke et al. 2011; Pincetl et al. 2012; Pincetl 2012) are searching for factors and drivers which are responsible for these variations. Kennedy et al. (2007) claim that the metabolism of cities should be analyzed in terms of four fundamental flows or cycles (water, materials, energy, and nutrients) and differences in the cycles may be expected between cities due to age, stage of development (i.e., available technologies), and cultural factors. Minx et al. (2010) found that metabolic flows are equally shaped by drivers such as land-use planning and infrastructure decisions or the economic role of the city under consideration as well as the lifestyles of its residents. Goonetilleke et al. (2011) define intangible inputs as knowledge, information, technology, values and culture, which are included within the integrated UM framework. Pincetl et al. (2012) suggest that UM analysis, to be effective, also requires consideration of variables such as demography, economy, health, mobility/accessibility, equity, community quality, policies and regulations, employment, and education. Furthermore they pointed out that interdisciplinary collaboration is necessary for matching energy and waste flows to land uses and social-demographic variables, in evaluation of the socioeconomic and policy drivers that govern the flows and patterns.

In this article it is suggested that examination of amount, generation, and character of social innovation also play an important role in expanding the UM concept. The aforementioned conditions for growth and development of social innovations share many common features with the factors and drivers expanding the UM concept as characterized by UM researchers.

They are both context-dependent and interplay in the socio-cultural development dimension. The character and rate of generation and implementation of social innovations shape such factors as lifestyle, stage of development, demography, economy, mobility, accessibility, values and culture.

For example, the growth of metabolic flows is due to the increase in urban population, but even more to the rising per capita demand of citizens for floor space, goods, leisure activities, etc. (Kennedy et al. 2007). It was proven that a reduction in household size and dwelling occupancy are a more important driver of CO₂ emissions than population growth (Minx et al. 2010). Drivers for new needs in terms of, for example, floor space, goods or leisure activities are closely tied to new possibilities (Mulgan 2006) arranged by innovations. Social innovations are introducing changes in a social landscape which are becoming mainstream, gradually forming urban lifestyles.

Much of what we now take for granted in social life began as radical innovation. A century ago, few believed that ordinary people could be trusted to drive cars at high speed, the idea of a national health service freely available was seen as absurdly utopian, the concept of "kindergarten" was still considered revolutionary, and only one country had given women the vote. Yet in the interim, these and many other social innovations have progressed from the margins to the mainstream (Mulgan 2006, p. 145).

In the western world, the ideas of individualism boosted new activities which were introduced and disseminated via social innovations. They shifted the traditional values of family life to those of self-reliance, self-presentation, and self-realization with tremendous effects on urban metabolic flows. Large family households gradually became obsolete and people began investing their time and effort into securing their self-reliance rather than raising many children. This transformation brought changes in terms of demography, represented by the decreased fertility rate and also affected city growth in the expansion of the areas needed for housing development. The implementation of social innovations such as kindergarten, work-free Saturdays, or various technological innovations like the electric washing machine, dish washer, and stove supplied even more time for self-presentation, and self-realization. New activities and opportunities now appeared, and were reflected by changes and creations of new metabolic flows. The use of airplanes for summer holidays, or self-organized weekend trips using a passenger car became standard for most western households. Inventions such as the World Wide Web, cell phones or internet shopping do not cause recognizable change in organizations of urban metabolic flows until they undergo the processes of diffusion and adoption involving the masses and thus become innovations. In the field of communication and transport, innovations are broadly extending accessibility of various materials, nutrients and energies, causing modern cities to no longer rely on their hinterlands; rather, they participate in continental and global trading networks (Kennedy et al. 2007).

In very early stages of the process of innovation, the presence of creative people is necessary because they come up with new ideas that can possibly become innovations (Mulgan 2006, Oliveira & Breda-Vázquez 2012). These people, including artists, writers, scientists, entertainers, actors, and designers, make up the core of the 'creative class' and they tend to cluster in certain places, not only for economic but also for lifestyle reasons (Oliveira & Breda-Vázquez 2012). They seem to be attracted to locations that offer diversity, authenticity, tolerance and inclusiveness, the so-called 'soft location factors' (ibid.). Compared to business innovation models in which bigger organizations have more 'absorptive capacity' to learn and evolve innovations, (Mulgan 2006) large cities are also often found to be the places which give birth to massive social changes. They can provide a pooled market for knowledge workers, more efficient suppliers to the industry (Teirlinck and Spithoven 2008) and also attract the creative class due to their soft location factors. The generated social changes are gradually transferred from the city of origin not only to similar cities which keep active exchanges of human capital, knowledge, and innovations, but also

between the city and its hinterland. This transfer can be observed in the example of backyard farming fading as the result of lifestyle change and eased accessibility of imported food. Initially it vanished from the urban outskirts and continued further to the hinterlands which were increasingly colonized by urban population spreading social innovation originally evolved in urban areas. This social innovation transfer significantly transformed nutritive metabolic flows, not only of the hinterland itself, but also of the city depending on it.

5. Sustainable urban metabolism

Urban metabolism provides a metaphorical framework to examine the interactions of natural-human systems and provides a basis upon which to consider sustainability implications (Pincetl et al. 2012).

The decision to concentrate on materials is based on the fact that there are reliable metrics for the assessment of urban material flows and stocks and that materials and substances are crucial for the sustainability of a city in terms of functioning resource availability, and environmental protection (Kennedy et al. 2007, p. 11).

Since the late 1980s 'sustainable development' and 'sustainability' have gradually become a main objective of the majority urban planning frameworks even though the concept of sustainable development and sustainability itself is still vague and undefined (Goonetilleke et al. 2011). Additionally, UM researchers have not achieved a stabilized consensus on what measures and characteristics represent its sustainable state. Nevertheless, the current set of practices defined by sustainable development research still represents the most reliable framework for UM. Minx et al. (2010) highlighted that the standard UM concept only provides information on environmental pressures in terms of the amount of resources extracted or the amount of pollution generated, but on the other hand it provides little information in terms of how this might change aspects of environmental quality or how this might relate to basic concepts of environmental sustainability. Pincetl et al. (2012) suggest that the sustainable city implies an urban region for which the inflows of materials and energy and the disposal of wastes do not exceed the capacity of its hinterlands. Newman (1999) stated that the best way to ensure that there are reductions in impact is to reduce the resource inputs. Kennedy et al. (2007) further pointed out that understanding the changes to storage processes—water in urban aquifers, heat stored in urban canopy layers, toxic materials in the building stock, and nutrients within urban waste dumps in some cities- may be as important as reducing the sheer magnitudes of inputs and outputs.

Resource depletion and energy deficiency are shifting the focus on other components of urban metabolism which can partially subsidize material and energy flows. This article suggests that innovations and their management have the ability to transform or redirect material, energy and nutritive urban metabolic flows. Minx et al. (2010) presented how three different approaches to content urban energy demands can impact the quality of the environment and thus determine urban sustainability.

For example, to meet increased urban energy demands, a city can build a new power plant increasing local air pollution. This might have detrimental health effects for at least some of the urban population and therefore diminish quality of life in the city. Alternatively, it can import the additional energy from elsewhere. In this case, whilst the metabolism of the city grows, urban quality would not be affected in the city of consideration (but potentially elsewhere). However, the global environmental effects could potentially be negative (even though not necessarily). A third alternative could be the replacement of an old, small inefficient power plant with a new, bigger and highly efficient one on the city's

territory, which provides more usable energy with a smaller pollution output. In this case depending on the degree of efficiency improvements and the level of additional energy demands, the metabolic change could even decrease local air pollution and improve urban quality.

In these three examples it can be easily observable how technological innovation offers the most environmentally friendly solution. Many more examples can be found where innovations shape, redirect or bring to the end various urban metabolic flows. Social innovations like community wind farms or zero-carbon housing developments are bringing considerable changes to the environmental impacts of per capita energy demands. Consideration of social innovation character and rate of generation can increase the accuracy of UM analysis and also outline sharper contours of its further development.

Goonetilleke et al. (2011) argues that waste should be viewed as a resource, to be used 'fit for purpose' rather than to be disposed as expeditiously as possible. Today's stock is tomorrow's waste, and can serve as a future resource because of the time gap between input and output: in a growing economy, the future amount of wastes will be much larger than today's (Brunner 2007). Ecological friendly innovation like recycling can turn the state of UM from a linear one to a more circular one in which resources are utilized multiple times and thus lower inputs are needed. Social innovation stimulation and promotion can be crucial, as the social change produced depends on how many people are being persuaded to abandon old habits (Mulgan 2006). Reduced dependency on external supplies of resources would increase the stability, diversity and resilience of the urban ecosystem (Golubiewski 2012).

6. Discussion

The aim of this article was to outline possible paths for further extensions of the concept of urban metabolism, which can overcome the inconsistencies in the theory and describe how social innovation determines and shapes technical and socio-economic processes that occur in cities. The research aiming to answer the key research question was limited to a generally applicable theoretical background for further studies and experiments regarding social innovations in UM.

To our knowledge, it is the first study that examines the role of social innovations in the UM concept. This article critically assessed the current state of the matter and outlined new approaches which expand the concept, and defined missing components which can possibly transform the UM concept into a widely applicable system-based approach. Better understanding of the processes in UM can reflect the interlinkages between the different drivers of urbanization, arising pressures and impacts, and identify appropriate response measures (Minx et al. 2010). Expanded UM has the potential to integrate sustainable development measures into the management framework for urban development and growth.

Social innovation determines and shapes technical and socio-economic processes that occur in cities because they form the development of an urban component, and their presence and attributes determine the extent and character of needs for certain material and energy flows. The character, and rate of generation and implementation of social innovations shape factors such as lifestyle, stage of development, demography, economy, mobility, accessibility, values and culture which were previously found to have an impact on UM. Social innovations significantly transform metabolic flows not only of the city of their origin, but also metabolic flows of its hinterland and similar cities with which it maintains an active exchange of human capital, innovation and knowledge. Innovations and their management have the ability to transform or redirect material, energy and nutritive urban metabolic flows and bring considerable changes in environmental impacts. They can turn the state of UM from a linear

one to a more circular one in which resources are utilized multiple times and thus lower inputs are needed.

Integration and implementation of the UM concept into planning institutional framework is perceived as a conditioning prerequisite for the utilization of its ideas in practice. Such a framework should provide a platform whereby different disciplines can appreciate, absorb and learn from other areas, and should have the flexibility to adapt to a range of dynamic scenarios of defined elements in the expanded UM framework (Goonetilleke et al. 2011). It should secure a balance between complementary and contradictory social, economic and environmental goals via negotiation, compromise and integration of technical designed oriented knowledge (ibid.).

Territorially rooted institutional context made up of formal and informal rules, values and practices is extremely hard to reproduce, but plays a crucial role in respect to social innovation adaptation and diffusion (Oliveira & Breda-Vázquez 2012). Organizations and government institutions should take the managerial role over the processes, and provide appropriate supporting mechanisms as some social innovations may fit better with diverse contexts than others (ibid.). On the other hand, regulating mechanisms are also necessary because not all social innovations in any extent support suitable UM. The supporting mechanisms have to be focused on creating an appropriate environment securing emergence of innovations, because social innovation cannot be directly planned and produced; it can only be stimulated by creating an environment conducive to the emergence of innovation (Biggs et al. 2010). The environment has to provide networks where apparently unrelated methods and ideas can be used together (Mulgan 2006).

7. Conclusion

Innovations need to be interpreted as new dimensions in the urban metabolism concept. Constantly accelerating innovations determine the orientation and also the existence of most urban processes, representing the key elements steering urban development and sustainability. Better understanding of the development tendencies and interdependences between material, energy, nutritive, and innovation flows can deliver a more comprehensive assessment of viability and efficiency of respective planned managerial interventions. The responses of various urban agents anchored in a city's institutional framework to innovations, in the context of socio-cultural specifics, co-determine urban metabolism processes. Further research will be needed to examine the tasks of urban metabolism management and to develop a consistent methodology utilizing the findings presented in this article.

Interrelation Between Micro-Blog Hotspots And Urban Spatial Network: An Empirical Analysis Of Tongji-Rim Intellectual-Economic-Zone, Shanghai, Based On Sina Weibo

Jing HAN, Lingyu KONG, Tongji University, China

Abstract

In the society with highly developed information technology, interaction of virtual world and physical space has become a hot topic for urban planners and architects. This paper tries to explore the mutual relation between information technology and physical space from a micro perspective of a small-scale urban area. We take the intellectual-economic-zone around Tongji University as target area. We propose a three-step methodology. First, we collect all the micro-blogs published on the Sina platform within Tongji-Rim during a week and create the hotspots density graph (heat map). Second, by Urban Network Analysis (UNA) toolbox of ArcGIS, we measure the five spatial network centrality indices of Tongji-Rim. Third, we overlay the heat map on the UNA graphs and compare the similarity. The outcome shows that there obviously exists interrelation between social network and urban spatial network. The order of the five indices' explanatory power for micro-blog heat map is: Reach, Straightness, Betweenness, Closeness and Gravity. Higher reach and straightness lead to more opportunities of arriving and micro-blogging. Betweenness represents necessity of passing by but not staying or more worthy news. The weak explanation of Closeness is the evidence that, although the virtual social network must be based on real individuals and space, information technology has already broken the geographic barriers. Location and distance are not the most significant factors for urban development.

1. Introduction

Information technology has been making dramatic impacts on the traditional space geography. It changed the way people understanding place and time, and built a new form of organization of space and objects in it. Many scholars have studied this variation from different aspects. Manuel Castells (1996) distinguished space of flow and space of place. He argued that the space of flow consists of the technical infrastructure network, the node and hub network, the dominant elite network and websites. This thought provided an important theoretical frame for physical and virtual space research.

After the traditional one-to-many and one-to-one media, the emergence of social networking services has brought human society into to a new many-to-many media era. Among various social networking services, micro-blogging has noticeably revolutionized the way information is consumed. Just as Nagarajan et al. (2009) pointed out, micro-blog has empowered citizens themselves to act as sensors or sources of information that could lead to consequences and influence, or even cause media coverage.

What's more, according to Liu Yang (2010) and Zhan Zihua (2011), by the end of June, 2011, the total number of netizens in China has amounted to 485 million and Internet penetration rate has reached 36.2%. The number of micro-blog users has increased to 195 million, while netizen utilization rate has been expanded to 40.2% from 13.8%. From the world's first micro-blog, Twitter, to Sina Micro-blog and Tencent Micro-blog in China, micro-blog has gradually become the fastest-growing Internet application and an influential social media.

Thousands of billions of micro-blogs are generated every day from all over the world, which makes micro-blog not only a platform for developing interpersonal relationship, but also a valuable huge database for studies. In this context, many experts mined the big data from different dimensions like space, time, theme, sentiment, impact, network structure, spreading mechanism etc. As for urban researchers and planners, does virtual factor have any relation with the physical space, what kind of interrelation is between them, and how do they interact with each other, are the questions they concerned most. To understand this, foreign scholars graphed and animated the heat map of Twitter. They proved that Twitter users can be considered as sensors that react to spatial static events or moving patterns (Sakaki *et al.* 2010), and it is possible to reliably detect relevant spatial changes (Eduardo Ruiz and Vagelis Hristidis 2013). Domestic scholars Zhen Feng *et al.* (2013) analyzed China's city network characteristics on Sina Micro-blog. The result shows a clear hierarchical structure and level distinction which are consistent with the real ones. They believed that the spatial "flow" and "viscosity" brought by this powerful new media will have a positive impact on urban systems.

Above all, scholars both at home and abroad have answered the questions from a national and regional macro view. But researches on the urban micro level are really rare. As a result, based on the previous theories and related works, this paper tries to explore the interrelation between micro-blog hotspots and urban spatial network from a relatively microscopic perspective of small-scale urban area. We take China's most popular social networking service site Sina Weibo as platform, and the intellectual-economic-zone around Tongji University as target area.

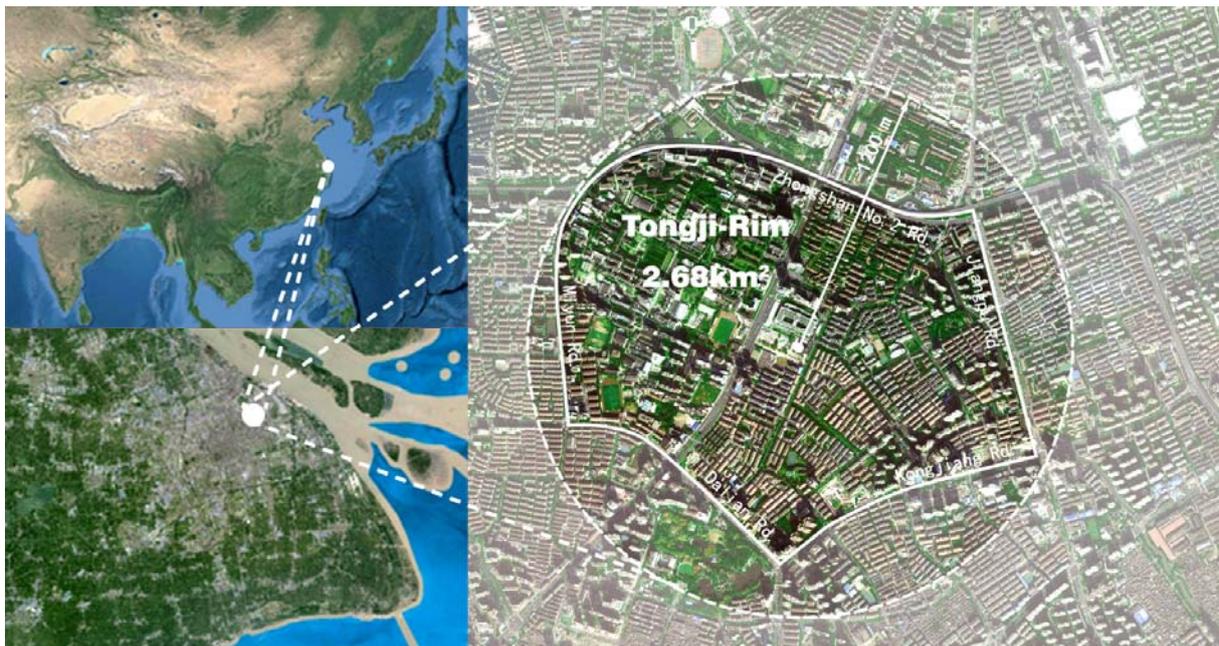

Figure 1: The location of Tongji-Rim Intellectual-Economic-Zone
Source: Author's self-drawn

The Tongji-Rim Intellectual-Economic-Zone (Figure 1) is currently China's largest design industrial cluster. Located in Yangpu District, Shanghai, reaching North Zhongshan No.2 Road on the north, Jiangpu Road on the east, Dalian Road and Kongjiang Road on the south, Miyun Road on the west, it occupies an area of 2.68 square kilometers. It mainly homes architectural design studios and urban planning offices, and is supplemented by various types of knowledge-based service enterprises such as education and training, landscape

design, art and media design, environmental engineering design, automobile design, software design and engineering consulting. There are tens of thousands of high-quality talents, who are the majority users of micro-blog, making it an ideal area to study the interrelation between micro-blog and urban spatial network.

This paper is organized as follows: After introducing the background and related studies in this section, we construct an innovative research methodology in Section 2. Section 3 presents the detailed research process in which a weekly micro-blog heat map of target area is drawn, a series of spatial traits are tested and the comparison of their similarity is made. Section 4 gives the ranking results of the spatial traits' explanatory power for micro-blog hotspots distribution and respectively analyzes the reasons. We discuss the meaning of results and conclude the paper in Section 5.

2. Methodology

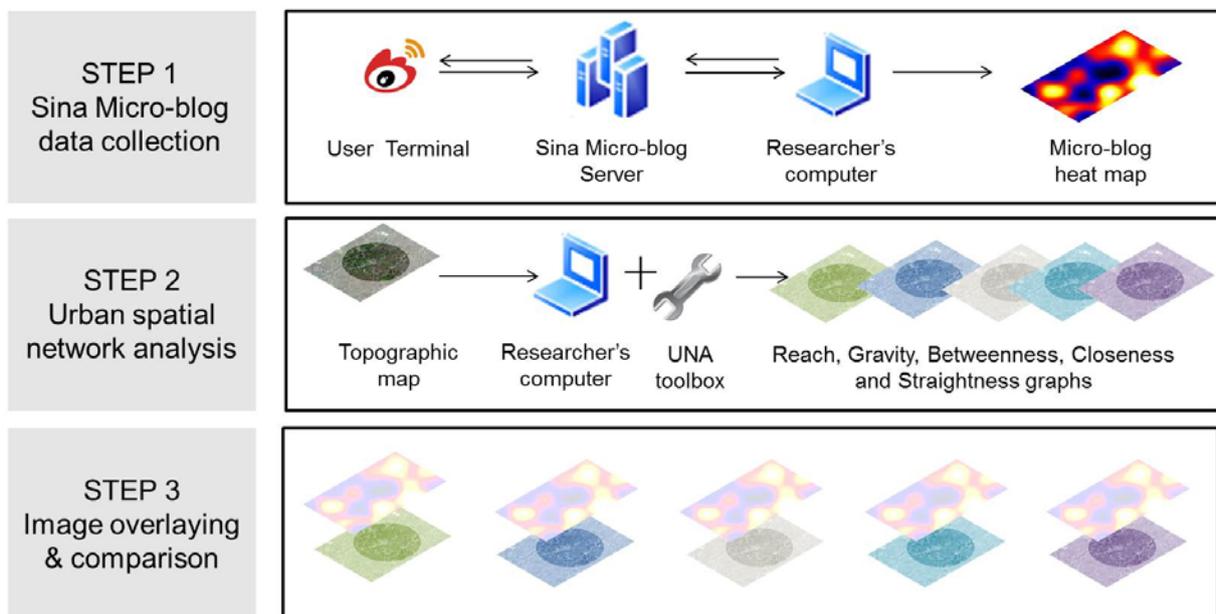

Figure 2: Framework of the research
Source: Author's self-drawn

This paper proposes a three-step methodology (Figure 2). The first step is data collection and visualization. We collect all the micro-blogs published on the Sina Weibo micro-blogging platform within Tongji-Rim for a certain period (a week). Then we extract time and geographic location information from every micro-blog posts, and organize them into a table. To create the hotspots density graph/heat map, we import the table into ArcGIS, and show it in a time-split way.

The second step is urban spatial network analysis. With the open-source software plug-in extension, Urban Network Analysis (UNA) toolbox for ArcGIS (developed by City Form Lab at the Singapore University of Technology & Design in collaboration with the School of Architecture & Planning at MIT), we compute five types of network centrality measures on spatial networks in the target area: Reach, Gravity, Betweenness, Closeness and Straightness. This toolkit applies to small-scale and detailed networks of dense urban areas, like Tongji-Rim.

The third step is image overlaying and comparison. We overlay the spatial network analysis results, Reach, Gravity, Betweenness, Closeness and Straightness images, respectively on the micro-blog heat map, to match the distribution of the micro-blog hotspots, and find out the spatial traits which best explain the visualized Sina Weibo data.

3. Research Process

3.1 Micro-Blog Data Collection

Sina Weibo Open Platform provides Application Program Interface (API) for developers. We choose "place/nearby_timeline" port to capture the dynamic information surrounding a particular location. To cover the whole Tongji-Rim area, we draw a circle with 1200-meter-radius and centered in the point of Shanghai No.1 International Design Square, whose specific latitude and longitude coordinates are 31°16'53.50" N, 121°30'10.21" E. The time range is the latest 7 days, from Jun 23 00:00:00 +0800 2013 to Jun 30 00:00:00 +0800 2013. By running the self-designed code, all the micro-blog containing users' personal information and post content are read one by one and output in the text form.

The statistical result shows that 6211 Sina micro-blogs were published altogether in the past 7 days around Tongji-Rim, 887 posts on average a day and 74 posts every two hours (Table 1). Every day there were two peaks, from 10:00 to 14:00 and 16:00 to 22:00, and two valleys, from 14:00 to 16:00 and 2:00 to 6:00 (Figure 3).

	Jun23	Jun24	Jun25	Jun26	Jun27	Jun28	Jun29	Total	Aver
00:00-02:00	63	54	54	54	67	45	52	389	56

Total	931	774	1076	845	824	838	921	6211	887
Aver	78	65	90	70	69	70	77	887	74

Table 1: The number of Sina Micro-Blogs around Tongji-Rim in every 2 hours of 7 days
Source: Sina Weibo Open Platform and the author's own study

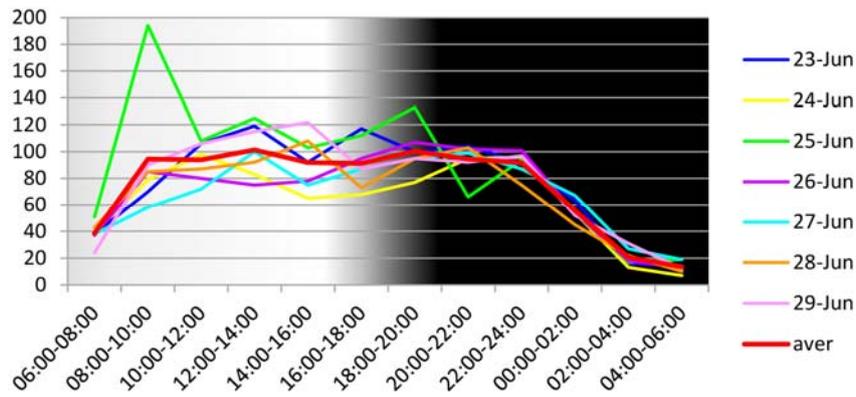

Figure 3: The line chart of Sina Micro-Blogs around Tongji-Rim in every 2 hours of 7 days
Source: Sina Weibo Open Platform and the author’s own study

Table 1 and Figure 3 only tell the distribution characteristics of micro-blog publication from date and time dimension. To make comparative study with real space, what is more important is to find out the exact places where micro-bloggers release every post, then we can analyze the relevancy. Therefore, we import the processed data into ArcGIS, align the coordinate system, and achieve the spatial-temporal graphs.

The left side of Figure 4 is the scatter plot of all 7 days. Each red spot corresponds to one micro-blog. The transformed heat map, which reflects the density of micro-blogs, lays on the right side. (The transformation method is to enumerate the dots in a circle with given radius. Here we use 100-meter radius for best image effect.) From it, 2 red super hotspots in the northwest and southeast can clearly be seen. Their real addresses are the Music Square near the College Students’ Activity Center of Tongji University, and the commercial area around Xinhua Hospital, respectively. On the periphery of them, as well as at the intersection of two thoroughfares (in the southwest corner) -- Dalian Road and Siping Road, there are some yellow secondary hotspots forming a triangle structure. Along the sides the heat falls off gradually with distance, and in the center very few micro-blogs are produced. Figure 5 illustrates the initial daily scatter plots from Jun 23 to 29, 2013.

Source: Author's self-drawn in ArcGIS environment

3.2 Urban Spatial Network Analysis

As a mathematical method of quantifying how centrally each graph element is located with respect to the surrounding elements, the UNA toolbox abstract and simplify the topographic map of Tongji-Rim into a framework to represent the built environment before computation, which is illustrated in Figure 6. The left side of the figure presents a fragment of Tongji-Rim in topographic map. The same plan drawing is shown in abstracted graph form on the right. Analysis results of the five metrics are illustrated in Figure 7 and described each in detail below.

*Figure 6: Left: Detail Topographic Map of Tongji-Rim.
Right: a graph representation of the same plan drawing
Source: Shanghai Surveying & Mapping Institute and author's self-drawn*

To eliminate the edge effect, we use a larger network that represents the metropolitan environment as a whole (see Figure 7, Row 1, Left). Then we clip off the surroundings from the analysis and only focus on our case study area.

The reach centrality of a node describes the number of other nodes in the network that are reachable from it at a shortest path distance of at most radius input by researcher (here we adopt 500-meter radius). The right graph in row 1 of Figure 7 illustrates the Reach measure applied to buildings in Tongji-Rim. We see that areas with higher Reach values result in areas, where buildings are repeated with nearly the same volumes, more densely spaced, or where the street network is denser. Along Fuxin Road, Jinxi Road and Anshan Road, a typical building reaches roughly 300 other buildings in a 500-meter walking radius. To the contrary, in a campus area around Tongji, ten times less buildings can be reached during the same walk.

The gravity centrality of a node in the network is based on the intuition that centrality is inversely proportional to the shortest path distance between itself and each of the other nodes in the network that are reachable from this node within a radius. Whereas the Reach measure simply counts the number of destinations around each building within a given search radius, the gravity measure additionally factors in the spatial impedance required to reach each of the destinations. First introduced by Hansen (1959), the gravity remains one of the most popular spatial accessibility measures in transportation research (Sevtsuk 2012). Gravity can be seen as a revised version of Reach, introducing the effect of the distance decay on each shortest path. The left graph in row 2 of Figure 7 shows how Gravity is applied to the same dataset in Tongji-Rim as above. Since the index is sensitive to distance, we see how the values are less spread out than in the case of Reach.

The betweenness centrality of a node in the network estimates the number of times lies on shortest paths between pairs of other reachable nodes within the network radius (Freeman 1977). If more than one shortest path is found between two nodes, as is frequently the case

Figure 7: Reach, Gravity, Betweenness, Closeness and Straightness centrality in a 600-meter network radius in Tongji-Rim
Source: Author's self-drawn in ArcGIS environment

in a rectangular grid of streets, then each of the equidistant paths is given equal weight such that the weights sum to unity. As the name suggests, Betweenness may be used to estimate the potential of passersby at different locations of the network. The right graph in row 2 of Figure 7 shows the betweenness centrality of buildings in Tongji-Rim. Buildings that are located along the main thoroughfares, especially at the intersections, intuitively obtain higher Betweenness results, since such routes offer long and straight geodesic paths between numerous surrounding destinations.

The closeness centrality of a node in the network is the inverse of the total distance from itself to all other nodes that are reachable within radius along shortest paths (Sabidussi 1966). Unlike Gravity, Closeness does not use the weights of destination buildings in the numerator, effectively making the measure purely illustrative of how far a building is from its surrounding neighbors. The left graph in row 3 of Figure 7 illustrates how the values of campus area and some commercial office buildings are higher than residential districts, which is exactly the opposite of Reach and Gravity.

The straightness centrality of a node illustrates how closely the shortest network distances between this node and others which are reachable within a radius resembling Euclidean distances (Vragovic, Louis et al. 2005; Porta et al., 2005). Mathematically, it is a ratio between the as-a-crow-flies distance and the geodesic distance from each location to the surrounding locations. The right graph in row 3 of Figure 7 illustrates how Straightness, like Reach, picks up the buildings along some of the longest and straightest thoroughfares in the network. This is because such locations offer more direct travel routes to all their neighbors than buildings along less continuous streets.

3.3 Image Overlaying and Comparison

After graphication of micro-blog hotspots and visualization of the urban network attributes, we add them together to observe the matching degrees. Figure 8 to 12 demonstrate the overlaying of Sina micro-blog scatter plot (7 days) and each spatial centrality index analysis.

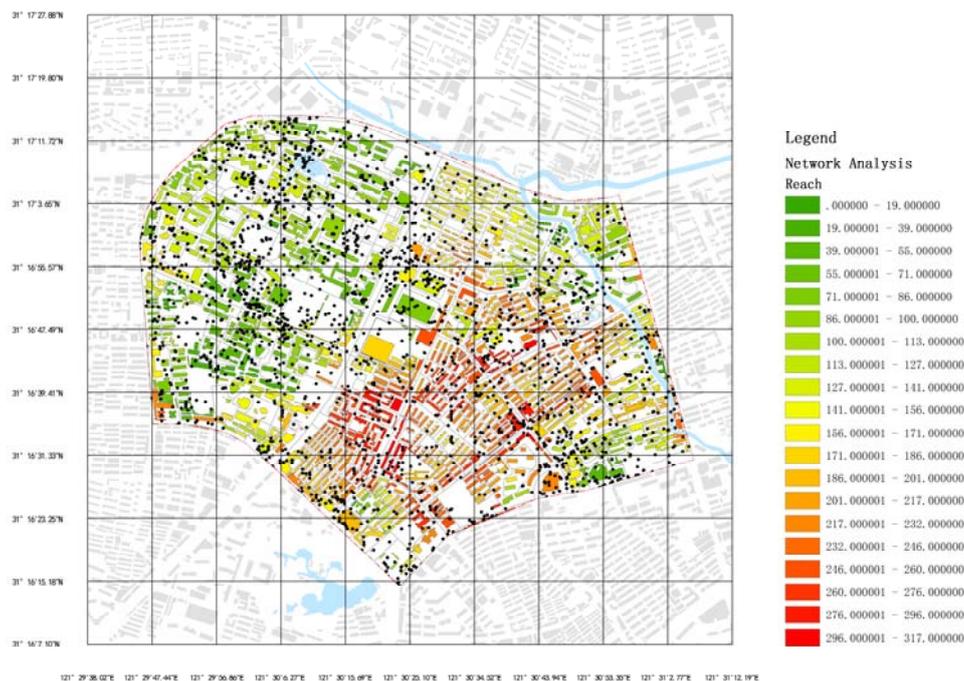

Figure 8: Overlaying of Sina micro-blog scatter plot and Reach centrality analysis
Source: Author's self-drawn in ArcGIS environment

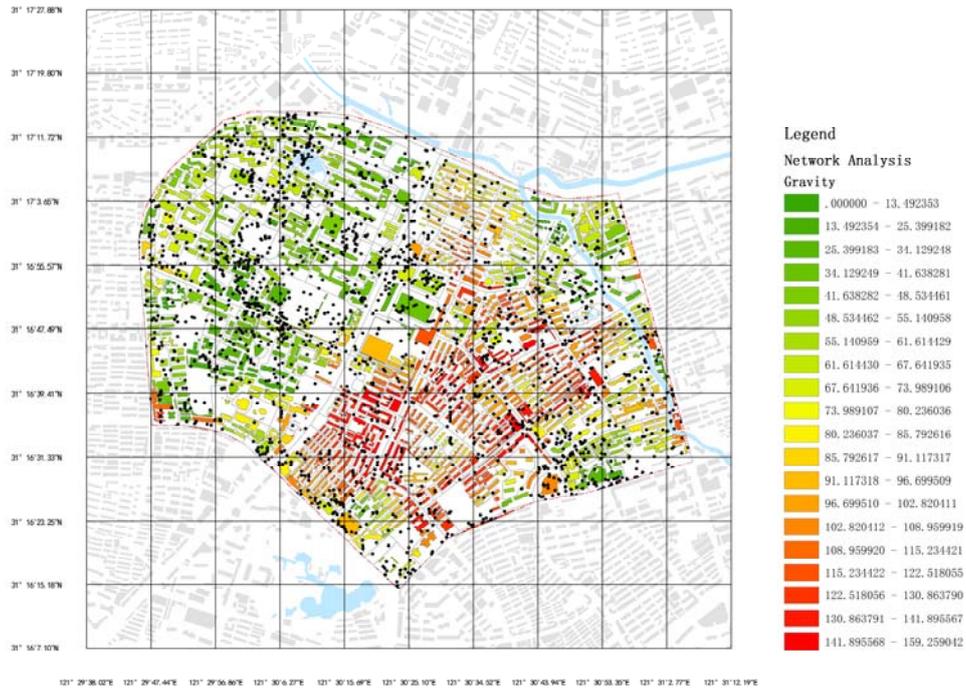

Figure 9: Overlaying of Sina micro-blog scatter plot and Gravity centrality analysis
 Source: Author's self-drawn in ArcGIS environment

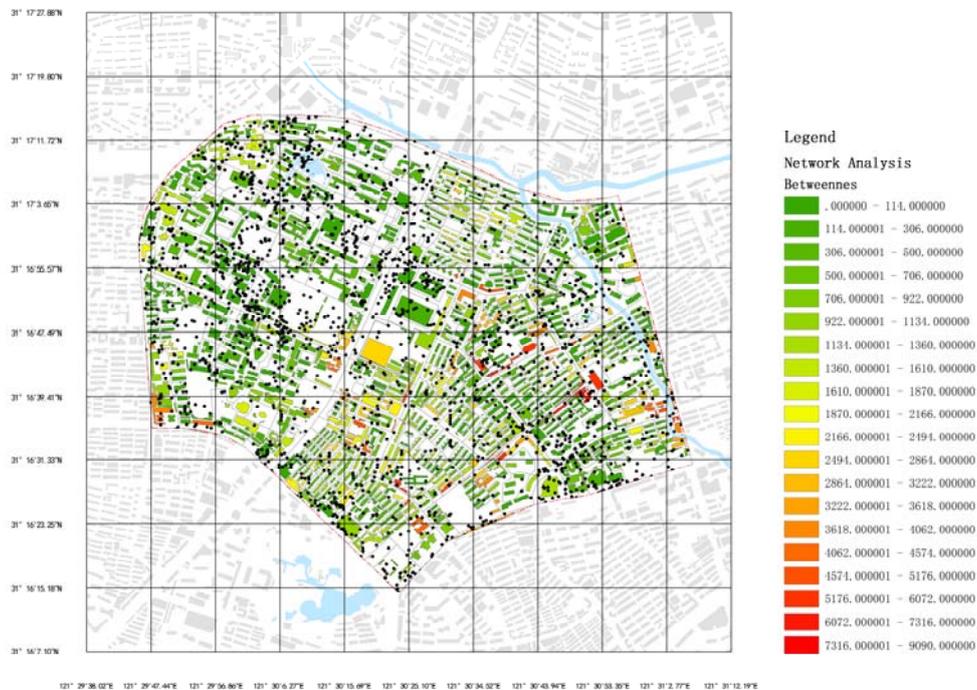

Figure 10: Overlaying of Sina micro-blog scatter plot and Betweenness centrality analysis
 Source: Author's self-drawn in ArcGIS environment

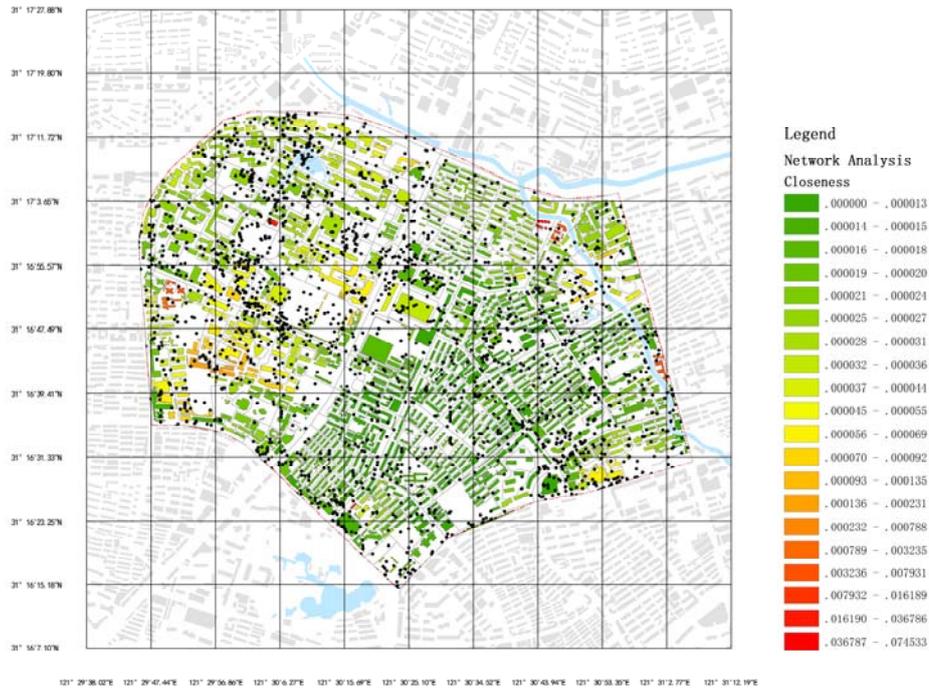

Figure 11: Overlaying of Sina micro-blog scatter plot and Closeness centrality analysis
Source: Author's self-drawn in ArcGIS environment

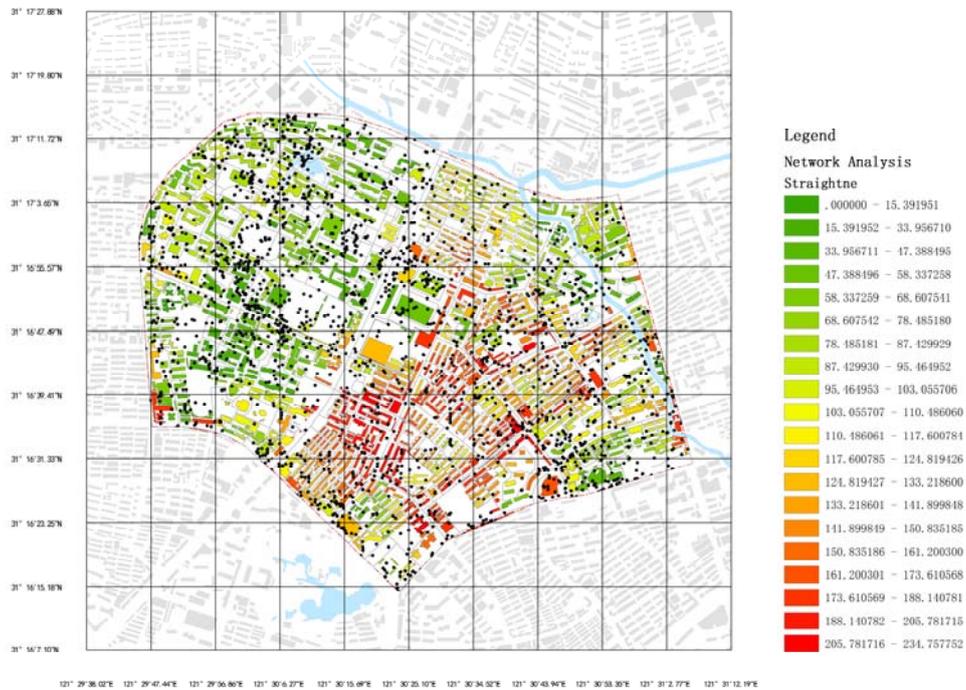

Figure 12: Overlaying of Sina micro-blog scatter plot and Straightness centrality analysis
Source: Author's self-drawn in ArcGIS environment

In Figure 8, the residential buildings in the southeast, especially some large public buildings at the gateway of the communities, have relatively higher reach values. However, the micro-blogs are not correspondingly denser in these areas. Obviously, more micro-blog dots emerge on Tongji campus, in the Tongji Union Square and the commercial area around Xinhua Hospital, where the building colors are green and yellow indicating lower reach levels. As a result, there is a negative correlation between micro-blog distributions and Reach centrality.

In Figure 9, like Reach, Gravity shows the same type of interrelation with micro-blog, just in different degrees.

Betweenness estimates the potential traffic passing by each location in the spatial network. In Figure 10, a small number of buildings with higher betweenness value, which look red and orange, are all situated in hubs or must-go-ways. There are micro-blogs showing up in these places, but more spots are also found in other greener region. Therefore, the interrelation of Betweenness and micro-blog appears more negative than Reach and Gravity.

Closeness indicates how close each of these locations is to all other surrounding locations within a given distance threshold. In Figure 11, most buildings with higher closeness values lie on the places where micro-bog spots are much denser and concentrated. Thus, contrary to Reach, Gravity and Betweenness, Closeness has a positive correlation with micro-blog distributions. This result can also be inferred through math deduction.

As in the above case of Reach and Gravity, Figure 12 shows that Straightness has the similar variation trend with them and resembles their correlations with micro-blog distributions as well.

4. Results

According to the three-step research methodology, we get the results as follows:

Firstly, in Tongji-Rim, the campus of Tongji University, the commercial area around Xinhua Hospital, and the intersection of the two thoroughfares -- Dalian Road and Siping Road are the hotspots of Sina micro-blog. Around these hotspots are the radiation areas, and the heat falls off gradually with distance.

Secondly, urban network centrality indices of Reach, Gravity and Straightness have the similar analytical outcomes that the multi-storey residential houses are the main objects with higher measuring values. Closeness performs oppositely, and Betweenness becomes more significant when buildings are located along the main thoroughfares, especially at the intersections.

Reach, Gravity, Betweenness and Straightness all have negative correlations with micro-blog distributions, but in different degrees. On the contrast, there is a positive correlation between Closeness and micro-blogs.

5. Discussion and Conclusion

The starting point of this paper is to make an exploration of the mutual relation between information technology and physical space, from a micro perspective of a small-scale urban area. The most interesting and challenging thing is that the former is unreal and the latter is real. To make the research more feasible, we choose China's widely popular social networking tools, Sina micro-blog as representative of information technology, and adopt the

spatial network centrality indices as measurement of physical space. After the three-step research above, we prove that there obviously exists interrelation between social network and urban spatial network. The former cannot exist isolated. It must take the latter as the support. In other words, any kind of information technology could not play its role without the material existence. While people utilize virtual social network tools, they must depend on the real space carriers. However, the reliance just means that virtual tools need a place for their users' existence. The place may overlap with everywhere of the users' lives. Information technology does not care about how far the place locates, and gradually takes away people's concept about distance. We can imagine that in the future a city's location or a building's site will become less and less important. The negative correlations between the four urban network centrality indices (Reach, Gravity, Straightness and Betweenness) and micro-blog distributions are explicit evidences. Meanwhile, the mathematically negative correlations of Closeness and Reach lead to the positive performance which exactly supports our points before.

To discuss in another way, people now share what they observe in their surroundings and their opinions about topics from a wide range of fields through micro-blog. Every piece of micro-blog they broadcast always is the thing they most concern about and want to show to others. Thus, in a sense, micro-blogging is a mirror that reflects people's real behaviors and preferences, or a filtered window through which we can see the most meaningful and significant parts of their daily life. Consequently, virtual network might be a digital attachment of the real world and their interrelation is reality and projection.

In addition, the residential communities where buildings have higher Reach, Gravity and Straightness values are actually the "model workers' villages", which are the special products of China's Planned Economy Era. These villages are characterized by the high-dense, multi-storey and same-looking buildings, as well as the large-scale parallel layouts, which provide a full explanation for the high level of Reach, Gravity and Straightness. Since last century the living condition of the "model workers' village" has deteriorated with the aging of the infrastructure, but there are lots of families who cannot afford a better habitat still abiding in it. The "model workers' village" falls into a gathering nest of the poor people, who are scarcely possible to use the micro-blog or other social networking service tools. By contrast, there are more chances that the college students, the white collars and the other upper-middle class micro-blog on campus, in the commercial offices or the apartments, where the building density is lower and the volume is larger. Hence, the correlations of the urban network centrality indices and the micro-blog distributions reveal the social rules and the meanings behind the appearances.

Admittedly, as a newly emerging social networking service tool, micro-blog is still in its infancy. Its interaction with the geographic entity space remains to be verified from various dimensions. But undoubtedly, the new urban spatial form brought by this powerful social dynamics will strongly change people's life styles and ideas.

From “Insertion” to “Incorporation”: the Hangzhou Example of the Transformation of the Railway in Chinese Urban Life

Shan He, University of Western Australia, Australia

1.0 Introduction

With the fast development of the national High-Speed Rail (HSR) network, the Chinese government is making efforts to maximise the geographical agglomeration effects that will be brought by the HSR, or in other words, it is planning to utilise the predicted “HSR” economy to “accommodate and channel the demand of urbanisation” (Chen, 2012: 315). We have subsequently witnessed a wave of building new towns around the station nodes in recent years. For instance, as Dong (2011) reported that, along the Beijing – Shanghai HSR line, almost all of the 24 stations have developed new town proposals, of which 16 are under construction. Therefore, we expect the development of an urban life that is tightly connected to, and fully oriented towards, the HSR infrastructure and station nodes within the new towns. Identifying how rail infrastructure has powered urban development and urban life over the century in China will help us to plan and design the new towns.

This paper takes Hangzhou City, capital of coastline Zhejiang Province, as an example, to explore such relationships between rail and urban developments in three typical historical periods: late imperial and early industrialisation (1900s-1930s), Communism industrialisation (1950s-1970s), and recent urbanisation (1980s-2000s). These periods witnessed noticeable developments in rail infrastructure and urban growth, which were however powered by substantially different mechanisms. By examining the connectivity between rail and urban life from various historical perspectives, we will have better understanding of today’s HSR town planning and design practices.

2.0 “Insertion”: The Late Imperial and Early Industrialisation Period (1900s-1930s)

Historically, imperial Hangzhou has a prestigious position within the urban hierarchical system in the Lower Yangtze Delta Region, and developed various scales of trading life in and outside of its city walls. The coming of the railways in the early 1900s, however, reshaped the urban system and the city’s identity, bringing a never before experienced prosperity to urban life.

2.1 Profile of Late Imperial Hangzhou

Sitting at the southern end of the Grand Canal and estuary of the Qiantang River, Hangzhou has been long established as the trading centre of the Lower Yangtze Delta Region, based on the water transportation network prior to industrialisation. Taking advantage of the canal’s role as the spine of north-south commodity trading in China, Hangzhou functioned as a trading hub. This trading system extended further west into the Jiangxi and Anhui provinces through the Qiantang River and its branches, which further consolidated Hangzhou’s dominant position among other cities since the period of the Southern Song Dynasty (AD 1127-1279), when this town was established as the imperial capital. Periods of prosperities have been recorded during near 800 years till late the Qing Dynasty (AD 1636-1912).

Over time, the walled up area of Hangzhou (i.e. the “Chengguo”) has most been retained and the area of city has remained relatively constant. As by the Hangzhou Municipal Government

in 1937, this is a traditional city with a long history; all of the buildings were built following ancient orders through dynasties, and variations in architecture were rarely challenged. There was however one area in Chengguo that distinguished Qing's Hangzhou from previous dynasties, also known as the "Qiyin", or, the Manchu Barracks. To symbolise the Manchus' occupation of this important town, especially as a regional military centre, the Qiyin was sited along the eastern edge of the West Lake, a place of natural beauty and cultural significance that the city had been long proud of. The Qiyin's 3-mile perimeter enclosure blocked direct contact with the lake from the town, and eventually shaped an urban life disconnected from the precious landscape (Wang, 1999). In-town commercial life was organised by the central axis street or, the "imperial spine" during the Southern Song. It was noticeable that the other major two markets were outside of the Chengguo: one in Gongchenqiao (wharf on the Canal) and the other in Zhakou (wharf on Qiantang River). This means the life inside and outside of the circumvallation was at different scales, the former focusing on local life while the latter represented the city's status in national trading.

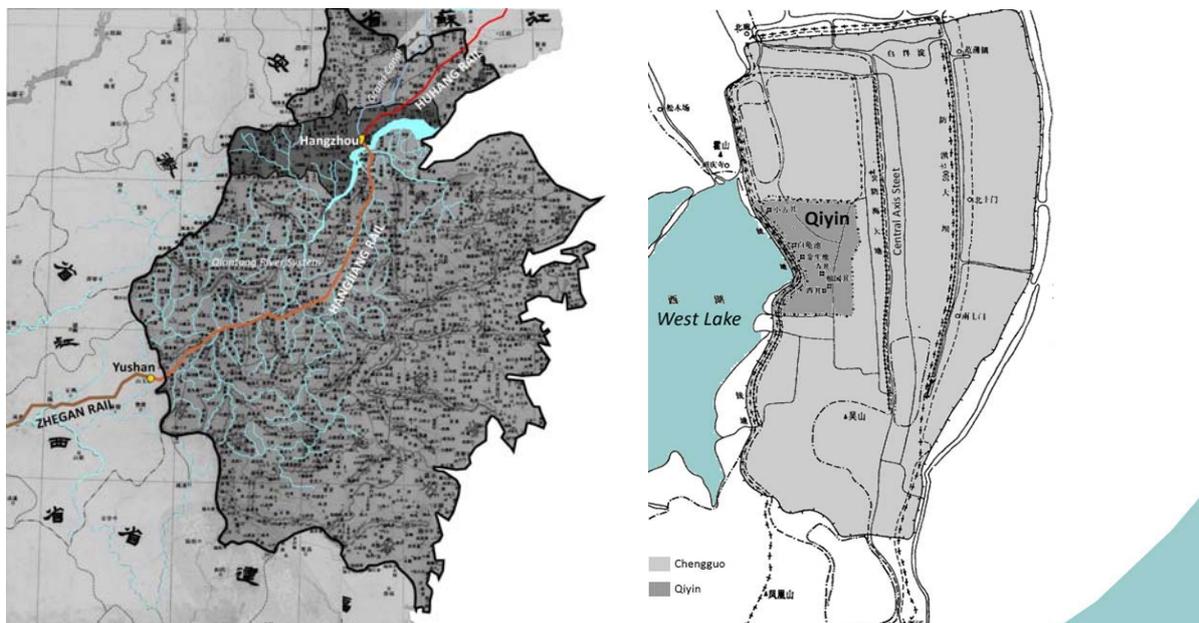

Figure 1: Map of Zhejiang in 1900s-1930s (left, adapted from ZASMAG, 2011: 150-1) indicating River and Rail systems and Hangzhou; Map of Hangzhou Chengguo (right, source: Yu, 1985: 63)

2.2 The Insertion of Three Rail Lines

In 1907, Hangzhou's first rail service, a 16 kilometre local line named "Jiangshu", was put into use after one year's construction. As a part of the proposed "Huhang" (Shanghai-Hangzhou) rail, this line connected both the wharfs of Gongchenqiao and Zhakou, which presented a clear attempt at improving the connections between the two water transportation systems of the Grand Canal and Qiantang River. This was a scale that did not involve the inner city life, which explains why the trains ran on a curve around the perimeter, and all of the five stations were placed outside of the city wall.

The Jiangshu Rail was partly connected with the Huhang Rail after two years' operation, and Hangzhou was for the first time linked with Shanghai by the 186 kilometre length of tracks in 1909 (Yu, 2005). This line was soon populated, but the stations outside of the city walls made trains less accessible, especially when the curfew system was still executed during the late Qing Period. Despite concerns of city defence, decision was later made to build a new station inside the "Chengguo" for direct connections. In 1910, parts of the walls were pulled

down and for the first time, the rail penetrated into the town to serve a new inner town station, "Chengzhan".

The third rail, initially named the "Hangjiang" Rail linking Hangzhou and Yushan County in Jiangxi Province has operated since 1933. In 1934, it was renamed "Zhegan" Rail with plans for further extension to Nanchang City, the capital of Jiangxi Province, and eventually Zhuzhou of Hunan Province, winding its way 1,008 kilometres (Yu, 2005). The extension was finished in 1937, stretching Hangzhou's accessibility further into the agriculturally productive inner-land provinces of Jiangxi and Hunan.

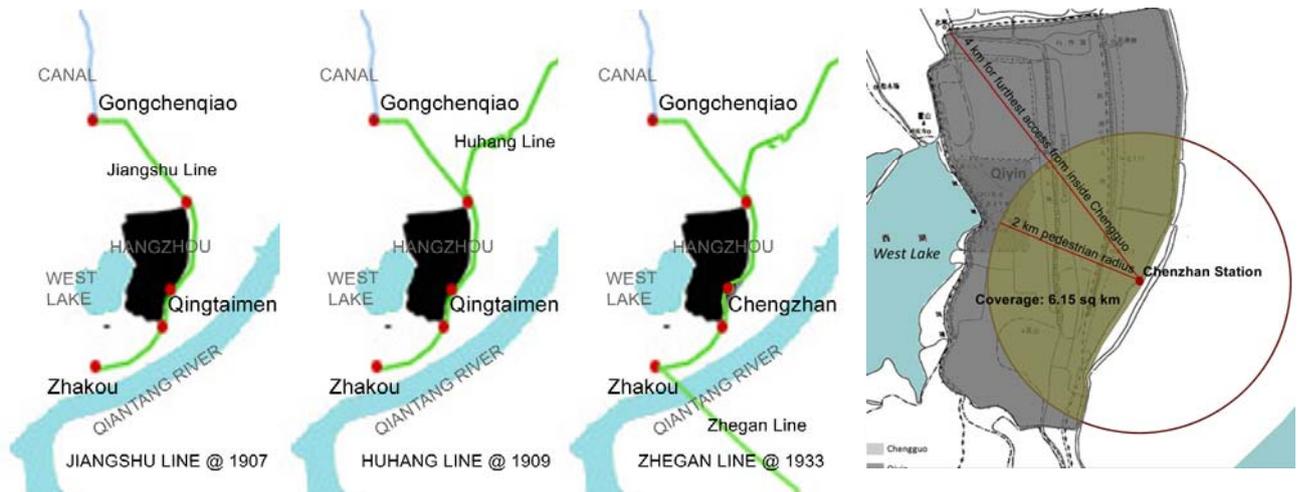

Figure 2: Insertion of three rail lines (source: Que, 1999; Hangzhou Archives, 2006) and the accessibility of Chengzhan (right end)

2.3 The Re-interpreted Urban Life of Hangzhou

By creating passage ways through the walls, the inner town of Hangzhou was connected into a new hierarchy networked by railways, which was centred in Shanghai. The increasing use of rail infrastructure (Ma, 2008) eventually defeated the traditionally dominating water transportation that had been historically established around Hangzhou, as widely documented (Ding, 2005; Su, 2011). Shanghai, powered by the rail lines linking Hangzhou and Nanjing and with the geographical advantage of the Yangtze River's estuary, experienced a dramatic industrialisation and expansion, and soon consolidated its leading role within the urban system of the Lower Yangtze Delta region.

Three urban changes were observed after the railways were built among Hangzhou's circumvallation, as discussed in the following paragraphs.

First, the direct contact of Shanghai with Hangzhou through the railway re-identified these two cities through increased competition and collaboration. As Shanghai became the industrialised centre of the Lower Yangtze Delta Region, Hangzhou was tightly integrated to this city by rail infrastructure, and gradually Hangzhou became the hinterland of Shanghai's economy (Tang, 2009). In fact, Shanghai nearly dominated the entire import and export trading businesses of Hangzhou (Han, 1951). Under the shadow of Shanghai, Hangzhou could hardly expect a return to the role of the "nationally important town of craft industries and enterprises" during the imperial era, as described by Fu (1985). By losing its long-established identities, Hangzhou City was in search of new methods to rebuild itself.

The rail brought this opportunity after the 1911 Revolution against the imperial monarchy. In Hangzhou, the new republican government took over power from the Manchus, and demolished the symbolic Qiying. Direct contact between lake and city was recreated. Based

on the natural and cultural landscape resources from the West Lake, land released from the Qiying provided an opportunity to shape a new industry: tourism. This land was developed fully oriented towards the needs of tourists, of which the emerging middle class in Shanghai made up the majority (Wang, 1999). With 3-5 hours' travel on the Huhang Rail, the Shanghai white collars were able to spend their weekends on the West Lake, which then earned the name of "Shanghai's backyard." The Zhegan Rail Company further amplified Hangzhou's importance in the new tourism industry by extending further west, into the freshly opened up mountains and rivers along its tracks. Through the rails, Hangzhou City successfully reshaped itself not only as a destination, but also a regional hub of the tourism industry, which has been lasting up to today.

Secondly, by passing through remote villages, the rail infrastructure powered Hangzhou's urban population growth in the 1930s. According to Ding (2009), the Zhegan Line penetrates the drainage areas of the Puyang River and Lanjiang River (both are branches of Qiantang River), with an estimated population of about 3.3 million during the 1920s/30s. Running on the Zhegan Rail, mountain topographies were never barriers, and images of the historically water-connected and rarely touchable cities such as Shanghai and Hangzhou were no longer mysteries. The rail access triggered the mobilisation of labour. Ding (2009) estimated that 7 million passengers travelled on the Zhegan Rail between 1930 and 1937, about one million annually, which was one third of the population along this rail. On the other hand, Hangzhou witnessed a fast population increase during the 1920s/30s. Ding (2007) revealed that between December of 1928 and July of 1930, a rise of about 42,000 urban dwellers was recorded, of which near 95% was from immigration.

Thirdly, the activated flow of passengers restructured Hangzhou's urban space. As the rail lines were serving as the artery of long-distance transportation, the historically dispersed inter-city traffics around the circular gates was condensed around the station area, gradually transforming it into a new market space. As recorded, there were hotels, restaurants (various flavours), and photo galleries clustering around the station (Yao, 2011). The flourishing market around the station area enriched the traditional single-core commercial layout of the city's inner area; and with the other emerging market on the Qiying's site, which was another benefit from the rail passengers, Hangzhou restructured its commercial layout into five markets of the city (Chen, 2008), each with a specific orientation and group of clients.

2.4 Analysis

To summarise, 1930s Hangzhou enjoyed a never experienced prosperity since the imperial ages. This was in large triggered by the insertion of rail infrastructure, bringing new industry, enriched constitution of population, as well as dynamic commercial life. If we have a closer observation, the following understandings are valuable for today's practice.

First, through the operation of rail, a certain level of urban agglomeration/competition between connected cities is observed. The increased mobility between cities allowed urban resources (especially the human and capital resources) to relocate themselves towards maximised efficiency/profit. This explains why Hangzhou lost its manufacture but gained the tourism industry. It is also noticeable that the capacity and efficiencies provided by rail infrastructure in 1920s/30s defines the geographical scope for such effect to take place. The 3-5 hour travelling time between Hangzhou and Shanghai indicates that cities within about 150km distance probably have the potential for effective urban industry re-distributions.

Secondly, increased connectivity between rural and urban China benefits cities with extended hinterlands into far remote areas. New resources such as raw material, market, and population were available to support the growth of industries and urbanisation. In Hangzhou, this was verified by the increased urban trading activities and population.

Thirdly, at the local scale, rail stations were easy to access. This enhanced the influence of rail infrastructure in urban life. In Hangzhou, the 13 square kilometre Chengguo extends about 5 kilometres north-south and 3 kilometres east-west. This is a typical size among the traditional walled-up Chinese cities, based on urban traffics from man/livestock powers. Even if the train station was sited to the east-south corner of town, the 2 kilometre pedestrian radius covers 6.15 square kilometres, nearly half of the urban footprint. And the furthest point from station was about 4 kilometres away, taking approximately one hour's walk. It was also important that the West Lake is 2 kilometres away to the west of the station, half an hour's connection on feet. Walkable connection of the station makes it accessible for almost the entire residents and visitors of this town.

3.0 “Isolation”: The Communism Industrialisation Period (1950s-1970s)

Within the Communism Industrialisation period, the national strategies for fast modernisation and socialisation dictated both rail and urban developments, and is typically represented in the policy of heavy industry development prioritisation and the “Hukou” (dual residence registration)¹ system between rural and urban dwellers. As a result, however, history witnessed a process that rail was disconnected from urban life.

3.1 Hangzhou’s Dilemma between “Consumption” and “Production”

In March 17, 1949, the *People’s Daily* published the editorial article, titled as ‘*Transform the Consumptive City into the Productive City*’. This announced that heavy industry developments would be prioritised following the establishment of the People’s Republic, as a fast way to achieve the nation’s modernisation.

The national orientation at the heavy industries put Hangzhou, with its established reputation of tourism, into a dilemma between “consumption” and “production”. Although the city’s first planning drafted in 1953 valued its established importance of culture and landscape (An, 2011), it was unfortunately hardly executed in the following years. Since the launch of Great Leap Forward initiated in 1958, the Chinese cities were exclusively involved in the national fever of industrialisation that “overwhelms everything” (Meisner, 1999). In 1959, Hangzhou drafted the second planning proposal with its urban character redefined as “hybrid industrial city based on heavy industries” (Bian, 2008).

In fact, Hangzhou did not see a booming urban transformation into an industrial centre during the years that followed. The new cluster of factories was built on remote agricultural lands far from the centre, typically as the Iron and Steel Factory of Hangzhou (ISFH). Within the planned economy system, this factory was later developed into a self-sustained industrial town that provides from “cradle to tomb” services for its “cadres and workers”. In compare, the conventional town area of Hangzhou was branded with “non-production”, and was unavoidably led to the wane during the three decades since 1950s. To secure the limited resource for developing heavy industry, the percentage of state investment in central Hangzhou dropped significantly from about 50% in middle 1950s to slightly over 20% in 1960s/70s (Hangzhou Revolution Committee, 1981: 7). No doubt the city was struggling to provide basic life support in the 1970s, and won it the famous folk saying, “beautiful West Lake, ragged town.”

3.2 Unbalanced Rail Development and Isolated Urban Life

Within 1950s/70s, the rail infrastructure saw an unbalanced growth in freight and passenger transportations, making unequal choices between “production” and “consumption.” The target of industrialisation powered sharp increase of freight transportation on tracks. In compare, the rail passenger number experienced fluctuations in 1960s and had a slower

growth afterwards (Ministry of Rail, 1999: 373), which is mainly accused to restrains in “consumption” and rural population movements.

In Hangzhou, the only new rail line built during this period was the freight line connecting the ISFH to the national rail network, to support the steel manufactures. Since Hangzhou developed a very different urban life in the ISFH area and city centre area, the following discussion will interpret their relationships with rail separately.

Given the poor social documentation during the decade of the Cultural Revolution (1966-1976), the *Simplified Hangzhou Traffic Map* published in 1971 is analysed in this study to describe the relationship between the rail and civic life. This map clearly shows the bus routes serving metropolitan and regional destinations. Considering Hangzhou's urban transportation of that age, when there was no metro-line, few taxis, and nearly zero private vehicles, the bus route map recorded the movements of urban life. Through summarising this map, we find that urban transportation was structured by a number of bus hubs, namely Wulinmen, Hubin, Nanxingqiao, Genshanmen, Gongrenlu, and Gongchenqiao. These hubs networked on both metropolitan and regional scales. The rail station, however, was not among the named hubs. It was connected only with in-town destinations, which means that regional passengers had to access the station via any of these bus hubs. If we do a closer study of the number of bus lines connected, the station was served by only three in-town lines, compared with Wulinmen, a hub next door to the coach station, which was served by 7 lines of which 2 were regional.

This map clearly indicates that: a) the rail station was connected mostly with urban dwellers, and; b) villagers from nearby rural Hangzhou were the major visitors in this town, as indicated by the number of bus lines connecting coach/rail stations. As rail was serving as the main transportation for long-distance travels, the weak connection between rail station and urban transportation hierarchy tells that 1950s/70s Hangzhou was not closely integrated with the rest of China, neither urban nor rural.

Figure 3: *Simplified Hangzhou Bus Map, 1971 (left) and Hangzhou Planning Map, 1973, showing the location of ISFH in relevant to the conventional centre (source: Que, 1999)*

The ISFH area is sited 12 kilometres north of central Hangzhou, therefore developed as an "industrial island floating on the agricultural lands." As a typical example of state-owned large size industry within the planned economic framework, a "worker's town" (Shenghuoqu) was

built near the factory site to accommodate its staff. Instead of a satellite town, this is a self-sustained "living workshop" incorporating various life supporting facilities, such as massive rowed apartment housing, hospital, schools, and shops. During the 1980s, the Shenghuoqu grew to a size of about 9,746 residents (Zhang, 1985). As described above, a rail line was constructed in the late 1950s to link the ISFH into the regional rail network. This line was then used exclusively for freight services. As there was only one direct road link between this industrial dwelling town and the city centre, with one bus route that normally took about 40 minute-1 hour to access the edge of the city, there was however never a plan to provide passenger service on the established rail.

3.3 Analysis

In general, rail developed very different connectivity of freight and passenger transportations for this period, as a result of the national strategies and policies. Rail played important role in developing national heavy industries. On the other hand, the connectivity between rail and urban life was declining or even missing, as presented in Hangzhou's case.

First, the practice of urbanisation during this period was applied as a facilitating instrument for national industrialisation, such as the Shenghuoqu in the ISFH case. The Communist pattern for "production" was developed in a self-sustained template and isolated from life in conventional urban centres. The move of goods is prioritised than people. There is hardly any necessary connection between the rail infrastructure and the urban life emerging around new factories, which explains the never appeared transformation of freight link into passenger service in ISFH.

Secondly, for the conventional cities, the compression of "consumption" led to serious damage of the urban industries which had been long established prior to the coming of Communist industrialisation. This included businesses born from the early coming of rails, such as the tourism. The decline of urban "consumption" industries limited rails connectivity with conventional city centres.

Thirdly, as the Hukou system successfully screened massive rural population out from immigrating into cities, urban China merely became destinations of short travels from nearby villagers. The connectivity between vast rural China and rail was unfortunately lost.

Although industrialisation promoted rail technologies into higher speed and capacities since 1950s, the dis-connectivity with people suggests that rail failed to power urban developments. This is also true for the emerging new towns around factories.

4.0 "Marginalisation": The Recent Urbanisation Period (1980s-2000s)

The fast and large scale urbanisation within the recent three decades re-powered developments in transportation. The rail, with a constant focus at the national scale operation, was not successful in keeping its connectivity with the fast physical expanding of urbanities. Eventually rail developed a marginal role in the urban life which was overwhelmed by roads and vehicles.

4.1 Hangzhou's Fast and Large Scale Urbanisation

Since 1980s, Hangzhou reshaped its identity through three urban planning amendments in 1983, 1999 and 2007, achieving a balance between "consumption" and "production". The tourism industry was rebuilt with respect to the city's rich culture and landscape resources, and targeted at national and international tourists. The re-oriented and growing urban ambitions triggered fast and massive urban expansion, as well as population inflation of Hangzhou during the recent three decades.

There were two municipal boundary expansions in Hangzhou between the 1980s and 2000s. Beyond the inherited municipal area of 430 square kilometres in 1970s, the first expansion in 1981 extended south across the Qiantang River for an extra 253 square kilometres to accommodate new industrial developments. In 2001, a second expansion merged two districts from north-east and south-west, making Hangzhou occupying 3,068 square kilometres and “the second largest city next to Shanghai within the Lower Yangtze Delta Region” (Zhu, 2002: 23).

In parallel, the urban footprint size rose sharply during the same period. Starting from 102 square kilometres in 1981 (Hangzhou Revolution Committee, 1981), about 80% increase was recorded within the two decades that followed. In the next ten years, however, soaring developments further doubled the size of urban footprint, standing at 413 square kilometres in 2010 (Hangzhou Statistics Bureau, 2012), 31.8 times of the ‘Chengguo’ size from imperial Hangzhou.

Hangzhou's population growth saw a similar record with the urban expansion which is not only a statistical increase, but geographical re-distribution. The entire population had a rise of over four times within the three decades starting from 1980, reported at 4.35 million in 2010 (Hangzhou Statistics Bureau, 2012). Meanwhile, the central area lost about 30% population between 1990 and 2000, with peripheral areas densified 3 times by new dwellers in the same period (Feng & Zhou, 2002).

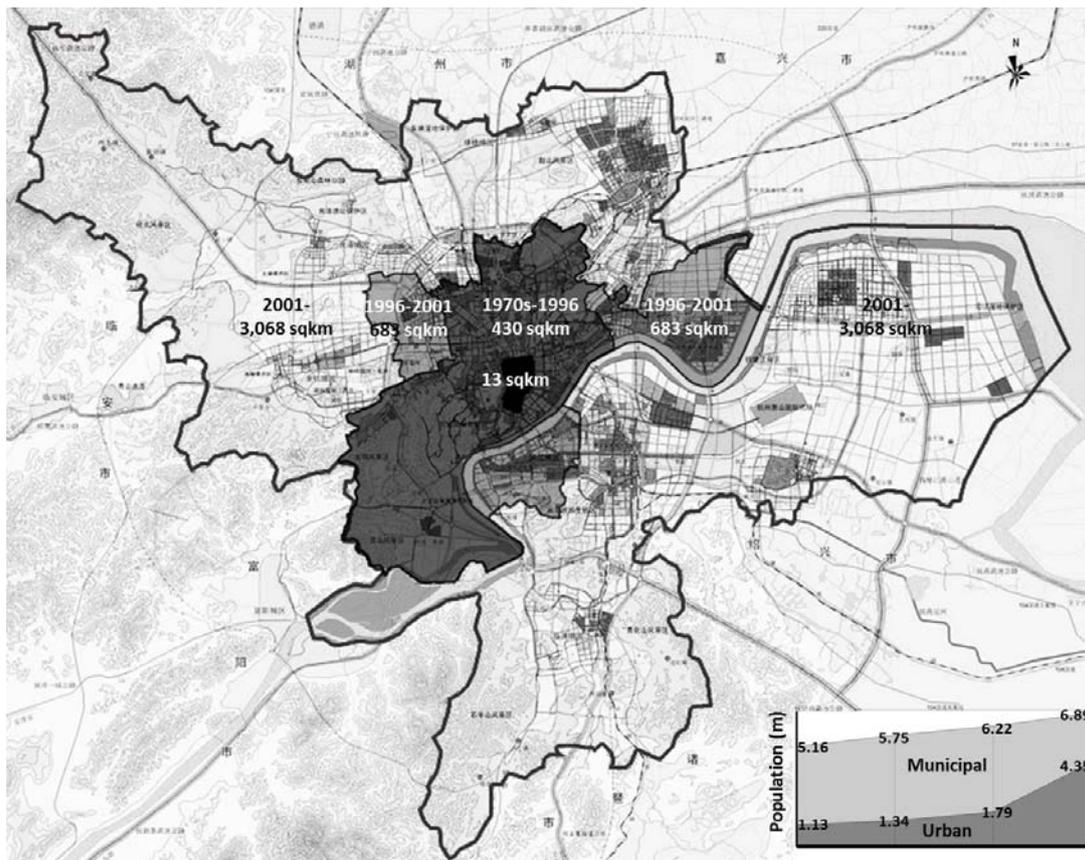

Figure 4: Municipal Boundary Expansion and Population Increase of Hangzhou (source: Hangzhou Planning Bureau; Hangzhou Statistics Bureau)

Despite the fast expansion, Hangzhou did not see the dispersing of its centre. The central area, which largely overlaps with the imperial Chengguo, remained a strong core integrating the major public urban lives, such as political, commercial, cultural, and financial centres

(Luo, 2005). The recently developed fringe areas were struggling to establish contact with the conventional centre.

By putting together the above information, we find expanded urbanity, a robust central core, an increasing population and growing fringes. It is a safe prediction that the traffic demands between the new developed peripheral areas and the conventional city centre will exhibit constant growth. How much, then, does the rail system channel these demands?

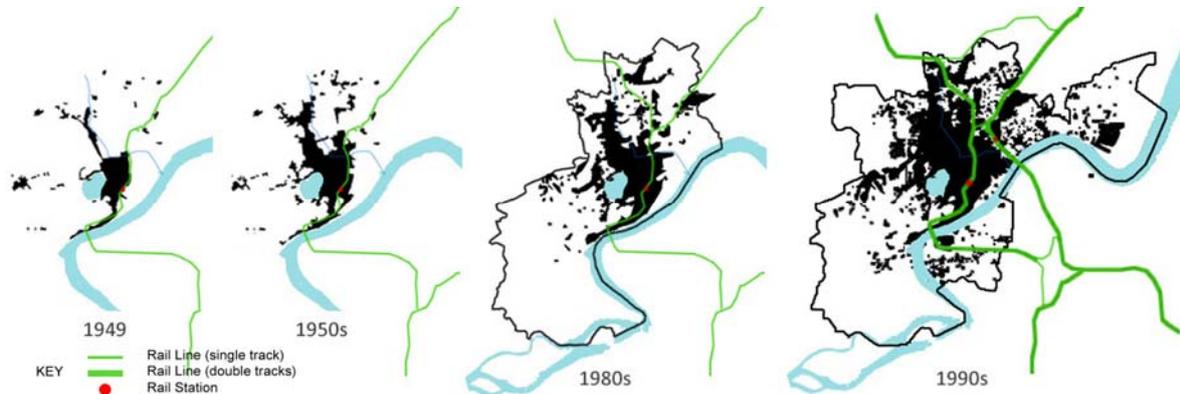

Figure 5: Hangzhou Urban Footprint and Rail Developments between 1949 and 1990s (source: Feng, 2003; Qin, 2010; Yu, 2005)

4.2 The Competition between Rail and Road Infrastructures

The rail lines around Hangzhou were improved since the 1980s principally in three ways: Existing single track rail lines connecting Hangzhou to major domestic destinations were upgraded to double tracks; new lines cutting through the town was built to release traffic pressure on old lines, including a second rail bridge on the Qiantang River; and a passenger line, named Xuanhang Rail linking Hangzhou to Xuancheng in Anhui Province about 230 kilometres away.

To accommodate the growing number of passengers, the old station, Chengzhan, was rebuilt in late 1990s and stretched vertically on its old site. The previous Nara style building was replaced by an 18 floor high-rise complex, integrating commercial, hotel and administration functions. Another station, “Hangzhou East” was built in 1992, sitting on the new rail link penetrating the east part of the city. As a complementary station, it serves the passenger trains that pass through Hangzhou, while the Chengzhan was targeted at termination services.

In principle, we have seen new tracks and stations developed between 1980 and 2000, targeting at improving Hangzhou’s connection with the rest of China, and enhanced the rail’s capacities on transportation. Nevertheless, if we overlap the rail map on top of the vastly expanded municipal boundary and urban footprint of Hangzhou, it is disappointing that the tracks are not supporting the city’s geographical growth. The railway has been focusing on linking national destinations while local/regional coverage was not within its scope. This is verified by the transportation performance statistics in Hangzhou, both for freight and passenger services. The percentage of passengers travelled on rails dropped over half during the three decades, while the percentage of freights unbelievably shrunk over 90% (Fig.6)

In compare, we have witnessed constant growth in road users in the past 30 years. The percentage of vehicle passengers rose nearly 1.5 times since 1980, close to 90% in 2010; while the freight traffic doubled respectively (Fig.6). This is even true by reading the increase

of road length, four times between 1990 and 2010 (Wang, 2005); and spring vehicle registrations, increasing near fifty times for the same period (Zhong et al., 2013). It is safe to conclude that the vehicles have channelled most of the growing demands for transportation that rail has failed to meet.

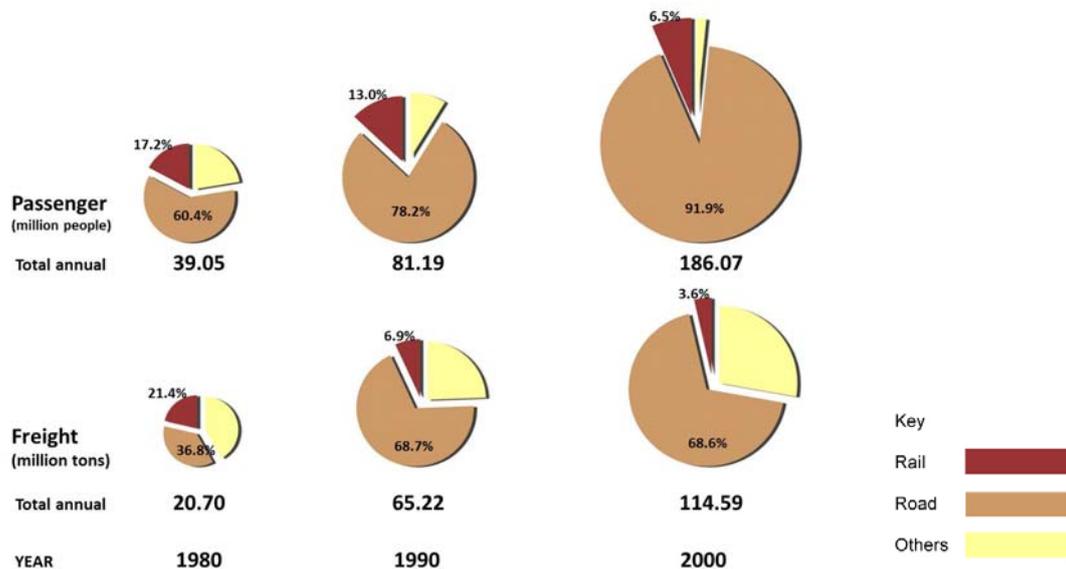

Figure 6: Total Annual Transformation Performance of Hangzhou between 1980 and 2000 (source: Hangzhou Statistics Bureau, 2012)

4.3 Analysis

Compared with the Communist industrialisation period, the economic reforms since 1980s triggered dramatic rise in urban mobility demands. However, the rail's strategies to connect cities at large scale make it disconnected with a big proportion of local urban residents, especially under the competition with road infrastructure.

On one side, the motorised urban transportation did not improve accessibilities of the rail station. Trains are less accessible with the fast expanding of urban footprint and population re-distribution. In Hangzhou, the reported average peak time vehicle speed on major metropolitan roads has been dropping down from about 26 km/h in 2006 (Yang, 2006) to about 15 km/h in 2013 (Hu, 2013). The half-hour vehicle accessibility radius to train stations shrunk into about 5 kilometres if considering reasonable parking time. Around the two currently operating stations, this radius covers about 110 square kilometres urban footprint, about 25% of Hangzhou's total urban footprint, and roughly 3% of the city's vast municipal area. For bus users, the half-hour travel radius is similar, as buses share most roads with vehicles. Due to the higher dwelling density in conventional centre, the population percentage covered by above radius is probably higher than 25%, but this will be declining in the long term along with the de-centralised population distribution trend.

On the other side, the use of vehicle transportation was stretching beyond local/regional scales, thanks to the large amount of new freeways between major and minor cities. In addition, the advantages of door-to-door travel convenience and ride comfort-abilities that trains were struggling to provide made road infrastructure able to challenge rails even at the inter-city scale transportations.

5.0 "Incorporation": A Fully Integrated Urban Life with Rail (Conclusion)

In 2010, the Huhang HSR was operating and connecting Shanghai and Hangzhou at 350km/h, which means the arrival of a "New HSR Era" in Hangzhou. The Hangzhou East

Station, built in 1992 as a complementary option to the Chengzhan Station, was upgraded into a giant terminal hub, standing among the largest of its scale in China, housing six HSR lines (including one Maglev Line) that connect to all domestic destinations. The new station is designed to serve 200,000 passengers daily. Around this terminal, a new town oriented at the predicted “HSR Economy” is proposed, covering an area of 9.3 square kilometres and accommodating 200,000 residents. This new town is centred around the HSR station physically and economically, and requires invention of new urban lives fully integrated with railway infrastructure.

The three studied periods present substantially different political and economic backgrounds to study the relationship between rail and urban development. It is however clear that the connectivity between rail and passengers dictates its role in urban life. The early years since 1900s saw urban prosperities fully powered by rails well connected with people from the widest range of background. However, this close integration disappeared during the following two periods. It is difficult to believe that this has happened in parallel with the soaring development of rail/train technologies from 20km/h steam engines in the 1900s to the 200km/h electronic locomotives a century later. If not considering the influence of policies between the 1950s and 1970s, a noticeable reason is that the higher the speed is, the less the train stops. Through improving speed, the trains are less accessible by people from remote and mid-way towns. It is even worse that within the expanding urbanities and fragile urban traffics, the stations are squeezed to peripherals in urban life, although they never moved away from the city centre.

With the arrival of new technologies that power trains at 350km/h, it is worthwhile to further discuss this disconnection. Certainly we cannot deny the progress of improvements in rail technologies, and in fact, we expect that the “HSR economy” as predicted will agglomerate urbanities from geographical distances.

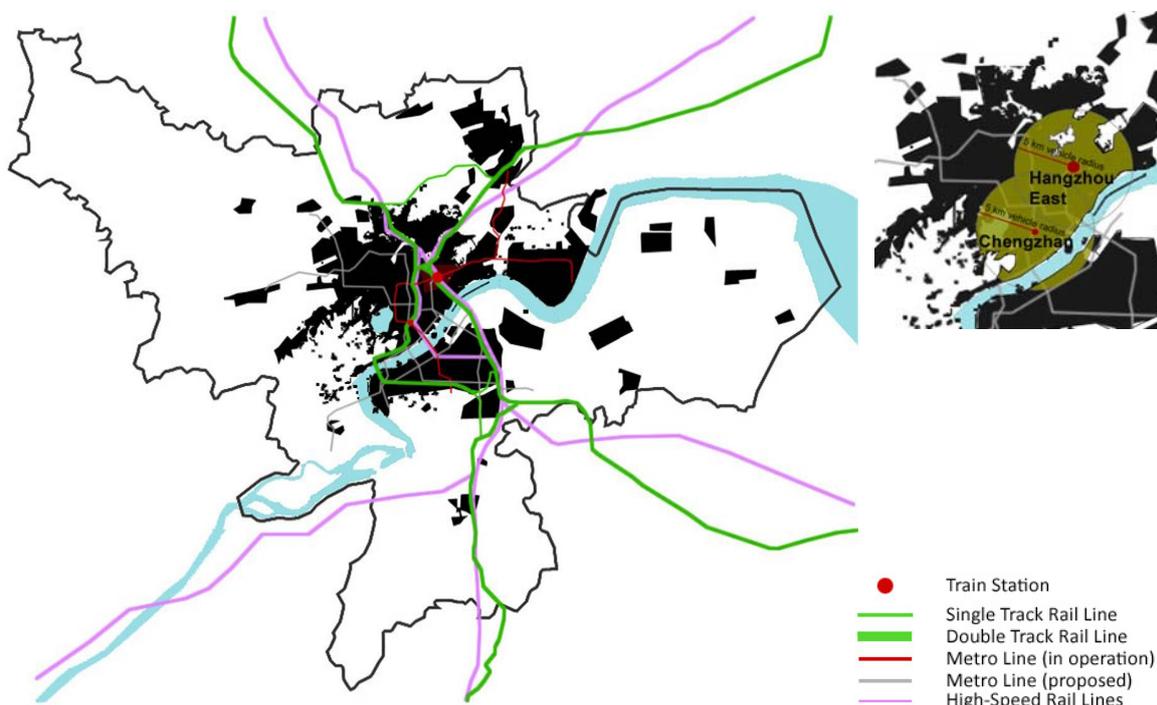

Figure 7: Proposed Hangzhou Rail Hierarchy in 2020 (left, source: Hangzhou Planning Bureau) and the half-hour vehicle accessibility circle overlapped with the urban footprint (top-right)

The missing part from a complete model for such an HSR-oriented urban life is the effective connectivity of the HSR that links with all scales of destinations, from local, regional to national, which includes rural and urban residents. This connectivity is provided by a complete hierarchy of the rail transportation system. The increased train speed and passenger capacity defines rail as a highly concentrated public transportation right, which cannot be dispersed immediately into private (vehicle) rights in the station area. A third level of transportation that bridges public/private rights should be introduced. This will help the HSR to extend its “roots” at the local/ regional scales that are now under the dominance of vehicles.

A second lesson to learn is for the urban functions around HSR station nodes. Within an urban hierarchy system structured by rail infrastructure, the urbanity around rail stations presents an interface of a city for dialogues with the rest. This trend is visible in the case of Hangzhou’s early year’s re-building of tourism industry, and is clearly reflected in the ISFH study where rail connected factories between cities to form a large scale “assembly line.” During the recent practice, as rail’s role faded in urban life, the station area developments were comparatively ambiguous.

Around the HSR infrastructures, as 3-5 hours’ commuting radius has dramatically increased from 150 kilometres in early years up to around 1,000 kilometres, it is predicable that new urban systems with never experienced sizes and complexities will appear. The planning around these stations will undoubtedly narrate the city’s position in the urban hierarchy. For the decision makers, it is important to realise how to avoid over flow of urban resources from lower level to higher level cities in the hierarchy. However, it is even vital that a city should be prepared to challenge itself with new urban identities, which is formed by its own characters and advantages, for future regional competitions.

Endnotes:

1. “Hukou” (dual residence registration): this system became effective in 1961, with the purpose of controlling rural residents immigrating into urban dwellings.

Greenway as a New Path for the Exploration of Urban-Rural Coordinate based on a Low-Carbon Model: A Case Study of Greenway Planning and Construction in Dongguan, Guangdong province (China)

Liangping Hong, Xiang Hua, Huazhong University of Science and Technology, China

1. Introduction

Since the beginning of the reform and opening-up policy, China's economic development has made remarkable achievements; however, the widening urban-rural gap has become important reasons leading to a lot of social and urban problems. How to achieve coordinate urban-rural development is an important problem China is required to face in terms of its future development. In general, urban-rural dual structure¹ is the fundamental reason why urban-rural gap is widening, which cannot be solved in one move; it still continues to exist in the near future even under the macro background of currently deepening structural reform. Therefore, when negatively expecting institutional innovation, actively seeking for an overall urban-rural development path which bypasses the current institutional barriers should be paid high attention to.

Coordinate urban-rural development does not indicate that rural development should follow the urban development mode, which is determined by different urban-rural resource endowment, and simple replication is inconsistent with objective development laws. On the one hand, most of cities in China adopt high-carbon development mode (Gu, C.L. et al., 2013), and replicating this mode in countryside will further increase the difficulties for our county to build a low-carbon society, and is inconsistent with global low-carbon development trend; on the other hand, such replication will lead to urban-rural homogenization phenomenon in terms of features and styles, and countryside's unique ecological characteristics, cultural characteristics and social characteristics will also disappear, which should be avoided obviously. Therefore, only actively exploring different urban-rural development paths under the low-carbon model should be the right choice.

As a hot research topic for Chinese planning scholars in recent years, the existing studies on coordinate urban-rural development problem mainly focus on the following three aspects: The first one is theoretical construction for coordinate urban-rural development plan, in which Zhao (2006) proposed that symbiosis theory, phased theory on industrial expansion and space growth and sustainable development theory are the theoretical basis for coordinate urban-rural development plan, Wang (2012) analyzed the complex relative relationship system on coordinate urban-rural development plan, proposed the basic concept of coordinate urban-rural development and built the theory of coordinate urban-rural development plan; the second one is comparative study for domestic and foreign coordinate urban-rural development cases, Zhang, et. al., (2009) summarized 7 suggestions by combing developed and developing countries' successful experiences in coordinate urban-rural development; the third one is the study on coordinate urban-rural development plan compilation and management, Zeng (2012) analyzed Chengdu's innovation in coordinate urban-rural development plan compilation and management, and pointed out that, close integration between compilation and management as well as multi-sector cooperation are the features for Chengdu's coordinate urban-rural development plan. Based on the existing studies, we may discover that, the study on coordinate urban-rural development combined with low-carbon concept is little, and the author thinks that low carbon is an important mean for human society to achieve sustainable development, while coordinate urban-rural

development is a core problem China must solve appropriately to achieve sustainable development; thus, the study on a combination of both has important practical significance and academic value, and it is necessary to conduct the corresponding research in the paper. In 2010, GPC, as one of implementation actions for Guangdong regional integration development strategy, was conducted very quickly in Guangdong province, which was designed to promote the urban-rural construction and improve the urbanization quality, and it also took the lead in exploring China's coordinate urban-rural development path based on the low-carbon model. The paper selects the case of GPC in Dongguan, Guangdong province as the object of empirical study, and will review the general situation of GPC in Dongguan, deeply analyze its management measures and implementation effects, summarize its successful experiences in promoting coordinate urban-rural development based on the low-carbon model, and finally discuss its limitation in promotion and potential problems.

2. Methods

2.1. Concept Definition

Many scholars at home and abroad define the greenway. For example, Guo (2003) put forward "the greenway usually goes along the natural corridors such as the water's edge, valley, ridge or railway and it can also be used for recreation or as the traffic road, landscape road, pedestrian crossing or bikeway. The open space that connects the park, nature protection area, cultural features, historical site, densely inhabited district and regional long and narrow or linear park is usually designed as the greenbelt or aesthetic road". This definition basically includes the key points concerned by all scholars. The research finds that it can clarify the connotation of greenway. And I agree and accept this definition.

2.2. Research Emphasis

Since the term of greenway was first created and used by William H. White in his monograph *Protect the Open Space of American Cities* published in 1959 (Little, C.E. 1990), it has been widely and deeply researched by scholars around the world for over 50 years. Their research focuses on environmental protection, historical and cultural heritage corridors travel and leisure development, green infrastructure and so on (Dai and Hu, 2013). The paper is different from the past research and puts emphasis on two aspects: First, how does the greenway affect the method of daily traveling of urban and rural residents in Dongguan to be low carbon as it is introduced into Guangdong of China as a new object that is beneficial to the common people? Second, how does the greenway play a part in promoting coordinating urban and rural development in Dongguan on the basis of satisfying the primary need in a popular style with the characteristic of low carbon? The two aspects include how does the specific policy of greenway avoid the current institutional barrier of city-countryside dualization, how to realize urban and rural green space integrated construction in Dongguan with the help of greenway and how does the rural tourism initiated by greenway promote the rural economy to develop in low carbon mode and promote the differentiation development with urban and rural characteristics, etc.

2.3. Study Area

Dongguan is located in southern Guangdong, at the east coast of Pearl River Estuary, bordered by Huizhou in the east, Shenzhen in the south, Guangzhou in the west and Zengcheng in the north. The city covers 2,465 square kilometers in total, with about 8,500,000 permanent residents in 2011. The weather in Dongguan bears a subtropical monsoon climate, with an annual average temperature of 22.7°C and annual average rainfall of 1,879mm over the period of 2002 to 2011 (Dongguan Municipal Bureau of Statistics & Survey Office of the National Bureau of Statistics in Dongguan, 2012); such comfortable climate creates conditions for residents to travel outside. Meanwhile, Dongguan has mountains in the southeast, waterfronts in the northwest, and rivers scattering in the middle,

which also provides a good foundation for building urban-rural green space with rich types and distinct characteristics.

2.4. Overviews of GPC

- *Overall objective*

The objective is, by investing about RMB 3 billion over the period from 2011 to 2014, to construct Dongguan greenway with 2263 kilometers (including regional greenway of about 225 kilometers, urban greenway of about 781 kilometers, and community greenway of about 1257 kilometers), achieve greenway network density of 0.9 kilometer/square kilometer, establish Dongguan 10-minute greenway riding cycle, build Dongguan greenway network system with regional, urban and community greenways linking closely and functioning reasonable, and build Dongguan greenway network into a people project with ecological, social, economic and cultural functions.

- *Overall Layout*

The greenways in Dongguan are classified into three categories, i.e. regional greenway, urban greenway and community greenway. There are three greenways passing through Pearl River Delta and 21 neighborhoods in Dongguan, with about 225 kilometers in total, which constitutes the framework (Figure 1) of greenway network in Dongguan, along with 26 service stations to serve about 4 million people; urban greenways are classified into five regions of “central part, Putian part, mountain forest, water village and coastal area”, covering 32 towns in Dongguan, with a length of 781 kilometers, forming Dongguan greenway network (Figure 1), connecting major natural and human resources points in Dongguan, along with about 173 interest points; community greenways, about 1257 kilometers, connect community parks, small gardens and roadside green space, provide residents with convenient greenways in slow traffic system, and are cell and micro-circulation tissue for greenway network.

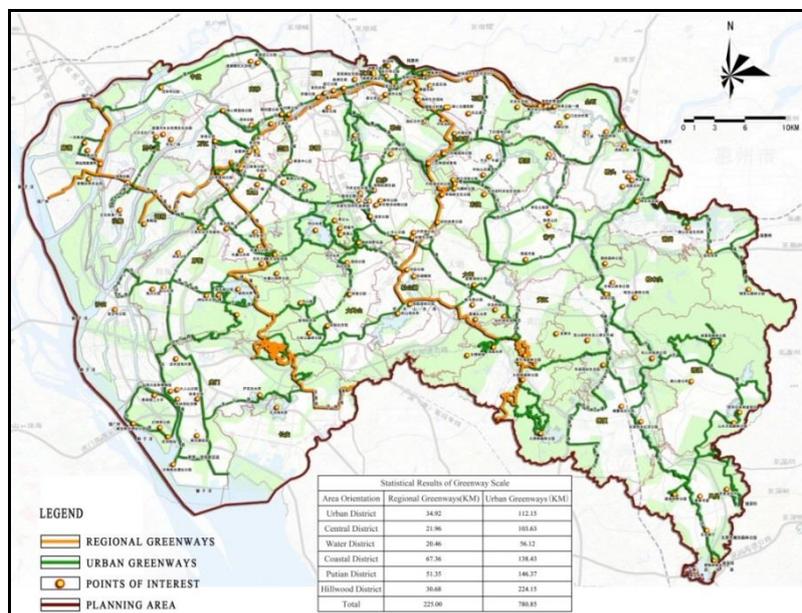

Figure 1: Dongguan Greenway Overall Layout
 (Source: The Comprehensive Planning of Greenway in Dongguan (2010-2020))

- *Construction Achievements*

Through more than two years’ construction, Dongguan greenway network has achieved initial success. By the end of 2012, Dongguan has constructed greenways with a length of 1148 kilometers in total, including having been built regional greenways of 225 kilometers, constructing 26 regional service area, and connecting over 200 tourist attractions and interest points along the way; urban and community greenways of accumulative 923

kilometers have been built, and 61 urban and community service area have been built (Figure 2).

Figure 2: Dongguan Greenway Service Area, Identifying & Landscape
(Source: Authors)

2.5. Analyses on Management Measures

Dongguan's management measures on GPC are designed to not only effectively promote the construction work, but also facilitate the management maintenance after the construction, and the measures include the following aspects.

- *Organization*

A team especially for Dongguan greenway network construction is established, consisting of Dongguan's relevant leaders as well as the principals of more than 20 relevant functional departments, such as development and reform bureau, finance bureau, land resources bureau and urban and rural planning bureau, to be responsible for Dongguan's overall arrangement on greenway network construction. An office is under the team, set up in Dongguan's urban and rural planning bureau, and is responsible for comprehensively coordinating and guiding the greenway network construction. The relevant functional departments, on the one hand, attach great importance to performing their own duties, on the other hand, try to simplify the procedures and improve the efficiency within the scope permitted by the policy, to ensure the effective promotion of greenway network construction.

- *Land for Project*

The land for greenway construction project is provided by each section, renting or acquiring land can be adopted not to change the ownership and property of the original land. To reduce the demolition, the land for greenway's trail, station and interchange station may be combined with farmland, water conservation, tourism and ecological land, and the construction land index would not be occupied in principle.

- *Financing*

City- and town-level greenway construction special funds are established through city- and town-level annual budgets. The construction capital for regional greenway is provided by city-level finance bureau, land demolition expenses, pipeline transfer expense, bridge construction and earthwork expenses occurred for urban greenways and community greenways in each town are provided by each town, while the project construction capital (including slow road, greening, sign system, water and electricity, station) is shared by city-level finance bureau and town-level finance bureau in accordance with 50%:50%. If the greenway in each town satisfies certain conditions and standards, city-level finance bureau will give back greenway construction subsidy.

- *Operation Management*

Dongguan urban comprehensive administration is responsible for formulating the uniform operation management standards for greenways (including regional greenway, urban greenway and community greenway) in Dongguan jurisdictions. Dongguan urban

comprehensive administration is responsible for managing the operation of greenways at each level within the road scope uniformly managed by Dongguan urban comprehensive administration, and the expenses are arranged by city-level finance bureau. The operation of the greenways at each level in other regions is managed by each region, and the expenses are arranged by town-level finance bureau.

2.6. Analyses on Implementation Effect

By the end of 2012, a professional research company has conducted an evaluation on Dongguan’s constructed greenways that the public participates in, applied questionnaire survey (about 9000 effective questionnaires), depth interview (more than 30 greenway users), enterprise merchant investigation (150 related merchants), network consensus combing (about 300 network reports), field observation (1 hour each for three times every day in 12 typical places) and network survey (more than 6600 netizens participating in), and made a comprehensive and deep summary about Dongguan greenway’s service efficiency, and completed the following analysis based on the data from the evaluation.

- *Service Efficiency and Purposes of Greenway*

In the investigation and evaluation, 80% of respondents know Dongguan greenway, 70% of respondents have used Dongguan greenway. Greenway’s usage frequency is closely related to the greenway’s construction level and location, the usage rate of the greenway located at place of residence nearby and tourism scenic spot is obviously higher than that in other regions (Figure 3), meanwhile, the recreation & entertainment, fitness and family activities are in the front rank (Figure 4) in the investigation in terms of the greenway’s intended use. Considering that such activities are basically conducted in holidays, still 30% of the respondents often or every day use the greenway to implement such activities, which indicates that greenway has been incorporated into the life of residents in Dongguan. In addition, besides using the greenway in the life, 11.6% of the respondents select greenway as the transportation means for commuting, while 64.1% of such respondents often or every day use the greenway (Table 1).

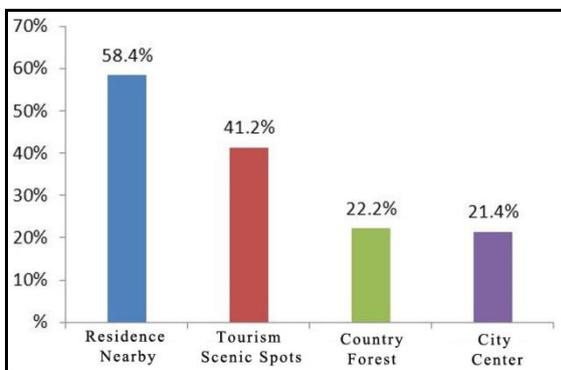

Figure 3: Service Efficiency of Different Regional Greenway
 (Source: Dongguan Greenway Comprehensive Evaluation Report, 2012)

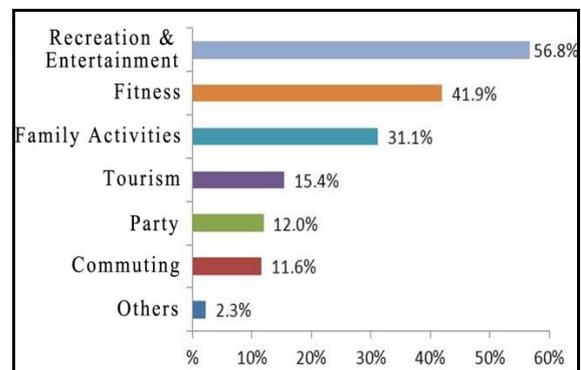

Figure 4: Rank of Intended Use of Greenway
 (Source: Dongguan Greenway Comprehensive Evaluation Report, 2012)

Purpose	Frequency	Almost Every Day	Often	Sometimes	Seldom
Recreation & Entertainment		5.2%	19.3%	57.9%	17.6%
Fitness		5.6%	24.0%	56.3%	14.2%
Family Activities		4.0%	21.1%	60.4%	14.5%
Tourism		4.9%	24.1%	53.8%	17.2%
Party		9.9%	27.4%	48.3%	14.4%
Commuting		30.8%	33.3%	27.5%	8.4%
Others		7.0%	14.8%	39.1%	39.1%

Table 1: Greenway Service Efficiency Based on Different Purposes
 (Source: Dongguan Greenway Comprehensive Evaluation Report, 2012)

• *Social Economic Benefits of Greenway*

After the greenway in Dongguan is put into use, the greenway has produced sound social benefits (Figure 5). Firstly, more than 90% of the respondents think that, the ecological environment surrounding greenways has been improved than before; secondly, the greenway has become an important place for Dongguan residents to communicate and interact, more than 75% of the greenway users often come to the greenway to play with their family members during the holidays, nearly 75% of the respondents think they are healthier than before after using the greenway, more than 85% of the respondents think they feel more comfortable than before after using the greenway. Therefore, the greenway has also been affirmed by the residents in Dongguan, nearly 60% of the greenway users are satisfied with the greenway, especially the greenway’s environment comfort level, scenery along the way, construction quality and convenience.

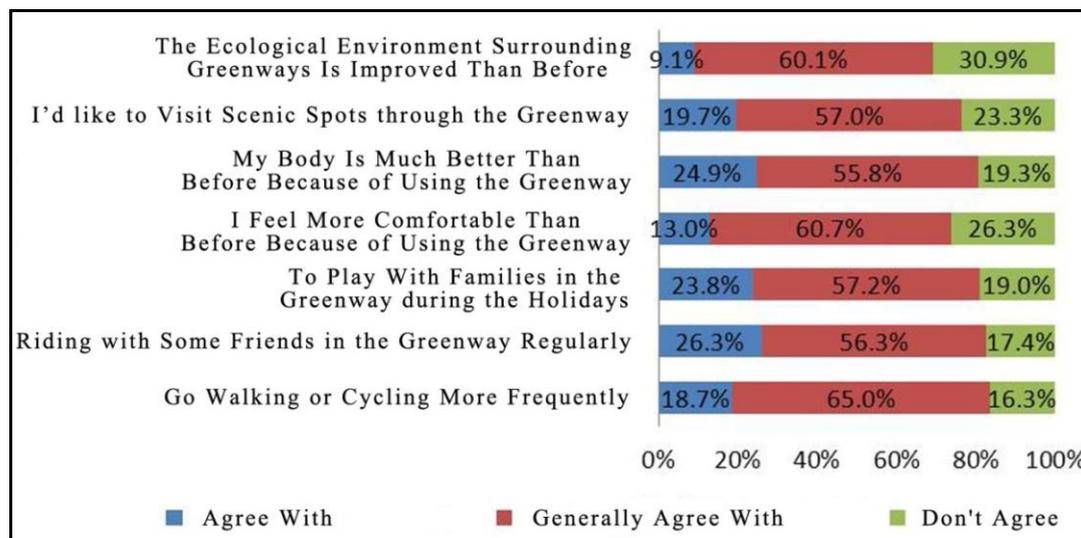

Figure 5: Greenway’s Impact on Residents in Dongguan
 (Source: Dongguan Greenway Comprehensive Evaluation Report, 2012)

In terms of the economic benefits, the greenway also performs well. In the depth interview and questionnaire survey with enterprises, such as restaurants, convenience stores and bicycle sales and rental along the greenway, more than 60% of the enterprises think that, the greenway has increased the passenger flow volume and turnover. Currently, the greenway exerts the biggest impact on bicycle sales and rental, including the following two aspects: One is an increase in the number of branded bike stores; Dongguan’s branded bike stores are increased from 42 in 2009 to 99 in 2012, forming a fierce competition pattern (Figure 6) since different brand stores densely open in the same district; the other is to promote the sales of the bikes. Take Mérida bicycle that captures 50% of the upscale bicycle market as an example, the annual sales increase from 5000 bikes in 2010 to 10000 bikes in both 2011

and 2012, and the accumulative sales amount exceeds RMB 60,000,000 during the past 3 years in accordance with the average market price of RMB 2,500 per bike. The sales volume of ordinary bicycles is also amazing; the sales volume of ordinary bicycles is 1,000,000 in 2011 and the sales amount exceeds RMB 500,000,000 in accordance with the average market price of RMB 500 per bike. It is expected that, as the greenway's supporting facilities are further constructed and improved, the greenway will comprehensively enhance the economic benefits of the related industries, such as restaurants and convenience stores, and provide a lot of jobs for society, and further enhance the social benefits.

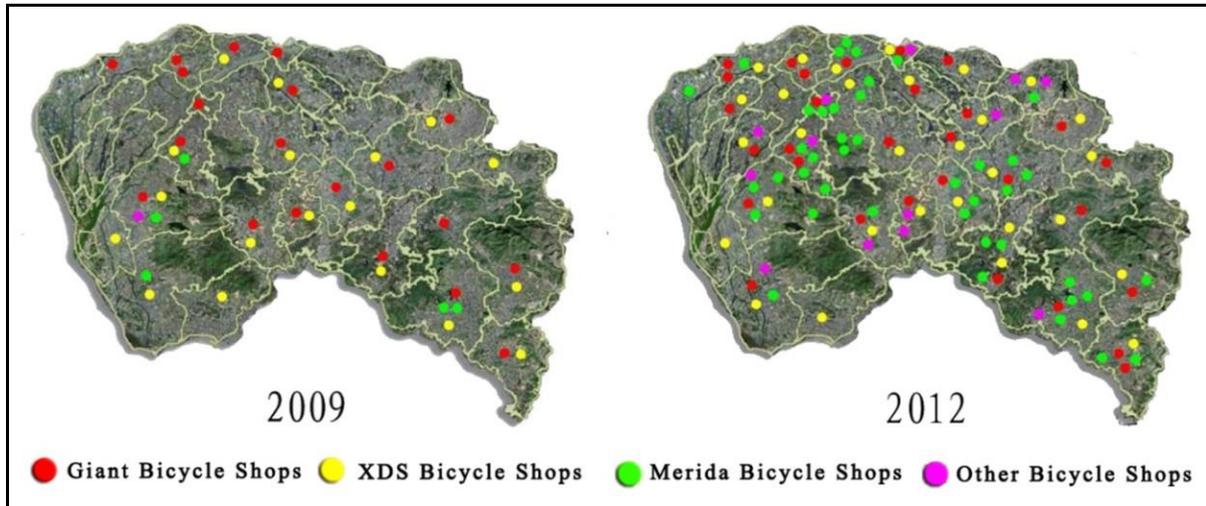

Figure 6: Dongguan Branded Bicycle Stores Layout in 2009 and 2010
(Source: Dongguan Greenway Comprehensive Evaluation Report, 2012)

3. Results

3.1 Contributions of Promoting Low-Carbon Travel

Since 2007, transportation has become the industry in China with the fastest consumption growth in the energy especially the oil, and the vehicle fuel consumed by vehicles on the road account for almost 70% of the total energy consumption of the transportation industry (Compile Committee of the Second National Assessment Report on Climate Change, 2011). A surge in private motorized vehicles is the primary reason why transportation energy consumption stays at a high level, and this problem is particularly prominent in Dongguan. In accordance with data from Dongguan statistical yearbook, over the period from 2001 to the end of 2011, Dongguan civilian vehicle ownership increases sharply from 183,600 to 1,061,400 by almost 6 times, including civilian passenger car ownership increases sharply from 89,700 to 906,500 by almost 10 times, and amazing automobile exhaust emissions and increasingly crowded traffic condition also appear. Therefore, low-carbon travel should become one of necessary means for Dongguan to achieve sustainable development in the future.

The current international main stream believes that a low carbon trip refers to travel on foot or by bike or other public transport means and the Factors of Energy Consumption of Each Transport Mode (Table 2) shows that pedestrian and travel by bike are absolutely the greenest transport modes. Though travel with public transport means should be the first choice to develop low carbon traffic as for transportation demand in modern city, to travel on foot and by bike should still be the most low carbon travel modes and be widely promoted, and the planning and construction of greenway offers a good spatial carrier for it. We can easily find from the analysis from the above text that the residents in Dongguan have widely adopted traveling in the greenway as a method of relaxation and body-building. It is thus clear that the planning and construction of greenway offers a simple and easy way for the

low carbon trip of Dongguan residents that is closely connected with life. It also provides an opportunity to let people gradually accept and pursue the idea of low carbon trip, which creates a good beginning for the change of trip mode of Dongguan residents to be more low carbon.

Transport Mode	Rail Transit	Bus	Motorcycle	Private Car	Taxi	Bicycle	Pedestrian
Energy Consumption (MJ / person-kilometer)	0.322	0.714	1.495	2.795	5.59	0	0

Table 2: Factors of Energy Consumption of Each Transport Mode

(Source: Lv, SH., Tian, F., Li, X.H. (2007) *Study on the Optimized Model of Urban Passenger Traffic Structure, Journal of Highway and Transportation Research and Development, Vol.24, No.7, pp.117-118.*)

3.2 Contributions of Promoting Urban-Rural Coordinate Development

- *Bypass Institutional Barrier*

China's urban-rural dual structure mainly reflects in urban and rural different management systems in land, population, industry, environment and public services, and land system is the core of so many problems. The urban land right is owned by the state, and is able to become capital by transferring the land use right in the land market, while rural land is owned by the collective, however, the village collective has no right to buy and sell it, which can only be purchased by the government; the government can obtain huge land capital gains by purchasing low and selling high, while the village collective cannot share such capital gains, which leads to a series of problems of urban-rural social conflicts and livelihood and social security of land-lost farmers. Therefore, the reform and innovation of the land system is the key to solve the coordinate urban-rural development dilemma, and cannot be solved overnight.

The land for greenways at all levels in Dongguan includes both urban state-owned land and rural collective land. If in accordance with the traditional management methods, the procedures on land acquisition and nature conversion are required before conducting the construction, and the dilemma incurred by the institutional barriers must replay, and the GPC may also be affected. However, Dongguan's GPC has relatively successfully avoided the dilemma, and the key is that the land for greenway construction project does not change the ownership and property of the original land, all the greenway land involved in the collective land are solved by rental, villagers are encouraged and guided to develop happy farmhouse along the greenway, share the benefits brought by the greenway construction, and largely arouse the enthusiasm of villagers to participate in and jointly promote the smooth development of Dongguan's greenway construction.

- *Promotion of Green Infrastructure Integration Construction*

In the traditional urban-rural dual management system, all urban green spaces and rural mountains, fields and rivers belong to different management systems and lack of coordinate operation platform and spatial paths, therefore, they exhibit relatively segmented cracked plaques in the spatial distribution, while overall layout and orderly development of urban-rural space should be based on sound networking green ecological foundation, which is also beneficial to deal with the increasingly remarkable climate change. Therefore, promoting urban-rural integration of green infrastructureⁱⁱ is a very important content in China's coordinate urban-rural development. It is required to incorporate building greening, roadside green space, park, scenic spot and green corridor into overall urban-rural structure on different scales to form greening ecological network (Zhou, L et. al., 2010), and the greenway is undoubtedly able to become the most effective way to achieve the objective.

The Dongguan City greenway planning takes coordinating the city green space as the basic goal at the beginning of the design and takes the integration of resource factors as the

important basis for deciding the route selection of greenway (Table 3). The planning analyzes all kinds of elements such as the natural ecology, historical humanism, urban traffic and cities and towns spatial arrangement to integrate all kinds of green spaces through the route selection of greenway as far as possible.

Type of Element	Content of Element	Specific Influence
Element of Natural Ecology	Places of interest, forest parks, nature protection areas, rivers and waterways, reservoirs, island, farming and sericulture fields and gardens, etc.	Guarantee the rational utilization of superior ecological bases; express the ecology landscape characteristics of different areas; and connect ecological resources.
Element of Historical Humanism	Historical remains, villages and traditional streets, etc.	Connect the human resources in various regions; enrich the connotation of greenway; and demonstrate the splendid culture of Lingnan.
Element of Urban Traffic	Traffic line network and traffic facilities such as the railway, motorway, expressway and arterial street	Demonstrate the urban construction characteristic of Dongguan; form multiple, convenient and fast transfer system and improve the accessibility of greenway.
Element of Spatial Arrangement of Cities and Towns	Current overall arrangement and the isolating greenbelt of the cities and towns	Improve the usage rate of greenway; control the disordered extension of city; and optimize the space environment of the cities and towns.

Table 3: Influence of Resource Factors to the Route Selection of Greenway in Dongguan (Source: Overall Planning of Greenway in Dongguan (2010-2020))

In accordance with Dongguan’s greenway planning, the ecological greenway constructed along the natural river, valley, coast and ridge line outside the city, relies on the open green space, water, coast and field surrounding the city’s built-up area to build suburban greenway, and relies on the human scenic spot, park square and green space on both sides of city roads to build urban greenway, both of which jointly constitute the linear green space network, and connect Dongguan’s 18 forest parks, 5 natural protection areas, 24 stream channels, 56 reservoirs, 5 islands, 14 fields and gardens as well as major parks and roadside green spaces in 32 towns, which integrates the green infrastructure within the city scope into a whole on the spatial layout. Meanwhile, due to that the existence of greenway construction work team and its office largely guarantees the orderly construction and effective management of the greenway, both the operation platform and spatial path effectively promote the integration construction of green infrastructure in Dongguan.

- *Promote Urban-rural Characteristic Differentiated Development by Pushing Rural Economic Development in a Low-Carbon Mode*

Under China’s traditional urbanizationⁱⁱⁱ model, the government development concept of “taking city as the core” reflects in favorable policy, capital and human resources concentrating on cities, which leads to the current prosperity of Chinese cities. By contrast, the countryside is underdeveloped, backward rural economy characterized by low-efficiency development of agricultural industry leads to farmers’ low income and lagging rural construction. And the chain reaction incurred is that, on the one hand, a lot of rural idle labor enters the city to work but is unable to enjoy fair treatment due to the existence of social dual structure, which incurs all kinds of social problems; on the other hand, the countryside’s original features disappear when pursuing the economic development by replicating the currently urban high-carbon mode, and what disappears includes not only low-carbon and ecology, but also the countryside’s unique social culture and landscape, which obviously is inconsistent with the ultimate goal of achieving sustainable development. Therefore, coordinate urban-rural development should not only break down the urban-rural dual structure barriers, but also select appropriate development mode combined with the countryside’s own characteristics, to avoid losing itself due to blindly replicating the urban

mode. From the perspective of reality, establishing low-carbon and ecological rural mode as well as preserving and developing material and non-material features should take developing rural economy and improving farmers' life level as the preconditions, while Dongguan's greenway, as a new path for coordinate urban-rural development, also makes good achievements in this aspect.

Dongguan greenway connects the major forest parks, natural protection areas, scenic spots and historical sites as well as human resources in the city; based on that, by combining tourist route setting and ecological agricultural sightseeing, combining greenway service area and happy farmhouse, travel and leisure will become a new growth point for rural economic development, which not only improves the economic efficiency of agricultural resources, but also extends and develops the countryside's production and life characteristics, and enhances the farmers' income. It is absolutely the right development pattern that suits the characteristic of the country in comparison with copying the high-carbon development pattern of the city and developing the process and manufacturing industry blindly. Considering that Dongguan's greenway construction begins to take shape, and it is difficult to obtain the data on the countryside's economic benefits along the way, the author uses the data on the contribution of greenway in Guangdong greenway pilot city - Zengcheng to the rural economy to verify the above analysis. Since constructing the greenway, Zengcheng's tourists and tourist income increase largely, only in 2012, it attracts greenway tourists of 526,100, driving the whole city's accumulative tourists of 17,640,000, achieving tourist income of RMB 4,580,000,000 (Chen, W.X. 2013), providing 1000 direct jobs and 3000 indirect jobs; the rural collective economy along the greenway develops faster than the countryside not along the greenway, the rural per-capita cash income is about RMB 10,000, increasing by 17%, and the greenway's contribution to increasing farmers' income is about 40% (Xiong, X.L. 2011). Dongguan, as a neighbor of Zengcheng, ranks first in Guangdong province in terms of per-capita disposable income, far exceeding Zengcheng, and theoretically have stronger economic consumption ability and more travel and leisure demand, therefore, Dongguan greenway will play a gradually prominent role in pushing rural economy along the greenway as the greenway is completed and improved.

4. Conclusions

4.1. Beneficial Exploration

Greenway, as a special channel for people's fitness and leisure, is able to provide a new idea on exploration of Chinese urban-rural coordinate, after thorough planning and construction as well as formulation of new management mode. Based on the above analysis, it is found that, Dongguan greenway connects the city's important natural and human resources points by selecting reasonable and careful routes, and is planned to push the coordinate urban-rural economy development, and management measures characterized by city and countryside integration as well as multi-sector cooperation have been formulated to ensure the smooth implementation of planning and construction, and Dongguan has made a bold attempt in promoting Dongguan residents to transform into low-carbon travel mode, implementing integrated construction for green infrastructure, developing urban-rural economy, protecting rural characteristics and bypassing institutional barriers, and has made remarkable achievements, and achieved beneficial exploration on a new path for Chinese urban-rural coordinate under low-carbon model.

4.2. Limitation of Dongguan's Experiences Promotion

Urban-rural coordinate is an exploration work, and the key to achieve it is, based on an overall scientific analysis of urban-rural difference and regional difference, to formulate appropriate policy guidance in accordance with the local conditions (Wang, G.T. 2012), and the success of Dongguan GPC in promoting urban-rural coordinate also comes from it. Dongguan greenway's successful experiences mainly reflect in two aspects, one is having

bypassed urban-rural dual land management system barrier, the other is pushing urban-rural coordinate by tourism and leisure, both of them are closely related to Dongguan's urbanization development stage and economic development level, which are also the limitations of Dongguan's experiences promotion by other regions in China.

Dongguan greenway construction bypassing urban-rural dual land management system barrier is mainly attributed to that all the greenway land involved in the collective land adopt rental method instead of land acquisition, and such choice has its underlying reasons. Due to the city's rapid development in the past 30 years, in 2006, Dongguan's built-up area accounted for 43% of the city's total area; on the premise of satisfying the requirements of ecological baseline, newly increased land resources are very limited, and limited land indicators are often used for the city's projects on investment attraction; even if the government is willing to provide the greenway with construction land indicator by converting the collective land, the cost is not low due to the strength of village collective economy. Thus, rental naturally becomes the best plan for the government a village collective to reach an agreement. While in China's other regions, especially the middle and western regions where urbanization level is relatively low and the rural economy development lags behind, there is a lower probability that the government adopts land rental since the construction land is relatively sufficient and the land transaction cost is low, which is why it is difficult to use Dongguan greenway experiences for reference.

Pushing urban-rural economic development by tourism and leisure require preconditions. Only when per capita income reaches or exceeds certain standards, people will begin to carefully consider participating in tourism and leisure activities and are able to achieve them. On the contrary, even if people have leisure time, they will use it to consider increasing income instead of consumption. It is the widely-held view in the international community that, per capita GDP exceeding USD 3000 is the basic standard to enter the leisure era, while Dongguan has met such standard in 2004, and Dongguan per capita GDP was USD 7847 in 2008, satisfying the standards for upper-middle income countries. Therefore, Dongguan residents are able to accept the greenway so quickly, and actively conduct tourism and leisure activities via it. Other cities in China that want to take example by the successful experience should be comprehensively assessed. The use of greenway will not be affected by the difference of regional economic development levels and difference of rich and poor residents as for the urban and rural residents' daily life and working trip, but the difference of economic development stages should be put with enough emphasis on if you hope the leisure tourism industry initiated by the greenway drives the urban and rural economies.

4.3. Potential Problems That Need to be concerned

- *Double-faced Influence to Regional Culture in the Country*

We've mentioned about the influence of greenway on the development of rural economy and promoting of urban and rural characteristic differentiation development. The essence of promoting the rural tourism industry with greenway as the supporter is to utilize the mutual affinity of different culture groups. The connotation that the characteristic of country is different from that of the city is also their cultural difference. Therefore, keeping the regional cultural characteristic of country is an important problem that needs to be emphasized and stressed in the future development of country.

From the dialectical standpoint, every coin has two sides. That also fits the influence of greenway to the regional culture of the country. The core of maintaining and inheriting any culture is people. The backward rural economy causes quite a number of rural populations, especially the young people who leave the country for work, which results in the hollowing out of large quantities of countries and the cultural fault in the development of rural regional culture. The planning and construction of greenway drives the rural tourism and brings new opportunities for the villagers to get job and become rich, which contributes to eliminating the phenomenon of hollowing out in the country to some extent. And the industrial characteristic

that it consumes rural regional culture also stimulates the renaissance and development of rural regional culture. As for the negative effects, the construction of greenway also offers a more convenient way and a more popularized platform for the contact of urban culture and rural culture. The conventional thinking in current China that “the city is more advanced while the country falls behind” and great potential difference of the two cultures causes the phenomena that the urban tourists despise rural culture and the villagers cater to the urban tourists, which will destroy the rural regional cultural connotation invisibly.

- *Possibility of Disorder Expansion of Town and Country Construction*

The adverse impacts of blind and disorder expansion of urban construction have gradually acknowledged by Chinese governments who have made corresponding management policies to control the expansion of cities. The greenways are the routes to provide relaxation, body-building and travel for the public. Though we can make strict construction and development system to avoid the spread of city boundary, the construction and improper activity of the greenway user may cause negative effects to the initial conditions of the urban and rural environment. Therefore, it is necessary to carry out comprehensive influence tracking assessment on greenway to find out the adverse impacts and make adjustment measures for effective control.

As for the construction of the country, as the greenway can effectively drive the development of rural tourist economy, it may cause profit-driven overdevelopment and disordered construction, which waste the rural resources and have negative influence on rural culture and profile control. We need to take comprehensive management measures after deep research to control the possible adverse impacts.

Acknowledgments

I express my sincere thanks to Dongguan Urban-Rural Planning Bureau and Dongguan Urban Planning & Construction Institute for their providing the paper with detailed basic materials, such as Dongguan comprehensive Planning on Greenway (2010-2020) and Dongguan Greenway Comprehensive Evaluation Report 2012.

Endnotes

ⁱ American economist Lewis W.A. proposed in 1954 that, the economy of the developing countries consisted of modern economic departments characterized by modern technology and traditional agricultural sector characterized by traditional backward technology, and the co-existence of such two departments is called as dual economy or dual structure. The dual economic theory has been quickly responded by Chinese academic society after being proposed. In 1988, the experts from the center for policy research of Ministry of Agriculture proposed Chinese dual social structure theory (Zeng, Y. 2012).

ⁱⁱ In 1999, a joint working team established by American Conservation Foundation and Forest Service of Ministry of Agriculture clearly proposed the concept of green infrastructure for the first time, defining it as national natural life support system, an interconnected network made up of water channel, wetland, forest, wildlife habitat and other wilderness and open space maintaining original species, promoting natural ecological process, protecting resources and improving people’s life quality (Zhang, Q.M. 2004).

ⁱⁱⁱ Chinese traditional urbanization refers to the urbanization road under the specific historical background since China’s reform and opening up, with the fundamental characteristics of labor non-agriculturalization taking city as the core and taking growth as orientation (Ye, Y.M. 2013).

Ralph BUEHLER
Virginia Tech, Urban Affairs and Planning
School of Public and International Affairs
United States

1. Introduction

Federal, state, and local governments in Germany and the U.S. strive to make passenger transport more sustainable. In this paper, we first compare the Washington, DC and Stuttgart regions to demonstrate differences and similarities of the German and US systems of land-use and transport planning. To illustrate local planning for more sustainable transport we compare planning in Arlington County in the DC Metro region and Scharnhäuser Park in the Stuttgart region—both localities are best practice examples for sustainable planning. We conclude that in spite of significant differences in motorization, travel behavior, sustainability, and planning systems, local governments in both countries rely on similar strategies to increase the sustainability of their transport systems.

1.1 Travel Behavior and Sustainability of the Transport System in Germany and the US

Germany and the U.S. are among the most motorized countries in the world. However, in 2010, Americans owned 30 percent more cars and light trucks per capita as Germans (766 versus 585). Americans also drove for a much higher share of daily trips (83% vs. 58%) than Germans. By contrast, Germans were 4 times more likely to ride public transport (8.5% vs. 1.9%), 2.5 times more likely to walk (23.7% vs. 10.5%), and 10 times more likely to cycle (10.0% vs. 1.0%). A higher share of trips by automobile in the U.S. is related to greater annual driving distances for Americans than Germans (21,500km vs. 11,000km).

Table 1 compares indicators for the sustainability of the transport systems in Germany and the U.S., covering three commonly cited dimensions of sustainability: equity, environment, and economy. Driving for fewer trips and shorter distances contributes to more sustainable transport in Germany. Overall travel, and especially walking and cycling, are safer in Germany than the U.S. Moreover, higher levels of walking and cycling in Germany contribute to more physical activity and lower obesity levels in Germany than the U.S. Compared to Germany, households and the public sector in the US spend more on transport. Moreover, governments in the U.S. spend more on roadways than they collect in taxes and fees from roadway users. In Germany, roadway users pay more in fees and taxes than governments spend on roadways. Public transport operation is more financially efficient in Germany. Finally, Germany's transport system is also more sustainable from an environmental perspective when comparing transport energy use and CO₂ emissions.

Selected Sustainability Indicators

		USA	Germany
Safety and Health	Traffic Fatalities per 100,000 Population	11,1	5,1
	Traffic Fatalities per 1 Billion Vehicle Kilometers	7,1	5,9
	Cyclist Fatalities per 100 Million Kilometers Cycled	5,5	1,6
	Pedestrian Fatalities per 100 Million Kilometers Walked	9,7	1,9
	Percent Population Considered Obese (BMI>30; self-reported data)	23,9	12,1
Cost	Share of Household Expenditures for Transport	17,0%	14,6%
	Annual Household Expenditures for Transport	\$7.677	\$5.117
	Ratio of Roadway User Fees & Taxes vs. Roadway Expenditures by all Levels of Government	0,58	2,22
	Government Subsidy as Share of Public Transport Operating Budgets	59%	25%
Environment	Annual Ground Passenger Transport Energy Use per Person (in million BTU)	54,6	18,0
	Transport Sector Share of CO ₂ Emissions	32%	19%
	Kg of CO ₂ Equivalent Emissions per Capita from Ground Passenger Transport	3.800	1.200
	Grams of CO ₂ Equivalent Emissions per Passenger Km	210	110

Table 1: Sustainability Indicators for German and U.S. Transport Systems (Source: APTA 2011, David et al. 2008, Buehler and Pucher 2011, Buehler et al. 2009, EPA 2012, IEA 2012, IRTAD 2012, USDOE 2012, Pucher and Buehler 2010, UBA 2010, 2012, USDOL 2010, VDV 2011)

2. Transport in the Washington and Stuttgart regions: differences and similarities

In this paper the Washington, DC region (DC metro region) and the Stuttgart region serve as examples for similarities and differences between Germany and the US in land-use planning, transport systems, coordination of transport and land-use planning, and sustainable transport. Although there are differences in land area, population size, administrative structure, and economy, both regions share many similarities that render a comparison meaningful (see Table 2): Both are among the wealthiest regions of their country with strong economies and labor markets. Both regions showed relative economic stability during the recent economic crisis and experienced strong population in-migrating, resulting in a more diverse population. Washington, DC has a larger government sector and more industries associated with government, while Stuttgart has a stronger manufacturing and industrial engineering base. The population in the Stuttgart region is characterized mainly by industry, attracting a highly skilled workforce, while the government functions of the Washington, DC region result in a high share of transient populations, moving to and from the area with each federal election cycle.

Travel behavior in the central city of each region is similar: public transport accounts for 22% of all trips in Washington, DC and 24% of all trips in Stuttgart. Similarly, walking and cycling (29 and 32%) and the car (51 and 44%) account for comparable shares of trips in both cities (MWCOG 2010, Broeg and Erl 2012). Travel behavior displays large differences for the region as a whole and for the suburban areas in particular: In 2008/2009, driving accounted for 80.6% of all trips in the DC metro region, compared to 56.6% in the Stuttgart region.

The differences in percentage of trips by mode of transport between core jurisdiction and suburban areas are much larger in the DC metro region than the Stuttgart region (see Figure 1). In the DC metro region, the automobile accounted for more than 90% of all trips in suburban Fauquier, Prince William, Prince Georges, Anne Arundel, Charles, and Fairfax counties (MWCOG 2010). By contrast, the two most car-dependent suburban jurisdictions in the Stuttgart region -Nürtingen and Geislingen- had car mode shares of 70 and 75% (VRS 2011). Walking and cycling only accounted for about 6% and public transport for less than 2% of trips in most suburban jurisdictions in the DC metro region. Even in the most car-oriented jurisdictions of the Stuttgart region, walking and cycling account for more than 22

percent of trips and public transport's mode share is above 3%.

	Stuttgart Region	Washington Region
Size [sqm]	1,411	3,967
Population [million]	2.67	5.58
Population Core City	~ 600,000	~ 600,000
GDP [\$/inhabitant]	45,000	71,000
Car ownership [per 1,000 inhabitants]	544	744
Cars/household	1.1	1.8
Trips/day	3.5	3.9
Median trip distance [km]	5.0	5.6
Distances per day [km]	40	44
Daily travel time [min]	75	80
Average trip speed [km/h]	27	28
Share of trips by car of all trips (region) [%]	56.6	80.6
Share of trips by public transport of all trips (core only) [%]	24	22
Share of trips by public transport of all trips (periphery only) [%]	70-75 (Note: data are for the most car-dependent jurisdictions: Nürtingen and Geislingen)	> 90 (Note: data are for the most car-dependent counties: Fauquier, Prince William, Prince Georges, Anne Arundel, and Fairfax)
Unleaded Gasoline Prices per Gallon 2010 [\$]	7.0	3.0
Gasoline Taxes [\$]	4.84	0.53

Table 2: Socioeconomic, Demographic, and Travel Data for the Washington and Stuttgart Region (Source: U.S. Census Bureau 2010, Statistisches Landesamt Baden-Württemberg 2012, MWCOG 2010, TPB 2010, Zumkeller 2011 IEA 2012)

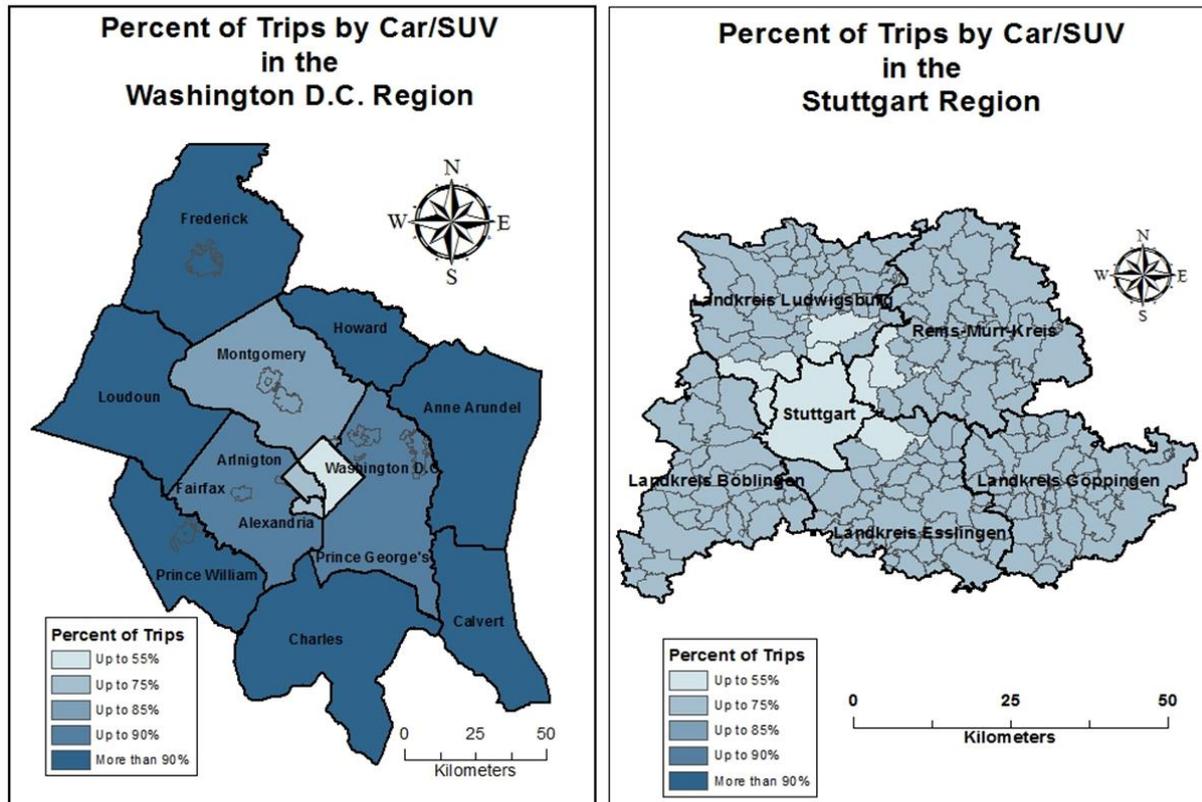

Figure 1: Shares of Trips by Automobile in Jurisdictions of the Washington, DC and Stuttgart Regions, 2008 (Source: Broeg and Erl 2012, MWCOG 2010, TPB 2010, VRS 2011)

3. Coordinating transport and land-use planning

Although the two central cities of Washington, DC and Stuttgart have similar travel mode splits, the overall regions show strong differences caused by the car-dependent suburbs of the Washington, DC Region. Differences in travel behavior can be explained by socio-economics, demographics, culture, and diverging transport and land-use policy and planning systems in Germany and the US. Due to space limitations, the following discussion focuses on transport and land-use planning systems. Detailed discussions about other factors can be found in our other publications (Buehler and Jung 2013).

3.1 Land-use planning

Differences in planning systems

In Germany, federal, state, regional, and local governments interact in a bottom-up and top-down land-use planning process, coordinating their spatial plans in an interactive way (BMVBS 2000). Municipalities in Germany have the exclusive planning right and draw up detailed land-use plans and decide the specific allowable uses of land. Local plans in Germany, however, are restricted by regional and state plans and must be in compliance with federal land-use, transport, and environmental laws (Kunzmann 2001). Federal involvement in spatial planning is limited to defining the legal framework for planning, ensuring consistency of planning techniques, and -in collaboration with the states- setting broad strategic goals for spatial development such as sustainability (Wiegandt 2004).

The regional level plays an important role in defining areas for Transport Orientated Development (TOD). The Stuttgart regional plan distinguishes between 'growth poles' that will capture most of the future settlement growth (Siedlungsbereiche) and areas with lower growth levels (Eigentwicklung). Areas designated for slower growth are typically not connected to public transport lines, while housing development is concentrated in the 'growth

poles' with public transport access. The goal is to reduce land used for settlements and to curb sprawl in the Stuttgart region.

In contrast to Germany, in the US there is no system of land-use planning that connects federal, state, regional, and local levels of government. US local governments play the predominant role in land-use planning and regulation. The US federal government does not engage in land-use planning and, in contrast to Germany's Federal Spatial Planning Act (Bundesraumordnungsgesetz) or Federal Building Code (Baugesetzbuch), there is no federal legislation prescribing the overall land-use planning process at lower levels of government. Federal programs in the US influence spatial development and land-use decisions on the local level, through federal transport policy and finance, environmental regulation, housing and economic development, military spending, and the management of nationally owned lands (Kayden 2001). However, there is no integrating framework and as a result, most land-use planning in the U.S. is fragmented, uncoordinated, and almost always in the domain of local government jurisdictions (Schmidt and Buehler 2007).

In contrast to the fragmented system in the US, coordination and negotiation of different levels of planning authorities in Germany facilitates coordination with regional transport planning. For example, development can be more easily concentrated along public transport routes to provide high capacity public transport connecting to the centers of the region. The Stuttgart Regional Plan allots higher growth rates to communities with rail public transport than for those without. In the DC metro region individual municipalities decide how to connect their land-use to the metrorail system. For example, Arlington County built high density mixed use around its metro rail stops, while Fairfax County chose to build park and ride parking lots next to its metro stops.

Differences in land-use planning on municipal level

In both countries, the municipal level has the main responsibility for regulating land-use and in both countries similar planning documents guide land-use planning. In Germany the main instruments for land-use planning are the Land-Use-Plan (*Flächennutzungsplan*) and Local Building and Construction Plan (*Bebauungsplan*). The Land-Use Plan is a preparatory plan laying out the general outline of existing and future land-use by type (general types of use include housing, mixed use, industrial and commercial, special purpose). Furthermore, the Land-Use plan defines the so-called "inner zone" (*Innenbereich*) and "outer zone" (*Außenbereich*) of a municipality. In the outer zone, no construction is allowed, besides those types of typical uses for outer zones, such as agriculture or energy production. The Local Building and Construction Plan consists of legally binding urban development ordinances. In the Local Building and Construction Plan, the specific categories of land-uses, defined by the Land Utilization Ordinance, are constituted for small areas. Although both documents traditionally separate land-uses (Albers 1992), all categories have some flexibility to allow other uses (see below).

At the municipal level in the US, the most common type of land-use plan is called a comprehensive or master plan, which typically consists of maps and text. However, zoning, and not land-use planning, is the main tool of land-use control in the U.S. (Hirt 2012). With a few exceptions, virtually all local governments have passed zoning ordinances that limit the use of land in the entire jurisdiction. In both countries, industrial and residential uses are deemed incompatible. However, in contrast to Germany, with a few exceptions, U.S. zoning has emphasized the separation of all types of land-uses. For example, in Germany residential zones can include doctor's offices, apartment buildings, businesses, small shops, and restaurants. As a result, many German "residential" areas would be considered 'mixed-use' in the U.S. Additionally, compared to the U.S., German municipalities apply their zoning to smaller land areas - sometimes as small as a block. U.S. municipalities typically apply their zoning to larger areas of land. This results in longer trip distances that often make walking and cycling impractical.

As in Germany, local planning in the U.S. is influenced by the need to achieve

development patterns that best support the local budget. However, compared to German municipalities who mainly compete for business taxes, U.S. local governments focus more on local property taxes to fund local expenditures, such as police, water and sewer, or court services (Orfield 2002).

Strict separation of land uses, exclusion of apartment buildings, doctor's offices, corner stores, and small businesses from single family residential zones, and larger areas of single-use zoning result in longer trip distances in the U.S. Long trip distances and the separation of trip origins and destinations necessitate more trips by car in the U.S. because different activities (e.g., shopping, work, leisure) are more dispersed. Germany's practice of zoning for smaller land areas and the more flexible zoning code has helped to reduce trip distances and car dependence - even when planners did not explicitly coordinate transport and land use.

3.2 Transportation planning

German state and federal governments jointly developed the Federal Transportation Plan, which delineates a national transport strategy. Until the early 1970s, this plan focused mainly on automobile travel, but since 1973 it has included societal goals, such as preserving open space, or reducing traffic fatalities, energy use, and vehicle emissions (Koeberlein 1997). Gasoline taxes have traditionally been higher in Germany than in the US. In 2013, a gallon of premium gasoline cost about \$8 in Germany and \$4 in the US (EIA 2013). Over the last 40 years the German gas tax was raised several times to fund government expenditures, but never with the explicit purpose to curb driving. Since the mid-1970s, the German federal government has also provided dedicated matching funds to state and local governments for public transport capital investments - if projects are part of local comprehensive transportation plans, comply with land-use plans, and consider the needs of the disabled and the elderly. German federal traffic laws protect cyclists and pedestrians and making their safety an integral part of the German driver's license written exam and road test. Since the early 2000s, the German government has also published a national bicycle master plan (FahrRad!). However, most innovations, such as integrated city-wide bicycling networks, were pioneered and then widely implemented at the local government level. The federal government supported local efforts with technical guidance and flexible funding, which allowed municipalities to divert highway funds to non-motorized modes.

US federal and state transport plans have a long tradition of prioritizing highways over other modes of transport. Since the passage of the Intermodal Surface Transportation Efficiency Act (ISTEA) in 1991, the US federal government has also increased funding for public transport, walking, and cycling. However, ISTEA's attempts to promote alternatives to driving were accompanied by simultaneous increases in federal roadway funds. ISTEA required and helped fund regional transportation planning and coordination. However, most metropolitan planning organizations (MPOs) do not have any legal authority to enforce regional policy priorities or to alter decisions made by local government jurisdictions or state departments of transport. Moreover, MPOs do not make any specific land-use planning decisions.

Transport Planning the Stuttgart Region

Besides the Federal Transportation Plan general aims and projects are laid down in the General Transportation Plan of the State of Baden-Württemberg. Projects for road and rail are listed, but not prioritized. The plan provides ideas how to plan for non-motorized transport, but these are only suggestions to the regions and municipalities. The Statewide General Transportation Plan acts as framework for the Regional Transportation Plan of the Verband Region Stuttgart, an integrated concept for mobility in the Stuttgart Region and guideline for all measures and decisions about transportation planning. Transportation planning on the regional level is further specified by Local Transportation Plans of the municipalities in which infrastructure projects, quality of services etc. are laid down.

Different levels of government, like the State of Baden-Württemberg, the Verband Region Stuttgart and the municipalities issue calls for tender for public transport services. Service is provided by different (often public owned) public transport companies. Calls for tender stipulate the quality and frequency of services and provide funding if farebox revenues do not fully cover the operation costs.

Backbone of public transport in the Stuttgart region is the Stuttgart Regional Public Transport Organization (Verkehrsverbund Stuttgart, VVS). Forty-one transport companies, either private or government owned, collaborate in the VVS to jointly serve the counties of Böblingen, Esslingen, Ludwigsburg, Rems-Murr-Kreis, and the City of Stuttgart. The VVS is not only responsible for the operation of public transport, but also for the planning and building of new railway lines.

The VVS network comprises all public transport in the region, and its tickets apply to all modes of public transport. This coordination and integration of different modes of transport (commuter rail, metro rail, light rail, and bus) and across different transport companies (including services, schedules, and fares) makes public transport seamless and customer friendly helping to increase ridership. For public transport passengers in the region it does not matter which specific company provides the service. Regional tickets are valid anywhere in the region, schedules are coordinated, and customers can get information about public transport in the region from one integrated database for trip planning (e.g. www.vvs.de). Also the VVS offers steep discounts for daily, weekly, monthly, or annual tickets, for companies, students or elderly. This is especially attractive for daily commuters using public transport as an alternative to the car.

Transport Planning in the Washington, DC Region

Federal legislation in the US requires long- and short-range transport planning for states and metropolitan areas. State Departments of Transport (DOTs), such as the Virginia and Maryland Departments of Transport (VDOT and MDOT), are responsible for statewide transport planning. In Washington, DC, the District Department of Transport (DDOT) receives state planning funds from the federal government. Statewide long-range plans identify a vision for the state's transport system in the next twenty to thirty years. Goals in the VDOT and MDOT long-range plans include enhanced quality of service, better safety and security, system preservation, and environmental stewardship. Based on the long range plan, states develop four-year short-term plans, which prioritize projects and identify funding sources.

Similar to the state level, MPOs are mandated to develop and maintain metropolitan long-range and short-range plan. Long range plans contain a region's transport goals for the next twenty to thirty years and describe strategies how to achieve these goals. These plans estimate a region's future transport needs based on land-use forecasts, are updated every four to five years, represent the region's priorities, and include a financial plan with reasonable cost and revenue estimates. The Transport Planning Board (TPB) is the main MPO for the DC region. Key challenges identified in TPBs long range plan include funding, congestion on roadways and public transport, serving dispersed populations, maintaining the system, environmental quality, and CO₂ emissions. TPB also published a policy vision that guides regional transport investments with the goals to provide a range of transport options, reduce auto dependency, increase public transport use, coordinate transport and land-use, and maintain the existing transport system. Short-range plans include projects to be built within the next three to five years, are updated every four years, are fiscally constraint, and are approval by the state governor. To be eligible for federal funding, a transport project has to be included in USDOT-approved statewide and metropolitan short range transport plans.

TPBs vision and its long-range plan are closely related to a region-wide plan titled Region Forward—developed by the regional council of governments (MWCOG). As a result, the three plans' transport goals are consistent with each other. The land-use vision and scenarios developed by MWCOG and TPB are not legally binding for member jurisdictions, but they provide a forum for regionally-focused discussion. However, most decisions are made on the local level.

4. Best-Practice – Comparison of Arlington County’s Rosslyn-Ballston Corridor and Scharnhauser Park in the Stuttgart Region

Both Arlington County’s Rosslyn Ballston Corridor and Scharnhauser Park in the Stuttgart Region are best practices cases of planning for sustainable transport. This section provides a comparison of local policies in both areas. In spite of large differences in transportation and planning systems, there are many similarities in coordinating transport and land-use at the local level to achieve more sustainable transport.

Arlington

Like many urban areas in the U.S., Arlington County experienced an influx of residents and development after World War II, and then steady decline as the "postwar boom" receded. During the 1960s and 1970s local opposition to the construction of Interstate 66 through Arlington County lead to a scaled-down version of the highway and the location of 5 stations of the new regional Metrorail directly under the then declining Rosslyn-Ballston Corridor (TCRP 2011). Plans focused redevelopment within a quarter-mile walking radius of stations to allow for easy pedestrian access. Metrorail service between Rosslyn and Ballston began in 1979. In spite of a quadrupling of office space and housing units since the late 1970s, redevelopment has only generated modest increases in car traffic on local streets (Leach 2004). Many of the newly generated trips are by public transport. Between 1990 and 2012, average weekday passenger trips by public transport in the corridor rose by 42% from 67,600 to more than 96,000. Approximately 16% of corridor households do not own a vehicle, and in some residential developments, an estimated 40-60 percent of tenants do not use a vehicle on a daily basis (Arlington County 2008). Single occupancy vehicle commuting has been declining in the corridor, while commuting by walking, biking, and public transport have been increasing.

Scharnhauser Park

Scharnhauser Park, belonging to the City of Ostfildern, is a former U.S. military site - Nellingen Barracks- that housed approximately 7,000 U.S. soldiers until it was abandoned in 1992 (Stadtchronik Ostfildern 2011). Enhancing the transportation infrastructure, especially public transportation, was required as a precondition for development not only for the regional but also local level. The mayor of Ostfildern stressed that the development of Scharnhauser Park would only take place if the light rail to the area was extended (Stuttgarter Nachrichten 1993; Bender 1994). Based on the Master Plan’s estimate of 10,000 passengers per day, the Stuttgart Straßenbahnen AG (SBB) decided to extend the existing railway line from Heumaden to Nellingen via Scharnhauser Park. That meant that Scharnhauser Park would not have been built without rail access and the rail line would not have been extended without development plans for Scharnhauser Park ("No light rail without Scharnhauser Park, no Scharnhauser Park without light rail.") (Bender 2004, p 178). Starting in the year 2000, just one line served the extension from Heumaden to Nellingen, but already in 2000 the city of Ostfildern and the SSB decided to establish a new line, the U8. In the beginning, the U8 ran only during peak hours; however, due to the success of public transportation within Ostfildern and the popularity of connections to Stuttgart, the schedules were extended to the entire day and the line was further extended using previously abandoned tracks.

From its founding in 1975 to 2011, the city of Ostfildern grew by 8,500 inhabitants, from 28,000 to 36,500 inhabitants. Most of these gains were due to the development of the settlement of Scharnhauser Park: More than 70 percent of this increase occurred after the development of Scharnhauser Park started in 1994 (own calculation based on Statistisches Landesamt Baden-Württemberg 2012).

Comparison of Local Policies to Coordinate Transport and Land Use

The wide array of policies and programs utilized in support of the development of the Rosslyn-Ballston Corridor and Scharnhauser Park are characterized by four key features that have contributed to the success in planning for sustainable transport:

First, building dense and mixed land uses around public transport stops.

In *Arlington*, this meant targeting "bull's eye" zones of mixed-use and high density development around public transport stations. The stations are about 1km to 1.5km apart so that access to a station is within a ten to fifteen minute walk from anywhere in the corridor. Density around the stations is planned so that the highest intensity development is in the immediate vicinity of the stations, while development density "tapers" down progressively as the distance from a station increases. The stations also serve as focal points for distinct neighborhoods with mixed land uses and varying emphases on government, educational, retail, and business development that foster a balance of land-uses throughout the corridor.

Scharnhauser Park is not a typical suburban, low-density settlement with single and semi-detached housing structure, but rather urban comprised of housing with a mixture of low, medium, and high-density housing (single and semi-detached houses, row houses, town houses, city mansions, tower blocks). There are also areas of mixed use and for commercial activities. The settlement pattern is characterized by short distances to the stops of public transportation -no part of the new town is farther than 500m away from the new railway station- and high density figures.

Second, long-range and comprehensive plans are important to assure sustained success.

Arlington County's Comprehensive Plan served as a blueprint for the corridor's development. As the main policy guide for development of the county, it establishes "the overall character, extent, and location" of development (Arlington County 2012). In conjunction, Sector Plans outline the overall vision of development around each Metro station, including design standards, public improvements to the streetscape and open space, and locations of various development uses. The result of this multi-faceted body of planning documents and adjoining processes is a blueprint of the planning vision for the corridor is coherent and dynamic.

In the case of *Scharnhauser Park* the establishment of the Master Plan as guidance for the development of the area determined several planning procedures in advance: the City of Ostfildern decided to change the Land-Use Plan in a way that identified Scharnhauser Park as a 'growth pole' (see above). The new housing area is seen as a new city quarter on its own, not an addendum to Scharnhausen or the center of the city of Ostfildern. As a matter of fact, the Regional Plan appointed Scharnhauser Park as a "regional center for housing" in the northern and "center for commercial development" in the southern part of the area. In 1992 a first feasibility study and urban design competition started to develop new ideas for how to re-use the site. After an interim use for the athletes of the World Athletics Competition in 1993, the city of Ostfildern bought the whole area and a development statute (Entwicklungssatzung) was enacted that gives the municipality the right of receiving the parts of gains of property value for parcels of land. These received gains were be used to build the infrastructure needed. In 1994, a master plan for the re-use was created and first developments undertaken. The master plan foresaw about 3,000 housing units for about 9,000 new inhabitants and retail spaces and office/commercial space for about 2,000 employees on an area of altogether 141.3 ha (349.2 acres).

Third, citizen participation is the key.

Arlington's plans have been developed through extensive outreach efforts to the community, developers, and other stakeholders. As a result, policymakers, developers, and community members have been able to work together using a broad and stable

understanding that is also conducive to refinements to the planning principles and innovations.

Public participation also played a major role in *Scharnhauser Park*: besides the two-tiered participation process for the Land-Use Plan and Local Building and Construction Plan as laid down in the Federal Building Code (Baugesetzbuch), the elaboration of the Master Plan as accompanied by public participation and citizens meetings, discussing critical points of newly roads, social infrastructure like kindergartens and schools as well as the design of public space, latter seen as a key feature for the new quarter.

A fourth major feature is the coordinated programming and policies that together support diverse transport, housing, and business opportunities.

In terms of transport, *Rosslyn-Ballston Corridor* planners leverage public transport service, pedestrian and bicycle facilities, parking regulations, transport demand management programs, and marketing in order to encourage and enable use of alternatives to the automobile. The corridor offers a wide array of transport options that are centered around the five Metro stations. Additional transport options include local and regional bus service via Metrobus and Arlington Transit, bike-sharing through Capital Bikeshare, and car-sharing.

In the case of *Scharnhauser Park*, by negotiations between the different levels of government and spatial planning agencies, financial support for the municipality was guaranteed, spatial aims of future development of the city of Ostfildern were changed, and further development was channelled to the area of Scharnhauser Park. This could happen in particular by their counter-current revised spatial plans of the Verband Region Stuttgart and the city of Ostfildern, by which the city of Ostfildern could get the right of additional land claims needed for the development of the Scharnhauser Park. The land-use agreement demanded higher population densities in the area to be developed. At the same time, Ostfildern, the county of Esslingen, and the transportation agency agreed on the simultaneous construction of Scharnhauser Park and the extension of the railway line, tying the new settlement to the transportation system of the Stuttgart Regional Public Transportation Organization.

Overall, *Rosslyn-Ballston Corridor* and *Scharnhauser Park* policies regarding transport work in concert with one another and also support each areas larger policy framework. The results have been increasing levels of public transport use, cycling, and walking.

Key future challenges for the both include affordable housing, historic preservation, the cohesive design of the built environment, and the continued improvement of facilities for pedestrians and bicyclists (Leach 2004). Housing affordability in particular is one of the greatest challenges facing the *Rosslyn-Ballston Corridor*. The primary tool to preserve affordable housing is the zoning framework, which provides a variety of incentives for affordable units, including density bonuses and a requirement of one-for-one replacement of affordable units in a designated area called the Special Affordable Housing Protection District. In addition, the county has established a revolving loan fund, the Affordable Housing Investment Fund, which finances affordable housing development in the county.

Housing is one of the major concerns also in the Stuttgart region. On the one hand, there is still a significant amount of population in-migrating to the Stuttgart region; on the other hand, land is a scarce resource in the region, resulting in a rather high population density and real estate prices. Politics and planning have to deal with the conflict of offering enough parcels of land for the population while at the same time protecting the landscape and nature from exhaustive land claims and reducing traffic caused by commuting. With the conversion of the former military site Nellingen Barracks to the Scharnhauser Park development, a unique but challenging opportunity arose for the city of Ostfildern and the region as a whole. For the rather small city of Ostfildern, this opportunity was beyond financial viability, but by negotiations with various levels of government (District, State, Federal), an agreement on assumptions of costs could be achieved as well as different funds e.g. the State Rehabilitation Program or grants for the State Garden Exhibition¹ could be used to buy the military site and invest in the infrastructure needed.

5. Conclusion

The Washington, DC metro and Stuttgart regions mirror the national differences in travel behavior. Outlying suburbs in the DC metro region are much more car dependent than outlying suburbs in the Stuttgart region and account for much of the difference in travel behavior (more than 90 percent versus 70 percent of trips by car). By contrast, the cities of Washington, DC and Stuttgart have almost comparable mode shares of car use (51 percent and 44 percent, respectively).

Reasons for differences in travel behavior can be found in the transport and land-use policies and planning. Since the 1970s, and especially since the 1990s, all levels of government in Germany have implemented policies that increase the monetary and time cost of car travel (gasoline taxes in Germany are about nine times higher than in the US: \$4.84 versus \$0.53 per gallon). Moreover, most German cities and regions have promoted walking, cycling, and public transport as attractive alternatives to the car. Compared to Germany, US federal, state, and local transport policies during the last sixty years have been more favorable for the automobile. Moreover, land-use policies in the US more strictly separate land uses and increase distances between trip origins and destinations.

In Germany different levels of government coordinate their land-use plans in an interactive process. As long there is consensus about certain policies, like reducing land claims, decreasing GHG emissions or car dependency, these policies are easier to implement on the local level, resulting in a more concentrated, denser development of settlements at the axes of public transport. In the US, land-use planning remains fragmented across jurisdictional boundaries, uncoordinated between levels of government, and typically not integrated with planning for transport. On the local level, land-use regulations in Germany typically foster mixed-used, denser land area compared to the US. This reduces the necessity of traveling and car use.

While fragmented land-use planning in the US is often seen as an obstacle to more sustainable transport, our case study from Arlington County, Virginia shows how a local jurisdiction can foster the integration of transport and land use. *Arlington County* successfully focused mixed-use, dense development around stops of a new metrorail system. Practices used in Arlington are similar to current efforts to integrate transport and land-use planning for more sustainable transport in Germany. As the case study of *Scharnhauser Park* highlighted, there is a reciprocal interest in the (re-)development of certain sites for the local transportation agencies while such a development is more likely to take place if accessibility is provided by high-capacity public transport infrastructure. By this, Scharnhauser Park gives a good example of how public transportation is a catalyst for the (re-)development of certain areas, while at the same time this development is the prerequisite for investments in public transport.

Planning for balanced Industrial development in Vidarbha region, Maharashtra, India

Asst. Prof. Amruta Khairnar, Vidya Pratishthan

1. Abstract

Disparity in India has been persisting since independence causing many socioeconomic problems and its removal has become the most prime objective of the planned development in India. Hence, initial segment of the paper deals with district wise level of development in Vidarbha region based on socioeconomic factors and identifies the most affecting factor responsible for imbalance in development. As a result of this segment, "Industrial Sector" has been taken as the prime factor responsible for such disparity through Regression analyses. Now, In order to achieve balanced industrial development, the later segment attempts to study district wise prospects of development in terms of investment through Location quotient analyses and also identifies district wise high potential local industrial clusters. The policy guidelines aim at cluster theory for competitive microeconomic development. The proposals mainly focus on micro-economic (firm level) development which will help the poorer districts to grow faster.

2. Introduction

Regional disparity in the level of economic development has become the vital problem for developed and developing countries. Disparity in India has been persisting since independence due to provincialism and sub provincialism causing many socioeconomic problemsⁱ and its removal has become the most prime objective of the planned development in our country. So ideally the development should enhance the human capabilities, ensure the equitable distribution of benefits of the economic growth and give an equal chance to everyone to participate in the working society. Such disparities can be observed at various levels like national, state, and regional. One of such states with the interregional and intraregional disparity is Maharashtra. It has a reputation for progress and development in economic terms and is considered as the most developed state since the time of Independence due to higher percentage of urban population. But as per the Human Development Report (HDR) published in 2010 there are widespread inequalities in the distribution of resources which have led to regional disparities, acute poverty and high level

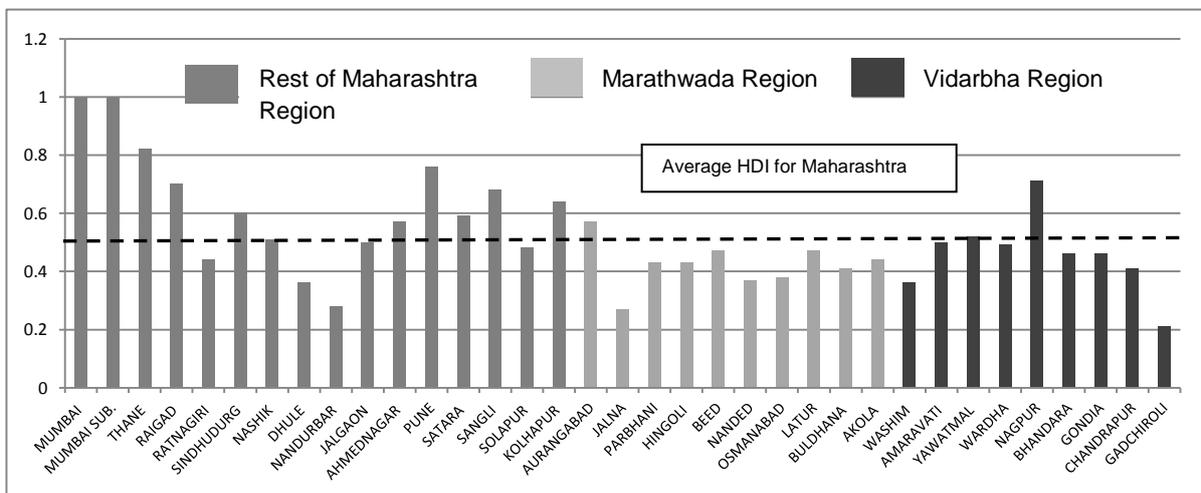

Figure.1 District wise HDI for Maharashtra state (Source- Human Development Report, 2010)

of unemployment. Maharashtra state comprises three regions namely, Marathwada, Vidarbha and Rest of Maharashtra. Vidarbha region comprises Nagpur and Amravati sub region. To work out the study at the regional level, Nagpur Sub region has been selected instead of Amravati Sub region because of the better data availability.

Vidarbha region of Maharashtra state lags behind in the overall development. HDR (2010) showed that human development index (HDI) is the lowest for Nandurbar and Gadchiroli districts (0.21) and highest for Mumbai. The average HDI for the state of Maharashtra is 0.58 (Refer Figure 1). In Maharashtra, 19 districts showed HDI less than the state average. Out of those districts most of the districts are belonged to the Vidarbha region. This region is completely neglected, unlike the Western and some of the South-Western districts, which get the Lion's share of State funding and attention. Recently Farmer's suicide has become the major concern in Vidarbha region. From 1997 to 2006, the region has witnessed 36,428 cases of suicide among cotton farmers owing to debt. It indicates that disparity within the state of Maharashtra has risen sharply. Hence Paper attempts to assess the development in Vidarbha region on the basis of socioeconomic factors and identifies the most responsible factor for the development and therefore Disparity. Aim of the paper is *firstly*, to analyse the district wise level of development on the basis of socioeconomic indicators and to identify the most affecting factor responsible for development. *Secondly*, to propose suitable development strategy based on the identified factor. Objective of the study is to induce balanced regional development which the most prime objective of the planned development in India.

3. Literature study

3.1 Location Quotient (L.Q.)

Location Quotient is basically the percentage of local economy to the reference economy. It gives the base of the economy weather it is 'Basic' or 'Non basic'. It can be calculated with the following formula.

$$\text{LOCATION QUOTIENT} = \frac{\text{LOCAL ECONOMY}}{\text{REFERENCE ECONOMY}} = \frac{\text{EMP. IN INDUSTRY 'X' IN DIST. 'A' (A) / TOTAL EMP. IN DIST. 'A' (B)}}{\text{EMP. IN INDUSTRY 'X' IN VIDARBHA (C) / TOTAL EMP. IN VIDARBHA (D)}}$$

Figure 2 Location Quotient formula

Location Quotient is always greater than zero. It could be less than one, equal to one or greater than one. If it is less than one that means the percentage of local economy is less than Reference economy. Hence the Industry is not meeting the local Demand for that particular District. That Industry could not Export so the economy is non-basic and it has non basic sector of employment. If the L.Q. is equal to one indicates that the Local economy is almost equal to Reference economy. Hence the Local Employment is just sufficient to meet the local demand. So Industries do not export and has the non-basic sector employment. Third condition, if the Location Quotient is greater than one that means the Local employment is not only meeting the local demand but also exports. Hence Jobs which are over above are identified as Basic sector.

3.2 Cluster Development

This was first proposed by Michael porter in 1990. It stimulates the Urban and Regional economic growth. Industrial clusters have increasingly been recognized as an effective means of industrial development and promotion of small and medium-sized enterprises. With the sectoral and geographical concentration of enterprises in an industrial cluster, the enterprises can better improve their competitiveness. This is due to the presence of specialized suppliers of raw materials, parts and components, machinery, skills and technology as well as other supporting services. Moreover, cluster development approach could be adopted as a key strategy for enhancing the productivity and competitiveness as well as capacity building of Micro and Small Enterprises (MSEs) and their collectives in the country. Clustering of units also enables providers of various services to them, including banks and credit agencies, to provide their services more economically, thus reducing costs and improving the availability of services for these enterprises.

3.3 Regression Analyses

Regression analysis is a statistical tool for the investigation of relationships between variables. It is used to ascertain the causal effect of one variable upon another- the effect of increase in development for a particular sector of the district upon the overall development of the district. In regression, the R² coefficient of determination is a statistical measure of how well the regression line approximates the real data points. An R² of 1 indicates that the regression line perfectly fits the data. Values of R² outside the range 0 to 1 can occur where it is used to measure the agreement between observed and modeled values and where the "modeled" values are not obtained by linear regression and depending on which formulation of R² is used. If the first formula above is used, values can never be greater than one. If the second expression is used, there are no constraints on the values obtainable.

4. Data and Methodology

First objective of the paper is to study the overall development of Vidarbha region on the basis of chosen socioeconomic indicators at district level. The socioeconomic indicators selected for this study are mentioned in figure. Vidarbha region is comprised of Amravati sub region and Nagpur sub region. In order to do analysis at regional level, the focus is on Nagpur Sub region because of the better data availability. It comprises 6 districts namely; Wardha, Nagpur, Gadchiroli, Gondia, Chandrapur, and Bhandara. In order district wise level of development related to particular sector socioeconomic Indicators have been selected (Refer Table 4). Secondly, based on those Indicators district wise Sectoral Development Indices (SDIs) have been calculated for each kind of indicator. Thirdly, Composite Development indices (CDIs) have been calculated which gave overall level of development of the Districts within Nagpur Sub Region. Finally, the Regression between each SDI and CDI has been performed to understand the most affecting factor in the overall development of the District. For this analysis particularly Demographic, Industrial, Transportation, Agriculture, Livestock and Health & Education Indicators have been chosen as per expert opinion and industrial report published by Directorate of Industries in Nagpur.

Indicators	Sub Indicators
Demographic Indictors	I. Density II. Literacy Rate III. % Of Urban Population

	IV. % Of Women Literates V. % Of SC-ST Population
Industrial Indicator	I. No. Of Industries II. Investment In Plant And Machinery III. Employment
Transportation	I. Road Length Per100 Sq.km. Of Geographical Area II. Railway Route Length Per100 Sq.km. Of Geographical Area
Agriculture	I. % Of Net Area Sown II. % Of Area Irrigated More Than Once III. Average Yield Per Hectare Of Cereals IV. Average Yield Per Hectare Of Pulses V. Average Yield Per Hectare Of Cotton VI. Per Capita Food Grain Production
Livestock	I. No. Of Cows & Buffaloes In Milk Per 1000 Population II. No. Of Livestock Per 100 Population III. Livestock per Sq.km. Of Total Geographical Area
Health & Education	I. No. Of Hospital Per Lakh Of Population II. No. Of Beds In Public Aided Medical III. Institutions Per Lakh Population

Figure 4 Selected Socioeconomic indicators and sub indicators for Objective one.

As a result of the Objective one the factor responsible for the disparity in Vidarbha region is imbalanced industrial development. Hence the further study aims to achieve balanced Industrial development. In order to achieve this firstly, the district wise investment potential has been studied for Vidarbha region through location quotient theory and district wise surprising areas of economic strength have been found out. Secondly, high potential 'Star' industries have been found out with the help of "Location Quotient – Employment Growth Matrix". The 'Star' Industries could be developed as a cluster. Consequently, the Cluster mapping is proposed for the districts of Vidarbha region.

5. Results and Interpretations of Socioeconomic assessment

Human development report published in 2010 has already revealed Vidarbha region of Maharashtra state lags behind in the overall development. Within Vidarbha region only Nagpur district has shown HDI more than states average and rest of district lie below state's average with Gadchiroli district at lowest level. Now to have an exact idea of district wise level of development related to particular sector, the SDIs have been calculated. For example, to calculate SDIs for Industrialization; initially the sub indicators (Refer Figure 6) have been multiplied by the weightages as per expert opinion and factor analysis. Summations of such resultant products give the SDI for Industrial Development. Once the SDIs have been calculated; CDI for a particular district could be calculated by adding all the weighted SDIs. ⁱⁱCDIs for each district give the idea of the overall development of the districts.

Indicators	Calculation of Sectoral & Composite Development Index
Demographic Indictors	$(1 \cdot G_1) + (0.337 \cdot G_2) + (0.602 \cdot G_3) + (0.72 \cdot G_4) + (0.649 \cdot G_5)$
Industrial Indicator	$(0.99 \cdot I_1) + (0.992 \cdot I_3) + (1 \cdot I_3)$
Transportation	$(1 \cdot T_1) + (0.1 \cdot T_2)$
Agriculture	$(0.503 \cdot A_1) + (0.447 \cdot A_2) + (0.995 \cdot A_3) + (0.995 \cdot A_4) + (0.545 \cdot A_5) + (0.915 \cdot A_6)$
Livestock	$(0.94 \cdot L_1) + (0.996 \cdot L_2) + (0.148 \cdot L_3)$
Health & Education	$(0.115 \cdot E_1) + (1 \cdot E_2) + (0.1 \cdot E_3)$
Composite Development Index	$(0.87 \cdot G) + (0.9 \cdot I) + (0.964 \cdot T) + (0.72 \cdot A) + (0.87 \cdot L) + (0.99 \cdot E)$

Figure 5 Calculations of the S.D.I. and C.D.I.

The composite development index shows that Nagpur (CDI- 14905.74) is developed in almost all the aspects. Chandrapur and Bhandara are moderately developed whereas Wardha and Gondia are proved to be less moderately developed. Gadchiroli has shown least values for almost all indicators. The regression performed between all SDIs and CDIs ascertain that CDIs have shown strong correlation with indices of Industrial Development ($R^2 = 0.998$) & Education and Health ($R^2 = 0.57$). It implies that higher CDIs of the developed regions are mainly due to the development in the Industries and advancement in Education & Health. Moreover, Most of the Industries are concentrated in and around the metropolis Mumbai (western Maharashtra), leaving rest of the regions mainly Vidarbha (eastern Maharashtra) backward in terms of industrial development. Though the state's Industrial policy offers several incentives for new Industries, those incentives are not area specific and do not really attract industries in the backward areas. This concentration of industries in western Maharashtra state has resulted in 'Backwash Effect' (Myrdal) which is forcing people from the adjoining backward districts to migrate to Mumbai and surrounding areas in search of opportunities putting additional burden on city's infrastructure. This results in regional imbalance. Hence it is proved that balanced development in Industrial sector plays an important role to minimize the regional disparity in Maharashtra.

6. District wise investment potential

The location quotient calculated for districts; Bhandara, Chandrapur, Nagpur, Wardha, Gadchiroli, Gondia, gives the level of development and surprising areas of economic interest. In figure 6 on horizontal axis the Location quotients are placed and on vertical axis the industries are placed. Industries from no. 15 to 36 are Manufacturing Industries and the rests are Service Industries. The names of the industries are mentioned in figure 11. All the districts are arranged as per their location quotients. Say for Industry no. 15 (manufacturing food products) only Bhandara and Chandrapur districts have shown L.Q. greater than one. Which means only these districts are able to export manufacturing food products and hence high investment should be done in that sector. Likewise all the districts are arranged. Industry no, 27, 28, 35 etc. show blank space which means none of the district from Vidarbha region produces that kind of product. For Industrial products like Metal, transport equipment, Computer based activities Vidarbha region totally depend upon surrounding regions

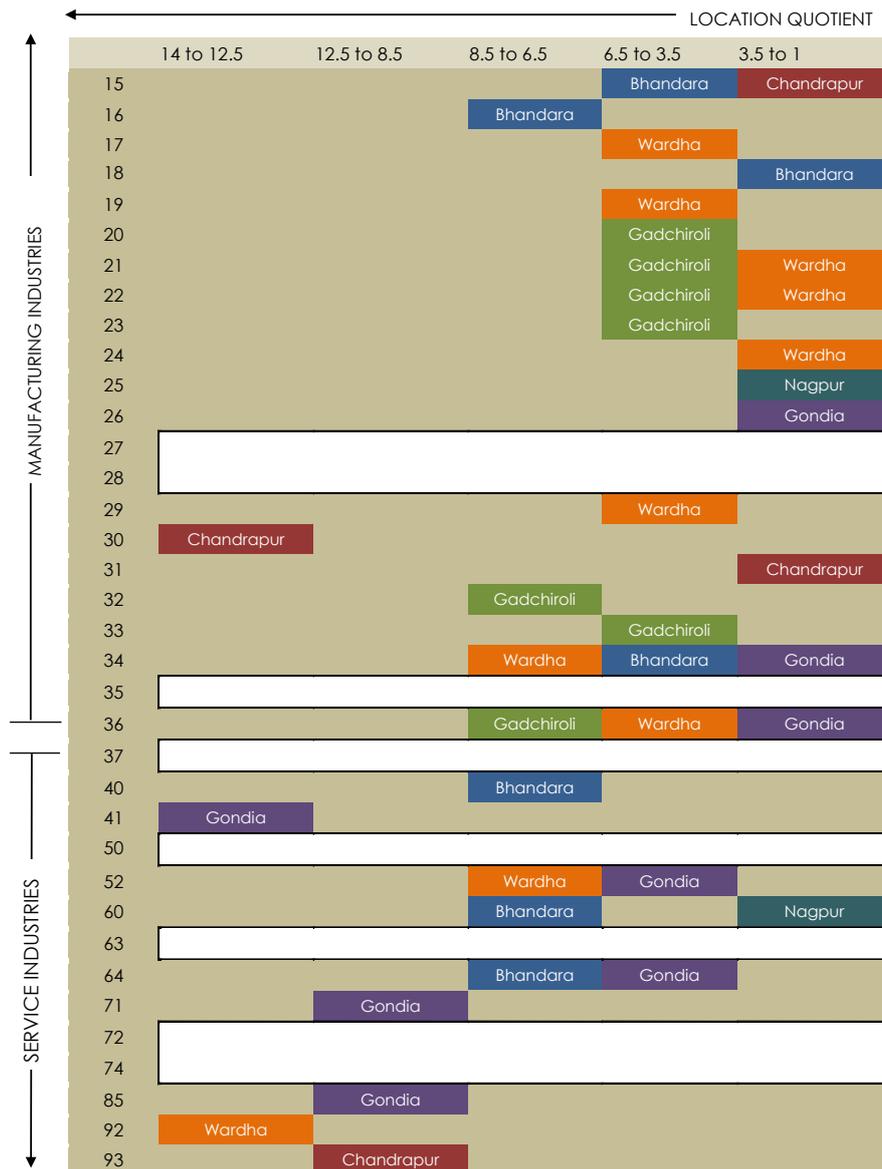

Figure 6 Location Quotient for all districts

Special attention should be given to those industries. In case of industry no. 31 only Chandrapur district is producing the Electrical and machinery apparatus. For that particular product whole Vidarbha Region has to depend on Chandrapur. Hence that Industry is the Surprising area of the economic. Similarly from figure 5 we can identify the surprising areas of economic strength for all districts. (Refer figure 7).

Districts	Surprising areas of Economic strength
Bhandara	Wearing Apparel, Dressing & Dyeing Fur , Electricity, Gas, Steam & Hot Water Supply , Tobacco products
Chandrapur	Food products & Beverages, Publishing & Printing, Electrical Material.
Gadchiroli	Wood, Products of Wood, cork, art
Gondia	Renting OF Transport Equipment (71), Other non-metallic mineral (26),
Nagpur	Rubber & Plastic Products (25), Land Transport (60)
Wardha	Tanning & Dressing of Leather; Manufacture of L, Recreation, Cultural & Sporting activities, Textile

Figure 7 surprising areas of economic strength

7. Cluster development approach

Since the best way to rise the productivity and innovative capacity is through local cluster development. For each district the high potential clusters have been identified with the help of 'Location quotient- Employment growth' matrix. It classifies industries into 'Stars', 'High potential', 'Low potential', and 'Threat'. Industries which come into star category have been selected as clusters for that particular district. (Refer Figure 8)

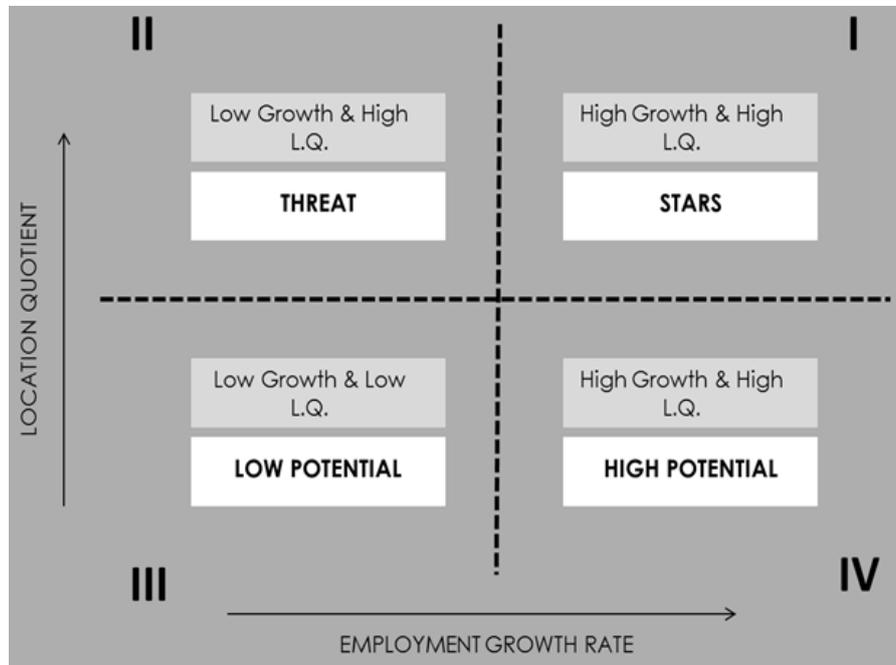

Figure 8 L.Q.- Growth Matrix (Source: USAID, Mahendra & Rashi Grover, Economic growth of the Mumbai Metropolitan region)

It gives the potential clusters for each district. As shown in the following Figure 8, L.Q. has been placed on the vertical axis and employment growth rate on the horizontal axis. The Industries which come under the right upper quadrant are termed as the "Star" industries. They have high location quotient and employment growth rate as well. These will be chosen for the cluster development. The industries which are coming under the second quadrant they are termed as "Threat" sectors. Although they have shown high L.Q. but the employment rate is declining hence further investment in those industries should be done carefully. In the third quadrant the industries are termed as Low potential Sectors as they have low LQ and low growth rates and therefore have low future potential. Sectors coming in the fourth quadrant have low location quotient but high employment growth rate. Although the L.Q. is low their employment growth rate is inclining. Hence these industries have investment potential. So they are termed as "High Potential" sectors and special attention should be given to them. In this manner from the L.Q –employment growth matrix potential industrial clusters have been proposed. The L.Q. - Growth matrix for each district have been worked out as shown in figure 8. Industries which are under first quadrant are chosen for cluster development.

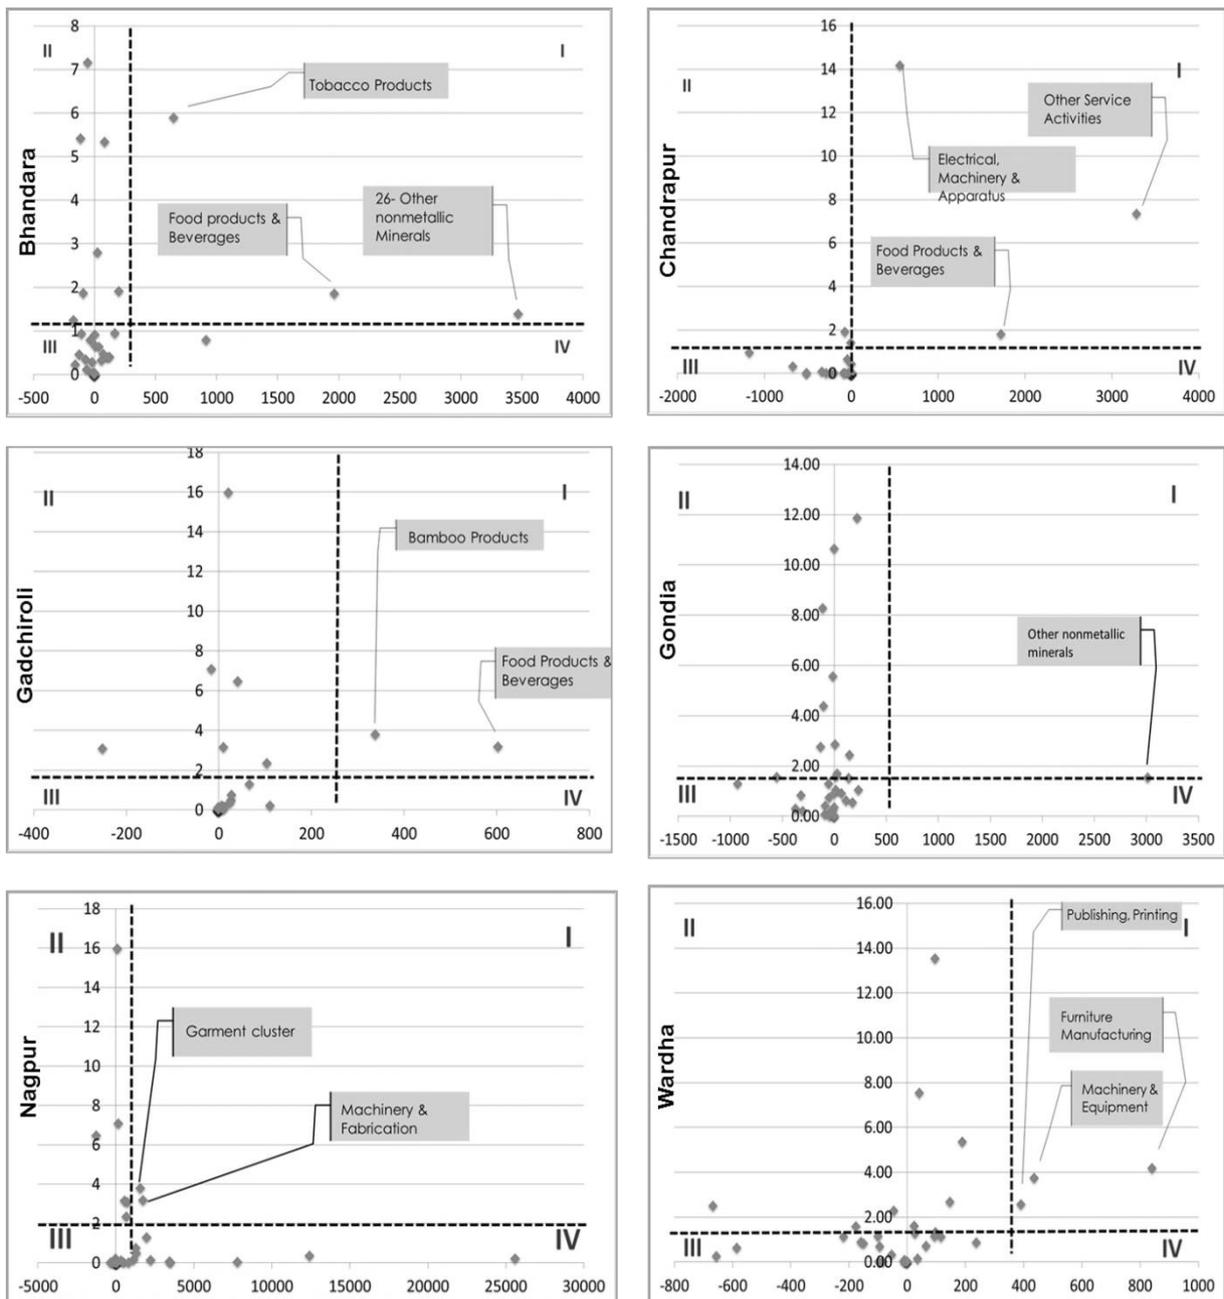

Figure 9 L.Q- Growth Matrixes for Bhandara, Chandrapur, Gadchiroli, Gondia, Nagpur and Wardha

Proposed cluster mapping

The probable clusters are proposed as per the L.Q. - Growth Pole Matrix (Refer Figure 8). The coloured symbol shows *Taluk*ⁱⁱⁱ boundary which could be developed as a cluster. It can be seen from Figure 9 that Nagpur district has a strong potential for Garment cluster and Dal cluster especially in Chikhali, Bagadganj and Kalmana district. Gadchiroli and Chandrapur have strong potential for Bamboo cluster. Non-Metallic clusters could be developed in Bhandara, Gondia and Chandrapur districts. *Taluk* wise clusters have been mentioned in the cluster map as shown in figure 10.

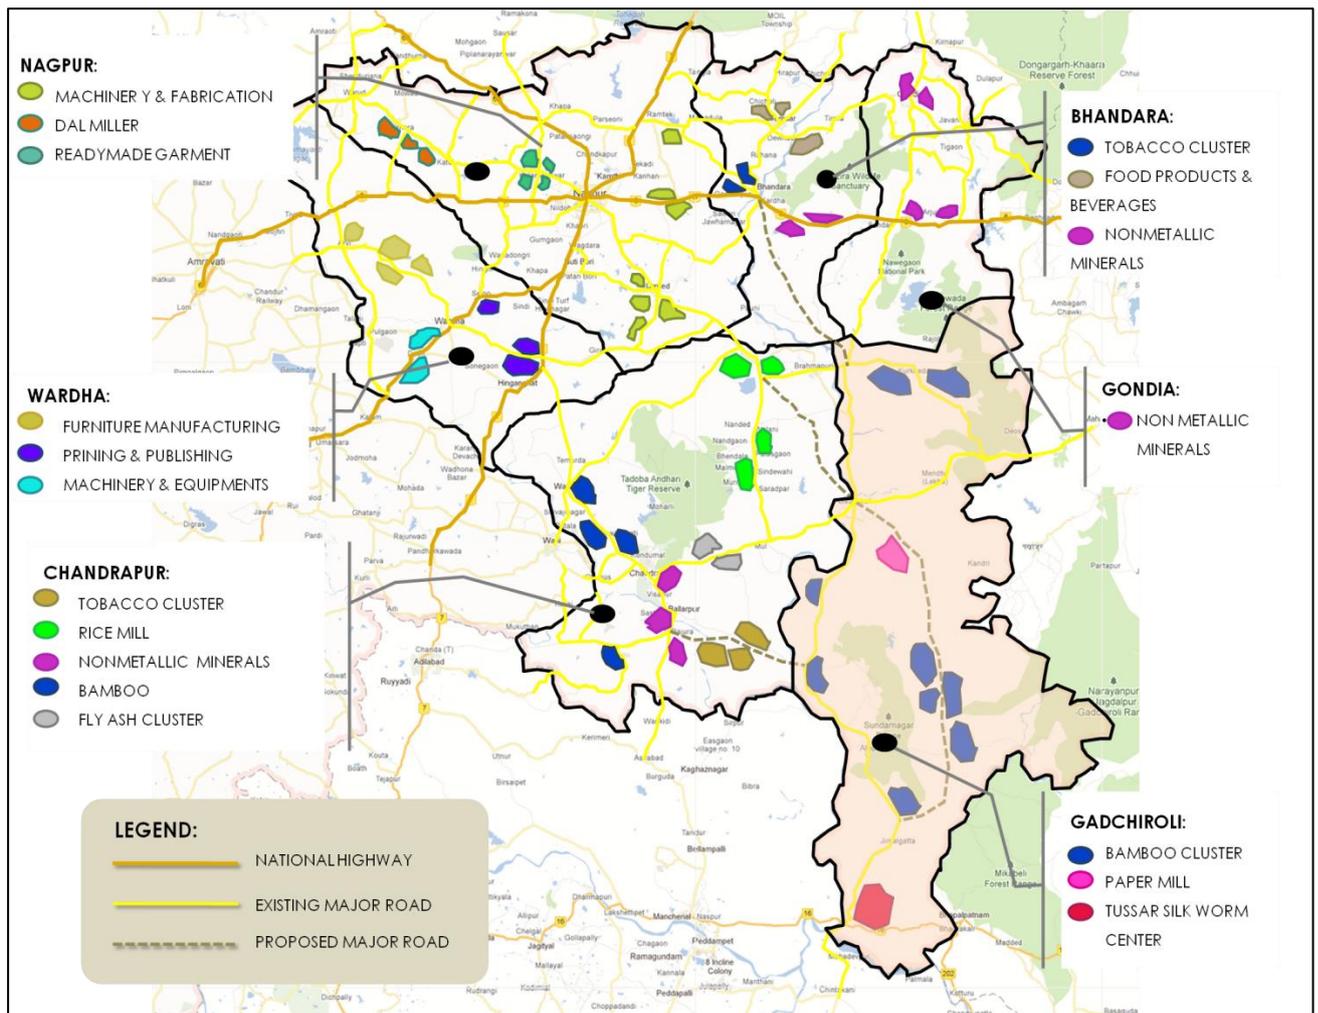

Figure 10 Proposed cluster Map for Vidarbha region (Nagpur sub region)

8. Conclusion

The empirical study in the paper ascertains that the developed regions are developed due to advancement in Industrial sector. This, however, is the prime reason for migration of adept class of society to developed region leaving rest of the region poorer. This puts extra burden on the developed city's infrastructure. Hence Backwash (Myrdal) effect could be seen in developed Nagpur district of Vidarbha region primarily due to Industrial development policies. Although Industrial policies give incentives they are not area specific and don't really attract industries in the Backward Region. The advancement in the Industrial sector which is the reason for development in developed districts and hence regional imbalance is the only solution for balanced development in Maharashtra state as well as in Vidarbha region. Hence it is important to find out high potential industries district wise and to propose the local industrial clusters to make the industries more sustainable since the best way to raise the productivity and innovative capacity is through local cluster development. In order to induce balanced industrial development aim of the proposal is to help poorer districts of the poorer region to grow faster. So that there will be less migration from poorer regions or districts. This will help to keep equal population density. Moreover due to the district wise Industrial development there will be same level of economic activity in each region or district.

Ultimately there will be equality of opportunity in each region which will help to minimize the inequality and will induce the balance development.

9. Annexure

Name of Industries

No.	Name of Industry	No.	Name of Industry
15	Manufacture of Food products and Beverages	33	Equipment of Medical, Precision & Optical
16	Manufacture of Tobacco products	34	Manufacture of Motor Vehicles, Trailers
17	Manufacture of Textile	35	Manufacture of Other Transport Equipment
18	Mfg. of Wearing Apparel, Dressing & Dyeing Fur	36	Manufacture of Furniture; Manufacturing
19	Tanning & Dressing of Leather; Manufacture of L	37	Recycling
20	Manufacture of Wood, Products of Wood, cork, art	40	Electricity, Gas, Steam & Hot Water Supply
21	Manufacture of Paper and Paper Products	41	Collection, Purification & Distribution of Wate
22	Publishing, Printing & Reproduction of Recorded	50	Maintenance & Repair of Motor Vehicle
23	Manufacture of Coke, Refined Petroleum Products	52	Maintenance & Repair of personal & household
24	Manufacture of Chemicals & Chemical Products	60	Land Transport (NIC Codes 1998 : 60211)
25	Manufacture of Rubber & Plastic Products	63	Supporting & Auxiliary Transport Activities
26	Manufacture of Other Non-Metallic Mineral	64	Post & Telecommunications
27	Manufacture of Basic Metals	71	Renting OF Transport Equipment
28	Manufacture of Fabricated Metal Products	72	Computer & related activities
29	Manufacture of Machinery & Equipment	74	Other business activities
30	Manufacture of Office, Accounting & Computing	85	Health & Social work
31	Manufacture of Electrical, Machinery & Apparatus	92	Recreation, Cultural & Sporting activities
32	Mfg. of Radio, Television & Communication	93	Other Service activities

An exploration of the informal backyard rental sector in South Africa's Western Cape Province

Louis Lategan & Dr Elizelle Cilliers
North-West University, Unit for Environmental Sciences and Management,
Urban and Regional Planning, Potchefstroom, 2250, South Africa

This research (or parts thereof) was made possible by the financial contribution of the NRF (National Research Foundation) South Africa.

Abstract

South African low-cost housing development is extremely complex. The post-Apartheid government struggles with a fragmented and segregated urban inheritance and also with a housing demand which far exceeds delivery capacity. In response to inadequate delivery South Africa's otherwise destitute have turned to informal backyard renting as a last resort. Backyard structures can house a multitude of tenants in single one or two roomed wood or corrugated iron structures, which are traditionally constructed by tenants in the backyards of homes provided by government under such housing programmes as the RDP (Reconstruction and Development Programme).

This paper examined the state of the backyard sector in the Western Cape Province (South Africa) and investigated if and how the province attempts to address the plight of backyarders who live in dire conditions. It was found that the prevalence of backyard accommodation dramatically increases densities and reduces urban sprawl, but simultaneously increases pressure on infrastructure and public facilities. Backyarders are also dependant on their landlords for access to basic services and the informal nature of lease agreements leave them vulnerable to eviction at any time.

The main research question to answer was: 'What is the scope of the backyard sector in the Western Cape and what is being done to address the complexities of the sector in order to improve living conditions?' This paper found that the Western Cape Province tolerates the backyard sector as a 'necessary evil', but also that, except in the City of Cape Town, very little has been done to address the issue. Although the sector has been on the radar for some time as an integral component of the country's housing stock, a provincial and national policy which attempts to regulate the sector remains absent.

The research for this paper included the results of surveys conducted in low-income areas in the province, interviews with municipal and provincial officials and private stakeholders, national and provincial policy reviews and an evaluation of existing literature sources from a variety of disciplines.

The conclusions drawn in this paper and the subsequent recommendations made, may inform the formulation of provincial and national policies on the backyard sector, which may improve the lives of millions of South Africa's previously disadvantaged by enhancing a sustainable planning approach.

Backyard housing
Informal renting
Sustainable development

1. Introduction: Setting the scene, the Apartheid city of today

There has never been a greater influence on urban South Africa, than the policy of Apartheid which forced segregated and uneven development; ultimately producing the fragmented cities inhabited today. Apartheid not only influenced urban development during its oppressive reign, between 1948 and 1994, but left a legacy of segregation which has proven difficult to thwart. Ever since, South African planners have faced a continuous increase in the demand for low-cost housing, restricted resources to meet needs and an urban structure which protects the real-estate assets of the wealthy, but continues to segregate communities according to income level and subsequently, race.

The high cost related to well-located land which would provide access to socio-economic opportunities and the facilities located in urban centres, has continued to force low-cost housing projects to the urban periphery and beyond. Apartheid produced a wasteful urban structure which generated a disseminated settlement arrangement, which still hinders service provision and access to socio-economic and cultural amenities in the modern-day South African city (Makamu, 2010:39). According to Goebel (2007:291), since 1994, low-cost housing provision has mostly involved developing serviced townships on urban peripheries, inferring numerous economic, social, environmental and political concerns.

The shortage in housing and the unsuitable locations generally sourced for the development of low-income projects, have forced 712,956 South Africans into the backyards of their subsidy-housed compatriots (STATSSA, 2011:68).

1.1 The backyard shack, a temporary residence with permanent problems

The informal backyard rental sector was established and gained momentum in the 1980's, when the sector responded to shortages in sufficient accommodation in proximity to economic opportunity nodes such as central business districts (CBD's) (Ebrahim, 2011). According to Crankshaw et al. (2000:3) the pre-1994 South African government tolerated the extensive establishment of informal structures in order to compensate for the shortage of housing units delivered. Government's tolerance soon cultivated a culture of unofficial and unintended acceptance, which made land invasions a common part of the South African development culture by the mid-1980's. Morange (1999:6) corroborates that municipalities were too tolerant of squatting and invasion in the past. The tolerance granted to informal squatting on invaded land, paired with the neglect to establish and support a resilient formal rental market, provided the perfect conditions for the establishment and continued growth of the informal backyard rental sector.

The backyard sector can be observed in every settlement found within the boundaries of South Africa, in urban centres and even in more rural locations where formal housing has been provided. The sector provides much needed shelter to those waiting to be housed by the South African government's Reconstruction and Development Programme (RDP). Eglin (2011:1) states that South Africans waiting for the keys to their RDP homes may be forced to continue living in rural areas, the homes of relatives or overcrowded backyard rentals for quite some time. Given the housing delivery backlog, rapid urbanisation, restricted funding, limited institutional capacity and wide-spread corruption, South Africa's otherwise destitute have turned to the informal rental market as a temporary residence. However, SDMS (2006:35) states that a quarter of backyard renters believe that they are destined to call backyard shacks home for the rest of their lives.

According to Lemanski (2009:474) backyard dwellings differ from other formal and informal housing options in that they share a demarcated stand with a formally developed unit in a formal housing area which is fully serviced. Watson (2009:3) states that two categories of backyard dwellings can be distinguished. Referring firstly to structures built by landlords with intent to rent to tenants. Secondly referring to structures built by tenants on spaces rented from landlords, mainly in the informal sector. The latter is a uniquely South African manifestation which distinguishes the local backyard sector from others in other developing countries (Crankshaw et al., 2000:1).

The shelter provided by backyard structures has largely been described as insufficient, unsustainable and detrimental to overall well-being. Morange (1999:6) states that backyard structures mainly consist of one or two rooms and are generally crudely constructed from wood, corrugated iron and even cardboard. These rooms are utilised for day-to-day living activities which include all culinary, hygiene and sleeping needs (Lemanski, 2009:473). Poor construction, limited space and the unhealthy conditions associated with the backyard sector make backyard habitation comparable to living in shacks in informal settlements. However even the restricted access to basic services enjoyed by backyard tenants, elevate their living standards above those of their counterparts in the shantytown townships, who are forced to survive on limited access to services, if any at all. According to Poulsen & Silverman (2005:4) backyard rooms increase residential densities, thereby combatting urban sprawl and may make more effective use of existing infrastructure investments. However the excessive establishment of backyard accommodation and the sector's dense proliferation throughout South Africa has placed an immense burden on the infrastructure networks already established.

1.2 The South African legislative and policy context

The existence and scope of the backyard sector has never been denied. Post-apartheid policies have continued to reference this segment of the market, but only to a limited extent. To date there has been no national policy aimed at addressing the management of current backyard stock, nor the regulation of future development in the sector. According to Watson (2009:6) past South African housing policies and policy makers regarded informal rentals as a transitory state, providing temporary shelter to those on their way to formal RDP projects. However Bank (2008:2) counteracts this notion; arguing that it has been wrongly assumed that backyard residents will naturally move to new RDP estates outside townships. In actual fact renters often remain in backyard structures, even when RDP estates are provided as alternatives, given the poor location of these projects, the transportation costs and the deficiency of economic opportunities associated with these new developments.

The sovereignty of the South African Constitution is obsolete. It is also one of only thirty (30) constitutions in the world which includes a right to adequate housing (Arenas, 2002:21). It thus follows that it is the Constitutional responsibility of the South African government to address the plight of those renting structures in the backyards of formal dwellings.

The most prominent housing policy to emerge after the advent of democracy was the White Paper: A New Housing Policy and Strategy for South Africa, released in 1994. The White Paper acknowledged the existence of the backyard sector and promoted concepts which could be reconciled with addressing the needs of the backyard segment. These concepts included: serving all segments of the housing market, enhancing the initiative of individuals to improve their housing circumstances, promoting access to socio-economic opportunities and basic services, promoting freedom of housing choice and removing past discriminatory mechanisms (RSA, 1994:8-29). However the White Paper did not independently influence or improve the regulation of the backyard sector at national or provincial level, nor did it contribute to the formulation of policies in this regard.

In response to escalating housing backlogs and the inferior quality of the units and neighbourhoods delivered, the South African government released *Breaking New Ground: A Comprehensive Plan for the Development of Sustainable Human Settlements (BNG)*, in 2004. The only direct reference to the backyard sector cited in BNG denotes the fact that more information on the 'scale, conditions, rental charges and facilities which are provided within this sector and the linkages between this sector and the broader residential property market', is required (RSA, 2004:8). The BNG continues the established trend of recognising the sector without providing guidelines for regulation and management.

Other key principles captured by BNG, which would be strengthened by a policy on sustainable backyard development, include: the establishment of new systems to address the housing backlog, shifting from product uniformity to demand responsiveness, informal settlement (and therefore informal unit) eradication, promoting densification and integration, enhancing housing and settlement design and quality and redefining the concept of social housing (RSA, 2004:7-19).

From a Provincial perspective there has also been little progress in addressing the plight of backyarders, in part due a lack of support by national government. The most notable attempts to address the sector can be found in South Africa's economic powerhouse, the Gauteng Province as well as in Western Cape. For the purpose of this study, the Western Cape's attempts will be considered.

2. The Backyards of the Western Cape

South Africa's Western Cape Province is located on the southern tip of the African continent. It houses 11.3% of South Africa's population and covers 10.6% of the country's land area (STATSSA, 2011:14). The Western Cape is also hailed as the most developed province in the country and is therefore widely recognised as a leader in innovative policy formulation and strategic planning. However the backyard sector in the Province has, just as in lesser developed areas of South Africa, remained largely underdeveloped. The Western Cape Department of Human Settlements (2010:7) states that in 2010 approximately 25% (375 000 across the Western Cape) lived in inadequate housing conditions which included shacks, backyard dwellings, overcrowded formal dwellings and formal dwellings with no sanitation.

Past provincial attempts to address the backyard sector have not been very successful and could not be effectively implemented. According to Wheelen (2013) the Western Cape Province's stance on the informal backyard sector is not officially represented in any policies or provincial frameworks. This does not however imply that the Province has no stance on the subject. The Western Cape Province's standpoint can be best synthesised as one of tolerance without much intervention. The Province has not attempted to address the sector, because it is a difficult problem to solve. Many of the most logical interventions could impose several unintended consequences, in effect cultivating more prospective problems. Only policies which can be introduced in an effective and sustainable manner will be considered by the Western Cape Province and to date no such backyard policy could be formulated. This is specifically related to the fact that policies need to be kept as simple as possible, whilst the backyard sector may require an overcomplicated approach, which would be difficult to implement at local municipal level.

According to Wheelen (2013) in the past the Western Cape Province considered a landlord subsidy. These subsidies would enable landlords to upgrade their backyards in order to improve the living conditions of their tenants. This initiative was formalised into an advanced policy, as words on paper, but was never piloted or introduced; largely due to the experience of the City of Johannesburg in Gauteng, where a similar programme inferred many unintended consequences.

Through these incentives landlords who already received housing subsidies were now further endowed with an improved housing product which inevitably increased backyard rent rates. This led to the displacement of tenants.

There are many pressing issues facing South Africa and the Western Cape Province in relation to housing delivery, with the backyard sector amongst the most in need of regulation. Wheelen (2013) states that it is recognised, especially from a health and safety perspective, that the backyard sector requires serious attention. However articulating this acknowledgment and formulating a policy based there upon, is a challenging prospect which the Western Cape government has not yet met.

The backyard rental sector has however been referenced in more recent provincial policies, including the Western Cape Province's Social Housing Strategy for 2010-2014. This strategy intends to increase the supply and effective administration of affordable rental accommodation as well as to unify the informal and formal rental markets. The Western Cape Department of Human Settlements (2010:19) states that the highest demand for rental accommodation is often found in the lowest income category, which is also the bracket in which backyard rentals are predominate. The strategy proposes to develop policies to support the expansion and formalisation of the supply in the backyard rental market (Western Cape Department of Human Settlements, 2010:7). However the broader success of this strategy in addressing both the formal and informal rental market is difficult to establish. The Social Housing Strategy 2010-2014 proposed initial implementation in eight leader towns, identified according to specific criteria. The general concept was to then expand the scope of the strategy to smaller towns in the Province. Yet, in 2013 the strategy had not yet made much headway in the eight leader towns identified and much less so in other smaller Western Cape towns. This may mainly be attributed to the fact that according to restrictions imposed by financing legislation and policies, municipalities may only use funding to improve property in ownership of the authority in question. This paired with the minimal (if any) number of rental units in the ownership of smaller local municipalities in the Province, may explain the lack of effectiveness. Restricted Division of Revenue Allocation (DORA) funding and the increased cost of developing rental units further burdens the expansion of rental stock and subsequently the regulation and improvement of the backyard structures which will inevitably be erected on these properties. The development of rental accommodation requires up to R200 000 (approximately \$20 000 USD) per unit. When this is compared to the development cost of a freestanding home for private ownership, with an average development cost of R100 000 (approximately \$10 000 USD) per unit, the latter is generally favoured by municipalities (De Beer, 2013).

Thus it follows that policies geared towards addressing the backyard sector, can only be effective where substantial formal rental stock in low-income areas exists. The City of Cape Town manages the largest rental stock in the Western Cape Province and as such has taken the lead in addressing the plight of its backyard subletters.

3. The City of Cape Town - Leading the cause

Cape Town is a metropolis which is called home by 3,74 million people, all from very different socio-economic backgrounds. It is a city which mirrors the inequalities and lack of integration seen in the rest of South Africa, even at the low-income level, where backyarders continue their hidden struggle in the yards of their fellow Capetonians.

In 2010 it was estimated that more than 41 000 backyard structures were located in the backyards of the city's 43 500 rental units, inferring a ratio of almost 1:1 (Mitchell, 2013). However the exact numbers of backyard tenants are in many cases based on estimations and outdated databases. According to HPC (2011:8) Cape Town's backyard settlers deserve targeted interventions which address the exposed, relegated and financially vulnerable state of their circumstances. In this regard the Metro needs to fulfil its Constitutional obligations by responding to the plight and basic rights of backyarders as Capetonians and South Africans.

Measures which attempt to address the plight of Cape Town's backyard tenants can be traced to as late as 2010, when the city's department of housing policy and research was mandated to further investigate the sector and identify possible measures for improvement (Mitchell, 2013). Following these instructions, three pilot areas were identified within the Metro. These pilot areas were Factreton, Hanover Park and Langa.

At the outset door-to-door surveys were conducted in order to establish the scope of the sector with regard to the number of backyard settlers and structures housed in the yards of properties which were part of the City of Cape Town's rental stock. Following these surveys the City approved an initiative to provide backyard residents in the pilot areas with additional basic services. These services include an additional enclosed flush toilet, running water, a prepaid electricity meter for up to three backyard families and one additional refuse bin (Mitchell, 2013). The City of Cape Town specifically targeted service provision as a primary initiative, because even where backyarders are on the housing waiting list, for many their backyard residences will remain home for a long time to come. In addition it was found that wherever there was any disagreement between backyard tenants and their landlords in main dwellings, disputes resulted in the refutation of access to services by the renters of main dwellings. In addition many backyard families were exploited by main dwelling renters, who charged exuberant fees for the use of services which they themselves receive for free or at a minimal service charge.

Programmes aimed at upgrading infrastructure, are however inevitably associated with a number of challenges and requirements which need to be met, including:

- Upgrading bulk capacity in order to meet increased pressure on infrastructure networks brought about by additional service connections.
- Preventing main dwelling landlords from demanding increased rents in return for the use of the services provided to their yards by the City.
- Effectively communicating that infrastructure upgrades are not implemented in order to convert backyard structures into permanent homes, but rather as a means to enhance temporary living conditions before relocation to formal units can be facilitated.
- Regulating and restricting the volume of water and electricity which can be accessed by backyard renters.
- Introducing minimal interference with established and fragile landlord-tenant relationships.
- Preventing the displacement of backyard renters in favour of the family members of main dwelling renters, who wish to take advantage of improved services.

Many of Cape Town's backyard structures in 2011 did not comply with the provisions of the National Building Regulations and Building Standards Act 103 of 1977. In compliance with Act 103 of 1977 provisions, the Housing Directorate is required to ensure that backyard structures in the backyards of the city's rental properties are safe and up to standard (HPC, 2011:9). The draft backyard policy currently under formulation does not prioritise the physical quality of the backyard structures to which services are being provided.

The policy may however require new backyard structures to be registered in order for tenants to apply for the extension of services to their dwellings.

At the time this research was conducted, it was not yet clear when the new backyard policy would be completed and implemented. However where basic services had been upgraded in the pilot areas identified, the initiative was very successful and provided valuable insight into best practice principles to be introduced across the Metro and beyond. However the manner in which the ultimate policy could be introduced across the Province remains uncertain, especially given the lack of rental housing in smaller towns. Thus the effects of an unregulated backyard rental sector will continue to be felt throughout the province, especially in smaller towns.

4. Oudtshoorn and the consequences of an unregulated backyard rental sector

The town of Oudtshoorn is located in the Garden Route, a picturesque part of the Western Cape, known for its diverse landscape and agriculture- and tourism based economy. Oudtshoorn is home to 95,933 people and covers a total area of 29,24km². Until as late as 2010, housing in the town was largely provided in the form of formal dwellings, backyard rentals and a small number of shacks, sporadically located throughout the extensions of Bongulethu and Bridgeton. However the status quo was irrevocably altered by the end of 2010, when large scale land invasion took place on the town's southern border. Now for the first time Oudtshoorn faced the prospect of housing and managing a sprawling informal settlement. This settlement was originally dubbed 'Riemvasmaak' by locals, but is now known as Rose Valley.

The origin of Rose Valley's settlers can for the most part be traced from migrations which took place from within Oudtshoorn's borders. It can be synthesised that Rose Valley was established not from the centrifugal forces exerted by the town on the surrounding area, but rather as a result of the centripetal forces within the town's borders; namely the unsustainable nature of its backyard rental sector. A survey conducted in 2012 found that 68% of the 100 participants engaged, migrated to Rose Valley from the backyards of formal units elsewhere in Oudtshoorn (Lategan, 2012: 189). According to Bruce (2012) these settlers were either asked to leave by landlords or chose to move to an area which offered some hope for individual home ownership in the future which improved on their backyard circumstances.

As is the case in the rest of the Western Cape Province and South Africa as a whole, Oudtshoorn's backyard sector was allowed to function autonomously, without much interference or guidance from the local authority; this in spite of the fact that the backyard sector continued to thrive and expand. According to Nortje (2013) it is very common to find up to five unattached backyard structures on stands located in the lower-income areas of Bridgeton. These structures may house family, friends or unrelated tenants of various ages. Although it seems that in Oudtshoorn most backyard tenants rent from family members who have extended a helping hand to their kin who would otherwise be destitute (Bruitjies, 2013; Julies, 2013).

In Oudtshoorn backyard living brings with it several social concerns, specifically related to crime and violent behaviour. According to Nortje (2013), although the South African Police Service cannot release official figures, a definite increase in crime levels can be observed in areas with a high concentration of backyard tenants. However this could relate to the low-income and unemployment levels also found here and not specifically to the prevalence of backyard structures.

Conversely, where backyard tenants are employed, a substantial percentage of their income is left to spend on alcohol and narcotics. The misuse of alcohol and cheap narcotics such as tik (similar to methamphetamine) then causes increased crime levels and worrying conditions for children to be raised under. As an outcome children become easy targets for sexual abuse, given the small spaces shared with family and unrelated neighbours who are constantly under the influence.

The relationships formed between landlords and backyard tenants are a further point of contention. The sheer number of Rose Valley settlers who moved to the area as a result of tainted landlord-tenant relationships, attests to this fact. As a result of the tension and conflict often associated with the backyard landlord-tenant relationship, 60% of the Rose Valley settlers who participated in the survey stated that they would not consider opening their yards to backyard settlers once they received their formal housing units (Lategan, 2012:195). In Oudtshoorn backyard renters generally pay anything from R50 to R400 (\pm \$5 to \$40 (USD)) to landlords for the spaces they occupy. Conflict frequently ensues because backyarders do not always comprehend the extent of the services and privileges included in their informal lease agreements. It seems that oral contracts are mainly negotiated, leaving great room for altercations. The majority of these conflicts can be attributed to disagreements regarding rents payable, access to services, including sanitation, and the volume of electricity and water (from the main house) to which backyard renters are entitled (Julies, 2013). In Oudtshoorn infrastructure provisions do not extend to backyard settlers and in this regard backyarders are dependent on the access granted by main dwelling landlords for their basic service needs. Thus, as seen in the initiatives underway in Cape Town, it seems as though providing backyarders with access to services may relieve the pressure on both infrastructure networks and landlord/tenant relationships. Improving access to basic sanitation may singlehandedly improve the health and overall wellbeing of backyard tenants. Sanitation is singled out, because most backyarders will still have access to water on the yards they occupy or at least within a 200m radius of their dwellings. However the lavatories currently provided and the infrastructure put in place to service them, are overburdened by the addition of countless backyard tenants who share facilities (Crouse, 2013; Andries, 2013). Conversely, upgrading infrastructure provisions may infer certain unintended consequences. Both the Brintjies and Julies families stated that they would feel entitled to an increase in rental income once their backyarders enjoyed improved access to services. Increased rent rates would render the backyard sector too expensive for many tenants who are unemployed or generate a minimal income, which may lead to eviction and displacement. In addition the problems related to the backyard sector are not limited to the level services enjoyed by renters, but also extend to the physical structures inhabited.

At present the construction of backyard units continues to infer legal and health problems. According to Crouse (2013) respiratory ailments such as tuberculosis is worsened by the lack of cross ventilation and the cold and wet conditions so often related to backyard living. According to Andries (2013) should other highly contagious diseases such as meningitis break out, the proximity in which many backyarders live in one yard, may have epidemic consequences. Where building plans are not submitted and structures not inspected, as experienced in the informal backyard sector in Oudtshoorn and beyond, basic building practices to ensure good health cannot be enforced (Andries, 2013). Crouse (2013) states that it is imperative that the current system of unregulated and mismanaged backyard settlement is addressed. Accordingly standards need to be established and enforced by formulating a set of guidelines for minimum construction standards which extend to location decisions, construction techniques and material choices.

With regard to choice of materials, Oudtshoorn's backyarders mostly shy away from the use of corrugated iron sheets given the immense temperatures experienced here in the summer. Backyard structures are more commonly constructed from wood fragments which are discarded by local timber yards and insulated with cardboard. Conflict often ensues over the best scraps of wood, which are used by some in the community for cooking and heating and by others for the construction of their backyard units. These clashes often end in violence. The use of recycled materials such as discarded wood may furthermore bode well from an environmental perspective, but also infers certain risks. For example wood structures are often not watertight and more importantly are fire hazards. According to the Julies family (2013) house fires are a common sight in Oudtshoorn's backyards, mostly as a result of a lack of electricity and the unsupervised use of candles; and secondly as a result of informal electricity connections which are exposed to extreme weather conditions. According to Crouse (2013) in some cases electrical wire barely suitable for indoor use is used to connect backyard structures with main dwelling units, mainly to overloaded sockets indoors. The resulting fires spread rapidly from yard to yard, leaving children especially vulnerable. As a result many backyarders sever their connections and choose to live without electricity rather than risk their own or the lives of their children.

Where corrugated sheeting is used, these materials are almost exclusively obtained illegally. In fact backyard residents often report their building materials stolen. After investigation these materials can frequently be found as components of backyard structures in close proximity from where they were taken. Especially in impoverished areas where individuals are not able to afford new or even used materials, the origin of their building supplies is always suspect (Nortje, 2013).

In spite of the hazards and harms so intertwined with backyard habitation, little has been done in Oudtshoorn to address the sector. Housing the settlers of Rose Valley will be the most significant step in support of backyard dwellers ever undertaken. This speaks volumes when one considers that the needs of these backyarders were only addressed once they took matters into their own hands, invaded land and exerted pressure on the local authority. However the Oudtshoorn Municipality is not to blame. The local authority can only function within the frameworks and funding allocations granted by Province and National government. In this regard Bruce (2012) states that there is no definitive policy which will manage illegal backyard structures in the Rose Valley development once housing delivery has taken place, as no such strategy exists, or is planned for the broader Oudtshoorn area. Housing recipients are however informed of the fact that the erection of temporary structures will be deemed illegal, but the enforcement of this principle has not proven to be effective in the past and did not deter the establishment of new backyard structures. Thus in Oudtshoorn the backyard sector will continue much as it has for the last thirty years, even when the new Rose Valley extension has been completed and new tenants inevitably welcomed into its backyards.

5. Conclusion

The apartheid city structure, past recklessness, restricted capacity and funding, current policy and legislative restrictions and housing backlogs which stretch into the millions, have all contributed to the unsustainable nature of present day backyard habitation in South Africa. The challenges faced in the Western Cape Province are echoed across the Republic, but the interventions recently attempted by the capital of Cape Town, may provide valuable best practice principles to be duplicated and more importantly, adapted to fit both local and national circumstances. As such, numerous conclusions can be drawn, which may influence future interventions at a national level.

In this regard it was found that the City of Cape Town's attempts at delivering basic services are admirable, but may only improve the lives of those renting backyard structures in the yards of properties owned by the City as part of its low-income rental stock. Broader implementation may be hampered by a lack of rental stock in smaller settlements and current legislation which prevents municipalities from administering municipal funds to develop properties not owned by the authority in question. Broader implementation of any strategy is discouraged by the fact that the Western Cape Province has not completed, piloted, or implemented any form of backyard policy, thereby implying, although not accurately, a lack of commitment and compassion. This has clearly impacted at both a Provincial and local level. In the small town of Oudtshoorn the impacts of a lack of policy and regulation can be noticeably observed. Here the conditions which resonate across the Western Cape Province and South Africa in general, convey the harsh and dire circumstances brought about by a completely autonomous informal backyard sector. In reaction to these conclusions, it becomes clear that policy interventions need to be sought which prioritise the regulation and management of the backyard sector at national level. Policies aimed at improving the lives of backyard tenants must prioritise both service provision and the physical quality of the structures inhabited, which can only be facilitated by policies aimed at upgrading existing stock and planning for the inevitable growth of the sector in the future. Any intervention will however need to address the restrictions imposed by current legislation and policies, and must most importantly empower local authorities to effectively manage and improve their backyard stock. Once some measure of control and improvement can be administered, the backyard sector may provide adequate shelter to those who will eventually be housed by subsidised housing schemes. For those destined to live out their days in the backyards of the Republic, effective policy intervention may not only provide dignity and the fulfilment of Constitutional rights, but may save the lives of South Africans who continue to struggle with both past and present injustices.

Does Polycentric Urban Spatial Development Lead to Less Commuting: A Perspective of Jobs-housing Balance

Dong LIN^{1*}, Andrew ALLAN¹ and Jianqiang CUI^{1, 2}

¹School of Natural and Built Environments, University of South Australia, North Terrace, Adelaide, South Australia 5001, Australia

²Urban Research Program, Griffith University, Nathan, Queensland 4111, Australia

1. Introduction

The research of whether polycentric urban spatial development lead to less commuting has created many debates during last decades (Cervero & Landis 1991; Naess & Sandberg 1996; Gordon & Richardson 1997; Cervero & Duncan 2006). There are two major reasons for the debates. One reason is whether polycentric urban development could provide more opportunities to enhance spatial matches between the job and housing location selections of workers. Accordingly, employment decentralization and polycentric evolution would shorten workers' commuting distance and duration. Another reason is that whether jobs-housing balance policies save on workers' commuting duration in metropolitan areas (Nowlan & Stewart 1991; Giuliano 1991; Wachs et al. 1993; Frank & Pivo 1994; Peng 1997; Scott, Kanaroglou & Anderson 1997; Levine 1998; Levinson 1998; Sultana 2002; Horner 2004; Cervero & Duncan 2006; Wang & Chai 2009). This paper will review empirical studies in relation to this crucially important research topic. An understanding of how urban spatial structure and jobs-housing balance influence commuting patterns can improve the management and strategic planning of cities to ensure that urban spatial pattern optimises the aggregate travel behaviour of urban commuters.

2. Urban Spatial Structure and Commuting Patterns

In a monocentric city, since there is a highly concentrated employment centre and residents generally live in suburb, there would be high commuting flows on radial routes into the centre because the urban commuting would have many origins for work trips but a concentrated destination. In reality, a polycentric city functions in a similar manner to a monocentric city – people are attracted by jobs from all over the city. But the commuting patterns are different (Bertaud 2003). There are two commuting models of polycentric city. One model is that the city has some sub-centres of employment of a similar scale and in such a kind of polycentric city, each sub-centre generates trips from all over the city. The characteristics of commuting present a wide dispersion of origins and destinations, appearing almost random. Another model is that there are also different sub-centres of employment but one sub-centre is more concentrated and stronger than others. The urban commuting flows would be composite of both random and radial patterns (Ingram 1997; Ding 2007; Bertaud 2003, 2009). Accordingly, various models of spatial structure have diverse influences affecting people's patterns of commuting particularly in trip duration, distance as well as modal choice (see Figure 1).

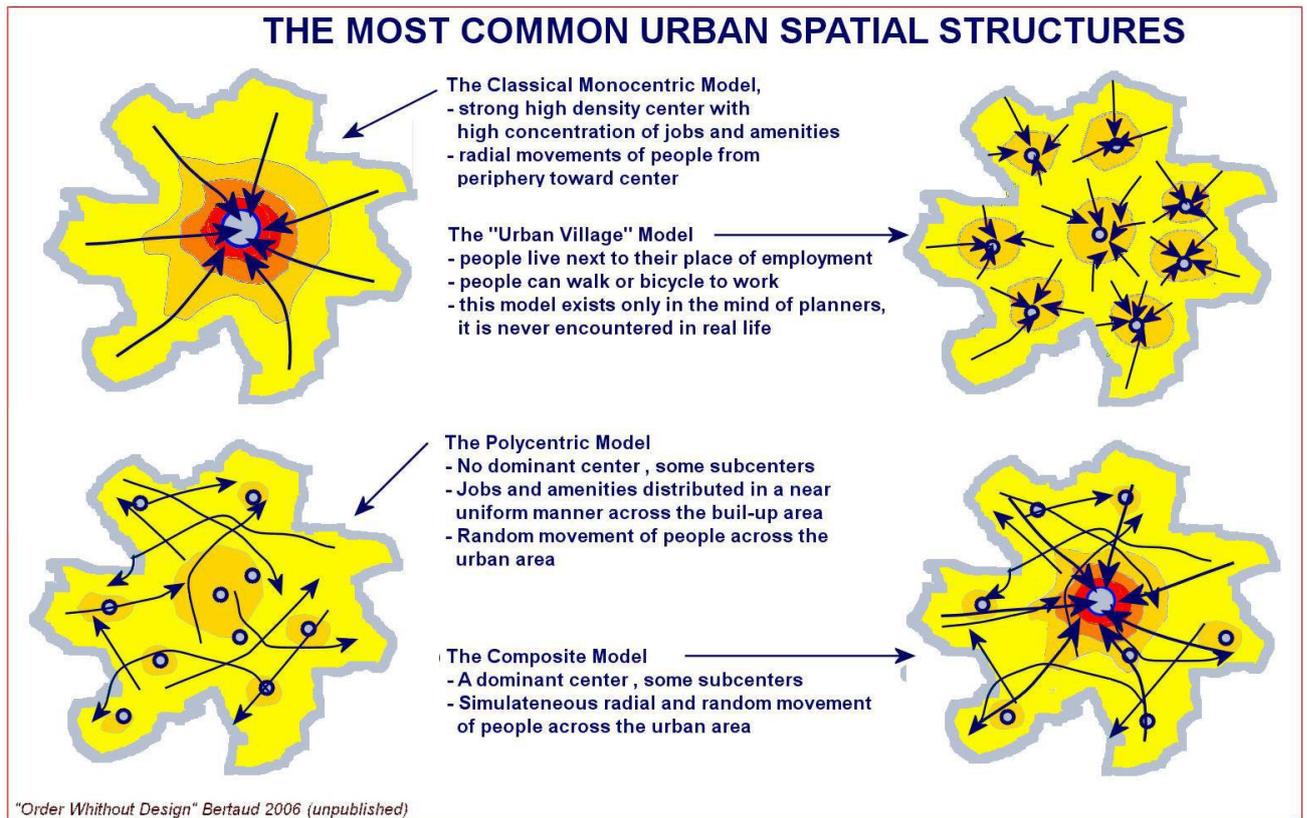

Figure 1: Commuting patterns in different models of urban spatial structure (Bertaud 2009)

3. Monocentric or Polycentric?

In the past twenty years, the issue of how employment decentralization and polycentric development in metropolitan areas has affected commuting patterns has led to many robust and continuing debates. Some scholars thought that a development pattern of highly concentrated employment centres in metropolitan areas is not as good as a dispersed and polycentric model for urban development. Suburbanization, as the main mechanism, has successfully reduced traffic congestion. It has altered roadway demand to routes with less congestion and away from central areas. With industry moves to the suburbs, the labour force has tended to follow, which has allowed many workers to enjoy reduced commuting times and less traffic congestion in traditional city centres (Gordon, Kumar & Richardson 1989; Giuliano & Small 1993; Gordon & Richardson 1997).

Previous studies based on analysis of detailed data of metropolitan travel from NPTS (Nationwide Personal Transportation Studies of U.S., 1977 and 1983-1984) and a commuting questionnaire included in the American Housing Surveys (1985) had showed that in monocentric or dense cities located in north east of the U.S such as Chicago and Baltimore, the commuting trips and time required tended to be longer as city size increased. But in some western coastal cities such as Los Angeles, the expansion of city size did not lead to an increase in trip distance. They also found that the trip distances of western cities were shorter than they were for north east cities in the morning peak time despite these cities' sizes being similar (Gordon & Wong 1985). There is another distinct difference in comparing commuting times for dense cities (New York, Chicago, Baltimore) with dispersed cities (Dallas, Phoenix, San Diego) - people who live in the downtown of a dense city spend 25% to 30% more time commuting (Gordon, Richardson & Jun 1991). Some scholars thought that dense cities result in much longer commuting times than decentralized cities (Gordon, Richardson & Jun 1991; Gordon & Richardson 1997). Hence, they believed that

this is an important point because it suggests that polycentric or dispersed metropolitan structures in western cities of the U.S. are especially suited to shortening trip distance and time. The reasons are that urban sprawl and polycentric development offer more and varied opportunities for faster commutes through changes of housing or employment, the relocation of enterprise, or the choice of uncongested roadways (Gordon, Richardson & Jun 1991).

There are also some similar case studies from European and Asian cities. One recent empirically based study from German urban regions based on data on commuter flows (German Census 1987 and German Social Security Statistics 2007) provides somewhat support for polycentric development. In their research they found that the polycentric city tends to be more travel-efficient when compared with a monocentric city. A polycentric city's commuting volumes are much higher than that of a monocentric city. The finding of their research shows that average distance of commuters in polycentric cities of Stuttgart (13.5 km) and Frankfurt (16.4 km) is lower than that experienced in the monocentric cities of Munich (19.0 km) and Hamburg (20.8 km) in 2007 (Guth, Holz-Rau & Maciolek 2009). There is another case study in Istanbul based on available data from 209 traffic analysis zones which showed that the average commuting time decreased in all the zones due to highway improvements with suburban clustered employment growth (polycentric development) in Istanbul from 1985 to 1997 (Alpkokin et al. 2008).

Some empirical studies from China also certified that polycentric development based on well planned sub-centres and regional policies would be beneficial to workers' commuting patterns. In research based on a household interview survey conducted in Beijing in 2006, Zhao, Lu & Roo (2011) argued that employment decentralization and polycentric development in Beijing would be beneficial to the jobs and housing relationship. Regional policies could impact on commuting patterns via the supply of various types of housing. The appropriate regional policies could be beneficial to polycentric development and control the dispersion of development and then achieve the aim of reducing commuting distances particularly for long distance commuters.

Several researchers have proposed a 'co-location hypothesis', that is, employment dispersion would enhance opportunities of residents and workers to change their housing or jobs locations as well as travel mode in order to avoid the congestion that lengthens commuting distance and travel time (Gordon, Kumar & Richardson 1989; Gordon, Richardson & Jun 1991). Accordingly, dispersion would reduce the phenomenon of urban congestion. One recent study from Italy corresponds with the findings from Gordon et al. It shows that the formation of a sub centre would enhance the probability of finding a job near the home. This in turn, allows a decrease both in workers' commuting distances and travel times (Veneri 2010).

This contrasts with some empirical studies show that polycentric development, dispersed metropolitan structures and suburbanization barely ameliorate the urban congestion phenomenon in metropolitan areas and indeed, actually increase workers' longer commuting distances and travel times (Cervero & Landis 1991; Levinson & Kumar 1994; Naess & Sandberg 1996; Cervero & Wu 1998; Aguilera 2005).

In research on submarket analysis of the San Francisco Bay Area, Cervero and Landis (1991) compared two subgroups of workers depending on whether their housing location at the time of job relocation was located either in the downtown area (i.e. city centre) or a suburb. The first sub group were those workers whose jobs moved from the downtown area but who retained a central city home address. Thus their commuting pattern changed from a central city commute to a downtown to suburb commute. With job relocation, the average commuting distance increased 477% and average trip duration increased by 75%. Another sub group are suburban workers whose housing was relocated to the suburbs. Generally, the results were that average commuting distances almost doubled, and commuting travel times

were also much more the same as before. And in further research, Cervero and Wu (1998) adopted two indices namely average one-way commute distance and average one-way commuting durations to examine the relationship between employment centres' growth and workers' commuting patterns during the 1980s. He found that among all 22 employment centres in the San Francisco Bay Area, from 1980 to 1990, average one-way commuting distances rose 12% and average one-way commuting time increased by 5%. These results show that, contrary to the co-location hypothesis, dispersed urban structure has not been related with shorter average commuting distances and time. In another similar study regarding how urban dispersion impact commuting patterns in U.S. metropolitan areas, after analysis detailed personal travel surveys data which were conducted by the Metropolitan Washington Council of Governments, it indicated that metropolitan Washington region's average work to home travel distance had increased from 6.6 miles in 1968 to 8.2 miles in 1988. The researcher thus supposed that the phenomenon of dispersion caused increase of commuting distance (Levinson & Kumar 1994).

Besides U.S. empirical studies, investigation of cities in Europe have also reached similar conclusions. Research of six companies in Greater Oslo, Norway showed that the distance from downtown Oslo to the workplace independently influenced the work commuting distance when other variables such as commuter train accessibility stayed constant. The further that companies were away from downtown Oslo, the longer the average commuting distance became. Analysis of data showed that when the distance from a company to downtown Oslo rose from 2 km to 12 km, the average work commuting trip increased from 10.5 km to 12.4 km. This study of the long-term effect of job relocations within Oslo's metropolitan area shows the obvious rise in average commuting trip length of a job location moving to the urban periphery (Naess & Sandberg 1996). A study based on census data of French metropolitan areas (Paris, Lyon and Marseille) in 1990 and 1999 showed that co-location hypothesis only can affect a minority of residents, of whom there were fewer in 1999 than there were in 1990. The majority of workers living in a sub-centre worked outside their sub-centre of living. This phenomenon was even more severe in 1999 than nine years earlier. In other words, the majority of jobs located in sub-centres are occupied by non-residents. Consequently the average distance of commuters increased during the past decade (Aguilera 2005).

4. The Role of Changing of Jobs-housing Relationship

From supporters of monocentric structure in above section, one key viewpoint of them is that polycentric development is associated with employment decentralization, and would easily create a jobs-housing imbalance within a given geographic area. Such an imbalance would cause rising transportation congestion and workers' commuting duration in metropolitan areas.

Accordingly, some urban and regional planners are turning to the jobs-housing relationship as a planning tool for seeking remedies for growing urban congestion phenomenon. And the concept of 'jobs-housing balance' has also become an urban policy in some local governments (Cervero 1996). Some scholars argued that jobs-housing imbalance is a key reason explaining how the problems of metropolitan congestion are induced and suggested that the government adopt policy to improve urban mobility. Cervero (1989) investigated cases of Chicago and San Francisco before confirming that two issues namely the high housing costs and housing shortages of suburbs were key reasons for suburban workers' longer commuting distance. In particular, many low income workers were excluded from the local residential market because of high housing prices. Moreover, data from 42 major sub-centres in metropolitan areas of the U.S. indicated that suburban job locations with jobs-housing imbalances tended to generate a low proportion of pedestrian and cycling trips and high levels of congestion on linking highways. Thereby, he suggested local governments adopt policies for reducing jobs-housing mismatches to improve regional mobility.

There were some other empirical studies to certify Cervero's opinion. Frank and Pivo (1994) revealed that both workers' commuting distance and time of jobs-housing balance's areas are less than that of imbalanced areas based on a case study of central Puget Sound Region of Washington State. On the aspect of commuting distance, the average distance of work trips ending in balanced areas was 29% shorter than that of ending in unbalanced areas. They also found that balance reduced workers' average trip time. The average time required for journey to work to balanced areas was 24% less than that of to unbalanced areas. Research by Ewing, Deanna and Li (1996) showed that locating jobs and housing in close proximity should rationalize patterns of commuting by reducing cross-haul travel. Research revealed that jobs-housing balance can reduce a region's vehicle miles travelled (VMT) by more than 15%. Another study using travel diary data from metropolitan Portland, Oregon, supposed that in areas with high accessibility to jobs, the average VMT was lower but trip frequency was higher (Sun, Wilmot & Kasturi 1998). Some more recent research done by Cervero & Duncan (2006) and Sarzynski et al. (2006) generated results consistent with the concept that jobs-housing proximity is inversely relevant to subsequent commuting time. And thus achieving jobs-housing balance is one of the most significant approaches that land use planning can contribute to decreasing commuting and congestion. There have been some jobs-housing balance policies launched by local governments for improving urban congestion phenomenon.

Wang and Chai (2009) conducted research from the view of China's housing reform to explore the relationship between commuting and jobs-housing balance in Beijing. They believed that jobs-housing imbalance has been become a main dynamic for congestion and air pollution issues in China's metropolitan areas along with China's economy and housing reforms. In Wang's research, after a data analysis of a household interview survey in Beijing in 2001, he found that Chinese '*danwei*' housing commuters have shorter commuting distance and duration as well as higher usage of non-motorized travel mode than those who live in housing obtained from the market sources. He believed that a good jobs-housing relationship may reduce travel demand and improve Beijing's urban environments. Accordingly, they believed that China's '*danwei*' housing reform and the market-oriented reforms induced a decrease of '*danwei*' housing and an increase of houses from market sources would deepen local jobs-housing imbalance and bring more severe urban congestion and pollution issues to China's mega cities.

Nevertheless, the concept of jobs-housing balance or co-location hypothesis remains greatly controversial. Critics of this view suggested that there were many other factors that caused the increase of urban congestion which is probably more significant than the jobs-housing imbalance. Jobs-housing relationship hardly influenced individual commuting behaviour (Giuliano 1991; Wachs et al. 1993; Giuliano & Small 1993; Scott, Kanaroglou & Anderson 1997; Levine 1998). Even jobs-housing balance policies possibly would generate subsequent urban issues (Levine 1995; Peng 1997; Bertaud 2003).

Some scholars argue that the link between where people choose housing and jobs is complicated, and may have little to do with job accessibility consideration. Insufficient evidence suggested that jobs-housing imbalance had vitally affected patterns of commuting. Furthermore, adopting a related policy of jobs-housing balance is not an effective way for reducing commuting in metropolitan areas.

Altshuler and Gomez-Ibanez (1993) think the implementation of jobs-housing balancing policies to be 'more of a romantic dream than a practical reality'. Giuliano and Small (1993) concluded that other factors must be more decisive for location choice than commuting expense, and that policies whose purpose is to change the jobs-housing balance will weakly affect commuting. Wachs et al. (1993) supported Giuliano's opinion. They supposed that workers' choice on housing location were based upon considerable factors besides the jobs-

housing relationship, such as the quality of neighbourhood and educational facilities and perceived safety. Their empirical studies also added credence to the arguments of those who doubt the effectiveness of policy proposals which encouraged changing the jobs-housing relationship as a principal policy for the release of urban congestion.

Based on a case study of Minneapolis Metropolitan Area, Levine (1998) certified that there was the potential for jobs-housing balance to change housing locations, but the potential was obviously restricted. Commuting time remained a dominant factor for determining housing location at the regional scale. The provision of affordable housing near employment centres can affect the choice of housing location for the households with low-to-moderate income and single-worker. But achieving a jobs-housing balance has hardly achieved releasing traffic congestion. Another study utilised aggregate data of measuring areas to examine the relationship between jobs and housing in the Portland, Oregon metropolitan area, found that it was only in greatly imbalanced neighbourhoods, in particular job-poor communities, where average VMT per capita was high. Accordingly, researcher argued that land-use policies for balancing jobs and housing, which targeted extremely jobs-poor and housing-poor areas, only had an impact on a very small part of the metropolitan area and thus the influence of the policies were very restricted in influencing the overall commuting patterns in the region. Researcher also concluded that changing the jobs-housing ratio is hard due to barriers from local authorities' land-use policies (Peng 1997).

Moreover, some scholars believed that jobs-housing balance strategy was not only ineffective in reducing commuting time and distance in metropolitan areas, but would also induce more urban problems such as urban sprawl and labour market fragmentation (Levine 1995; Peng 1997; Bertaud 2003). Bertaud (2003) commented influence of jobs-housing balance policy for urban development from an economics view. He argued that some scholars of urban studies often assumed that in polycentric cities, jobs-housing balanced communities were likely to grow around an employment cluster. Accordingly, considerable jobs-housing balanced economic clusters would then integrate a large polycentric city and in this kind of metropolis, workers' commuting trips would be very short. However, such a concept of metropolitan structure would conflict with the classical theory for the existence and continuous growth of metropolitan areas and ultimately caused labour market fragmentation.

5. Conclusion

The findings of advocates of monocentric structure as previously discussed, one common and significant viewpoint is that both urban dispersion and polycentric development are associated with employment decentralization, which would easily create a jobs-housing imbalance within a given geographic area. Such an 'imbalance' would lead to increasing trip commuting distances and time in metropolitan areas. Conversely, some scholars argued that sub-centres or given geographic areas of a polycentric or a dispersed city provide sufficient housing choices and jobs that are matched in both quantity and quality (when measured by their social-economic characteristics), then these areas could be considered as 'balanced' thereby resulting in workers selecting residential locations as close to their jobs' location as possible. Some economists doubted the need for public policies that promote jobs-housing balance and believed that government intervention may cause labour market fragmentation. They argued that over time the 'natural processes' of the market has the capacity to balance jobs and housing without government intervention (Bookout 1990). Imbalances are supposedly 'self-correcting' phenomena (Altshuler and Gomez-Ibanez 1993). However, crucial studies certified that government intervention and institutionally influenced jobs-housing balance do play a positive role in reducing commuting in polycentric metropolitan areas of both the United States and China (Weitz 2003; Zhao, Lu & Roo 2011).

In addition to the jobs and housing relationship, some other factors such as mixed land use, residential densities, regional policy as well as improvements of transport infrastructure and services appear to influence commuting patterns in a polycentric city. On one hand, in the dispersed cities of developed countries, mixed land uses and residential densities of sub centres and suburbs play a role in influencing commuting distances. On the other hand, managed and planned polycentric urban structure whereby urban growth is directed towards dispersed activity centres could potentially reduce commuting trip distances and time (Dieleman, Dijst & Burghouwt 2002; Buliung & Kanaroglou 2006; Zhao, Lu & Roo 2011a). In particular, some empirical studies show that regional policies and improvements of transport in a polycentric city would have an effect on people's commuting trip patterns (Alpkokin et al. 2008; Zhao, Lu & Roo 2011a). The argument in this regard, is that commuting trip distances could potentially be substantially reduced due to improvements in transport infrastructure and services that serve the sub centres of polycentric cities. Furthermore, a polycentric city in which all of its centre nodes are networked would provide greater overall metropolitan trip efficiencies through a networked transit infrastructure than could be achieved with a monocentric focused transit network. Crucially, regional policies can also play a significant role in reducing commuting distances via the supply of various types of housing that would be beneficial for optimising the ratio of jobs-housing balance.

Notes

1. *Danwei* is a generic term denoting the socialist working place in China (Bray 2005). Apart from salary, danwei used to provide workers a comprehensive package of welfare including housing (Chai 1996). Before the launch of economic reforms, danwei were encouraged to become self-sufficient communities within the city, providing not only work, but also housing, health care, food distribution and other social services (Gaubatz 1999).

The Research of Farming and Livestock Development in the Area of Ili River Valley of Xinjiang Uygur Autonomous Region

Wei qi LIU, Xie CHEN

Jiangsu Institute of Urban Planning and Design, China

Abstract: this article analyses spatial political, economic and social contexts of successful of farming and livestock development in the area of Ili river valley (AoIRV). AoIRV is located on Xinjiang Uygur Autonomous Region (XUAR), where is a vital and historical agricultural area in this region. In the Context of 'Western Development Drive' of China, central government enhance the support for western region and cities continually. According to the 'XUAR 12th Five-Year Plan', the region governance and local authorise plan to improve modernisation of agriculture, especially on farming and livestock industries, that improve economic development and social regeneration. Yet, the local agricultural development still faces kinds of problems, such as lack of higher quality labours, extensive recourse using, developing farming structure and ecological pressure. This article bases on *the Urban System Planning of Area of Ili River Valley* and point out the urbanisation is the core strategy for the local development and resolution of current problems. The planning regulates the building of countryside resident settlements in order to create much more intensive urban-town system that lead urbanisation in this local area. The local urbanisation could not only offer higher quality public service, such as healthy service and education for local people, but also improve the qualities of labour and set up basis of service industry. Meanwhile this planning advises the spatial arrangement of agricultural industry for adjusting the industry structure based on local agricultural community. Furthermore it plans a sustainable agricultural manufacturing via spreading organic standard and environment friendly policy.

Key Words: Area of Ili River Valley, Farming and Livestock Development, Countryside Residents

1. Introduction

Xingjiang Uygur Autonomous Region (XUAR) locates at northwest of China and a drawback province for long time. In 2011, the Gross Domestic Product (GDP) of XUAR was 661bn Yuan, just one percent of GDP of China. In its economic structure, agricultural is a vital part of GDP. The agricultural industry contributed 17.2% GDP for XUAR, manufacturing industry and service industry contributed 48.2% and 34.0% separately (China Statistical Yearbook, 2011). Therefore, to enhance agriculture development situation was believed the first step for XUAR economic development. Therefore, central government supports agricultural development in XUAR strongly and comprehensively.

According to *Xingjiang Uygur Autonomous Region National Economy and Social*

Development 12th Five-Years Plan Outlines, local government planned to propose to utilize modern development concept to lead agricultural and livestock industry, utilize modern material conditions to equip agricultural and livestock industry, utilize modern science and technology to transform agricultural and livestock industry, utilize modern industry system to upgrade agricultural and livestock industry, utilize modern operation mode to impel agricultural and livestock industry. Meanwhile it continuously enhance agricultural and livestock industry level and overall level, greatly improve production efficiency and the income of farmers and shepherds, and facilitated XUAR's transmission from agricultural and livestock industry big regions to agricultural and livestock industry strong region. Take the promotion of modern agricultural and livestock products processing industry development as key breakthrough of the transmission from agriculture big region to agriculture strong region, and the realization of modern agricultural and livestock industry. Construct four huge platforms of information services, science and technology support, industry parks and agricultural products and processed products export sales. With leading enterprise as dependence, and cantered by cotton, grain and oil, fruits, animal by-products, regional feature agricultural products, vigorously develop agricultural products precision and deep processing industry of high scientific and technological connotation, high class, high added value. And form industry layout with south XUAR characterized by feature fruits precision and deep processing being given priority to, and north XUAR characterized by feature agricultural and side-line products and animal by-products precision and deep processing being given priority to.

This research based on *the Urban System Planning of Area of Ili River Valley* which is a part from supporting policies, and introduce the main methods of this planning on agricultural development in this area. This research will introduce the basic situation of natural resource and key issues of agricultural development firstly. Secondly, the main strategies of the planning are to upgrade the agricultural structure and improve the eco-technique in using of agriculture and livestock produce. Finally, the planning will solve the key issues and reality the strategies via several approaches. The planning construct seven producing bases for different agriculture productions in order to re-arrange the agriculture industry structure and the spatial layout. Meanwhile, the planning promotes the water-saving technique and spices of plant for reducing dependant of water by agriculture producing. Furthermore, planning adjusts the arrangement of rural resident's layout. The planner considers that the new town will be built that can improve the life quality of residents, increase the quality of labour and create a more intensive energy using life-style. Meanwhile, these new town will create thousands job opportunities in new service industry, such as tourism.

2. Background

2.1 Natural Resource

Ili River Valley is a "wet island" in the dry regions of Eurasia. There is vast territory, various species and resources, sufficient water, soil, light, and heat sources. The Valley is possessed with unique agricultural and livestock advantage and huge

potential. It used to be named as “Jiangnan beyond the Great Wall”. The water resource in Ili is rich. There are several rivers including Tekes River, Kashen River, Gongnaisi River, and Ili River. The annual volume of runoff of surface water reaches 16.7 billion cubic meters, accounting for 20% of total volume of runoff of XUAR. The water volume held per capital is 4 times of national per capital. It is of typical valley climate. The frost-free period is 103 days to 191 days. The annual sunshine hours are up to 2,992.3 hours. Such conditions are not only appropriate for the growth of stable crops such as wheat, corn, soybeans, oil, but also good for the planting of carious feature crops such as rice, sugar beets, potatoes, malting barley, vegetables, edible mushrooms, melon and fruit, red flower, processed tomato, processed peppers, herbs, and aromatic plants. In the same time, premium livestock such as XUAR fine-wool sheep, Ili horse, XUAR brown cow, China Merino fine-wool sheep, and Ili white hog are also nurtured.

2.2 Key Issues

Low labour efficiency of agricultural and livestock industry

In 2010, Ili River Valley thrice industry GDP proportion were 24.2:35.8:40.0. From the perspective of population employment structure, in 2010 there were 993 thousand employed workers, and the proportion of three industries employment were 56.0:12.6:31.4. The primary industry only created 24.2% economic contribution with 56% employment proportion. Hence, compared with secondary industry and tertiary industry, agricultural and livestock labour production level was relatively low, and the development of agricultural industrialization was lagged. In 2010, there were 444.4 thousand hectares of arable land in Ili, yet every agricultural labour only shouldered 11.11 Mu arable land. It was of huge distance in relation to developed countries and regions. For example, in 2007, every agricultural economically active person had 5.7 hectares (85.5 Mu) of arable land in Israel, equalling the total of 8 farmers in Ili. Therefore, the labour production level of farmers and shepherds in Ili River Valley has much room for improvement.

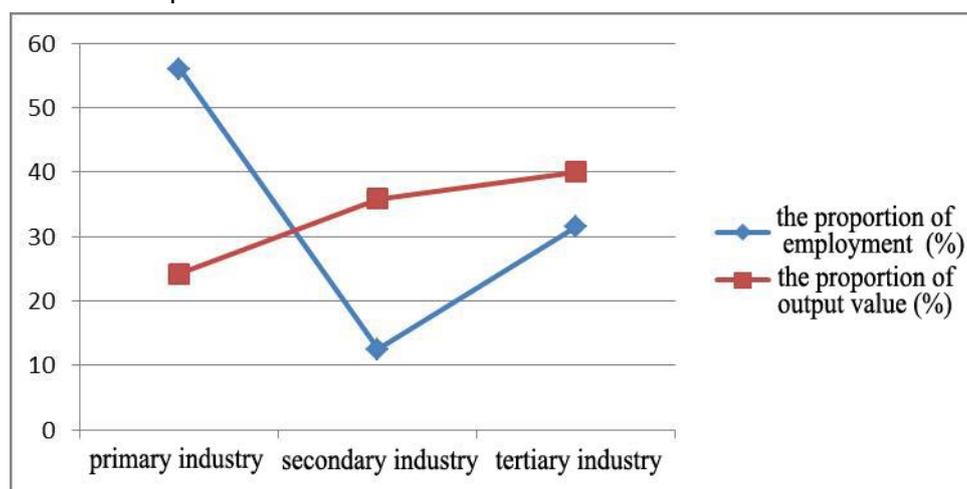

Figure 1: Ili River Valley Employment Proportion and Output Value Proportion Correlation Analysis (Xinjiang Statistical Yearbook, 2011)

Extensive agricultural water using

At present, China adopts irrigation method with water utility rate at 40% at maximum, 60% of the water is wasted. In Israel, irrigated lands commonly use pressure irrigation technology system, which reduces 50% to 70% of water consumption on unit land. This system delivers water via plastic tube and directly to the roots of plants where water is mostly needed. The maximum water utility rate is 95%. Israel has 420 thousand hectares of arable land and an annual usable water resource of 2 billion cubic meters. Agricultural water use accounts for 60% to 70% of all water consumption. The average agricultural irrigation water consumption is only 300 cubic meters. However, the average agricultural irrigation water consumption in Ili River Valley, XUAR, and eastern China is 700, 850, and 600 cubic meters respectively. Although the river valley regions has comparatively higher agricultural water utility rate in XUAR, it still has room of improvement when compared with eastern China regions and international level.

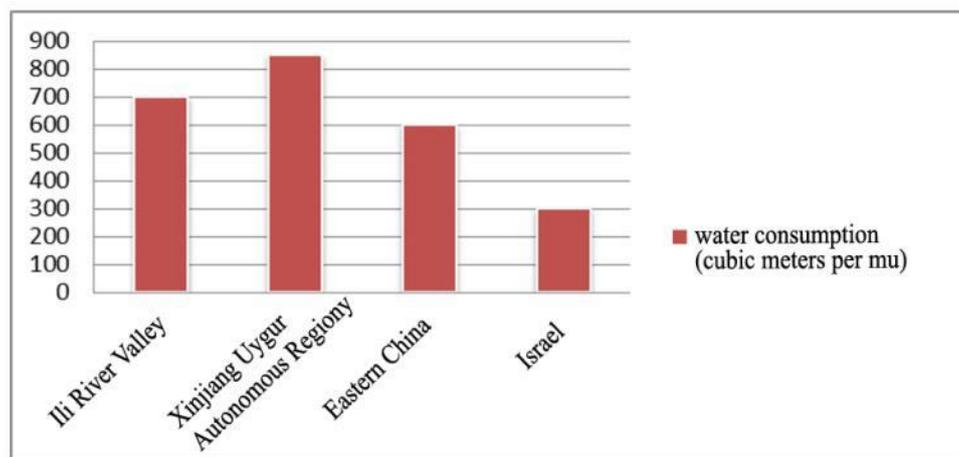

Figure 2: Agricultural Irrigation Water Consumption Comparison between Ili River Valley Region, XUAR, Eastern China, and Israel (Wang etc, 2010)

Insufficient technical training, low rural labour quality

In Ili River Valley, rural labour with education level lower than middle and primary school accounts for 40%, while those with middle and primary school education level account for 40%, and those higher than middle school education level only account for 20% (Selection data, 2012). The bilingual level is low, the ability to learn and grasp new knowledge and apply new technology is poor, and the concept is comparatively backward. Thus, agricultural labour technical level in river valley region cannot adapt to the needs of modern agricultural development. In particular, with the development of second industry and third industry in rural areas in recent years, the majority of young and educations peasants no longer stay for agricultural work. The knowledge level and agricultural technical application ability of those engaged in agriculture declines comprehensively. At the same time, most of the agricultural population is minority. Influenced by language barrier, their market competition recognition is poor, and ability to accept new technology is weak, which cannot live up to the demands of developing agriculture through science and education, accelerating the process of industrialization, and promoting high output, high quality, and high efficiency

agricultural development. The development of modern agriculture is significantly restricted.

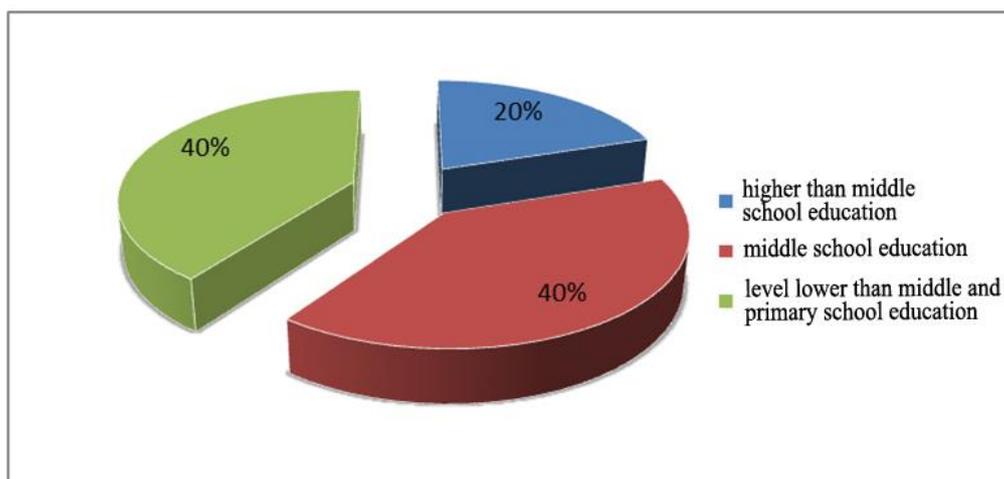

Figure 3: Ili River Valley Region Rural Labour Educational Level (Xinjiang Statistical Yearbook, 2011)

Week in Agricultural and Livestock Industry Cluster

In recent years, traditional industry in Ili River Valley, lead by agricultural and sideline products processing. In sugar refining, there are three enterprises in river valley, COFCO Sifang Sugar, COFCO Xinning Sugar, COFCO Xinyuan Sugar. The daily sugar beet processing amount is 25 thousand tons, the annual sugar beet processing amount is 2.5 million tons, and hence the annual sugar production capacity is 290 thousand tons. In fat processing, the river valley has formed production scale of 200 thousand tons of edible vegetable oil. In special fruit juice processing, there is extremely strong growth. In 2006, Ilite wild fruit juice processing project. Nongfushanquan was introduced to reorganize Huocheng county cherry plum production project. In dairy processing, by “the Eleventh Five-Years”, there were 29 dairy production enterprises in river valley, a number of comparatively large scale dairy enterprises, and a capacity of 30 thousand tons of industrial milk powder and casein on annual basis. Meat processing has become traditional advantage industry of Ili. Meat processing enterprises led by Bakouxiang industrial limited company have formed. In white wine processing, the production capacity in river valley regions has reached 35 thousand tons, holding 50% of total output of XUAR. In flax processing, the annual production is 150 thousand tons. Ili has become important base for flax industry in China. On the whole, agricultural and livestock products processing industry in Ili River Valley is still at its preliminary stage. Most of the agricultural and side line products processing projects do not have high added value. It is demanded to explore in aspects of deep processing and precision processing, to extend industry chain.

Increasing grassland vegetation degradation

Deterioration of grassland resource and environment is severely influencing the sustainable development of animal husbandry in Ili. 2.45 million hectares of

grasslands are resembling different levels of degradation, desertification, and salinization, accounting for 80% of utilizable grassland. By the end of 2010, the number of livestock had increased 3.5 times of that of initial post-liberation period. Affected by the policy of concentrating on agriculture while neglecting grazing in Cultural Revolution, newly reclaimed grassland at flatland, desert, piedmont hills with less than 300mm annual precipitation reached 200 thousand hectares. Therefore, 1 million standard livestock was reduced. Among the reclaimed 200 thousand hectares dry hill grassland, 83.3 thousand hectares of low production dry land had not been returned from farmland to woodland. In addition, in some area, phenomenon of arbitrary reclamation of grassland emerge constantly, which devastated grassland desertification and soil erosion. Pasturing area grassland, particularly Spring and Fall Grassland are severely overgrazed. The conflict between grassland and livestock is intensified. Plus, 350 thousand hectares of lands are suffering from frequent occurrence of drought and pest.

Table 1: Ili River Valley Region Grassland Grazing Capacity Statistics (Primary Data, 2011)

Grassland	Area (0'000 Mu)	Theoretical Grazing Capacity (0'000 Sheep Unit)	Actual Grazing Capacity (0'000 Sheep Unit)	Overloaded Grazing Capacity (0'000 Sheep Unit)
Summer Grassland	1517.10	887.22	1150.37	253.15
Spring and Fall Grassland	1263.45	338.99	485.13	146.14
Thermal Inversion Layer Warm Grassland	1254.90	559.63	629.48	69.84
Winter and Spring Grassland	583.05	132.08	228.01	96.11
Total	4618.50	1917.92	2492.99	565.24

3. Development Strategy

3.1 Strengthen local feature, build agricultural and livestock industry brand

Integrating resource, local authority will vigorously develop green agriculture, organic agriculture, and facility agriculture, and build distinctive Ili agricultural and livestock products brand, actively nurture feature agricultural and livestock products. Meanwhile, local authority could deepen export agricultural and livestock industry development. Moreover, considering the various characteristics of counties and cities, the local authority should help local enterprises to add value of agricultural and livestock products and increase regional reputation via precision and deep processing and improvement of local feature agricultural and livestock products, extend industry chain.

3.2 Transform production methods, realize economic breakthrough

The local authorities need to vigorously promote technologies of land saving, water saving, fertilizer saving, medicine saving, seed saving, and energy saving. Introduce water saving irrigation technologies appropriate for regional development. Energetically develop water saving agriculture, and effectively save water resource. Transform four-seasons grazing to winter point indoor feeding plus summer grassland grazing. Change the over-grazing condition of grassland. Strengthen the integration of frost and grassland to develop animal husbandry. Protect grassland ecology. Combine the project of “settle down and develop grazing, enable people to earn material gain and have stable living” to greatly perfect the living condition of farmers and shepherds, and improving the quality of life.

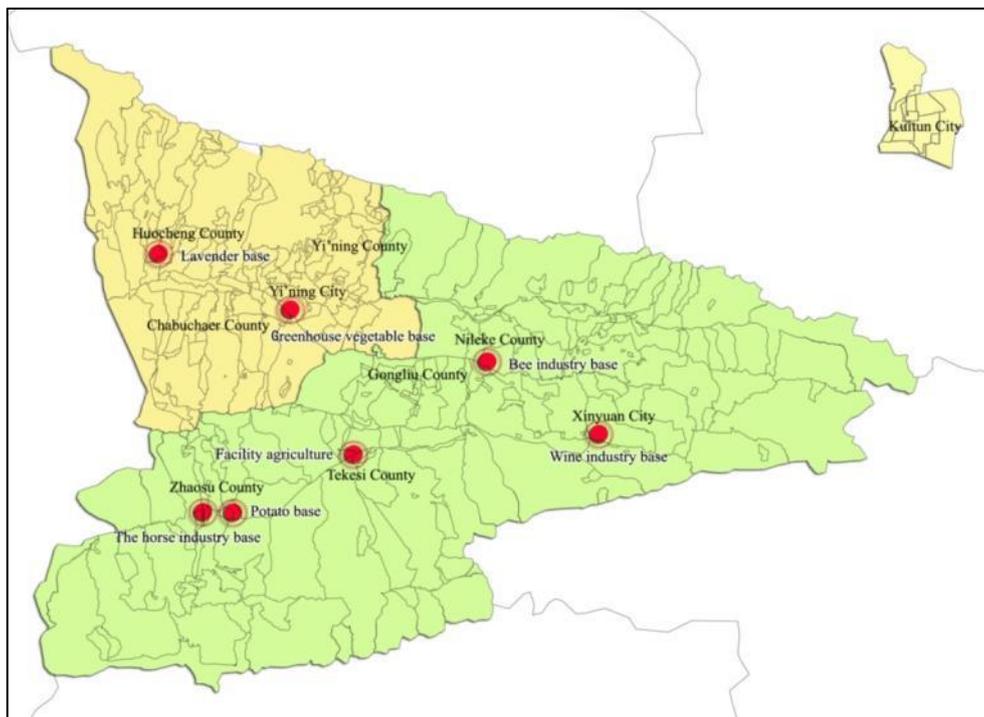

3.3 Implement developing agriculture through science and education, develop efficient agriculture

Local authorities should help the farmer to learn and use new eco-technique via raising the level of agricultural mechanization and automation, strengthen agricultural science and technology innovation.

4. Planning Strategy

4.1 Agricultural and Livestock Industry Development Layout

This agriculture industry planning will highlight the characteristics of agricultural and livestock industry development in Ili River Valley region, and set up “Seven Features Industry Bases”.

Pic 1: Seven Agriculture Industry Base in Ili River Valley Area

Seven Features Industry Bases: With Ili stud farm and Ili Zhaosu stud farm as core, radiate to horse industry bases in surrounding counties and cities; centered by Yi'ning city, take Yi'ning county, Cha county, Huocheng county as supplementary greenhouse vegetable production bases; centered by Huocheng county lavender base, build "Eastern Provence"; with Xinyuan city as the center, form wine industry base, build "No.1 county of XUAR white wine"; with Nileke county, Gongliu county at the heart, shape bee industry base; with Tekesi county as the middle, form facility agriculture base; take Zhaosu county as the core, form potato and rape bases.

Table 2: Ili River Counties Agricultural and Livestock Industry Features Table

Name	Agricultural and Livestock Industry Features	Main Agricultural and Livestock Industry
Yi'ning City	Greenhouse vegetable base	Greenhouse vegetable, dairy products
Kuitun City	—	Food processing
Yi'ning County	Apricot blossom village	Corn, wheat, soybeans, sugar beets, dairy farming, dried apricots
Chabuhaer County	Rice base, dairy products village	Rice, dairy products, feature greenhouse and vegetables, grain grinding, vegetable oil
Huocheng County	Eastern Provence	Flavors and fragrances, fat, health care products, apples, food deep processing
Gongliu County	Wild fruits village	Wild nuts, wild berries, wheat, soybean, oil sunflower, corn, bee industry
Nileke County	Black bee village	Bee products processing, bee culture display, beef and mutton processing, dairy products
Xinyuan City	White wine base	Feature food processing, animal by-products processing, brewing industry, sugar refining industry
Tekesi County	Facility agriculture	Greenhouse vegetables, bee industry, agricultural sideline products processing, food and manufacturing, fruit forest industry deep processing
Zhaosu County	Organic food, Pegasus village	rape, potatoes, garlic, beef and mutton processing, dairy products, Pegasus, brown cows

4.2 Water Saving

Adjust Plant Structure

The concept of plant structure adjustment is to limit the planting of crops with large amount of water consumption, and aim to obtain maximum economic benefit with minimum water resource. Take references from Israel, before the 1970s, the development of Israel depended on self-sufficient planting industry with the production of food. After the 1970s, the development of Israel depended on export planting industry with gardening. Peasants made a living by exporting. The adjusted plant structure demanded less of land and water resources, but increased the planning of

economical crops with higher requirements on science and technology. These crops could bring substantial economic income. Ili River Valley region should actively adjust agriculture plant structure, increase the planting of economical crops with less demands on land and water, and realize maximum economic benefits.

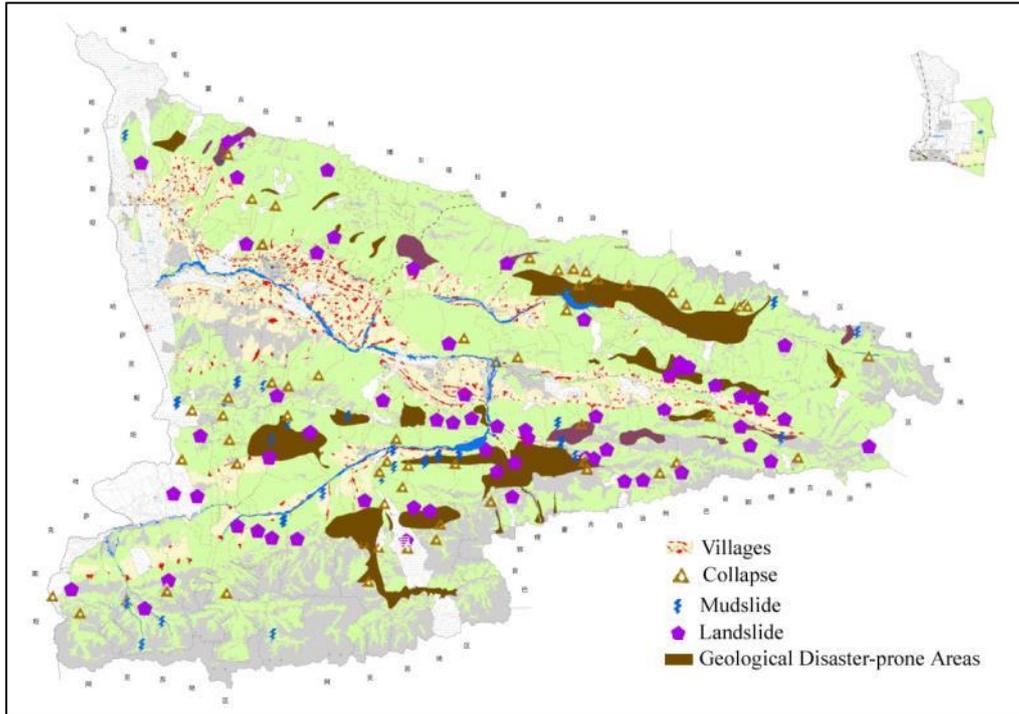

Support Water Saving Technology

Local authorities should pay much attention on promoting water saving tech in using of local agriculture producing. First of all, the investment should be paid on water saving infrastructure and help farmer to use them. Meanwhile the government implement relevant tax policies and finance policies to encourage local farmer to use water saving technique. Moreover, these policies should enhance agricultural scientific and technological innovation conditions, greatly increase agricultural scientific and technological investment, particularly water saving innovation, gradually improve agricultural research and development investment percentage in agricultural added value, and construct long-term and effective mechanism with stable increase in investment.

To Build Intensive Rural Residential Areas

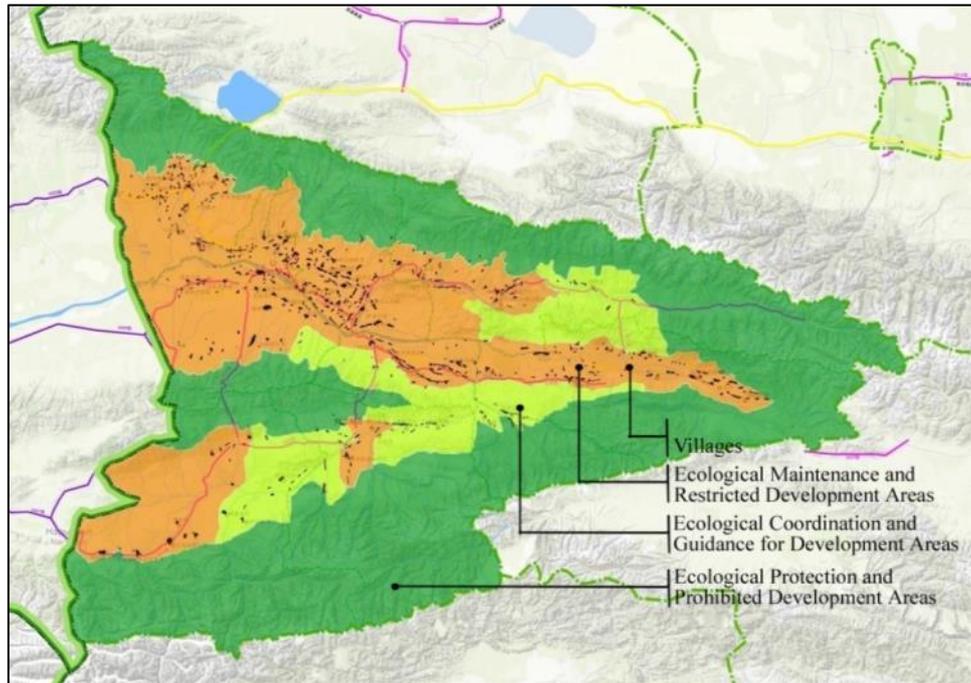

Improve the utility level of rural residential areas, speed up rural infrastructure construction and centre village construction, coordinate the arrangement of new rural area construction land, guide appropriate summon of rural residential areas, appropriately optimize space distribution.

(1) Avoid geological disaster-prone areas (spots): According to “XUAR Ili region geological disaster prevention and treatment planning”, geological disasters in Ili River Valley region mainly include the three types of collapse, mudslide and landslide. Geological disaster-prone areas are majorly distributed at Nileke county (mainly located at the mid-north part, in stripe shape, also sporadically incur in other places), Xinyuan county (mainly located at north-east part, and south mid and low mountainous areas), Gongliu county (mainly located at the south part, and cleugh), Tekesi county (mainly located at the south part, main cleugh and west-north part), Huocheng country (incur in small area, mostly at cleugh, in stripe shape, in G312 Guozigou section), Yi'ning county (incur in small area, in stripe shape, mostly in cleugh), Zhaosu county (mainly near the juncture with Tekesi at Qitemisigou). In future development, residential areas for farmers and shepherds should at the best avoid geological disaster-prone areas. In mid-and-low prone regions, rational avoidance and prevention measures are to be adopted.

Pic 2: Farmers and Shepherds Residential Areas Distribution and Geological Disaster-prone Areas (Spots) Overlapping Map

(2) Relocate villages at ecologically sensible regions: this plan to divide Ili River Valley into ecological protection and prohibited development areas, ecological maintenance and restricted development areas, ecological coordination and guidance for development areas. In ecological protection and prohibited development areas, protection of ecological space is of crucial importance. All exploration and construction activities that are harmful to ecology are prohibited. In the region, concentration is placed upon agricultural and livestock industry. Over grazing is controlled. Residential areas for farmers and shepherds should be placed at regions where ecological sensitivity is comparatively low and construction conditions are comparatively good. Rich natural resources and natural landscapes in the region should be fully utilized. Appropriate ecological travelling can be developed. Yet, travelling exploration utility strength is to be under control. The construction of tourism facilities should be in harmony with surrounding landscapes.

Pic 3: Farmer and Shepherd Residential Area Distribution and Ecological Function Partition Overlapping Map

4.3 Rural Labour

The development of agricultural and livestock industry is of significance to the development of national economy in Ili. Nevertheless, in the long period of development, irrational grazing had caused damage to grassland resources. Lagging agricultural technology led to the fact that a great number of peasants are engaged in agricultural production, which affected the process of regional economic development. therefore, it is planned to abide by the principle of “restore grazing with grassland, settle down people with grazing, develop agriculture with farmland”, to realize ration transfer of rural labour, and facilitate the speedy development of urbanization.

Studies show, the bearing capacity of Ili River Valley grassland under low utility rate, mid utility rate and high utility rate are 4,233.3 thousand, 4,491 thousand and 4,788.1 thousand sheep. Calculated at 100 sheep per shepherd, with grassland bearing capacity under high utility rate, 4,788.1 thousand sheep demand for approximately 50 thousand shepherds. In 2010, Ili River Valley had permanent resident population of 2,756 thousand, agricultural population of 1,590 thousand, among which shepherds account for 50,844 households and 258,836 persons, hence 100 thousand surplus labour can be displaced. Besides, with the continuously improvement in intensive operation level in agriculture, the every arable land of each agricultural economic activity will also increase. Calculated by 10 Mu arable land per capital, 650 thousand agricultural labour is needed, and hence 200 thousand surplus labour can be displaced. These farmers and shepherds can engage in agricultural and livestock products precession and deep processing industry, tourism, and feature catering industry, and offer reserve forces for urban second and third industry development.

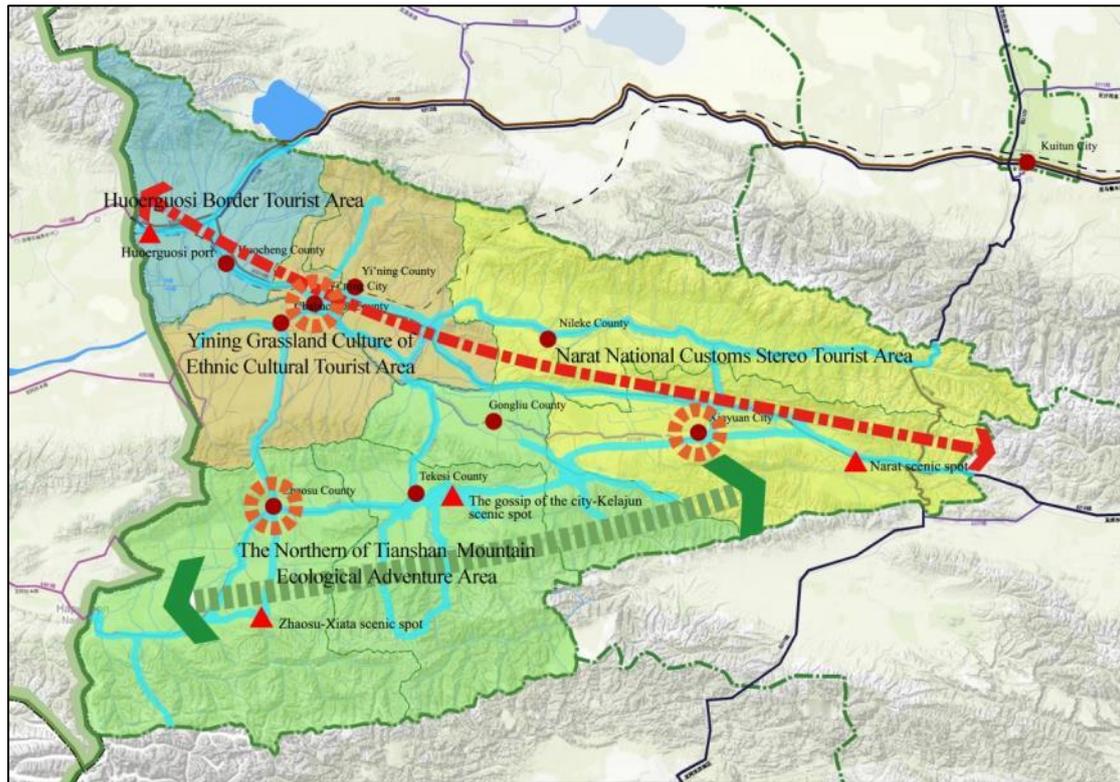

4.4 Rural Tourism

Through integration of various resources, create world level ecological valley tourism and leisure destination, build Ili River Valley brand, enrich the image of Ili River Valley tourist destination, enable Ili River Valley region to be leisure and tourist destination with distinctive features.

(1) Travelling and Shopping: Upon travelling routes setting, allocate feature streets and districts for the sales of feature tourism products, and offer souvenir for tourists, in order to expand the reputation for regional products. At the same time, provide employment opportunities for surplus labour, help farmers and shepherds increase their income. e.g. via promoting local food (Badanmu, jujube, dried apricots, nuts, honey, crusty pancake, etc.), agricultural processed products (lavender essential oil, mask, etc.), medicines and chemical reagents (deer blood wine series, lycopene, toadstool , bulb of fritillary, etc.) and crafts (tapestry, harness, wooden products, musical instruments), create feature tourism shopping base.

(2) Leisure on Farm: Through methods of home visiting to farmers and shepherds, enable tourists to feel the combination of local characteristics and exotic flirtatious expressions, nurture diversified feature tourism village. Via eating ethnic foods, dancing ethnic dances, living in ethnic houses, form interactions and affinity to local farmers and shepherds, enable tourists to sense the hospitality of local farmers and shepherds, increase sense of belonging of the tourists, improve local feature food reputation, e.g. roasted whole lamb, lamb skewers, noodles, cold noodles, bean jelly, crusty pancake, etc. further advertise ethnic feature food brands.

(3) Tourism Festival: In the aspect of tourism festival, there are Pegasus festival, and cycle racing on sands at the moment. And the festivals expected to develop are Baguacheng ecology festival, Ili Silu International Ethnic Cultural Festival. Via the set-up of Horse Cultural Festival, enable to tourists to have some understanding of the culture of horse through drinking horse milk, eating horse meat, riding on horse, racing horse. In addition, integrate horse jump performance and traditional customs activities, to expand impact, improve image, attract tourist, and increase benefits.

Pic 4: Structure Picture of Tourism Planning of Ili River Valley Area

5. Spatial Planning

5.1 Town-Rural Spatial Structural Planning

This planning will create “one circle, one pole, three development axis” spatial structure. Based on this spatial structure, local authorities will comfier the scale of urban in different level that will make relevant spatial policies and investment to support these urban physical construction and economic development.

“One Circle”

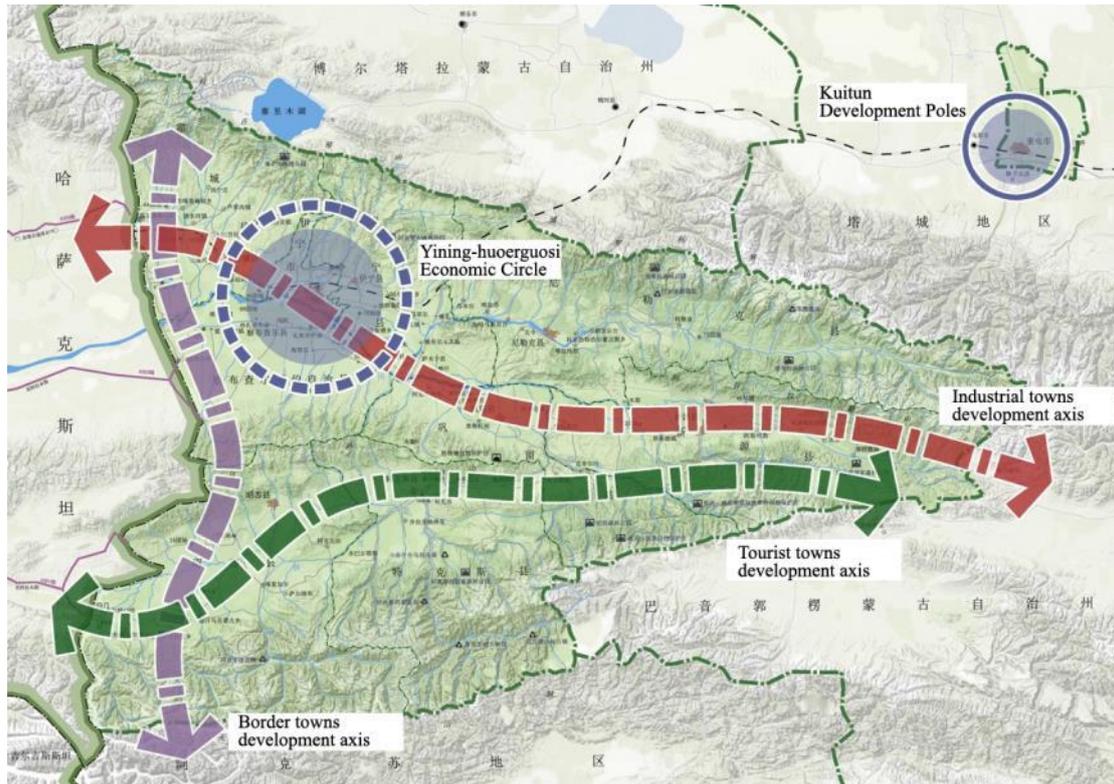

The Yining city will the core of this circle and the radius will be 100km that to growth an urban intensive development area which based on modern service industry and advanced manufactory industry. This circle area should be the biggest urban area which concentrate main function of urban, meanwhile, a more intensive land using principle introduce to land-using strategy that lead to building an spatial intensive urban area. This circle will be the core to promote Ili Region economic development

“One Pole”

One Pole means Kuitun development pole.

“Three development axis”

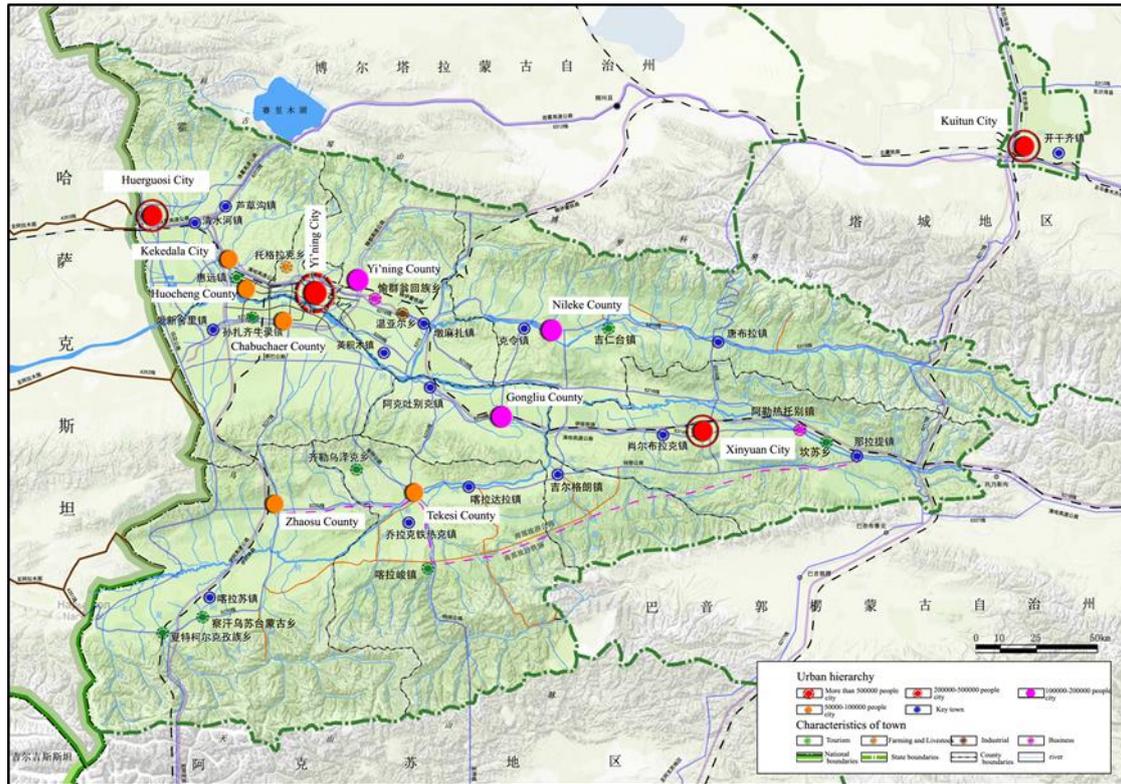

This planning sets three development axis which are *Northern Industry and Commeasure Town Development axis*, *Southern Tourist Town Development Axis* and *Western Border Town Development Axis*.

Pic 5: Ili Region Urban-Rural Structure Planning

5.2 The Urban Scale Levels

This planning set 5 levels for different urban scales which **centre urban, vice-centre urban, county, important town** and **common town**. While the end of Planning period, the centre urban could contain no more than 1 million people. And vice-centre urban will contain 500 thousand people. And there will be no more than 200 thousand people, 30 thousand people and 10 thousand people living in the **country, important town** and **common town** separately. Depend on the law of China urban and rural planning, this planning predicts and set the properly population for different urban in these different scale levels.

Pic 6: Structure Picture of Urban System Planning of Ili River Valley Area

5.3 The Rural Settlement Planning

The aim of rural settlement planning

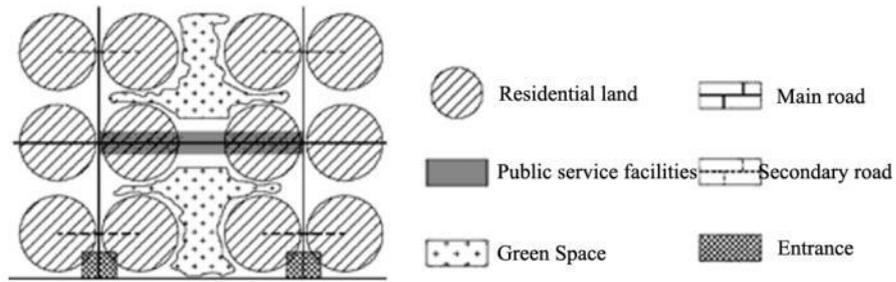

According to the prediction of population growth and urbanization trend in AoIRV by this planning, there will be still 12 million people to live in rural area, when the urbanization level maintain 70%. Therefore, rural are development will be the most vital contents for urban-rural area coherence development.

Thus, this planning sets intensive spatial polices that introduce farmer and herdsman to move in sentiments via infrastructure investment and urban construction. the main centre settlement will contain 300-500 houses and the based settlement will contain 50-200 houses. The this planning hope that all of farmer and herdsman can move into settlements till 2015, furthermore, Ili Region can build 1500 settlements with full function and which can meet anti-seismic standard.

The Model of Rural settlement

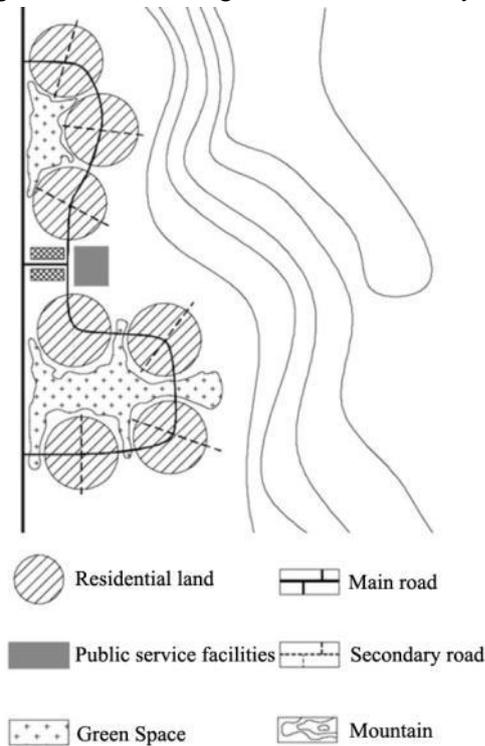

Depending on different geographic condition: This planning set three models of rural settlement as follow:

- 1): Suburban area: the large scale settlement will be built here with intensive building spatial structure. This settlement will be constructed closed to county or town, meanwhile, road and river will influence on this kind of settlement distribution.

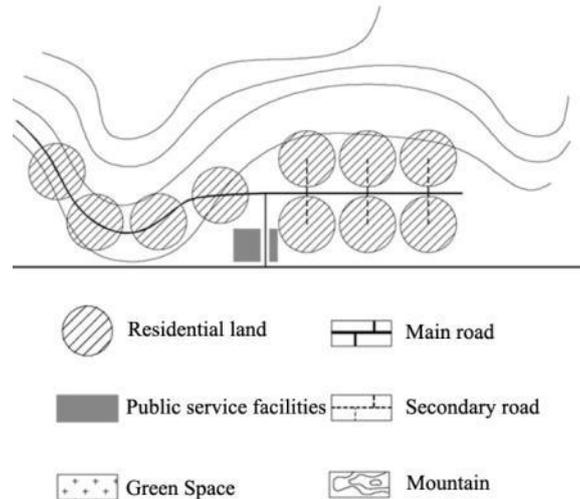

Pic 7: Model of settlement of Suburban Area

2): Road-side area: metro way is a big attractive for settlement. Comparing with model of suburban settlement, it contains less house for this model. Depending on the different conation of road, it is better to set these settlement just in one side, meanwhile, the planning controls the length of settlement by roadside.

Pic 7: Model of settlement of Road-side area

3): Hinterland area: because of poor condition of transportation and economic function, it will be difficult to spread the settlements in this area. The main principles of build this kind of settlement are closed to water resource spot and tourism spot, meanwhile, improving efficiency of resource using and reducing the construction cost.

Pic 8: Model of settlement of Hinterland area

6. Conclusion

This research pointed out the key problems faced by local agriculture and livestock development in Ili river valley area, which concentrate in three aspects. Firstly, the agriculture industry structure only offer primary produces. Current industry structure cannot add high value to their produces and cannot create high reputation of brand. Secondly, because of this primary industry structure, the style of resource using is extensive for long time. That leded a deep pressure on local environment, such as water resource and grassland resource. Finally, the recent urban-town structure cannot offer better public service, especially on public education. That could be a strong barrier for upgrading industry structure, improving value added produces and promoting environment friendly tech.

Therefore, *Urban System Planning of Area of Ili River Valley* implements relevant schemes in order to solve every single problem. First of all, the planning set seven industry clusters based on local special agriculture produces in spatial aspect in order to create unique local brand. Meanwhile, investment from government will pay for enhancing the industry chain that can increase the added value of local produces. Secondly, local authorities encourage the promotion of eco-tech using via investment, tax and governance ways. On the hand, there is a massive investment on irrigation infrastructure, on the other hand, the farmer and shepherd will be taught how to use the eco-tech, especially on water saving technique. Thirdly, of cause, the most directly scheme is to build new rural residents town. Via building intensive residents town, the resource using could be more intensive, and reduce the pressure on deterioration of grasslands. Meanwhile, it is easy to enhance the public education in order to improve quality of labour. Moreover, the industry of further processing on agricultural produces could be settle down based these new town that could extend current industry chain. Finally, new service industry, such as tourism, are emphasised by this planning.

Lisbon at a turning point: metropolitan patterns, trends and cultures

Sofia Morgado, João Rafael Santos, Inês Moreira, José Vargas
CIAUD – Faculty of Architecture, University of Lisbon, Portugal

(Important notice: this is a working paper; a first version was presented, not yet shared in text, at the AESOP-ACSP 2013 Conference, in Dublin, July)

1 Research outline: Lisbon as a metropolitan laboratory

The paper presents the overall structure and preliminary findings of the research project *Forms of metropolitan spatial production in Lisbon [1940-2011]*, currently developed by the team of M^{urbs} – metropolitan studies and forms of urbanization research group (Faculty of Architecture/ Technical University of Lisbon).

The research project stems from the opportunity to discuss recent metropolitan development under the light of new census data (2011) and of an on-going revision of regional and municipal plans. Thus, expected results are considered to adding new perspectives and further development to findings obtained in previous research. These previous experience includes a range of projects with subjects that span from the morphogenesis and development of metropolitan Lisbon, to comparative studies with other metropolises as well as the adaptability and sustainability of recent land-use policy instruments to managing urban change. A critical and conceptual update of the forms of urban production and territorial planning take into account innovative approaches, not only in metropolitan Lisbon, but also with regard to national and European trends.

Murbs – metropolitan studies and forms of urbanization research group is a research group (Faculty of Architecture/Technical University of Lisbon) with a focus in topics specifically related to metropolitan and urban space issues, including their morphologies, genesis and transformation processes, urban planning and spatial design.

The team gathers several researchers with previous expertise in these themes, especially in what the Metropolitan Area of Lisbon and comparative and multidisciplinary studies with other metropolises are concerned. Besides giving continuity to previous research activities, *Murbs* offers new challenges for future contributes to the scientific community.

The research project *Forms of metropolitan spatial production in Lisbon [1940-2011]* is seen as an opportunity to further develop previous findings and perspectives regarding Lisbon's metropolitan morphogenesis and development in comparative perspective with other 13 Southern European metropolises (George and Morgado, 2004), as part of the "*Explosion of the City Territorial Transformations in the South Europe Urban Regions - Ferrara, Venice, Genoa, Milano, Naples, Valencia, Donostia-Baiona, Vallès-Barcelona, Lisbon, Oporto, Montpellier and Marseille*" (coord Font, 2004). This research proposed a morphogenetic approach according to an identical periodization for all cities, the reading of the shapes and forms of the urban occupation, taking into consideration their dynamics and planning.

The research had as one of the major innovations the production of cartography at various time periods for each metropolitan area, which was published and exhibited in various cities involved. In the specific case of Lisbon, a digital and georeferenced cartographic database (scale 1:25000) was developed, including the buildings, the road and rail network, costal lines, topography and hydrography for 1940, 1965, 1992 and 2001. The urban occupation and land use was analyzed for these time periods, emphasizing an interpretative approach of the relationship between the urbanization phenomena, the census data

and the regional plans (both with publication dates close to the obtained official cartography).

The results from this first comparative study were an opportunity to participate in the project *Dinâmicas de Uso e Ocupação do Solo da Área Metropolitana de Lisboa 1940-2001* (Land Use Dynamics and Occupation in *Lisbon's Metropolitan Area 1940-2001*), developed under a protocol between the CCDR-LVT (Lisbon and Tagus Valley Regional Coordination and Development Commission) and the Faculty of Architecture of the Technical University of Lisbon.

Some members of this team were also involved in *Super Cities, Sustainable Land Use Policies for Resilient Cities* project (a comparison of five European metropolis, three of them Mediterranean; coord. Eraydin, EU, 2010), addressing the topic of the adaptability and sustainability of recent land-use policy instruments for managing urban change.

Figure 1. Birdseye view, Lisbon. Source: APL, nd.

2 Trends of change – responding to societal challenges

The metropolitan area of Lisbon reveals meaningful differences when compared to other European metropolises. The production of territorial features and urban fabrics into rather contiguous and continuous morphologies, upon which superimposed infrastructural and specialized land uses has often result in spatial disconnection and lack of legibility.

In this context, Lisbon offers a unique opportunity to address the emergence of specific forms of urban space production, related to a changing structural configuration, the stabilization of the national planning system and the shifting of urban policies towards regeneration and metropolitan-wide environmental structures.

Recent urban development issues are critically confronted with the impact of the economic and financial crisis situation, especially after the beginning of the financial assistance programme in 2011. Both long term and short term perspectives regarding urban development have been subject to reassessment and increasing uncertainty as to their feasibility. Conventional urban planning tools and formulas to foster

urban development are met with the collapse of a long established and growth-oriented real estate market.

As the Portuguese social and economic fabric fall into a new and still unpredictable state of unbalance and scarcity, a renewed focus on the living spatial conditions in the metropolis stands as a research commitment to societal development, not only in what Lisbon is concerned but also as a contribution to the theorizing of today's European urban condition.

Additionally, the research is in line with the vision of current European Societal Challenges, particularly those concerning the spatial, environmental and creative aware fields of society and policy.

3 From description to engaging challenges

The project aims to developing research on the topics: 1) Configurations and territorial trends in metropolitan Lisbon 1940-2011, with an emphasis on the 21st century; 2) Planning culture and planning system in Portugal, where Urbanism holds a representative role regarding the European context; 3) Questions and Debate: from metropolitan planning to metropolitan design.

New census data (2011) and an update of highly detailed cartographical representation of Lisbon metropolis are the background sources for outlining the socio-spatial characteristics of this new stage of metropolitan development.

The opportunity for the research project stems from this data as well as from the conceptual discussion and innovation regarding the spatial planning agenda, namely in a number of multi-level (national, regional and municipal) territorial and urban plans and guidance documents (e.g. Europe 2020).

As drivers for competitiveness in a globalized world cities and urban regions are at the core of current EU's policies. Accordingly, recent literature on European metropolises has critically explored the process of extended urbanization, regarding the understanding of such a specific and historically grounded urban condition as a step forward into the adjustment of the policy making, the spatial planning and the urban design.

A critical update on the urban production course of action and respective planning has been conducted, having in mind innovative approaches in the international panorama, as well as the identification of the contemporary trends in metropolitan Lisbon.

Exploring and renewing the conceptual framework regarding multilevel planning for the metropolis, over the last decade, under the scope of EU recommendations and National policies are also envisaged through: i) an outline of updated spatial configurations regarding Lisbon metropolis and its emerging morphologies; ii) a systematized identification of structuring fields for spatial and social cohesion in a fast changing context (i.e. infrastructures and open space systems); iii) a contribution to theorizing urban planning cultures and their adjustment in the face of economic and financial crisis and societal challenges.

4 Conceptual framework - changing fields in the metropolis

The location of the Metropolitan Area of Lisbon in the crossroads of remarkable Atlantic and Mediterranean landscapes contributes to its unique urban development, combining the access to the ocean and global trade and the potential of an inner sea – the Tagus Estuary – as a morphological and identity reference. Its territorial specificities and historic background give rise to characteristic forms of urbanization.

Literature and previous research about the westernmost European capital have shown the contours of leading processes of urban growth in different time periods of metropolitan development. Until mid-20th century by resorting to urban contiguity, then

by introducing spatial disjunction and functional specialization, as a reaction to modern city concepts. However, a third period starts evolving from the late 90's onwards, with characteristics which, so far, may only be sensed.

After three decades of public policies in a democratic political context, current planning in Portugal is gradually changing perspectives on priority areas and sectors. As major urban problems (slum clearance, housing, supply of basic infrastructure and facilities) had been tackled by local and national funding, planning priorities now focus on urban renewal, environmental protection and public space improvement.

Current urban planning – being developed simultaneously at metropolitan/regional and municipal levels – is targeting precisely key topics such as shrinking prevention and the urban and environmental qualification of former sprawl fabrics. Risk assessment, ecological networks and mixed uses associated to a more reticulate infrastructural network is now in the planning agenda. A stronger commitment to multi-level planning approaches, urban-landscape relationships, and to flexibility and resilience concepts is also foreseen in Lisbon's Municipal Master Plan (approved in August 2012).

Trends of change and innovation are also noticeable by analyzing recent patterns of urban occupation and statistical data. A complex mosaic of land uses associated to the knowledge economy, logistics and retail is emerging along with new patterns of urban shrinkage.

The sprawling drifts which characterized metropolitan development after the 1940's – following railroad and motorway suburban axes – are increasingly combined with transversal lines of settlement filling in the open spaces left in-between. These patterns include not only highly connective and specialized land uses – giving evidence to a polycentric system –, but also the spaces of everyday life – housing, working, studying, shopping.

Conversely, population loss and unbalances in the housing market became noticeable in areas other than old districts, increasing the complexity of shrinkage phenomena. Together, they are shaping the contour of what can be perceived as a new stage of metropolitan development.

However, the difficulty in defining a comprehensive conceptualization for the contemporary metropolis, has led many authors to come up with different and exploratory paths for decoding this type of urbanized landscape and in the fields of urban morphology (Font, 2007, Mangin, 2004), metropolitan landscapes (Tatom, 2009, Llop, 2009) and infrastructures (Graham and Marvin, 2001, Shannon and Smets, 2010). A state of *in-betweenness* (Sieverts, 1997) remains a sharp metaphor for the stage at which Lisbon and many European cities stand as they are faced with such unexpected and deep change in recent times.

In spite of representing ground breaking concepts in their context, these contributions to the decoding of contemporary critical fields still require further discussion. The issue is now how to bridge the cutting-edge trends of global urbanization with the reconstruction of an operative and conceptual common ground for intervening in clashing fabrics, such as today's southern European metropolises.

5 Methodology and lines of development

The team developed an update of specific cartography (based on official military charts M888 series/2009, scale 1:25000), resorting to previously tested methodology. This work preceded the exploring and renewal of the conceptual and critical framework regarding the forms and planning of metropolitan - spatial production, under the scope of relevant innovations in the Portuguese planning system.

Due to its specificity, in definition and time span, this cartography is considered both as a result – by extending a vision of a certain territorial development in time – and as a tool for further research in two dimensions: (1) contribution to the definition of a metropolitan design

and morphology, and inherent epistemology; (2) as a basis to share and to cross with other data, for instance, by resorting to GIS potentialities.

The cartographic production is complemented with the identification and classification of the metropolitan changes and its emergent morphologies, by combining a theoretical approach with the direct contact with the territory.

Thus, the territory will be examined according to different sorts of data which will include digital cartography and orthophotomaps analysis (in several scales), available plans and policies documents, statistical and economic data. The vectorial data includes different layers (buildings or blocks, infrastructures, public space and landscape cadastral information), adjusted to a local perspective in various dates in order to examine its morphogenesis and integration within larger metropolitan structural and functional patterns. Relevant data include statistics and planning tools joinable to cartography using CAD and GIS techniques to be displayed spatially, according to the time scope sequence.

The empirical approach is based on field work, analysis of official cartography / documents, statistical data and morphogenetic reading of three interconnected layers of the metropolitan fabric: infrastructures, filaments and the open space system. Thus, the analysis consists in the systematization of the dynamic process of transformation of the metropolitan landscape, by decomposing the relations established between these different elements, with the overall configurations, the demographic trends and the Portuguese planning system, focusing the last 20 years.

The research aims at tracking the contemporary city-making processes, patterns and challenges in metropolitan Lisbon, following three lines of development, which will further be crossed and worked to sort out transversal conclusions. These lines of development include four main fields: i) the patterns of change in the wake of crisis, scarcity and shrinkage; ii) the spatial structures for a smart and cohesive metropolitan landscape; iii) an update on a socially engaging urban planning and theoretical framework.

Although separated under the different layers, the analysis points out the impossibility of their decoupling and their influence on the overall system, inviting to a transversal reading of the various types of relationships established. Four contributions address these trends through the lens of i) infrastructural intermediation spaces; ii) metropolitan filaments; iii) from in-between to a designed open space system and iv) the urban shrinkage and its impacts at the local scale.

5.1 *Infrastructural intermediation spaces – metropolitan interfaces in Lisbon*

Considering emerging forms of spatial development associated to infrastructure in Lisbon metropolis in the last decade, a specific focus will highlight spaces where the recent improvement in mobility networks has rendered a very well connected and interfacial metropolitan fabric.

The last decade can be seen as stage of transition in Lisbon's metropolitan infrastructural strata to what it was called the layering of a connective fabric (Santos, 2012). This fabric is established through: 1) the multi-scalar recombination of various mobility, supply and communications networks; 2) the development of well-connected patches of urban development bridging or regenerating spatial and functional gaps in the metropolitan fabric; and 3) the introduction of landscape and intermodal interfaces in nodal spaces.

In the meantime, transformations at a local level in the city of Lisbon begin to be sensed as the underground system is expanded and connected to the railway, the airport, and to river and bus terminals in a number of new intermodal stations. Public space qualification and urban renewal projects start to be programmed in the areas adjacent to these new stations, taking a role in the framing of a better balanced and cohesive urban structure.

The emerging of a *connective fabric* as a metropolitan configuration is therefore being simultaneously being produced at various levels and through the recombination of transport links, spatial and landscape continuities and multifunctional urban facilities. Three areas in Lisbon show how this incrementally being achieved: the riverside threshold, the national and international mobility hubs of the airport and the main train station in *Oriente*, and the border spaces along CRIL – the first metropolitan ring motorway.

5.2 Metropolitan filaments

This approach to the urban fabrics and its morphogenesis focuses on a set of emerging urban morphologies, arising from processes of concentration of economic agglomerations specialized in the production, distribution and consumption in Lisbon's metropolitan territory, during the last 20 years.

The changes in the physical, economic and political context of the last twenty years have boosted the transformations in the metropolitan structure and the constitution of functionally specialized urban formations, which specific morphologies (*metropolitan filaments*). These are product of the metropolitan infrastructuring and densification, resulting in a system of areas of high concentration of economic activities related to the tertiary (and quaternary) sector and, in parallel, the abandonment and restructuration of large peripheral industrial areas.

The *metropolitan filaments* are the result of processes of great dynamism that, according to their nature and location, have their origins related the industrial fabrics established until the 70s, followed by the exponential growth of the tertiary sector during the 90s and the current presence and strengthening of the quaternary sector. The adaptation to the new demands of the knowledge society, along with the turn from an industrial to a services economy, was materialized in metropolitan Lisbon with the atomization and fragmentation of small/medium scale industrial and logistical activities through the territory, as well as the emergence of dense knowledge-intensive production or commercial clusters. A main feature of the genesis of the *metropolitan filaments* is the presence of an industrial structure as the engine that created the conditions for the establishment of subsequent activities. Although many of these factories are currently inactive, abandoned or converted, the logics supporting their morphology and location are still present in the territory in the dialogue with the (biophysical and anthropogenic) surroundings. The strategic location with regard to the physical support (topography, hydrography, wind and solar orientation, etc.), to the availability of land for occupation and connection to the infrastructural networks laid the foundations for the synergic relations with complementary activities that shape the contemporary urban formations.

The main objective is the identification of these specialized areas and their morphologies, revealing its transformation processes and determinant factors that shaped them, discussing their role in the metropolitan structure and how they can adapt and relate to their surroundings, in the current context.

5.3 Towards a designed open space system

On a wider scale, the main areas of concern focus on transition areas between dissimilar situations. On the one hand, it addresses the ambivalent characteristics of its fabrics, and, on the other, the need for a disciplinary approach that, in terms of projects, answers trans-scale situations and allows working in areas with scientific and conceptual borders that simultaneously encompass urbanism and landscape architecture.

Accordingly, and in the light of recent works, we are probably looking for projects that instead of attempting to mend urban splinters aim to reinvent a fabric composed

of many distinct pieces, conveying the city a territorial coherence through a public realm oriented structure of metropolitan characteristics (Morgado, 2012).

Fringe and splinters slashed the metropolitan support, sometimes in between highly qualified modern neighbourhoods and superposed with major infrastructures. Dereliction and social segregation opened unsuspected issues in modern and post-modern experiments.

However, since recent adjustments to a worldwide crisis have either frozen on-going important infrastructures or impelled the need for a greater proximity with the place. From kitchen gardens to urban parks: the unseen, unperceived, becomes the protagonist of the recovery, through the design of a collective system of open spaces.

These concerns raise the need to clarify the nature of current metropolitan fabrics, as they hold different qualities - from urban and infrastructural to rural and natural - and the indispensable skills to intervene in them. In this process, the growing importance of the space in-between cities is highlighted.

As a result, literature and practices keep on emphasizing the same topics:

- Open space is a key element for the full understanding of current metropolitan and urban morphogenesis and
- The most flexible design component in the articulation of different and scattered elements in the metropolis.

5.4 The urban shrinkage and its impacts at the local scale

Presently, Europe is facing both population decline (shrinkage) and ageing. Eurostat estimates that population decline is experienced in one quarter of the European regions, and it is expectable that the ratio would continue to grow in the near future. In the same way, the life expectancy is predicted to increase.

Although the highest percentage of younger residents can be found in Lisbon's Metropolitan Area (AML), the city of Lisbon is also one of the European capitals with higher percentage of population aged 65 years and over (65+). The already existing oversupply of dwellings, associated to a selective out-migration of younger households towards the city periphery, also lead to a change in the age structures in city centre (most residents are in the 65+ group age), housing vacancies and thus to a situation of underused urban infrastructures.

The demographic trends verified in AML are largely a consequence of a deficit of choices, once the possibility of choosing to live in the city over living in the suburbs shows less affordable for the middle class, who cannot find an adequate housing supply that would fit their economic capacity and housing demands. These trends are accompanied by a decrease in the household size and changes in its classical structure, resulting in a minor density and in the under-usage of dwellings and consequently in a higher per head consumption of housing space.

The housing, especially in the core city, is hardly affected by the population decline and high elderly population proportion. The cheap rental dwellings close to the city centre, mostly occupied with elderly residents due to inflexible rent control laws in effect between 1948 and 1985, and the inability of owners to rehabilitate their dwellings engaged in these low income rents, lead to a state of degradation in the buildings, to a decline of expenditure on maintenance and to a devaluation of the municipal parish property and quality of life. Both the physical deterioration of most of the buildings and urban amenities and the fact that they don't provide the requirements for actual housing standards led to an inner-city decline and depopulation in most of the metropolitan municipalities. (CML, 2009; CML, 2012)

6 Preliminary findings and perspectives for an on-going research

Over the last years, individual research lines (e.g. PhD and Post-doctoral research) have been building a multi-layered database, contributing to the identification of topics where “change” is critically acknowledged. Further developments will allow for a multifaceted synthesis, exploring plural and transversal findings.

The project is expected to render a synthesis regarding: 1) Configurations and territorial trends in metropolitan Lisbon 1940-2011, with an emphasis on the 21st century; 2) Planning culture and planning system in Portugal, where Urbanism holds a representative role regarding the European context; 3) Questions and Debate: from metropolitan planning to metropolitan design.

The research has also been a field to develop a network with a wide spectrum of debate. This includes different approaches from field work to design workshops, publications and development of bonds with several university and research teams, in partnership with municipal and central government authorities, or even under the scope of Thematic Groups and Teams within AESOP and ISOCARP, amongst others.

The project has been a common ground for crossing several lines of research which share Lisbon metropolis and its contemporary condition as its field of study. In its current stage, it has already allowed for a deeper understanding of Lisbon’s emerging forms of spatial production, not only from the statistical and spatial data already developed, but from the opportunities for inquiring into societal changes currently perceived as critical in the face of uncertainty and scarcity.

Besides the dissemination and debate of the research findings, resorting to publications, participation and organization of international seminars and workshops, the project *Forms of metropolitan spatial production in Lisbon [1940-2011]* and *Murbs* multidisciplinary activities are an opportunity to constitute ground-breaking knowledge by contextualizing a reality only sparsely perceived as a wider phenomenon.

The contributions and expertise of the different team members allow for a intertwined link with planning education and scholarship, namely through: 1) the development of theoretical units at PhD level concerning metropolitan territories; 2) the organization of design studios and advanced research workshops aimed at doctoral and master level candidates; 3) the contribution to already concluded post-doctoral research and doctoral theses of team members and 4) the contribution to on-going doctoral theses by team members.

These results are expected to give rise to social externalities, allowing for innovation and debate in the academic field as well as in local and national public administration.

Developing an urban sustainability toolbox using earth observation data and GIS for monitoring rapid urbanisation in developing countries

Dr Walter Musakwa, Department of Town and Regional Planning, University of Johannesburg, South Africa

Prof Adriaan Van Niekerk, Center for Geographical Analysis, Stellenbosch University, South Africa

Mr Mbinza, Department of Town and Regional Planning, University of Johannesburg, South Africa

1. Introduction

Urban planners require data to monitor sustainable urban development. Accordingly this study is a synthesis of a studies by Musakwa (2013) and Musakwa and Van Niekerk (2013) who evaluated the potential of earth observation (EO) for monitoring and modeling sustainable land use in urban centers using Stellenbosch, South Africa as a case study. The unavailability, unreliability, outdatedness and unstandardised nature of urban land use planning data in developing countries was the motivation for the investigation. Many local authorities are inadequately equipped to plan for sustainable development in hyperchanging environments. Because sustainable land use, like sustainable development, are elusive concepts to put into practice in routine decision-making, an emerging structured framework, decision consequence analysis (DCA) was proposed to aid decision making for sustainable urban land use planning. DCA breaks complex problems, such as sustainable urban development, into increasingly smaller units until the particular component can be accurately analysed and understood within the context of the overall problem. Therefore, sustainable urban land use was divided into three themes, namely land use change and land use mix, urban sprawl and the urban built-up area. Sustainable urban land use indicators for each theme in the toolbox was identified from literature (Table 1)

2. Urban sustainability toolbox

An overview of the toolbox is summarised in Table 2. For the exploration of the socio-economic impacts relating to social and spatial integration, health and safety, the Global Land Use Mix Index (GLUM) and Local Land Use Mix Index (LLUM) indexes and Land Use Frequency (LUF) can be used. Similarly, land use change, impervious surface concentration and the urban extent highlights environmental impacts and are useful for determining the rate of land transformation, human-nature interaction and growth of the urban footprint. LUC informs decisions pertaining to the preparation of local and zoning plans and spatial development frameworks (SDFs). SDFs and local plans illustrate projected land patterns and developments.

Table 1: Selected sustainable land use indicators

Theme	Indicators	Unit of measurement	Analysis scale	Significance and thresholds	Sources
Land use change and land use mix	Land use mix index (global or local)	0 to 1	Neighborhood or city	A land use index of 0 denotes low sustainability and 1 highly sustainable.	Song & Knaap (2004); Song & Rodriguez (2005)
	Land use frequency	Frequency	Neighborhood	A high number of complementary land uses per neighborhood is desirable for sustainability, unlike low mixing intensity.	
	Land use change	Percentage	City or town	Land use change impacts all the other indicators. A change from natural ecosystems to urban use is generally unsustainable.	
Urban sprawl	Global Moran I	-1 to 1	Global	A value close to 1 denotes compactness, which is highly sustainable, a value close to 0 indicates random scattering, while -1 denotes a dispersed pattern, which is highly unsustainable.	Anselin (1995, 2003, 2005)
	Local Moran I	A positive value denotes spatial clustering and a negative value indicates presence of outliers.	Neighborhood	HH and HL denote hot spots, which are relatively unsustainable, whereas LL and LH denote cold spots that are relatively sustainable.	
	Spatial cluster and outlier identification	High-high (HH), low-low (LL), low-high (LH) and high-low (HL). HH and LL are spatial clusters while LH and HL are outliers.			
Built up-area	Building density	Buildings per hectare	Neighborhood	20 or less building units per hectare (bu/ha) is regarded as low density, between 20 to 50 bu/ha medium density and greater than 50 bu/ha as high density	Angel (2010); Ewing (1997); Urban Land Institute (2010); Jabereen (2006); Jones & MacDonald (2004)
	Building height	Storey's	Neighborhood	2-12 storeys reduce environmental, social and social costs. Above 12 storeys increases cost significantly	Ding (2013); McLennan (2009); Yabuki, Miyashita & Fakuda (2011)
	Impervious services	Impervious surface per hectare	City and neighborhood	A mix of pervious and impervious required for cities to breathe	Nowak & Greenfield (2012); Weng (2012)

Table 1.1: Urban sustainability toolbox

Component	Indicator	Impact on urban sustainability	Urban planning decisions which the indicators can inform	Ideal data sets
Land use change and land use mix	Land use change (LUC)	Environmental	<ul style="list-style-type: none"> Promote efficient use of space by managing change from non-urban to urban uses, that is reduce land transformation and growth of the urban footprint. Facilitate development of spatial development frameworks, zoning and local plans. 	<ul style="list-style-type: none"> Land use data Cadastral data
	Global land use mix (GLUM) index	Socio-economic	<ul style="list-style-type: none"> Promotion of mixed-use cities Planning for spatial and social integration as well as urban designs that promote the pavement-cafe idea (social vibrancy). Planning for safe and healthy communities Improved access to socio-economic opportunities 	
	Local land use mix (LLUM) index			
	Land use frequency (LUF)			
Urban sprawl	Global Moran index (Moran I)	Environmental and socio-economic	<ul style="list-style-type: none"> Identification of urban sprawl hot and cold spots Land parcel intensification, subdivision and consolidation as well as densification strategies Promotion of social and spatial interaction through planning of different land parcel sizes. Efficient use of space to facilitate development of compact cities or the alternative making room paradigm. Planning for public transport Planning for new developments that amortize infrastructure costs. 	
	Local Moran index (Moran I _s)			
	Urban extent	Environmental	<ul style="list-style-type: none"> Demarcation of urban edge and planning for future growth Rate of land transformation, i.e. non-urban to urban uses 	
Built-up area	Building count and density	Environmental and socio-economic	<ul style="list-style-type: none"> Densification and intensification strategies Service provision, i.e. amortization of infrastructure costs Provision of public transport, circulation, accessibility, and parking Other urban planning issues such as flood risk management, informal settlement upgrading, population estimates and disaster management Encouraging social and spatial integration 	<ul style="list-style-type: none"> Land cover data
	Impervious surface concentration	Environmental	<ul style="list-style-type: none"> Minimizing negative land transformation and indiscriminate growth of the urban footprint Planning for a healthy mix of built-up areas and open spaces to allow cities to breathe (green infrastructure). Managing the urban microclimate through landscaping techniques which are important tools in mitigating climate change. 	<ul style="list-style-type: none"> Land cover data
	Building height	Cross-cutting	<ul style="list-style-type: none"> Conserving the cultural heritage Managing the urban microclimate Promoting efficient utilization of space, intensification and amortization of service costs 	<ul style="list-style-type: none"> Digital elevation model Digital terrain model Digital surface model

Impervious surface concentration is a vital indicator in the preparation of sustainable urban designs and plans, which allow cities to 'breathe' while creating urban microclimates which conserve energy and are comfortable for citizens. The urban extent is important for demarcating sustainable urban growth boundaries as well as a guide for future developments within a defined precinct.

The global Moran and local Moran indexes, building density and count as well as building height constituents of the toolbox are cross-cutting (socio-economic and environmental) indicators of urban sustainability. Building density, count and height as well as the Moran indexes are convenient for formulating densification and intensification strategies, promoting efficient use of space, and the amortization of infrastructure and service costs.

The Moran indexes, building densities and building count are useful for determining the feasibility and capacity of public transport systems and parking facilities and for conducting accessibility studies in urban areas. These indicators also facilitate decision making about practical approaches to urban sustainability that is, selecting between compact-city development or the making room paradigm, depending on the circumstance. Building height is also essential in the conservation of the cultural heritage.

The toolbox can also guide the approval of new urban developments. For example, Stellenbosch is experiencing growth in the number of gated communities marketed as being 'green' or 'sustainable' (Musakwa & Van Niekerk 2013). The toolbox can test whether these proposed developments are sustainable by applying various indicators to their proposed layouts and the results used for approval of plans or for making suggestions on how property developers can improve their designs and layouts. For instance, the layout of the proposed De Zalze 2 security state (Stellenbosch Municipality 2011) can be analyzed by using the built-up area indicators to test whether the design envisages medium-to-high densities which will enable sustainable urban development targets to be met. Moran analyses can be done on the De Zalze 2 proposal to test if it encourages efficient use. LUC will determine whether the new development will cause indiscriminate transformation of land to urban uses while the LLUM index can be used as a measure of social and spatial integration. Such analyses will help local authorities to approve new developments that are more sustainable.

The urban sustainability toolbox provides the means to monitor sustainable urban land use planning. The toolbox can be applied annually to produce objective sustainability reports and

to answer the why, when and what if questions integral to land use decision making. Such reports provide an overview of sustainability status and enables decision makers to identify specific problem areas. In Stellenbosch, Musakwa (2013) revealed that Welgevonden has medium-to-high densities, an average building height of two storeys, a low-low cluster outlier type, and a high (0.8) LLUM index. Such developments should be encouraged at the urban edge because they significantly reduce the environmental, social and economic costs of urban development.

An important feature of the toolbox is that it uses EO data and GIS analysis which enable the visual, graphical and spatial representation of urban sustainability making the information produced more comprehensible and usable for decision making. Unlike tables, which show rate of change, maps show where the change is occurring and this assists decision makers to prepare strategic actions and to target specific areas. The interoperability of EO data with a variety of GIS systems (ArcGIS and GeoDa) is also demonstrated by the toolbox. The indicators in the toolbox can also be incorporated into a SDSS for scenario building.

2.1 Data requirements

The urban sustainability toolbox requires certain data sets. For land use change and the land use mix analyses, land use and cadastral data is needed. Google Earths' Street View, available for major cities and towns in Africa and other developing countries, can help in the classification of vertical and horizontal land use mix. Three-dimensional city models and digital surface models, where available, are also invaluable for identifying mixed land uses and other land use classes such as commercial and industrial.

The calculation of Moran indexes requires cadastral data which is available for most developing countries. Scanned layout plans or designs projected for use in GIS software such as ArcGIS can be used for calculating the Moran indexes because they contain land parcel data. The global Moran I requires urban extent data, which can be derived from land cover maps.

The analysis of building density and count also requires land cover data. Three-dimensional building models derived from light detection and ranging (LIDAR) data can be used to demarcate settlement structure as well as building density and count. Land cover data is also necessary for calculating impervious surface concentration. Improved land cover classification of urban surface material calls for hyperspectral satellite imagery because it can better distinguish urban surface materials (Nichol et al. 2007; Weng 2012). Building

height calculations require a digital terrain model (DTM) and a digital surface model (DSM) derived from VHR stereo-pair imagery or LIDAR. DSMs are also useful in land use classification and for demarcating the urban extent.

Urban planning has traditionally used VHR 0.5 m aerial photographs for mundane tasks such as property identification. The availability of VHR 0.5 m spatial resolution satellite imagery holds great potential for assisting urban planning because it has the required finer spatial resolution to discriminate urban features and a high temporal resolution to detect changes at high frequency. Consequently, it is possible to produce up-to-date data sets of land use and land cover, which is crucial for understanding human-nature interactions.

The urban sustainability toolbox is flexible and can be modified by adding indicators or by choosing specific indicators depending on the issue in question. For transport issues, for instance, the requisite travel-related data can be added. The toolbox is also not confined to urban sustainability studies as it can be applied for population estimates, disaster management and telecommunications planning. This flexibility and applicability ensures cost-effectiveness and data sharing, which can lead to better urban planning decisions.

The urban sustainability indicators used in the toolbox are normalized and presented in standard format. This implies that they are universally applicable and can be used for rapid comparative studies of urban centers and development of place-independent models. Furthermore it facilitates rapid comparative studies of urban centers, learning from best practices, knowledge sharing (particularly in developing countries), identification of problem areas, modeling of future scenarios, and the effecting of policy changes

2.2 Limitations

Paradoxically a weakness of the toolbox is the reliance on remotely sensed data (satellite imagery and aerial photographs). The presence of errors in EO-derived data sets (e.g. land use, land cover, building height) is acknowledged and should always be taken into consideration when the indexes are used in decision making. Fortunately, the relatively high accuracies of (>75%) attest that EO is a reliable source of spatial data (Musakwa & Van Niekerk 2013). A further limitation of the toolbox and EO in general is the difficulty of determining mixed land use using remotely sensed imagery. This is a major constraint for automating land use mapping using remotely sensed imagery, as field surveys are in most cases necessary for producing accurate land use maps of urban centers. New sources of data, such as Google Earth's Street View product, holds much potential for reducing

expensive and time-consuming field surveys for determining vertical and horizontal mixed land use. This data is, however, not yet available for all urban areas.

The use of cadastral data in calculating the various indices by the toolbox can also be regarded as a potential limitation of the toolbox because it may not be available in all urban centers. This type of information is difficult to extract from remotely sensed data, particularly in urban areas. Air pollution data is important in monitoring urban sustainability (NASA 2009; Nichol et al. 2007), but it not available at a suitable resolution. Hopefully new initiatives such as the scheduled launch of a space borne sensor for monitoring air pollution in 2017 (Geoinformatics International 2012) will address the lack of such data. Travel-related data is also critical for urban land use planning but is normally not available at an intra-urban scale in developing countries. The lack of travel-related data is a general problem in developing countries (Hicken 2009). Cellphones equipped with global navigation satellite systems (GNSS) and volunteered geographical information (VGI) may provide a solution to monitoring movement of people in urban centers, but this kind of data was not explored in this research.

Census data, another important data source for urban planning, is not used in the toolbox It has, however, been shown that EO can be employed to monitor population dynamics (Almedia et al. 2011; Ural, Hussain & Shan 2011).

3 Conclusion

Local authorities often rely on various formats of data, some of which are inadequate, unreliable and outdated. This inevitably makes the monitoring of sustainable land use planning and urban growth unworkable, hindering local authorities capacity to leverage resources towards sustainable development. The use of EO data and GIS analysis is a resolution to the issues of unavailability, out-datedness and unreliable forms of data experienced in most developing countries undergoing rapid urbanization which makes it difficult to monitor and plan for sustainable urban development. Consequently the toolbox enables local authorities to carry out a holistic, systematic and objective view of the trajectory of sustainable urban land use development. The developed toolbox empowers role-players to make evidence-based decisions as opposed to incremental planning, subjective decisions and advocacy planning or merely accepting compact development as the only sustainable urban development paradigm.

Towards a Food Sovereignty Strategy in Singapore

WAIKEEN NG, National University of Singapore, Singapore

Synopsis

Given its size and dense urban environment, it is not realistic economically or spatially to meet Singapore's entire food needs through in-country cultivation. A more pragmatic and viable solution would be to build flexibility and adaptability in the planning and development strategies so that land and space can be quickly deployed for food production when the need arises.

1. The Impending Food Crisis

The global population is expected to grow from the current seven billion to over nine billion by the mid-century. In addition, the global population is also expected become increasingly urbanised. At the same time, farming and fishing yields are declining through increased demand, reduced amounts of arable land, unsustainable agricultural and fishing practices, not to mention the impact of climate change.

The recent International Food Policy Research Institute (IFPRI) studies on the impact of climate change on monsoons cycles suggest that South Asia will experience large agricultural declines. Breakthroughs in food production – another “green revolution” – are urgently required, as will be urban agriculture, which will be increasingly important to supplement traditional, rural agriculture.

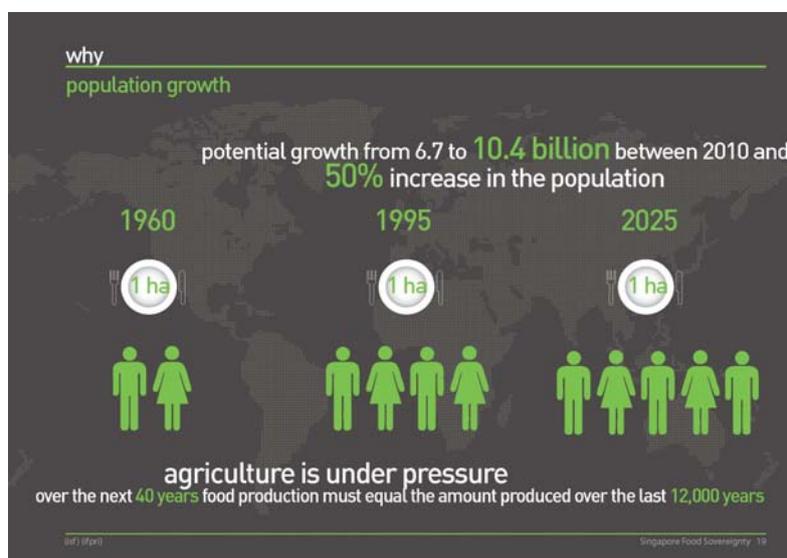

Figure 1: Agriculture under pressure

Singapore is almost completely reliant on food imports (about 90%), and therefore is in a very vulnerable position when the food crisis occurs. The National Research Foundation (NRF) recently issued a call for research innovations in this area, and the Singapore government, through the Agri-Food & Veterinary Authority (AVA) is actively seeking to diversify the source of our food imports. This includes the creation of food zones overseas, such as the China-Singapore Jilin Food Zone. However, the question remains: given Singapore's small size and already dense urban environment, how can we address the spatial requirements to attain a satisfactory degree of food sovereigntyⁱ and security?

Over two semester-long studios with fourth-year architectural students at the National University of Singapore, I explored the food aspect of urban resilience, to understand the spatial implications of an island-wide planning and design strategy that could help Singapore extend its “total defence” approach to include food sovereignty during a crisis situation. The study area, naturally, covers the entire territory of Singapore, including the off-shore islands. The “five pillars” of Singapore’s existing strategy are: military, civil, economic, social and psychological. This strategy is comprehensive and extensive, and the government has invested heavily in the physical elements required, such as emergency shelters in metro stations and schools, and in all public housing apartments. The studio contends that food sovereignty should be an integral consideration.

2. Assumptions

A key assumption for the studio explorations is that, given Singapore’s small size, large population and economic profile, it is not realistic, nor would it be economically or spatially viable to attempt to meet Singapore’s entire food needs through in-country cultivation.

Instead, the more pragmatic and viable solution would be to build flexibility and adaptability into the urban planning and development strategies so that land and space could be requisitioned by the government, and be quickly re-deployed (say, within three to six months) for food production as and when the need arises, that is, during critical or emergency situations. At all other times, when the sources of imported food are secure, these land and spaces would retain their “normal”, everyday functions.

Another key assumption for the studio explorations is the notional food crisis that will be precipitated in 2030. The choice of this date was informed by the research scenarios proposed by IFPRI and other food, population and climate change studies. Adopting 2030 as the notional “crisis year” to work towards, also helped to outline the other assumptions (such as the one-year duration of the crisis, the amount of stockpiled food available, the capacity to requisition buildings, etc) within which the policy proposals could be framed.

3. The Food We Eat

The first, more quantitative, part of the studio examines Singapore’s food sources: (i) the amount and type of food we consume; current food production areas in Singapore; where are we importing food from and at what ecological cost (ii) our actual food requirements in calories; the calorific content of different type of foods available in the region; and the spatial implications for growing our own food.

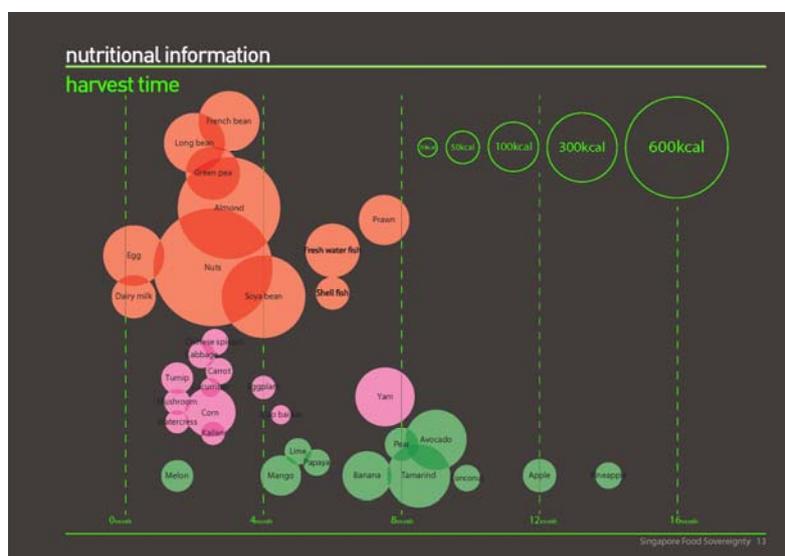

Figure 2: Nutritional Value and Harvest Times

Information from the Urban Development Authority (URA), the Agri-Food and Veterinary Authority (AVA) and the Ministry of Health (MOH) that provided insight into the food production and consumption patterns of Singaporeans were compiled and analysed. Likewise, site visits to the AVA's Sembawang Research Station and the Marine Aquaculture Centre on St John's Island broadened the technical understanding of the issues.

Figure 3A: Land required for production of carbohydrates

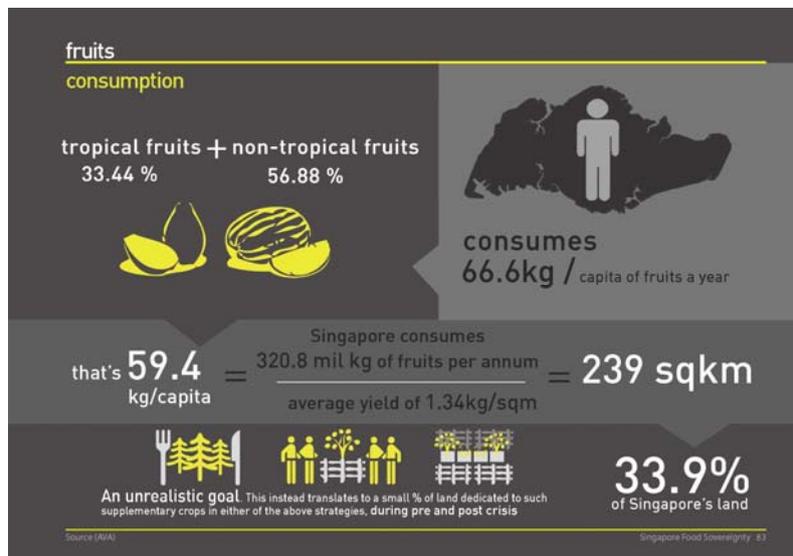

Figure 3B: Land required for production of carbohydrates

Formulating a Strategy

Quite early in the first studio, the discussions began to coalesce into three major strands, namely, **vertical (stacked) farming** (primarily green vegetables and egg production), **aquaculture** (primarily off-shore fisheries) and **productive landscapes** (for carbohydrate substitutes). International case studies, such as Cuba’s Urban Agriculture Movement, WWII “Victory Gardens”, Norway’s Svalbard Seed Vault, even traditional fish-rice farming practices in the region, etc, informed the studio of the multi-faceted aspects of the challenge.

In Singapore, only 1% of the total land area of 700km² is formally allocated for agricultural use. However, this includes land used for non-food production activities such as orchid farms or ornamental fish farms. The actual amount of land dedicated to food production is much less than 1%. It is a measure of the efficiency and productiveness of Singapore’s agricultural sector that we produce about 7% of the green vegetables we consume (including 100% of bean sprouts) and 23% of chicken eggs.

Singapore is also short of sea space. The amount of “usable” sea area for open sea farming is constrained not only by the water depth, currents and quality, but also by active port uses or as anchorages. In spite of this, the existing fish farms produce about 8% of the fish that is consumed annually.

While there is substantial scope for increased productivity through rotating planting structures or open sea fish farms, if the need for secure food sources is considered important enough, perhaps the land (and water) areas could be allocated for agricultural uses.

For each of the three strands, we developed strategies to increase the capacity for increased food production during the pre-crisis, crisis and post-crisis periods. In reference to the realistic possibility of an impending food crisis, the strategies were designed to encompass an initial increase in food production with a further increase during a crisis period.

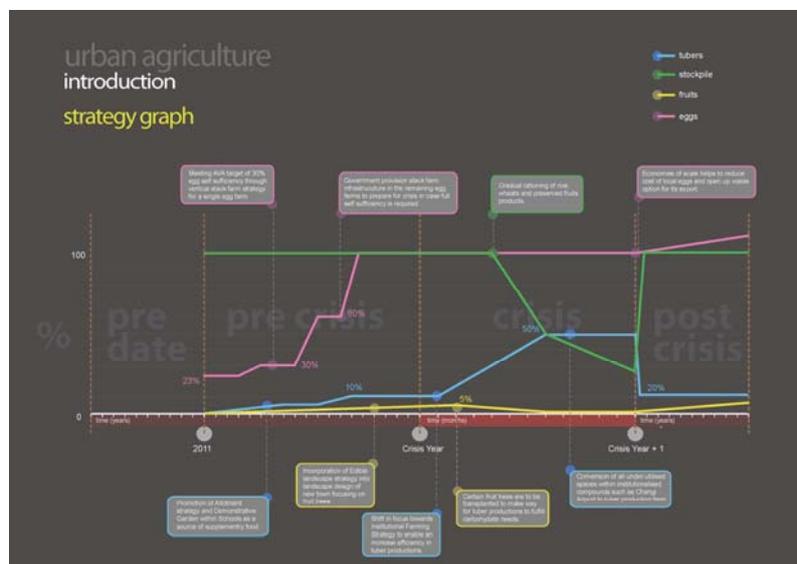

Figure 4: Timeline of the proposed Food Sovereignty Strategy

Over the two semester-long studios, the students first identified/developed strategies for each, at the national level, and then zoomed into a new town to examine potential spatial ramifications for efficient deployment during emergency situations. Bedok New Town was chosen for its mix of mature public and private housing, as well as the industrial area, not to mention the canal, reservoir and coastline. Underlying the proposals is an understanding of the key technical/scientific requirements of each “strand”, sensitivity to the political and social

contexts, and the adoption of the ethos of sustainable urbanism. Some of our key recommendations/proposals are:

Vertical farming:

- Pre-Crisis: Expansion of farms using rotation structures to increase productivity to meet 15% of green vegetable needs. Stockpiling of materials, soil and seed.
- Crisis: Conversion of HDB multi-storey car parks during an emergency to fully meet 100% of green vegetable requirements.
- Post-Crisis: Car parks revert back to regular usage. Car park roofs can be retained as community gardens.

Figure 5: Location of HDB Carparks

A key architectural component of the studio comprised (i) the design adaptation of HDB car parks to be converted into vertical farms during emergency situations, including solar energy, planting modules, water harvesting, composting etc, and (ii) vertical farms that can be used as car parks during non-emergency situations. The design for these components included the cost of fabrication and stockpiling of materials.

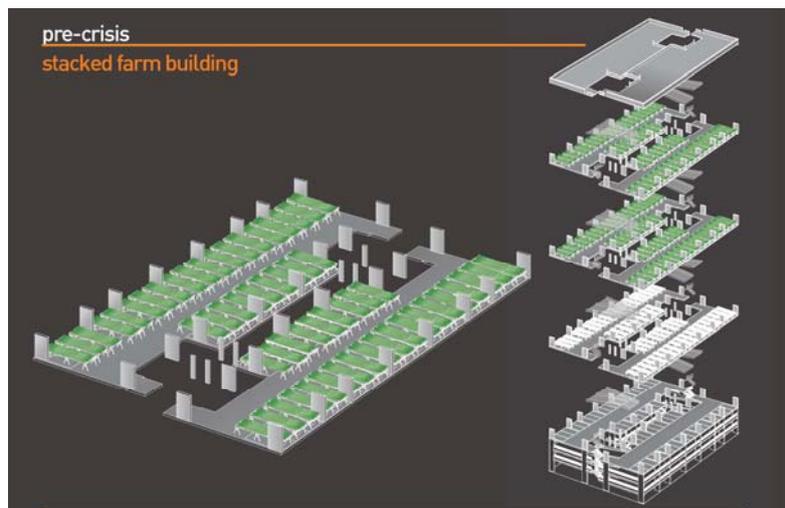

Figure 6A: Conversion of HDB Car-Parks to Vertical Farms

Figure 6B: Conversion of HDB Car-Parks to Vertical Farm

Egg Production:

- Pre-Crisis: Construction of stacked egg farms. 30% self sufficiency
- Crisis: Ramping up egg production requires lead time of 9 months for chick to mature, but potentially can be major source of protein.
- Post-Crisis: Revert to pre-crisis levels. Extra eggs produced for export.

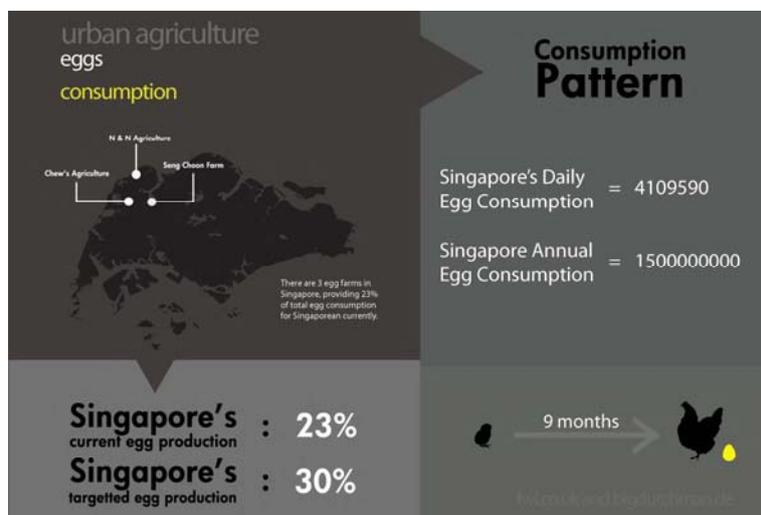

Figure 7: Egg consumption statistics

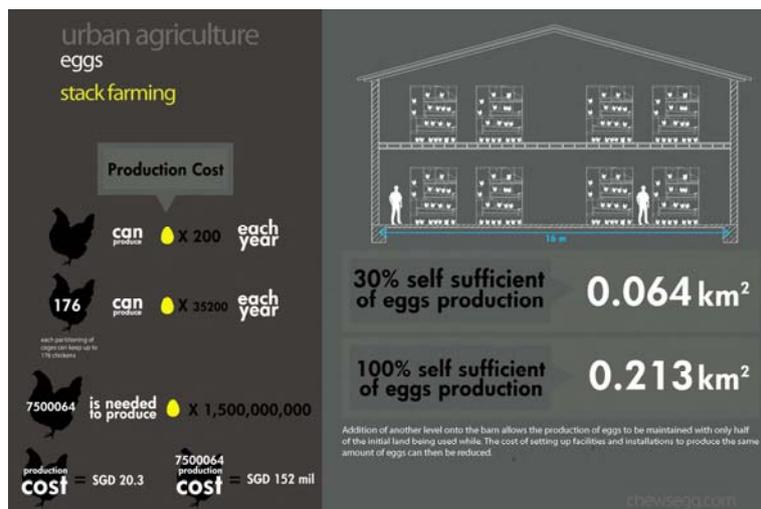

Figure 8: Egg production statistics

Aquaculture:

- Pre-Crisis: Expansion of intensive open-water fish farms, possibly in collaboration with Indonesia. Conversion of some inland fish farms to hatcheries to supply open-water farms. Aim to meet 100% protein requirement. Requires long lead time.
- Crisis: Export component redirected for domestic consumption instead
- Post-Crisis: Revert to pre-crisis status. Extra fish produced for export.

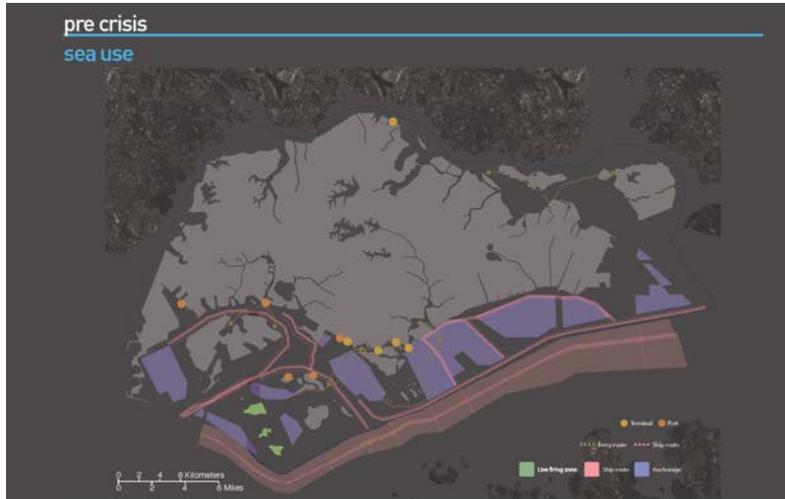

Figure 9: Existing Usage of Sea Space

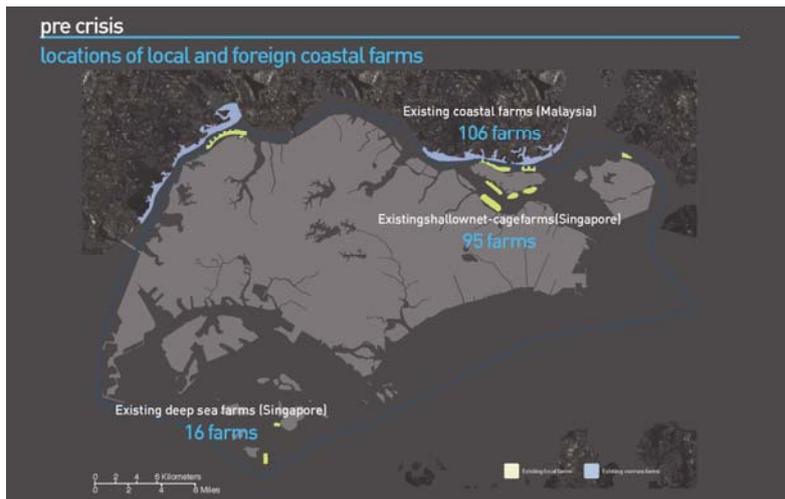

Figure 10: Location of existing fish farms

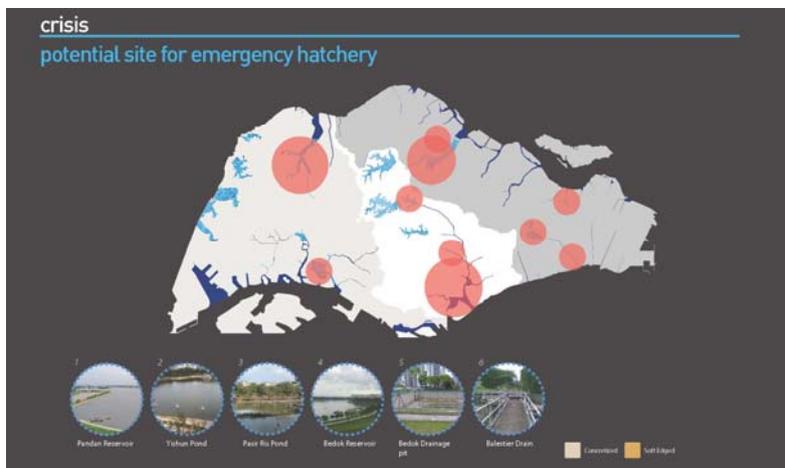

Figure 11: Potential locations of hatcheries

Productive Landscapes:

- Pre-Crisis: Stockpiling of food, materials, soils and seed. Pilot projects to increase food literacy, community/institutional farms, allotments, incorporate more edible landscapes
- Crisis: Achieving 50% sufficiency in carbohydrates; rationing of stockpiled food
- Post-Crisis: Gradual reversion to pre-crisis status, but some areas can be retained as allotments or community/institutional farms.

Figure 12: Potential land for productive landscapes

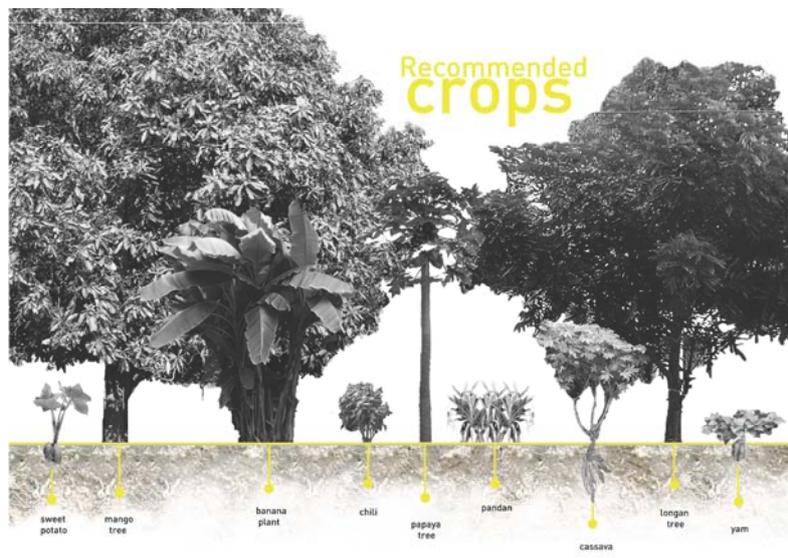

Figure 13: Suggested Crops

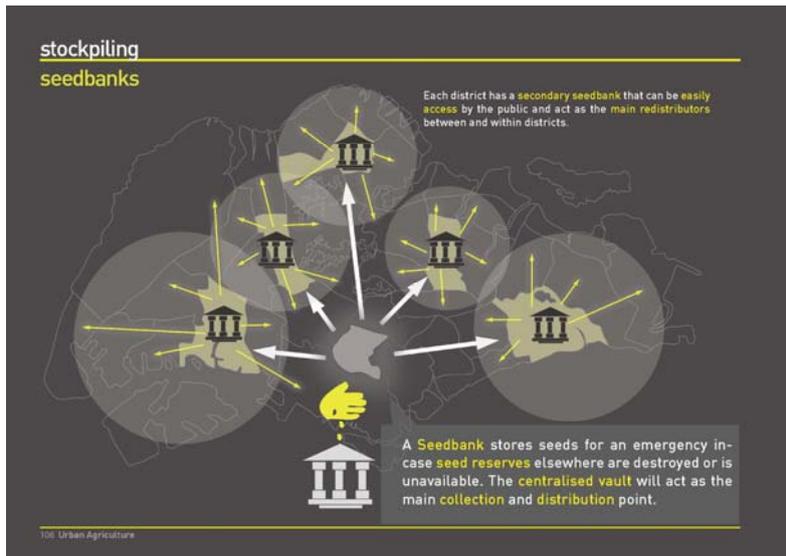

Figure 14: Stockpiling: Seedbank policy

stockpiling equipments

mobile farming denotes farming at a mobile, flexible and individual level. it is small scale and requires minimal attention and strain on resources.

found often in modular units and can be hooked onto an automated irrigation system if necessary. otherwise, it can be used for education purposes and can be brought indoors, as plants grown at this scale do not require as intense lighting as crops such as tubers and fruit trees.

the above shows how mobile farms make use of recyclable materials such as plastic bottles and rubber tires. materials, that during the event of a crisis, would peak exponentially and is easily accessible to all, and can be stacked or hung.

4. Bedok New Town

Following the development of the three “strands” at the national level, Bedok New Town was selected to test out the potential deployment/implementation at the level of the new town. Bedok New Town has a population of about 300,000 people, and the study area covered about 15 sq.km.

5. Conclusion

The two Food Sovereignty studios was an experiment in bringing together research and teaching on an issue related to urban resilience. Designed as a prototype “research by design” studio, the studios first examined Singapore’s vulnerability (to risks such as energy, water, food, climate change, etc.). The second part of each studio focussed on the developing possible policy and design solutions.

The study demonstrated that that even if it is not economically viable for Singapore to dedicate land during non-crisis periods for agriculture, with flexible and innovative land-use planning and urban design, it is very plausible for Singapore to achieve some level of self-sufficiency during a crisis situation. Indeed, the study argues that is essential that the country dedicates resources towards developing the missing “sixth pillar” of Singapore’s “Total Defence”. In the case of the vertical farms, it is anticipated that further studio-based design research will deepen the not only the aspects of building design, but also enable us to produce vertical farming modules that could be commercially viable.

ⁱ Food sovereignty refers to the right of all persons, communities and countries to have safe, nutritious and culturally appropriate food within their unique resource, social, economic and cultural circumstances (Foodfirst, 2002).

Size, Shape and Dispersion: Urban form evolution in Saigon River Basin and its impacts on hydrologic performance from 1990 to 2010

Dzung Do NGUYENⁱ, CPG Consultants, Vietnam/Singapore

Abstract:

Urban form evolution causes hydrologic effects. Therefore, an understanding of this critical relationship can provide planning and design solution to make communities more sensitive and resilient to flooding. While several studies have raised concerns on the impact of rapid and uncontrolled urbanization in Ho Chi Minh City on the rise of Saigon River's water level, none has tried to quantify the urbanization process at basin-scale and associate this spatial phenomenon with water upheaval. In addition, the search for a hydrologic-optimal urban form is critical for Ho Chi Minh City region given the low infiltration rate of soil and rapid urbanization so that minimizing impervious surface is a less relevant solution. Response to this research gap and base on landscape ecology approach, this paper provides an empirical study of urban form evolution in term of size [urbanized area], shape [compactness and fractal] and dispersion [aggregation] within 2503 sqkm of Saigon River Basin during a 20-year period of rapid urbanization. During this period, impervious surface increased by 4 and 8 times in the whole basin and in the flood-prone areas respectively while the population increased by 2 folds only. Urban development in the Basin also became less compact, more fractal but more aggregated. Using 5 landscape metrics and a hydrologic index demonstrating run-off coefficient, the author presents potential relationship between those form variables and the hydrologic performance of the Basin. The result of this paper highlights that a more compact and concentrated urban form for Saigon River Basin may result in lower flood risk for Ho Chi Minh city.

Key words: Ho Chi Minh City, hydrology, landscape ecology, urban form;

Saigon River Basin is home to Ho Chi Minh City, the largest city of Vietnam. The Basin is the land of a sophisticated interlacement between human settlements, interconnected watercourses, wetlands and crop lands. From 1990 to 2010, one can observe an aggressive invasion of urban development into low lands and water territory within the Basin boundary. As the consequence, the hydrologic system has taken an unexpected turn at the end of the 20th century. The river water has suddenly and frequently risen to inundate thousands hectares of land and disrupting lives of almost two millions people. The urban cause of this disaster, however, is yet understood and quantified.

Therefore, the purpose of this research is to relate the spatial evolution of urban form in the Basin with the hydrologic performance of Saigon River. An understanding of this interconnection will shape an informed urban planning and design interventions, which will hopefully lead the city into a more resilient future in the wake of climate change and sea-level-rise.

1. The city and its flooding challenge

In two decades from 1990 to 2010, Ho Chi Minh City experienced a rapid population growth and fast-paced urban development. The city's population is estimated to grow at an annual average rate of 3% and increase almost by two folds from 4.1 to 7.4 million in this period. These numbers can be much higher if we take into account unregistered population and commuters from neighboring provinces, which are estimated to be approximately 2 million in 2008 (Dapice, Gomez-Ibanez et al. 2009).

In addition to rapid urbanization, Saigon River Basin has a very complicated hydrologic system characterized by powerful semi-diurnal tidal influence, interconnected watercourses, seasonally extreme rainfalls, and extensive amount of wet and low lands.

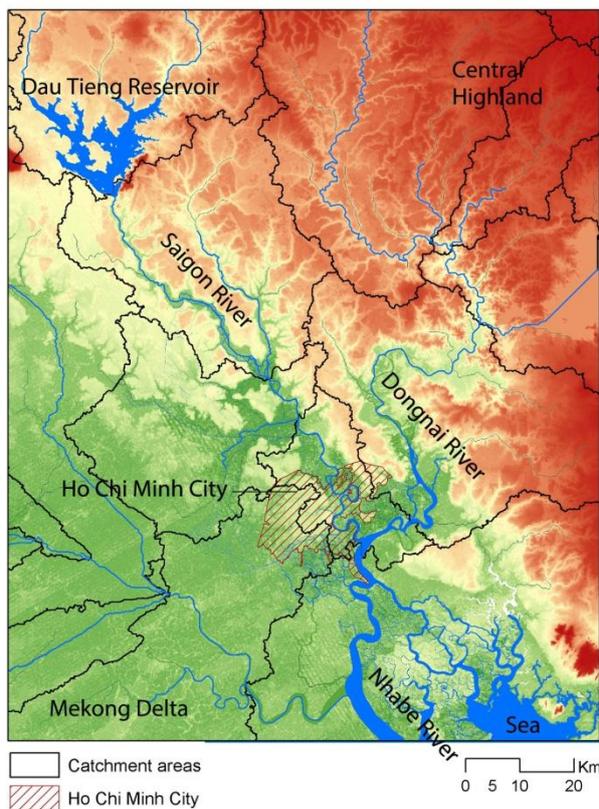

Figure 1: Topography and stream networks in Ho Chi Minh City region. Cartography by the author;

concentrated in the wet season that usually ranges from May to November. This period also coincides with high tide season (Ho 2008, Luong 2009), causing floods in the city.

Ho Chi Minh City is at high risk of inundation caused by heavy rainfall, upstream discharge and high tides. Over 60% of the provincial area has a 1.5-meter elevation or lower, while daily average peak water elevation on Saigon River rose quickly, as high as 1.58 m recorded on November 26, 2011 (Vnexpress 2011). Since the 1990s, floods have occurred all over the city with increasing frequency (Ho 2008). A report in 2006 revealed that a total of 35 sqkm of urbanized area and 230 sqkm of agricultural land had been flooded (Research 2006). In terms of the administration unit and population, 154/322 of wards and 1.8 million people, 28% of the city's registered population, are affected by floods (Research 2006, Management 2010).

High tides and extreme rainfalls are usually blamed for causing inundation (Truong 2008, Luong 2009). Data, however, show that peak the water elevation of Saigon River in Ho Chi Minh City segment has increased at a much faster rate than those upstream or along other rivers in Saigon-Dong Nai River basin and has no statistical correlation with peak sea-level, which in average has slightly decreased in the last 20 years (Ho 2010). Base on this statistical analysis, Ho (2010) hence concludes that urban flooding in Ho Chi Minh City is a product of local processes instead of global climate change. One question thus arises among researchers and in the public that if the fast-paced urbanization in Ho Chi Minh City is the cause of the dramatic hydrologic change of Saigon River. However, no empirical study has been done on the relationship between the size of impervious surface in particular and urban growth in general and the hydrologic change.

Saigon River begins in the highland of Loc Ninh, near Vietnam-Cambodia border. The river then flows downstream along the western boundary of Binh Duong before entering the territory of Ho Chi Minh City [Figure 1]. In Dau Tieng District of Tay Ninh Province, the river is dammed to create Dau Tieng Reservoir, whose functions are flood control and irrigation for agricultural production in Ho Chi Minh City region. Dau Tieng Reservoir usually discharges into Saigon River during the months of October and November. For the rest of the year, water elevation of Saigon River is influenced mostly by semi-diurnal tidal, which change four times a day (Truong 2008). Besides tidal influence, flows volume of Dong Nai River also contributes significantly to the variation of water elevation on Saigon River (Ho 2010).

The city has a tropical monsoon climate with wet and dry seasons. The average annually precipitation is as high as 2000 mm (Office 2010). However, rainfall distributes unequally throughout the year. Over 90% of annual rainfall is

While an understanding of the impact of impervious surface in term of land area on hydrology is important, this knowledge may not be sufficient to contribute to planning and design interventions in Ho Chi Minh City. For such a dense urbanism in Ho Chi Minh City, there is little space to be converted into permeable surface. Even if we can reduce impervious surface in Ho Chi Minh City, the impact of urbanization on hydrology may not change significantly, since the groundwater table in the region is high and thus the infiltration capacity of the soil is low (Ho 2012). Therefore, the fundamental question to the city's planners is not only about the size of impervious surface, but also what kind of shape, pattern, and dispersion of impervious surface patches which do the most and the least harm to the hydrologic system.

2. Landscape ecology and the study of urban form - hydrology interrelationship

The relationship between urban development and hydrologic performance has studied heavily (Booth 1991, Arnold Jr and Gibbons 1996, Paul and Meyer 2001, Alberti, Booth et al. 2007). Literature on this subject summarizes this relationship in three aspects. First, the pavement of land surface and soil compaction due to buildings and infrastructures reduce the infiltration rate and thus increase surface run-off significantly (Alberti 2008). Second, compacted, stripped and paved soil has lower storage capacity so that even if infiltration rate of land surface is maintained, the soil reaches saturated state at a much faster rate (Booth 1991, Arnold Jr and Gibbons 1996). Therefore, urbanization generates more run-off and causes storm-water overflow. Third, urbanization alternates natural drainage with artificial ones that allow storm-water to flow fast and intensively in paved and straighten channels (Arnold Jr and Gibbons 1996, Alberti 2008). These modern modifications of natural drainage system increase the peak flow, transport more storm-water downstream and reduce the lag time to reach peak volume. The artificial drainage system thus ultimately causes flooding downstream.

In these studies, urban development is merely represented by aggregate measurements such as impervious area. However, landscape ecologists have made an important argument that not only aggregate characteristics of a city's urbanized area such as total impervious area and population density but also the structure and urban form pattern of that city affect the hydrologic condition (Whitford, Ennos et al. 2001, Alberti 2005, Greve 2012). In the last ten years, landscape ecologists and planning scholars have tried to quantify the relationship between urban form and ecological performance (Alberti 2008). The study conducted by Alberti, Booth et al. (2007) show significant statistical relationships between spatial configurations of urban pattern and streams' ecological conditions throughout 42 sub-basins of Puget Sound basin in Washington State [US]. Studying the same basin, Greve (2012) finds linear relationship between the fraction of the year that annual mean discharge is exceeded and Floor-Ration-Area, lot coverage, and dwelling unit density. The fraction variable also has strong inverse relationship with Aggregation Index of high-and-medium density urban areas. Schueler (1994) and Klein (1979) generalize the impervious surface percent as a major indicator of aquatic health of the ecosystem: 10%-30% indicating

'impacted', and 30%-100% 'degraded' condition. Recent study by Olivera and DeFee (2007) on the impact of urbanization over hydrological changes reaffirms the significance of impervious surface and its 10-percent landscape threshold of an ecosystem to maintain its hydrologic function.

3. Research design

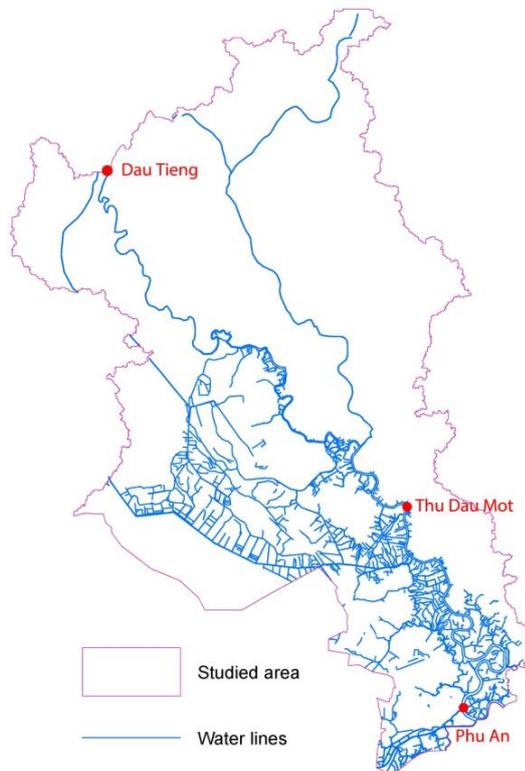

Figure 3: Stream network in the studied area which is defined by the catchment area along Saigon River and between Dau Tieng Reservoir and Phu An hydrologic station.

region. There are 2 rationales for this selection:

- **Spatial extent of urban and hydrological changes:** The research is focused on area along Saigon River in Ho Chi Minh City and Binh Duong province where rapid urbanization and hydrologic changes are observed. Saigon River forms the backbone of the area of which its northern edge is defined by Dau Tieng Reservoir and its southern edge by urban districts of Ho Chi Minh City. More importantly, upstream inlet of Saigon River is controlled by Dau Tieng Reservoir which discharges only few times a year, and the downstream outlet flow is measured by Phu An Station of which data is accessible to the public [Figure 3].
- **Intervention possibility:** Understanding the connection between human activities and, hydrological changes at this metropolitan scale is critical. It is because there is clearly a window for policy intervention and recommendation since the city administration is under pressure to take immediate actions to address flooding problem and future climate change challenges.

Temporal scale of analysis: This research is focused on the 1990-2010 period when Ho Chi Minh City region experienced rapid population growth and dramatic hydrological change and thus the impact of urbanization on water system are observable. In addition, Dau Tieng Reservoir was only completed in 1989 and thus made the studied area hydrologically independent from upstream storm events.

Three following research questions will be addressed in this paper:

1. How has Ho Chi Minh City metropolitan area grown from 1990 to 2010, particularly in hydrologically sensitive areas: wetland, low land, and upstream?

2. How has the form of Ho Chi Minh City metropolitan area evolved over 20 years period, from 1990 to 2010, when the city experienced rapid population growth?

3. How do these changes of the urban form affect the hydrological regime?

Hypothesis: The overall hypothesis of this paper is that the change in landscape composition and spatial configuration and the dispersion of urbanized areas in 1990 - 2010 period cause negative impacts on hydrological regime. I also speculate that a ratio of incremental water elevation between Phu An and Nha Be over the regional average precipitation can be an alternative indicator of hydrologic performance while run-off data is unavailable.

Spatial scale of analysis is 2503 sqkm of Saigon River Basin which contain the most developed area of Ho Chi Minh City metropolitan region.

Hydrologic data: There are 2 hydrological stations on Saigon River in the studied area, Thu Dau Mot station locating in Binh Duong province and Phu An station in Ho Chi Minh City's downtown [Figure 3]. These stations record only water elevations per hour. There is no data on flow quantity available due to the complication of measurement caused by diurnal tide. In addition, there are 2 nearby stations: Nha Be locating downstream on Nha Be River into which Saigon River empties, and Vung Tau in the coastal city of Vung Tau to record sea-level. Boundaries of watersheds within Ho Chi Minh City jurisdiction are provided by Center for Water Resources and Climate Change [National University of Ho Chi Minh City]. The data take into account hydraulic system and man-made topography in defining watershed boundaries. Boundaries for upstream watersheds are delineated from NASA SRTM Digital Elevation Model data [90-meter resolution] using ArcGIS.

Year	Data source	Major Satellite	Major acquisition date	Band used	Cell size
1990	USGS GLS	Landsat 5	1/16/1989	2,3,4	30.0
1993	USGS Landsat Pr.	Landsat 4	2/4/1993	1,2,5	30.0
1996	USGS Landsat Pr.	Landsat 5	2/21/1996	3,5,6	30.0
2000	USGS GLS	Landsat 7	11/6/2000	2,3,4	26.9
2002	USGS Landsat Pr.	Landsat 7	2/13/2002	2,4,5	26.9
2005	USGS Landsat Pr.	Landsat 7	1/4/2005	1,2,4	26.9
2010	USGS GLS	Landsat 5	12/9/2009	2,3,5	26.9

Table 1: Satellite Data Sources and Characteristics. Source: USGS Earth Explore.

Development Data: To compare development states over a 20-year period, it is fundamental that data have the same resolution and level of details over time. Therefore, the author decides to use Landsat Global Land Survey [GLS] dataset and other Landsat data which covers the entire world and accessible to the public. This satellite imagery contains multi-spectral and multi-temporal information that allows different image classification purposes and land-cover comparison over time. For the purpose of this research, the author use GLS Enhanced imagery of 1990, 2000 and 2010 and original Landsat 4, 5 and 7 images of 1993, 1996, 2002 and 2005 respectively [Table 1].

4. Measurements

4.1. Urban form measurement

To measure urban and landscape's spatial configurations, one basic unit is patch. Patch is defined as a nonlinear discrete area of relatively homogeneous environmental conditions and is relevant to a given organism or an ecological phenomenon (Forman (1995), p.39; Alberti (2008) p.100). Patch characteristics are important to the understanding of ecological processes because size, shape and dispersion of patches affect ecological regeneration and succession (Forman, 1995). Saigon Basin contains 5 major types of patches: built-areas, bare soil, vegetation, wetland and water.

Using image classification tool in ArcGIS and Landsat satellite data, landcover raster data, which contain different compositions of 5 landscape patches in 1990, 1993, 1996, 2000, 2002, 2005, and 2010, are produced [Figure 4]. Among these landscape components, only urban patches are investigated in this research. Although spatial configurations of landscape patches such as vegetated areas, wetlands and water-bodies also affect hydrologic performance, they are not included in this research due to their seasonal variations caused by agricultural activities and monsoon rainfall. The urban components of landscape composition are then separated into single-value raster data for further analysis.

Base on literature review, we select 5 metrics [Table 2] to measure urban form or spatial configurations of urban patches that relate to their impacts on hydrologic performance. Except compactness, all metrics are calculated in FRAGSTATS Software using its pre-defined formulas [Table 2]. The results of calculation are presented in Table 3.

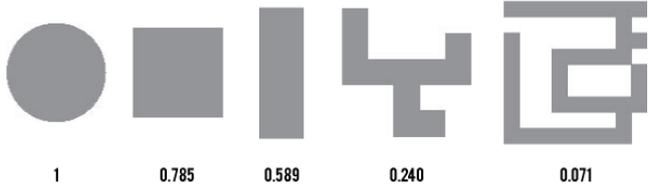

Metrics	Formula	Explanation
<p>SIZE: Total size [CA] [hectare]</p>	$CA = \sum_{j=1}^n a_{ij} \left(\frac{1}{10,000} \right)$ <p>a_{ij} = area of patch ij</p>	<p>CA and PLAND comprising a landscape mosaic are perhaps the most fundamental measurements of the spatial extent of urban development and its impacts on hydrologic system.</p>
<p>SIZE: Landscape percentage [PLAND] [%]</p>	$PLAND = P_i = \frac{\sum_{j=1}^n a_{ij}}{A} (100)$ <p>P_i = proportion of the landscape occupied by urban patch. a_{ij} = area of patch ij. A = total landscape area</p>	<p>Since PLAND is a relative measure, it may be a more appropriate measure of landscape composition than total area for comparing among landscapes of varying sizes. Previous studies affirm that landscape percentage of urbanized patches can determine ecosystem's capability to maintain its hydrologic function (Arnold Jr and Gibbons 1996, Olivera and DeFee 2007).</p>
<p>SHAPE: Compactness [K]</p>	$K = 2\sqrt{[\pi CA/10,000]}/TE$ <p>CA: Class area [hectare] TE: Edge length [m]</p>	<p>K is ecologically meaningful for the urban patch form because it concentrates the built area in a more enclosed form and conserve land for the ecosystem's hydrologic functions such as retain and filter storm-water run-off (Yang 2007).</p>
 <p>An example of urban patch shape and corresponding compactness scores.</p>	 <p>An example of complex urban edge in an unplanned settlement north of Ho Chi Minh City.</p>	
<p>SHAPE: Fractal [D]</p>	$D = \log CA / \log TE$ <p>CA: Class area [hectare] TE: Edge length [m]</p>	<p>D is the measurement of edge complexity. The implication of Fractal dimension of urban form in regarding to hydrologic performance is not yet known. Greater fractal value could mean an increase of accessibility to natural landscape for urban run-off, and thus a reduction of peak volume and flow velocity.</p>
<p>DISPERSION: Aggregate index [AI]</p>	$AI = \left[\frac{g_{ii}}{\max \rightarrow g_{ii}} \right] (100)$ <p>g_{ii} = number of like adjacencies between pixels of urban patch. $\max \rightarrow g_{ii}$ = max number of like adjacencies between pixels of urban patch.</p>	<p>AI measures the probability that urban patches are adjacent to each other throughout a landscape. Previous studies confirm that aggregated urban area has a negative impact on stream conditions and result in higher storm-water discharge volume (Alberti, Booth et al. 2007, Greve 2012).</p>

Table 2: Variables and metrics to measure urban patch configurations. Formula Source: Mcgarigal, Cushman et al. (2002) and Forman (1995);

Results: In 20 years, from 1990 to 2010, Saigon River Basin has experienced an unprecedented increase of impervious surface in terms of the total land area, landscape percentage, and the number of patches, regional distribution, and low land occupation. Base on the classification of Landsat images, a spatial evolution of urbanization process in the Basin is drawn out [Figure 4, Figure 5 & Table 3].

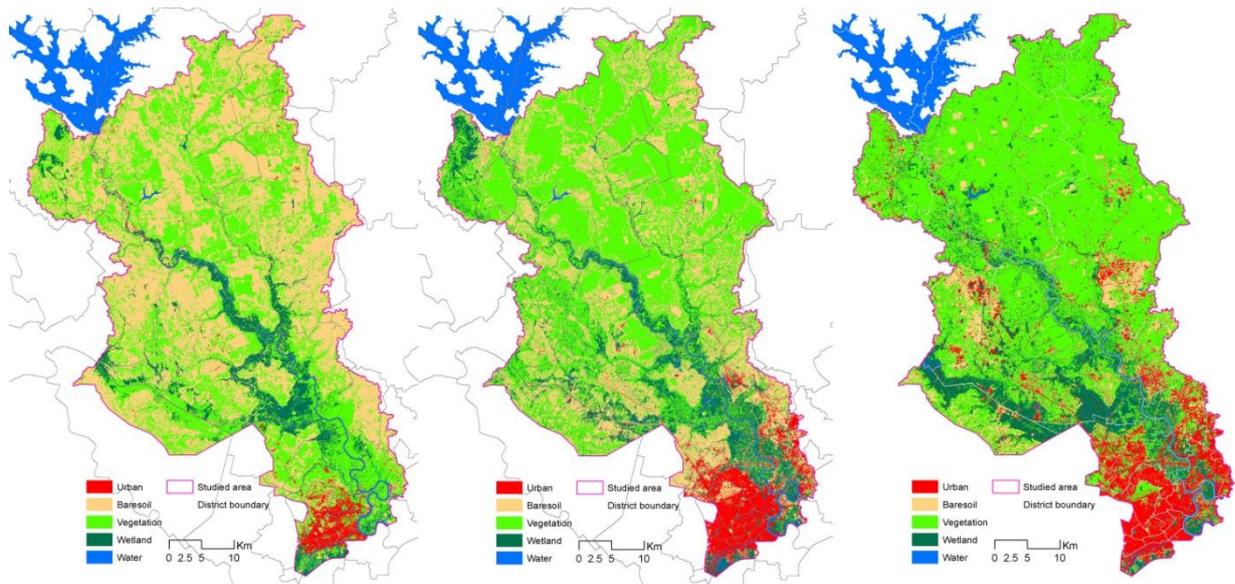

Figure 4: Landcover of Saigon River Basin in 1990, 2000 and 2010.

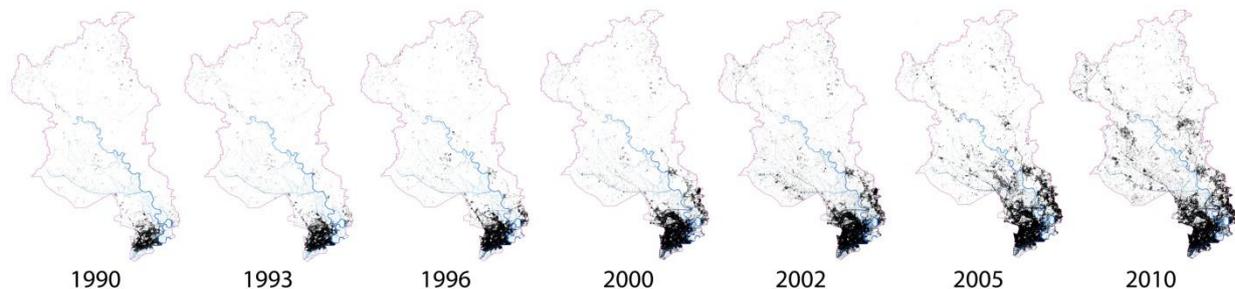

Figure 5: The expansion of urban patches in Saigon River Basin from 1990 to 2010.

In general, impervious surface or urban land cover has increased from 67 sqkm or only 2.69% of the Basin landscape in 1990 to 296 sqkm or 11.80% in 2010. Thus, impervious surface expanded by 4.4 times. Within the same period, the population was estimated to increase approximately 2.2 times only. In addition, over 44 sqkm of low land [below 1.3 meter] had been drained out to build housing and factories. As a result, the settlement area below flooding alarming rate III [1.3 meter] increased by almost 400%. Urban development also occurred in the upstream catchment area of Saigon River, especially in Binh Duong Province. About 70 sqkm of land here were urbanized from 1990 to 2010. The greatest rate of urbanization usually found in 1996 to 2010 when we also observe significantly increasing trend of Saigon River's water level. In total, 229 sqkm of agricultural and wetland were converted into impervious surface within 20-year period.

The urbanized areas in Saigon River Basin were not only changed in term of size, but also in term of shape and dispersion. Overtime, the compactness of the Basin's urban areas as well as Ho Chi Minh City urban area had been reduced from the score of 0.11 and 0.043 in 1990 to 0.07 and 0.026 in 2010 respectively. Figure 6 explains the decrease of the city's compactness as the result of urban developments, perhaps unplanned ones, along major transportation corridors such as Highway No.1 and No. 13 in the outskirts of the city – a popular phenomenon in Vietnam due to the limit access to basic infrastructure in rural areas far from transportation corridors. In contrast to the Compactness Index K, Fractal measurement D in general increased slightly during the 20 years of urbanization following a sine curve. The K value increased from 1.27 in 1990 to 1.32 in 2010. The increase of Fractal dimension might reflect the increasing dominance of informal developments along the urban edge during the 20-year period.

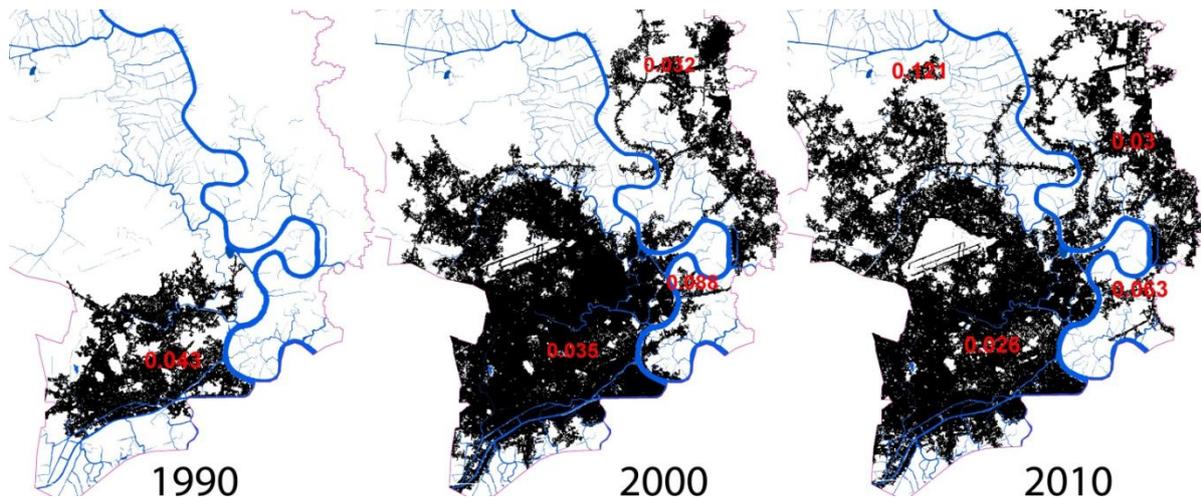

Figure 6: Compactness scores of Ho Chi Minh City urban area.

Year	Unit	1990	1993	1996	2000	2002	2005	2010
[CA]	hectare	6739.7	7177.4	10665.5	16038.1	20581.3	25077.5	29530.0
[PLAND]	%	2.69%	2.87%	4.26%	6.41%	8.22%	10.02%	11.80%
[K]		0.11	0.25	0.17	0.12	0.07	0.09	0.07
[D]		1.27	1.31	1.28	1.31	1.30	1.32	1.32
[AI]	%	70.3%	87.4%	85.0%	82.3%	74.2%	81.8%	76.7%

Table 3: Results of 6 metric calculation using FRAGSTAT software.

On the other hand, urban areas were transformed to a more aggregated distribution in the basin. Aggregation Index was first increased from its lowest value in 1990 [70%] to its highest value in 1993 [87%]. This dramatic change could be explained by an intensification process inside existing urban patches that filled the gap between separate patches and reduced the total number of patches in the Basin. From 1993 to 2010, the Index was gradually decreased from 87% in 1993 to 77% in 2010 as urban development occurred outside the existing urban cores.

4.2. Hydrologic performance measurement

Measuring the hydrologic change in Ho Chi Minh City is a challenge. Due to the dominant influence of South China Sea' semi-diurnal tide on Saigon – Dong Nai River Basin, stream flow direction at Phu An station on Saigon River changes four times a day, making it extremely difficult to measure downstream flow volume. Thus, there is no flow quantity and no run-off data collected in the region. To measure the hydrologic performance of the basin ecology, an alternative indicator, so-called *hydrologic index*, is used. *Hydrologic index* is measured by the ratio of water elevation at Phu An after removing external influences [i.e. tidal and discharge from Dongnai/Nhabe River] influence and the precipitation depth. The larger the hydrologic index is, the more run-off volume produced per unit of rainfall. The index thus strives to reflect hydrologic change by resembling run-off coefficient concept in hydrology. The urbanization of Saigon River Basin is expected to increase the hydrologic index overtime and thus, raise water elevation of Saigon River beyond the tidal-influenced levels.

To remove the tidal influence on Phu An water elevation, we simply subtract hourly water elevations at Phu An by Nha Be water elevations recorded one hour earlier [Figure 9]. Nha Be records are of downstream with strong tidal influence. More importantly, Nha Be elevations are statistically correlated with [significant at the level 0.01] and predict 94% [$R^2 = 0.9377$] of Phu An records. The variation of water elevation at Phu An from the influence of water level of Nha Be river should be a result of rainfall and hydrologic performance of the

landscape within the studied boundary. One-hour time lag is applied to take into account the time needed for water to travel between the two stations. Additionally, to minimize the inclusion of upstream discharge, to further lessen the tidal influence and emphasize the precipitation's influence on water level, the author selects only data collected in rainy days of July to calculate water-elevation difference.

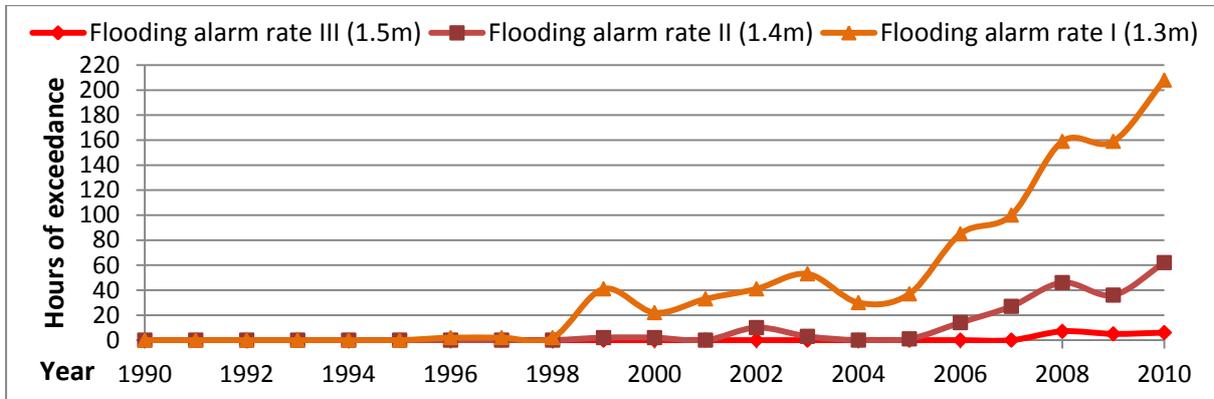

Figure 7: Number of hours of exceedance of 3 flooding alarm rates recorded at Phu An station in 1990 – 2010 period. Data source: Ho Long Phi 2012.

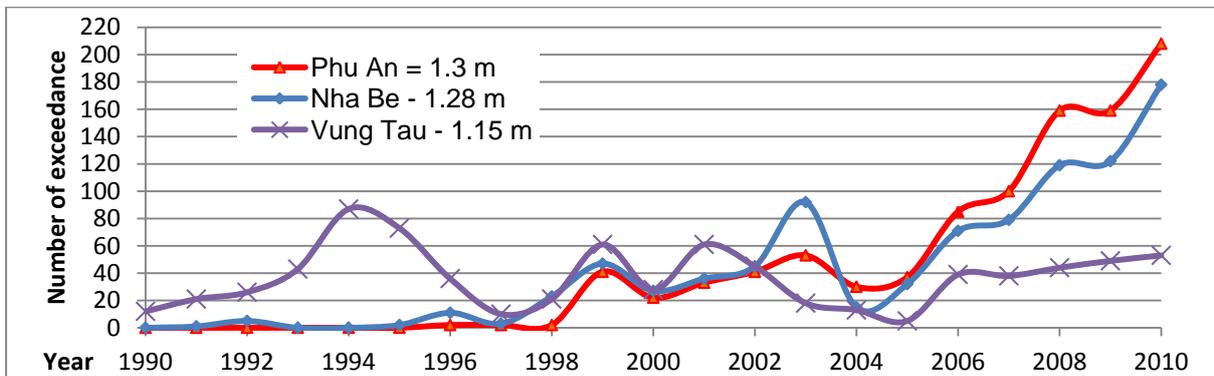

Figure 8: Number of exceedance of X thresholds recorded at Thu Dau Mot, Phu An, Nha Be, and Vung Tau for 10-year water elevations. Data source: Ho Long Phi 2012.

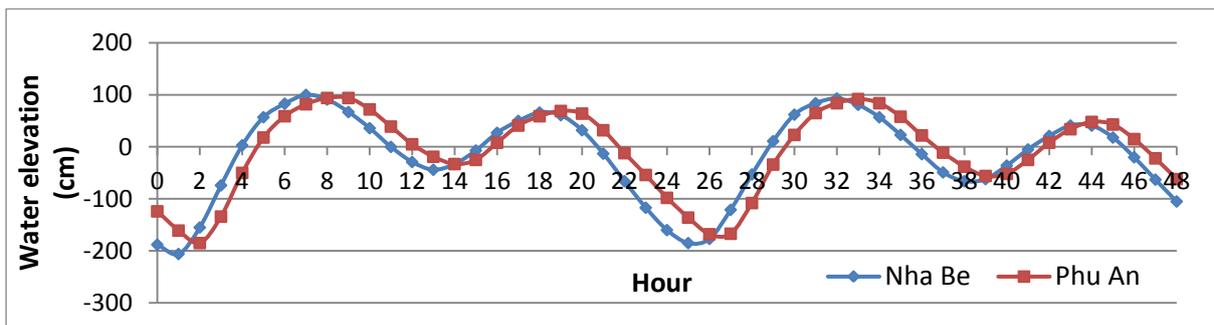

Figure 9: Water elevations recorded at Nha Be and Phu An station within 48 hours from July 7th to 8th of 2000. The graph shows the one-hour gap between Nha Be and Phu An records. Data source: Ho Long Phi 2012.

Furthermore, for the easy of calculation, the regional rainfall depth is estimated as an average of daily precipitation data collected from three stations in July: Tan Son Hoa near downtown area, Hoc Mon and Cu Chi in rural districts north of the city. The regional precipitation value is then tested its correlation with water-elevation difference between Nha Be and Phu An to examine whether the water-elevation difference is a function of rainfall. The test result proves that water elevation difference variables and average July rainfall are correlated at the significant level of 0.05 and a coefficient of determination at $R^2 = 0.21$.

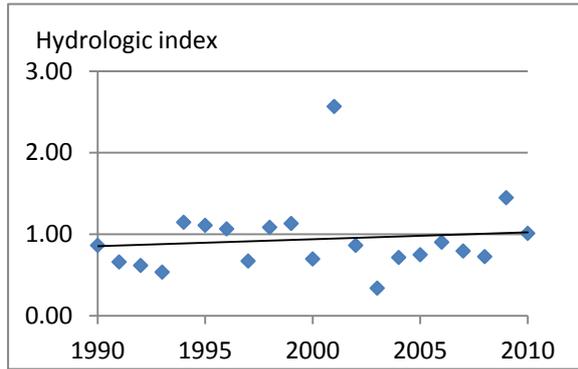

Figure 10: Hydrologic index during the 20-year period.

Results: The number of hours of exceedance of the water elevation beyond flooding alarm rates demonstrate the overall hydrologic change of Saigon River [Figure 7]. Before 1998, there was barely any exceedance. At the beginning of 1999 – 2010 period, number of exceedance hours beyond alarm rate I suddenly increased to 41 hours per year. For the rest of this period, the number of exceedance hours increased at an average rate of 14 hours per year. This is very serious since at Rate I, over 1425 sqkm [55.9 sqkm of urbanized area] of Ho Chi Minh City territory will be at risk of inundation. In term of urban influence, the urbanization of

Saigon River Basin is expected to increase the hydrologic index over time and thus, raise water elevation of Saigon River beyond the tidal-influenced levels. This phenomenon is reflected in the overall increasing trend of hydrologic index at Phu An station from 0.86 in 1990 to 1.01 in 2010 [Figure 10].

5. Urban form evolution & hydrologic change

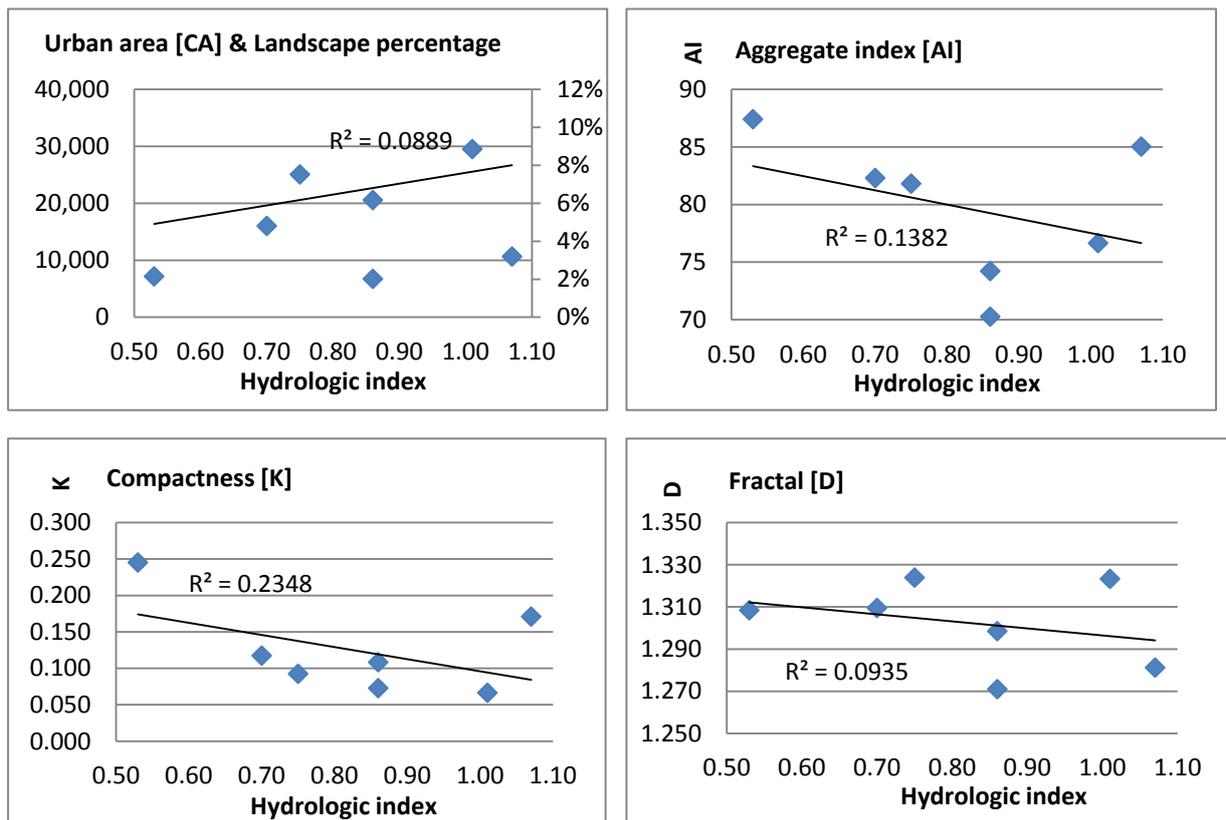

Figure 11: Potential relationship between urban form metrics and hydrologic performance.

To assess the potential relationship between urban form variables and hydrologic condition, each variable is plotted against the hydrologic index. Due to a small data population size [7 observations of each variables during 20-year period], a regression operation to delineate the relationship between urban form configurations and hydrologic index is not applicable. Instead, this relationship is examined through simple arithmetic equations.

The relationships between the measurements of urban form in term of size, shape and dispersion and the hydrologic index resonate the findings in the literature. The hydrologic index, which demonstrate run-off coefficient, is a converse function of the total area and landscape percentage of urban patches but an inverse function of compactness, fractal, and aggregation index.

Assuming these relationships are statistically significant as found in the literature, we can have some critical observations. First, while the size of impervious surface still matters, it is not an important predictor of hydrologic performanceⁱⁱ. This is logical since the Basin has high ground water level and low infiltration rate (Ho 2012). Compact and concentrated urban growth, which means higher Compactness and Aggregation Index, will also lessen hydrologic index and reduce flood threat for the region. In other words, we may expect that a fragmented and dispersed regional urban form will have negative impacts on hydrologic regime. Lastly, Fractal, the measure of boundary complexity, informs that straight and simple urban edge is unhealthy for flow regime. However, this shape dimension has a very low predicting power of the hydrologic index.

6. Conclusion

With limited data availability, this research is aimed to explore the evolution of urban form and its hydrologic impact in Saigon River Basin by quantitatively spatial analysis. The research shows the potential of landscape ecological analysis to explore the interaction between the built and natural environment at regional scale. The result of the research, though lack of statistical confirmation, echoes findings in the literature and layout some potential planning solutions for the rapid growing and vulnerable Ho Chi Minh City: a compact and aggregated metropolitan area will be a more hydrologically resilient one as well.

Furthermore, while other spatial urban compositions such as population density, road density, or floor-area-ratio are the determining factors of storm-water run-off, they are not included in this study due to lack of data. Urban form is a complicated aggregation of many spatial dimensions. It is impossible to comprehensively measure or represent urban form in few metrics. Therefore, there is a clear need for further research to continue exploring the measurement of urban form and its potential hydrologic impacts.

Ultimately, urban flooding of Ho Chi Minh City is a multi-faceted problem to which tidal variation, regional hydrologic system, extreme rainfall, upstream discharge and rapid urbanization may all have contributed significantly. However, for a more comprehensive understanding of the causes of the hydrologic change in Ho Chi Minh City, it is critical to have a better data collection, particularly the data on run-off quantity, an accurate watershed boundary. If those data are available, the same methodology demonstrated in this research can be applied with a larger pool of spatial dimensions which will uncover the connection between urban forms and hydrologic flows and unveil spatial solutions for current and future flooding challenge.

ⁱⁱ Perhaps, the amount of wetland and water areas, both seasonal and permanent, converted into urban development may be a better predictor of hydrologic performance in Saigon River Basin. These areas, however, can only be detected fully in the wet season when Landsat images of the Basin are covered with clouds.

Planning beyond the boundaries: Perspectives on the challenging intergovernmental collaboration towards a sustainable regional governance in Indonesia

Mahesti OKITASARI, Tetsuo KIDOKORO, The University of Tokyo, Japan

1. Introduction

Cities and regions are rarely stagnant, especially during the fast-paced development stage in the growing economy such as Indonesia. In the past decade, governments in Indonesia have been struggling to cope with growing urban problems as urbanization spilled over the city administration boundary. With urban problems are getting more scaled up to the regional level as well as increasing demand in urban service and the lack of sources available, collaborative governance has become an important strategy. Collaborative forms, such as partnerships and networks, are emerging in many urbanized cities in Indonesia. While collaborative movements have been popular in the developed countries for the past several decades, it is considered as a new initiative in Indonesia.

Managing cities during the rapid urbanization is not the only challenging issues for Indonesian governments and planners. Following the regional autonomy on fiscal and administrative policy enacted in 1999, Indonesia experienced a sudden transformation from centralized to decentralized system. 15 years after this big-bang decentralization policy, not only the local and regional planning system that undergone rapid and multiple changes but also the collaborative governance system. In looking over the array, it is no surprise to find that the institutional structure of regional governance has also undergone restructuring. With the shift in intergovernmental relations gone is the once dominant principle of authority-based, hierarchical organization that was central pre the decentralization. Yet the replacement is not necessarily the other ideal type of institutional form of delivery. In one side, the new policy was deemed successful to make government closer to the people by empowering the local governments, but it has also largely contributed to the inward-looking behavioral orientation of these local governments. In this sense the government has responded in many ways to maintain their newly acquired autonomous power while minimize their operational expenses and maximize their service coverage. Some have kept their intergovernmental collaboration or have decided to steer away toward contract arrangements with nonprofit and for-profit organizations. And, some have tried a mix of both.

Building on a debate about the challenging nature of the collaboration, the paper argues that conceptualize, measure and compare cases of intergovernmental collaboration will bring another step towards understanding the different approaches for enabling regional governance to cope with contemporary Indonesia. It aims to draw the reasoning why one local government decides to exercise a certain type of collaborative arrangement while the other chooses different type. In order to explore this potential the paper starts with an analysis of intergovernmental relations using a dimensional approach to measure the vertical and horizontal structure of Indonesian regional governance. To limit the scale of collaboration, this paper will focus on collaborative activities in providing urban service taking place in the metropolitan area. The paper also identifies the establishment and transformation of intergovernmental collaboration to draw a clear overview of the collaborative mechanism. Time series based analysis of local fiscal power diffusion index is examined to bring the reasoning from financial context.

This paper is divided into five parts. The first part revisits the relevant literatures on regional governance and intergovernmental collaboration, drawing from theoretical perspectives and

international experience. The second part introduces the Indonesian intergovernmental collaborative mechanism. The third part explains the methodology used in this research, a taxonomy of the metropolitan region and fiscal decentralization index that both have been modified to suit the Indonesian context. The fourth part covers the result of the analysis and elaborates discussion on its implication to regional governance policy. The concluding part offers a contribution to further research in collaborative governance in general and in Indonesia.

2. Intergovernmental collaboration

Governance is a topic that has long been studied by organizational scholars both in the business firms and the nonprofit context (Mizuchi, 1983; Fama and Jensen, 1983; Provan, 1980). Concern about governance and collaborative activities among city's stakeholders have produced some of the most important and enduring questions in the field of political science, planning and public administration. A lot has been crafting the conceptual tools needed to decode the process of governance (Olson, 1965; Ostrom, 1990, 1998). Within the smaller context, recent research in collaborative governance basically focuses on the two branches, intergovernmental collaboration which represents the long-standing tradition of government cooperation within the public system (Conlan, 2006; Gough, 2008) and cross-sectoral collaboration which goes beyond the implicit delegation of authority sharing that occurs with outsourcing of government service delivery (McGuire, 2006; Agranoff and McGuire, 2003; O'Leary et al , 2006).

The need to address pressing regional problems without having renounced autonomy or created concentrated power calls for intergovernmental collaboration or to some extent collaborative governance across sectors. This type of decentralized approach to regionalism emphasizes self-governance through horizontally and vertically linked organizations. On this issue, collective action theory provides the building blocks to understand a system of metropolitan governance without a metropolitan government (Feiock, 2004). This theory posits that local governments can act collectively to create a civil society that integrates a region across multiple jurisdiction through a web of voluntary agreements and associations and collective choices. Investigations of successful collaboration among decentralized actors challenged with common-pool resource issues provide a useful starting point for understanding how collaboration can be forged among local actors (Weber, 1998; Lubell et al, 2002). The recent study by Luo and Shen (2009) provided many insights on the building of collaborative research especially regarding the formation process of collaboration and actor partnership. Other research focuses on investigating how collaborative network is formed (Heeg et al, 2003; Provan and Kenis, 2007) as starting point to analyze the process of collaboration.

While research in planning stresses the value in intergovernmental collaboration, there is little attention paid to the factors that form and sustain collaborative relationships for planning. Even less research acknowledges why local government decides to exercise intergovernmental collaboration instead of cross-sectoral collaboration or vice versa. Understanding the collaborative arrangement characteristics and formation is undeniably an imperative step to have a clear idea of government's collaborative preferences. This is important due to the political nature of planning and the complexity of the decision making process that demand collaborative problem solving. However as much as understanding the formation and process of collaboration is important, the pressing challenge is to move away from describing processes and behaviors or focusing on how actors function within the network and examine the whole system in greater depth, including how they are governed, is needed. The question on how each collaboration comes into its specific governing form has not yet much explored. Addressing this issue will help governments to choose the most proper collaborative arrangement that suit their situation and help to improve the current

system. Thus examine how the system as a whole network works through measuring the collaboration and observing the dynamics that inter-dimensional interactions are generated (Miller and Lee, 2009) becomes important.

Table 1: A typology of collaborative governance.

	Limited partnership	Hierarchical partnership	Hybrid partnership	Voluntary partnership
Mobilization	Either higher-level or local/subordinate government	Higher-level government	Both higher-level government and its subordinate government	Local government
Mechanism	No regulation/ from higher-level government	Regulation from higher-level government	Both mutual interest and state regulation	Mutual interest
Actors	Higher-level government as provider, less participation from subordinate	Government at higher levels as leader, subordinate government, academics	Governments at various levels, other actors	Governments, NGOs, private sectors, academics
Role of higher-level government	Moderate	Greatest	Great	Small
Goal consensus	Low	Low	Moderate	High
Trust	Low	Low	Moderate	High
Degree of dependency towards higher government	Moderate	High	Moderate	Low
Need for network competencies	Low	Moderate	High	Low

Source: Reconstructed from Luo and Shen (2009) and Provan and Kenis (2007).

In spite of the multitude of empirical research on governance, current research on intergovernmental collaboration in Asian context is still limited, far behinds its counterpart in the United States or European countries. There has been yet research regarding Asian intergovernmental collaboration which delves into the structural differences of each collaborative arrangement as a whole or takes into detail conceptual clarity to distinguish its pattern of collaboration. The current literature mostly focuses on identifying micro aspect of collaboration such as effectiveness, mobilization and historical formation (Luo and Shen, 2009; Firman, 2010; Zul Fahmi et al, 2010).

3. Indonesian intergovernmental collaboration: Background and challenges

Indonesian government's first efforts to establish an intergovernmental collaborative arrangement in planning were started in the late 1970s with the formation of a development coordinating body in Jakarta. It aimed to collaborate development occurred in the Jakarta metropolitan region and considered as a coordinating initiative, as a necessary ability to play their role in controlling the implementation is missing. During the span of more than twenty years, the first initiative in Jakarta is only replicated in a few other metropolitan regions across the country. Intergovernmental collaboration then started to emerge again following the enactment of the decentralization act in 1999. Various types of collaborative arrangement, range from intergovernmental to contracted collaboration, is practiced due to different economic development, political situation and governmental culture as a result of Indonesian nature as an archipelago country with a number of tribes, language and culture. Since the Indonesian system does not recognize a supra-local level government there is no formal and rigid structure of governance in the metropolitan region to frame how, why, when and where local governments engage in their rational action with each other. With all of these fragmented attributes between distinctive and often opposing urban system, it is difficult if not impossible to put one single type of intergovernmental collaboration to provide the basis for lasting regional partnership, resurgence of planning, planning effectiveness and relationship.

Table 2: Transformation of Indonesian intergovernmental collaboration

Metropolitan region	Initial	Present
<i>Mobilization of the collaborative arrangement</i>		
Jakarta	Top-down (provincial) – top-down (central) – top-down (provincial)	
Surabaya	Top-down (provincial)	Top-down (provincial)
Yogyakarta	Top-down (provincial)	Bottom-up (local)
Denpasar	Bottom-up (local)	Top-down (provincial)
<i>Mechanism of the collaborative arrangement</i>		
Jakarta	Hierarchical partnership	Limited partnership
Surabaya	Hierarchical partnership	Limited partnership
Yogyakarta	Voluntary partnership	Voluntary partnership
Denpasar	Voluntary partnership	Hybrid partnership
<i>Type of network governance structure</i>		
Jakarta	Lead organization	Communicating
Surabaya	Lead organization	Network administrative organization
Yogyakarta	Shared partnership	Shared partnership
Denpasar	Shared partnership	Shared partnership
<i>Main partners for collaboration</i>		
Jakarta	Provincial government	Other local government, private sector
Surabaya	Provincial government	Other local government, private sector
Yogyakarta	Other local government	Other local government
Denpasar	Other local government, private sector	Provincial government, other local government, private sector

As can be seen from Table 2 above, three among four metropolitan regions observed transformed their collaborative arrangements at least once during the time from its mobilization to present time, albeit in various levels of changes. It also shows the tendency of local governments to shift away from the authority-based hierarchical type of partnership. With the local government gaining more power financially and administratively in developing their planning and infrastructure provision, the change is expected. While in the past planning is rather subjected to central government control, at present it becomes a local affairs. However, at some regions, the provincial government retained its position as the coordinating or mobilizing agency even after the decentralization. Denpasar, for example, shows interesting movement from a bottom-up type of collaborative mobilization towards a provincial based mobilization type of collaboration. It may occur due to the institutional capacity of provincial government in responding to the decentralization policy. The ability of provincial and local governments to respond to the decentralization has been considerably variable, depending on their capacity (Firman, 2010) and their relationship with each other. Maintaining and improving regional relations and capacities are quite challenging even without the sudden power gained by local governments and their unsurprising inward looking behavior. Under this circumstance, local governments are only interested in bargaining with the higher-level government to maximize their own interest while have less interest to collaborate with other cities, especially in delivering planning implementation. This fragmented attitude of local governments could be counterproductive with the objectives of the decentralization and has resulted in a number of problems in bigger scale service delivery which requires cross-border cooperation. The current regional collaboration mostly covers smaller scale of cross-border collaboration projects such as coordinating infrastructure projects planning along the border as observed in Jakarta and Surabaya. The problem with limited partnership is that implementation delivering heavily depends on the wistful intention of each local government in putting the project as their priority development.

Unlike Jakarta and Surabaya, the collaborative arrangements in Yogyakarta and Denpasar from the beginning were initiated by local governments not long after the decentralization law was enacted. For Yogyakarta case, it was then supported by the provincial government, making it essentially as a top-down type of mobilization with a bottom-up initiation. Even though prior to the establishment of the cooperating agency, the management of infrastructure development in the region was planned and implemented by the provincial government (Firman, 2010), gradually the provincial government only acts as a facilitating actor. The three local governments agreed to tackle regional infrastructure service provision

problem together by creating a common pool resource, including financial and personnel resources. On the other hand, collaborative arrangement in Denpasar is genuinely mobilized by local governments without any support from the central or provincial level government. From its mobilization, Denpasar already exercised both intergovernmental and cross-sectoral type of collaboration between local governments and private sector. Together, four local governments contracted their solid waste management's operational service to the private sector and cost shared the transportation service. After several years, Denpasar sees the growing interest from the provincial government in coordinating collaborative activities with the regional government starts to mobilize intergovernmental collaboration in another sector that has been tackled yet by local government such as regional transportation.

Looking over the changes taking place in each metropolitan region, even though some of them are heavily influenced by the new regionalism movement, it indicates that each local government has their specific consideration in adopting certain type of collaboration. Such outcomes imply that transformation happens due to certain situation experiencing by local government at certain moments. Now the question is how to learn from these changes and why it happens to improve collaboration for more sustainable regional governance. As basically collaboration based on relations among its actors, it becomes necessary to understand the structural relationship taking place behind those collaborative arrangements. Thus this study utilizes a dimensional approach to analyze the structural relationship and employs the fiscal power diffusion index to understand the fiscal-institutional structures of local government. The application of the fiscal power diffusion index makes it possible to explore collaborative policy questions and analyze the correlation between fiscal dependency and collaboration.

4. Methodology

4.1 Dimensional approach on regional governance

The main idea of metropolitan taxonomy done by Miller and Lee (2009) is analyzing all types of relations occurred among actors in dimensional perspectives; vertically and horizontally. It tries to capture both macro-foundational and micro-foundational studies of metropolitan regions in one taxonomy. The research defines the vertical dimension of metropolitan regions as the fundamental relationship between the state government and the constituent local governments within its jurisdiction. In the same sense that a city charter defines the structure of governance of the city, the general grant of authority from the state to local governments defines the vertical structure of governance for the region. It also describes the second dimension as horizontal and involves the fundamental relationships among the local governments within a metropolitan area. This dimension consists of three layers, one that involves the relationship between the local governments within a metropolitan area and captures the inter-organizational interactions within the public sector which closely related and sometimes can be referred to intergovernmental dimension. The second layer of the horizontal dimension involves the nature and pattern of relationship that exists within a metropolitan area between the local governments, the civic sector and the private sector. The third layer involves the relationship between the local governments within the region and regional institutions.

Figure 1: Dimensional model of governmental relations in Indonesia.

The first step to apply this dimensional-based approach to measure regional governance in Indonesian cases is by recognizing how the Indonesian system differentiates itself from the United States system. Vertically, the Indonesian system consists of central, provincial and local governments interacting in a hierarchical manner. The vertical dimension of the governmental structure can be divided into two layers; first that consists of the relations between central and local government and second that represented the relations between provincial and local government (please refer to Figure 1 for illustration).

The measuring instruments used for the analysis were retracted from the governance collaborative activities survey originally developed by Agranoff and McGuire (2003), including: joint-policy efforts, resource exchange, project based work, information seeking, and adjustment seeking. Weigh is added to the activities which more likely to involve interest accommodation or policy integration since these kind of collaborations represent an individual rational choice and norm of reciprocity that will promote voluntary cooperation (Axelrod, 1984) as well as surviving economic challenges and become the social capital that facilitated fast economic development (Putnam, 1993).

Table 3: Collaborative management activities

Vertical dimension		Weighted
Information seeking	New funding of programs and projects	
	Financial assistance	
	Policy guidance	
	Technical assistance	
	Review of plans/plan approval	
Adjustment seeking	Request resolution of conflicts with other local governments	✓
	Change in policy (flexibility)	✓
Horizontal dimension (intergovernmental and cross-sectoral relations)		
Joint policy efforts	Consolidate policy effort	
	Engage in formal partnership	✓
	Engage in the joint policy making	✓
	Engage in joint policy implementation	✓
Resource exchange	Pool/Share financial resources	
	Pool/Share personnel resources	
	Exchange information/share ideas	
Project based works	Partnership for particular project (planning, implementation)	
	Asset specificity and measurement (monitoring)	

A structured survey was conducted during two periods, from October to November 2012 and from May to June 2013. The survey targeted chief officers from the local development planning board and public works agency who responsible for planning and implementation for collaborative activities in their respective cities. The respondents were asked to check each activity they participate with various kinds of organization, including central and provincial government agencies, neighboring city agencies, state owned enterprises as well as private and civic sector. Respondent's experiences, accounts and opinions were documented through semi-structured interviews that were designed to encourage discussion about decision to collaborate with a certain actor.

Table 4: Summary of observed regions.

	Jakarta	Surabaya	Yogyakarta
Population (million) (2010)	26.6	9.1	2.4
Area (sq.km)	6,175	5,862	1,114
Density (per sq.km) (2010)	14,508 (core)	8,304 (core)	13,253 (core)
	2,874 (inner zone)	1,807 (inner zone)	1,902 (inner zone)
	3,621 (outer zone)	850 (outer zone)	1,798 (outer zone)
% Share of National GDP (2009)	24.0	7.2	0.7
Average GDP per capita (US\$) (2011)	8,185 (Jakarta only)	3,514	2,138
	3,202 (other cities)		
Number of local governments	14	7	3
Total respondent (collected)	18(16)	14(12)	6(6)
% Response rate	88.89	85.72	100.00

4.2 Fiscal power diffusion index

The fiscal power diffusion index (FPDI) used in this paper is extracted, generated and developed from fiscal decentralization model (FDM) used by Uchimura and Suzuki (2009) to meet the availability of data while adequate enough to explain the Indonesian situation. The idea is derived from an acknowledgement that decentralized governments are those that have more governing bodies making decisions on public services and has enough fiscal autonomy to implement their plan while more centralized governments have fewer governing bodies making the same decisions and more fiscal dependency to higher-level government. Unlike the metropolitan power diffusion index (Miller, 2002) which employs a single score that measures how many separate local-level governments in the United States provide common public services and how much each of those governments spends on providing those services, the FDM examines the intergovernmental fiscal relationship between higher and lower level of governments including the local expenditure responsibility and local fiscal capacity to show local governments' fiscal diffusion from higher-level government. The sole reason to use FDM as a basis for this study at this moment is mostly due to data constraint but the possibility to utilize MPDI for more comprehensive result is not closed.

The data used in FPDI address the present need for an adequate fiscal assessment in relation to local government fiscal dependency. Three major variables are used and all data are collected from 1998 to 2013 annual local government financial report issued by the Ministry of Finance to sufficiently cover the difference between before and after the decentralization era. The result is divided into four periods according to the year when a new fiscal balancing budget policy was issued, first period covers 1998 to 2000, second period (2000-2006), third period (2007-2010) and last period (20011-2013). The first period will give an overview of fiscal balancing power before the decentralization, the second will represent the situation of local fiscal power in the wake of decentralization and the last two will show the result of fiscal balancing policy update post-decentralization issued in 2004 (new fiscal decentralization act) and 2005 (new budget balancing regulation).

Table 5: Indicators for fiscal power diffusion index.

Indicators	Description
Local dependency on fiscal transfer	% fiscal transfer from central, provincial governments on local total revenue
Local fiscal autonomy	% local revenue compares to local total revenue
Local fiscal responsibility	% local expenditure funded by local compares to total expenditure

5. Findings and discussion

Table 5 shows the pattern of collaborative governance in three Indonesian metropolitan regions based on their vertical and horizontal activities. Both dimensions can be viewed broken down into two component parts each. The two components for the vertical dimension are central and provincial interaction while the horizontal dimension consists of intergovernmental and cross-sectoral interaction. The information given from the results demonstrated that the pattern of vertical interaction for both central and provincial is fairly comparable in the three regions. One important aspect of this result is that it rejects the common belief which claim that Jakarta as a capital region has a historical legacy of closer relations with central government. This claim may have been correct during the pre-decentralization era when planning system and Indonesian government system as a whole are highly centralized and hierarchical at best where central government controlled all aspects of planning. At that time, as the capital region, Jakarta has been given development priority which resulted in the high level of primacy compared to other major cities across Indonesia. In the post decentralization era rather than closer proximity, proactive approach from local government to central government plays more important role in shaping local-central interaction. Indeed, in this study, the Jakarta region demonstrates about the same

level of activity with the Surabaya region and has less activity compared to the Yogyakarta region.

Table 5: Mean of collaborative arrangements.

	Unweighted			Weighted		
	Jakarta	Surabaya	Yogyakarta	Jakarta	Surabaya	Yogyakarta
<i>Vertical dimension</i>						
Central interaction	7.06	7.30	9.17	8.12	8.90	10.67
Provincial interaction	7.00	6.30	11.67	8.17	8.10	14.00
<i>Horizontal dimension</i>						
Intergovernmental interaction	11.65	9.20	18.67	15.53	11.70	24.00
Cross-sectoral interaction	15.12	13.70	6.83	18.06	16.80	8.00

The result of the statistical analysis of the provincial interaction follows a similar pattern as the central interaction where a significant score gap occurred between Yogyakarta and the other two regions. Yogyakarta maintains a high level of activities with its provincial government, almost doubled compared to Surabaya. Looking into the detail of the provincial interaction, it is partially understandable that the Yogyakarta region enjoys a higher level of provincial interaction given it is also a special provincial region where the sultanate system still employs a strong influence upon the provincial governmental system. Unlike other provinces in Indonesia, the Yogyakarta special province is basically a sultanate government system where the head of the province is not directly elected by citizen but an inherited position given to the king. Historically, it has a strong Javanese tradition embedded in its social and political culture which is hierarchical in nature.

When the extent of change from weighted to unweighted measures for the vertical dimension is compared, it is found that Surabaya shows the biggest change, which may indicate that local governments in Surabaya are involved more in adjustment-seeking activities with the central and provincial governments among other observed regions. This means that the region puts more consideration and emphasis towards activities to accommodate its interest to the higher-level governments. Between Jakarta and Yogyakarta, when the indexes are weighted, there are not many differences which means that both regions are much similar in their priority activities directed to the central and provincial governments.

The horizontal dimension produces the most complex results of all the indices in both intergovernmental and cross-sectoral interaction, with Surabaya and Yogyakarta located at the extreme ends of the spectrum and Jakarta is falling in the middle. On the intergovernmental interaction, the score from the Yogyakarta region is twice higher than the Surabaya region, showing that the extent of interaction and collaboration between local governments is significantly higher in Yogyakarta. With this result, it means that the local governments in the Yogyakarta region are more likely to interact, exchange information and collaborate with each other than its counterparts in Jakarta and Surabaya. The Jakarta regions fares better than Surabaya with Jakarta officials are at least 30% as likely to interact with its neighboring local government compared to Surabaya. In the other hand, the exact opposite result is found in the cross-sectoral interaction. Whereas local governments in the Yogyakarta regions are the most frequent users of the intergovernmental interaction, they are the least frequent users of the cross-sectoral interaction. The score is strikingly different which lead to assume that the Yogyakarta region employs a limited cross-sectoral collaboration and more focused to develop their intergovernmental collaboration. Unlike Yogyakarta, instead of interacting with their neighboring municipalities, the local governments in Surabaya tend to put more focus to form a collaboration with the non-governmental organizations. Similar tendency is employed by Jakarta albeit in a less drastic manner.

When we further look into the weighted result of the horizontal interaction, a closely similar value increase in the intergovernmental interaction shows that all three regions have a corresponding view on their priority in developing its intergovernmental collaborative environment. The change on the cross-sectoral interaction is more diverse with Surabaya

puts the most changes, followed by Jakarta and finally Yogyakarta. This further explains the collaborative preference of each region whereas Surabaya is less likely to have interest to collaborate with its neighboring municipalities than with the public or private sector and Yogyakarta employs the exact opposite preferences. It can be translated that the local governments in the Surabaya region are more open in accommodating non-governmental sectors in their planning and infrastructure provision, while the local governments in the Yogyakarta is more accommodating towards other governmental entities. Moreover, Jakarta shows another different preference as the region inclines to put the same amount of attention for both its intergovernmental and cross-sectoral collaboration. The planning policy of local governments in the Jakarta region is more likely to accommodate all sectors, both governmental and non-governmental.

The considerable involvement of the non-governmental sector in the horizontal collaboration of Jakarta and Surabaya might be explained by the economic situation of the regions. As two of the biggest metropolitan areas and as a trade and industrial regions, the Jakarta and Surabaya region generate more capital compare to Yogyakarta. Regions with large and growing population create more opportunities for growth because they have more capital and in turn bring more economic revenue to the local government. It is unsurprising to find that local governments in both regions are more open and familiar with other stakeholders to collaborate. Yogyakarta which is more famous as a cultural region rather than a commercial or industrial region most likely has less non-governmental organization located in its area. Thus making it more challenging to form a cross-sectoral collaboration than an intergovernmental partnership.

Both Jakarta and Surabaya show a similar tendency on their vertical and horizontal interaction with other entities with respect to levels of intergovernmental collaboration, create a weak interaction with the central and provincial government and a strong relationship with other non-governmental organizations. It is also interesting to note that the Jakarta and Surabaya regions are statistically similar but with different reasons. Surabaya represents the example of an inward looking behavior government system given the tendency to deliver their service provision by themselves and maximize their own interest through a top-down assistance from the higher government if needed. In a sense, the absence of a coordinating agency in the region, the municipalities tends to communicate less with their neighbors adding to the almost non-present influence of provincial government in the region. Jakarta on the other hand, the lower score of intergovernmental collaboration might be explained by the physical location of the region. Since it covers 14 cities under three different provinces, inter-local or regional policy issues must be dealt within the context of two layers of government system and three different institutional arrangements, making negotiating with these issues are very challenging. Even though the Jakarta region has a coordinating agency, this result further clarifies that the agency is not functioning properly as it should be. In situations like this, building a strong regional institutions as policy coordinator or facilitator with a strong power to implement the policy is a viable option for the local government if this institution does not threaten local authority.

Table 6: Fiscal power diffusion index.

	Local dependency on fiscal transfer (Central government)				Local fiscal autonomy			
	1998-00	2001-06	2007-10	2011-13	1998-00	2001-06	2007-10	2011-13
Jakarta	69.70	70.16	63.38	56.71	24.51	20.39	21.43	29.50
Surabaya	79.91	80.95	75.79	70.10	15.91	13.03	14.55	21.45
Yogyakarta	78.68	79.44	74.04	69.87	17.36	13.41	15.16	18.24

Fiscal decentralization are expected to have a net positive effect on collaborative initiative and performance. Local autonomy growth affects the local dependency to the higher-level governments and is in turn affected by growth in the economy. Growth in the local autonomy means less centralized and hierarchical system of administering the plan. In assessing the result of the fiscal power diffusion analysis, it is found that each region observed displays

similar tendency of fiscal decentralization experienced over the years, with movement inclines towards higher fiscal autonomy and less dependency albeit in different levels.

As can be seen in Table 6, among all three regions, the Jakarta region has the least local dependency and the most local fiscal autonomy throughout the years. It can be explained due to its status as the economic engine of the country and fact that for years before the decentralization urban development is mostly focused in and around the region. The region possesses more opportunity to gain local revenue compare to other regions, making it more independent in directing their development using local revenue. Looking into more detail of the FPD, all three regions show similar increases in fiscal dependency from the higher-level governments and decrease on local fiscal autonomy in the wake of decentralization. It is understandable considering during that time the central government poured the central balancing fund to the local government following the enactment of first fiscal balancing policy. During 2001 to 2006, the local fiscal autonomy of the Yogyakarta region declined more compared to the Jakarta and Surabaya region even though all three regions receive an almost similar raise on their local dependency to the central government. There is a strong incline that it happened due to high provincial fiscal transfer from the provincial government to the local municipalities in Yogyakarta to help improving the local governance capacity.

The period of 2007 to 2010 and 2011 to 2013 shows the increase of local fiscal autonomy and the decline of local dependency on fiscal transfer in all regions observed. The increase saw the Jakarta and Surabaya regions as more fiscally autonomous regions compared to the pre decentralization era and the Yogyakarta region is slightly building up towards a similar place. The declining local dependency on fiscal transfer from central government in the last three years follows the central government's target to reduce the local dependency. However, it means that we expect to see an increasing fiscal transfer from the provincial government as the central government policy aims to increase the role of the provincial government to the local level. So far, the fiscal transfer from the provincial government is not significant enough, in some regions it is less than the grant and fiscal transfer from the non governmental sector and other local governments.

Matching the results from the dimensional analysis of collaborative arrangements and the FPD, we find that different tendency to perform cross-sectoral collaboration is subject to the fiscal decentralization power possessed by each local government while the same cannot be applied to intergovernmental collaboration as it depends more to interaction between local governments. As we can see, Jakarta and Surabaya with higher local autonomy have more tendency to form a cross-sectoral collaboration. Yogyakarta which possesses similar local dependency with Surabaya around the year 2001 successfully formed an intergovernmental collaboration while Surabaya failed. In a sense high level of interaction with the higher level governments has more significant effects in developing intergovernmental collaboration than the local fiscal autonomy. At present, two of three regions observed are still focusing on rather inward looking behavior tendency which is counterproductive for developing a good intergovernmental collaboration environment. With local governments only focusing on maximizing their own interest and the intergovernmental collaboration remained largely as slogan in many governmental agreements and documents rather than concrete actions.

6. Conclusion

This article has provided an examination and discussion of the structure of collaborative governance, offering a perspective on how interaction among organizations involved in planning and service provision as well as local government's fiscal power can shape the collaborative arrangements. Considering the various types of collaborative arrangements taking place in each region with its underlying characteristics such as local culture, financial and political situation, this research agrees with previous research by Ostrom (1990) that

locally evolved self-governing institutions that are adapted to specific local circumstances may provide more effective resolution of collective action problems than central intervention in many circumstances. By referring to a precedent study from Provan and Kenis (2007) we can classify those structures as lead organization structures for the first collaborative mobilization in Jakarta and Surabaya, network administrative organization structures for the current collaboration in Jakarta and voluntary structures for mobilization in Yogyakarta. Furthermore, the current challenge is how each local government can self-transform their collaborative arrangements into a sustainable collaborative governance. Given the likelihood and the desirability of change as contingency conditions evolve, how exactly the new collaborative arrangement does take place? We argue that change from one form of collaborative governance to another is predictable, depending on which form is already in place and what kind of structure it inhibited.

The above analysis demonstrates important findings at several levels. First, dimensional approach from Miller and Lee's metropolitan taxonomy is moderately effective in explaining the extent of institutional interaction and mechanism of collaboration. Second, intergovernmental collaboration depends on several factors with structural interaction among institutions and fiscal decentralization deliberately play significant impacts to determine the transformation of collaborative arrangements.

Horizontal interaction, is the most flexible and adaptable form since they are shaped by the participant sitting at the same level of governments. Since there is less fiscal dependency involved in this interaction than the vertical collaboration, it highly depends on the good intention of the local government. In the other hand, it is less stable due to its nature of push and pull of bargaining tendency where participants can enter and leave the arrangements, especially when needs and expectation change, partially due to change of local government leadership. We argue at this point, shift to a better cross-sectoral collaboration, for example, will require more fiscal autonomy from the higher-level governments as cross-sectoral collaboration is highly shaped by economic development and local government openness towards non-governmental sector which usually achieved when it is developed and independent economically. However high fiscal autonomy should also be accompanied by increasing local government capacity and balancing the network structure. Balance in network is needed since it plays an important role in intergovernmental collaboration where cities with a more central position in the network, as indicated by connections to more economic development actors, are not more likely to engage in intergovernmental collaboration since they will prefer to form collaboration with non-governmental sector. The role of balancing network can be handled by an intermediate organization. Other than balancing the vertical network, there is a recognized need or demand for having an intermediate organization outside the local government to help supporting the horizontal interaction. In a sense that the Indonesian system does not acknowledge another supra-local level of government, the provincial government has to play its role as regional government.

Another issue is to improve the interaction among organizations, especially local governments, in order to develop a collaborative environment in intergovernmental relations. More attention should be paid to the process of intensifying communication and interaction among cities. As the interaction among organizations gives significant effects on the probability collaborative outcomes, it can be translated that local government has to pay attention in increasing trust and consensus among all actors involved to sustain the collaborative network.

Further research is needed in this study to test the findings using estimation models in order to give a more appropriate and straightforward interpretation as well as observing some variances. There is still much work to do to build and test theory related to governance tendency, structures, and outcomes. This article should be viewed as a starting point for explaining the correlation between government structural interaction and transformation of intergovernmental collaboration, what forms it takes, how it evolves and how it might matter for sustainable collaboration.

Poverty Alleviation in Lagos Urban Informal Settlements: A Sustainable Livelihood Approach

Oluwafemi OLAJIDE, School of Architecture, Planning and Landscape, Newcastle University, UK

1. Introduction

Poverty and incidence of urban informality, especially in the developing countries, are on the increase in the face of the current high trend of urbanisation. Currently, More than half of the world population now lives in urban areas while over one third of the world's urban population live in informal settlements with high incidence of urban poverty (UN-HABITAT, 2006; UN-HABITAT, 2008; Odero et al., 2009; Mundy and du Plessis, 2010; UNHSP, 2010). Informal settlement can said to be a spatial manifestation of certain living conditions which do not conform to formal planning and legal rules, standards and institutional arrangements, and the situations are often dynamic and complex, while poverty is the outcome of various dimensions of exclusions and deprivations. The proliferation of informal settlements and urbanisation of poverty as being currently experienced in the cities of developing countries, including Lagos, pose serious challenge to local, national and international urban managers as well as the attainment of most Millennium Development Goals (Barry and Ruther, 2001; UNECE, 2009).

Lagos, one of the fastest growing cities and urban agglomerations in Africa is characterized by high presence of the urban poor who are mostly accommodated in informal settlements, with a growing multi-dimensional poverty profile. In Nigeria, various poverty alleviation programmes and strategies have been lunched and implemented by both Federal and state governments, including Lagos state. It is evident, based on the current trends of poverty and incidence of informal settlements that the strategies have achieved little to no success. As noted by various researchers and urban analysts, poverty alleviation strategies have been unsuccessful in Nigeria, just like many other African countries, because poverty and poverty alleviation strategies have been narrowly conceived to mean lack of income and economic growth (Forae, 2011; Aluko, 2003; Lewu, undated). Also it has been noted that most of these programmes and strategies were either focused on rural areas or urban areas generally without distinction between formal or informal settlements.

In the recent time, in 2006, there has been a renewed effort to improve the living conditions and alleviate poverty of informal settlements dwellers in Lagos through land regularisation which is expected to grant formal title to every land owner within informal settlements and uncommitted government's land. On the one hand, this strategy is employed against the backdrop that it will facilitate access to official credit and markets, promote individuals' investment in housing, and lead to poverty alleviation. And on the other hand, to get Lagos rid of slums through eviction and demolition of squatter settlements on committed public land. Internationally, there have been arguments for and against the effectiveness of land titling as the main poverty alleviation strategy of the informal settlements dwellers. However from Lagos context, the study of Oshodi (2010) has shown the inadequacy of land regularization through land titling for poverty alleviation, as the intended beneficiaries have largely not interested in the policy.

Against this background, this paper argues that land title may be important for poverty alleviation, but titling is just one of the assets needed by the urban poor while tenure insecurity is just one of the numerous vulnerability contexts within which urban poor pursue their livelihoods. This argument is in line with the current global thinking that policy framework for poverty alleviation can no longer ignore inclusive strategy, which simultaneously takes into consideration poverty in all its dimensions as well as aspirations and needs of the poor. Therefore, this paper, through the lens of Sustainable Livelihood Approach examines the livelihoods of the urban poor. Specifically, it discusses in details various capitals upon which urban poor build their livelihoods. It however, briefly outlines vulnerability contexts within which urban poor pursue their livelihoods. This is taking as a starting point to comprehensively understand the issue of poverty in Lagos' informal settlements, which could help policy discourse at evolving sustainable poverty alleviation strategies.

2. Livelihood Approach and Poverty: Exploring the Literature

Globally, there is a general and renewed consensus that issues of poverty must be properly addressed if the sustainable human settlements and millennium development goals are to be attained. However, poverty has remained complex and contested phenomenon. However, current literature on poverty has shown that poverty is multi-dimensional and any strategy or approach aiming at poverty alleviation must be comprehensive enough to capture various dimensions of poverty. In line with this thinking, many approaches have been developed. One of such approaches is Livelihood Approach. Conceptually, as defined by Chambers and Conway (1991, p.6)

“A livelihood comprises the capabilities, assets (stores, resources, claims and access) and activities required for a means of living: a livelihood is sustainable which can cope with and recover from stress and shocks, maintain or enhance its capabilities and assets, and provide sustainable livelihood opportunities for the next generation; and which contributes net benefits to other livelihoods at the local and global levels and in the short and long term”.

According to Sanderson (1999) sustainability of individual or household livelihood is premised upon adequate access to income and other assets, which enable them to meet basic needs and to build up capabilities to resist or recover from shocks and stresses. Based on livelihood approach, several frameworks have been developed for livelihoods' analysis. Notable among these frameworks is Sustainable Livelihood Framework (SLF) (Carney, 1998, 1999; Scoones, 1998), which has been promoted by various development agencies and organisations such as DFID, UNDP, CARE and Oxfam. Also, various researchers have adapted the framework for understanding and analysing poverty in different contexts (Chambers and Conway, 1992; Ashley and Carney, 1999; Radoki and Lloyd Jones, 2002; Rakodi, 2002; Frankenberger and Drinkwater, 1999; Ellis, 2000). Although, the approach has a rural origin but in the recent years, it has been applied to understanding poverty in the urban context (Farrington et al., 2002; Beall and Kanji, 1999; Satterthwaite and Tacoli, 2002; Schütte, 2005). Sustainable livelihoods framework is a comprehensive approach which takes into consideration livelihoods assets, vulnerability context, livelihoods strategies, livelihoods outcomes, and policies, institutions and processes which influence livelihoods of the poor (Chamber, 1989; Chambers and Conway, 1992; Chamber, 1995; Carney et al., 1999; Kantor and Nair, 2005; Lyons and Snoxell, 2005). At the core of poverty lies livelihood. Poverty is linked to livelihood through five capitals (human, social, physical, financial and natural) (DFID, 1999). Livelihoods, on the one hand, are vulnerable to trends, shocks and seasonality and on the other hand, are mediated by institutions (both formal and informal) (UN-SPIDER, 2012).

Although the SLF has been criticised (see Norton and Foster, 2001; Krantz, 2001; Carney, 2003 for SLF criticisms), however, its application remains popular among various development originations earlier mentioned. It is not surprising because, it was purposefully developed for analysing poverty and developing effective poverty alleviation strategies (source). Also, its strengths as sustainable, people-centred, holistic and dynamic approach as well as its flexibility of adaptation have made it more popular than any other Livelihood Framework. As noted by Farrington et al. (2002), SLF can be used as an analytical tool or an overall development objective. In studying poverty, SLF provides a comprehensive platform for understanding the links between all factors that affect households' livelihoods ranging from how assets are secured, what they do with assets, what obstacles they come across while obtaining assets and who controls the assets on which livelihoods are based (Bebbington, 1999).

3. Research Methodology

This study adopts Sustainable Livelihood Framework as methodological and analytical framework to understanding poverty in informal settlements. More specifically, it explores, in details, livelihood assets and briefly explores livelihood vulnerability of the urban poor. The need to focus on livelihoods approach is based on the realisation that poverty is multi-dimensional. Sustainable Livelihoods Framework (SLF) however, provides a framework which integrates various dimensions of poverty. This framework enables a broad range of quantitative and qualitative research design and data collection methods. Consequently, for the purpose of this research, both quantitative and qualitative

data collection methods, which included household survey, households' in-depth interview, key informants' interviews, direct observation and published documents, were used. The study was undertaken in Lagos metropolis. Specifically, four (4) informal settlements (Ajegunle, Ipaja, Oko-Baba and Sari-Iganmu) were selected for further empirical study. In each settlement, a total of 100 questionnaires were randomly administered to households' heads giving a ground total of 400 questionnaires across the four settlements. In addition, a total of 40 interviews, including both households and key informants interviews were conducted. The materials presented in this paper are based on data from an on-going research which is looking at the factors, other than tenure, which influence livelihood of the urban poor. The analysis and discussions in this paper is majorly based on the quantitative data (400 questionnaires).

4. Livelihood Asset Portfolios of the Urban Poor

In this section, livelihood assets of the selected informal settlements and their residents are discussed under five sub-headings, corresponding to the five livelihoods' capitals- human, physical, social, financial and natural as contained in Sustainable Livelihood Framework (SLF).

5.1 Human Capital

The most important human capital examined includes household's demographic characteristics (marital status, household size, and age distributions and gender of the households' heads), literacy and education level, and employment and occupation status as presented in table 1. Household demographic structures and compositions play important role in income generation. The average household size is 6 persons. This is a little higher than the average for Lagos state of 5 persons as indicated in the Lagos State Household Survey Report (2012). Dependency ratio is particularly useful in assessing vulnerability; the higher it is, the more the likelihood that a household will be vulnerable to shocks and stresses, particularly economic and financial shock (Sanderson, 2000; Holmes and Jones, 2009). On the average, as shown in table 1, the number of people who are capable of working (excluding children, students and elderly who are above working age) is 2.95 while the average number of people that are actually working is 2.49. This is an indication that there is more economically active labour force which a household can mobilise for work than those who are currently working. Households' formation is predominantly male-headed with 87.8% of the households headed by male (table 2).

Number of People	0	1-2	3-4	5-6	7-8	9-10	>10	Mean
Household Size		6.6	32.6	30.8	13.3	8.6	8.7	6.0
Working Group	-	57.3	27.7	10.8	3.0	0.7	0.5	2.95
Actually working	1.8	67.0	22.7	6.8	1.2	-	0.5	2.49
Dependants	4.5	43.3	29.7	9	8	0.5	5.0	3.51

Table 1: Household Size and Dependency Ratio (Percentage, n=400)

Ability to read and write is an essential skill for the socio-economic and human development of any nation (Save the Children, 2012; OECD/Statistics Canada, 2011; UNESCO, 1998). As shown in Table 2, 89.8% of the respondents have formal education. A further disaggregation of the households heads with formal education into highest level of education reveals that almost half (49.8%) completed secondary school while 32.2% completed primary school. Only 18% completed tertiary education. Generally, in Lagos, the literacy rate is high. According to the Lagos state Household Survey 2012 Report, 89% are literate in any language while 84.7% can read and write in English. Literacy level in the four case study settlements is similar to the general literacy situation in Lagos. This was evident during the fieldwork for this study, as majority of the respondents were able to communicate effectively with the researcher in at least three different languages (English, *pidgin* and Yoruba) which the researcher has high proficiency in. In a way, this shows a group of human assets with potential to develop socio-economically, if given the right opportunity and the right environment to pursue their

individual livelihood objectives. However, it must be noted that knowing how to read and write, on the one hand, is important for individual and national development but, on the other hand, it is not enough. Quality of access and what is learnt is equally important.

	Names of Settlements				
	Ipaja	Ajgunle	Oko-Oba	Sari-Iganmu	Total
Households Heads Gender					
Male	81.0	91.0	89.0	90.0	87.8
Female	19.0	9.0	11.0	10.0	12.2
Education Status of the Households' Heads					
Formal Education	83	92	94	90	88.9
No Informal Education	17	8	6	10	10.2
Highest Level of Education					
Primary	42.2	22.8	40.4	23.3	32.2
Secondary	47.0	51.1	46.8	54.4	49.8
Tertiary	10.8	26.1	12.8	22.2	18
Occupational Status					
Self-employed	82.0	75.0	75.0	70.0	75.5
Paid work	15.0	17.0	20.0	20.0	18.0
Unemployed	.0	2.0	.0	10.0	3.0
Retired	3.0	6.0	5.0	.0	3.5
Nature of Main Occupation					
Formal	21.6	22.8	11.6	11.1	16.8
Informal	78.4	77.2	88.4	88.9	83.2
Adequate Access to Education (No)	71.0	89.0	64.0	57.0	70..3

Table 2: Household Head Demographic Characteristics

Physical access to school among the respondents is high; the majority of respondents claimed that members of their households, who are currently within school ages, have access to education. However, as reported by various respondents, their major challenges are associated with adequacy and affordability, which are majorly, manifested in the poor quality, poor infrastructure, inadequate classrooms, lack of libraries and laboratories, poor learning outcomes and cost of attendance. Therefore, in contrast to physical access, a majority (70.3%) of the respondents affirmed that their households do not have adequate access to educational facilities (table 2). Two-thirds of the households' heads are self-employed while only 18% is in paid work (see table 2). A further analysis indicates that 93.5% (including self-employed and paid workers) of the household heads are in employment while only 6.5% (including unemployed 3% and retired 3.5%) are not in employment. More than four-fifths of the employments are in the informal sector.

5.2 Physical Capital

In urban areas, housing is one of the most important physical assets that a household can possess, as it can be used productively and to ease the pressure on finances (Moser, 2006; Moser, 2007; Schütte, 2009). In fact it has been referred to be the commonest physical asset to many households either as a paying tenant, family owned, owner occupier or, even, as a squatter (Farrington et al., 2002). In the context of the current study, general assessment of housing tenure shows that a majority (77.5%) of the households are rent paying tenants (table 3). Houses in Ipaja and Sari-Iganmu are built with permanent materials (sandcrete blocks and mud). Larger proportions of the houses in Oko-Baba are built with temporary materials (wood/plank), and they can be generally referred to as shacks. In Ajgunle, housing constructions are a mixture of both permanent and temporary materials. The number of habitable rooms range from one to five rooms as shown in table 3. Habitable room, in this thesis, refers to number of rooms available for exclusive use of a household, excluding bathroom, toilet, kitchen and store since they are mostly shared among multiple households. For many households, the only habitable room serves multiple purposes, including bedroom (sleeping), living room, home-based activities and sometimes as the kitchen. Just like many other informal settlements

in developing countries, housing conditions in the four case settlements are generally poor. Overcrowding is noted at both household and community levels. The result is manifested in pressure on the available utilities, and poor housing and general environmental conditions. Conditions of sanitation facilities are generally poor. Ironically, as revealed by the household's survey, access to sanitation facilities is quite high among the residents with well over three-quarters of the households claimed to have access to bathrooms and toilets. However, challenges with toilets and bathrooms facilities are associated with inadequacy, poor quality and over-use. More than four-fifths, as indicated in table 3, of the households (including those who do not have access) confirmed not to have adequate access to bathroom and toilet facilities. On the average, as shown in table 4, one toilet is shared among 7 households while one bathroom is shared among 6.88 households. With an average household size of 6 persons, on the average 42 people share 1 toilet while about 41 people share 1 bathroom. In most cases, toilets and bathrooms are located away from the main buildings (outdoor) and the conditions are generally poor. Similarly, kitchen facilities are located outdoor with very poor conditions. Kitchen space is generally small and shared among multiple households, with an average of 7.29 households to a kitchen.

Housing Tenure	Names of Settlements				
	Ipaja	Ajgunle	Oko-Oba	Sari-Iganmu	Total
Owner occupied	8.0	31.0	12.0	5.0	14.0
Tenant	63.0	56.0	88.0	95.0	75.5
Family owned	29.0	13.0	.0	.0	10.5
Number of Habitable Rooms					
1	65.0	51.0	84.0	81.0	70.3
2	24.0	29.0	16.0	17.0	21.5
3	6.0	17.0	.0	2.0	6.3
4	3.0	2.0	.0	.0	1.3
5	2.0	1.0	.0	.0	.8
Adequate Access to Toilet and Bathroom					
Adequate access to toilet (No)	84	87	90	85	86.5
Adequate access to bathroom (No)	89	91	85	91	88.8
Connection to Water Supply (NO)	80.0	92.0	91.0	83.0	86.5

Table 3: Housing Tenure, Number of Habitable Rooms and Access to Sanitation Facilities (Percentage)

	Mean	Median
Number of households sharing toilet	7.00	6.00
Number of households sharing bathroom	6.88	6.00
Number of households sharing kitchen	7.29	7.00

Table 4: Average Households Sharing Toilet, Bathroom and Kitchen

Access to both physical/economic and social infrastructure is essential for overcoming poverty and vulnerability. Electricity is mainly provided by Power Holding Company of Nigeria (PHCH). All the four case study settlements are connected to the public power (electricity) supply. However, the major challenge face by respondents is associated with the inadequacy of power supply, which is manifested in poor quality (low voltage) and inefficient (irregular), and high cost (unaffordable) of the services. Electricity in Nigeria is erratic. On daily basis, as expressed by many respondents and equally confirmed through personal observation, there are frequent power cuts, which often hinders productivity and livelihoods. Consequently, the use of generators, as alternative source of power supply, is common in the four case settlements.

Water is essential for human life and health, production and livelihoods (World Water Forum, 2000; Brauch, 2009). Across the four settlements, most (86.5%) of the houses are not connected to any

water supply system (table 3). Consequently, a majority of the respondents buy potable water from water vendors which come at a higher cost. Also, since a majority of the houses are not connected to water supply system, a lot of time is wasted, mostly by women and children who are mostly responsible for fetching water. In general, inadequate access to water supply is associated with quality, cost and time spent.

Many of the houses are not connected to drainage system and access roads. Available roads are mostly not tarred, and they are without street light and drainage systems, and they are in poor condition. Where drainages are available, they are mostly opened, blocked and dilapidated. The case study settlements, just like many other informal settlements in Lagos, are not adequately covered by waste collection services. This study reveals that there are no adequate healthcare facilities in the four settlements. However, there are chemists' shops where residents get treatments and buy drugs, mostly, without prescriptions.

5.3 Social Capital

Social capital could come in form of social networks, relationships, reciprocity, kindred (Putnam, 1993). In this study, social capital is operationalised as social networks and membership of organisations, social relations and feeling of trust, and sources of information and communication. In the current study, respondents were asked if they or any member of their households belong to any forms of organisations or associations. The result is presented in table 5

Names of Associations/Organisations	Names of Settlements				Total
	Ipaja	Ajegunle	Oko-Oba	Sari-Iganmu	
Co-operative/thrift and credit society	33.0	29.0	35.0	37.0	33.5
Community development Association	34.0	48.0	25.0	20.0	31.8
Religious association	84.0	77.0	78.0	80.0	79.8
Youth organisation	5.0	25.0	30.0	20.0	20.0
Political Party	9.0	11.0	7.0	12	9.8

Table 5: Members of Associations/Organisations (Percentage)

From table 5, about one-third belongs to Co-operative/thrift and credit society, 31.8% belongs to community development association, one-fifth belongs to youth organisation, 9.8% belongs to political party and about four-fifths belongs to religious organisation. Religion remains the most populous organisation. Place of worship is not just a place to only fulfil religious or spiritual obligations but, it is also a place to seek help and share other people's burdens. As noted by a respondent:

"...in our church, we have different groups. We have women, men, youth, working class, those looking for jobs and prayer groups....They give information and help people with jobs. In fact, the current job my first born is doing, someone in the church helped him."

Only a small proportion of the sampled households have any of their members in political party. The reasons, as noted by various respondents, why they did not join any political party was because they consider Nigerian politics as a do-or-die (dirty and dangerous), and secondly, they feel neglected and they have been severally disappointed by the political class and government at all levels. From observations, as an outsider, the level of interactions among residents seems high. However, this is not an indication of an optimal level of trust. Felling of trust was measured through residents' willingness to leave children and keys with their neighbours while they are away. About three-quarters of the respondents will leave their children with neighbours while they are away. Some of those who will leave their children with neighbours however noted that their willingness depends on the particular neighbours and not just any neighbour. For instance, a respondent expressed:

“There are few people I can leave my children with in this area. We have been together for long. I know them inside-out, including their families and they also know me very well.”

On the contrary, willingness to leave their keys with neighbours shows a different trend as only 39.5% of the respondents will leave their keys with their neighbours while a majority (60.5%) will not leave their keys with neighbours. This is attributed to safety and security reasons. Issue of privacy was equally noted by some respondents. This is understandable since a majority of the households occupy only one room; they consider it as a personal space which is meant for only the family members. This study reveals that respondents have access to various sources of information and communication. However, the use of a particular source as the main source of information largely depends on the nature of the information. For instance, Information about government policy on the larger society, such as economic policy, often comes from radio and television. Information about government policy as it affects their communities largely comes as rumours from neighbours, often described as ‘mouth radio’, and later places of worship when such information become prayer points and announcements.

4.4 Financial Capital

In urban areas, possession of financial asset is important in accessing and accumulating other livelihood assets. In this study, financial capital is measured as household’s monthly income, savings and ability to meet basic needs, and access to credit and sources of credit. Household income is essential for maintaining sustainable livelihood. Living in an urban area is characterised by a high level of commoditization which means urban dwellers have to pay for most of the goods and services consumed (Moser, 1998; Rakodi and Lloyd-Jones, 2002).

Monthly Income in Naira (=N=)	Lagos State Household Survey (n=10,000)		Informal Settlements (n=106)	
	Percentage	Cumulative Percentage	Percentage	Cumulative Percentage
20,000 and Below	27	27	60.4	60.4
20,001 - 40,000	37	64	21.7	82.1
40,001 – 60,000	21	85	15.1	97.2
60,001 – 80,000	8	93	2.8	100
80,001 – 100,000	5	98	-	-
Above 100,000	2	100	-	-

Table 6: Comparison of Lagos State Household Survey Monthly Income and Informal Settlements Household’s Monthly Income Group

As shown in table 6, a majority (60.4%) of the households have a monthly income of =N= 20,000 and below. In fact, majority of those who earn =N=20, 000 and below actually earn between =N=7,500 and =N=17, 000 which is lower than the national monthly minimum wage of =N=18, 000. Precisely put, about half of the sampled households have monthly income lower than the national monthly minimum wage. It must be noted that the national minimum wage has been described, by Nigerian workers, as not adequate for a living.

Table 7: Savings and Ability to Satisfying Household’s Needs (Percentage)

	Names of Settlements				
	Ipaja	Ajegunle	Oko-Oba	Sari-Iganmu	Total
Difficulty in Satisfying Food Needs (Yes)	83.0	80.0	73.0	70.0	76.5
Difficulty in Paying House Rent (Yes)	85.7 (n=63)	83.9 (n=56)	73.9 (n=88)	76.8 (n=95)	80.1 (n=302)
Difficulty in Satisfying Other Needs (Yes)	84.0	85.0	80.0	81.0	82.6
Ability to Save (No)	79	75	57	61	68

Table 7 reveals that a majority (76.5%) of the sampled households find it difficult to satisfy food needs while (80.1%) find it difficult paying their rents and 82% find it difficult to satisfy other needs. As shown in table xx, majority (68%) are unable to save. This is not surprising as many of them are already experiencing difficulties in meeting their basic needs. As expressed by a respondent, when asked if he is able to save money after meeting all basic needs:

“Savings, how? How do I save when I don’t even have enough money to put food on the table for the family, pay children school fees and some other important family commitments?”

Inability to meet basic needs and save is associated with the irregular and inadequate income of the majority. In the absence of regular and adequate income, access to credit facilities becomes essential to livelihood security (Meena and O’Keefe, 2007). As shown in this study, there is limited access to formal (banking) credit source. Hence, there is minimal use of loan from formal financial institution as source of income among the residents. However, a majority of the sampled households do have access or prefer to access credits from informal sources like relatives, friends, cooperative, and thrift and credit society (ajo). The reasons attributed to this include ease of access, little or no interest rate, and convenient repayment plan. It was however noted that access to informal credit, particularly from friends and relatives is often not reliable because they (friends and relatives) also have limited financial capability to always offer such help. The current study equally reveals that access to informal credit is not only limited to cash. Credits also come in form of goods and services. Question on how households cope with difficulty in meeting basic food needs indicates that a significant proportion of the households do take food stuffs on credits. This is achieved by building relationships and trusts with different food stuffs retailers.

4.5 Natural Capital

In livelihood analysis, the importance and contributions of each component of natural capital differ between rural and urban environments. It is generally believed that natural capital is less important to livelihoods of the urban poor. However, as noted by (Farrington et al., 2002) natural capital and services offered by natural capital are becoming important to urban poor’s livelihood. Within the context of the current research, the identified natural capitals which are used in the livelihood of the residents of the case study settlements include water bodies and refuse dump.

Lagos is a coastal urban agglomeration. Hence, water is its most significant topographical feature. In fact, water bodies, ranging from sea, lagoons, rivers, creeks and swamps, cover about 40 percent of its total landmass. Ajegunle and Oko-Baba communities have direct access to water bodies. Oko-Baba has direct access to Lagos lagoon while Ajegunle has direct access to Ogun River. The water bodies are used for different purposes based on local circumstances. For instance, in Ajegunle, Ogun River is used for purposes such as bathing, sanitary, washing (cloths and plates) and fishing. Though, as noted by various respondents, fishing is not done at commercial quantity, but it does form part of residents’ livelihood strategies for meeting food needs. Lagos lagoon occupies a central position in the existence of Oko-Baba sawmill and the survival of Oko-Baba residents. The lagoon is used for transporting logs from the hinterland, and for logs storage before they are cut into timber/plank of different sizes at Oko-Baba sawmill. Equally, the lagoon is used for sand mining, though on an informal and small scale levels but it does serve as source of livelihood for some of the residents as noted by a key informant. It is also used as sanitary facility. Sari-Iganmu is very close to a refuse dump site. Although it must be noted that the settlement has existed before the dump site but it has become a dominant feature on the Northern part of the settlement. The dump site generates income opportunities for some categories of people- ‘area boys’ (street boys), scavengers and traders who use the place to display their goods as a result of its closeness to a major road (Lagos-Badagry Expressway) as well as a major transport node.

5. Livelihood Vulnerability of the Urban Poor

Urban poor pursue their livelihood’s objectives within political, social, economic and environmental contexts which make them vulnerable to poverty. Often, vulnerability manifests in form of trends,

shocks and seasonality (DFID, 1999). As reveals in this study the major trends which have influence on urban poor livelihoods include urbanization and population trends, economic trend and trend in climate change. These trends however reinforce one another.

Urbanisation is a global phenomenon resulting into increase in the number of people living in the urban areas. However, in Sub-Saharan Africa, urbanization has been identifies as one of the major trends affecting urban poor livelihoods (Hedrick-Wong and Angelopulo, 2011). Though urbanisation on its own is not a problem, but when poorly managed, which is the case in many developing countries including Nigeria, it results into problems. The results of poorly managed urbanisation is evident in Nigerian cities as epitomised by the condition of urban poor in Lagos. Over the years, particularly in the last five or six decades, Lagos has been experiencing unprecedented urban expansion and population growth. As the pace of urban population continues to increase coupled with the poor national economic situation, the challenges of providing employment, basic infrastructure and adequate and affordable housing to meet the need of the ever increasing urban population persist and becoming intractable (UNECE, 2009). Over the years, Lagos has expanded from core areas unto marginal areas, ecologically fragile sites and hazardous locations such as flood plain, swampy areas, and canal setbacks, where the residents are exposed to climate change related hazards, particularly flood. Majority of the population in Lagos now live in informal settlements under precarious environmental and housing conditions, and engage in informal economic which offers irregular and inadequate income. As reveals in this study, the working conditions and working environment as well as the living environment of the urban poor expose them to occupational and environmental health risks. These on the one hand often reduce their ability to labour and earn income and on the other hand increase household expenditures, particularly on healthcare.

Furthermore, shock as an essential component of vulnerability has profound influence on individual and households' livelihood sustainability, and poverty alleviation. The summary of the identified shocks, as expressed by the respondents in the study settlements, is presented in table 8

Shocks	Frequency	Percentage
Threat eviction or actual eviction (Yes)	241	60.3
Loss of property (Yes)	197	49.3
Loss of Social Network (Yes)	206	51.5
Loss of Job/ Unemployment (Yes)	219	54.8
Flooding (Yes)	270	67.5
Violence and crime (Yes)	252	63.0
Pollution (Yes)	307 (n=398)	77.1
Diseases/ Sickness/Health problems (Yes)	254	63.5

Table 8: Vulnerability to Shocks

The above table shows various dimensions of shocks influencing urban poor livelihoods in Lagos informal settlements. Majority of the residents are vulnerable to pollution, including land, water, air and noise pollutions. Incidence of pollutions in the study areas is associated with the lack of adequate facilities, particularly sanitation facilities. About two-thirds of the respondents are vulnerable to health problems. Common health problems among the residents include malaria, diarrhea and typhoid. These illnesses are associated with the prevailing poor and inadequate sanitary facilities, and the general poor environmental conditions in the study areas. In the past few years almost every part of Lagos has experienced, and has been affected by flood incidence. As reveals in this study, over-two-thirds of the respondents have experienced flood incidence. The effects of flood incidence on urban poor livelihoods are enormous. On the one hand, flood hazards worsen the already vulnerable and impoverished conditions of the urban poor. On the other hand, hinder their capabilities to move out of poverty. As noted by two different respondents:

“I cannot say this is the total amount of what I lost to flood between last year (2011) and this year but, the point is that many of my properties, I mean my household items, were damaged, and I am yet to replace most of them because I have no money to do so.”

“I do not know what to do neither do I know where to move to, everything I have laboured for over the years, including my certificate have been lost to flood that ravaged last two weeks. Now I am empty, left with nothing.....I am practically back to square one, where do I even start from.”

The effects of flood on urban poor livelihood, as expressed by many respondents include damage to properties and community infrastructure, damage and loss of households' productive and non-productive assets, disruption of economic activities, loss of human life and social networks, and ill health and injury

6. Conclusion

This paper, through the lens of Sustainable Livelihood Framework, has detailed various capitals that together construct asset portfolios and livelihoods of the urban poor in Lagos. The study reveals that urban poor have unbalanced and inadequate access to both public and private livelihoods assets. The inadequacy is manifested in both the quantity (generally limited) and quality (generally poor) of livelihoods assets. Basic infrastructure and urban services are physically available to the residents of the case study settlements. However, the quality remains poor and access to them remains inadequate. Access to urban services comes at higher costs to the urban poor, relative to their income; hence, affordability becomes a major challenge. This is against the backdrop that majority earn below the national minimum wage, which is not adequate for a living. In the absence of adequate cash income, credit as source of income becomes important. Unfortunately, as shown in this study, a majority of the residents do not have access to credits from financial institutions; hence use of formal credit as source of income is limited. However, they do have access to credit inform of cash, goods and services from informal sources. On human capital, two contrasting conclusions can be made. On the one hand, a combination of high dependency, relatively low level of highest education attainment, high incidence of unemployment, ill health, currently prevalent among household's members, are indications of poor and weak human assets. On the other hand, a high number of household's members within working age group points to potential strong human capital base that individual household can mobilize for income generating activities if the general employment situation and education system in the country improve.

This study further reveals that urban poor in Lagos informal settlements pursue their livelihood objectives amidst vulnerability contexts, which further impoverished them. Livelihoods' trends of the urban poor are associated with uncoordinated urban expansion, climate related hazards and poor national economic performance. Major livelihoods' shocks include threat of eviction, loss of property, loss of social network, unemployment, flooding, violence and crime, pollution and health problems. These shocks however reinforces one another thereby worsen the condition of the urban poor. Although it must be noted that occurrence of many of these shocks are not in any way limited to informal settlements, however, urban poor are disproportionately vulnerable and affected because they are already experiencing multiple deprivations and exclusions in terms of infrastructural and urban services provisions. More importantly their livelihood is based on unbalanced and inadequate assets. Also, these vulnerabilities are, often, either not understood by policy makers or they are deliberately over look, as not important, when developing poverty alleviation strategies. Hence, there is a disconnection between poverty reduction policies, and reality, aspirations and needs of the poor.

This study therefore suggests that one important element in reducing poverty is a policy framework that guarantees inclusive provision of livelihoods assets and at the same time reduces livelihood's vulnerability. It however recognises that provision of assets may not be enough to achieve the desired poverty reduction; right of access, which is also currently missing, to wide range of livelihood's assets, including right to city, for the urban poor is of necessity. This view is in line with the current global thinking that policy framework for poverty alleviation can no longer ignore inclusive strategy, which simultaneously takes into consideration poverty in all its dimensions as well as aspirations and needs of the poor.

Rio de Janeiro's transformations for the mega-events: history, urban regeneration and grassroots creative experiences in the port area.

Luiza Farnese L. SARAYED-DIN, Faculty Built Environment, University of Malaya, Malaysia

Rosilawati Binti ZAINOL, Faculty Built Environment, University of Malaya, Malaysia

Abstract

Trying to answer the question 'For whom are the urban transformations?' associated with the host of the World Cup 2014 and Olympics 2016, this paper aims to present the history, urban interventions and potential of learning from grassroots creative experiences within Rio de Janeiro's port area. In doing so, this descriptive effort wishes to collaborate with the major discussion about the challenges and opportunities of city making in Global South cities.

1. Introduction

Porto Maravilha is returning a **historical treasure to Rio**, and at the same time integrating areas with great housing, cultural and economic potential, which will be **transformed** into an **example of modernity**. (CEDURP, 2013b)

In the context of huge city transformations associated with the host of the World Cup 2014 and Olympics 2016, this paper aims to present the urban regeneration project that is taking place in Rio de Janeiro's port area: the *Porto Maravilha* project. This descriptive effort focuses on the overall contingency of these recent urban transformations presenting the historical relevance, abandonment period and socially excluded population of Rio de Janeiro's port area. Casting a critical eye towards official phrases such as the one quoted in the beginning of this session the paper explains: firstly, why the port area is considered the historical treasure of Rio de Janeiro; secondly, the sequence of urban interventions that transformed the port throughout the years; and thirdly, the different discourses and interests behind the idea of transforming the area into an 'example of modernity'.

Trying to answer the question 'For whom are the urban interventions?' and based on the analysis of official documents and ten days of observation and application of semi-structured interviews with key stakeholders, this paper briefly presents both an overview of the expected social impact of the mega-events in Rio de Janeiro port area and two grassroots creative experiences that are already taking place within this area. However, it is important to highlight that these two experiences are presented having in mind the postcolonial urban studies claim of an urban theory able to learn from cities everywhere (McFarlane, 2011, Robinson, 2006, Robinson, 2011) and conscious of the role of creativity in city-making (Sandercock, 2003, Landry, 2008) . Fleshing out the importance of learning from these experiences, which for a long time were the few initiatives that have encouraged the dialogue between this forgotten area and the city, this work discusses the revitalization process related with mega-events and underscores the potential for learning from creative urban experiences in both Rio de Janeiro and other cities of the 'Global South'.

2. Historical treasure: Rio de Janeiro and its port area

Rio de Janeiro dates back to 1565. Slowly spreading along the seashore and developing on top of, and limited by, four hills, the city took almost 300 years to properly blossom. The turning point happened with the arrival of the entire Portuguese Court in 1808 and consequent transference of the Kingdom of Portugal from Lisbon to Rio de Janeiro, Brazil (Sigaud, 2000). Escaping from the Napoleonic forces in Europe, the King of Portugal declared Rio de Janeiro the new capital of the United Kingdom of Portugal, Brazil and Algarves and implemented huge transformations within the city. From allowing the commercial exchanges between Brazil and all nations considered friends of Portugal to urbanizing the city to properly house the Portuguese Court, the presence of the King John VI propelled Rio de Janeiro's development, particularly surrounding the port area where the city was born.

Economically, other than the services related to the court, the city's development has been based on three main activities. The historical compendium book *História dos Bairros: Saúde, Gamboa e Santo Cristo* details each of these economic activities and how they have influenced Rio de Janeiro's urban landscape, particularly focusing on the history of three neighborhoods that formed the port area, and consequently the beginnings of the city. One of the most important activities was the exploration of regular stones for the construction of houses and for doing earthworks in many of the native mangroves areas that used to bring mobility difficulties and harden the city connections. These quarries were actually something broadly available, since they used the hills that once limited and was within the city. The second economic activity was the coffee trading. Following the arrival of the Portuguese Court, the coffee started being produced on a large scale, which were then stored and distributed via Rio de Janeiro's quays. As Cardoso et al. (1987) have mentioned, with the advent of the coffee, quays and warehouses multiplied in the region (Cardoso et al., 1987, author's translation). The expansion of the coffee culture throughout Brazil during the 19th century brought wealth to Rio de Janeiro, allowing then investment in transport, such as train, services and urban infrastructure to support the booming urban population.

The third activity was associated precisely with maritime commercialization, more specifically with the quays and associated warehouses, which previously had developed slowly throughout the years and that subsequent to the royal family arrival, had flourished. Initially inhabited by fisherman and slaves dealers, the quay area became a place of smithies, warehouses, in particular coffee warehouses, which were built at the seashore and more often on the land reclaimed from the sea. Associated with the construction of the Railway station and train lines connecting this port area with the countryside, the area's infrastructure had reached breaking point. As indicated by Cardoso et al. (1987), after 10 years of the distribution of imported products via Rio de Janeiro and the exportation of Brazilian products, mostly coffee, through the same quays, the port area of Rio de Janeiro became developed, diverse and populated. This population, in turn, was mainly comprised of workers from the quays and the industries located in the local area due to the available infrastructure.

However, Cardoso et al. (1987) highlighted that although Rio de Janeiro's vocation to be a port area and all the quays and commercialization in the region, the area was not properly equipped to be described as such. Despite the implementation of small initiatives such as the D Pedro II Docks and Maritime Station, launched respectively in 1875 and 1879, the establishment of a proper port area only happened at the beginning of the 20th century, in the context of other urban regeneration processes around Rio de Janeiro. Featuring among the world's 15 biggest ports at that time (Cardoso et al., 1987), in 1903 the port finally received the necessary financial and technical investment from the federal government in a contract with a British company and support from the Technical Commission for the Port Constructions.

Launched in 1910, the port was then considered the symbol of the huge transformations of Rio de Janeiro's old coast. Being built on a vast piece of land reclaimed from the sea its construction has 'permanently distanced the old maritime neighborhoods from the sea, and the land reclaimed areas have never truly integrated itself with the old areas' (Cardoso et al., 1987, author's translation). More importantly, the port construction and associated urbanization have consolidated the grassroots character of the area. For instance, it was within these maritime neighborhoods that the port, mill and warehouse's workers managed to live and mingle, and was there that the first slum of Brazil appeared [which was called *Favela Hill* and is the reason for all the slums areas in Brazil being called *favelas*].

The remarkable character of the port area population is what explains the area being the cradle of samba and other cultural grassroots manifestations that are so associated with the Brazilian melting pot of culture, races and beliefs. The catholic celebrations and other cultural traits from the Portuguese and some Spanish have mixed with the African roots of the black people that were also historically connected with the area. Being the place where the slave market was established, where the African Gods has been worshiped [in Pedra do Sal, place that till nowadays hosts samba and other cultural manifestations] and where most of the slaves and free men worked and lived, the port area has also been known as 'Little Africa' [*Pequena Africa* in Portuguese]. Actually, all the urban interventions and the lack of them have somehow fostered the segregation of this area from the rest of the city, as well as the crystallization of the port area of Rio de Janeiro as the living history of Brazil and metonym of the country's mixture.

2.1 The urban interventions and the abyss between port area and city

If we want to work towards a politics of inclusion, then we had better have a good understanding of the exclusionary effects of planning's past practices. (Sandercock, 2003)

As a consequence of all the above-mentioned transformations that Rio de Janeiro had witnessed throughout the 19th century, the capital of the new Brazilian republic was facing many urban issues and had its first comprehensive urban renovation process in the beginning of the 20th century. Besides the economic, urban and social changes boosted by the arrival of the royal family, the slavery abolishment in 1888, the Republic proclamation in 1889 followed by increasing migration to the city, has accelerate the need for Rio de Janeiro's 'modernization, sanitation and civilization' (Cardoso et al., 1987, author's translation). Known as Pereira Passos's Renovation, due to the name of Rio de Janeiro's mayor at that time, from 1902 to 1906 urban renovation focused on widening existing roads and building new roads – especially in the city center, and the construction of the port and revitalization of its surrounding area. Besides these urban interventions, which were inspired by Haussmann's Paris, the government has created rules and regulations changing and disciplined the life within the city, followed by sanitation campaigns against such outbreaks as yellow fever and bubonic plague.

History shows that the Pereira Passos's urban interventions have been based on large demolition projects as well as the eviction of a huge number of people from the city center and port area. However, 'regardless of the destruction of a big share of the houses in the area, the old maritime neighborhoods have absorbed a huge population of low income earners displaced during the demolitions that were taking place in the city' (Cardoso et al., 1987, author's translation). Therefore, in addition to the naval workers immigrants, mostly Portuguese and Spanish, and the black population that used to be based in these maritime neighborhoods, who after the abolishment of slavery, also remained in the area, the port area received the huge number of evicted people from the Pereira Passos's interventions. The *Favela Hill*, which is known as *Providência Hill*, is an example of that, since the number of deprived houses increase from 100 in 1904 to 1458 in 1933 (Cardoso et al., 1987).

Additionally, despite the aimed revitalization of the port area, these urban interventions of the beginning of the 20th century marked the physical separation between the port and the city. For instance, the two large avenues constructed on the reclaimed land have materially 'delimited the differences between the 'modern' and previous occupation' (SMU & IPP Prefeitura da Cidade do Rio de Janeiro, 2003)

It is important to highlight that although this urban renovation is considered the first comprehensive plan with this objective for Rio de Janeiro, other initiatives have happened before. For instance, due to the precarious constructions and disorderly occupation, around 1870 urban works and renovation projects were necessary in these hill settlements with some of them having been done to avoid landslides. Moreover, the urban development of the second half of 19th century has opened up streets and other smaller thoroughfares towards and within these hills. However, the vertiginous increase of population and construction on these hills did not follow on the same path as the urban services and required infrastructure. It is due to the fact that most of the investments at that time was focusing on the maritime coast (Cardoso et al., 1987). Another initiative in urban 'renovation' happened during the administration of Rio de Janeiro's mayor Barata Ribeiro who from 1891 to 1893 has focused on evicting the unsound collective habitations in the center of the city and ended up removing a lot of poor people from their homes.

Other than the Pereira Passos's urban interventions, Rio de Janeiro have passed through two more urban plans, called Apache Plan [1926] and Doxiades [1960 to 63], that have not impacted the situation of the port area, and the construction of *Presidente Vargas Avenue* and the *Perimetral Highway* which have magnified the physical urban divide between port and city. From the 1940 to the 1970, the functionalism way of thought has influenced the urban interventions in Rio de Janeiro and the construction of these two large avenues are a symbol of that. At more than 3.5 kms in length and connecting the *Mauá Square* at the heart of the 'old Rio' and the north region of the city, the federal president Getúlio Vargas constructed the 4 carriageways avenue in 1940, as a way of modernizing the capital of Brazil at that time. The *Perimetral*, on the other way, has its construction started in the 1950's but was only completed at the beginning of 1970, after Rio de Janeiro had lost its post of capital city of Brazil for the newly constructed Brasília. At 4 km in length, the elevated avenue connected the main entrance road of Rio de Janeiro, called Brazil Avenue, directly to the city center, crossing over the port area that has been since then entirely isolated and fragmented from the city.

All in all, the 3 constituent neighborhoods of the port area, namely *Santo Cristo*, *Gamboa* and *Saúde*, were excluded from the city's development. As Cardoso et al. (1987) comments, whilst the city was being modernized through its high-rises, the port neighborhoods had their forms, activities and traditions crystalized. This neglecting situation is reflected in the demographic numbers of these neighborhoods. For instance, this area that is considered the Administrative Region One [RA 1] by the city management has the 24th Human Development Index between the other 32 RA's of Rio de Janeiro and has witnessed the continuous decrease of its population. Whilst the city's population has increased, from 1991 to 2000, these maritime neighborhoods have decreased in population, and the ones who stay are mostly living in deprived conditions. In 2000, from the 40,486 people who were living there, 43%, or 17,409 people was living in slums (Prefeitura da Cidade do Rio de Janeiro, 2010).

3. Mega-events and Rio de Janeiro's urban transformations

Following the widespread belief that hosting mega-events represents a way to expedite the country's economic and social development, Brazil, in particular the city of Rio de Janeiro, has channeled efforts in attracting such events since 1990s. Although Brazil has already hosted the World Football Cup in 1950, the aim of bidding for a mega-event as a 'mechanism for transforming the space of the city while at the same time acting as a platform to project

those transformations to the international community' [Gaffney, p.24] date back to the unsuccessful bids of Rio de Janeiro for hosting the Olympics in 2004 and 2012. Within this mindset, Brazil, more specifically Rio de Janeiro has hosted the Pan-American Games in 2007, which despite costing 10 times more than its first projection, was considered a 'successful' event by the media and international sports organizations. Consequently, counting on the 2007's experience and with a comprehensive bidding document highlighting the importance of such events in Latin America and the social, environmental and economic impact of such mega-events, Brazil has won, firstly the FIFA World Cup 2014 and Confederation's Football Cup 2013, and secondly the Olympic Games of 2016. The Olympic Games 2016 will be exclusively hosted by Rio de Janeiro.

However, it is important to highlight the 'ongoing critical analyses regarding the ability and likelihood of sport mega-events to deliver sustainable, tangible, and egalitarian development in the Global South, as well as the propensity for sport-focused development initiatives to align with modernization and/or neo-liberal approaches and philosophy that may fall short of challenging or redressing structural inequalities' (Darnell, 2010). Agreeing with that, Lenskyj (2008) underscores that financial loss, temporary cessation of democratic process following the big international organizations rules and regulations [FIFA, IOC, etc.], production of militarized and exclusionary spaces, home evictions, among other dramatic city changes are the common ground of most of the mega-event's city hosts. Diving more deeply in the specific case of Rio de Janeiro, Gaffney (2010) argues that 'the transformations that mega-events wreak are permanent, impose temporary forms of governance that elide democratic institutions, install new and enduring surveillance and disciplinary mechanisms, while both creating and exacerbating unequal geographies of power within the city at large' .

Reflecting the above-mentioned challenges and blurry facts related with hosting such mega-events, Rio de Janeiro is facing huge urban transformations that are mostly guided by the extra-governmental entities which drives the transformation of the city from a place for living and working, to a place to be consumed (Gaffney, 2010). From the 55 billions of Brazilian Reals that Rio de Janeiro will receive as an investment for the World Cup and Olympics, 33,1 billion of Brazilian Reals will be for infrastructure (Tabak, 2011). However, as highlighted by Gaffney (2010), from the transportation system to the Olympic Villas that will be constructed, the transference of public money to serve the private interest is clear. This affirmation can be clearly seen in the report made by the National Coalition of Local Committees for a People's World Cup and Olympics (2012). This document highlights that among the huge investments in infrastructure and transport, which is extremely necessary to the current challenges of mobility within the city, are mainly focusing in connect touristic and sports facilities. Furthermore, this report as well as other authors such as Gaffney (2010); Mello and Gaffney (2010); and Darnell (2010) have mentioned the bias choices regarding the areas where the *Bus Rapid Transit* [BRT] and *Light Rail Transit* [LRT] transportations have been chosen to pass. For instance, the LRT that will cross the *Barra da Tijuca* neighborhood area are requiring the removal of houses of low income families that are just next to middle and high class areas, literally freeing the area from the 'undesirable' slums and consequently increasing the value of that land.

The investments in Rio de Janeiro for the mega-events include the above-mentioned transport infrastructure comprising the modernization and expansion of the subway, construction of BRT and LRT and the renovation of the international airport. Other than that, sports facilities will be constructed and renovated. For instance, the *Maracanã* Stadium, which has recently been renovated for the Pan-American games at the cost of 430 million Brazilian Reals, has just finished another renovation exercise costing 1.049 billion Brazilian Reals. Furthermore, the Olympics and World cup will have a huge impact in developing urban regeneration projects. Regarding these projects, one of the most important and ambitious is the *Porto Maravilha* project. After a long time being forgotten by the government, the historical port area of Rio de Janeiro is the object of a huge urban regeneration process.

3.1 *Porto Maravilha Project*

After more than 50 years of abandonment and following the global trends of revitalizations of old industrial and port zones in a reconfiguration of land use, the previously mentioned historical maritime neighborhoods of Rio de Janeiro have regained government attention. Hidden beneath the *Perimetral* Highway and facing problems such as lack of renewed sewage and light systems, crime and violence, the governmental eye came back to the area a few years before the announcement of the Olympics in 2009. However, it was in October 2009, with the advent of the mega-events that the federal, state and municipal governments have made a joint effort to redevelop the area, using the mega-events and developing specific rules and regulations as a way of attracting the private initiative to invest in the area. Then, after a comprehensive study about other port area revitalization experiences, in particular Puerto Madero Port in Buenos Aires, Argentina; the Barcelona experience during the Olympics of 1992; the Rotterdam port revitalization and even another Brazilian experience in the capital of Pará state, the docks revitalization in Belém, the *Porto Maravilha* project has been launched (CEDURP, 2013b).

Thus, after experiencing the different stages of being from the heart of the history to a simple passageway, the port area has received the biggest Public Private Partnership [PPP] in Brazil, with an investment of 7.3 billion Brazilian Reals. After winning a bidding process, the *Porto Novo* Consortium, which is the result of a partnership between three of the biggest construction companies in Brazil, namely Noberto Odebrecht, OAS e *Carioca Engenharia*, has assumed the planning, execution and maintenance of the *Porto Maravilha* project. This project covers 5 million square meters of the city and includes the three old maritime neighborhoods with their more than 20,000 people. This area has been chosen for this major urban intervention for different reasons, in particular due to its huge tourism potential and the fact that 75% of this area belongs to the state. Based on this later aspect, the decision makers involved expected that this land ownership peculiarity would ease the necessary expropriations and consequently decrease the public resistance (Mello and Gaffney, 2010).

One of the project's premises is to undertake the urban intervention without using public money, relying principally on private investment. In order to do that, the CEDUR – Rio de Janeiro Port Region Urban Development Company, which is the mixed economy company formed by a municipal complementary law to manage the *Porto Maravilha* Project, has created the CEPACs. As highlighted at the *Porto Maravilha's* official website, the acronym CEPAC describes the name, in Portuguese, of Certificates of Additional Construction Potential, and they are the 'titles used to finance Urban Operations in Consortium, which recover degraded areas in the cities' (CEDURP, 2013b). More specifically, these CEPACs are titles that could be financially negotiated allowing the investor to buy the rights of building edifices with more floors than what was originally allowed in the area. As Mello and Gaffney (2010) criticizes, the CEPACs acquisition represents the buying of the right of disrespecting the urban laws previously established for the region. Despite such criticisms, the CEPACs were sold in 2011 in a single package for 3.5 billion Brazilian Reals. The money has been transferred to the *Porto Maravilha* project and as a consequence nowadays some parts of the port area will have buildings with 40 floors and above.

The main urban transformations aimed through the *Porto Maravilha* project concentrate on changing the current status and feature of the neighborhood. The objective is to develop a new cultural and entertainment center, attracting both private investment related with that as well as various population profile, increasing the number of residents from the current 22,000 to 100,000 within 15 years. Under the administrative concession of *Porto Novo* Consortium, one museum has already been constructed – MAR [Art Museum of Rio] – some areas such as *Morro da Conceição* has had its electrical cables renovated, part of the *Perimetral* Highway has been demolished and one tunnel has almost been completed as a substitute for the demolished highway. Other than that, this urban intervention intends to build another

museum designed by the Spanish 'star' architect Santiago Calatrava, to construct a Light Rail Transit [LRT], renovate the whole area's urban infrastructure from sewage system to water and public light and to implement new urban standards in approximately 70% of the streets. Moreover, within the 35 years concession, this private consortium is responsible for both the maintenance of the area's infrastructure and the service provision, which ranges from trash collection to traffic control and urban sanitation (CEDURP, 2013a).

Despite recognizing the importance of an urban regeneration project in the area given that the current local population deserves access to public services and infrastructure, many urban specialists [(Gaffney, 2010); (Mello and Gaffney, 2010); (Darnell, 2010); (Passos and Sánchez, 2011, Passos and Sánchez, 2012); (National Coalition of Local Committees for a People's World Cup and Olympics, 2012)] criticize the way it has been done until now. The common ground of understanding among these specialists is that the *Porto Maravilha* project, utilizing the mega-event's urban boosting discourse, represents the privatization of urban planning and transformation of the city from a place to live to a place to be consumed. As emphasized by Gaffney (2010), 'as with most mega-events, development is highly uneven and tends to benefit private developers and construction interests while creating spaces for wealthy residents and the international tourist class'. What is more, in its yearly report, the National Coalition of Local Committees for a People's World Cup and Olympics (2012), has highlighted that other than removing some people from the place where they have been living for years in order to open space for the 'development', the non-participative urban interventions that are taking place in the port area will indirectly force the majority of low income population to look for another place to live due to the high cost of living and the neighborhood's drastic profile modification [gentrification]. This highlighted fact can easily be confirmed when checking the vertiginous increase of the land price within the port area, which since the beginning of the project in 2010, has already increased 300%. (Passos and Sánchez, 2011)

4. For whom are the urban transformations?

'Rio de Janeiro has fully engaged the process of making itself into an Olympic City where the workers will stream down from the favelas to built sportive constellations that are intended for use by the international tourist class and the upper state of Brazilian society'. (Gaffney, 2010)

The provocative question of this section reflects the current challenging scenario not only of the urban interventions, related with the mega-events within the port area, but also in the whole country. Particularly in the case of *Porto Maravilha* urban revitalization process, as highlighted before, it targets a specific type of tourist and serves private companies and a particular group that sees the area as a place to be consumed. Thus, one may ask: after such a long history and with a large population living there for generations, are the port area's people really being represented in this urban 'revitalization'? More broadly, starting from 13th of June 2013, while the Confederation Football Cup was taking place as a training experience for the World Cup, the whole country came out onto the streets in demonstrations against a huge list of issues related, among others, with a crises of the current democratic representations in Brazil. From the outset, criticism against the way the *Porto Maravilha* project have been planned is just one among other examples of why Brazil's population went to the streets. Far from discussing the reasons and outcomes of these ongoing demonstrations, it is important to highlight that they do represent the Brazilians dissatisfaction regarding the way things have been planned and executed. The 'crises of representativeness', as it has been called during the manifestations, are expressed by the 200 million Brazilians who pay the high taxes and vote, and then expect to receive the basic public services that addresses the population's general issues and represent the country's will.

Saying that and adding Gaffney (2010)'s quotation that opened this section, the 'crises of representativeness' within the port area urban intervention become explicit. With almost half of its population living in slums and with a strong sense of solidarity in order to handle the everyday life, it is easily assumed that the 50 floor buildings and other 'modern' artifacts are not necessarily being constructed to address the basic needs of this population. For instance, analyzing the official documents and through interviews with *CEDURP*, it has been clear that although the *Porto Maravilha* project has some initiatives related with 'capacity building' within the area, most of the small commerce of the region will not survive the urban transformations. Moreover, as much as the official discourse says the opposite – justified under the existence of the 'Cultural Port' and 'Citizen Port' initiatives within *Porto Maravilha* project – the grassroots character of the region will not be fully reflected in a museum or other initiative addressed to an international tourist. As mentioned by Mello and Gaffney (2010), the current situation of the mega-events in Rio de Janeiro, as well as historically in their previous editions in other Global South countries, fosters the already existent social inequalities. As highlighted by Preuss (2004), 'in developing countries, the economic impact created by the Games is smaller than in industrialized countries [...] if the games neither support an urgently needed city development nor the economic impact to be expected then only a positive image and promotion effect may occur' [p.285].

More broadly, recent debates in urban theory, which not necessarily address the mega-event's social legacy but defend the importance of learning from cities' experiences everywhere, have also advanced in the discussion of the question: 'for whom are the urban transformations?' The postcolonial urban theory has put a question mark on the well-accepted assumption that for a city to be modern, it should follow certain patterns well accepted in the mainstream urban theory. Jennifer Robinson (2006, Robinson, 2011), one of the key scholars of this area, defends a postcolonial urban theory committed to challenging the 'colonial and neo-imperial power relations that remain deeply embedded in the assumptions and practices of contemporary urban theory'. For her,

'these are certainly evident in the practice of dividing, categorizing and assuming hierarchical relations amongst cities, but they are also visible in accounts of urban modernity – the creativity, dynamism and innovativeness of cities – which have assumed a privileged relationship with certain wealthy, Western cities. By contrast, a post-colonial urban studies would draw its inspiration from all cities, and all cities would be understood as autonomous and creative (Robinson, 2006)."

This means, to take the provocative question on the title of this session, that when the mega-events urban transformations are driven to develop the city in a way that it can position itself among the other 'western' 'modern' 'global' cities, the grassroots experiences are usually suppressed in order to give space for the city progress and development. If the above-mentioned issue is exactly 'for whom are the urban interventions?', the collaboration of the postcolonial urban discussions goes on the revision of 'why the city should follow the same 'First world' features in order to be 'modern'. Using this different approach toward the urban regeneration process such as the one that is taking place in Rio de Janeiro's port area, the question becomes how to learn from the things that have already taken place within the urban terrain?

Addressing this question, McFarlane (2011), who is another postcolonial urban study's advocate, focuses on these everyday practices of cities everywhere and raises the question, among the discussion of urban learning, of how these grassroots experiences take place and how to learn from and with them? For him, and also for this paper, 'the urban learning is not exhausted by the specificity of particular encounters with urban form or process, but is instead embedded in the current of people's lifeworlds and is shaped **relationally**' (McFarlane, 2011). Saying that, and looking more narrowly to the Rio de Janeiro's port area revitalization, one would agree that is possible to draw a more 'situated' urban practice if paying attention to the ways that the local population already copes and addresses their own

issues. For instance: How this people, who have been there for generations, dealt with the structural and symbolic separation between the port area and the city?

5. Bridging the gap: grassroots creative experiences within the port area

The aforesaid sequence of occurrences and urban interventions within Rio de Janeiro port area have briefly explained the abandonment and fragmented situation that the area and its population were facing until 2010, when the mega-events have triggered a series of transformations. However, as discussed in the previous section, the premises of such mega-events' driven urban revitalization do not necessarily address the priority issues of the local area and its population. Moreover, another point discussed above incorporates the importance of learning from the urban solutions that are already taking place within people lifeworlds.

Therefore, using McFarlane's idea of urban learning as something 'embedded in the current of people lifeworlds and shaped relationally' (McFarlane, 2011) and focusing on potential examples taking place within Rio de Janeiro's port area, two initiatives will be briefly presented here. Among the various issues, this paper has chosen the abandonment situation and the lack of connections and dialogue between the city and its port region as the area to looking for these grassroots creative experiences that could trigger a further discussion about more situated ways of addressing these population latent urban issues.

Nevertheless, it is important to highlight that the option of calling these grassroots experiences as 'creative' draws on Landry (2008) discussion of the need for a paradigm change within the urban realm. For Landry, the urban transformations are nowadays 'moving from an 'urban engineering' approach to urban development, to a 'creative city-making' approach' (Landry, 2008). Saying that, and also stressing the importance of learning within this process, he defends that creativity is 'applied imagination using qualities such as intelligence, inventiveness and learning along the way' (Landry, 2008). Another author that has also addressed the role of grassroots creative experiences as a way of urban planners to learn and discuss potential urban interventions is Sandercock (2003). She argues that:

'There are different kinds of appropriate knowledge in planning. Local communities have experiential, grounded, contextual, intuitive knowledges, manifested through speech, songs, stories, and various visual forms. Planners have to learn to access these *other ways of knowing*' (Sandercock, 2003) [p.34].

Hence, one of the experiences worthy to comment here is the Samba group *Escravos da Mauá*. For 21 years, this group composed by government employees, who work in the public buildings of the port area, some port dwellers and friends have fostered the revitalization of Rio de Janeiro's port area through art, culture and fun. With monthly open rehearsals, this group brings people from the 'city' and from the local area to sing and dance samba inside the port area. As something done by people who are truly committed to the region, the *Escravos da Mauá*, whose name is a tribute to the slaves and other black people who were the reason for the are been called 'The Little Africa', has not only 'sang' the local area, but published historical CD-ROMs telling the story of these maritime neighborhoods. Using lyrics that celebrate the pioneers of samba, who were originally from that location, the samba group that plays every carnival has received various prizes for its value and appreciation effort within the port area. One of them, for example, is from the Architects Institute of Brazil in Rio de Janeiro that honored the group with the 'Urbanity prize' of 2000, which is given to the initiatives that foster the preservation and revitalization of the historical and cultural heritage, and occupies the public space in a creative way. As it is stated in *Escravos da Mauá's* website,

'The samba group *Escravos da Mauá* and the samba gathering of Mauá represent our strong commitment to occupy the public spaces of Rio de Janeiro with happiness, samba, love and peace' (*Escravos da Mauá*, 2013, author's translation)

Another grassroots creative experience that has taken place for more than 10 years in *Morro da Conceição*, which is one of the historical hills of the port area, is the Mauá Project. It happens on 8th of December of every year, at the same day of celebration dedicated to worship the catholic saint *Nossa Senhora da Conceição* within the region. On that day, the artists, who live and work at their houses at *Morro da Conceição*, open their doors to the visitors displaying their arts and the particular features and lifestyles of one of the first inhabited hills of Rio de Janeiro. This initiative, which has encouraged dialogue and attracted people from in and outside the port area, is currently passing through an interesting process that reinforces McFarlane (2011)'s understanding of urban learning as something 'embedded in the current of people's lifeworlds and shaped **relationally**' (McFarlane, 2011). Recently, a private institution, which is associated with the *Porto Maravilha* project, has approached the core group of artists of Mauá Project looking for the possibility of institutionalizing the event, amplifying its impact, number of visitors, etc. However, this effort generated some clashes between the artists and the relational sense that used to connect the group throughout the years has slightly changed to a more capitalist relation. Some of the artists, for example, have requested salaries from this private institution in order to do something that once had been started under their own mutual help and interest.

The recent urban revitalization process undertaken by the *Porto Maravilha* project has somehow impacted both of these cases. In the Mauá project, the impact was expressed through the attempt to institutionalize something that was strongly connected with the relation of trust among the core artists and also between them and *Morro da Conceição's* neighborhood. After some clashes, some of the artists have stuck together and decided to do the event again in the way they have always believed. The *Escravos da Mauá's* case, on the other hand, has felt the impact and answer it in a different way. After witnessing the discussions about urban revitalization, the *Escravos da Mauá* group has felt the importance of shedding light on the historical actors and cultural groups that throughout the long period of port area abandonment have kept the area alive and conscious of its importance within Rio de Janeiro scenario. This can be seen in the lyrics and performance of *Escravos da Mauá* during the last carnival [2013]. For the first time after 20 years of performances, they have changed their usual route. They have done that in order to show the crowd most of the historical treasures and main cultural and artistic groups within the port area. These other groups in turn have joined the performance and done their share of the show, which can be considered as the art materialization of the relational aspect of the urban learning process.

However, drawing on Sandercock (2003) one should agree that the *Porto Maravilha* urban intervention is just one point of view of how the port area should be regenerated. These grassroots creative experiences have been shaping the city and particularly the port area in their own way. They are shaping their own history intersected 'with struggles over space and place-claiming, with planning policies and resistances to them, with traditions of indigenous planning, and with questions of belonging and identity and acceptance of difference'(Sandercock, 2003). They represents, as mentioned by McFarlane (2011), the 'inseparable mixture of habits of craft and literature with popular images and slogans *that* is obviously a means for making a living, but it is constituted by forms of knowing that are at once spiritual, popular, traditional, fantastical, and modern.'

6. Conclusion

After presenting the history, urban transformations and potential of learning from grassroots creative experiences within Rio de Janeiro's port area, this paper wishes to collaborate with the major discussion about the challenges and opportunities of city-making in the Global South. Bringing back the quotation presented in the introduction, which says that the '*Porto*

Maravilha is returning a historical treasure to Rio, and at the same time integrating areas with great housing, cultural and economic potential, which will be transformed into an example of modernity' (CEDURP, 2013b), the question that urges to be addressed is: For whom Rio de Janeiro's port area will be an 'example of modernity'? Based in which principles?

Looking forward to answering that, this paper first commitment was to have a better 'understanding of the exclusionary effects of planning's past practices' in Rio de Janeiro, and particularly in the port area in order to understand how the future plans could address the local citizens ways of being modern. (Sandercock, 2003) In doing so, the historical value of the port area, its urban segregation and consequent need for an urban intervention that takes into account the connection of this area with the city were highlighted. However, this later emphasized need has been recently driven by the mega-events urban transformations in Rio de Janeiro. For instance, utilizing the mega-event's urban boosting discourse, the Rio de Janeiro's port area urban regeneration – the *Porto Maravilha* project, represents the privatization of urban planning and transformation of the city from a place to live to a place to be consumed.

Nevertheless, this paper has also showed the exclusionary side effects that mega-events urban interventions have brought to Rio de Janeiro, a case that does not differ from other developing cities. As mentioned before, the current impact caused by mega-events in Rio de Janeiro, as well as historically in other Global South cities, stimulates the already existing social inequalities in these areas. As highlighted by Preuss (2004), 'in developing countries, the economic impact created by the Games is smaller than in industrialized countries [...] if the games neither support an urgently needed city development nor the economic impact to be expected then only a positive image and promotion effect may occur' [p.285]. In line with this argument, both issues – the economical deprivation of former citizens of the areas of Rio de Janeiro that are under huge urban transformation; and its consequent gentrification process – were discussed by the National Coalition of Local Committees for a People's World Cup and Olympics (2012).

Saying that and following Sandercock (2003)'s argument about an urban planning dedicated to diversity, one should agree that in order to urban interventions to be considered effectively inclusive, the planners would have to take into consideration both the exclusionary effects of the urban transformations in Rio de Janeiro's port area throughout the years and the '*other ways of knowing*' that take place in the everyday life of people who live and use the area. Therefore, the option of looking at the creative grassroots experiences as a creative way of city making represents the attempt of learning from what is already taking place on the ground. Their attempt to bridge the gap between the city and the port area calls the urban specialists attention to the everyday experiences that usually take place within the urban terrain of cities everywhere. This is particularly common in Global South cities due to their recent city booming and associated social urban issues. These locations have witnessed many forms of improvisation of their dwellers learning to 'negotiate cities through incremental experience'. As mentioned by McFarlane (2011),

'Improvisation is, however, just one way in which people learn to negotiate cities through incremental experience. For example, given the diverse nature of many large cities, urbanities often need to learn to negotiate a wide range of groups, identities and places'. [p.43]

All in all, the analyses of the grassroots creative experiences that are already taking place in a city requires open eyes committed to seeing things differently and capable of understanding the importance of creativity as something constructed relationally within the urban terrain. The briefly presentation of the two cases intends to highlight the importance of learning from these experiences, as they have already invented their own ways of addressing their social issues. On the other hand, they do not necessarily reflect the expectations of the private companies, international tourists or other types of interest that

look at the city as a place to be consumed. Other than that, these grassroots creative experiences are calling the urban planners to learn from 'another ways of knowing' (Sandercock, 2003) that happen in cities everywhere (McFarlane, 2011, Robinson, 2006, Robinson, 2011) and showcase the role of creativity in the city making (Landry, 2008).

Simulating the Impact of Urban Morphology on Energy Demand - A Case Study of Yuehai, China

Chuan SHANG, School of Architecture, Southeast University, China

Ko-Yang LIN, Welsh School of Architecture, Cardiff University, UK.

Guoying HOU, Welsh School of Architecture, Cardiff University, UK.

1. Shortened Abstract

The aim of this study is to attempt to explore the impact of urban morphology on the energy demand of buildings, using simulation tools developed by the Welsh School of Architecture, Cardiff University, called VirVil Plugin and HTB2. The process of simulation is applied to one proposed project with four different scenarios, while the study considers one parameter for each scenario as follows: 1) building forms; 2) average building height; 3) orientation of building; and 4) community pattern. The project is chosen from an urban design scheme of Yuehai Eco-City in Yinchuan, China, designed by Architects& Engineers Ltd of Southeast University, China. The simulation results indicate a quantitative correlation between urban morphology features and the energy performance of buildings at urban scale. Furthermore, the results provide several perspectives for developing constructors to reduce the energy demand at the master planning stage. Moreover, the study also suggests that the method could spread globally.

2. Introduction

It is now widely accepted that enhancing energy efficiency of buildings is one of the primary approaches to achieve sustainable development. Most previous studies discussed this issue primarily from the perspective of individual buildings. A large number of reliable architectural design guides have been summarized, such as raising the thermal performance of fabric, improving energy efficiency of device systems, designing envelopes giving priority to climate and site, and even net zero energy buildings have been constructed. However, most of these researches and observations were conducted for a standard non-urban environment (Futcher et al., 2013). In this regard, it is important to recognize that if a cluster of buildings with good energy performance is assembled into a block in a non-optimal arrangement, the interactive influence generated by the surrounding buildings may increase the energy consumption of the buildings and the whole block. In contrast, greater reduction in energy consumption could be achieved in advance by considering urban form and micro climate at a master planning stage.

Only a few (but a growing number of) researches concerning building energy performance at urban scale have been addressed from the viewpoint of urban climatology, particularly with regard to the impact of urban morphology on the energy demand of buildings. Wong et al. (2011) simulated a three-storey office building located in a tropical climate city, Singapore, over one day. They employed 32 scenarios to represent different surrounding urban settings, accounting for three parameters: greenery, building height and building density. The

simulation results showed that increasing the height and density of the surroundings (greenery and buildings) lowers the temperature of the external microclimate and reduces the cooling load of the building by around 5%. Strømmandersen and Sattrup (2011) found that the total energy consumption of low-energy buildings in the north-European setting may be affected by the geometry of urban canyons in the range of up to a 30% increase for offices and a 19% increase for housing, demonstrating that the geometry of urban canyons is a key factor in energy use of buildings. Adolphe (2001) developed a simplified spatial model based on a set of original morphological indicators of the environmental performance of urban patterns, to define urban morphology in terms of various parameters, such as density, rugosity, sinuosity, contiguity and solar admittance, anticipating the application of this approach to simplify the analysis of outdoor microclimate tendencies and the energy balance of urban patterns. Cheng et al. (2006) examined the relationships between built forms, density and solar potential based on a sky condition of low geographic latitude, by simulating 18 generic models with reference to three criteria: sky view factor at ground level, daylight availability on building facade and PV potential on building envelope, revealing that randomness in both horizontal and vertical layout and low site coverage with a higher building can provide helpful insights for planning solar cities. Fitcher et al. (2013) examined the suitability of urban settings for buildings with a change-of-use function (from office to residential) in a typical city street and with the current and projected climate of London. By calculating the heating and cooling demands of buildings, they found that urban setting (and in particular street geometry) plays a significant role in regulating the solar access, and should be considered as a building and urban energy management parameter in the early design stages. Jones et al. (2009) simulated buildings in a proposed new city with hot and dry climates and considered four design parameters, including orientation, over-shading, construction type and internal heat gains. Salat (2009) observed a district of 96,000 existing buildings in Paris and compared some environmental metrics of urban forms. Their study revealed the impact of urban morphology and building typology on energy efficiency in the different zones of Paris. Finally, they emphasized the necessity of optimizing the parameters of urban form at the stage of urban planning and management.

The previous researches presented above demonstrated that urban form can play an important role in regulating energy performance of buildings at urban scale. Thus, considering the parameters of urban form (e.g. building shape, density, green ratio, orientation, street geometry, sky view factor) at the early design stage should help to minimize the energy demand of buildings. Therefore, there is considerable scope to explore the energy performance of blocks in environments with complicated climatic conditions and to establish the impacts of the parameters relating to urban form.

3. Methodology

Energy performance calculation at urban scale can be subdivided into two categories: top-down and bottom-up approaches. The top-down method focuses on long-term statistics and considers pertinent parameters and on-going changes in order to estimate the effect on energy consumption of buildings. The parameters commonly adopted are gross domestic

product (GDP), employment rates, price indices, climatic conditions, housing construction and demolition rates, appliance ownership, and units (Swan and Ugursal 2009). On the other hand, the bottom-up method contains statistical and engineering aspects (ibid.). The statistical aspect uses similar historical data as the top-down method, but considers more information relating to the end-user. In contrast, the engineering aspect, which is strongly supported by technology and calculated in dynamic systems, accounts for the energy consumption with a massive amount of detailed information, such as diary and small power application. The advantage of the method is to allow researchers not only to simulate and analyze the energy performance of existing buildings, but also to predict the changes that will result from design strategies or technical improvements.

3.1 Framework of methods

The research method employed here is based on the concept of the engineering aspect in the bottom-up approach. In the first stage, detailed information relating to local weather, geometrical background, diary of occupancies, materials and layouts of buildings, and outdoor environmental information is considered in order to create a prototype. This prototype is then used as a basis in simulations for comparing with the results of experimental models. Within the simulations, four different experimental models are constructed, with each model considering a different parameter. The parameters considered are: form, average height, orientation and community pattern. Finally, through dedicated discussion and analysis of the simulation results, the principles required to save energy demand of buildings for the Yuehai Eco-City master planning are established (Figure 1).

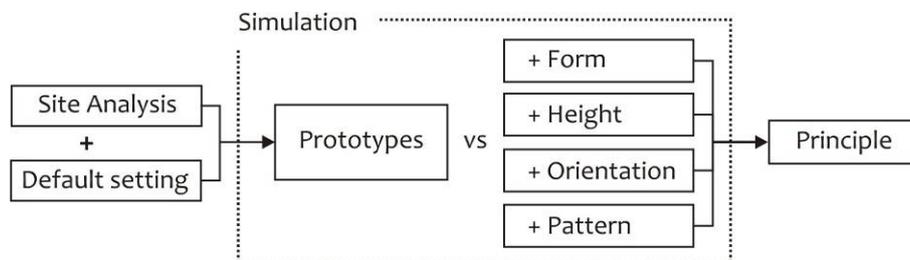

Figure 1 The framework of methods.

3.2 Technical tools

The proposed calculation engine was developed to simulate buildings at urban scale, and is integrated by SketchUp (@Last Software and Google), HTB2 v2.10 (WSA 2008), and Virvil Plugins (WSA, 2012). SketchUp is among the most popular software for 3D building used by architects and urban designers, while HTB2 is recognized as one of the most reliable calculation engines for energy use and internal temperature prediction (Alexander, 2003). Virvil Plugins are updated tools to connect both of them, helping to extend the limited scope of HTB2 to consider the relationship of buildings to the nearby surrounding areas (Lin, 2013). These tools were adopted in this research because of their high reliability, applicability and user-friendly interface.

4. Subject

This case is chosen from an urban design scheme of Yuehai Eco-City in Yinchuan, China, which is designed by Architects & Engineers Ltd. of Southeast University, China. Yinchuan is located in the northwest region of China, between 37°29'N~38°53'N and 105°49'E~106°53'E. The average elevation of Yinchuan is 1,010 to 1,150 metres. Yinchuan has a continental desert type of weather, with an annual average temperature of 9.4°C. Also, it is characterized by long hours of daily sunshine, intensive solar radiation, observable differences of diurnal temperature and four seasons.

The planned area of Yuehai Eco-City is 317.4 hectares, located at the north of Yinchuan city centre close to the Yuehai Wetland Park. In order to make a low carbon and ecological living environment and to meet the local government's requirements of energy performance for buildings, this planning aims to create a pleasant urban environment and to reduce the overall energy consumption of the eco-city.

The simulation prototype of this study is based on block numbers 6, 7 and 8 of the Yuehai Eco-City Planning Scheme. Building types are categorized as domestic, commercial, school and office (Figure 2). Building form has been simplified in order to reduce the simulation time, but without compromising the accuracy. The default settings for the construction, layout and materials of buildings are based on high standard building regulations. The parameter settings for different types of window-wall ratio and indoor conditions are given in Appendices A, B and C. The four simulated scenarios considered in this study are created by adjusting the building form, the average building height, the orientation of buildings, and the community pattern. The context of the proportion of building types, total floor area, and building construction are not changed, and are again set to satisfy the requirements of local planning regulations.

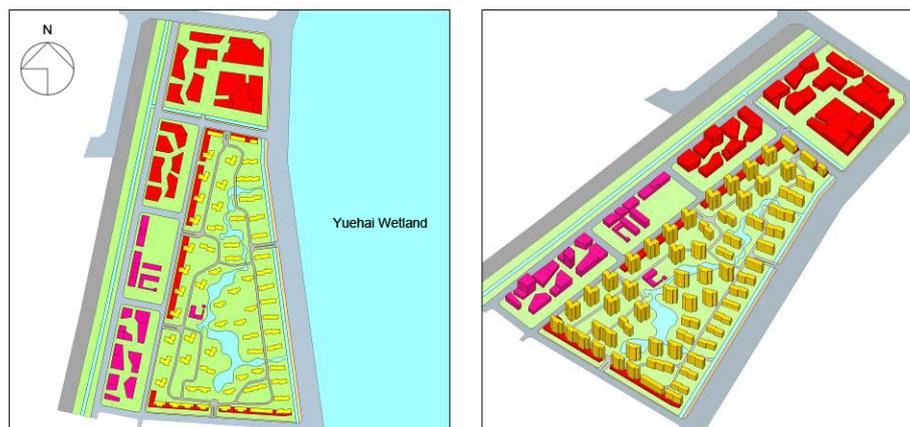

Figure 2 Images of the prototype used in this research: domestic (yellow), commercial (red), school and office (pink).

5. Discussion and Analysis

The simulation results of one prototype have been compared with four different experimental models based on consideration of the following four parameters: building form, average building height, orientation of buildings and community pattern (Figure 3). In the following sections, each of these parameters is analyzed and discussed.

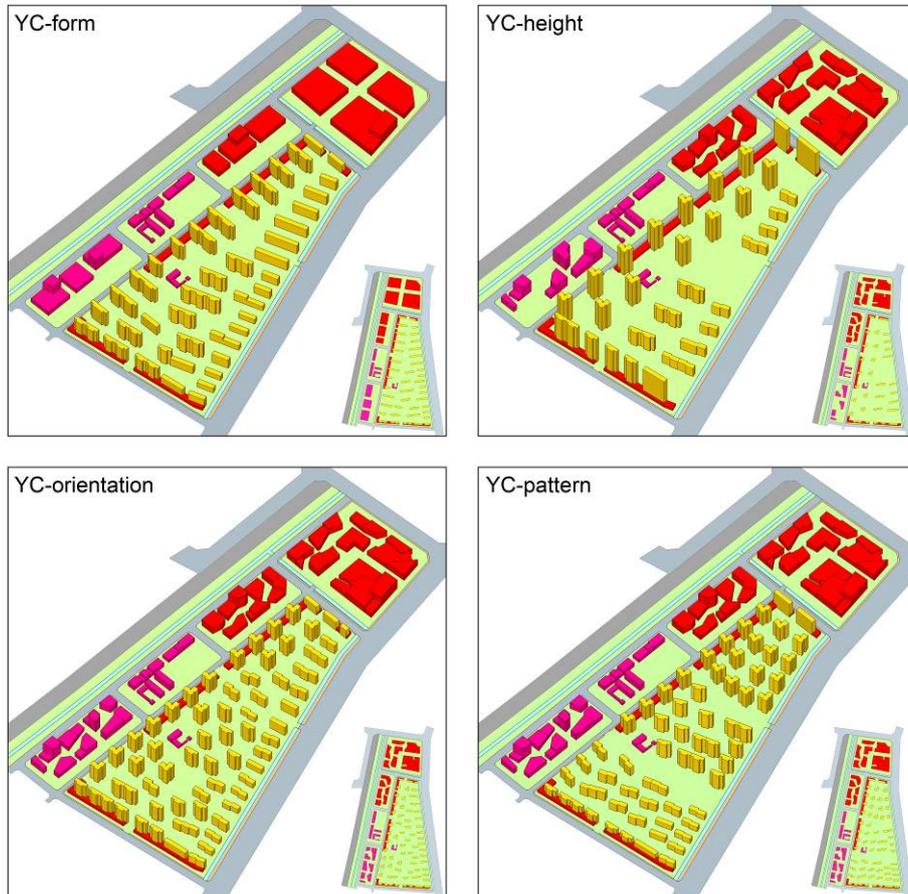

Figure 3 The four experimental models based on consideration of the following parameters: form (upper left) average building height (upper right), orientation (lower left) and community pattern (lower right).

5.1 Building form

Building form, which refers to the geometrical characteristics of the buildings, affects the solar gain and energy demand of buildings in the urban environment by changing the wall-to-volume ratio and the corresponding effect of over-shading (Lin, 2013). In northern China, the two most popular forms of domestic buildings are point block and slab block. For commercial buildings, the most popular types are commercial blocks and shopping malls. The prototype, YC, adopts the point block form for domestic buildings and commercial blocks for commercial ones. On the other hand, the experimental model, YC-form, adopts slab block and shopping mall types.

The simulation results show that integration of the slab block form for domestic buildings and the shopping mall form for commercial buildings decreases the energy demand (Figure 4).

The heating demand of slab block domestic buildings is generally 2.3 kWh/m²/yr lower than that for domestic buildings with the point block form, whereas the cooling demand is nearly the same in each case. For commercial buildings, the shopping mall form consumes less energy both for heating and cooling. Although the dependence of energy demand on building form may be much less than the dependence of energy demand on other mechanical strategies, optimization of building form is nevertheless a passive design strategy that can improve the overall energy performance of buildings.

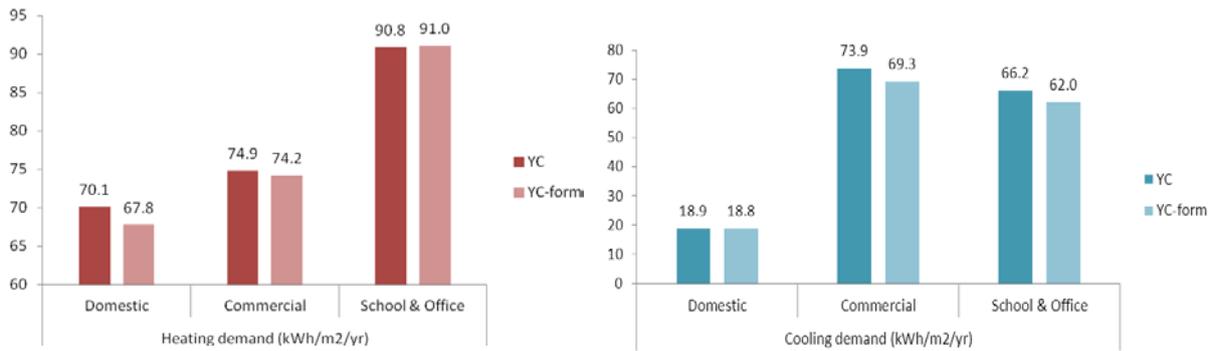

Figure 4 Comparison of energy demands between the prototype and the experimental models with different building forms.

5.2 Average building height

The impact of building height on the energy demand of buildings mainly arises from their role as practical obstacles in the urban environment. In particular, the building height not only shapes the skyline of a city and alters the amount of open space at ground level, but also affects the sunlight accessibility and solar gain. Based on the same building floor ratio of the site, an experimental model, YC-height, with higher average height of domestic buildings (78.3 metres) was created to explore the relationship between building height and energy demand (the average height of domestic buildings in the prototype model is 41.2 metres).

The simulation results indicate that the overall energy demands, considering all building types together, are higher as the building height increases. The annual heating demand of buildings in the YC-height model is higher for commercial and school/office buildings and slightly lower for domestic buildings compared to the prototype model (Figure 5). For commercial buildings, there is an increase in heating demand of 1.2 kWh/m²/yr for the YC-height model, whereas for school/office buildings, the increase in heating demand is 6.3 kWh/m²/yr. Furthermore, in the experimental model, over-shading brought about by higher buildings increases slightly, which is supposed to be the reason underlying the rising requirement of heating during the winter time in Yinchuan.

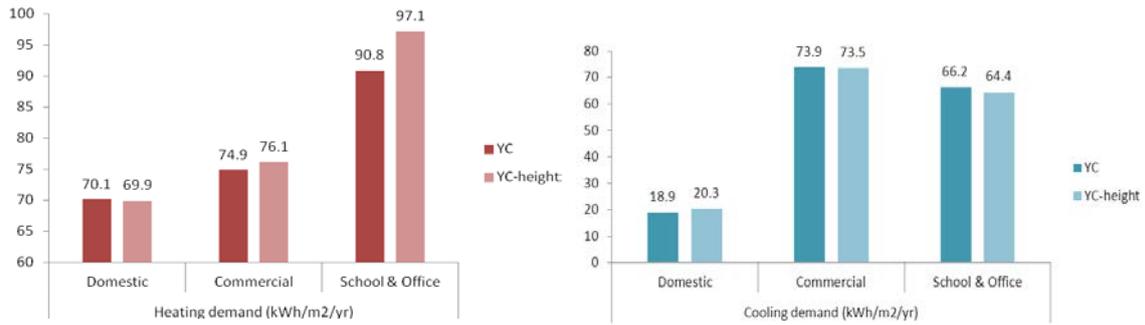

Figure 5 Comparison of energy demands between the prototype and the experimental models with different average building height.

5.3 Orientation of buildings

The orientation of a building is defined as the direction perpendicular to the main surface of the building. Clearly, the orientation of a building affects the solar gain and the energy demand by altering the incident angle and duration of sunlight. It is regarded as one of the most important parameters in housing design in northern China. In the prototype, YC, the direction of the domestic buildings is within plus or minus 15 degrees of a directly south-facing orientation. In the experimental scenario, YC-orientation, all domestic buildings have the orientation of facing south exactly.

The simulation result shows only minor differences in the energy performance of buildings between the two models, with differences of no more than 0.4 kWh/m²/yr for all types of building (Figure 6). Thus, the results suggest that the energy performance of buildings facing directly south and facing close to south in the community scale in Yinchuan are almost the same. The same situation is observed both for the heating demand in winter and the cooling demand in summer. In short, the orientation of buildings in the modelling situation has very limited impact on the energy demand of buildings.

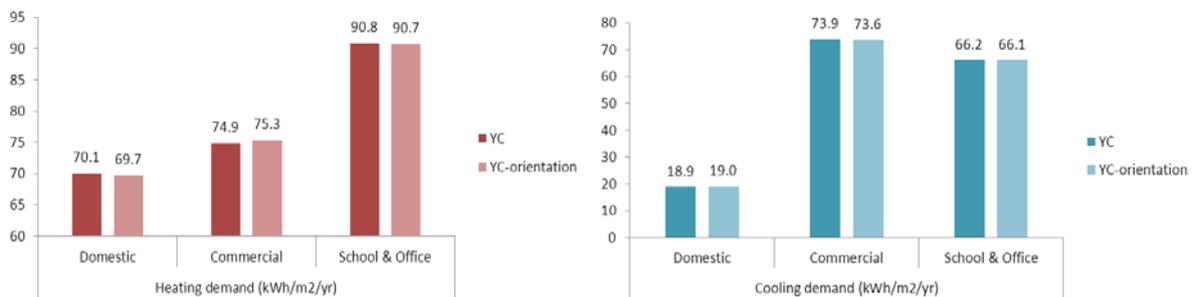

Figure 6 Comparison of energy demands between the prototype and the experimental models with different orientations of buildings.

5.4 Community pattern

Community pattern is another major issue, which has been analyzed by previous researchers with regard to the street geometry formed by buildings and the different horizontal and vertical layouts of buildings. It was demonstrated that the juxtaposition of buildings and the form of external spaces outside the envelopes affect airflow below roof level, cause over-shadow, and change the reflected light, which consequently influence the entire energy consumption of the buildings.

In the experimental model, YC-pattern, the three different types of domestic building (multi-storied apartment group, point block group and slab block group) are arranged from north to south respectively. In contrast, in the prototype, YC, the different types of domestic building adopt a random layout.

The simulation results indicate that the differences in energy demand of buildings between the two models are within 0.5 kWh/m²/yr, with the exception of the heating demand for domestic buildings (Figure 7). Thus, for domestic buildings in YC-pattern model, the heating demand is approximately 2.3 kWh/m²/yr higher than the heating demand of the prototype. Furthermore, for each type of building, a negative correlation is observed between the heating demand and cooling demand in comparing the experimental model and the prototype model. In short, our results imply that over-shading arising from a relatively concentrated and unified community pattern should give rise to an increase in the heating demand of domestic buildings in winter and a decrease in the cooling demand in summer.

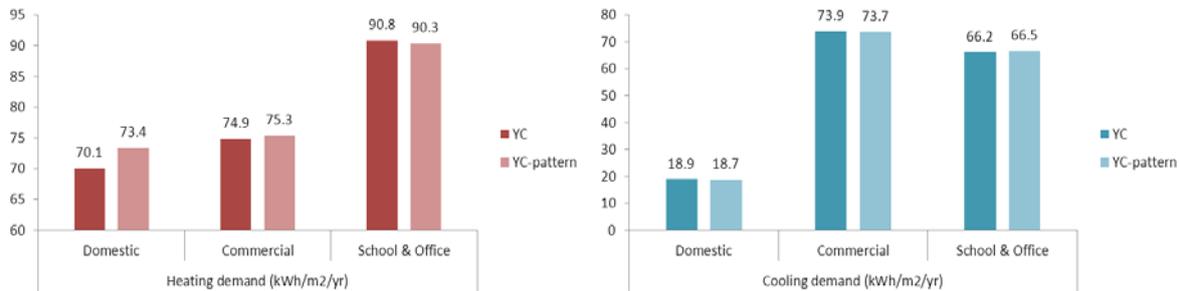

Figure 7 Comparison of energy demands between the prototype and the experimental models with different community patterns.

5.5 Summary

From detailed comparison of the simulation results for the prototype and the four experimental models, several significant conclusions emerge. Importantly, the total energy demand of YC-form is lower than the prototype by 1.6 kWh/m²/yr, the total energy demand of YC-orientation is nearly the same as the prototype, and the total energy demand of YC-height and YC-pattern are higher than the prototype by 2.5 and 3.2 kWh/m²/yr respectively (Figure 8). Consideration of the implications of our results in terms of building design strategies leads for the following conclusions: (1) compact building forms and horizontal and vertical random layouts are one of the most effective strategies for reducing the energy demand of buildings at

urban scale, (2) when the average height of buildings is over 75 metres, the energy demand increases as the average height increases, and (3) moderate changes in the orientation of buildings do not have any significant effect on the energy demand at urban scale. Furthermore, the effect of altering the compactness of building forms may be interpreted in terms of changes in the wall-to-volume ratio of the buildings. Lower wall-to-volume ratios avoid massive heat exchange, leading to better energy performance of buildings.

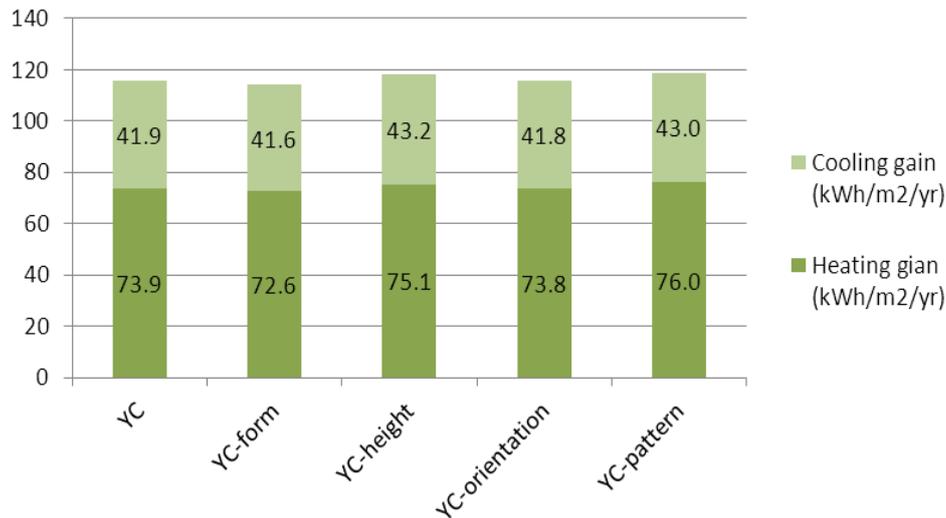

Figure 8 The comparison of annual energy demands between the prototype and experimental models

6. Conclusion

This paper simulates the energy performance of a community based on the urban design scheme of Yuehai Eco-City in Yinchuan, northern China. Four scenarios have been employed representing four different experimental models to investigate the effects of building form, average building height, orientation of buildings and community pattern on the energy demand of different types of building (domestic, commercial and school/office buildings). By comparison with the prototype model, the results of experimental simulations indicate that more compact building forms and horizontal and vertical random layouts of buildings can help to reduce the energy demand of buildings at urban scale. Additionally, when the average height of buildings is over 75 metres, increasing the average height has a detrimental effect on the energy demand. Moreover, moderate changes in the orientation of buildings only have a weak effect on the energy demand of buildings at urban scale.

The findings of this study provide some valuable principles for energy-efficient community design at the master planning stage for cities with continental desert weather type. The primary recommendation from this study is to choose compact building forms; thus, given the same amount of floor area, a decrease in the average wall-volume ratio of buildings should reduce the total energy demand. Furthermore, random layouts in both horizontal and vertical levels are shown to be advantageous over regular layouts. Finally, a lower average height of

buildings is found to give rise to better energy performance, in contradiction to the widely held view that increasing the compactness of cities, in particular by increasing the average height of buildings, should be advantageous for reducing energy consumption.

Lastly, it is relevant to highlight some limitations of this study. Firstly, the prototype model was selected from a proposed design scheme which already incorporated consideration of energy efficiency through the experience of the designer. Thus, there is only limited scope for the experimental models considered in the present study to achieve improvements in energy efficiency relative to the prototype model. However, the accumulative effect of all relevant parameters that influence energy demand at urban scale still requires to be investigated, and such studies should lead to the development of better passive design approaches. Thus, further studies should focus on understanding the effects of groups of parameters and their individual impacts on energy performance in more aggressive situations.

Challenges of Spatial planning in the context of ICT: lessons from actual research projects – new frontiers for spatial planners and cities.

Didier VANCUTSEM, Faculty of Architecture,
Université Libre de Bruxelles (ULB), Belgium

1. Introduction

The emergence of ICT (Information and Communication Technologies) since the 90's modified profoundly our urban environment and the way spatial planning is implemented. This case study aims to explain the importance of the relationship "ICT - Spatial Planning", connected to future frontiers of spatial planning and is based on the results of three projects Plan4all, HLandata and plan4business, where ISOCARP was involved as consortium partner.

2. Role of the ICT in today's Society

In the past 250 years, the World experienced five major technological revolutions and each of these was linked to a specific technological innovation (1771, The First Industrial Revolution in Britain, based on the mechanization of the cotton industry; 1829, The Age of Steam and Railways; 1875, The Age of Steel and Electricity; 1908, The Age of Oil, the Automobile, and Mass Production; and finally 1971, The Age of Information and Telecommunications). Every technical invention and development has resulted in advantages and disadvantages, which have influenced the well-being and prosperity of mankind. But somehow, they have provided the conditions for a long period of sustained economic growth as a process of economic development, which is usually described as a series of waves (Kondratieff waves) (Kondratieff, 1925).

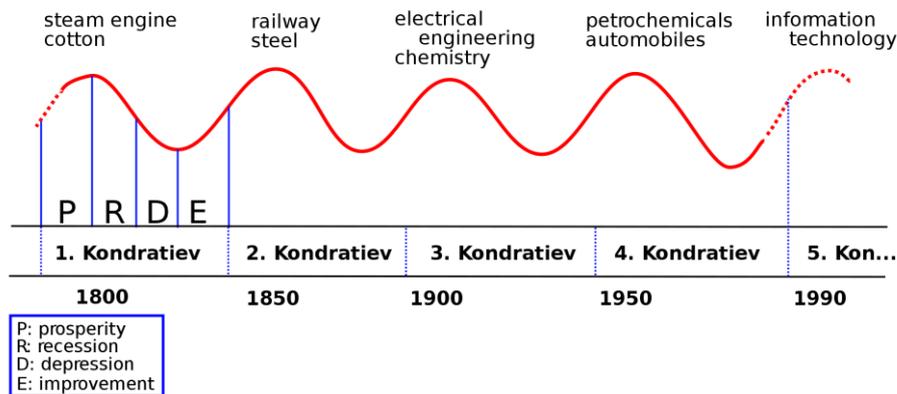

Figure 1: Simplified Kondratieff Wave Pattern (2009), Wikipedia

These technological innovations, characteristic for each periods of technological revolution, had a fundamental influence on the behaviour of man and consequently on society. Such influences can be seen in every level of daily life including living conditions, housing and recreation, and have changed our habits and our culture.

They have also a number of aspects in common. First of all, specific technologies have a wide applicability to a variety of different production processes, generating both process and product innovations. Secondly, because of this feature, they generate a whole series of new applications. Thirdly, because of large and increasing demand for this bundle of innovations, they create and shape new industrial complexes, which can be characterised by a large number of horizontal and forward reaching linkages: **Everything is interlinked.**

Among the five technological revolutions, three are directly linked to the means of transportation and communication: the developments of the steam engine, the combustion engine and the microchip technology in the 60s together represent a shift from the moving of goods, to an increased ease of moving people and exchanging information and ideas.

The integration of digital technology and computers finally resulted in the development of communication technology and the introduction of the term ICT (Information and Communication Technology). Regarding the microelectronic revolution, we are still in the **middle of a learning process**. Considering the on-going developments in cloud computing, multi-touch screens, intelligent systems for houses and communication, broadband and broadcasting, also related to nanotechnologies, it seems evident that the Information and Communication Technology is already dominating and will continue to dominate our way of life in the near future. One aspect is however evident from the past 250 years:

Technological change involves both technical change and organisational change.

It remains difficult to evaluate the effects of ICT on the organisation of society and on spatial and urban planning because the topic is very complex and the microelectronic revolution is still in process. Nevertheless, it is evident that the ICT influence is not direct, but indirect via social and economic trends, which cause changes in the behaviour of each individual in society, the economy and, consequently, in culture.

A rapid transformation is currently taking over advanced industrial cities. Old ideas and assumptions about the development, planning and management of the modern, industrial city seem less and less useful. Accepted notions about the nature of space, time, distance and the processes of urban life are similarly under question. Boundaries separating what is private and what is public within cities are shifting fast. Urban life seems more volatile and speeded up, more uncertain, more fragmented and more bewildering than at any time since the end of the last century.

Related to urban and spatial planning, the use of Information and Communication Technology (ICT) has been under constant development over the last decade and is **becoming a standard today in the worldwide Urban and Spatial Planning context**. Publishing information via the internet, communicating via e-mail, chatting and using interactive, real-time virtual reality to show the results of a planning process is the planners new normal day. Actual development is the “e-planning” philosophy, which refers to the use of electronic processes in delivering planning and development services, such as the online placement and processing of development applications, and the provision of web-based information such as maps, regulations and state and local policies. Such processes are already installed in several administrations around the world and give positive feedback with strong support from government, industry and communities.

Only as an example, the European Union launched in 2010 the Digital Agenda for Europe (DAE), which aims to reboot Europe's economy and help Europe's citizens and businesses to get the most out of digital technologies.

3. Interaction of ICT and spatial planning

Cities and spatial planning are becoming more and more influenced by the use of ICT in the industrial change.

Emerging trends of urban evolution are supported by:

- Digital telecommunication networks such as the Internet and broadband technology;
- “Nomadic” tools facilitating mobile lifestyles, such as mobile phones, wireless, laptops, PDAs, smart phones, pagers, GPS, etc.;
- Decentralised networked intelligence embedded everywhere, in the Internet itself, including also cloud computing; and
- IP services, sensors, smart electrical supply, electronic road pricing and navigation.

Digital telecommunication networks are new types of urban infrastructure, following in the footsteps of water supply and waste disposal, transportation, electrical supply, telegraph and telephone networks. They often replicate the routes and nodes of earlier networks, which both fragment and recombine urban activities and spaces. New networks infrastructures selectively loosen spatial and temporal linkages among activities. Latent demands for adjacency and proximity become reality. This produces simultaneous fragmentation and recombination of urban types and spatial patterns. Some traditional spatial types may disappear, others may transform themselves and new types and patterns emerge.

In the time of information, different combinations of local and remote interactions, together with synchronous and asynchronous modes of communication provide the “glue” that holds communities together. Many options simultaneously exist, with differing costs and advantages. Citizens are able to choose among them within an increasingly complex economy of presence.

The relationship between spatial settlement pattern and modes of communication is illustrated in the table below. The emergence of the information society is demonstrated in a massive shift across the diagonal of the table, from local synchronous interaction to dispersed asynchronous communication. These shifts affect markets and organisations as well as communities, as they produce a new cycle of fragmentation and recombination of familiar spatial types and patterns.

Settlement pattern	Modes of communication		
	synchronic	Semi-synchronic	A-synchronic
local	face-to-face agora 9-5 workplace	post-it notes whiteboards	non-circulating libraries old-fashioned databases
partially dispersed	churchbells sirens loudspeakers	pedestrian and bicycle messengers	LANs Intranets
dispersed	telegraph telephone live broadcast teleconference	Mail systems voicemail email	Internet www dot-coms

Figure 2: Adapted from “Information in the Urban Age”, ISOCARP Congress 2002. Source: Mitchell, 2002

ICT is a significant factor affecting spatial change and consequences can often be rather surprising. This necessarily provides planners with some challenging problems. Spatial change from the point of view of urban and regional planning is always both an opportunity and a threat. However, current on-going changes offer opportunities to use the new possibilities inherent in ICT to enable regions, cities and rural areas to partake in new types of development. New development trends can also threaten the future of these areas. Therefore planners have to find ways to try to forestall such possible negative effects.

On the other side, decentralisation, multilevel governance, public participation, bottom-up approaches, empowerment, local government, regional approach, environmental policies, strategic planning, participative budgets, council of regions, public private partnerships, administrative links, local agendas 21, low carbon concepts and climate change, vertical and horizontal integration, are some of the actual topics considered today in legal bodies and planning practices.

4. Challenges of spatial planning and ICT

Spatial planning has been around for hundreds of years while the World Wide Web is a relatively fresh arrival that has yet to celebrate its 20th birthday. As a consequence, the predominant practices within spatial planning have evolved out of a non-technological environment.

Spatial planners are concerned about spatial features such as residential, commercial, mixed use and industrial areas, about traffic, transportation, and utilities infrastructure, about community facilities and about all information, which impacts the distribution and suitability of the aforementioned areas. The only way to get an overview of and correlate this type of information is maps. Due to the long traditions of spatial planning, this very often means paper maps.

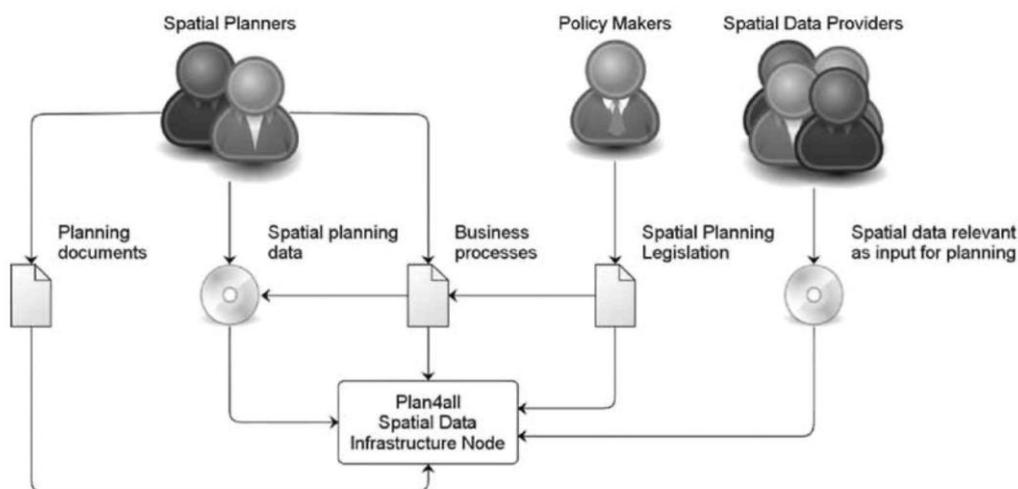

Figure 3: The business of spatial planning is not only a question of maps – spatial planning is about legislation, processes, data, documents and all available information about of a planning area, making spatial planning not only a provider but also a consumer of spatial data. (Plan4all Book, p. 126)

Spatial planners like to draw and conceptualize on maps and, as many are not oriented towards abstract concepts of GIS, express their professional capabilities much more effectively using pen on paper than they would work directly in a digital environment.

While from a GIS perspective, information resulting from the spatial planning process is considered data, the spatial planner will often consider the same information as sketches or drawings – and as a result the often rich by-products of the planning process will not be shareable as it does not conform to any standards interpretable by third parties.

The logical next step for a spatial planner who is used to draw on a paper map is to shift into a CAD environment, which effectively replicates the drawing board in a software environment. In CAD scale and micro-accuracy is of great significance, whereas spatial location and orientation often is not observed. The output is also self-contained drawings,

which print well – but which often do not conform to any form of standard, which makes it possible to transform the drawing into data – shareable and re-usable in a GIS environment.

The first impediment to publishing of spatial data on the Internet is the fact that in most planning laws, the paper map, including its map scale, cartography and underlying base map is what is adopted as the legal spatial plan. This means that publishing the spatial plan as data will not constitute legal data – and may not be desirable from the perspective of the planning authority as it may cause dissent due to use of the data at larger scales and with different cartography which may render boundaries extended or contracted compared to the legal plan.

The second impediment is that introducing static pre-defined data models, controlled vocabularies and GIS software into the equation of spatial planning is a major paradigm shift for the traditional planner.

It is also a shift, which may consume a disproportional share of the spatial planner's professional resource in resolving technical obstacles – and which may curb her or his ability to produce high quality professional work. It must therefore be assumed that the transition from drawings to data will take a significant amount of time.

Such a transition is however necessary if we want to effectively enable not only the use of spatial data as input to planning processes – but also get spatial data as output from the same.

The big software actors in the CAD domain such as Autodesk are currently enabling more comprehensive data intelligence to be embedded into drawings, gradually bringing the universes of CAD and GIS closer together, whereby facilitating the INSPIRE Directive objectives of enabling and efficient use of spatial data across professional disciplines.

5. Learning from research projects

During the past years, several research projects were developed in the European Union, related to the European Directive of “INSPIRE”: the INSPIRE (INfrastructure for SPatial InfoRmation in Europe) Directive aims to establish a European Spatial Data Infrastructure and entered into force in May 2007. The Directive defines SDI (Spatial Data Infrastructure) as “... metadata, spatial data sets, spatial data services; network services and technologies; agreements on sharing, access and use; coordination and monitoring mechanisms, process and procedures, established, operated or made available in accordance with this Directive...” (EC, 2007, art. 3.1).

INSPIRE does not aim to establish new infrastructures, but it is based on infrastructures created by Member States that are made interoperable by common Implementing Rules (IRs) and measures established at the Community level. The purpose is to align national legislation and achieve a joint result within European Member States.

Although the Directive specifically aims to support European environmental policy, INSPIRE is having a great impact on the European GI community. The correct implementation of the INSPIRE Directive could represent a big step towards effective information sharing to support problem solving. INSPIRE represents a solid foundation on which to build wider interoperability of spatial planning in Europe, since it takes into consideration current standards and practices in the field of SDIs, and summarises the point of view of most stakeholders.

The plan4all project was a European project co-funded by the Community programme “eContentplus” between May 2009 and October 2011. Plan4all was a consortium of 24 partners including universities, private companies, international organisations and public

administrations, and where ISOCARP contributed to the findings on spatial planning and dissemination. The main objective of the project was to harmonise spatial planning data and related metadata according to the INSPIRE principles. The project focussed on 7 aspects of the INSPIRE directive: Land cover, Land use, Utility and Government services, Production and industrial facilities, Agricultural and aquaculture facilities, Area management / restriction / regulation zones and reporting units, as well as Natural risk zones.

For this purpose, the Plan4all project first promoted Plan4all and INSPIRE in countries, regions and municipalities; designed the spatial planning metadata profile; designed the data model for selected spatial data themes related to spatial planning; designed the networking architecture for sharing data and services in spatial planning; validated the metadata profile, data models and networking architecture on local and regional levels; established a European portal for spatial planning data; and finally deployed spatial planning data and metadata on local and regional level. www.plan4all.eu

The second project (April 2011- April 2013) called “HLanData – Harmonisation of land use and land cover datasets”, was aiming to demonstrate the feasible European level harmonization of the Land Use and Land Cover datasets taking into account both the data categorization and the data models, for any of their possible uses and users, through the development of user oriented value-added services.

Starting point of the project was that there is no valid data harmonization model for the Land Cover and Land Use datasets, taking into account both the data categorization and the data model and the end users’ specificities, which could be valid for all the application areas and at a European level. Therefore, the project HlanData aimed at making a significant step forward in overcoming the aforementioned barrier, fostering the use of the Land Use and Land Cover geographic data at a European level, through the creation of value-added European services. In order to achieve this objective, newly developed web services were used for the implementation of 3 pilot projects in 3 different application areas, used to validate the harmonization proposal made:

- PILOT 1: Land Use- Land Cover Data Analysis System for intermediate-level users
- PILOT 2: Harmonized and Interoperable Land Information Systems
- PILOT 3: Stratification of waste dumps

The conclusions of the HlanData project and the harmonisation methods of the data models were integrated into the INSPIRE geoportal.

The project plan4business (April 2012 - April 2014) is focussing more on the implementation of the Directive and the accessibility of harmonized datasets. In this case, plan4business is developing a platform serving multiple providers and thus offering users a full catalogue of planning data such as transport infrastructure, regional plans, urban plans and zoning plans. Such an aggregation platform will not just offer clients the data itself in integrated, harmonised and thus ready-to-use form, but will also provide rich analysis and visualisation services. Such services can be offered via different interfaces, such as an API and an interactive web frontend (Web GIS).

6. Conclusions

The work of urban and spatial planners has shifted from maps to data.

The most promising feature offered to spatial planners by SDIs is the ability to quickly identify all available spatial data for a planning area. As opposed to the business process changes required to create spatial data, the changes required to efficiently use spatial data as input to the planning process are considerably less.

By using and having harmonized spatial datasets, the spatial planner is able to control and develop much wider and integrated solutions, by tacking into account all parameters of spatial development.

It is also to be noted that whereas GIS used to be an expert discipline reserved for domain professionals, the art of digital map making, combining information from a multitude of sources and browsing it on the computer screen is now at the fingertips of any contemporary computer user. This may facilitate a behavioural change whereby less of the map information will have to be printed and more may be accessed directly online from decentralized View and Download services.

Therefore, Spatial Data Infrastructures Networking architectures have a great potential to improve the quality of spatial planning enabling quick overview of and access to all spatial data available for a certain planning area, thus ensuring quality input to the spatial planning process.

It is however necessary to understand that spatial planning is not only maps and spatial data but also planning documents and planning laws, which needs to be available to unambiguously interpret the planning data.

Furthermore, a bridge between the mapping and digital cartography environments of CAD and GIS is needed in order to support the flow of information between homogeneously GIS oriented SDI infrastructures and highly heterogeneous mix of CAD and GIS being used in spatial planning authorities.

In addition to the possibilities offered by the technology, behavioural change is required among the spatial planners to effectively exploit the possibilities of the SDI Networking architectures in their day-to-day operations.

New spatial strategies for the densely built-up Flanders region (Belgium)

Guy Vloebergh, CEO of the private planning company OMGEVING cvba, Lecturer at ARTESIS University College Institute and University Antwerp - BELGIUM

1. Introduction

In 1997 the Flemish parliament approved the Spatial Structure Plan, and a coherent spatial vision was formulated in this policy plan under the motto of “Flanders, open and urban”. Flanders, the northern part of Belgium, is in fact characterised by a high population density (450 inhabitants/km²) and an extremely spread-out pattern of construction. From this ambitious spatial policy plan, over the subsequent 15 years there followed a great deal of planning processes concerning urbanicity, living, open space, infrastructure and industry, steered by the Flemish government. Provinces and municipalities likewise drew up spatial structural plans for their regions. In addition, and in order to realize these visions, these three policy levels are also engaged in spatial implementation planning (land use plans). In spite of all such activity, and the accompanying expansion of administrative services for spatial planning on the three policy levels, the further urbanisation of open spaces in Flanders continues apace. Between 1990 and 2007, the total area of developed space increased by +22 %, housing space by +37 %, and space for commercial and industrial activity by +27 %. Agricultural space shrank by 6.5 % and 3 % of woodlands and nature reserves disappeared. Forecast figures for 2050 indicate that, without changes to the existing policy and additional measures, this fragmentation will record an enormous increase. It is, especially, the central region between Brussels, Antwerp, and Ghent that will witness ongoing urbanisation towards the creation of a major urban conglomeration of continuing and ever-spreading lateral expansion.

Figure 1: Increasing fragmentation of space in Flanders

Aside from its involvement in the above-mentioned regular plans, the Flemish authorities have since 2004 been in the process of developing a subsidisation instrument in the form of financial support for complex and strategic projects with a view to accelerating their implementation. These successful 30 strategic projects are not initiated but subsidised by the Flemish government. To a greater degree than other projects steered top-down, these are focused on the effective realisation of spatial policy in Flanders.

Working with 'strategic projects' has developed into a new spatial strategy in densely built-up and spread out settlement structure Flanders. In this paper (1) the success factors of this approach are defined and (2) two strategic projects are explained more comprehensively.

2. Success factors of this approach

2.1 Strategic projects

What are strategic projects in Flanders? A strategic project is a multi-faceted planning assignment that interconnects and harmonizes existing and current planning initiatives by various administrations and partners. When this attempt is successful, the project effectively becomes strategic, acquires a sustainable character, and is thus enabled to continue for the long term, hence spanning a number of legislatures. The development of each and every strategic project is different and, in all cases, customized and tailor-made. Common to all of them is the fact that their realisation is area-focused and integrated. What is generally lacking is, on the one hand, spatial cohesion and harmonisation amongst the diverse sectoral plans and, on the other, insights into the links between vision and concrete realisations. Many problems and opportunities remain mired in contradictory visions, lack of dialogue, and the absence of a project structure. In order to re-energize these situations of stagnant immobility, the Flemish authorities have decided to subsidize the appointment of a project coordinator, with proviso that the application for accreditation be worked out and submitted by the local partners.

2.2. Strategic projects arise 'bottom-up'

Strategic projects arise 'bottom-up' and are initiated by local authorities (municipalities, provinces and other partners), in a collaborative partnership spontaneously arising around a set of issues. Of essential importance is the conviction amongst the local partners that the project will generate added value. Strategic projects ought at least to possess characteristics that transcend municipal boundaries, which should lead to a new kind of collaborative partnership. Some strategic projects extend across several provinces or even national borders. Many actors already find it a challenge in itself to collaborate with their neighbours in a project structure. This local embedment is especially valuable given that also the realisation of large-scale projects at the Flemish provincial level needs to be implemented and realized locally. The orientation towards the realisation of such projects means that the pursuit of a local platform is, in fact, particularly important. When the 'engine' that drives the strategic project is made up of a project team with adequate representation of local actors, chances for success are excellent.

2.3. 'Seizing opportunities' resulting from autonomous processes is central in these strategic projects

Every municipality, every province, the Flemish Region itself, and each and every sectoral policy area within these administrative structures are drawing up plans. Flanders is suffering from an increased partitioning in its diverse sectoral planning (environment, mobility, economy, tourism, agriculture, commerce, etc.), each in its own way laying claim to the available space. In area-focused projects, chances and opportunities are embraced that by the very fact of an integrated approach are very likely to lead to a win-win situation. Given that strategic projects are oriented precisely towards implementation, these opportunities may lead to realisations. There is, nonetheless, the condition that the partners involved are

prepared to work together in an atmosphere of sufficient openness and with a taste for dialogue and are willing to collaborate in a search for solutions. Starting from a strong project structure, it is likewise possible to entice reluctant actors to join in the collaborative partnership instead of staying on the sidelines. Also in terms of the collaboration, it is possible here to book good results. It would even be better if this were also further extended into joint financing towards the implementation of the (part)projects.

2.4. Financial support for the salary and operational costs of a project coordinator

After selection, the Flemish government provides financial support for the salary and operational costs of a project coordinator for 3 years, amounting to 100,000 Euro p.a. By means of this financial stimulus, the local actors generally manage to erect a transparent project structure that is being continuously reinforced and directed by the project coordinator. Furthermore, the local actors involved in the project are being asked to contribute an additional 20 % financing. This increases local responsibility for, and commitment to, the project. The local actors establish independently how to give form to the project coordination and where to allocate the subsidy amount. Semi-annually, the Flemish authorities request a progress report while, annually, a progress meeting is being organized. It is important here to create a subtle balance between making funds available towards the project coordination and monitoring the objectives and the results of the implemented process.

2.5. A professional and independent project coordinator

A professional and independent project coordinator is an essential condition for being able to achieve complex and strategic projects and results with an exemplary and leverage role. The project coordination of strategic projects is hardly a task to be entrusted to inexperienced individuals. The assignment is mostly offered to professional senior spatial planners, seeing that they possess both a broad knowledge of the complex range of implementing instruments and the ability to fashion the links between vision formulation, operationalisation, and implementation. Ever more frequently, the project coordination is being handed to a team that will be responsible for the project's realisation, monitor its continuity, and steer the process in all of its facets, both on the official administrative and the political levels. The ability to function independently is likewise a must for the project coordinator. He/she needs to gain and enjoy the confidence of all actors and partners. He/she ought to be able to operate with sufficient authority and legitimacy. The strategic projects, the coordination of which is being entrusted to, for instance, a civil servant of one of the involved administrations / partners, hence may (not infrequently) demonstrate a greater rigidity in the way in which they are being run. In addition, the project coordinator must ensure synchronisation and consultation. He/she looks for opportunities to create visualisation of various aspects of the plan, thus generating a savings in time. This kind of coordinative process thus ensures that the breadth and scope of the plan is being suitably clarified for the partners.

2.6. Land purchase subsidy

On implementation, land policy often proves to be crucially important for achieving spatial objectives. For this reason, a subsidy of up to 500.000 Euro can be requested on top of the project coordination for land purchases. During the implementation of a strategic project, land policy frequently proves of crucial importance. It is often necessary to change the ownership of land and buildings in order to realize spatial objectives. To circumvent impediments of that kind, this additional subsidy presents the project partners with an interesting opportunity towards the realisation of (part)projects in the field.

2.7. The organisation of a strategic project

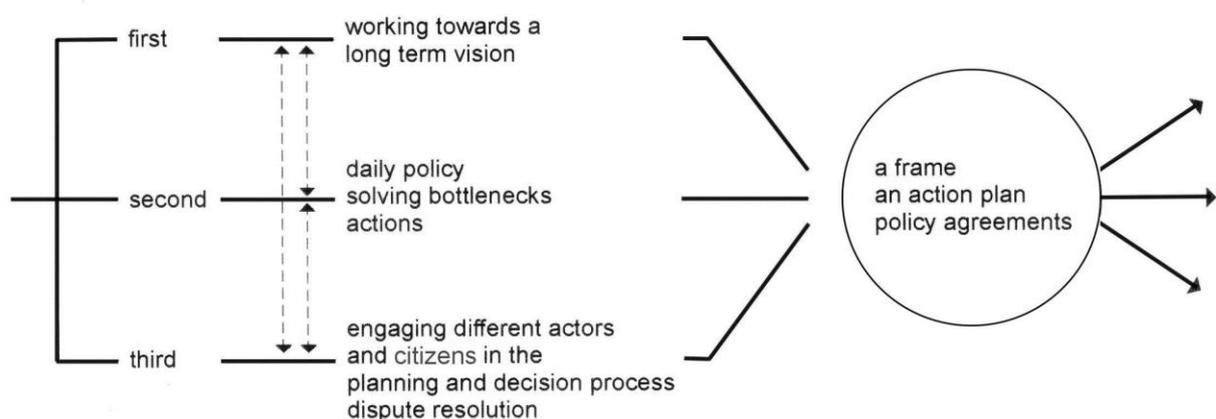

It is advantageous to consider the structure and composition of the collaborative partnerships, and the interaction in each strategic project. Customisation is a keyword in this respect. A strategic project is characterized by the presence of key actors such as

municipalities, provinces or Flemish services, non-profit organisations, or enterprises that jointly constitute the project structure of the core group and participate in subscribing to the project. The official applicant of a strategic project, however, needs to be a public body. In addition, there are a host of other partners that, in a less formal manner or to a rather indirect degree, are involved in the project. Some of the projects may attract the participation, in some way or other, of more than one hundred actors. How do all of these partners collaborate with one another? Generally, we distinguish within the organisation of strategic projects a project group or key team, a steering group wherein managers are brought together in order to arrive at decisions in a process of policy consultation, diverse working groups deliberating about themes, part-problems and/or part-areas, and groups acting as sounding boards, or more scientifically oriented advisory groups. Important is the fact that the manner of collaboration be organic and attuned to a process 'in motion'. Working groups keep coming and going on an ongoing basis, steering groups gather with a frequency as determined by the process itself, the project group or the key team ensures continuity and provides direction for the project coordinator on a daily basis.

2.8. All strategic projects are multiple planning tasks

All strategic projects are multiple planning tasks that are only realised if a robust basis is built up within the context of open plan processes. Three tracks run throughout each process: (1) working at a long-term vision for the project in the form of a structural sketch, masterplan, visual quality plan, and the like; (2) reacting to concrete problems, permit applications, chances to realize part-aspects and to ensure that no short-term decisions be taken that are contradictory to the long-term objectives; and (3) the building-up of a platform through consultation and communication. The creation of a platform is essential for the successful realisation of concrete actions in the field. The idea is to effectively involve the citizen in the process by means of open and pro-active communications. To this end, a variety of instruments are being deployed, such as the development of a house style and logo, website, brochures, newsletters, meetings, walking tours, exhibitions, events and animated and imaginative entertainment, and the like. The key to success for the project coordinator consists in his/her ability to properly manage the coupling and intertwining of these three tracks, to ensure that decisions be taken promptly, and to ascertain the continued realisation of part aspects within the strategic project.

Figure 2 Methodology for 3-track planning

2.9. Dynamics arise at micro level

Dynamics arise at micro level through the innovative capacity of individuals and groups, stimulated by governments. Various different strategic projects have been experimenting with all sorts of forms of innovative agreements: charters, statements of intent, collaborative

agreements, in principle decisions, and administrative agreements are just a few examples. The creativity to have the process advance and achieve progress via interim decisions needs to be present at the local level within the project group and with the project coordinator. Decision moments create tension, which is welcome at regular intervals in the process. Certainly for what concerns long-term strategic projects, regular monitoring and evaluation of progress in the project are self-evident, indispensable conditions for the engagement of the partners.

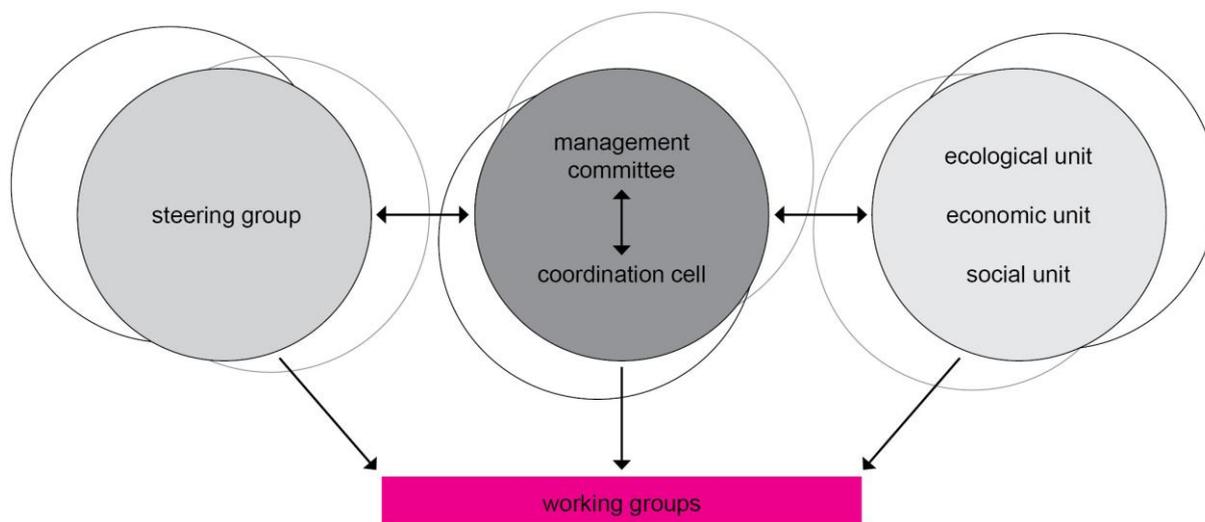

3. Two strategic projects : (1) BOSLAND, the development of the largest and most child-friendly woodland in Flanders, and (2) ALBERTKNOOP, the realisation of a cross-border, innovative and multi-modally developed business area adjoining a substantial green belt.

3.1. BOSLAND

As the largest wooded region in Flanders, Bosland enjoys international recognition. The strategic project aims at the creation of the largest child-friendly woodland in Flanders (ca. 10.000 hectares in area) and at the further development of the region in a sustainable and socially integrated manner. The project pursues the creation of a qualitative environment wherein woodlands and the general natural environment be protected against further encroachment of intrusive forces. Project partners in this are the Flemish Agency for Nature and Woodland, the municipalities of Hechtel-Eksel, Lommel and Overpelt, Tourism Limburg, and the Regional Landscape of the Lower Kempen. These partners have been united within a steering group and a management committee, bodies that also direct diverse working and deliberative groups.

Figure 3 Project structure BOSLAND

An Open Project Organisation

The Bosland Story can be told on the basis of three main themes:

- 'Boom in – *All About Trees*' tells the story of woodland and timber within the project area
- 'Terug in de wortels – *Back to the Roots*' recounts the project area's rich history
- 'Bijt in het zand – *A Taste of Sand*' examines the subsoil level and examines the use of sand throughout the centuries.

The Masterplan Bosland 2020 presents an integrated future picture as a framework of diverse concrete actions, amongst them additional forestation, fragmentation, new pathway connections for walkers and hikers, bikers, and horseback riders. Also in Bosland there is ongoing groundbreaking research work, for instance, in the area of woodland development, timber production, biomass(energy), eco-system services, ecology, the protection of natural floral varieties, in concert with the use of the area for recreational purposes. Via child-friendly activities, people, school groups, and tourists are being attracted the region (www.bosland.be).

3.2. ALBERTKNOOP

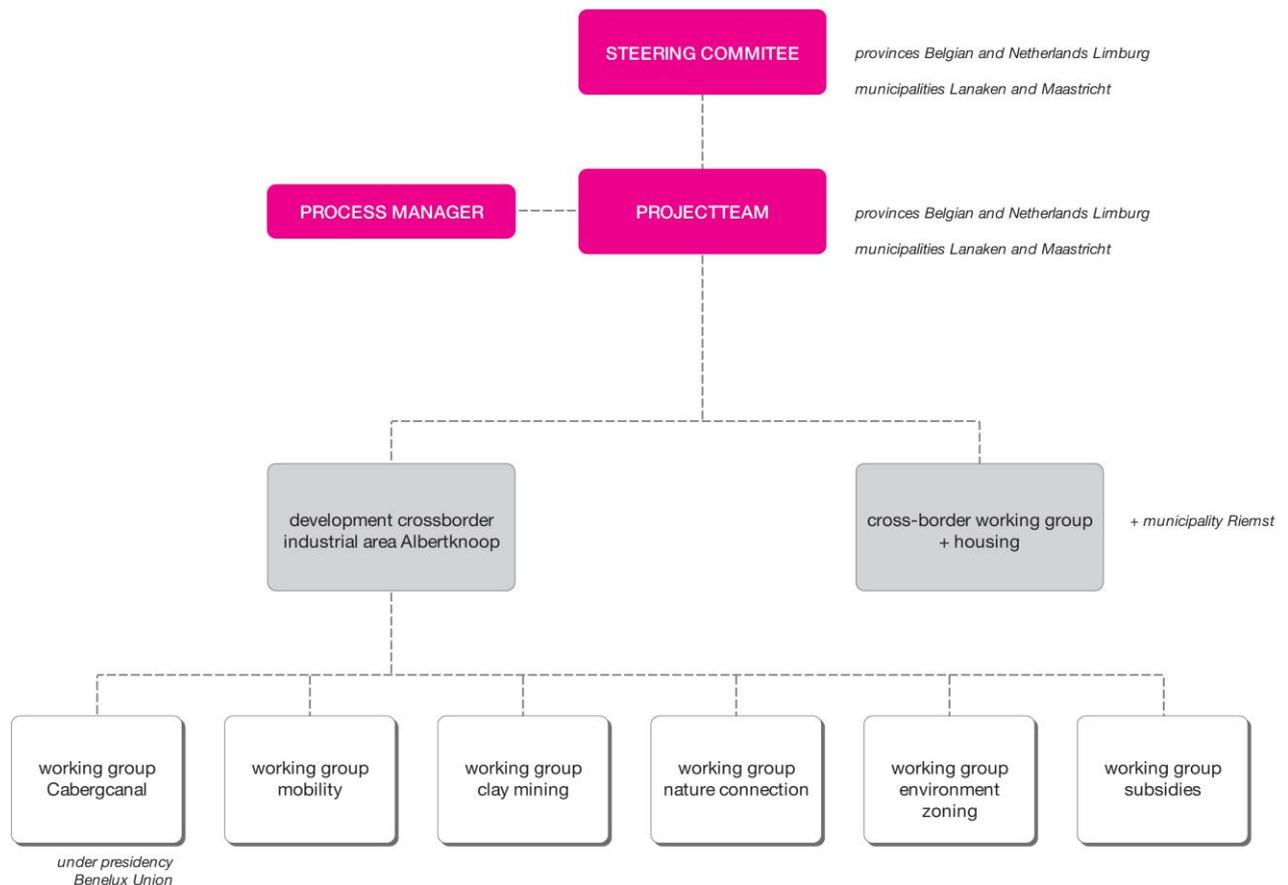

The strategic trans-border project ALBERTKNOOP was started with the aim to create and open up within the border region between the Dutch city Maastricht and the Flemish municipality of Lanaken a multimodal and regional industry park, to be situated within the area in a sustainable and integrated manner. The project fits within the Albert Canal Economic Network (ENA), which in the Spatial Structural Plan Flanders is designated as an important region for the future spatial economic development of Flanders and the Euregion. The national frontier between Belgium and the Netherlands runs straight through that project area, which is further bordered by the currently back-in-service freight transport railroad connection Maastricht-Lanaken, the Albert Canal up to the Veldwezelt Bridge, the trans-border open space Zouwdal, the existing housing development Malberg (Maastricht), and the restructuring and urban renewal area Belvédère, located within the territory of Maastricht.

Project partners are the provinces of Belgian and Dutch Limburg, the City of Maastricht, the Lanaken municipality, and the company NV De Scheepvaart.

In the course of an extensive consultation process with the involved actors, the project coordinator (called the border manager) is here to sweep away all impediments that are compromising and prejudicing the realisation of a trans-border, sustainable, integrated, and tri-modal accessible industry park covering 90 hectares in surface area.

Themes up for discussion are, amongst others, the scrapping of the Caberg Canal from the 1961 Treaty concluded between the Netherlands and Belgium, the unlocking of multi-modal potential, the advance loam extraction, the planned nature connections, water management, and the integrated organisation of the border region. In a more distant future, (2020-2030) as an adjunct to the existing industry park 'Europark' in Lanaken, one new large-scale trans-border industry park will be created. This trans-border harmonisation of reciprocal development objectives and permit trajectories remains as always a central focal point in the process. The steering group ALBERTKNOOP, the decision-making body within the consultative process, explicitly is opting for a area-focused approach wherein, from a spatial perspective, special attention is being devoted to problems that are inherent in the region, and solutions are presented on the basis of the qualities and potentialities offered by the region. This way, not only due attention is given to a conflict-free border zone, but also the border itself stimulates an array of win-win situations and joint projects within a new urban and suburban context. Aside from the project work in function of the industry park to be established in the future, the steering group likewise placed the problem of trans-border living on the agenda (www.albertknoop.be).

Figure 4 Project structure ALBERTKNOOP

4 Epilogue

With these strategic projects, the Flemish government is taking a major step from generic to specific policy: the area-focused approach and the importance of 'governance' are becoming more important.

Thanks also to this strategy, the spatial policy within Flanders is evolving towards an open network structure wherein activities are becoming ever more area-focused and integrated. The Flemish authorities are concentrating more and more on realisation-directed planning, with much operating room and initiative offered to local partners. In Flanders, any ambitious local project will, because of the scale, turn invariably and quickly into a project at the Flemish level.

Major challenges are found in (1) quality control and the further enhancement of the professional dimension of the instrument 'project coordination', to which ever more recourse will be had for the realisation of strategic projects, and (2) the indispensable financing of the realisation of the strategic projects in the field, where it behoves Flemish authorities to assume their responsibilities. The more strategic projects lead in the practice to qualitative realisations in the field, the better this instrument can be deployed strategically to counter the further fragmentation of space and the loss of ecological diversity.

Biography

Guy Vloebergh (Belgium) has been CEO of OMGEVEING cvba since 1998, a private design and planning company with a passion for the living environment (guy.vloebergh@omgeving.be), since 2004 a professor of urban planning at ARTESIS University College of Urbanism and Spatial Planning in Antwerp, since 2009 Manager of the Strategic Cross-Border Project ALBERTKNOOP and since 2012 chairman of the National Delegation of Belgium planners in ISOCARP.

Synopsis

Working with strategic projects has been introduced by the Flemish government since 2004. More than 30 projects got the label 'strategic' and got money to organize the project coordination. The beginning of a new spatial strategy for the densely built-up Flanders region?

The concept of Sustainable Land Management: a comparative discussion (at a global scale)

Thomas WEITH, Annegret REPP, Christian BESENDÖRFER, Leibniz-Centre for Agricultural Landscape Research (ZALF), Germany

ID 182

Synopsis: The paper seeks to initiate a discussion about the concept of sustainable land management in an internationally comparative perspective, based on experience from a German research funding measure. To enable exchange and mutual learning, it will particularly focus on the variety of definitions and main contents like governance approaches towards the solution of land use conflicts with regard to main drivers for land use demands and with regard to different multi-level governance frameworks and modes.ⁱ

1. Sustainable land management – diversity of terms and contents

What is "sustainable land management"? What is behind this term and what does it mean? Is it all just "old wine in new bottles"? Or - on the contrary - a new paradigm with different overall concepts, objectives, action principles and implementation forms? Is it a new type of cooperation between science and practice, or a greater focus on the effectiveness of action approaches? Up to now there is no definitive and generally accepted definition for the term in scientific literature and communities of practice.

Mankind has influenced landscape for centuries and created different types of land use. With regard to the development of land use in Europe, main drivers of currently increasing influence comprise changes in values (e.g. sustainability), economic and social trends (e.g. globalisation, demographic change), technological innovations and political priorities (e.g. in climate and biodiversity policy). A high variety of institutional arrangements and regulatory schemes on several policy levels (EU, national, regional, local) has been initiated in order to deal with these land use demands and resulting land use conflicts. Examples include European agricultural policy (e.g. cross-compliance rules) and water policy (Water Framework Directive), national development procedures (e.g. spatial planning in Germany, Austria and Switzerland), regional development schemes (e.g. in the UK) or local planning and building schemes.

Land management questions and activities vary considerably, with the usage of the concept of sustainable Land management being related to different understandings and governance approaches, depending on the geographical area and policy context (Weith et al. 2013). The German funding measure "Sustainable Land Management", financed by the German Federal Ministry of Education and Research (BMBF), comprises 13 joint projects within Module B, working on the development of innovative system solutions for sustainable land management in different regions in Germany. Due to the high variety of involved actors and complex interactions one main aspect of research refers to handling complexity by inter- and transdisciplinary methods (Klein et al. 2001). Public actors, companies or civil society actors are seen as starting points, nuclei, and development partners for the implementation of sustainable solutions in land management. In that context, all projects seek to combine contents of governance in a synergetic way. Examples include the combination of water management with waste management, water management with energy supply, settlement development with mobility aspects or housing and energy consumption. However, these approaches are

mainly embedded in and adjusted to the German and EU policy context. Enhanced international exchange on the understanding and concept of sustainable land management and a comparison of approaches will thus enable researchers and practical experts to benefit from each other.

Even the subject area, "land", is open to various interpretations. It would be easy to associate it with slightly simplistic limitations, such as restricting it solely to non-water-covered areas outside the city (city *and* land). Recent works (e.g. HABER ET AL, 2010) make it clear, however, that this definition is too narrow. The focus is rather on the struggle for land use in the human-environment system, with a variety of competing and sometimes conflicting utilization claims and the natural capacity of ecosystems and their compartments.

The use of land, or in this context, soil, is always in a tension field between conservation, development and the restoration needs of the functions of a public good (e.g. habitat function, groundwater replenishment function) due to its different capabilities (e.g. development potential, ecological functions) and utilization opportunities in connection with assigned property rights. The differentiation of *land values* by DAVY in to *exchange value*, *use value*, *territorial value* and *existence value* (2012: 89ff.) reflects this and also highlights the need for an explicitly spatial view. Reflecting this spatial focus, approaches to further include material and energy flows when considering land use questions in terms of spatial use structures have existed since at least the late 1980s (see e.g., HOFMEISTER/HÜBLER, 1990). Balancing concepts for resource flows, such as urban metabolism, were developed as early as the 1960s (e.g. WOLMAN, 1965).

The concept of sustainability in sustainable land management refers to a diverse and long-running dispute over the direction of societal action. For all the ambiguity and diversity involved in defining the term precisely, the definition contained in the Brundtland report is often mentioned as a general starting point. It contains the formulation, "Sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs." (WCED 1987). Resolutions from the Rio Conference of 1992 are referenced just as often in social discussions. This is accompanied by a claim to validity which can be characterized by the key words, global, inclusive, future-oriented and anthropocentric (JÖRISSEN 2005). The key aspects are intragenerational and intergenerational equity and the three-dimensional approach (the ecological, economic and socio-cultural dimensions).

The management concept refers to anthropogenic activities in different contexts. The existence of terms, such as city management, regional management, site management or water management, highlights the fact that limiting the meaning to functional and process-oriented, business-related actions would fall significantly short. The concept of governance, a term often used in social-scientific spatial research, as "coordinating and controlling regional processes in complex structures" (BENZ 2003:505) opens up many possibilities for subject-related discussions and clarification. A key aspect of such refocusing is the lack of a central manager. Rather, it is interactions between the different stakeholders that can lead to readjustments in social structures (control systems) as well as physical and material aspects (BURNS 2006). Influencing stakeholders' behaviour or actions (also inaction) always raises the question of the need for transformation or innovation processes.

Even common management literature refers to a central challenge in such constellations: dealing with complexity (STAEHLE 1999: 43). Therefore, systemic thinking can be considered

crucially important to understanding the interdependencies between the various system elements.

2. Explicit use of terms

Having already discussed various regulatory aspects in Agenda 21, as part of the World Conference of the United Nations in Rio in 1992, which have a close relation to sustainable land management (statements on re-use of land, urban development, agriculture, forestry, etc.), the term *sustainable land management* was explicitly used for the first time in an FAO document (SMYTH ET AL.1993) entitled "FESLM: An international framework for sustainable land management", reaching a wider expert audience. The aim of the authors was to create a basis for evaluating "sustainable land management" as an accepted harmonization of the economic and ecological aspects of food security. The underlying understanding of the term was based on discussions at a series of workshops at the beginning of the 1990s in various countries (Thailand, Kenya, USA, Canada). The workshops were organized by the International Board for Soil Research and Management (IBSRAM) and the University of Lethbridge, Alberta, Canada (SMYTH ET AL, 1993). In 1996, in a separate document with a similar focus, the United Nations (UN) described land management as process-oriented resource management in the context of ecological and economic perspectives (UN 1996: 13). However, the social dimension is not considered here.

In consequence it is obvious, that the term "sustainable land management" or "sustainable land management" is often used with a specific bias in the context of development policy. In addition to the FAO, other United Nations sub-organizations and programmes (e.g. UNEP/UNU, UNDP), the World Bank, the Latin American Development Bank, the European Commission and the German development agency, GIZ, use it in their work. The focus is on dealing with the problems of soil protection. In this context, the term is also normatively used for demands for participation, rights of access to land, sustainable marketing and reforestation (World Bank/Global Environmental Facility) and combating urban poverty (access to resources).

In its "Rural Strategy", the World Bank refers to investment opportunities to increase agricultural growth and reduce poverty. Sustainable land management is also seen as a possible solution here, whereby both increases in productivity and ecosystem services are addressed (WORLD BANK 2008: 3). According to the perspective of the World Bank, knowledge as a resource is equally important to be able to integrate different management areas, "Sustainable land management [SLM] is a knowledge-based procedure that helps integrate land, water, biodiversity, and environmental management (including input and output externalities) to meet rising food and fibre demands while sustaining ecosystem services and livelihoods. SLM is necessary to meet the requirements of a growing population. Improper land management can lead to land degradation and a significant reduction in the productive and service functions." (World Bank 2008, quoted according to the World Bank 2006).

For some years now, an explicit use of the term has also found its way into discussions at European level. One example is the work conducted by the EU-funded URBACT programme, a city network promoting sustainable development. In contrast to development aid, the working group of the LUMASEC project (Land Use Management for Sustainable European Cities) with its completely different framework conditions and initial situations, such as the differentiated institutional systems of spatial and environmental development, uses the term to mean the *process management of land use and development*. The focus is on *coordinat-*

ing the spatial, sector and temporal aspects. The different functions of land and related conflicts should be considered as part of sustainable land management (ENGELKE/VANCUTSEM 2010: 70).

The discussions mentioned draw explicitly and implicitly on statements made in scientific publications. Works by HURNI (2000) and HABER ET AL. (2010) are worth particular mention here. HURNI bases his deliberations on the target parameters of sustainable land management. This includes not only an integration perspective by linking ecological with socio-economic and political aspects, but also an intertemporal dimension taking account of intergenerational equity. In addition, HURNI'S approach is a "multi-stakeholder perspective", stressing the importance of considering a wide range of stakeholders in sustainable land management (HURN2000: 85). HABER ET AL see sustainable land management in the context of climate change, as well as a possible answer to reducing associated problems (HABER ET AL. 2010: 378). In order to implement objectives in connection with the issue of sustainability, they are based on a broad understanding of management which includes "technological, political and legal measures and activities" (HABER ET AL 2010: 379). In addition, reconfigurations of the instrument set are important in influencing land (HABER ET AL 2010: 378).

Few countries use the term, "sustainable land management", explicitly as part of national policies and programmes. In addition to the identically worded German research programme yet to be implemented, it is worth mentioning that both Australia and New Zealand formulate this as part of a government programme concerned with climate change. In Australia, an environmental protection perspective is of central importance, "sustainable land management means managing land without damaging ecological processes or reducing biological diversity"ⁱⁱ. In neighbouring New Zealand, the government has followed a "Sustainable Land Management Strategy" since 1996. The focus here is on the land users. They should be shown better ways to use the land employing cooperative control mechanisms, especially with regard to stakeholders from the service sector.ⁱⁱⁱ

In Germany, sustainable land management has been politically anchored alongside development support as a topic of the BMBF Framework Programme, "Research for Sustainable Development" (*Forschung für nachhaltige Entwicklungen*, FONA) since 2009. The following key aspects were identified as part of the "Sustainable Land Management" funding measure of which this discussion paper is also a part (BMBF 2008):

- Considering land use, land-use change, impact of land-use change and land-use decisions
- Considering complex interrelationships, interdependencies between land-use options (conflicts, synergies, etc.) and cross-sector action
- Regional approach (regional value-added networks, regional energy and material flows, considering urban/rural relationships)
- Interdisciplinary and cross-disciplinary project orientation
- Developing innovative concepts and strategies:
 - Innovative value-added networks to strengthen sustainable regional economic development
 - Technologies/methods and forecasting tools to make informed assessments of adaptation needs for land-use systems and the need for innovation
 - Services to promote sustainable land-use systems
 - Information and knowledge management in added-value networks, strengthening cooperation and communication among stakeholders

- Concepts for decentralized supply including renewable energies
- Resource-efficient and low-emission urban development
- Efficient and sustainable use of resources for production and energy generation
- Integrated use of land and water resources, paying special attention to regional supply and disposal services
- Adjusting land use and infrastructure facilities and associated services to allow for a sustainable attenuation of extreme events
- Adapting technical infrastructure systems whilst taking account of overlapping and multiple uses.

3. Interim conclusion

The lines of discussion mentioned include various dimensions that are important for sustainable land management. The following table lists these in an overview and outlines a very ambitious claim for the governance of land use. At the same time, it shows there is no fully coherent picture. Conflicts are to be expected, especially when fleshing out the content of the different dimensions.

Dimensions	
Subject area	
	Human/environment relations
	Land
	Land use
	Material and energy flows
	Regional added-value
	Land-use conflicts
Setting normative objectives	
	Sustainability
Relation to activities and impacts	
	Management/governance (especially coordination)
	Integration
	Conflict minimization, conflict resolution, synergies
	Complexity
	Transdisciplinarity
	Situational, structural and systemic aspects
	Change and innovation
	Information and knowledge
Spatial reference	
	Region
Time reference	
	Intergenerational equity
Stakeholder reference	
	Politics, administration, business, civil society, science
	Interdisciplinarity and transdisciplinarity
	Participation

Table1: Summary of the aspects shown; Own compilation (based on sources mentioned above)

"Sustainable land management" defined in this way cannot be seen as a static concept. Rather, it represents an approach to further develop existing conceptual ideas to influence land use (cf. GAASCH & WEITH 2011), some of which are developed evolutionary (e.g.

stakeholder reference, process design, the evaluation process), but in some cases also require innovative damage (e.g. in the governance of differentiated sector policies).

4. Discussions in the context of research

As indicated, depending on the definition of the term and its understanding in scientific discourse, various lines of discussion are indicative of sustainable land management. Without going into detail here, the authors recognise growing awareness of the issue. On the one hand, this is because of the development of explicitly scientific networks, such as the "Global Land Project", and also because publishers and journals are devoted to the topic, as the establishment of the magazine "land" shows. On the other hand, European or European-wide public funding have increased in this area (EU 7th Research Framework Programme, funding of the European Spatial Planning Observation Network ESPON, cooperation in ERA-Nets like WoodWisdom and RURAGRI).

Research initiatives and departmental research are particularly important for Germany since both support obtaining application-oriented knowledge and promoting implementation activities. In addition to the institutional and programme and project-based approaches by the German Research Foundation, the Leibniz Association, the Helmholtz Association, the Fraunhofer Society and the Max Planck Society, the activities of the BMBF are worth particular mention, which, in advance of the current funding measure, have considered and are still considering some aspects of sustainable land management. These are:

- Sustainable Forestry,
- REFINA (about governance of settlement and infrastructure development),
- Megacities,
- KLIMZUG (about climate change adaptation)
- and overall approaches as part of socio-ecological research.

There are also indications of new lines of discussion among professional societies, e.g. in surveying. A document by the International Federation of Géomètres (FIG) from 1999 emphasized that sustainable land use should be achieved on the basis of a variety of data about effective land management (FIG 1999). In the mean time, references have been made by surveyors to the explicit diversity of lines of discussion. "Others are doing land management too!" (MAGEL, 2006: 156).

5. Action fields for sustainable land management

The described lines of discussion show a high variety of political action fields that are of relevance to sustainable land management. At the same time, they point to the need for large-scale change processes setting framework conditions and new social challenges to adequately reflect content and procedures. Economic globalisation, climate change, global food security, biodiversity, water supply, migration, demographic change processes, and the world's growing energy needs are key here. They lead to changes in land use in almost all major regions (WBGU 2011, FÜRST & MÄDING 2011).

The energy transition has established different demands on spatial use, particularly in Germany. In addition to the space required, e.g. for wind energy or photovoltaic systems, significant areas need to be established for infrastructure development, both for transmission routes and for new decentralised system types. At the same time, new priorities are being set within existing types of land use, such as agriculture, and e.g. the cultivation of food is being replaced by the cultivation of energy crops.

It should also be noted that a considerable number of land-use changes leading to land-use conflicts have been discussed politically and scientifically for decades. It is worth mentioning, in particular, the processes of land use for housing and transport purposes in the context of complex urbanization and suburbanization, and more urban/rural interactions (see REPP ET AL, 2012).

This leads, in part, to new and old rivalries between different land-use claims. A differentiation should be made between arising (1) conflicts *between* types of land use (e.g. agriculture versus development and infrastructure) and (2) conflicts *within* one type of land use (agricultural food production versus energy crops). In Germany these developments run, in part, parallel to processes of regional differentiation between growing versus shrinking regions with an increase in spatial disparities.

6. Current policies relating to sustainable land management

The above statements show that sustainable land management concerns itself with key societal challenges and, at the same time, also discusses, at least part, required changes to current policies. What specific policies might this affect? In line with the character of this article, a first overview should be made of current political activities which reflect or flesh out important land-use related content. According to the focus of the core content of the module, "Innovative System Solutions" (Module B) of the described funding measure, this will be limited to the European dimension and the strategic-instrumental debate in Germany embedded therein. All forms of land use (particularly settlement, infrastructure, open space with agriculture and forestry, nature conservation, water) are addressed here.

6.1 EU policies

At first glance, the term "sustainable land management" currently plays no important role in core EU policy agendas. This applies to the Lisbon Agenda^{iv}, the sustainability strategy/Gothenburg Strategy^v, and its revised version from 2006 (COUNCIL OF THE EUROPEAN UNION, 2006b), the Territorial Agenda/Leipzig Charta - Towards a More Competitive and Sustainable Europe of Diverse Regions (BMVBS 2007) and the Europe 2020 Strategy: A strategy for smart, sustainable and inclusive growth (EUROPEAN COMMISSION 2010). However, both the Gothenburg Strategy and the Territorial Agenda/Leipzig Charta address some significant aspects of sustainable land management. Consequently, terms such as *sustainable forest management*, *sustainable resource management*, *coastal zone management* and *risk management* are used in the revised EU Sustainable Development Strategy.

The aspects of sustainable land management play a very important role in specific land use-related EU policies. In accordance with the responsibilities of the Directorates-General, the activities of regional policy, environmental policy, agriculture, rural development and maritime policy are worth mentioning explicitly.

Regional policy includes the action fields of sustainable infrastructure development, eco-innovation, implementation and reuse of brownfields, reduction of urban sprawl, and protection against natural hazards (see COUNCIL OF THE EUROPEAN UNION, 2006a). For the Environment Directorate-General, in addition to activities on climate policy, and, in particular, the introduction of Impact Assessment Tools (EIA/SEA), reference should be made to the ongoing discussion about the "Soil Framework Directive" (EUROPEAN COMMISSION, 2006a) and the "Roadmap to a resource efficient Europe" (EUROPEAN COMMISSION, 2011) from 2011.

Another important field of work is the international network of nature protection areas, NATURA 2000.^{vi}

In agricultural policy, new regulations were recently adopted for managing agricultural areas (i.a. for greening). Cross-compliance obligations and payments for ecosystem services have been in existence for some time. Also aspects of process management, such as the LEADER approach should be mentioned here, which provides strong local commitment and bottom-up initiatives as the basis for regional development. The objective of the EU's Forestry Strategy from 1998 was sustainable forestry. It includes the elements of multi-functionality, an increased use of wood and non-forest products and the development of rural areas (Council of the European Union 1999). The EU Forest Action plan (2007-2011) calls for the management, protection and sustainable development of all types of forests and it supports long-term development prospects. Dialogue processes at all levels play a central role in this (EUROPEAN COMMISSION, 2006B). The European forest policy reflects international lines of discussion for sustainable forest management which is represented, for example, by the International Forest Panel at the UN. Activities to store CO₂ as part of the implementation of REDD+ strategies are becoming increasingly important here.^{vii}

6.2 Action approaches in Germany

The adoption of the Sustainable Development Strategy 2002 (GERMAN FEDERAL GOVERNMENT, 2002) marked a new cross-sectional policy approach on the part of German federal policy which also included aspects of sustainable land management. As a result, in the *quality of life* section, the formulation "Maintaining a vibrant city - developing rural areas" was included as an aspect of its guiding principle. The indicators mentioned here include *resource conservation, land utilization, climate change, renewable energies, biodiversity, mobility and nutrition*.

The political significance of this federal policy approach, which also continues diverse policies that have been pursued for decades, was already clearly demonstrated a year earlier by the establishment of a Council for Sustainable Development in the German Federal Government and was afforded further political and social import by the establishment of the State Secretaries' Committee on Sustainable Development. In particular, the Council for Sustainable Development promotes discourse on sustainability objectives and processes and thereby contributes to a constant presence of the topic in public debate.

Meanwhile, there are many reports on the state of sustainable development. An overview of core sustainability indicators are, for example, periodically listed in the Progress Report of the Federal Government along with an assessment of their development. The Progress Report of 2012 (GERMAN FEDERAL GOVERNMENT, 2012) points out some areas still requiring considerable change and action for today's most important land-management indicators, such as *land utilization, biodiversity, landscape quality and land management*.

In addition to this approach, some aspects of sustainable land management, now with a close interdependence on European discussions, have been part of various policy fields of action for decades.^{viii}

Particularly important in the authors' view are^{ix}:

- Regional spatial planning, with the basic objective of sustainable spatial development, diverse content and procedural components and currently with a wide variety of approaches for adapting to climate change
- Urban development, with the sub-aspects

- Plans (particularly land-use plans and development plans)
- Site management and recycling (reduction of land utilization)
- Informal concepts/re-urbanization processes
- Environmental planning, with its statutory legal definition and various implementation forms (landscape planning, strategic and project-specific environmental impact assessment, (major) nature conservation projects)
- Agricultural policy, with the sub-sections
 - Land cultivation, i.e. agricultural policy with cross-compliance and greening
 - System of property ownership/land consolidation/soil management^x with approaches for the necessary segregation of usages (intensively managed versus extensively/non-managed areas)
- Forest policy with continued discussion about agricultural and forestry management tools to include more aspects of biodiversity and forest management, multi-functionality and the integration of regional economic aspects^{xi}
- Water management with its content and procedural realignment after the adoption of the European Water Framework Directive.

7. Particular challenges for sustainable land management

Assuming the existing policies, structures and dynamics of land use can not be called sustainable and that changes in land management towards *sustainability* can be, at least generally, interpreted as a rational problem-solving process, in the view of the authors, there are special challenges in steps to *define the problem* and in *alternative developments* and their *governance-related implementation*.

7.1 Problems and problem diversity

Current and future land uses are influenced by a variety of factors. They range, as outlined, from global developments such as climate change, water shortages or the loss of biodiversity, to local influencing factors such as individual entrepreneurial decisions. In the scientific context, only partial correlations and clear cause/effect relationships, in particular, have been analysed to date. This becomes particularly evident in the area of demographic change. Only limited direct interdependencies have been established here so far (BEHRENS ET AL, 2012).

If an explicitly transdisciplinary approach is pursued in land management, variety of perceptions of problems will grow bigger. But not all stakeholders have the same resources to position their views, like influential lobby groups will do (e.g. agriculture, food industry, landowners, etc.). Simultaneously, the formulated problems are also often subjected to a dynamic process of change and adaptation, so that recursive problem formulation processes should be implemented repeatedly.

7.2 Control and management: diversity of options

Difficulties in problem analysis and assessment subsequently lead to open questions regarding the possible need for necessary changes and opportunities for influencing forms of land use. In addition, there are a large number of control tools (planning, financial incentives, information systems, etc.), whose affect is often only partially known due to a lack of evaluation results. At the same time, these management approaches influence each other so unintended interactions occur. In part, the policies contradict each other. As a result, spatial planning over many years tries to reduce suburbanization processes supported by economic incentives (promotion of home ownership, commuting allowances etc.). In this context,

"innovative" approaches should come into play, i.e. change existing tools to further increase the complexity of assessing possible consequences.

With a view on the cross-disciplinary focus, it is significant that, in addition to the variety of existing management instruments mentioned, the full involvement of the different rationales of the stakeholders (politics, administration, business, civil society) must be taken into account.

8. Approaches of joint projects in the "Innovative system solutions for sustainable land management" module (Module B)

The joint projects promoted as part of the Sustainable Land Management funding measure in Module B have each found independent ways of developing solutions in the key areas they deal with (energy and land use, water and land use, etc.). An initial evaluation of project activities shows many differences and similarities between the enforced eligibility criteria that could serve as initial evidence of further development of the term "sustainable land management" (see also WEITH ET AL, 2010.)

- The early and simultaneous involvement of politicians, the government, business representatives and civil society
- The combination of different thematic fields of action, such as water management, the restoration of wetlands and biomass production
- The linking of governance of flows and governance of space and place, such as combining water management, fuel wood production and the protection of open spaces
- The combination of several strategic action principles, such as resource efficiency, adaptation and energy/material cascade utilization
- Combination instruments, such as linking regional planning and economic incentives with modelling and evaluating project-related impacts.

The further progress of the project and, in particular, the findings gained in the cross-disciplinary context promise continuative results.

9. Outlook

Discussions conducted as part of the described funding measure and beyond about changing problems and the need for action in the context of "land management" still highlight some "blind spots", in the authors' view. Although a wide range of issues and approaches are discussed and further developed, the following issues remain ignored up to now:

- An up-to-date political and, in particular, ethical debate about equitable land use in the context of developed countries (generational equity, distributive equity) which has a long tradition in the old German Federal Republic (e.g. social obligation of property)
- The interrelations and impacts between local and global changes in land use, as reflected in discussions about footprints (see WACKERNAGEL, 1994)
- The inclusion of the discussion about systemic risks, which in the context of the discussion about GMOs or the financial crisis, has lead to important impulses for better understanding of and dealing with the challenges (see WBGU, 1999)
- The discussion about new forms of transfer (e.g. via social networks; see ZSCHEISCHLER ET AL, 2012) and new forms of stabilizing launched initiatives, such as the efficiency of an early and targeted involvement of civil society stakeholders.

The authors believe the term "sustainable land management" also needs to be further developed, not only to provide an overview of sources, but to increasingly involve the practical experience of individuals and groups. This could provide more information about the action orientations realised in practice.

Are we all neoliberals now? Urban planning in a neoliberal era

Ian WRIGHT, Partner | Planning Government Infrastructure and Environment | Herbert Geer, Australia

ABSTRACT

The modernist perspective of planning is concerned with making public and political decisions in respect of the planning of our places more rationally and consistent with an overarching public interest.

However the modernist perspective of rational planning action has been challenged by a postmodernist perspective of pragmatic planning, and more recently, by a neoliberal perspective rooted in the economic and political conditions of Milton Friedman's monetarism and Friedrich Hayek's classical liberalism.

This paper considers the ideology of neoliberalism in the context of the competing ideologies of postmodernism and modernism to identify the following:

- > an urban change model which identifies the relationships between urban change, ideology, planning theory and planning models;*
- > the cultural, social, economic and political conditions of neoliberalism;*
- > the broad policy setting of a neoliberal government;*
- > the key features of the neoliberal strategic management planning model which is used by neoliberal governments;*
- > the key features of planning practice arising from the use of the neoliberal strategic managerial planning model;*
- > the role of urban planners in a neoliberal state.*

The paper concludes that the neoliberal project is contestable and suggests that the adoption of collaborative planning processes and evidence based strategic management planning offers the opportunity for planners to reassert their professional status, rebuild the trust of the public and politicians and lift the planning profession out of its current malaise.

INTRODUCTION

Neoliberalism = Classical liberalism + (Theory of growth + Keynesianism)

"In one sense, we are all Keynesians now. In another nobody is any longer a Keynesian". (Milton Friedman, Time Magazine, February 4, 1966)

With these words in 1966, Milton Friedman the leading conservative economist of his generation, announced the passing of post war Keynesianism and the birth of neoliberal economics.

Whereas Keynes was concerned with achieving prosperity and stability from the depression and war scarred world of the 1930s and 1940s; Friedman was focussed on growing the already prosperous world of the 1950s and 1960s.

Friedman's neoliberal economics was an extension of the classical theory of growth which built upon but supplanted Keynesianism. As Keynes might have put it; Theory of growth + Keynesianism = Neoliberal economics (*Time Magazine, December 31, 1965*).

Friedman's neoliberal economics also built upon Friedrich Hayek's political philosophy of classical liberalism which espoused limited government, individual freedom and the rule of law.

The socio-economic and political conditions resulting from the fusion of monetarism and classical liberalism is known as neoliberalism.

Ian WRIGHT, Are we all neoliberals now? Urban Planning in a neoliberal era, '49th ISOCARP Congress 2013'

Neoliberalism is an ideology that involves a commitment to the rolling back of the Keynesian-welfare state's collectivist institutions and the ethos of universal provision and the rolling out of market mechanisms and competitiveness to achieve economic growth (Peck and Ticknell 2002:384; McGuirk 2005:61).

Waves of neoliberalism

Neoliberalism should not be seen as an end state or condition but rather as a process of changing the relationship between the public sector, private sector and civil society to facilitate economic growth.

Neoliberalism has advanced across the world in a series of four waves with Australia at the vanguard of each wave as summarised in Table 1.

- > The rollback of Keynesianism in Australia under the rubric of economic rationalisation was commenced by the Fraser government in the 1970s and 1980s which preceded both Thatcherism in the United Kingdom and Reganism in the United States.
- > The moderation of the rollback of Keynesianism under the Hawke and Keating governments in the 1980s and 1990s also preceded the Third Wave governments of Blair and Brown in the United Kingdom and Clinton in the United States.
- > The roll out of neoliberalism under the Howard government in the 1990s and 2000s also preceded both the Bush presidency in the United States and the Cameron prime ministership in the United Kingdom.
- > Finally, the moderation of the roll out of neoliberalism in Australia under the Rudd and Gillard governments since 2007 has preceded similar efforts under the Obama administration in the United States.

Table 1 Neoliberal waves

Australia	United States	United Kingdom
First wave (1970s to 1990s) - Neoliberalism roll back		
Economic rationalism - Fraser Liberal National Party governments (1975 - 1983)	Reganism - Regan and Bush Snr Republican governments (1980 - 1992)	Thatcherism - Thatcher and Major Conservative governments (1979 - 1997)
Second wave (1980s to 2010) - Neoliberalism roll back moderated (Third Way)		
Hawke and Keating Labor governments (1983 - 1996)	Clinton Democrat government (1992 - 2000)	Blair and Brown Labour governments (1997 - 2010)
Third wave (late 1990s to current) - Neoliberalism roll out		
Howard Liberal National Party government (1996 - 2007)	Ownership society - Bush Jnr Republican government (2000 - 2008)	Big society - Cameron and Clegg Conservative / Liberal Democrat government (2010 - onwards)
Fourth wave (late 2000s to current) - Neoliberalism roll out moderated		
Rudd and Gillard Labor governments (2007 - onwards)	Obama Democrat government (2008 - onwards)	?

However the moderation of neoliberalism arising from the Global Financial Crisis and the resulting Great Recession / Stagnation has not lead, as Prime Minister Kevin Rudd had predicted in 2009, to the death of neoliberalism, and its replacement by social-democratic capitalism; which Rudd described as "a system of open markets regulated by an activist state

Ian WRIGHT, Are we all neoliberals now? Urban Planning in a neoliberal era, '49th ISOCARP Congress 2013'

and one in which the state intervenes to reduce the great inequalities that competitive markets will inevitably generate" (Rudd 2009).

Since 2009 Australians have elected neoliberal governments in most states and territories and if opinion polls are to be believed will elect a neoliberal Commonwealth government.

The reports of the death of neoliberalism therefore appear to be exaggerated; as are the claims that "*we are all Keynesians now*" (Rudd 2009). Indeed, the history of the last 50 years would indicate a jump to the right with only small steps to the left.

Urban planning in a neoliberal era

The neoliberal dominance has significant implications for urban planning. From a neoliberal perspective, much of urban planning is seen as distorting land markets and increasing transaction costs through bureaucratisation of the urban economy; which should be rolled back by contracting the domain of planning (deregulation) and then privatising segments of the residual sphere of regulation (outsourcing) (Gleeson and Low 2000b:10).

As a result the *raison d'être* of planning as a tool of correcting and avoiding market failure is dismissed; and planning is subsumed as a minimalist form of spatial regulation to provide certainty to the market and facilitate economic growth.

Ideology, theory, policy and practice

Whilst it is unclear how ideology influences planning theory and in turn how planning theory effects planning practice, a consideration of ideology and planning theory does provide a basis for understanding how planning policy and practice may evolve as a result of a neoliberal planning reform agenda.

As Forester (1989:12) observes:

"Theories can help alert us to problems, point us towards strategies of response, remind us of what we care about, or prompt our practical insights into the particular cases we confront".

Themes of paper

This paper has 6 themes:

- > First, it establishes a model of urban change; a model that seeks to show the relationship of ideologies, planning theories and planning models to the components of urban change and the institutions responsible for that change.
- > Second, it seeks to flesh out the cultural, socio-economic and political conditions of neoliberalism in the context of the competing ideologies of postmodernism, modernism and premodernism; to provide an ideological context to both the broad policy settings of a neoliberal government and the use of planning theory in a neoliberal state.
- > Third, it seeks to flesh out the debate on planning theory to provide a theoretical context for the consideration of the neoliberal strategic management planning model in the context of the competing postmodernist collaborative planning model.
- > Fourth, it discusses the key characteristics of the neoliberal strategic management planning model to provide context for the consideration of the potential implications in planning practice from the use of this model.
- > Fifth, it seeks to identify the planning policy outcomes which are likely to be associated with a neoliberal government, to provide context to the potential scope of future urban planning reform in a neoliberal state.
- > Finally, it discusses the role of the urban planner in a neoliberal regime and provides a suggested path out of the malaise that currently afflicts the planning profession in Australia.

URBAN CHANGE MODEL

Components and institutions of urban change

Urban change occurs as a result of the interplay of three institutional components (Newman 2000:1):

- > the market represented by the private sector;
- > the government represented by the public sector; and
- > the community comprising a civil society (the so called third sector).

The characteristics of the institutional components and associated institutions of urban change are summarised in Table 2.

Table 2 Components and institutions of urban change

Market – private sector	Government – public sector	Civil society – third sector
Institutional stakeholders		
Consumers, producers, employers, employees, trade associations and unions	National, state and local government including public sector entities	Communities including media, churches, educational bodies, associations and community groups
Institutional role		
Provision of wealth for development	Protection of rights and public realm	Guardian of culture and ethics
Institutional outputs		
Goods and services	Laws and regulations; infrastructure and services	Values and vision
Institutional focus		
Focussed on an aggregated criteria of choice based on the notions of utility or satisfaction	Focussed on an overall idea such as 'the spirit of history' or the 'essence of society'	Focussed on the society (modernist) or societal groups (postmodernist) as the first ethical subject and consequently on a common conception of the common good of the society (modernist) or a societal group's conception of good (postmodernist)
Institutional horizons		
Short term	Medium term (based on the term of office)	Long term

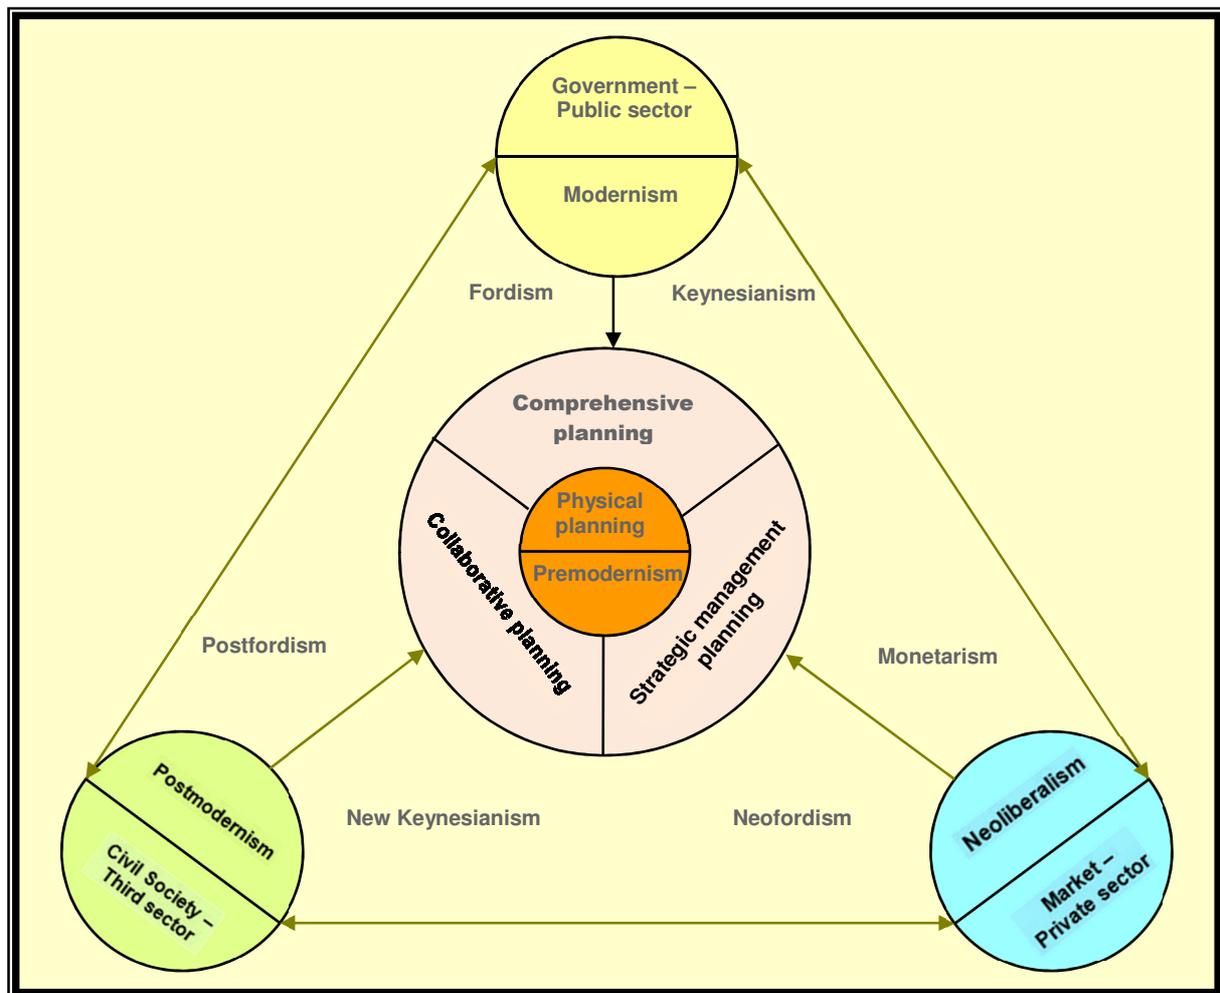

Source: Newman 2000:2; Moroni 2004:155; Alexander, Mazza & Moroni 2012:75

Planners influence all components of urban change; the market, government and civil society. They work through the private, public and third sectors using a collection of planning theories and practices to influence urban change; or on some occasions to prevent urban change.

Relationship of planning theory and practice to urban change

The interrelationship between the planning theories and practices used by planners and the components and institutions of urban change is shown in Figure 1.

Figure 1 Urban change model

It is clear that planning and the capacity to effect urban change is critically influenced by planning theory and practice; although the extent of this influence is not well understood.

An understanding of planning theory requires it to be placed within the context of broader cultural, socio-economic and political change; being the historic shift from premodernism to modernism, and then to postmodernism and more recently to neoliberalism.

Neoliberalism in a historic context

The broad cultural, socio-economic and political changes that have influenced western societies such as Australia, have had a profound effect on planning theory and practice.

These changes exist in a historic century-long linear process of transition from premodernism, to modernism, to postmodernism and finally to neoliberalism.

The cultural, socio-economic and political conditions of modern, postmodern and neoliberal ideologies are summarised in Table 3.

Table 3 Cultural, socio-economic and political conditions

Modern	Postmodern	Neoliberal
Period or era		
<i>Modernity</i> – The period of modern thought from the Enlightenment to the present	<i>Postmodernity</i> – The period of postmodern thought from the 1960s to the present	<i>Late capitalism</i> – The period of neoliberal thought from the mid 1970s to the present

Modern	Postmodern	Neoliberal
Political conditions		
<p><i>Social democracy</i> – The political conditions involving:</p> <ul style="list-style-type: none"> • a universal society existing as a structure • the collective good of the society • welfare services that are delivered to ensure equality of opportunity and removal of differences within society 	<p><i>Social liberal (deliberative) democracy (Third way)</i> – The political conditions involving:</p> <ul style="list-style-type: none"> • multiple societal groups existing as networks and flows • the good of each societal group • welfare services that are delivered to ensure personalised integrated services to reflect the differences within society 	<p><i>Liberal democracy (New Right, Thatcherism, Reaganism)</i> – The political conditions involving:</p> <ul style="list-style-type: none"> • individuals; there being no society or societal groups • the good of the individual • welfare services that are delivered by the market with limited targeted welfare services
Cultural conditions		
<p><i>Modernism</i> – The cultural conditions which accompany a method of thought in which human reason is able to identify objectively existent and knowable laws of reality that can be used to effect change to achieve a unitary common public good or truth (Hirt 2002:3)</p>	<p><i>Postmodernism</i> – The cultural conditions which accompany a method of thought in which human reason is able to identify the subjectively constructed views of groups that can be used to effect change to achieve a good as defined by those groups</p>	<p><i>Neoliberalism</i> – This economic theory has little to say about the cultural conditions of society</p>
Social conditions		
<p><i>Fordism</i> – The social conditions which accompany industrial mass production using repetition and simplicity of standardised products for mass consumption by a mass market (Goodchild 1990:126)</p>	<p><i>Postfordism</i> – The social conditions which accompany flexible small batch production of specialised products for consumption by different groups in niche markets (Goodchild 1990:126)</p>	<p><i>Neofordism</i> – The social conditions which accompany the provision of services using information technologies to niche markets that predominates over declining industrial and manufacturing activities</p>
Economic conditions		
<p><i>Fiscalism (Keynesianism, Welfarism)</i> – The economic conditions of a mixed economy involving predominately the private sector but also a significant role for the public sector in terms of monetary policy by central banks and fiscal policy by governments to stabilise output over the economic cycle</p>	<p><i>New Keynesianism</i> – The economic conditions of a market economy involving the private sector where the role of the public sector is limited to macro-economic stability, investment in infrastructure and education, containing inequality and guaranteeing opportunities for self-realisation (Giddens 2000:164)</p>	<p><i>Monetarism</i> – The economic conditions of a market economy involving the private sector where the role of the public sector is limited to monetary policy by central banks</p>

Neoliberal cultural, socio-economic and political conditions

In the context of a consideration of the planning reform agenda it is important to understand the potential cultural, socio-economic and political conditions of a neoliberal state:

- > *Cultural conditions* – Neoliberalism has little to say about the cultural conditions of society as it is a theory derived from economics.

- > *Social conditions* – Neoliberalism is premised on the social conditions of a services based economy where the provision of services using information technologies to niche markets predominates over declining industrial and manufacturing activities (the so called deindustrialisation of western societies).
- > *Economic conditions* – Neoliberalism is premised on the economic conditions of a market based economy involving the private sector; where the role of the public sector is limited to monetary policy by central banks. Neoliberalism rejects the use of fiscal policy by government to stabilise output over the economic cycle.
- > *Political conditions* – Neoliberalism is also premised on the political conditions of a liberal democracy which involves the following:
 - individuals who have the right to pursue a good life that does not harm others;
 - services that are delivered by the market or subject to competitiveness;
 - a limited role for the government in providing information and guidelines; as well as targeted welfare services for areas of social exclusion.

These broad socio-economic and political conditions provide the ideological context which will influence the broad policy settings of a neoliberal government.

NEOLIBERAL POLICY SETTINGS

The broad policy settings which are generally associated with modern, postmodern and neoliberal ideology are summarised in Table 4.

Table 4 Policy settings

Modern	Postmodern	Neoliberal
Government function		
Big centralised government involving political-administrative control	Smaller but better integrated centralised government where political-administrative control is maintained	Decentralisation Depoliticalisation Agencification
Government policy focus		
Social policy focus to ensure social cohesion	Social policy focussed on social exclusion and economic policy focused on full employment and planning	Liberalisation
Government economic management		
High taxes and spending	Lower but better targeted taxes Spending on social exclusion areas	Financialisation Fiscal conservatism
Government regulation		
Regulation	Regulation to address areas of social exclusion	Deregulation

Modern	Postmodern	Neoliberal
Central and local government relationship		
Central and local governments address the public interest	Central and local governments address group interests, in particular areas of social exclusion Local governments are well funded but are also more accountable to central government	Growthism Entrepreneurialism
Government and private sector relationship		
Government provision, commercialisation and corporatisation	Public-private partnerships Reliance on volunteer and faith based institutions	Marketisation Privatism
Government and civil society relationship		
Government help for citizens	Community self-help Government help for areas of social exclusion	Individualism Individual self-reliance and entrepreneurship Clientelism / consumerism

Source: Jackson 2009:405; Robinson 2011:1100

In the context of neoliberal ideology the following broad policy settings are likely to be adopted by a neoliberal government:

- > *Decentralisation* - Neoliberal governments tend to favour small central governments with decision making and implementation being delegated vertically to international governance (internationalism) and down to regional governance (regionalism) and local governments (localism) and horizontally to private sector and civil society partnerships and networks. Central governments seek to either steer (but not row) or direct (but not implement).
- > *Depoliticisation* - Neoliberal governments favour tools, mechanisms and institutions to separate political and administrative functions so that an issue, policy field or decision is no longer the responsibility of politicians in order to remove the political character of decision making (Flinders and Butler 2006: 296).
- > *Agencification* - Neoliberal governments favour structural disaggregation of integrated administrative structures into single purpose task specific semi-independent agencies (Sager 2009:69).
- > *Liberalisation* - Neoliberal governments tend to focus more on economic policy directed to competition and innovation rather than on social and environmental policy.
- > *Financialisation* - Neoliberal governments tend to favour financial markets and institutions having a greater influence over economic policy.
- > *Fiscal conservatism* - Neoliberal governments tend to favour lower taxes to increase consumer choice, lower spending (austerity) and a user pays approach.
- > *Deregulation* - Neoliberal governments tend to focus on market led development with lesser regulation in terms of rules, processes and internal considerations like expert jurisdictions and job security to reduce the role of government (Sager 2009:70).
- > *Growthism* - Neoliberal governments tend to focus on the soliciting of growth, in the case of central governments, and the facilitating of growth, in the case of State and local governments, to create a favourable business climate.

Ian WRIGHT, Are we all neoliberals now? Urban Planning in a neoliberal era, '49th ISOCARP Congress 2013'

- > *Entrepreneurialism* - Neoliberal governments tend to support entrepreneurial spirit, such as risk taking investment and profit motives, rather than political-administrative managerialism involving the provision of public services.
- > *Individualism* - Neoliberal governments tend to emphasise individual self-help, entrepreneurship and freedom of choice over government and community help.
- > *Clientelism/consumerism* - Neoliberal governments tend to focus on the satisfaction of users, clients, customers and consumers who will optimise their own individual benefits in exchange for political support rather than serving citizens who have rights and obligations within the context of a civil society.
- > *Marketisation* - Neoliberal governments tend to focus on the provision of services through privatisation, outsourcing, sub-contracting, competitive policies and market proxies in the residual public sector.
- > *Privatism* - Neoliberal governments tend to focus on the facilitation of private sector activity rather than government or community activity.

These broad policy settings together with the broader socio-economic and political conditions of neoliberal ideology, provide the context for the consideration of the use of planning theory by planners.

PLANNING THEORY IN A NEOLIBERAL STATE

Neoliberal planning theory

Given the neoliberal socio-economic and political conditions and broad policy settings which have become entrenched within governments across the world in the last 50 years, it is likely that the use of neoliberal planning theory will become more dominant amongst planners.

The approaches to planning theory that are embodied in premodern, modern, postmodern and neoliberal ideologies are summarised in Table 5.

Table 5 Ideological approaches to planning theory

Premodern	Modern	Postmodern	Neoliberal
Humanistic premise of planning (the planning end)			
<i>Utopia</i> – An end state in which individuals are emancipated towards an ideal society	<i>Collective public interest</i> – An end state in which society en masse is emancipated towards a common good for the society	<i>Group interest</i> – An end state in which groups within society are emancipated towards a good defined by those groups	<i>Individual interest</i> – There is no end state for society or societal groups; but rather the right of each individual to pursue a good life that does not harm others
Epistemological premise of planning (the planning means)			
<i>Artistic design method</i> – Universal laws of physical and aesthetic design principles which can be objectively defined by human reason	<i>Rational scientific method</i> – Universal laws of planning principles which can be defined through value-free scientific reason (positivist knowledge)	<i>Participatory method</i> – There are no universal laws; only the subjective value laden principles of individuals which can be defined through a participative process (culturally subjective knowledge)	<i>Managerialist method</i> – There are no universal laws; only an individual good which can be pursued through a managerial process of defining and implementing goals, objectives and strategies

Premodern	Modern	Postmodern	Neoliberal
Planning theories			
Physical planning (Unwin 1996; Triggs 1909)	<ul style="list-style-type: none"> Rational planning (Sharp 1940; Abercrombie 1959; Keeble 1969) Systems planning (McLoughlin 1969) Procedural planning (Faludi 1973) 	<ul style="list-style-type: none"> Advocacy planning (Davidoff 1965) Incremental planning (Lindblom 1959) Radical (action) planning (Friedmann 1987) Participatory planning (Arnstein 1969) Communicative planning (Habermas 1984; Healey 1997) 	Strategic spatial planning (Kaufman and Jacobs 2007; Healey 2007)
Planning models			
Physical planning	Comprehensive master planning	Collaborative planning	Strategic management planning
Planning era			
Before First World War	<ul style="list-style-type: none"> 1930s – avant-garde movement 1940s to 1980s – adopted by Government 	<ul style="list-style-type: none"> 1960s to 1990s – part of counter culture 1980's onwards – adopted by Government 	<ul style="list-style-type: none"> 1970s to 1990s - Neoliberal roll back Late 1990s onwards - Neoliberal roll out

Source: Goodchild 1990:126; Hirt 2002

Planning theory is based on two different premises; the end and the means. The first premise is that planning has a humanistic or social emancipation end. The second is that planning theory has an epistemological premise being the means by which planning delivers the identified end (namely social emancipation).

Humanistic premise of planning theory

In neoliberal planning theory, the planning end is not an end state for society such as the collective public interest of the society in the case of modern planning theory or societal group interests in the case of postmodern planning theory.

Rather it is the individual interest; the right of each individual to pursue a good life that does not harm others.

Epistemological premise of planning theory

Neoliberal planning theory postulates that the end of an individual good life is not pursued through the rational scientific method of value-free scientific reason to define a societal public interest in the case of modern planning theory or a participative process to define societal group interests in the case of postmodern planning theory.

Rather the neoliberal end of an individual good life is to be achieved through a strategic management process of defining and implementing goals, objectives and strategies.

In neoliberal planning theory, it is the managerialist method which is embodied in strategic management planning that is the predominant planning model.

STRATEGIC MANAGEMENT PLANNING MODEL IN A NEOLIBERAL STATE

Strategic management planning is a planning model that is focussed on the definition and implementation of specific and attainable goals, objectives and strategies. It differs from the comprehensive master planning model which aspires to an abstract common public good or interest of the society. It also differs from the collaborative planning model which focuses on societal group goods or interests as defined by those groups.

It is anticipated that strategic management planning will become the predominant planning model amongst urban planners in a neoliberal state.

The key features of the strategic management planning model, as compared with other planning models, are summarised in Table 6.

Table 6 Key features of planning models

Physical planning	Comprehensive master planning	Collaborative planning	Strategic management planning
Concept of the region or city			
<i>City Beautiful</i> – Cities are a symptom of social order and disorder	<i>City Functional / Mechanistic City</i> – Cities are an object that can be rationally ordered and mass produced	<i>Just City</i> – Cities are an expression of the social diversity of its citizens and the ecological diversity of its environment	<i>Entrepreneurial / Competitive / Productive City</i> – Regions and cities are an economic object that are competing against each other for economic growth
Planning governance			
Limited uncoordinated community and government initiatives	Government led with limited community involvement	Government led with significant community involvement	Private sector led through the market
Planning approach			
Government top down with no bottom up community involvement	Predominantly government top down with some bottom up community involvement	Predominantly bottom up community involvement with top down government involvement	Bottom up through the market with limited top down government involvement
Planning scale			
City with some district level planning	City and district level planning	City and district level planning with some local and site planning	Strategic planning at city and district scale with development planning at local and site levels
Planning horizon			
Long term	Medium term	Medium term at the city and district levels and short term at the local and site levels	Short term
Planning focus			
Physical urban form and aesthetic design based planning at the city	<ul style="list-style-type: none"> Detailed spatial urban form and infrastructure based planning at the city 	<ul style="list-style-type: none"> Infrastructure based planning at national and state levels 	<ul style="list-style-type: none"> Strategic spatial urban form and infrastructure based planning at city and

Physical planning	Comprehensive master planning	Collaborative planning	Strategic management planning
<p>level (city visions)</p>	<p>level (master, blueprint and layout plans)</p> <ul style="list-style-type: none"> • Development control based land use planning at the district level (zoning plans) 	<ul style="list-style-type: none"> • Detailed spatial urban form and infrastructure based planning at the regional level (regional plans) or city level (master plans) • Development control based land use planning at the district level (zoning plans) • Urban design based planning at local and site levels 	<p>district level in place of detailed master plans (strategic spatial plans)</p> <ul style="list-style-type: none"> • Development based planning at local and site levels in place of development control based zoning plans
Regional, city and district planning themes			
<ul style="list-style-type: none"> • Promotion of massed suburban expansion • Promotion of garden cities • City beautiful movement • Parks and open spaces movement 	<ul style="list-style-type: none"> • Redevelopment of slums with high rise buildings in open spaces • Controlled low density suburban expansion • New towns within green belts • Urban neighbourhoods criss-crossed by freeways 	<ul style="list-style-type: none"> • Renewal and regeneration of central cities and infill sites • Increased urban density within compact urban space • Containment to minimise land consumption, preserve open space and reduce infrastructure costs 	<ul style="list-style-type: none"> • Place branding, marketing, promotion and competition (Euro cities; capital cities; world cities; cool cities; creative cities) • Attraction of the creative class (IT; arts; biotechnology; science) • Attraction of corporate investment (free land or buildings; lower infrastructure charges; grants; tax relief such as stamp duty and payroll tax) • Central city and adjoining areas redevelopment for commercial office space and residential apartments • Employment centres focussed on the services sector • Mega infrastructure projects seen as strategic economic assets • Social infrastructure including exhibitions and arts, cultural and sporting venues and events for the creative classes

Source: Goodchild 1990:126; Jackson 2009:405

A strategic management planning model operating in a neoliberal state is anticipated to have the following significant characteristics:

- > *Concept of the region or city* – Strategic management planning is focussed on ensuring that the region or city is an economic growth object which can compete efficiently against other regions or cities for economic growth. The focus is on an entrepreneurial, competitive and productive region or city.
- > *Planning governance* – Strategic management planning is market led by private sector developers.
- > *Planning approach* – Strategic management planning is a bottom up market led approach rather than the predominantly top down/bottom up approach characteristic of the comprehensive master planning model (associated with modern planning theory) or the predominantly bottom up/top down approach characteristic of the collaborative planning model (associated with postmodern planning theory).
- > *Planning scale* – Strategic management planning is focused on local and site level planning with limited regional, city and district level planning rather than on the city and district level planning characteristic of the comprehensive master planning model and local and site level planning characteristic of the collaborative planning model.
- > *Planning horizon* – Strategic management planning has a short term horizon reflecting the reality that planning is intended to be capable of continual revision in response to the market.
- > *Planning focus* – Strategic management planning is focussed on strategic spatial urban form and infrastructure based planning at city and district levels and development based planning at the local and site levels in place of the detailed plans and zoning plans associated with comprehensive master planning and collaborative planning.

Ian WRIGHT, Are we all neoliberals now? Urban Planning in a neoliberal era, '49th ISOCARP Congress 2013'

- > *Regional, city and district level planning themes* – Strategic management planning is focussed on the following themes at the regional, city and district levels:
 - urban branding, marketing, promotion and competition;
 - central cities and adjoining areas as key economic growth areas;
 - employment centres traditionally focussed on industrial areas but increasingly focussed on the service sector;
 - mega infrastructure projects such as road and public transport which are seen as strategic economic assets;
 - key social infrastructure such as exhibition centres, science and technology parks, sports stadiums and cultural districts which are focussed on the creative classes;
 - suburbs that are seen as residual places not to be touched; the 'heartlands'.
- > *Local and site planning themes* - Strategic management planning is focussed on the following themes at the local and site levels:
 - performance based controls;
 - flexible standards;
 - integrated development control;
 - reduced infrastructure service standards (to avoid so called gold plating);
 - reduced garden space for houses;
 - urban design.

The increased use by planners of a strategic management planning model will have a significant influence on planning practice.

PLANNING PRACTICE IN A NEOLIBERAL STATE

Neoliberal planning practice

The broad neoliberal socio-economic and political conditions and associated policy settings which have emerged under neoliberal governments will encourage the use of neoliberal planning theory and models that will have an increasing influence on planning practice.

Generally speaking it is expected that policies and processes associated with the comprehensive master planning model (in the case of modern planning theory) and collaborative planning model (in the case of postmodern planning theory) will be rolled back; whilst policies and processes associated with the strategic management planning model will be rolled out through public policy and legislative reform.

The anticipated implications for planning practice of the increased use by planners of neoliberal planning theory and a strategic management planning model is summarised in Table 7.

Table 7 Implications for planning practice of neoliberal planning theory and models

Policy settings	Policy implications	Political implications
Government function		
<ul style="list-style-type: none"> • Decentralisation • Depoliticalisation • Agencification 	<ul style="list-style-type: none"> • Reduced central government planning • Limited central government control of local government planning 	<ul style="list-style-type: none"> • Greater electoral accountability • Stronger role for local clientel relationships

Policy settings	Policy implications	Political implications
	<ul style="list-style-type: none"> Contracting out of planning functions Central government off-loads unfunded risks and responsibilities to local governments Policy solutions borrowed or adapted across jurisdictional boundaries 	<ul style="list-style-type: none"> Fiscally constrained local governments
Government policy focus		
<ul style="list-style-type: none"> Liberalisation 	<ul style="list-style-type: none"> Focus on innovation and competitiveness rather than on full employment and planning Social wage is seen as a cost of production rather than as a means of redistribution to maintain social cohesion Welfare to work to reduce welfare expenditure 	<ul style="list-style-type: none"> Reduced social cohesion Increased social exclusion
Government economic management		
<ul style="list-style-type: none"> Financialisation Fiscal conservatism 	<ul style="list-style-type: none"> Limited provision of infrastructure and services Less maintenance of infrastructure and services Greater private sector provision Reduced developer contributions in new growth areas Reduced focus on urban renewal projects Focus on cost recovery and user pays 	<ul style="list-style-type: none"> Fiscally constrained governments Infrastructure and services failures Price hikes Cross-subsidies are increased Rent seeking by the private sector
Government regulation		
<ul style="list-style-type: none"> Deregulation 	<ul style="list-style-type: none"> Removal of comprehensive master planning and collaborative planning policies and practices Simplified planning regulation Plans that are more flexible Plans that give less direction to local government Plans that give more certainty and predictability to developers Plans with fewer directives and more negative regulation Plans that specifically integrate central and local government priorities Enabling regulations for major or mega projects Use of reserved planning powers (Ministerial call ins and directions) to facilitate projects Speeding up of development assessment, public inquiry and plan preparation processes 	<ul style="list-style-type: none"> Less importance of rules, processes and expert jurisdictions Less concern for development externalities Stronger role for the private sector in determining the form and location of development Potential impact on the spatial cohesion of cities Reduced oversight and increased risk of corruption Risk of regulatory capture

Policy settings	Policy implications	Political implications
Central government and local government relationship		
<ul style="list-style-type: none"> • Growthism • Entrepreneurialism 	<ul style="list-style-type: none"> • Local governments focus on place branding, marketing, promotion and competition rather than place making • Local governments focus on economic growth projects generally in central city locations at the expense of investment elsewhere • Politicians and planners gain financial acumen and act as urban entrepreneurs • Governments mimic corporate style and logic • Public services seen as ineffective and wasteful and a drain on entrepreneurial activity 	<ul style="list-style-type: none"> • Local governments forced to compete with each other for economic growth • Reduction in public services
Government and private sector relationship		
<ul style="list-style-type: none"> • Marketisation • Privatisation 	<ul style="list-style-type: none"> • Rise of the intermediate services sector (private professional advisers who do planning work) • Developer led development rather than plan led development • Developers take over plan making • Developers are stakeholders in major public infrastructure projects • Public assets privatised or divested • Privately governed community interest developments such as residential subdivisions, apartment developments and master planned gated communities with private streets, services and governments such as Homeowner Associations • Compulsory purchase of private land for public benefit by private landholders • Business improvement districts (UK/US) where revenue from a district is spent in a district • Privatised planning regulation (for example private certification) • Limited public review of public infrastructure projects (focus is on selling the project not evaluating the project) • Private sector involvement in financing and operating infrastructure • Competitive bidding for urban renewal and infrastructure projects • Private sector provision of rental housing rather than public housing • Privatisation of public spaces (public 	<ul style="list-style-type: none"> • Loss of citizen entitlements • Excess profits • Price hikes • Asset stripping • Poor driven to the worst located areas • Profit seeking by private contractors increases public sector expenses

Policy settings	Policy implications	Political implications
	plazas; pavements; urban parks; government land and buildings <ul style="list-style-type: none"> Privately governed and secured neighbourhoods through management (for example gated communities, community interest developments (US) and Homeowners Associations (US)) and passive design (for example master planned residential estates) 	
Government and civil society relationship		
<ul style="list-style-type: none"> Individualism Clientelism 	<ul style="list-style-type: none"> Corporate style advisory boards replace community based consultative groups Focus on owner occupied and rental housing rather than public housing, community houses and housing associations Focus on private schools rather than public schools, TAFE and other public educational facilities Focus on private hospitals and private health insurance rather than public hospitals Limited investment in social infrastructure to address areas of social exclusion 	<ul style="list-style-type: none"> Downsizing of services Limited access to shelter and services for the poorest Rise in informality in cities

Waves of neoliberal planning reform in Australia

In Australia, three distinct waves of neoliberal planning reform by State governments can be broadly identified as summarised in Table 8:

- > *First wave* - Neoliberal roll back associated with Liberal National Party State governments where state, regional and city strategic planning was eschewed in favour of standardised district level land use based zoning plans to maximise development control efficiency and local and site level development control plans to facilitate development.
- > *Second wave* - The neoliberal roll back was subsequently moderated by State Labor governments under which State planning policy guidance was provided on balancing social, environmental and economic matters, detailed spatial plans were prepared at regional and local government levels and standardised land use zoning plans and neighbourhood plans were prepared to guide future development.
- > *Third wave* - The neoliberal roll out has been reintensified since 2010 by State Liberal National Party governments which have implemented or proposed:
 - State planning policies focused on economic growth;
 - strategic spatial plans for regional and local government areas;
 - land use zoning plans and neighbourhood plans that are development not control oriented.

Table 8 Waves of neoliberal planning reform in Australia

Planning scale	First wave - Neoliberal roll back	Second wave - Neoliberal roll back moderated	Third wave - Neoliberal roll out
State governments	QLD - National and Liberal Party governments (1970s - 1989) NSW - Greiner/Fahey Liberal governments (1988 - 1995) VIC - Kennett Liberal government (1992 - 1999)	QLD - Goss, Beattie and Bligh Labor governments (1989 - 2012) NSW - Labor governments (1995 - 2011) VIC - Bracks and Brumby Labor governments (1999 - 2007)	QLD - Newman Liberal National Party government (2012 onwards) NSW - O'Farrell Liberal government (2011 onwards) VIC - Baillieu and Napthine Liberal National Party governments (2010 onwards)
State level planning	Apparatus dismantled as district level planning is seen as the appropriate planning scale	State planning policies provided guidance for a wide range of economic, social and environmental matters	State planning policies amended to prioritise economic growth over social and environmental matters
Regional level planning	Apparatus dismantled and State government devolution to regional government offices	Detailed spatial urban form and infrastructure plans for metropolitan areas and regional cities	Strategic spatial urban form and infrastructure plans for metropolitan areas and other regions
City/town level planning	Rejection of strategic spatial planning	Detailed spatial urban form and infrastructure plans for local government areas	Strategic spatial urban form and infrastructure plans for local government areas
District level planning	Standardised land use based zoning plans to maximise development control efficiency	Standardised land use based zoning plans with increased self-assessable and code assessable development to maximise development control efficiency	Standardised land use based zoning plans which are development not control oriented
Local and site level planning	Development control plans to facilitate local or site level development	Neighbourhood plans to protect local areas and facilitate known local or site level development	Neighbourhood plans which are development not control oriented

However it is critical to note that the characterisation of neoliberalism planning reform into three waves obscures the hybrid nature of neoliberalism where there have been multiple configurations of neoliberalism at different planning scales within and between Australian states and where the processes of neoliberal roll back of Keynesianism and the roll out of neoliberalism have been in conflict (McGuirk 2006:61).

ROLE OF THE PLANNER IN A NEOLIBERAL STATE

The emergence of neoliberal planning theory and its associated strategic management planning model and consequential implications for planning practice have inevitably resulted in a re-evaluation of the role of the planner in urban change.

The role of a planner under the physical planning, comprehensive master planning, collaborative planning and strategic management planning models is summarised in Table 9.

Table 9 Planner's role under different planning models

Physical planning	Comprehensive master planning	Collaborative planning	Strategic management planning
Knowledge and skills			
Specialist knowledge of utopian ideals and planning principles	Specialist knowledge of planning principles and specialist skills to manage the planning process to define the public interest and planning principles	Specialist knowledge and skills to manage the planning process to facilitate consensus of group interests	Specialist knowledge and skills to manage the planning process to facilitate economic growth outcomes
Decision making			
<i>Utopian rationality</i> - Rational vision	<i>Instrumental rationality</i> - Rational plan	<i>Communicative rationality</i> - Rational process	<i>Economic rationality</i> - Rational outcome
Ethical perspective			
<i>Technician</i> – Value neutral adviser to a decision maker	<i>Technician</i> – Value neutral adviser to a decision maker	<i>Politician</i> – Value committed activist that advocates policies for group interests	<i>Hybrid</i> – Hybrid of a technician and a politician that advocates for economic growth outcomes

In a neoliberal state it is expected that the planner will be required to develop specialist knowledge and skills to manage the planning process to facilitate economic growth outcomes; in preference to social and environmental outcomes and in preference to a common public interest for the society or societal group interests.

In a neoliberal state, a planner is expected to make decisions (or provide recommendations) based not on instrumental rationality (that is the rationality of the plan) or communicative rationality (that is the rationality of the planning process) but rather on the basis of economic rationality. A rational decision is one which is in the general interest of the public as defined by means of a potential Pareto improvement; namely that a policy should only be implemented if those who benefit from the policy could compensate those that lose from the policy and still be better off (Gleeson and Low 2000b:15).

This will require the planner to gain greater financial and economic acumen and act as an urban entrepreneur.

This will inevitably require the planner to adopt a hybrid role involving the following (Howe 1980; Steele 2009:4):

- > first, as a technician that seeks to be a value neutral adviser to a decision maker; but
- > secondly, and more significantly, as a politician who is a value committed activist that advocates economic growth outcomes.

Ian WRIGHT, Are we all neoliberals now? Urban Planning in a neoliberal era, '49th ISOCARP Congress 2013'

It is this second political role that is likely to cause an ethical dilemma for some planners for the following reasons:

- > first, there is currently a strong professional and in some cases personal commitment on the part of some planners, to sustainable development (or ecological sustainability) and its goal of balanced economic, social and environmental outcomes;
- > second, to actively facilitate development could be seen by some planners as co-opting planning to the private sector which is only one of the sectoral interests involved in urban change and whose focus is quite appropriately limited only to profit.

CONCLUSIONS - ARE WE ALL NEOLIBERALS NOW?

The planner plays a critical role in influencing and sometimes preventing urban change through their work for the private, public and third sectors; which are the institutions responsible for urban change in our society.

The traditional modern and postmodern perspectives of planning that have underpinned the planners' use of planning theory and practice are being challenged by an energised neoliberal ideology.

Neoliberalism rejects planning's role as a tool to correct and avoid market failure and seeks to subsume planning as a minimalist form of spatial regulation to provide certainty to the market and facilitate economic growth.

Planners must understand that neoliberalism is but a process; it is not an end state of history or geography. The neoliberal project is neither universal, monolithic or inevitable; it is contestable (Peck and Tickell 2002:383).

Neoliberalism is simply the process of restructuring the relationships between the public, private and third sectors, to rationalise and promote a growth first approach to urban change. As stated earlier in this paper; Neoliberalism = Classical liberalism + (Theory of growth + Keynesianism).

Each planner must personally and professionally determine where they stand in relation to the restructuring of the institutions of urban change that is being heralded by the neoliberal reform of planning and the planning system in Australia.

As a profession it is critical that planners regain the trust of the public and their elected representatives. This can only occur where the decision making and knowledge and skills of planners is seen as independent from politics. This requires planners to play to their strengths:

- > Collaborative planning should be used to identify societal interests whilst acknowledging to the public that not all of the public's interests can be translated to a physical outcome in a planning instrument.
- > Comprehensive evidence based planning should be used to demonstrate to politicians both the money that will be wasted on policies that do not work as well as the benefits that will accrue from policies that will work.

In short planners must reclaim their professional credibility by asserting their right to contradict the public and politicians. The first step involves the planning profession taking an active and positive part in the forthcoming contest between planning and neoliberalism.

Peri-Beijing–Tianjin–Hebei Cross-boundary Mega-region Planning towards Sustainability in Urbanizing China

Huiliang YIN, China Academy of Urban Planning and Design, China

Fangxin YI, China Academy of Urban Planning and Design, China

1. Introduction

China has experienced unprecedented urbanization and the urban population increased from 10.64% in 1949 to 49.95% in 2010 (Zou, 2010; Zhou, et.al, 2013). Under the rapidly urbanization, mega-region planning have become the motors of the global economy in the accelerated urbanization. Facing the fiercely competition pressure between metropolitan areas, cross-boundary mega region are engaged actively in cooperation and collaboration in planning and institution building in an effort to turn urbanization and globalization as far as possible to achieve sustainability.

It is well known that there has been a mega-region planning fever since 2000s in post-reform China (Lin, 2001; Yang and Wang, 2008). There are abundant of research on Chinese urbanization. However, recent studies on mega-region planning are confined to the discussion of city-region or urbanization pace and rate of China. This study attempts to discuss the mega-region Peri-Beijing-Tianjin-Hebei Area (*Huanshouduquan*, PBTHA) planning as a cross-boundary case to probe into the significances and difficulties of the cross-boundary mega-region planning. It is not only preliminary enquiry on the practice of mega-region planning, but also an experimental attempts to discuss the cross-boundary planning and mega-region governance at the international planning platforms.

This paper is organized as follows. The first part considers the current status of mega-region area and mega-region planning in post-reform China to provide a background for this study. Following that, the paper introduces the characteristics of the PBTHA. Three main features are analyzed in this part. In the third section, the major issues and main ideas of the planning are discussed. It addresses the difficulties and main contributions of the planning. Moreover, the process of planning implementation is analyzed and assessed. Experience in the cross-boundary planning is discussed in the final parts.

1.1 Chinese Mega-region Area Planning

In recent years, many city governments have attempted to build mega-region area planning during the transition from state socialism to market economy in post-reform China. In order to enhance the competitiveness of the region to achieve sustainability, mega-region planning is becoming a new initiative in Chinese spatial planning (Gao, 2004; Qian and Xie, 2004; Zhang, 2003; Luo and Shen, 2008). A series of mega-region planning has been phased and proposed from central government to provincial government, including Jingjinji Mega-region planning, Pearl-delta River Mega-region planning, Chengyu Mega-region planning. Most parts of mega-region planning are cross-boundary plan, which cover different provinces and the difficulties and significances of the planning are self-evident.

1.2 Peri-Beijing-Tianjin-Hebei Area

Peri-Beijing-Tianjin-Hebei Area (*Huanjingjinji*, PBTHA) refers to those areas which locates around the outside of the capital city of Beijing (*Huanshoudu*) and includes four prefecture-level cities Zhangjiakou, Chengde, Langfang and Baoding. The four cities include 12 districts, 6 cities, 45 counties and 359 towns with a total area of 103, 000 km². The Upper Peri-Beijing

area (*Huanshoudu Qianyan Diqu, UPBA*) includes those 17 counties, which locate tightly with the capital city of Beijing and have a total area of 34.8 km².

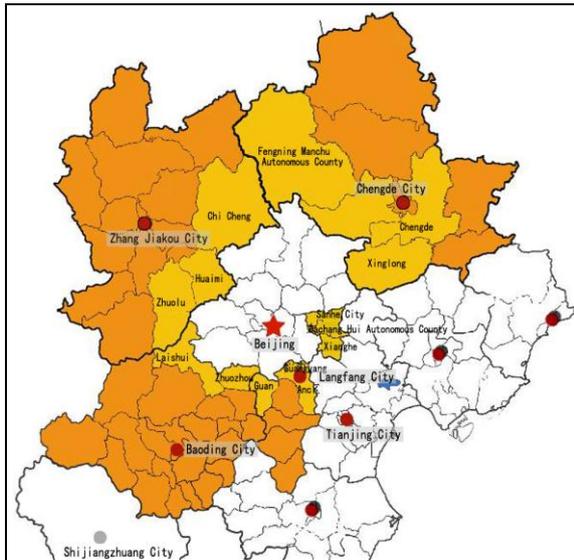

Figure 1: PBTHA Cities

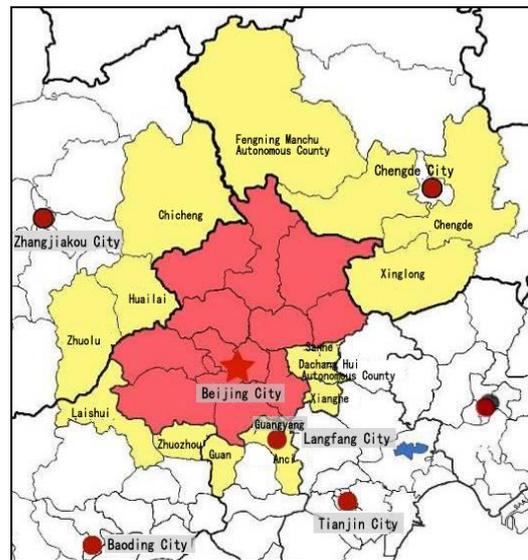

Figure 2: UPBA Cities

Table 1 PBTHA Cities Statistics

SCOPE	AREA (km ²)	TOTAL POPULATION	Urban population	The urbanization rate (%)	GDP (Billion Yuan)	GDP per capita (Yuan)
Zhangjiakou	37,000	4235,000	1863,000	44.0	80.03	19,000
Chengde	40,000	3442,000	1330,000	38.6	76.01	22,000
Langfang	6,000	4122,000	1950,000	47.3	114.75	28,000
Baoding	21,000	11017,000	3950,000	35.9	173.0	16,000
Sum	103,000	22816,000	9093,000	39.9	443.8	19,000
Hebei Province	188,000	70344,000	30769,000	43.7	1723.55	246,000
Proportion of four cities in total province (%)	548,000	324,000	296,000	—	2.57	—
Beijing	16,000	17550,000	14918,000	85.0	1186.59	69,000

Sources: HBSB, 2009

2. Characteristics of PBTHA

2.1 Significant differences in natural condition

The total area of PBTHA is five times more than the area of Beijing and UPBA area is twice more than the total area of Beijing. There are significant differences in natural condition of the four cities of PBTHA. Besides the huge differences in the total area, the natural condition varies with the topography and natural landscape. The cities in the northwestern part, Zhangjiakou and Chengde, are mainly mountains and hilly and the cities in the southeastern part, Langfang and Baoding, are mainly plain landform. Thus, the huge differences of natural condition lead to the imbalance distribution of the regional population. The total population of four cities is one thirds of the population of Hebei province, equals to 1.4 times more than the population of Beijing. Furthermore, the total population of UPBA is one thirds of the population of Beijing and the urban population difference is even larger. The urbanization

rate of UPBA is merely 37.3%, compared with the urbanization rate of Beijing of 84.9% in 2008.

Table 2 UPBA Cities Statistics

SCOPE	TOTAL POPULATION	AREA (km ²)	Urban population	The urbanization rate (%)	GDP (Billion Yuan)	GDP per capita (Yuan)
UPBA	5629,000	33,000	2101,000	37.3	121.2	20,200
Beijing	16950,000	16,000	14391,000	84.9	912.2	60,100

2.2 Poor economic condition and primitive industrial level

Compared with the economic development of Beijing, the total GDP of PBTHA four cities are much lower. The per capita GDP of UPBA only accounts for one thirds of per capita GDP of Beijing. Among them, the economic development of Baoding and Langfang is comparatively higher than the economic development of Chengde. However, the per capita GDP of most parts of the counties are much lower than the average provincial per capita GDP level.

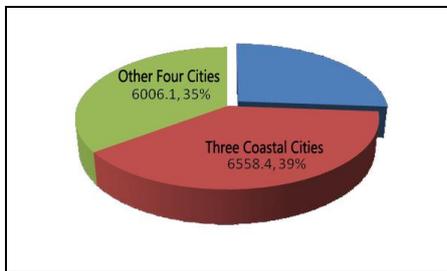

Figure 3: UPTHA cities and coastal cities economic proportion (0.1 billion, %)

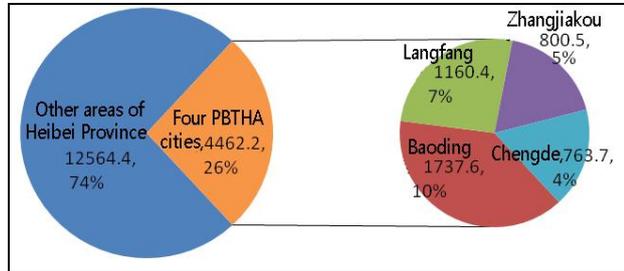

Figure 4: UPTHA cities economic proportion

Concerning the economic level of UPBA, the 17 counties could be divided into three groups, with the phenomenon of “east rich, west poor”. The first group includes those counties with GDP 10 billion above, including Sanhe, Zhuozhou and Xianghe, which accounts for 43.48% of total GDP of 17 counties. The second group includes those counties with GDP level between 5-10 billions, which accounts for 40.43% of total GDP of 17 counties. The third group includes the counties with GDP level above 5 billion.

In regard to the development level of the PBTHA four cities, all of them stay at the primitive industrial development stage. Most of the cities mainly focus on the development of heavy industry, which make a significant impact on the environment of the whole area.

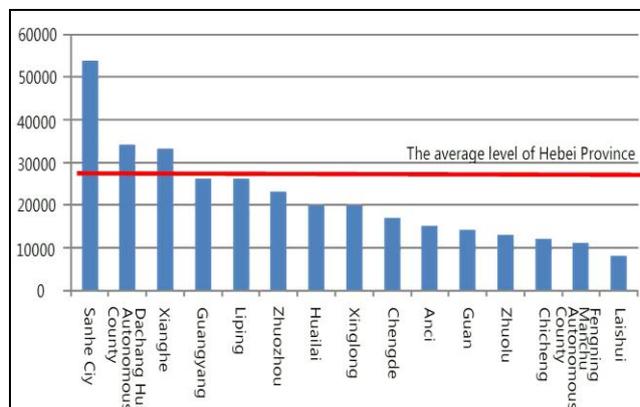

Figure 5: Per-capita GDP of UPBA Cities (Yuan)

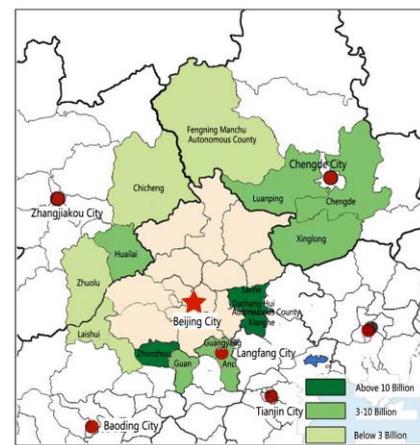

Figure 6: UPBA three groups

2.3 Imbalance Urbanization Development

Another significant feature of the whole area is the imbalance urbanization development. In 2009, the urbanization rate of PBTHA four cities are merely 39.9%, lagging behind the average urbanization rate of Hebei province 43.7% and national average rate of 46.6%. Regional differences of urbanization lie in different cities. Among the four cities, the urbanization rate of Langfang, Zhangjiakou, Baoding and Chengde is 47.3%, 44.0%, 35.9% and 38.6% respectively. However, the urbanization growth rate is comparatively amazing. The average PBTHA urbanization growth rate has increased from 32.0% to 40.1% with an annual increase rate of 1.35%.

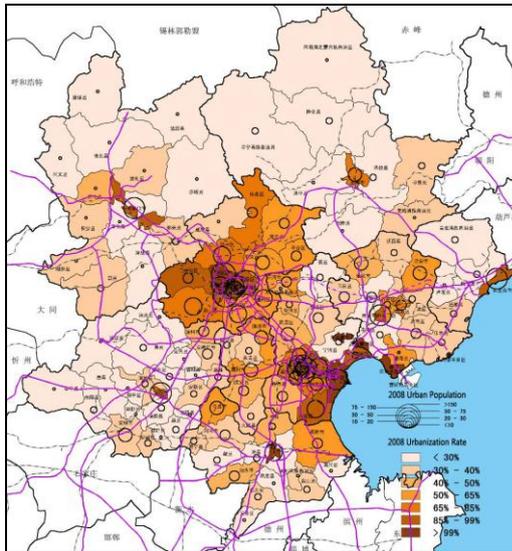

Figure 7: Urbanization Rate

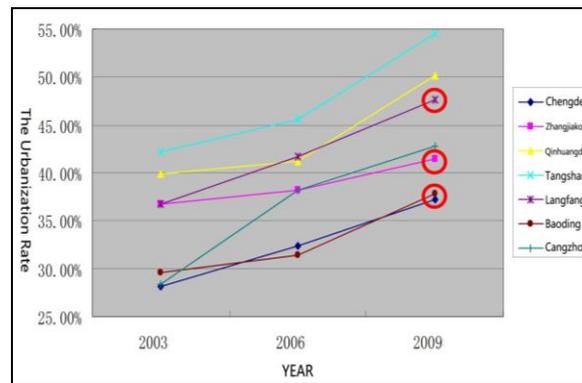

Figure 8: Urbanization Growth Rate

The urban population of four cities distribute along the traditional transportation corridors. The towns and counties are main attractors to the total population. As shown in Figure 9, towns contribute most to attracting urban population to cluster around the main urban area. It is suggested that the urbanization pattern of PBTHA shows a form of urbanization from below, different from those urbanization from above. Theoretically, the prefecture-level cities, often known as core cities, should be played a significant role in attracting urban population. However, the contribution index shown in the figure 9 suggests that the counties and towns play a more significant role in attracting urban population. This urbanization pattern identifies that there are regional inequalities of the cities of PBTHA.

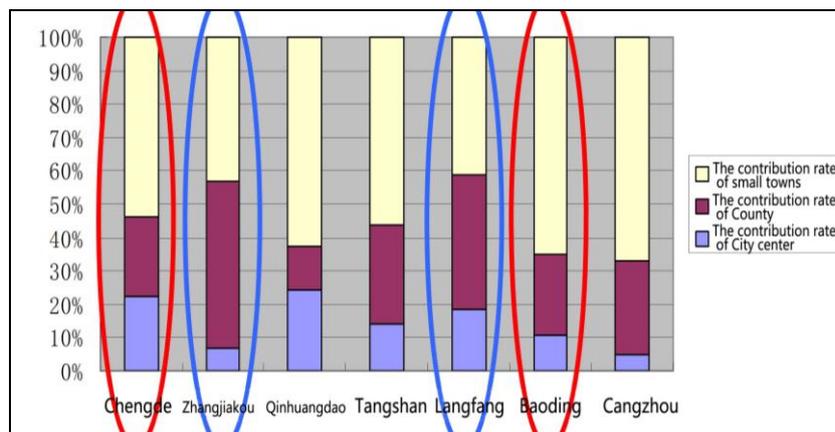

Figure 9: Contribution Rate of Towns/County/City Center

2.4 Discussion

Generally speaking, the three main features of PBTHA illustrate the significances and difficulties of the project that need to be solved and working on. The diverse natural

conditions contribute to the unequal development of the cities and different economic level of the cities. The unequal distribution of urban population attributes to the imbalance level of urbanization rate. The regional inequalities make the cross-boundary regional cooperation hard to put forward. Thus, the planning proposes a series of strategies and planning measures concerning the regional inequalities.

3. Key Issues of Cross-boundary Mega-region Planning

As discussed above, the PBTHA mega-region consists of four prefecture-level cities of Hebei province, Zhangjiakou, Chengde, Langfang and Baoding, which locate outside the capital city of Beijing. The PBTHA region can be seen as a new regional entity created by the Hebei provincial government. Previous research by Asian Development Bank has identified that there was a significant poor belt around the capital city of Beijing, quoted as Peri-capital Poor Belt (*Huanshoudu pingkun dai*)¹. The economic development of PBTHA cities has been lagged thousands of times behind the capital city of Beijing. Moreover, the PBTHA cities have less advantage in competition for foreign direct investment (FDI) and infrastructure projects such as railways and airports with the giant Beijing. As shown in figure 10, the different economic level between Beijing, Tianjin and the PBTHA cities had been exacerbated during 1994 and 2008.

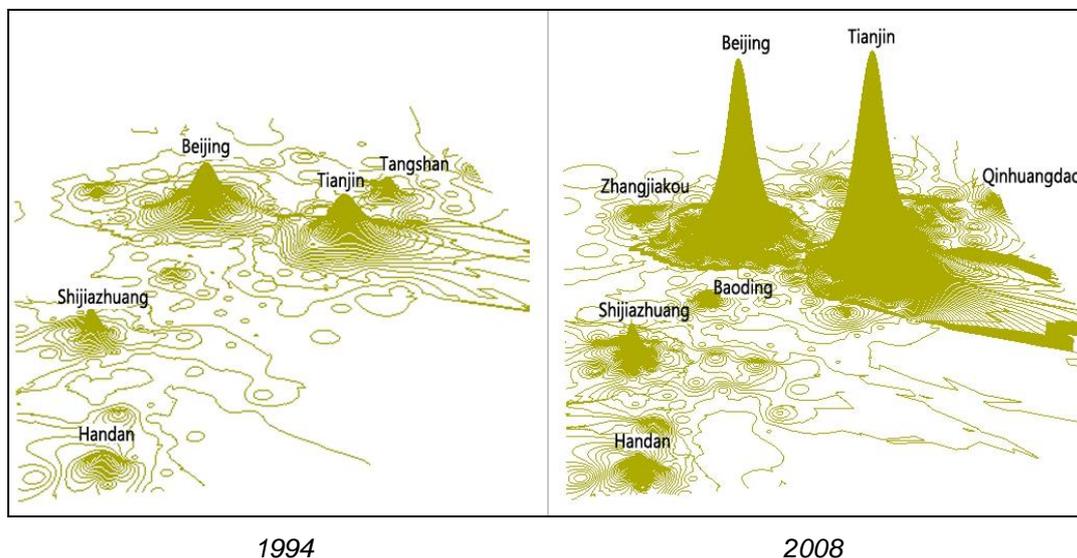

Figure 10 Jingjinji Cities Economic Energy Level

In order to alleviate the serious problems of vicious urban competition between Beijing and PBTHA cities, the provincial government of Hebei initiated the cross-boundary mega-region planning to coordinate the development of four cities to probe into a balance way to achieve sustainable development for both Beijing and PBTHA cities, when Beijing intends to rephrase its master plan. The provincial Construction Commission authorized the planning task to China Academy of Urban Planning and Design to produce the plan. The PBTH mega-region plan can be viewed as a blueprint for cooperation initiated by the higher-level provincial government of Hebei. Actually, it is the good wishes of Hebei province to solve its development problem rather than a cooperation and negotiation between Hebei and Beijing. Officially, major objectives of PBTH mega-region planning are stipulated.

- The first objective is to make use of the dominant role of the capital city of Beijing for regional economic development. The PBTHA region should become an engine of development in the Beijing-Hebei-Tianjin (*Jingjinji*) Metropolitan area. Most importantly, it will pursue a difference strategic development role to enhance the cooperation with Beijing, stimulating the development of northern regions of Hebei.
- The second objective is to alleviate problems of environmental pollution and serious vicious urban competition between PBTHA cities and Beijing and to enhance urban and regional competitiveness and achieve regional sustainability.

- The third objective is to improve the relationship between the PBTHA cities and Beijing. It is self-evident that development of PBTHA cities has not been benefited from its proximity to Beijing. On the contrary, Beijing plays a negative role in the regional economic development, plundering the capital and resources of the PBTHA cities. Many preferential policies were offered to manufacturing investors of Beijing, competing against the investment of the region and decreasing the competitiveness of PBTHA cities in manufacturing industry. The planning intends to probe into the adjustment of the relationship between Beijing and PBTHA cities.
- The fourth objective is to enhance regional competitiveness to achieve sustainability in post-reform China. Beijing is the capital city of China. It is undeniable that the role of PBTHA cities is also significant politically as well as economically.

Thus, the planning focuses on poverty alleviation between different regions, increasing of environmental protection, cross-boundary infrastructure construction and establishment and cross-boundary mega-region governance. It was a comprehensive process covering industrial development, spatial planning, environment protection, poverty alleviation and more.

3.1 Poverty Alleviation

The planning proposes industrial development to alleviate the regional poverty and inequality regional economic distribution. It plans to increase the economic level of PBTHA four cities to a certain level. The GDP will achieve 35% of the total GDP of Hebei province. The added-value of tertiary industry will account for 45% and the total industry of the area will upgrade from the labor intensive manufacturing industry to capital intensive industry. It advocates developing low carbon industry and high-tech industry. It also illustrates to transform and upgrade the traditional equipment manufacturing industry, electronic information industry and urban industry and actively incubate new energy, new material and bio-industry. Furthermore, it calls for actively develop leisure industry, modern logistics industry, financial services,

On the other land, the planning proposes to accelerate the urbanization through an accelerated urbanization strategy to achieve poverty alleviation. The urbanization strategy is stipulated as follows:

- The first strategy is to enhance the development of the urban center of PBTHA four cities, Chengde, Zhangjiakou, Langfang and Baoding. The first strategy is to adopt the urbanization from the above strategy to reinforce the development role of urban center cities. The specific different development strategy of each city is as follows:
 - Changde, previously known as Jehol or Rehe, situated northeast of Beijing, best known as the site of the Mountain Resort, a vast imperial garden and palace formerly used by the Qing emperors as summer residence, aims to become international tourist city. It is phased to become an extra-large city with the population of over 1 million in 2020.
 - Zhangjiakou, bordering Beijing to the southeast, best known by its critical transport node for travel between Hebei and Inner Mongolia and connecting northwest China and Beijing, aims to build regional center city and ecological tourist place with a population of over 2 million in 2020.
 - Langfang, located approximately midway between Beijing and Tianjin and bordering Baoding to the southwest, Beijing to the north and Tianjin to the east, is the smallest prefecture-level division in Hebei province by land area. It intends to adjust the administrative zone, promote the urban development with different parts of districts and incubate it become the regional growth pole for the whole mega-region area.
 - Baoding, bordering Beijing to the northeast and Shanxi to the west, aims to establish capital modern infrastructure and high-tech base, national historic and cultural city and national low-carbon experimental zone, aims to achieve over 2 million population in 2020.
- The second is the strategy to develop new towns. The planning proposes a series of new towns in PBTHA to construct the public transportation and railways by two sides.

- The third strategy is to improve the quality of the urbanization of the towns and counties from the below. Counties and towns are considered the bottom-up engine for the urbanization from below. The planning proposes to improve the construction of the towns and counties through different channels, including increasing the public transportation and public facilities, promoting the upgrade of the industries.

3.2 Regional Spatial Strategy

Due to the different distribution of regional resources, the planning stipulates a spatial development strategy, which is centered to build multi-layer spatial development framework and adopt a diverse strategy to different cities. The establishment of the multi-layer spatial development framework is based on the transportation corridor.

In the first place, the regional spatial strategy is centered on the spatial strategy of Beijing. Concerning that Beijing intends to develop along the transportation corridors towards the east and north side, the first layer is centered on Beijing metropolitan region, called commuter ring. It includes the towns and counties within a radius of 30 kilometers of East fourth Ring Road and the North Fourth Ring Road. The first layer served for Beijing and the spatial structure is transitioned from the corridors-led to network. The layout is consistent with the urban transportation of center city of Beijing.

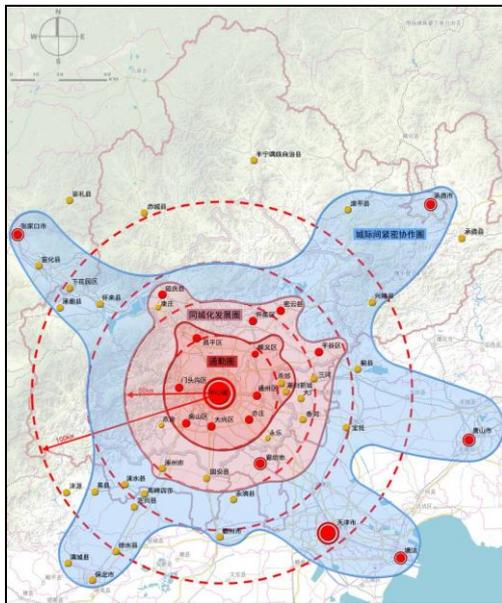

Figure 11: Regional Spatial Layout

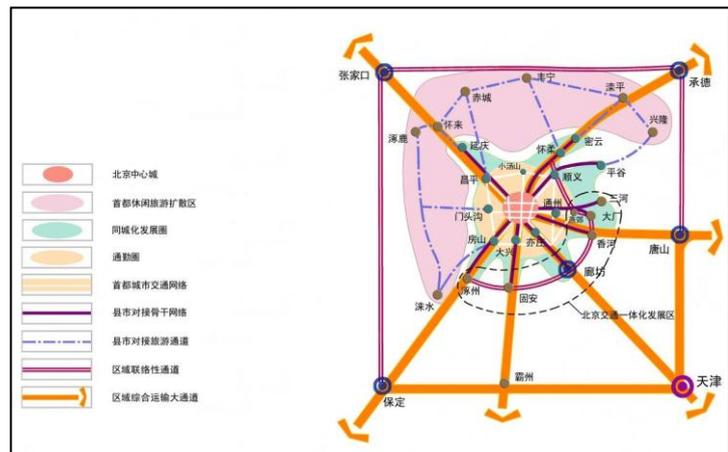

Figure 12: PBTHA Transportation Spatial Structure

The second layer is the city development circles. It is extended 20-25 kilometers out from the commuter ring. It allocates the new towns and those core nodes to serve for the capital. It serves for the transportation of Beijing and reinforces the main roads connection between those new towns and Beijing to avoid the outside sleeping cities.

The third layer is inter-city cooperation circle, which is centered within a radius of 70 kilometers and extended to a radius of 150 kilometers to Beijing, Tangshan, Baoding, Zhangjiakou and Chengde-which serves for the industry transition and commercial and logistics connection. It depends on the inter-city transportation and extends along Beijing six radial integrated transport corridors and distributes outside center cities and professional integrated nodes.

The fourth layer is Jingjinji North integrated development zone, which is based on a radius of 150-200 kilometers and covered those metropolitan areas to promote the competitiveness of capital city area.

Generally, the whole spatial structure will be formed as the figure 12 shown.

3.3 Environmental Protection

The planning stipulates a series of measures to promote environmental protection to achieve sustainable development. The most important part of the planning is to phase an ecological planning protection structure (Figure 13), which is structured by green screen-corridor-ring. Green screen is to protect and restore those northwestern mountains, water conservation areas, and to reinforce the protection of natural protection areas and forests to protect the regional ecological security barrier.

The green corridors are six main rivers from the mountains to the plains to protect the river ecosystem of water and improve the water landscape.

The green rings are those green ecological corridors, serving as the significant ecological isolated belt to effectively improve the spatial environment of the PBTHA mega-region.

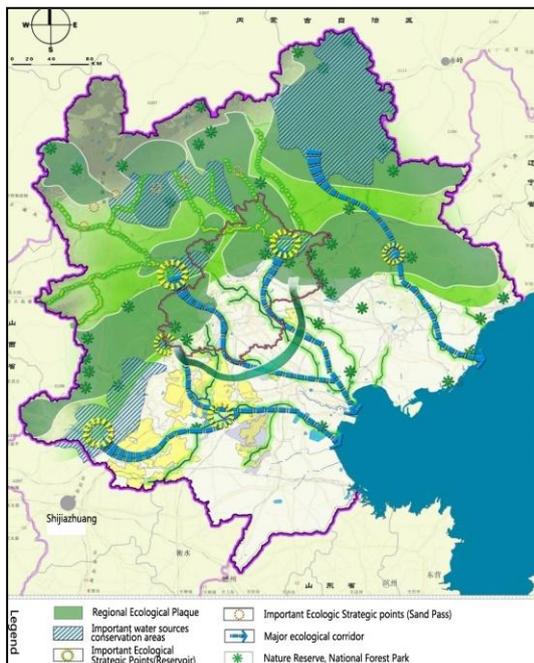

Figure 13 UBTHA Cross-boundary Ecological Protection Planning Structure

3.4 Cross-boundary Infrastructure Construction

The planning also proposes cross-boundary infrastructure construction plan to serve for the whole region. A series of railways, airports, highways are proposed in the infrastructure parts. Under the plan, it aims to establish a series of transportation hubs, including international gateway hubs, national transportation hubs, regional transportation hubs and regional connecting hubs. International hub includes Sanhe and Dachang, which are within the international airport serving area and Langfang, Guan, Yongqing, Zhuoahou, which are within the second international airport serving area.

National transportation hubs are those national stations which serve for national highways and high-speed railways, including Beijing station, Beijing south station, Beijing west station, Beijing north station and Fengtai station.

Regional transportation hubs include those five hubs, Tongzhou, Langfang, Baoding, Chengde and Zhangjiakou, which act the regional transportation services.

Regional connecting hubs include those new towns to serve for the connecting hubs.

The cross-boundary infrastructure system serves for the cross-boundary region to form a systematic transportation structure as figure 14 shown.

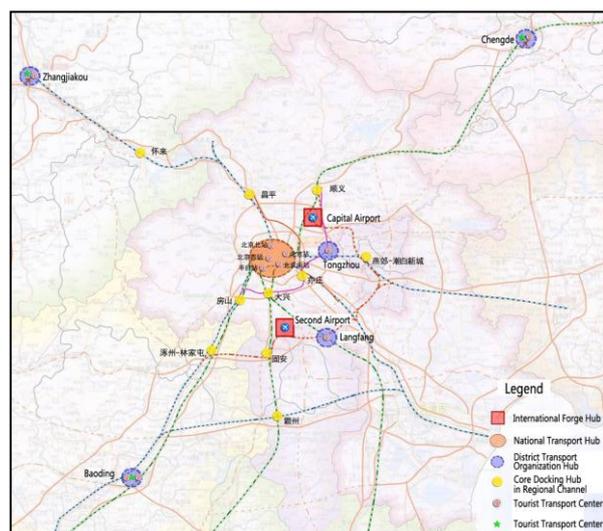

Figure 14 UBTHA Cross-boundary Systematic Transportation Structure

3.5 UBTHA Mega-region Planning Spatial Structure

Under the strategy proposed above, the planning stipulates a spatial structure for the mega-region area, characterized as one-center, four-cores, six-axes, four-zones and multi-points (Figure 15). One core is Beijing-centered and four cores are Baoding, Langfang, Chengde and Zhangjiakou, four regional cores. Six axes are six developmental corridors. Four zones are four growth poles in peri-capital areas. Multi-points include those industrial parks and towns. The spatial structure of the UBTHA identifies the main cores and nodes to serve for the whole regions.

Figure 15 PBTHA Spatial Structure

3.5 Cross-boundary Mega-region Governance

In the final part of the planning, it proposes to organize cross-boundary commissions to put forward the implement of the plan. It proposes

the State Council to act as the leaders and governed by the central ministries and Beijing, Tianjin and Hebei provinces. It also proposes a bottom-up approach from the market to the state. A series of policies are suggested to implement the planning, including the establishment of experimental zone to reinforce the cooperation and public fund for particular cross-boundary environmental protection projects.

4. Assessing

The planning is still undergoing, thus it is hard to evaluate the performance of the plan implementation now. However, it could be assessed the planning scheme process. The first experience is that the cross-boundary mega-region planning is an important instrument for building competitiveness and sustainable development of the whole region. Although cooperation is reinforced during the planning scheme, there is much competition in the cross-boundary region and cooperation is rare. With the accelerated urbanization of Beijing, a series of urban problems have emerged, including server urban transportation, environmental pollution, urban explosive expansion and etc. On the other hand, the lagged economic condition of Hebei has not benefited from the proximity to Beijing. Moreover, it causes a series of vicious problems to the whole regions. Thus, the development of the PBTHA cities have become the core issues of the development of the whole region. However, the planning is proposed by the provincial government of Hebei. The political power of the provincial government is hard to compete with the government of Beijing, the national capital city. Thus, it calls for the central government from the above to coordinate the cross-boundary issues and put forward the implement of the planning. Moreover, the phase of the planning is intended to act as a negotiation platform for both sides to discuss the cross-boundary issues of the regions in post-reform China. Thus, a bottom-up approach is still needed in the implementation process and an effective coordinating mechanism among cities for plan implementation should be further introduced and put forward and the items specified in the plan should be materialize though the involvement of central government into concrete actions.

5. Conclusion

In the western world, city-regions planning are considered effective instruments for situating the institutions of post-Fordist economic governance (Scott et al., 2001). Cross-boundary planning are also important arenas for city and regional to negotiate and cooperate in different spheres. The paper uses a case of PBTHA cross-boundary mega-region planning to probe in to the significances and difficulties of the planning. The contributions and main points of the planning have been discussed and the implementation and experience has been elaborated. Several lessons could be learnt from the planning. In the first place, regional inequalities lead to the uneven development of the whole area. Poverty alleviation, environmental protection and cross-boundary infrastructure construction are three important issues needed to be solved in the planning process. Another experience is that the cross-boundary regional government relies on the effectiveness of the power of central government. The up-bottom approach will be needed. A powerful coordination from above will be effective in the implementation. Although the provincial government should play an enabling role in the regional coordination, the higher-level government should also launch some concrete initiatives to put forward the implementation process. Thirdly, the successful of the planning is the establishment of an urban forum which may serve as the platform for member cities to share their views and visions on the development of the region. The planning offers a platform for the Hebei province to call for the preferential policies to further promote the sustainable development for the whole region.

Zhongguancun Cottage Redevelopment: Prospects for Low-Middle Income Housing

Tamara WHITE and ZHOU Jinnan

China Academy of Urban Planning & Design

Introduction

China is experiencing a wave of transformation, with an unprecedented speed and scale of change in the economy, demographic flows, built and natural environments, and socio-cultural mores. This has enormous impact on the country's housing system, particularly in China's fast growth cities.

This paper explores several aspects of low-middle income housing, amidst the pressures of China's sweeping changes. It provides a historical context of housing privatization, market reforms, and government regulatory measures. Elements of the modern housing system, as pertain to low-middle income (LMI) households, are then presented: current LMI housing strategies, market conditions, and policy and programming frameworks. The discussion is then grounded in a study of the Zhongguancun Cottage Redevelopment in Haidian District of Beijing. Zhongguancun is a dynamic and strategically important growth area, with steep competition for land uses and redevelopment funds. We offer some recommendations for preserving and producing LMI housing at this local level.

100 yuan = 16 USD

China's Housing System and Market Reforms

China's housing system has undergone a complete metamorphosis over the last thirty years. Under Mao Zedong, housing was provided by the work unit – *danwei*—to the vast majority of society. Following Mao's passing, political leader Deng Xiaoping ushered in a sweeping Reform Era, that brought about the "Open Door" policy and a socialist market economy. With this came a gradual, then explosive transition to commercialized housing, now strongly based in private home ownership and market provision. This process has been referred to as "probably the largest neo-liberal reform project ever implemented in the world" (Wang, *et al*, 2012:356). In 1981, over 80 percent of urban housing was in public ownership. Within two decades, over 80 percent of public housing had been sold, "mainly to their occupiers" (*ibid*: 345). While overall physical housing conditions (quality, services, and overcrowding) have improved since housing reform (Zhang, 2011:234), these improvements have been experienced unequally across the income classes.

The market transition process has had its share of problems. Massive housing speculation, housing inequality, residential segregation, and large-scale evictions mar the housing landscape in many of China's cities (Cook, 2013:10; Yang and Wang, 2011:386; UN-Habitat, 2012:129). There is a stark mismatch between the housing needs of most urban residents and the types (and prices) of housing offered by the market. Some scholars contend that there is now "[an] overdependence on the urban housing market as the major provider of housing" (Chen, *et al*, 2011:7).

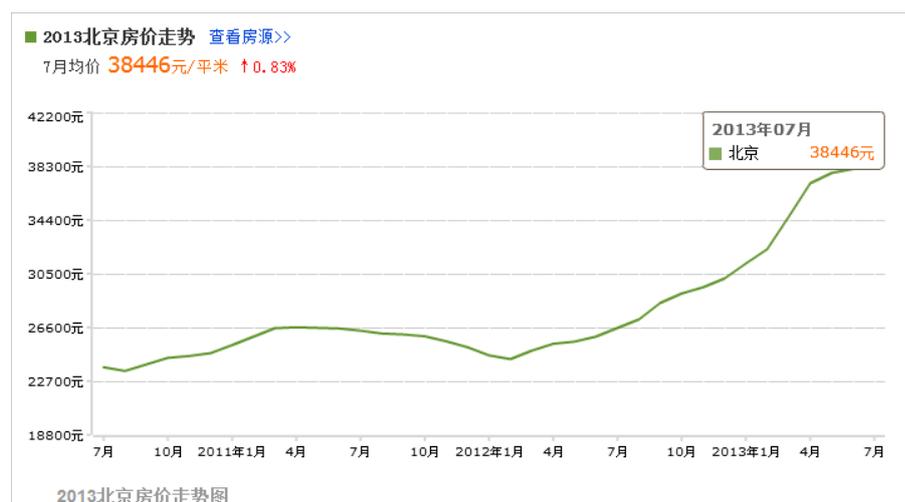

Figure 2: Beijing Housing Price, over past three years

Source : Anjuke Beijing, 2013. <http://beijing.anjuke.com/> (a real estate transaction network)

Over the last decade and a half, housing prices have skyrocketed. At 2011 house prices in Beijing, "It would take a person earning the average salary 50 years to save enough money to buy a 100 square meter apartment, assuming he saved every penny he earned" (Wang and Qin, 2011:1). Figure 2 displays the trend over just the last three years: a 60 percent increase in sale price per square meter.

Chinese housing policy has clearly reached a critical stage in which free market mechanisms must be more equally balanced with growing public needs. Though the central government has regularly attempted to curb speculation and guide the housing system with a series of incentives, restrictions and regulations over the years, the capitalistic pursuits of developers, housing investors, and the government itself have proven difficult to subdue. (Note: local governments may earn a large portion of their revenue from land sales to developers.)

In addition to the transition to a market-based system and the speculative frenzy that ensued, the demographics of Chinese cities are in major flux. Mass migration from the Chinese countryside and an influx of foreign nationals, have placed added stress on urban housing systems and have increased the complexity of housing planning and provision. There is currently a substantial knowledge gap “regarding urban housing demand from low-income urban families and rural-urban migrant workers in the urbanization process” (Chen, *et al*, 2011:1).

Under-housed Populations

A variety of urban populations are widely considered to be under-housed. The “floating population” or *liudong renkou* is comprised of mostly low-skilled rural-to-urban migrants who have limited access to urban services, due to China’s *hukou* system which was intended to restrict population movement. The floating population is “usually excluded from urban population statistics” (Chen, *et al*, 2011:3) and faces “major barriers to full participation in the housing market” (Cook *et al*, 2013:7). According to a 2008 Beijing Bureau income survey, migrants earned an average of roughly half that of local Beijingers (Zheng *et al*, 2009:435). Due to limited income and a desire to save for remittances, migrants commonly live in overcrowded arrangement, often with less than 10 square meters of space per person (Deng *et al*, 2011:177). Many migrants find housing in urban villages, discussed in the following section. Other housing strategies include living in overcrowded market-priced apartments, or in illegal basement and rooftop homes. Very little research has been conducted on households living in these latter arrangements.

Young college graduates are another population that is commonly under-housed. Occasionally referred to as “the ant tribe”, these educated young professionals are simply out-priced from the housing market. Like migrants, they too tend to “concentrate in urban villages, often in ‘edge city’ developments” (Cook *et al*, 2013:11) and in high density living arrangements. Still other populations, such as inner city residents in old and poorly serviced settlements (like *hutongs*, or low-rise alleyway neighborhoods) and apartment dwellers, living in low-quality mid-rise blocks from the Maoist era, have special housing improvement needs.

Collectively Owned Urban Villages and Inexpensive Housing

China has a unique dual land ownership regime in which rural and urban lands fall under different administrative and governance systems. Rural areas are collectively owned, while cities (at least initially) exist on state-owned land. This seemingly clear distinction, however, has been blurred with the demographic and economic shifts of the last few decades. As urban areas swelled following the Open Door policy, they engulfed rural villages in the peri-urban areas. Some were administratively absorbed into the city proper, while others retained their rural status, and distinct legal and governance structures. These areas are sometimes referred to as *chengzhongcun* or “village within the city”.

Collectively owned lands represent a significant and growing proportion of potential construction areas within Beijing. In fact, in 2010, the total land area of construction-ready collective land (1540 sq. km.) exceeded the total area of state-owned construction-ready land (1230 sq. km.) (Beijing Master Plan (2004-2020) Implementation Evaluation Report, 2010:12).

Collectively owned lands are already a major source of low-middle income housing in Beijing, especially for LMI populations who seek very low rents. But there are many legal

grey zones surrounding the collective lands or villages, which operate under somewhat collective ownership with restrictions on land uses and sales. While it is common practice to rent residential space to those outside of the collective, its legality is dubious at best.

Living conditions are typically cramped: A 2007 survey found that “the mean per capita living space is 8.2 square meters, less than one-third that of Beijing’s formal housing sector (27.0 m²)” (Zheng *et al*, 2009:434, referencing Beijing Bureau, 2008). Basic facilities and services are also often lacking: “With these compact living spaces 90% of [residents]... don’t have bathrooms or kitchens, 86% don’t have heating, and 93.3% don’t have air conditioning” (Zheng *et al*, 2009:432).

The villages’ relationships with adjacent municipal governments also vary widely. With a toolbox of carrots and sticks, municipal governments often exert some planning and development pressure on the villages. But, entrepreneurial villagers who have “found themselves in possession of prime land for migrant worker rental... respond rationally by maximizing the yield of their [land] assets. Self-built high density is thus the norm rather than exception in [these] areas” (Wu *et al*, 2012:7).

These urban villages are under major threat of redevelopment, in which informal landlords make “windfall gains” and renters (largely migrants) are displaced (Wu *et al*, 2012:4). As of 2008, compensation to villagers was calculated as “six to ten times the average annual output of the farmland in the previous three years”, plus relocation cost and additional compensation based on household size (Wu *et al*, 2012:6, referencing: Tian, 2008; Zhao and Webster, 2011). However, such compensation may still fall short of the rents amassed from owning a dense bundle of substandard apartments. In fact, rental rates within urban villages are nearly that of the surrounding market prices, per square meter: “On average, rent per square meter in adjacent formal rental housing is only 1.23 times that of urban village housing” (Zheng *et al*, 2009:436). Hence, many villages “resist any formal development control by the municipal government over the use of their land and in some cases to resist urban redevelopment” (Wu *et al*, 2012:9).

Redevelopment has serious consequences for the housing security of the LMI populations who access this unique housing form. Further, there may be negative repercussions for local economic vitality: “the dominance of the beautification and modernization narrative in discussions about urban village redevelopment is rarely balanced with a discussion of the opportunity cost to the local economy of removing the main source of low-cost homes” (Wu *et al*, 2012:13).

Government Low-Middle Income Housing Programs

As previously mentioned, the formal market is now the primary mechanism for housing provision in China. However, for those in the low-middle income (LMI) classes, the market has done very little to supply appropriate housing. The term “LMI housing” will be used broadly herein to refer to housing types accessible to low-middle income households (as defined by local income categories). This includes housing provided through urban villages and government-supported housing. Further housing strategies, such as overcrowded living in market rental units, and informal settlement are pursued by LMI households to varying extents in different cities.

Though the government has privatized the housing system, it has continued to produce policy documents that detail plans for LMI housing provision through market mechanisms and publicly supported programs. The scope and objectives of these plans have, however, been reduced over time. Development restrictions aimed at limiting housing costs have

been enacted. For example, since 2006, it's required that every development devote 70% of its finished space to units less than 90 square meters (Deng *et al*, 2011:177). However, given high costs per square meter, this form of housing is still unaffordable to LMI populations.

Several federal programs, called *bao zhang fang*, exist to support LMI housing. Two rental programs (Public-Rental Housing; and Low-Rent Housing) providing mostly-publicly-owned housing, and subsidized market rentals, respectively. Two other programs (Economical and Suitable Housing; and Capped-Price Housing) support home ownership through substantial subsidies, unit size restrictions and developer profit caps. Also, the Housing Provident Fund "is a compulsory housing savings program in which both employers and employees contribute a certain percentage of the employees' salaries" which may be withdrawn for home purchase, home improvement, or self-construction (Deng *et al*, 2011:174). Additionally, all capital gains from this fund must be reinvested into Low-Rent Housing (*ibid*:177).

The central government's principal policy document, The Twelfth Five-Year Plan, dedicates 619 billion yuan to help build and acquire 36 million units of LMI housing units, and puts new emphasis on the importance of rental housing forms. If the government meets this target, then "social housing will be available for 20% of urban households, compared with about 7% today" (Wharton, 2011:1). However, the Ministry of Housing and Urban-Rural Development (MoHURD) estimates that the central government's dedications will only cover a fraction of the cost of production (*ibid*:2). Local governments are expected to pick up the balance.

Herein lies one of the primary pitfalls in China's LMI housing policies and programs: inordinate responsibility is placed on local/district governments to finance (through land gifting and other subsidies), facilitate, and regulate LMI housing production and allocation. In 2011, though local and central governments each collected roughly 50% of government revenue, local governments made 85% of the reported expenditures (China Statistical Yearbook, 2012). In terms of "housing security" expenditures, local governments contributed a whopping 91% of the proportion (China Statistical Yearbook, 2012). However, local governments have very few real incentives to support LMI housing, as one of their principal sources of revenue (perhaps up to 50-60%) is derived from market-priced land sales to developers and associated fees and taxes, under the state-controlled land market (Wharton, 2011:1; Wang, *et al*: 2012, 355).

Developers also have little incentive to become involved with LMI housing production. Profits are lower, market changes are rapid, and frequent government policy adjustments provide a risky and unattractive business environment. "Only 30 out of 100 developers participated in [LMI] housing projects between 2007 and 2010," according to a report on the corporate social responsibility activities of China's real estate companies by MoHURD (Wharton, 2011:2).

Since the Reform Era, LMI housing programs and plans have rarely been fully achieved, due to lack of stable funding, lack of incentives, and little enforcement. Though total housing construction has swelled over the last decade, less government-supported LMI housing was constructed in 2010 (just under 400,000 units), than was in 2000 (more than 600,000 units). In 2000, 28% of all housing units constructed were government-supported LMI housing. By 2010, the percentage had dropped to just 7% (Wang *et al.*, 2012:348 and Cook *et al*, 2013:11).

	Target of Beijing's Five-Year LMI Housing Plan (2006-2010)	Actual Achievement
Public-Rental Housing	no target value	1.5 million sq.m
Low-Rent Housing	1.5 million sq.m	1.1 million sq.m
Economical and Suitable Housing	15 million sq.m	10.1 million sq.m
Capped-Price Housing	15 million sq.m	16.9 million sq.m

Figure 3: Progress of Beijing's LMI Housing Programs

Source: Liao Zheng Xin, 2012

Beijing's LMI Housing Commitments

Beijing is a rapidly growing city of over 20 million residents that is gaining an average of 600 thousand newcomers per year. Within Beijing's tight land market, low-middle income housing is in high demand and low supply. As shown in Figure 2, the city's housing prices have exploded. Several government programs and regulations work to provide low-middle income housing (both rental and ownership models), however results have been insufficient when compared with levels of demand.

In Beijing's newest Five-Year LMI Housing Plan (2010-2014), the Municipality outlines general strategies for promoting LMI housing stock and makes concrete land and financial commitments to LMI housing through budgetary expenditures and development dedications. Several methods for promoting LMI housing stock are proposed, including 1. Mixed-Use residential with manufacturing; 2. Encouraging companies to develop employee housing; 3. Buying investment- and other vacant properties, and 4. Placing increased emphasis on promoting rentership over ownership housing forms.

Beijing has committed 8 square kilometers of land for LMI housing projects in 2013, and has "pledged to start building 160,000 affordable housing units" (Zhang, 2013:1). The Plan further outlines general land development stipulations: 30% of units in new developments, 50% of land converted into residential use and 10% of local governments' land resale profit should be dedicated to LMI housing (Beijing People's Government, 2010b). Though these appear to be strong policy measures, the compliance with and effectiveness of these regulations remain unclear. Beijing's real commitment to LMI housing is certainly questionable: within the Beijing region, only 1.7% of the general budgetary expenditures were allocated to housing security, compared with an average of 3.8% when considering all of China's regions (China Statistical Yearbook, 2012).

Much of the responsibility for actually implementing the Plan has been delegated to local districts, which are also required to develop their own District LMI Housing Plans. The Beijing Municipal Land Bureau has announced that districts must complete 70 percent of their annual plan during the first half of the year, "and those who cannot meet the requirements will be suspended to develop the land" (Zhang, 2013:1). The Ministry of Housing and Urban-Rural Development has further called upon local authorities to innovate new ways of financing and expanding low-middle income housing, in line with the country's history of "gradualist and experimental" housing reforms, based in "trial and error" (Deng *et al*, 2011:168).

Applied Study: Zhongguancun Cottage Redevelopment in Haidian District

Introducing Haidian District

While population growth has certainly spurred an outward expansion of the Beijing's footprint, there is now a major focus on infill and redevelopment. One of the major districts slated for redevelopment is the Haidian District in northwest Beijing. With a booming economy (its GDP has tripled over the past decade) and a burgeoning population (see Figure 4), Haidian is faced with both accommodating new growth and improving the quality of the urban environment and services (Haidian Bureau of Statistics, 2012). While we authors recognize that redevelopment is a highly contentious issue which can involve large-scale eviction of residents, we also understand it as a common structural element of land development in urban China. As such, this makes for a good applied study case, with potential recommendations and implications for other redevelopments.

	2004	2005	2006	2007	2008	2009	2010	2011
Population (10,000 persons)	249	258	269	281	293	308	328	340 *(150 are migrants)
Non-Natural Growth Rate (Immigration) (10,000 persons)	31.2	41.7	-9.3	19.8	25.5	23.3	18.0	24.9
Households Dismantled & Removed					2112	5070	2074	2352
# Sets of Rental Housing					4879	4927	2934	1061

Figure 4: Haidian District Statistics

Source: Haidian Bureau of Statistics. 2012. *Haidian Tongji Nianjian* (Haidian Statistical Yearbook).

This compilation of officially-published statistics clearly shows that Haidian is a district experiencing rapid change. We see steady population growth, with a 44% migrant population as of 2011. The non-natural growth rate has fluctuated wildly, and even flipped directions in 2006 (perhaps due to a large scale removal effort). Again in 2009, we see a major increase in household clearance. Further, over the four years of data provided, it is apparent that the net supply of rental housing has seriously declined (though the unit of measurement is unclear). Unfortunately, clear and accurate data on LMI housing stock in Haidian were not available for this study. Certain inferences may be made, though, for example presuming that a large percentage of the rental stock is home to LMI households. And while owners of households that are dismantled and removed through redevelopment receive compensation in the form of new apartments (sometimes multiple) and remuneration, renters of such apartments have no recourse. Also, it may be presumed that the myriad informal arrangements that provide housing to LMI households are not likely to reappear in new formal developments.

Haidian District's Housing and Construction Committee is the principal entity responsible for the low-middle income housing sector within the district. They are certainly faced with many challenges associated with the retention and production of LMI housing amidst massive redevelopment plans and population growth. However, there are also many opportunities. The Committee may act to balance redevelopment pressures with the (growing) public's growing housing needs. This may include mitigating the impacts of redevelopment evictions and inserting LMI housing as a priority use for newly acquired redevelopment lands.

The District does have stated LMI housing objectives: The District's Five-Year LMI Housing Plan includes securing 75,000 units (average of 15,000/year) at a total of 7 million square meters (average unit size of 93 square meters). Rentals are intended to comprise 60% of these units. As of 2012 (over 2 years into the Plan) only 14,000 units had been created, including 5,000 rentals and 9,000 under ownership (well under the 60% rentership guideline). In government statistics, both compensation apartments and new LMI housing are bundled into the same category. So, while it is difficult to discern true net increases in LMI housing, it can be deduced that 50% more land area is dedicated to compensation apartments than is to publicly-supported LMI housing in Haidian District (Beijing Municipal Bureau of Land and Resources, 2013:1).

Within the current land development regime, it is observed that the Haidian District is disincentivized to retain existing LMI housing in low density sites. Low-density areas are principal targets for local government purchase, as they would logically require lower levels of compensation than other areas, because there are fewer units. Given the rapid rise in land values, there is also incentive to purchase properties hastily. Furthermore, as compensation apartments for removed residents count towards a district's LMI housing construction goals, there is further incentive to simply expand removal efforts.

Introducing Zhongguancun

The Zhongguancun area of Haidian District in Beijing was used as a study case, to assess some of the issues and opportunities associated with LMI housing provision. Zhongguancun is a dynamic and strategically important growth area, with steep competition for land uses and redevelopment funds. What follows is a description of the Zhongguancun context, and a list of LMI housing solutions, that we propose for trial application in the Zhongguancun redevelopment area. These recommendations were developed through a review of applicable area plans, including proposed area redevelopment plans; a review of literature on China's low-middle income housing programs and funds; semi-structured interviews with experts in Chinese low-middle income housing development and development finance; discussions with sub-district leaders, and; site visits.

Within Haidian, the Zhongguancun area is 75 sq.km. and includes universities and research institutes (65% of the core land area), collective lands (11% of the core land area), expanding manufacturing zones, and a growing cluster of IT, high-tech, and creative industries. It is home to 1.2 million residents (including 33.8% migrants and 24.8% college students), with a population density of 22 thousand people/sq.km.

Within the Zhongguancun area, the government has identified a number of strategic priorities that it seeks to address through a major redevelopment program that will roll out over the next few years. Primarily, a strong emphasis has been placed on facilitating and spatially accommodating economic development activities. There is also a push to improve quality of life in the densely populated city, which is (arguably) overbuilt in many areas, including development on environmentally sensitive lands. In these areas, the city government wishes to insert parks, public services and amenities, and improve connectivity and emergency vehicle access through road development. We (the authors) also see this

redevelopment project as a great opportunity to strategically address low-middle income housing needs and meet official government housing objectives.

The Zhongguancun Cottage Redevelopment project is in fact already underway. Planning, rezoning, and the clearance of present uses and residents are all taking place concurrently. Sixty-four sites, including many low-rise residential sites (building with 5 or few stories), have been identified for clearance.

Local Solutions to Improve Low-Middle Income Housing Supply

There are many potential policies and plans of action that could promote LMI housing retention and production within the Zhongguancun redevelopment area. Layers of development regulation and public finance reform at the central and municipal levels would indeed have an enormous impact. However, this section focuses on actions that are within the control of the district government.

These recommendations would require local government officials to take a very proactive role in directing, facilitating and collaborating on a variety of LMI housing initiatives.

We recommend that the Haidian Housing and Construction Committee focus their efforts in the following eight areas: 1. further research of local LMI housing needs; 2. stricter conformance with existing development regulations and revenue dedications; 3. a standardization of the discretionary elements of the development approval process; 4. the preparation of targeted and well-orchestrated developer deals; 5. preservation of existing rental stock; 6. collaboration with collectively-owned villages; 7. expansion of student and workforce housing, and 8. experimentation with developer-operated LMI rentals.

There must be a clear assessment of the district's current and projected LMI housing needs. To date, housing construction objectives have been made to be generally in compliance with municipal objectives, but without a strong understanding of local housing demand. Future

housing plans should be in alignment with demographic trends and the strategic development trajectory of the district. Information on the types of LMI sub-populations and household structures will help tailor housing plans and programs. While this knowledge gap is not a major issue at the moment (because *any* form of well-located LMI housing will be filled immediately), housing programs will need to become more targeted and refined over time.

Many improvements can be made within the existing policy and regulatory structure. The District should review its current policies and plans for conformance with local, municipal, and central LMI housing guidelines and regulations. According to central and city government, the following should be dedicated to LMI housing: 30% of units in any residential development; 10% of profit from local government land sales; and 50% of land area in any newly designated residential zone. Local conformance with these regulations has lacked clear documentation and anecdotal evidence points to a lack of enforcement. The District's current Five-Year LMI Housing Plan is also not in accordance with the Beijing municipal guidelines restricting unit size (in an attempt to limit sale price). The District's housing plans include the production of units with the average floor space of 93 sq.m., which is well above the 60 sq.m. guideline stated in the Beijing LMI Housing Policy (Beijing People's Government, 2010b). Units of this size are not affordable to low-middle income households. A more appropriate plan would increase the number of units, while retaining the same (or more) total floor area. Greater enforcement and transparency on these measures would surely support increased LMI housing production.

Haidian District government may also be more proactive in designing LMI housing deals that are attractive to developers. This may include bundling or packaging sites into single deals that provide developers with access to coveted properties, while also securing substantial levels of LMI housing production. Additional developer incentives may also be offered, such as increased FAR, lower land prices, waived development fees and taxes, and streamlining development processes. However, as these incentives are already common elements in standard development negotiations, they wield limited power in leveraging LMI housing production. Local government may consider formalizing and standardizing the discretionary elements of the development approval process. In this way local governments can achieve more leverage when offering easements or perks as incentives for special cases, such as the development of LMI housing stock.

There must be a more thorough consideration of the rental housing stock, with careful planning to both retain current stock and promote increased future stock. In accordance with the Beijing Five-Year LMI Housing Plan, as well as the Haidian District Plan, rentership must be promoted as an integral housing form. Yet, rental units are quickly disappearing. As of the 2012 update on Haidian's progress towards its Plan, the proportion of rentals produced (versus owner-occupied units) is well below the projected 60% mark. At the very least, local government policies should support the replacement of housing forms that have been removed. This means that when rental housing is removed, it should be replaced with nearby rental opportunities at similar cost and (ideally) a prioritization of placement for removed renters.

To help preserve existing rental stock, local officials may also choose to reconsider the purchase of select redevelopment sites. Through a calculation of site densities, land acquisition costs, land sale prices, and maximum allowable FARs, we have identified several sites for which dismantling and removal should be reconsidered. These sites are expensive to acquire (with current FAR exceeding 1), small (less than 10,000 sq.m.) and unattractive to developers, because of the difficulty of construction.

Further, local officials may consider delaying the clearance of housing on newly acquired sites. Instead of immediately clearing all sites that transfer into local government ownership,

we recommend that the government consider retaining rental units on sites with a high proportion of rentals and temporarily transferring them into a public rental regime. This would allow many residents to remain *in situ* until perhaps other rental options are developed. In the meantime, the local government's ownership of the property has already been secured and values are accumulating, should future redevelopment be desirable.

Collectively owned village lands offer a unique opportunity for local officials to collaborate with village residents on LMI housing provision. Officials may encourage the improvement of the environmental quality and safety of current LMI housing, while partnering with villagers in the construction and management of public rental housing. In myriad past cases, village redevelopment has almost always meant an expulsion of the low income renter population. So, special safeguards must be put in place to ensure that massive displacement does not occur. It is helpful to note that migrants currently pay almost market rate per square meter (Zheng *et al*, 2008). The important element would be to create rental units with appropriate size to meet the affordability requirements of these individuals and households. Housing could include communal facilities and amenities, with privacy partitions that may be removed over time, should the conditions of the housing system change.

Student and workforce housing should also be avidly pursued. On low-density university-owned lands (such as the Zhufangcun site of Beijing University), universities should be encouraged to produce housing to meet the needs of students, professors, and staff. When universities have knowledge development partnerships with start-ups or other small enterprises in IT, high tech, and creative industries (as is commonly the case in this district), they should be further encouraged to support housing development for their employees. Design competitions may be held to stimulate innovative thinking and build awareness around workforce housing, university housing, and migrant housing. Such competitions have been conducted elsewhere with great success.

Finally, the District may wish to partner with developers that are interested in managing buildings for LMI rentals. As the supply of developers has saturated the local demand for development services, many are exploring related sideline business ventures. The Beijing government has expressed interest in pursuing this strategy. However, there would need to be close regulation of rental prices, to ensure that the units are actually serving LMI households.

Within the Zhongguancun Cottage Redevelopment, ample opportunity exists to promote LMI housing through improved conformance with current policies and regulation, more proactive dealings with developers, universities and urban villages, and innovative and experimental arrangements. The overall structure of Chinese government, and its role in the land market and the banking industry provide a unique combination of traits that could, if wielded correctly, bring about fantastic improvements in low-middle income housing provision. Housing policy is maturing over time. Market shocks and distortions are being incrementally addressed. However, structural changes in local government finance, stricter enforcement of existing development regulations, and reliable LMI funding mechanisms are needed in order to bring about deeper and lasting change in LMI housing provision.

Conference Theme: *Forum on Planning Education: Are we doing it right?*

Abstract

Recent reviews identified the need for development of new skills and qualities in graduating planners in Australia, including collaboration, communication, critical thinking and understanding complexity (Gurran et al. 2008; Jones et al. 2009). Students can construct such knowledge, skills and values by means of direct experience in a real world context, through a purposeful process of engaged, active learning known as 'experiential learning' (EL) (Kassem 2007, p2). Learning in an EL context is dependent on a meaningful interaction between quality experiences and personal reflection of those experiences (Fowler 2008; Harvey et al. 2010). To date, the criteria used by the Planning Institute of Australia (PIA), the national accrediting body, to assess planning schools, has not given adequate weight to the contribution made by EL in student learning and development of graduate attributes.

This paper reports on a multi-university project with two main goals: to document and improve EL practices in tertiary planning schools in order to enhance student learning; and to ensure that planning education is relevant to a global future, in collaboration with PIA and industry, by recognising the value of EL in the planning school accreditation process.

The project commenced with a baseline survey of Australian and New Zealand planning schools to identify the extent of EL. In the second stage, the project team developed and tested activities and assessment methods over two semesters in five Australian universities, based on a collaboratively developed EL framework of principles and criteria. The main project output is a freely available online toolkit of resource materials for use by planning educators to credibly extend the use of EL and improve assessment of student learning. Importantly, the project outcomes benefit planning schools and practitioners around the globe where educators aim to facilitate students' and graduates' continuous learning and adaptation to a rapidly changing world. This paper focuses on recommendations to the accrediting body, PIA, about how to adequately recognise and evaluate the benefits of EL for planning graduate attributes.

Context

To prepare students for the complex world of planning is challenging. Planners need to have spatial, economic, social, legal and political understanding to be able to positively contribute to the built and natural environment. They need to be able to work in multi-disciplinary teams, and embrace continuous learning as they adapt to a world of uncertainty.

Recent reviews have identified the need for development of new skills and qualities in graduating planners in Australia, including collaboration, communication, critical thinking and understanding complexity (Gurran et al. 2008; Jones et al. 2009). Students can construct such knowledge, skills and values by means of direct experience in a real world context, through a purposeful process of engaged, active learning known as, 'experiential learning'"(EL) (Kassem 2007, p2). Learning in an EL context is dependent on a meaningful interaction between quality experiences and personal reflection of those experiences (Fowler 2008; Harvey et al. 2010). Thus, we argue that to grow future planners, educators need to expand the provision of EL approaches to teaching and learning.

Professions around the world, such as medicine, engineering as well as planning, require their tertiary education programs to produce their future employees so that new graduates have the skills and knowledge to carry out a certain level and range of work. There is also growing evidence that students, particularly in applied fields of education including urban and regional planning, nursing, teaching, social work, engineering and management, benefit from the incorporation of experiential learning into curricula and programs (Elwood 2004; Davis 2006; Fowler 2008; Trigwell & Reid 1998). Professional bodies review the curriculum, faculty expertise, and evidence of teaching outcomes to assess if they meet required standards of content, and teaching and learning. Program reviews generally take place every five years, depending on the accrediting body. Students not only accept, but also expect that the profession is guiding their education so they will be employable and contribute to the future.

To date, it could be argued that the criteria used by the Planning Institute of Australia (PIA), in its Accreditation Policy (PIA 2010) to assess planning schools, has not given sufficient weight to the contribution made by EL in student learning and the development of graduate attributes. EL is generally only referred to as work experience or a practicum and is seen as desirable but not essential.

This paper briefly describes a multi-university project with two main goals: to improve EL practices in tertiary planning schools in order to enhance student learning, and to ensure that planning education is relevant to a global future. Project participants collaborated with the PIA in order to inform the planning school accreditation process about the benefits and importance of EL in training future planners. The paper proposes that an activity has to display certain attributes in order to be considered EL. These attributes need to be demonstrated in courses throughout the planning curriculum, and made evident during the planning school accreditation process. Thus, the intention is that EL be embedded in PIA accreditation criteria.

Australian Planning School Accreditation Requirements

Curricula and pedagogy in Australian planning programs are guided by the PIA Accreditation Policy (PIA 2010). The current policy provisions reflect similar developments which are occurring in the Royal Town Planning Institute (RTPI, 2012) and the American Planning Association (APA 2012) which expect planning programs to establish relationships with professional planners and provide a variety of practical experience opportunities (practicums) which may result in 'professional placements' (RTPI) or 'internships' (APA). All professional institutes recognise that work experience may not always be available. However, it is expected that a good planning program should be able to offer some kind of alternative experience if work placements are not offered within the program.

In Australia, several studies have identified the importance of practical experience in the education of planners. The 2004 National Enquiry into Planning Education and Employment (PIA 2004, p17) recognised that young planners in particular value the inclusion of a compulsory work experience as part of a planning degree. Gurran et al. (2008) go further,

recommending industry support for work placements, scholarships, and cadetships. They believe that

it is critical to ensure that students engage with some form of meaningful professional experience and have the opportunity to reflect on this experience during the course of their planning degree. Alternative models to structure this experience deserve further discussion and debate, in the context of PIA's educational policy and accreditation requirements.' (Gurran et al. 2008, p 44).

The current PIA accreditation policy does not specifically refer to EL but provides for practical experience to be gained using a variety of learning activities, including practical studies of a supervised nature, structured workplace placements, or appropriately supervised projects. The structure and approach to all practical experience is of concern to the PIA, which differentiates between professional work experience and work integrated learning in its accreditation policy that states:

Where professional work experience is a formal requirement of a qualification, the Visiting Board will evaluate the quality and supervision of the work experience. It will seek to ensure that it assists in the acquisition of core knowledge and skills. Where a program does not include a formal requirement for professional work experience, the Visiting Board will consider prepared, supervised, and reflective work-integrated learning that forms part of the educational curriculum to demonstrate how skills, knowledge and competencies obtained through work experience are acquired'. (PIA 2010,p8).

However, these policy provisions would be significantly improved by the inclusion of criteria by which the quality of both professional work experience and work integrated learning alternatives may be assessed by Visiting Boards.

Study Methods and Outcomes Provide a Foundation for our Proposal

1) Benchmarking Survey

A baseline survey of all planning schools in Australia and New Zealand conducted by the project team in 2012 identified that EL was a key component in over 100 courses/units within the 18 out of 23 universities that responded. Teaching and learning activities involving EL varies widely, including work placements, design studio design, field trips and role plays. The number of courses assessing student learning from the EL activities varies depending on the particular learning activity; for example 11 out of 13 formal work placement courses and 18 out of 19 studio courses are assessed but less than half guest speaker activities are assessed in any way. Reflection is a key component of Kolb's (1984) learning model so both formal and informal assessment should be used to give students feedback on their learning progress and to gauge the benefits of an activity. Of further interest to the project is whether existing assessment methods are adequate for measuring the transformational learning that occurs in EL activities.

2) Trial and Test of EL Case Studies Against EL Principles

The project team developed and tested activities and assessment methods over two semesters in five Australian universities, based on a collaboratively developed EL framework of principles and criteria (presented later). The framework is founded on Kolb's experiential learning model (Kolb 1984; Kolb & Fry 1975) in which learning is viewed 'as a process of experience, reflection, cognitive processing, and applying new knowledge in new situations' (Turunen & Tuovilla 2012, p. 116). The principles aided course designers to draw maximum EL benefit from a wide range of activities, including activities with less 'real world' integration, such as in-class role plays and guest lectures. Activities were evaluated by use of student

surveys and interviews with external participants, who were mainly professional planners. Based on this data, a number of case studies were developed that exemplify the relationships between EL activities, assessment and the EL principles.

3) Online Toolkit of Resources

The main project output is a freely available online toolkit of resource materials derived from the case studies. The intended audience for the website includes planning educators to provide them with resources to credibly extend the use of EL and improve assessment (see www.usc.edu.au/explearning). The toolkit is expected to be of particular benefit to new planning educators, and planning schools and practitioners around the globe who endeavour to facilitate students' continuous learning and adaptation to a rapidly changing world.

4) Recommendations for Accreditation

Members of the project team work shopped the outcomes to extract insights from the process so as to inform the planning school accreditation process delivered by the accrediting body, PIA. A particular focus was how to adequately recognise and evaluate the benefits of EL to planning graduate attributes. At the time of writing this paper, plans are to workshop the draft recommendations with planning school advisory committees, PIA state and national education committees, and a network of professional planners over the next few months. The outcomes will be reported at the ISOCARP Conference.

The remainder of this paper focuses on our project team recommendations for strengthening the accreditation process.

Implications for Accreditation

Based on the outcomes of this project, EL should be an integral element of each year of an accredited planning program. In seeking accreditation, a university needs be able to demonstrate how it is using EL across the four year program, with courses in each year building in greater complexity and exposure to real world experience. EL could be evidenced through a range of activities, from guest lectures, field trips, role plays, and design studios of a 'real' site or client. While study tours or international field trips would not be mandatory, their value as a transformative experience should be recognised. Early in a planning course, EL could include shadowing a professional planner for a few days, or experiencing a 'Day in the Life of a Planner'. The culmination would be a latter year structured work experience under guidance of a professional planner, accompanied by formal assessment.

Our team proposes that in order for an activity to be considered to provide EL, it should meet most, if not all, of the following principles:

- purposeful
- student-centred
- theory-practice dialectic
- real world context
- guided practice
- reflection
- evaluation, and
- community-university partnership.

Several of these principles are attributes of good learning and teaching, such as 'student-centred' and 'purposeful', but we suggest that others, such as a dialogical exchange between theory and practice, and 'reflection' are core to EL. The process of reflection involves an individual exploring their past or present experiences in order to gain new

insights and understanding (Boud et al 1989). Learning the skills of self-assessment through reflection of EL whilst at university establishes a lifelong practice for graduates to meet their own learning needs (Boud 2000). As such, either formal or informal assessment of student learning during or linked to an EL activity contributes significantly to effective learning. For example, a field trip or site visit that incorporates guided learning about planning issues or techniques (e.g. pointing out and discussing attributes of water sensitive urban design) could be classified as EL, but might not be assessed, other than through group reflection on observations shared at the end of the field trip. However, the field trip might be core to development of an assignment, a policy, code or design, which is then formally assessed.

Feedback from our student surveys of EL activities is that these learning outcomes cannot be achieved in any other way. Benefits of integrating EL throughout a planning education are that it:

- improves student confidence about having the skills to be able to deal with complex issues;
- exposes students to issues of diversity of communities such as age, gender, cultural, disability, and Indigenous; and
- contributes to graduate attributes desired by prospective employers such as communication, teamwork, and critical thinking.

Developing effective EL activities, however, takes additional time and effort by educators. If this is not recognised in accreditation processes, then it can jeopardise uptake and integration of EL into planning curriculum.

Conclusion

Our principles for EL were used to improve course curriculum and assessment of student learning among the participating five Australian universities. A key outcome is a toolkit to assist planning educators nationally and globally to improve the integration of EL into tertiary planning education.

Such education supports, at an early stage of a planner's career, the PIA's objectives to instill lifelong learning concepts to continue to deepen the knowledge base of planners and planning specialists. An EL approach supports self-efficacy to focus, invigorate and position the profession to be committed to championing and delivering good planning (PIA 2012; PIA 2013).

As a result, we propose a series of recommendations that should be considered in a review of PIA's accreditation policy and would like to take the opportunity provided by the ISCOARP Conference to gain feedback from overseas colleagues.

What do planners do? Define Your Discipline to drive undergraduate curriculum renewal

Marita Basson, University of Southern Queensland, Australia

David Dowling, University of Southern Queensland, Australia

The debate about the nature of planning continues as the profession seeks to maintain currency in an ever changing world, where environmental, educational, societal, and technological changes are rapid and often unpredictable. In these dynamic contexts, universities are expected to ensure that planning education programs continue to produce competent professional planning graduates who can adapt their practice to cope with change. The question is: how should universities decide what planning reality to prepare students for? Is it one where planners are scarce and graduates need to be job ready or is it a reality where planners are change managers who use higher order thinking skills and systems theories to guide their practice? Or, is it a mix of these separate realities? To prevent a skewed definition of the nature of the discipline it is important that all of the stakeholders have an opportunity to freely and equally contribute in any process used to define the planning discipline. The authors used the inclusive Define Your Discipline (DYD) Stakeholder Consultation Process in a pilot study in Queensland to create a draft Graduate Capability Framework for planning degree programs. Once complete, the Framework could be used to inform not only curriculum renewal, but also professional accreditation processes.

Key words: capability frameworks, graduate attributes, Define Your Discipline, accreditation, planning education

1. Background

1.1. Changing Higher education contexts

In Australia, the Tertiary Education Quality and Standards Authority (TEQSA) was established in 2012 to oversee the quality and standards of higher education programs and the service provided by universities and other providers. The Tertiary Education Quality and Standards Act 2011 also established the Higher Education Standards Panel (HESP), an advisory body that works independently from TEQSA, the regulator. HESP's functions are:

- To advise and make recommendations to the Commonwealth Minister(s) responsible for tertiary education and research on the Higher Education Standards Framework; and
- To advise and make recommendations to TEQSA on matters relating to the Higher Education Standards Framework (HESP, 2012).

HESP is currently reviewing the Tertiary Education Threshold Standards legislated in the 2011 Act (HESP, 2013). The Panel is consulting widely and reporting its findings in regular communiqués. Importantly, it is proposing to include the following components in the revised Threshold Standards:

- *Learning Outcome* and *Course Design* standards; and
- *Reference Points*, which are not standards but national codes and frameworks (including discipline specific materials) that will be of value to providers thinking about demonstrating achievement of particular standards (HESP, 2013). For example, PIA's accreditation documents may be listed as a Reference Point for planning programs.

It is therefore expected that the definition of learning outcomes will become an important component of course (program) design. This would mean that discipline groups would have to develop learning outcomes for their disciplines, preferably at the national level.

One option for the planning discipline would be to fully develop the draft Graduate Capability Framework for planning degrees discussed in this paper, so that it becomes a nationally recognised framework. Then, if appropriate, PIA could recommend that HESP list it as a Reference Point for planning degrees. It would then become an important tool for universities undertaking reviews of their curricula and pedagogies.

1.2. Educational context

The educational context of the Graduate Capabilities defined by the DYD Process is illustrated in Figure 3, which shows the four phases of a policy-driven cyclical process for the review, design, delivery and evaluation of the curriculum for a program (Dowling, 2005). The cycle may be completed annually, or it may be aligned with an accreditation cycle, which in the case of the Planning Institute of Australia is five years.

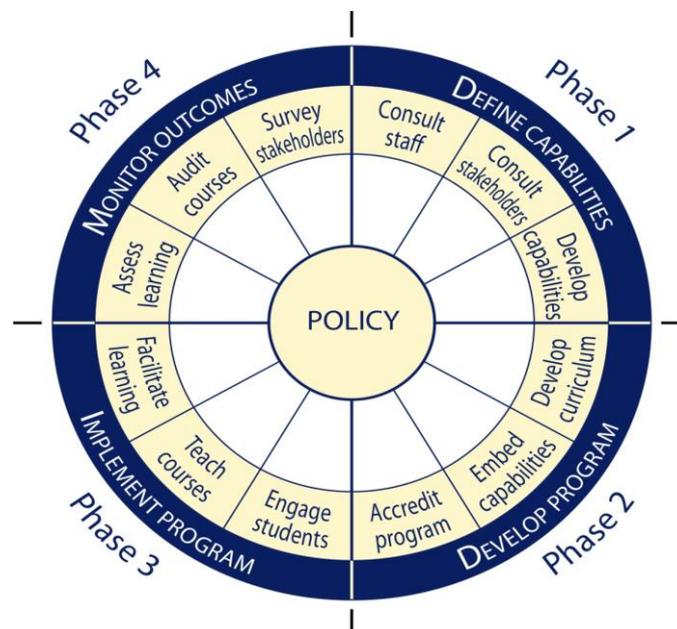

Figure 1: Title of Figure 1

Figure 3: A graduate capability driven curriculum design and delivery process
(Adapted from Dowling, 2005)

The four phases of the cycle are:

Phase 1: A set of Graduate Capabilities is defined for a program, or an existing set is reviewed.

Phase 2: The Graduate Capabilities are used to inform the development of the curriculum for a new program or to review the existing curriculum for a program.

Phase 3: Students acquire the Graduate Capabilities through their engagement with learning and teaching activities.

Phase 4: Student capabilities are assessed and the stakeholders evaluate the program.

The DYD Stakeholder Consultation Process can be used to inform Phase 1 of the cycle, i.e. the definition or review of the Graduate Capabilities for a program.

1.3. Changing planning contexts

Both planning practice and theory have evolved substantially from their nineteenth century reformist roots due to the fact that the intellectual basis of planning is exceptionally flexible and fluid (Davoudi, 2010). Planning now facilitates economic, social and environmental change in our cities, and planners are working in jobs that did not exist a decade ago or in jobs that were not considered to be part of the planning discipline in previous decades, for example: writing climate change policy for a local authority; assessing development loans for property developers; or finding sites for hard infrastructure for energy companies (Coiacetto et al., 2011). Not only are planners doing novel jobs, but the complexity of what they do has also increased due to socio-political changes and government responses to those changes (Dredge and Coiacetto, 2006).

One of the broader changes impacting on planning practice has been the return to an emphasis on the global perspective of planning, leading to an increasing focus on international content in planning programs (Yigitcanlar et al., 2009). This brings with it certain challenges in terms of maintaining a focus on local planning contexts (Whitzman, 2009). The expansion of the domain of the planner has led to the criticism that the boundaries of planning have become too diffuse due to the increased breadth of the profession (Siftel, 2009). Other scholars argue that planning has been reduced to solving current problems rather than creating a vision for the future (Meng, 2009). The debate about the nature of planning is impacted by the fact that the complexity of planning as a profession is further compounded by the highly political contexts within which planning occurs (Planning Institute of Australia, 2012).

2. What is planning?

2.1. Planning as a profession

Planning as a discipline is a social construct that has evolved through historical processes and involves both objects and methods of study (Davoudi, 2010). Planners have a common set of knowledge even though they might specialise in other substantive areas (Association of Collegiate Schools of Planning, 2012). Reeves' (2009, p.30) definition of an excellent planner suggests what these common elements might be:

An excellent planner is someone skilled at envisioning the future and communicating the possibilities; showing an outstanding understanding of how the environment (both built and natural) impacts on different groups of people; expert at thinking and acting strategically, highly effective at making connections, looking to the long term. An excellent planner interacts with other professionals, works effectively with the community, comes up with creative solutions and builds the evidence base to plan ahead.

Planning as a profession does, however, have local geographical and political contexts as well and for the purpose of compiling an Australian framework of graduate capabilities for planners, the Australian context is important.

Of course, the question is, how will this vision, or another vision, be translated into the curricula and pedagogies that will equip graduates with the knowledge and skills to practice in this manner?

2.2. Planners and planning in Australia

The planning specialisations currently recognised by the Planning Institute of Australia (PIA) are: social planning; environmental planning; economic planning; planning law; transport planning; and urban design (Planning Institute of Australia, 2012). Although the critical skills shortages experienced in these fields over the last decade appear to have abated because of government cutbacks and the global financial downturn, historically there has been an

almost perpetual imbalance between supply and demand in the profession (Planning Institute of Australia, 2012, March et al., 2012).

Gurran et al. (2008) suggest that periods of planner shortages generate greater pressure for job ready graduates. A focus on providing staff to fill critical skills gaps results in less focus on pedagogy: the teaching of planning and the development of excellence in planners (Reeves, 2009, Gurran et al., 2008). Reeves argues that the time has come to consider how to best develop excellence in planning education while ensuring an adequate supply of job ready planners (Reeves, 2009).

The persistent shortage of planners in rural and regional areas was investigated using online surveys of planners (85 respondents) and PIA members (50 respondents) (Miller et al., 2011). In their report, Miller et al. (2011) stated that the shortage of planners can in part be attributed to people leaving the profession. They also found that empirical research into the actual experience of 'being a planner' is almost non-existent.

DEEWR (2012) reports that nearly ten percent of the professional group that includes planners leave their profession each year (DEEWR, 2012). In particular, there was a leakage of women from the planning workforce into allied professions and a leakage of graduates with one to five years' experience (Planning Institute of Australia, 2004). The leakage of recent graduates has been attributed to firstly a mismatch between planning education and the roles graduates undertake in their first years of practice, and secondly the lack of practical professional development activities, including the development of the coping skills required by young planners (Planning Institute of Australia, 2012). Stress and burnout are evident in some areas of planning practice according to a national inquiry into planning education and employment (Planning Institute of Australia, 2012, Bosman et al., 2011). It is evident that these trends and the trends in planning education need to be researched concurrently so that evidence based solutions can be developed and implemented (Bosman et al., 2011).

3. Planning education

3.1. A international perspective of planning education

Australian planning educators should be conscious of, and informed by, international trends (Budge, 2009). For example, what impact will the 1999 Bologna Accord have on planning education in Australia? With 29 European countries as original signatories, the Accord recommends a three year undergraduate course followed by a two year master's course, with the minimum planning qualification being a master's degree (Whitzman, 2009). Internationally, there is evidence to suggest that planning schools are yet to find an optimal home in universities, a place where they can reside comfortably with a compatible mix of cognate disciplines. This is because, in different universities, planning schools are found to be residing with different mixes of disciplines such as architecture, engineering, surveying, geography and the social sciences. Some schools have also shifted one or more times within their university. The result is that the content and focus of planning programs is variable and has often shifted over time due to the influences of the co-habiting disciplines (Bosman et al., 2011).

In the nineteen eighties, plan implementation tools were core components of the curricula and course work included zoning and subdivision regulation, impact assessment, site plan review, and conflict resolution (Siftel, 2009). Since then the focus has shifted because of a renewed interest in design, particularly New Urbanism, walkable communities, and urban design, driven in part by the emphasis in European policy on spatial planning (Siftel, 2009). More recently, planning and education schools have been pressured to adopt a one-world focus and address issues such as rapid urbanization, mega-city growth, and climate change. The question is how do planning schools prepare graduates who can skillfully operate in these contexts and address all of these competing issues and stresses (Siftel, 2009). Over

all, there appears to be a lack of research into the impact these changes are having on planning education. This needs to be addressed (Budge, 2009).

3.2. An historical perspective of planning education in Australia

Although there is little research on planning education in Australia (Bosman et al., 2011) it is known that undergraduate planning programs are the most important source of professional planners in Australia (Dredge and Coiacetto, 2006) and that the number of planning schools is at an all-time high, as are student numbers and the rate of growth in student numbers (Siftel, 2009). The fact that universities are the main source of planners, necessitates the consideration of how professional attributes are developed in the university setting (March et al., 2012).

In the early days, university planning cohorts were small and planning education was mainly problem-based studio-learning (Bosman et al., 2011). In the late nineteen forties planning education at the South Australian School of Mines and Industries (now the University of South Australia) and the University of Sydney were very much focused on the traditional design topics. During the nineteen fifties there was an adoption of applied social science theories and techniques to the extent that, by the late nineteen seventies, planning school curricula covered a range of Australian policy matters that impacted on the settlement of people (Siftel, 2009). Coinciding with the broadening scope of planning education and the sharply increasing student numbers in the nineteen sixties and early nineteen seventies, was criticism that too much technical content had been lost from planning curricula (Siftel, 2009). This era partly coincided with the modernist acceptance of greater stakeholder participation in planning following the social unrest of the nineteen sixties (Siftel, 2009).

The recent shortage of planning academics impacted on teaching styles and led to mergers with allied disciplines resulting in common and core subjects being taught by academics with diverse 'home' disciplines (Heywood, 2006). A fundamental question planning educators face when school mergers are proposed is: what are the competencies that distinguish planners from geographers, architects, environmental scientists or professional mediators, i.e. the competencies that no other professions can legitimately claim as their own? It is only when they can answer this question that planning educators can ensure that planning programs continue to enable graduates to acquire these core competencies.

The shortage of planners and planning academics also led the Planning Institute of Australia to undertake a review of planning education in an effort to determine the underlying causes of the shortages. The review covered topics such as the skills and capabilities of planners, teaching methods, and the role of accreditation and the responsibilities of the various stakeholders in planning education. The results were reported in the publication: 2008 Planning Education Discussion Paper (Siftel, 2009). The key findings related to: the tension between the needs and expectations of industry and the broader role of planning education; the possible role of the TAFE sector as well as online and distance education and training; and the need for a greater convergence between higher education quality assurance processes and PIA accreditation requirements (Gurran et al., 2008).

3.3. What should planning schools teach?

So, how can planning schools decide where the emphasis should lie in their programs when both the breadth and depth of the planning profession continually change and grow in response to the needs of urban and regional communities in an ever-changing world? What importance should be attached to the following topics: the technical planning skills (e.g. statutory knowledge, strategic planning and urban design skills, computerised modeling); the soft or generic skills (e.g. communication, conflict resolution, project management, leadership); the emerging fields (e.g. social planning, economic planning, transport planning); and the wicked problems such as climate change, population growth, sustainability, and food security (Budge, 2009, Miller et al., 2011)?

Miller et al. (2011) have suggested that planning schools should start with the question: What knowledge, skills and abilities do planning graduates need to pursue a rewarding and successful career as a planning practitioner?

Certainly, the planning industry is eager to have job-ready applicants (Whitzman, 2009) and young planners express the need to be job-ready (Gurran et al., 2008). They have good reasons to expect this, as the Department of Education, Employment and Workplace Relations reported that for the majority of graduates who were rejected for planning positions in South Australia in 2012 the reason was the fact they had insufficient experience in assessing development applications (Australian Government, 2012). Employers want proof of more than students' credentials, they want to see evidence of competence (Reeves, 2009).

However, Bosman et al. (2011) argue that there is an overemphasis on the needs of the planning industry, and that the education discussions should be balanced against the wider education context. Budge (2009) picks up from Davoudi's (2010) statement that moving beyond disciplinary boundaries is important, and argue the very diversity and adaptability of planner education is increasingly valuable. For example the range of subject matter that: promotes the development of skills; promotes inquiry; and that develops the capacity to deal with new agendas and conflict. This diversity is required because planning is a way of thinking, acting and operating in a political economy that produces spatial outcomes (Budge, 2009). Budge (2009) also emphasises the need for planners to be able to cope with change by stating that: if planning schools do nothing else, they should equip students with skills that will enable them to adapt to change (Budge, 2009), who are resilient, innovative and can cope with diversity (Yigitcanlar et al., 2009).

This "creative tension" between the needs and expectations of industry and the broader role of planning education may, in future, lead to the division of the current role into two roles: planning technicians and professional planners. Professional planners would use their critical thinking skills and interdisciplinary knowledge to complete complex tasks and to address non routine strategic and other planning issues. Planning technicians would apply codes and standard techniques to undertake routine tasks such as development assessment activities. Whitzman argues that such a split might be a positive development (Whitzman, 2009).

In the meantime, planning educators need a good understanding of the roles that current and future graduates will undertake in future planning environments. This paper describes how the simple, but elegant, Define Your Discipline (DYD) Stakeholder Consultation Process (Dowling and Hadgraft, 2013a) was used during a Planning Institute Australia (PIA) sponsored pilot study in Queensland to shed light on the nature of the planning discipline by focusing on the perceptions of different stakeholders about the tasks planning graduates are expected to undertake in industry (Dowling and Basson, 2013).

3.4. The PIA Accreditation Policy

The National Education Committee of the Planning Institute of Australia developed an Accreditation Policy following a consultative program during the period 2009-2010 (Planning Institute Australia, 2011). The Policy was intended to assist PIA accreditation panels in conducting accreditation reviews of tertiary education planning programs.

The Policy defines three components, or knowledge domains, and a series of Competency Areas for each domain (see Table 1). The policy also lists:

- a set of *Performance Outcomes* for each of the three Competency Areas in the *Core Curriculum Competencies* domain (B); and
- a *Competency Statement* and set of *Performance Outcomes* for each of the five Competency Areas in the *Supporting knowledge areas* domain (C).

Table 1: PIA Accreditation Policy: Competency areas

Knowledge Domains	Competency areas
A. Generic Capabilities and Competencies	1. Problem identification
	2. Research
	3. Analysis
	4. Self-Reflection
	5. Spatial thinking and application
	6. Strategic thinking
	7. Problem solving
	8. Communication
	9. Team work
	10. Work readiness
B. Core Curriculum Competencies	1. Professionalism, Practice and Ethics
	2. Plan making, Land use allocation and management, and Design
	3. Governance, Law, Plan implementation and Administration
C. Supporting Knowledge Areas	1. Urban design
	2. Economic planning
	3. Social planning
	4. Environmental planning
	5. Transport planning

It should be noted here that the seven PIA Practice Contexts (see above) are related to seven of the *Competency areas* (B2, B3, C1, C2, C3, C4, and C5).

4. Methodology

4.1. The DYD Stakeholder Consultation Process

The Define Your Discipline Stakeholder Consultation Process is an efficient, effective, and inclusive consultation process that can be used by a discipline to define, at a national level, a Graduate Capability Framework for programs in their discipline at each of the relevant AQF levels (Dowling and Hadgraft, 2013a). It is designed to capture the views of all relevant stakeholders (such as practitioners, recent graduates, and academics) about the tasks graduates undertake in their first few years of practice. Since 2010 the DYD Process has been used to define Capability Frameworks in six disciplines and at three AQF levels (levels 6, 7 and 8). For example, a Graduate Capability Framework was developed for four-year environmental engineering degrees (Dowling and Hadgraft, 2013b). That project was sponsored by the Environmental College of Engineers Australia and the published Guide includes the accreditation requirements for environmental engineering programs.

When applying the DYD process a national or state approach is recommended because:

- It is more efficient for a discipline to undertake this work at a national level rather than at the single institution level;
- It provides a discipline with the opportunity to develop a shared understanding about the capabilities of graduates from the various programs offered in their field; and
- It overcomes the risk of a School's locally-defined Graduate Capabilities not being aligned with the views of the members of an industry accreditation panel that are from other states or territories (Dowling and Hadgraft, 2013a).

A nationally agreed set of detailed Graduate Capabilities for a program would be a valuable resource for discipline leaders tasked with reorienting their undergraduate programs to meet current and emerging trends in their discipline (Dowling and Hadgraft, 2013a).

4.2. The Queensland Planning Pilot Project Workshops

During 2012, the DYD Process was used to develop a draft Graduate Capability Framework for planning degree programs from data gathered during a pilot study undertaken in Queensland. The capabilities were based on data gathered during six DYD Workshops: three in Brisbane, two in Toowoomba and one in Cairns at the PIA Queensland Conference.

During one of the workshop activities participants are asked to write down up to 20 tasks that they would expect a graduate to undertake in their first three years of practice. The 42 planners (3 academics, 21 practitioners and 18 recent graduates) who participated in the workshops provided more than 600 task descriptions and comments.

The number and type of participants that attended each workshop are shown in Table.

Table 2: The number of participants at each workshop by category

Participants at DYD Planning Workshops				
	Toowoomba	Brisbane	Cairns	Total
Practitioners	8	8	5	21
Recent graduates	4	9	5	18
Academics		3		3
Total	12	20	10	42

Forty three percent of the participants were recent graduates, ensuring that the view of this group was well-presented. One cause for concern was the poor representation of academics at the workshops, as only three academics attended a workshop.

The rural-urban split was 52:48, ensuring a balanced view of tasks expected of recent graduates in different geographical contexts.

Figure 1 shows the employment category of the practitioners. It can be seen that local government and consultant planners were equally represented at the workshops while planners from government departments had a lower representation rate.

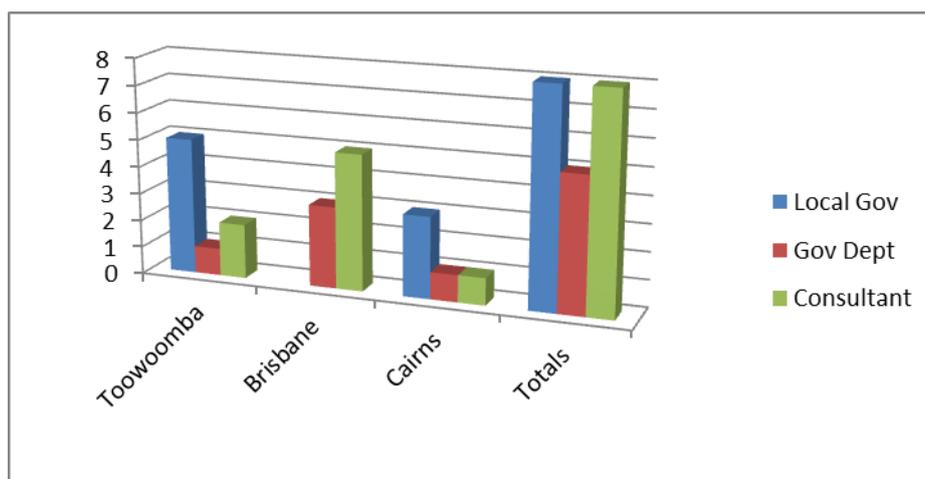

Figure 1: The number of practitioners by employment sector and city

Figure 2 shows the employment category of the recent graduates. It can be seen that government, local government, and consultant planners were well represented at the workshops.

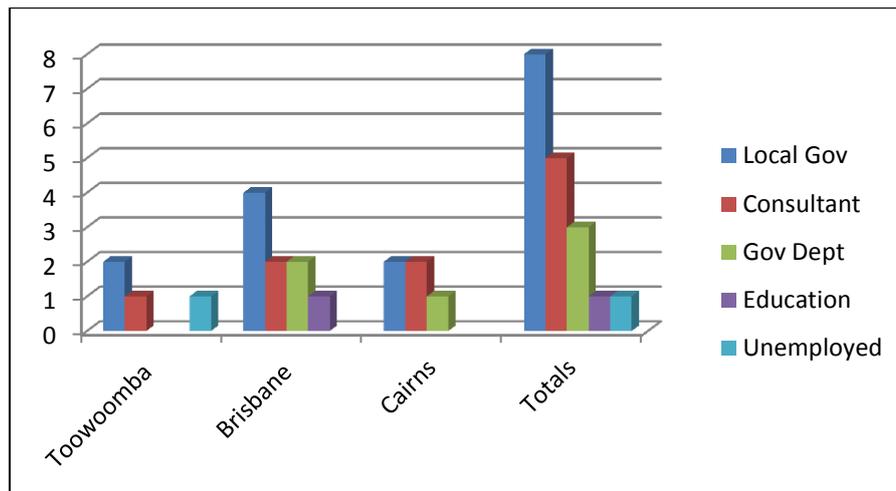

Figure 2: The number of recent graduates by employment sector & city

4.3. Post workshop methodology

The task descriptions and comments were numbered and then entered into a database along with relevant metadata. The tasks were then sorted using the cluster headings supplied by the participants during the convergent phase of each of the workshops. The cluster names nominated at each workshop were compared and it was found that the only name supplied by all of the groups was 'Legislation'. This would appear to indicate that the participants do not have a shared understanding of the profession, or a clear understanding of the knowledge framework defined by PIA.

Initially the Project Team allocated each task to the most appropriate PIA Competence Area (Knowledge Domain A) or Performance Outcome (Knowledge Domains B and C). A summary was also prepared for comparison purposes. The Project team then began the process of developing a Graduate Capability Framework for planning degree programs. Firstly, the clusters names nominated by the participants were synthesised to form a draft set of Capability Clusters and a set of Domains within each Cluster. This process was informed by the PIA Competence Areas and Performance Outcomes.

Each task was then allocated to the most appropriate Cluster and Domain. Normally, the tasks in each Domain would then be synthesised to develop the final set of capabilities. However, this process will not be undertaken until a DYD Planning Project Reference Group reviews, refines and then adopts a draft set of Clusters and Domains. The timing of this will also depend on whether the Pilot Project is extended so that it becomes a national project.

5. Findings and discussion

The key findings from the DYD Queensland Planning Pilot project were:

- Sample size:** The fact that only small numbers of tasks were identified and allocated to some of the key PIA membership areas, such as Transport Planning and Social Planning, highlights the fact that the sample size for the study is too small to adequately represent the breadth and depth of planning as it is practiced in Australia.
- Variations in the size of the Competency Areas:** There are significant differences in the size and complexity of the PIA Competencies and Performance Outcomes. Many could be split into a number of sub-categories, for example: A10: Work readiness; A8: Communication; B1: Ability to use planning tools; and Self-management, teamwork and professionalism.

- c. **Overlaps:** Many of the tasks could have been allocated to two or more Competency Areas due to the similarity of the PIA competencies or statements. For example: Spatial ability in A5 and B1; Teamwork in A9, A10 and B1; and Problem solving in A1, A7 and B1. While it is recognised that the emphasis of the competencies in each Knowledge Domain (A and B) is different, the differences may not be obvious to PIA members.
- d. **Inconsistency of approach:** Some of the PIA Performance Outcomes refer to a knowledge requirement rather than a performance criteria. It is suggested that, for consistency, these should be rewritten as performance outcomes.

For these reasons the DYD Planning Project Team believes that the Pilot Project should be extended into a national study. The key outcomes from a national study would be:

- a nationally authenticated Graduate Capability Framework for planning degree programs at Australian universities which could be used to inform future PIA accreditation requirements; and
- a shared understanding of the breadth and depth of planning as it is currently practiced in Australia. From this perspective, the DYD Stakeholder Consultation Process may be viewed as an educative process because it engages the members of a discipline in informed discussions about their profession. This is particularly so for the DYD Workshop participants.

6. Application

It is expected that the members of each stakeholder group may use the Graduate Capability Framework in different ways:

- **Planning Schools** will use it to support the review and revitalisation of the curriculum in their programs, and to prepare for accreditation reviews by PIA.
- **PIA** members may use it as a companion resource to the PIA accreditation requirements when they participate in a PIA accreditation panel.
- **Planning students** may use it: to gain a better understanding of planning practice; to inform decisions about their career and specialisations; and to help manage their learning so they acquire the knowledge and skills required to commence practice in their chosen specialisation.
- **Employers** may use it: to define graduate roles in their organisation; to assess capabilities during the recruitment process; and to prepare staff development and training activities.

7. Conclusion

The shortcomings in planning education have been apparent in the planning education literature over the past decade. In spite of this, there has not been a coordinated and well-funded attempt to further investigate and report on a capability framework for planners. Projects such as the ALTC project Generating Academic Standards in Planning Practice Education (Jones et al., 2009) have shed much-needed light on certain aspects of planning education, in this case planning practice education, but they do not fulfill the need for a more holistic investigation of planning graduate capabilities.

Jones et al. (2009) remind the profession that the professional accrediting body “plays an important role in achieving a more conjoint and coherent approach between the university and the planning industry”. PIA, on the other hand, acknowledges the need to continually review planning education within Australia (Planning Institute of Australia, 2012a) and hence supported the DYD pilot study.

Planning education, certification and deregulation in Poland.

Sławomir Ledwoń, PhD, Architect, Gdansk University of Technology, Poland

1. Introduction

Two background factors are important to understand Polish the system planning education. First one is the history of planning itself, and the second one – the methods and focus on teaching urbanism so far.

The recent history of planning in Poland may be divided in to two main periods. After Second World War planning was characterised by governmental regulation of new development that was strictly connected with central policies of the country in communist times. The breakthrough was marked by the system transformation in 1989, when new opportunities for spatial development quickly arose. It shifted the intention of planning laws form comprehensive planning of the country to rather setting the grounds for specific development. Since then the spatial growth was exposed to the pressure of private needs and demands.

Many of the changes that Poland has undergone influenced the planning culture. There was a need to quickly rebuild the country after the demolishment of wars, communist times focused on building new industries and housing. Transformation has brought market led development that was driven by unfulfilled development demands. This was boosted by the accession to European Union in 2004, which enabled substantial European funds to be transferred to Poland. The recent crisis has slowed down the development, but not stopped it at all, as yet there was no recession in Poland. The roles of the architect and urban planner (or “urbanist”) had to change accordingly. Mostly they were driven by the market demand and had to reflect the needs of the developers, sometimes forgetting about higher principles of planning.

As for the second one – teaching urbanism – it refers to educating more often architects and urban designers rather than spatial planners. And also the demand to teach more universal skills after Polish planners were allowed to work internationally more easily.

The above two factors impacted the way that planners are taught in Poland now and how they will have to be taught in the future. On the example of Gdansk University of Technology the article argues what are the differences in teaching architects to be urban designers compared to teaching spatial planners, as well the changes implemented in curriculum at the national level. The article also describes the efforts of newly formed Union of Spatial Management Schools to recognise by Polish government the new field of studies – Spatial Management, as nowadays only Architecture is formally established. It refers to the accreditation issues that were also discussed in Europe by the Association of European Schools of Planning – AESOP. On top of these issues, Polish government has recently taken steps to deregulate planning profession in order to make these jobs more available.

The article is based on the author’s experiences as a member of the Chamber of Urban Planners and active urban planner, a Professor at Gdansk University of Technology, co-author of the New Spatial Management programme at Gdansk University of Technology, a member of the Programme Committee at Architecture Faculty, Gdansk University of Technology and a member of the Task Force for Education and Carrier Development in the field of Spatial Economy at the Committee for Spatial Economy and Regional Planning, Polish Academy of Sciences.

2. Urban planning in Poland as a profession

The profession of urban and regional planners in Poland is regulated by the law of 15 December 2000 on self-governments of architects, building engineering and urban planners (published: Dz. U. z 2001 r. Nr 5, poz. 42). In this law the principles, requirements and rules for working in these professions are set and all professionals must comply with them. According to the article 2 paragraph 3 "practicing urban planning means designing spatial development in regional and local scale, according to the principles of spatial order, protection of architectural and landscape values, with respect to requirements of environmental protection, rational development of settlements and infrastructure as well as education in that matter". This law sets grounds for creation of self-governments that would associate members of these professions.

A member of the Chamber can be anyone that meets any of the below requirements (article 5 paragraph 3 of law on self-governments) those who:

1. have been granted rights to design under the Planning Law of 1994;
2. have been granted rights to design under the Planning Law of 1984;
3. have a diploma from studies in the field of architecture, urban planning or spatial management and have experience of working in the planning industry for at least two years;
4. have a diploma from studies other studies with at least 90 hours of architecture, urban planning or spatial management in the obligatory curriculum and additionally a postgraduate course in spatial planning, urban planning or spatial management and also have experience of working in the planning industry for at least three years;
5. have finished studies other than above and additionally a postgraduate course in spatial planning, urban planning or spatial management and also have experience of working in the planning industry for at least three years plus have passed an exam on practical knowledge of laws concerning spatial planning;
6. are citizens of the European Union member states that have received the design qualifications that meet any of the above requirements and have an appropriate decision confirming this requirement.

The Chamber of Urban Planners in Poland is organised into two tiers. There is the National Chamber and four Regional Chambers. They are organised according to the general regulations of law on self-governments as well as internal regulations set by the organisation itself within the competences of the Board. The latter regulate national conventions, elections, qualification process for new members, disciplinary measures, finances and fees. When needed the chamber has the right to determine whether a member is following all the regulations and professional ethics and reprimand, suspend or even exclude from the chamber.

According to the resolution no. 5/2010 of the National Board of the Chamber of Urban Planners from 23 January 2010 there is a requirement for each member of the Chamber to improve their competences and qualifications. This process is assessed every three years. In that period the member has to gather points for actions such as: participation in training courses, lecturing in such trainings, receiving prizes or honourable mentions in urban competitions, postgraduate studies, receiving a scientific title in the field of urban planning or publishing articles referring to urban planning.

The idea of the above requirement is meant to ensure that all members are working on improving their qualification. Prior to 2010 once someone became a member there was no procedure of rechecking their qualifications, whether they follow the changes in law, market and contemporary design principles. This meant that members did not have any obligation to improve their qualifications nor to be actively involved in the activities of the Chamber. In practice there were ones that were very active and some that did not take part in any

additional activities. The authorities wished to fill this gap by such requirement and make sure that all members provide better service to the clients.

The first review cycle ended in 2012, and the majority of members have met the requirements sooner. There were however some that were not able to gather enough points and had to take supplementary training in the end of this period. It is too soon to assess the results in overall improvement of the members' qualifications, but there was a visible improvement in the participation rate in courses.

3. Teaching urban planning

3.1 Background – specific issues of planning education in Poland

To fully understand the background of developing the planning education in Poland one should get familiar with the specific issues concerning the learning process and the professional market in Poland.

When trying to define the roles of designers there are two main domains – architecture and urbanism. Both have their own professional chambers and responsibilities in the development process, as architects and urban (comprehensive) planners. In terms of education there also two main groups of programmes teaching the required skills – Architecture and Spatial Management. What is of importance is that being trained as an architect and having a diploma from architecture faculty allows to work both as an architect and an urban planner, whereas graduation from Spatial Management programme allows only the latter.

The above makes it difficult to shape programmes at Architecture faculties – whether they should train architects with some understanding of planning processes or focus also on more in-depth knowledge of urban matters for future planners. Most of the times it is the first case, which is also expressed by the interest of students. They enrol with the intention to become architects and are not much aware of the possibilities to work in the urban planning field. In this case there is more demand for urban design skills, which seems more appealing to students, rather than planning issues, which are treated as unnecessary and boring. Although after all some of the students will eventually work as professionals in the planning sector.

Gdansk University of Technology is a good example of Architecture faculty that has a programme in Architecture and Urbanism. Each school year (class) has around 150 students. Bachelor is 7 semesters long and Master takes 3 semesters to finish. That gives 5 years and approximately 750 students. All state universities in Poland are public, so there are no direct costs to the students, such as tuition. But they have to pay for their accommodation, books, prints etc. Most of the theoretical classes are lectures. This means a very passive way of passing on knowledge. There are many students attending. Exercise classes focus on utilising the knowledge from lectures in a practical situation (calculating construction, designing technical details, etc.).

The above differences in teaching systems may result in their different abilities to answer the arising demands of contemporary world. In this fast paced environment it is difficult to keep up with the new needs. We need to adapt to changing demands of the market, requirements of new policies and social needs as well as trends in planning and design. As nowadays graduates are more mobile we should also be able to teach them more universal abilities and knowledge than before.

Spatial Management programmes are quite different, as they are focusing on skills and knowledge related strictly to urban planning matters. These focus not only on educating designers that will be drafting master plans (which would be closest to urban designers), but

also regional planners and administrative staff in municipalities. There are 51 schools teaching Spatial Management in Poland at the moment. And what is of most importance that these schools are based on faculties in diverse scientific fields, such as e.g.: geography, forestry, management, economy and natural environment. This is both an advantage and a disadvantage. On one hand graduates have variable skills and approaches to planning, but on the other there are few elements that these schools and approaches have in common. These matters will be discussed more thoroughly in the following chapter.

3.2 Restructuring the curricula

There were some changes in the higher education system in Poland. One was readjusting the whole teaching process to meet the agreements of the Bologna Process towards consolidation in the European Higher Education Area. Some of the improvements implemented in Polish higher education were: introducing European Credit Transfer System (ECTS) making points awarded from different universities widely recognisable, dividing one cycle studies (Master) into two cycles (Bachelor and Master) and allowing better mobility of students and teachers as also collaboration at international level. The most visible impact of these changes was on reforming and dividing the existing 5 year full Master studies curricula to two cycle curricula in all cases. All higher education institutions have already adapted their programmes to these changes.

The second change stems from the European Qualifications Framework (EQF). These were set by the recommendation of the European Parliament and of the Council of 23 April 2008 on the establishment of the European Qualifications Framework for lifelong learning (Official Journal C 111, 6.5.2008). It was meant to make qualifications of learners transferable across Europe. It will make it easier for employers to recognise skills of workers from different countries by bringing them to one common layer. To obtain this all national qualification systems have to be adjusted to the European standard. From 2012 on all qualifications issued in Europe have to refer to the common European Qualifications Framework.

The legal framework of this reform in Poland is rooted in the Directive 2005/36/EC of the European Parliament and of the Council of 7 September 2005 on the recognition of professional qualifications; ordinance of the Minister of Science and Higher Education 29 September 2011 on the standards of education for architecture and veterinary studies (published: Dz. U. z 2011 r. Nr 207, poz. 1233); and the ordinance of the Minister of Science and Higher Education 4 November 2011 on the standard effects of education.

According to the above regulations in higher education there are three levels of qualification: first cycle – Bachelor (or Engineer), second – Master and third – Doctorate. The learning outcomes have to be described in three fields: knowledge, skills and competences. They have to be described on reference levels: what the learner knows, what the learner understands, and what the learner is able to do. There are requirements at the national level for each field of sciences. These have to be included in detailed effects of learning at each programme. Finally these are broken down into detailed learning outcomes of each subject. In this system it is possible to trace which subject is “working” for which result in the educational process.

Another improvement that was implemented in the curriculum concerned grouping individual subjects together to form modules. The idea underlying this was to make modules interdisciplinary so that students benefit from a broader approach to one problem. For example auxiliary subjects – e.g. transport planning – were included with design studios into one module on urban design. In this case students will be able to correlate their transportation analysis with an corresponding urban design project. For programmes that were offered before these reforms it caused fundamental changes, and also many confusion among teachers. Different departments and professors had to work together on elaborating

a common description of the module and share responsibilities. They were not used to that before, and some had a very individualistic approach to their classes that they were used to.

At the moment there are two types of programmes thought simultaneously. For those started before 2012 (both Bachelor and Master level) the old curriculum is used. Whereas all programmes started in 2012 and later have to follow the new programme, that comply with the National Qualifications Framework.

3.3 Spatial Management programme at Gdansk University of Technology – case study

The new Spatial Management programme that was recently launched at Gdansk University of Technology is a very good example of a curriculum that is fully built upon the new regulations. It complies with the requirements of the National Qualifications Framework, offers a unique combination of subjects and teaching approaches. Therefore it can be treated as a model for building other programmes.

The above programme was elaborated as part of the European Union project “Development of the Gdansk University of Technology, Faculty of Architecture, by building new educational offer in the field of space management” (Human Capital Operational Programme Priority IV - Action 4.1 - 4.1.1, Competition number 2/POKL/4.1.1/2008). It is ongoing since 2009 and will end in 2014 and is co-funded by the European Union from European Social Fund. The Main Coordinator of this is professor Piotr Lorens, while Justyna Martyniuk-Pęczek is the Auxiliary Coordinator.

The main aim of the project is to develop an interdisciplinary teaching offer for Spatial Management at Architecture Faculty – both at Bachelor and Master levels. The latter will be taught entirely in English, which is a unique offer for the whole Central and Eastern Europe. There are two additional postgraduate programmes available Managing Spatial Development of the City, and Architectural and Urban Revitalization of Urban Areas. Both were developed as part of the EU project and are offered to students free of charge. Architecture Faculty students also benefit from the programme. A few hundred new and up to date books were purchased to retrofit the library with professional literature. A total of six scripts will be written and published with free copies available to students. The best students are offered paid internships in urban design companies and municipal offices. Current and prospective teachers prepared individual course programmes and lectures. They also benefit from taking part in funded study trips, individual development courses and programmes. The above together offers a very broad approach to improve the quality of teaching and offer a new Spatial Management programme.

The new Spatial Management programme (Lorens et al. 2012) was initially developed under previous regulations in 2010. It had to be thoroughly readjusted in 2011 and 2012 to match the new requirements of National Qualifications Framework. In this matter three elements were integrated together:

1. General qualifications for competences field that was elaborated as common requirement for the all faculties at Gdansk University of Technology.
2. Qualifications that have to be common for the Union of Spatial Management Schools, elaborated by the Task Force for Education and Career Development in the field of Spatial Economy at the Committee for Spatial Economy and Regional Planning, Polish Academy of Sciences (it will be described in the following chapter).
3. Originally and individually developed programme that based on the creators' individual experiences from teaching at Gdansk University of Technology as well as engagement at other universities internationally.

Generally the programme has been drawn upon grouping individual subjects into modules and thematic clusters. Together these work for one, common topic but also collaboratively add to interdisciplinary approach to the topic. This fits into the current needs of the market to

solve complex problems. As this curriculum has been drafted from scratch, before any of the classes started, it was much easier to coordinate different teachers and methods than in the case of Architecture programme, where tutors were already used to their previous methodology.

In order to manage the modules each one has been assigned a leader. That most usually is the teacher responsible for the most important subject or the most time consuming. They are in charge of the syllabus (merging syllabuses of single subjects) and coordinating qualifications framework to match general requirements. When the module is taught this person gives a final grade based on grades from individual subjects and their weights. The module as a whole is worth a certain amount ECTS points. All elements have to be passed in order to receive the final grade and ECTS points.

The full programme consists of subjects and modules such as: general contents, basic contents, major contents, diploma project and internships. General contents are mostly classes that relate to the technical profile and provide a basis for further development. These are for example foreign languages, informatics, philosophy, physics, law, economics and gymnastics. Basic and major contents are programme specific and relate to the Spatial Management field. Basic contents have three modules that give basic knowledge, skills and competences in development of space: graphic and presentational techniques; description and interpretation of space; and design basics. These contents are then developed further in six major contents modules: urban planning and natural environment; urban planning and society, culture and heritage; urban planning and economy; urban planning and infrastructure; urban planning and development policy; and regional planning and territorial self-governance. Each of these looks at spatial planning in a different context of various interdisciplinary approaches. Moreover each module has obligatory and optional elements (sub-modules). The student can choose from classes that differ in the method (traditional and workshop) or the project scale, location and scope.

In 2012 started the first year class of the Spatial Management at Gdansk University of Technology. It turned out to be the most popular programme at the whole university. We have received 480 applications with a rate of over 10 persons per one place. As a result of this popularity it was possible to choose the very best applicants and the programme immediately has become exclusive. The students are very capable and talented. This also creates demands for the teachers to perform at their best possible level. In a few years, when the first cycle comes to an end – the second Master level programme in English will start.

4. Organising for Spatial Planning / Union of Spatial Management Schools

4.1 *Committee for Spatial Economy and Regional Planning, Polish Academy of Sciences*

Polish Academy of Sciences (PAN) is a renowned and top Polish institution being an academy of sciences. It has two functions. One is to associate the most prominent scientists, and the second is managing the network of national institutes to perform the topmost scientific research. The Committee for Spatial Economy and Regional Planning (KPZK) is a part of this organisation. Its main objectives are to carry out research and expert consulting referring to regional policy and spatial policy of the country as well as institutional and legal aspects of planning at European, national and regional levels.

The Committee has brought into being a set of special task forces to work on specific problem areas. One of these is the Task Force for Education and Career Development in the field of Spatial Economy, led by professor Tadeusz Kudłacz. The author is a member of this group of experts. The main tasks are to ensure the most appropriate advances of the spatial

economy (or spatial management) programmes, cooperation between schools and serve as an expert panel for the future development.

4.2 Union of Spatial Management Schools

The main outcome of the Task Force was to found the Union of Spatial Management Schools. This is a formal organisation that associates 17 Polish schools that have Spatial Management programmes. These are: Gdansk University of Technology, Lodz University of Technology, Warsaw University of Technology, Wroclaw University of Technology, Warsaw University of Life Sciences, Warsaw School of Economics, Adam Mickiewicz Poznan University, University of Economics in Katowice, Cracow University of Economics, Poznan University of Economics, University of Lodz, Poznan University of Life Sciences, Wroclaw University of Environmental and Life Sciences, University of Agriculture in Krakow, University of Warmia and Mazury in Olsztyn, University of Warsaw and West Pomeranian University of Technology. In 2012 rectors of all these universities have signed the agreement.

The main aims of the Union are to (according to the 2012 Agreement):

1. Integrate the research and teaching society around the contemporary issues of highly qualified staff for spatial management.
2. Improvement of educational process with respect to the current trends in university education as well as present-day needs of the industry.
3. Taking actions in shaping a positive image of Spatial Management graduates among potential employers.
4. Overcoming the scientific development barriers in the field of Spatial Management by creating a separate scientific discipline, that would give the rights to grant scientific titles – this would be the most important and revolutionary change in the current situation and is described in the following chapter.

The above aims will be mainly realised through (according to the 2012 Agreement):

Cele Porozumienia realizowane są w szczególności poprzez:

1. Exchange of thoughts, opinions, information and experiences in the development of staff.
2. Agreeing on the core curriculum common for all schools.
3. Organising educational and scientific conferences for exchange of didactic experiences, also with invited guests from the industry.
4. Organising conferences for the society concerning the needs of practice for highly qualified staff.
5. Organising interuniversity and interdisciplinary research teams to undertake better joint projects in the field of Spatial Management.
6. Exchanging students and teachers, including organised field classes and internships.
7. Collaborating with international organisations related to training regional and spatial planning specialists.
8. Elaborating common promotional materials, that contain the characteristic of Spatial Management programme graduates as well as possibilities to take on the challenges of contemporary spatial planning needs.
9. Setting up Certification Committee that would monitor the quality of teaching Spatial Management programmes.
10. Collaboration with the Committee for Spatial Economy and Regional Planning, Polish Academy of Sciences and the Society of Polish Town Planners to improve the qualifications of staff and increase their competitiveness in the labour market.

4.3 Spatial Management core curriculum

In order to allow unification of teaching standards and some common elements of the programmes, a list of shared teaching effects (related to National Qualifications Framework) has been elaborated. These were set by the Task Force for Education and Career

Development in the field of Spatial Economy at the Committee for Spatial Economy and Regional Planning, Polish Academy of Sciences for all schools associated in the Union of Spatial Management Schools. All of them have incorporated these in 2012 while reorganising their curriculums with respect to the educational reform.

4.3 The new scientific discipline – Spatial Management

The schools associated in the Union of Spatial Management Schools represent different scientific fields. These range from economy and management, through architecture and geography to life sciences. But the most visible obstacle for further development is that Spatial Management is not a separate scientific discipline. This means that academic titles cannot be pursued and granted by faculty members of these schools in the common field. They can be granted but in various disciplines, and there is no common factor between these schools in that matter.

Therefore the Union of Spatial Management Schools has put forward a proposal to create a new scientific discipline – Spatial Management. The principles underlying this are that this field of studies will become more attractive to staff that will be able to pursue their career in the new discipline. Moreover, a common discipline would mean more independence of the individual schools from their original faculties.

As for the time being the proposal to create a separate scientific discipline has been drafted. It is being signed by the member schools and will eventually be submitted to the Minister of Science and Higher Education. Even at this moment there were some tensions and divisions. Mainly they concerned the science disciplines. At the moment it is agreed that Spatial Management would be interdisciplinary integrating the three following disciplines: economic, Earth and technical sciences. But there are some schools that have other backgrounds – life sciences, forestry and agriculture for example. In the end it was agreed that classifying the proposed discipline in more than three fields would be rather an obstacle in granting permission by the Ministry.

4.4 Accreditation

In Poland there is a statutory accreditation body for higher education. It is called State Accreditation Committee (PKA). The body is convened by the Minister of Science and Higher Education, based upon the law of 20 July 2001 that amended the Higher Education Law. The Committee has the right to assess the quality of teaching at all Polish universities both on the request of the minister and the accredited university. The State Accreditation Committee is the only official and statutory body that can evaluate higher education in Poland. All resolutions and opinions are binding. But its competences and expertise focus rather on general regulations than on discipline specific issues.

Union of Spatial Management Schools has discussed that it might be advisable to call another body, more specific one, that would assess the level and quality of teaching in the member schools. A similar concept has been analysed in the Association of European Schools of Planning (AESOP) during the workshops of AESOP Heads of Schools Meeting, 4-5 May 2012, held in Oslo. Although the main principle is reasonable and obvious, there might be a couple of inconveniences in pursuing this idea. Some of them have been identified as follows:

1. Schools differ much because of their different backgrounds, regulations and cultures. What would be the fair and justified set of issues assessed during this accreditation process?
2. Any committee would be drawn from the member schools' representatives, meaning that they would be assessing their own organisation. Then how independent this process would be?

3. Nowadays schools are competing with each other to have more students and have to be attractive. This is mostly aided by their reputation and the perceived quality of teaching. What about conflict of interests in this case?
4. There are also schools teaching in the same fields that are not members of these institutions. How would they be certified?
5. What will happen when there are remarks or faults identified? There are no legal means of requesting the school to improve on that.
6. Such accreditation would have to be recognised by the industry and prospective students to become a reasonable and effective method of assessment.
7. What are the possible means of funding such enquiries?

After discussing the above remarks and doubts both organisations (AESOP and the Union) have come to similar conclusions. For the time being, without any binding regulations, it would be best to form bodies or expert panels that would rather analyse programs of different schools rather than accredit them. This would be closer to a friendly peer assessment, where the results are confidential and for the assessed party only. In this case each school would know its weaknesses and could work on resolving these problems without the fear of losing its reputation. As a result the quality of teaching could be improved without the inconveniences of an open and public procedure.

5. Current issues – deregulation of planning profession in Poland

The last, but most current issue concerning planning in Poland is a proposal of the Polish government to deregulate some of the professions, including urban planning. This project has been started in 2012 by the Ministry of Justice. The general idea is to loosen the regulations that block access to many professions in Poland. Currently there are many licences, exams and additional requirements for people to be allowed to work in practice. Most of them are paid. In the face of crisis and unemployment, when more and more graduates have problems finding their jobs, the government wants to make these more accessible.

The process of deregulation is divided into three sets. The first one, already enacted on 13 June 2013, has opened 51 professions, including for example attorneys, real estate agents, geodesists and detectives. The second one is planned to apply to 91, and the last one – another 104 professions. The changes, varying depending on the profession, include for example shortening periods of gathering required experience, resigning from obligatory exams, closing institutions self-governing some of the professions. Some are more affected than the others.

By the second set architect and urban planner professions will be affected. The process is still in legislation, but on 23 July the project was accepted by the parliament and directed for further work. In case of architects there are for example shorter periods of gathering experience in designing and on the site. Not all applicants will have to pass exams, which are obligatory at the moment. But nevertheless their experience and abilities will be assessed.

In case of urban planners the modifications are much more fundamental. The requirements described in the previous chapter will be changed. The only prerequisite for practicing as an urban planner is graduating from designated studies, such as architecture, urban planning or spatial management or graduating from other higher studies supplemented by postgraduate courses in such fields as mentioned above. The institution of chamber will be entirely resolved with no need for professionals to be members if any self-governance bodies.

The rationale underlying this proposal, as presented by the government, is to make the profession more available. As urban planners work mostly for public offices, the requirement of checking the experience of a planner is to be verified by these offices, according to their

needs. The profession will no longer be defined as a public trust occupation, as the government believes that urban planners have direct contact only with public offices, not the society directly. As for ensuring the proper quality and level of professional experience this would be regulated by the market. In cases the urban planner breaches laws – there will be no disciplinary measures from the chamber, but they would be tried in court according to general laws.

There will obvious threats to the profession, if the governmental plan is carried out. There will be no institution capable of ensuring that the general abilities and quality of service in the profession is at any level of professionalism. Moreover the client will also have problems in executing this. In all public bids the choice of the winner is based on the lowest price only. And when there are additional requirements set to the competitor – there are suspicions of favouring some of them.

Probably deregulation of urban planning profession would also be against the graduates and unemployed. Now the crucial moment is to start working as an assistant and gather the experience to have it finally recognised by the chamber that grants membership. Later the membership is a proof of abilities. But after the changes, most of the clients will be asking the planners for proofs of experience working as a leader of certain types of projects. This will be easy to achieve by existing planners, but very difficult for those entering the market.

6. Summary

There are several comments and lessons learned from the matters presented above that summarise the situation of planning education and profession in Poland:

1. At the moment practice in the urban planning profession is regulated and controlled by the Chamber of Urban Planners, which is a self-governance body.
2. There is a requirement for the members of the Chamber to improve their qualifications by additional training.
3. There are two major groups of schools that teaching urban planning. One focuses on architecture, where urban planning is an addition. The second concerns spatial management itself.
4. Polish universities recently had to readjust their teaching programmes twice. First it was a result of dividing the one cycle Master studies into two cycle Bachelor and Master studies. Second concerned compliance with National Qualifications Framework that relate to European Qualifications Framework.
5. An individually developed Spatial Management programme at Gdansk University of Technology has been presented as a case study. It has successfully merged the requirements of the teaching reform with an innovative approach to teaching.
6. The Committee for Spatial Economy and Regional Planning, Polish Academy of Sciences has been working on development for education in the field of Spatial Management.
7. As a result of the above actions 17 Polish schools have formed the Union of Spatial Management Schools to integrate their efforts for development of the profession and teaching.
8. The Union has agreed on elements of core curriculum that will be common for all schools.
9. There are efforts to call Spatial Management a separate scientific discipline, which would allow better development of staff and professionals in this field.
10. There were discussions on additional accreditation of planning schools both at European and national levels. Both were not yet executed.
11. Currently the Polish government is planning to deregulate the urban planning profession in order to allow easier access for graduates. It will resolve the institution of Chamber of Urban Planners.

Shaping the new planning curricula in the post-socialistic context – lessons from Poland and Russia

Piotr Lorens*, Dorota Kamrowska-Zaluska*

*Gdansk University of Technology, Poland

The planning education was, to a large extent, non-existent in the formerly socialistic countries. Therefore, after successful political and economic transformation, the need arised to develop the new planning curricula, focused on situation and problems that have to be dealt with in the context of post-socialist countries.

Introduction

Planning education is the issue widely discussed during various conferences and seminars, especially ones grouping the representatives of universities offering professional education in this field. But to a large extent this discourse is dominated by the realities and specifics of the highly-developed countries, which is also reflected in the structure of the organizations of universities offering those. At the same time planning education in these countries is in many cases limited to socio-economic issues, with no attempt towards dealing with physical planning or urban design. This situation is characteristic to many highly developed countries, as those of Western Europe or North America.

A different situation occurs in the post-socialistic countries, where the planning profession is traditionally dominated by graduates from the programs in architecture, frequently (and traditionally) treating planning as the “large scale architectural design”. Graduates of these programs have very little knowledge of the social and economic processes and are not ready to deal with modern planning regulation-making processes. At the same time, the cities in Central and Eastern Europe (as well as in other post-socialistic countries, including ones in various parts of the world) are in desperate need of modern planning solutions and planners able to deal with their problems.

New roles of planners in the post-socialistic countries

After the transition from communist and centrally planned economy to market-based system, the role of planners in Poland and Russia has changed. In the formerly socialistic countries, the majority of planning professionals had traditionally an architectural background, with some exceptions of e.g. transport engineers and economists who were dealing mostly with economic development strategies. In the past both spatial and economic development strategies were in most cases completely separated.

With the beginning of integration of strategic planning on all levels of the Central and Eastern Europe countries starting from local and regional up to national, new skills and interdisciplinary approach was needed. The planner is no longer only a creator of a vision plan or a large scale urban designer and even though some large scale development still happens, especially in Russia, in most cases planners work on small scale interventions.

Even if a large number of planners work in the public sector in local regional or national level administration, their role has changed. Some still are traditionally working on development control or land use regulations, as well as in the regional scale. But one has to note that

these regulations usually take form of new “zoning-like” documents. At the same time the traditional urban design is either vanishing (like in Poland) from the planner’s workshop or is preserved in the form of “large-scale architecture approach” (like in Russia). What is interesting, this also has consequences in using certain names: i.e. in Russian there is no widely used term for urban design, and the usual term of “city builder” is used for the traditional large-scale design of the city development plans, defining precise locations of new buildings but not much more. Similarly, in Polish the term “urban planner” is used for a person who just deals with zoning – and the broad sense of this term has been vanished.

But at the same time there is an increasing number of those who are managing development or working with new planning instruments. Some planners are negotiators, facilitators of participation process and managers of change. They are responsible not only for creating plans, but also for their implementation - improving the life conditions of inhabitants and delivering high quality spaces. To achieve this goal they have to understand economic and social aspects of the development process, be able to create durable partnerships with all actors of this process and understand their aims and needs. Numerous planners are working in private sector. Some of them owe their own companies so they need entrepreneurial and managerial skills.

Nowadays, most planners work either in administration or in planning offices, but this situation is already changing. Many future graduates of planning schools are going to work for NGO, some for non- and low-profit or quasi-public bodies, with very different organizational models. It is important to consider the types of skill they will need, especially that this kind of work very often requires versatility and flexibility. Some of them are going to work abroad or for international companies and need to be prepared to work in this context.

One of the most important aspect of the planning process is civic participation. However, the majority of practitioners in Poland – 62% of the respondents in the survey conducted by Wrocław University of Technology (Damurski Ł. 2012) - think that their education didn’t prepare them to conduct public hearings (a major step of regulatory public approval in planning process in Poland). The greatest doubts are expressed by graduates of architectural courses, who make up the majority of practicing planners in Poland.

In the end we can conclude that the new planning workshop is developing and knowledge about contemporary approaches is available, but planners frequently do not wish to use these. In fact, many of them still believe in the omnipotent role of the planning profession and tend to believe they know best and do not need to learn or use any other modern planning instruments.

Need for new planning curricula in the post-socialistic countries

The abovementioned changes imply that there is a need to rethink the curricula of the universities dealing with planning education within these countries. These changes and adjustments are needed on all levels of education, starting from undergraduate courses to postgraduate ones and finishing on mid-career programs for professionals already on the labor market.

Both in Poland and Russia new planning programs are being introduced. In Poland in the last decade new interdisciplinary spatial economy programs are emerging from Economic Geography, Business, Architecture and Agriculture Faculties. Depending on their roots, these programs have very different emphasis and focus. Also, the profile of their alumni

significantly differs. There was a need to set standards for knowledge, skills and competences, which the graduates of all planning programs in Poland should possess. A body which was deeply involved in this process is the *Committee for Spatial Economy and Regional Planning of Polish Academy of Sciences* with its *Expert Panel for Education and Human Resources Development of the Land Management Studies*. Finally *Union for Development of Spatial Management Studies* was created and 17 major planning schools in Poland are now its members. A new *Law on Higher Education* increased the dynamics of this process. In general it helped to relate national qualifications systems to a common *European Qualifications Framework* which was an important step; to compare the qualification levels of different countries and different education and training systems.

One of the examples of a new generation *Planning and Urban Design* curriculum is the program of *Spatial Management* course implemented in 2012 at the Faculty of Architecture of Gdansk University of Technology. The program is based on training modules, which consist of a theoretical part, as well as practical seminars, studios and field studies. The aim of the course is for its graduates to acquire basic knowledge, as well as important skills and social competence to be able to work in the development process (Ledwon S., Martyniuk-Pęczek J. 2012).

In recent years in many Russian cities, first of all in Moscow, but also in Sankt Petersburg, Perm and others, we can observe a significant number of new post-graduate planning programs. These initiatives are undertaken by both public and private institutions. One of the most spectacular examples is the *Strelka Institute*, a postgraduate school for media, architecture and design, which offers a 9-month postgraduate educational program in English, that focuses on the urban environment. Education at Strelka is cross-disciplinary and is combining economics, social and political studies as well as art & culture. Both lecturers - designers, architects, government officials, city activists and entrepreneurs - as well as participants come from all over the world. The alumni are prepared to work for both public and private institutions, to work in academia or to shape new urban movements.

As experience from wide range of programs and initiatives on national level in post-soviet countries should be capitalized, there is a need for international cooperation. This spring a consortium of high educational institutions from five EU countries including two from Central Europe, three universities from Russian Federation and two from Kazakhstan applied for TEMPUS grant for international cooperation in the field of planning education. The objective of the project is to modernize the planning education in Russia and Kazakhstan, in order to improve its quality and relevance to current situation. Development of effective planning education will help to support the economic growth of Russian and Kazakh cities. This objective will be met through creation and implementation of the new Master level program in Urban Planning and Development. The pressing need to develop new methodologies and models of education provides unique opportunity to have much wider impact on the national level.

Mid-carrier programs

There is more need for new under- and postgraduate planning curricula. People who are already working as planners frequently realize they need more knowledge in the specific areas. Also, the newcomers to the profession tend to look for the opportunities of getting the skills and knowledge required for their professional development. This also relates to the

process of reshaping their education and to developing planning skills among people who have different mode of education – like i.e. transportation engineering. In many cases they require new knowledge and abilities to strengthen their knowledge and gain new qualifications which they need in their everyday praxis. This is not only the case of professionals working in public administration or in local and regional development agencies, but also employers of private sector development companies or even research institutes with the spatial planning profile. Those planners often work in responsible positions, such as elaborating planning policy in local, regional and central administration, they lead comprehensive local development process working in local and regional development agencies or work as project managers in development companies, both for private and public sector.

A good example of such an approach are two mid-carrier programs: *Architectural and Urban Revitalization of the City Structures*, *Spatial Management of the Urban Areas* co-financed by the European Social Fund. These programs are taught at Gdansk University of Technology by professors from several Polish universities (Wroclaw, Silesia, Lodz) and also practitioners of different specializations, private and public sector, owners of planning offices, executives from public bodies and politicians. The programs started in 2009 and during its first editions the majority of students were architects and engineers who sought to widen their knowledge about the social and economic processes they dealt with in their work - the knowledge, which they lacked having only engineers' education. In later editions there were more and more urban planners, geographers, lawyers and civil engineers who, on the contrary, wanted to improve their physical planning or urban design skills.

A survey carried out every year shows that in both programs planners understand that opening to global and European trends in urban planning and changes in legislation is a cause for constant need for knowledge complementation. Adaptation to organization culture and the efficiency of learning are the skills that today must be constantly and dynamically developed. Moreover, more and more often the educational background does not determine today's career paths of planners in Poland. Polish employers often do not treat degree in a specific field as a condition to get a job; they often employ those who did not complete studies in planning, but people with a related degree, who have basic knowledge necessary to meet specific work requirements. The interest in this mid-carrier programs in the field of revitalization and spatial management is very strong. Students appreciate that most classes are in the form of study tours, workshops and design studios, which shows the need for practical education. There is a need for training experts to carry out the regeneration process and to work as managers of space in Poland. Highly qualified professionals with different specialties in regional and local governmental structures are required. Most respondents emphasized they had insufficient knowledge for the current position they held, resulting from the lack of broad enough undergraduate education. People participating in these courses want to become experts in the field of urban planning, fill the gap that exists in this area of the labor market, and thus count on career progression and improvement of their working conditions.

The Ministry of Science and Higher Education in association with *United Nations Development Programme Design Office in Poland (UNDP)* invited Polish Universities for partnership to prepare curriculum for postgraduate studies on Sustainable Human Development and Transition. Gdansk University of Technology will be responsible for the module concerning smart cities' development. It is also a way to propagate planning

education, especially that this program is addressed for the local and regional development actors. For the past six years the UNDP is also implementing, in cooperation with the Central European University of Budapest, a summer school in the field of social development. This school is addressed to officials and policy makers, postgraduate students and scientists from Central Europe and West Asia countries, as well as practitioners interested in the subject.

Conclusions

At present significant changes in the planning paradigm, such as recognition of traditional urban values, can be observed. There is a search for the ways of including them in the planning system. Moreover, there is also a rising understanding of what the planning paradigm should be based on: creation of urban spaces, participatory process leading to definition of the desired urban form and understanding the implementation powers (Lorens P. 2010). To make these changes happen, new curricula need to be involved in the urban design, planning skills and competences. Graduates should also have knowledge and understanding of the development issues, both in general theory, but especially those emerging from the political and socio-economic specifics of post-soviet countries. Not only socio-economic conditions, but also planning culture specific to these countries have to be taken into consideration. International cooperation and capitalizing different experience could be a useful tool to achieve these goals.

Under this condition there is a necessity of evaluation of the planning profession challenges: still some practitioners will be "traditional" regulatory planners, some will be "old-new" urban designers, but the rest will become "new" action planners. They have to be able to design urban space and be ready for undertaking the participatory processes (Lorens P. 2010).

Further challenges for planning education include further recognition of the needs, validation and verification of the present programs and courses offered in regard to requirements and paradigm changes. It is vital to link the educational offer with changes in planning system and new roles of planner.

SHARED AND LEARNT LESSONS FROM LISBON

Designing the city and the territory from an Urbanistic viewpoint

Sofia MORGADO, CIAUD – Faculty of Architecture, University of Lisbon

Synopsis

The article addresses a systematised outlook from previous experiences in teaching syllabus and programs, research, active integration with theory and practice, especially at the Faculty of Architecture [Technical] University of Lisbon, within the 3 Cycles of the EU Bologna Agreement. The roles of Education, Research and Practice are to be referred in the wider context of a Contemporary Culture of the City.

1. Introduction

Unexpectedly enough, spatial planning does not merely stand for *expanding* the urban onto a *passive* landscape anymore. Did it ever? Or was humanity deterministically daydreaming of it, while the tentacles of *reality* were already taking over the actual urbanization?

Although functional changes start emerging since the 70's, the last decade has proven that changes are becoming progressively faster and calling for innovative approaches, that is to say, in recouping the design from the fabrics of the *terræ* themselves; *Some authors identify these options in a three-tiered approach* on how the synaptic and conjunctive fabric that forms the basis of the current City, evolves (for instance, seminal work by Paola Viganò at the Venice School: doctoral courses by design, pivotal design and planning such as greater Paris, with Secchi and Studio 09, and theoretical developments in several references; other references could be Waldheim at the Harvard University or Joan Busquets at the Polytechnic School of Catalonia/Barcelona and Harvard University and Llop, also at Barcelona).

In an attempt to go beyond the frontiers of Planning, the approach seeks to explore the condition of these days' cities – seen as a paradoxical state of *in-betweenness* both in the territories of practice and the ones of knowledge.

These concerns have raised the need to clarify realities holding different qualities - from urban and infrastructural, from rural to what is understood as *natural* - and the vital skills to intervene accordingly in the best local interest. At the same time, societal dynamics, economic trends, job and production relocation have opened - if not enforced - questions which are often answered very differently, depending on the geographic area and, as such, on backgrounds and culture.

The article stems from a preliminary systematisation outlook from previous experiences in:

- Urban design and planning studios within the general layout of teaching programmes
- Frontier and applied research as ways of reasoning reality and look for alternative answers and
- Integration of education activities with present-day topics both in theory and practice.

While further development would still be needed, the paper seeks to explore these topics by drawing a three folded approach:

1. Contextual approaches from a cultural perspective – Planning Cultures in Europe and the role of Urbanism;
2. The field of urban design and planning education - Oriented didactics and learning strategies;
3. Education, Research and Practice - Contributing to interconnected activities in a cross-border, trans-disciplinary line; recent experiences.

The last topic will be developed in its own presentation (debate at the ISOCARP Forum of Education), thus only sketched in the concluding part of the paper, as *an open agenda* for discussion.

2. Contextual approaches from a cultural perspective

The word *Urbanismo* was born from a Spanish neologism *urbanización*, rooted in the Latin etymon *urbs*, when Cerda faces the need to invent new words to name urban phenomena, while he was designing the *Eixample* Plan for Barcelona. His theory, in 1867, would give rise to a new professional field, expressing a specific culture of building cities, with resort to an architectural lexicon, much attached to the places themselves. It was a major contribution to a paradigmatic epistemology of the city, persistent until these days in the neo-Latin speaking countries.

In the USA, *metropolitan* is the expression and aim of the Urbanism itself. And of course the core of the *City Beautiful theory*, much in line with the English common Law system, the referent to the Anglo-Saxon way of “building” cities. Only, cities would also become the most symbolic expression of the power of men, by inventing power infrastructures and machines, sky defying buildings (Chicago or New York), yet designing them as classical as possible.

Still, *Urban Design* (coined by Abercrombie and Forshaw, cfr. Shane, 2011: 9) would only appear as an autonomous professional activity after WWII, in order to fulfil the need to rebuild housing and to deal with the “car” effects on the urban. After previous attempts, Abercrombie would articulate different levels of planning, and finally implement the first urban sprawl containment tool: the green belt, on grounds made public by the force of law (1945).

Modern would then become a sort of urban Esperanto, by promoting functionalism, sometimes indifferent to local singularities and cultures. In the urgency of the post war, *modern* becomes *normal* – an easy way to build fast commuting cities – suburbs became suburbia, a mere stereotype of once beautiful urban ideals. Sometimes a caricature of what city and citizenship should mean. After WW II and in a period marked by successive crises, the end of the *Cold War*, Cartesian and Rationalist as fundamentals in the Modern unity would be inevitably discarded. From the 70’s onwards, the Post-“something” starts leading: post-Industrial (D. Bell, 1967), Post City Age (Melwin Webber, 1967), *Posturbain* (Françoise Choay, 1970), Post-modern condition (Lyotard and Harvey), amongst others.

Vattimo would state the acceptance of what is human, ephemeral, and erroneous. Jürgen Habermas would focus on communication, the public realm, and everyday life. The European political reconfiguration after the fall of the Berlin wall in 1989 and its enlargement start introducing a new era, introducing a current conjuncture that put emphasis on:

- Neoliberal models, namely in the government of cities (ex: London)
- Regional separatisms leading to cultural differentiation (ex: Spain)
- Post-secularization exacerbation (ex: Islamic Spring from 2010, amongst others).

In Urbanism two main paths would unfold thereon:

- Post-industrial with concrete functional and configuration effects - regional
- The Postmodern aesthetics – sometimes too local.

Generally speaking, from there after *Urbanism* would mean the same as *Urban Design*. Urban and Regional Planning, conversely, would take over the leading role in the functional and pragmatic development of the urban, thereby unintentionally designing Cities,

with much loss to the public realm diverse qualities, the perception of citizenship and diversity, only recently recouped.

This would occur either from an entrepreneurial or real-estate position, in line with *strategic planning* ideas, or from a *sectorial perspective* (e.g. infrastructures), to where the welfare state would start retreating, mostly acting at the regional level.

Grounds and Backgrounds

One of the most recurrent questions in this broad field of work lies in the necessity - required by the dialectic between actors coming from different backgrounds (scientific fields and complementary actions) which share the same object – to bring some light into the differences between Urbanism and Urban Planning. While substantive, there is no final answer in sight, since different scientific viewpoints have been leading to different understanding and really is of course somewhat complex.

In this case, the arguments lay from the urban point of view. The other perspectives are unquestionably relevant; however this approach holds on to resources which are often dismissed, even if they are the roots of the urban development itself, such as place, people and their ways of living – their cultures and landscapes.

It is undeniable that human beings, their societal structures, the development of their activities from the most elementary (driving a car, for example) to most complex involving manifold activities and infrastructures (e.g. an airport) unfold in:

- i) Space, with dimensions and characteristics materiality conditioned by their own conditions, and
- ii) A time span, with its own rhythmic of events and circumstances.

In addition to dynamic contours and flows, difficult to determine in these terms, people live in an environment determined by their own physicality, as well as by the surrounding territory, designing cultural roots, the content of the landscapes, traditions and customs.

In the case of Southern Europe, the attachment to place is particularly important, thus, expressed in various forms. City is understood as a value of permanence that unsurprisingly extends to landscapes of various hues.

With this starting point, Urbanism stands for a particular way of seeing, analysing, designing the territory. Formal acknowledgment by the EU (European Communities, 1997)

follows, and is followed by several authors after, the idea of a broad and diverse systemic framework with regard to the city.

The need to connect the characters of the territory with the process of intervening in it, by resorting to specificities of the urban lexicon and how this impacts on planning was also examined in the research project *Super Cities - Sustainable Land Use Policies for Resilient Cities*, offered an opportunity to clarify some of these aspects in an integrated perspective (Pinho, P. et al 2011; Morgado, S.& Dias, L., 2013) based on documents of the European Union and renowned experts (et al, 2010, EC 1997 and 1999, among others).

After a documented study of metropolises in their urban, environmental and socio-economic contexts, planning systems were also analysed: i) the specificity of urbanism as Southern Europe, with the example of Portugal, ii) Sweden as distinctive in terms of inclusive, integrated approach, iii) economic and regional perspective in the Netherlands, and iv) management of land use as a strategic tool in Turkey. This study allowed understanding some relationships between policies and options contained in agreements signed within the European Union and their respective impacts when transferred into national legislation (Morgado & Dias, 2013)

This approach allowed as well for a contextualization of the role of Urbanism within the Faculty of Architecture of the [Technical] University of Lisbon and the pivotal role of *design* in the syllabus of the three cycles of Bologna Programs (Bachelor, Master, Doctor).

TIME FRAMEWORK ACCORDING TO PERIODS OF PLANNING

	Ideas for the Metropolis; Key topics	Main urban developments
Fordist Industrial Models Modern City	Physical Planning, Formal Urbanism: Modern and Garden City Concepts Urban Expansion Port and Railway development Green Belt Concept /Rural Transition Housing development Metropolitan centralities and land uses Key infrastructures and centralities	Sprawl
Post-fordist Post-industrial Models Knowledge and creative based economies	Strategic Planning, Plan-Process approach: urban requalification and regeneration concepts Metropolitan corridors and ecological network Urban requalification, heritage and sustainability	Sprawl, Shrinkage
ESDP (Postdam, 1999) Sustainability; Polycentricism; knowledge infrastructures	Resilience-oriented planning concepts and policies: multi-level, flexibility, adjustment capacity [translation of our attributes into the planning tools each case raised]	
Lisbon Strategy (Lisbon, 2009) Territorial Cohesion and Competiveness	Metropolitan centralities and sustainability Metropolitan Ecological Network, Environmental and risk assessment, Shrinkage prevention – mixed land uses and higher connectivity and multimodal networks	Sprawl, Shrinkage, Polycentricism
Strategic Planning → Territorialism Integrated Systems Giving evidence to a territorial body; <i>Planning is Spatial</i> (Pain, 2010)

3. The field of urban design and planning education - Oriented didactics and learning strategies at the Faculty of Architecture, Lisbon

The Faculty of Architecture at the [Technical] University of Lisbon (further information available at www.fa.utl.pt), offers teaching programmes in line with its design-oriented structure based in Architecture, Urbanism and Design

Since 1992, this understanding would be translated into the creation of new degrees, in the fields of Urbanism and Design, as well as MSc Programmes that would later adapted be and further reviewed, following the *Bologna Agreement*. These actions represented an innovation in the context of national Architecture and Urbanism, allowing the school to become a pioneer in the pedagogical, scientific and scholarly in these areas, as well as in the schools' of architecture panorama, even internationally speaking.

Current programs have been updated, according to national legislation and accreditation procedures by the National Agency (A3ES) and renewed version are to be introduced already from September on, in 2013/14.

Teaching Programs in Urbanism

In the context of cultures, Urbanism is a relevant agent of the expression an expression of societies culturally advanced, in the change of the territory. Therefore it is recognized as a fundamental activity and constitutes a privileged object of study and in the history of contemporary thought.

Also for these reasons, it is relevant material for research and education in the most prestigious schools of architecture, particularly in Brazil, France, England, Spain and the United States of America, among others.

Under the scope of the *Bologna Agreement* and its due implementation, the Faculty of Architecture offers teaching programs in Urbanism in its 3 cycles.

Therefore Bachelor and Masters Degrees form a single body. At the end of the 1st cycle, students receive a bachelor's degree in architectural studies, with direct access to the 2nd cycle of expertise in the field of Urbanism.

Upon its completion they may apply to be granted the professional title, under the conditions established by the Architects National Professional body (Ordem dos Arquitectos

Portugueses), since the syllabus of the programme is organized in accordance with European Directive 2005/36/EC

In its various profiles - in which Urbanism is included - the teaching of architecture, supposes a didactic founded in the conception of space and its various design dimensions: spatial, aesthetic, technological and cultural. In particular, the Master in Architecture with specialization in Urbanism is not an exception to this. In the Architectural and Urban Design Studios, topics range from the metropolitan perspective to urban design and architecture, mixing relevant issues – public space, resilience, demographic challenges, and so forth - nationally and internationally speaking.

The education need to become an Architect, relies on the acquisition of a diverse set of skills, mainly established from an increasing complex vertical structure where Studios are fundamental. It is in this perspective that the group of Design Studios establishes trends and general characteristics, but also defines expertises in the fields of Architecture and Urbanism. Didactics result to experimental methods, encouraged by the development of monitored assignments, individually or in small groups, stimulated by the proximity to the teaching team.

Further to the professional level granted by the Master, an important effort towards an up-to-date life-long education was made. The Doctoral Program in Urbanism (which evolved from traditional individual supervised processes) and post-graduate programs, urbanism related, that may vary according to audiences and panoramas (e.g. Advanced Studies Programs in Portuguese Urban Culture or in Computation applied to Architecture, Urban Planning and Design, amongst others) have been introduced with very positive results so far.

Master of Architecture with specialization in Urbanism (1st + 2nd Cycles)

This profile has as main objectives a strong background in architecture with specific practical and theoretical focus on Urban and Architectural Design, as well as Urban Planning. Professionals with training in this area find opportunities ranging from architecture and urban planning offices and private companies to municipalities and other public bodies such as universities.

The 4th year curriculum is the preferred grade to resort to international programs and protocols of exchange (such as Erasmus, Smile, others), aspect that the implementation of the new Bologna cycles intensified. As such the 2nd cycle plays a key role, both in the progress of program and in its external visibility. The Design Studio courses play a

fundamental role in the coordination and liaison with the *corpus* of each semester, according to the character of each scientific field.

Recent experiences have shown some interest in deepening work started at an earlier stage (e.g. at the 4th grade), in order to complete the Final Thesis (which may assume the form of a detailed Design Assignment or a written research). Thus, the 5th grade is pivotal to the access to the profession after the successful assessment of the Final Assignment. This must show autonomy, ability to develop intellectual challenge, and skills to frame a complete and complex exercise in terms of maturity and scientific criticism.

Doctoral Program in Urbanism (3rd Cycle)

The University [Technical] of Lisbon, via Faculty of Architecture grants the degree of Doctor in Urbanism and holds the responsibility for implementing the program leading to it. The 6 semester's program corresponds to 180 ECTS.

The Doctoral Program in Urbanism would be approved in the Scientific Council in 2007 with a view to registration in DGES - Directorate General of Higher Education, which would occur in 2008, under the n.º R / B-AD -63/2008, in the context of the creation of the three Bologna cycles. Nowadays the Faculty offers 3 different Doctoral Programs in its main fields: Architecture, Urbanism and Design. The Faculty form also part of networked doctoral programs, with other institutions.

The Program in Urbanism, promotes the spatial and cultural qualities of the City, its reciprocity with the land uses, dynamics, and social groups. This allows providing training that is specific, complementary and not overlapping with other Doctoral Programs, in urban-related fields, such as Social Sciences or Engineering in other Faculties and Universities. Doctoral Programs with a specific dimension in the fields of social sciences, environment and infrastructure, widely recognized, follow different methodologies with the aim of representing and explaining various facets of the same object: the City nowadays.

4. An open agenda

Education, Research and Practise go together well in the experimental environment that have be fostered in these programmes, by triggering new agendas, but also by including consistent backgrounds and know-how.

As such, while teaching syllabuses always try to include up-to-date topics, they are usually framed by mature theoretic research and stakeholders are called to draw attention

and provide technical assistance to the Design Studios process (e.g. the bi-univocal involvement of municipalities and the classes).

Sometimes, singular events are organized in the form of workshops to intensify the debate and brainstorming around a specific issue. That has been the case of several ones, such as the workshop “from splinters to Parks”, (available at: <http://metropolis.fa.utl.pt/metropolis.htm>) organized at the Faculty of Architecture, last May with the endorsement of the ISOCARP.

A steady network of colleagues from different Universities, the cooperation of different institutions and stakeholders, but above all the enthusiastic participation of the students allows drawing a preliminary positive assessment.

Other experiences will follow soon.

‘From Pedagogy to Paideia’: Physical Planning Education in Nigeria

Olusola OLUFEMI, University of Ibadan, Ibadan, Nigeria

Usman Umar JIMOH, University of Ibadan, Ibadan, Nigeria

Abstract

Moving from pedagogy to paideia (Py-dee-a) in planning entails practical civic engagement and authentic dialogue with the community through collaborative rationality in planning education in Nigeria. Planning education is changing from the normal spaces (classroom) to the virtual spaces (online teaching, Webinar, Twitter, Facebook, blogging, LinkedIn etc.) and the adoption of GIS and other new technologies. Pedagogy is the art/science of teaching, which is the methodology while paideia is the education of the whole person. Paideia is a system of education or learning that empowers the planner to focus and situate planning within the context of a person’s assets (intellectual, physical, spiritual, social, natural, political, environmental and financial capital). In what ways do Planners seek to achieve Paideia or just Pedagogy? This paper contends that physical planning education should seek to impart knowledge and empower the whole person planner in attempts to produce new knowledge, skills and imaginaries that prepare practitioners to inform, influence and integrate new frontiers in planning.

Introduction

Urbanization of poverty and spaces; and urban sprawl with pockets of impoverished ghettos in the middle of affluent neighbourhoods, hyper mobility and changing urban lifestyles are seemingly becoming the norm that planners have to address. “In many countries planners are increasingly exposed to and challenged by a hyper-dynamic context that tends to characterize socio-economic as well as environmental change in a highly interrelated, increasingly urban world” (Rau, 2012:15).

For instance in Nigeria the population is estimated to be about 193m in 2020 (was 158m in 2010) (UN-Habitat 2008) and the population, extended metropolis and urbanization dynamics poses a huge challenge for planners in the country. There are about 44 Planning Schools in

Nigeria located in urban and peri-urban areas and 2673 registered planners in a country of about 160million people. The high-speed and hyper-dynamic urban change requires a fast forward response (Rau, 2012) or even a forward looking response. However, greater breadth of knowledge among planners is required to plan effectively (Friedmann 2005a; Irazábal, 2008a) to respond adequately to the challenges our human settlements are facing in the 21st century. “A planner must learn to be jack of all trades. Today’s planner works in a complex intergovernmental web of plans, policies and regulations. Planners must have the patience and understanding to work in a changing world of politics. Planners must comply with a large body of land use law, make reasonable forecasts, need a knowledge of economics, understand the fiscal situation and how to protect the environment”(So and Getzels, 2009:241). Thus, between expanding and shrinking settlements, planners inevitably need to re-tool both in teaching, learning and practice. It is no longer business as usual for planners. Planners need a new dynamic in their approach to planning human settlements and responding to the challenges.

The approach by various planning schools should move from pedagogy (traditional planning) to paideia (problem solving) to able to address these problems and achieve tangible and with realistic outcomes. Pedagogy is the “art, science or profession of teaching” (Webster’s New Encyclopedic Dictionary, 2002:1345; Abercrombie et al, 2006:289). Paideia, on the other hand has been defined by Adler (1982) as “... signifying the general learning that should be the possession of all human beings”.

Lucus (1972) observes that the focus on means rather than ends, methods rather than objectives, results in exclusive concentration on pedagogical and administrative emphases, and in the student with a focus on the utilitarian end of acquiring marketable skills and competencies in the universities. Students become manipulated to become nothing more than “instruments of production” by business or industry (Lucus, 1972:8-9). Seemingly, students rather than acquiring the skills and knowledge to allow them to solve problems, only acquire knowledge that is inapplicable (theory without practice) and their focus is to graduate and get a job (any job as long as they are employed). These are the challenges brought about by the complexity of urbanization, poverty and unemployment.

This paper contends that physical planning education should seek to impart knowledge and empower the whole person planner in attempts to produce new knowledge, skills and imaginaries that prepare practitioners to inform, influence, innovate and integrate new frontiers in planning. Engaged acclimatization and collaborative rationality moves planning from

pedagogy (methodology or planning content) to paideia (planning context, intellectual excellence and practice) specifically in Ibadan School of Planning.

Using data from secondary sources, this paper gives a conceptualization of pedagogy and paideia, an overview of planning education in Nigeria focusing on the Ibadan School of Planning (ISOP) (often referred to as Department of Urban and Regional Planning) and the embeddedness of paideia principles in ISOP's program using examples of the Sustainable Ibadan Project and the University of Ibadan master plan as attempts to promote intellectual culture and forge authentic civic engagement and collaborative involvement of students, faculty and the community. The paper suggests Planners require a new response, new knowledge and skills; and a new intellectual culture (paideia) to respond to the challenges brought about by urbanization, population growth, poverty and climate change. Paideia should be seen as an innovative and integrative approach to respond to these hyper-dynamic, hyper-mobility and high-speed changes in the environment.

Conceptualizing Pedagogy and Paideia

This section gives a conceptual explanation and definition of terms used in the paper. It defines education, learning and teaching. It also gives insight into the meaning of pedagogy and paideia. Definition, clarification, pedagogy, paideia.

Education, as an institution, is responsible for the transmission of particular knowledge, skills, values and attitudes deemed desirable in a given society (McClinchey, 2013:237). Education is a means of producing good citizens (Bromley, 2011; Osborne, 2000). Formal and informal education contributes to social reproduction; that is, by stressing societal norms and values, education works to socialize next generations (McClinchey, 2013:237). Education is the action or process of educating or being educated; knowledge and development resulting from an educational process (Webster's New encyclopedic Dictionary 2002:577).

What planning education does is to provide the knowledge, skills, training and development through teaching and learning. This in turn informs and influences the behavioural tendency and the social reproduction and engagement of the planner in practice.

Pedagogy is the "art, science or profession of teaching" (Webster's New encyclopedic Dictionary 2002:1345; Abercrombie et al, 2006:289).

According to Abercrombie et al (2006:289) distinguished between conservative and liberal pedagogy:

- Conservative or closed pedagogy sees learning as the absorption of specific bodies of knowledge, regards the child's ability as determined by hereditary and environmental factors, external to the school, identifies appropriate teaching style as one where teachers are experts, have authority over pupils and direct learning subordinates, and sees curriculum as the relevant classroom knowledge as defined by teachers.
- Liberal or open pedagogy conceives learning as a process and not the acquisition of specific knowledge, the child's mind as capable of development, teaching as simply guiding this development, and curricula as tailored to suit pupils' owned expressed interests`.

The spread of 'progressive' and 'child-centered' teaching methods since the 1960s, the open pedagogy, has been interpreted in different ways (Abercrombie et al, 2006:289). Freire (1972) argues that the open pedagogy has radical political implications because it emphasizes personal autonomy rather than social control, others claim that fully developed 'progressive' methods are rarely found beyond the early years of the primary school and are unlikely to have any lasting influence on attitudes, or that open pedagogy reflects the middle-class value system and is therefore unlikely to have radical implications beyond the school. Bernstein (1977) suggests that the manner in which schools modify 'progressive' ideals in practice suggest that pedagogical practices remain fundamentally conservative.

Beauregard (2003: 110) asserts ``University based education appeared in the late 1920s and remained relatively vocational until after World War II. At that time, planning education began to fracture into two camps: practitioners with professional degrees and theorists ordained as doctors of philosophy. Moreover, education became not only an occupational gateway but also a strong link between the practice and theory of planning, and between the actions of planners and the ideology that encased them`.

Beauregard (2003) notes the pedagogical model of lecture and seminar; knowledge was fragmented into sub disciplines and students learnt through texts rather than direct problem solving gives planning graduates only a dose of on-the-job training was needed and it severs professional training from academic training by creating a career path for teachers of planning that did not necessarily intersect with planning practice.

Beauregard (2003:111) notes ‘the combination of an academic pedagogical model, severance from practice and creation of alternative career paths was fertile ground for the emergence of abstract theorizing distanced from the performative demands of practitioners’.

However, conversely, there are significant regional variations in terms of the relative importance given to technical skills, communication skills and analytical skills in planning curricula in the various planning schools globally. The variations are linked to the prevalence of policy/social science approaches, as opposed to physical design. For example planning schools in Asia rate analytical skills as most important, followed by technical skills and then communication skills. In Latin America, technical, rationalist perspectives are then the norm, with skills such as master planning, urban design and econometric modelling being more common than those of participation or negotiation (UN-Habitat 2009: xxvii).

However, ‘planning education has grown exponentially and diversified broadly in the last 100 years. Most schools have reconceptualised planning from a rational modernist perspective and have come to emphasise deliberative and participatory processes that advance civic engagement and promote citizen participation’ (UN-Habitat, 2009:197).

‘Urban planning education in most countries has moved from a focus on physical design towards an increased focus on policy and social science research. Graduates from planning schools focusing on physical design find themselves increasingly marginalized in a situation where planning processes progressively require knowledge of issues related sustainable development, social equity and participatory processes’ (UN-Habitat 2009: xxvi).

Planning education in Nigeria until now has been dominated mainly by social science thinking, a thinking which also influenced the location of planning schools in many universities (Falade, 2003). The Ibadan School of Planning continues to differentiate itself from other planning schools in Nigeria by adopting current methodology and embracing paideia through engaged acclimatization and collaborative rationality.

Paideia is a system of education or learning. Paideia in physical planning would look at the character of cities, communities and virtues, acquisition of knowledge. The aim is true planning knowledge and the end is sustainable, liveable, prosperous and tolerant human settlements.

Adler (1982) defines paideia as ‘... signifying the general learning that should be the possession of all human beings’. Lewis Mumford (1961:56) used the phrase ‘from pedagogy to Paideia’

when discussing university city as the Greek word that means “rearing and education of the ideal member of the polis. It incorporates both practical, subject based schooling and focus upon the socialization of individuals within the aristocratic order of the polis. An ideal member of the polis would possess intellectual, moral and physical refinement”. In Greek paideia is the idea of perfection of excellence (Werner, 1945; Oxford English Dictionary, 2005).

In the rearing (nurturing or making or learning process or the process of becoming a planner) and education of a planner, in addition to the content of planning, the context of planning is very crucial in achieving excellence in practice.

Mumford (1961:168) asserts `this education of the whole man, this paideia as Jaeger has called it to delimit it from a narrower pedagogy, has never been equalled in another community so large`.

Lucas, (1972:8-9) indicates `` The older goal of universities to gather up the surrounding culture in all its breadth and complexity, to organize, systematize, and render it coherent to a group of students was called “paideia.”

Paideia situates planning challenge or problem within the whole context of a person’s and the community’s assets that is the intellectual, physical, spiritual, social, natural, political, environmental capital-person, environment, emotional, spiritual, physical, financial. Paideia signifies general learning that should be the possession of all human beings, a complete pedagogical course of study necessary to produce a well-rounded fully educated citizen (Richard Tarnas, undated).

Fotopoulos (2005) distinguished between paideia as civic schooling and personal training:

- Paideia as civic schooling involves the development of citizens’ self-activity by using their very self-activity as a means of internalising the democratic institutions and the values consistent with them. The aim therefore is to create responsible individuals capable of interrogation, reflectiveness, and deliberation. This process should start from an early age through the creation of educational public spaces and the values implied by the fundamental principles of organisation of society: autonomy and community.
- Paideia as personal training involves the development of the capacity to learn rather than to teach particular things, so that individuals become autonomous, that is, capable

of self-reflective activity and deliberation. A step for learning, discovering and inventing and knowledge is conveyed through reflective activity.

Paideia as civic schooling and personal training is about the development of the planners (and citizens') self-activity, reflective activity and the capacity to learn and acquire knowledge in spaces guided by the fundamental values of planning. Paideia is critical for legitimising new dynamic and new planning frontier in the knowledge economy and spaces both in teaching, learning and practice.

Paideia is the process of educating the planner and the process of planning which in turns educates the planner. Paideia is an ideal embodied in the community (Castle, 1961).

Paideia signifies education in its totality, its wholeness and this encapsulates intellectual, moral and aesthetics. In essence paideia embraces the values of planning namely comfort, beauty, orderliness, equity, health, safety, security and participation. Paideia is an intellectual culture (Lucus, 1972)

Paideia Approach to Knowledge in Planning: ISOP Experience

Paideia approach to knowledge within the content and context of planning helps in reshaping the planning curriculum and produce new frontiers of planning knowledge in a holistic way that embraces the totality of whole person planning. The planning content, context, and process must reflect paideia and incorporate both practical civic engagement and authentic dialogue with the community. This section examines paideia with the content and context of Ibadan school of Planning.

Paideia, as its derivation (from the Greek pais, paidos, the nurturing of a child) suggests, has to do with the proper upbringing of a child. The term implies a holistic education that leads to physical, emotional, spiritual, *and* intellectual maturity over the course of a lifetime. The Paideia Program was introduced as an approach to American education in the early 1980s by Mortimer Adler and the "Paideia Group" in a ground breaking book entitled *The Paideia Proposal: an Educational Manifesto* (Adler 1982). Accordingly, it describes a philosophy of education based on a core curriculum with emphasis on equity combined with rigor. Paideia embodies an educational experience that prepares students to participate fully in a democratic society over the course of their entire lives.

By application the planning education that will affect the society at large must be deeply engaged in politicking within and ambit of citizen engagement and authentic community dialogue in the content, context and process of planning.

Paideia helps therefore in empowering the planners to focus and situate planning within the context of the environment in question of the person's assets (intellectual, physical spiritual, social, natural, political environmental and financial capital). Paideia upholds the notion that planning education should impact knowledge and empower the whole person in attempt to produce the new knowledge, skills and imaginaries that prepare practitioners to inform, influence and integrate new frontiers in planning. There could not be a better forum to discuss moving planning from pedagogy (methodology or planning content) to paideia (planning context, intellectual excellence and practice) than the ISOCARP Forum of Planning Education.

A. Planning content

ISOP Program

The Master of Urban and Regional Planning (MURP) program evolved from the then Master of Planning Science (MPS) program that was run by the Department of Geography, Faculty of the Social Sciences between 1974/75 and 1978/79 sessions (Sanni, 2013). The MPS course had to fold up due to non-recognition of the graduates of the program by the Nigerian Institute of Planners.

In 1981, the University of Ibadan master's program in urban and regional planning emerged as a response to the growing social consciousness and advances in methods of studying the various challenges posed by the environment. Domiciled at first in the Department of Geography, and later as an autonomous entity from the department of geography (Centre for Urban and Regional Planning), ISOP became a full-fledged department of urban and regional planning in March 2004. The program was renamed Master of Urban and Regional Planning (MURP) on advice of the NITP and it started anew in the 1982/83 academic session with 17 students. A new syllabus was formulated with the knowledge and input of the NITP education committee; a visiting professor was appointed and the course was resuscitated to train professional Urban and Regional Planners at the master's degree level.

Today, ISOP continues to distinguish itself in the design aspect as well as other areas such as environment, housing, transportation, indigenous knowledge, computer application and urban

management among others in its curricula. Urban and regional planning is eclectic in scope and this is why this ISOP program is broad-based and interdisciplinary.

ISOP started with one program in 1982, the MURP which was regarded as a terminal professional program while the MSc Housing program started in 2000/01 academic session. ISOP continues to evolve and reassess its programs and by 2013, ISOP has 5 programs namely:

1. Master of Urban and Regional Planning (MURP) professional
2. MSc. Urban and Regional Planning (Professional and academic)
3. MPhil in Urban and Regional Planning (Academic)
4. MPhil/PhD and PhD in Urban and Regional Planning (Academic)
5. MSC Housing (Professional)

ISOP vision is to be the most outstanding School of Urban and Regional Planning in Nigeria in terms of quality of training and research; and the goal is the pursuit of excellence (a paideia principle) in Urban and regional planning. These ideals are reflected in the planning content of ISOP. ISOP continually seeks to ensure that the quality and diversity of teachers, students and graduates meets globally acceptable standards. Gihring (1975) observed the University of Ibadan planning curriculum was rather unique being the only one influenced substantially by economic/regional geographers. The uniqueness or difference of ISOP from other planning schools is reflected in the content and context of planning curricula.

Ibadan Planning School is a graduate school running a two-year Master's programs in Urban and Regional Planning and Housing and accredited by the Nigerian Universities Commission and Town Planners Registration Council (TOPREC). It is recognized that while enough premium should be placed on the aspect of the practical learning process, a rigorous theoretical foundation is very desirable for both studio and field work. The application of computer to planning design and problem solving has been included in the curriculum to enable students to be at breast with contemporary developments in ICT. Core course components include: Planning theory and traditions, Planning methodology, Design and Planning practice, Internship, and Independent research project. Required courses: include broadly computer applications, land surveying, environmental engineering, while electives include: regional planning, housing,

transportation, urban management, environmental resource planning and management. These courses have been expanded to capture the market need. The courses are a balance between design, computer applications-theory-practice; the courses focus on the need of the National (Nigeria); Regional (West Africa/Africa) and Global (Asia/North America/Australia/South America) (though there are no specific courses on global contexts, global references and case studies are used in the teaching and learning process and the faculty is broad . The faculty also comprise of graduates from both national and international backgrounds and exposure. Experienced and planning experts particularly urban and regional planners in academia and practice constitute the faculty (teaching staff). They are complemented by existing expertise built-up over the years in other departments such as geography, economics and sociology.

It can be said with all certainty that the focus of planning education is in the right direction though more still needs be done in the area of policy, land use planning, infrastructure planning, enterprise planning (informal sector); extending the courses to include the African and Global context for example, Planning in different cultures; Globalization; focus on subject areas that are indicative and reflective of the Nigerian context for example informal sector, poverty ,energy, urbanization/urban studies. Land use planning is still critical and relevant to planning education monitoring and evaluation aspects of physical planning; communication course in planning.

Linkages

ISOP established a linkage program with the World Health Organization (WHO) and noted as the first to be designated as a Collaborating Centre for Research and Training in health and physical planning with all its rights and responsibilities in English speaking Africa. Notable among the work carried out by department was a research on food safety using the much less known and appreciated Hazard Analysis and critical control point (HACCP).

ISOP is also a member of the Association of African Planning Schools; and students from the program participated and won awards at the International Urban Design project in Porto Novo, Benin.

B. Planning Context

Globally there are about 550 universities offering urban planning degrees. UN-Habitat (2009: xxvi;193) indicates 342 universities are members of at least one or more of the planning school

association that are members of the Global Planning education Association Network (GPEAN) and about 60% (330 schools) of these are concentrated in 10 countries. The remaining 40% (220 schools) are located in 72 different countries. In total there is at least 13000 academic staff in planning schools worldwide. While developing countries contain more than 80% of the world’s population, they have less than half of the world’s planning schools”.

In Africa there are about 69 planning schools (table 1) and planning education in Africa is often closely tied to the educational systems of former British colonial powers on master planning tradition (UN-Habitat, 2009). While technical and physical planning education approaches dominated for many years, this has changed in recent decades with greater attention being paid to economic development, environmental planning, participatory and collaborative ideas (Orange 2008; Mabin and Todes 2008; Kussima 2008; Nnkya and Lupala 2008).

Ibadan School of Planning is located within the University of Ibadan main campus and usually referred to as the Department of Urban and Regional Planning (DURP). University of Ibadan is the premier university in Nigeria Ibadan established in 1948. Ibadan has a population of 2.8m in 2010 projected to reach 3.7m and 4.2 m in 2020 and 2025 respectively.

Planning Education in Nigeria dates back to 1961 when a sub-professional town planning programme was set up in the technical College, Ibadan, now The Polytechnic, Ibadan. The sub-professional programme was upgraded in 1974 to produce professional town planners which has since 1976 been turning out professionals (Obateru, 2010:105). The Polytechnic, Ibadan became one of two pioneering planning schools in Anglophone West African countries that were purposely set-up to train planners up to the intermediate professional level of RTPI of Great Britain (Falade, 2003:9). Egunjobi (2008) notes the heavy influence of British colonial government on planning in Nigeria. The 1946 Town and Country Planning Ordinance (modeled after British planning) which had become obsolete for the physical planning needs of the 20th century Nigeria came under review in 1988. A new urban and regional planning law was enacted by the Federal government in 1992 referred to as; the Nigerian Urban and Regional Planning decree no. 88 of 1992. The law is the subsisting statute governing physical planning administration in Nigeria.

The Nigerian Institute of Town Planners (NITP) was formed in 1966 with about 35 town planners in attendance while the Town Planners Registration Council (TOPREC) was established in 1988 by Decree no. 3. The council in collaboration with the Institute accredits physical planning schools in Nigeria, vets and approves the curriculum of urban and regional planning studies in Nigeria at all levels of education and training. TOPREC legalizes town planning as a

professional discipline of study in the country. There is also the Association of Town Planning Consultants in Nigeria (ATOPCON-practising planners).

Paideia: Intellectual Engagement and culture

The paideia principle of intellectual engagement and culture is demonstrated by Ibadan School of Planning (ISOP) involvement in the Sustainable Ibadan project, the University of Ibadan master plan, the University gateway project and the new ISOP building.

1. Sustainable Ibadan project: One of the ways by which university of Ibadan has been able to achieve paideia is through the collaboration with the UN-Habitat on the Sustainable Ibadan Project (SIP). SIP was established in 1994 (together with 11 similar projects across the world) by UN-HABITAT as part of the Sustainable Cities Programme and participants included ISOP academic staff. A City Consultative Forum was organized in 1995 and projects on waste management and conversion to organic fertilizers were top priorities for Ibadan and jointly identified aerobic composting technology using windrows as a viable method to collect and recycle waste, generate income, and use compost for urban agriculture were submitted. One of the pioneer community-based projects is the “Ayeye Waste Sorting Centre”. In collaboration with Urban Basic Services (sponsored by UNICEF), the project has been able to generate economic returns and employment for the local economy (Sridhar and Adeoye, 2003).

Problem identification and prioritization were carried out and the community members were trained in waste assessment and how to source separate biodegradable and non-biodegradable wastes. UNDP and UNICEF provided major funding, while the Oyo State Government and other stakeholders, including the University of Ibadan, provided other support through materials and human resources. The initiative was set up to develop practicable solutions to the solid waste problems by converting wastes to fertilizer. By improving environmental health and employment and generating income as well as food security, it also aimed to benefit the community (particularly women and children, who are the most involved in waste collection and disposal and thus the most vulnerable to its hazards). Improving sanitation and training community members on food security, health care and waste management issues were also part of the project.

The community members collected solid wastes from their homes and food waste from the Ayeye-Agbeni food market. Household wastes were sorted into major components (plastics, metal and glass) and then transferred to a sorting centre (where separate cubicles were provided for the segregated waste) at a location designated by the community. Biodegradable wastes were converted into organic fertilizer. A 5-t per day capacity plant was commissioned in November 2002. It was to produce 45-50 bags of 50 kg organic fertilizer per day to be sold to farmers within and outside the community. The project was executed in three phases (in 2001-2002), a quick appraisal survey; construction, mobilization and training; and community participation in the composting process, and field trials of compost utilization on identified farms. At the end the project was handed over to the community.

2. Master plan: ISOP was also privileged to prepare a Master plan for the University of Ibadan. The department was commissioned to review the 1982 plan and prepare a new and updated plan which will incorporate unused Ajibode (University of Ibadan landed property) as extension of the University. The plan was professionally prepared by robust team drawn from the students' core courses and assisted by the lecturers with some key professional from the allied professionals.

University of Ibadan master plan university master plan, the intellectual strength and diversity of ISOP students came to bear on the timely response and efficient handling of the project. ISOP admission requirements differ considerably from other planning institutions in Nigeria. While other planning schools emphasize urban and regional planning as a prerequisite to getting admission into graduate school, University of Ibadan continue to make the selection process to accommodate a wide range of students from other disciplines such as architecture, quantity surveying, estate management, economics, geography, sociology, civil engineering, building engineering, history, land survey, psychology and the like. This diversity of background helped in the master plan project.

When the university commissioned the department to undertake the second phase of the University of Ibadan, ISOP took advantage of the Advance studio design course, a second year compulsory course in the master's programme. The students constituted themselves into working groups (all were involved in the socioeconomic survey of the area and the conscientization of the people in order to avoid the fear that might have assail their mind of the people who were relocated by the university community at a time when the university was established.

3. Gateway design: The university also commissioned ISOP to prepare an alternative designs for the wall fence of the main gate and the design on the second gate.
4. ISOP new building: ISOP was also involved in the new Urban and Regional Planning building in Ajibode (University of Ibadan new campus)(see picture). This project evidently distinguished ISOP from other planning schools in Nigeria and catapulted ISOP into a new frontier in planning knowledge and practice.

What was done practically was to engage the students (figures 1-6) in the design of the building as we did for master plan. Students constituted themselves into professional groups. The civil engineers among them prepared the bill of quantity; the architects did the drawings and the supervision of the work. To ensure that the job was best and properly delivered, the architects further divided themselves into four groups and prepared the alternative plans out of which eventually the best option was chosen. Before the final choice, presentations were made on several occasions. After each presentation, interventions were made by the academic staff and correction was effected. The valuation and the costing were done by the quantity surveyors and estate surveyors respectively. All these were done by ISOP students and funding and necessary materials were provided by the university.

From Pedagogy to Paideia: The ‘Excellectual’ Learning Curve

Planning education continues to be relevant as Nigeria celebrates her 100th birthday in 2014. As a result planners must do due diligence to ensure educating the whole-person planning is reflected in the curricula. A curricula that embraces paideia-emphasises and develops-intellectual culture and rigor, and engagement with the broader community. The integration of paideia-wholeness, intellectual culture, rigor- in planning content and context by ISOP forges a creative way of teaching and learning that moves beyond pedagogy and embodies paideia. The academic pedagogical model was based on lectures rather than problem solving. Planners must develop an intellectual culture of knowledge-Paideia-that is evidenced based, embraces and emphasises wholeness or whole person planning, and promotes an intellectual culture that is informative, influential, integrative and innovative.

Planners require a new dynamic to respond to the changes brought about by what Rau (2012:16) characterized as the “urban speedometer”. It is no longer business as usual for planners. This new dynamic is paideia, a new frontier in planning education and practice. ISOP without any doubt has and continues to integrate the content of planning and the context of planning. ISOP combines the theoretical/methodological aspects of planning (pedagogy) with paideia (planning context, intellectual excellence and practice).

ISOP has developed an intellectual culture in the process of engaging the community, engaging the planner to confront the challenges encountered in the environment in which we live, work and play. Paideia is evidence-based and integrates multiplicity of knowledge (knowledge from various educational backgrounds) with experiential diversity.

In regards to the various projects ISOP program was involved six core components worked effectively to produce the intended effects and produce positive outcomes on the community and the program itself. There was commitment, collaboration, cooperation and communication on the part of the students, academic staff, the university and the community. Holistically, these four C’s were premised on authentic engagement, engaged acclimatization and interdisciplinary nature of the program.

Through engaged acclimatization, a paideia principle, ISOP program was able to map out conceptually and practically their intention, approach, and practice reflectively. “Engaged acclimatization is a synthesis of research ideas and practices that refers to a process of

embodied and reflexive knowledge production occurring through immersive encounters...”(Grimwood et al, 2012:214). Exploration, reflection, care, creativity and interaction characterize these encounters (Stevenson 2006). Engaged acclimatization can help researchers develop a relational perception and intuition that informs preliminary research objectives, design, and procedures; how research is actually carried out; and later stages of analysis, writing, reporting and future project identification (Caine et al, 2009).

Paideia approach to knowledge within the content and context of planning was demonstrated clearly in the ISOP various projects discussed above. The combination of methodology of planning (planning pedagogy) and practice was broadly articulated and integrated to inform planning and influence practice.

Paideia enhances the Intellectual capital of the planner through knowing, understanding and doing (KUD) and this helps to reshape the approach to teaching and learning in planning. With a vibrant students association, the Ibadan planning journal created in 2012 and partnership with the newly created Physical Planning unit of the University of Ibadan, the move beyond pedagogy to paideia by ISOP is evident.

Paideia as understood within the context of this paper therefore refers to intentional and authentic engagement within the intellectual culture that is reflective and translates into praxis. Intentional and authentic engagement is realised through commitment, communication and cooperation in an excellent and intellectual way (‘excollektual’).

By embracing the paideia physical planning education seeks to impart knowledge and empower the whole person planner in attempts to produce new knowledge, skills and imaginaries that prepare practitioners to inform, influence and integrate new frontiers in planning and respond to the hyper-dynamic age.

Planning for sustainable communities: Layout and design approaches

Sanmarie Schlebusch & Elizelle Juaneé Cilliers
North-West University, Unit for Environmental Sciences and Management, Urban and
Regional Planning, Potchefstroom, 2520, South Africa

1. Abstract

The composition and dynamics of the urban environment have become increasingly complex. The planning and development approach of a specific area and its adjacent areas should primarily promote specific lively elements that will effectively enhance liveability, sustain meaningful and continuous community development and subsequently attract and retain more people to that particular place. However, cultural diversity in regions, cities, towns and local communities has emphasised the need to reconsider and redesign, planning and design approaches that aim to harmonize the natural environment and resources of an area with the diverse needs and aspirations of the community.

Resourceful design approaches, strategies and policies employed in the planning of sustainable communities and the redevelopment of existing areas, will ultimately lead to well managed and protected, healthier, safer, greener, economic sustainable and liveable communities. Varied use of activities and facilities such as employment centres, residential neighbourhoods, natural areas, parks, local trails, schools, and public places can lead to a physical connection to create authentic neighbourhoods. Sustainable communities tend to have lower transportation costs, less traffic, are more economic in terms of housing and market demands, decreasing costs in terms of infrastructure, reduced air pollution and the ability to create a safer environment.

This research aims to explore and understand international and local integrated planning and design approaches currently utilised to guide the planning of sustainable communities. Reviewing different international and local layout and design approaches will aid to define and create improved planning approaches for sustainable communities. Place making and planning approaches should closely observe social and environmental complexities of modern society. Public participation therefor plays an essential role in determining the basic needs of the community and must be included as a fundamental building block in the planning process

2. Sustainable communities

Hart (2012) contends that “a sustainable community seeks to maintain and improve the economic, environmental and social characteristics of an area for its members can continue to lead healthy, productive, enjoyable lives”.

The concept sustainability explores the relation among economic development, quality of the environment and social equity.

Policies and strategies for sustainable development should simultaneously promote continuous economic opportunities, enhance environmental fundamentals and focus on the social well-being of the community to ensure an evenly balanced environment. Policies have to advocate impartiality between different generations, races and genders to ensure equal and uncomplicated access to available opportunities and facilities.

Quality of life is a main objective of sustainable development. The principle of planning for human wellbeing is thus of paramount importance and hinges significantly on immediate and visual changes to lifestyle.

The major features of sustainable community development include; ecological protection, density and urban design, infill village centres, local economy, sustainable transport, affordable housing, liveable community, sewage and storm water, water, energy and the three R's: construction waste recycling, environmental sound building materials, provision of in-housing recycling areas (Peck & Dauncey, 2002).

3. Planning for sustainable communities

A sustainable community underwrites objectives that reflect respect for both the natural environment and human nature. In this regard the use of appropriate technology is invaluable. A sustainable community should essentially strive to achieve the following characteristics and goals:

- Place a high value on quality of life. A sustainable community accepts that communities are first and foremost for people and that the primary objective of the planning and development process is to improve the quality of life of its residents, socially, economically, psychologically, and spiritually. It implements policies to achieve quality of life and does so in a fair, open, and democratic manner.
- Respect the natural environment. A sustainable community recognizes its relationship to nature and sees nature's systems and components as essential to its well-being. It provides access to nature through metropolitan parks, open-space zones, and urban gardens. It understands the sensitive interface between the natural and built environment, develops in a way that will support and complement-not interfere with--nature, and avoids ecological disasters.
- Infuse technology with purpose. A sustainable community uses appropriate technology, while ensuring that technology in the built environment is a means to an end, rather than an end unto itself. It emphasizes learning and understanding how existing and new technology can serve and improve communities, not vice versa. It sets clear and measurable goals for what it wants technology to achieve.
- Optimize key resources. A sustainable community takes an inventory of its human, natural, and economic resources and understands their finite quality. It ensures that forests are not overused, people are not underemployed, and the places of the built environment are not stagnant and empty. It reduces waste and reuses resources: it creates conditions in which all these resources can be used to their fullest and best potential, without harming or diminishing them.
- Maintain scale and capacity. A sustainable community recognizes the importance of scale and capacity, with regard to the natural and human environment. It ensures that the environment is not overdeveloped, overbuilt, overused, or overpopulated. It recognizes the signs of tension that indicate when the environment is overstressed and can adjust its demands on the environment, to avoid pollution, natural disaster, and social disintegration. (Geis & Kutzmark, 2006).

The planning and design of sustainable communities are essential. "Everyone has the right to an environment that is not harmful to their health or well-being; and to have the environment protected for the benefit of present and future generations through reasonable legislative and other measures that prevent pollution and ecological degradation promote conservation and secure ecologically sustainable development and use of natural resources while promoting justifiable economic and social development" (United Nations (UN). 1997).

4. Layout and design approaches (Place making)

“You have to turn everything upside down to get it right side up” (Project for public spaces, 2011). This emphasises the bottom-up approach and community-scale of planning. Place-making was introduced in the planning sphere to address community-scale planning with the objective to create qualitative, liveable environments that adhere to the principles of sustainability. Figure 1 highlights and summarizes important elements of place-making.

The place-making-approach can be employed to realise liveability by implementing various functions within one space. This ensues in the transformation of areas from solely being places that people occupy, so called ordinary spaces, into liveable places. In order for this to realize, the main focus should be placed on current public spaces within communities that has potential, and the development of these spaces according to this place-making approach in order to create places in which people can socialize and interact (Cilliers *et al.*, 2012:11).

Hence, an ordinary space within a community is developed through the inclusion of lively elements, whereby a space is transformed into a place with good genius loci. In these lively public spaces that are now created, numerous functions and activities regarding community life will take place, and the people inhabiting this place will possess a feeling of ownership and connectedness according to Cilliers *et al.* (2012:11).

The idea is also to include more than one great place in a neighbourhood for a city or town (or in this case a rural community) to be regarded as a truly lively place (Cilliers *et al.*, 2012:12), thus integrating a variety of functions within one space, as illustrated by Figure 1.

Figure 1: Place making elements

Source: Baltimore City Department of Planning (2010:90)

4.1. *Current place-making theories and principles*

When citizens are effectively engaged in a design process then designers and planners can be their most effective too; facilitating a process that synthesizes local experience and wisdom with design principles and technical expertise. Designers can help people uncover their common interests and work towards practical, creative solutions that build on local character and assets. (McBride, A. 2013) Irrespective of the environmental attributes of an area, the community should be the primary source of information when planning and designing a specific place.

Participation can be seen as an approach to lively planning or as an element needed to create a lively place. The inclusion of the public in creating places is a difficult and complex process because of the diversity of the members it tries to accommodate: The more diverse the group, the more needs that need to be taken into consideration and therefore the more complex the participation process and input will be (Breman *et al*, 2008:17). Even though it is difficult to implement, participation still remains a critical part of planning for sustainable communities and public places and this participation of all residents along with supervision, reviews and awareness are important for effective place making (Loudier & Dubois, 2001:9). According to Cilliers *et al.* (2012:11), this qualitative participation approach is needed to address and successfully implement a bottom-up approach and ensure the planning of functional and usable spaces that can be regarded as lively. To create this type of situation where active participation is present, the community needs to play a bigger role in terms of discussions with authorities, policy formalization, creating solutions.

Equally important is that planning and design approaches should at all times endeavour to harmonize the needs of the community with the natural layout and resources of the environment to ensure an effective and sustainable design.

Continuous monitoring of the implementation and progress of the place-making and design process is imperative. Therefore transparent management and evaluation of the approach should be maintained to ensure that effectual amendments can be made timeously when deemed mandatory.

4.2. *The role of green spaces in place-making*

A community is often identified by the quality of their parks, gardens and open green spaces. This ultimately raises a sense of accomplishment and delight in the people of that community. Green spaces furthermore enhance the environmental appearance of a neighbourhood and contribute to the biodiversity of the eco-system. Table 1 describes the 3 key principles established by the Perth and Kinross Council to achieve the objectives and accomplish their vision of greens-paces.

Principle		Description
Provide for nature		<ul style="list-style-type: none"> • Environmental sustainability • Provide for a range of habitats for wildlife • Link habitats together
Provide for people		<ul style="list-style-type: none"> • Economic and social sustainability • Face the greenspace • Provide access to and within the greenspace • Encourage activity • Provide amenity and interest
Maintain		<ul style="list-style-type: none"> • Physical sustainability • Design and build to last • Good maintenance - funding of up keep is more important than capital • Involving the community and encourage use

Table 1: The 3 key principles of green-spaces

Source: Perth and Kinross Council, 2013

4.3. The status quo of South Africa

South Africa's policy of apartheid that prevailed between 1958 and 1994 has had an enormous impact on the existing layout and design in this country. Policy makers, Urban Designers and Regional Planners are presently confronted with fragmented, spatially segregated and detached urban and rural areas and communities. According to Asmal (cited by Donaldson, 1999) "The victory over the apartheid state in 1994 set policy makers in all spheres of public life the mammoth task of overhauling the social, political, economic and cultural institutions of South Africa to bring them in line with imperatives of a new democratic order."

What complicates the South African settlement patterns further is the difficulty in categorizing settlement types. Due to separate development and apartheid policies, a unique set of settlement categories developed, unlike the familiar urban and rural differentiation. The White Paper on Local Government 1998 (cited by Donaldson, 1999) lists 9 categories:

- Urban core
- Urban fringe
- Small towns
- Dense rural settlements
- "Betterment" settlements
- Informal settlements
- Villages
- Agri-Villages
- Dispersed and scattered settlement

Each of these categories is "complicated by variations in features such as land tenure systems" (Donaldson, 1999)

Sustainable development is undeniably part of the present-day and future layout and design approaches in South Africa. Since 1994, gigantic steps have been taken towards a more sustainable community planning approach. The Government continuously endeavors to devise policies and approaches that will promote sustainable livelihoods inside urban and

rural areas. It is therefore prudent, as for any government, to frequently compare relative policies and approaches thus assessing the efficiency of their own attempts.

The following table illustrates the South African and International approaches regarding primary aims and focusses, different programs implemented and the success with regards to livability.

	South African approach	International approach
Primary aims and focus	<ul style="list-style-type: none"> Improving opportunities and well-being of people in communities by implementing sustainable elements. Improving rural-urban linkages Eradication of poverty Job creation 	<ul style="list-style-type: none"> Mainly focused on creating lively places and reducing the number of people living in poverty.

Table 2: Summary of sustainable community development planning and design approaches internationally and locally.

Source: Own creation (2012)

However the composition and cultural diversity of the people of South Africa is complex and there remains much to do to amend and eradicate the unsustainable circumstances and elements in communities. Only a small portion of the population has a high quality of life and has access to quality services and infrastructure. The inequitable distribution of resources and wealth are the reality of our society and economy.

5. Conclusion of layout and design contribution to sustainable communities

The purpose of layout planning is to provide a framework within which numerous collective and individual investments may be accommodated over time, in a mutually reinforcing and development manor Behrens and Watson (1996:7-12). This implies that the layout plan should indicate a minimum set of spatial interventions rather than attempt to be more comprehensive. Behrens and Watson (1996:13)

Fundamentals that impact an effective layout plan are: land use management systems, the availability of land, the financial status and the accessibility of finances, level of implementation of policies and legislation and political determination.

Planning for sustainable development is directed by a combination of broad planning guidelines and normative planning concerns. General planning guidelines for urban planning include the movement network and transport, the open space system which is made up of the hard open spaces and the soft open spaces, public facilities, public utilities, land subdivision, cross-cutting issues such as: environmental design for safer communities, ecologically sound urban development and fire safety, economic services such as employment generation, urban markets, manufacturing infrastructure and urban engendering services (Guidelines for Human Settlement Planning and Design: 2000: National Department of Housing)

The normative planning concerns include place making, scale, access, opportunity and choice Behrens and Watson (1996:66)

A familiar planning approach for sustainable development is the linking of various planning guidelines and normative planning focusses.

PLANNING FOCUS

LAYOUT PLANNING PRINCIPLE

PLACE MAKING

- Focus on a hierarchical system of hard public places (for example squares, markets) and the main structuring element of urban areas, in order to establish loci for social interaction and community events and create places that shape enduring impressions of the settlement.
- Respond to the cultural context of a site by understanding traditional ways of making local cultural landscape (for

example patterns of planting, road alignments, locations of symbolic buildings or sacred buildings and spaces.) incorporating these into layout plans in order to ensure existing forms of the cultural landscape are mentioned.

- Respond to the cultural context of the site by identifying the implications of natural characteristics (For example topography, vegetation, climate etc.) for layout planning, in order to accentuate uniqueness, and bring the presence of natural landscape visually into settlement.
- Define hard open (for example, squares, road reserves) through the juxtaposition of public buildings, public furniture and tree-planting, in order to create outdoor 'rooms' which provide a sense of enclosure, greater safety through public surveillance, and protection from the natural elements.

SCALE

- Link soft open spaces (for example, public parks, playing fields, etc.) in order to form networks of recreational space that provide opportunities for the creation of continuous walkways and greater levels of urban biodiversity.

ACCESS

- Provide middle and lower order road networks with a continuous functional gradation of road types, in order to reconcile the needs of numerous road functions (for example, social, economic, aesthetic) and road users (pedestrians, street traders, motorists) and accommodate different modes and types of traffic movement (for example, through, stop-start, access seeking)
- Integrate the local road network with surrounding movement system and land use pattern, in order to improve levels of interconnection, extend important routes through the area, and provide opportunities for increased coverage and penetration of public transport operations.
- Prioritise pedestrian movement by providing direct, safe and convenient routes between different land use activities and public transport stops, in order to increase levels of intra-district access for the most vulnerable and very often poorest group of users.
- Design open and flexible middle and lower order road geometries which offer numerous possibilities through connections, in order to enable complex systems of movement to emerge (for example, the mix of through, local and pedestrian movement associated with vibrant 'activity streets') to facilitate unrestricted pedestrian movement, to provide public transport vehicles with direct and convoluted metropolitan movement patterns, land-use distribution and modal split.

OPPORTUNITY

- Expose the public facility system by locating the majority of facilities along main public transport routes, in order to make them as accessible as possible, enable complex patterns of use between different neighbourhoods, and create the

conditions necessary to encourage private commercial and industrial investments.

- Concentrate local through-movement onto continuous connecting 'activity' routes through the routing of public transport services and location of movement generators (for example, public facilities, modal interchanges etc.), in order to create the passing consumer thresholds necessary to support viable small end large-scale commercial activities.
- Provide hard public spaces as points of greatest access (for example, modal interchanges, intersections), in order to create the spatial conditions necessary for formal commercial investment and informal trading opportunities.
- Cluster collective service points around hard public spaces in order to create favourable small-scale manufacturing and trading conditions (by providing the necessary utility services and attracting potential consumers to specific points in space), and in cases where these services perform residential functions as well, enable a single trip to satisfy numerous household needs.

EFFIENCY

- Incorporate public markets (for example, agglomeration services and stalls) at points of greater access, as an element of essential public infrastructure, in order to assist small-scale manufacturers and traders by providing central trading locations and creating agglomerations of small traders capable of competing effectively with larger commercial establishments.
- Cluster public facilities according to their hierarchical and lateral functional relationships (for example, medical referrals, book circulation), in order to facilitate the sharing of resources (for example halls, playing fields, teaching equipment) between facilities, and enable a number of household needs to be satisfied in a single trip.
- Integrate public open space networks with high utility services like major storm water management systems (for example, retention and retarding ponds and solid waste disposal sites, in order to enable these spaces perform numerous functions, public open spaces acting as overflow facilities in the event of severe storms, and storm water storage facilities providing landscaping features.)
- Facilitate efficient service provision and land utilisation by optimising the layout for particular combination of service options provided (for example, avoiding steep or flat road gradients, reducing road length per erf) in order to enhance the affordability of the development through reductions in the unit cost of land acquisition and service provision.

6. Conclusion

Albert Einstein said: "We shall require a substantially new manner of thinking if mankind is to survive"(Geis, & Kutzmark, 2006).

Resourceful design approaches, strategies and policies employed in the planning of sustainable communities and the redevelopment of existing areas, will ultimately lead to well managed and protected, healthier, safer, greener, economic sustainable and liveable communities. When planning and designing layouts for sustainable communities, a new and innovative way of thinking is desirable regarding interrelationships between economic, environmental and social well-being of the community. Quality of life is a main objective of sustainable development. The principle of planning for human wellbeing is thus of paramount importance and hinges significantly on immediate and visual changes to lifestyle.

More recent theories conversely depict that the objective location of people is not directly related to their subjective contentment. The latter can be manipulated by sustainable and lively initiatives that will enhance the quality of life irrespective of income, education, age or gender. Hence policies and strategies should not merely endeavour to eradicate poverty, create jobs or deliver houses, but embrace decisive sustainable and innovative initiatives that will effectively transform an area in a liveable and sustainable community.

Community participation and education will ensure the essential effective management of available resources to sustain this objective. Planning and design approaches should at all times endeavour to harmonize the needs of the community with the natural layout and resources of the environment to ensure an effective and sustainable design.

Adaptive Mechanism of Collaborative Planning for City-region's Large-scale Compound Disasters in Taiwan

Kuang-Hui PENG, National Taipei University of Technology, Taiwan
Yao-Chi KUO, National Taipei University of Technology, Taiwan
Mei-Yin KUAN, National Taipei University of Technology, Taiwan

Taiwan is one of the most vulnerable countries in the world. The paper aims for coping with large-scale compound disasters mainly caused by climate change in which a disaster adaptive mechanism to be taken, and how to use cross-border cooperation in city-region to initiate adaptive mechanism in Taiwan by reviewing the past experiences. Through a literature review, the paper expects to provide adaptive model for spatial planning and disaster prevention planning so as to reduce the impact of large-scale compound disasters and to protect people's lives and properties of city-region in Taiwan. We first redefine the concept of cross-border cooperation and governance. Then we review the present cross-border cooperative strategies to figure out the issues we are facing. Finally, we suggest that at different levels of government should build up an adaptive mechanism of network-integration of cross-border cooperation by a triple-layer cooperative framework in both vertical and horizontal aspects to help the central and local governments to work together effectively as a response to city-region's large-scale compound disaster.

Keywords: adaptive mechanism, cross-border collaborative planning, city-region, large-scale compound disaster

1. Introduction

Climate change is a comprehensive change in the worldwide scale, disaster caused by climate change is now spreading into various fields and issues, crossing the geographical border of cities, regions and countries. They are now being connected with cross-regional and international compound disasters and becoming an interactive issue. The cross-border issue might not be responded and handled by the conventional administrative structures and strategies. Thus, an interactive thinking crossing the present administrative structure and government hierarchy is essential to cope with this unprecedented event.

Frequent typhoon, earthquake and intensive rainfall in Taiwan make it vulnerable when facing heavy disaster particularly caused by the global climate change. Large scale compound disaster like the 921 Earthquake in 1999 and the Marokot Flood in 2009 are the significant evidences of that. Since natural disasters might not be restricted by administrative boundaries that single local authority might not be able to deal with all disaster mitigation, rescuing and recovery so that cooperation between cities is though unavoidable.

The research aims to break through the conventional limit on cross-border cooperation that highly focused on social and economic aspects and toward disaster governance. Besides, an epochal adjustment on administrative boundary have just done in Taiwan that cross-border cooperation thinking might be noticeable at this time. How city-region formed in Taiwan will be helpful in the future? How should they cooperate to deal with emergency? How to build up their partnership? All the issues are worth to be discussed while facing global climate change accompanied with compound disasters. Thus, the study tries to build up an adaptive framework of collaborative planning as cross-border cooperation for disaster mitigation that will hopefully be helpful for Taiwan.

The research first discusses about the concept of cross-border cooperation through literature review and focus on the definition, formation of it. We try to make clear of the concept of cross-border, city-region and disaster governance to realize how the concept "adaptive mechanism of collaborative planning" is applied within the spatial planning. Second,

we focus on comparing cases to figure out the condition of cross-border cooperation strategies for disaster mitigation. We choose the 921 Earthquake and the Marokot Flood of Taiwan and the 311 Tōhoku Earthquake and Tsunami of Japan to analyze the experience and institutional difference among these cases for inspiring future strategies. The research also held an expert focus group to discuss about the issues and strategies of compound disasters in Taiwan to figure out meaningful inspirations. In the final, we propose cross-border cooperation strategies for disaster mitigation with a long term perspectives.

2. Literature Review

2.1 Cross-border Cooperation

OECD (2001) indicates that the governments at different levels are trying to build up a mechanism for public, private, and volunteer sectors to work together as partnership to improve effectiveness, this might be regarded as a global trend. Cross-border cooperation existed in different levels and spatial boundaries so that factors affecting it might be complex and various including professions, political thinking and executor (Sullivan and Skelcber, 2002). Cross-border cooperation emphasizes the character crossing regions, levels and essentials, so this research defines cross-border as a partnership consists across central and local governments, public and private sectors and professional fields. Not only geographic boundary could be crossed, administrative level and department also. This makes actor and department from different level and different place working together to share their resource and functions to resolve their mutual problems.

2.2 City-region

It's a geographic region that contains both urban and adjacent regions that far from a single city and putting an emphasis on the interaction between them. Unlike the conventional way separating cities by administrative boundary, city region focus on "region" instead, meaning that several cities coordinate across boundaries and levels for their mutual interest, it also helps cities embraced in the region to co-exist in peace (Tewdwr-Jones and McNeill, 2000; Keating, 2001; Robson et al, 2006; Welsh Government, 2012; Lin and Li, 2005; Yeh and Wu, 2006; Chen, 2007). The importance of city-region is not only about its operation and management of each government in it but breaking through the constraint of rigid administrative boundary and bureaucrat and emphasizing the territorial governance. This allows bureaucrat from different cities to work together in both vertical and horizontal way. Characters of city-region contain operation in multi-layer of space; emphasizing the efficient use of resource, social inclusion and creativity.

2.3 Large-scale Compound Disaster

The starting point for reducing disaster risk and for promoting a culture of disaster resilience lies in the knowledge of the hazards and the physical, social, economic and environmental vulnerabilities to disasters that most societies face, and of the ways in which natural hazards and urban vulnerabilities are changing in the short and long term, followed by action taken on the basis of knowledge (UN, 2005). We define the large-scale compound disaster is directly or indirectly causing more and other disasters. Disaster events frequently occur more than two in the area with the characteristics of temporality, spatiality, contagion, cumulative, and complexity, which are simultaneously or consecutively happen and related to cross-border cooperation. Taiwan is one of the most vulnerable areas in the world cannot use only one way thinking of disaster impact. We have to prepare for any contingency and set up adaptive mechanism for restoration and recovery.

2.3 Adaptive Mechanism of Collaborative Planning

Adaptive mechanism of collaborative planning is a bottom-up interaction in which the target and consensus are confirmed with each other through cooperation, coordination as a partnership. It refers to disaster governance including pre-disaster preparedness, prevention, mitigation and post-disaster response measures, which focus on building up a systemic

policy framework that operated under a cooperative model of cross-field, cross-administration, cross-sector, cross-region, cross-organization and cross-level involving public and private sectors, NGO and NPO to set up disaster-mitigation partnership to resolve disaster issues together.

3. Case study

3.1 Spatial Planning Cooperative Model in Taiwan

The spatial planning strategies have been proposed in the "Strategic Plan for National Spatial Development" approved by the Executive Yuan in Taiwan in 2010, which emphasized cross-administrative-border cooperative model and develop toward three city-region's areas, seven development regions and six special municipalities directly under the jurisdiction of the central government (including so-called 5 capitals and 1 preparing to be special municipality) as Figure 1 (Lee, 2012). The cooperative planning strategies for each city-region, development region and special municipality depend on the issue and function of the region has. The central government encourages individual administrative unit to resolve cross-border issues by setting up collaborative planning mechanism, which is based on the nature of issues and functions with neighboring local governments for cross-border cooperation.

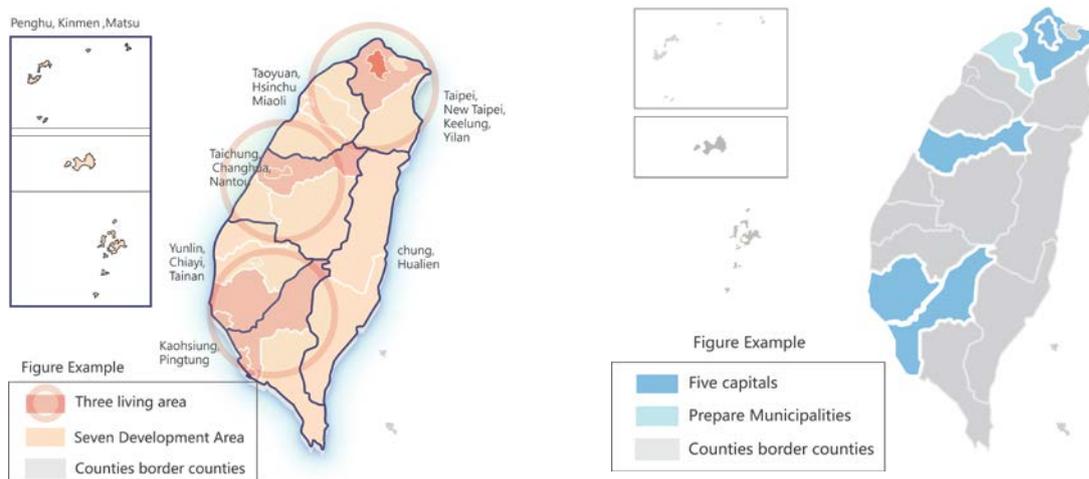

Figure1. Spatial Planning Cooperative Model in Taiwan

Lai and Pai (2011) indicate that after checking the disaster governance and planning strategies in Taiwan, disaster governance is quite disintegrated and isolated between each other, and local general development plan is not legalized which makes local governments with difficulties to implement adaptive strategy to climate change in a way of cross-border cooperation smoothly. However, the cross-border cooperation model could be categorized into several patterns by some of previous experience, which including adjacent-bilateral, adjacent-multi, remote-bilateral and remote-multi cooperation models. The adjacent-bilateral cooperation is the most popular model now, e.g. Tamsui River Basin Governance Committee was established to deal with the Tamsui River basin where covers jurisdictions of Taipei and New Taipei cities. Northern Taiwan Development Committee could be a case of adjacent-multi cooperation including several local authorities as shown on the right of Figure 2. Lin (2012) mentioned that Taipei city supports Kinmen County for building water supply plant and Kaohsiung City supports Penghu County for building incineration as indicated on the left of Figure 2, which could be regarded as a remote-bilateral cooperation model. The remote-multi cooperation model could be seen in the case of post-disaster reconstruction, e.g. municipalities and NGOs from anywhere gathered and cooperated to support restoration and recovery.

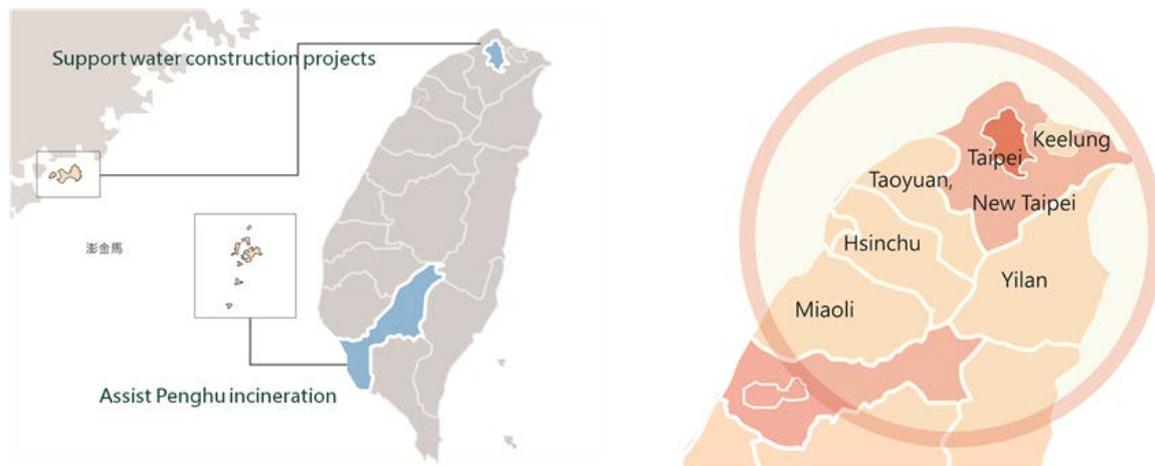

Figure 2. Cross-border Cooperation Model Categorized by Geographic Relations

3.2 Cross-border Cooperation Cases

3.2.1 The 921 Earthquake

The 921 Earthquake was measuring a 7.3 on the Richter scale earthquake which occurred on September 21, 1999 in Nantou County, Taiwan. The earthquake and its aftershocks killed 2,455 people and caused about NT\$360 billion (US\$11.25 billion) in a total economic loss, it was the second-deadliest earthquake in Taiwan's recorded history. Over 11,305 people got injured and 50,652 houses completely destroyed, and 53,615 half-crumbled; and 102 bridges and 37 highways destroyed across the affected areas, central Taiwan got most badly shocked and it was the most horrible disaster after World War II in Taiwan (Peng and Kuo, 2008).

During the post-921 Earthquake period, several policy issue could be pointed out due to the insufficient responsive strategy, including command system was in panic as a reason of unclear division of labor between central and local government; emergency warning system broke down after the earthquake works unsuccessfully; unfair resource distribution. Also, Yang (2009a) tends to attribute all these problems to a lack of rescue experience and unavailable information about disaster area. Hsiao (2011) takes the post-921 recovery as an example, indicates that the power released from the central government made room for the local government and grassroots citizen group get empowered and cooperate well, like up with external NGOs and central government and so carry out the recovery successfully.

A temporary organization was formed after the 921 Earthquake as a result of absence of planning and a clear framework for responsive rescue strategy. Information could not be well transmitted as a result of disconnection between different departments coping with disaster affairs and were not well trained. A more proper rescue and recovery works were not implemented until the arrival of foreign rescue groups.

3.2.2 The Marokot Flood

It's also called the 88 Flood, caused by Typhoon Maorakot during 6th-10th Aug. 2009, giving rise to severe mudslide in several places in the central and southern Taiwan. The entire village, Xiaolin in the rural township of Jiaxian, Kaohsiung County was nearly razed to the ground by the mudslide and only one building still stood and is regarded as the most severe cases in the Maorakot Flood. In this case, emergency measure enforced by the government are not quite appropriate, the problems including real situation and scale of disaster were not clearly seized; principle for evacuation and refuge were not explicit enough; the damage was underestimated that the capacity of refuge was totally insufficient; lack of official direction and planning that the situation of distributing material was in a mess (Yang, 2009b; Control Yuan, 2010; Lee & Yeh, 2010).

However, the civil cooperative relation has developed from the post-921 experience since then and showed good interaction and cross-border cooperation. Feng & Huang (2010) indicate that the civil NPO established “Marokot Flood Service Network” right after the disaster and got involved in the rescue and recovery affairs, acted as a platform of coordinating civil sector and government. Chen (2011) also points out that for the purpose of reinforcing the reconstruction and rescue ability, several measures were carried out after the Marokot Flood including:

- (1) Legalizing the division of labor for each department under the cross-border cooperation framework;
- (2) Providing disaster area service and reconstruction work through cross-border cooperation, government, NGO and enterprise are included;
- (3) Integrating the reconstruction work under the base of special ordinance, building up the reconstruction committee to provide special budget and conduct these affairs.

3.2.3 The 2011 Tōhoku Earthquake and Tsunami

The 2011 Tōhoku Earthquake and Tsunami occurred March 11, 2011 in Japan, was recorded magnitude 9.03 (Mw) with the epicentre approximately 70 km east of the Oshika Peninsula of Tōhoku and the hypocenter at an underwater depth of approximately 30 km. Damage caused by it was far more greater than Great Hanshin earthquake, 1995. Prefecture including Miyagi, Iwate and Fukushima was shocked mainly and the damaged area across 36,000m². Building crushed in the 2011 Tōhoku Earthquake was approximately five times, and seven time the amount of death, sixty times the amount of missing than in the 921 Earthquake (Ke, 2012).

Japanese government built up emergency operations center 4mins later right after the earthquake, missions given to this center including calming the nationals down; collecting information about disaster; sending the army to disaster area; confirming the route of human resource and goods distribution. Regarding the goods distribution, the damage caused by the earthquake in each district was estimated respectively first, the command and order for goods and material then passed to each group, enterprise and asking for support after the estimated situation was reported to the center. However, since those goods and material were sent to the center first so it wasted time and caused delay on transportation. It did not become smooth until professional logistics concept was taken into the system with the help of private logistic company (NCDR, 2011); Civil sector also mobilized over 30 thousand, various kinds of volunteer for providing medical and reconstruction service, a national network was formed by more than 140 private groups to stretch their service into remote area. Telecommunication companies and convenient stores provide free wireless service and food to support the basic need of refugee (Tang, 2010).

NCDR(2011) points out that several measures that carried out within the 2011 Tōhoku Earthquake and Tsunami are quite impressive and worth to learn including early warning system in emergency save time for evacuation; completely built up tsunami warning system works perfectly; nationwide disaster prevention drills; good distribution in disaster area through professional logistics system; real time monitoring camera system; establishment of platform for public participation; emergency placement with cross-border cooperation; clear convention about reporting disaster news for media.

4. Cross-border Cooperative Strategies

To realize the technical method dealing with the disaster in the real world, an expert focus group discussion was held on 10th Dec. 2012. Experts from government, academic and enterprise who has had involved in disaster mitigation, prevention, rescue and recovery affairs were invited. After this discussion, we concluded some viewpoints and meaningful inspiration. The group discussion mainly focuses on issues existed in disaster governance process and could be listed as: first, the interior and foreign experience and suggestion on disaster governance and cross-border cooperation; second, review the issues about cross-border cooperative strategy for disaster governance; third, establishment of public and

private partnership; fourth, crucial factors affecting disaster rescue; fifth, strategy and planning for disaster governance in the future.

4.1 Necessity of Cross-border Disaster Governance

We have gone through the painful experience of the 921 Earthquake and the Marokot Flood or even the 2011 Tohoku Earthquake that a perfect and effective mechanism of disaster governance is proved essential. Consider the characteristic of disaster that occurs crossing administrative border, as an adaptation strategy for compounded disaster, the labor of division under the present administrative system and administrative border must be reviewed and revised. A cross-regional or even cross-borderland institution for disaster governance might be essential.

The necessity of disaster governance strategies was proposed by the expert focus group. They are: facing with the hazard of large-scale compound disaster, we can derive a reasonable assumption under the scale-economy theory that the risk might be much lower as many as the partners are involved, the cost either. The benefit will get much bigger as a consequence that various partners with various abilities may cover each other and form a strong network with high responsive ability as Figure 3. Since that cross-border cooperation is a long-term issue with high complexity and difficulty and condition of science technology, society, economy etc. Change rapidly in the real world that the model for cross-border cooperation we had defined will also changes according to the conditions, however, we could not deny the necessity and should be aware of how cross-border cooperation can help refugee and resource distribution and information flow when facing emergency.

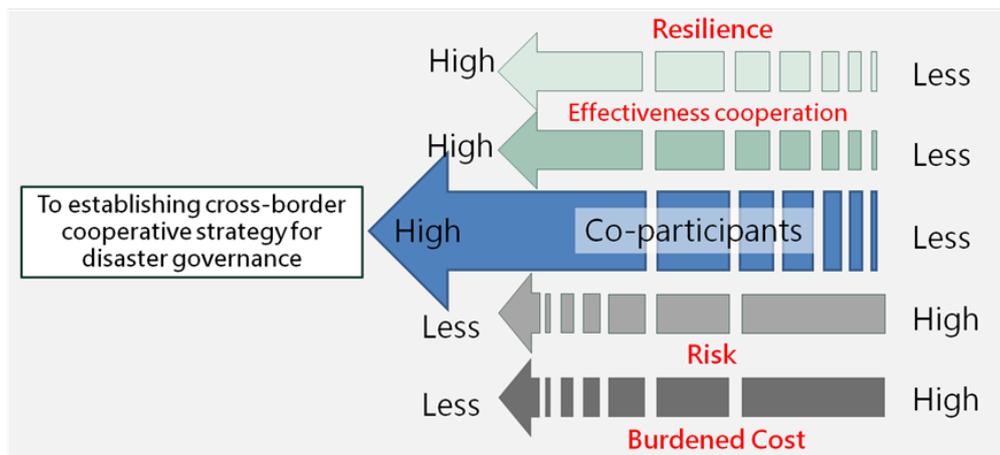

Figure3. Necessity of Establishing Cross-border Cooperative Strategy for Disaster Governance

4.2 Cross-Border Cooperative Strategy

- (1) Administrative integration: An integrative platform is essential. However, the division of labor is not clear enough for departments to cooperate with each other, an interior integration is needed. As a matter of fact, cooperation between departments under the present framework is quite weak and lack of connection. Staffs that are not well-trained and activated could also be the barrier of interior and cross-department integration. In short, the followings are essential strategies: ① an interior integration; ② a cross department integrated platform; ③ professional training program form personnel; ④ interchange and interaction of personnel between departments.
- (2) Cooperation crossing sector and geographic space: Public sector has much more abundant resource than private sector be also highly constrained by legal regulation. Private sector gets more flexibility and vitality that they could activate the disaster governance network if got involved with the cross-border cooperation. Public sector itself should also reconsider the present condition of division of labor between central and local. Regarding the public construction and resource management or also public

service could all be provided through cross-border cooperation. That is to say that the public sector should act as a coordinator to provide way for different actors to work together and take responsibility jointly, exploring their partnership network from local through central, across the border and boundary, get all public, private and academic sector in to share their resource and function together.

- (3) Planning cross-border cooperative strategy according to the local condition: Couple of issues should be dealing with before enforcing cross-border cooperative strategy, for example, as emphasized before that the issue that exists under the present framework of three metropolitans is definitely different from the offshore islands. The structure of organization and strategy should thus be different according to local condition. The concept cross-border cooperation could also be extended into cross-marine, cross-national boundary etc. Consider the specificity of offshore island such like Kinmen or Penghu, the best partner for them to build up cross-border cooperative relation might be cities geographically adjacent in mainland China. The achievement of encouraging the interaction between them and pursuing support from main city like Taipei or Kaohsiung to offshore islands might be expectable.
- (4) Emergency route and critical infrastructure: Facing large-scale compound disaster, issues including the refugee planning and emergency infrastructure to provide lifeline service, how neighbor area provide help to disaster area might be important. Government should plan a refugee ring to provide the above needs according to the character of each area and fundamental database of national land use and disaster. What's more, contract for providing emergency good and delivery to disaster area should also be concerned in advance with cross-border cooperative thinking.
- (5) Education and training to improve disaster awareness: Gap in the awareness and understanding about disaster exists between citizen and government. Explanation meetings are frequently held but not really work. It's important to connect the real life with disaster training to make people possible to realize the present issue and condition regarding disaster governance and prevention. Community-based or township-based level disaster training program could be explored into national scale and combined with mega event.
- (6) Cross-border cooperation promoted with community participation: Since community is the basic unit of society and thus plays an important role on disaster prevention. Hasemi (2012) considers that disaster governance consists of self-help, mutual-help and co-help refers to people help themselves, people help with each other in community and relief service provided by public sector as Figure 4. The concept "community of disaster governance" must be promoted with the assistance of technology to empower the power of community itself.

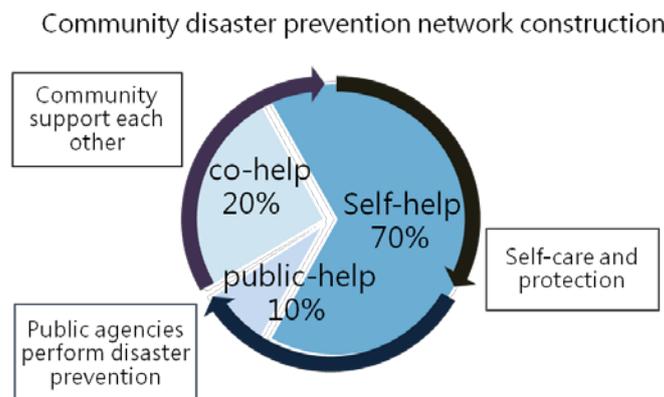

Figure4. Community Network for Cross-border Cooperative Disaster Governance

Resource: Hasemi (2012).

Besides, it's important to consider how to get people involved. However, in the case of demand on refugee, urban area is much bigger and the space is relatively confined. Due to these condition that the cross-border cooperation combined with community

participation must be taken much seriously. As some concrete strategies, we might combine disaster prevention training with festival in urban area to improve the participation rate.

- (7) Post disaster planning and governance in cross-border cooperation: In the case of large-scale disaster, government must first consider the cross-regional refugee and sheltering, second, source of goods and goods distribution planning, logistics planning are also important as well. However, issues come out during the post-disaster period might be much tougher such from refuse disposal and waste discharge to social coordination of reconstruction and recovery. All these issues must be considered under the cross-border cooperative thinking generally in advance so that the responsive strategy could be carried out instantly.
- (8) Integration and popularization of disaster information: Information about disaster prevention released from government could not be effectively used by people is now a crucial issue. For example, disaster map and disaster prevention planning map is unreadable for normal people that they couldn't take refugee smoothly in emergency. Enforcing the popularization of disaster information is very important. Strategies includes getting people well trained with disaster emergency survival skill and familiar with their community environment and realize the emergency information rapidly. Besides, government should unify and integrate disaster index system and sign system to make it easier to realize.

4.3 Integrated Network of Cross-border Cooperation

Confront with the hazard of large-scale compound disaster, it's essential to respond with cross-border cooperation method and build up a both vertical and horizontal integrated disaster governance network:

- (1) First layer of horizontal cross-border cooperation: Departments including water resource, construction, social affairs, fire, police in the local government should build up a fundamental network to cope with the disaster governance affairs in local level (shown as the thick solid line in Figure 5).
- (2) Second layer of horizontal cross-border cooperation: The very fundamental first layer of horizontal network in local level, namely each local government should cooperate and work together to form a second layer of cross-border cooperation network (shown as the dotted thick line in Fig.5). The network could be formed under the consideration of their character and resource exchange rather than their geographic relations. It's a layer greater than the local level but subordinate to the central level with vital interaction.
- (3) Third layer of cross-border cooperation: Besides the first and second layers of horizontal integrated network stated above, a third layer of vertical integrated network is also essential which connects the central network with the first and second layer vertically. Since departments in the local government are subordinate to department in the central that them must communicate and cooperate with each other more effectively by this kind of vertical integration. However, some departments in the central have no one directly under them in the local such as the Central Weather Bureau, since that these kind of departments have higher independency and profession that they could consider interact with local through the way like temporary personnel exchange program or co-training program to build up an effective platform for dealing disaster affairs.

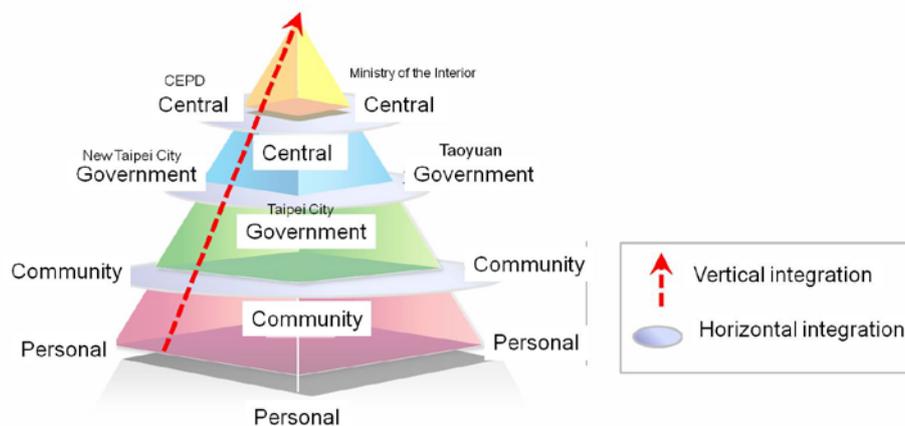

Figure5. Vertical and Horizontal Integrated Network for Cross-border Cooperation

5. Conclusion

Since Taiwan has quite vulnerable geographic condition that the responsibility of disaster governance and mitigation are quite heavy for the government to burden alone. Thus, building up the partnership with private sector might be one of the best ways to resolve this issue. Drafting all possible strategies together under the cross-border cooperation framework is important to cope with the climate change and global warming issue.

Regarding disaster governance strategies, cross-border cooperation must be more positive and active to change the conventional thinking of cooperation between adjacent cities and areas. Pre-disaster governance strategy is as important as post-disaster governance strategy, preventing and mitigating disaster could be much helpful than taking afterward rescuing and adapting. Local government and community might be a crucial role on establishing the disaster governance partnership, however, appropriate training and pipe for communication is essential and will be possible to make the defects of present administrative and institutional system. However, the central must also respect the independency and autonomy of the local regarding cross-border cooperation affairs. Local should also make good use of this chance to get integrated with each other to acquire and share more resource and chance together to empower themselves to handle hazardous compound disaster.

From 'Place Apart' to Place Making: The Reinvention and Transformation of James Cook University, Townsville

Alan CARPENTER

Project Director of Discovery Rise, James Cook University, Australia

and

Caroline STALKER

Director, Architectus, Australia

Author ID: 108

Universities are facing existential challenges through reductions in funding, international competition and the emerging Massive Open Online Courses (MOOC). New wireless technologies proliferate; new pedagogies are being created for the digital natives such that the form of the physical campus is under a profound review. This paper describes one such response to these challenges.

James Cook University in Townsville was originally conceived in the 1960s as a 'place apart', separate from the City - a hallowed halls of splendid monumental buildings set in landscape designed for quiet contemplation rather than active engagement. In the 21st century JCU is a progressive institution of excellence in Tropical health and Marine science, looking to engage strongly with its city, community and the tropical regions. The campus as it has been does not support the ambitions of the institution, nor does it respond to the challenges of the future and the University is now seeking to recast itself as a vibrant mixed community, a hub of interaction and knowledge - a knowledge community within a city. This overlaying of a mixed community on the institution entails a complete transformation of the physical setting. This transformation is called Discovery Rise.

JCU is in a unique position to be able to create new models of sustainable development for the tropics, and is working with the City to deliver a community and environment which builds strongly on the connections between the institution, its partners and the city. In addition JCU's progress is offering new models of Tropical Urbanism to the city, the approach is to build on the opportunities of climate and place to create an interactive urbanism that is open, porous, shaded and cool; suited to its climate and place, and leverage strongly from the relationships between existing university buildings and a new residential community.

Key notions in design include creating a built environment in which a knowledge ecology and can flourish and evolve and a 'structured serendipity' in which innovation arises through chance encounters across disciplines, institutions and commerce.

The paper will describe the history, drivers and design of Discovery Rise as a response to the challenges, highlighting how local climate, place values and the institution itself has formed the core of the identity of the project whilst the setting is 'urbanised'.

Introduction

JCU is a multi-campus university with its principal campuses in Townsville, Cairns and Singapore and is positioning itself as an important tropical university with its strategic intent being:

A brighter future for life in the tropics, world-wide through graduates and discoveries that make a difference.

JCU's Townsville Campus bears the legacy of the 1964 master plan, which reflected campus planning principles of its day. Campus as institution was the formative typology, wherein the campus was disengaged from 'everyday distractions', which together with a 'back to nature' ethos

was regarded as beneficial to academic success and social maturity. This was a time when space was abundant and the private motor vehicle ensured access and convenience.

The 1964 plan of course reflects thinking and funding arrangements of the day. There was an expectation that tertiary education would be almost completely publicly funded with periodic grant funding for new buildings. For JCU Townsville this was the experience for almost two decades with each new building allocated its separate space sequentially around the ring road.

However since the Dawkins reform policies in 1987, Australian higher education has undergone a fundamental transformation from a traditional public service provider to a market-driven commercial enterprise.

The Dawkins reforms in 1987 provided for larger and more business-like universities with mixed public/private funding. In this era competitive advantage is gained by entrepreneurship, management skill and business acumen. Then the 2003 Nelson reforms encourage advantaged through mission diversity, specialisation and research quality.

The Bradley "Review of Australian Higher Education" in 2008 completed the process by recommending further deregulation of the sector by introducing a "demand-driven entitlement system for domestic higher education students, in which recognised providers are free to enrol as many eligible students as they wish in eligible higher education courses and receive corresponding government subsidies for those students .

For a regional University, this creates a significant challenge. We can no longer rely on allocations of funded student places, and caps on other institutions to keep our numbers up. We must be competitive with city universities, which aside from prestige and course offerings means offering amenity and a vibrant social environment.

In addition Universities are facing existential challenges through international competition and the emerging Massive Open Online Courses (MOOC). New wireless technologies proliferate; new pedagogies are being created for the digital natives such that the form of the physical campus is under a profound review.

The Campus

Many Australian university campuses, especially those in suburban areas established after WW2, have created an Australian version of the monastic model, being very institutional in appearance and atmosphere, often planned as bush campuses on a 'pavilions in the park' model. These arrangements positively encourage the development of disciplinary silos and separation from the community.

JCU's original campus design is an example of high modernist ideals from the 1950s and 60s par excellence. In the 1920s LeCorbusier's Ville Contemporaine had envisaged an 'ideal city' of free-standing buildings in park-like settings with widely spaced freeways. This model was widely embraced as a potent symbol of post-war modernity and democracy. It strongly informed the post war reconstruction of bomb-damaged European cities, and the now infamous housing 'projects' of lower Manhattan. Oscar Niemeyer took this model to a new level in an entire modernist city, Brasilia, built between 1956 and 1960, where large sculptural forms were set in grand landscape axes. The school of thinking that had produced Oscar Niemeyer also influenced James Birrell, the campus planner/architect for JCU in the 1960s. Brasilia and JCU share in common key monumental buildings set in strong landscape axes as important organisers.

¹ Out Place in the Sun – a Brief history of JCU, Dr Peter Bell, 2010

² Commonwealth of Australia, Review of Australian Higher Education, (Bradley Review) 2008 pxxiii

In the context of contemporary universities, these arrangements positively encourage the development of disciplinary silos and separation from the community. The 'hallowed halls' of city edge campuses is no longer an appropriate model for the delivery of world class tertiary education – it needs to be delivered in a dynamic environment where collaboration and interaction are the foundation of innovation and discovery. This means creating a more lively and dynamic environment.

For JCU the physical context is changing, as the city has grown and is now very much on the doorstep of the campus.

THE OPPORTUNITY

Whilst many universities in Australia are developing their land to deliver community connected urban campuses, James Cook University in Townsville is better positioned than most to achieve this due to its land resource and its proximity to urban Townsville and the Townsville Hospital. Add to this the potent unifying theme of tropical research and innovation towards a better life in the tropics worldwide and it is clear JCU has an outstanding opportunity for the development of an interconnected knowledge community.

Many of the building blocks for such a knowledge community already exist at James Cook University in Townsville, with the major weakness being the 'quality of place' and infrastructure required to sustain and grow a knowledge community. Discovery Rise also holds out the opportunity for the creation of a university community of staff and students, alumni, retired and former staff, business partners and friends of the University in a knowledge centred community with a network of collaboration, support and influence. Add to this people engaged in companion organisations including The Townsville Hospital, CSIRO, AIMS (the Australian Institute of Marine Science) and private research and development ventures and we have a diverse and effective knowledge community.

Timing appears to be apposite as well with Asian Century gathering momentum, with a consequent long boom forecast for this minerals rich province of North Queensland, strong economic and population growth will surely follow. JCU is positioning itself regionally as a great tropical university with its campuses in Singapore and Cairns prospering and growing links to South East Asia and Melanesia. Great universities require great campuses and the Discovery Rise project can deliver such an outcome for JCU Townsville.

Townsville itself is on a strong growth trajectory having the most diverse economy of any regional city in Australia and the status of Queensland's second capital. The Douglas Knowledge Community centered on the JCU and The Townsville Hospital has been identified as an "economic turbocharger in the Townsville Futures Plan with Discovery Rise being the enabler for this.

There is a growing realisation that the best enabler of a sustainable future is to have people living in close proximity to their places of work, leisure and commerce. Discovery Rise can be a leader in this regard by creating a residential community with its own economic agents at its core, with its own employment, recreation and retail opportunities; a situation which is unusual in the developed world and in Australia and unique for Townsville.

James Cook University Townsville – Knowledge Community the Urban Plan and Design Work

To become a thriving Knowledge Community clearly the campus of JCU needs to be 'retrofitted' with spaces, places and activities that encourage interaction and exchange. This means a more mixed and compact arrangement of activities and outdoor spaces that invite occupation.

The Urban Plan for Discovery Rise was prepared in close collaboration with The Hornery Institute, who are social and community planners. Their role was to help JCU to understand 'who would come' and what needed to be provided to get them there. The Urban Plan is a direct result of an integrated process of community-plan thinking and design thinking, to provide JCU with both a physical and a social framework for its reinvented campus.

The Hornery Institute's (THI) research told us that there would be different 'audiences' for Discovery Rise, who would want to be 'embedded, adjacent or afar' in relation to the University core facilities. They provided housing numbers, types and additional facilities to create a sustainable community as a design brief for the physical urban planning. Their research also told us that there were drivers for a significant town centre between JCU and the hospital, student/postgraduate village, a residential village hub, and a residential community anchored by a school within walking distance of the university core. THI's qualitative research also told us that students, post grads and residents wanted a range of facilities, a lively social environment, great public spaces, places to walk, and markets.

The planning and design challenge then was to interweave and integrate all of this new activity and life into the existing campus setting, and to create a new whole rather than 'the housing next to the uni'.

Site Structuring

The design framework for Discovery Rise emphasizes a strong urban structure to integrate, connect and mix new activities, to providing strong 'bones' to pattern change over the next 20 years or more. It builds on the Birrell legacy but 'retrofits it' as a contemporary mixed use community.

For the master plan we developed a spatial structuring defined by the key 'connectors' in the town, which build upon the original Birrell axes. These connectors link the core to the edge, creating the integration and blurring of the edges between the JCU campus and its town, create the underlying structure for land use, public space, building edges, hubs, pedestrian paths and roads.

Overlaid on the landscape connectors are:

- The public space network – incorporating the central green spine, and east-west linkages comprising streets, squares and lanes
- Ground level activation (e.g. retail)– to create lively places along the connectors
- Density - the highest residential densities are focused along these connectors
- Pedestrian and bicycle paths which converge on the connectors as well as provide permeability throughout the town
- The vehicular network supports the connectors as well as permeability throughout the town
- This gave us a street and public space structure where east-west links are characterized by cool, shady, more intimately scaled streets, courtyards and squares, and north-south connectors build on the existing loop road and central green campus spine to create larger scale spaces of movement and gathering.

The emphasis on creating a lively, continuously shady and inviting public realm on the campus is extremely important; it will provide the spaces for interaction and collaboration that a contemporary university needs, as well as the basic 'tissue' of a more compact, walkable campus.

(Dry) Tropical Urbanism

To re-cast itself as a thriving Knowledge Community it needs to be very rich in the type of spaces it currently lacks; lively, engaging public spaces of informal interaction. Air-conditioned lifestyles are very habit forming, and to successfully invite people into the public realm on this campus, even in those gorgeous winter months, needs some compelling places underpinned by some very strong planning. At present there are clues on campus for the kinds of places and spaces that invite external occupation; the earlier Birrell buildings which have very deep shaded terraces and (irrigated) shaded gardens are very successful .

In a dry tropics environment such as Townsville, it can be a challenge to get people out of their cars and turn off the air conditioning! Again it was important to be clear about the qualities of the overall environment that would encourage walking and reliance on passive cooling in buildings, and a focus on landscape, shade and breezes at the urban scale was considered vital in achieving this. This translated to an urbanism with the following characteristics:

The Fragmented/Perforated Perimeter Block;

The perimeter block is the optimal urban form for defining urban spaces and creating activity along edges. However walled urbanism in Townsville creates heat islands. Fragmenting the perimeter block to facilitate air movement and the planting of large shade trees will avoid the creation of heat islands.

Shady Edges;

Buildings edges can provide important refuges from hot sun particularly as colonnades and shaded building recesses.

A Combination of Built and Planted Shade;

Shade plays an important role in creating an inviting urban environment in Townsville. Due to the low rainfall regime for many months of the year we adopted a strategy to combine built with planted shade to create a shady network of streets and squares.

Density, Landscape and Orientation;

It's important to locate denser housing forms where there is the possibility to create openness for penetration of cooling breezes into the dwelling, provide appropriate solar orientation, and offer outlook over a benign environment. Without being too dogmatic about orientation we found that this configuration worked particularly well with the idea of shady and green east-west connecting streets.

Discovery Central and The Ideas Market

Discovery Central, located between the Hospital and the heart of JCU, is the perfect location for the first centre of Discovery Rise to develop; and the first building of this new centre is now under construction. Discovery Central is envisaged as a mixed use hub incorporating research and teaching facilities, housing and accommodation, and localized retail. The master plan for Discovery Central revolves around a new main street – Mt Stuart St – which picks up on the original Birrell axis and lines up with the bluff of Mt Stuart. Mt Stuart St will be a shady low speed highly pedestrianised environment with trees in the street reserved to cool the tarmac and interactive street frontages along its length.

The anchor public space for Discovery Central is the JCU Ideas Market. The JCU Ideas Market is a concept that is at the heart of the creation of a Knowledge Community: it is a place of intellectual, social and commercial exchange, bringing together JCU and the Townsville community. The concept has at its centre a strong idea, shared by JCU stakeholders, to create a new beating heart for its campus, and in doing so invite all the endless possibilities of exchange into its place. The Ideas Market is envisaged as a kind of 'Souk' of activities – markets, shops, living, Uni activities around the edge of a significant shaded, cool and welcoming public space.

The Clinical Practices Building is the first building of the town centre containing Dentistry, Physio and other clinical uses including teach areas, as well as a small scale fresh food supermarket and small scale retail. It is designed to address and shelter the street, and create an interactive lively street on Mt Stuart St.

Discovery Village

The design of Discovery Village – the primary residential village – needs to offer new models for denser housing in Townsville; this work is being monitored by Townsville City Council who is keen to see local exemplars develop of denser housing forms suited to the climate and place.

The principles for creating climatically suitable housing in Townsville are well known by local architects and those living in homes built before air-conditioning; we didn't set out to re-invent the wheel but to build on good knowledge. Local architects and pre 1960s housing utilized devices such as: shallow (one room deep) plans and fragmentation of the overall form to facilitate cross ventilation; 360degree shading of walls (including with vegetation); use of thermal mass to create thermally stable 'tanks' of cool air (e.g. under the house, shaded courtyards); and optimum solar orientation. What has been lacking is a similar 'accepted wisdom' or exemplars about denser housing forms or how these would come together in an 'urbanism'.

Our earlier work had helped us to establish urban design principles of cool narrow east-west streets for people, wider shaded north south streets for cars, fragmented perimeter blocks, and 'cool tanks', but in the Discovery Village project we needed to consider how the two scales of the urban and the individual building might mesh to create an urbanism. The idea of a 3-dimensional lattice seemed to capture the idea of an environment that was close knit, but permeable to air movement, trees and people, with cool shaded pockets. We first tested these conceptually using balsa models then developed these as three denser housing forms; the Courtyard House (on 320m²), the To-To (Townsville Townhouse) and the Lattice Apartment.

The Courtyard House takes a simple shallow plan, split by a breezeway, to capture a cool courtyard at its heart. The To-To uses either a stepped plan to capture light and breezes, or an internal covered courtyard to move cooler air through the dwelling. The Casbah Apartments use a fragmented plan and a stepped section to create light and air movement around central courtyards, whilst providing a strong inhabited edge overlooking the street and the green corridor at the heart of the precinct.

IMPLEMENTATION

The scope and ambition of Discovery Rise is such that primary development will take place over 10 to 20 years, but in another sense will never be 'finished' as success will be embodied in a flexible and open community an urban landscape, continuously morphing as new enterprises respond to new opportunities.

Rather, the primary role of implementation is to establish what Jeb Brugmann has termed a practice regime. In his *Welcome to the Urban Revolution – How Cities are changing the world*, he has that successful cities and urban precincts are characterised by a „practice regime with three necessary components

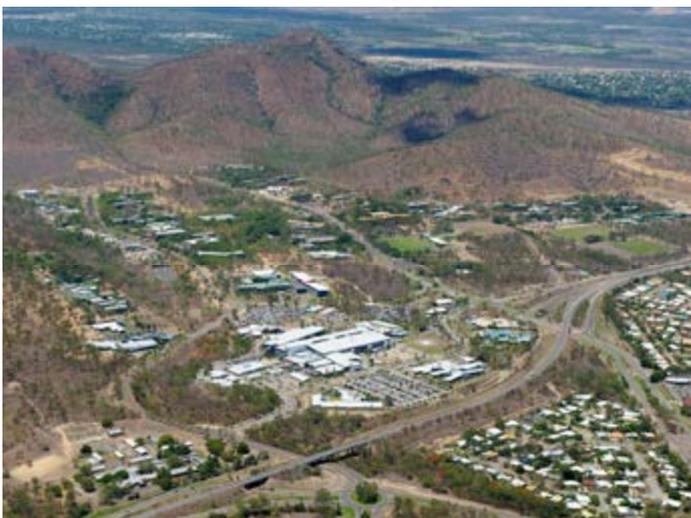

- **Strategic Alliance:** A stable alliance of organisations with power and resources to align interests and to form or reform policy and the regulatory and administrative apparatus in pursuit of a common strategic purpose. Towards this end JCU is engaging with all levels of government with a view to building alliances. This intent is illustrated by a recent MOU with the Townsville Hospital towards an alliance for collaborative development in Townsville towards the creation of a Tropical Knowledge and Health Services Precinct.
- **Strategic Institutions:** A set of dedicated institutions with the technical talent, financial and entrepreneurial capability and administrative power to advance the knowledge community and its new practices of urbanism. Towards this end JCU is establishing a separate entity whose charter it is to implement and realise the Discovery Rise Vision.
- **Practices of Urbanism:** An explicit and detailed body of urbanist practices which translate the vision into a fit for purpose built environment and social and cultural milieu. Towards this end JCU has developed its physical planning from initially process driven formulaic work to highly sophisticated plans with university community development and the knowledge economy underpinning the more obvious elements.
- This paper has given the outline of the urban design response towards the third component. Work on the other two arms is proceeding in parallel – but that is another story for another paper.

From 'Place Apart' to Place Making

The Reinvention and Transformation of James Cook University Townsville

Caroline Stalker Director, Architectus
 Alan Carpenter Project Director of Discovery Rise, James Cook University

architectus™

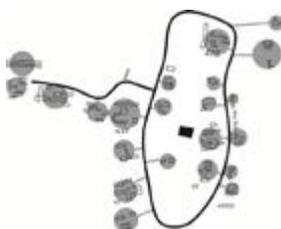

Existing Conditions: Key Influences

Landscape setting - primary organiser for 1964 Birrell master plan
 Need for evolution of this to respond to urban connections, western campus

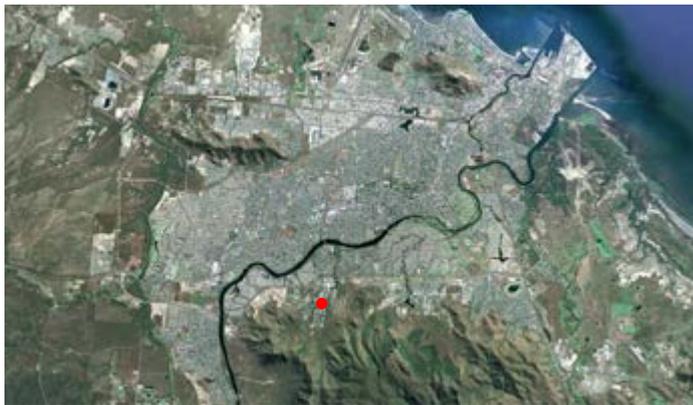

architectus™

architectus™

Car dominance and fragmentation

- Landscape setting powerful.
- Birrell buildings important 'set pieces'
- Open, relaxed tropical landscape setting essential quality of JCU
- Good bones exist - axes, landscape, Birrell buildings.

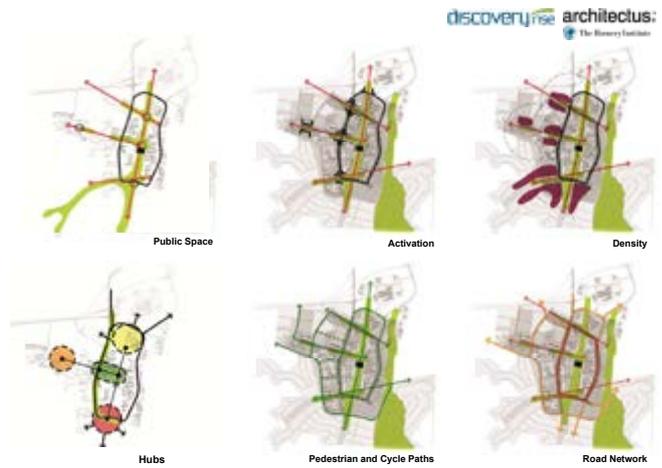

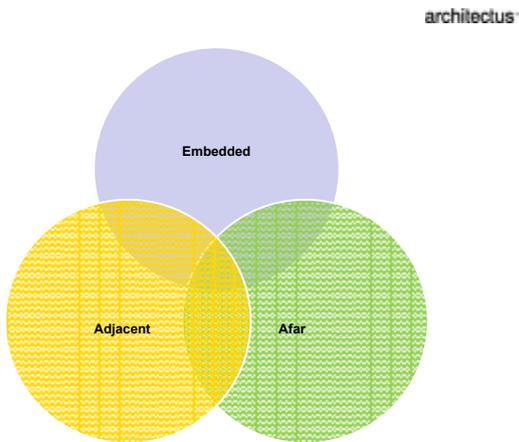

JCU's Vision

The creation of a university town with a distinctively Australian tropical ambience which will incorporate energetic academic, social, artistic and commercial environments. It will be an integrated community of living and learning that will set a new benchmark in sustainability.

Community Plan Elements

New population for Discovery Rise of 5444 people. This population would be made up of the following audience segments. In addition there are 1000 students already living on campus.

Scenario 1 - Discovery Rise Residential Hub		AUDIENCE AND DEMOGRAPHICS		Total DR	Townsville
A	A Privileged Prosperity	6.00%	268	2.76%	4,249
B	B Academic Achievers	37.40%	1,644	3.51%	5,392
C	C Young Ambition	5.00%	214	1.68%	2,588
D	D Pushing the Boundaries	20.70%	923	14.29%	21,971
E	E Family Challenge			36.07%	55,449
F	F Metro Multiculture				22
G	G Learners and Earners	24.49%	1090	4.76%	7,320
H	H Provincial Optimism	1.40%	63	6.22%	9,558
I	I Farming Stock			8.63%	13,268
J	J Suburban Subsistence	3.30%	149	16.18%	24,876
K	K Community Disconnect	1.70%	78	5.87%	9,019

Climatically Responsive Urbanism

The Fragmented Perimeter Block

Shady Edges

Shady Edges

Dry tropics – same rainfall as Brisbane but all in the wet season

Encouraging walking a challenge in summer

Avoid heat islands

Minimise A/C reliance

Tweed Coastal Hazards – Is The Plan Working?

Mike Svikis, MikeSvikisPlanning, NSW, Australia

Katrina Burbidge, GHD, NSW, Australia

1. The Tweed Shire Coastal Hazards Development Control Plan (Section B25)

With the threat of coastal erosion and inundation on public and private property so evident up and down the NSW coast, governments of all levels need to equitably manage the impact of this on coastal landowners without unfairly penalising them or the general community.

GHD planners worked closely with Tweed Shire Council to prepare a Development Control Plan (DCP) that recognizes the potential threat of coastal erosion and rising sea levels on existing and proposed development along the Tweed Coast in Far North Coast NSW. The DCP was adopted by Council in September 2011.

Property in the coastal hazard zone (despite its potential hazard) will probably always be in high demand because it has unique characteristics such as ocean views, short walk to beach, cool coastal breezes and a high current utility value. Coastal property buyers are more likely to be influenced by interest rates, unemployment levels and the current state of the Australian economy than a 50 year plus prediction of coastal erosion. There will also always be a need for public infrastructure and facilities in the coastal hazard zone including our iconic surf lifesaving clubs.

It is therefore appropriate that local government uses planning policy to inform prospective purchasers (and coastal zone users) that some coastal property is affected by a natural hazard that should be considered when evaluating what a property is worth, what it can be used for now and what it might be used for in the future. It is also appropriate that the level to which property is affected by coastal hazards correlates with the level of controls that are imposed upon it.

The DCP draws on existing sources of data (Coastal Zone Management Plan (2005) and the Tweed Coastline Hazard Definition Study (updated in 2010)). It adapts the approach of other coastal Councils such as Byron Shire Council and Pittwater Council as well as referencing key State government guidelines and policy advice. GHD had to work closely with various stakeholders to achieve a balance between the NSW State government position (which has since changed) and the local Council and community.

The DCP assists in allowing land affected by coastal hazards to be used in a way that is proportional to that hazard over a suitable time frame. It will also ensure that new development incorporates resilience to coastal hazards. It provides a clear basis on which to evaluate development applications in the coastal areas of Tweed Shire. The development controls are grouped into three “Hazard Zones” which are illustrated in Figure 1:

Figure 1: Application of Hazard Lines and Zones on the Tweed Coast

- Immediate Hazard Zone – that land between the Immediate Hazard Line and the waterline. No habitable development permitted. Development relating to uses that are required in the Immediate Hazard Zone and are temporary in nature (e.g. lifesaving observation structures, access structures) may be considered.
- 2050 Hazard Zone – that land between the Immediate Hazard and the 2050 Hazard Lines. Permissible development to be subject to a Coastal Risk Management Report and where development is granted consent, it is granted on the proviso that if the erosion escarpment comes within 20 metres of any building then the use of the building will cease. It is proposed that Section 88E of the Conveyancing Act, 1919 be used to achieve this. If the use of the building does cease then the owner of the land will be responsible for the removal of any or all of those buildings (possibly to a location further than 20 metres from the erosion escarpment, if relocatable).
- 2100 Hazard Zone – that land between the 2050 and 2100 Hazard Lines. Permissible development to be subject to a Coastal Risk Management Report. The main considerations in this zone are that development is positioned to avoid the risk of damage from coastal processes and avoid the need for physical structures to protect that development.

The DCP not only provides clear direction, it also strikes a balance between respecting the existing land use rights for owners of private coastal lands and users of public coastal lands and the need to avoid excessive public expense on protecting private assets.

The DCP through the use of hazard zones overlaid on digitally corrected air photos for easy interpretation, takes a risk based approach with controls being less onerous the further landward you proceed. Landowners have a right to enjoy their property while it is still there

even if it cannot be protected in 40 or 50 years' time. There is a place for planned retreat of privately owned lands in the coastal zone and it is an important planning tool to include in this DCP. Importantly, the planning tool reflects the existence of a hazard that does not discriminate between public and private coastal land.

A number of government and non-government stakeholders have a role in managing coastal pressures and issues. The local Council plays the most important role in managing built form and development through the day to day application of the land-use planning system.

Land-use planning decisions often have long-term implications. The Tweed Coastal Hazards DCP is an example of how local government can take an informed and precautionary approach to planning for new development, infrastructure and services to avoid or reduce the consequences of coastal hazards over the expected lifespan of the development.

2. What Has Happened Since Then?

Soon after the DCP was adopted there was a series of major coastal erosion events on the east coast of Australia, including the Tweed Coast. The beach at Kingscliff was hit hard with the southern end losing around 50 m including the entire dune system, all mature vegetation as well as open parkland and a public road (refer to Figure 2). A caravan park and the Cudgen Surf Life Saving Club (SLSC) were also threatened. More recently this erosion has impacted on the Fingal Head area.

Figure 2: Coastal Erosion at Kingscliff

Tweed Shire Council has been implementing its Coastal Zone Management Plan which nominated protection for the Kingscliff embayment. This has taken the form of 6300 tonnes of rock placed along the foreshore as “interim” protection and a permit to pump sand from the nearby Tweed River onto the beach at Kingscliff to restore dunes and the beach profile in front of the new rock wall. The first installment of 14,000 cubic metres of sand has been already been placed on the beach.

Council has commissioned a study to update its coastal hazard definition lines in light of improved modeling and data on sea level rise predictions. Early indications are that the 2050 and 2100 hazard lines may move a little more to the east. When new hazard lines are available and are adopted the DCP will be amended to include them. In the event of a dispute, keeping the DCP up to date will assist Council if it needs to enforce its conditions such as cease of use and removal of structures.

A general slowing of the sale and development of property on the Tweed Coast in response to the Australian economy has led to there being less than ten development applications for land affected by the DCP (about 185 privately owned lots are affected). The majority of the applications have been for minor alterations and additions. Several applications have demonstrated the application of the DCP and two examples are provided below.

2.1 Fingal Rovers SLSC, Fingal Head

The Surf Life Saving Club (SLSC) at Fingal Head is located on Crown land at the eastern edge of Fingal Head village on the Letitia Spit and services the northern beaches of Tweed Shire.

The existing club house is located in the 2050 Hazard Zone but is hard up against the Immediate Impact Zone. The club house was old and in poor condition and the club initially wanted to build a re-locatable structure. A re-locatable structure would be difficult on the current site as it is surrounded by a caravan park owned by Crown lands and is in close proximity to open space.

However, the application that was finally submitted was for the re-use of the existing site. This included utilising the existing slab and some of the existing structure but with a new fit out based on the old footprint. The intent was that the kitchen, toilets and showers could be moved to the back of the building so that the front could be abandoned if the erosion escarpment came too close. The club thought they would get 25 years of use from their fully renovated building. It was approved and construction of the front section was completed by December 2012.

At the time of approval there was approximately 35 to 40 metres of stable and mostly vegetated dune system to the east of the club house. A major erosion event occurred in May 2013 and 15 metres of beach and dunes was lost over two days. The beach escarpment was in excess of 3 metres high and over the next week came to within 11 metres of the new club house (refer to Figure 3).

Figure 3: Beach Erosion at Fingal Head in August 2013

In accordance with the DCP Council had imposed a condition on the SLSC as follows:

“As the development subject of this consent has been identified as being within one or more of the Coastal Hazard Zones as described in Tweed Development Control Plan B25 this consent is subject to the owner of the subject land PRIOR TO THE ISSUE OF AN OCCUPATION CERTIFICATE creating a positive covenant under section 88E of the (Conveyancing Act, 1919) on the following terms:

“(i) The registered proprietor of the subject land acknowledges that the subject land is within a Coastal Hazard Zone as described in Tweed Development Control Plan B25 or any other subsequent iteration of that planning instrument.

(ii) The registered proprietor also acknowledges that any development within the subject land must comply with the terms set out herein as follows:

a. In the event that the erosion escarpment comes within 17 metres of any habitable building/s on the subject land then the use of any building/s shall cease and the registered proprietor of the subject land shall remove any or all buildings to a location on the subject land that is further than 17 metres from the erosion escarpment where possible, or off site where not possible. In the event that relocation is not possible, then any affected building shall be demolished.

b. The registered proprietor of the subject land shall bear all costs in relation to the relocation or demolition of any or all buildings located on the subject land.

c. The terms "Coastal Hazard Zones", "erosion escarpment" and any other references of this covenant are to be read as having the meaning in accordance with their definitions in the Tweed Development Control Plan B25.”

The SLSC did cease use of the new building, however the erosion event subsided and the sand has now been restored so that the escarpment is approximately 20 metres from the club house. Its occupation has resumed, but the beach is still vulnerable to further erosion and the club is still within one “storm bite” of being abandoned and demolished.

The new club house has cost the surf lifesaving movement and various levels of government and the community about \$650,000 and requires an additional \$250,000 to be completed. Although the DCP has been effective in imposing conditions on the application that ensured public safety, it is not clear that the imminent danger to the existing site was recognized by the applicant in lodging an application for a permanent structure in that location. The involvement of the Crown in selecting a less erosion prone site on Crown land nearby may have been a wiser use of scarce community resources in the long term. If the beach rebuilds and the surf club gets its estimated 25 years of use out of its new club then so be it. However, if the erosion returns sooner than that (as predicted) and the new building becomes dangerous and requires demolition it should be a clear lesson to take the Hazard Definition lines in the DCP seriously and look harder for alternative sites for valuable public infrastructure.

2.2 Dwelling at Hastings Point

In this situation a privately owned block of residential land at Hastings Point contained three small older style single storey holiday units. The existing structures were all within the 2100 Hazard Zone though quite close to the 2050 Hazard Line. The lot is located on an old parallel beach dune that is quite elevated, at about 15 m above sea level. At the time of the application there was at least 80 metres of stable and mostly vegetated dune system to the east of the site. The application was to demolish the three units and build a single large dwelling on the lot. A three storey block of units had been approved on the lot beside it several years earlier.

This application poses some interesting dilemmas. Reducing the number of dwellings in the 2100 hazard zone from three to one is a good outcome. The new dwelling was to be located as far back from the 2050 Hazard Line as it could be. The shape and geography of the site is unusual as it is a "battle axe" lot and a demountable dwelling would be difficult to remove. The height of the dune means as the escarpment comes closer; the dune becomes more unstable with potentially a 15 metre drop to the beach. The coastal risk management report recommended deep pile foundations to keep the building as safe as possible, for as long as possible. Council required the landowner to acknowledge in writing the coastal hazard on their own land and accept the risk and responsibility with construction of this building in this location.

In the case of the Hastings Point embayment the recent coastal erosion has not been as severe and the new house has been completed and is occupied. There is still 70 metres of vegetated dune east of the site. In this case the DCP has allowed useful occupation of the land for as long as possible, which should be another 35 years if the modeling is correct. The awareness of the hazard has been created and the applicant has invested in the safety of their building at the outset, acknowledging that in the long term it is likely to be at risk.

Figure 4: Beach Erosion (or lack of) at Hastings Point

3. Conclusion

It's still early days for the Tweed Shire Coastal Hazards Development Control Plan (Section B25). With about 185 private properties affected by coastal erosion plus numerous parcels of public land, there is still plenty of opportunity for controversy and mistakes as well as good planning outcomes. However, early indications are that the DCP has raised awareness of the issue of land affected by coastal hazards and has made applicants think about how they approach their development. The most recent examples of erosion at Kingscliff and Fingal Head have silenced some of the community that previously suggested the erosion was never going to happen and that the Hazard Definition Study was over stating the risk. The cost of protecting the Kingscliff embayment with an interim rock wall has demonstrated that protection works are not a cheap or easy alternative to good planning. The interim works have cost \$2.5 Million. A permanent, engineered rock wall 450 metres long with sufficient sand nourishment to restore the beach in front of it is estimated at between \$10 Million and \$20 Million depending on sand nourishment costs.

Coastal risk management reports have been produced for applications with site specific recommendations and Council has imposed conditions acknowledging risk and responsibility and requiring action when certain erosion events occur. Purchasers of land are notified when it is affected by coastal hazards before they purchase it. So far the DCP is doing its job, let's hope the political will (at local, State and Federal level) to support such controls remains in place.

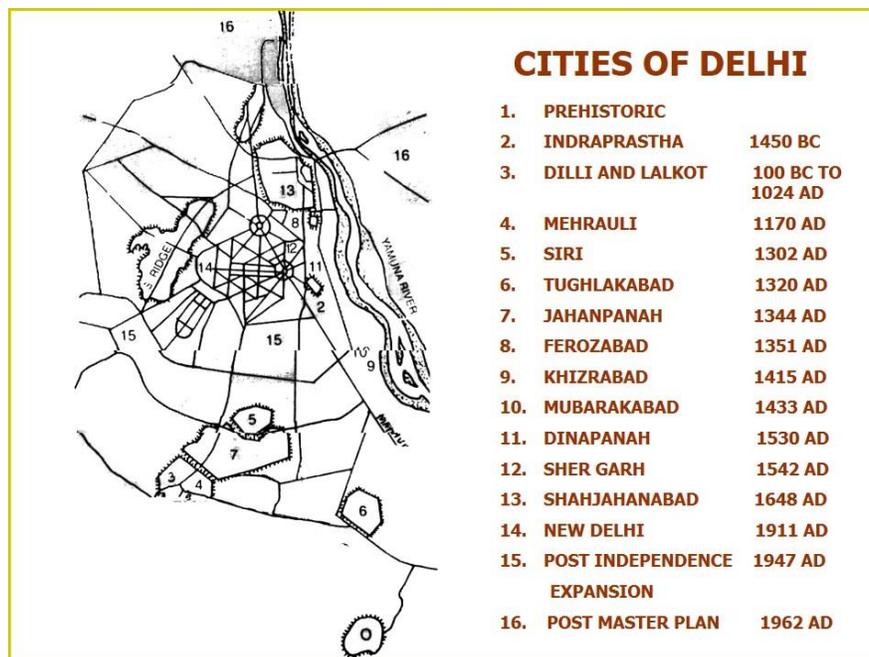

The authors acknowledge the assistance of Jane Lofthouse and Barry Stegman of Tweed Shire Council for supplying with photographs and information on Development Applications.

AN APPROACH TO CONSERVATION OF BUILT HERITAGE – DELHI MASTER PLAN PROVISIONS.

By – P.S.Uttarwar
 Director (Planning)
 Delhi Development Authority
 (psuttarwar@gmail.com)

ABSTRACT

Delhi is an ancient city with rich historical mile stones and heritage. Historically Delhi has been a capital city for many dynasties and rulers. Each ruler and dynasty left its impression and foot prints in the form of monuments, heritage buildings and capital complexes. The rulers have been conscious of Delhi’s past. Their desire to protect the past has influenced protection and conservation of built heritage. Archaeological survey and Public Works Department of British India began this task in the later 19th century and after independence ASI has become protector of India’s heritage. At a later date Master Plan documents attempted to make provisions for protection and conservation of built heritage. Right from the first Master Plan of Delhi 1962 to the Master Plan of Delhi 2021, each document contributed and perfected conceptual frame work, approach and policies for protection and conservation of monuments in Delhi.

1. INTRODUCTION

Delhi's Heritage

Delhi is an ancient city whose history dates back to the time of Ashoka. This region is uniquely situated in terms of its location. It is a triangular area bound by Yamuna on east side, and by the Aravalies on the south and west side.

For the most part of its history it has been a capital city. The history of Delhi begins from the Ashokan rock edict and comes through centuries to Lutyens Imperial capital and finally to being the capital of the Indian Republic. Delhi has witnessed numerous ups and downs during this history.

Protecting this heritage represented by a mosaic of Capitals and villages is a very big challenge. Through the years right from perhaps Ferozshah's time, rulers have been conscious of Delhi's past, their attitudes and the thinking about past which has influenced protection and conservation of built heritage. Alexander Cunningham's Archaeological Survey and the PW Departments of British India were responsible for protection and maintenance of monuments. After independence, ASI has become sole agency for protection of heritage. Even today it continues to function with the same rules and regulations drafted during colonial times. Following is a brief summary of the agencies involved in conservation and provisions of the previous Master Plans.

- a. **ASI:** The rules and legislations for protection of Heritage laid down by the British have not changed much till date. Their definition of Built Heritage is monument based.
- b. **Master Plan for Delhi 1962:** The first Master plan was prepared during a time when the concepts of Heritage and Conservation in India were in their infancy stage. The master plan provided for a number of green spaces to be reserved for the city. Most of these greens were around monuments and this has resulted in protection of a number of monuments.
- c. **Master Plan for Delhi -2001:** In the second Master Plan the aspect of conservation is dealt under a different subheads. Environment is section that talks about the conservation of the walled city. The section on Special Areas also mentions restoring the glory of the Walled City. Urban villages, which are an important component of the heritage are under the section of Shelter, it rightly mentions that heritage development should be a part of the overall development. The Master Plan was in accordance with the conservation thought of the day. Due to scattered scheme of conservation thoughts, implementation was a difficult task.

In the 90's, MCD and NDMC published lists of buildings, which were 'Protected'. In absence of any legislation or procedures, these monuments remained protected theoretically only.

The ASI protects 164 odd heritage structures in Delhi, besides these the local bodies have also published lists are follows:

MCD: 775 buildings

NDMC: 112 buildings

These are ridden with number of problems.

- The World over thinking about heritage has changed radically. The 'Monument' approach has been discarded as being insufficient to protect the Built Heritage. This built heritage needs to be treated as heritage areas or zones.
- It is necessary to identify what is to be done with these buildings? Who will do it? and What conceptual approach lies behind the whole process?
- The lack of appropriate plotting and mapping has resulted in encroachments and deterioration in heritage areas/buildings.

INTACH inventory of Delhi of built heritage of 1208 buildings was published in the year 2000.

2. Conceptual Framework On Conservation Aspect For MPD 2021

Our heritage is the result of interaction of three forces. i) **People** - occupies a geographical area ii) **Place** – where building activity takes place and through iii) **Time** buildings and cities take shape. Understanding of People, Place and Time gives us the context for understanding Heritage. It also helps us in evaluating the heritage. Fundamental to the approach for conservation of the build heritage is the understanding of heritage as a **Resource**. Such an understanding means that like all Natural resources built heritage is also subject to development pressures and exploitation and has to be protected from these threats. The notion of sustainability widely used for natural resources is also applicable for built heritage. Sustainability necessarily means the use of the resources in a matter that does not compromise on the ability of future generations to use and enjoy it.

Managing the natural and built heritage of this complex cultural entity is an enormous task. This cultural entity or **Culture Region** has a range of **Natural and Built Heritage**. This heritage is a valuable resource but is threatened due to pressures of urbanization and development. Historically there had been a symbiotic relationship

between the natural and the manmade heritage. This relationship can be identified as cultural landscapes. Tughlaquabad, the capital of the Tughlaqs utilized the landform for construction of the capital. Even if the Natural and Built heritage are within this Culture Region there is a whole range of components that have to be identified and conserved. Some of these components are as follows:

The River

Ridge: Northern, Central and Southern

Streams

Agricultural areas

Water Bodies: Ponds, tanks and lakes, Quarried lakes

Villages : Chirag Delhi, Nizamuddin, Kotla Mubarak etc.

Historic Capitals: Tughlaqabad, Jahanpahah, Shahjahanabad etc.

Conservation is not freezing a place in time or denying development. Rather it stresses that the development has to occur in relation to the existing built heritage and the relationship with the natural resources. Conservation of Built heritage can not be compartmentalized under a heading and done with. Effective protection and Management of Built heritage requires that the concerns of heritage be reflected in all areas and be integrated with Planning process.

The aim therefore is to formulate a **Conservation Management Plan** for Delhi's heritage, based on understanding of Heritage as a resource.

- Definition of Heritage Zones: The definition of the zones have to be based on understanding of the wholeness of the particular resources. New Delhi is one entity and has to be defined as such. The walled city of Shahjahanabad is again another entity.

2.1 GENERAL POLICIES

Policies to be applied in conservation areas of Delhi has to based on database of built heritage resources of Delhi. However a broad generalization may be done based on an accepted attitude towards heritage.

- **Information Management**

A detailed database is very important for informed decision making. The database has to be comprehensive and open ended. It has to be compiled from detailed inventories. The database has to be organized so that it can be answer multiple criteria queries and is updateable. The decisions for resources management can only come from a thorough database.

- **Legal**

Certain terms, processes, powers, responsibilities duties etc. regarding Conservation, should be defined and included in the Act/Master Plan. Once it is defined in the act, the process becomes mandatory and ensures that Conservation of Cultural Heritage remains a priority.

- **Administrative**

In administrative setup the role of any special body should be strictly advisory in nature. There might be a tendency to leave the heritage entirely to this body while the planning process continues regardless.

- **Financial**

The financial policies are to be based on the understanding of ownership status of the structure to be protected. For the private properties various instruments like soft loans, tax relief and tax concessions have to be worked out.

- **Technical**

Structural conservation is a very technical subject and there is a serious lack of data on construction processes and materials. Regular maintenance and the awareness of the occupants is very crucial for the health of the building. At building level following need to be prepared.

- Specifications for conservation work
- Manuals on structures and materials
- Manuals for housekeeping and maintenance
- Architectural control guidelines for new development

- **Education and Awareness**

Heritage is a vast source of learning and education. Awareness about heritage is very crucial for conservation. All possible means should be used for this purpose. The results of the collected database can be synthesized to feed into the awareness programs.

- **Monitoring and Reviewing**

Monitoring and reviewing are very important if the Master Plan provisions are to be implemented. Preparing action plan with prioritization and setting of long and short-term objectives is a very important task.

3. PLAN FOR A CONSERVATION ZONE

Conservation of the historic areas has to be an integral part of the planning process. The qualities to be conserved include 'all the elements that express the character of the place'. This identified as Heritage Components, which can be defined in terms of spatial extent.

a. Qualities to be preserved

- Urban patterns as defined by plots and streets.
- Relationship between buildings and green and open spaces
- The formal appearance, interior and exterior of buildings as defined by scale, size, style, construction, materials, colour and decoration
- The relationship between the urban areas and its surrounding setting, both natural and material
- Various functions that the area has acquired over time

b. Delineation of zones

It is clear from the statistics that two most critical things are the identification of ownerships and secondly the demarcation of exact boundaries on the map. The boundary delineation is a critical process and includes the following tasks:

- A detail inventorying of the heritage components.
- Identifying the spatial extent of these components on plan
- Defining the extent of the zone based on the inventories and the historical studies
- Identifying a buffer around the zone for protect.

The definition of the zones has to be based on understanding of the entity.

Understanding of Delhi as Historic Capitals and Villages interlinked by numerous water bodies and streams gives us a better perspective for defining the '**zones**'.

Capitals

- Lal Kot, Quila Rai Pithora
- Siri
- Tughlaquabad, Nai Ka Kot, Adilabad
- Jahan Pahah: Chirag Delhi, Khirki, Begumpur, Hauz Rani

- Firoz Shah Kotla
- Purana Quila
- Sharhjanabad: Chandni Chowk, Katra Neel, Bazar Lal Kuna, Dharampura, Jama Masjid, Red Fort, Lothian Road, Daryaganj
- Lutyens Delhi: Connaught Place, Jantar Mantar, Central Vista, Bungalow Zone

Historic Villages

- Nizamuddin: Humayuns Tomb, Barapulla, Hazarat Nizamudding
- Mehrauli: Zafar Mahal, Mehrauli Bazaar, Qutb Complex.
- Hauz Khas

Clusters of monuments

- Lodhi Gardens
- Delhi Golf Club

This perspective also opens up the possibility of identifying more heritage zones based on the techniques of inventorying. Such as definition is a big exercise in itself and needs comprehensive understanding of the heritage resources of Delhi.

Urban Villages

Many of the urban villages are historic and remains of the past are worthy of conservation. However they have undergone various degrees of transformations. These have to be surveyed for their heritage resources.

4. Contents of the Conservation Plan

For any conservation plan participation of the occupants of the area is very crucial. Such plan may have following components:-

- a. Heritage components and their ownership**
- b. Traditional and historic Housing Stock**
- c. Land use policy**
- d. Physical Infrastructure**
- e. Traffic and Transportation**
- f. Information management**
- g. Education and awareness**
- h. Tourism**
- i Capacity Building**

'Capacity building' is the process and means through which individuals and Organizations develop the necessary skills and expertise to manage their environmental and natural resources in a sustainable manner within their daily activities.

5. MASTER PLAN 2021 PROPOSALS

For the first time Master Plan for Delhi 2021 included a separate and dedicated chapter on "conservation of built heritage" in the text of Master Plan, this chapter includes.

- **CONSERVATION STRATEGY**

A common conservation strategy for all the agencies concerned with protection of Delhi's built heritage is necessary. All the agencies should prepare appropriate action plans with the aim of framing policies and strategies for conservation. The strategy should include promotion of conservation of the civic and urban heritage, architecturally significant historical landmarks, living monuments, memorials and historical gardens, riverfront, city wall, gates etc. Interaction and coordination between all these agencies must be part of overall strategy. All the agencies should follow common database, definitions and guidelines for development, redevelopment, additions alterations, repairs, renovations and reuse of the heritage buildings.

- **HERITAGE ZONES**

Heritage Zones an area, which has significant concentration, linkage or continuity of buildings, structures, groups or complexes united historically or aesthetically by plan or physical development. The following areas have been identified as Heritage Zones as indicated in the Zonal Plan.

- i) Specific heritage complex within Walled City of Delhi, Shahjahanabad.
- ii) Specific heritage complex within Lutyens Bungalow Zone.
- iii) Specific heritage complex within Nizamuddin and Humayun's Tomb Complex.
- iv) Specific heritage complex within Mehrauli area.
- v) Specific heritage complex within Vijay Mandal-Begumpur-Sarai Shahji-Lal Gumbad.
- vi) Specific heritage complex within Chirag Delhi.

- **ARCHAEOLOGICAL PARK**

Archaeological Park in an area distinguishable by heritage resource and land related to such resources, which has potential to become an interpretive and educational resources for the public in addition to the value as a tourist attraction.

Though the priority are the historical structures and the built heritage, ecological and landscape aspects are not excluded.

All decisions regarding Built Heritage in general and Archeological Parks in particular should be based on evaluation of the pertinent aspects like form and design, materials and substance, use and function, traditions and techniques, location and setting, spirit and feeling and other internal and external factors.

The following areas have been designated as Archaeological Parks:

- i) Mehrauli Archaeological Park.
- ii) Tughlazuabad Archaeological Park.
- iii) Sultant Garhi Archaeological Park.

Other area can be added to the list on the basis of studies.

- SPECIAL CONSERVATION PLANS

Each local body/land owning agency should formulate "Special Development Plans" for the conservation and improvement of listed heritage complexes and their appurtenant areas. Alteration or demolition of any listed heritage building is prohibited without the prior approval of the Competent Authority.

The development plans/schemes for such areas shall conform to the provisions, in respect of Conservation of Heritage Sites including Heritage Buildings, Heritage Precincts and Features Areas.

CONCLUSION

The Master Plan 2021 has brought focus and vision with respect to Conservation of Built Heritage. For the first time the idea and concept of Heritage Zone, Archaeological Park has been introduced in the Master Plan document. The scope of Heritage encompasses monument along with linkages or continuity of buildings, structures or complexes united historically or aesthetically. Similarly Archaeological Park is an area distinguishable by heritage resource and land related to such resources. Inclusion of these entities in Master Plan document makes it potential area for protection, conservation and an integral part of planning process.

CONSERVATION OF DELHI'S BUILT HERITAGE

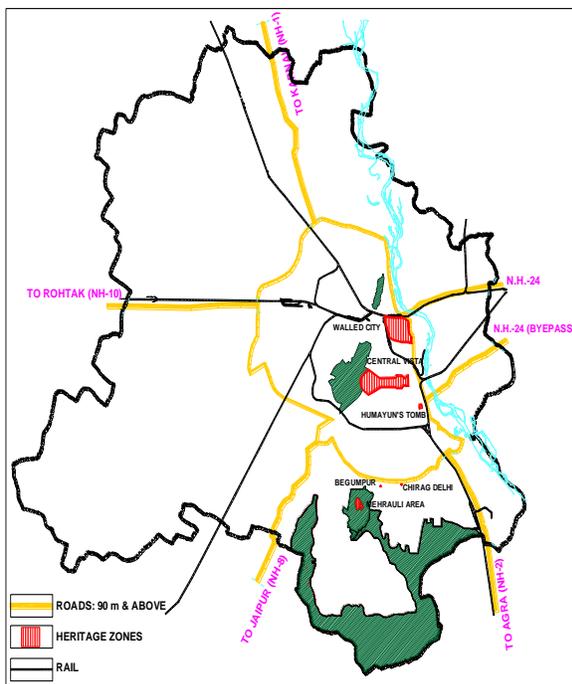

CONSERVATION OF BUILT HERITAGE

HERITAGE ZONES

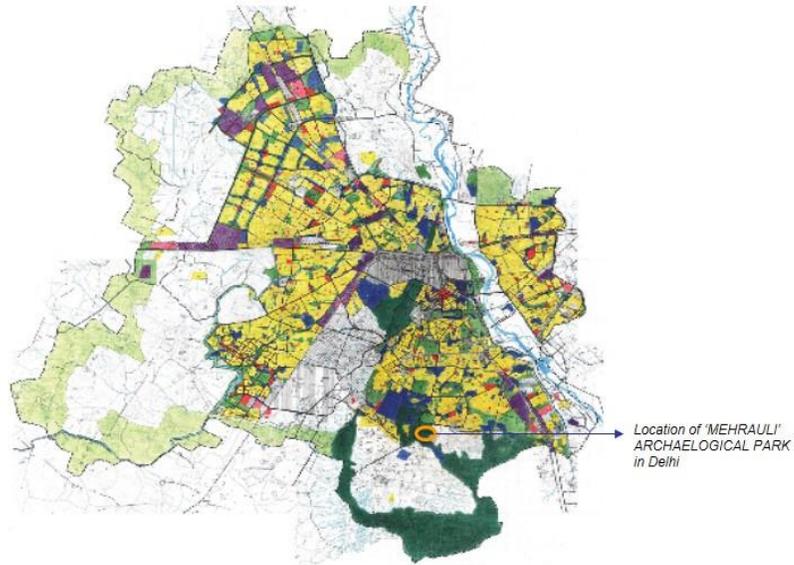

The following areas have been identified as Heritage Zones:

- Walled City of Delhi, Shahjahanabad
- Central Vista
- Nizamuddin and Humayun's Tomb Complex
- Mehrauli area
- Vijay Mandal – Begumpur – Sarai Shahji – Lal Gumbad
- Chirag Delhi

AN APPROACH TO CONSERVATION OF BUILT HERITAGE – DELHI MASTER PLAN PROVISIONS.

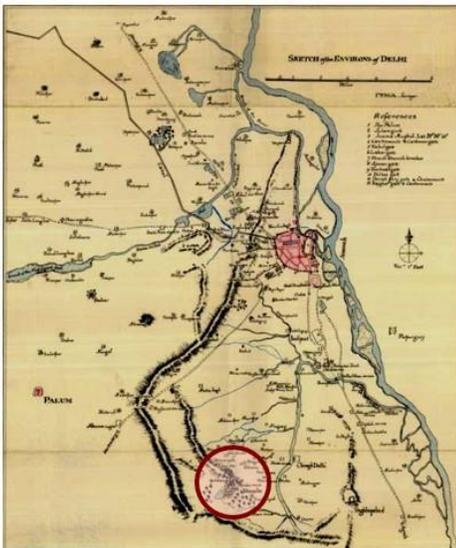

Case Study : Village- 'MEHRAULI' ARCHAEOLOGICAL PARK
