Introduction

Martina Juvara
General Rapporteur

"With urbanisation continuing at pace, megacities offer a different model of urban development, which is no longer the unexpected by-product of fastgrowing countries: it is a beacon to be followed for some, and for others, simply dehumanizing. The Congress will be a unique opportunity to explore what megacities can do for humanity and how we can make sure we move towards a better and fairer future: for children, for the environment and for our own identities of citizens in a globalising world. Around 250 presentations, debates, training sessions and inspirational speeches: a great way to start sharing knowledge for a better future."

Our aim with the 55th ISOCARP World Planning Congress is to investigate the future and explore the opportunities offered by cities without limits: what makes them successful and why they are so appealing and to whom. We want to focus on their supposed inevitability but also on the possible alternatives for achieving global influence without the mega-scale.

This is our target for this year: exploring 'planning beyond limits'. This does not mean that the work of last year at Bodø is being put behind our backs: sustainability, resilience and the role of cities in our changing planet is at the forefront of everyone's thinking this year too. Jakarta provides the perfect context: It is the second largest agglomeration in the world (over 30 million), one of the biggest plastic waste generators (up to 2,400 tons daily) and the fastest sinking city (up to 15cm a year, with almost half the city below sea level already). Such a mega challenge, that the Government has decided to relocate its national capital functions. In addition, almost 40% of Indonesian citizens are dissatisfied with the living quality of their cities.

Environmental challenges, well-being and citizen quality of life and the role of cities are only some of the themes explored by the Congress this year. No better place to discuss them than Jakarta, a no better place to open to the whole world and gain a truly global perspective about what's happening and what different experts are thinking from all parts of the world.

On the one hand, the global role of megacities and how scale is becoming power: what are the dynamics that lead to the emergence of megacities? Are they necessary to achieve global influence or are there alternatives? Can cities without limits be planned, nurtured and grown as a way to promote a positive future for a country and for the planet?

On the other hand, we will also explore the strategies, considered or maybe tried out, to promote liveability, well-being, exemplary sustainability, innovation and responsive governance. If megacities develop into powerful regions, they also play an unprecedented role in shaping the social, economic and environmental evolution of our planet: megacities have the chance to lead the world and change the fate of global challenges such as climate change, security, innovation, financing and digitalisation. They can provide the test-bed and the drive to experiment with new technologies and proactive governance that respond to all scales, from global to local, and to all people from international leaders to children and the migrant poor.

It will be a very busy week: comfortable shoes and fat notepad in hand – as hundreds of researchers, professionals, government officials and international agencies will congregate in Jakarta to share knowledge and learn from each other.

It will be an opportunity to hear about the progress of the Sustainable Development Goals directly from UNHabitat, discuss the future of democratic and participatory planning, learn how to embed children friendly policies into planning and share experience about governance from all parts of the world. The role of heritage in our future identity and the challenges of water management will be explored across cultures, and different governance and resource frameworks.

The Congress will provide a true platform to share ideas and best practice across the globe: from Jakarta, Samarang, Wuhan and other cities in China, the work being done in cities of India, Africa, Australia, Europe and America. With several technical visits, panel discussions, debates and round tables, we expect no less than future orientated thinking and limitless horizons.

All this, like being among friends! It would be a great mistake not to be there, with us.

Track 1

Limitless cities and urban futures

Planning for scale

CONGRESS TEAM

Peter Newman
(Australia)
Luo Wenjing
(China)
Stephen Goldie
(United Arab Emirates)

LOCAL EXPERTS

Budi Situmorang
Khairul Rizal

Through holistic exploration, this track will provide an opportunity to discuss why megacities are emerging, how they are influencing the world (positively and otherwise) and how planners can think ahead about their future. Megacities and city-regions are challenging the notion of the traditional city and even the metropolis. Larger and more powerful than countries, they become global nodes of migration, trade, knowledge exchange and innovation that seem to be limitless. Are megacities unstoppable and the fastest way to a prosperous future?

The track also explores the needs and impacts of megacities, from infrastructure to food and waste, and the range of strategies needed, imagined or already being explored, to make them lead the way towards efficiencies of scale and innovative resource management. Are they part of a global interconnected network that can lead planetary change or a threat to life on Earth?

How best to plan for an efficient, liveable and regenerative megacity? What lessons can already be learned from the leaders in this journey?

Sessions

Session 1.1
Understanding Megacities: Scales (1/2)
How can one understand the growth of megacities? Are megacities limitless? This session discusses the scales of megacities as well as the method of controlling the growth boundary of megacities.

Session 1.2
Understanding Megacities: Linkages and Structures (1/2)
How can one understand megacities as a whole and as individual parts? This session explores the structures of megacities including linkages, relationships, disparities, synergies and connections.

Session 1.3
Understanding Megacities: Scales (2/2)
How can one understand the growth of megacities? Are megacities limitless? This session discusses the scales of megacities as well as the method of controlling the growth boundary of megacities.

Session 1.4
Understanding Megacities: Linkages and Structures (2/2)
How can one understand megacities as a whole and as individual parts? This session explores the structures of megacities including linkages, relationships, disparities, synergies and connections.

Session 1.5 (Special Session)
How to Plan Ahead: Wuhan Metropolis Experiences
This session specifically focuses on Chinese megacity planning using the case study of Wuhan, located in Central China. With a population of more than 11 million and an area of more than 8,000 square kilometres, it aims to become a sustainable, efficient and liveable megacity.

Session 1.6
Planning for Megacities: Sustainability
How can one plan for a sustainable megacity? This session focuses on resource consumption, resource utilisation, and environmental preservation in planning strategies of megacities.

Session 1.7
Planning for Megacities: Efficiency
How can one plan for an efficient megacity? This session focuses on improving the efficiency of megacities, especially in the areas of transit-oriented development, smart cities and the like.

Metropolitan Management: Expansion, Governance, and Finance

Metro-Urban expansion is challenging world development. Only 3 cities in world history have been one million-plus inhabitants. Now we have 500. These Metro-Cities produce 75% of world GDP. Many are expanding at a 5% annual rate. They double their size every 14 years. Lack of a methodology for expansion is producing an uncontrolled pattern, jeopardizing development and equity. Challenges and alternatives will be discussed.

The Spectrum of Metropolitan Areas across the World, and Detection of Potential Metropolitan Areas with Chinese Characteristics

The paper proposes a spectrum of MAs with respect to their inner network and interactive structures based on metropolitan development experiences in the US, Japan, and China, and identifies 32 MAs in China with a unique three-circle structure: a core circle, a commuting circle, and a functional metropolitan circle.

Ali Alraouf

The Value of Less and Small: Transforming Metropolitan Doha into Connected, Human and Resilient Urban Settlements

The paper analyses different urban planning strategies and policies adopted to shift the focus from creating a mega city with an image which resonate with typical global cities to a more sustainable, resilient, knowledge-based and decentralised urbanity. It discusses the transformation of Doha from a metropolitan exploiting the oil and gas revenues to a multi-centered model of sustainable urbanism.

Prihadi Nugroho

Bringing creative Economy to Community Resilience towards better Urban Governance: The Case of Semarang City, Indonesia

Semarang City has been transforming from a port city to a multifunctioning city, creating fragmented physical urban transformation and separate formal and informal economy. This paper aims to examine how the recent urban transformation has been fueled by creative economy activities. Results show that kampong-based creative economy is beneficial to enhancing the informal economy and urban settlement development.

Session 2: Understanding Megacities: Linkages and Structures (1/2) 1.2

10 September (Tuesday), 11:30 - 13:00

Eunice Yorgri, Leng Hong

The Role of Urban Slums in the Evolution of Megacities; A case of Nima and Old Fadama, Accra, Ghana

Accra, Ghana's capital city is progressively morphing into a mega-city. The rate of transformation is largely attributed to the influx of poor unskilled rural migrants into the city and its periphery. This assertion is a result of the increasing number of migrant slums in the city. Therefore, two migrant communities are used to justify this assertion.

Anna Katrina Karaan

Negotiating Spaces of Exception: Metro Manila's Planned Unit Developments - The Case of Eastwood City

This qualitative case study uncovers how Planned Unit Developments (PUDs), a type of urban enclave increasingly common in Metro Manila, are negotiated into legitimised spaces of exception where private interests remain dominant yet largely accepted. In exploring relations of state-society-space, the study points towards more inclusive futures for PUDs through continuously sharing the power to negotiate to all.

Ivan Rwampungu, Mishima Nobuo

Evaluation of urban form of a mountainous city from the perspective of compactness characteristics

This study aims at analysing and understanding the urban form in Kigali, capital city of Rwanda. Two dimensions of spatial organisation and spatial distribution of population were measured to objectively evaluate physical compactness. Findings reflected trend of decrease in compact form with absence of sustainable concepts. Suggestive measures were provided for future consideration in sustainable urban development of the city.

Yixuan Peng, Gerhard Bruyns, Darren Nel

Chinese Megablock Urbanism: a Tool of limitless Urbanization in an Unprecedented Speed and Scale

By studying cases in the Pearl River Delta region of south China, the paper explains how megablock urbanism shapes Chinese cities and deliver insights in terms of their impact on urbanization, urban morphology and prevalent planning strategies. The paper argues for the cultivation of an urbanization practice that needs to become systematic in its sustainable focus and outcomes.

Session 3: Understanding Megacities: Scales (2/2) 1.3

10 September (Tuesday), 14:00 - 15:30

TRACK KEYNOTE

Dushko Bogunovich

How Big Is Auckland: Planning a City-Region for Resilience and Regeneration

The authors argue that Auckland, New Zealand's largest metropolitan area, should abandon its 'compact city' model due to weak evidence to support its liveability-sustainability agenda. Instead, planning should acknowledge decentralisation and polycentric metropolistation, and support a linear, metropolitan conurbation to achieve higher levels of resilience and regenerative in the face of climate change.

Swarna Bintay Kadir, Mohammed Hamidul Hasan

Megacity - Mega Challenges: A case of Dhaka City-Capital city of Bangladesh

Bangladesh's capital Dhaka is the 7th largest megacity of the world, and by 2030 it will be the fourth biggest city in the world with 28 million inhabitants. It is facing the combination of high pressure of housing, high population density, and rapid population growth, consequences in urban growth taking place in natural hazard-prone areas.

Manuela Negrila

The role of sprawl towards the megacity. Eastern-European sprawl, the case study of Bucharest, Romania

Cities nowadays are either growing at a never-before seen rate or shrinking due to technology, globalisation and increased mobility. Some of these changes are planned but, most are not, like urban sprawl. Seeing how the forces that drive this phenomenon are in their majority economic, how can planners integrate this chaotic element into a planned and structured megacity?

Chandan Mysore Chandrashekar, Bharath Haridas, Prakash PS. Aadithyaa Jayanthi SenthilNathan

Machine learning for building extraction and Integration of Particle swarm optimization with SLEUTH for Urban growth pattern visualisation for liveable cities

Unplanned irreversible urbanisation with increasing population in the administrative boundaries of existing and upcoming megacities have developed imbalance in the system. Sustainability as prime agenda, this research article aims to understand the urban pattern and its modelling using a novel PSO based SLEUTH. This also included extraction of individual building using SVM to understand regional dynamics and energy demand.

1.4 Session 4: Understanding Megacities: Linkages and Structures (2/2)

10 September (Tuesday), 16:00 - 17:30

Shuai Li

Space of flow including capital and information shape the megacity groups: based on the example of Chengdu-Chongqing city groups in China

With globalisation, “space of flow” like capital, information and talent are moving around the world, combining separate cities into influential urban groups. This research takes Chengdu-Chongqing urban agglomeration in China as an example to analyse the information and capital networks among its 27 cities, and to argue that the role of planning is to attract these flows and enhance competitiveness.

Huihui Nan, Qian Zhao

Comparative analysis of Beijing-Tianjin-Hebei urban agglomeration, Yangtze River Delta urban agglomeration, Guangdong, Hong Kong and Macau Bay Area based on gravity model

The purpose of the study is to compare China’s three major urban agglomerations based on their economy, government management and spatial structure, to determine regional potentialities and future development direction by using gravity model as a method.

William Zuo

Multi-scale Spatial Layout Structure System: Experiences of Shanghai Mega-city Spatial Planning

This paper focuses on the spatial planning system established by the Shanghai Masterplan 2035 to reduce the negative effects of overpopulation on the emerging Shanghai megacity region. Research on the detailed planning process and Shanghai experiences are valuable for megacities facing similar challenges.

Felicia Atmadja, Dushko Bogunovich

Shaping Compact Cities with TOD for Liveability, Sustainability and Affordability: A Comparative Assessment of Jakarta and Auckland

Auckland and Jakarta have chosen the TOD strategy, incorporating vertical housing, to slow down the sprawl. But citizens are concerned about the impacts of higher density development. We make a comparative assessment of TOD’s ability to achieve liveability, affordability, and sustainability (L-A-S) in two cities - Jakarta and Auckland- while using Singapore as a benchmark for both.

1.5 Session 5: (Special Session) How to Plan Ahead: Wuhan Metropolis Experiences

11 September (Wednesday), 11:30 - 13:00

Moderators: Wenjing Luo, Frank D’hondt

Wenjing Luo

The Corridor Strategies in the Megacity development: Case Study of the Optical Valley Knowledge

Based on the Optical Valley Knowledge Mega-Corridor, the paper illustrates the use of knowledge mega-corridors as a loop for innovation systems, a boom for knowledge economies, a bundle of infrastructure axis and a mutual force for environment conservations in developing livable and efficient megacities. The paper also present challenges to implement spatial strategies lying in policymaking at the local level.

Wenjing Luo

How to Define the Boundaries of Metropolitan Areas : Case Study of Wuhan, China

Based on analyzing the current development stage of Wuhan as well as its surrounding areas, this paper attempts to define the boundary of Wuhan metropolitan area in dimensions of its urbanization, geography, transit, economics, ecology, psychology and culture. The paper concludes that Wuhan’s methodology of defining its boundaries can be applied to other metropolitan areas.

Session 6: Planning for Megacities: Sustainability 1.6

11 September (Wednesday), 14:00 - 15:30

Silvia Croce

Urban parameters analysis and visualization. A Support to planning decisions for the definition of urban surface usages

This study presents a systematic framework to support planning decisions on the use of urban surfaces based on accurate and spatially explicit information. The method, which is tested in Bolzano (Italy), implies the assembly of a spatial database of significant morphological and environmental parameters that influence the distribution of surface uses in cities and affect the priorities for their definition.

Bo Bian

The application of micro-regeneration strategy in urban renewal in Lima, Peru

Current developing strategy shows little positive impact on dealing with urban problems in Lima, Peru. This paper analyzes current situation of a typical district in northern Lima. By introducing micro-regeneration strategy, which mainly includes urban catalysts, space design and corporate mechanism construction, this paper hopes to provide a new mode for the development of the city and similar practice.

Daniel Petrovics

Integrating Vertical Farming at Scale in Urban Food Planning - Practical Considerations for Planners

Vertical Farming has been promised to potentially reduce the climate impact of urban food systems. Nevertheless a holistic perspective assessing what elements urban planners should consider whilst integrating this technology into urban food planning in a sustainable manner is missing. A number of factors are discussed in detail among them operational arrangements, policy, market, social-cultural, and built contexts.

Latifah Latifah, Dayinta Pinasthika

Smart Growth Approach in Planning Bogor City Infrastructure

While Bogor's rapid growth, as a satellite city to Jakarta, see investment in new housing development rising, urban infrastructure provision remains limited. To address this problem, the Ministry of Public Works and Housing's smart growth approach has focused on designing public transport oriented, mixed-use and compact development, with emphasis on walkability, human scale planning, and public space in Bogor's center.

Session 7: Planning for Megacities: Efficiency 1.7

12 September (Thursday), 11:30 - 13:00

Vaishali Aggarwal

Smart Cities in India- Branded or Brain-dead?

The notion of 'smart cities' is increasingly visible in discourses on the future of cities. The paper seeks to answer if 'branding of technology' can be used as a tool to create a new identity for the mobility of Delhi or 'upgrade' the existing situation. How can the context of Delhi be decoded to describe the perceptions of the people?

Mariana Reis Santos

Does the implementation of Special Zones of Social Interest (ZEIS) encourage adequate housing in precarious settlements? The case of Sapé, São Paulo

This paper evaluates to what extent the implementation of ZEIS encourages land regularisation procedures and public investments in precarious settlements. It also analyses the quality of State interventions conducted within the zoning. By focusing on qualitative aspects, the paper aimed to establish whether ZEIS has been promoting decent housing conditions to the urban poor or reinforces precarious patterns of development.

Putrikinasih Santoso

Finding Housing Affordability in MRT Jakarta TOD Areas

This paper aims to posit an exercise on the implementation of TOD concept in a built existing environment including the challenges in implementing TOD concept in such areas and possibilities for redevelopment within those TOD areas. To exemplify, several case studies will be presented, including Dukuh Atas, Cipete, and Haji Nawi TOD areas

Track 2

Besides the megacity and other cities
Planning for balance

CONGRESS TEAM

Tathagata Chatterji
(India)
Fedor Kudryavtsev
(Russia)

LOCAL EXPERTS

Ari Krisna Tarigan
Adiwan Aritenang
Harya Setyaka Dillio

This track explores alternative themes beside and beyond the megacity: one explores the paths of cities that aspire to being influential, but also aim for balance and perhaps containment (to provide an alternative model where there is less pressure and life is more balanced).

The other looks at aspects of the regions around megacities: the hinterland and its rural towns, which play an essential role supporting and providing resources to the megacity, sometimes being left behind by the economics and policies of large urbanisation, and sometimes reaping the benefits of nearby growth, prosperity and innovation.

Are megacities the only option? What would be the future role of secondary or non-global cities? Can they only be subservient or irrelevant? How to strengthen economic roles of smaller cities as counter magnets – to generate more job opportunities closer to home and reduce population pressure on megacities? How does megacity expansion transform the countryside and their own hinterlands? How can megacities and peri-urban areas develop a synergetic and maybe positive relationship? How is rural development providing spaces and resources for city dwellers? Does it make sense to invest and modernise agriculture around a megacity and reinvent the rural into a new model?

Sessions:

Session 2.1
Beyond Megacities: Key Challenges and Alternatives
Discussions under Track 2 broadly explore two key areas – the contemporary urbanisation context under which the megacities, their scale economies and their regional linkages are embedded, and what the possible alternative spatial models are. These two broad themes then lead to more detailed explorations around seven sub-themes. This introductory session, involving keynote speakers from all the sub-themes would touch upon key challenges and alternatives in planning at a regional scale and lead to further deliberations under specific sub-topics.

Session 2.2
Megacities Backside: Peri-urban Interface
Peri-urban interfaces of dynamic metropolitan regions are spaces which are forever in a state of flux, where land use patterns and built forms frequently undergo rapid change, where urban and rural land livelihood and lifestyle patterns coexist, often within a person's everyday routine. Hereunder this sub-theme, we not only explore some of the complexities involved in peri-urban transformation, but also seek to understand how megacities and peri-urban areas can develop a synergetic and perhaps positive relationship.

Session 2.3
Metropolitan City and Its Shadow Regions
Megacities and global metropolitan regions often tend to cloud our imagination through the sheer magnitude of their scale, their glitz and glamour, and their deprivation and squalor. Needless to say, megacities dominate and overshadow their hinterlands. Here, we seek to shed light on such shadow regions. We ask what it means to be a shadow region. Can life be good in the shadow of the megacities? How does megacity expansion transform the countryside? What are the conflict points and how are they being negotiated?

Session 2.4
Urban Expansion and Food Supply: Megacities Resiliency

Rapid expansion of urban footprints-often in unplanned chaotic ways-are harming

photo: Atik Sulianami, Unsplash

our ecosystems and green covers; fertile agricultural lands are shrinking; wetlands and waterbodies are depleting. This sub-theme explores how we can manage urban expansions more sustainably. We shall discuss how to implement global sustainability goals through local processes. What are the linkages between peri-urban agriculture and urban sustainability goals? Does it make sense to invest and modernise agriculture around a megacity and reinvent the rural into a new synergetic model?

Session 2.5
Managing Megacities and Hinterlands Relations - Planning at a Regional Scale
Megacity – hinterland relations are often seen as one-way traffic, where market advantages of agglomeration economies dictate flows of population and material resources. Here we question how we can bring greater balance through innovative regional planning strategies. How do we strengthen economic roles of smaller cities as counter magnets – to generate more job opportunities for rural migrants closer to their home and reduce population pressure on megacities?

Session 2.6
Alternative Models of Spatial Development: Neither Urban nor Rural?
Here we discuss settlement typologies beyond urban-rural binaries. We try to understand what the possible alternative models of spatial development are, and which ones are neither urban nor rural. How to strengthen rural economies, culture and lifestyle, in this age of rapid urbanisation? How do newly planned cities impact existing rural settlements? How are land and environmental conflicts being mediated?

Session 2.7
Beyond Megacities: Role of Mega Infrastructure in Hinterland Development
Mega logistics hubs, such as special economic zones, container terminals, and ports; and network infrastructure, such as railway corridors and highways anchor global supply chains in megacities. But how do such mega-infrastructure projects shape regional settlement patterns and backward linkages? How do they shape industrialisation and urbanisation processes?

Session 2.8
The future of urbanisation: decentralization of functions, dispersal of urban form?
Discussions under the theme would revolve around various alternative possibilities regarding mega-urban regions – What are national level planning strategies regarding spatial concentration or dispersal? Is it still necessary for capital and other core administrative and economic functions to be co-located in a single urban centres? Or is it possible to envision that constellation or a network of different small towns connected by smart technologies will surpass megacities of today? And why do countries still need centralized cities as it was thousand years ago despite the all-around digital maze of our times?

Session 1: Beyond Megacities: Key Challenges and Alternatives 2.1

10 September (Tuesday), 9:00 - 11:00

TRACK KEYNOTE

Jean-Claude Bolay, Eleonore Labattut

Sustainable development, planning and alleviation of poverty

Many small and medium-sized cities in the global South can be considered as poor cities and are home to half of the world's urban populations. Through case studies from Burkina Faso, Brazil, Argentina and Vietnam, this paper brings attention to these intermediary cities and argues that revitalising urban planning from these perspectives is imperative.

TRACK KEYNOTE

Ratoola Kundu

The Informal Syndicate Raj:Emerging urban governance challenges in newly incorporated villages of Bidhan Nagar Municipal Corporation, West Bengal

This paper investigates the complex governance and livelihood transformations following the State-driven merger of an existing township with the surrounding unplanned and severely underserviced village and urban areas. Understanding the frictions over access to urban services and resources between erstwhile rural-urban jurisdictions reveal the hybrid forms of institutional governance, which characterises the peripheries of cities of the Global South.

TRACK KEYNOTE

Teresa Marat-Mendes, Joao Borges

The role of food on re-imagining the sustainable city: from the neighbourhood to the region.

In search of a new socio-ecological metabolic perspective, this paper presents the preliminary findings of a research project, which aims to identify urban planning policies to support sustainable transitions towards low-carbon cities at the regional and neighbourhood scales. The results call for a stronger integration of the food system within urban planning and new theorising of the city in sustainable transition.

10 September (Tuesday), 11:30 - 13:00

TRACK KEYNOTE

Esther Vlaswinkel, Minze Walvius

The City of the Future - a new paradigm, a new vocabulary

Planning 'The City of the Future' requires a new way of thinking and therefore a new vocabulary. This new conceptual framework which has been explored in the city edge of Utrecht, shows how transitions in mobility, energy, climate can be integrated in the cityscape of the future.

Zhao Chen, Chunxiao Huang

The Weak-sided Urban Fringe and the Flexible Planning Approaches: case study of Yuhuatai District, Nanjing

An uneven development of urban fringe caused the diverse of the strong-sided fringe and the weak-sided one. The weak-sided urban fringe in China is characterised with mega-project driven urbanisation mode, unbalanced infrastructure supply, the fragmented governance etc. A flexible planning methodology could be adopted including the repair of embedded structure and the action-oriented organic regeneration.

Dani Muttaqin, Soelaeman Soemawinata, Adhamaski Pangeran

Township Development by Private Sector: Lesson Learned from Jakarta Megapolitan Area

This paper describes the history and process of Township Development in Jakarta Area since the 1980s, its location and distribution, challenges and opportunities and how private sector can become vital stakeholder in minimising negative impact of urbanisation.

Soumya S Warrier

The Anti-city

Cities like Gurgaon are witness to the rise of an era of privately planned "anti-cities" that serve a select few. With an intense cauldron of activities and transformations wrapping India, how does the profession of architecture and urban design, as capacity holders, evaluate and streamline the growth of the contemporary urban landscapes of our cities?

Mirza Permana

Settlement Development Analysis of Malang City Peri Urban Area and Its Conformity with the Regional Spatial Plan

The development of Malang City, Indonesia, has consequently led to an upturn of new residential, trade and industrial centres in the suburbs area. The paper presents a research, which aims at determining the characteristics of settlements in peri-urban area; analysing conformity to the regional spatial plan (RTRW), and establishing development direction.

Sohini Maiti, Satyajit Mal

Defining the RUrban - a case of Hyderabad

It is time to redefine both Rural and Urban through a sustainable future for the secondary cities - the Rurban dream of planners and designers. To conserve the rural soul while having the urban facilities is the aim but if that is a viable possibility is the subject of discussion.

2.3 Session 3: Metropolitan City and Its Shadow Regions

10 September (Tuesday), 14:00 - 15:30

TRACK KEYNOTE

Liang He

From one-way to interactivity: difficulties and strategies in the planning of adjacent areas of metropolis

This planning study combines the author's planning practice, focusing on the adjacent area of Shanghai and Zhejiang. Analysing the functional coordination and infrastructure convergence in regional coordination from the microscopic perspective. Key issues such as administrative barriers, some planning strategies are carried out.Based on this plan, the three major difficulties in regional cross-border coordination planning are as proposed.

Tianzhu Liu, Jingsheng LI

Out-migrate Elites as Rural-Urban Link: an Innovative Pathway Toward Rural Development Around Metropolis

This paper questions what the role the Out-migrate Elites (OMEs) play in rural development. Participatory research method was employed to conduct the research. The binary nature that OMEs have was concluded: their social relations with the village are the motivation of their participation in rural affairs, while their urban life experience contributes to the significant resources that the village requires.

Ivana Angelova

Building moratorium as a future instrument for tackling unsustainable urban growth

To regulate the undesirable urban growth, a local government may impose a moratorium on the issuance of building permits. Meanwhile, authorities will often conduct urban surveys based on which a new satisfactory urban plan and/or updated building regulations will emerge. This research looks at a few cases using this tool, focusing on the moratorium in Skopje, North Macedonia.

Erie Sadewo, Delik Hudalah, Ibnu Syabri, Pradono Pradono

Deciding Where to Live in The Suburb: Linking Utility-Maximization and Residential Mobility in Polycentric Urban Region Context

This paper questions the extent to which residential mobility between peripheral municipalities is linked to utility-maximisation, in polycentric urban region context. The results could only validate the importance of housing cost in polycentric setting. Residential mobility within suburban areas does not seem to be motivated by lower housing or transportation cost, nor to be near to major employment districts.

Dianhong Zhao, Ding Shi

A Study on the Approach of Sustainable Development on Traditional Cultural Landscapes Surrounding Metropolitan Shanghai

This study focuses on the methodology of effectively utilising cultural landscape resources and promoting further harmonious development of urban-rural relations in Shanghai. By classifying the cultural landscapes, the paper puts forward the mode of protection and sustainable development of cultural landscape resources, thus providing a basis for heritage protection, urban and rural planning and tourism planning within Shanghai.

Yanqun Li, Hong Geng, Erpeng Shi

Response path adapted to the unbalanced shrinkage of small towns in metropolitan areas: A case study of Wuhan in China

By taking Wuhan city as an example, this paper comprehensively measures the external characteristics of "unbalanced shrinkage" of small towns in metropolitan areas, and explores the formation mechanism of "balanced shrinkage", and puts forward the adaptive response path, so as to promote the healthy urbanisation of metropolitan areas.

2.4 Session 4: Urban Expansion and Food Supply: Megacities Resiliency

10 September (Tuesday), 16:00 - 17:30

Thomas Weith, Meike Fienitz

Just Schwerin - Balanced urban-rural development?

The transdisciplinary study analyses current challenges, conflicts and approaches to solutions regarding an integrative urban-rural development, using the case of the German city Schwerin and its surroundings. The focus is on the question as to how far solutions for conflicts between city, surroundings, and rural areas can be.

Jason Hilgefort

Rural Revolution, leveraging emerging infrastructures

There is a global issue facing the rural, from Italy, USA, to SEAsia, that has left them behind rapidly expanding urban centers. Within Asia model is emerging. In key

areas, new infrastructures are being leveraged to allow for new opportunities for countryside places within the larger constellation networks of cities.

Antonella Contin, Sandy Jiyoon Kim

How to Grap the Power of the Place: The TELLme Project and Metro-dology

As a response to contemporary metropolitanisation processes, the ongoing TELLme Erasmus+ project attempts to define a holistic methodology, the Metro-dology; structure a training lab where academia and practitioners can discuss the issues, principles, and gaps of the metropolitan area; and develop mapping tools to comprehend the metropolitan complexity and support the training.

Yi Li

Analysis of the Correlation between the Establishment of Rural Land Share Cooperatives around Shanghai and the Government & Villager Satisfaction - A Case Study of Jinxi Town, Kunshan City

Cooperatives have become an important buffer for migrant workers in Shanghai's surrounding villages, increasing the employment rate, providing green agricultural products, inheriting agricultural technologies and activating local communities. Cooperatives can promote the large-scale operation for agricultural land. It is suitable for areas with deep industrialisation and urbanisation. Cooperatives need to be improved in equity distribution and agricultural production.

QiuYi Jiang, Guoquan Zhang, Xiaoyi Wen

Exploration and practice of formulating strategic planning for rural revitalisation in the Shanghai metropolitan area - take the rural revitalisation of Jinxi town in Kunshan as an example

At present, China's rural revitalisation research mainly focuses on rural theory and lacks rural research from a regional perspective. Taking Jinxi Town in Jiangnan as an example, this paper analyses the relationship between regional development and measurement and demonstration through big data relative comparison, which is expected to provide new ideas for rural revitalisation in metropolitan areas.

Zhengyin Lu, Xiaoyi Wen

The Shrinkage and revitalisation of villages in metropolitan area of mega cities

Water system and water-related activities are weakening during the rapid development of mega cities. Taking two Asian cities and their surrounding villages as examples, water's connectivity and productivity can be crucial for villages and its balance with big cities.

Session 5: Managing Megacities and Hinterlands Relations: Planning at a Regional Scale 2.5

11 September (Wednesday), 11:30 - 13:00

Dianhong Zhao

Construction and empirical study of evaluation index system of rural revitalisation in China's metropolitan areas from the perspective of social ecosystem - taking villages and towns around Shanghai as examples

This paper looks at the rural revitalisation of 20 villages around Shanghai, China, to test the feasibility and application value of the evaluation index system based on social ecosystem perspective, and to suggest the direction of policy intervention.

Huimin Qi

Analysis on Integration Path of Urban and Rural Industries Based on Economic Data Model - A Case Study of Overall Strategy Planning of Taiyuan Rural Revitalisation

In the background of ongoing urbanisation in China and prominent, dualistic, contradiction between urban and rural areas, rural revitalisation is extremely urgent. Currently, common problems concerning industry, ecology and humanities exist in rural areas. This paper attempts to figure out the causes of differences in industrial development in rural areas on the basis of macro data analysis and industrial spatial distribution.

Tathagata Chatterji

Balanced Regional Development through District Planning - A comparative analysis of Indian and South African planning frameworks

This paper compares approaches towards balanced regional development through district planning in India and South Africa to draw policy lessons. The comparative analysis of two major transitional economies shows potential of district planning to achieve balanced regional development. It also underscores the need for the regional planning mechanism to combine features of top-down strategic approach and bottom-up participatory approach.

Xue Jiang, Tianyu Zhao

Whole-region Tourism Greenway Network Organization Mechanism Based on Gravity Model Flow Measurement

Greenway plays an important role in the integration and connection of urban and rural environment with the continuous expansion of metropolis. This research is based on the gravitational model flow measurement to constitute potential greenway network structure with comprehensive factors formed by the minimum cost path method, which improves the scientific of greenway network evaluation and organisation.

Session 6: Alternative Models of Spatial Development: Neither Urban nor Rural? +Panel Discussion 2.6

11 September (Wednesday), 14:00 - 15:30

Bin Li, Weihong Guo, Yuqing Zhang

Rural revitalisation of Batang village in Guangdong province under the background of balancing urban and rural development

Balancing urban and rural development by rural revitalisation is happening current in China. With the lack of infrastructure, unbalanced economic development, dilapidated living environment and insufficient sharing between urban and rural areas, this paper based on ReBAM theory, field survey and literature review to solve these problems in an example of Batang village from living, production, ecology and governance aspect.

Ye Liu, Xiaoyi Wen

Planning Practice in Areas Beyond Megacities under the Rural Revitalisation Strategy in China: Case Study of the New Jijiadun Village - A Concept of "Co-Creation Community for Rural Life"

This paper describes an emerging pattern of rural life in areas around Shanghai, under the background of the Chinese Rural Revitalisation Strategy. It focuses on how these planners have broken the boundaries between the urban and rural areas, taking the city dwellers back to the rural and natural life while bringing vitality to the rural areas.

Bakti Setiawan, Sita Rahmani

Global-Local Dynamics in Urbanisation: The transformation of the desa-kota in Bali and the roles of Adat institutions

This paper shows and argues that in the dynamics process of urbanisation in Bali, Indonesia, local actors and forces have play significant roles in the production of urban spaces. It argues that the existing centralised - Indonesia, formal/legal, urban policy and planning system does not fit with the existing dynamics of local-cultural variations of urbanisation.

2.7 Session 7: Beyond Megacities: Role of Mega Infrastructure in Hinterland Development

12 September (Thursday), 11:30 - 13:00

Roni Susman, Thomas Weith

Factors Influencing Land Use Conflicts in Parimban Seaport Indonesia

Our study from Patimban Indonesia explores the influencing factors of large scale land transformation for seaport development resulting in land use conflicts and options for governance in the future.

Haixuan Zhu, Sai Liu, Xiaoyu Jia

Urbanisation Mechanism Study under the Dynamics of State Capitalism: A Case Study of the Far East with the Construction of the Siberian Railway in the Early 20th Century

Due to special geopolitics in China at the end of the 19th century, focus on the construction of port and railway, become the government's top priority. This induced capital competition among China, Japan, and Russia, formed the export-orineted urbanisation mechanism, and laid the hub-railway network - hinterland cities structure, which rapidly promoted the modern urbanisation process in Northeast China.

Muhammed Ziya Pakoz, Ahmet Bas, Fatih Eren

An Analysys of the Changing Role of Istanbul as a Megacity in the World

This paper focuses on the city of Istanbul and aims to discuss the changing position of the city within the globalised world in terms of economic, social and cultural interactions, and to follow the changes in the hinterland relations and the spatial structure of the city in time.

Dwitantri Rezkiandini Lestari, Latifah Latifah

Anticipation Strategy for Urban Conurbation in Semarang - Surabaya Corridor

Semarang-Surabaya corridor is the backbone for economic growth of Central Java and East Java. Semarang-Surabaya corridor development is expected to create positive externalities, such as creating spillovers in urban areas along the corridor. Besides creating positive externalities, the development of semarang-surabaya corridor is expected to create uncontrolled urban conurbation, as it happened in Jakarta - Cikampek corridor.

2.8 Session 8: TheFuture of Urbanisation: Decentralization of Functions, Dispersal of Urban Form?

12 September (Thursday), 14:00 - 15:30

Paramita Rahayu, Fadjar Mardiansjah, Deden Rukmana

Urban Population Growth and the Growth of Towns and Cities in Indonesia: the challenge of non-statutory town development

This study examines the emergence of new tendencies in the current Indonesian urbanisation process that face the development of non-statutory towns in many urbanised Kabupaten (non-urban districts). These towns also bring significant challenges in urban future in Indonesia since they play significant roles in the future urbanisation process still they lack capacities in managing urban development.

Pietro Elisei, Elena Batunova, Miruna Draghia

The CRISALIDE Project: When innovative planning processes re-balance urban development and create new quality of life using the opportunities provided by the rise of the digital city.

CRISALIDE, a collaborative project involving EU and Russian researchers, is experimenting with the creation of a digital innovative platform aimed at facilitating the renewal and regeneration of brownfields in Rostov on Don. By creating a user-friendly tool, this project supports strategic, smart and integrated urban management to promote stable growth and effective processes of innovation based on participatory planning.

Derry O'Connell

The Smaller Town as Component of an Urban Settlement Cluster

The development of fast sustainable transport has introduced the concept of complementary settlement clusters as an alternative to the large city. Recent research in a number of towns in Ireland examines how the typical small town is adjusting to this.

David Green, Sulaiman Al Rashad, Paul Knight, Nicole Cammelli

A 21st Century National Ordinance

This paper explains the theoretical foundations of the National Ordinance in Kuwait and provide a series of case studies across scales that describe the operational aspects of the Ordinance for both spatial structuring for new and existing development, and projecting and tracking sectoral development. It also discusses the universality of this system and its application in the USA and the UK.

Track 3

Liveable places and healthy cities

Planning for people

CONGRESS TEAM

Jens Aerts
(Belgium/ USA)
Mahak Agrawal
(India)

LOCAL EXPERTS

Aji Pamungkas
Irwan Prasetyo

Migration, unplanned urbanisation and urban inequities affect the well-being of city dwellers on an individual and collective scale across the world. Cities expand more rapidly than can be sustained by infrastructure and services, and the cost of living is rising far more rapidly than wages. Lack of basic services affect a sizeable part of the population. In addition, the physical urban environment introduces new types of vulnerabilities that require a systematic approach through urban planning: obesity, mental diseases and the decrease of play and physical activity, multiple forms of exposure to pollutions and unsafe public spaces. These challenges come with a high cost for the weakest but also for the community, leading to high public health costs, social unrest, fragmentation, urban violence and terrorism, ethnic tensions and more.

Planning for and with people is at the core of creating a viable future: Improving the quality of life together, planning safe spaces and clean infrastructure, promoting child-responsive and multi-generational environments. Engaging communities in the process of planning will spark innovation, improve knowledge and decision making for the best solutions, accelerate change and ensure citizens adopt sustainable behaviours from early age on.

Is liveability a luxury or a human right? How can it be defined and measured? Can we plan for it? Are there universal principles or different ones depending on culture?

Sessions:

Session 3.1 (Special Session)
UNICEF Opening Session: Children and Cities, Planning for the Future
Discussions under track 3 highlight the complex relation between urban health issues, spatial inequity and environmental challenges. Especially in large and fragmented urban contexts, this requires a focus on equity and people-centred urban planning approaches, to ensure urban development and upgrading translates in healthy, safe and inclusive spaces. Analysing the evidence, successful initiatives, strategies and projects, this opening session, organised by UNICEF and supported by a panel of experts, will highlight priorities for action in order to build and plan healthy cities for children and their communities.

Session 3.2
Planning and Design for Collective Space and Transport for Children and Communities
Public space networks are the backbone of many planned cities and allow access to the city on various scales and in all its meanings: as a functional place to undertake a journey, but also to meet, play, learn and grow up to become a citizen, to build the community for all generations. If all children have access to public space, cities are successful for everyone. This session shows how crucial planning and placemaking approaches for collective spaces and safe mobility are for children and communities.

Session 3.3
Participatory Planning and Multi-generational Well-being
Community-led planning is more and more recognised as a sustainable approach to address urbanisation challenges, in absence of or as a complement and alternative to formal planning. Various examples show that participatory planning ensures inclusion in decision making and fosters community development on a neighbourhood level, as fundamental building stone of any size of city.

photo: Rahmatharman, Wikimedia

Session 3.4 (Special Session)
Planning Sustainable Urban Childhoods for the Youngest
Planning and designing a city to better meet the needs of babies, toddlers and the people who care for them is one of the best investments a city can make. Growing evidence from neuroscience, public health, education and economics makes it clear: Experience shapes the developing brain. One of the best ways to ensure good experiences is to support the people who care for babies and toddlers, beginning in pregnancy. City planners have a big role to play: If you could experience a city from 95cm – the height of a 3-year-old – what would you change?

Session 3.5
Sustainable Mobility and Streets for People
Despite the potential of urbanisation to reduce distances, increase density of activities and enhance walking, biking and mass transit, transportation planning seems to prioritise individual car use. This leads to clogged street spaces, traffic injuries and polluted air. This session explores sustainable urban mobility strategies that prioritise the well-being of people and looks for inclusive solutions for all (gender, ages).

Session 3.6
Data, Indicators and New Paradigms for Public Health
Data is key for sustainable urban planning: to collect it, to use it for decisions making, to evaluate initiatives and to monitor progress. There is quantitative and qualitative data, to be collected with new technologies, but also through social innovation, as this allows communities to engage and to share knowledge. This session explores the sense of open data, indicators, evaluations methods and mapping tools that foster community engagement, to support better planning of healthy and just cities.

Session 3.7
Public Space, Public Life
Public spaces are the core of cities. They can be formally planned, but the public life can be informal at the edges and make unexpected spaces more inclusive and welcoming for specific vulnerable groups such as migrants and women. This session explores the relation between urban form, liveability and values of public spaces and how the latter is also about the daily process of making meaningful places from neutral spaces.

Session 3.8
The Right to Housing and Livelihoods
Housing is more than four walls equipped with basic services of water, sanitation, drainage or electricity. Housing is a human right, strongly interlinked to livelihood, and a critical part in redressing the complex multi-dimensional challenges of poverty, inequalities, inequities and exclusion. The sub-track discusses and reflects upon lessons learnt from housing plans, schemes and projects in different parts of the world. It also explores varied perceptions to housing and livelihoods across various generations in diverse geographies and the feasibility of select tools and techniques that can tackle housing issues.

3.1 Session 1: (Special Session) UNICEF Opening Session: Children and Cities, Planning for the Future

10 September (Tuesday), 9:00 - 11:00

TRACK KEYNOTE

Jens Aerts, Thomas George

Panel Discussion on Children and Cities

The growth of safe and sustainable cities in East and Southeast Asia are inextricably linked to the well-being of the region's children. The panel session offers insight from panel experts on challenges for children in cities and how urban planning can be a support to ensure children get the urban childhood they deserve in accordance with UNICEF's recommendations.

Lynn Tang, Vivian Pun, Ririn Radiawati

Importance of air quality management for public health and development progress in Jakarta, Indonesia

This talk highlights approaches to combining strategic use of innovations in air pollution monitoring, emissions estimation and source apportionment modeling to inform near-term control measures for priority sources at a local and regional level in Jakarta.

3.2 Session 2: Planning and Design for Collective Space and Transport for Children and Communities

10 September (Tuesday), 11:30 - 13:00

TRACK KEYNOTE

Gregor Mews

Realising the potentials of a design-dividend towards a loveable urban future

Urban living in the early part of the 21st century has not been good for children and young people. The contribution shares valuable insights on challenges associated with the need for a paradigm shift that takes a design-dividend into consideration and enables better health outcomes in urban developments.

Dhea Andriani, Indarti Komala Dewi, Janthy Trilusianthy Hidayat

The Implementation of Children Friendly City in DKI Jakarta through Assesment of Child-Friendly Integrated Public Space (RPTRA). (Case Study: Kecamatan Kemayoran, Jakarta Pusat)

Child-Friendly Integrated Public Space is an integrated public space for several ages, functions as green open space, child development facilities, and community empowerment. DKI Jakarta built 6 RPTRA in Kemayoran subdisctrict. RPTRA characteristics depends on facilities, activities, location, and land area. Two RPTRA, namely Mutiara Sumur Batu and Harapan Mulya, have met the policy standards of DKI Jakarta government.

Ran Guo

Outdoor Public Space Activities Characteristics of Children and Their Inter-generational Parents and Design Strategies from the health perspective: a case study in Harbin, China

Taking care of children by their grandparents has become one of the most important forms in the current Chinese urban families. To design and build appropriate outdoor public space (OPS), this paper studies the connection between OPS, space comfort, facilities arrangement, the social attribute of children and their inter-generational parents and healthy activities.

Shuai Li

Children-friendly design of Urban public space: based on the study of Shanghai, China

With SP method,this paper found the factors in spatial traffic and social aspects influencing children's safe path in high-density urban environment. Among them, the path space factor and the path traffic factor have more significant influence. Recreation of places, dangerous places, and crossing the street without any help are the top three influential factors.

Session 3: Participatory planning and Multi-generational Well-being 3.3

10 September (Tuesday), 14:00 - 15:30

Xuhui Liu, Yu Yifan, Xin Sui

Neighborhood Environment and the Elderly's Subject Well-being

This paper analysed the relationship between neighbourhood built environment and the elderly's subjective well-being in Shanghai. The results show that under the control of socio-economic variables, neighbourhood built environment can significantly affect the subjective well-being of the elderly. Per capita green space area, road network density, location, and housing construction area are the significant environmental elements.

Mengqi Zhong, Yuanyi Shen, Yifan Yu

Association between Neighbourhood Built Environment and Body Mass Index among Chinese Adults: Hierarchical Linear Model

This paper examines the association of built environment and body mass index based on the data from 29 provinces in China. The paper concludes that living in walkable neighbourhoods is associated with more physical activity and lower overweight/obesity, while adults in higher-income neighbourhoods have lower BMI and higher mental condition. These findings have implications for urban planning which are presented.

Constant Cap

The Importance of Participation and Inclusion in Developing Livable and Affordable of Housing, Transport and Social Services in Kenya

The paper looks at the importance of proper communication, participation and inclusion in urban development. It lays some focus on how they have impacted the eventual outcomes of some of the recent housing and transport projects that various African Governments and Development Partners have undertaken as a response to the ever increasing challenges within urban centres.

Poeti Akbar Jurian Edelenbos

Temporal and Regular Place-making in Indonesian Kampung: Creating Urban Spaces that Enhance Local Empowerment

This study aims to examine the impact of place-making through 'regular' everyday life and 'temporal' art-cultural festivals on the local capacity of Indonesian kampung. In order to achieve a better quality of place-making, the enhancement of relational resources across age group is necessary. Challenges on the viability of place-making were noted as well.

Slawomir Ledwon

Health and the city: creating built form and planning for the physically active

This study explores the relation between the city, built form and citizens' physical activity, in order to maintain a healthy population. Taking running as the main case study, it shows the examples of best practices encouraging exercise in urban areas, while mitigating obstacles and introduces the runnability concept.

Session 4: (Special Session) Planning Sustainable Urban Childhoods for the Youngest 3.4

10 September (Tuesday), 16:00 - 17:30

Speaker: Rushda Majeed

Planning and designing a city to better meet the needs of babies, toddlers and the people who care for them is one of the best investments a city can make. Growing evidence from neuroscience, public health, education and economics makes it clear: experience shapes the developing brain. One of the best ways to ensure good experiences is to support the people who care for babies and toddlers, beginning in pregnancy. City planners have a big role to play. Clean air and water. Walkable neighbourhoods that cater for the basics a young family needs. Multi-generational public spaces close to home that allow small children to explore safely. Safe routes and reliable transport that make it easy for caregivers traveling with small children to get to healthcare, childcare and healthy food. Such urban amenities help lay a crucial foundation in the early years of life for good health and learning into adulthood. And they make cities better for people of all ages. Yet babies, toddlers and the people who care for them can be invisible to city leaders and planners as a group with specific needs. That's why the Bernard van Leer Foundation's Urban95 initiative supports cities worldwide to ask and answer a bold but simple question: if you could experience a city from 95cm—the height of a 3-year-old—what would you change?

This workshop will take participants through India's Infant, Toddler and Caregiver Friendly planning, policy and design guidelines developed for and at the request of India's Smart Cities Mission by a team convened by the Bernard van Leer Foundation's Urban95 initiative. The workshop will also feature presentations by the World Resources Institute (WRI), Indonesia on safe routes to schools for young children and their caregivers and the Institute of Transportation and Development Policy (ITDP), Indonesia on its kampung project to improve accessibility and provide public spaces in consultation with communities and with input from children and women. The workshop will be hosted by the Bernard van Leer Foundation.

3.5 Session 5: Sustainable Mobility and Streets for People

11 September (Wednesday), 11:30 - 13:00

Yang Ye

Residents -Perceptions of Walkability Attributes in Cold Region Chinese Cities: Reliability and Validity

This study tries to develop a model , NEWS-CRC , to reflect the characteristics of cold region Chinese city built environment in residential areas and people's behaviour mode, and prove the model could illustrate residents' perceptions of walkability attributes in cold region Chinese cities and could be use in other Chinese urban attributes studies related to walking.

Cheng Peng, Jingsheng Li

Research on the built of Healthy Walking System for Urban Central Business District: A Case Study of Jiangbeizui CBD in Chongqing, China

Jiangbeizui CBD in Chongqing, China, is facing sub-healthy conditions: the urban space is fragmented in mobility system, service system and landscape due to topography and construction. The paper proposes three hierarchies of healthy demands in walking system design together with spatial strategies to help build a continuous pedestrian system for CBD's benign circulation in both space and society.

Fenita Indrasari

In between luxury of housing and affordability of transportation: Exploring automobile dependency of housing estate residents and kampung dwellers in suburban Bandung, Indonesia

Housing estates in Indonesia are built similar to gated communities where residents are forced to be automobile dependent. However, it can be reduced by providing public access points which contribute to a more active travel.

Laksmi Tungga Dewi Jaya Wisnu Wardani, Natalia Tanan

The Pedestrians' Stories: Towards Walkable Cities in Indonesia

The paper discusses the process of providing walkable pedestrian facilities in three cities in Indonesia which is considered lacking due to the limited number and poor quality. Through identifying problems and recommendations to improve the quality of pedestrian facilities, the findings aid policy development on pedestrian facilities and green planning at the Ministry of Public Works and Housing.

Sebastien Goethals

Planning Transit-Oriented Development (TOD) in an African City Facing Rapid and Informal Urban Growth: the Case of the Urban Mobility Plan of Conakry, Guinea

Responding to the lack of urban governance and planning culture, in particular to the lack of urban development strategy and land use control, in Conakry, Guinea, the article illustrates the methodology of the capital's Urban Mobility Plan as an operational decision-making tool, and a strategic investment plan to build people-oriented urban infrastructure and healthy mobility.

Fernando Caetano, Jeronimo Meira, Suzi Rodrigues

The definition of accessible routes on sidewalks: a new challenge for Brazilian cities

The purpose of this paper is to present a method (virtual audit) to support Brazilian local administrations, in particular of small cities, to define accessible routes on sidewalks. It is expected that this method encourages local administrations to audit sidewalks situation aiming to include walkability's improvement in their investment agendas; and to define public policies towards urban environment qualification.

3.6 Session 6: Data, Indicators and New Paradigms for Public Health

11 September (Wednesday), 14:00 - 15:30

David Green

Health Districts: Creating Healthy Cities

The paper examines several specific cases across the globe that problematise scientific research that informs methods of urban and city design and argue for protocols to frame a scientific method for planning and urban design at a consistent, international level.

Daniel Mambo Tampi, Linda Darmajanti, Irene Sondang Fitrinitia

Sustainable Urban Development: Building Healthy Cities in Indonesia

In 2045, the projection results show 61.7% of Indonesia's population will live in urban areas. The purposes of this paper is to find out actors, factors, and top healthy cities in Indonesia. The analytical method in this study is log frame analysis. The result is building healthy cities with closely related to aspects of life in urban areas: health services, environmental, and socioeconomic aspects.

Chengcheng Liu

Strategies on Healthy Urban Planning & Construction for Challenges of Rapid Urbanisation in China

This paper studies how to achieve the equalisation of medical and health services and the sustainability of urban environment in China through four strategies of healthy city. China has formulated a national plan for healthy cities, reformed its territorial and spatial plans, formulated local plans for the distribution of health care facilities, and carried out urban repair and ecological restoration

Gabriela De Souza Tenorio

Better places for a liveable - and lively - city: a method of Post-Occupancy Evaluation of public spaces.

This paper brings together the knowledge and repertoire available on public spaces' design, translates, complements and structures them into a method of Post-Occupancy Evaluation of public spaces. It is offered as a tool to support those who deal with public spaces at different levels - from academic studies to municipal management.

Dayinta Pinasthika, Puteri Rizqi Amelia, Elkana Catur Hardiansah, Adriadi Dimastanto

IAP Indonesia's Most Livable City Index (MLCI): A Perception-Based Survey to Measure City Liveability Index

The Indonesian Association of Planners (IAP) developed the "Most Livable City Index"; (MLCI), surveying city liveability based on citizen's perceptions. It has been conducted since 2009 and was last held in early 2017. The indexing measurement was based on 28 assessment criteria, which were conducted in 26 cities throughout Indonesia. The result showed the most and the worst cities in terms of best liveability.

Authors are responsible for the content of their work.

Raeesa Ghoor, Keneilwe Pholo, Karishma Busgeeth

Developing a Spatial Transformation Scoring Tool to Monitor South African Catalytic Housing Projects

The Spatial Transformation Scoring Tool (STST), developed by the Monitoring and Evaluation, Knowledge Management and Research Planning unit in the Housing Development Agency is currently being used to assess housing projects classified as catalytic projects. This presentation intends to explore the challenges, opportunities and lessons learnt of the STST in monitoring housing projects in South Africa

Session 7: Public Space, Public Life 3.7

12 September (Thursday), 11:30 - 13:00

Hang Sui, Dongfeng Yang

Analysing the perceptions of the elderly on space vitality and related environmental factors based on residential community

Taking Dalian, China as the research range, this paper identified the potential environmental factors which related to the perceived level- and actual satisfaction- of the elderly offered by the "space vitality" of the residential community, and put forward the environmental optimisation strategies promoting mental health for the elderly.

Juan Li, Anrong Dang

Empirical study on the evaluation of publicness of public space: taking Chinese megacity as the case

This study proposes a pragmatic model to evaluate the publicness of public space and come up with a systematic framework based on the Chinese context. It has been applied to a community within Beijing to find out how public the public spaces are in the Chinese megacity. The empirical study will provide suggestions for urban planning and governance.

Matej Niksic

Liveable and just public space - Conceptual approach to urban walkability on the case of Ljubljana, Slovenia

The research aims to point out the power and responsibility of urban planning as a discipline in providing the urban walkability conditions within the just city agendas. It points out the need for the planners in the transitional socio-economic contexts to develop new skills and competences to assure social and spatial cohesion as a precondition for the truly livevable places.

Apostolos Kyriazis

Urban morphology and behavior mapping in Abu Dhabi's public spaces: informality as an interaction of cultural context and urban form.

This paper presents findings for a link between the design, use and the surrounding morphologies within the diverse sociocultural context of Abu Dhabi. Fourteen public spaces were examined in terms of their typology, functions, social profile, urban context and connectivity. The program amplifies the importance of informality as an indicator of urban health, programming, social cohesion and inclusivity.

Adriadi Dimastanto, Rachmatika Fitri Insani Tanjung, Tri Saptiwi

Improving the Quality of Public Space in Bogor City Through CSR Founding Scheme

This paper aims to explain one of Bogor's park development projects using the corporate social responsibility (CSR) fund scheme. The municipality's budget available for improving the quality of public spaces, especially to build city parks, were limited. However, by inviting the private sector, the city government could innotvate the provision of city parks and set an example in Indonesia.

Session 8: The Right to Housing and Livelihoods 3.8

12 September (Thursday), 14:00 - 15:30

Akino Tahir, Risye Dwiyani, Saut Sagala, Nino Viartasiwi

Secondary cities and forced migration: accommodating refugees and asylum seeker in Indonesia

Secondary cities are impacted by forced migration trend around the world. Such cities attract forcibly displaced migrants who view them as more accessible and 'friendly' compared to primary cities. The study explores the capacity of secondary cities in Indonesia in accommodating the influx of displaced people. By understanding the system, we hope to identify improvement to the city resilience.

Mengqi Zhong, Yifan Yu

The Spatio-temporal Disparities in Healthy Food Accessibility: A Case Study of Shanghai, China

This paper examines the spatio-temporal disparities of health food accessibility through a case study of Shanghai communities. Based on the disparities, we use the spatial autocorrelation to analyze the spatial patterns of healthy food accessibility and propose the corresponding improvement strategy.

Fujun Xia

Discussion on the Fairness in the Planning of Relocation Community - Taking the Constructive Detailed Planning of Longhai Community as an Example

Through the research on the constructive detailed planning of Longhai South District, the strategies for community planning of demolition and resettlement under the background of urbanization in China are proposed, which are to strengthen public participation, innovate organizational management system, consider the future livelihood of residents and fairness and homogeneity.

Mahak Agrawal

A Dream of open defecation free India? Decolonise and innovate urban sanitation to reach those left behind

There is no delicate way of describing matters of shit. Through evidence, urban narratives from India, the project reflects upon the less spoken dimensions of sanitation deprivation in India and most importantly why and where we are going wrong, and what we can do to truly achieve an Open Defecation Free India- as there is no one 'right way'.

Rouve Bingle

Hunger in revered spaces: Exploring the impact of planning on the university campus food system in South Africa

This exploratory study examines how campus planning and its spaces affect the food security of students. The study is conducted on the campus of the University of the Free State in South Africa and uses a mixed methods approach which includes an online survey, qualitative interviews and a site inspections.

Track 4

Knowledge economies and identity
Planning for culture

CONGRESS TEAM

Nasim Iranmanesh
(Iran)
Piotr Lorens
(Poland)

LOCAL EXPERTS

M. Faisal
Dias Budiati Prasetiamartati
Ratna Sri Widyastuti

Culture and heritage are both taking globalising cities forward and being put at risk by them. Relentless pressures of urbanisation and 'urban marketing' initiatives sometimes promote an image of the city that hides or even removes local diversity and 'unwanted pasts'. Yet culture and heritage are essential to retain cohesion and create local identity in a megacity, which would otherwise be faceless.

Within the themed sessions the interrelations between locality, local identity and megacities will be explored, focusing on the four key sub-topics:

- Historic cities, local identities and city branding
- Design for urban regeneration
- Culture-sensitive approaches to city planning
- Culture, heritage and sustainable development.

In addition, a special session dealing with culture as urban renewal resource will become an introduction to the entire track. Accompanied by keynote speeches, all sessions will build a vast picture of contemporary issues associated with 'planning for culture'.

As a result, it will be possible to discuss how local identities and modern approaches towards dealing with heritage can be reconciled with global marketing of city and globalising urban models. Also, the issues associated with shaping the planning strategies for culture and identity different in a megacity will be dealt with. These shall allow reflection on the role of cultural development and creative industries in contemporary city planning and development along with redefining the approaches to mass tourism and its role in preservation of the local identities. At the same time, within the sessions it will be possible to discuss the reverse questions: How can cities and megacities promote their culture and local identity to establish a dynamic knowledge economy, capable of shaping locally sensitive urban solutions?

Each of the track sessions will start with the pre-selected keynote presentation. This will be followed by a discussion panel, during which each of the presenters will be asked by both track coordinators questions regarding the most important messages associated with their papers. Afterwards, a more general discussion with active participation of all session participants will follow. Such a structure shall allow focusing on key messages delivered within the papers submitted and-at the same time-drafting clear conclusions regarding the sessions' topics.

Sessions:

Session 4.1
Cool Planner in South East Asia: City Resilience Design

Understanding urban conditions of our cities in a new way – embracing informality, reconsidering built environment policies, and encouraging formation of new public landscapes – is at the very base of climate change resilience. What is the role of designers and planners in this process, in the Asian context?

At this year's World Planning Congress in Jakarta, ISOCARP continues with its interactive Cool Planner Talks, tackling the challenges, the thrills and the responsibilities planning profession faces in the context of climate change. The

photo: DAVIDSONLUNA, Unsplash

upcoming Cool Planner Session focuses on South East Asia and examines the profile and the design skills Cool Planner needs in this region, in order to help cities become more resilient. As the first Cool Planner Session during 2018 ISOCARP's 54th World Planning Congress in Bodø, (Norway) has shown, the profession of urban planning is no longer limited to urban space. It has expanded to other fields and merged with other expertise. The aim of this year's Cool Planner Session is to showcase and discuss examples and challenges of "designing for resilience". Can we frame the main ingredients of the City Resilience Design? How can we further develop and promote it? What is the role of technology and what do planners need to know and learn in this field? How can design help make realistic, bankable climate resilience projects for neighbourhoods and districts? The Session will host four short talks from invited speakers and a peer-to-peer experts' panel. The talks will highlight projects, best practices, and experiences from urban professionals across many fields of climate change resilience, with relevance to Asian, South Asian and particularly Indonesian context. Guests and speakers at this year's Cool Planner SEA Session are experts from international planning practices, financial institutions, academia, cities governances and governmental planning institution

Session 4.2
Culture-sensitive Approaches in City Planning
The scope of the topics associated with this session will include a vast array of issues associated with city planning in culture-sensitive areas. Both the tangible and intangible cultural assets and issues will be dealt with. At the same time the issues associated with minority cultures and specific manifestations of cultural activities and heritage will be discussed. On this basis the specific concepts and solutions for diversified places, cities and regions will be presented, with the special focus on "non-traditional" heritage sites. The cases analysed will include location in Europe and Asia, with interesting presentations from – among others – Germany, China and Indonesia.

Session 4.3
Historic Cities, Local Identities, and City Branding
Within this session the issues associated with managing local identities will be discussed. Topics dealt with will include both reinventing heritage as notions of local identities as well as development of interrelations between heritage and city branding. A number of issues will be discussed, including the "shared heritage" (e.g., colonial cities), non-traditional types of heritage (e.g., hydraulic infrastructure or underground built heritage) as well as interrelations between heritage and socioeconomic development. Also, the ways of using the new technologies and concepts for the purpose of shaping the modern urban development strategies will be part of the session discussion. The cases analysed will cover a wide range of locations, including China, Dubai, Indonesia, Central Asia, Iran and others.

Session 4.4 (Special Session)
Beyond Heritage: Culture as Urban Renewal Resource
The Beyond Heritage: Culture as Urban Renewal Resource Session focuses on the contemporary approaches in using cultural heritage as a tool for urban renewal. Based on the results of the recent two very different UPAT workshops in China – Suzhou's "Panmen-Shantang Street in the Grand Canal National Culture Park" and Wuhan's "New Hangzheng Avenue" - the Session will look beyond the layers of history, and examine how to use heritage as a motor to promote cultural values, restore social cohesion, foster sustainable economic growth and revive public spaces.

Session 4.5
Design for Urban Regeneration
This sub-theme will include a number of papers / presentations associated with new approaches toward design for transformation of cities. Both general concepts and particular tools will be discussed, including the real-life cases. These will span from regional to very local scales and include the discussion of both analytical and decision-making tools and instruments. In addition, a number of concepts associated with urban regeneration, such as resilient planning and healthy cities will be discussed. The cases analysed will cover mostly Asian locations, although a strong set of references to other parts of the world will be made.

Session 4.6
Culture, Heritage and Sustainable Development
The main purpose of this session is to discuss the culture and heritage issues in the wider context of the sustainable development concept and practice. In particular, the interrelations between urban form, socioeconomic issues, environmental concerns as well as heritage and identity aspects of urban transformation will be put in the centre of this debate. On that basis, more specific issues will be dealt with, such as roles of various types of development and economies as well as emerging and re-established knowledge hubs in the process of sustaining urban and regional development. Furthermore, social problems associated with gentrification and social exclusion will be debated on. The cases analysed will include both (but not exclusively) Asian and African cases, including South African, Nigerian, Indonesian and Chinese ones.

In addition, a special session dealing with culture as urban renewal resource will be organised. Accompanied by keynote speeches, all sessions will build a vast picture of contemporary issues associated with 'planning for culture'.

Session 4.7
Panel Session on Culture-led regeneration: Issues and challenges for planning and development processes

Session 1: (Special Session) Cool Planner in South East Asia: City Resilience Design 4.1

10 September (Tuesday), 9:00 - 11:00

Moderators: *Milena Ivkovic*

Speakers: *Dushko Bogunovich, Rogier van den Berg, Beverley Salmon, Bert Smolders*

Understanding urban conditions of our cities in a new way – embracing informality, reconsidering built environment policies, and encouraging formation of new public landscapes – is at the very base of climate change resilience. What is the role of designers and planners in this process, in the Asian context?

Panel leading questions:

- What are the main ingredients to City Resilience Design, from planning, but also societal point of view?
- What do planners need to learn and be aware of when they have to make climate resilient "bankable projects" in the SEA context
- How can design help make realistic climate resilience projects working together with the local communities? How to maintain dialogue throughout the project design and implementation process?

4.2 Session 2: Culture-sensitive Approaches in City Planning

10 Septemeber (Tuesday), 11:30 - 13:00

TRACK KEYNOTE

Ehsan Ranjbar

The Power of Culture in Creative Placemaking for Future Urban Economy; Evidence from Contemporary Iranian Urban Spaces

Based on socio-economic changes of cities in 21th century, urban design as an interdisciplinary science which concentrates on public domain needs to introduce new lens to a improve quality of contemporary urban life. This presentation emphasizes on cultural approach to urban design and reviews the European cities experiences and analyses Iranian cities efforts using the cultural approach.

TRACK KEYNOTE

Benjamin Scheerbarth

An Awkward Dance: Nightlife and Urban Development (Lessons from Berlin)

Berlin, like few other cities, exemplifies the productive synergies between alternative culture, identity, and the emergent knowledge economy. While history created a testbed for cultural diversity, today's planning administration threatens its existence; while politicians begin to recognize the value of vibrant nightlife, resourceful actors of the subcultural scene turn to urban development themselves - join in the awkward dance.

Vicky Ariyanti

Cultural sensitive approach in water management for a volcanic river basin of Yogyakarta Metropolitan Area

In the literature on integrated water resources management and multilevel governance of water, less attention is given on how and why cultural values contribute to the integration level of its implementation. This paper examines how cultural ecological knowledge impacts current water management practices in Opak sub-basin, Yogyakarta, which is threatened by the volcanic activities of Mt. Merapi in its upstream.

Lin Chen

Inheritance and Development of Traditional Minority Culture in Southwest China: A Case Study of Miao, Dong and Dai Nationalities

This paper introduces the inheritance and development of traditional cultural changes in Guizhou, Yunnan Province in Southwest China from the perspective of anthropology. Government, media and Miao, Dong ,Dai minorities not only retain the essence of culture, but also inherit and develop traditional culture in the new era by encouraging tourism, increasing cultural and tourism projects, publicising intangible cultural heritage.

Haixuan Zhu, Sai Liu, Xiaoyu Jia

Study on Urban Morphology Optimization Based on the Construction of Urban Memory Structure - Take Dazhi Street in Harbin as an example

"In order to cope with the lack of urban characteristics in the process of rapid urbanisation in China, this paper takes Dazhi Street in Harbin as the research object, through the construction of urban memory structure, puts forward the optimisation strategy of urban morphology, hoping to provide reference for other cities.

Dian Zhang, Suning Xu

Research on Humanistic Technology of Urban Design of Historical Blocks in Harbin

This paper analyzes the status and problems of conservation planning of two historical blocks in Harbin from the perspective of humanism, and attempts to propose humanistic technology including human and culture aspects as the research foundation of urban design, emphasizes the importance of humanistic care in planning and design.

4.3 Session 3: Historic Cities, Local Identities, and City Branding

10 September (Tuesday), 14:00 - 15:30

TRACK KEYNOTE

Peter Starr

Old Deira, Dubai: The Role of Culture, Identity and Planning in a Global City

"How do we plan for multi-cultural cities? Dubai's Old Deira district may have an answer. From colonial outpost to global trade hub, via petrodollar wealth and neo-liberal urbanism, Deira is now one of the world's transnational capitals. As such, this paper reflects on the organic growth of cities and ponders the success of Old Deira and Dubai.

Giuseppe Pace

Underground Built Heritage as catalyzer for Community Valorization (Underground4value)

This paper tells the story of how a well-motivated group of people can transform a network activity, with a little budget, the COST Action CA18110 "Underground Built Heritage as catalyser for Community Valorisation", in a research and on field project and how such a network can provide innovative tools for engaging and empowering local communities.

Citra Persada, Yunita Kesuma, Fadhilah Rusmiati

A City Branding Framework in Planning: The Case Study of Pringsewu Lampung, Indonesia

City branding is not about slogans and logos but it has to be a practical program framework of the local development planning. The three branding strategies selements for Pringsewu case study: 1) involving and strengthening branding in planning and strategies, 2) infrastructure revitalisation, and 3) community empowerment. The city branding can represent the community entity, geographical wideness, and potential local comodities.

Nasim Iranmanesh

Improving the identity of historic city by considering hydraulic infrastructure (the case study: Qazvin city)

The water of most cities of Iran mostly harvested from underground water by a technic which is called Qanat which irrigate city and farms. Water supplement in urban fabric and locating the hydraulic structure in cities had an important effect in forming the city whose impact should not be ignored in reparation or rehabilitation of their urban fabric.

Roman Pomazan, Alexandr Khvan

Culture capital of the Turkic World

Presenting the masterplan strategy for urban transformation of Turkistan, one of the oldest cities in Kazakhstan. Responding to the Kazakhstan state authorities' key objectives to create a new administrative center and culture capital of Central Asia and the Turkic World, the team of Urban Sustain Architecture and Frame Art presents its core strategy to meet these objectives.

Luni Shen

The activation and revitalisation of Yihe, Nanjing

Based on the revival planning of Yihe, Nanjing, this paper emphasizes the importance of culture to the metropolis, explores the alignment of new formats and historical spaces, and generalises several strategies of historical space activation on the respects of culture revitalisation, industry innovation and space activation.

Session 4: (Special Session) UPAT Session Beyond Heritage: Culture as Urban Renewal

4.4

10 September (Tuesday), 16:00 - 17:30

Moderators: *Milena Ivkovic*

Speakers: *Xiuli Yao, Zichao Liu, Emilie Roell, Matt Benson, Su Hong, Keith Davis,*

The Beyond Heritage: Culture as Urban Renewal Resource Session focuses on the contemporary approaches in using cultural heritage as a tool for urban renewal. Based on the results of the recent two very different UPAT workshops in China – Suzhou's "Panmen-Shantang Street in the Grand Canal National Culture Park" and Wuhan's "New Hangzheng Avenue" - the Session will look beyond the layers of history, and examine how to use heritage as a motor to promote cultural values, restore social cohesion, foster sustainable economic growth and revive public spaces.

Panel leading questions:

- How to plan within preservation and conservation rules in a complex, dynamic urban environment?
- How to define unique, place, culture and community responsive approaches?
- What can be the applicable recommendations for adapting the heritage to the modern tourism-and-culture consumers demands?

Session 5: Design for Urban Regeneration

4.5

11 September (Wednesday), 11:30 - 13:00

TRACK KEYNOTE

Milan Sijakovic, Ana Peric

Recycling of industrial heritage: promoting local diversity and cohesion in globalising cities

Global capitalism, network society and multiculturalism impose spatial patterns that lack distinctiveness: continuous change of urban layers lead to the loss of readability, local diversity, and identity of a place. To tackle the issue of preserving local identity in a globalising world, an emphasis is on industrial heritage and the effect of its recycling on a local urban area.

Ferdous Farhana Huq, Imzamam Ul Khan Shuvo, Nidalia Islam

Essence of Urban form and its Relationship with Urban Aesthetics: A case from Rajshahi City, Bangladesh

This research explores the weaknesses of current building codes regarding the compatibility of the design of the building elements as well as the relationship between building and street which leads to degrade the urban aesthetics. The research findings suggest some strategic and design solutions with a view to improving the look of the urban form of Rajshahi city.

Xiaoxiao Deng, Dihao Zhang, Shuang Yan

Revitalising historic urban quarters by Cityscape Control Plan: The case of Xi'an , China

Taking the historic urban quarters around the Daming Palace National Heritage Park as an example, the Cityscape Control Plan is researched as a method to preserve and optimise the cityscape in the historic area during the process of urban regeneration.

Zhiqing Zhao, Jie Zhang

Regeneration of Railway Industrial Heritage-Protection, Renovation and Development of Hengdaohezi Town

Hengdaohezi Town is the railway industrial heritage in the period of Russia building railways by borrowing land in Northeast China. Taking Hengdaohezi Town Conservation Project as an example, this paper introduces the measures of protective development at three levels buildings, areas and town. Then through the questionnaire survey to evaluate the satisfaction of the protection status quo.

Małgorzata Hanzl, Lia Maria Bezerra

Healthy City versus Resilient Planning paradigm

The study addresses healthy and resilient cities paradigm and focuses on physical structures. For this, we use a qualitative assessment and typo- morphological approach. The evaluation uses health indexes and looks for healthy lifestyles and climate-resilient development. The case study applies the method to the city centre of Lodz, Poland.

Weisi Zhou, Wei Xiong, Qi Hong

The Road Of Rebirth - Place making in Bidur from the Perspective of CulturalLandscape

As the Nepal history capital, Bidur has prosperous historical and cultural resources with unique landscape, but developed slowly due to the limitation of natural conditions. This paper sets Bidur as example, from the perspectives of cultural landscape, putting forward the place making strategies of 'Promotion with Protecting, Form with Function' to explore the developing country urbanisation path.

4.6 Session 6: Culture, Heritage and Sustainable Redevelopment

11 September (Wednesday), 14:00 - 15:30

TRACK KEYNOTE

Natasa Zivaljevic Luxor, Petar Mitovic

Forever frenemies: built heritage, megacities and new technologies

Having on one side heritage experts who value their legacy according to success in preserving heritage, on the other side planners facing new economic and societal challenges due to historic growth of urban population and, in addition, new technologies, which develop faster than our capacity to apply them adequately, we discuss approach which may lead to desired outcome.

Qinglian Wang, Zhiqing Zhao, Bocheng Zhang

Cultural Heritage Conservation and the Sustainability of City's Orderly Development: identification, conservation and construction of historic space

Chinese Eastern Railway is the most well-conserved linear cultural heritage in China in the 20th century. In this paper, Hengdaohezi Town, a station-located town along Chinese Eastern Railway, is taken as an example to explore its conservation of cultural heritage and sustainable ways for the city's orderly development from the view of historical space.

Harini Septiana, Noora Al Naema, Amna Khalid J A Al-Jaber, Fatma Al Bader, Lolwa M. Alfaya Al Khaldi

Forward Thinking on Culturally Urban Imprint in the Contemporary Era Rejuvenating the Traditional Neighbourhood Values and Characters: An Urban Morphology Review on Qatari Cities

Qatari cities and towns have adopted the globalised language of urbanism, which overshadows the country's historic blend of maritime, rural and urban culture. This paper examines the morphology of traditional neighbourhoods that are still intact in Doha and elsewhere and seeks to capture their principal characters to inspire modern spatial layout that fits the Qatari context.

Qi Shen

Informal entrepreneurs in old districts in central city Shanghai

This paper focuses on the informal sectors in old districts in Shanghai, including family-owned retail shops, street vendors, recycling, delivery, which plays a significant role in the current economic structure and offers enormous work opportunities for migrant labour. The discussion asks how strategies can integrate native community and migrant workers into the process of urban development.

Tubagus Furqon Sofhani, Fikri Zul Fahmi, Dika Fajri Fiisabiilillah, Brigitta Sadnya Wulandari

Community capacity for creativity-based rural development in a developing country: Case studies from Indonesia

This paper aims to investigate the extent to which a rural community develops a capacity to support the establishment of a local creative economy despite various limitations. This study employs qualitative research methods in examining two villages in Indonesia. The findings show that the community capacity and actor networks potentially spark the development of rural economies.

Yang Yang, Jilong Zhao, Qian Sun

Research on Online Public Participation and Platform Construction of Historical Block Protection in Data Age

The issue of public participation has become an essential issue in the process of urban renewal in China. This article discusses (1) the method and mechanism of public participation in the protection of urban historical blocks and (2) the content and structures of public participation platforms for historical districts.

4.7 Session 7: Panel Session on Culture-led Regeneration: Issues and Challenges for Planning and Development Processes

12 September (Thursday), 11:30 - 13:00

Moderators: *Michael Stott*

Speakers: *Ana Peric, Tubagus Furqon Sofhani, Peter Starr, Ehsan Ranjbar, Natasa Zivaljevic Luxor,*

Panel leading questions:

- How to plan within preservation and conservation rules in a complex, dynamic urban environment?
- How to define unique, place, culture and community responsive approaches?
- What can be the applicable recommendations for adapting the heritage to the modern tourism-and-culture consumers demands?

Track 5

Smart futures and sustainability
Planning for innovation

CONGRESS TEAM

Dorota Kamrowska-Zaluska
(Poland)
Awais Piracha
(Australia)

LOCAL EXPERTS

Abdullah Kamarzuki
Melyana Frederica

Smart cities are appearing everywhere and are sometimes a little more than marketing devices for new towns. Yet there is no doubt that all cities are moving towards automatisation and data-driven provision of services. In addition, it is thought that smart technologies will drive cities' economic capacity and global position in future. Within this frenzy of change, we need a pause to explore critical theories and successful case studies on smart cities, smart regions and smart communities. We need to understand how virtual worlds (and our data alter egos) will interact and shape the real one; and how disruptive technologies (block-chain, crypto-money, robotisation of production, drones, hyperloop, autonomous mobility) will change the management and planning of cities and urban life. How will it change the urban form and public space? What will be the habits and behaviours of urban citizens?

What kind of policy is needed so that smart technologies answer citizens' needs and promote equitable solutions? How to encourage co-creation in the post-digital era? How to protect people from disruptive virtual worlds?

Sessions:

Session 5.1
Mobility in Smart Cities
Case studies in this track explore how smartness can assist in improving mobility. The topics in this area range from electric vehicles, smart mobility, promotion of non-motorised transport, freight analysis to autonomous vehicles and underlying themes in this sub-area.

Session 5.2
Knowledge Economy and Innovation Milieu
Papers in this session explore how new knowledge and innovation can lead to enhanced smartness and sustainability in the city. Some of the topics explored in this session are Green Heritage Tourist Circuit Design, transforming Indonesian petroleum cities into innovative green economies, improving space structure of traditional resources-based cities in China, and building energy efficiency in urban planning.

Session 5.3
Cities of Future - User-oriented Services
This session looks into how user-oriented services can be provided in cities using big data and other smart technologies. Use of big data such as mobile phone, smart travel card and other large data in planning is fast emerging as a very promising area of study. Papers in this track present case studies of big data use for providing user-oriented services for improving various planning related issues such as land use, housing provision, mega projects, commercial activities and more.

Session 5.4
Co-design and Participation in Smart Cities
Papers in this session present case studies which discuss how to ensure participation of citizens/beneficiaries in planning projects. Research in this session grapples with the following questions: Are citizens able to participate in co-creation or at least consultations related to shaping smart polices and solutions? Are their voices being heard? What are the instruments ensuring that quest for smartness does engage with the marginalised? Or is smartness leaving sections of society even further behind?

Session 5.5
Smart City Strategies in Urban Planning and Design
Along with the positives that come with densely populated cities in terms of human capital and increased productivity, there also arises the need to tackle increasing challenges such as traffic management,

photo: Octavian Rosca, Unsplash

management. The focus of this session is to examine how urban planning and urban design professionals are responding to these challenges within an ICT-led smart city framework.

Session 5.6
Smart Public Spaces
Papers in this session discuss how public spaces can be made to interact and inform public in matters that are useful and easy to understand for the public. In particular, how can planning and design professionals engage design strategies in conjunction with the new ICT technologies to make outdoor public spaces smart?

Session 5.7 (Special Session)
Cities and Digitisation: Perspectives and Challenges of the Smart City Technologies on Urban Planning and Design
The session will be chaired by Southeast University of China, based on the outcomes of the ISOCARP-SEU International Digital Urban Design Week that happened in June 2019 in Nanjing, China. The perspectives, impacts and future challenges of urban studies, planning and design disciplines will be discussed under the angle of digitization, big data, Internet of Things and blockchain communities, with practical illustrations.

5.1 Session 1: Mobility in Smart Cities
10 September (Tuesday), 9:00 - 11:00

TRACK KEYNOTE

Ozge Celik, Ozhan Ertekin
Re-thinking the city: Başakşehir Living Lab (Case of Istanbul)
Aim of the paper is to understand the challenges and potentials of new ICT technologies and its applications in an urban setting while surveying urban innovation units and living labs. While presenting the Basaksehir Living Lab, the research put focus on how planning practice advances smart planning and projects that contribute to the local development.

Daniele Vettorato, Adriano Bisello
Startdust Smart City Project in Trento
STARDUST is an EU H2020 Smart Cities project, which brings together advanced European cities in a holistic approach to transform the carbon-based cities to smart, highly efficient, intelligent and citizen-oriented cities, and define a new Urban Metabolism. The project presents its results from city of Trento, Italy.

Alloysius Joko Purwanto, Dian Lutfiana
Future Urban Mobility Development Framework to Maximize Benefits of Plug-in Electric Vehicle Penetration in ASEAN Countries
This study identifies the importance of electrification of the transport sector for future urban mobility development, especially in the ASEAN region. Electricity supply and demand have to be analyzed carefully to avoid additional stress on urban electricity grid systems. This study aims to provide insights on which factors have to be considered in penetrating electric vehicle in this region.

Andrey Borisov
Presenting the prospects for Ropeway Implementation as a Public Transport Mode, the case of Moscow
The paper analyses international ropeway commissioning experience as a mass transit component used in urban environments. We suggest factors can influence decision making in favour of aerial cableways as a form of public transport in Moscow. Within the proposed approach, we identify adjacent districts pairs where cableways could be sufficient as an element of an intermodal transit system.

5.2 Session 2: Knowledge Economy and Innovation Milieu
10 September (Tuesday), 11:30 - 13:00

Yu Sun, Hong Leng, Wei Tian
The Framework Research on building energy efficiency in urban planning : Integrated Visioning Based on Agent-based modelling and Spatial Analysis approach
The research is a preliminary study, in 12 districts of Harbin in China, on an integrated energy model approach with a standard bottom-up model and an Agent-Based behavior Model that interact with geospatial parameters, building design and operations. The findings contribute to understanding the link between energy consumption patterns and buildings at the district scale.

Mariana Fiuza, Gabriela Uchoa, Flavia Maia
The Goldilocks Zone for the public sector innovation: Teresina 2030 towards resilience to climate change in the developing world
The term Goldilocks Zone refers to the habitable zone around a star where the conditions are just right for liquid water to exist on the surface of a planet. Just like in astronomical science, there is evidence of a public sector Goldilocks Zone, where the conditions are perfect to find thriving innovation in the public sector.

Dianhong Zhao
Improving Space Structure of Traditional Resources-Based Cities Transformation in a Background of Supply-Side reform: a Case Study of Yantai City of Shandong Province
China's resource-dependent urban transformation not only faces the threat of 'urban disease', but also faces the 'resource curse'. This report takes the reconstruction of resource-based urban space as the starting point, and proposes to establish a compact spatial structure optimization model. Taking Yantai as an example, this paper discusses the spatial structure optimization model of resource-based cities.

Session 3: Cities of Future - User-oriented Services 5.3

10 September (Tuesday), 14:00 - 15:30

Jianxiang Huang

Data Empowering Planners: Sensors, Simulation and Machine Learning

Emerging smart technologies provide new opportunities for planners to tackle urban issues of growing complexity. Examples are drawn from Hong Kong, in which academic researchers work side-by-side with practitioners to improve community environment and the quality of lives. People-centric values, combined with the power of data are the keys.

Ming-Chun Lee

People, Places, Memories and Mobile Apps: Understanding the Potential of Augmented Reality in Public Participation and Community Development

Augmented Reality goes beyond the dichotomy of passive methods of engagement with the public. It offers an interactive method to expand visualisation techniques in participatory planning. This paper discusses three mobile apps developed to support community events aimed at increasing overall public participation and civic engagement with a goal of increasing awareness of community history through data visualisation and stories.

Qinglai Zhang, Jiatian Bu, Yifan Yu

Measuring Visual Quality of Street Space Based on Deep Learning and Street View Picture: Pilot in The Linong Area in Shanghai

Built environment indicates that street space quality have been carried out in a profound influence on the image of city, human behavior and public health. We attempts to measure subjective qualities of the Lilong environment comprehensively and objectively in Shanghai with the method of image semantic segmentation techniques and Street View Picture dataset.

Dian Hasanuddin

Smart Cities and The People: Urban Planning Collectives in Indonesian Cities

In the past decade, urban planning collectives have been growing organically, attracting a new generation of young, energetic, and critical urban professionals. These collectives demonstrate the civic and democratic aspects of city initiatives, one without government support, and put forward another vision for being 'smart' which extends into horizontal learning in between the intellectual elite and general citizenry in Indonesian cities.

Daniele Vettorato, Adriano Bisello

The next generation of EU smart city projects: turning "clean energy for all" into "clear benefits for all".

This paper discusses the results of ongoing research on multiple benefits of EU smart city projects. It suggests the steps to analyse the multiple benefits in a coherent framework, in order to make them an effective communication tool or even including them among the KPIs to be used in the assessment phase of the smart city projects all around the world.

Session 4: Co-design and Participation in Smart Cities 5.4

10 September (Tuesday), 16:00 - 17:30

TRACK KEYNOTE

Amandus Jong Tallo

Why We Need Participatory Mapping ?

By using participatory action research method for mapping boundaries of forest management area, the method addresses the spatial challenges of land tenure rights, land history, spatial layout, and sustainable village development in Mensuai, a village in rural Indonesia. More than a map, the outcome is a collective, village product that reveals the lack of food security of the local community.

Tian Qin

Comprehensive Evaluation and Dynamic Evolution Analysis of Shanghai's Urban Vulnerability

This paper takes Shanghai as an example, using the comprehensive evaluation system which includes natural resource, eco-environment, economic and social aspects. From 2002 to 2017, Shanghai's comprehensive urban vulnerability has been declining and has changed from a dominant eco-environment vulnerability to a more balanced one, while declining co-environment vulnerability has still been the dominant factor.

Huiyi Xia, Nankai Xia

Urban living environment assessment index system based on psychological security

With the development of urbanisation and the continuous development, construction and renewal of the city, the living environment of human beings has also undergone tremendous changes, such as residential community environment and service facilities, urban roads and street spaces, and urban public service formats.

Xuhui Liu, Xin Sui, Yu Yifan

Measurement of spatial equity : a case study of nursing institution

The results of accessibility measured by 2SFCA of nursing facilities are used to find the degree of the inequity about getting this service among elderly in Shanghai caused by this location pattern. Results of the study help the urban planners to further arrange the nursing facilities and improve the equity of public service facilities caused by location.

Silja Tillner, Eva Maria Kuehn

Habitat 5.0 - Towards affordable and sustainable housing in the developing world: A pattern- and block chain-based approach

The need for affordable housing leads to the surge in informal settlements. The approach Habitat 5.0 to upgrade informal settlements in situ uses 'disruptive innovations' to build communities by following urban design patterns for sustainable settlements. Blockchain guarantees the secure transfer of qualified know-how that enables residents to build their houses with ecological materials - safer, cheaper, faster.

5.5 Session 5: Smart City Strategies in Urban Planning and Design

11 September (Wednesday), 11:30 - 13:00

Thibault Pilsudski, Si Ying Tan, Devisari Tunas, Fabien Clavier, Andrew Stokols, Araz Taeihagh

Smart planning in Southeast Asian cities: the role of urban governance and knowledge transfer

This paper analyses how smart city planning and urban governance inform each other and how these are translated and adopted by cities in Indonesia. It is part of an ongoing research; its final output will be an analytical framework that can be used by technology producers, city authorities and funders, to help them strategise and plan for better smart cities.

Dorota Kamrowska-Zaluska

Smart city and regenerative city – complementary or contradictory approaches

The aim of the study is to recognise relation between smartness and regenerative sustainability in contemporary cities. There is a need to determine how new technologies affect the development of cities and wellbeing of their inhabitances.

Hanna Obracht-Prondzyńska

Big data based assessment on metropolisation processes in Poland

Due to new determinants influencing and shaping urban and regional structures and new analytical possibilities, the aim of the research is to assess the impact of the metropolisation processes on the small towns' development in Pomeranian Province in Poland. A two-phase model allows to study the impact on both functional and spatial development of the regional settlement networks.

Fadhilah Rusmiati, Citra Persada, Dini Hardilla

The Tourism Concept of Emergency Shelter: A Strategies For Community Resilience In The Coastal Area of South Lampung

This paper aims to provide a new perspective and strategies on developing emergency shelters not only for evacuating residents and improving disaster preparedness infrastructure in South Lampung, Indonesia. It also aims to explore their potential for community-based tourism planning in vulnerable areas.

Jassim Al-Sorour, Noor Alamri

How can cities succeed and boom in the long run? CASE IN QATAR

As technology is advancing, the places we live in need to be adapted as well. In the modern times, we are bombarded with many gadgets and gizmos that are making life easier and enabling us to do more in less time. How can cities succeed and boom in the long run?

5.6 Session 6: Smart Public Spaces

11 September (Wednesday), 14:00 - 15:30

Mennatullah Hendawy

Urban Planning in a Mediatised World , case of Egypt

While urban planning in Egypt still follows a centralised, large scale, top-down and entrepreneurial approach, demands for democratic and communicative planning practices are growing. In the context of digital and information revolution, the research explores how media structures the way planning is communicated and how, in turn, this is reflected in planning decisions.

Mayank Dubey

Smart signals and corresponding challenges in heterogeneous traffic conditions

Smart signals dynamically optimise the signal phases by analysing trend and real time data to increase the throughput at intersections. But in mixed traffic conditions where neither the traffic flow parameters nor the corridor specifications and hierarchy are uniform, the efficacy of such signals gets questioned. This study attempts to answer some questions around smart signals in India.

Le Dong, Chen Xu, Baolu Chen

Investigation about tourism image optimisation of Lugu lake scenic area based on internet reviews

The utilisation of online information becomes an important way to explore the scenic areas image and improve tourist's satisfaction. This essay takes Lugu lake scenic area as an example, firstly focus on comments extraction about tourism resources, infrastructures and service, then deals with the analysis of tourists' behaviors and perceptions. Lastly, this paper proposes the optimisation strategy.

Vaishali Aggarwal

Spaces of becoming- Space shapes public and public (re)shapes their own spaces

This paper looks at the social production of space, inspired by the right to the city movement, in Delhi, India. In particular, the question is raised if cinema and digital technology can be used to empower a new citizenry who is not a mere user of the city but a participant in creating and interpreting the space which is actively produced.

5.7 Session 7: (Special Session) Cities and Digitisation: Perspectives and Challenges of the Smart City Technologies on Urban Planning and Design

12 September (Thursday), 11:30 - 13:00

Moderators: *Yi Zheng*

Speakers: *Sebastien Goethals, Fedor Kudryavtsev, Junyan Yang*

The session will be chaired by Southeast University of China, based on the outcomes of the ISOCARP-SEU International Digital Urban Design Week that happened in June 2019 in Nanjing, China. The perspectives, impacts and future challenges of urban studies, planning and design disciplines will be discussed under the angle of digitisation, big data, Internet of Things and blockchain communities, with practical illustrations.

Track 6

Changing environment and risks
Planning for resilience

CONGRESS TEAM

Markus Appenzeller
(The Netherlands)
Juanee Cilliers
(South Africa)

LOCAL EXPERTS

Mangapul Rudy Saut Sagala

Continuing the conversation from last Congress in Bodø and the need to urgently address disaster prevention and adaptation to the consequences of climate change: Jakarta and other megacities are showing dangerous vulnerabilities to extreme pollution, sea level rise, salt-water intrusion and water shortages. This is, however, matched by steadily decreasing poverty that runs in parallel to the increasing urbanisation. If cities with their consumerist nature are part of the solution to poverty, what models can they use to minimise their impact on the environment and become leaders in the fight to respond to climate change? What is already being done and what are the outcomes?

Food, water, transport and energy systems need resilience to climate change to avert catastrophic events and to cope with a further increase of global and urban populations. Pollution and waste demand the urgent understanding of urban metabolism to achieve better social justice and to safeguard the balance of the planet. What are cities doing to transition their urban economies to achieve improved well-being and environmental justice and to transform dependence on non-renewable materials to resource-efficient and renewable flows and better management of ecosystems? What role should planning/ planners play in developing resilient plans, designs, buildings and infrastructures?

Sessions:

Session 6.1
General Introduction: Climate Change - Globally
Climate change is probably the biggest man-made global threat we are currently facing. This comes in a time where our cities are growing in an unprecedented way – often in areas that are affected the most by climate change. This session wants to give a general introduction to the topic, outline its main fields of impact and evaluate what we can do to steer measures globally.

Session 6.2
The Currencies of Climate Change: Water
Water is the currency of climate change. It is the impact of too much or too little water that will have the biggest impact on human lives. This session will evaluate the scale of impact and how water can and ideally should be dealt with in different urban conditions.

Session 6.3 (Special Session)
Planning for Climate Change

Session 6.4
The Currencies of Climate Change: Heat
One of the main consequences of climate change is global warming. In the future we will not only see higher overall temperatures but also more extreme heat. Without measures, this can very well lead to places, especially cities becoming uninhabitable. The session will look at planning tools and approaches that help mitigate the effects of heat, especially in those global regions that will be affected most.

Session 6.5
Climate Change and Operating Cities - Metabolism
The biggest indirect-and therefore a lot less directly mitigatable - impact climate change has on mankind is through the changes in the ecosystems. This puts our food base at risk, and it threatens other species. This session will investigate the order of challenge and identify possible ways forward.

Session 6.6 (Special Session)
Building Unique Cities: An Imperative for Sustainability and Liveability in the Global South

photo: Tom Zimmerman, Unsplash

Session 6.7
Climate Change and Operating Cities - People
Climate change affects the lives of people. At the same time, it is those very people that have to be the agents to limit climate change and to implement measures for its mitigation. Planning that involves local communities is imperative in achieving the goals set out. This session investigates means and processes to involve the local residents in climate change mitigation.

Session 6.8
Climate change and Urbanism: Planning Tools
Next to all other players, we as urban planners, designers and policy makers need to take responsibility for the effects of climate change. This session looks at our own tools, the tools of the planner and how they (can) accommodate this responsibility.

Session 6.9
Planning - Looking Forward
In this session we want to summarize the findings of the previous days and we want to define a set of planning measures, paradigms, policy proposals for planning for more resilient cities from now on.

6.1 Session 1: General Introduction: Climate Change – Globally

10 September (Tuesday), 9:00 - 11:00

Natalie Rosales Pérez

Expanding an understanding of urban resilience in the realm of adaptation planning

By using the case study of Mexico City's Climate Action Programme, this work contests the way in which resilience has been embedded in urban adaptation planning. This descriptive research incorporates urban-regional metabolism dynamics and environmental data such as carrying capacity, into the climate change scenarios and vulnerability analysis matrix.

Mattias Vansteenwegen, Etienne Drouet

360cityscan: integrated solutions to face urban challenges

Tractebel has developed the 360 city scan, a methodology to assess cities and guide them according to their needs and priorities. Based on this scan, we offer integrated and tailormade approaches to our clients using our urban engineering expertise.

Juanee Cilliers

Trans-disciplinary planning approaches towards resilience

In South Africa, like elsewhere, the depletion of natural resource, including green spaces, are leading to cities that are far removed from the safe, clean, and liveable environments, as envisioned in planning theory. Resilience thinking could pose solutions in this regard, drawing on trans-disciplinary planning approaches to manage change and steer Spatial Planning towards the era of transurbanism.

6.2 Session 2: The Currencies of Climate Change: Water

10 September (Tuesday), 11:30 - 13:00

Matej Niksic, Jernej Cervek

Changed precipitation patterns and the need for a novel approach to building plot planning: The lessons learnt in the sub-alpine climate zone of Slovenia

Developed by the Urban Planning Institute of the Republic of Slovenia, the paper presents a tool to reform the urban planning system in the face of challenges posed by climate change. To respond to heavy rainfalls, urban design criteria for building plots planning is under revision to allow for rainfall penetration into the ground.

Ramya Sakkeri, Devadas V

Systems' approach: Climate change, glacier melt and development planning of the Himalayan region

A gradual increase in global temperatures coupled with erratic precipitation patterns has a serious impact on the socio-ecological system. Therefore, in this paper, authors developed a methodology to effectively understand the dynamic inter-linkage and interdependence of the complex systems and sub-systems in a region by using system dynamics technique.

Priyanjali Prabhakaran, Suja Kartha

Flood resilience planning for Disaster prone Panchayaths. A case of Karumaaloor Panchayath in Ernakulam District,Kerala

Karumalloor panchayat, a rural area in Ernakulam district of Kerala in South India was one of the severely affected areas in one of the worst floods in a century in August 2018. The aim of this paper is to explore the issues in such panchayats and to identify the need and strategies.

Tanaya Sarmah, Sutapa Das

Determining urban flood vulnerability using an indicator-based approach and HAZUS-MH

Urban flood (UF) is becoming frequent and intense in terms of death and building damage. This study aims to develop a UF vulnerability index (UFVI) for Guwahati, India by combining human and building vulnerability indices. It gives a theoretical explanation of the method to be incorporated. The UFVI will help to improve resilience of the population and buildings against UF.

Theresa Audrey Esteban

Living with water: how memory and experience help build community resilience in Dordrecht

In Dordrecht those who experience flooding more frequently have more built in memory and knowledge. This memory-based disaster experience can be a starting point in building knowledge on disasters.

Session 3: (Special Session) Planning for Climate Change 6.3

10 September (Tuesday), 14:00 - 15:30

Travis Bunt

Sinking, growing, resilient: a multidisciplinary approach to climate adaptation in Semarang, Indonesia

2018, the Netherlands Enterprise Agency kicked off Water as Leverage, a program aiming to bring water-based solutions to address climate and urban risk in three Southeast Asian cities: Chennai, Khulna, and Semarang. The 'ONE Resilient Semarang' team - a group of designers, engineers, economists, ecologists, art activists, and academics - was tasked with developing design-driven, bankable project ideas following an initial phase of research, analysis, stakeholder engagement, and on-the-ground coalition-building with agencies and institutions. In this presentation, members of four partnered organizations on ONE Resilient Team (One Architecture & Urbanism, Kota Kita, Deltares, and Wetlands International) will bring multidisciplinary perspectives to Semarang's current catch-22: it is a city economically dependent on the same extractive coastal industries that exacerbate its subsidence and flood risk, projected for even more drastic urban densification and economic expansion in the coming years. Instead of developing one-off infrastructure proposals for the city, ONE Resilient Team instead chose a more holistic approach centered around a widespread reorientation of water use across the entire city, from coast to upland, from Kendal to Demak - altogether comprised of potentially hundreds of projects. The embedded goal is to address challenges in a programmatic manner, potentially sparking transformational, bottom-up and top-down change in processes and governance. With the combined disciplines of urban design, community-based planning, water / coastal engineering, and ecological restoration, ONE Resilient Team's conceptual proposal aims to find integrated solutions to the combined water related risks of climate change and socio-economic growth by drawing from expertise across sectors and backgrounds from across the globe. This presentation will seek to address these issues through the prism of four disciplines among many more represented within the team, asking how resilience can operate beyond an individual project as a guiding development principle for climate-vulnerable cities and landscapes.

Session 4: The Currencies of Climate Change: Heat 6.4

10 September (Tuesday), 16:00 - 17:30

Shuo Zhang

Research on the Spatial Effect of Urban Construction on Heat Island Effect in Shanghai Based on Remote Sensing Data

Taking Shanghai as a typical case, this paper concentrates on the urban heat island effect under the influence of urban construction by Landsat-7 ETM+ remote sensing image data. We analyse the spatiotemporal distribution of land surface temperature and summarises the evolution characteristics of urban heat island effect, analysing the spatial impact of urban construction related factors.

Olufemi Ojo-Fajuru, Sijekula Mbanga

Green Landscaping - an Interventionist Approach to Build Cool, Healthy and Liveable Future African City: The Case of Ado-Ekiti, Nigeria

Rapid urbanisation and population explosion account for urban socio-economic and environmental challenges in the developing countries of the world as evident in Ado-Ekiti, Nigeria. The study examines the extent of public space contestation, effects on urban environment and liveability, and intervention with green landscaping techniques to re-naturalise the cityscape towards building a green, liveable and sustainable environment.

Ferdous Farhana Huq, Nidalia Islam, Sakib Zubayer, Nessar Uddin Ahmed

Green Roof: An Approach to Repair the Climate of Dhaka City

This study employs satellite and GIS technology to identify the buildings with and without the green roof in Dhaka, Bangladesh, and present the hardscape to softscape ratio of the city. Findings suggest a gap between the user and the government on green roof perspective and recommends measures to make this approach successful.

Adinarayanane Ramamurthy, Anusha Roy

Green and Blue Infrastructure to Regulate Thermal Comfort in High Density City Planning: a Case of Navi Mumbai, India

This Research work is an attempt to understand how urban climate maps can be operational to arrive at plausible decisions in high density city planning, thereby undertaking measures to regulate thermal comfort in the city through green and blue infrastructure.

Session 5: Climate Change and Operating Cities – Metabolism 6.5

11 September (Wednesday), 11:30 - 13:00

David Mathewson

Effects of ongoing infrastructure improvements in relation to planning policy for flood resilience and historic urban morphological development in Jakarta

This paper explores historic institutional responses to flooding and the influences of such planning policies on the spatial development of Jakarta within the context of pressures from severe flooding and rapid urban development. Next to the local and city scales, where new flood defense and mitigation measures are being implemented, the article's scope extends to a wider city-regional perspective.

Shivangi Singh Parmar, Joy Sen, Arkopal Goswami

An assessment and delineation of Socio-economic Resilience Landscapes of the Region based on the inherent latent factors of vulnerabilities

The socio-economic resilience of the region is the capacity to absorb or adapt shocks caused by external forces and inherent latent weak conditions of the regional system. The present paper contributes to delineate the socio-economic resilient landscape by measuring arrivals and departures of socio-economic resilience to the degree of socio-economic vulnerabilities of the region.

Natalie Rosales Pérez

Relict ecosystems in urbanised contexts. Challenges and opportunities to renature cities, ecological restoration, and biodiversity enhancement through planning for sustainability.

How can planning assist cities to transit from natural resources into natural spaces that enables ecological processes that support life, sustains flora and fauna, enhance biodiversity, and promote sustainable development? Comprehensive planning strategies can promote regional and urban environmental development as illustrated by a case study in Morelos, in Mexico.

Wiwandari Handayani, Barry Beagen, Santy Paulla Dewi

Promoting Water Resilience in Semarang: Building a Coalition through the Water as Leverage (WaL) Program

Semarang is chosen as one of the three cities in Asia for the Water as Leverage program initiated by the Government of Netherlands in 2018. This study documents and examines the Water as Leverage program as an opportunity to build a coalition amongst stakeholders to promote water resilience in Semarang.

Thai Son Pham

Identifying climate resilience challenges in Vietnamese cities: case studies of Can Tho and Da Nang

This paper aims to discuss major issues regarding urban climate resilience in urban areas in Vietnam, through an investigation on Can Tho and Da Nang cities. Resilience challenges from natural conditions, urbanisation patterns, climate change conditions and risks are identified. Besides, resilience capacity is limited with weak coordination mechanism and plans and community resilience are not sufficiently addressed.

Aishwarya Talluri

Spatial planning and design for food security ; Building Positive Rural-urban Linkages

The Agenda 21 Document strongly advocates for urban-rural continuum and food security, this paper is an attempt to translate the ideas into spatial guidelines, as it is observed, that often the spirit and intentions of the project is lost in translation from text to space: with cultural resilience and ecology as a prime focus.

Dani Muttaqin

Earthquake Post-Disaster Relocation Identification in Meuredu Pidie Jaya Nangroe Aceh Darussalam

Through micro zonation mapping of earthquake-prone areas, the Indonesian Government aims to reduce the impact of earthquake risk and restrict the development of settlements around active fault lines. Identifying suitable locations, in line with spatial regulations and land requirements, for relocation is central to this process and carried out by GIS analysis.

Sani Nuraini, Imam Indratno

Embodied Carbon Emission Analysis of Industrial Sector Based on Input-Output Analysis : Case Study in Bitung City, Indonesia.

Bitung City has experienced environmental degradation, even though economic growth continued to increase. This study aims to build a model of environment-economy linkages through Input-Output (I-O) Environment and to calculate the impacts of the economic sector in Bitung City. The paper presents the conceptual and analytical framework of the Input-Output approach of the Bitung City.

Raka Suryandaru

How to Plan in a Volcano-related Disaster Prone Area? Lesson Learned from Adaptive Spatial Planning in Dieng Plateau, Central Java

Located in the Asia Pacific's Ring of Fire as well as has one of the longest shorelines in the world, Indonesia is prone to various kind of disasters. Over the past few years, Indonesia has made headlines around the world due to devastating natural disasters that resulted in environmental damage and thousands of casualties. The result obtained from this project is an adaptive spatial planning that is tailored to the region's disaster risk profile and aimed at achieving a higher standard of living.

6.6 Session 6: (Special Session)Building Unique Cities: An Imperative for Sustainability and Liveability in the Global South

11 September (Wednesday), 14:00 - 15:30

Olga Chepelianskaia

Cities face an unprecedented urbanization pressure, which led cities of the Global South to building infrastructure hurriedly, compromising on their natural ecosystems, cultural distinctiveness, human scale, wellbeing and liveability. As a result, many cities in developing countries are charac¬terized by vovercrowded, poor quality and insufficient infrastructure services, low-quality building stock and a uniform cityscape. Negative consequences related to building uniform go far beyond a cultural loss and severely compromise urban sustainability, economic vibrancy and quality of life.

6.7 Session 7: Climate Change and Operating Cities – People

11 September (Wednesday), 16:00 - 17:30

Rolf Schuett

Building Dignity: A participatory concept for climate change-impacts mitigation in informal settlements in North Jakarta

Analysis of current challenges of Jakarta, including overpopulation, sprawl, environmental stress, social inequality and poor mobility. The concept of gotong royong or communal cooperation is introduced as an opportunity to inspire participation in tackling these issues, including physical implementation to incorporate these approaches in informal settlements in Pandemangan, North Jakarta.

Priyanjali Prabhakaran, Suja Kartha

Role of Women Self Help Groups in Disaster Resilience and Livelihood Regeneration: Post Flood Experience from Kerala

A study of one of the worst affected villages after the 2018 floods in Kerala was conducted. Community level women self-help groups called 'Kudumbashree' units came forward in post flood reconstruction and livelihood restoration through collective farming on leased land, poultry rearing and homestead farming which proves to be a successful model in disaster resilience.

Andie Arif Wicaksono

Participatory and Good Governance: The role of stakeholders in increasing the adaptive capacity of the poor to cope the impact of climate change. Case studies: Surakarta and Yogyakarta, Indonesia

The collaboration of government and riverside resident's community-based organisations (CBOs) in Yogyakarta and Surakarta illustrates how pro-poor planning approach can build the adaptive capacity of the urban poor to climates change-induced flooding. Findings indicates that stakeholders have a critical role in maintaining active collaboration for this adaptation strategy to become successful.

Niken Prilandita, Saut Sagala, Jeeten Kumar, Teresa Retno Arsanti

The Stakeholders & Stakeholder Network - Role in Sustaining the Renewable Energy System in Sumba Island

Indonesian government, through the Sumba Iconic Island program, attempts to increase the electrification rate to 100% in 2020 and also encourage the implementation of more renewable energy systems. There are various stakeholders involved in this program, and this research aims to examine and evaluate the stakeholders? role in sustaining the renewable energy system in Sumba Island.

Anastasia Widyaningsih

Community responses to displacement threats in flood prone areas. The case of Ciliwung River, Jakarta

This study deals with displacement phenomena occurring around the Jakarta Urgent Flood Mitigation Project during the period 2013-2017 and explores the emergence of social innovation in the affected communities by taking Bukit Duri and Kampung Tongkol as the case studies. It reveals how the crisis become a moment of change and an opportunity for Jakarta to co-produce a resilient city.

Session 8: Climate change and Urbanism: Planning Tools 6.8

12 September (Thursday), 11:30 - 13:00

Peijun Lu, Yimin Sun, Bilin Chen, Sheng Xia

Urban Design Study of Resilient City in Guangdong-Hong Kong-Macao Greater Bay Area

Based on theory of resilient city, this paper discussed the resilience of Greater Bay Area due to the contradiction between the vulnerable natural conditions and rapid urbanisation and developed three resilient urban design principles and a research-design-feedback loop pattern, which apply into various urban design stage in Pazhou, one of the more resilient areas in Greater Bay Area.

Shuang Zheng, Xiaowen Huang

Resilient Infrastructure Framework of China Coastal Cities

Taking Binhaiwan Bay Area as an example, this paper combines infrastructure framework with resilient city theory, then analyse the strategies of some world-class coastal cities coping with the problems of urban public security, and deduces the resilient infrastructure strategies for coastal cities, so as to provide references for the further study of the resilient coastal cities.

Muhammad Shamsuzzaman

Challenge of planning the Coastal Cities of Bangladesh: A Case for Chalna.

This paper studies spatial planning challenges of Chalna, a coastal town of Bangladesh following the Structured Geospatial Analytic Process. Identified challenges are primarily in the process of planning and decision making rather than lacking in technical know-how, such as weakness in the regional planning framework, undermining values of environmental/public goods, defying rule/regulations, and not accounting public opinions.

Cong Cao, Suning Xu

Research on Strategies of Low-impact Urban Design in China

This paper aims to provide theoretical method support and practical experience for creating environment friendly urban space in China by low-impact urban design methods, and discussed on two aspects of theory and practice.

Session 9: Planning – Looking Forward 6.9

12 September (Thursday), 14:00 - 15:30

TRACK KEYNOTE

Theresa Audrey Esteban

Mind the gap: Stakeholders perspective on resilience building in the City of Rotterdam

The study seeks to investigate the institutional and community actors perspective on resilience and the environmental threats in the City of Rotterdam. The research assumes that knowledge and experience on Rotterdam's environmental vulnerabilities and threats lead to better collaboration between and among stakeholders in making the city resilient

Rahul V

Reimagining Pamba; Sustainable design strategies for Sabarimala Pilgrimage.

As a pilgrimage centre with more than five million pilgrims, Sabarimala holds a special attention due to natural setting. Due to the ephemeral activities and recent devastating climate changes in the state, its necessary to study and redesign the whole pilgrimage architecturally and non architecturally in order to conserve the natural heritage of the state.

Tuan Manh ,Julia Babcock, Hien Bui, Thi Khanh Nguy

Capacity and Trade: Alliance for Green Actions

As nations shift planning around the reality of climate change there is an opportunity to redefine incentives across industries that promote clean energy and lower emissions in building, transportation and land use. In turn, workforce training and education across a broad international network can help ensure a just distribution of benefits as markets transition.

Track 7

Urban governance and planning profession
Planning for future

CONGRESS TEAM

LOCAL EXPERTS

Teti A. Argo
Deden Rukmanaty

Large cities and megacities are a main feature of human settlement in the 21st century. The level of complexity of large cities requires new governance systems that are different from traditional urban and municipal administration. Soft power is necessary to mobilise actors from different levels of government, sectors, and territories. Multiform management across sectors and issues (water, economy, environment, mobility, housing etc.) need to share visions, strategies and policies with the support of technical bodies, political platforms and a variety of actors. Building the structures of a functioning megacity is an iterative process, which ranges from the very local to the regional and metropolitan scales. New methodologies are emerging, and this will be an opportunity to share the experiences of building large scale governance and consider the consequences on planning. People participation is different in a megacity, with more complex relations between local communities, local governments, and metropolitan governance. Informal dynamics also represent a bottom-up approach to the expansion drive of the city.

Urban governance and planning are some of the cross-cutting themes at this year's congress with an element of it visible in each of the other tracks. But within Track 7 these two themes will be explored and discussed in greater detail owing to the wide range of abstracts accepted for presentation in different forms, such as papers, case studies, research projects and special sessions. This track received close to 100 abstract submissions with rich and interesting content around megacity governance and planning from all parts of the world. As governance requires both top-down and bottom-up interaction in various forms between many different actors in the quest of planning, the importance of this track cannot be overemphasized. Planning for the future by exploring urban governance and planning in seven fully packed sessions of which two are special sessions will bring forth approaches, strategies and best practices for congress attendees. The sub-themes for the track include cross-border governance, territorial planning, regional cooperation, metropolis management, local leadership, metro-hub, democratic urbanism and metropolitan governance.

Sessions:

Session 7.1
Cross-border Governance
Megacities and large metropolis are expanding out of the national or regional limits. The different spatial management systems in each country should be articulated to better manage these megapolises. How to manage functional metropolitan areas located on several national or regional jurisdictions with contradictory laws, standards and management systems? The coordination tools are crucial for managing spatial and social dynamics, offer cross-border infrastructures and services. How should these multi-actor and multi-level spaces ensure effective cooperation and collaboration?

Session 7.2
Territorial Planning
Territorial planning covers different scales with strategic documents and regulations. The articulation is crucial to make policies a reality at the local level, to face huge challenges as climate change, social and spatial inequalities, heritage protection or limitation of urban sprawl. Territorial planning needs specific bodies to develop policies and strategies, to feed the public debates and to monitor the spatial development. Well-coordinated planning across different scales should speak governance.

photo: Bagus Ghufron, Unsplash

Session 7.3
Local Leaderships
Building a metropolitan governance requires a flexible system of decision making with local authorities, with the support of State government. What are the processes to build the metropolitan governance? How can one make efficient decision making with a large number of actors? How to manage the different scales and sectors to deliver public services and invest in infrastructures? How to foster economic development efficiency through city marketing? How to ensure social and spatial equity in metropolitan areas? Local leadership is the key to manage metropolitan areas.

Session 7.4
Metropolis Management
Metropolises, as they expand, cover several jurisdictions. Infrastructures and public services are managed on different areas. The share of competencies between the different administration levels (State, regions, local authorities) is complex. The metropolis management requires specific tool for coordinating sectors, territories and communities. The international experiences on metropolitan management offer innovation on governance and innovation mechanisms for the well-being on communities.

Session 7.5 (Special Session)
Democratic Urbanism
Democratic Urbanism is a method of city-building that integrates democratic ideals into the urban design process and applies broader shared governance models to the implementation of community aspirations, creating places of deep meaning that are broadly "owned" in the civic mindset. This interactive session will include a number of case studies, short films and exercises demonstrating the value of democratic approaches to city-building, highlighting communities that have applied democratic urbanism to achieve remarkable transformations across a variety of contexts. These demonstrate our civic capacity to overcome the stark challenges of the 21st century and reinvent our communities, illustrate the advantages of a democratic method for city-building that is broader than conventional practice, one based in a collaborative approach to governance that offers guidance to local leaders across the world working on the front lines of change today.

Session 7.6 (Special Session)
Using Metro-Hub
Metropolitan areas have a key role in achieving the 2030 Agenda for Sustainable Development and the New Urban Agenda. Despite being innovation and opportunities hubs, they encounter many challenges in governance, planning and financing. To support integrated approach to metropolitan development, UN-Habitat and its partners have developed the MetroHUB approach that embraces different aspects of metropolitan development and management including planning, governance and finance, that aims to foster capacity of metropolitan stakeholders on how to address and better manage urbanisation challenges at a metropolitan scale. It provides a vital pool of resources, tools and expertise for developing institutional and human capacity, directly contributing to the New Urban Agenda objective of leaving no one and no place behind.

Session 7.7 Metropolitan Governance
Metropolises, as expanding, are covering several jurisdictions. Infrastructures and public services are managed on different areas. The share of competencies between the different administration levels (State, Regions, local authorities) is complex. The metropolis management require specific tool for coordinating sectors, territories and communities. The international experiences on Metropolitan management offer innovation on governance and innovation mechanisms for the well-being on communities.

Session 7.8
Debate: Governing the Metropolis
This session is devoted to a general discussion on governing the metropolis, deliver key messages for the conference regarding governance and the role of planners and to fix recommendations for the final declaration of the conference. The discussion will have 4 steps: keynote; debate; synthesis; recommendations for Isocarp and the final declaration

Session 1: Cross-border Governance 7.1
10 September (Tuesday), 9:00 - 11:00

TRACK KEYNOTE

Sindi Haxhija, Karina Carius De Barros
Breaking through rigid administrative boundaries - synergies in 'soft' spaces of cooperation
Through case studies at the Dutch-German and the Finnish-Russian border areas, the paper explores the institutional and cultural challenges of 'soft' territorial cooperation. Challenging conventional regional or urban governance regimes, cross-border cooperation demonstrates a need for soft and more flexible decision-making powers, to mobilise stakeholders across various levels of governance, sectors and territories in the interest of functional territorial cooperation.

Khaled Abdellatif
Integrated Metropolitan Governance Framework for the GCC Future Metropolis
Due to gap between the current Gulf Cooperation Council (GCC) country's urban governance systems and the future of its newly born metropolitan areas, this paper examines and tackles various patterns, problems and challenges of the current urban governance system, to reach to the optimum scenarios for governing the future GCC metropolis in an integrated metropolitan governance framework.

Zivile Simkute
Practical point of view: preparation of the National Urban Policy Framework
The proposal for the National Urban Policy Framework for Lithuania is an attempt to restart the urban planning tradition and culture in a country that historically has a difficult relationship with it. The case presentation will review the preparation process, structure and the content of the document with questions raised about the necessity of such a policy in other countries.

Daniel O'Hare
Towards effective planning of transborder city regions: three Australian case studies
Polycentric city regions are expanding worldwide, often crossing national or state borders. Using literature review and document research, comparative case studies of regional planning of Australia's emerging internal trans-border city regions are presented. Evidence is provided that effective trans-border planning of city regions depends on overcoming differing levels of commitment to trans-border planning by the state jurisdictions involved.

Serin Geambazu

Dynamics of public urban waterfront regeneration in Istanbul, the case of Halic Shipyard Conservation

The global embrace of waterfront regeneration is widely recognized, however it is incompletely understood in planning theory due to dominance of North American and European case studies. The analysis of the Halic Shipyard Conservation project in Istanbul offers an opportunity to challenge this theoretical bias, and reevaluate the governance and planning process of urban waterfront regeneration in developing countries.

7.2 Session 2: Territorial Planning

10 September (Tuesday), 11:30 - 13:00

TRACK KEYNOTE

Huihui Nan

Planning and Management Experiences of Global Metropolitan Area - Lesson of New York Metropolitan Area, Tokyo Metropolitan Area, Paris Metropolitan Area, and London Metropolitan Area

New York metropolitan area, London metropolitan area, Tokyo metropolitan area, and Paris metropolitan area are internationally recognised as the four major metropolitan areas around the world. After reviewing their development process, some factors, including urban functions, regional division of labor, transportation, social equality and environment protection, necessary for the success of urban development were discovered.

Serin Geambazu

The New Istanbul: the expansion of a metropolis

As global capital proliferates, new spatial patterns emerge among which megaprojects denotes the biggest investment boom in recent times. Megaprojects are examples of new governance styles and policy targets, and this study looks at how the development of the new Istanbul Airport distinguishes itself from other build-operate-transfer megaprojects.

Slawomir Ledwon, Fatma Al Bader, Noora Al-Suwaidi

Developing the regulations for rapid urban growth: the new centres of the Doha metropolis, Qatar

Qatar's capital Doha has developed rapidly from a town a metropolis in a short time, being boosted by winning hosting FIFA 2022 World Cup and oriented around the new metro system. This presentation discusses how the regulations of a young planning system have evolved to introduce new urban centres and TODs, including the rationale for such changes and their applicability.

7.3 Session 3: Local Leaderships

10 September (Tuesday), 14:00 - 15:30

TRACK KEYNOTE

Ery Supriyadi Rustidja, Teti Argo

The Role of Local Leadership in Fragmented Urban Development : the Case of Higher Education Town - Jatinangor, West Jawa, Indonesia

The Higher Education Town HET is a campus area, park of cultural technology science and an urban center. As a part of metropolitan, HET faces deterioration environment and urban space problems. The local leadership role in managing urban strategy and must have strong networks in quadruple helix context. Leadership behaviour and capability of local leaders detemine performance of urban planning .

Xiangyi Meng, Taofang Yu

Infrastructure Imbalance, Financial Investment and AIIB's Role: Non-state Actor in Regional Governance

The Asian Infrastructure Investment Bank (AIIB) is an emerging force to solve the problem of infrastructure imbalance in Asian developing countries. Based on the economic geographical framework of density, distance and division, the paper analyzes traditional governance phenomena and the AIIB?s role in spatial governance. Cases indicate the infrastructure-led development will widen differential rent gaps and bring agglomeration economies.

Thai Son Pham

Organising urban governance in Vietnam: an investigation on housing development in Ho Chi Minh City

This paper investigates the governance of urban housing development in Ho Chi Minh City (HCMC) in Vietnam. By focusing on capacity, finance, diversity, security and authority dimensions of governance, the paper conclude that current configuration of urban governance in HCMC is not sufficient to address housing as cross-cutting and multi-faceted issue and proposes integrated approaches towards a good governance system.

Olga Chepelianskaia

Fostering Local Leadership for Climate Resilience in Asian Cities

Ecosystem based climate resilience has been globally recognised as viable, cost-effective and generating multiple co-benefits for cities. However, it requires a transparent and supportive local governance and leadership, which remains a critical challenge in Asia. The paper looks at potential solutions to overcome these challenges and foster local leadership, as exemplified by Tri Rismaharini, the Mayor of Surabaya.

Tathabrata Bhattacharya

Fixing the wrongs against 'rights' in Kalyani (India): slum sanitation, land tenure, a municipality and the state

Working on a participatory slum sanitation programme, Kalyani Municipality (West Bengal) utilised people's participation to negotiate urban land governance by triggering voluntary habitat improvement by slum-dwellers. The paper explores the manner in which a municipality can impact the established land administration system that limits its constitutional powers and transform the perception of land tenure in two slums.

Session 4: Metropolis Management 7.4

10 September (Tuesday), 16:00 - 17:30

TRACK KEYNOTE

Eric Huybrechts

Urban planning agencies: a key support for metropolitan governance

Metropolitan governance is facing technical high complexity and several shape regarding scales, sectors and political changes. Permanent technical bodies are essential to provide scientific knowledge, prepare policies and strategies and support the public debates. Decision makers find in several shapes of territorial planning agencies the interdisciplinary tools to help them to define visions, prepare strategic decisions and manage metropolitan areas.

Mennatullah Hendawy

Visual Communication and the Mediatised City: From Billboards to Offices of Urban Planning in Cairo

Today, by simply walking in the streets of Cairo or opening one of the national TV channels, one get captured by hundreds of real estate ads. To what extent these dominant narratives and visuals impact/construct the professional planning practice, is interrogated in this paper through adapting an assemblage ontology and employing Actor- Network-Theory starting from street billboards.

Ana Peric, Theodora Papamichail

Informal planning: a tool towards adaptive urban governance

By using the example of a 'test planning' procedure that links both formal and informal planning, and observed through the lens of collaborative rationality as a theoretical background, the paper elucidates the following pillars of adaptive (collaborative) urban governance: 1) flexible and agile institutional arrangements, 2) proactive and imaginative planners, and 3) inclusion of numerous stakeholders.

Marc Wolfram

Un-planning the metropolis: Urban transformative capacity as a transdisciplinary heuristic and disruptive sustainability strategy

The concept of urban transformative capacity offers novel perspectives for addressing the metropolitan sustainability crisis: It focuses on dismantling path dependencies and supporting emergence for reconfiguring urban systems across scales domains.

Haward Wells, Frank D'hondt

Beyond the Plan: Building In-House Capacity to Plan, Design and Implement Territorial Transformations, Case of 'Castries Vision 2030'

Written by practitioners who were involved in drafting of the 'Castries Vision 2030' in Saint Lucia, the article testifies their experience with in-house and rapid planning to address pressing challenges related to depopulation of the core-city, informal housing, urban crime, environmental degradation, traffic congestion and imminent threats triggered by climate change in the context of insufficient and ineffective planning capacities.

Session 5: (Special Session) Democratic Urbanism : A Method for City-building 7.5

11 September (Wednesday), 11:30 - 13:00

Moderators: *Erin Simmons, Joel Mills*

When urban democracy expands, cities flourish. Democratic urbanism is a method of city-building that integrates democratic ideals into the urban design process and applies broader shared governance models to the implementation of community aspirations, creating places of deep meaning that are broadly "owned" in the civic mindset.

Session 6: (Special Session) Using Metro-Hub 7.6

11 September (Wednesday), 14:00 - 15:30

Maria Del Pilar Tellez Soler, Michael Kinyanjui

By adopting the NUA (Paragraphs 90. 91, 95, 96, 130 and 131 mainly), Member States of the United Nations committed to support the strengthening of the capacity of subnational and local governments to implement: Metropolitan governance, planning and financing. To do so, renewed metropolitan management that incorporates new capacities, competences and new ways of managing cities and urban agglomeration is needed. Therefore, in collaboration with different Partners, UN-Habitat has developed the "MetroHUB" initiatives. MetroHUB focuses on innovative capacity development for key-actors on metropolitan management. This novel approach to plan, govern and finance the urban and territorial development is gaining momentum. The event will showcase one of the innovative tools within the MetroHUB: "The Pyramid of Metropolitan Management". The tool demonstrates how 12 metropolitan management topics can be effectively talked to support the achievement of the NUA on "Leaving no one and no place behind". The tool is highly relevant for those interested in metropolitan development, because it identifies which are the fundamental topics facing a metropolitan area and then find pathways to simultaneously unleash, integrate and articulate the pyramid of governance, planning and financing. One of the key results of that the Pyramid of the Metropolitan Management Tool is to enable an integrated and holistic approach to manage multi-governance planning and financing of metropolitan áreas.

7.7 Session 7: Metropolitan Governance

12 September (Thursday), 11:30 - 13:00

Ananya Ramesh, Nirupama M Vidyarthi

Decentralisation and Devolution in Growing Megacities: Case of Bangalore, India

Unpacking decentralisation and devolution in megacities, an element of 'disconnectedness' emerges; between parts affecting the whole, embodied as intents and outcomes. How do we then retain decision-making within the democratic realm and strengthen the role of local bodies. This is critical across megacities globally, as cities continue to seek autonomy in functioning, identity and influence, within networks of global flows.

Ali Alraouf

Towards a New Paradigm in City Branding and Marketing: The Case of Doha, Qatar

The paper articulates a model for Doha city banding which is based on a balanced approach. It considers traditional assets and includes contemporary and innovative assets resulting from the last decade's unprecedented investments in the sectors of education, research and culture. The paper suggests holistic approach to city branding which would balance between social equity, economic prospertiy and ecological intergrity.

Metropolitan governance in Southern Europe: working across sectors and boundaries

This comparative study of governance structures across southern European metropolitan areas ask how inter-sectoral cooperation and coordination, and multi-jurisdictional collaboration is best achieved. The analysis focuses on the scope of their mandates, and management and legislative authority, and highlights best practices.

Mapping institutions and actors in urban coastal management of Jakarta's Bay

This research has a comprehensive understanding of governance on Jakarta's bay. Having a mixed method methodology through content analysis and actor mapping tools, this paper describes a network of interactions between state and non-state actors regulating the planning process until implementation in the coastal development of Jakarta.

Jyoti Vijayan Nair

Making TOD Implementable in Indian Megacities : From theory to practice

India's unprecedented economic growth and ubanisation require innovative solutions over traditional planning practices. Transit-Oriented development(TOD)- widely acknowledged as a solution to sprawl, has been a popular buzzword in Indian urban policies for a decade, yet the first fully implemented TOD is still awaited. This paper examines key TOD projects to develop a framework for feasibility analysis of future TODs.

Papers

Research Paper

Smart Cities in India: Branded or Brain-dead?

Vaishali AGGARWAL, Bauhaus-Universität Weimar; Germany

Abstract

The notion of 'smart cities' is increasingly visible in discourses on the future of cities but Change is coming to transportation, whether we are ready for it or not. But how sustainable and digital innovation can unlock better people health and well-being, enhance safety and security and provide seamless mobility experiences. It can be argued that smartening the mobility infrastructure enables the citizens to make informed decisions, and this is indeed true- if done well, but it has a big "if."

This research engages with the key drivers of change and provides affirmative aspirations for mobility in the not-so-distant future in order to facilitate conversations about change. However, the development of possibilities (scenarios) for the government policies and business innovation is dependent on the advanced technology and socio-economic values, which are embedded in the context and culture. The research paper aims to visualize through foresight by design, plausible alternatives of sustainable future for passenger transport in Delhi to stimulate sustainable innovation developments for transportation and analyse the present innovative influences for smart mobility in Delhi to accelerate the adoption.

The first part of the paper analyses how do urban planners use the discourse of smart cities and how it has defined in India then later suggest future scenario for the future which will empower users, changing mobility models and transforming eco-system where intelligent connectivity would unite varied rage of emerging technologies to enable smarter, healthier and more resilient and economically vibrant urban life. This research considers smart mobility by outlining current challenges, suggesting technological, infrastructural and policy solutions and distilling explorations of the future into a series of 'user journeys.' It seeks to answer if 'branding of technology' can be used as a tool to create a new identity for mobility of Delhi or 'upgrade' the existing situation. How can the context of Delhi be decoded to describe the perceptions of the people?

Keywords

Livability, Sustainable Transport, Narrative transportation, Personas, inclusive design, integrated transportation system, user journey & experience

1. Introduction

Future is fiction, but the cities of the future will be 'smart.' 'Smart cities' is the most fashionable concept in urban policy nowadays but the meaning of the term is often obscure in a different context. But is "smart city" just another buzzword or does it have some meaning? Smart City is considered like a winning urban strategy using information and communication technologies, **business models**, and solutions to increase the operational efficiency, share information with the public and improve both the quality of services and citizens welfare.

Mobility shapes the cities, but cities are not static, they change and adapt like living organisms over time. Though historically, mobility was primarily viewed as a 'product' that includes vehicles, physical infrastructure, fuels required to move around but now mobility is approached as a 'service' for seamless movements from place to place. Therefore, strategies for measurable economic and environmental sustainability and improved traveller experience would be achieved by reducing the use of fuel and power consumption for vehicles, reduction in congestion and traveller frustration and promoting the efficient, cost-effective system to eliminate adverse impacts on health and environment and would provide improved accessibility and affordability of transport providers and travellers.

However, **if "smart cities" is the answer, then what was the question? How can technology and intelligent design be used for creating a better world for people?** Therefore technology will be used in a manner which is no longer isolated in different devices or services; rather it would be used to surround us, support us and promise us for a better urban experience. Will everyone get the benefit from the technological transportation advances or will it be accessible only to those who have the resources or knowledge to use them? Therefore, 'how' is the **crucial key for smart city/mobility** solutions. However, in a rush for the smart cities, we are seeking for wrong questions.

"Smart cities" has become a **buzzword in India** since Prime Minister Narendra Modi outlined his vision. But the smart cities **ambition remains elusive in the Indian context** as cities in India face a range of challenges to meet demand and supply gaps in urban regions in areas such as water, waste management, energy, mobility, the built environment, education, healthcare and safety and if timely and adequate action is not taken, these challenges may worsen and could derail India's growth (world economic forum, 2016). **Ironically, this is precisely why India desperately needs a system of smart(er) cities.** Delhi, which is a second most populous city in the world (world population review, 2019) has a car-centric landscape with trends of rapid urbanization, rapidly growing economies and high level of transport related problems such as pollution, accidents, and congestions, which has an adverse impact of urban quality of life.

Can technology allow us to rectify the mistakes of the past? What **new possibilities** will exist with the creative use of technologies? What is the 'value' which smart mobility will provide to Delhi? To accomplish the **inclusivity** in mobility, we need to ask if this is the role we want mobility to play then how do we ensure things are in place for this to happen? **Smart mobility for whom? Cities for whom?** The question is **not** how do we make my city smarter by smart mobility? or even 'how do I make it more efficient?' Rather we should ask, 'how can smart mobility be implemented in the places like Delhi where planning is both essential and broken? How can the **gap between the bottom up and top-down initiatives** be reduced? Does smart mobility provides solutions for the transportation problems in Delhi or does it raise the questions of resistance of being 'alternative smart' with a power of 'image'?

2. Smart Cities

2.1. Definition

Despite the ongoing discussions over the past few years, there is no agreed definition of a 'smart city.' The label "smart city" is a fuzzy concept and is used in ways that are not always consistent. There is neither a single template of framing a smart city, nor a one-size-fits-all

definition of it (O'Grady and O'Hare, 2012). There is still confusion about what a smart city is, especially since several similar terms are often used interchangeably. **Collective smartness** is an important aspect of smart cities because it supports creative human capital, learning, technological development, and citizen participation. The definition of 'smart city' is not just based on the use of 'ICT.' According to Hollands (2008), the smart city is based on "urban labeling" phenomenon that downplays some of the adverse effects networked infrastructures on cities. Cities by nature are supposed to be smart, creative and cultural, and by using this marketing label a disjuncture between reality and image is created (Hollands, 2008).

2.2. Frameworks

Smart city is defined in three ways- technology- oriented vision, approach oriented vision and service oriented vision.

- **ICT oriented vision** system which interconnects to promote optimum performance & efficiency to create 'systems of systems'.
- **Service oriented vision** which further consists of dimensions of Smart Economy, Smart Governance, Smart Mobility, Smart Environment, Smart People and Smart Living for self-decisive, independent and aware citizens.
- **Approach oriented vision** which empowers the collective intelligence and in co-creating capabilities of the 4P model public, private, people and partnership.

3. Understanding the Indian Context

3.1. Urbanisation in India

Urbanization is one of the biggest challenges which both developed and developing countries across the world are facing. In 2015, the urban population in India was 410 million people (32% of the total population) and was expected to reach 814 million (50%) by 2050. Three of India's metropolitan areas are among the most populous in the world: Delhi (25 million), Mumbai (21 million) and Kolkata (15 million) rank 2nd, sixth and 14th, respectively (WEF, 2016). This 'disordered urbanization' is indicative of the failure to adequately address congestion constraints that arise from the pressure of urban population on infrastructure, essential services, land, housing, and the environment (Velmurugan, S. et al., 2016).

3.2. Emerging urban landscape of India

According to World economic forum (2016), the landscape of India has undergone a dramatic change between 2004 -2014 where India witnessed an increase in urban population from 14% to 27% while the rural population grew only 8%.

This shortcoming is due to the weak local governments and the complex urban regime, which prevails in the cities.

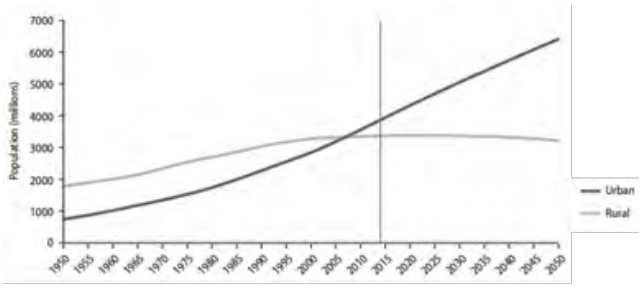

Figure 3 Urban and rural population of the world. World urbanization prospects, 2014

3.3. Why Delhi is a special Case

New Delhi, India's capital, is of particular interest not only because of the high level of air pollution and traffic congestion but also because of the exposure levels experienced by a population of 18.6 million. Delhi has astounded the World with its transformation, from feudal backgrounds to modernity, Delhi with its rich past is the perfect contrast between Occident and the Orient. It is a relevant example of a city that responds to the dualities of urban India while keeping its physical form legible. The government of India launched the scheme to create hundred smart cities across the country where the national capital Delhi was chosen to be the frontrunner to decongest national capital and facilitate modern abilities despite its limitations in the current scenario of economic & environmental performances & people's perceptions.

Spatial structure - According to Delhi development authority (2014), Delhi has grown as a borderless city where the urban agglomeration area has increased from an ordinary 43.2 sq. Km (1901) to 888.74 sq. Km (2001) while the density increased from 5501 (1901) persons per sq. Km to 14521 (2001) sq. Km.

Economic Profile - Delhi is India's second largest economy with per capita income of € 4125 (2018) which is three times higher than the national average. The gross state domestic product (GSDP) has recorded a growth rate of 8.14% and presently is € 93.2 billion.

Governance complexities - Delhi faces complex issues in an administration with the government running at three different levels- macro, state & local body. The New Delhi municipal council is one of the five urban local bodies in the national capital territory (NCT) of Delhi, while the central government has most of the controlling power.

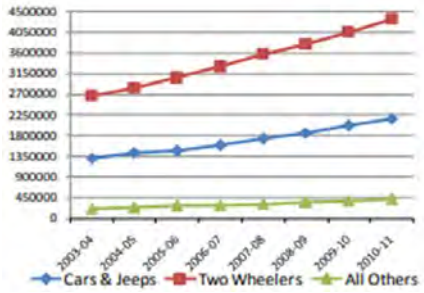
3.4. Urban Transport Scenarios in Delhi

Delhi seems to lack an institution that holds an overarching responsibility for managing and coordinating the entire transport sector. Delhi is in a situation where things need to move quickly for the present as well as precisely for the future for the safe travel with reduced level of pollution and congestion.

I. Emerging patterns and characteristics

Vehicle ownership-

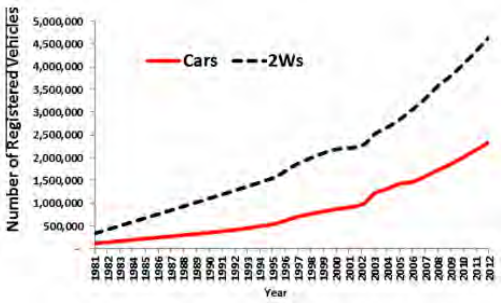
According to Delhi Statistical Handbook 2011, the vehicles in Delhi have grown at the rate of 7.41% per annum between 2003-04 and 2010-11 where the number of private vehicles has increased substantially from 3.98 million to 6.52 million during that period where the growth rate of commercial vehicles (9.42%) is higher than the growth rate of private vehicles (7.29%).



S.N.	Category of Vehicle	No. of vehicles (in million)		Annual Compound Growth Rate
		2003-04	2010-11	
1.	Private Vehicles	3.98	6.52	7.29%
2.	Commercial Vehicles	0.22	0.42	9.42%
	Total	4.20	6.93	7.41%

Figure 2- Vehicular growth in Delhi, Census of India, 2011

II. Vehicle density



The vehicular population o Delhi has increased by more than nine times from 1971 to 1991 whereas the road length increased by only 206 times which has resulted in high vehicle density because of reduced vehicular speed causing more extended time travel, accidents and extra fuel consumption (Kumar et al., 2002).

Figure 3- Vehicle registration in Delhi, Census of India, 2011

III. Travel demand

Sl. No	Mode of Transportation Facilities	2001			2011		
		Rural	Urban	Total	Rural	Urban	Total
I	No. of Households	169528	2384621	2554149	79115	3261423	3340538
1	Bicycle	48.70	36.80	37.60	44.20	30.30	30.60
2	Scooter/ Motor Cycles	20.70	28.50	28.00	38.50	38.90	38.90
3	Car/ Jeep/ Van	7.30	13.40	13.00	10.80	21.00	20.70
4	None of the Specified Mode of Transportation	38.90	43.40	43.10	34.70	37.20	37.10

The travel demand arose from 4 million trips per day (1994) to 20 million trips per day by 2011, in which the road based transport need to fulfil 12 million trips (403% increase) while the daily trips were 22.5 million in 2011(Kumar et al., 2002).

Figure 4- Distribution of mode of transportation in Delhi, Census of India, 2011

3.5. Transportation problems in Delhi

Road congestion

The increases in population directly co-relates to the average travel distance and intensity. The average trip length for Delhi is around 22 km and this trend in trip length and frequency is only expected to increase with an increase in income levels, migration, participation of women and service-oriented economy but since more people travel over longer distances on a regular basis for employment and education purposes, it leads to road congestion (IIHS, 2015).

Parking problems

The acute shortage of parking spaces both on and off the street in Delhi increases the time spent in searching for a parking spot, which induces traffic congestion. 14% of road length in Delhi used on-street parking, and the public parking charges are fixed and low (€ 0.13 for 8 hours) (IIHS, 2015).

Air pollution

Delhi's air quality has become worse than before. According to the Environment Pollution Control Authority (EPCA) report for the decade 2002 to 2012 shows that the number of vehicles increased by 97 percent, contributing enormously to pollution and direct exposure to vehicular toxic fumes to nearly 55 percent of Delhi's 17 million people who live within 500 meters from any roadside (CSE, 2014).

3.6. Barriers

Based on the literature study and expert interviews, the barriers (Rana, NP et al., 2018) which hinders the smart mobility in Delhi.

	category	barriers	description
1	Governance	Lack of cooperation and coordination and confused priorities & inefficient inspection Strategies	Lack of co-ordination and confused priorities
		Institutional gap & unclear vision (for IT management)	Multiple agencies with multiple mandates & lack of vision on how IT management can be imposed
		Political instability & lack of trust (between governed and government)	Until there is political stability, smart cities Delhi cannot become a reality
		Poor private-public participation & lack of development of common information system model	Poor PPP interaction creates negative impact but to ensure end-to-end visibility, a common model is missing.
2	Economic	Shortage of High IT infrastructure and intelligence & lack of competitiveness	Lack of IT infrastructure and capabilities of artificial intelligence & lack of competitiveness lies within the local firms
		Cost of IT training and skills development	High cost of IT training and skills development programme to the IT professionals
		Global economy unpredictability & higher operational and maintenance cost	Increasing instability, uncertainty in the global economy & high maintainance cost is a concern
3	Social	Lack of citizens participation/sense of ownership	Lack of citizen's engagement in realising the smart cities according to their experience
		Low-level community awareness, Increased cost of travel for economically low class & geographical diversity	lack of understanding among the public towards the idea of smart city and its implications but due to lack of public supportnn & obstruction due to unbalance
		Degree of inequality & rise in traffic congestion	High degree of inequality lies within citizen's education and increase in the usage of private transportation
		Changing lifestyle, demand for customer groups	Cause poor customer experience if their demands are not met
4	Technology	Lack of technological knowledge among the planners	Lack of enabling or transformative technological knowledge within planners and policymakers.
		Lack of access to technology	Lack of access to modern digital technology to majority of citizens
		Lack of technological knowledge among the planners	Lack of enabling or transformative technological knowledge within planners and policymakers.
		Lack of access to technology	Lack of access to modern digital technology to majority of citizens
		Privacy and security issues & System failures issues	Issues related to privacy and security tend to be a major concern for smart cities development
		Lack of integration of IT solution with public transportation & poor data availability and scalability	Integration of IT solutions with public transportation is missing & lack of specific data and corresponding scalable methods
5	Environmental	Growing population & lack of ecological behaviour in practise	Rapid increase in population & lack of ecological view in pro-environmental behaviour for consumption.
		Influx of intermediary public transport (IPT) & rising vehicular Pollution	IPT services like auto rickshaws, e-rickshaw, and cycle rickshaws adds congestion – flouts traffic & ever-increasing number of diesel vehicles due to subsidies on diesel has again led to high levels of air pollution
		Urban sprawl,mobility needs & lack of sustainability	Lack of awareness about sustainability
		Carbon emissions effect & degradation of resources	lack of strict emission checks and control have led to increased carbon emissions and noise pollution
6	Legal and ethical	Cultural issues (demographic pattern) & perception of the status & aspirational nature	Lack of inflow of creative & sharing culture of the people living together & vehicle ownership behaviour
		lack of women safety, road safety & standardization	Lack of gender based infrastructure and increased number of deaths due to road infrastructure
		Issues in openness of data & lack of transparency and liability with regulatory norms, policies and directions	Open data and its accessibility can obstruct the smart city services delivered to cities residents and business & lack of transparency and unclear lines
7	Physical	Insufficient infrastructure, incomplete last mile connectivity & Poor infrastructure for NMT	Lack of inflow of creative & sharing culture of the people living together Insufficient cost advantage & unsafe and inadequate infrastructure

Table 1: Barriers in the India to adopt smart city principles quickly

3.7. Megatrends influencing smart mobility

Following key technologies can bring a range of new functionalities to reduce congestion, bring the social and economic changes for future of mobility 2040 for Delhi.

- Automated Vehicles
- Next generation connectivity using ICT
- Intelligent processing using Big Data and User applications
- Internet of things
- Innovative materials and Sensors in infrastructure
- User centred
- Pricing and payments
- Public and private innovation

4. Analysis

4.1. Annual household disposable income

	2015 - 2025	Category	Income	Characteristics	Categories
1	-13%	Deprived	<$ 1969	Poorest Group	Engaging in un-skilled or low-skilled activities
2	-7%	Aspirers	$1969-$4376	Struggle to live comfortably	Small-time shopkeepers/ service workers
3	+13%	Seekers	$4376-$10,941	Varied in employment, attitude, age and other factors	- Mid-level government official - Traditional white collar jobs
4	+8%	Strivers	$10,941-$21,882	Very sucessful Financially stable	Businesspeople/ traders Established professional/
5	+1%	Global Indians	>$21,882	New breed of upward mobile-mid-level executives	Senior corporate executives/ large business owners

Table 1: Comparable from Deloitte, McKinsey & Company, Rise -Indian consumer market 2007

4.2. Existing Personas

Figure 5- Analysis of 10 different existing user journey on their painpoints & future goals

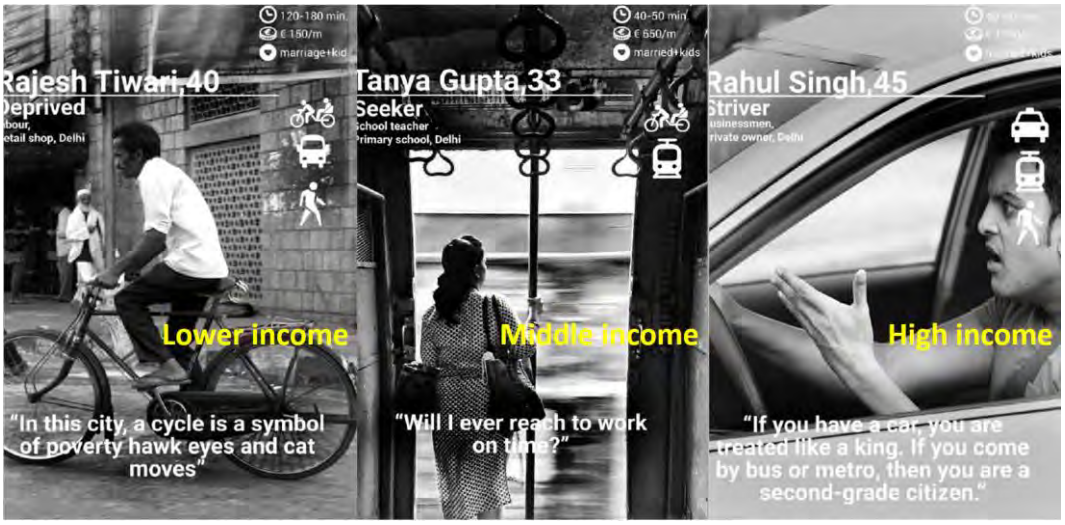


Figure 6- Three classifications of existing users based on income scale

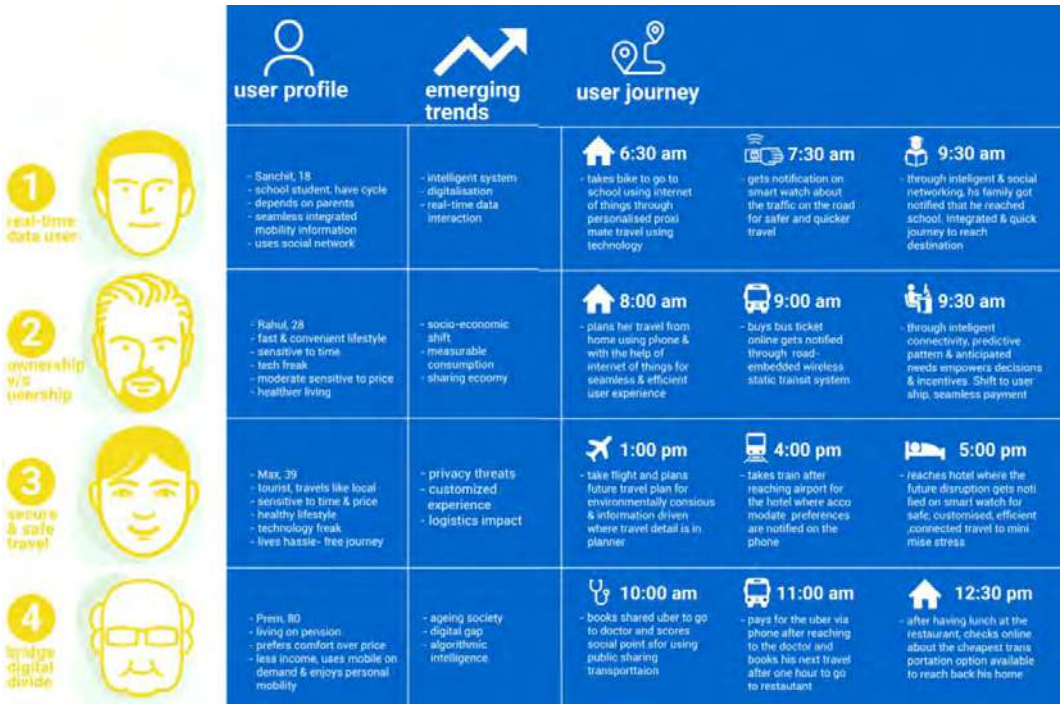

Figure 7- Future User journey based on the emerging trends

5. Recommendations

Future Scenario: Live Glocal

Though it's difficult to make detailed predictions for the future of mobility, but it's not so hard when current trends are grouped with features of being enormously networked, integrated, dynamic pricing, user-centered with the development of both public and private stakeholders since we have to recognize that no single solution would save transportation from in this rapidly urbanizing and complex world. This scenario is notable by the lower per capita travel and the high use of digital substitution of ICT, user applications and internet of things for travel. **Changes in the environmental and social behaviour** for travel demand is visible with focus on uplifting the informal transportation, increased employment, and last mile connectivity. In this scenario, automation is not widely adopted by the public. The future of mobility is likely to be fundamentally based on broadly connected vehicles, or "the internet of cars", prices as per demand and supply; and transportation decision making through social networking but would be highly dependent on the interplay of various stakeholders from public (government, institutions) and private sector (manufacturers, entrepreneurs) as reflected in the scenario below. What will be the possible steps to reach there?

Economic Trends

11,000 new e-rickshaws are expected to ride on the streets of Delhi every month by 2021 where annual sales are supposed to increase by 9 percent making it €1.32 billion markets (Economic times, 2018). However, with increased demographics by 2040, the demand for informal transportation using ICT would be increased and thus encouraging an affordable ecosystem of technology.

Technology

The E- mobility is shaping the informal transportation for Delhi with the increased use of E-rickshaws, thellas, etc. which play a significant role for enhancing the last mile connectivity and thus improving the air quality of Delhi. Technology-driven trends like electrification, shared mobility and connectivity would be a disruption in this scenario. However, due to several loopholes, initiatives have to be taken by the government to improve the informal transportation sector (Down to earth, 2018).

Travel implications

Though the travel will be much more expensive by 2040 in this scenario for informal sector due increased road pricing, digitalization, higher travel demands but a change in the acceptance and commuter's behaviour would be visible due to improved technological advancement in transportation industry with rising in ride-sharing apps, travel information applications with increased user's experience and seamless travel.

5.1. Step: 1- Dynamic payment

Transportation industry is moving towards the notion where services will no more be priced statically due to widespread of mobile technology, location-based services, and predictive forecasting will allow to pay actual costs of the services used where the price (supply) would be based on the demand which will allow the users to make **better decisions** about their travel as per their needs. This will allow the commuter to choose their between the lowest cost and quickest routes with the help of real-time reporting traffic conditions for their final destination.

Figure 8- Dynamic payment

Concern

- Who would be in charge to determine the difference between the benefits, loses/ negative impact of the system where the providers have set the prices as per the demand, and other considerations of the services on their own? What will be the overall impact for setting the prices as per demand?
- Should there be a potentially competitive market for the mobility as a service or should the pricing be dependent on the community or economic background of the social group for the commuter?

How to get there?

- By exploring new payment business models
- Promoting digital payments
- Predicting about the needs and desires of the future transportation market

5.2. Step: 2- Social Move

Existing transportation systems lacks in connecting all the various transportation system directly but with the rise of networked cars, awareness, social network, the future of transportation will be based on socially informed decisions of the communities, government, traffic controllers, **real-time travel conditions** and community values from people who have already used it for experiential travel. Creating **gamified experience** which encourages fitness, saves money and provide business benefits and loyalty with the users to the services.

Figure 9- Social move

Concern:

- Difficulties in getting a holistic view as information would be scattered and based on the decisions of various people.
- Might create differences with the people who will not be able to attend the network or lack the ability to influence or engage to become second-class inhabitants. Will these people be able to take the benefit of such social network system?

How to get there?

- Analysing the changing behaviour and designing user-centric solutions
- Providing social points as incentives and creating a gaming experience for users which allows to compare their social points for changed travel behaviour

6. Conclusions

Cities are dynamic. Cities are its people. It changes and adapts over time in response to economic, political and environmental shifts where the infrastructure is not the driver but an enabler, a side effect or a by-product of people and culture.

However, a city cannot be 'smart' and inefficient at the same time and therefore, high activity is far more important than the big idea for enabling the citizens to make informed decisions. For smart cities, **context is more important than the product** but can this smart city be simply rebooted through the integration of digital technologies? Is this 'smart urbanism' branded, exaggerated in offering **'new possibilities'** for the future transformation of cities or it is a brain-dead idea of **'business as usual'** value propositions for tweaking the existing scenario through technology and influence from western countries? To access the technology advancements and its potential impacts for the society, monitoring of the future technologies is substantial because technology is not the **'shortcut for development'** but it **'can be an accelerator.'**

As transportation is the **backbone** of economic, cultural, social and industrial development, the transformation of existing urban areas to mitigate the existing challenges in a traditional society like India was a concern despite its rising economy and therefore understanding the existing spatial dynamics, hopes and fears about the technology, core needs and expectations of the transportation users was accomplished by analyzing the existing user groups to propose the experiential design for users using technology and services. India gives the appearance of just waking up to the urban realities and the inevitable transformation awaiting its cities. India's attempts to urbanization have been at a snail's pace, and the smart cities mission seem to be a knee-jerk reaction to the sudden realization of not wanting to be left behind (Chandrasekar, S. et al., 2016).

Delhi is a paradox where despite the increasing challenges it provides opportunities to shape the future of mobility. **No single solution** can be recognised for the rapidly urbanising and complex mobility situation of Delhi as the innovations are rarely linked and optimized to provide convenient, practical, affordable and sustainable door-to-door trips for the users. Connectivity is the key, but accessibility is the goal for the future of mobility as transportation is a system, or rather a 'system of systems' which connects modes, services, technologies, and designs according to the purpose and needs of the people.

The **future of mobility** lies in the **seamless transportation experience** can be accomplished by physically connecting the transportation modes and services for the community, bringing together the telecommunications framework which offers real-time information of availability (departures and arrivals), access to affordable or convenient ride and quick payments. In some places, it is almost therein Delhi but not evenly distributed. It can be achieved through **connecting** Spatial (physical linking the transportation modes), component (enhancing the accessibility capabilities with improved infrastructure), technological (technologies to support multi-modal transportation for seamless experience), institutional (transforming collectively on local and regional level with the help of planners, city officials, innovators, etc.) and economic (developing new business models, creating jobs and increasing competitive market) optimisation of Delhi

With the shifting mobility needs and customer expectations, the future of mobility has to evolve and adapt to provide intelligent connectivity for enabling effective, seamless and end-to-end journey experience. Analysing the existing users' needs and desired helped to explore the future user journey under the themes of user-ship vs ownership, big data eco-system, Bridging digital divide and safe travels to engage the range of issues: enable better choices with smarter decisions; predictive dependable and productive mobility; cybersecurity; public safety; and mobility opportunities for everyone where distinct stakeholders like users, municipalities and owners/operators play a critical role for a safer, healthier and better user journey experience.

Live Glocal scenario describes a future of moderate growth in which incomes do not rise quickly in future informal transportation but high usage of technology for travel steered the economy towards a more sustainable path for growth and enacted constraints on vehicle ownership and driving to try to reduce their negative impacts which results in a future of strong travel demand across all modes of transportation and improved last mile connectivity. **Dynamic payment and social transport** to widen the recognition of 'information everywhere' to disrupt the transportation status quo and bring new ways of using existing infrastructure more efficiently with high speed and offers the chance to

rethink the existing challenges for mobility of Delhi and prepares the eco-system with set of features. Through reshaping how urbanites in Delhi would get around by introducing mobility as a service and collective intelligence of the citizens might help in making better decisions but cities will need to explore the digital mobility platforms to accelerate the realization of the integrated transportation system.

Successful urban planning process can be creative, flexible and democratic because reality comes into being through interaction. However, the more significant question lies in what is next for the smart city in India? Smart cities will not be a recipe for social segregation only if inclusivity is considered along with the booming of technological development has encouraged multiple vision for urban futures of India and analyzed the 'surface' of many cities but there exist troubles with determinism and attitude of government towards the socio-political changes and consequent ways of owning and managing the initiatives as this give rise to the **'classic dilemma'** for urban space and governance which affects the lifestyles of the emergence of the information society. Does this 'virtually enhanced city' in which we would live and communicate need more control or does it need more open participation? How can these two aspects be integrated? Should the smart city's ethos be oriented towards service provision with better city management or should it focus on enhancing the social and political linkages for public discourses? Does the policies and technological initiatives aim at the 'end-users,' or it is aimed by the 'actors and owners' of the city?

Technology will only enhance the future of smart mobility if the technology works around the **'existing behaviors'**. Technology is interesting and is the future only when it interacts according to the human understanding and therefore, understanding the value exchange is important which can be implemented by encouraging gamified experiences that is helpful to get the loyalty of the services using the long-term relationship and big data. Though the future lies in the hidden connections as it is not difficult to change the city but to change their **mindsets**. Therefore, evolving a mobility landscape after understanding the patterns of consumer behavior and analyzing how to build the services around the existing infrastructure with **'on-demand'** and personalized mobility services also known as **'mobility as a service (MaaS)'** will unlock the potential for innovation for the city to function on a larger scale.

Things which are hardly mentioned in the 'smart cities propaganda' is the 'other side of the city' and therefore the 'branding' of smart cities have to do by keeping and creating the spirit and emotions of India. Who wants smart cities and who does not want to be seen as being smart? Does the discourse of smart in India explore the **global explorations** with the value of smart cities or with the needs and realities or urban India? In order to understand the algorithmic urbanism of smart Indian cities, the examining of the politics of a country is essential. What is next to cities or what could be next for cities if we dare to reimagine ourselves? What is next for the future of mobility? Are we there yet? **Will Delhi be a city of things or a city for people?**

Research Paper

The Value of Less and Small: Transforming Metropolitan Doha into Connected, Human and Resilient Urban Settlements

TITLE

Subtitle

Ali ALRAOUF, Prof. of Architecture and Urbanism; Qatar

Abstract

Qatar is one of few Middle Eastern oil producing countries that realized the vitality of a needed swift transformation from resources to knowledge economy. Until a few decades ago, Qatar was dominated by nomadic people whose livelihood depended on fishing, pearling, camel breeding, and fishing ships building. However, the discovery of oil and gas has encouraged not only socio-economic change, but environmental change as well. The discussed account will cover the main strategies adopted by the country to create a distinctive model of development in the Middle East. The study also analyzes the shift over the past decade which reveals how Qatar views investments in knowledge-based urban development as essential vehicles to survive in a globalized and competitive world. More significantly, the study illustrates an interesting form of urban resilience in the face of major challenges which faced Qatar in the last decade including, winning the bid to host the FIFA World Cup 2022, the decline of oil prices and the air, sea and ground blockade imposed by its adjacent neighbors. The study sheds light on different urban planning strategies and policies adopted to shift the focus from creating a mega city with an image which resonate with typical global cities to a more sustainable, resilient, knowledge-based and decentralized urbanity. The model of Qatar is analyzed holistically in the paper to go form the strategic planning decisions all the way to case studies and best practice planning projects. The study demonstrates how Qatar has captured the world's imagination by balancing global aspirations and local necessities in a sustainable and resilience context. This paper examines a framework for city and urban regions inspired by the theory of placemaking and its relevance to the boundaries of human urbanism. The paper sheds new light on the transformation of the city from a metropolitan exploiting the oil and gas revenues to a multi-centered model of urbanism. In doing so, the city adopted a number of significant strategies include the well distributed livable urban centers, transit-oriented development, introducing compacted urbanism and encouraging models of mixed use development. The paper concludes with a planning matrix which suggest that for Qatar, adopting such strategies and the deliberate move towards multi=centered urbanism is inevitable in the age of post globalizing world, the need for an urban human scale and the challenges of post-Carbon paradigm.

Keywords

Metropolitan Doha, Urban Resilience, Doha Sustainable Development, Transit Oriented Development.

1. Resilience in Urbanism and City Planning

1.1. The Conceptual Discourse

The holistic understanding of urban resilience resonates with the Sustainable Development Goals (SDG) as compiled by the UN Habitat. Particularly, goal 11 suggests the importance of creating inclusive, resilient, sustainable and safe cities. This paper provides an overview of the development of the resilience concept in the domain of urban development and planning. Over the last two decades the concept of resilience has experienced escalating interest. However, due to a lack of consistency in defining and measuring this theoretical construct within and across disciplines, the recent explosion of literature on resilience has contributed more to confusion than clarity among researchers and policy makers. The notion of resilience is gaining increasing prominence across a diverse set of literatures on cities and climate change. Although there is some disagreement among these different literatures about how to define and measure resilience, there is broad consensus that: (1) cities must become resilient to a wider range of shocks and stresses in order to be prepared for climate change; and (2) efforts to foster climate change resilience must be bundled with efforts to promote urban development and sustainability (Leichenko, 2011). Resilience is the ability of a system, community, or society exposed to hazards to resist, absorb, accommodate to, and recover from the effects of a hazard in a timely and efficient manner (Jha and al., 2013). (Pizzo, 2015) problematizes the introduction of the concept of resilience into the planning domain from three main starting points: 1. The nature of the events which are said to require resilience; 2. The different nuances in meaning that resilience assumes according to those different events, and 3. The theoretical and operational problems the concept entails. The paper sustains that multiple sub meanings are embedded within one interpretation of resilience that leave the concept open to rather large margins of ambiguity, which emerge considering its operationalization. The concept seems to fit and to be appropriate within different paradigms, planning traditions and policy frameworks. Its alleged 'neutrality' is one of the main reasons of its pervasiveness, but also of its ambiguity, showing latent controversial implications, which are progressively emerging in critical planning theory. Hence, the interpretation of holistic urban resilience should start with the people and their social dynamics. Here, the notion of the interaction between the people and the city should be based on concepts like just city and cities for all without any form of segregation or marginalization.

Hence, the paper calls for a need to revisit the concept and its utility to the prosperity of cities. However, resilience has been closely associated with sustainability for more than a decade, although without precise meaning and often as an additional label attached to pre-existing research (Timon, 2014). Urban resilience is a broad concept that is sometimes blurred and abstract. Part of the effort to render the concept to a clearer interpretation is first to assert that Urban resilience addresses adaptation as well as mitigation. It is associated with spatial planning policy-making in the context of different levels and forms of uncertainties. Therefore, urban resilience provides a new way of framing and responding to uncertainty and vulnerability. Considering this interpretation, urban resilience offers an alternative paradigm for planning strategies.

Figure 1 The urban growth of Doha witnessed unprecedented rates due to the use of oil revenues in reshaping the image of the city at the end of the twenties century. The city moved through a decade of change from 1995-2005.

2. The Narrative of Qatar: Qatar's Context and Territorial Background

2.1. The Contextual Understanding

Qatar is a peninsula in the east of Arabian Desert and covers an area of 11,437 km2, with a coastline of 563 km. The country is a mostly low-lying and flat stretching into the Gulf from the lands of Saudi Arabia. Until few decades ago, Qatar was dominated by nomadic people whose livelihood depended on fishing and pearling. However, the discovery of oil and gas has encouraged not only socio-economic changes, but urban and environmental changes as well. The newly acquired wealth and associated development have not come without challenges. Since 1984 the population has grown from just under 350,000 to 1.5 million in 2008 and to over 2.2 million in January 2015 (Qatar Statistics Authority, 2015). Qatar's overall population witnessed unprecedented increase since 2010 after the declaration of the State's wining a bid to host the FIFA world cup 2022. The current population is 2.5 million, of which only around 15 percent are native Qataris. Today, the capital, Doha is home to more than 90% of the country's 2.7 million people, the majority of whom are professionals from all around the globe (QSA, 2015). Up to the mid-1960s, the majority of Doha's built environment was composed of traditional houses that represent local responses to the surrounding physical and socio-cultural conditions. During the 1970s and 1980s Doha was transformed into a modernized city because of extensive use of oil revenues in modernization projects particularly housing, infrastructure, roads and community facilities.

Figure 2: An aerial photo captured in mid-forties showing Doha's waterfront, AL Jessra Area, the cemetery and Al Khot Fort (Source: Ministry of Municipality -MME).

2.2. The Post-Independence Paradigm

Qatar was under the British Protectorate from the year 1916 and gained independence in 1971. Since that time, it has been going through tremendous growth in different sectors. This growth has mainly been facilitated by the country's massive oil and natural gas reserves. The revenues have been used to streamline sectors such as health, construction, education, financial, and manufacturing. Conditions for doing business are friendlier as there is no income tax and corporate tax for domestic firms, but only foreign firms are charged a 10% corporate tax (Almfraji, Almsafir, &Yao 2014). Qatar is currently ranked among the highest GDP capita globally. The country has continuously experienced a high level of economic growth, averaging to 25.4% between the years 2004 and 2012 (World Bank, 2013). The economy in Qatar is diversified into various sectors, all of which contribute significantly towards achieving the growth of the country. Even tourism, especially in the last decade, is becoming one of the main platforms for diversifying Qatar's post-oil economy (Phelps, 2013). Over the past decade, Qatar has become one of the major world producers and exporters of Liquefied Natural Gas (LNG). The wealth produced by Qatar's oil and gas exports has generated a construction development boom in the capital, Doha, and the surrounding vicinity. This resulted in significant growth at all levels from urban development and infrastructure provision to cultural, recreational, health and educational facilities.

Figure 3: The patterns of accelerated growth in Doha resulted in uncontrolled urban sprawl which created a major challenge for the city's urban future.

2.3. Moving Towards Knowledge and Creative Economy: From Oil to Knowledge

Qatar has embraced the idea of developing a knowledge-based economy and successful steps have been implemented. One example of this is the support of human capital development in the founding of the Qatar Foundation in 1995 with a fund of $2 billion and in 2009/10, education accounted for 13% of government expenditures. Qatar Foundation supports education, research, capacity building and open dialogue at all levels, supporting activities such as the Doha Debates and Al Jazeera television station. Al Jazeera, an overwhelmingly successful Arabic language news channel, has provided a forum for open discussion and criticism. In terms of Qatar's National Vision 2030, the security of the peoples' standard of living is to the fore, but the government realized that this cannot be the main and only goal of a country. With the focus on its values, Qatar has to balance some further challenges: modernizing traditions while ensuring their preservation, serving the needs of this and future generations, managing the country's growth and expansion, controlling the targeted size and the quality of the expatriate labor, going a path of development that is compatible to it, managing the economic growth and the social development and protecting the environment (J. Gremm et al., Transitioning Towards a Knowledge Society, 2018). To resolve these challenges and to fulfill the transformation of Qatar into an advanced country until 2030, the government outlines and promotes four pillars that the Vision rests on.

Qatar leaders are convinced that post oil paradigm is becoming a reality. Hence, moving from industrial economy to knowledge economy is a global and inevitable transformation which requires understanding and better engagement. Therefore, Qatar National Vision 2030 (QNV) was articulated to construct a roadmap for the alternative future of the State. The vision outlines the development of Qatar over the next twenty years. The QNV 2030 is based on four supporting themes: human development, social development, economic development and environmental development. To facilitate the realization of QNV, Qatar is positioning itself as a knowledge-based society, principally in the fields of education, research, energy and technology. Qatar is determined, due to its awareness of the swiftly arrival of the post carbon era, to diversify its economy and go beyond the total reliance on oil and gas. The plan is to educate and train nationals properly to pave the way to a global knowledge society. This proves that the willingness to pursue the status of a knowledge and creative city definitely exists. According to Stephenson and Al-Hamarneh (2017) despite the fact that Qatar has been rapidly modernized, it has not enough developed to be considered an international tourism destination. Nevertheless, hosting mega events like the 2022 FIFA World Cup will motivate Qatar to work on developing different tourism types such as ecotourism. For this reason, Qatar has established and developed different ambitious goals of tourism development by adopting a strategy called Qatar National Tourism Sector Strategy 2030 in the year 2014.

Figure 4: The iconic development in the real-estate sector which characterized the pace of development in the beginning of the third millennium as a reflection of globalization.

3. Towards a Holistic Urban Planning Framework

3.1. Subheading 3.1

Through the wise insights of His Highness Sheikh Hamad Bin Khalifa Al-Thani, Father the Emir (AlAmir AlWaled), a National Vision (Emir Decree No. 44 (2008)) has been prepared to set out the long-term direction for the country, to inspire its people and to develop a set of common goals related to their future.

"The National Vision aims at transforming Qatar into an advanced country by 2030, capable of sustaining its own development and providing for a high standard of living for its entire people for generations to come." (QNV, 2008). In December 2006, Pacific Consultants International (PCI) provided a proposal for Qatar National Master Plan (QNMP). The suggested QNMP was needed to cope with the long-range strategic vision of Qatar. The physical development was not only considered but also economic, social, cultural and environmental factors and challenges were included and confronted to guarantee the comprehensiveness of the proposed plan. Consequently, the Oriental Consultant (OC) was hired to prepare a comprehensive urban plan for Qatar. QNMP is to guide urban development for the State over the next 25 years. And comprehensive development scheme is the main tool that will benefit all segments of society. On a strategic level and to translate QNV 2030 and other national policy directions into physical and spatial development plans, policies and actions for implementation, a structured process was used to prepare the Qatar National Development Framework (QNDF). The QNDF provides the framework for managing growth, change, land use and development in Qatar to 2032. The QNMP is the spatial representation of the QNV2030. The QNDF sets the strategic framework for sustainable development and provides plans for the country, for Metropolitan Doha and for the Municipalities that make up the nation's principal administrative structure (QNDF, 2016).

Figure 5: Qatar national spatial strategy 2032 where Metropolitan Doha is subdivided using the concept of hierarchical urban centers (Source: QNDF, MME).

3.2. Contesting Doha's Model of Resilience

In this section, an analysis of the most dominant forces that challenged the development of Doha city in the last decade will be provided. Hence, all the strategies, processes and policies which were adopted by the city will be shared to illustrate the city's resilience model. Interestingly, some of these dominant forces were celebrated like winning the bid to host the 2022 FIFA World Cup, while other were a substantial shock and have created a seismic impact on the city's people, economy and development. Doha was alert for the critical need for a flexible and dynamic approach to building resilience that goes beyond risk mitigation. Therefore, in the coming sections, three main challenges will be narrated and Doha's answer to each of them will be illustrated. Three milestones which are representing the most alarming challenges that Doha have faced in the last decade, analyzed in a chronological order. The analysis provided illustrates the wider interpretation of the challenges which require a resilient plan. The notion of city challenge is also extended as it doesn't all the time implies negativity. Cities need resilience also to deal with positive challenges facing its development and progress. Therefore, the milestones analyzed go all the way from economical threats, hosting a global event to a comprehensive blockade.

3.3. The Inevitability of the Post-Oil Paradigm and the Urban Planning

A major challenge which the paper addresses is the fluctuation of oil prices and how Doha is structuring a vison for the city in the post-carbon paradigm. Such a paradigm implies a move from oil-based economy to a knowledge-based economy and how to plan the city to facilitate such a new economical paradigm. With an unprecedented financial resources, creative strategic thinking and political commitment, Qatar is constructing a new development and urban brand; Dohaization which is a brand but also a continuous dynamic process. The case of Doha is stimulating as new mega projects are made to pave the way for a new development vison structured upon the value of knowledge economy and knowledge-based urbanity. By any measure, Qatar's growth is phenomenal; in the past decade the population has trebled, and the size of metropolitan Doha has increased fourfold. From its humble origins as fishing and pearling village, Doha has emerged as an expanding world city, where ambition and means are fuelling exciting experiments in education, health, sports and culture (Framherz, 2012; Jodido, 2014; Alraouf, 2016).

For a better understanding of how Doha came to structure its current identity, an investigation into the State's main strategy and the articulation of Qatar's role regionally and internationally is crucial. In this section, we will discuss the State's main strategies which affected the development of Doha. The Paper sheds light on the concept of Doha's attempt to construct a new identity which transcends the model that was created by Dubai's iconic development and real-estate fantasies. Then, the notion of knowledge economy as adopted by the State and clearly articulated in QNV 2030 will be analyzed to illustrate the quantitative and qualitative shift towards knowledge-based urban development in Doha. Evidently, in the last decade a new pattern of planning interventions can be clearly observed in the urban fabric of Doha. These new interventions described as the city's mega projects due to its size, location, population served and visual and urban impact.

4. Beyond the Metropolitan

4.1. Deconstructing the Metropolitan: Introducing Hierarchical Urban Centers

Doha's future urbanity is crystalized around the move from centric to polycentric urban planning. One of the most significant strategies adopted to deconstruct the metropolitan extended boundaries which was created during the years, is based on introducing the concept of hierarchical, vibrant and livable urban centers. The centers were planned to have certain common attributes that are summarized as follows: The appropriate density, the distance between land uses and community needs, the diversity represented in the mixed-use developments and finally the design and place making approach which would focus on public spaces, streetscapes and the ability to accommodate multiple forms of transportation. The significance of the previous attributes is manifested in the urban independence of such center in proportion with the relevant community it serves. More importantly, centers planned as such facilitated introducing the concept of transit-oriented development (TOD) and the move towards reliance on public transportation. Evidently, the future growth of Doha includes multi urban centers. In addition to their strategic locations, the relationship of these centers to each other and to their service catchments in a hierarchy and the mix of uses that exist or can be guided to each center in the future are major elements of the QNDF National Spatial Strategy.

As clearly explained in the QNDF, the hierarchy of centers was identified using a sequential strategic assessment based on five key criteria:

- Level of existing population and employment density, economic investment and infrastructure.
- Level of existing Government/Municipality office and community facility provision.
- Potential accessibility to the future strategic transportation Network.
- Proximity of committed mega projects or other major Government developments including Qatari national housing schemes.
- Availability of vacant land and potential for regeneration or urban infill.

This hierarchical structure promotes mixed-use, mixed density centers and enables more efficient and equitable use of national level investment in transportation and utility infrastructure, which in combination, provide the sustainable development pattern that the QNV2030 strives to achieve (QNDF, 2016 P.40)..

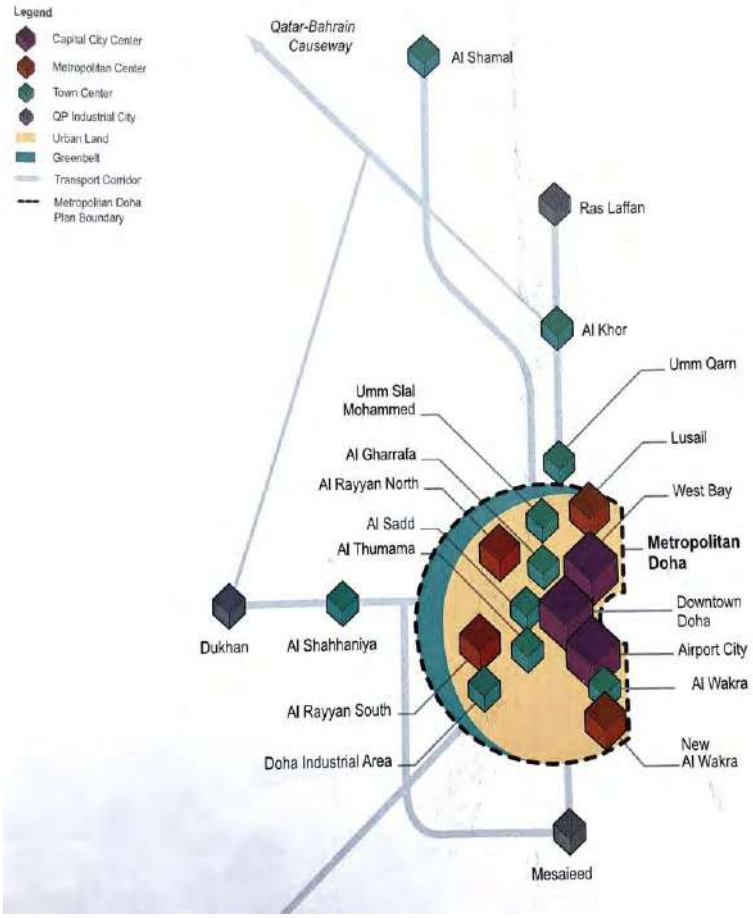

Figure 6: The Spatial Strategy Concept 2032 indicating the location and hierarchy of urban centers.

5. Less is Beautiful: Strategies to move beyond the Metropolitan

5.1. The Transformation from Car-dependent Sprawled Urbanity to Transit Oriented Development (TOD)

The Qatari society is in dire need to move from a car-based development to a TOD approach for the urban growth. The future plans adopted set of actions and policies to gradually encourage the needed transformation. These policies include; Vibrant Metro Stations, Accessible Public Transportation, Streets for People not Cars, Water Transportation and Connected Bike Routes. The aim is to establish a high quality and integrated public transport network that results in a modal shift from private motor vehicles to public transport across Qatar. Additionally, to ensure radial routes act primarily as public transit corridors designed to reduce private motor vehicle usage and environmental costs and promote orbital routes to aid the creation of balanced growth. For a more effective transit-oriented development and pedestrian-friendly cities in Qatar, a comprehensive plan to encourage bicycle riding was also prepared. The Qatar Bicycle Master Plan suggested the proposed Greater Doha bikeway network. Three categories of routs were suggested; green (Bicycle Paths) for recreational, blue (Cycle Tracks) for major transportation and red (Bicycle Lanes) for local transportation

(see map below). The form of urbanism which was produced during the availability of lucrative oil revenues was predominantly car-oriented urbanism. The whole process of Doha evolution was characterized by unlimited urban sprawl due to the population increase and the dominance of a single-family house as the only form of housing for Qatari families. These patterns of urban growth facilitated the unprecedented investment in roads network which can connect all such scattered urbanism. Hence, singles or Families, locals or expatriates consider private vehicles as the only form of transportation. While the local bus services company, Karwa, provides well-distributed routes all over the city but with the availability of cars, the cheap gas and lack of positive culture of walkability, people opt to use their cars in all their daily activities from going to work, dropping their kids at schools, buying groceries and recreation activities. More significantly is the social barrier towards public transportation as it becomes gradually associated with workers and low paid expatriates. On the other hand, Qataris were considering using public transportation in the form of bus riding as a social degradation and inappropriate behavior. With such background, the introduction of Doha's new metro will create a substantial change. The metro which is composed of four lines covering all of Doha's main destination and connecting the city with the airport, universities, industrial area, cultural facilities, shopping centers and main residential areas would be seen as an excellent solution for both locals and expatriates particularly giving the fact that commendable effort were invested to create state of the art transportation experience in the metro' stations, compartments and trains. The stations and trains are designed to accommodate the peculiarities of the cultural and social context of Qatar by providing privacy for families and women in designated sections of the trains.

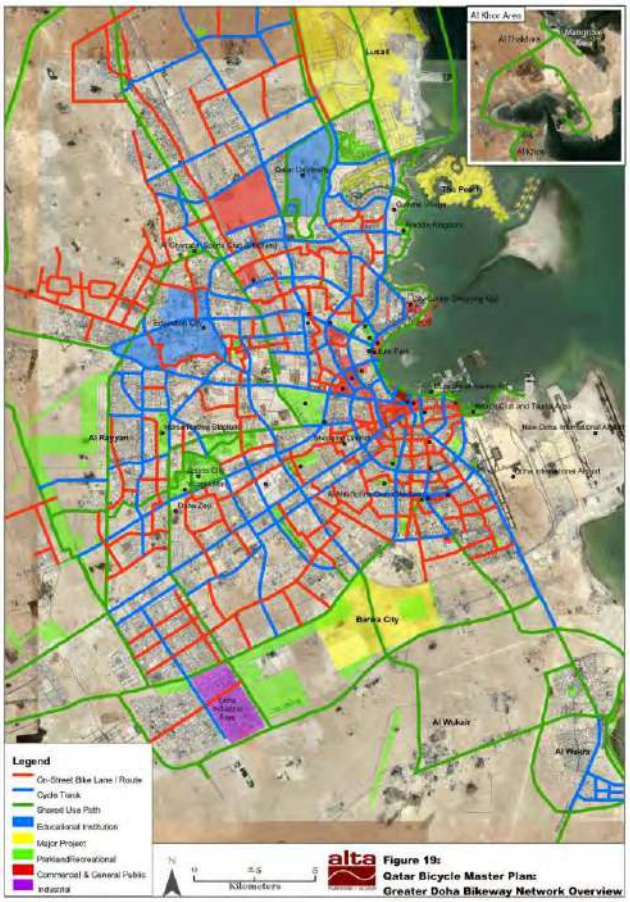

Figure 7: The Greater Doha Bicycle Network is based on three categories of Bicycle movement; Green: recreation, Blue: major street transportation and Red: local street transportation (Source: Ministry of Transportation).

Figure 8: The relation between metro stations and mixed use urban centers as a strategy to decentralize Doha and move towards small and compacted form of urbanity (Source: MME).

Figure 9: The post-oil urbanism suggests a paradigm shift towards walkability and transit-oriented development in Doha and hence Doha Metro is introduced as a main from of transportation in future Doha.

Encouraging Walkability and Livability

One the direction of urban development in Doha moved from horizontal expansion and unlimited sprawl to a multicenter urbanity which is based on the needs of the community, new values are injected in the Doha's urban scene. The principal two values introduced to the city of Doha are Walkability and Livability. Both are so interrelated and substantially support each other. To enhance livability, an emphasize on the social life in public space is becoming a priority. Public spaces -particularly lively streets and squares- among buildings enhance livability and help to animate the neighborhood. Open spaces have the role to make people passing near or stopping by and feel them welcome. Introducing the culture of walkability in Doha and doing the needed steps to have a truly walkable community, number of actions have to be made. Encouraging people to walk in the city requires positive infrastructure which includes wide vibrant sidewalks, nodes of commercial and recreational side activities, footpaths, safe pedestrian crossings exciting and informative signage, creative street furniture and more importantly shaded areas resulted from landscape features like tress or artificial elements like wooden or textile pergolas. Schemes to enhance public realm, streetscapes, open spaces, small parks or shaded town squares. The urban planning department in Qatar (UPD) is conducting a number of projects and studies to achieve these aspirations including the National Strategy for open and recreational Spaces, The National Urban Design Compendium, Streetscape Design Guidelines and National Landscape Guidelines for Vibrant Streets.

Figure 12 & 13: Creating Pedestrian friendly environments to encourage the shift towards walkability and vibrant public spaces (Source: Msherib Properties).

5.2. Doha as a Network of Knowledge-based Urban Development Centers

In a post carbon paradigm, Qatar's identity is articulated around the notions of knowledge, research and education. Qatar National Vision 2030 is a development strategy which outlines how Qatar will use the vast revenues from its hydrocarbon resources to transform itself into a modern knowledge-based economy. Within this understanding, the Doha's future was envisioned as a manifestation of the country's future vison. Hence the following actions were adhered: Engaging people in knowledge experiences, constructing an Urban Campus; a creative and inspiring urbanity and Establishing a Network of Museums, Galleries and Cultural Centers. Currently, Doha is considered by many indicators as the most advanced city within the Middle East to adopt knowledge economy as a conceptual base for its 2030 vision. Qatar did a radical transformation to go beyond the typical image of a Gulf city relaying on presumably endless assets of oil and gas. A move towards being a regional center for education, knowledge and culture is the new aspired sense of identity for the Gulf State. A major investment in knowledge-based urban development characterizes major projects in the country during the last five years (Alraouf, 2008; 2014). This new identity of Qatar paved the way for a new paradigm in Doha's urbanity which can be best described as the Knowledge-based urban Development Paradigm. Qatar has become a showplace for renowned architects, several U.S. universities have established campuses there, and it will host the FIFA World Cup in 2022. The quantity and the quality of architectural and urban projects which will be added to the city's urbanity to facilitate hosting the 2022 FIFA World Cup would make Doha a very unique world destination. Significantly, Doha has gained global significance through the growth of knowledge economy related projects. The city's new urban development and its spatial qualities contribute to the global attractiveness of Doha for knowledge economy investments, firms and people. Such urbanism fulfills the requirements of Knowledge workers coming to the city from literally every spot of the globe anticipating an attractive smooth quality of life which would foster their creativity and innovation. With increasing awareness about the carbon emissions and the negative impacts of climate change, the paper evaluates Doha's attempt to transform its urban movement pattern from purely car-dependent city to a model for a transit-oriented development with the vitalization of connected network of public transportation, pedestrian streets and bicycle routs. Doha's model of urban resilience as reflected in the city's masterplan is answering the fundamental question of how to design and operate the city, so it can withstand major threats and how to recover from them? Yamagata and Maruyama (2016) argue that land-use planning and carbon-neutral scenarios for urban planning are fundamental tools in urban management leading to a better urban resilience.

Figure 14 & 15: The new cultural centers help Doha in establishing a new form of Knowledge-based Urban Development (KBUD); the case of Museum of Islamic Art and National Museum of Qatar.

5.3. The Social Cohesion as a Catalyst for City Resilience

Many scholars in the field of urbanism, through their research, have highlighted the importance of the human dimension in urbanism (Jacobs, 1961; Gehl, 2013) and offered insights into systematically studying environmental behavior (Zeisel 2006) through international studies in public life (Whyte, 1980; Gehl, 2013). Studying public life offers immense insights to urban environment professionals by bringing users back into focus when they may be overlooked in design (Gehl, 2013). The expected outcomes could play an essential role in achieving the needs of the visitors who are considered as tourists that would need to spend half of their day to explore the city. Baldwin and King (2018) emphasize that strong social networks and social cohesion can be more important for a community's resilience than the actual physical structures of a city. That what was exactly noticed in Doha after the activation of the blockade. More significantly, urban planning and design support these critical collective social strengths by stressing the necessity of creative spaces for all

and enhance the inclusivity of the city's urbanity. In the process of realizing the goal of both sustainable and resilient development, we should see the dominant role of social factors such as urban governance in the process of urban adjustment and adaptation. The social aspect will be also addressed in the paper as Doha, like most of Gulf cities, has a much-diversified population coming from all corners of the world. The urban future of Doha is planned to encourage inclusivity and transcend the concept of gated development and isolated urbanism. Hence, the social and cultural diversity was perceived as an asset. Planning Places for People, The Heart of the City is for All and Inclusivity as a Fundamental Development Base for the Whole city. More significantly, the city is taking a number of measures to create better connections between expatriates and the city significantly sense of belonging and ownership which would radically help in inspiring the city's overall population of locals and expatriated to better defend the city and take a solidifying position towards realizing its future aspirations. The paper concludes with articulating a more holistic framework for city resilience which takes into consideration the multifaceted nature of the city and better prepare it for different forms of changes and transformations which might occur in the future. Coaffee and Lee (2017) examine how the concepts and principles of resilience exert increasing significant influence over the form and function of planning. Their discussion of the 'politics of resilience' in which fundamental questions of social and spatial justice are posed is relevant to the notion of social cohesion in Doha after activating the blockade.

Figure 16: The city spaces are planned to accommodate the different social groups and emphasize the social cohesion.

Conclusions

As a conclusion, Doha's readiness for the post-oil paradigm can be perceived on three levels; strategically, urban planning and architecture. As explained in the earlier section, Doha is moving strategically towards a development vison articulated around the concept of the inevitable move towards knowledge and creative economy. On an urban planning level, Doha is moving towards a compacted model of urbanism by relaying on multicenter-city development to stop the unsustainable sprawl which was the dominating pattern in the last three decades. In addition, the city is activating a solid transit-oriented development approach to consider public transportation as the main mode of transportation within the city. Finally, on the architectural level, both Qatar Green Building Council (QGBC) and Gulf

Organization for Research and Development (GORD) were established to produce, develop and monitor the implementation of green and sustainable architecture principles in the new buildings designed and built in Doha and all Qatari cities.

Intensifying the idea of a balanced social inclusion between major population sectors; the local citizens and working expatriates to create a sense of belonging, appreciation and recognition of mutual value and distinct roles of the country's rich human mosaic. Part of the city' success story stems from the fact that social cohesion was considered as a pillar in enhancing the resilience capabilities of the city. It describes and illustrates the ideas, tools, and tactics being used to help engaged citizens, civic leaders, and urban professionals to work together to build viable urban society. Also, adopting the principles of sustainability and environmental compatibility as the main pillars of development for Qatar National Master Plan (QNMP). ONMP is based on a set of sustainable urban development values like transit-oriented development (TOD), sustainable urbanization, social balance and the preservation of the historical and cultural identity. More significantly, dealing schematically and planner with major cities especially Doha as a framework for knowledge-based urban development through a network of research centers, universities, museums and the knowledge forums and make it available to all sectors of society in a way which would stimulate citizen and resident alike in a balanced manner.

The Future plans of Doha as described and observing its comprehensive impact on the city dwellers and visitors, cemented a paradigm shift in Doha's urbanity. The shift is based on the success of the project to introduce qualitative changes and new perceptions about the role of the built environment, historical urban areas, mixed use development, car-free planning and knowledge based urban development. The Planning of future Doha manages to adopt comprehensive inclusivity, which made the city for all a reality in all of its connected spaces. The project successfully and sensitively activated the heart of Doha and connected its veins. It is a success story, which resulted from adopting alternative planning approach, considering the environment, and more importantly allowing local communities and stakeholders to participate and gain an endless ownership.

Research Paper

SHAPING COMPACT CITIES FOR LIVEABILITY, AFFORDABILITY AND SUSTAINABILITY (L-A-S)

A Comparative Assessment of TODs in Jakarta and Auckland

Author 1 Felicia ATMADJA, University of Auckland; New Zealand
Author 2 Dushko BOGUNOVICH, University of Auckland; New Zealand

Abstract

Rapid urban population and territorial growth is becoming a general trend across the world, driving planning policies to promote a more compact city. As an alternative to sprawling patterns of urban development, the compact city emerges as a spatial form characterized by three key elements: densification, connectivity and accessibility. All three are articulated by transit-oriented development (TOD) strategies in today's urban context. TOD aims to encourage densification, mixed land uses, walkability and public transportation, as well as vertical housing typologies. There are now many examples around the world in which TOD has influenced the verticalization of the city, and we can expect further translations into other contexts. Auckland and Jakarta have too chosen the TOD strategy, incorporating vertical housing, to slow down the sprawl. But citizens are concerned about the quality of life in high-rise, higher density housing, as well as its price. We make a comparative assessment of TOD's ability to achieve liveability, sustainability and affordability in two cities – Jakarta and Auckland – while using Singapore as a benchmark for both. Two case studies have shown that some of the residents' complaints are justified. In the conclusion of the study we suggest improvements in planning and design strategies and produce further recommendations for an effective city transformation.

Keywords

TOD, Liveability, Affordability, Sustainability, Jakarta, Auckland

1. Introduction

1.1. The Aim and Scope

This paper is about the effectiveness of the well know urban planning and design strategy called 'Transit Oriented Development' (TOD). The 'effectiveness' in this case is defined as achieving the nowadays widely shared urban development goals of: (a) good city life – commonly labelled as 'Liveability'; (b) acceptable housing costs – commonly labelled as 'affordability'; and (c) environmental responsibility – commonly referred to as 'sustainability'.

The paper aims to assess the achievements of comparable TODs in two rather different cities – Auckland, New Zealand, and Jakarta, Indonesia – to then draw useful conclusions, some of which may have international relevance. The conclusions are then reframed into recommendations that aspire to be of practical value to the city authorities, developers and

planning professional in Auckland and Jakarta, as well as, hopefully, to other large cities in the world which operate with the 'compact city' model. This paper is accompanied with a presentation which summarises and illustrates the main points of the study.

1.2. Compact City and TOD: A Brief History

Historically, the compact city concept can be seen in medieval and ancient cities which were compact in size following a clear wall boundary surrounding the city. Following the middle ages and Renaissance, came the age of public transport in the Industrial Age, which, mainly in the form of tramway and railway, enabled a degree of urban expansion, but still with a rather compact urban fabric. After that, came the Automobile Age, and the compact city concept started to be used as a strategy to tackle rapid and expansive urbanisation in the late 20th century. In the 1980s, the emergence of sustainable development promoted the concept of compact city as the most sustainable urban form, in order to ensure that cities, as they grow, become more efficient in their use of the natural environment (Jabareen, 2006; Newman and Kenworthy, 1999; OECD, 2012). As an alternative to sprawling city development, the compact city is a spatial form characterized by three key elements (OECD, 2012). The first is a dense and proximate development pattern which is usually achieved through intensification of development and activity in an urban area. The second is connectivity which involves public transport systems to facilitate mobility in urban areas. The third is accessibility, which suggests the mixed-use development integrating residential, commercial and business activities within walking distance.

There has however been criticism of the 'compact city' idea as well, mostly arguing that the environmental sustainability effects have been exaggerated (Neuman, 2005) and never properly proven (Asa, 2018). Other studies argued that the advent of climate change has changed the priorities, so that adaptation and resilience are now more important than mitigation and sustainability (Bogunovich, 2009). In this light, the lower, suburban densities have more advantages for survival than the higher densities in the heavily infrastructure-dependent central city areas (Bogunovich, 2009 and 2012). Leaving these debates aside, the dominant position remains that excessive urban expansion is unwanted; that very large metropolitan areas must have strong public transit networks, and that the most logical urban form policy is that the nodes of these networks, should be allocated for higher density and mixed use.

In contemporary urban context, the three characteristics of compact city can be articulated by transit-oriented development (TOD) strategies. TODs – before that were called that – came into existence almost 200 years ago, as soon as public transport (PT) in its initial form started appearing in fast growing cities of Europe and Asia, after walking the new urban distances became impractical. But in its modern version, under the 'TOD' label, the concept is about 50 years old. It can be traced back to American planners who tried to offer alternatives to the seemingly endless expansion of the suburban development in the North American metropolitan areas. Since the late 20th century the model has been accepted in theory, policy and actual practice in other parts of the world, as the low density, sprawling suburbanisation became a global phenomenon.

The main strategy of TOD is densification - transforming low-density and car-oriented urban development forms into inclusive, compact, and people-oriented cities (Marks, 2016). This strategy has driven the verticalisation of cities in accommodating population growth. There are several examples around the world in which TOD has influenced the verticalisation of the

city such as Singapore, Curitiba in Brazil and Arlington County in the USA (OECD, 2012). In Singapore, TOD strategies have successfully delivered a liveable compact city with sustainable growth (Chye, 2019). Opportunities to translate and transfer such TOD strategies into other urban context can be seen in cities like Jakarta, Indonesia and Auckland, New Zealand.

The future of TOD is bright, because most big cities are still growing and the pressure for more accommodation is relentless. The pressure is for cities to grow both out and up, and while the former is faster and cheaper, the central areas remain more attractive as a location and the pressure is now building up for 'intensification'. Intensification (or 'densification') is now preferred by most city authorities as the way to slow down the horizontal sprawl, but rather than letting the free market decide where the new high-density will occur, they try to channel the intensification to PT nodes. Typically, these are inner city and suburban rail stations, above the ground, or under the ground.

2. Context

2.1. Background of Compact City and TOD in Jakarta

Jakarta is the fastest growing city in Indonesia. It encompasses a total land of 656 km2 and 9.6 million inhabitants (Indonesia Statistical Report, 2011). The prominent urban challenges – due to rapid population growth in the city - include traffic congestion, air pollution, and housing shortages. More than 1,100,000 people commuting to the city every day results in a perpetual gridlock, which established commuter satisfaction in Jakarta as the lowest among major cities in Asia. Rapid population growth has also impacted urban spatial growth, which has created a sprawling development and converted more than 30 ha of agriculture areas and green open spaces into urban settlements (JICA, 2012). According to Jakarta SWOT analysis done by JICA to establish Greater Jakarta MPA, the urban development in the city is under pressure from insufficient infrastructure, exposure to natural disasters, and a large, rapidly expanding population. However, the large population can also be an opportunity for development since it will contribute to a robust economy (JICA, 2011).

Transit-oriented development (TOD) was introduced into Jakarta planning policy in the 1990s. The first initiation of TOD in Jakarta comes from the Ministry of Transportation, who proposed an integrated transportation concept to address the bad traffic congestion, and The Ministry of Public Works who proposed high-density housing developments around the public transport routes. The first masterplan for public transport integrating railway, light rail, and buses was proposed by The Ministry of Transportation in 1992. However, the decision from the Governor of DKI Jakarta Province for Mass Rapid Transit (MRT) only came in 2004, which inaugurated TOD in Jakarta. In 2012, the MRT project was also included as one of the fast-track projects in Greater Jakarta MPA. After years of feasibility studies and design revision done by the collaboration of the Ministry of Transportation and the MRT operator company, the project kicked off in 2013 and the first phase was completed in 2019. The first phase of the MRT provides 15.7 km of rail-based urban transportation with seven elevated stations and six underground stations, from the South Jakarta to Central Jakarta.

Following the completion of MRT, the Ministry of Public Works aims to expand the development of TOD, intensifying development density around the new transit stations. The TOD development in Jakarta seeks to adapt several principles such as (1) diversity; (2)

density intensification; (3) accessibility; (4) liveability; (5) social cohesion; (6) sustainability; (7) infrastructure resilience; and (8) economic renewable. With Jakarta's housing demand currently reaching 800,000 units/year, the Ministry of Public Works and Public Housing aims to provide 50 new housing developments as TOD projects, which will be the combination of middle-up-class apartments and affordable units. The TOD development sites are planned around five existing train stations and 13 new MRT stations with mixed-use development comprising of housing, business, and commercial. The existing train stations which are planned to be developed under the Ministry of Public Works and Public Housing are (1) Pasar Senen; (2) Tanjung Barat; (3) Juanda; (4) Manggarai; and (5) Tanah Abang. The MRT operator company will undertake the TOD development in 8 new stations: (1) Dukuh Atas, (2) Lebak Bulus, (3) Blok M, (4) Senayan, (5) Istora, (6) Bendungan Hilir, (7) Setiabudi, and (8) Bundaran HI.

2.2. Background of Compact City and TOD in Auckland

In New Zealand, the early examples of development favouring nodes of PT are related to the development of tramway networks in the main boom towns of the mid-to-late 19th century – Nelson (1862; horse), Thames (1872; steam), Dunedin (1900; electric). They were, followed by the main three cities – Wellington, Christchurch, and Auckland.[ii] The tramway was followed by suburban train networks in Wellington and Auckland in the early 20th century. These nodes were rarely developed in the TOD fashion as the stations were seen as only transport-related, while housing was strictly low rise suburban and separately zoned. [iii]

Auckland stopped developing its suburban railway in the 1950s, after a significant change in government policy and switch of funding to motorways (Harris, 2005). TODs never took off, until very recently, in this century, when the local councils decided to pursue the compact city model of urban form, invest more in PT and develop nodes and corridors of TOD (Auckland Council, 2018). TOD in Auckland has been the strategy to accommodate the population growth since two decades ago. However, the urban intensification has just started in 2003, since the concept is quite new.

The significant point of TOD in Auckland happened in 2003, when the new Britomart station re-open; then in 2010, when Auckland Council (AC) and Auckland Transport were formed, and then in 2016, when the City Rail Link (CRL) project started. Big improvement of TOD in Auckland happened after the governance changed in 2010 when the Royal Commission on Auckland Governance established Auckland Council (AC) as a single unity authority, replacing the Auckland Regional Council and seven territorial authorities (Blakeley, 2015). AC immediately launched the metropolitan urban limit (MUL) as the tool to control growth, so that infrastructure can be provided more efficiently. Auckland Transport, as a council-controlled organization, launched the Integrated Transport Management Plan which aims to build an outstanding public transport within one network. The plan called New Network prioritises in the City Rail Link (CRL), electric trains, rapid transit network (RTN), and building or revitalise stations.

AC, adopting the principles of TOD, is focusing the high density and mixed-use living options within a close proximity to reliable and frequent public transport. By focusing the urban growth on centres and transport nodes, the government also aims to reduce the usage of private cars and seriously promoting walking and cycling. There are at least 21 locations where the TOD will be applied including New Lynn, Onehunga and Avondale.

2.3. Singapore As the Benchmark for Liveability, Affordability and Sustainability

The third city featured in this study is Singapore. The city-state of Singapore is widely regarded as one of the best managed cities in the world, with consistent vision and planning policy aiming for a high level of liveability, affordability, and sustainability (L-A-S). This can be seen in its planning policies: Liveable and Sustainable Cities Framework, and the 10 Principles for Liveable High-Density Cities of Singapore development. It is a relatively compact city, as this policy has been the only way to develop such big and important international city on a small island.

In terms of transit-oriented development, Singapore has a long tradition of integrated land use and transport planning – it started soon after its MRT was first proposed in 1971 (Niu et al, 2019) – and has had TODs even earlier than developed western countries. The key principles learned from Singapore TOD involve incremental development of public transport capacity; integration of land use, land ownership, and transport; management of transport demand; and leveraging innovative technologies for TOD (Chye, 2019). Beginning in 1966, Singapore initiated a programme to centralise land ownership to the state in order to enable extensive transit infrastructure development. The centralization of land ownership also enabled the government to shape long-term planning for the urban renewal, followed by periodic reviews to ensure plans remained relevant for the changing population (CLC and ULI, 2013). Today, these TODs are the vitally important hubs of the entire metropolitan transport system, including a few new town centres. Singapore MRT and TOD system is mature and can be taken as the template for cities far behind, like Jakarta and Auckland.

Singapore also proves how high density can be used as an advantage to provide L-A-S to the city. Having a population density of over 7,000 persons per square kilometre, Singapore maintains a high ranking in liveability surveys - for example, Mercer's 2010 Quality of Living Survey (CLC and ULI, 2013). This paper uses Singapore planning policies as the L-A-S benchmark.

3. Methodology

3.1. Case Study Selection

The two case studies were selected based on the original, and the current place of residence and studying of the first author of this paper. She is familiar with both Jakarta and Auckland, both as a citizen-participant and a researcher-observer. The other obvious reason for the choice of Jakarta is that the ISOCARP Congress in 2019 is in this city. That makes this case more interesting for a large portion of the Congress delegates – not only the local planning professionals, academics and government officials, but also to the international visitors who want to see and understand Jakarta in the few days of their visit.

Looking globally, one could also argue that Jakarta, being one of the biggest city in the world, still growing fast, and being in a developing country is typical of the urban problems today. From a purely research perspective, the choice of Jakarta and Auckland as a pair offers a good mix of differences and similarities. The differences probably amplify the global relevance of the results; the similarities should enhance the reliability and accuracy of the results. The following table explains the differences and similarities of both cities.

Table 1 Differences and Similarities of Jakarta and Auckland

	Jakarta	Auckland
Area	661,5 sq km	1,086 sq km
Population	10,638 million	1,657 million
Population Density	4,383 people/sq km	1,210 people/sq km
Urban form	Radial-concentric	Linear conurbation
Climate	Tropical	Temperate
GDP per capita	$10,641	S35,152
City government	Ministry of Land and Spatial Planning Ministry of Public Works and Public Housing Ministry of Transport	Auckland Council
Planning system	DKI Jakarta Provincial Spatial Plan No 1/2014	Resource Management Act
Long term plan	DKI Jakarta Spatial Planning 2030	Unitary Plan

Source: Indonesia Statistic 2011 & NZ Statistic 2013

3.2. Data Collection

The main sources of information in this study are gathered from: (1) government documents such as policies, regulations, reports, plans and maps; (2) professional and commercial documents such as planning publications, property development plans, company annual reports; (3) research literature such as books, journals and conference; and (4) public news/general media; (5) site visits/field observations.

3.3. Comparative Assessment

To understand the extent to which TOD policies are achieving liveability, affordability and sustainability in the context of Jakarta and Auckland development, the research uses a qualitative methodological approach. The approach includes a critical review of key reports and project intentions, followed by a comparative assessment of TOD concept policies in both countries. Considering the limitation of the research, the analysis of TOD concept policies in both countries focuses on two concrete areas - Dukuh Atas and Lebak Bulus in Jakarta; and New Lynn and Onehunga in Auckland.

The analysis of source material is done using the comparative assessment on three criteria: liveability, affordability and sustainability (L-A-S), and it takes Singapore city-state as a benchmark. This research focuses on L-A-S goals from Singapore planning policies to assess the TOD projects in Jakarta and Auckland including (1) Liveability – walkability, density, diversity and public facilities; (2) Affordability – long-term planning and housing supply; and (3) Sustainability – green open space, carbon reduction, and resilient infrastructure.

4. Findings

4.1. TOD in Jakarta, Indonesia

Location

TOD project sites in Jakarta are planned according to the location of transit stations, both the existing ones, and the new ones. Considering the limited scope of this paper, the analysis will focus on the TOD planned in the new MRT stations. After 13 new mass rapid transit (MRT) stations were completed earlier in 2019, the operator of the services - PT. MRT Jakarta - along with the government plan to continue with TOD development, prioritised around 5 MRT stations, including Dukuh Atas and Lebak Bulus.

Lebak Bulus Station is the first elevated MRT station - connecting South Jakarta to North Jakarta – and is expected to be the new transport node for people commuting to Jakarta. As the starting station, the development of Lebak Bulus TOD will determine the whole project of MRT Jakarta (JICA, 2015). Dukuh Atas Station is the underground MRT station located in Central Jakarta. This is a strategic location due to its close proximity to Jakarta CBD, the famous Hotel Indonesia roundabout, and Sudirman Station (commuter line). Dukuh Atas area will soon become the largest urban transportation hub in Indonesia, integrating six transportation services such as MRT, Transjakarta Bus, commuter line, airport train, and LRT. Lebak Bulus and Dukuh Atas TOD projects are planned to be the regional urban core in Jakarta. Both projects are under the same company operator and generally using the same strategies.

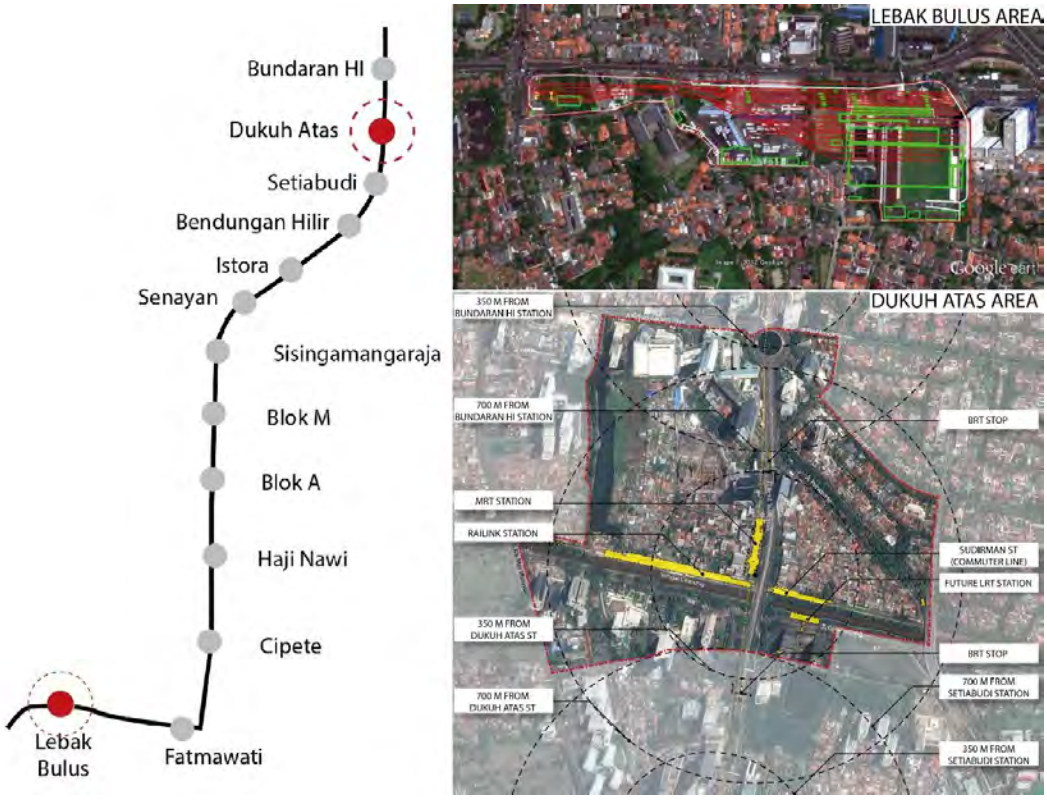

Figure 1 Jakarta TOD Areas (JICA, 2015; PDW, 2019)

TOD Strategies

TOD strategies in both areas involve densification, accessibility, connectivity and green open space. In Dukuh Atas TOD, the strategy for densification is increasing the floor area ratio (FAR). Based on the UDGL 2012, FAR for buildings along the Sudirman Street will be raised up to 6.0 from the current 1.8 – 4.5. The FAR structure has four different layers according to the distance from transit stops, where buildings inside 800-metre radius from transit stops have the maximum FAR to 12.0 while buildings outside 1,200-metre radius from transit stops have the maximum FAR to 3.5. Areas inside 400-metre radius from transit stops with the highest FAR will be the priority for mixed-use development combining business, commercial and residential. Same strategies also applied in Lebak Bulus TOD to provide higher density with diversity of uses. The development focuses on the 14-ha site located in 500-metre radius from the station accommodating residential, businesses, and retails. Thus, the significant transformation from the densification can be seen on the verticalization along the transit corridor in both areas (Figure 2).

Figure 2 Verticalization in TOD Areas (MRT, 2017; Totalindo, 2018)

Pedestrians are fundamental to achieve liveability in TOD projects. In the existing condition of Dukuh Atas, pedestrian activities are generally concentrated around Sudirman Station (commuter line) and can reach more than 5,000 people/hour during peak hours. According to the masterplan, pedestrianisation in both areas will be focused on providing different types of pedestrian movement and activity, with cycleways, a pedestrian bridge, a pedestrian tunnel, and street-level pedestrian facilities. This strategy aims to improve the permeability of pedestrian networks and provide ease of changing between public transport modes. The street level pedestrian spaces which were previously considered unfriendly are planned to be revitalized by adding disabled access, street furniture, and shading. The pedestrianisation then followed by the creation of great streets within 100-metre radius from transit stops. The great streets approach will intensify activity around the mixed-used developments along the transit corridor, through direct pedestrian access from the transit stops. This strategy also aims to improve the local economy of both areas.

In Dukuh Atas, there is a recently completed pedestrian tunnel under Sudirman overpass, connecting Sudirman Station to MRT Station and Airport Railink Station. Before the redevelopment made it pedestrian only, this tunnel was filled with private vehicles heading towards the CBD area. In the centre of the four quadrants, the main pedestrian bridge is planned to connect the whole area of Dukuh Atas. However, in Lebak Bulus, many public news reported that the pedestrian is considered unfriendly with lack of canopies and street lighting.

Figure 3 Walkability in TOD Areas (PDW, 2019; Totalindo, 2018)

The next strategy is connectivity which translates in the integration of transport hubs for ease of changing public transport modes within the area. The masterplans show that transport hubs will also be integrated into a park and ride facilities accommodating more than 300 vehicles and developed into mixed-use facilities supporting retail tenancies,

businesses, and public spaces. In Dukuh Atas, new transport hubs are planned to connect six public transport modes in four areas, which are (1) MRT station, (2) Blora market, (3) BNI Tower, and (4) Landmark Building. In Lebak Bulus, the MRT station is integrated into the Park and Ride facilities.

The next important strategy is the placement of green open space in TOD areas (Figure 5). The masterplans show that the preservation of green open space is combined with the creation of public space. The strategy includes the place making of a civic plaza and a renewal of the Ciliwung River corridor in Dukuh Atas area. In Lebak Bulus, it is also planned to provide different kinds of public open space inside the mixed-use development such as outdoor café, event plaza, multi-layered terrace garden, and semi-outdoor courtyard.

Figure 4 Open Space Strategy (MRT, 2017; Totalindo, 2018)

One civic plaza example can be seen from the Dukuh Atas Garden which located above the recently completed MRT station. Dukuh Atas Garden is a revitalisation project since the MRT station was built on the existing open space. The aim of this garden is to be a new node in the area where community activities can take place. Upon the completion of the project, Dukuh Atas Garden seemed to accommodate many public events and improved citizens enjoyment, supporting liveability (Figure 6). The next strategy in Dukuh Atas is the renewal

of the Ciliwung river corridor which is located at the centre of Dukuh Atas TOD area and divided the four quadrants. The intention of the renewal is to improve the riverbank area and support more activities along the river corridor, accommodating retails and public space, and a new river walk connecting the riverbank to the pedestrian bridge in Sudirman Street.

Figure 4 Civic Plaza in Dukuh Atas TOD (MRT, 2017)

4.2. TOD in Auckland, New Zealand

Location

There are some areas planned for urban intensification using TOD as stated in Auckland Plan 2050. These areas usually designated for town or metropolitan centre with high-density development, which integrated through strategic public transport network, including New Lynn and Onehunga.

For New Lynn TOD, AC going through a characteristic study of TOD versus the adjacent development to determine the opportunity and constraint of the projects. The study outlined that the existing condition such as suburban street pattern, low density, parking area dominance, unfriendly pedestrian space, and segregated land use are the weaknesses that planned to be improved using TOD strategies. New Lynn TOD is the first part of the district's transformation and one of the largest urban regeneration projects in New Zealand. The project starts with the completion of the new transport interchange which since then has been followed by range of projects including town centre's revitalisation, open space upgrade, and high-density housing development. These new developments establish New Lynn, which was neglected before, as one of the most important town centres in Auckland, accommodating people who work close to home, living in vertical housing, with options of public transports, also walking and cycling to get around. New Lynn is claimed to be Auckland's first true TOD.

Onehunga is one of the areas outside CBD that designated for higher density development and town centre targeted for transit-oriented development, as defined by AC. In 2014, a new

town centre and a perimeter block comprises 112 units were completed. This town centre is identified to be the future population and employment growth. In 2017, AC, through Panuku, another council-controlled organisation, launch a High-Level Project Plan (HLPP) for Onehunga which aims to transform the district into a TOD area. This project will be a long-term development, build on the existing potentials around the town centre.

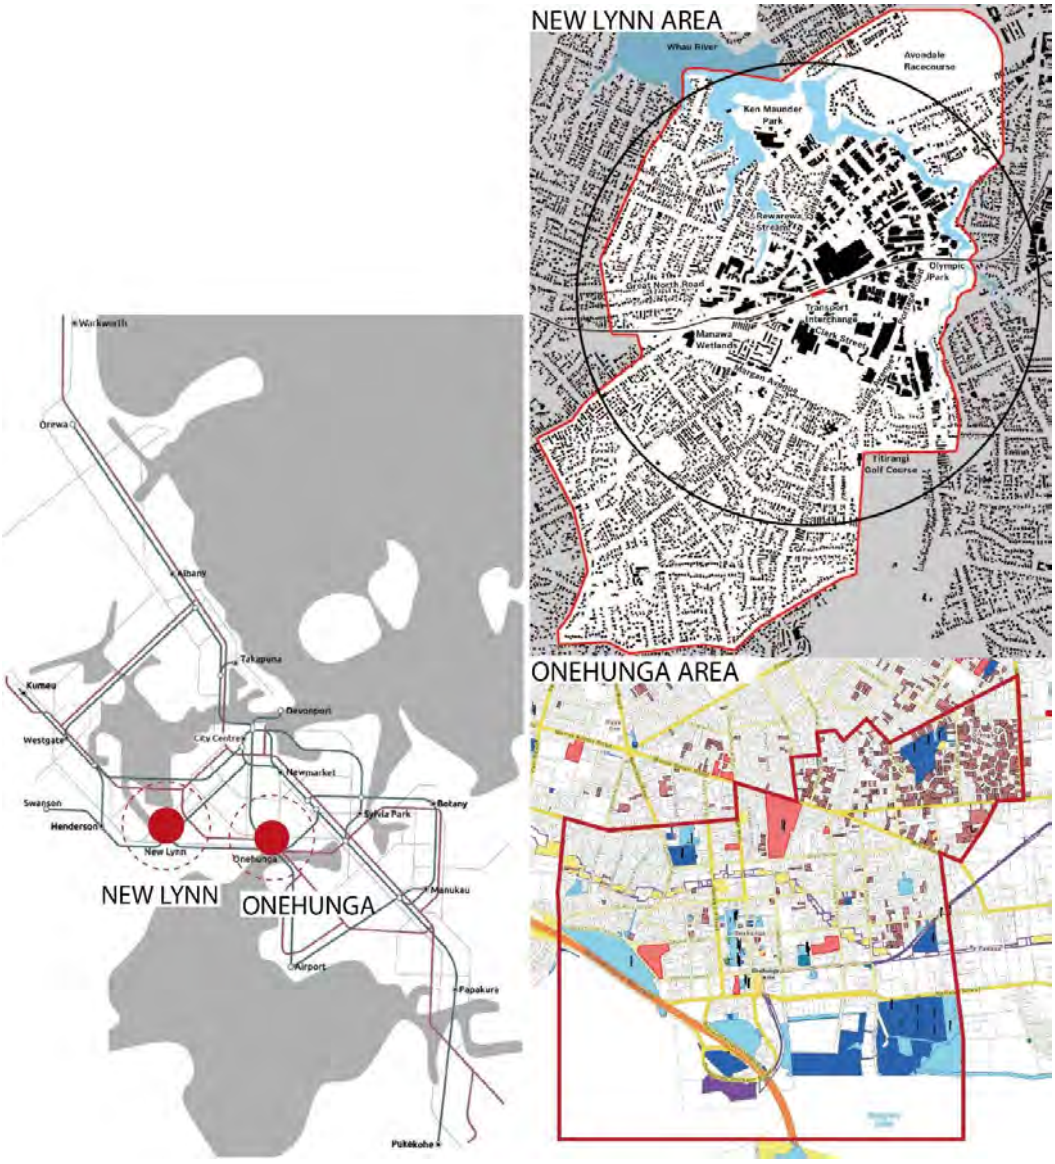

Figure 5 Auckland TOD Areas (New Lynn UrbPlan, 2010; Panuku, 2017)

TOD Strategies

The TOD strategies in both areas include (1) densification; (2) open space strategy, (3) movement and connectivity strategy, and (4) social and economic strategy. The densification strategy starts with planning priority sites for development and dividing them into precincts according to the timeline, such as high priority sites, medium-term opportunities, and longer-term opportunities. There are 10 precincts in New Lynn and five precincts in Onehunga. The densification focuses on providing mixed-use development, high-density housing, and redevelopment of the existing industrial block. In New Lynn, the densification can be seen from mixed-use development in Merchant Quarter, Crown Lynn and The Mall

precincts accommodating 12 ha business area, more than 2000 new residential units, and 9-ha new retail area which located within 400-metre radius from the transit interchange. In terms of housing, the development uses a 'carrot and a stick' approach, which limiting the suburban-style development and transforming it into a compact urban living. The densification aims to create New Lynn as an urban place centred on a transit interchange, accommodating 20,000 residents and 14,000 workers in 2030 (New Lynn Urban Plan, 2010).

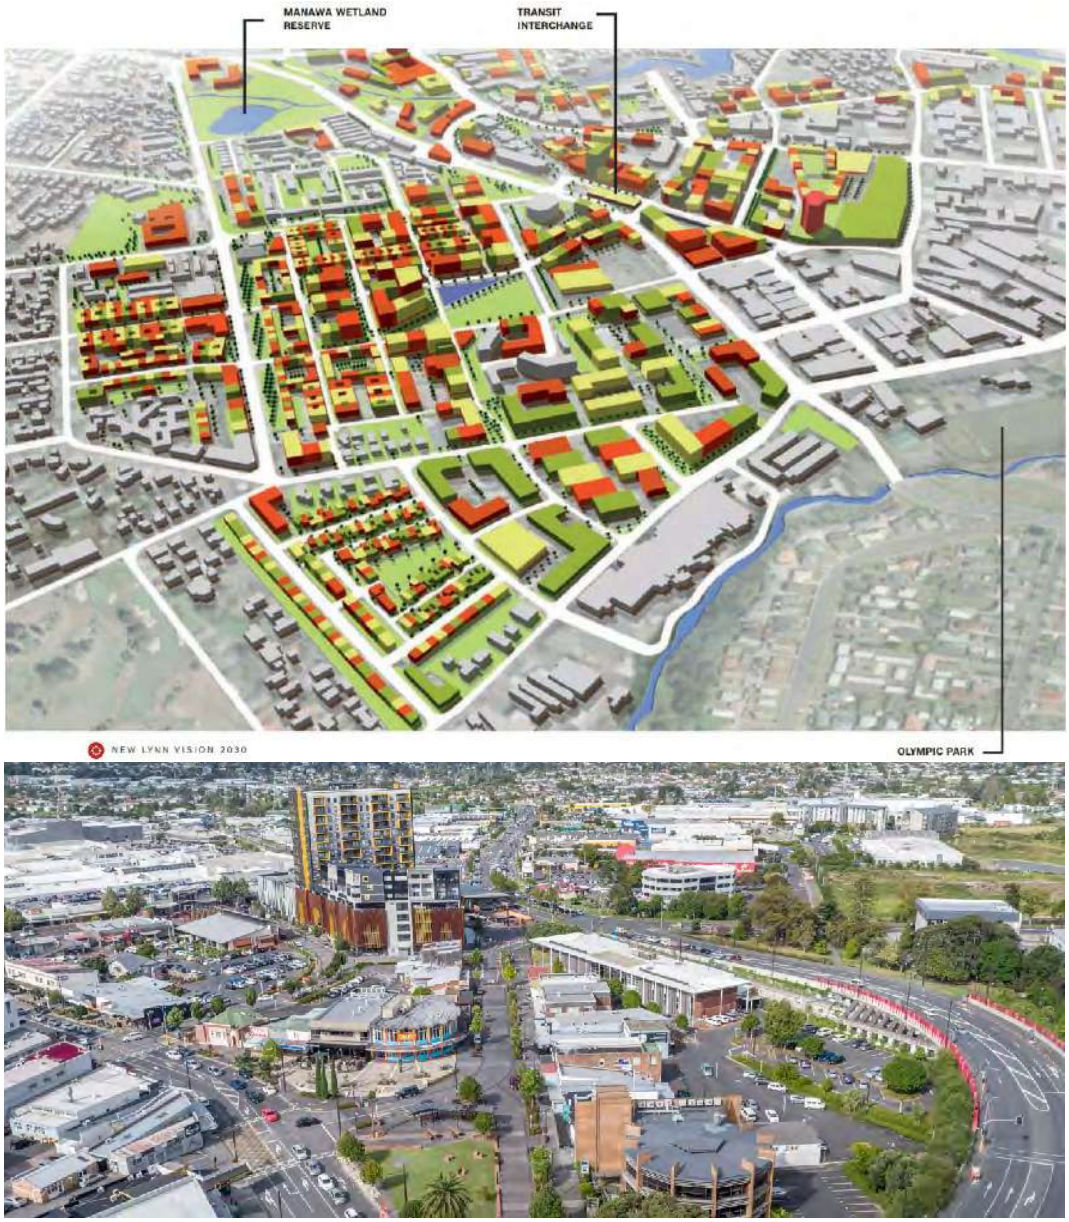

Figure 6 New Lynn densification area (New Lynn Urban Plan, 2010)

In Onehunga, the densification is planned to address the growth projection and the changing market demand from predominantly conventional freestanding family housing into medium-density housing. Similar with New Lynn, densification in Onehunga is also providing various mixed-used developments integrated with public transport and concentrated in town centre core precinct for short to medium term. The precinct has existing potentials including retail, businesses and train station, in addition to which are planned 650 new dwellings and more than 15 ha of new commercial and businesses spaces area (Panuku, 2017). In terms of

housing, there are several Special Housing Areas (SHA) sites in Onehunga. SHA is a housing development policy which establishes fast-track housing development sites and encourages private sectors to develop. Both in New Lynn and Onehunga, densification focused in the town centre is expected to be the catalyst for future developments due to land ownership. The development in town centre is expected to be easier and faster, since most of the council's land is located there.

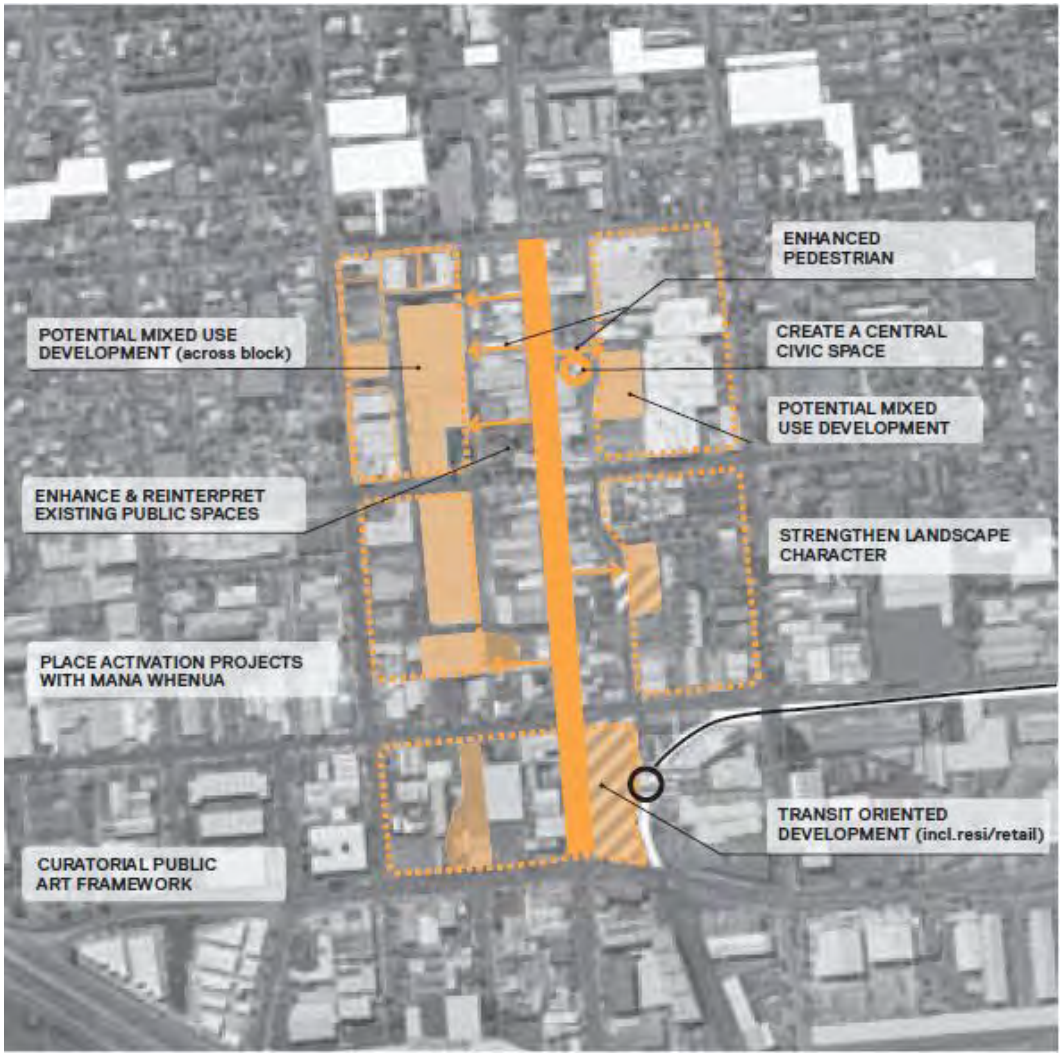

Figure 7 Onehunga densification area (Panuku, 2017)

The next important strategy in both areas is the open space provision, since Auckland is a coastal city abundant with natural heritage. In New Lynn, the open space strategy is called the 'power of ten' which includes the preservation of five 'hard' and five 'soft' spaces within 500-metre radius from the transit interchange. This strategy is implemented through maintenance and improvement of the existing open spaces. This approach also aims to improve the connection between open spaces through high-quality pedestrian areas which are centred in New Lynn Park, a large (one hectare) urban park in the Crown Lynn precinct.

The next open space strategy is to create a green-blue loops and links which link river streams to green open spaces and open the river corridors for public activities. Besides open spaces, the Whau River and the Rewarewa Stream are another important natural features which are often neglected. In addition to this strategy, streets in New Lynn are also designed to be green streets lined by trees with generous footpaths widths and cycle way. These open

space strategies are also being included in the development design guidelines. For example, all new housing developments will be required to front onto the river or green streets. Also, housing development more than 10 units shall be located within 200-metre radius from public open space.

Figure 8 New Lynn Open Space Strategy (New Lynn Urban Plan, 2010)

The open space strategy in Onehunga is heading to the same direction with New Lynn, it aims to improve people's well-being through the enhancement and restoration of the natural environment. The strategy includes the improvement of green-blue networks enhancing the value of Manukau Harbour and its foreshore through the redevelopment of Onehunga's waterfront as public open space. The waterfront is planned to be the new recreational and cultural destination promoting ecological corridors for public use.

The third strategy is about movement and connectivity which are fundamental to the success of TOD project. According to the New Lynn 2030 vision, the area aims to be a showcase of pedestrian and cycle friendly place. The framework plan established a transport hierarchy to place pedestrians as the top priority together with cyclist and public transport while private vehicles become the least priority. The walkability is planned through a detailed design guideline including the 1.8m minimum width, crossing facilities every 100 metres, and the street lighting improvement. This strategy is also the continuation of the green street strategy to improve pedestrians by planting trees along the footpaths and providing street furniture.

The cycling network is planned to be integrated within two km of the transport interchange. The existing street transformation was done into 3 different types such as shared path, slow street and calmer street. The cycling plan is complemented by the provision of cycle stands and storage lockers with 1:4 ratio (one cycle stand for four car parking space). The cycle racks also planned to accommodate rentable bikes offering cycling opportunities for visitors arriving in New Lynn by train or New Lynnians who do not own a bike. In order to be a sustainable TOD area, the movement strategy also manage the limited car parking provision in the area using 1:40 ratio (1 car park space per 40 sqm of floor space). Onehunga also planned similar initiatives with New Lynn by targeting key streets to be transformed into

pedestrian and cyclist friendly environment, and reduced vehicle movements. The recent investment of cycling facilities can be seen in the cycle lane in Onehunga Mall. The cycling network is also planned in the foreshore, connecting the town centre to the Onehunga Wharf.

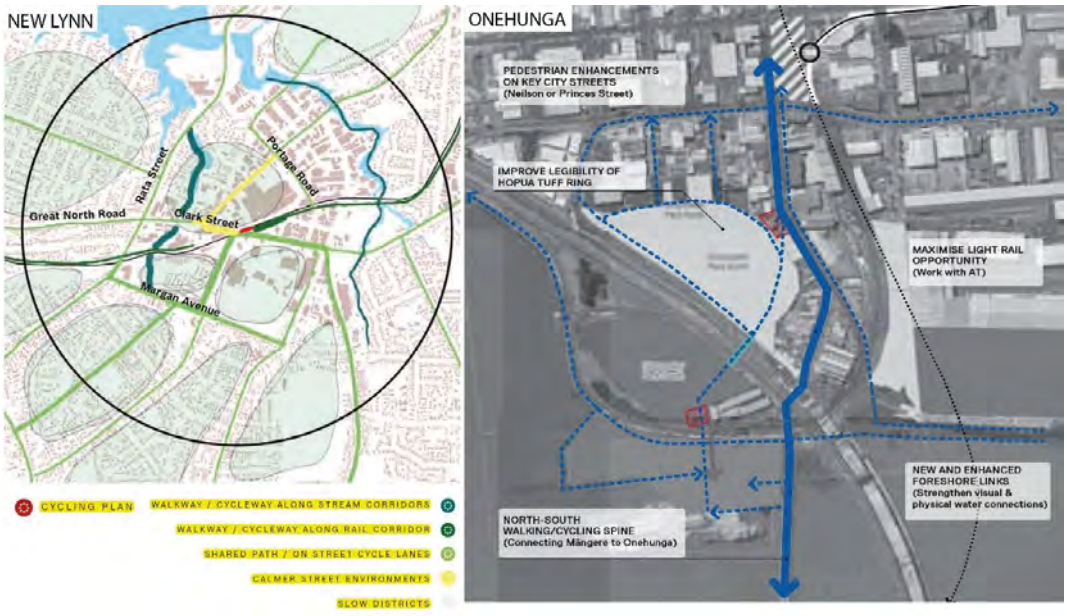

Figure 9 Movement and connectivity strategy (New Lynn Urban Plan, 2010; Panuku, 2017)

The last TOD strategy is regarding social and economic aspect. Part of the New Lynn 2030 vision is to improve the social and economic conditions through the provision of affordable housing integrated with community facilities and a high-density employment hub. To achieve the affordability, housing development in New Lynn is planned to have a mix of quality housing size and form to retain the current diversity of the existing community. The next step of providing affordable housing integrated to the community facilities such as primary schools, local shops and civic anchors. Strong economic base is also the critical part of the successful TOD in New Lynn and this is planned to be achieved with the creation of new employment and commercial hub focused on precincts close to transit interchange: Merchant Quarter and Crown Lynn. In Onehunga, the social and economic strategy focuses on retaining the existing commercial activities around the town centre and revitalising the existing industrial area to be a mixed-use employment precinct.

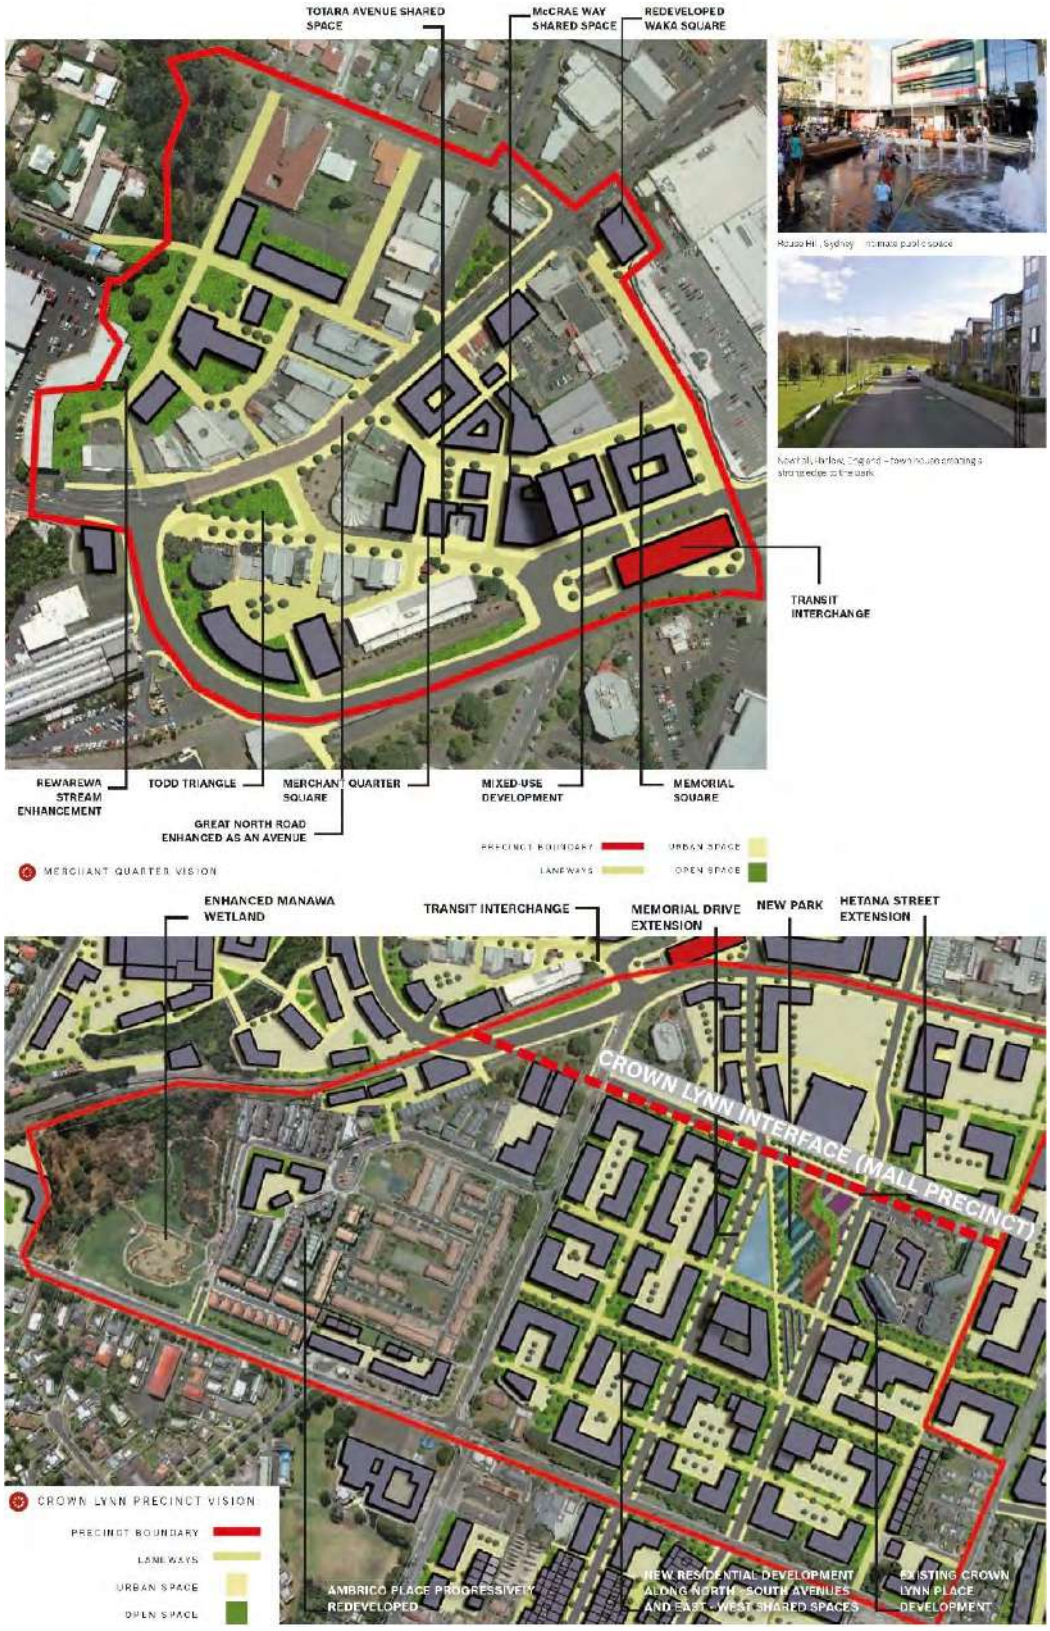

Figure 10 New Lynn social economic strategy (New Lynn Urban Plan, 2010)

4.3. Comparative Assessment

The Liveability

To understand the extent to which TOD strategies in Jakarta and Auckland are achieving the liveability, the research focused on the walkability, densification, diversity, and public space provision.

Jakarta

In Jakarta, pedestrian networks in TOD areas have been planned in detail to improve pedestrian accessibility and provide shorter trips. However, implementation will be constrained by the fact that the development will be done on the existing, active built environment and overlaps with other projects. For example, in Dukuh Atas, the transit stops have been fully in operational while the pedestrian facilities are still under construction. The same thing happened in Lebak Bulus, since the MRT station is fully operated but many complaints that pedestrians to the station and park and ride facilities are currently inadequate. The cycling facilities, which are should come as one package with the pedestrian networks, will also need more detailed planning in a macro scale providing the ratio of bike rack and storage, and the continuity of bike lanes outside the 500-metre radius from the station.

The next issue relates to land-use planning in Dukuh Atas TOD, which is still predominantly segregated between residential and public amenities, similar to the existing condition (Figure 11). While some of the existing residential areas on the west side of Sudirman Street are being transformed into a mixed-use zone, the remaining residential areas are still located behind the business zone and outside the 400-metre radius from transit stops. The segregation of residential area and public amenities can reduce liveability and exacerbate social injustices, which may also lead to the Jakarta-typical slum problems in future developments. The TOD area also need a sufficient amount of high-quality public space to be successful. The TOD strategies of Dukuh Atas and Lebak Bulus usually integrate public space with the transit-hub and green open spaces. The new Dukuh Atas Garden above the underground MRT station is a good example of public space in TOD area. This example should be used as a reference in other TOD areas.

Figure 11 Dukuh Atas land-use plan transformation (Jakarta Spatial Plan, 2011)

In terms of densification, the strategy to verticalize and intensify are constrained by land acquisition, because most of the land in Jakarta is under private ownership. In Dukuh Atas, for example, the government is currently own the green open spaces and the existing market in Blora Street only, which resulted in slow progress of development since the land acquisition process usually take a long time. The densification is also sensitive to vertical transformation since culture and lifestyle preferences in Indonesia are still not adjusted to vertical living. Failed verticalization can be seen from the previous attempts by the government to relocate the people living in low-rise high-density residential settlements, known as *kampong* into affordable vertical housing. In 2015, people who live in Kampung Pulo were evicted and moved into vertical housing development called Rusunawa Jatinegara Barat. However, public news reports based on interviews with residents stated that they now face numerous problems in the vertical housing contexts, such as poor building quality, lack of living space, unaffordable rent; and decreased income due to lack of space for their kiosks. This evidence shows that there is a lack of specific design guidelines and monitoring function of the vertical housing development.

Auckland

In Auckland, pedestrian networks in TOD areas also have been planned thoroughly encouraging people to walk and cycle. The robust planning shown in New Lynn 2030 vision is the showcase of pedestrian and cycle friendly place. The vision is followed by various strategies like transport hierarchy prioritising pedestrian and cyclist, green streets, cycling infrastructure, also bike renting. The pedestrian networks also completed by the right amount of diversity of land uses, for example, Merchant Quarter and Crown Lynn precinct in New Lynn. For the public space provision, both New Lynn and Onehunga have large amount of existing open public space that can be improved, since the current conditions have been neglected.

In terms of densification, Auckland is facing a similar problem with Jakarta which is land acquisition. The limitation of land owned by government resulted in the slow progress of urban development, while the housing crisis in Auckland keep getting worse. This is also the reason behind the emerge of SHA policy encouraging fast-processed developments. The other issue of densification is regarding the people's traditional lifestyle. Most Aucklanders prefer to live in a free-standing family housing, rather than in a high-rise apartment. The verticalization of housing is a new concept in Auckland, since the urban intensification has just started in 2003. One of the strong public reaction towards the verticalization is called 'not in my back yard' (NIMBYism), where people usually rejected higher-density development near their area. This public pressure made AC reducing height limits and density in new housing developments (Blakeley, 2015). The NIMBYs also caused many proposed development projects never took off (Donovan, 2013) and show the low ability to integrate new people into the existing community as the area intensifies.

Singapore

Singapore was able to create dense developments that were both functional and liveable as the result of integrated master planning and development and dynamic urban governance (CLC, 2014). The city provides ease of travel by walking and cycling through detailed and continuous strategies like "Walk2Ride" programme which integrate 88 MRT and 38 LRT stations with high-quality pedestrians and Walking and Cycling Plan (WCP) that must be included in each new development (LTA, 2018). The built structure also designed according

to the measure of comfortable walking distance - for example - in Marina Bay, blocks are designed in a grid structure with manageable size and underground walkways between buildings (Ollivier and Djalal, 2017).

Regarding land acquisition, the government approach that can be learned from Singapore is the integration of land ownership since 1966, through its "1966 Land Acquisition Act", from which it now owns more than 90% of land in the country. Dominating urban land ownership has enabled the Singaporean government to coordinate multiple urban developments. This can be a good example for urban development in Jakarta and Auckland. The verticalization was done in accordance with "Housing & Development Act of 1960" which succeeded in achieving that 82% of Singaporeans lived in HDB apartments in 2015 (HDB Annual Report, 2015). This policy sets up design guidelines in providing a liveable vertical housing, setting standards for water supply, sanitation, building materials, and access to public amenities.

In terms of land use, planning guidelines in Singapore consistently co-locate residential areas with public amenities within a 400-metre radius of the neighbourhood centre, so they can easily be reached by walking. Land in Singapore, especially in CBD areas, was parcelled to provide flexible developments. In Marina Bay, for example, land-use planning also provided a clear urban grid framework, which enabled a mix of housing, commercial and business activities within close walking distance of the CBD area (CLC and ULI, 2013) (Figure 6b). Aside from these issues, the planning of pedestrian networks in Dukuh Atas TOD is considered to have a high level of success in improving the liveability of the neighbourhood.

Figure 12 Singapore land-use plan (CLC and ULI, 2013)

The Affordability

To understand the extent to which TOD strategies in Jakarta and Auckland are achieving the affordability, the research focused on the affordable housing development and long-term planning.

Jakarta

The most prominent challenge of affordability in Jakarta is the lack of housing options regarding types and tenure. Also, the allocation of affordable housing in new developments is considered inadequate. According to UU 20/2011 regarding vertical housing called "*rumah susun"*, the minimum allocation of affordable housing is 20% of the total floor area. It is not clear yet the ratio of affordable housing allocated in Dukuh Atas and Lebak Bulus TOD will be achieved since the master planning is currently in the early stage. However, we can refer to Pasar Senen and Tanjung Barat TOD which planned to be built around the existing train

station. The development aims to provide 480 out of 1,362 units of affordable housing in Pasar Senen, and 300 out of 1,232 units of affordable housing in Tanjung Barat. Both developments allocated 35% of the total unit for affordable housing. However, it is still considered insufficient as public media observed that there are almost 15,000 people wait-listed for the allocation in affordable housing, while there are only 9,000 of available units (Kompas, 2018).

Another issue of affordability is regarding the development stakeholders. Most of the vertical housing development in Jakarta was done by private developers, for whom the importance of these projects resides in more business opportunities, rather than the provision of affordable units (Sumandoyo, 2017). The lessons from past developments have not been learned - Kalibata City, which was originally declared as affordable housing in the built permit, was eventually built into a medium-high class apartment by private developers. This apartment complex is facilitated by parking lot, anchor retails from big brands and is located in the town centre area. This is in contrast with the affordable housing built by the government, which usually is located far from public amenities, had low qualities, and later grew into a 'vertical-slum' (Kresna, 2017). Since the TOD areas are mostly located on expensive land in the town centre, it is quite uncertain if the new housing development can be affordable. Also, TOD masterplans are focusing more on the catalyst projects and not providing the long-term planning especially for affected areas outside the TOD site.

Auckland

According to the Auckland Plan, the housing development planning already aimed to provide flexible housing options with variations of types and tenure due to the city's diverse community. The land use planning also covered the future development of areas outside the TOD site, which shows the long-term planning in the wider-context. However, Auckland is still having a housing affordability crisis. Affordable housing is generally achieve when the median house price is three to four times the median household income, but in 2015, the median house price in Auckland is almost ten times higher than the median household income (Blakeley, 2015). This has made home ownership becoming less likely for young generations.

The challenges come from the lack of land supply, private land ownership, and densification restrictions in the planning policies as the result of public rejections of high-density developments. The demand for housing in Auckland keeps on increasing while the housing supply is low, the unaffordability persists (Blakeley, 2015). The housing development is considered slow due to expensive construction and long consenting process. The emergence of SHA did bring improvement to the Auckland's housing development by putting several sites across the city for fast-track development, but it is not as fast as needed (Harman, 2016).

Singapore

Affordable housing supply in Singapore started from the initiation of Housing and Development Board (HDB) in 1960. The main purpose of HDB is to provide public housing which affordable and yet has a high-quality. In 1959, only 9% of Singaporeans live in the public housing, but today more than 80% of them resided in HDB apartment. Each year the government sells the un-built apartments predominantly to first-time buyers which price are lower than the market price. The public housing in Singapore was designed with flexibility of types and tenure. The unit types range from two types of one-bedroom apartment, three

types of two-bedrooms apartment, five types of three-bedrooms apartment. There is also a medium-high class unit called "Executive Condominiums" (EC) which were allocated for private developers.

The affordability is also achieved through variation of home ownership schemes to give citizens the flexible purchasing method, such as Additional CPF Housing Grant (AHG), Special Housing Grant (SHG), and Parenthood Priority Scheme (PPS). Singaporean also helped by the low instalment interest which resulted in 90% people who resided in the public housing actually owning the unit (HDB Annual Report, 2015). The housing development planning is also complemented by the public housing quota system which ensures the balanced mix of ethnicities to address the diverse community in Singapore. In addition to the housing affordability, the government also located hawker centres which is famous of the cheap price in a close proximity to the housing blocks.

Another interesting concept from planning policies in Singapore are "white sites", which are areas allocated to developers for future developments that can have flexible functions to match changing market demands. This policy helps to maintain the liveability and economic value of the sites, also encourages developers to analyse the market based on people behaviours. The fast and affordable development of public housing in Singapore is the result of long-term planning combined with responsive land-use policies and development monitoring. City planning in Singapore is based on a 50-year period of concept planning, translated into detailed masterplans for each project with a shorter time frame (CLC and ULI, 2013). Also, with 90% of the land owned by government, the affordable rent becomes feasible.

The Sustainability

To understand the extent to which TOD strategies in Jakarta and Auckland are achieving the sustainability, the research focused on the open space, resilient infrastructure, and carbon reduction.

Jakarta

Open space strategy in Jakarta can be optimized to achieve the sustainability since it has the potential to form the centre of a TOD area where public activities take place. This can be seen from citizens' positive reactions for the recently completed Dukuh Atas Garden. However, when looking at the future plans, the public open spaces are concentrated in the MRT station and along the river, while the rest of the area has an only small portion of it. The greenery strategy should be taken seriously since Jakarta has less than 13% green surface area (Jakarta Spatial Planning, 2011). The renewable river corridor which is also included in the open space strategy is a good initiative. However, based on the master plan, the renewal of river corridors is based on more on economic development than ecological restoration. It can serve multiple functions if the restored river corridor can be also an element in resilient infrastructure needed for addressing Jakarta's vulnerability to flooding problems and protecting biodiversity.

Another sustainability constraint is the large amount of park-and-ride provided in the transport hub plan. This is a typical of mixed-use development in Jakarta, where the area will be car-oriented with a large parking structure and usually has no integration with public transport (Adi, 2010). While future transport hubs are considered to have a high chance of solving the problem of disconnected public transports, the park and ride facilities seem to

contradict the purpose of TOD itself. The weakness of park and ride as stated by Laconte (2011: 180) is that "Park-and-ride consumes a huge amount of urban land that could be used more efficiently". The planning should provide a detailed approach to the change expected of the people in the way they travel by restricting car usage and integrating transport hubs with pedestrian and cycling networks. Aside from reducing carbon emission, restricting car usage can also help to solve the congestion problems in Jakarta.

Auckland

Both areas in Auckland have great natural assets that are planned to be improved through various strategic approach adjacent to the "Low Carbon Strategic Action Plan" policy established by AC. The plan also aims to reduce carbon emission through strategic approach for walking and cycling, combined with the use of public transport. Auckland has problems regarding the high auto-dependency and poor patronage of PT since its networks do not cover the whole areas. Similar with Jakarta, there is no congestion pricing or other policy to reduce the car usage. However, the TOD plans have already shown the initiative restricting car usage through limited provision of park-and-ride facilities.

Singapore

Singapore managed to allocate more than 46% of its land for green surface area (Singapore Stats, 2012) through the 'pervasive green' approach, making nearly half of all urban areas green open spaces, despite its limited land area. Another strategic planning policy called 'Park Connector Network' has enabled the Singaporean government to establish a multi-functional infrastructure network which connects open spaces within the city and accommodates walking, cycling, and non-recreational functions like storm water drainage system (Chan, et al., 2011). Furthermore, there is also regulation regarding the density of trees and green buildings to complement the open space preservation.

Learning from Singapore, the government chose to switch to sustainable mobility in order to preserve liveability and reduce air pollution from private vehicles. The transit system in Singapore is designed to provide seamless connectivity through integrated and affordable public transportation, which is the same direction as Jakarta and Auckland. However, Singapore has complemented its transit system with policies that discouraged the use of private vehicles. With its policy called 'Singapore Area Licensing Scheme 1975-2000', the city-state become a pioneer in restricting car ownership, introducing congestion pricing, and encouraging the use of public transport (Laconte, 2011).

Another important aspect of Singapore's sustainability is the resilient infrastructure addressing flood problems. Singapore is a coastal city, similar with Jakarta and Auckland, and therefore has integrated the disaster risk management with its urban planning. Singapore's drainage system is a multi-function infrastructure - it also serves as parks. These parks then become the flood retention areas. Another example of this resilient infrastructure is the Marina Barrage which serves three main functions: storm water drainage system, water resource, and outdoor recreational space (Brecht, 2016). These infrastructures are the result from detail design guideline called "Active, Beautiful, Clean Waters Design Guidelines".

Table 2 Comparative Assessment Summary

Goals	Singapore (SGP) BENCHMARK	Jakarta (JKT)	Auckland (AKL)
Liveability:	• "Walk2Ride" programme • Walking and Cycling Plan (WCP) for every new development • Public housing Renewable programme • 1966 Land Acquisition Act • Design guidelines for vertical housing • Easy access to public spaces	• Late development of pedestrian network • Need detailed planning for cycling facilities supporting pedestrian • Segregated land-use leads to slum problems • Successful civic plaza in Dukuh Atas Garden • Land acquisition causing slow development • Verticalization constraints by current culture & lifestyle preference	• Robust planning of walking and cycling • Large amount of existing public space to be improved • Dividing areas into precincts according to the timeline • Special Housing Area (SHA) • Land-use is planned with the right amount of diversity but constrains by land acquisition • Verticalization constraints by current suburban-lifestyle
		Recommendation: • More detailed planning for walking and cycling • Integration of land ownership under the government for future developments • Providing vertical housing guidelines to preserve the liveability	**Recommendation:** • Integration of land ownership under the government for future developments
Affordability:	• Public housing developed by the government • Flexibility of housing types and tenure • Variations of purchasing method with low interest • Affordable rental price • Quota for racial diversity • "White sites" policy	• Lack of housing options of types and tenures • Low percentage of affordable housing development • Affordable housing development by private developers in town centre areas resulted in unaffordability • TOD masterplans need to consider the long-term planning outside TOD area	• Housing development planning already provides housing options with variations of types and tenures • Land-use accommodating long-term plan • Affordable housing crisis due to lack of land supply, private land ownership & densification restriction • Housing developments

			constraint by expensive construction and long consenting process
		Recommendation: • Providing flexibility of housing types and tenures • Consider increasing the ratio for affordable units provided in TOD housing development and enforce them • TOD housing development under government monitoring • Providing long-term planning for areas affected by TOD projects	**Recommendation:** • Allowing more high-density housing development near PT and public amenities to reduce the high PIR • Considering planning policies to maintain land values and encouraging new developments in addition to SHA
Sustainability:	• 'Pervasive green' approach allocating half of the area for green space • Green building regulation • Sustainable mobility • Policy restricting car usage and ownership • Resilient and multi-functional infrastructure integrated with disaster management	• Open space strategy can be optimized to solve the lack of green surface area • Renewable river corridor has potential for resilient infrastructure addressing flood problems • Large amount of Park and Ride facilities tend to support car-oriented travel mode and discourage the use of PT • No policy to reduce car usage	• Low Carbon Strategic Action Plan to maintain existing natural assets • High auto-dependency due to poor patronage of PT • Limiting park and ride facilities (1:4 ratio) • No policy to reduce car usage

		Recommendation: • Optimization of open space to encourage public activities in the TOD area • Space allocation for Park and Ride can be used for other facilities like multi-function public open spaces • Considering planning policies to reduce car usage and encouraging the use of PT	**Recommendation:** • Improve the patronage of PT • Considering planning policies to reduce car usage in addition to limited park and ride

5. Conclusion

Similar with many growing cities in the world, Jakarta and Auckland adapted the TOD strategy in facing the challenge of rapid population growth and land shortage, and the desire to build a more compact city. But the compactness is not an aim in itself – the aim is quality of life, at a reasonable price, in balance with the nature's capacity to support the urban way of life of the millions. We have termed these three goals for short – Liveability, Affordability and Sustainability (L-A-S). This paper investigated to what extent TOD strategies can achieve the L-A-S in both cities using four redevelopment areas: Dukuh Atas and Lebak Bulus in Jakarta, New Lynn and Onehunga in Auckland, as the relevant case studies.

According to the literature of TOD and compact city, the compact urban form is considered liveable, affordable and sustainable when it comprises of mix of uses within the walking distance from supporting extensive transit systems. The concept of TOD is relatively new in both cities and the outcomes are still questionable with respect to the L-A-S criteria. Drawing examples from Singapore as one of the most successful compact cities in the world, this paper offers recommendations for TOD projects in Jakarta and Auckland to achieve the L-A-S goals.

In the case of Jakarta, TOD concept policy can actually achieve the L-A-S subject to the following conditions: that the extensive transit system is complemented with robust planning of walking and cycling; land integration under the government enabling long-term planning; verticalization framed by vertical housing guidelines providing variations of types and tenures; open spaces optimised for human comfort while also creating resilient infrastructure; and the limitation of car usage to encourage the use of PT.

Likewise, in the case of Auckland, TOD concept policy can actually achieve the L-A-S subject to the following conditions: that the transit interchange is supported by extensive walking and cycling networks; integration of land ownership for long-term developments; high-density housing and mixed-use developments; improved patronage of PT; and planning policies to reduce car usage.

It is also clear that there are other factors influencing the success of TOD projects such as the synergy between planning policies and TOD; active public-private partnership for TOD developments; community engagement; and government support for the vision stability.

Considering the limited scope of this paper, further study is required to analyse the implementation of TOD concept policy in a bigger sample of projects if we are to assess comprehensively the L-A-S outcomes. Also, the research into case studies cannot limit itself to the analysis of master plans of projects currently under construction - future research must investigate the completed, post-occupancy outcomes too. Finally, there should be a finer level of detail on this type of research, assessing the urban design, landscape and architectural solutions at the level at which they actually touch the lives of residents.

Bearing in mind the relentless expansion of cities worldwide and the popularity of the TOD approach as a chief policy for moderating that expansion, it is fair to say that monitoring and investigating the actual L-A-S outcomes of this policy is one of the most important avenues in the 21th century urban planning research agenda.

Research Paper

The application of micro-regeneration strategy in urban renewal in northern Lima, Peru

Bo Bian, School of Architecture, Southeast University; China

Abstract

Lima, the capital city of Peru, is situated within the country's desert region on the Pacific coast and bordered by the Andes Mountains to the East. It is one of the most fast developing city shifting from both formal and informal urban construction. While traditional renewal model and strategy cannot deal with new situation and complex urban problems of this mega city due to its inner and outer contradictions and complexity.

This paper analyses the current situation of San Martin de Porres, a typical district in the northern part of the city, which grew towards the Chillon river corridor mainly during the second half of the twentieth century. It conducts investigation and analysis on the current situation related to social, economy and infrastructure system in this district. It shows that from the perspective of planning and design, urban scale top-down interventions have little positive impact on individual realities. On the opposite, much of the society's knowledge and useful space are created by the residents' active behaviour and informal activities, which belong to the bottom-up strategy, and they provide the source for urban vitality.

Based on the above content, the paper puts forward the micro-regeneration strategy based on the theory of organic renewal and daily life, which mainly includes three aspects: urban catalysts, space design and corporate mechanism construction.

The paper investigate different potential urban catalysts based on the feature of different functional space. It includes the most symbolic area that the latter design would applied to the whole province practically. Space design consists of four aspects: riverbank reuse, street renovation, community building and neighbourhood space transformation. The paper introduces community-based organization and governmental structure based on current top-down model and residents' activities in order to push on the practical work that all the other area could follow.

It tries to stimulate the improvement of the current situation and hopes to provide a new mode for the development of this mega city and similar practice.

Keywords

Lima, micro-regeneration, urban renewal, bottom-up

1. Introduction

Globalization and neoliberalism have caused dramatic changes in urban labor market, leading to the rapid development of informal economy and houses in developing countries, which formed the informal city (Hansen & Vaa, 2004). Normally it comes from small scale activities for the purpose of survival that are self-conducted by the poor people whose needs

that the government could not meet of (Hernando, 1989). Although the majority of informal activities are classified as illegal because they lack governmental control, these activities are considered normal rather than exceptional since informal employment take up more than half of employment in developing countries. At the meantime, some scholars use the concept of informal sector in the area of ethnic groups and activities (Kate, 2009). The urban poor who want to improve their living conditions conduct these activities. They volunteered to organize groups to mediate or confront with government or other interest groups. As a result, a self-determined informal social network was formed (James, 2011).

Lima is the capital city of Peru, a typical developing country that informal economy, informal houses and informal social groups are important parts. While most research on informal sector that have been done are focusing on economy and policy, little have been done on urban planning and design. We have to admit that we do not achieve desired effect by using policy-making tools to control the informal city. While it is great opportunity to reorganize and improve the informal city from the perspective of space planning and design. This paper proposes to use micro-regeneration strategy in terms of space design to provide a sustainable method for northern Lima based on our research.

2. Current condition

2.1. Basic information

Lima is situated within the country's desert region on the Pacific coast and bordered by the Andes Mountains to the East with the Rimac River flowing through its center towards the Pacific just north of La Punta in Callao. Modern Lima connects multiple historical centres: the colonial city centre (and the government seat of Lima) was established inland on the Rimac River but later expanded towards the Pacific coast connecting to the towns of Callao to the west, Magdalena del Mar, Miraflores and Chorrillos to the south. The city also grew northward towards the Chillon river corridor mainly during the second half of the twentieth century (Marwan, 2017).

(a) (b) (c)

Figure 1 Basic location; (a) Peru in Latin America; (b) Metropolitan Lima in Lima city; (c) Lima district

Source: www.mapsofworld.com/south-america/

2.2. Problem

Unlike the centre area and the southern area, which already have been preserved and renewed to some extent, the northern area is suffering from unlimited urban sprawl and

low-quality urban renewal. As a result, the northern area appears inequality and geographically segregation in different fields such as social level, working opportunity, infrastructure provision etc. In the northern area, much of the formal workers and formal houses are near the main north-south road and the city center, where there are more high quality educational and health institution, as well as better transportation, electricity and water facilities. In addition, the average income of informal workers (take up 2/3 of all workers in metropolitan Lima) is less than 1/3 of that of formal workers.

2.3. Cause

2.3.1 Government's oppression on informal sectors

The Metropolitan Municipality of Lima is the utmost authority of the entire city while each district has its own local government and local political leaders. What makes things worse is that, since Lima is the capital of the country, the central government often contravenes its urban planning. This three-tier government system creates high negotiation costs in infrastructure-building programs in Lima and lowers the efficiency of government bureaucracy. The municipalities have only paid attention to the need for urbanization land, but not to the provision of services and equipment, such as housing production, issues which are principally in the hands of the central government (Li, 2014). It does not construct a reasonable top-down governmental system, nor a rational mass basis. The district government usually puts money in the formal area where there are more high-income residents to achieve high profit instead of improving the living environment of low-income residents, thus increasing the gap between the formal and informal, as well as the high-income and low-income residents.

Informal economy is one of the main working patterns in metropolitan Lima, and it is the choice of the majority of low-income workers. This kind of economy are well received in the informal area and the informal system are complete enough to run by themselves. However, the government controls the overall system of the city. As a result, informal economy does not occupy position in formal economy; some informal workers with high education level cannot get chances in formal working. The government is fears that the grassroots' nature of informal economy will overthrow the formal economy (Hernando, 2010).

2.3.2 Low quality of informal groups

The government controls the construction of infrastructure in Lima, any organizations and individuals as well as local administrations and groups are unable to provide necessary infrastructure. Thus, informal residents can only get access to the infrastructure by illegally connecting themselves to the infrastructure in formal area. This inefficient and illegal activity is the main way for many informal residents to obtain public facilities includes water and electricity, as well as education and medical facilities, which are at relatively low level.

Economic crisis from 1973 has caused the cut of formal jobs; many highly educated and skilled workers lost their original jobs and entered informal jobs. People with low educational level and low working skills are losing opportunities to compete in the increasingly fierce job competition. A growing number of people are becoming unemployed residents or even vagrants (Gustavo, 1996).

2.4. Cause

Urban scale top-down interventions have little positive impact on informal individual realities. On the opposite, much of the informal society's knowledge and useful space are created by the residents' active behaviour and activities, which belong to the bottom-up strategy, and they provide the source for urban vitality. In addition, informal sector has long been considered as illegal while the type and scale of informal sector is huge enough that it benefits the development of the whole city. However, the barriers between formal and informal sectors result in inability of informal activities and growing gap between them. This will make the inequality problems between formal and informal groups even worse. We should manage to give suitable rights to informal groups and place them in the right position to solve the problems we are facing and let them play effective roles in the future.

3. Exploration and practice on informal sector

Based on the above studies, this paper hope to review the research on informal sectors, especially the various theory of policies and practices, looking for the opportunity to promote the urban renewal and urban development of informal area in a positive way.

3.1. Need for space design

In early stages, policies and related research are mainly focus on informal houses. The majority believe that the urban poor who live in the informal houses are rational actor. It means that they build these houses because the government and market did not provide enough suitable houses for them. As a result, they build these cheap and simple houses to meet their demands.

In 1976, World Bank published a report (George, et al., 1976) on developing countries and it tells that governments in Asia, Africa, and Latin America have implemented a range of policies to integrate informal settlements—spatially, economically, and politically—in the overall management of cities (Angel, et al., 1993). It was popular for architects and urban designers to use planning and design methods to improve the physical environment. However, those plans ignored the social reality of informal communities and it turned to be ineffective (UNHCR, 2010).

At the same time, the World Bank proposed an In-situ upgrading strategy under the resistance to moving out from informal residents. In addition, it continued to proposed service-sites plan, which was very attractive to the local people (Bishwapriya, 2014). However, in early 1980s, it proved to be not sustainable because it required too much subsidies and public organizations could not earn from it (Michael, et al., 1983).

3.2. Inefficient policies

From the 1980s, the government started to turn from a few projects into comprehensive management as well as public policies and it provide better markets for land, housing and commercial functions (Michael & Robert, 1984). However, many of the reform programs were difficult to be put into effect because those programs were not practically relevant to the residents. On the opposite, residents were still willing to accept the specific community plans made by developers (Mukhija, 2016).

In addition to the top-down strategies, bottom-up process was also of vital importance. While informal residents had their own groups, they were not free from political and economic power. The organizations that wanted to get rid of governmental control still needed to receive support from the higher authorities or folded into government organizations (Elliott, 1984) and the government still needed to maintain its status and manage the community resource (Elinor, 2000).

3.3. Reform of informal sectors

Scholars such as De Soto held the view that informal residents should receive legal rights of their houses. While it was difficult to form such a complex system, De Soto thought that suitable reform of the system could help to promote the building of the whole system (Hernando, 2000). As a result, public organizations and informal residents who received legal rights could quickly put the system into effect at a lower cost, which was similar to the process of promotion between democracy and capital system. Other organizations such as NGOs could get involved and act as mediators between government and residents to cut the

cost and speed up the formation of the informal community system (Ruth & Esther, 2009). De Soto's concept of legalization was a tentative idea and the International Labour Organization in the conference responded this concept in 2014 and 2015. It called on that the existing informal lifestyle should be preserved and improved. Public space could become the working space for informal workers and suitable regulations should be made to guarantee the rights of using the public space and resources (ILO, 2015).

3.4. Conclusion

The consequence that informal urban sprawl caused in Lima cannot be reversed while the gap between formal and informal sectors is widening because of the de-legalization of informal sectors and government's focus on formal area. The voice of constructing informal legalization system in metropolitan Lima is getting higher while it is difficult to predict and control the consequences caused by major changes in policy and system based on past events. It is more acceptable for informal residents to receive the changes of surrounding space and daily activities in relatively small scale. It is impossible for the government to provide countless affordable houses or to reform the fundamental informal policies rapidly. On the opposite, it is practical to form a system controlled and financially supported by government, led by residents' association, mediated and invested by non-government associations to renew the informal communities and to improve the informal activities in a relatively small scale. Therefore, the paper proposes to use micro-regeneration strategy in focusing area in northern Lima.

4. The concept of micro-regeneration and its application

4.1. Origin and definition

The concept of "micro" originated from the "Internet plus" period in China. With the development of internet, cost of acquiring resources for the individuals become cheaper, which means that it is easier for individual development and exchange of knowledge. As a result, there exist a variety of idea and product taking the concept of micro as core idea. Micro-regeneration is the application of micro concept in urban planning and design and it was first applied to old building renewal in historic cities. Nowadays, it is difficult to use traditional planning methods to solve all the city problems at one time. With the popularity of urban renewal, professional teams and organizations started to use micro-regeneration strategy in community and city level.

Micro-regeneration strategy is based on the theory of organic renewal, keeping the overall city structure and cityscape. At the same time, it emphasizes the bottom-up process and encourages residents' association to take part in urban renewal process. As city is a complex system, the strategy follows the developing order to avoid unpredictable consequences. It renews part of local site to stimulate continuing self-regeneration process and it hopes that this small-scale renewal will have positive effect on local residents that they would like to follow. As a result, micro-regeneration will achieve influential and sustainable changes that would solve the city problems. This strategy may be suitable for the social and space renewal in informal area.

4.2. Form and mode

Under the influence of early renewal methods, traditional urban renewal lacked consideration of the public interest. Urban renewal a tool to reflect the will of the

government, realize the personal values of designers and profitability of developers. With the development of society, the urban organic renewal model began to pay attention to two important topics of public participation and non-material environmental protection. Compared with the urban renewal under the intervention of external forces, the micro-renewal concept advocates the development model based on endogenous power, and the public's renewal demand is the core.

Under the influence of the early renewal methods, traditional urban renewal lacked consideration of public interest. It usually became tools to show the authority of government and to realize the personal values of designers and profitability of developers. With the development of society, organic renewal method started to pay attention to public participation and intangible environment protection. Compared to traditional urban renewal that was under the intervention of external forces, the micro-regeneration strategy follows the core idea of organic renewal and advocates the method based on endogenous power from the residents.

Overall, micro-regeneration mainly includes three aspects.

(1) The development mode is based on the residents' interest. Traditional urban renewal is top-down mode, which is too simple that residents could only observe or even resist. On the opposite, micro-regeneration pays much attention on residents' needs and emphasizes on following the inherent characteristic and of the area to increase the continuity of urban renewal in time. As a result, residents will initiate to form self-renewal system based on the bottom-up community cultivation.

(2) Source of funds become wider. Source of funds in traditional urban renewal are mainly from governmental subsidies and developers' investment. While trustworthy groups' funds from community residents and NGOs can guarantee the reliability of the use of funds in micro-regeneration.

(3) Organizational structure changes from top-down mode to bottom-up mode. The government dominates traditional urban renewal with developers putting it into effect. Designers only exist in the initial stage and residents can hardly participate in the process. While residents are at the core in micro-regeneration process and they raise their needs and goals. Developers become professional advisers with designers helping the work. Government will do the managing works with NGOs act as mediators between different groups to achieve multi-party services and protect every groups' interest.

4.3. Operation process

Micro-regeneration mainly includes three operation stages: urban catalysts selection, space design and corporate mechanism construction.

(1) Micro-regeneration manages to choose suitable urban catalysts based on current situation. In 1989, Wayne Atton and Donn Logan put forward the idea of urban catalysts (Wayne & Donn, 1989). It tells that urban catalyst is not the final product of simple urban renewal while it can stimulate and lead the follow-up development. This action is aimed to promote the development of the area in a continuous and gradual way.

(2) Space design not only focus on the practical plan of public space, but also emphasize on the implementation on stages. It changes current static planning into dynamic planning and it combines planning-making with management and construction action. By doing so,

government and residents can work together to manage the area from target setting to strategy practicing and space renewal. At the same time, it can adjust the plan based on the change of political, economic and social factors at any time to renew the area in the most realistic and suitable way.

(3) Corporate mechanism mainly includes two aspects. On one hand, it guarantees that the developing mode, resources of fund and main body of responsibility are shown clearly to the public in every steps of the construction. On the other hand, bottom-up feedback mechanism can be formed among the residents to keep the sustainable renewal after the initial project at the center public space.

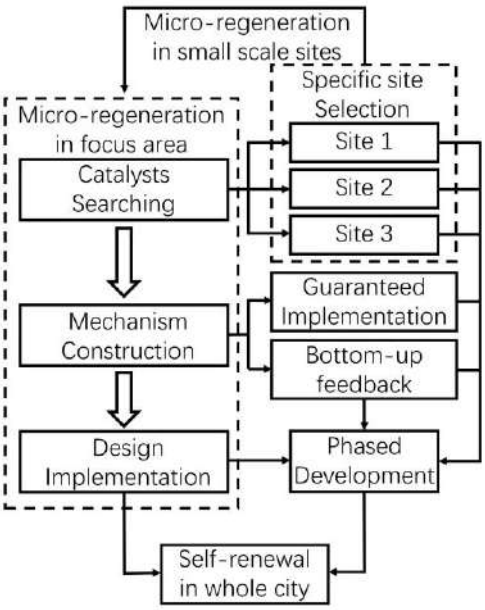

Figure 4 Process of micro-regeneration strategy

5. Proposal of micro-regeneration in northern Lima

5.1. Selection of focus area

Based on the above research, the focus area in San Martin de Porres near Los Olivos is the place where the gap between rich and poor is the greatest. It is practical that we use this most typical area as an example to get involved.

Another reason why we choose this area is that the proximity of space to wealthy area brings certain opportunity to the informal area (Janice & Fernando, 2011). Perman's research shows that poor residents who live near the rich area have higher possibility of improvement in living conditions than those who live in the periphery area. More working opportunities, closer distance between working place and residence, gaining more knowledge and information through contact with employers, better education for child are all reasons that lead to the result. As a result, in-place renewal and upgrading residential area are highly supported by the public.

Figure 5 Location of focus area

5.2. Planning and design process

Based on the operational strategy of micro-regeneration concept, this paper summarizes the specific planning and design process into three parts.

(1) Classify the whole area into different semi plots according to the space, social, cultural and economic characteristics. Summarize the core problems and feature of different plots.

(2) Search for potential catalyst sites different plots that ensure the representativeness and typicality of the selection. Guarantee that the planning and design methods can be applied to other sites.

(3) Study the characteristics and needs of different political bodies. Design a complete and renewal mechanism to provide sustainable space update guidance and political system.

5.3. Catalyst design

Based on the above analysis of current problems and concept of micro-regeneration, this paper finds three typical catalyst sites as listed below, aiming at the problem such as poor operating of social environment, disordered informal market, insufficient supply of public facilities, and low quality of public activities' space. The paper discusses the design and planning potential and formulate corresponding renewal mechanism based on current conditions.

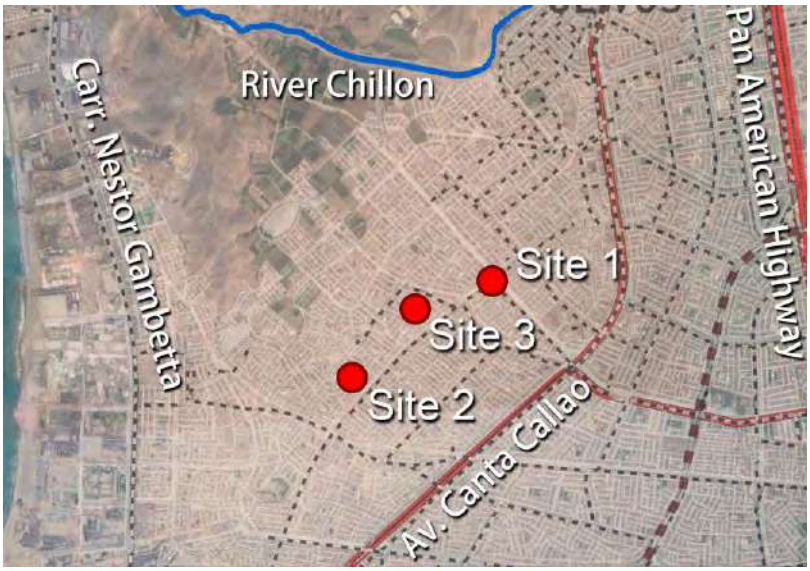

Figure 6 Map of selected sites

5.3.1 Site 1: Main street and central market

This site is located at the intersection of two major streets in the district; the planning area is about 24,000m2. The east-west street is the widest in the site while the north-south road is just a secondary road. Most cars pass through the east-west street to reach the expressway on the east. However, all the roads are in low condition with too much dirt. Residential houses and some undeveloped open ground take up most of the space in this area.

It is a region with a large population but lacking enough infrastructure and basic central markets. While the location and commercial environment of this area make it have the potential to become the public center of leisure and business function. At the same time, not only vendors or market sellers that need the public space, but also the pedestrians, vehicles and people doing recreational activities. Normally, planning and design are based on land use zoning that one particular area of land can only have one single category of use. But in Lima, various people and activities, as well as function space should be adapted to each other. It is because that mixed, flexible land use and eclectic management by free and active idea are the characteristics of informal society. Therefore, this paper hopes to use the core functions of commercial and daily living activities to form a cluster space of multiple functional activities in district level. The renewal process is divided into three stages.

(1) Early market formation period.

The government seldom understands the specific and differentiated location and service requirements of informal residents. They also do not know the informal activities match the local, national and even international value chains (Rosemary & Peter, 2009). Therefore, informal groups formed by experienced residents should lead the informal sellers to gather and conduct their activities especially the informal economy activities, forming a preliminary business and activity environment. Then the sellers together with developers and NGOs can form a market committee to decide how to use the public space and unused houses, and to build a central market or even commercial complex. At the same time, the committee act as supervisor to manage and control the operation of the market.

(2) Market upgrade period

The government can intervene appropriately to provide part of funds, and they can call on the local experienced developers and designers of mega projects to help to build the central market or to transform and rebuild the existing buildings. As a result, central market with elements of informal sectors as the core can be formed, and a variety of commercial and leisure activities can be conducted at this site to improve the social, cultural and economic environment.

(3) Complete development of market leisure area

In order to avoid the negative effect caused by informal activities that was popular in other area, residents' association and the government as well as other interests' groups are involved in the management and supervision of the site. It is important to change the existing chaos of the streets but also to maintain the social vitality of informal activities.

It hopes to form a self-renewal mechanism led by the residents' association and supported by the government and other interest groups. Integrate informal economy carriers such as vendors or retailers in bad business who do not have suitable physical space and provide them with an area to play a role of informal sectors. At the same time, it will improve the upgrading of the physical public space in the surrounding area, realizing the sustainable renewal of this commercial and leisure center.

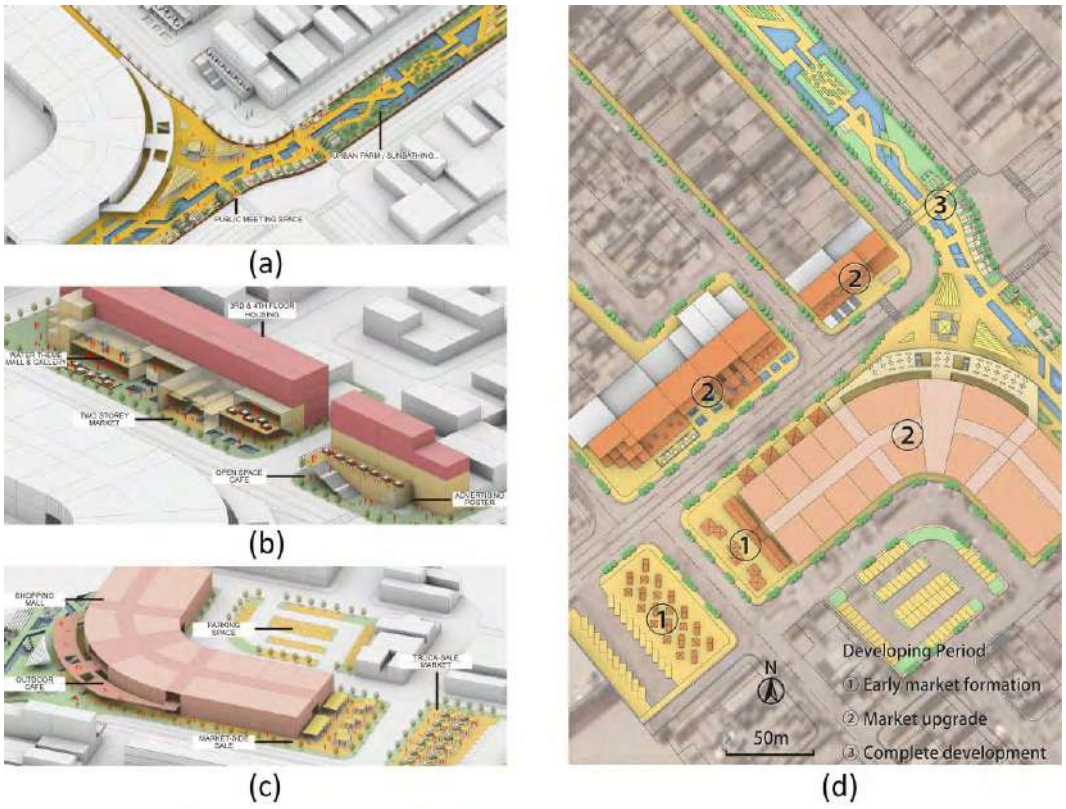

Figure 7 Space design in market renewal; (a) Street leisure area; (b) Building transformation; (c) Market transformation; (d) Plan of market renewal

Figure 8 Map of market renewal mechanism

5.3.2 Site 2: Community center

This site is located near the secondary road inside the main community; the planning area is about 24,000m2. This site is one of the typical undeveloped area that is in large scale within the community. On one hand, its location is good for the internal and external exchanges of various activities. On the other hand, large area undeveloped space has the potential to supplement the infrastructure of nearby communities. Moreover, the renewal process is divided into three stages.

(1) Early community center formation period

The formation of community center needs the gathering of public enthusiasm, increasing of public activities as well as building of community social networks. We encourage vendors and informal market sellers to conduct their selling here, but in small scale that take up only part of the space. Once the accessing to public space is guaranteed, basic infrastructure such as running water and toilets, as well as services such as garbage removal, are urgently needed, which is generally beneficial to all users, including residents (Sally, 2014). This is the starting point of improving infrastructure quality for the whole community. The funds of early improvement should come from residents themselves and reliable residents' association, as well as local developers. When small shops and enough power supplies are in in place, vendors will carry out more profitable and more valuable business activities such as sewing and repairing (Richard, et al., 2009). It provides great opportunity for daily gathering and other activities.

(2) Community management upgrading period

With the daily gathering of residents and the availability of basic infrastructure, residents' association and other community groups can form a community agency and start to manage and coordinate among the community. During this period, the community agency leads investigate and record the basic information of residents, forming a file management system. On one hand, it is easy to find and to try to solve the core problems in community. On the other hand, multi-groups formed by residents and various local groups can prevent from single organizational structure and the inequality of interests' distribution. As a result, the overall quality of social and living environment can be improved.

(3) Community training maturity

When infrastructure quality and social networks are relatively mature, what still need to be addressed is the quality and ability of residents and government's knowledge of informal sectors. On one hand, it is important to provide more education agencies to increase the knowledge level and thus increase the working opportunity for informal residents. On the other hand, government staff should come to informal communities and learn about the specific needs of the informal society. It provides the fundamental opportunity to build up connection between informal and formal sectors in the future.

On the whole, based on the current situation that existing informal groups have their own social networks but are unable to improve their social level, the paper attempts to use the undeveloped area in the site to improve the infrastructure level, to cohere the informal community, and to build better managing groups. Thus, it hopes to achieve an overall improvement of the informal community.

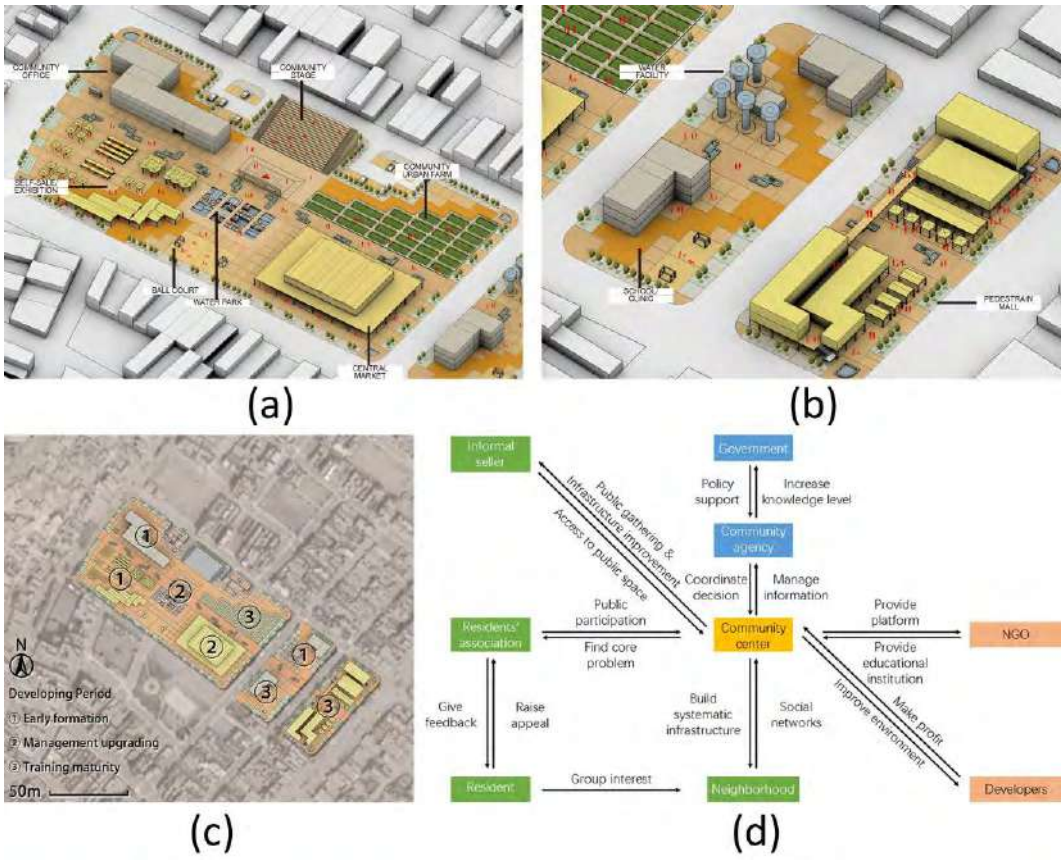

Figure 9 Maps of community center renewal; (a) Space design 1; (b) Space design 2; (c) Plan of community center; (d) Corporate mechanism of community center renewal

5.3.3 Site 3: Neighborhood public space

This site is located in one of the common neighborhoods; the whole planning area is about 75,000m2. The specific design plots are the undeveloped area and demolition space between the residential houses. It is common that it lacks activity space and physical contact in the neighborhood. Based on this situation, the design hopes to increase the possibility of daily activities inside the neighborhood and to interact formal and informal sectors by the connection of space.

(1) Partial transformation period

The initial space utilization mainly focuses on local intervention to avoid interference to the residents. Compared with traditional neighborhoods, the organic combination of low-level and medium-density buildings in informal area is similar to the new urbanism advocated by planners (Janice & Fernando, 2011). The renewal should retain this kind of urban form while meeting the needs of residents. Evaluate existing neighborhood structure and poor-quality buildings as well as unused public space, sort out the space available for renewal operation, and determine the links between possible resources and functional area.

(2) System formation period

In terms of choosing potential public space, the levels should be clearly graded, and the size of each level should be relatively average. Residents in a particular small area can organize together to manage the investment and use of nearby public space through neighborhood raising and introducing of NGOs. It is even possible that developers can engage to invest in the public space managing and transformation. As a result, residents will be provided with more suitable activity venue through the installation of functional facilities and components. They will also be guided to more open space though the path, thus forming a multi-level activity space system and providing residents with multiple choices in daily life. Through the "street eye" mentioned by Jane Jacobs, the coherence and mutual care of the neighborhood guarantee the safety and enhances the overall comfort of the neighborhoods (Jane, 1992).

(3) Systematic connection period

Historically, it is difficult to integrate informal area with a high degree of identity directly into formal cities, because this kind of integration means that urban informality is replaced by urban formality within a certain space. Therefore, it is reasonable and effective to conduct spatial, social and cultural connection between the urban informality and formality, in order to bridge the gap. However, the residents themselves control this kind of connection and communication. They determine the function and continuous direction of the public space. At the same time, formal sectors need to value the informal sectors, thus bring the downward connection so that two separated groups can create useful communication and connection.

Finally, this paper hopes to promote the connection between formal and informal area through the gradual construction of public space system and to encourage the bottom-up renewal of the informal area from the perspective of spiritual and institutional support.

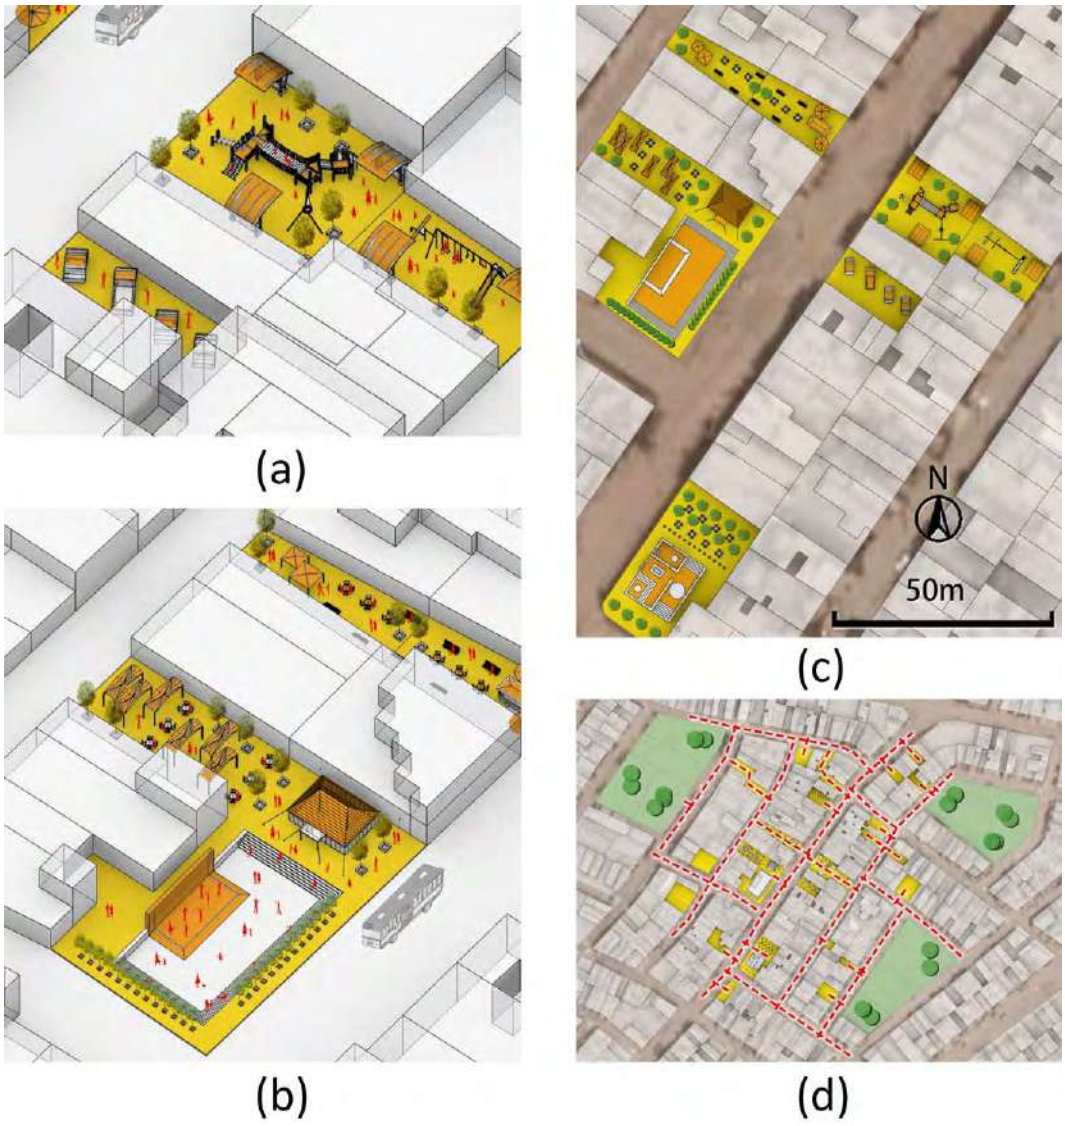

Figure 10 Maps of neighbourhood renewal; (a) Space design 1; (b) Space design 2; (c) Plan of neighbourhood space; (d) Connection system of community

6. Conclusion

The informal sectors constitute one of the dominant factors in metropolitan Lima and they are highly embedded in urban politic, economy, and culture. They actually have the potential to help the city to develop in a better way. However, recognizing informal factors and establishing their status should not be dramatic and rapid. On one hand, slight changes in policies have proved that it is difficult to have positive effect on informal factors. On the other hand, informal residents tend to accept space plan and suitable legalization. Planners and designers as well as policy makers can work together to use micro-regeneration strategy, taking informal residents as main body to renewal the unequal informal area.

Based on fully recognizing the situation in the informal area, it is realistic to construct the space and policy action mechanism. It hopes that the informal residents have the ability to

gradually renew by themselves and form an independent system, thus promoting the better development of the informal area and the whole city.

The application of micro-regeneration has some successful cases in China and Europe, but this paper is only a theoretical discussion and proposal on the renewal in a specific area in Lima. Whether the concept can be implemented and promoted is unknown, more practice is needed to verify in the future.

Case Study / Project

How Big Is Auckland:

Planning a City-Region for Resilience and Regeneration

Dushko BOGUNOVICH

Abstract

New Zealand's local authorities and planners have embraced the 'compact city' model as the magic formula for the livability-sustainability agenda. Yet, the evidence is weak that policies of stopping urban expansion and densifying the exiting urban fabric deliver better quality of life or lessen impacts on the ecosystem. Overall, compact city policies have been more effective in aggravating the housing land price inflation and irritating local residents in intensification zones, than in actually containing urban sprawl. On the other hand, as global warming is accelerating, the risk of urban disasters and crises threatens to affect high density areas more severely, due to their high dependency on traditional, centralized urban infrastructure.

Auckland, New Zealand's largest metropolitan area, illustrates these dilemmas very poignantly. Its recent tumultuous process of preparing and adopting the new long term plan has shown that the politics of compaction and intensification is divisive and expensive, while the economic and ecological efficiency gains are uncertain, if not meager. The city keeps growing through market-driven and opportunistic development, mostly ignoring the arbitrary Rural Urban Boundary which was supposed to arrest urban sprawl. The centrifugal forces which fuel the horizontal growth of the metropolitan area range from technologies of transport and telecommunications, to energy generation and waste disposal. At the same time, climate change trends suggest that the resilience agenda (adaptation) is now more pressing than the sustainability agenda (mitigation) and that further concentration of people and assets is unwise.

We suggest that Auckland Council has failed to recognise and acknowledge the unstoppable forces of regional decentralization and polycentric metropolitanisation, while at the same time underestimates the threat of climate change and Auckland's overall exposure to hazards of various kind. The Plan must be based on a more realistic concept of the size, extent and influence of Auckland. Auckland is no more a'city'; it is a 'city-region'- a linear city-region. It is emerging and should be planned as a linear conurbation, with one major central spine of key transport systems (motorway and railway) and many nodes of density. In fact, Auckland is even bigger than that, as its influence affects the entire upper, northern North Island. Auckland is at the centre of a triangle of three smaller cities: Hamilton, Tauranga and Whangarei. It is also a part of a 300 km coastal arc of development along the northern, Pacific edge of New Zealand, ruled by four regional councils: Northland, Auckland, Waikato and Bay of Plenty. In Europe, planning authorities have long ago realised the inevitability of urban sprawl, and of neighbouring cities and towns coalescing into conurbations. But they have strived to steer growth, rather than contain it, resulting in strategies is decentralised, polycentric, development which cover large areas, while including plenty of open space.

We suggest that the Auckland City-Region could do even better and by 2040 become a metropolitan conurbation with high quality of life, a high level of resilience to a range of climate-triggered events and significant regenerative capacity in the peripheral, low density areas. The conclusions - and dilemmas - presented in this paper have global significance in the light of worldwide problems of rapid urbanization, urban sprawl, metropolitan governance, social exclusion, infrastructure capacity and cost, resource depletion and climate change.

Abstract

Rapidly increasing population and migration from rural areas to nearby urban agglomerations develop tremendous pressure on system of the existing cities without compromising socio-economic and cultural linkages. Policy interventions, both at global and local scale, have created newer avenues for the researchers to explore real-time solutions for problems world-wide. For instance, the outcome of 2015 United Nations agenda for the achievement of the Sustainable Development Goals (SDGs) by the year 2030 primarily focuses on urbanization issues and probabilistic modelling of future scenarios to obtain a robust alternative for resource utilization and further for maximizing sustainability through land use pattern analysis. This is the clear indication toward the very important role of "ever dormant" urban planning, especially in the case of a rapidly developing country such as India. Remote sensing and geo informatics along with Machine learning can provide extremely relevant information about the pattern change in cities and as input to visualize the future growth pockets. In this context, potential of cellular automata (CA) in urban modelling has been explored by various researchers across the globe. In the recent past, models have been drawing majority of the attention along with geographic CA processes about urban growth and urban sprawl studies. Most recent approaches include optimization of transition rules based on machine learning techniques and evolutionary algorithms that follow nature-inspired mechanism such as Genetic Algorithm, Ant colony optimization, Particle Swarm Optimization (PSO), simulated annealing, Grey Wolf optimizer etc. Irrespective of any modelling technique, model calibration remains one of the challenging and most crucial steps towards obtaining realistic results. This research communication tries to demonstrate a novel idea of integrating PSO with SLEUTH post calibration of the spatial-temporal footprint of urban growth from the year 1990 to 2017 for Kolkata, a historical megacity of Eastern India. Results were evaluated and validated using statistical fit measures reveals PSO-SLEUTH performed substantially better compared to traditional Brute Force calibration method (BFM). Another significant development was in terms of

computation time of optimized values from days (BFM) to hours (PSO). The study identifies Kolkata region to be sensitive to spread and road gravity coefficients during calibration procedure. Results indicate growth along the transport corridors with multiple agents fuelling the growth. Further, with the aid of high spatial resolution data, buildings were extracted to understand the growth parameters incorporating neural networks. Using the results, renewable energy aspects were explored to harness and provide a suitable local solution for energy issues in energy gobbling cities. Pattern of landscape change, development of better process of modeling and extraction of building from machine learning techniques for planning smart cities with self-sustaining energy is presented in this research work.

Keywords

Cellular Automata, Particle swarm optimization, SLEUTH, Urban modeling, Pattern recognition

1. Introduction

Asia alone is projected to house 54% of total world urban population (6.3 billion) by the year 2050 against 50% in the year 2010 (UNDESA, 2015) indicates the need for liveable cities that are more likely urban areas. Urban areas, over years have been reorganised and are reorganising due to increased population mostly migration. This ever increasing and irreversible urban growth has given impetus to understand urban morphology in depth and its implications on surrounding nature. Rapid urban growth in Indian scenario can be attributed to rural to urban migration, re-classification of cities, availability of improved health facilities, jobs, improved living, availability of essential amenties etc. in urban areas (Bharath et al., 2018). With the commencement and successful implementation of urban development policies and schemes such as Smart Cities, AMRUT, JNNURM, etc. have promoted migration from rural area to urban core (Shaw & Das, 2017). In 2010, India accounted for 30% of urban areas with 367.5 million people residing within. A clear jump in can be observed in urban population post 2000 (figure 1).

An important decision was taken during September 2015, UNSDS with title “Transforming our world: the 2030 Agenda for Sustainable Development” in thinking of global community in adopting the Agenda for Sustainable Development (SD) through vision 2030. Goal number 11 of 17 Sustainable Development Goals (SDG) elaborates ‘Sustainable Cities and Communities’ and guidelines to meet these criteria. In addition, article 76 of 2030 agenda pronounces use of geospatial data for tracking and monitoring the progress of various projects under the umbrella of SDG’s. In this regard, the creation of big data pertaining to cities, specifically the buildings that are the significant portion will be of paramount importance. The recent development of machine-learning algorithms coupled with geospatial data are among the front-runner technological tools, expected to play a crucial role. Geospatial data sets provide the means to study large area of the earth surface and helps to generate necessary data from complex urban surface features. Geospatial data majorly comprises of satellite data and GIS data. Satellite remote sensing (RS) has been credited for its quickest and lesser cost available method of mapping large areas. The availability of high resolution and multi-spectral satellite imagery provides the best accuracy needed for assessing urban growth pattern (Bharath et al., 2014). Satellite technology and data analysis are adopted by both regional and national governments (Chen et al., 2000; Ji et al., 2001). It helps to map urban areas at finer scales,

both temporally and spatially with consistent images of Earth surface. Remote sensing, its analysis and integration with geographical information systems (GIS) forms a robust technology to monitor temporal urban growth. GIS platform has entered majority of the service sectors by providing facilities to capture, manage, store, retrieve, analyze and display geospatial data on a real-time basis. Further strength to GIS comes from its distinguished built-in database, decision support system and application-specific plugins, makes more reliable tool for urban studies (Tran et al., 2015; Boori et al., 2015).

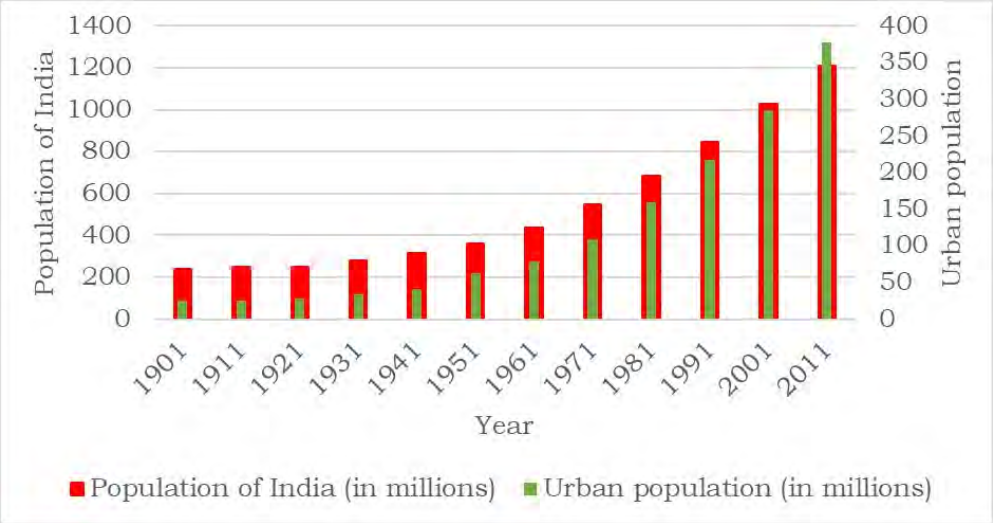

Figure 1 Trends of urbanization in India 1901-2011

Recently, machine learning techniques for building extraction information from remote sensing images has become easier with the advent of integrating various approaches on the same platform. Speed and accuracies of digital image processing have improved significantly with the use of several machine-learning algorithms. Random forest (RF) and Support Vector Machine (SVM) methods of learning algorithms proved efficient in information extraction from satellite imagery (Thanh & Kappas, 2018). Having previous and present years' temporal data, it is necessary to have a vision of development for the near future in terms of urban modeling. It is the process of identifying a theory, could be translated into a mathematical model as well as developing specific computer-aided programs to feed the model with data to calibrate, validate, verify and predict future urban trends (Verburg et al., 2002; Batty, 2009).Theoretical assumptions, method followed, spatial, temporal aspects and geographical extents might vary from each model types, but the final outcome of these models are to understand the complex interrelationships between natural ecosystem and urban environment by observing irreversible heterogeneous patterns of change (Li & Liu, 2006; Crooks, 2010). Wu and Silva, 2010 reviewed urban land dynamics and related models, depicted in figure 2. They highlight the significance of artificial intelligence (AI) and its deep theoretical understanding of urbanization process and relative pressure on land use pattern change. Figure 2 shows broad categories of AI systems used in urban models. In this research paper we discuss briefly about cellular automata (CA), SLEUTH model, optimization techniques such as genetic algorithm (GA) and particle swarm optimization (PSO), its application to urban growth models. The structure of the paper is organized as follows: sub sections 1.1-1.3 provides a brief overview, literature review of Cellular automata and SLEUTH urban growth model, its improvement over last two decades, integration of stochastic optimization

techniques to SLEUTH and building extraction for urban growth application. Section 2 describes the study region selected to implement modeling and extraction of building information along with data sources. In section 3 we describe the novel integrated method adopted to solve time-consuming conventional modeling problem countered with PSO-SLEUTH. Results are discussed with statistics and visualization in section 4. Finally, conclusions are given in section 5.

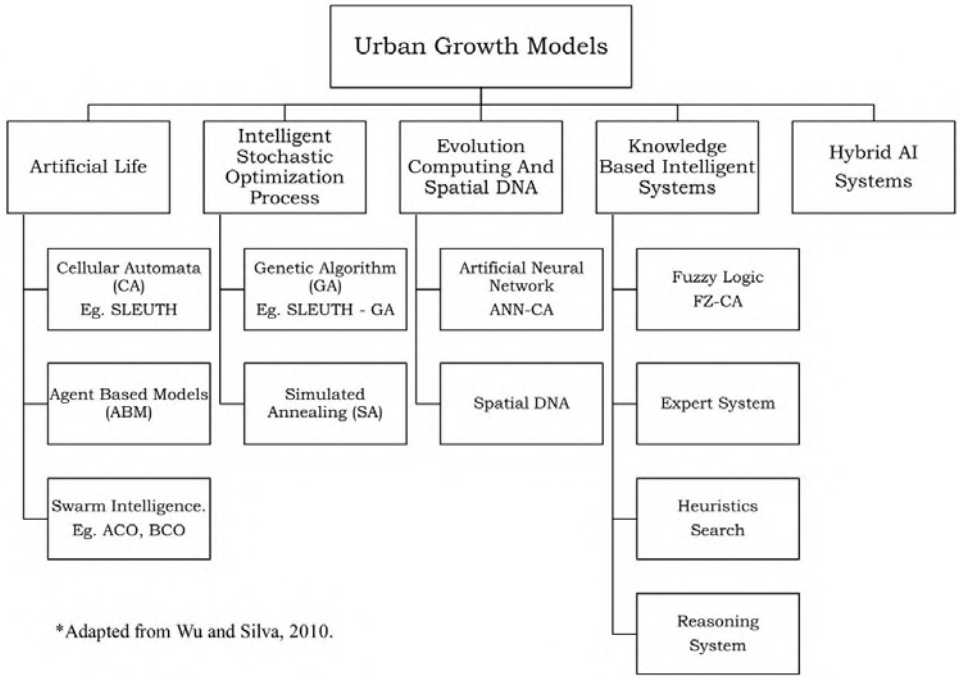

Figure 2 Types of urban growth models

1.1. Cellular automata and urban growth models

Wolfram, 2002, defined CA as discrete two dimensional dynamic systems in which local interactions among components generate global changes in space and time. Torrens, 2000 explains CA is composed of the below four components:

1. Cell space represented by an array of cells
2. Several finite states that qualifies the state of each cell
3. Neighborhood
4. Transition functions, define the next state of the cell in the next period, based on the given state of the cell itself and its neighborhood cells

Standard cellular automata apply a “bottom-up” approach. The approach argues that local rules can create complex patterns by running the models in iterations (Batty & Xie, 1994). Itami, 1994 states that CA are seen not only as a framework for dynamic spatial modeling but as a paradigm for thinking about complex spatial-temporal phenomena and an experimental laboratory for testing ideas. Researchers have successfully used CA in urban modeling over the decades and now have tried to address various related research questions with the help of CA-based models (Alves & Albrecht, 2010; Yang et al., 2012; Torrens & Benenson, 2005).

SLEUTH is a CA-based urban growth model, started as open source, has witnessed numerous applications over different parts of the world. The acronym of SLEUTH stands for slope, land use, excluded, urban, transportation and hillshade, the layers used as input for the model, consists of C-language, using UNIX or UNIX based operating systems (Nimish et al., 2018; Chandan et al., 2019). It has an ability to predict urban/non-urban land use dynamics based on two sub models: urban growth model (UGM) and Deltron land model (DLM) (Dietzel & Clarke, 2004). Model is dependent on five factors controlling the behavior of growth: diffusion, breed, spread, slope resistance, and road gravity. It also considers four growth rules: spontaneous growth, new spreading center growth, edge growth, and road-influenced growth. Best set of coefficients are derived for the five factors using these four rules. Traditional brute force method (BFM) takes days together to arrive at three phases of calibration i.e., coarse, fine, full and shortlisted values for prediction. Most researchers have made successful attempt to reduce SLEUTH computation time and therefore to increase its efficiency. The original version includes SLEUTH UGM and DLM. To reduce computation time, Dietzel and Clarke, 2007 worked on the development of optimization of SLEUTH metric called optimal SLEUTH metric (OSM). OSM narrows down the parameter range and returns a single goodness of fit metric. OSM is the product of various individual metrics like compare, population, edges, clusters, slope, X-mean and Y-mean providing reliable calibration results. The source code for OSM is also available in Project Gigalopolis website and one can readily implement OSM technique. Sakieh & Salmanmahiny, 2016 explored OSM and implemented to Gorgan area of Iran. Authors have mentioned the term “cancer-treating” to understand and predict the urban spread in three different scenarios: afforest protection, rangeland protection and historical growth (without any restrictions). They have also adopted a comparative assessment to measure association between landscape metrics and land suitability values using Spearman correlation to address cancer-treating urban growth pattern. Other improvements of SLEUTH include pSLEUTH, SLEUTH-3r and SLEUTH-Genetic Algorithm (GA) (Guan & Clarke, 2010; Jantz et al., 2010; Clarke-Lauer & Clarke, 2011). GA returns a single best fit statistic for the entire dynamic range consisting of several Monte Carlo iterations. Research in the area of improving run time and various variable optimisation in SLEUTH model is yet unexplored by scientists and this paper presents this novel technique of integrating PSO rules with existing sleuth model to improve its run time by optimising the initial set of variables.

1.2. Integration of genetic algorithm and particle Swarm optimization techniques with SLEUTH

GA includes heuristic search algorithms based on natural selection and natural genetics using the key concept of simulating, imitating or mimicking evolution process to obtain optimized results (Holland, 1975; Goldberg, 1989). It adopts Darwinian “Survival of the fittest” theory, only the fittest shall survive, reproduce and successive generations shall become superior compared to older generations (Mayer et al., 1999). Developed by Holland in early 1970s, the central theme of GA is robust optimization technique which considers independent variables of the model and converts them into genetic pairs (binary).

SLEUTH-GA is adopted to improve calibration process and to obtain optimized values in less computation time. Figure 3 shows SLEUTH-GA model calibration approach. Coarse, fine and final calibration procedure employed in BFM is replaced by GA calibration, apart from which other procedure remains same. Strength of GA comes from its ability to explore search space with improved results after each iteration. GA applied to SLEUTH follows a four-step process:

Population initialization, Selection strategies, Crossover breeding and finally Mutation. In SLEUTH procedure, the minimum and maximum value for a gene is fixed as 1 and 100 respectively, defining the range of each coefficient. Overall GA analysis involves calibration of metric values, number of iteration needed for calibration and assessing forecasting behaviour (Jafarnezhad et al., 2015).

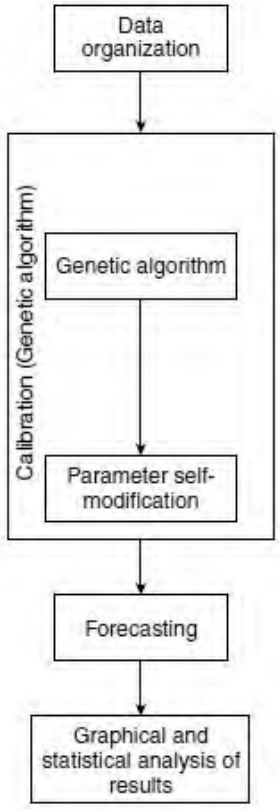

Figure 3 Genetic algorithm and SLEUTH model calibration approach (a Proposed approach based on Goldstein, 2004)

PSO is a population-based stochastic optimization technique inspired by social behaviour of birds flocking and fish schooling (Eberhart & Kennedy, 1995). Each solution to a problem is considered as a bird called particle. All particles have fitness values, and these values are calculated from objective function. Each particle has personal best and global best performance; velocity of the group is adjusted based on best performer in the group. While the advantage of PSO is that complex problem can be solved cost effectively with improved performance whereas unlike several Swarm intelligence-based optimization techniques, PSO also has limitation of particles escaping local optimum and decreased chances of finding global optimum (Shi et al., 2011). Feng et al., 2011 conducted a study to explore advantages of integrated CA and PSO approach. Objective of the study was to stochastically optimize transition rules and therefore reduce computation time, prediction uncertainties as well as improving location accuracy, a case of Fengxian District, Shanghai, China. Authors claim similarity between PSO and CA drives to search global optimum parameters of CA rules. Further, this concept can be applied to SLEUTH-PSO spread optimization to reduce computation time and predict accurate transitions. PSO optimizes allocation of pixels by

considering 3 x 3 kernel and returns a set of eight values that represent Moore neighborhood as illustrated later in figure 10.

1.3. Urban building structure extraction

Machine learning techniques such as Random Forest (RF) and Support Vector Machine (SVM) are employed by scientists to extract buildings in urban areas. Random forest classifier is made up of an ensemble of multiple decision trees, here majority voting from the decision tree classifiers with 'yes' or 'no' outputs are used to classify the data (Breiman, 2001). The outlier in training is well handled by RF is advantageous in classifying spatial data efficiently (Horning, 2010). SVM works on the principle of identifying right hyperplanes that maximizes the distance to the closest data points on both sides of the classes (Vapnik, 1995; Dixon, 2008; Das et al., 2018). SVM is a supervised learning technique and it can be applied to a multiclass classification. In SVM classification, four kernel functions could be used based on the transformation needed, namely sigmoid, radial basis function, linear and polynomial. Previous studies showed that radial basis function performs best for binary classification from satellite images (Prakash et al., 2018).

There currently exists a gap in planning and visualization of urban structures at metropolitan scale and beyond, that modeling can fulfill with agenda of developing sustainable smart cities. It is also necessary to have insights through dynamic integrated urban growth models. Based on above discussion and detailed literature survey, we have identified the research gaps, aiding in forming major objectives of this research communication as: a) Extracting building from high-resolution satellite imagery, b) Analyzing spatio-temporal changes in urban land use for Kolkata Metropolitan Area, c) Modeling future trends of urban growth using an integrated CA-based SLEUTH-PSO approach.

2. Study area and data

Located at the eastern part of India, Kolkata has been considered for study is also famously known as "The city of Joy" or "Calcutta" during the British rule in India. The city is built on the banks of River Hooghly. The geographical extents of Kolkata metropolitan area (KMA) are (depicted in figure 4) 22°19'59" - 23°0'20" N and 88°4'23" - 88°32'37" E. Kolkata lies about an average of 3-9m above the MSL and situated very close to Ganges delta and Bay of Bengal. The city served as former capital of British India from the year 1772-1911 and presently it is the capital of West Bengal state. The region is also famous for numerous number of wetland ecosystem, natural tanks and lakes. Taking advantage of all four transport modes i.e., road, railway, airway and waterway, Kolkata has emerged as one of the dominant urban centers of Eastern India. Metropolitan urban agglomeration has an area about 1886 km^2 (KMA) with population of 14,035,959 (Census of India, 2011), makes it to the 3rd rank in metro cities of India after Mumbai and Delhi. Currently the physical infrastructure, services, planning and development of the region is administered by Kolkata Metropolitan Development Authority (KMDA).

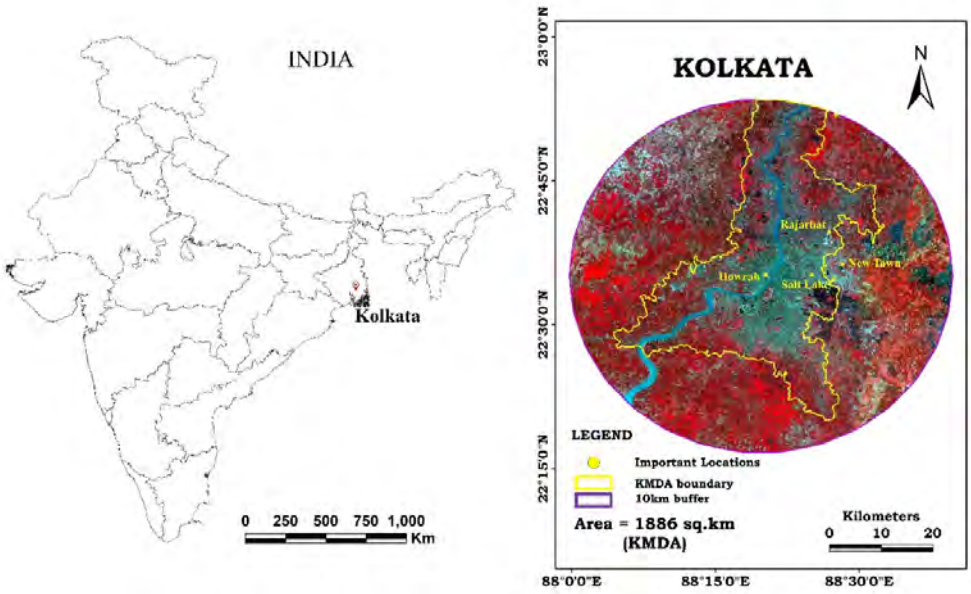

Figure 4 Location map of Kolkata with false color composite as background derived from IRS LISS4 satellite data (Bands: 2,3 and 4)

Stable and floating population can be attributed to a majority of people commuting as tourists, state and central governmental office affairs, academia, healthcare, economy-oriented conferences and so on. Apart from these, region is a commercial hub of East and North-East India with Rs 1.84 trillion GDP in 2014. Figure 4 illustrates the KMDA with 10 km buffer to understand the influence of expanding urban trends, its influence on environment, and future scenario on the periphery. Data required for the study are listed in table 1.

Landsat series (5 and 8), ASTER, Indian Remote Sensing LISS 4 and Cartosat satellite data were obtained from United States Geological Survey (USGS) and National Remote Sensing Center (NRSC). During field visit (figure 5), GPS was used to collect ground truth data of various points and polygons, geo-tagged images were also obtained, aiding in validating land use maps. Toposheets from Survey of India online repository, of scale 1:25000 and 1:50000 were also considered to delineate base layers of administration and other boundaries. City development plan maps obtained from governmental agencies helped in understanding and digitizing restricted areas of future urban expansion for instance: lakes, military area, reserve forest, parks, wetland regions etc. Google earth platform was used as ancillary data in places which were not accessible for GPS data collection. Road network was digitized directly from Google earth and open street maps (OSM).

3. Method

An integrated method adopted for building extraction and urban growth visualization is depicted in figure 6.

Table 1 Data and layers used for the analysis

Data/Layers		**Purpose/Source**		
Google earth		Geo-correction, classification and validation. Collection of point, line and polygon data.		
Boundary maps and raster layers		To create excluded maps or regions restricted from future development data sets based on City Development Plans.		
Survey of India Topographic maps, online portals (Google and Bhuvan data).		Base layers of the administrative boundary.		
Field data – Using GPS		Geo-correction, training data and validation data, Agents Extraction		
Slope and Hillshade		Processed from ASTER DEM (raster)		
Transportation (Roads)		Street data (OSM, Bhuvan and Google maps) updated with classified images (originally vector, rasterized).		
Satellite data		Land use analysis, slope, hillshade maps, building and urban data extraction		
Satellite/Sensor	Resolution (m)	Date	Path/Row	Remarks
Landsat 5 TM	30	06-Mar-1991 28-Mar-1999 07-Mar-2009	138/44	--
Landsat 8 OLI_TIRS	30	13-Mar-2017	138/44	--
ASTER GDEM	30	17-Oct-2011	N22E088	Reprojected to UTM
IRS LISS 4	5.8	17-Mar-2018	108/56	Reprojected to UTM
IRS Cartosat 2	1	02-Jan-2018	N. A	--

3.1. Pre-processing

To avoid inconsistency between different datasets, pre-processing of data along with geometric correction, resampling wherever necessary (to maintain similar resolution) and

image enhancement were conducted. Satellite images were geo-corrected using ground control points (GCP) collected during field visit and data pertaining to study regions were cropped according to buffer boundary. Contrast stretching was performed wherever necessary to maintain the dynamic range. Satellite data were registered to world geodetic system (WGS) 84, universal transverse Mercator (UTM) Zone number 45.

Figure 5 Data collection during field visit to Kolkata metropolitan area. A) Waypoints collected using GPS B) Wetland area and surroundings, Kamduni C) Hindustan motors industry (abandoned), Konnagar, Uttarapara and surrounding environs as seen from IRS LISS 4 FCC image (D) Panoramic view of Hindustan motors lake. (Date taken: 25 Aug, 2017, Source: Author)

3.2. Application of machine learning to extract buildings

The resourcesat LISS IV imagery of 5.8 meters multispectral is merged with the Cartosat 1.0-meter panchromatic image using Hyperspherical Color Sphere (HCS) method (Ghosh & Joshi, 2013). The resultant high-resolution color image is clipped for the study area KMDA with 10 km buffer. The training dataset is prepared for two classes; building and non-building category with the help of ground truth and observation from the spatial imagery. Machine learning classifiers (SVM and DT) are trained using the training data obtained from the multispectral image. The training set contains data from three bands that are labeled as '0' and '1' for non-building and building classes, respectively. The predicted output from the classifiers is divided into classes by judiciously identified threshold value to obtain a binary map containing building and non-buildings.

3.3. Land use analysis

Primary step of land use map generation is image classification. It involves various steps such as creation of FCC (false color composite) image directly helps in identifying heterogeneous patches in the landscape (Bharath et al., 2019). Bands green, red and near infrared are chosen to generate FCC image. Training polygons are digitized based on the spectral reflectance of

various features in FCC, covering the study area ensuring that polygons are well distributed throughout study region. These polygons and its coordinates are entered into GPS and ground truth data is verified during field visit to identify various land use types. A supervised classification technique famously known as Gaussian maximum likelihood classifier (GMLC) is adopted for the study. The classifier proves best amongst others because it takes into account variance, covariance and probability density contours to evaluate the land use class of every pixel under consideration (Duda et al., 2000; Ramachandra et al., 2012). Four land use classes were chosen for the study based on literature, they are: urban, vegetation, water and others (Anderson, 1976; Nimish et al., 2017).

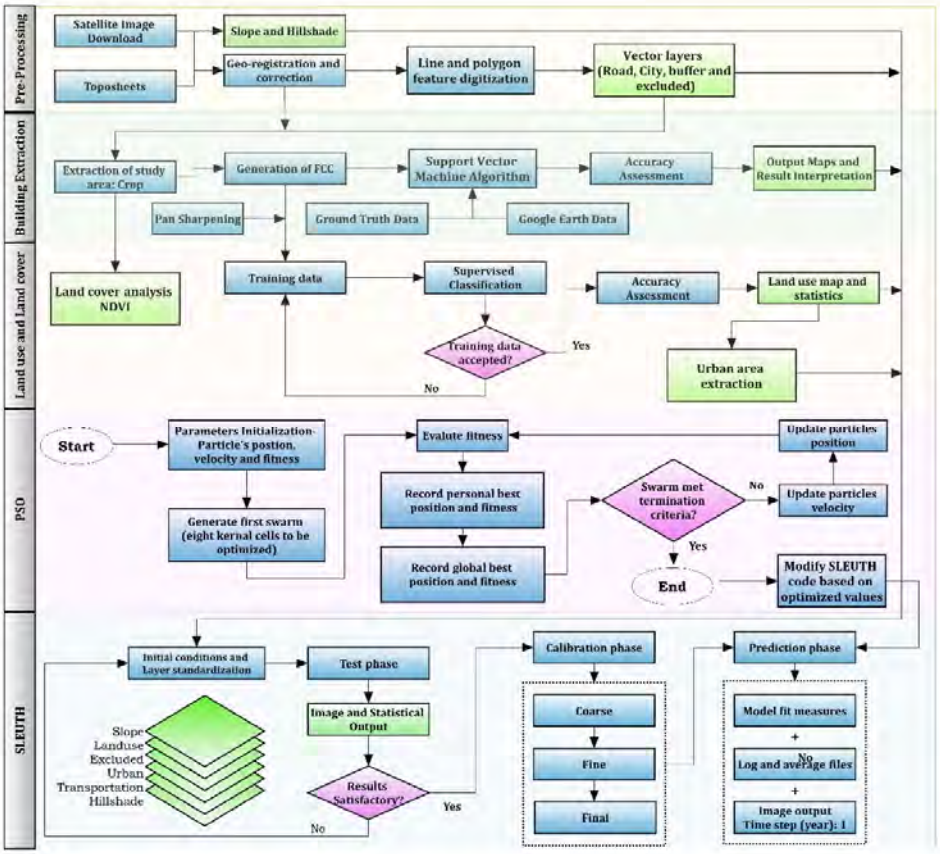

Figure 6 Integrated method adopted for the study

Accuracy assessment was performed in terms of overall accuracy and kappa statistic by comparing the classified map with the validation map. Error/confusion matrix generated helps to estimate producer's accuracy, user's accuracy, overall accuracy and kappa coefficient (Bharath et al., 2016).

3.4. Implementation of PSO and SLEUTH

PSO is popular among various nature-inspired techniques for its simplicity, minimum mathematical computation, achieving improved optimization in less computation time and ease of application to general engineering problems (Rabbani et al., 2011; Yao et al., 2015; Hu et al., 2018). PSO resembles the behaviour of a bird flock or fish school. PSO, in terms of bird flock can be understood as a) Search space of optimization can be treated as birds flying space

b) Every bird is treated as particle and has its own solution or its own space closer to food c) Optimum solution to the problem is considered as food to all birds d) Each bird will search for food, during this process one of the important strategy adopted is search for peripheral region very close to food e) All particles has fitness values f) Estimating position of food by personal flying experience, regarded as Pbest or pid g) All particles preserve their independent best performance h) Group adjusts their velocity based on best performer in the entire group, i.e. best value obtained at any time interval in the entire population is called as global best, gbest or pgd (Stephen et al., 2013). An assumption is made that in a D-dimensional search space with n particles includes possible personal best solutions and global best solutions. These are represented as given in equation 1.

$$V_{id}^{(t+1)} = WV_{id}^{(t)} + c_1 r_1 \left[p_{id} - x_{id}{}^{(t)}\right] + c_2 r_2 \left[p_{gd} - x_{id}{}^{(t)}\right] \quad (1)$$

Where,

i = Particle index; d = dimension/iteration

c_1 and c_2 are cognitive/social constants between 0 and 2

r_1 and r_2 are random numbers between 0 and 1, regenerated after every velocity update

p_{id} = population best or present best solution

p_{gd} = globally best solution

$V_{id}^{(t)}$ = particle's velocity at time t

$x_{id}^{(t)}$ = particle's position at time t;

Each particle keeps track of its coordinates in hyperspace which are associated with the best solution (fitness) it has achieved so far. The value of that fitness is also stored after every iteration. Each particle's position is updated using the equation 2.

$$X_{id}^{(t+1)} = X_{id}^{(t)} + V_{id}^{(t+1)} \quad (2)$$

Integrating concepts of PSO with SLEUTH includes creation of a new script (Script.sh) file containing eight Moore neighborhood cell values (as illustrated in figure 10) that are to be automatically updated after each swarm iteration and storing best values. PSO provides optimum spread solution ranging between 1 and 99 for these cell values. 1 indicating least chance of urban spread in that direction and 99 indicates highest chance. These best values obtained are then adopted in spread file of SLEUTH3.0 code with p01 patch. Standardized input layers (select) used for model is illustrated in figure 7. Routine full calibration was performed using brute force method (BFM), output controlstat.log file was carefully examined to obtain model fit statistics and optimum SLEUTH metric (OSM), calculated by multiplying metrics such as compare, population, edges, cluster, slope, X-mean and Y-mean. Best OSM was chosen and corresponding coefficient values were replaced in the scenario file during prediction phase.

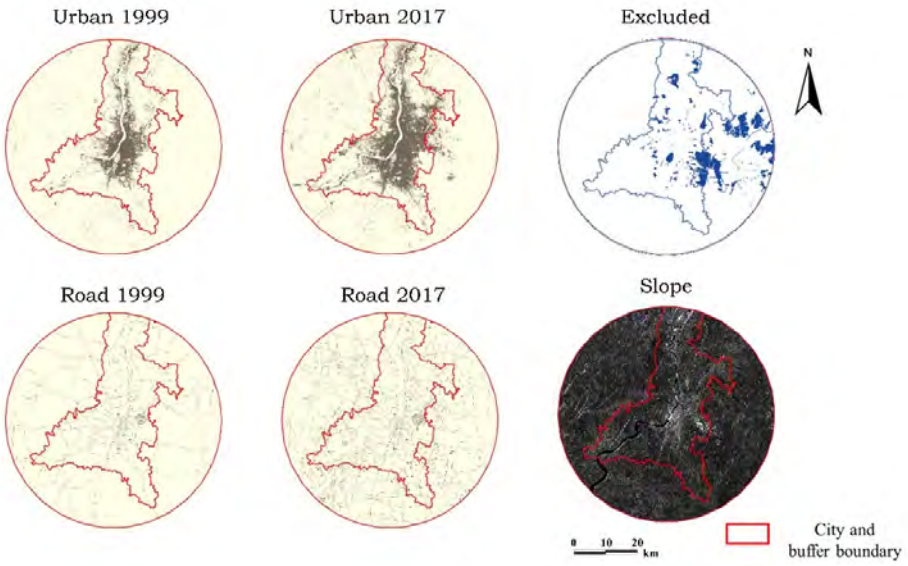

Figure 7 Standardized input layers used in PSO-SLEUTH model

4. Result and discussion

4.1. Building extraction

The data preparation for building extraction involves pan-sharpening of multispectral image using higher resolution panchromatic image. Figure 8, shows the subset of study area, Salt Lake, Bidhannagar, Kolkata, containing the dataset and extracted buildings. It is evident that from a closer look shows improvement in the quality due to image fusion in the picture (8C) and hence to obtain more detailed building information. In the binary output of reclassified image, white pixels represent the buildings and dark area corresponds to non-building class. Artifacts present in the output needs to be removed by performing morphological clean-up operations for further improvement of results. Outcome of this exercise is directly used in land use analysis and modeling as an ancillary urban dataset to describe the pace of urban growth as discussed over the next sections.

4.2. Land Use Analysis

For better understanding of the region, land use analysis was performed and results are as shown in Figure 9, corresponding statistics are tabulated in table 2. There has been significant increase in the urban areas consistently from 1990-2017. Strong economic and administrative base, high profile living, efficient service delivery mechanism, ease of access to public transport system and varied employment opportunities have been the major stimulators of urban growth in the study area. Nearby smaller villages have evolved into larger ones and many new settlements can be recognized along the transport corridors. Urban area saw an increase of 181% in just 27 years. Building extraction from high-resolution data also helps in quantifying urban growth on a microscopic scale. Water body has also seemingly increased in 2017, this can be understood on basis of visualization (temporal scale on Google earth) as well. Increase in water body, especially towards NE and SE directions are attributed to evolving aquaculture and pond ecosystem in the periphery of KMDA. However, significant waterbodies

in the form of ponds, lakes, wetlands, swamps, marshland etc. have been converted into other land use types or encroached over the period. Vegetation category shows consistent statistics, whereas other categories have decreased. Table 2 shows the kappa coefficient and overall accuracy of the classification.

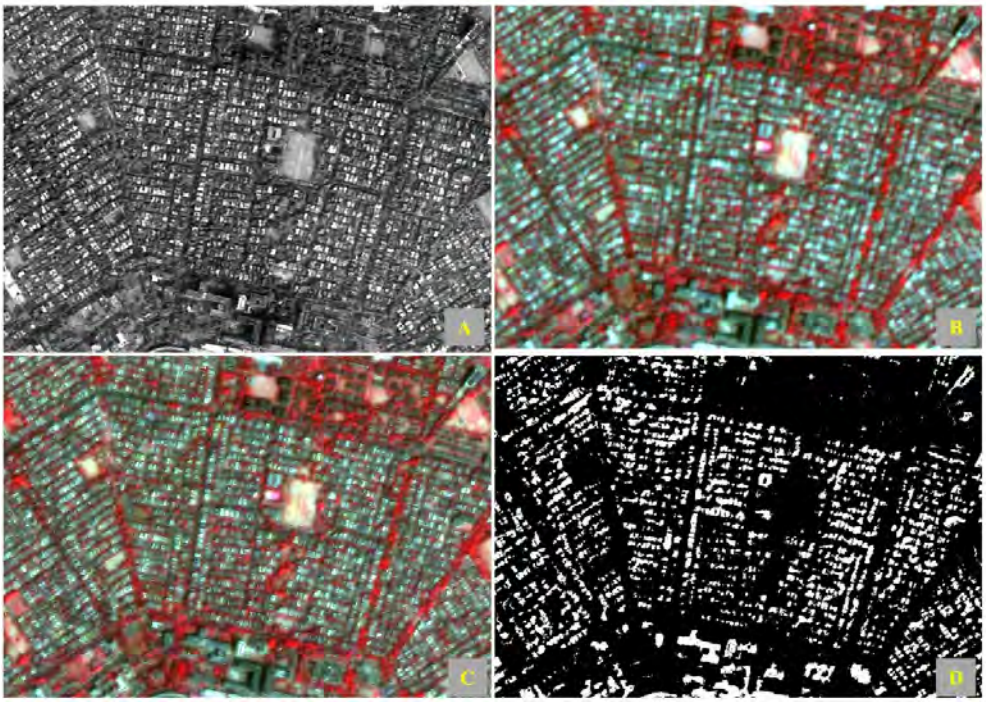

Figure 8 Data used and building extraction results for subset of study area, Part of Salt Lake, Bidhannagar, Kolkata: (A) Cartosat – 2, panchromatic, (B) LISS-IV multispectral, (C) Pan-sharpened image, (D) Extracted buildings

4.3. PSO-SLEUTH model

SLEUTH codes were modified with respect to spread optimization obtained from PSO. Spread optimization gave eight best fit values indicating eight directions of optimum growth as shown in Moore neighborhood network figure 10C. Best PSO results were achieved at run number 83 with an OSM value of 0.824. After adopting coefficients from BFM, the spread.c, script.c and scenario file were modified accordingly and routine run to obtain control stats and therefore model fit measures.

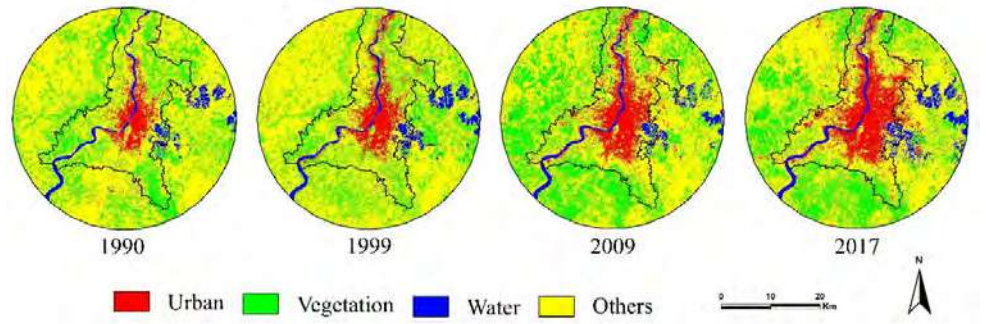

Figure 9 Land use results for KMDA region 1990-2017

Results obtained from PSO were compared with traditional brute-force method (BFM). Corresponding statistics are pictorially shown in figure 11. Substantial enhancement in terms of metrics such as Product, Compare, Edges, Clusters, Size, X-Mean and Y-Mean were observed by adopting PSO technique, while Population, Slope, % Urban and Rad showed minimum difference between these two methods. Leesalee metric was higher in BFM method with a value of 0.519 and lesser in PSO with a value of 0.480. OSM was calculated, achieved OSM was 0.0501 during BFM and 0.600 during PSO-SLEUTH. This clearly shows significant improvement in calibration of coefficients with PSO improvised spread optimized pixel values. Another important development was observed in computation time. Post full calibration process, PSO took 4hours, 12mins and 32 seconds to yield model fit statistics. These results not only indicate the model robustness by integrating PSO, but also it can deliver excellent fit statistics without compromising optimum coefficients.

Table 2 Land use and accuracy statistics

Year	Land use categories				Accuracy assessment	
	Urban	Vegetation	Water	Others	Overall accuracy (%)	Kappa statistic
1990	4.12	23.08	4.2	68.61	88	0.94
1999	6.45	21.17	4.7	67.68	93	0.96
2009	9.04	28.23	4.73	58	91	0.85
2017	11.58	22.18	6.24	60	91	0.89

Further, prediction for KMDA was performed using best-fit coefficients. After three phase calibration, optimum growth coefficients were derived. Of all the coefficients, breed (52) and spread (64) showed medium values whereas road gravity was the highest (80). This indicates Kolkata region has a significant influence of breeding a new urban site in the periphery or spreading type of urban growth from already existing core urban area, can also be referred to as sprawling at the outskirts. High values of road gravity reflect road acting as key urbanization factor. To name a few, Kolkata region has major connecting roads (AH1) towards NW direction, Bardhaman, Durgapur and Asansol; SW direction Kharagpur and further this road (AH45) connects to Orissa; NE direction, AH1 connects to Jessore (Bangladesh) and other important road network such as: Grand trunk road, NH 34, 35, 117, SH 1, 2, 3, 13 and 15. Diffusion and slope resistance showed the lower values of 8 and 16 respectively. Prediction was performed using PSO-SLEUTH to potentially visualize the scenario of urban growth and it was estimated to reach 757.91km^2 in comparison with 494.73km^2 in 2017, can be observed in figure 12.

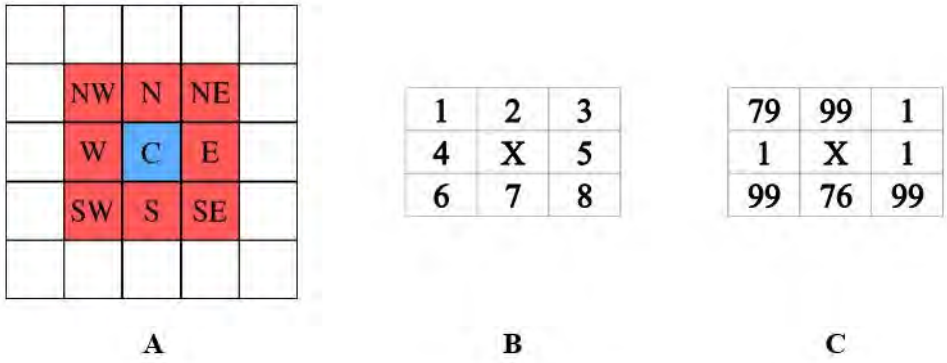

Figure 10 Optimization of pixel values based on Moore neighborhood. A) 3 x 3 kernel and directions B) Allotment pattern of pixel values in code C) Values achieved after running PSO

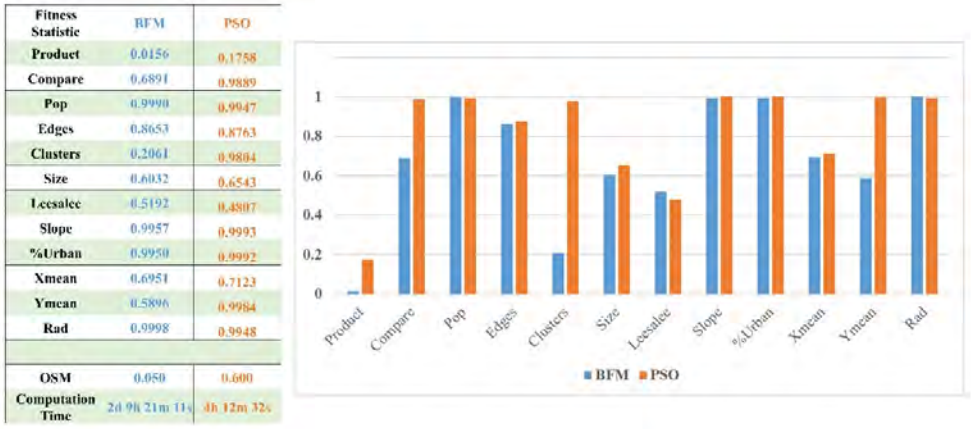

Fitness Statistic	BFM	PSO
Product	0.0156	0.1758
Compare	0.6891	0.9889

Figure 11 Summary of model fit statistics, comparison of metric values between BFM and PSO

5. Conclusion

Urban land use change is widespread, rapid and has direct effect on ecosystem and environment. It is mainly driven by human-induced activities carried out beyond limits and exploring natural resources to the fullest without any regard to concepts of sustainability. Extraction of building data from satellite imagery has always helped government agencies and planners to assess critical impacts of urban expansion on other land use categories. This research article highlights the significance of building extraction using high-resolution imagery and also discusses the potential of data merging, i.e., panchromatic image and multispectral image using pan-sharpening method to obtain binary classification of buildings, further this data can be used for modelling purpose as an ancillary dataset. This study also demonstrates the successful implementation and monitoring spatio-temporal urban growth using satellite data over a period of 27 years. Accuracies ranging from 88%-93% and kappa between 0.85-0.96 indicated excellent agreement between generated land use image and real-time dynamics.

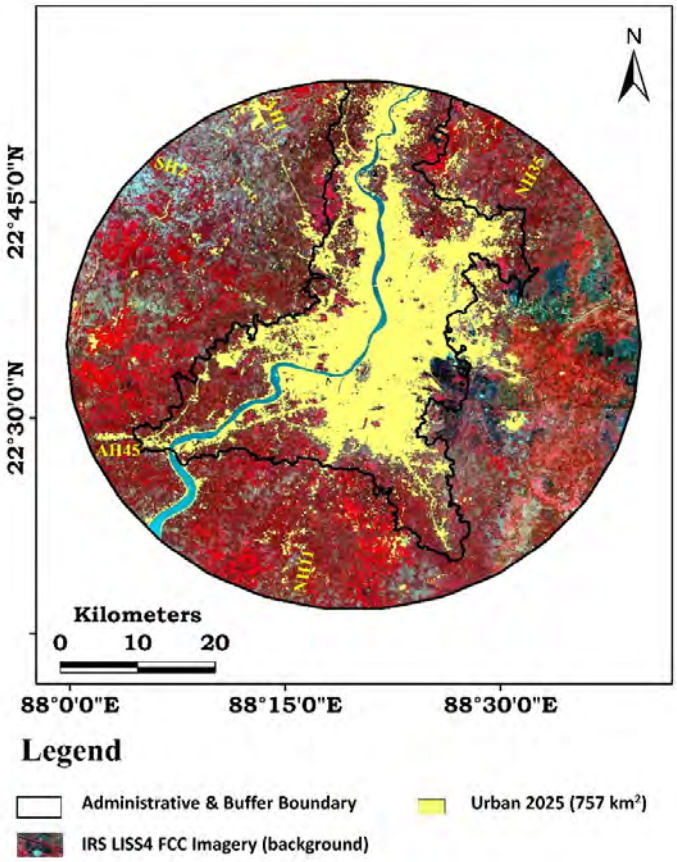

Figure 12 PSO-SLEUTH modeled output for the year 2025, KMDA region

Modeling and visualizing these changes have always been regarded, helps in formulating effective local, regional and national level sustainable environmental policies and management strategies. CA-based models, SLEUTH model in particular, its origins, theory behind, application and its strength when integrated with multiple tools, multi-disciplinary approach and recent advanced techniques such as genetic algorithm, particle swarm optimization, ant colony optimization etc. proves to be worthy urban models. In this study, we perform an integrated novel method of adopting PSO-SLEUTH to optimize spread using Moore neighborhood, calibration and prediction of urban expansion for the year 2025. Unlike other optimization techniques, PSO is faster in terms of computation time, efficient, reliable and has lesser parameters for human intervention. These advantages are explored in this paper, BFM based PSO-SLEUTH calibration saw excellent improvement in results and it can be realized by obtaining OSM of 0.6 using PSO in comparison with 0.05 using traditional BFM. Apart from OSM, other model fit statistics also showed satisfactory values suggesting the robustness of SLEUTH model to integrate with any other improvised algorithm. Visuals from model output suggests KMDA to have at least 757.91km^2 of urban land use by the year 2025, which is 53% increment from 2017. There appears to be a considerable gap in research when it comes to validation and accuracy of models. Adopting optimization techniques along with agent-based models seems to be governing aspects of future efforts. These statistics and findings insists administrators, planners and concerned government officials to focus on emerging land use issues and sustainable urban growth concepts.

Research Paper

URBAN PARAMETERS ANALYSIS AND VISUALIZATION

A Support to planning decisions for the definition of urban surface usages

Silvia CROCE, Institute for Renewable Energy, Eurac Research; Italy
Daniele VETTORATO, Institute for Renewable Energy, Eurac Research; Italy

Abstract

Several mitigation and adaptation strategies are proposed to tackle the environmental issues associated to massive urbanization and climate change. All these solutions are highly related to the utilization of urban surfaces (i.e. building envelopes, streets, public spaces, etc.). However, the existing trends demonstrate the lack of a systemic approach able to integrate multiple possible functions and avoid sub-optimal solutions. In this context, urban planning can play an essential role in managing conflicts among different surface uses and ensuring their integration. This involves making spatially explicit decisions about the types of surface use allowable, and their extent and location. The decision-making process needs to be supported by accurate and detailed knowledge about the spatial distribution of a variety of parameters that influence the surface uses in cities.
This study presents a systematic framework to support planning decisions based on accurate, diverse and spatially explicit information, and discusses its application in a residential district located in Bolzano (Italy). The proposed method implies the assembly of a multivariate spatial database of significant morphological and environmental parameters acquired through environmental simulation techniques and on-site data collection. The three-dimensional visualization of this database represents a solid base to relate urban planning decisions on surface uses to their effects in terms of microclimatic conditions, thermal comfort, and on-site renewable energy production.

Keywords

Urban surface use, urban microclimate, urban morphology, spatial information, data visualization

1. Introduction

Massive urbanization and rapid growth of urban population worldwide are exposing cities to several stressors, many of which are largely driven and intensified by global climate change. More than half of the world population and the majority of the economic activities are located in urban areas (World Bank, 2018); this makes cities among the major contributors to climate change as well as particularly vulnerable to its impacts, facing major weather and environment-related challenges (Baklanov et al., 2018). Therefore, it is becoming essential for cities to develop strategies for controlling local climatic and biophysical conditions, protecting inhabitants and infrastructures from extreme weather events, and using their resources

efficiently. In this context, city planning is emerging as a key practice to contribute to the well-being of the urban environment. Hence, one of the most effective ways to address the challenges posed by urban development and climate change is to include responsive resilience strategies into the current planning processes. This arises the need for sets of data and information able to support urban planners and decision makers in implementing effective measures to address the most critical issues and vulnerabilities (Giordano *et al.*, 2019).

Climatic conditions in cities constitute a relevant issue for urban design, as they affect human thermal comfort, impact the energy consumption for heating and cooling, and influence the use of open and public spaces. These conditions are determined by the physical and morphological features of each urban areas, such as the distribution and density of the buildings, the materials characterizing their surfaces, the presence of vegetation, etc. Hence, the analysis and understanding of this environmental and geometrical attributes is an important step to identify responsive solutions at the urban and building scale during the design process (Silva et al., 2018). In this scenario, urban design and urban planning play a key role. However, despite the development of numerous studies and scientific techniques, current city planning processes does not thoroughly make use of the knowledge generated by the available research on the field. Furthermore, current policies, such as those aimed at the reduction of urban heat island (UHI), are often applied uniformly to all the areas of a city, neglecting the spatial variation of climatic conditions in relation to the urban form (Danahy *et al.*, 2015). To address this lack of awareness, there is the need for going beyond both abstract analyses on single physical and atmospheric processes, and studies on single urban areas, by implementing an interdisciplinary approach to consider the interrelation of climate, city structure, and thermal comfort (Eliasson, 2000; Martinelli and Matzarakis, 2017). Two- and three-dimensional (3D) visualization processes can increase awareness of the role of urban and environmental features and their spatial variability. Moreover, they can support urban decision makers in investigating the local effects of general policies, in comparing several strategies, and in communicating the different options to the involved stakeholders and to the citizens (Danahy *et al.*, 2015).

This work proposes an approach to reduce the gap between scientific research and the real challenges of its integration into practice at urban scale by setting a framework to inform urban planners and decision makers about the relevant characteristics of each area, and the impact of their decisions on microclimate, human thermal comfort, and on-site renewable energy production.

1.1. Urban surface use definition: the role of urban planning

In the current scenario of urbanization, growth of urban population, and global climate change, several strategies are being proposed to tackle the correlated environmental issues. All these solutions are highly related to the utilization of urban surfaces, which are considered as key element in our approach. The term “urban surfaces” identifies all the surfaces that characterize physically and morphologically the three dimensions of the built environment, including the horizontal and vertical surfaces of the ground and of the building envelopes (Croce, Vettorato and Paparella, 2019). Ground surfaces comprise the road network and the urban open spaces, while building envelopes’ surfaces include façades and rooftops. Urban surfaces can be characterized by different materials and can host several functions. With “urban surface usage” we define the way a surface is deployed to address urban resiliency - protection of people and infrastructures from extreme climate events - and sustainability - efficient use of resources - objectives. The term encompasses all the materials and solutions

that can built-up the different surfaces or be applied on them. The main solutions, clustered in five main categories, are schematized in Figure 1.

Figure 1. Overview of the main categories of urban surface uses.

Once being seen only as a cost, due to their maintenance (Becchio *et al.*, 2011; Augeri, Greco and Nicolosi, 2019), urban surfaces are becoming a key opportunity for cities in latest years. Their exploitation offers the opportunity to increase resource efficiency, to exploit renewable energy sources, and to reduce the overall environmental impact (Kellett, 2011; Sadineni, Madala and Boehm, 2011; Toboso-Chavero *et al.*, 2018). However, the common approaches to urban surface use definition are still mainly focused on single solutions (e.g. urban vegetation, use of reflective materials, etc.), and on pursuing single objectives. Furthermore, these approaches are often bi-dimensional, still strongly connected to the concept of land use (Davoudi, Crawford and Mehmood, 2009; Yiannakou and Salata, 2017), disregarding the three-dimensional complexity of the build-environment.

The existing trends demonstrate the lack of a systemic process able to integrate multiple possible solutions, and to avoid sub-optimal solutions. For example, in cities, conflicts are arising between the surface uses for renewable energy production, urban agriculture, and green solutions (Penaranda Moren and Korjenic, 2017). Urban planning is essential to manage conflicts among different surface uses and ensure their integration in the process toward resilient and sustainable cities (Kellett, 2011). This involves making spatially explicit decisions about the types of surface use allowable, and the extent and location of these. This decision-making process needs to be supported by accurate and detailed information about the spatial distribution of a set of parameters. Indeed, many environmental and morphological features influence the distribution of surface uses in cities and affect the priorities for their definition. These parameters not only include the morphological and geometrical features of the urban areas, which can be easily assessed and are already part of traditional urban design processes, but also a variety of environmental and microclimatic parameters. Hence, a clear understanding of the physical interaction between the built environment and the climate boundary conditions is crucial to determine truly responsive strategies.

2. Morphological and environmental parameters

This study presents a systematic framework to support planning decisions about the mix of surface uses and their spatial arrangement in the urban environment, based on accurate,

diverse and spatially explicit information. The method implies the assembly of a multivariate spatial database of significant morphological and environmental parameters, obtained from environmental simulation techniques and on-site data collection. The three-dimensional visualization of this database represents a solid base to relate urban planning decisions on surface uses and their effects, e.g. in terms of microclimatic conditions enhancement and on-site renewable energy production. Furthermore, it provides an easily understandable way to recognize specific elements of the urban environment and orient the design process. This section presents an overview of the main parameters, their role, and characteristics.

2.1. Morphological parameters

Several studies have demonstrated that the urban spatial configuration can influence the local climate (Pisello *et al.*, 2018; Shooshtarian, Rajagopalan and Sagoo, 2018). Indeed, the replacement of natural, permeable surfaces, with mineral materials is the main responsible of both UHI and surface storm-water runoff problems. The low albedo of materials applied on the majority of the urban surfaces is cause of the increase of solar radiation absorption and consequent high surface temperatures. Furthermore, the territorial expansion produced by the urbanization increases the land consumption and causes relevant changes in the land use. Consequently, the reduction of green spaces due to the territorial expansion produces a serious environmental degradation with the loss of urban ecosystems. The increase of buildings heights and urban density is responsible for low induced wind velocities, which impede suitable heat removal rates. Therefore, the proper understanding of the site geometry and urban surfaces features is crucial.

Among the main parameters used to characterise the urban structure there are the building height, total height-to-floor area ratio, building volume density, the aspect ratio and the sky view factor (Oke, 1990). The aspect ratio (H/W) defines ratio of the mean building height (H) to road width (W). The larger is the H/W, the denser is the urban area. The sky view factor (SVF) is defined as the portion of sky visible from a specific point inside the urban area. Its values ranges from 0 to 1, which refer respectively to a completely obstructed and unobstructed sky. SVF has an important role in determining the receipt and loss of radiation in the built environment. During the day, a low SVF will result in less incoming solar radiation in the urban canyon, affecting the ground surface as well as the air temperature. While during nighttime, it reduces the loss of long-wave radiation to the sky and the turbulent heat transfer in the canyon air.

The urban built environment is constituted by a variety of surfaces, whose properties play a key role. The most relevant thermal and radiative properties of urban mineral surfaces include the type of material, its albedo, emissivity, and thermal conductivity. Albedo plays an important role in the surface energy balance; it is defined as the ratio of solar radiation reflected to the amount of radiation absorbed by a surface (Kotharkar, Bagade and Ramesh, 2019). With regard to natural, permeable surfaces, soil type, and vegetation type and species influence the variability in local urban climate (Vuckovic, Kiesel and Mahdavi, 2017).

2.2. Environmental parameters

Environmental parameters include the main physical quantities characterising the microclimatic conditions in an urban area, i.e. air temperature (T_{air}), surface temperature (T_s), mean radiant temperature (T_{mrt}), global shortwave solar radiation (Irr_{SW}), and wind speed (W_s) and direction (W_{dir}). These variables are also used to calculate the thermal environment by means of suitable indexes, such as the Universal Thermal Climate Index (UTCI), which

evaluates the human thermal perception and the correlated grade of physiological stress (Jendritzky, de Dear and Havenith, 2012; Pappenberger *et al.*, 2015).

2.3. Data sources

Access to spatialized data at the appropriate resolutions is important to correctly represent the distribution of morphological and environmental features, and to characterise urban phenomena, such as the microclimatic conditions. Figure 2 presents an overview of the main parameters and the main data sources.

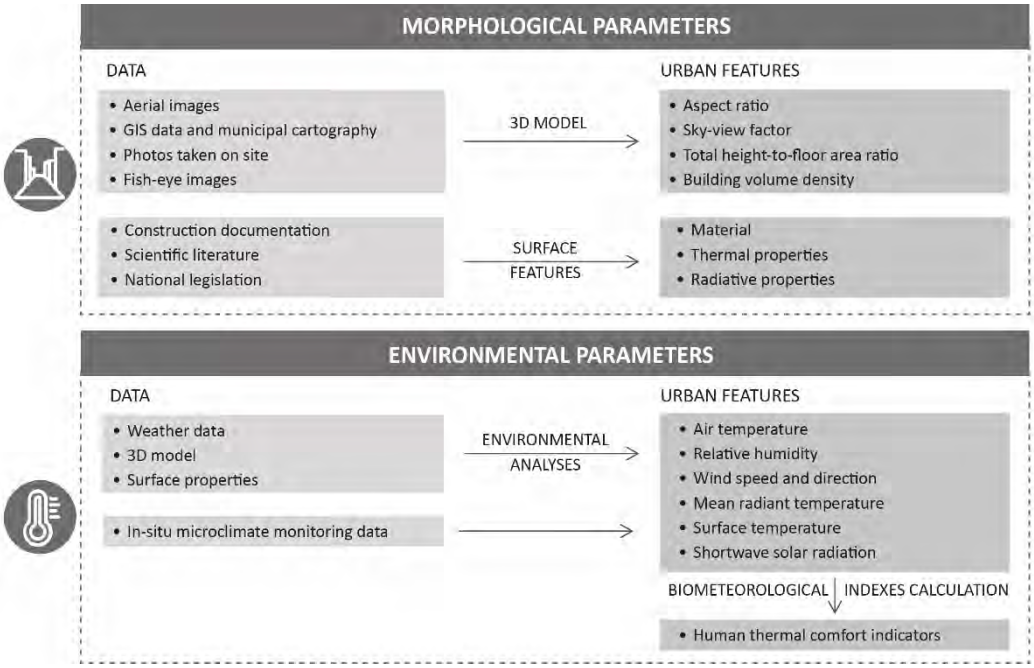

Figure 2. Parameters influencing the definition of urban surface uses, and main data sources.

A variety of data is suitable for the creation of the 3D model of an urban area. Aerial images and photos taken on-site are used to define the geometrical characteristics of the buildings, the finishing materials of the urban surfaces, and the presence and typology of the vegetation. Based on this, different methods and techniques are available to analyse urban morphological parameters, ranging from spatial metrics to the use of satellite images.

The local climate conditions can be assessed by measuring the main microclimatic parameters in-situ, with the use of weather stations (Pyrgou et al., 2017), extensive sensor networks (Tong et al., 2018), or mobile meteorological stations (Chokhachian et al., 2018). However, setting up and maintaining an in-situ monitoring network is resource and time consuming, and not always feasible due to technical reasons. However, the interactions between the built environment and the climate boundary conditions can also be modelled and evaluated by means of numerical simulations. Several models and tools allow to conduct environmental analyses. Depending on the selected tool, it is possible to calculate single variables, such as the incoming solar radiation, or complex atmospheric process, such as wind flow, turbulence, processes of heat and vapour exchange at urban surfaces, and exchanges of energy and mass between the vegetation and its surroundings (Lobaccaro *et al.*, 2018). In this study, different tools have been chosen depending on the aims of each investigation; an overview is presented in Table 1.

Table 1. Main typologies of environmental analyses, aims, and tools used.

Analyses *(Parameters)*	Aims	Tools
Solar potential *(Irr_{sw})*	Identify the most irradiated areas and the surfaces most affected by overshadowing	*Rhinoceros*, *DIVA-for-Rhino*, *Honeybee* for *Grasshopper*
Microclimate *(T_{air}, RH, T_{mrt}, T_S)*	Define local microclimate conditions and verify impacts of specific modifications of surfaces uses	*ENVImet*, *Ladybug* tools for *Grasshopper, Rhino-2-ENVI*
Urban airflow *(W_s, W_{dir})*	Evaluate the natural ventilation and identify the prevalent winds in the district	*Butterfly for Grasshopper, OpenFoam*
Thermal comfort *(UTCI)*	Assess the human thermal comfort conditions	*ENVImet - BioMet*, *Rayman*

3. Data analysis and visualization for urban surface use definition

The traditional products of environmental simulation tools, abstract climate maps or descriptive texts can be confusing to non-experts, and lack the flexibility necessary for informing planning decisions in complex urban environments with competing demands. Relating urban form to local climate conditions plays an important role when facing several urban issues, such as urban heat island, energy resiliency, water availability, etc. Visualization can be used to guide an effective decision making process and to effectively represent the effects of surface use choices in a 3D model, making them more tangible. Figure 3 schematizes the structure of the proposed framework.

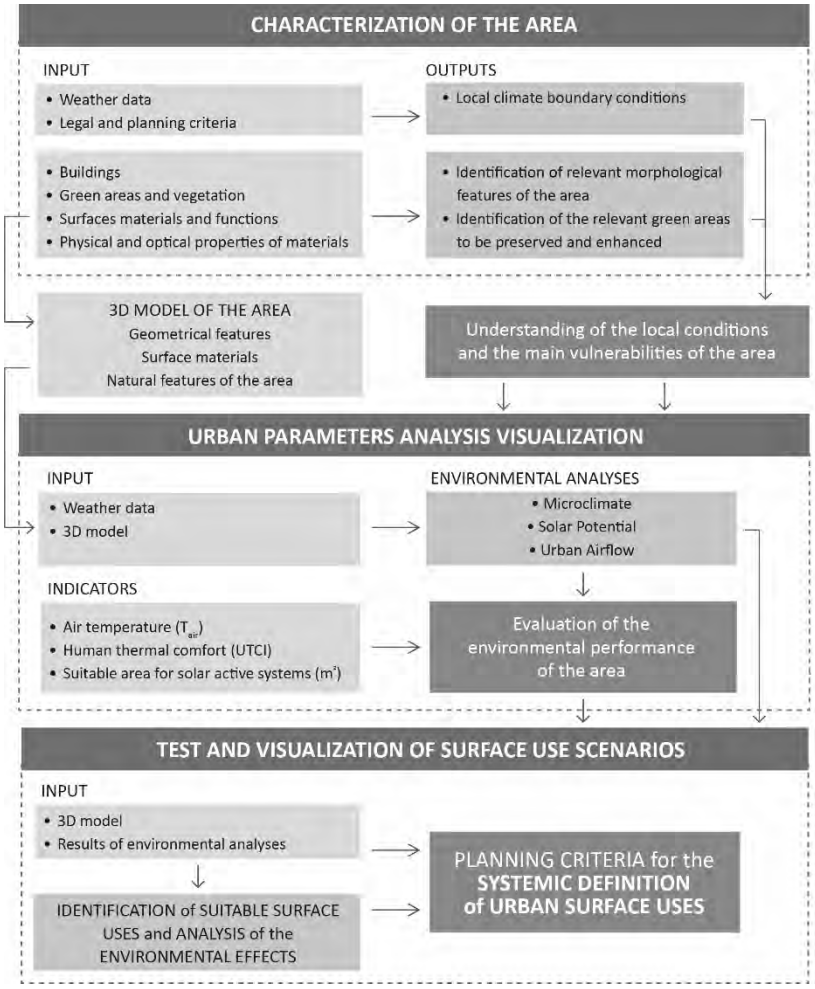

Figure 3. Scheme of the proposed process.

4. Application to a case study in Bolzano

In this section, the application of the proposed method is tested for the analysis of the current conditions and for the definition of suitable surface uses in an existing district in Bolzano.

The city of Bolzano (UTM 46°29'53.8" N, 11°21'17.1" E) is located in the north-east of Italy, at a height of 265 m above sea level; its climate is categorized as moist continental (i.e. “Dfb” Köppen-Geiger classification) and is characterized by strong seasonal fluctuations. The location of the city, which is situated in a basin surrounded by mountain ranges, often exacerbates high temperature and heat waves during summer, when T_{air} frequently exceeds 35 °C. In this context, the municipality of Bolzano is committed in mitigating the effects of climate change through several actions, such as the exploitation of RES, the energy retrofit of buildings, and the increase of urban vegetation by planting new trees and supporting the diffusion of green roofs.

The residential district selected as case study is one of the five areas in Bolzano taking part to the Smart Cities European project SINFONIA (SINFONIA, 2017); it includes two social housing blocks, being innovatively refurbished in the framework of the project, and the nearby buildings.

4.1. Characterization of the area under study

The area is characterized by the presence of five urban canyons: *Via Milano* and *Via Cagliari* from north to south; *Via Brescia*, *Garden*, and *Via Palermo* from west to east (Figure 4). *Via Palermo* is one of the main roads connecting the eastern and southern areas of Bolzano; due to its importance in the traffic network of the city, together with *Via Milano* and *Via Cagliari,* is considered as geometrical invariant. Therefore, the possible surface uses are restrained to the solely modification of the materials, while original geometrical and functional features are kept unvaried. On the contrary, *Via Brescia* and *Garden*, the central vegetated public area, are regarded as possible variants.

Figure 4. Aerial view, urban canyons, and morphological parameters in representative locations.

Being the mitigation of summer temperatures among the main objectives of Bolzano Municipality’s planning actions, the environmental characteristics of the area have been assessed for a typical hot summer day. Figure 5 visualizes the main surface uses in the district, together with the spatial distribution of some representative microclimatic parameters that have a major influence in defining the thermal conditions in the districts, i.e. Irr_{SW}, T_S, and T_{air}. The data visualized in 3D have been obtained from environmental analyses.

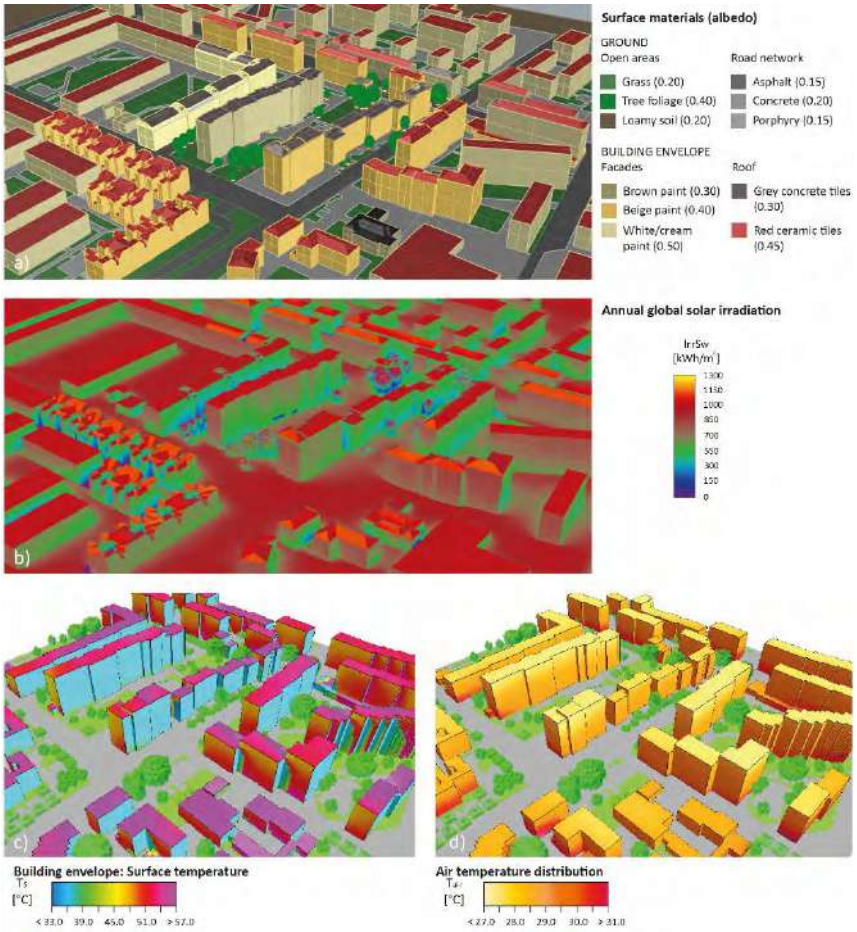

Figure 5. Surface uses (a), and spatial distribution of microclimatic parameters in the district.

The characterization of microclimatic conditions in the district is not only conducted through the use of tools for environmental analyses. Hence, since July 2019, the area is subject to an in-situ monitoring campaign, which will last for one year and collect data relatively to all the main meteorological parameters. The monitoring network is constituted by two high resolution weather stations, installed on *Via Brescia* Sinfonia building roof, and in *Garden*, and 15 custom made sensor nodes, which are positioned at different height on the external surfaces of *Via Brescia* Sinfonia building. The configuration of the network and its main characteristics are shown in Figure 6.

Figure 6. Sinfonia in-situ outdoor monitoring network.

4.2. Definition of surface uses

Some main evidences emerge from the analysis of the environmental parameters' spatial distribution: (i) the area is affected by summer overheating and the hotspots are localized in the urban canyons due to high asphalt T_s, (ii) T_{air} is mitigated in the green areas, and (iii) several surfaces present suitable Irr_{SW} levels for the integration of solar active systems. Based on the existing conditions in the district, several configurations have been analysed in order to evaluate the effects of applying different solutions for surface uses (e.g. green solutions at building scale, water surfaces, solar active systems, etc.). The main objectives defined for the area are: (i) mitigation of high summer temperatures, (ii) energy production from RES, and (iii) increase of green areas in the district for environmental enhancement and community well-being. Based on these, and on the results of several environmental analyses, a possible final configuration of the urban surfaces has been defined as schematized in Table 2.

Table 2. Final configuration of urban surfaces in the case study area.

Surface		Solution
Ground	Open areas	Increase of green areas of + 15% Water basin close to *Via Cagliari* hot spot
	Road network	Cool grey asphalt (albedo = 0.40)
Building envelope	Façade	Vertical greening on façades (i) exposed at south, (ii) along roads with high T_{air} BIPV on the surfaces with suitable solar potential
	Roof	PV panels on the most irradiated surfaces Cool paint on the remaining areas (albedo = 0.80)

The environmental analyses demonstrate the effectivity of this configuration. In terms of microclimate conditions, the air temperature is reduced in all the hot spots (Figure 7), with an average T_{air} decrement up to - 0.50 °C in *Via Cagliari* and *Via Milano*, and - 0.40 °C in *Via Palermo* and *Via Brescia*. Furthermore, the combination of increased relative humidity, and decreased surface and mean radiant temperature, produces an improvement of human thermal comfort. Hence, the UTCI is reduced on average of - 1.00 °C, decreasing the thermal stress from "very strong" to "strong" compared to the current configuration (Park, Tuller and Jo, 2014). Simultaneously, the production of renewable energy through solar active systems is guaranteed. The installation is possible on 6 500 m^2 of building envelope surfaces with suitable solar irradiation (i.e. $Irr_{SW} \geq 950$ kWh/m2), with a corresponding annual solar potential of 6 320 MWh/a.

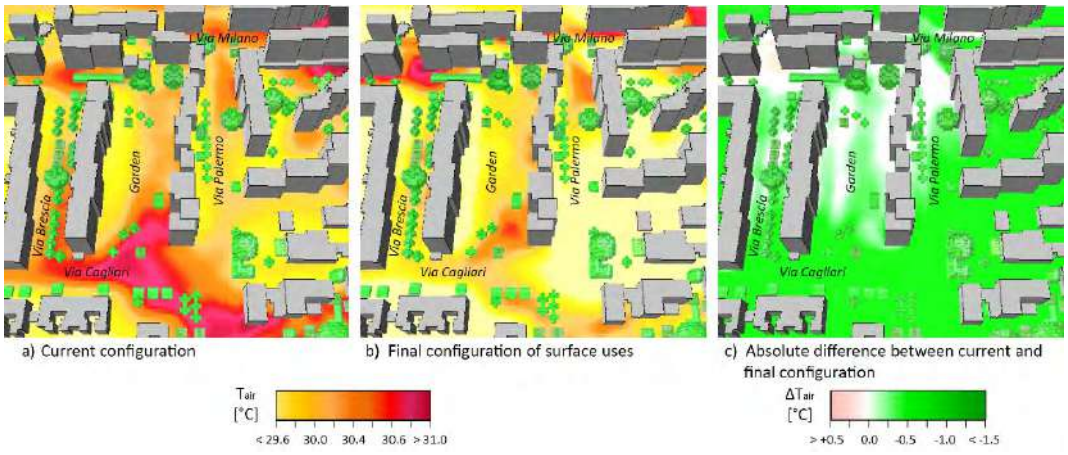

Figure 7. Distribution of air temperature at pedestrian level at 15:00 in summer conditions - Current (a) and final configuration (b); Absolute temperature difference (c).

5. Conclusions

This study presented a systematic framework to support planning decisions based on accurate, diverse and spatially explicit information. The method implies the assembly of a multivariate spatial database of significant morphological and environmental parameters that influence the distribution of surface uses in cities and affect the priorities for their definition.

The application of the proposed method to a case study in Bolzano demonstrates the importance of understanding the distribution of urban parameters for taking spatially explicit decisions about the types of surface use allowable, and the extent and location of these. The three-dimensional visualization of the morphologic and environmental variables represents a solid base to relate urban planning decisions on surface uses and their effects in terms of microclimatic conditions, thermal comfort, and on-site renewable energy production. This is demonstrated by the results obtained in the final configuration, in which several uses have been systematically integrated on the urban surfaces of the district. With regard to high summer temperatures mitigation, the air temperature is reduced on average of – 0.50 °C, and the outdoor thermal comfort in the district is improved, with an average decrease of UTCI of - 1.00 °C. Simultaneously, the production of renewable energy through solar active systems is guaranteed, existing green areas are preserved, and + 15% of new vegetation is added.

Future developments of the study will address the need for (i) a set of indicators and quantitative thresholds to identify the suitability of each surface to different uses, and (ii) more comprehensive criteria for the evaluation of the environmental effects of each use. Furthermore, the possibilities and potentialities for the inclusion in the current urban planning processes of the proposed framework and of indications on the surfaces uses will be investigated and tested in collaboration with the municipality.

Case Study Paper

Megacity – Mega Challenges:

A case of Dhaka City – Capital city of Bangladesh

Swarna Bintay KADIR, Lecturer, Institute of Disaster Management, Khulna University of Engineering and Technology (KUET); Bangladesh

Mohammed Hamidul HASAN, Executive Board Member, Bangladesh Institute of Planners (BIP); Bangladesh

Abstract

Bangladesh's capital Dhaka is the 7th largest megacity of the world having 20 million of the population with an annual growth rate of 3.60% and by 2030 it will be the fourth biggest city in the world with 28 million inhabitants. Like other megacities of the global south, Dhaka is facing the combination of high pressure of housing, high population density, and rapid population growth, consequences in urban growth taking place in natural hazard-prone areas. The city is characterized by rapid mass urban transformation, high level of social vulnerability and high level of poverty, shortage of infrastructure, housing and social services, poor quality of the social and physical environment, lack of urban governance and ineffective urban management. The paper aims to explore the physical, geographical and social characteristic of Dhaka city which transformed into a megacity in recent decades. This research is based on secondary data analysis and literature review and also highlights some recommendations.

Keywords

Dhaka City, Megacities, Climate Change, Population growth,

1. Introduction

The capital city of Bangladesh – Dhaka is one of the fastest-growing cities in Asia and by 2030 it will be the fourth largest megacity of the world (UN, 2008). This city consists of 38% of the whole country's urban population with an estimated number of 17.6 million which covers 1528 sq. km of land (area of Dhaka metropolitan) and by 2035 this number will be raised up to 28 million (The World Factbook, 2015; RAJUK, 2015; UN, 2016). Dhaka metropolitan comprises of six municipalities named as Dhaka North City Corporation (DNCC), Dhaka South City Corporation (DSCC), Gazipur City Corporation, Savar Paurashava, Kanchan Paurashva, Narayanganj City Corporation, and many other sub-district towns (known as 'Upazila') and rural areas as well (RAJUK, 2015). Geographically, Dhaka is located on the north bank of 'Buriganga River' and Geo-morphologically which is flood plain of the world's largest river system (Dewan, 2013).

In recent decades Dhaka has transformed into a megacity which is not proportionate with its development pattern. Hossain (2006) has highlighted four major characteristics of Dhaka. They are – 1) Shortage of housing, infrastructure, and social services. 2) High level of poverty and social vulnerability. 3) Poor quality of the physical and social environment. 4) Inefficient urban management.

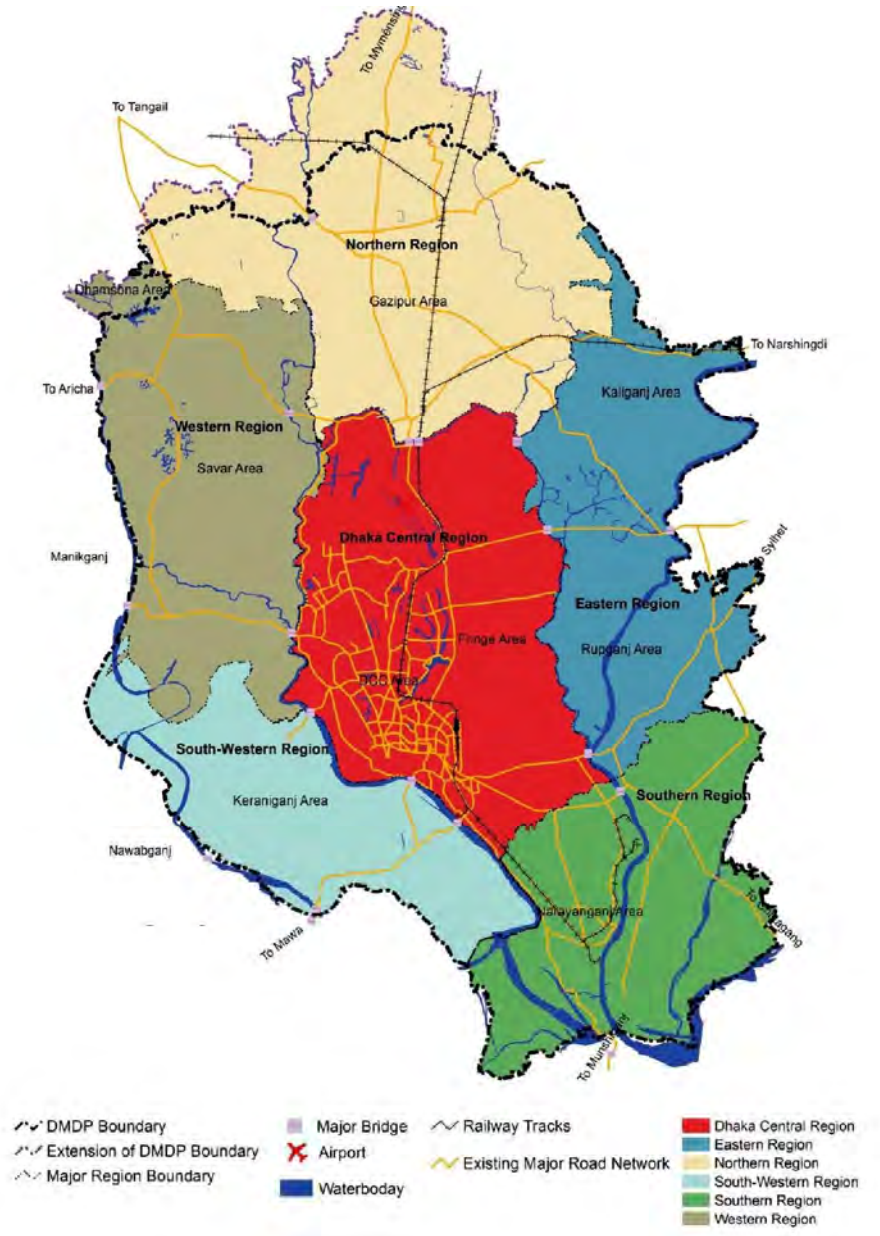

Figure 1 Map of Dhaka City **Source: RAJUK (2015)**

2. What is Megacity?

United Nations has defined a megacity as an urban area with a minimum population of 10 million. There is no standard of geographical area or population density to define a city as a megacity. In the current world, there are 37 megacities and by 2030 there will be 41 megacities (Omondi, 2018). Among these megacities, 80% are in Asia, Africa and Latin America (Kuo, 2016). According to Hossain (2006), these megacities, especially from developing countries, have some problems like – 1) High Population Growth 2) Urban

Poverty 3) Massive Infrastructure Deficit 4) Pressure on housing and land 5) Environmental Degradation 6) High risk on public health 7) Economic dependency on federal/state government and Capital scarcity.

3. Major challenges of Dhaka city

According to the Economist Intelligence Unit's (EIU) survey, Dhaka is the second least liveable city in the world (Mohiuddin, 2019). In recent decades, the overall condition of Dhaka is getting worse. The major challenges and problems of Dhaka city are described in this chapter.

3.1. Population growth and rapid urbanization

The estimated growth rate of Dhaka's urban population is 4% each year since 1971 whereas the national growth rate was 2.2% (World Bank, 2007). According to the Dhaka Structure Plan (2016-2035), there are three major reasons behind this high population growth rate of Dhaka city. They are – 1) Reclassification of rural areas into urban areas – 2) Natural urban population growth – 3) Rural to urban migration (Only 16% of the total population of Dhaka city is local people and rest of 84% is migrated from the other part of the country).

Dhaka has 400 years of history. In course of time, the geographical boundary of the city, population, and density has been changed. In last, 60 years Dhaka city is expanded geographically by 1.8 times and the population density is increased by 27 times. Some statistics are given below:

Year	Area (sq. mile)	Population (million)	Density(Person/sq. mile)
1956	320	0.40	1,250
2019	590	20.00	33,900
2035 (Projected)	590	28.00 (Projected)	47,457 (Projected)

Source: Mahmud (2017); World Population Review (2019); RAJUK (2016)

Rapid urbanization and population growth are one of the main reason for increasing land values of Dhaka which resulted in haphazard fillings of flood plains and low lands and sprawling peripheral land developments (Alam, 2011). The annual increase rate of the land value is 22.26% between 1990 and 2000. In the next ten years (2000 to 2010) the land values have increased by an average annual rate of 74% (Alam,2018) whereas, the price hike of land values of the neighboring cities are not that high. For example, The average increase rates of land price in Karachi (Pakistan), Kolkata (India), Kathmandu(Nepal) are 70%, 50%, and 50% respectively (Makathy 2008; Seraj 2007; Mayo 1998).

Rapid urbanization consequences environmental changes at multiple scales and like other big cities of developing countries, Dhaka has faced rapid urbanization due to land use change in large scale (Dewan et al. 2012). Persistent population growth creates extreme pressure on existing land use and land recourses. In the last few decades, Dhaka has been undergone break-neck and unplanned urban growth through expansion in adjacent low-lying areas. This kind of expansion has some negative impacts on the land market, socio-economic and environmental arena.

3.2. Traffic congestion

Traffic congestion is a curse for Dhaka city. A study of World Bank shows that the average traffic speed has dropped from 21 kmph to 7 kmph in last ten years. It is also predicted that the speed might be dropped to 4 kmph by 2035 which is slower than general walking speed. Traffic congestion also causes great economic loss. Another study by BRAC Institute of Government and Development mentioned that In Dhaka, the amount of loss of working hour is 5 million hours/day which costs 31.2 million USD. On the other hand, traffic jam can cause serious mental and physical problems (Haider, 2018).

The accident rate in Dhaka is also high. According to Bhuiyan and Islam (2018), more than ten thousand accidents occurred in Dhaka between 1998 and 2014 and around 4,514 pedestrian have died.

3.3. Hazards and Disasters

Dhaka is among the most vulnerable cities in the world with its high population density and rapid urbanization located in an area of valuable assets. Unplanned physical development and along with increased population has made it susceptible to diverse natural and manmade hazards like urban flood, earthquake and fire hazard. The unique geographic location and topographic condition also contribute to exacerbate the disaster situation. The city's exposure to hazard is often aggravated by the multitude pressure of climate change. Intense poverty and poor governance are also likely to amplify the impact of these disasters. Distinct urban characteristics of Dhaka associated with a various dimension of vulnerabilities has made its urban communities more fragile and sensitive to this adverse condition. Besides, there is no specific demarcation of duties and responsibilities among the authorities and agencies and there is negligence in duties as well. Lacks of co-operation among these organizations and misunderstanding between implementing agencies and local people make several policies unimplemented in the field.

The main natural hazards affecting Dhaka include floods, which are associated with river water overflow and rainwater stagnation. The city is endowed with a network of rivers, numerous 'khals' and canals: the 'Turag' on the west, the 'Buriganga' on the south, the 'Balu' on the east and the 'Tongi Khal' on the north (Faisal, 1999). On the other hand, the elevation of 70% of the total City varies within 0.5 to 5 m which is very low and act as a temporary detention basin for flood water (Rahman, 2006). The scenario of floods in Dhaka is most common during the monsoon season (June to September) due to water level rise in these rivers and trans-boundary flows. The City experiences about 2000 mm annual rainfall, of which more than 80% occurs during the monsoon season (Dewan et al, 2007). Flooding due to drainage congestion is also a regular phenomenon here. Encroachment of flood retention ponds and agricultural lands for constructing building and industries by land developers is leading to rapid loss of natural drainage system and severe drainage congestion in the city. According to the city development authority, 12% of the urban area should be set-aside as retention ponds Currently the total area of retention is about 365 ha which is only 4% of total DCC area and it is gradually decreasing with an increasing population (Faisal,1999). The problem is further aggravated by poor maintenance of the surface and underground drainage network of the city, inadequate embankment, culverts, and pumping facilities. In addition, lack of institutional coordination has significantly contributed to worsening the flood situation. (Faisal, 1999). Dhaka has experienced many disastrous floods in the past of which the 1998 flood is said to be the worst in memorable records (Dewan et al, 2007).

Floods in 1998 were caused by extreme river levels, 23% of the area of the western city was inundated. Other catastrophic floods hit Dhaka in 2004 and in 2007 mainly caused by prolonged seasonal rainfall overwhelming the capacity of the urban drainage system (Khan et al., 2018). Experts fear that the flood vulnerability of Dhaka is likely to exacerbate in the effect of the probable climatic change. (Dewan et al, 2007).In the past floods, people experience severe waterborne diseases caused major health impacts. Innundation of roads often causes traffic congestion and thereby massive economic losses. Although all parts of the urban area are distressed by these floods, dwellers of slums and squatter settlements are particularly vulnerable to flooding, because of inadequate provision of storm sewers in there (Rashis et al., 2007).

The city is one of the active seismic regions of the whole world for being located at the junction of several active tectonic plate boundaries: the Indian plate, the Eurasian plate, and the Burmese microplate. The city is believed to be awaiting a destructive earthquake at any time due to the shifting of or collision between these plates (Ahmed and Morita, 2018). Besides the locational disadvantage, the city is poised to more threat due to its enormous population, highly dense structure, unplanned growth, and poor management systems. The demand for housing settlement, infrastructure, and other facilities is increasing gradually with population expansion. Vertical expansion has become the common development trend of Dhaka to cope with the extensive population pressure. Most of the buildings do not follow minimum standard though there is a comprehensive set of rules and regulation and a complete guide for building design and construction named as Bangladesh national building code (BNBC 2015). Additionally, haphazardly grown settlement on filled up marshland and low-lying flood flow zones have also made the capital highly vulnerable to earthquake. According to statistics, 30% of buildings of Dhaka city are constructed on soft soil by filling up the low land (Sadat et al., 2010). Theses densely constructed, unreinforced and non-engineered buildings are increasing the risk of damages by a disaster. There are some incidents of building collapse even without an earthquake like ‘Rana Plaza’ Incidents. Therefore, the risk of an earthquake in Dhaka is easily imaginable. It has estimated that about 72,000 buildings which are 90 percent of the total buildings would collapse in a major earthquake of 7.0 or greater magnitude on the Richter scale (Haque, 2016). In addition to structural vulnerability, people have little knowledge about this hazard and precautionary measures because there were no big earthquakes in the last 100 years. They are not aware of the adverse effects an earthquake may bring upon them.

Along with flood and earthquake, a rising trend in the number of fire incidents in Dhaka has become a key concern for the citizens. Notable fires incidents have taken place like ‘Nimtoli' Fire, ‘Bashundhara' City Complex Fire, Bangladesh Steel and Engineering Corporation (BSEC) Bhaban Fire and ‘Tazreen Garments' Fire, etc. (Rahman et al., 2015). According to the Fire Service and Civil Defence (FSCD) Department, there were about 80 fire accidents in Dhaka city last year alone. The deadliest fire in recent times was the ‘Chawkbazar' fire this year (Helali, 2019). Fire hazard also affecting the readymade garments sector, which is generating 78% of the country's total foreign earnings (Wadud et al., 2013). Vulnerability of Dhaka City dwellers to fire hazards has been increased due to reckless building construction and disobedience of Fire Protection Act, 2003 and BNBC (Islam et al, 2008). Sometimes these rules are not sufficient because they are only concerned about only fundamentals of fire safety. These rules often do not consider the surrounding land uses and does not identify the risk emerging from the collective impacts of storing different hazardous materials together..

The coexistence of housing and unsafe factory, warehouses and business establishments in the same locality and multipurpose use of a building especially both as a residential and a workshop or factory are dangerous for public safety. The structural inefficiency of buildings and no maintenance of setback between buildings may aggravate the situation. Most of these buildings lack in precautionary measures like wide fire safety stairs, up to date fire extinguisher, smoke alarm, auto sprinkler system, etc. Even if all the precautionary measures exist in a building, most of the dwellers do not know how to use the fire fighting equipment for combating the fire. On the other hand, narrow road hinders the rescue activity after a hazard. Institutional inefficiency, insufficient equipments and lack of proper training of firefighters are worsening the situation. Therefore, institutional reform, strengthening of capacity at the individual and institutional level is needed in order to reduce fire hazard risks of Dhaka City. But it is not possible to bring an overnight change to the infrastructures of this city.

3.4. Climate change

There is a complex relationship between climate change and cities-based activities. Cities may contribute significant amounts of greenhouse gases in the atmosphere which in turns affecting earth's energy budget and thereby resulting in gradual global warming. However, increasing of earth's temperature is one of the major characteristics of climate change. On the other hands, cities are often more vulnerable to the impacts of climate change like urban heat island effects, heat waves and cold waves, groundwater depletion, water shortage, seasonal climatic variability, excessive rainfall, increased water logging, etc.

Dhaka, the capital city and only megacity of Bangladesh is considered as one of the most vulnerable cities to climate-induced hazards. It contributes a major portion of Bangladesh's greenhouse gases although the contribution is negligible relative to total emissions worldwide (Alam and Rabbani, 2007). But the generation of greenhouse gases is increasing with the city's population expansion, rapid urbanization and industrialization, electricity and fuel consumption and growing motor vehicle use. Deforestation combined with the encroachment of agricultural land to meet the demand for housing of growing population is also worsening the situation. At the same time, Dhaka is facing multitude pressures of different climate-induced hazards along with other non-climatic challenges and stresses. Unpredictable changes in temperature and rainfall causing increased frequency of floods and droughts. It is posing adverse effects on different sectors including infrastructure, industry transportations, utility services, sewage management, and human health and livelihoods, especially for the poor.

Dhaka is acting as a concentrated urban island, a renowned phenomenon that absorbs heat and exerts profound effects on both regional weather and global climate. This phenomenon is associated with a number of local problems such as biophysical hazards (e.g., heat stress), air pollution and associated public health problems. The city is experiencing a slight increase in average temperature over long term (Rabbani et. al., 2011) Climate-induced temperature fluctuations, heat and cold waves pose additional challenges for city dwellers in Dhaka particularly for children and the elderly. These events have been observed frequently in recent years. While there is no significant change in the annual average rainfall, the number of days without rainfall is increasing (Alam and Rabbani 2007) and winter in Dhaka is decreasing (Rabbani et. al., 2011). Non-climatic factors like poverty, poor living standard, increasing slum and squatter settlements are aggravating the overall situation.

3.5. Environmental Pollution

Environmental pollution including air and water pollution in Dhaka is a growing concern as it poses a significant impact on public health. Most of these environmental problems are human-induced, resulting in either from a lack of compliance with national policies, rules, and regulations, or from resource constraints to implementing different measures (Alam and Rabbani, 2007).

Air pollution is a major environmental risk to health throughout the world. Bangladesh is the fourth, among 91 countries with the worst urban air quality in its recent air pollution monitoring report of the World Health Organization, 2016 (Alam et al., 2018). Deferent air pollutants such as VOC, CO2, CO, O2, SO2, NOx, H2S, SPM, PM10, PM2.5, and Pb are significantly responsible for the deterioration of air quality. Most of these air quality parameters have been significantly increased at different locations in Dhaka (Alam et al., 2018). Problems associated with air pollution have been enhanced due to the increasing number of automobiles, industrial operations, urban constructions and adjacent brick kilns around the city. Meteorological parameters like temperature, rainfall, relative humidity, and wind speed are also one of the important factors to influence the urban air quality. According to national standards, the daily particulate matters exceed the optimum limit during the dry season, whereas it has been reported slightly lower during monsoon(Kayes et al., 2019). Air pollutants pose several health risks such as eye irritation, headaches, damage to kidneys and central nervous system, skin cancer, cardiovascular diseases, nausea, asthma, and anemia (Alam et al., 2018).

Dhaka city is surrounded by a number of rivers and canals of which Turag, Buriganga, Dhaleshwari, Balu, and Shitalakhya are the important ones. The quality of water in these rivers have reached a very critical situation and are not suitable for instant use due to different anthropogenic activities like the dumping of industrial, medical and household waste and untreated sewage effluent into these rivers. Inadequate solid waste and sewage management and lack of the water resources management plan and policies are also contributing to deteriorating the water quality gradually. The poisonous waters of these rivers have not only been killing all its aquatic life but also been posing health hazards to the dwellers of the city (Haldar and Islam, 2015). By using river water for washing clothing and bath many water born disease like yellow fever, cholera, dengue, malaria, and other epidemic diseases spread man to man. The people live nearby these rivers are also suffering from the odor pollution.

Waste management is also an important sector which may significantly contribute to improving the quality of the environment. The rate of the waste generation in Dhaka city is increasing with the growing population. Dhaka City produces more than 4000 Metric Tons of solid waste per day of which 200 Metric Tons waste contain toxic chemicals, radioactive elements and pathological substances (Yasmin and Rahman, 2017). Management of this huge quantity of waste is difficult as they are generated at a faster pace. Unsuitable methods of waste disposal, poor selection of dumping sites and lack of public awareness and adequate policies are making the waste management practices in this city most unsatisfactory. The most common problems associated with improper dumping include: diseases transmission, fire hazards, odor nuisance, atmospheric and water pollution, aesthetic nuisance and economic losses (Yasmin and Rahman, 2017).

4. Recommendations and Conclusion

4.1. Recommendations

- **Decentralization:** Dhaka is packed with a large number of physical structures and people. This kind of unplanned expansion can be solved through rapid political decentralization. It means strengthening the various tiers of the local government. In Bangladesh, most of the local government is not truly dependent. They are dependent on the central government to discharge their duties.
- **Good Governance:** Dhaka is a good example of lack of good governance. According to RAJUK(2015), *'It is a system that individuals and institutions, whether public or private, plan and follow to manage the common affairs of a city'*. In Dhaka, there are some strong government and development agencies. It needs proper coordination among these bodies of different levels.
- **People-Oriented Development:** In recent decades, the physical growth of Dhaka doesn't represent the picture of development. All the development steps should be people oriented and demand driven.
- **Law Enforcement and Implementation:** There are several rules, regulations, and projects to control the unplanned development of Dhaka city. It needs proper implementation of rules, regulations and Law enforcement.

4.2. Conclusion

The megacity – Dhaka plays an important role in the national economy of the country although it covers only 1% of the whole country. Its contribution to GDP is 36% and provides 44% of the country's total employment (Haider, 2018). The government and the dwellers of Dhaka should work in a collective way to revive this city.

Negotiating Spaces of Exception

Metro Manila's Planned Unit Developments: The Case of Eastwood City

Anna Katrina KARAAN; Philippines

Abstract

Urban enclaves have come to define the growth of many contemporary cities, subdividing society spatially into homogenous groupings. In the global south, this has been translated even more distinctly due to the excessive disparity among social classes. With their predisposition towards exclusion, urban enclaves are often portrayed as particular sites of unsustainability. However, a specific version of these enclaves, the Planned Unit Development (PUD) and its current manifestation of high-density mixed-use townships, has been championed as a concept that inculcates more sustainable practices due to its innate flexibility. Utilizing a localized actor-centric approach, this study uncovers how PUDs in Metro Manila are negotiated as spaces of exception. The study uses a representative case study of one of the pioneering PUDs in Metro Manila, Eastwood City, and applies a qualitative methodology to explore how relations of state-space-society creates and continuously shapes these spaces. Eastwood City is uncovered to be a legitimized space of exception, where dominant narratives have prioritized private over public interests, but crossed into the realm of acceptability due to its claims of sustainability, particularly of the "live-work-play" lifestyle. However, this study also reveals how the narratives of the dispossessed are exhibited in the margins and how this is continuously (re)shaping the development. These point towards the possibility of alternative futures for PUDs by shifting the power to negotiate to all stakeholders, not only in the creation but also throughout the lifespan of the project, which can then lead to more inclusiveness and equality in the process. By operationalizing the PUD concept, urban enclaves can cease to be purveyors of singular interests but become dynamic spaces of exception that are constantly negotiated by their actors.

Keywords

Urban enclaves, planning tools, zoning exemptions (3-5)

1. Introduction

Narratives of urban development around the world have seemingly taken similar storylines. Cities have bought into the neoliberal ideology of privatization and competition, manifesting into the formation of enclaves that subdivide society into homogeneous groupings (Agnotti, 2013). In the global south, this phenomenon has been translated even more distinctly due to the excessive disparity among different societal classes, leading to further inequality through exclusion. This is a story that is exceedingly evident in Metro Manila, the capital region of the Philippines (Murphy & Hogan, 2012).

A rapidly urbanizing megacity, Metropolitan Manila is an agglomeration of seventeen municipalities that politically subdivide a contiguous urban area. These local government units (LGUs), despite sharing a functional area, remain highly disparate with their own policies and agendas (Porio, 2009). While the political scenario is weak, powerful elites have been shaping Metro Manila's urban fabric in the form of urban enclaves to fill in the gap (Shatkin, 2008: 388). These developments, usually targeted to the middle and upper classes, present a common model of the privatization of space (Roderos, 2013: 99).

Recently, a unique type of enclave development in Metro Manila has arisen. Planned Unit Developments (PUDs) in the form of urban townships are driving much of the national capital region's urban (re)development, where large areas of land are purchased and converted into high-density mixed-use developments by the private sector (Aquino, 2015). However, the nature of these types of enclaves contradict existing regulations and can only exist as an exception, facilitated by LGUs that desire this type of development in their city.

This particular type of enclave opens discourses on their existence as spaces of exception that are negotiated through power/knowledge relations among various actors. By taking Eastwood City as an exemplary case, the study is able to examine one of the pioneering urban townships in Metro Manila using a qualitative methodology to uncover the processes that underlie how these are being shaped.

2. Literature Review

2.1. Enclave Urbanism

Due to their prevalence, urban enclaves have spawned numerous studies (see Agnotti, 2013; MacLeod & Ward, 2002; Sidaway, 2007; Genis, 2007), often focusing on the way these are shaped by the rise of neoliberal ideology, which "mobilises urban space as an arena for market-oriented economic growth and elite consumption practices" (Sager, 2011: 149). A common manifestation of these is the mono-use gated community. These typically enclose a homogeneous class of people who can afford to pay for reliable services and security that, in many cases, only the private sector can provide (Grant & Mittelsteadt, 2004). In developing countries, these communities provide a sense of separation from the poverty prevalent in the city (Webster et al., 2002: 317).

Enclaves, however, are not only defined through the physical gating but also exist in spaces "that are presumed as part of an open city" (Agnotti, 2013: 115). They have co-opted urban movements that aim to provide more sustainable urbanity than what is present in modern cities through the creation of mixed-use communities, such as *new urbanism* (Council for New Urbanism, 2015), *urban villages* (Franklin & Tait, 2002), and *compact cities* (Hofstad, 2012). While these spaces ideally create sustainable communities and have become ideal city models (Jensen et al., 2011), reality reveals that these promulgate other unsustainable practices through exclusion instead (Jenks & Jones, 2010).

Recent studies on enclaves have shifted beyond dystopic representations of the city based on "overextended neoliberalism" into more nuanced approaches that explore localized manifestations (Pow, 2015), placing more importance on specific political, economic and social processes (McGuirk & Downling, 2009; Johnson, 2010; Koch, 2015). While not discounting neoliberalism as a driving force, the discussions emphasize enclaves as locally produced spaces that be seen as decision-making moments. *Arranged urbanism* evaluates

the interactions of state and non-state actors in the creation of space, and showing the close interaction of formal and informal practices in these enclaves (Koch, 2015: 409). The concept of *borderland urbanism* shifts from how enclaves are formed to how they are constantly changing at its boundaries through "continuous negotiations of power and control" and "continuously changing and evolving relational linkages" (Iossifova, 2015: 104). These borderlands become sites for alternative ways of being that challenge the static definition of enclaves (ibid.).

A similar thread among these concepts is the aim to redefine these spaces through processes of negotiation among different actors. However, as inequality is present and normalised as an intrinsic part of contemporary urbanism (MacLeod et al., 2003: 1667), negotiations tend to favour those who possess power while the bargaining of the powerless occurs at the margins. Refocusing on these interactions allows for enclaves to be seen not just as results of a global neoliberal process but as dynamic spaces that are continuously being shaped by localized relations.

2.2. Metro Manila's Urban Enclaves

The issue of enclave-ing is clearly prevalent in Metro Manila, a city that has been referred to as "the world's most fragmented, privatized, and un-public of cities" (Murphy & Hogan, 2012: 27). While this may be a hyperbolic statement, urban space in Metro Manila have been subdivided into private spheres to such a degree that "everyone except the utterly dispossessed … erects gates and fences and walls around their property and themselves" (ibid., 2012: 12). Enclaves in Metro Manila are not only the realm of the elite but are used by all classes to segregate themselves from one another (Garrido, 2013: 1343). With this kind of urbansim, the notion of public space has been relegated to quasi-public spaces within the private.

Neoliberalism has indeed spurred the formation of enclaves in the capital region with imaginaries of a sanitized "global city" through private-sector led mega-projects (Shatkin, 2006; Connell, 1999; Michel, 2010; Kleibert & Kippers, 2015). These are informed by a strong postcolonial identity that produces these "visions of a world class and modern metropolis" (Ortega, 2016: 35) with a "cultural distinction on the basis of progress" that has been internalized by the citizens (Garrido, 2012: 182). Moreover, these are facilitated by a highly patrimonial society, which places the power to plan in the hands of influential landed families (or those with ability to accumulate land), "[creating] what is in effect an urban feudalism … [building] their own 'manorial' cities within Metro Manila" (Murphy & Hogan, 2012: 23).

It appears that the government has conceded much ground to these private actors due to "intense fiscal and external pressures … and a local political economy that has fostered the political power of elite families" (Shatkin, 2008: 398), and has facilitated the dominance of private sector-led planning in the development of Metro Manila through the creation of "for-profit utopias" (ibid.: 399). With the diminished role of the public sector, uneven development and social divisions through the creation of exclusive spaces have become the common mode of urbanisation, often leading to the dispossession or displacement of the poorer members of society (Choi, 2014; Ortega, 2016; Roderos, 2013). However, while these descriptions present an overly powerful private sector, these developments can also be seen as a means to fulfill national or local agendas, which may mark them worthy of state facilitation (Kelly, 2003).

2.3. Planning for Exemptions

The congruence of factors involved in the urbanisation of Metro Manila has led to the popularization of a particular manifestation of urban enclaves: the Planned Unit Development (PUD), a planning concept and tool that originated from the United States of America in the 1950s and 60s (Burchell, 1973: 3). PUDs began as a reaction to the Euclidean zoning system that separated land uses and enforced uniform regulations. This system was criticised for being highly unsustainable as it encourages urban sprawl, perpetuates homogenous communities, prevents the development of useable open spaces, and discourages innovations in land use or design. The PUD concept answers these critiques as it allows for a more integrated form of development, and has since become increasingly popular (Mandelker, 2008: 420).

However, PUDs require more flexibility of uses than what the current system sanctions, which necessitate exceptions from zoning and other regulations as these "[do] not employ pre-set regulation but rather emphasizes land conversion through the art of negotiation" (Burchell, 1973: iii). This discretionary nature of PUDs has been seen as both a solution and a problem. While it provides flexibility that could enhance quality of life and form more sustainable communities, issues arise in the processes of negotiation, regulation, and the subsequent implementation of these in the urban space, as PUDs left unchecked often become exceedingly geared toward private interest (Committee on Public Regulation of Land Use, 1972: 62-64). Although controlling PUDs is said to defeat its purpose, recommendation on how to tackle these developments have been brought forward (Burchell, 1973; So, et al., 1973; Meshenberg, 1976), and some of these remain relevant: a sound policy base, a range of allowable discretions, submitting a plan for review, and collaboration with experts (Meshenberg, 1976: 2).

Planning tools that aim for increased flexibility in land use are not unique to the PUD, and can also be found in other countries with varying degrees of success. While these are known by different names and follow different processes, they ultimately have similar intentions – shifting from comprehensive plans to projects allowable through public concessions (Mosciaro and Pereria, 2019). Two prominent examples are the French *zone d'aménagement conserté* (ZAC) and the Brazilian *Operação Urbana* (Urban Operation - UO). Unlike the PUD, these are characterized more by the heightened role of the public sector, with the developments considered a public-private partnership, than a primarily private initiative.

The ZAC is a widespread instrument for implementing development schemes in France. Under the authority of the local government (though often initiated by interest private investors), designated areas for comprehensive redevelopment are granted special planning regime (*plan d'aménagement de zone* or PAZ), and revenues from land sales/leases and concessions granted by the ZAC is intended to fund the infrastructure of the development. While initially intentioned for new large-scale urban projects, it is also used in smaller development projects which facilitates complete private-sector funding, or projects in existing urban districts, which necessitates tighter control favoring rehabilitation over demolition (EC, 2000). In any case, even with the presence of private sector partners, the public sector still holds principal control over the development. This is attributed to the historical institutional culture of France that promotes collaborative processes, which extends to the inclusion of other interest groups and undergoes a public participation processes. For instance, in the ZAC Bercy in Paris, private sector partners were not given

preference treatment over environmental considerations (Nelson, 2000). However, the number of actors involved has made the process long and complex, and the control of the local authorities are oftentimes seen as restrictive.

Similarly, the Brazilian Urban Operations (UOs) aims to become a vehicle for joint efforts among public and private sectors in urban projects. UOs are enacted in law by the local government and "addresses issues such as the perimeter of the intervention, the zoning and building rules applied inside it, the aggregate stock of development rights, the conditions for negotiating these rights, the general guidelines for infrastructure improvements, and the basic governance framework to manage the project" (Moscario and Pereira, 2019: 4-5). One main mechanism is its use of additional development rights within the UO perimeter to finance improvements. These development rights (CEPACs) allow developers to exceed the standard floor-area ratio (FAR) permitted in UO, up until the maximum allowable FAR, increasing the flexibility of the use of space. While UOs are promulgating within Brazil and often seen as a best practice, it has been critiqued as further increasing uneven development due to the prevalence of market-interest over social-interest typical in these types of enclaves (Moscario and Pereira, 2019).

In the Philippines, where land use zoning and building codes are closely patterned after the US zoning system, the concept of PUD has been vaguely defined at the national scale, and enclaves that follow this definition are quickly becoming a main form of urban (re)development. Urban townships, which are privately owned and managed, often high-density, mixed-use "compact" developments, is emerging as the prevailing type of PUD (Kleibert & Kippers, 2013). However, while the intention may be similar to the developments described from the cases of France and Brazil, unlike in those countries, there is little evidence of regulatory measures or practices operationalising these developments in most cities in the Philippines, implying a scenario where PUDs exist as exceptions facilitated primarily through discretionary bases.

2.4. Defining Spaces of Exception

Throughout the literature reviewed, shifting discourses and practices on urban enclaves and their enabling planning frameworks considers spaces as "defined less by a pre-given property and more by the assemblages they enter and reconstitute" (McFarlane, 2011: 208). However, because enclaves are often sites of inequality, difference in power affects the ability of actors to negotiate in decision-making processes. According to Foucault, power is in flux and is constantly negotiated through the reinforcement or redefinition of knowledge or "truths" that are legitimized through various means (Mills, 2003: 33).

A prevailing discourse is the role of states of exception where suspension of norms creates opportunities for decision-making, and at the same time, the legitimacy of the decision maintains this exception as within order (Agamben, 2005). This is facilitated through the blurring binary between formal/informal (Roy, 2005), and further explained by Yiftachel as "gray spaces", which are either "whitened" if deemed beneficial to those in power, or "blackened", if not (Yiftachel, 2009: 243). This challenges the notion of exceptions being a static categorization; instead, as a practice, (in)formality has an active involvement in the production of space and its legitimacy (McFarlane, 2012: 105).

This argument presents space as dynamic and constantly negotiated through practices of (in)formality, and allow for places that can be highly adaptable to the ever-changing local and global contexts (Herrle & Fokdal, 2011: 12). PUDs, whose very nature depends on

flexibility, can be offered as examples of space of exception. Metro Manila, where PUDs are defining much of the urban (re)development yet is not regulated in the planning system, is an ideal context to explore how assemblages embody power/knowledge relations and is used to negotiate spaces of exception.

3. The Case of Eastwood City

The study on Eastwood City aims to uncover the processes that underlie negotiating Planned Unit Developments in Metro Manila, specifically the private developer-led urban township, using a representative case study approach by qualitatively analysing how these occur in the assemblage of state (particularly local and sub-local/*barangay*[1] levels), society, and space. The perspectives of both state and society were gleaned through a series of interviews and further supported by documentary analysis of various regulatory plans, guidelines, ordinances and marketing materials. Space was assessed based on how state and society perceive and interact with it, and further supplemented by site observation and mapping. Following this, the results were analysed through the description of how Eastwood City was created, and by placing the PUD within the discourses of power, in order to examine how this space of exception was and continues to be negotiated.

3.1. Creating a Space of Exception

Eastwood City widely promotes its exceptional-ism: the first integrated township that first delivered the live-work-play lifestyle concept through incorporating the first Cyberpark in the country targeting the emerging service industry of Business Process Outsourcing (BPO). Its very selling point was that it did not conform but set itself apart through its difference. Even now, years later and succeeded by numerous copycat developments, it still claims this difference by repeatedly highlighting that it was the first—the original.

This exceptional-ism is not only present in its marketing campaign. Its existence began through seeking exemptions from current zoning plans. The area where Eastwood City now stands was originally an industrial zone occupied by factories and warehouses, except for an existing low-income/working class community that classified as a socialized housing zone[3], referred simply as Barangay Bagumbayan. Opportunely, the industrial area ran adjacent to a major highway (C-5) that links the north to the south of Metro Manila, and surrounded by large swathes of residential areas. This generated sufficient traffic and high market catchment, making the area appealing for commercial developments.

In 1996, Empire East Holdings (now known as Megaworld Corporation) was able to purchase some contiguous industrial lots in the area to create a mixed-use Planned Unit Development. While no formalized planning mechanism are in place to operationalise PUDs in the local level, these developments still persist through co-opting existing processes, beginning with the request for a change of zoning from industrial to Special (Urban) Development Zone under the QC Zoning Ordinance of 1992, reserved as "areas characterized by deteriorated or deteriorating conditions but with high potential for environmental rehabilitation and socio-

[1] "The basic political unit [in the Philippines] which serves as the primary planning and implementing unit of government … activities in the community" (Endriga, 2004).

[3] A socialized housing zone is an area assigned primarily for housing of the underprivileged or homeless (Endriga, 2004).

economic improvement" (QC Ordinance No. SP-1369, S-2003). Once zoned as SUDZ, more flexibility is granted in the uses the lot can exhibit. Eastwood City was presented to fit this definition through the argument that "the subject site being in the growth corridor of C-5 is strategically located and highly accessible, thus presenting itself as another potential growth center for Quezon City" (QC Ordinance No. SP-432, S-96).

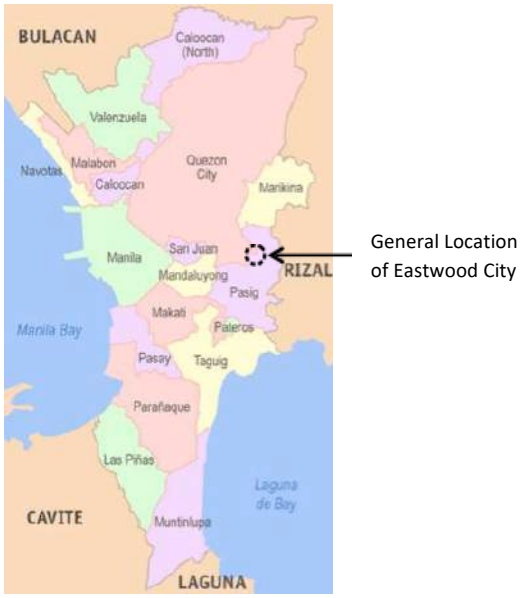

Figure 1 Political map of Metro Manila (with Eastwood City), source: Philippine Maps

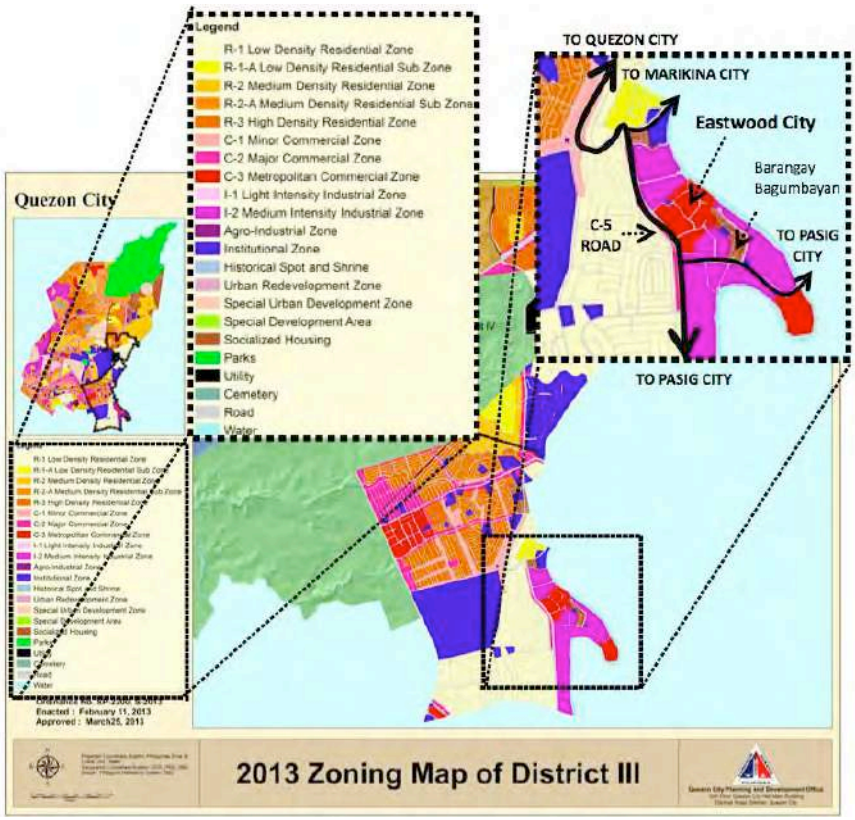

Figure 2 Quezon City 2013 Zoning Map of District III (with insets), source of base map: Local Government of Quezon City

The reasoning of being a growth centre was appealing. The highly residential nature of Quezon City has spurred its local government to encourage diversification of land uses that could lead to increased economic opportunities (Quezon City Development Council, 2010). With this, Eastwood City was granted uses allowable in a Metropolitan Commercial Zone (C-3) (Quezon City Ordinance No. SP-432, S-96), which has the least restrictions: no height limit, generous floor-to-lot area ratio (FAR) allowances, and the ability to mix uses in one development. However, this also means that in terms of planning the development, there is barely any input from the city's planning department, whose statement was "we don't know what's happening inside Eastwood; only Megaworld knows that." (Interview, 17 July 2016)

In order to be rezoned, the developer needed to make a request to the City Council, which has the sole power to enact and revise zoning ordinances. While the national agency Housing and Land Use Regulatory Board (HLURB) has prescribed guidelines on when and how zoning exceptions should be allowed in order to limit adverse effects of zone changes, it appears that the council has procedures of its own. While a high-density commercial development in the midst of a low-density industrial and residential area can most definitely be foreseen as causing adverse effects, the zoning exception was approved without limitations, enabling the developer to proceed with the kind of development that would best maximize its profits.

This process of exceptions clearly shows a mutually beneficial transactional relationship between the local government and the developer. For the developer, the benefit is that the desired development was approved at all and with few restrictions, allowing them to economize space and maximize profit. For the local government, the benefits are multifaceted. Vehicles of economic growth such as these high-density developments are seen as desirable additions to the city. These developments provide higher tax and other revenues to the city and its officials, as well as services to the citizens that the local government is incapable of providing (Porio, 2012: 7).

This sentiment persists not only in Quezon City but in other cities of Metro Manila as well. The strong presence of private investments underlies much of the progress in terms of services and infrastructure issued by the local governments (Shatkin, 2006: 593). Due the competitive atmosphere present and a lack of metropolitan governance, there is a race among these LGUs to attract these investments to their cities. Oftentimes, the winning strategy of the LGUs is their willingness to give concessions, from allowing much higher densities than what is advisable to sacrificing required spaces for amenities to benefit the private developer (Land Use Expert, interview, 27 July 2016).

In this scenario, power is constantly shifting through various levels of informal negotiations. On one side, the state wields land policies as an important bargaining tool; on the other, the developer presents desirable resources. The general public, however, plays little role in these initial negotiations that generally occurs behind closed doors. Thus, while the system does not follow what is officially prescribed, the rules of the game are known by their players who use this knowledge to put forward their own agendas. It is not an unregulated system, as usually follows the common notion of informality, but a deregulated one. As Roy (2009) states, "[deregulation] indicates a calculated informality, one that involves purposive action and planning, and one where the seeming withdrawal of regulatory power creates a

logic of resource allocation, accumulation, and authority" (2009: 83). Through deregulated systems, it is possible for (in)formally negotiated decision-making to take place.

3.2. "Whitening" the Grey

Figure 3 View of Eastwood City from C-5 Road, source: author, July 2016

Though not playing an active role in its creation, a general sense of satisfaction with the development is echoed by those interviewed, including those who would seem typically excluded from these types of development such as the working class population and residents of the adjacent poorer community (Roderos, 2013). For them, Eastwood City delivers a unique type of urban space that suitably answers their needs. This sentiment reveals that Eastwood City is a gray space that has been "whitened" (Yiftachel, 2009: 243). Instead of being seen as unacceptable, the PUD has been legitimised through the shared power/knowledge of the state and developer that capitalises on certain narratives.

While it should be noted that these are not representative of all stakeholders of the PUD, not one interview failed to mention the convenience that Eastwood City has brought to them. The location of this development places it as the easternmost commercial and business district in Metro Manila and close to the vast residential areas characterizing the eastern portion of the capital region, bringing employment opportunities and commerce/recreational areas closer to where many people reside. In addition, it hosts the Business Process Outsourcing (BPO) industry, which has been responsible for much of the country's economic growth in the past several years (estimated at 7.3% of GDP and 1.3 million jobs for 2016) and has allowed many working class Filipinos to improve their economic standing (Oxford Business Group, 2015).

Locating a business centre in Eastwood City has not only supported the direct users of the development, but also those who live nearby. For the residents of Barangay Bagumbayan, the low-income community adjacent to the PUD, having Eastwood City as a neighbour enabled new forms of income-generation through means such as room rentals and food sales that serve as low-cost alternatives to options inside the PUD. These accounts show that there has been an improved access to opportunities for a diverse group of people. This decentralisation of economic activity was indeed the claimed aim when Quezon City allowed for the reclassification of the industrial lot, and the development seems to have delivered on this. This has particularly strengthened its legitimacy in the eyes of various stakeholders, emphasizing the PUD's "whiteness".

Moreover, its main selling point, creating a live-work-play lifestyle, is particularly attractive not only to its users. Compact developments, touted as the anti-thesis to the unsustainable urban sprawl, aims to deliver a more sustainable lifestyle through dense mixed-use communities and has been promoted by the international community as a model of urban development (Jensen et al., 2011). The main advantages include more efficient services and shorter travel times leading to improved quality of life, less reliance on private vehicles that subsequently lessens consumption and pollution, and availability of diversity of opportunities, all of which lead to a better urban environment (Hofstad, 2012).

The compact city and similar developments, however, have been challenged as fallacious when its concept is translated into reality. Instead of being an instrument of sustainability, it becomes "a static product of developer's marketing campaign rather than an evolving process of human development" leading to inauthentic communities (Neuman, 2005: 22) and is implemented through "cherry-picking those aspects of the compact city as a sustainable urban model most attractive to their needs, such as increasing densities... which largely reflect dominant economic or environmental interests" (Dempsey & Jenks, 2010: 119). This densification tends to lead to further degradation of the environment, as it increases congestion, pollution and lack of open space. Furthermore, because social issues are not central to the concept, these developments tend to exclude those who cannot afford to pay for the lifestyle (Smyth, 2005: 92). Thus, compact developments tend to be exclusive spaces that favour the affluent, and encounters issues such as gentrification and displacement.

These critiques against compact developments are highly evident in Eastwood City, such as traffic congestion, open space deficit, and overloaded utility services. Rising concern about the development's vulnerability to disasters also gripped many of those interviewed because, coupled with the dubious quality of the buildings, Eastwood City is located next to often flooded Marikina River and the West Valley Fault Line. These emphasize that Eastwood City's claim to offering a "good life" may not be entirely valid. Arguments of sustainability focus mainly on economic aspects, while social and environmental aspects remain secondary, leading to very real concerns about the impacts of the development in the urban area.

Recently, doubts about the development have been increasing due to these issues, prompting the new Comprehensive Land Use Plan (CLUP) of Quezon City to remove its status as a growth centre due to these "built-in site limitations" (Quezon City Development Council, 2010: 22), but this has not yet been enacted and Eastwood City continues to grow. However, while these factors lessen the legitimacy of Eastwood City, for most of those interviewed, these still stand secondary to the benefits that the various stakeholders continue to enjoy: the convenience, the opportunities, the lifestyle. Everything else was overshadowed by the "whitened" image of Eastwood City.

3.3. Normalising Inequality

The stark inequality present in Eastwood City is the one thing that was rarely complained about by those interviewed. For some, the most attractive part about it is its very exclusivity, founded on aspirational imaginings. This sentiment is not only prevalent among the upper classes but is also echoed by the working class who would typically be among the most excluded. It would seem like inequality has been normalised in the system through layering of exclusive practices.

Eastwood City, like other urban enclaves, exhibits exclusivity in multiple levels by differentiating itself from its surroundings (Agnotti, 2013). The most obvious is physical isolation, with high-rise buildings forming an enclosure, secured access points, and obvious change in environs. Once inside Eastwood City, a curious combination of an international business district and a western-themed architecture can be immediately observed. There is little to connect the place to its local context; on the contrary, much effort has been made to displace Eastwood City and locate it in a fantasy world of global convergence, with the physical design just as one representation of this. Because much of the employment offered by Eastwood City is from the BPO industry, this creates a community that is highly tied to global processes, creating in itself a global identity (Kleibert & Kippers, 2015: 10), and setting itself as temporally apart from the outside (Michel, 2010).

Figure 4 Towers enclosing Eastwood City, source: author, July 2016

However, unlike in mono-use enclaves, this mixed-use characteristic creates a sense of conditional openness to the enclosure (Agnotti, 2013: 115). It grants access to the development to different users, yet segregates the space into layers of exclusivity. This can be observed by how different classes are spread out inside the PUD in unofficially designated areas, with the most dispossessed finding their space in the margins.

Figure 5 Jeepney waiting for passengers at No Loading and Unloading Zone, source: author, July 2016

At every entry point, one can find vibrant and often informal activities that cater to Eastwood City: transient food vendors lining, jeepneys stopping at "no loading/unloading" zones, "colorum" [unlicensed] public shuttles waiting surreptitiously for passengers. These alternative spaces can be found not only in the boundary, but also within the perimeter of the development: the common presence of technically illegal condo-sharing, a dormitory-type business/living arrangement to cut down costs of rent; lunch vendors disguising their wares and bring it into offices and shops; deals with the security crew allows for a blind eye in imposing restrictions. When asked about these exhibitions of informality, an interviewee replied, "If we don't do anything [about our situation], then nothing will happen." (Store cashier, interview, 26 July 2016)

These instances show that within and around the development are further states of exception, tolerated because they are used to address the needs of those the developer does not provide for, and existing as part of the deregulated system that persists in the PUD. These emphasize that space continuously changes due to the manifestations of these relations in the margins. However, while these can be seen as exhibitions of power, these can also further embed practices of exclusion into the system, as they remain in the peripheries of acceptability. How can there be a move towards equality when inequality has been normalised as a truth?

Barangay Bagumbayay, literally at the periphery and separated from the development, exhibits a significantly different case from the aforementioned examples of power at the margins. Because Eastwood City is located within the territory of Barangay Bagumbayan, it is actually under the jurisdiction of the barangay and must answer to their requirements. This status has given the barangay bargaining power despite being a poor community. To build, occupy, and operate, Eastwood City must coordinate and claim clearances with the barangay.

Figure 6 Barangay Bagumbayan with Eastwood City towers behind, source: author, July 2016

The imbued power of the barangay has given them a sense of control over their surroundings. They can deny or allow access, demand reparations and make concessions. While displacement is an ever-present concern, there is a sense of protection. The experience of Barangay Bagumbayan is an unexpected counterpoint to the dispossession of other sectors in Eastwood City. The power of the barangay does not come from the margins but from an acknowledged place: policy. Thus, in the effort to open various narratives and normalise equality in these PUDs, these spaces of exceptions, a turn to improvement of policy regarding these developments may be a step in the right direction.

3.4. Negotiating Planned Unit Developments

Through the example of Eastwood City, PUDs have been argued as spaces of exception that are shaped through the (in)formal relations of various actors. However, because the power/knowledge of these relations are inherently unequal, so too are the places these shape. This assemblage of relations, however, is not set in stone and is indeed open for reassemblages that can imagine new potentials (McFarlane, 2011: 211). Providing policies, like that in Barangay Bagumbayan, can provide new ways of inclusion.

Flexibility in planning processes does have numerous advantages such as allowing for spaces to be more responsive to changing contexts and leading to better designed environments. It is for these reasons that the concept of PUDs and other similar spaces of exception were initially formed (Herrle & Fokdal, 2011: 12). While these developments indeed have a tendency to be abused, these can also facilitate more inclusiveness in the planning process due to its openness for negotiations. However, leaving it as status quo tends to create spaces that focus primarily on private interests (Mandelker, 2008). Thus, there is a need to achieve a balance between regulation and flexibility towards "a model that accepts unpredictability and informality without surrender to the ravages of market-led ideology…

that does not kill the vitality, productivity and adaptability that sustains lives" (Dovey, 2012: 365).

One possible approach is to operationalise the concept of PUDs as a public planning tool, wherein various stakeholders outside the state-developer relationship are treated as active participants taken into consideration from the outset instead of mere passive consumers of the delivered product (Sager, 2011: 181). International examples exist, for instance the ZACs of France and UOs of Brazil, but due to stark differences on how these places are manifested in the Philippine context, care should be taken in transferring ideas from varying realities (Patel, 2014), such as placing too much trust on how the state can advocate the needs of the community during the process and ensuring that the benefits acquired from these developments are used for public services. However, institutionalizing this continuous negotiation processes among different actors would at least "[enable] people as citizens with political roles, rights, and agendas" (Sager 2011:181).

In trying to answer how these developments should be negotiated, this study does not attempt to create definitive recommendations. Rather, it exposes factors and opens up possibilities on how PUDs can actually be negotiated to enable inclusiveness: with the continuous sharing of power throughout its lifespan. While this is difficult to achieve because power's demarcations are ingrained in the system, recognizing and operationalising PUDs as spaces of exception can instigate this shift, promote the long-lasting legitimacy of the PUD and, ideally, move towards truly inclusive and sustainable societies.

4. Conclusion

The findings of this study uncover Eastwood City as a story of potential. Eastwood City is presented as a space of exception whose mutability is negotiated by the power/knowledge relations. Its need for flexibility from rigid land use plans is facilitated through a deregulated system of mutually beneficial (in)formal negotiations between state-developer. This space is legitimised through narratives of sustainability, yet normalizes unsustainable practices of over-densification and exclusion. While the public seems satisfied with Eastwood City due to these narratives and even appears to appreciate the exclusivity it espouses, their dispossession is evident and exhibits power in the margins of the development. Barangay Bagumbayan, the poor community along the edges of the development, acts as a counterpoint whose recognized status over Eastwood City as part of its jurisdiction has given the community power through policy.

This brings the discussion to how Planned Unit Developments should be negotiated through uncovering the processes that may lead to more inclusiveness in the continuous (re)shaping of the PUD. Based on the experience of Eastwood City, it is in operationalising PUD as a planning tool through legitimising the act of negotiation and sharing this power among all stakeholders, not only during the creation but also throughout the lifespan of the PUD, that can ideally lead to more inclusive and sustainable enclaves.

While this study can be further strengthened by exploring more manifestations of PUDs in different cities of Metro Manila (as well as in other developing cities), Eastwood City as one of the first and most established can reveal processes that may have similarities to the experience of other PUDs and act as a starting point in understanding them. This can lead to more in-depth analysis of PUDs, comparing how they are implemented in various contexts,

observing their changes over time, or networking these within the urban systems of the megacity. Furthermore, these findings can be a resource for a more inclusive approach on planning for these spaces of exception.

Case Study / Project

SMART GROWTH APPROACH

IN PLANNING BOGOR CITY INFRASTRUCTURE

fah LATIFAH, Dayinta PINASTHIKA

Abstract

Bogor as a satellite city in Greater Jakarta Metropolitan Area (40 km to the south) is rapidly growing with its main function as a center of the residential area, tourism, and education. As a residential center for Jakarta workers, during 2015 there were 114 thousand peoples commuted every day from Bogor to Jakarta by train, excluding car and bus commuters through highway (source: PT KA, 2015). The data shows that Bogor had already become the main provider of the residential area for Jakarta workers. Data also shows that more than 60% of property transaction in Bogor during last 5 years involved Jakartans (source: urbanindo). The rapidly growing of built-up areas and urban activities in Bogor have caused many problems such as the increasing numbers of slum areas, traffic congestion, informal sector occupancy in public spaces, pollution, etc. As a residential city, Bogor finds it difficult to stem the rapid investment in new housing developments while the provision of infrastructure is very limited so that these problems arise. The Ministry of Public Works and Housing as the leading sector in urban infrastructure provision initiated a planning project to improve the quality of infrastructure in Bogor to overcome the problems.

This project was run for 7 months in April to October 2016, which we served as consultants who assisted the ministry. The project found that to improve the quality of the urban spaces in Bogor, interventions need to start from the city center area as the urban acupuncture. This area was delineated in an area of around 500 hectares in the heart of Bogor, where the main activities of the city took place. A smart growth concept was used as the planning approach in this project by focusing on designing mixed-use and compact development, walkability, public transportation oriented, human scale oriented, and public space emphasis. The concept was derived by first dividing the area into 15 micro sub-area (each around 30 hectares) which have different themes and characteristics one to each other, with each sub-area having one local public service center. The division also took into account the walking radius in each sub-area and the possibility of developing a public transportation node in each service center. It can also be learned that it is necessary to set a minimum service standard for each sub-area in accordance with their service scale and main activity as a basis for determining the type of infrastructure that needs to be provided.

This project also provided infrastructure programs in a microscale context (human-scale infrastructure) to improve the quality of each sub-area, so that accumulatively would give a positive impact in terms of improving the quality of the whole city center. The resulting infrastructure program will be an input for the city government to formulate the annual budget.

Research Paper

Space of flow including capital and information shape the megacity groups：

based on the example of Chengdu-Chongqing city groups in China

SHUAI LI, Tongji University; China

Abstract

With globalization,space of flow ,such as capital, information and talent are moving around the world, which combine separated cities into influential urban groups. This research takes Chengdu-Chongqing urban agglomeration in China as an example, whose GDP exceeded 900 billion dollars in 2018.From this example ,we are concerned about its formation process and future planning. As for theory, this study utilizes Castel's theory of Network Society, which holds that "space of flow", such as, capital and information create "space of place" (cities) under globalization. Meanwhile, the key point to urban development is the information and capital. The key point to Urban planning is the attraction of external information(including talent and news) and capital. As for the method, focusing on the information and capital, this paper build the analyzing network model among 27 cities of Chengdu-Chongqing urban groups . For the information model,the intensity of information flow among cities is simulated and measured by using Baidu Index big data, in order to reflect the information attractiveness. We can find the the character of this city group network and space organization of the city groups under the view of "space of flow.As for the results, firstly,it is found that the flow factors of capital and information are positively correlated with the level of economic development, which means that the cities with high GDP ,such as Chengdu and Chongqing, have a strong flow of capital and information. Secondly, the status of cities in urban groups are determined by the value section of their enterprises. For example, Chengdu and Chongqing at the highest level, mainly hold companies with high economic value such as finance, trade and law firms, while sub-level areas share companies with slightly lower value such as manufacturing, medicine and so on. The higher the value of the company occupied by the city, the more power of the city. If the city owns multinational corporations, it can influence the world by global capital. Thirdly, cities are likely to form group development, because capital and information have agglomeration effect. As long as capital and information can flow to the region, this city can participate in the operation of urban groups. Finally, for future planning methods, under the influence of globalization, capital and information will flow more frequently, and cities will develop in groups. The core of planning is to highlight the characteristics and advantages of the city to attract the space of flow such as new companies and talents, so as to enhance its own competitiveness for better development.

Keywords

Space of flow,Chengdu-Chongqing urban agglomeration,information model

1. Theoretical research

1.1. Space of flow

With the development of economic globalization, cities have formed economic activities that combine geographically highly diffusive and functionally deeply integrated activities (P. Dicken, 2011), and form collaborative and complementary relationships through industrial chains, thus forming interrelated production networks and urban networks. The networked urban system is the advanced form of urban agglomeration development. (J. Friedmann, 1986). In 1996, M. Castelles (1996) put forward the theory of "social network" to explain the essence of urban network. He believed that cities, as "space of place", are hubs or nodes of global urban network, while "space of flow" such as capital flow, information flow and people flow, is the "space of flow". It has created a network of links between cities around the world. In the empirical aspect, there are three main research perspectives: infrastructure research, enterprise organization research, virtual network research. Infrastructure research is mainly based on Derudder (2008), Burns (2008) and other scholars through highways, railways, aviation and other carriers to study the flow of people and goods between cities.For enterprise links, Professor Peter Taylor created Locking network method,which is used to measure global urban links and is represented by GaWC's chain network model. For the researches of information flow network ,are represented by virtual network (Krings, et al. 2009; Zhenfeng, et al. 2016), especially using the data from social media and microblog .

1.2. Urban network under the perspective of information flow

The essence of urban network is the relationship between cities reflected by the factors of folw.,and information is an important supporting condition in the form of urban network (Mingfeng, Gaofeng, etc.2007). Because information flow is faster and more dynamic than other flow elements which need "actual carrier" such as enterprise organization and infrastructure.Furthermore it can better reflect the potential changes and the latest developing demand of urban network. At the same time, the Internet itself does not have a strict hierarchy of urban information exchange, so it reflects the characteristics of urban network more objectively to a certain extent, and complements other urban network studies with "actual" carriers, providing new perspectives and opportunities for the development of cities around the world.

Scholars have done a lot of research on this: Mitehelson(2002) and others use information flow such as telephone to describe the links between metropolitan areas; Zhenfeng (2012) and others, taking Sina Weibo as an example, have explored the characteristics of Chinese urban network based on cybersocial space. Xiong Lifang (2014) and Cao Ziwei (2016) used Baidu Index to interpret the the city hierarchy of Yangtze River Delta city network.

1.3. Urban Space in network form

With the rapid transmission of information and other flow elements, the relationship between cities is gradually weakened by the influence of proximity. Traditional research on urban regional spatial organization is based on the principle of spatial proximity, following the logic of "core, side and edge" spatial organization and the traditional paradigm of "central place" theory. However, professor Castel's "space of flow" gave birth to a new form of spatial organization - Urban network, which refers to the networking urban system. The shorter distance between cities will not reflect the strong connection .The importance of the distance between cities tends to weaken, and the urban system has evolved into a multi-

center, complex network and flat open system (Tang Zilai, 2010). The spatial study of urban agglomeration has also turned to how to quantitatively calculate and visualize the information flow, transportation flow, enterprise connection flow and the urban system represented by them. The status of a city is also determined by its proportion in various "flow elements" and the frequency of its connections (Xiong Lifang, Zhenfeng, etc.2013). Then under the network city organization, how to layout the urban regional space and how to attract the “space of flow have become important factors for the future development of the city.

2. Rearch subject and methods

2.1. Chengdu-Chongqing city groups

The area of Chengdu-Chongqing urban agglomeration was determined by the <Chengdu-Chongqing Urban Agglomeration Development Plan>in 2016 from central government (Fig. 1). The total area is 185,000 square kilometers,including 27 districts,such as Yuzhong, Wanzhou, Qianjiang, Fuling, and parts of Kaixian and Yunyang, as Chengdu and Ziyang in Sichuan Province. Gong, Luzhou, Deyang, Mianyang (except Beichuan County and Pingwu County), Suining, Neijiang, Leshan, Nanchong, Meishan, Yibin, Guangan, Dazhou (except Wanyuan City), Ya'an (except Tianquan County, Baoxing County), Ziyang and other 15 cities .It has a total area of 185,000 square kilometers, with a permanent resident population of 900,940 in 2014 and GDP of 376 trillion yuan, accounting for 1.92%, 6.65% and 5.49% of the country respectively.

Figure 1 Research area

2.2. Data——Baidu Index

Baidu Index is based on the search volume of one city's residents for another city. According to the report released in October 2017 by StatCounter Global Stats, the proportion of Baidu search engine usage in China is as high as 82.99%, accounting the largest part. Therefore, Baidu Index can reflect the degree of concern of urban people to another city (which can be

called "attention"), and simulate the information flow between cities. At the same time, based on the current research of "Baidu Index" to simulate the information flow between cities, it is confirmed that Baidu Index reflects the economic and social links among cities to a certain extent, and reflects the comprehensive strength of cities (Xiong Lifang, etc., 2013). In order to study the development of Chengdu-Chongqing urban agglomeration before and after the publication of "Chengdu-Chongqing Urban Agglomeration Plan" in 16 years, and considering the availability of data.This paper takes the average of user search index in 2015and2018.

2.3. Research method

Referring to previous scholars'methods (Xiong Lifang, et al., 2013), the algorithm is as follows: The information flow intensity between two cities is calculated by the **Rab** formula of network attention product between cities A and B.

$$Rab = Ab * Ba$$

(Among them, **A**. For the user attention of City A in City B, **B**. For city B in city A user attention.

If the total amount of information flow in city A is N, it is the sum of information flow in city A and other cities in core area.

$$Na = Rab + Rac + ... + Raz$$

The relative attention (relative information flow) of a city is expressed by **P**, which is the relative position of the total information flow of the city in the core area in the region. Calculating formula:

$$P = Nk/Nh$$

(Among them, **Nk** is the total amount of information flow of a city, and **Nh** has the corresponding value of the largest amount of information flow of a city in the study area.)

3. The network character of Chengdu-Chongqing city group under the view of information flow

3.1. The variation character with year

From 2015 to 2018, the total amount of information flow of Chengdu-Chongqing urban group increased, and the increase was larger. The total amount of information flow in each city has risen from 7151724 to 9648844, and the average amount of information flow in each city has risen from 446982 to 603052, an average increase of 35%. At the same time, the annual variation of the total information flow in Chengdu-Chongqing urban agglomeration is measured by the variation coefficient C (the relative amount of standard deviation relative to the average size). The C value in 2015 is 1.223, which is less than 1.344 in 2018. It can be seen that the information links between cities are becoming closer and closer, and the stability of urban network based on information flow is becoming stronger and stronger (Figure 2).

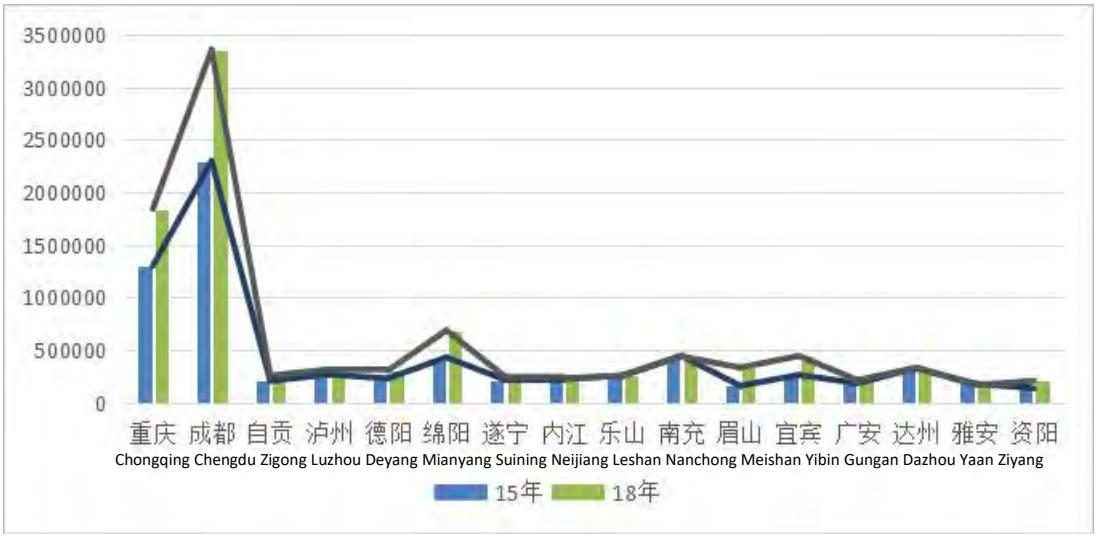

Figure 2 Change of Information Total Amount in Chengdu-Chongqing Urban group

3.2. Hierarchical character

The urban network levels of Chengdu-Chongqing urban agglomeration in 2015 and 2018 were obtained by clustering method with spss method. (Table 1).

Table 1 Information Network Hierarchy

Level	city (2015)	city (2018) (the change of the ranking)
1st	成都 chengdu	成都 chengdu
2st	重庆 chongqing	重庆 chongqing
3st	南充 nanchong、绵阳 mianyang、达州 dazhou、泸州 luzhou、宜宾 yibin、乐山 leshan、德阳 de yang、内江 neijiang	绵阳 mianyang (+1) 、宜宾 yibin (+3) 、南充 nanchong (−2) 、眉山 me shan (+9) 、达州 dazhou (−2) 、泸州 luzhou (−2) 、德阳 deyang
4st	遂宁 suining、自贡 zigong、广安 guangan、雅安 yaan	自贡 zigong (+2)
5st	眉山 meishang、资阳 ziyang	乐山 leshan (−3) 、遂宁 suining (−1)、内江 neijiang(−3)、广安 guangan(−1)、资阳 ziyang(+1)、雅安 yaan(−2)

(1) The urban network presents the development trend of "double core". Chengdu and Chongqing occupy the core position of the network, with the strongest directivity of network information links, exceeding one million in both cities, and their linformation amount are over 50% in the total network. Further, they are still in the rising stage,from 50% (15 years) to 53.8% (18 years). Among them, Chengdu has a more prominent position, accounting for 34.7%, which is 1.82 times that of Chongqing.

(2) The network presents a distinct hierarchical development trend. The first three cities developed well, while the latter two cities lagged behind. In 2015, the network level of Chengdu-Chongqing urban agglomeration was "1+1+8+4+1", and in 2018, it was "1+1+7+1+6" (fig. 3). It shows that the information of the first three cities develops rapidly

(information accounts for more than 80%) and the gap between the first three cities and the second one is increasing, which leads to the increase of the number of the last series cities.

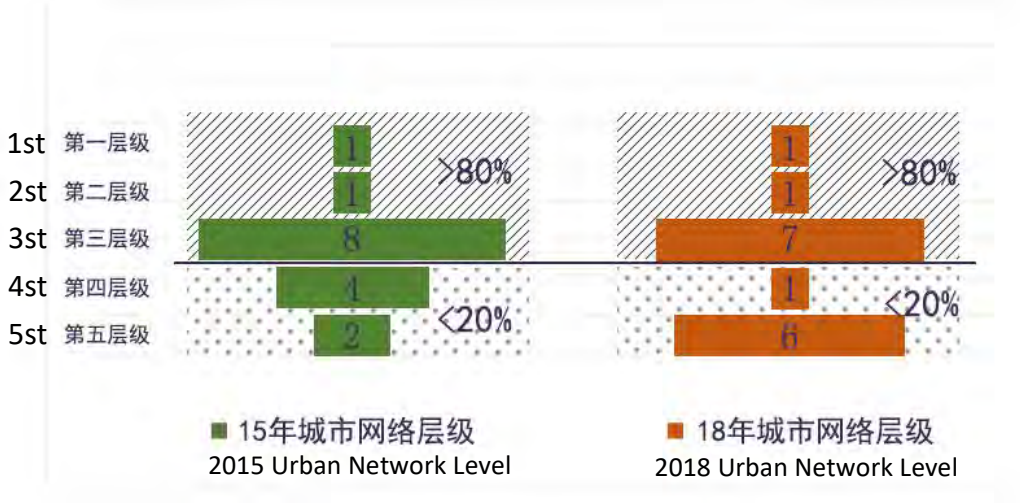

Figure 3 Image example_ISOCARP logo

(3) In the network, Yibin and Meishan have achieved good development, of which Yibin has risen by 3 places, with the increase of information amount reaching 118%, and Meishan has risen by 9 places more rapidly, with the increase reaching 207%. The status of Leshan and Neijiang has declined considerably, falling three places respectively, and from the third level to the last level.

3.3. The variation character with year

In order to further compare the structural characteristics of Chengdu-Chongqing urban agglomeration network, the influence before and after the establishment of Chengdu-Chongqing urban agglomeration is analyzed. From the perspective of space-time evolution, urban network maps are drawn based on the information flow intensity matrices of Chengdu-Chongqing urban agglomeration in 2015 and 2018 respectively (fig. 4), and a backbone network with information flow intensity more than 50,000 between cities is selected (fig. 5). At the same time, considering the status of Chengdu-Chongqing urban agglomeration network in the country, and also based on the intensity of information flow, the structure of Chengdu-Chongqing urban agglomeration in the national layout is drawn (fig. 6).

(1) From an external perspective, Chongqing-Chengdu has a prominent core position and upgraded urban links. As the dual core of Chengdu-Chongqing urban agglomeration, Chongqing and Chengdu have frequent exchanges of information elements between cities, which has leaped to become the second strength connection similar to Beijing-Tianjin and Guangzhou-Shenzhen . At the same time, the status of the two places as information nodes in the West has been strengthened, and their links with the Yangtze River Delta, the Pearl River Delta, Tianjin, Beijing and Hebei have been further strengthened. The status of Chengdu (5 links) is better than Chongqing (3 links).

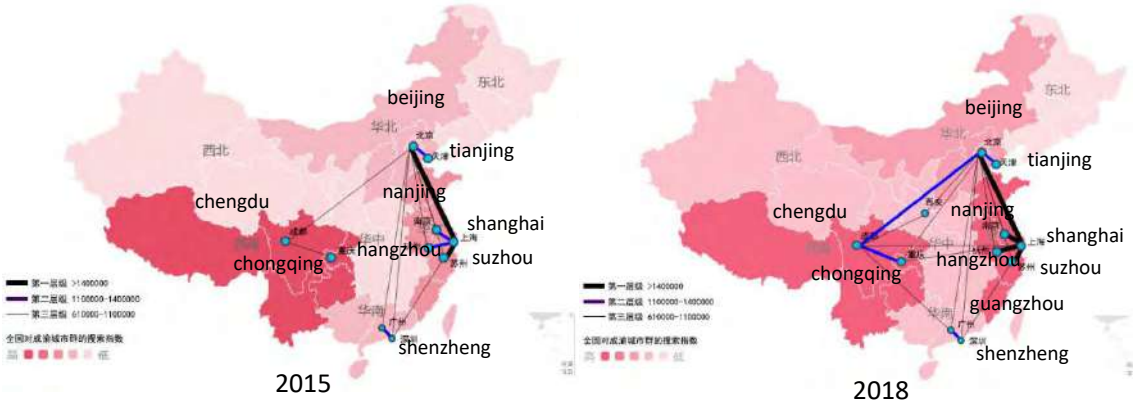

Figure 4 Structural Map of National Backbone Information Network

(2) From an internal perspective. The overall network structure of Chengdu-Chongqing city has been continuously optimized and gradually matured. The information links between cities in 18 years were stronger than those in 15 years. The network shows the frequent interaction structure between Chengdu and Chongqing, and the increasing interaction between Chengdu and Chongqing as the core city and other cities.

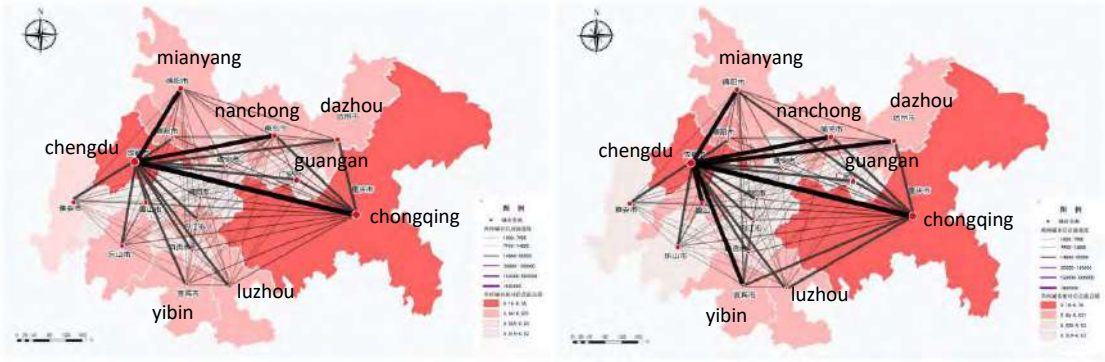

Figure 5 Chengdu-Chongqing Information Network Structure Map

(3) As far as the backbone network is concerned, the secondary nodes have been developed and the whole structure is diamond-shaped. Chongqing has broken through the administrative boundary and expanded its influence in Sichuan. Reflected in Chongqing and Sichuan provincial cities, the amount of information has increased, and interaction is more frequent. Chongqing's main links include Dazhou, Nanchong and Guang'an, with the addition of Yibin, Luzhou and Mianyang.

The network has also expanded from a single northern triangle connection to a diamond-shaped network structure with Mianyang, Nanchong and Dazhou as the core in the South and Yibin and Luzhou as the core in the north. Correspondingly, in the planning of Chengdu-Chongqing Urban Agglomeration, Yibin and Luzhou in the south are regarded as the core cities of the region, and the regional transportation links are strengthened. Therefore, the southern cities are closely connected with Chongqing's information network.

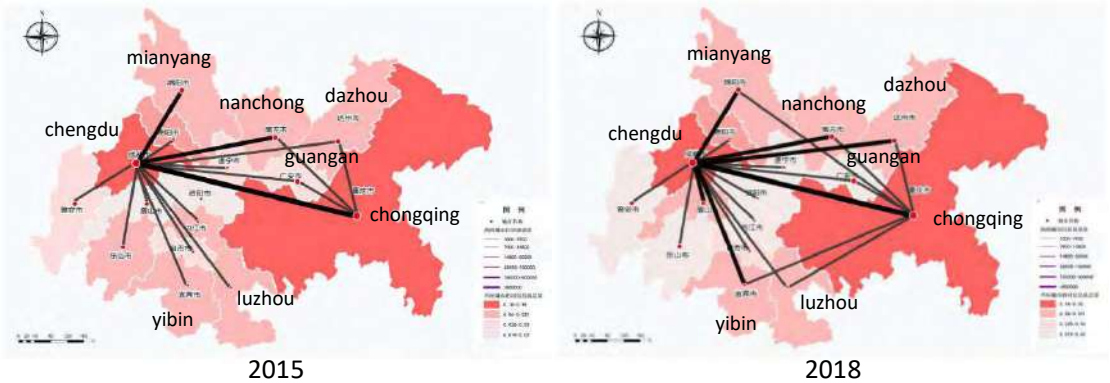

Figure 6 Structural Chart of Chengdu-Chongqing Backbone Information Network

4. Re-recognition of Chengdu-Chongqing Urban Space from the Perspective of Information Flow

4.1. Development of urban groups relying on gateway cities

In 2016, the State Council's approval document for the development plan of Chengdu-Chongqing urban agglomeration (State Letter No. 68, 2016) clearly pointed out that "by 2030, the radiation-driven role of Chongqing, Chengdu and other national central cities will be significantly enhanced, and the integrated development of urban agglomeration will be fully realized." From the perspective of information flow, it is found that Chongqing and Chengdu, as "information portals" in the west, play a two-way role in connecting the national network and radiating the urban agglomeration inward. Externally, the second and third largest cities in Chongqing and Chengdu are Beijing and Shanghai, and the top ten cities all come from the outside of the urban agglomeration (Table 3).

Table 3 Priority of Chongqing-Chengdu Urban Linkage in 2018

city	Connectivity	Relative correlation value	city	Connectivity	Relative correlation value

	7. hangzhou	19. 33		7. guangzhou	27. 38
	8. suzhou	16. 37		8. wuhan	20. 95
	9. wuhan	15. 63		9. nanjing	20. 49
	10. kunming	8. 52		10. suzhou	17. 86

Internal aspect: From the analysis of the relationship network within the urban agglomeration, it is shown that the first and second first cities of Chengdu-Chongqing urban agglomeration are Chengdu and Chongqing, and are the dominant flow direction of the city (Figure 7 takes Luzhou and Guang'an as examples). From the analysis of both external and internal sectors, it can be concluded that Chongqing and Chengdu play a portal role in Chengdu-Chongqing urban agglomeration, and they are important media inside and outside the urban agglomeration and information hub inside (Figure 8).

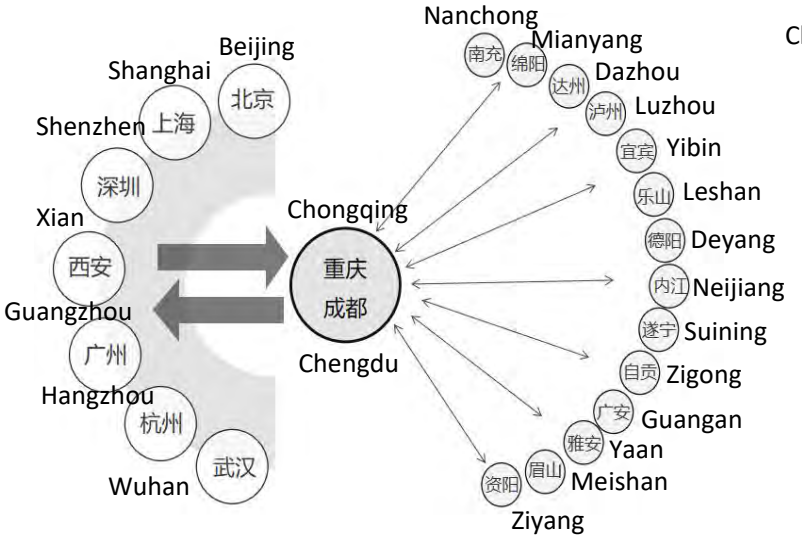

Figure 7 Chongqing and Chengdu as two sectors of information portal

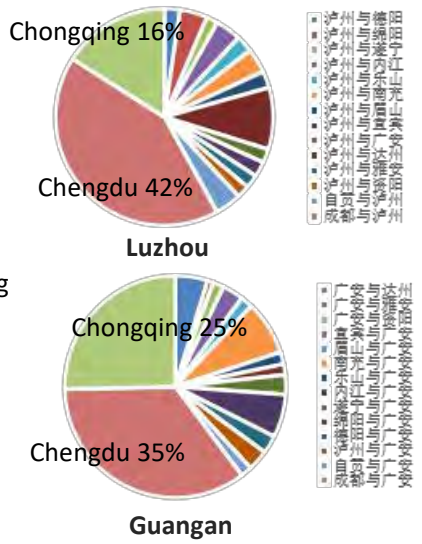

Figure 8 Analysis of the First City in Urban Agglomeration

4.2. Spatial Economic Basis Behind Information Flow

In today's highly informationized global economy, invisible information network has a great impact on urban areas, but information flow will not exist in isolation. The development of information network is often influenced by the level of urban development. It will gather and disperse with capital, labor force, and other factors of production in the geographic space (Hall, 2009). Therefore, the economic development foundation and labor force of the city itself are the important influencing factors of the development of Chengdu-Chongqing network pattern.

This paper chooses 16 cities of Chengdu-Chongqing urban agglomeration in 2018 to analyze the correlation between the Gross Regional product, the number of permanent residents and the total information flow of these cities in 18 years. The results show that the correlation is significant at 0.01, and the correlation coefficient is greater than 0.7 (Figure 9), which means that the total urban information has a relationship with the total regional urban value and the permanent population. Significant and strong correlation. At the same time, by means of SPSS regression analysis, it is found that there is a positive correlation between the amount of information and GDP, permanent population respectively (Figure 9).

Figure 9 Analysis Table of Relevance between Information Quantity and GDP and Population

To sum up, in Chengdu-Chongqing urban agglomeration, the amount of urban information is highly related to the regional gross domestic product and the permanent population, and will grow with the growth of the gross domestic product and the permanent population. The information network between cities is not only the reflection of people's attention to the city, but also the economic and demographic basis of the city as an important support. On the one hand, only when a city has a strong economic foundation and talent gathering, can it produce more information exchange. On the other hand, cities can stimulate more elements of information flow, which also indicates opportunities for urban economic and labor growth. In the 18-year Chengdu-Chongqing urban agglomeration, we can see that economic development, population density and information activity have a high degree of overlap in space (Figure 10). Information flow network also represents the economic and demographic basis behind it to a certain extent. Therefore, paying attention to the change of information flow and becoming the core of information flow can often be a city. Bring good opportunities for development.

Information GDP Population

Figure 10 Information, GDP and Population Distribution of Chengdu-Chongqing Urban group

4.3. Gradually break through the traditional "core-edge" level of network development

Different from the spatial organization logic based on "central place" theory, which determines the location of center or periphery, the degree of connection between urban node and other nodes in urban network determines the location of the urban node at the core or periphery of the network (Doreen Massey, 2010). Using NetDraw to further abstractly analyze the information network structure of Chengdu-Chongqing urban agglomeration, we can clearly see that the information flow links between secondary cities

are constantly strengthened, and the overall trend of network urban system is presented (Fig. 11, 12).

In 2015, Chengdu and Chongqing are in the absolute core leading position, presenting obvious "core-edge" secondary structure, and Chengdu has a slightly stronger position. Secondly, the status of nodes in Nanchong, Yibin, Mianyang and Luzhou has been improved, which can also produce stronger networks in other areas, such as Yibin and Luzhou, Mianyang and Suining, Mianyang and Dazhou, which change the previous situation of radiation from Chengdu and Chongqing alone and show the trend of flattening network characteristics. From the evolution of the network, we can see that the free flow of information between cities is not bound by administrative and regional constraints. Not by the traditional administrative hierarchy of "municipalities directly under the Central Government, provincial, prefectural and county-level cities", but homogenization for all cities. The development of urban agglomeration also has the relative edge of the city to enhance the status of contact, strengthen information interaction with other cities, so that the network from a single core to network development.

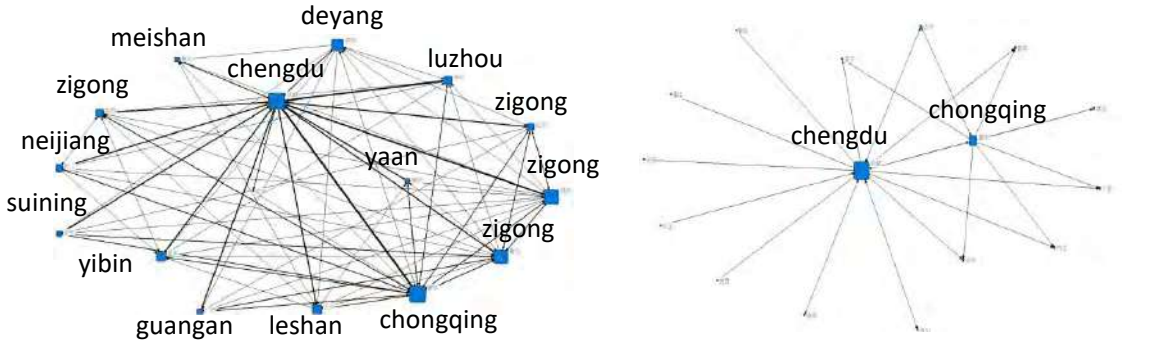

Figure 11 The obvious "core-edge" secondary structure in2015

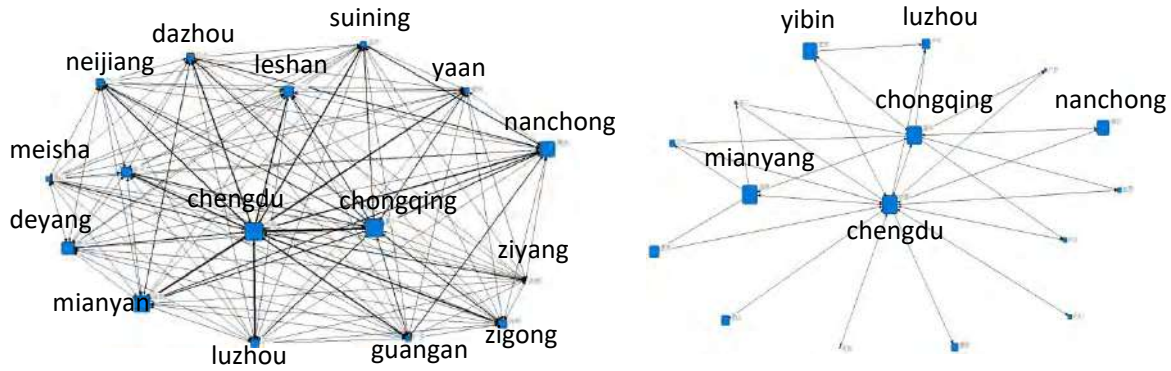

Figure 12 The obvious trend of network structure in 2018

5. Conclusions

Spatial flow promotes the reorganization of the spatial structure of urban areas (Ravetz, 2016). The focus of urban agglomeration has shifted from the traditional urban material structure and urban form itself to the social network beyond spatial perception (Davoudi,

2008), and from the "flow element" to consider the "place space" carrying the flow element. This research is from the perspective of information flow elements, using "flow data" to construct urban network relevance. On this basis, the author reflects on the "Chengdu-Chongqing Urban Agglomeration Planning" put forward in 16 years, hoping to provide more scientific technical support and a new perspective for the future Chengdu-Chongqing Urban Agglomeration Planning:

(1) Chengdu-Chongqing Urban Agglomeration refers to the full play of the dual-core driving function of Chongqing and Chengdu, giving play to its advantages of communicating East and West, and speeding up the development of the western region, which is fully based on. Chongqing and Chengdu are "information portals" in the western region, and they are important external media and internal information hub of urban agglomeration. The relationship between Chongqing and Chengdu has been growing steadily, and has risen to the second level of information connection intensity in the whole country, similar to that between Beijing and Tianjin, Guangzhou and Shenzhen. The strengthening of the core city links has brought a better information base for Chengdu-Chongqing urban agglomeration, and is also conducive to enhancing the intensity of information links within the urban agglomeration, which is conducive to the development of other node cities in the region.
(2) Planning the connection channel between urban entity and virtual entity will become an additional part of the new planning. The elements of information flow do not exist alone, but are related to the mixed elements of urban economic flow and human resource flow. Therefore, on the one hand, cities should pay attention to marketing and promotion effects in their development. For example, Chengdu-Chongqing urban agglomeration has been approved as a national-level central city group, and the overall urban information attention has been greatly enhanced. For the city itself, the enhanced information attraction contains the potential of economic and human attraction; on the other hand, new urban development. It is to enhance the information connection with other nodes and promote information exchange. In addition to network attention, convenient links such as physical transportation and enterprise communication will also be conducive to the dissemination of information and promote the development of the city.

(2) Networked urban agglomerations have open boundaries and interactive breakthroughs in administrative hierarchies. Therefore, the new planning encourages cross-regional cooperation, builds a shared and efficient infrastructure network, and allows flow elements to flow freely. From the perspective of network, the energy level of a city depends more on its network capability than on the population size and administrative level that most traditional planning considers. We find that the open and interactive relationship between the networked urban agglomerations, such as the rapid increase of the links between Chongqing and Sichuan cities, especially in Neijiang, Luzhou and Nanchong. At the same time, the urban network has broken the original single radiation structure of Chongqing and Chengdu, and the secondary radiation nodes such as Nanchong, Yibin, Mianyang and Luzhou have appeared, especially the upgrading of Yibin and Luzhou, which has expanded the whole network from the original "triangle" to the "diamond" type, and the development of secondary nodes is no longer affected. Because of the hierarchical system, future planning cities should focus on building their own links with foreign cities, and not restrict themselves by traditional planning languages such as administrative boundaries, metropolitan boundaries and axle belts, so as to carry out multi-regional cooperation and free circulation of flow elements.

Research Paper

The Spectrum of Metropolitan Areas across the World, and Detection of Potential Metropolitan Areas with Chinese Characteristics

Qing LU, Peking University; China
Liyan XU, Peking University; China
Zhen CAI, Urban Space Planning and Architectural Design CO., LTD; China
Xiao PENG, Peking University; China

Abstract

When people talk about the Metropolitan Area (MA), they mean differently in different parts of the world with different contexts. Based on its spatial extent, internal structure, socio-economic function, and network characteristics, an MA can refer to various entities from a metropolis to a Megacity-region. In an effort to clarify the MA concept, we review the origin of the MA concept and its development in various parts of the world, especially the United States, Japan and China, so as to propose a spectrum of MAs, and their relationship with specific human and natural geographical contexts. Particularly, we find MAs in China typically have a unique three-circle structure, which is composed of a core circle, a commuting circle, and a functional metropolitan circle. By international comparable standards which include factors such as population density, facility density, and economic activity intensity, and adjusted with reasonable context-dependent considerations in China, the three circles are designated as follows: the spatial extent with the highest development intensity and assuming a central regional role is identified as the core circle; the districts and counties around the core circle with a commuting rate greater than 10% are identified as the commuting circle; and the districts and counties within an one-hour accessible zone are identified as the functional metropolitan circle. To test the model, we utilize eight sources of big data covering ecological background, population, economy, transportation, real estate, land use, infrastructure, and culture characteristics, and with a fusion analysis of the data we show how the factors combined give rise to the three-circle structure in typical Chinese MAs, and why the combination of the same factors in the US and Japanese contexts works otherwise to fill different niches in the spectrum of MAs mentioned above. For a further inquiry, within the framework of the same model and using the same dataset, we identify 32 cities from all 338 prefecture-level cities in China that would qualify as an MA or potential MA, which we call "the Metropolitan Areas with Chinese Characteristics", and designate the spatial extent of the three circles within each of the MAs. Additional analyses are also conducted to locate the main development corridors, key growth poles, and currently underdeveloped regions in each of the MAs. We conclude the paper with discussions of potential challenges of MA development in China vis-a-vis current policies, such as cross-administration collaboration between jurisdictions within the same MA, and cross-scale collaboration between MAs, cities, and city groups. Placing the research in the global context, and considering the vast similarities between China and other developing countries in terms of population density, land resources, urbanization

level, and socio-economic development status in general, we argue that China's model of MAs may be also applicable to other developing countries. Therefore, this research may shed lights to planning researchers and practitioners around the world, especially in developing countries in understanding the development conditions of MAs in their own contexts, and also in methods for identifying and planning potential MAs to achieve their specific policy objectives.

1. Introduction

1.1. Metropolitan area concepts

Metropolitan area is a complex spatial system. Urban geography, population geography and urban planning provide theoretical support for summarizing the development of the metropolitan area from the perspective of regional differences and spatial structure evolution. In 1961, Jean Gottman first mentioned the concept of "Megalopolis" in the book " Megalopolis: the urbanized northeastern seaboard of the United States ", which refers to the phenomenon of urbanization in the northeastern United States (Gottman,1961). The first naming of the phenomenon, that is, a central city or a few large cities that play a central role, plus an urban economic region surrounded by areas with strong connection from the central city (Gottman,1957; 1978). In the 1950s, Japanese scholars proposed the concept of "Toshiken" and applied it to regional urban planning (Tomita,1975). In 1951, the Japanese scholar Kiuchi Shinzo proposed that the metropolitan area should be composed of three parts: the central area, the surrounding area of the city and the vast hinterland of the suburbs by studying the cross-sectional changes and regional structure of urban population increase and decrease (Kiuchi,1954). His ideas were further developed into the metropolitan area concept of Japan, and as one of the important spatial organization characteristics of Japan, western countries and other urban areas. The definition of the metropolitan area in Japan basically refers to the American standards, and then sets various metrics according to the specific national conditions such as the population and area of Japan (Kanemoto,2002). Because China and Japan belong to the East Asian Chinese character culture circle, Japan's theoretical exploration and successful practice in the metropolitan area has been widely quoted in China. Chinese scholars, including Yixing zhou, Shimou Yao, Chaolin Gu, Chuanqing Wu, etc., began to study the concept of urban agglomeration (Zhou,1986; Yao,2005; Gu,1994). There is never a unified academic definition about metropolitan area. However, most definitions indicate that the metropolitan area is an interconnected whole formed by cities of different grades, types and sizes, with the help of regional transportation networks. Combining the existing concepts of metropolitan area, metropolitan area in this paper is defined as a region consisting of a densely populated urban core and its less-populated surrounding territories, sharing industry, infrastructure, and housing. This definition highlights the dominant position of the central city, the close relationship between the internal social economy and the boundary of the economic development of the circle.

1.2. Criteria of metropolitan area

The New York metropolitan area is a geographic unit defined by the US Bureau of Statistics （NY-NJ-PA Metropolitan Statistical Area）. A core-based statistical area (CBSA) is a U.S. geographic area defined by the Office of Management and Budget (OMB) that consists of one or more counties (or equivalents) anchored by an urban center of at least 10,000 people plus adjacent counties that are socioeconomically tied to the urban center by commuting (Vicino,2007; Luo,2007). The standards of urban areas and non-urban areas are according to different national conditions . Japan refers to urban areas as “Shigaichi”, an area with a population density of not less than 4,000 people per square kilometre (Sorensen,1999). People have a tolerance for the length of commuting time, so the long axis radius of the metropolitan area is stable around 50 kilometers, that is, the size of the commuting circle determines the size of the metropolitan area. In the 1950s, the Japanese Administrative Office defined the metropolitan area as: a one-day cycle that can accept the geographical scope of a functional service in a certain aspect of the city (the population must be more than 100,000). The metropolitan area is the spatial scope that is closely related to the various regions formed by the city when it exerts its functions. It is usually measured by logistics, people flow, economic flow, information flow, etc. And the city's own external control ability and economy radiation capacity is also an important measure of metropolitan area. The Japanese Administrative Office revised the concept of the metropolitan area in 1960, and defined the commuting population in the central city and the periphery, and the logistics traffic volume in the metropolitan area. It pointed out that the metropolitan area is centered on the designated city of the central government. An area consisting of one or two or three mega-central cities with a population of more than 2 million and a number of neighboring cities with more than 500,000. The commuting rate from the peripheral area to the central city is not less than 15% of the population, and the amount of material transportation between metropolitan areas cannot exceed 25% of the total transportation volume(Qiu,2009). The commuting rate from central cities and peripheral cities largely reflects the economic, transportation and other links between metropolitan area.

2. Metropolitan area identification

2.1. Research objects

In this study, 32 major cities (excluding Hong Kong, Macao and Taiwan) were selected as research objects, 31 of which were located in the east of Heihe-Tengchong Line, including 4 municipalities (Beijing, Shanghai, Tianjin, Chongqing), 5 cities with separate plans (Shenzhen, Dalian, Qingdao, Ningbo, Xiamen) and 10 sub-provincial cities (Guangzhou, Nanjing, Hangzhou, Wuhan, Chengdu, Xi'an, Harbin, Changchun, Shenyang, Jinan), 12 provincial capital cities (Zhengzhou, Hefei, Changsha, Kunming, Nanchang, Nanning, Taiyuan, Guiyang, Fuzhou, Shijiazhuang, Haikou, Urumqi) and a prefecture-level city (Suzhou). We conduct in-depth research on the national metropolitan area, judge its development stage, and fully grasp the development of China's metropolitan area, and establish a methodology for the identification and scope of metropolitan areas.

2.2. Data source

Sources of this research data include national and local statistics(2013,2015,2017), China Unicom's “smart step” mobile phone signaling data(2018), AMAP point of interest(POI)

data(2018), DMSP/OLS remote sensing lighting data(2015), remote sensing image data(2018), and official website of local government.

2.3. Metropolitan area identification method

According to the factors such as population density, facility space density, and economic production activity intensity, the spatial unit with the highest development intensity in the region and taking the central function in the region is identified as the core circle. The determination process of the core area is as follows: (1)Assign multisource data to the kilometer grid. (2)Extract weighted scores greater than 15 points as the base layer after normalized processing of different kinds of data. (3)Screen the township street data to obtain the initial boundary of the core circle, and then use the light index data which can reflect the concentration level of economic activities to complete the boundary check. Extract the area where the light index value is greater than a certain threshold, and combine it with the initial boundary of the core area. And then get the boundary urban core circle of metropolitan area.

The urban circle is a spatial unit that is closely related to the core area in the region, and the commuting level that can directly reflect the degree of contact in different regions is selected as an indicator. Based on AMAP map commuting data, take the districts and counties around the core area as the basic unit. And the district or county units with the commuting rate to the core area greater than 10% are identified as the urban circle of the metropolitan area.

The metropolitan circle is a spatial unit that is closely related to the urban area within the region. It is also based on the commuting rate to realize the identification of the metropolitan area. Based on AMAP map commute data, calculate the commuting rate of districts and counties around the urban circle. Extract the district and county units with core circle and urban circle commuting rate greater than 1% as metropolitan circle. So far, the scope of the metropolitan area has been formed by the core circle layer, the urban circle layer, and the metropolitan circle layer.

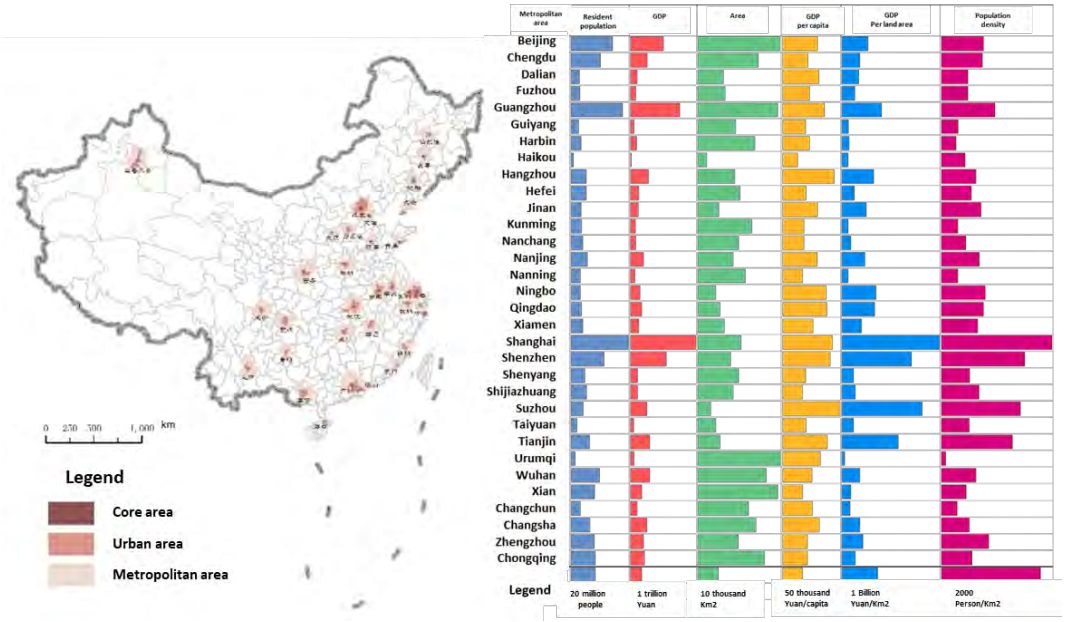

Figure 1 Diagram of 32 metropolitan areas in China and statistical results of basic data

3. Spatial Logic of China's Metropolitan Area Evolution

" Core-Near-Area-Node" : The evolution Process of the spatial structure of the metropolitan area

Based on the development cases of large cities and their surrounding areas at home and abroad, and combined with the researches in fields like urban and geographic science, it can be found that the spatial development of metropolitan area will focus on the core part of metropolitan area, the node cities near the core part, and the important node cities in the wide area. Experiences from the development process of foreign metropolitan areas reveal that the formation of metropolitan areas has obvious characteristics of stages, often going through the process of "single-center agglomeration- diffusion near the center- diffusion in the wide area- diffusion in a network way" (Fang,2009). At first, the spatial development of metropolitan area will go through the absolute concentration stage, that is, the rapid development of the core area, the rapid growth of population in the urban center, and the aggregation of peripheral resources and population to the core, which could be concluded as "single-center aggregation" in spatial. As core cities' economic development, metropolitan areas will enter the stage of " diffusion near the center ", characterized as the stable development of core circles and industrial transformation and separation of employment and residence. Industry and population will also spread to the suburbs of cities in spatial, thus foster the rapid development of the areas near the metropolitan areas (Dong,2005). After that, "diffusion in the wide area " as the residential functions and economic activities spreading to more peripheral areas along transport trunks and rivers, will appear in the metropolitan area. With the gradual integration of industry and city along the main corridors of some node cities, the city develops from a single-function city to a comprehensive-

function city. The functions of the region are more sound through the form of new industrial new towns, thus the region evolves into a more advanced "multi-center network" structure.

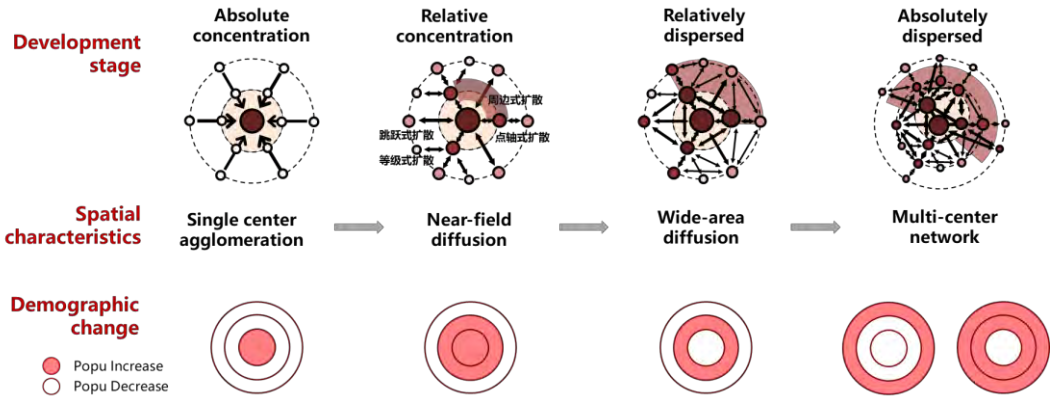

Figure 2 Metropolitan space development stage model

Metropolitan areas of Beijing, Chengdu and Guiyang are chosen comparing cases by observing night-light maps. It could be found that, the core part of Beijing and the adjacent metropolitan areas have a higher development level, and the important node cities along Jing-Ha, Jing-Jin, Jing-Bao, Da-Guang and other high-speed corridors also have higher development levels, such as Guan. For Chengdu metropolitan area, the development center is the adjacent area near the core city circle, such as the new area of Tianfu. A few node cities along the development corridor have begun to develop rapidly in the meantime. Guiyang metropolitan area is in the initial stage of core circle development without significant expansion, which has an impact on the peripheral areas.

Table 2 Characteristics of different types of metropolitan areas in China

Type	Core area scale	Radius	Area	Typical metropolitan area
Developed metropolitan area	>1000km^2	120-150km	40-50thound km^2	Beijing metropolitan area
Mature metropolitan area	500-800km^2	80-100km	2-3.5thound km^2	Chengdu metropolitan area
Developing metropolitan area	200-300km^2	50-80km	1.5-2.5thound km^2	Guiyang metropolitan area

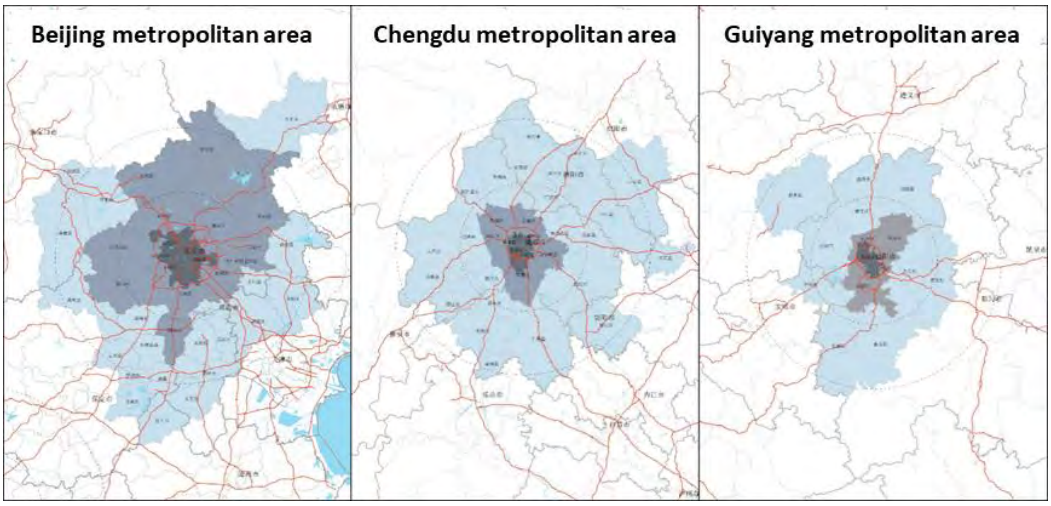

Figure 3 Diagram of Beijing, Chengdu and Guiyang metropolitan areas

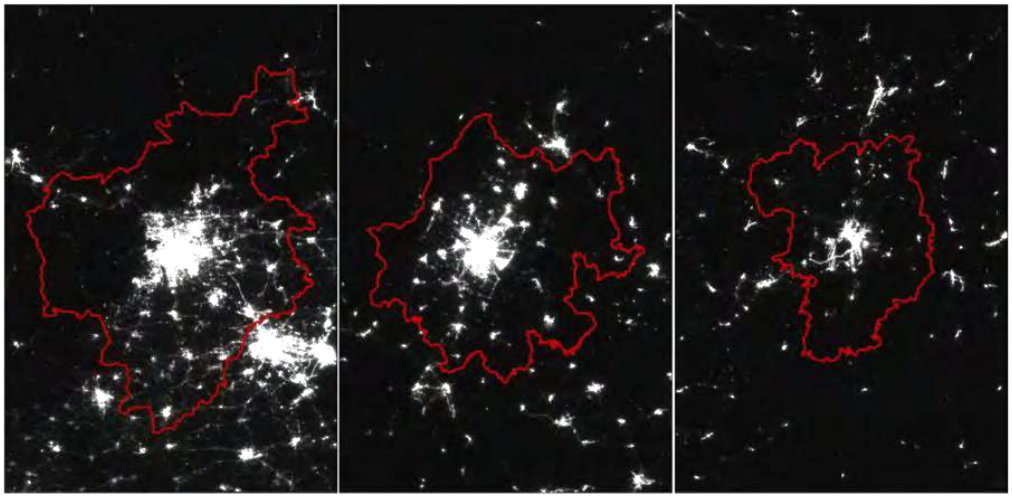

Figure 4 Night lighting index map of Beijing, Chengdu and Guiyang metropolitan areas

4. Spatial components of the metropolitan area structure

Metropolitan areas in China are mainly in the stage of the single-center formation, and influences on the peripheral regions are gradually increasing. Based on the relevant researches at home and abroad, the basic components of metropolitan area can be summarized as the following five items:

1 Strong nucleus: The central area of a large city with a large population and developed economy is the core support of the metropolitan area. Normally, the nucleus radius ranges from 15 km to 20 km. The population is highly concentrated, and the population density is more than 10,000 people/km2. The leading industry is high-end service industry, which has a strong comprehensive service function.

2 Radiation circle: The circle area composed of several surrounding towns located in the radiation region of the central area is the vast hinterland of supporting the development of core cities. The area is determined by the 1-hour commuting circle, with a radius of 50-80

km and an area about 120,000 km2. The minimum population density in the region is about 1,000 people/km2.

3 Expansion axis: The expansion of metropolitan area is not uniform, but forming the development axis connecting the central area and surrounding towns along the traffic corridors, which constitutes the development artery of the metropolitan area.

4 Key points: The node towns which play key roles in the hinterland of metropolitan area are the new growth poles supporting the high-quality development of metropolitan area.

5 Close network: Elements such as human flow, material flow and information flow between different cities form the close network in the metropolitan area. And the network guarantees integration development of metropolitan area essentially.

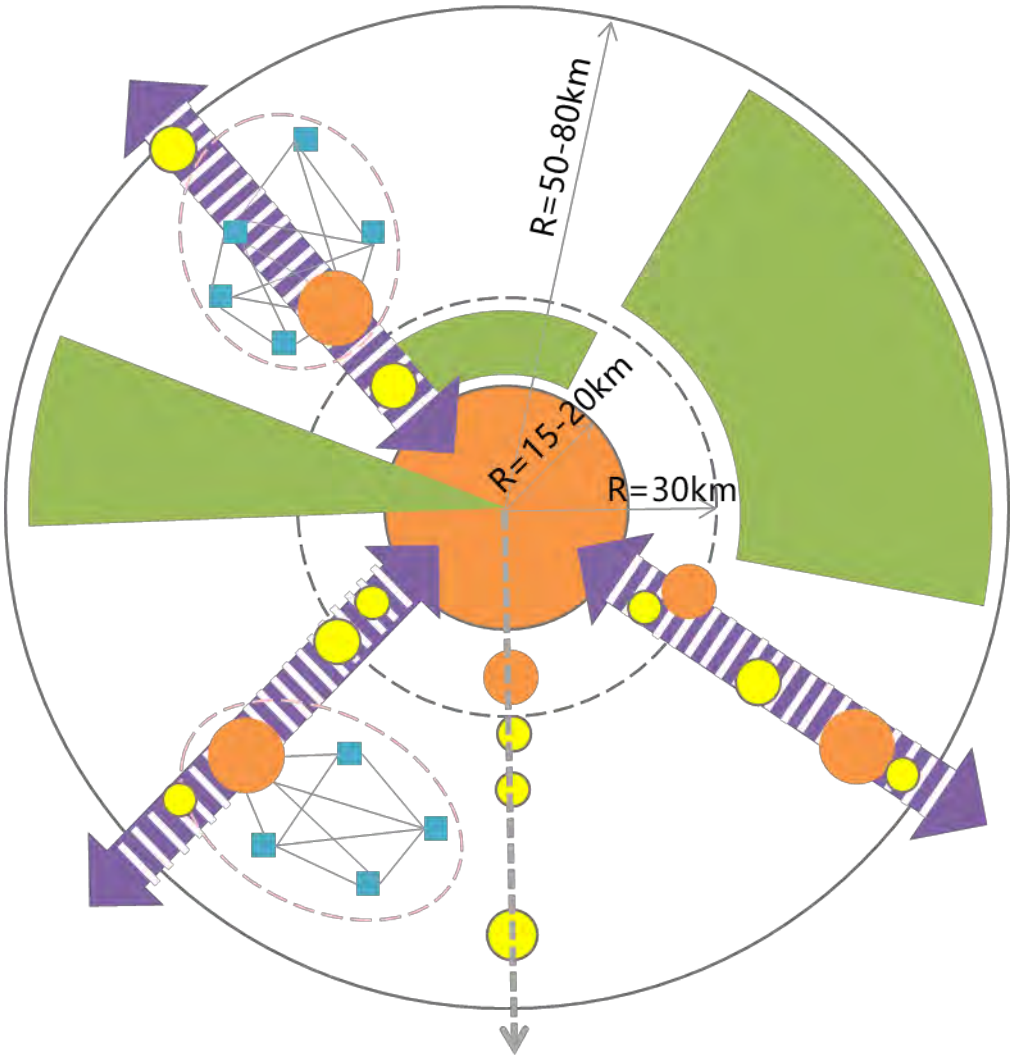

Figure 5 Metropolitan area structure model

5. Spatial development characteristics of metropolitan areas in China

Based on above components, the spatial development characteristics of metropolitan area can be summarized as the following four aspects:

1 The strong and sustained center city is the basis and guarantee for metropolitan area development and gradual maturation. In China's urban system, the basic condition for the formation of metropolitan area is the density of population in core city more than 10,000/km2. However, the "big city disease" will become prominent when the population density is more than 20,000/km2. It is necessary to promote the healthy development of the metropolitan area by means of regional coordination.

2 Limit commuting time exists, and "one-hour commuting circle" is the boundary of the hinterland of metropolitan circle. Under the current residence-employment conditions, the maximum commuting time that residents can accept is 45 minutes to 1 hour. That is to say, the scope of "one-hour commuter circle" often determines the maximum radial distance from the center to the edge of a metropolitan area. Most of the new towns in the London metropolitan area are located within the 50 km circle, The towns in the Paris metropolitan area are also mainly within the 50 km circle, while the radius of the whole metropolitan area is about 80 km.

3 Relying on the main corridors, the core circle and the outer circle are closely related by population, transportation and economy. Within the metropolitan area, most of the traffic links through expressways and rail transits, supporting the higher commuting rate from the outer circle to the core circle. Based on the good-condition corridors, direct investment activities are happened closely among the cities, and division of labor and cooperation among the cities in the metropolitan area are also promoted efficiently and orderly.

4 The coordination of the ecological pattern and the protection of resources in the metropolitan area should be emphasized. And high-quality development of the metropolitan area could not be separated from the sustained advancement of the construction of ecological civilization. In recent years, regional and watershed-scale environmental problems have replaced single and individual environmental events, and become the main factors constraining the conversions to a high-quality stage of China's developed areas. Establishing a reasonable and organized regional eco-spatial system through regional coordination, integrating economic and social developments, are necessary conditions for the healthy and sustainable development of metropolitan area.

Case Study Paper

How to Define the Boundaries of Metropolitan Areas:

Case Study of Wuhan, China

Wenjing LUO, Wuhan Planning & Design Institute; China

Li XU, Wuhan Planning & Design Institute; China

Yunming GENG, Wuhan Planning & Design Institute; China

Abstract

To plan ahead for an efficient and smart growth, this paper explores the methodology of defining the boundaries for metropolitan areas. Using Wuhan as a megacity in Central China with a population of more than 10 billion as an example, this paper attempts to set up an analytical framework to define the boundary of metropolitan areas by quantitative analysis on urbanization, geography, transport, economics and qualitative analysis on ecological, spatial and cultural aspects.

Keywords

Urban boundary, Metropolitan areas, Megacities, Wuhan, China

1. Introduction

To plan ahead for a smart growth of urban clusters and megacities, there has been a trend of developing metropolitan areas for megacities in China, which considers defining the boundaries of metropolitan areas as the basis and premise. Defining a city boundary has already been a challenge for urban planners and geographers let alone metropolitan areas considering their cross-bordering characters. Where do metropolitan areas start and end? Is there a continuum of rural and urban land uses to define them? If is, what kinds of factors are the boundaries of metropolitan areas relevant to? Based on literature reviews and case studies, this paper explores the methodology of defining the boundaries of metropolitan areas by the case study of Wuhan, China.

With a population of more than 10 million, Wuhan has already become a megacity in terms of its population, economic development and regional roles in Central China. Along with the paced-up city expansion, Wuhan has moved into the stage of regional collaboration with the goals towards a more competitive and liveable metropolitan area in smart growths. However, the role of metropolitan areas is missing in the case of Wuhan. Compared to megacities home and abroad, the scale of Wuhan municipality and Wuhan clusters, which also include 6 cities surrounding it, is too small and too big to be defined as a metropolitan area. To plan ahead for a more efficient and sustainable megacity, it is necessary to define the boundary of Wuhan metropolitan area.

The reminder of the paper is structured as follows. The next section provides an understanding of metropolitan areas and the methodologies of defining their boundaries based on literature review and case studies. The third section focuses on Wuhan contexts and discusses the current development stage of Wuhan as well as its relations with the surrounding areas. Based on the trends of regional cooperation, it is necessary to define the metropolitan area between the municipality and urban cluster. Following this, the next section attempts to define the boundary of Wuhan metropolitan area in dimensions of its urbanization, geography, transit, economics, ecology, psychology and culture. First, layers of analysis on urbanization rates, economic relations and traffic commutes have been overlapped so as to define a rough boundary of Wuhan metropolitan. Then, ecological and cultural factors have been made to check and adjust the boundary. Last but not least, further investigation has been made to correct and adjust the boundary by considering the local cultural and phycological factors. The conclusion has been made that the methodology of defining the boundaries by the case study of Wuhan could be also applied to other metropolitan areas.

2. Literature Review

The research on metropolitan areas initiated at an early age. It was in 1910 the concept of metropolitan area first brought up in the USA. After the World War Ⅱ, metropolitan areas have become a new model of urban structures with the rapid development of economics. In the middle ages of 20th century, the concept of metropolitan area has been elaborated in Tokyo and large amounts of new town practices have been carried out in Britain. It was in the 1980s that the new town theories and the concept of metropolitan area have been brought in China influenced greatly by the former Soviet urban planning ideas. In 1993, the concept of metropolitan area has been brought up in Shanghai, which initiated a series of research on metropolitan areas and new towns in China. However, the existing literature focuses mostly on the understanding of metropolitan areas but not on the methodology of defining their boundaries, which can be referenced in practices.

2.1. Metropolitan Areas

In the Tokyo Plan 1960, the concept of metropolitan area was brought up, indicating an area including the central city with the population of more than one million surrounding by towns with over half a million residents. The central city, well connected with towns by highways in a radius of 50 kilometres, would attract more than 10 percent of its population from its surrounding towns, with the commuting time of 1 hour to 2 hours. In 1990, Kenneth Fox has formally established the concept of metropolitan area based on the research of Jean Gottmann. It implies that the central city with more than 50 thousand residents are surrounding with central towns and peripheral towns, with the population density more than 50 people per square miles and the increase percent more than 15 percent every 10 years. At least 15 percent of the non-agriculture labours of the peripheral towns, which should take account for more than 70% of the whole towns, would commute to central towns or 20% of the non-agriculture labours would commute back and forth. On this basis, the metropolitan area can be defined as central cities and their surrounding towns, with frequent commutes and convenient transits, which usually take 1 or 2 hours.

Based on the practices, metropolitan areas consist of central cities and their surrounding towns, the scale of which is between cities and urban agglomeration. Within the metropolitan area, central cities and their surrounding towns have been working closely with each other with between 10 and 20 percent residents commuting in between at a distance ranging from 60 to 80 kilometres. London, as an example, can be used to better understand the spatial scale of metropolitan areas and their function structure. The metropolitan area of London covers an area of 12109 square kilometres at a radius of about 60 kilometres centring at the city London covering an area of 1580 square kilometres, which has been defined by the commuting distance. With the cities and towns in the east, London metropolitan area have developed as an urban agglomeration area or megalopolis, covering an area 39 thousand square kilometres. The metropolitan area of London includes 8 new towns surrounding the city of London, working closely with each other with different functions. Some are mainly residential like Wokingham, while some are dominated by commercial and administrative functions like Crawley Town and some are famous as university towns like Reading. The frequent commutes between London and its surrounding towns like Crawley and Kent have relieved the overpopulation of London city and also increase the population of periphery areas. Tokyo metropolitan area, as another example, consists of the city Tokyo as the political, administrative, financial, informative, economic and cultural centre and towns with specific functions like educations and port industries. In 2008, a commuting circle has been formed between the city Tokyo and its surrounding towns, from which residents come to the central city for work or school above the age of 15 and accounting for more than 10 percent of the whole population. Based on this, metropolitan areas, exemplified by these cases, can be considered as units made up of central cities and their surrounding towns between urban municipality and urban clusters. Within the radius of between 60 and 80 kilometres, the central cities and their surrounding towns with between 10% and 20% of their residents commuting to central cities have been working closely with each other.

2.2. The Boundaries of Metropolitan Areas

The practices of defining the boundaries of metropolitan areas can be reviewed based on the examples of New York, London, Paris, Tokyo, Shanghai and Beijing. In the cases of New York, the boundaries of the metropolitan area have been defined at a radius of 60 kilometres centred at New York city. Made up of the central city and 26 counties from 3 states, the metropolitan area of New York covers an area of 32 thousand kilometres with the population of 178 million. Also at a radius of between 60 and 80 kilometres from the centre, the metropolitan area of Paris covers an area of 120 thousand kilometres with the population of 11 million. Similar to the radiuses of the previous two cases, the metropolitan area of Tokyo, consisting of Tokyo city, Kanagawa-Ken, Saitama-arena and Chiba-ken, has an area of 134 hundred square kilometres and a population of 36 million. At a larger scale, the metropolitan area of Beijing has a radius of 90 kilometres and an area of 27 thousand square kilometres including Beijing city and 9 towns in its surrounding area. With a much bigger radius of 120 kilometres, the metropolitan area of Shanghai consists the central city and its surrounding 6 towns, taking up almost 30 thousand square kilometres. The methodologies of defining the boundaries of the metropolitan area of Shanghai is based both on quantitative and qualitative analysis. The towns not only within the 90-minite travelling distance but also with closer economic connections, more frequent transits and more similar culture identities can be included in the metropolitan area of Shanghai.

Based on the literature reviews, the methodologies of defining the boundaries of metropolitan area focuses more on quantitative analysis with the indexes of populations, coverages, economic development, commutes and etc. It has been proposed that towns adjacent to central cities with the non-agriculture population of more than 200 thousand, non-agriculture products taking up more than three fourths of GDP and non-agriculture economic activities taking up more than 60 percent can be included into the metropolitan area(Zhou,2000). On this basis, a system of 14 indexes including economic development, traffic conditions, telecommunications, Gini coefficient, urban densities, capital ratios, industry location quotient index, coverage of built-up areas, growths of enterprises, commodity circulation, industry trophy, economic export-oriented degree, urbanization and industrialization level has been established (Fang, 2005). Meanwhile, it has been estimated that there could be about 20 metropolitan areas in the plains of China, which can cover an area of between 40 and 50 thousand square kilometres with a population of 50 million and a radius of 120 kilometres.

3. The Wuhan Contexts

As a geographic central megacity in China, the municipality of Wuhan covers an area of 8569 square kilometres with a population of about 11 million. Wuhan and its surrounding cities including Xiaogan, Hanchuan, Xiantao, Huanggang, Ezhou, Daye, Xianning and etc all make up the Wuhan cluster covering an area of 58 thousand square kilometres (see figure 1). Aimed to be one of the national centres, Wuhan has been proved to be at the very stage of urban agglomeration according to the statistics of its urban development. With the development of service industries, the proportion of which will increase and surpass the manufacturing industries, it is estimated that Wuhan will enter the stage of dispersed development and the era of post industries around 2030. It is also has been exemplified by the cases of megacities worldwide that their growth will bring about functional complementation across borders and regional corporations at different scales. Therefore, it is necessary for Wuhan to define different scale of areas to plan ahead for an efficient and sustainable megacity. However, the scale of Wuhan municipality and Wuhan clusters is either too small or too large to achieve spatial integration at the first step, in comparison with the cases of other megacities home and abroad (table 1). The case study of Tokyo and London has demonstrated that the metropolitan area, as a spatial scale between municipalities and urban clusters, can help with the regional cooperation based on the division of labours and the allocation of regional resources.

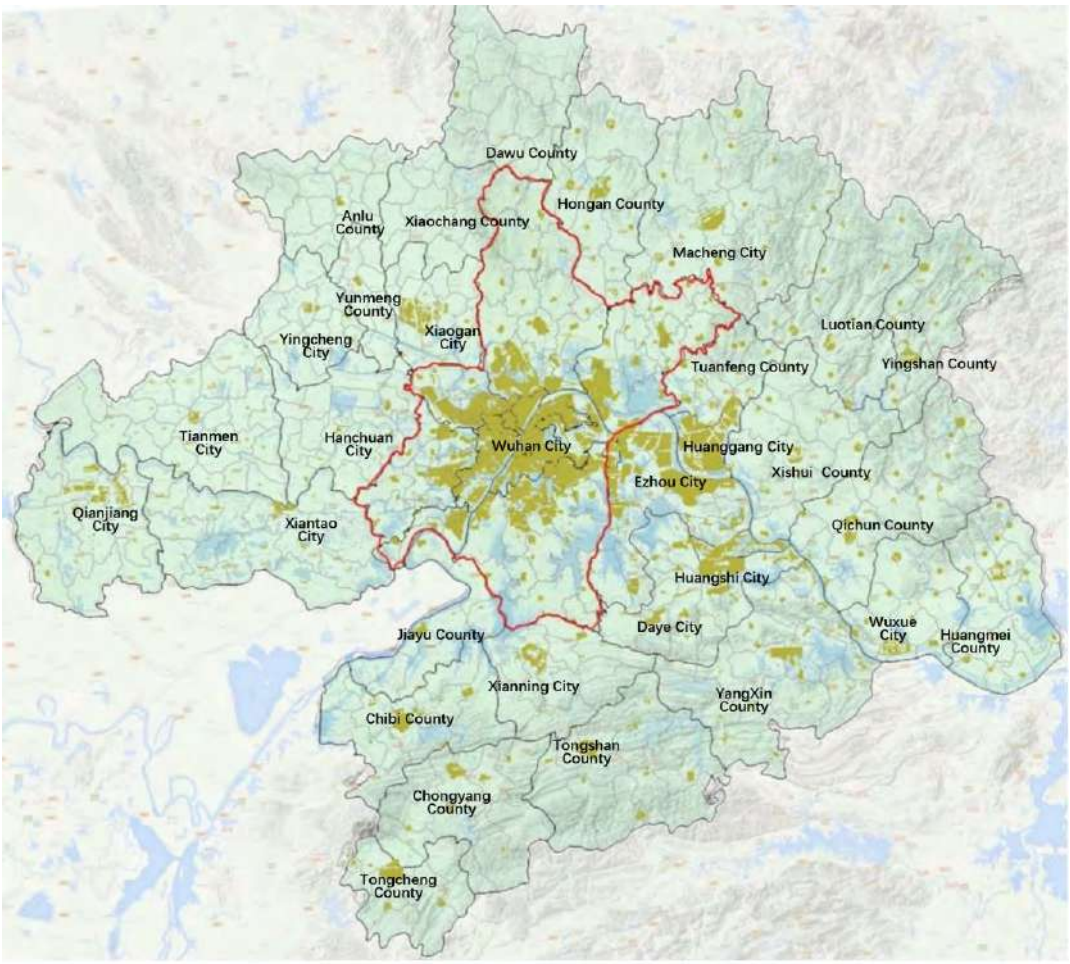

Figure 1 The Wuhan Cluster

Table 2 The Scale Comparison of Megacities Home and Abroad

Cites	The Areas of municipalities	The Areas of metropolitan areas	The Areas of Urban Clusters
Tokyo	2200km^2	13.4 thousand km^2	36.9 thousand km^2
London	1600km^2	11.4 thousand km^2	45 thousand km^2
Shanghai	6340km^2	17.1 thousand km^2	212 thousand km^2
Guangzhou	7434km^2	11.3 thousand km^2	56 thousand km^2
Wuhan	8569km^2	——	58 thousand km^2

On one hand, the cities and towns surrounding Wuhan have demonstrated the potential to share the responsibilities of Wuhan as a future national centre. With the Shunfeng Airport aimed to be the largest freight hub in the world located in the municipality of Ezhou adjacent to Wuhan, lots of logistics and e-commercial enterprises have been attracted to locate around. Besides, there are already industrial parks around Wuhan, which can help with the commercialization of science and technology research due to their abundant land resources and cheaper costs. Meanwhile, industrial parks in Wuhan have also found their partnerships in the surrounding areas, which has improved the efficiency of regional cooperation and the levels of urbanization. On the other hand, the fast-paced urbanization has made the built-up area of Wuhan expand out of its urban growth boundary, which there

is also a tendency that the adjacent cities are gradually expand to. With the regional cooperation between Wuhan and its neighbours, it is obvious to find urban agglomerations around the municipal borders, in the Wuhan-Xiaogan, Wuhan-Hanchuan and Wuhan-Ezhou adjacent areas. With the strong intention for more regional cooperation between local governments, there will be more resources to be allocated and more functions to be shared in a larger scale. For example, the neighbouring city Xianning and Ezhou intend to share tourism and manufacturing functions with Wuhan based on their resources.

Therefore, developing metropolitan areas, as universal law for megacities, is an important strategy for Wuhan to realize its goal as the national centre, a necessary step for Wuhan to achieve regional integration and an essential tool to plan ahead for an efficient and sustainable megacity. Based on the current development stage of Wuhan, it is necessary to define the metropolitan area between the municipality and urban cluster which have an average commuting distance of 40 and 150 kilometres respectfully.

4. Research Contents

Based on the literature review and case studies, according to the local conditions in Wuhan, the metropolitan area of Wuhan could be interpreted as an area with adjacent spaces, frequent communications, close economic connections and complementary functions. Thus, the methodologies of defining the boundaries of the metropolitan area should be based both on quantitative and qualitative analysis. Indexes like commuting distances, economic connections and population mobilities can be used to define a rough boundary of the metropolitan area. On this basis, the boundary can be checked and adjusted according to the ecological and cultural factors. The quantitative analysis will be conducted by GIS tools, which can spatialize the data of population, economics, industries and commutes so as to define the boundary. Data has been collected not only from relevant government departments of Wuhan and its six surrounding cities but also on internet like the immigration of inhabitants, railway and bus transits as well as the economic connections between headquarters and branch companies. Based on the literature reviews and case studies, not only quantitative analysis has been made on social and economic connections, but also qualitative analysis has been made in the ecological, spatial and cultural aspects.

4.1. Quantitative Analysis

（1）Analysis based on commuting distances

Based on the case studies, the areas within one-hour's driving distance could be included into the metropolitan areas. Thus, analysis has been made on the GIS platform to define the boundary of the areas within one-hour's drive by planned networks starting from the residential and business districts in the central city of Wuhan, which can be shown in the Figure 2. In addition, commuting by public transport has also been included. With the same method, the boundary of the areas within 30-minute's travel by train starting from the train stations in the central city of Wuhan has also been defined (Figure 3). On this basis, the areas in the above two boundaries have been combined to be included within the boundary of the Wuhan metropolitan area based on commuting distances, which includes 11 administrative unites surrounding Wuhan (Figure 4).

Figure 2 The Areas within One Hour's Drive from the Central city of Wuhan

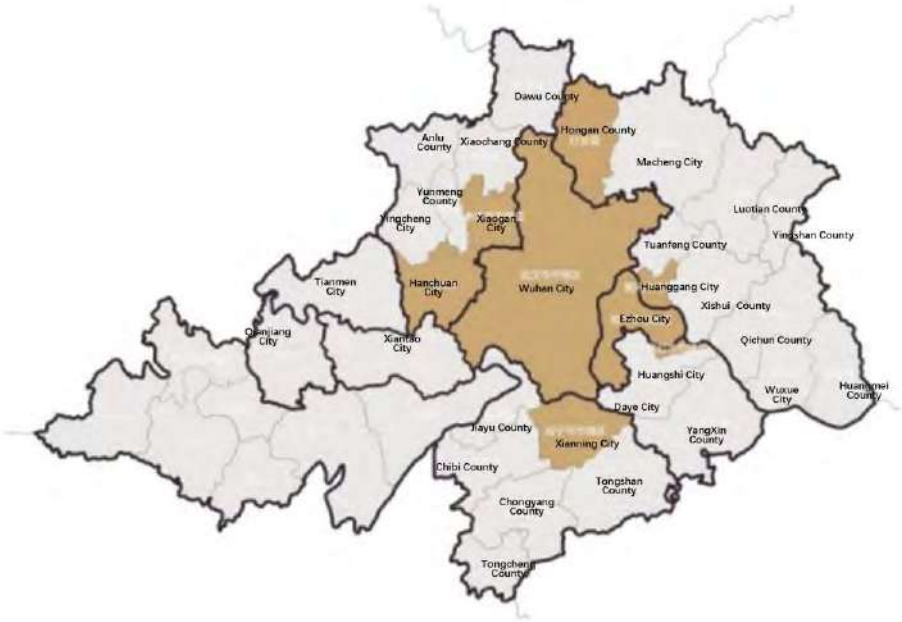

Figure 3 The Areas within 30-mintue Train from the Train Stations in Wuhan

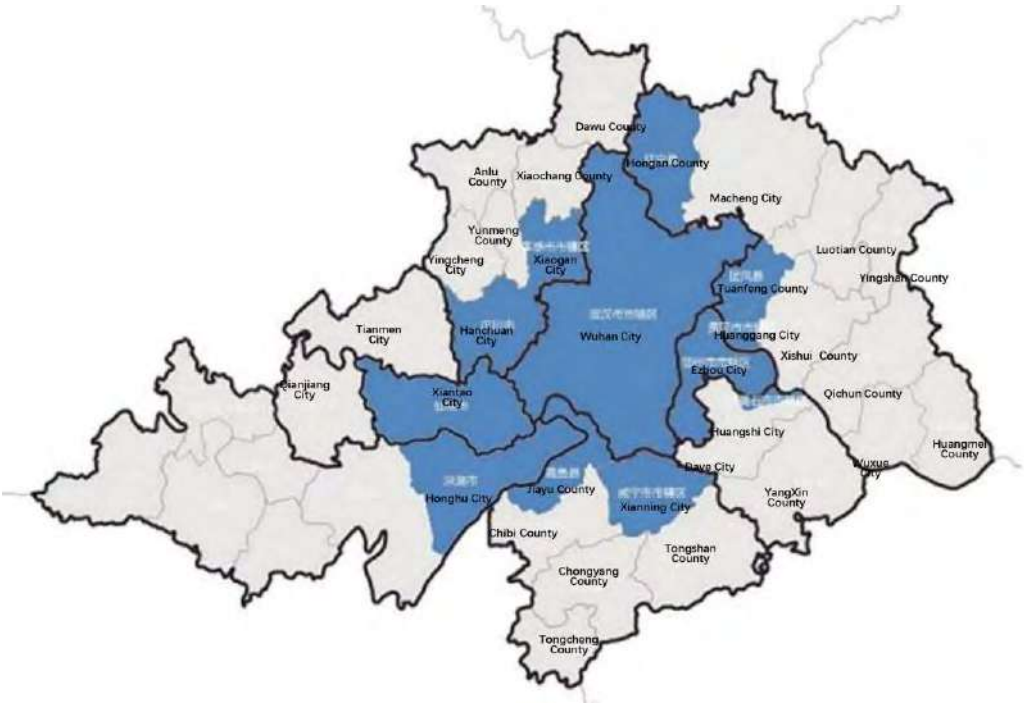

Figure 4 The Boundary of Wuhan Metropolitan Areas by Analysing Commuting Distances

(2）Analysis based on population mobilities

Population mobility can be measured not only by analyzing the statistics from governments but also by counting the timetable of buses and trains. On one hand, the numbers of in-migrants and out-migrants between Wuhan and its surrounding cities have been collected and the cities with the top numbers can be selected (Figure 5). On the other hand, analysis have been made on the timetable of intercity buses and trains between Wuhan municipality and its surrounding cities, which can define the cities with more train services to Wuhan ranking in the top (Figure 6 and 7). On this basis, the boundary of Wuhan metropolitan areas in the analysis based on population mobilities has been defined, which includes 8 administrative unites surrounding Wuhan (Figure 8).

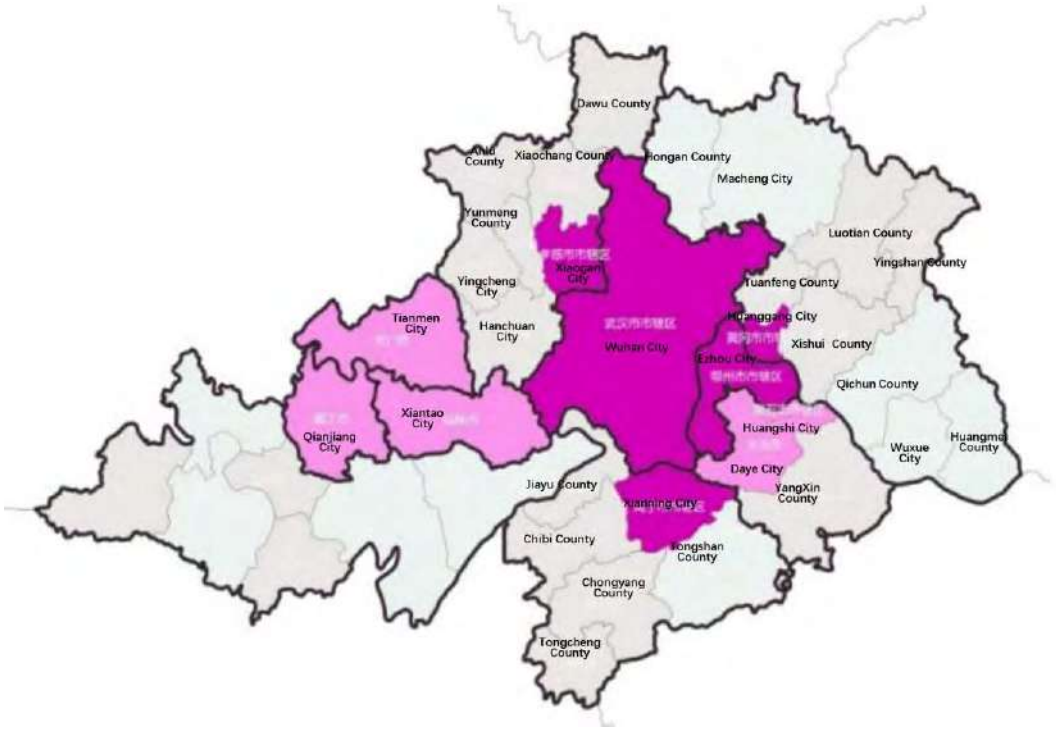

Figure 5 The Areas with More In-migrants and Out-migrants between Wuhan

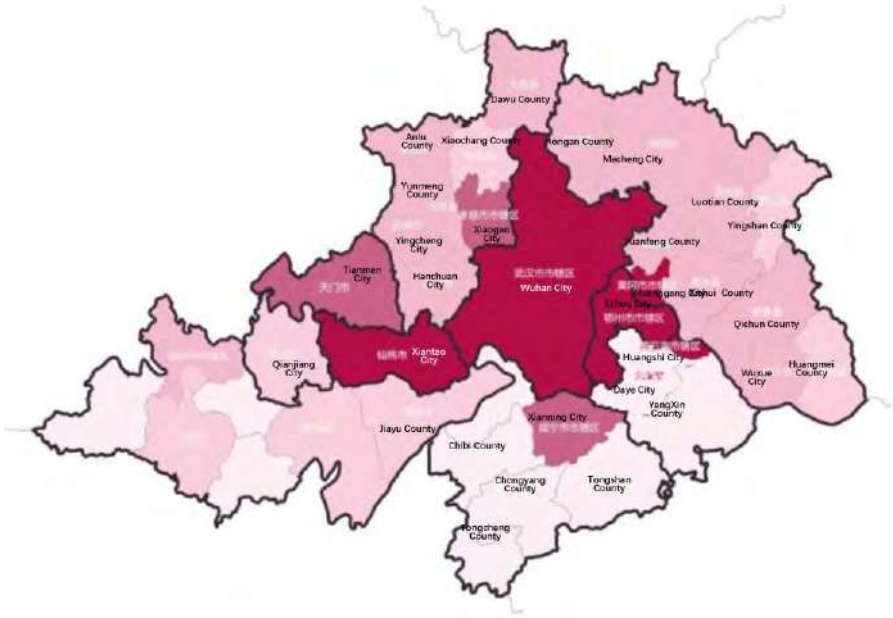

Figure 6 The Areas with Relatively More Intercity Bus Services between Wuhan

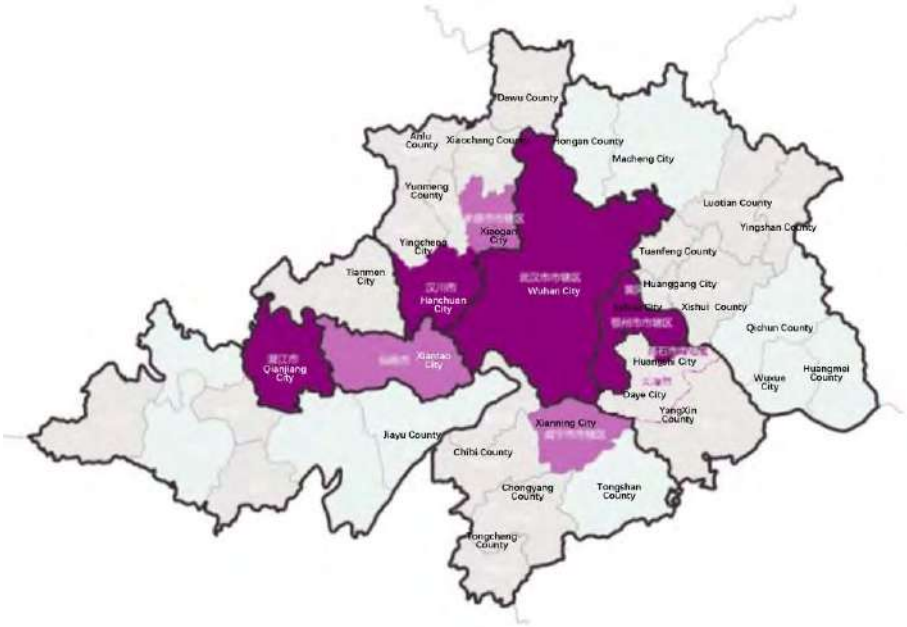

Figure 7 The Areas with Relatively More Intercity Train Services between Wuhan

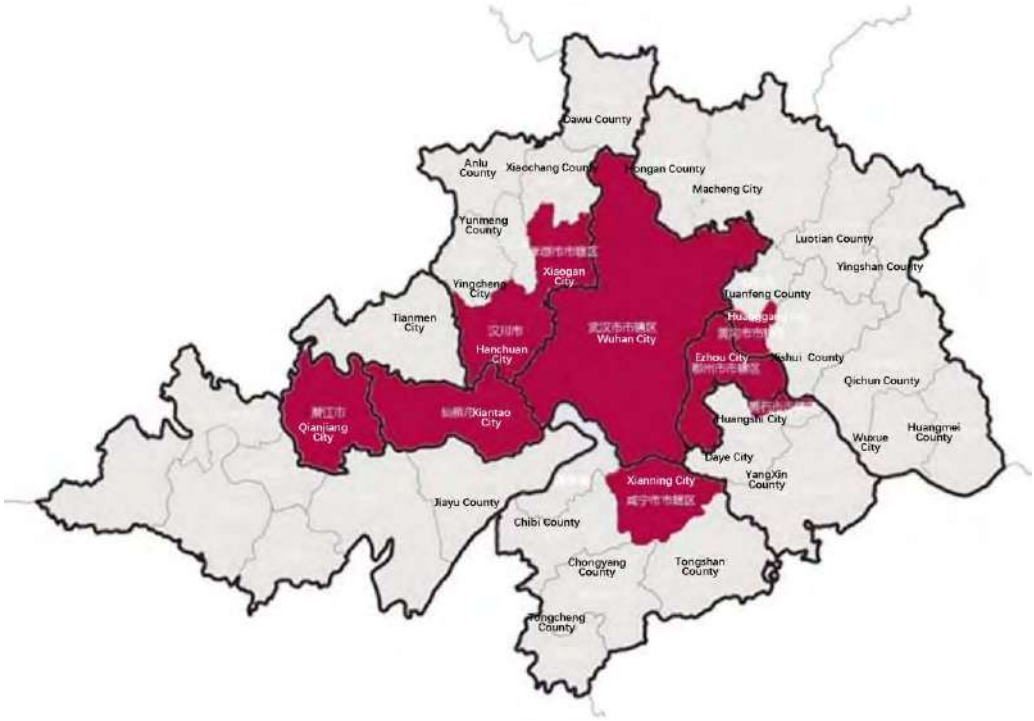

Figure 8 The Boundary of Wuhan Metropolitan Areas based on the Analysis of Population Mobility

(3) Analysis based on economic connections

Economic connections, although complicated and difficult to measure by several indexes, can be demonstrated by analysing the geographies of headquarters and their branch offices

as well as the investment statistics. First, the cities which locate more branches with their headquarters in Wuhan have been selected (Figure 9). Then, the cities with more investment by Wuhan can also been defined (Figure 10). In this way, the boundary of Wuhan metropolitan area by analysing economic connections can be defined, which includes 5 surrounding administrative units surrounding Wuhan (Figure 11).

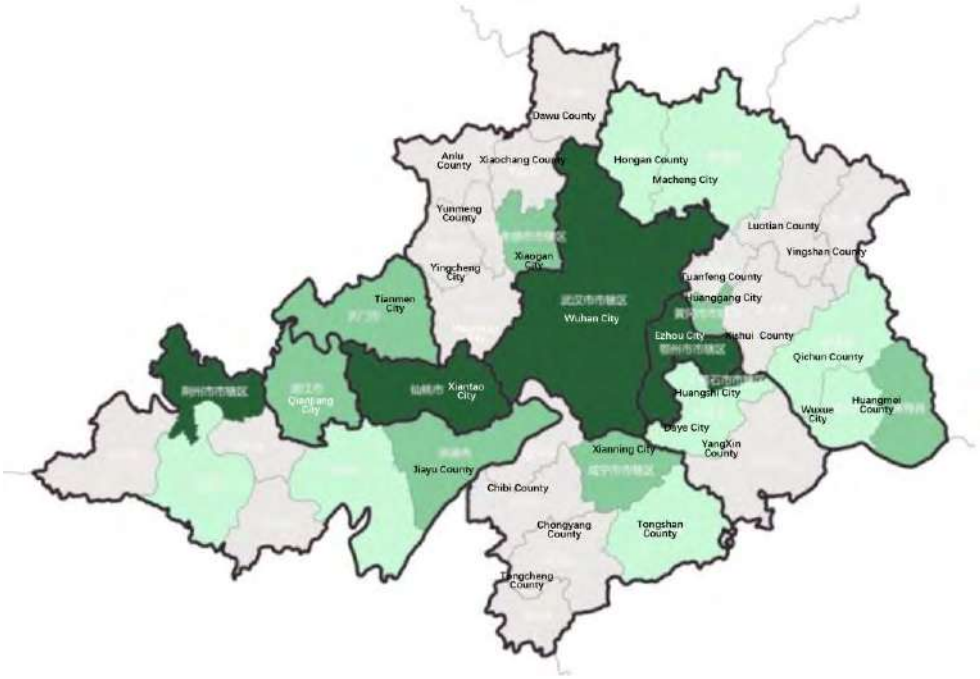

Figure 9 The Areas with More Headquarter-branch Connections

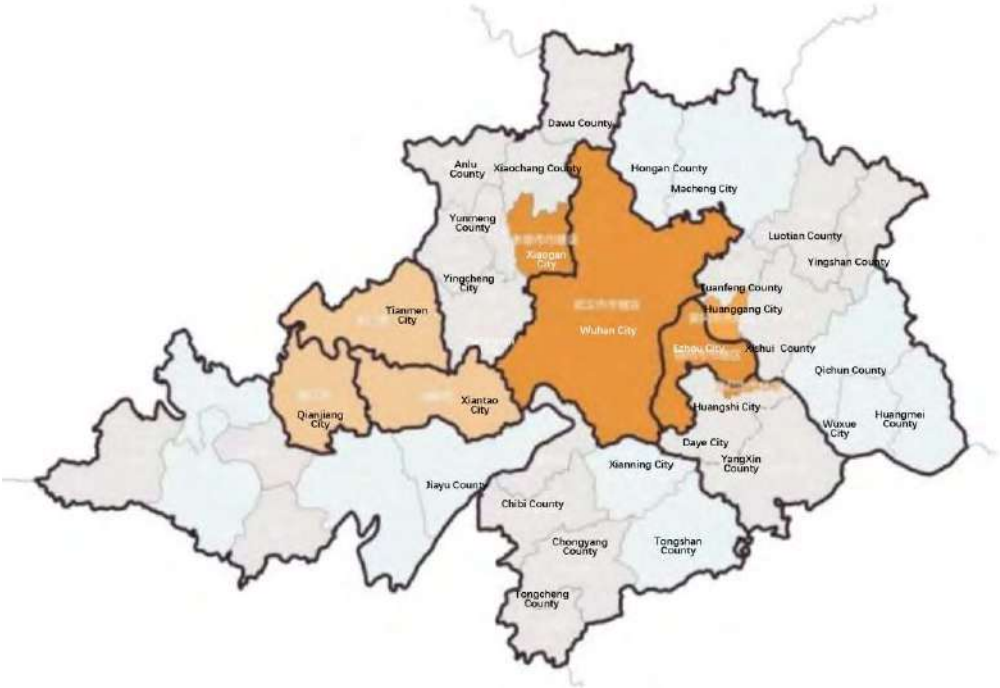

Figure 10 The Areas with More Investment Connections between Wuhan

Figure 11 The Boundary of Wuhan Metropolitan Areas by Economic Connections

Based on the analysis of commuting distances, population mobilities and economic connections, 13 cities surrounding Wuhan have been selected as the potential components of Wuhan metropolitan area. However, cities without meeting all the requirements of commuting distances, close economic connections and population mobilities have been excluded. Thus, the boundary of Wuhan metropolitan area has been defined based on quantitative analysis, which includes 7 cities surrounding Wuhan (Figure 12).

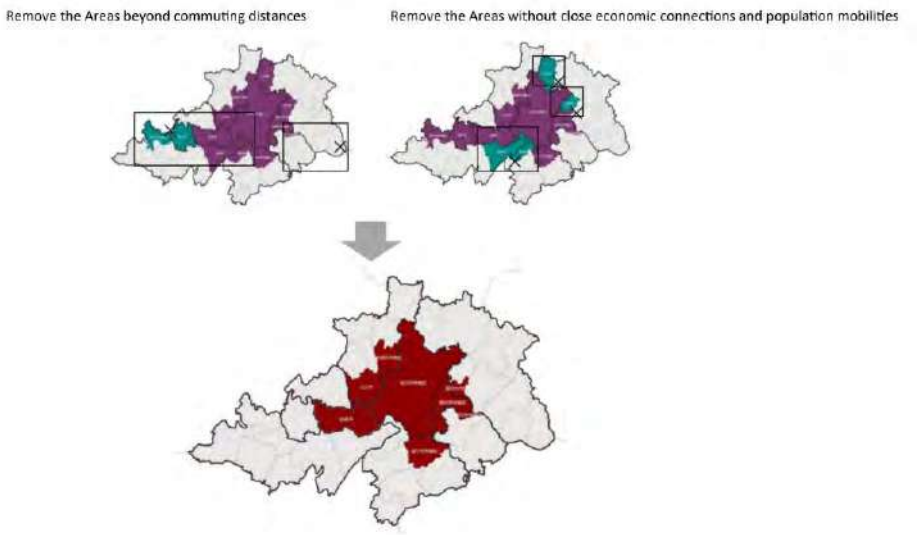

Figure 12 The Boundary of Wuhan Metropolitan Areas by Qualitative Analysis

4.2. Qualitative Analysis

To complement the quantitative analysis, ecological, cultural and spatial factors have been taken into consideration in the qualitative analysis.

(1) Analysis based on ecological resources

Ecological resources, as key elements to maintain regional sustainability, should be included into the boundary of metropolitan areas. In the cases of Wuhan, major ecological elements like forest parks, wetland parks and lakes have been taken into accounts which concern five cities surrounding Wuhan. Among the ecological elements, there are two lakes locating in the cross-bordering areas of Wuhan, Xianning and Ezhou, one of which is not only the alternative reservoir of Wuhan but also the one of best-maintained wetlands in Asia. In addition, ecological resources with tourism functions could also been included into the metropolitan area to complement the regional roles of central cities, which can increase the competitiveness as a whole (Figure 13). By analysing the attractiveness of existing tourist sites, hot touring spots concerning two administrative units should be included into the Wuhan metropolitan areas.

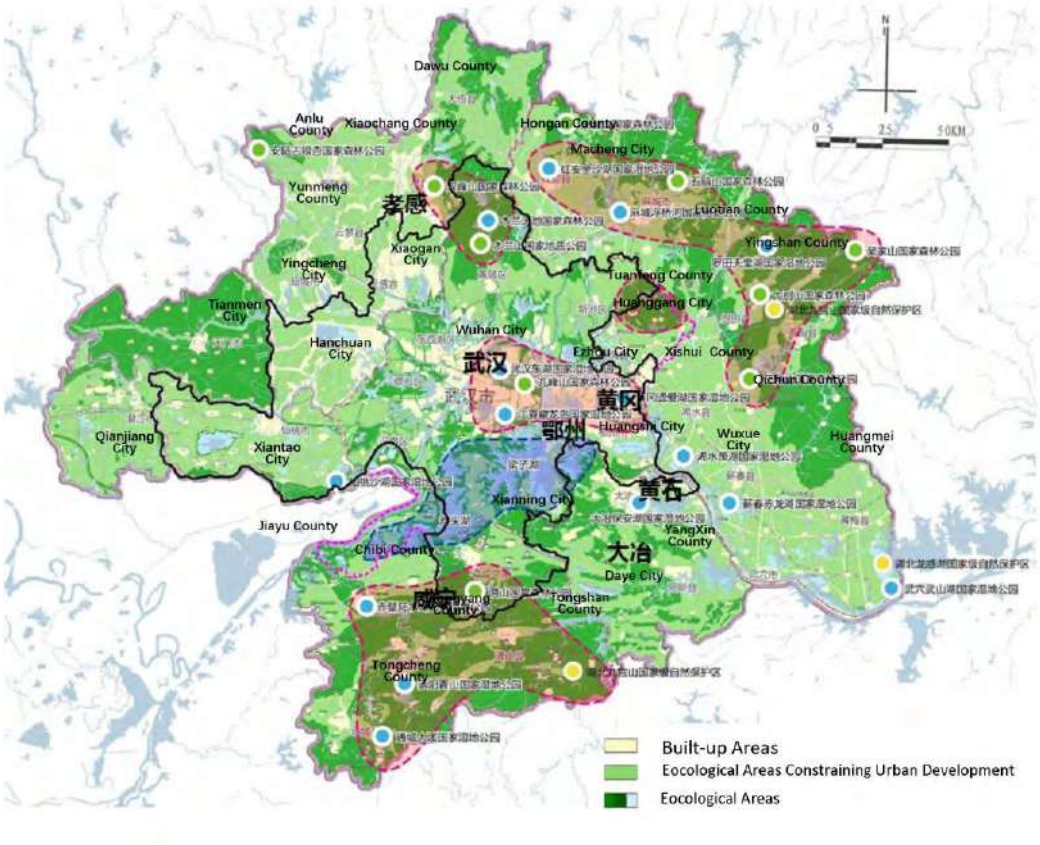

Figure 13 Analysis on Ecological Resources surrounding the Wuhan Municipal

(2) Analysis based on adjacent spaces

Although quantitative analysis based on commuting distances has taken the adjacent spaces into account but failed to pay attention to the functions. On one hand, there are some areas with similar functions like industrial parks adjacent to Wuhan, which have achieved mutual cooperation along with competitions and longed for regional integrations. On the other hand, it is obvious that Wuhan municipality has expanded to neighbouring areas as the early forms of urban agglomerations, like the bordering areas between Wuhan and Ezhou, Huangshi(Figure 14). Therefore, major infrastructures like airports and harbours which will

have great impact on regional integrations should also be included into the boundary of metropolitan areas. In the cases of Wuhan, one existing airport, two planned airports and five harbours have all been taken into account.

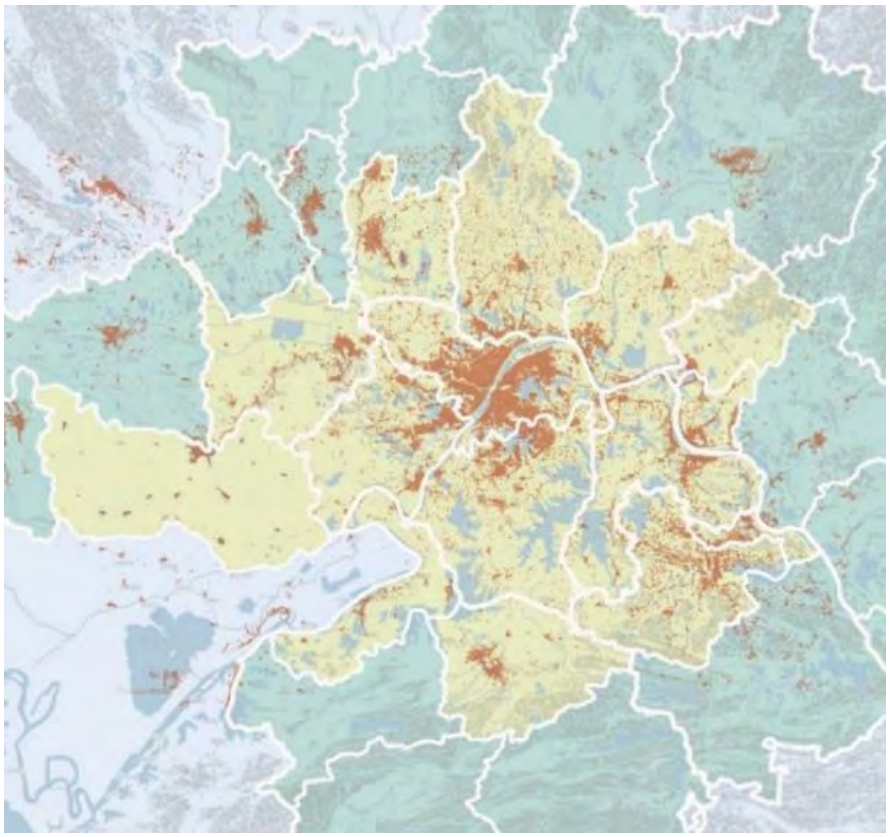

Figure 14 Analysis on the Adjacent Spaces the Wuhan Municipality

（3）Analysis based on cultural factors

As the root of urban developments, culture can exert unseen but profound effects on regional developments. Throughout history, the cities in the Wuhan Cluster have been underwent several administrative changes from the same affiliation to different ones. In addition, there is also a shift of the central city geographically from the west to the east, which used to be Wuhan and Ezhou. Base on the analysis on the histories, it is necessary to include Ezhou into the boundary of Wuhan metropolitan areas. If urban histories can demonstrate the regional city structures in the past, dialects as important means of communication can be used to reflect regional connections at present. In the cases of the Wuhan Cluster, there are mainly at least three kinds of dialects, based on which cultural zones can be defined to readjust the boundary of Wuhan metropolitan area by including 3 more administrative units.

4.3 Summary

First, quantitative analysis based on commuting distances, population mobilities and economic connections has been made to define the rough boundary of the areas in which Wuhan municipality has been well connected with its 8 surrounding administrative units. Then, qualitative analysis based on ecological resources, adjacent spaces and cultural factors has readjusted the boundary by including 3 more administrative units. Therefore, the

boundary of the metropolitan area has been defined which includes 11 administrative units surrounding Wuhan municipality. With an area of 21thousand square kilometres, a population of 17.68 million and a GDP of 1.45 hundred million RMB, the metropolitan area accounts for 36%, 57% and 79% of the whole area, population and GDP of Wuhan Cluster respectfully.

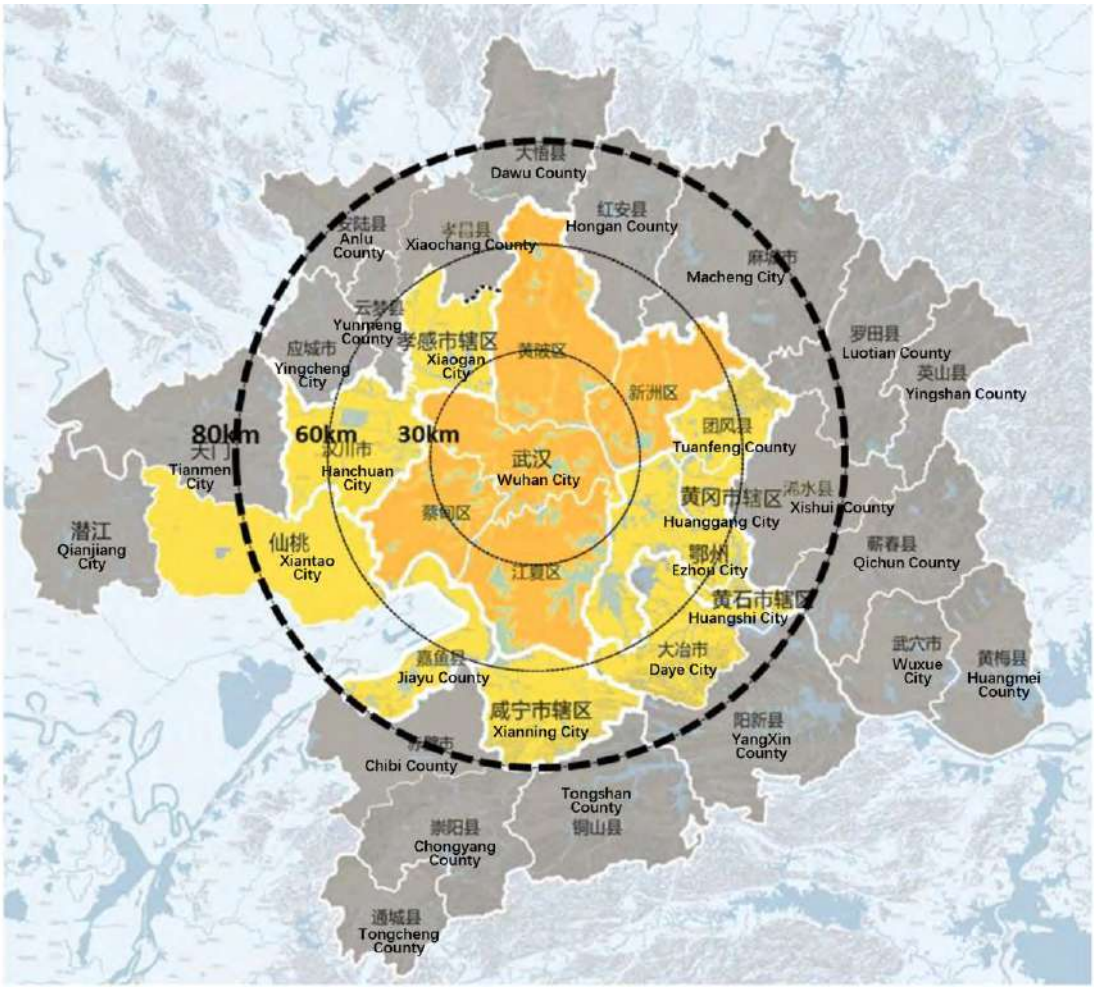

Figure 15 The Boundary of Wuhan Metropolitan Area

5. Conclusions

As an intermediate spatial form between megacities and urban clusters, metropolitan areas are not only sharing adjacent spaces but also close social, economic, ecological and cultural connections, which could define their invisible boundaries. Base on the literature review and case studies, according to the contexts of Wuhan, a method to define the boundary of metropolitan areas has been proposed by both quantitative analyses on commuting distances, population mobilities and economic connections and qualitative analysis on ecological resources, adjacent spaces and cultural factors. It is necessary to mention the shortcomings and limitations of the method. On the one hand, the boundary defined by this method may be not entirely correct and accurate. One the other hand, as the contexts of

metropolitan areas concern different factors, the goal of this paper is not to be taken reference from but to establish a framework to shed lights on other megacities to define their boundary of municipal metropolitans.

Case Study Paper

The Spatial Strategies of Knowledge Corridors in Megacity Development:

Case Study of the Optical Valley Knowledge Corridor, China

Abstract

As a comprehensive spatial concept, corridors especially mega-corridors and knowledge corridors have played irreplaceable roles in developing megacities. This paper uses the case of the Optical Valley Knowledge Corridor in China as an example to illustrate how to make spatial strategies of knowledge corridors in the dimensions of innovation networks, knowledge economies, environments and urban amenities, transportation systems and urban governance towards making a liveable, sustainable and efficient megacity in the backgrounds of knowledge-based urban development.

Keywords

Corridors, Knowledge-based urban development, Knowledge economies, Megacities

1. Introduction

Originated from the linear city model more than a century ago, the term “corridor” is not only an urban model fully tailored to the transport technology but also a comprehensive spatial concept in dimensions of infrastructures, economics, urbanizations and ecology. It is in the 1990s that the modern version of the corridor concept namely mega-corridor has been brought up in the Europe 1992 project, which aimed at the physical integration of European Territory. Especially with the addition of a prefix “mega”, mega-corridors have been assumed to play key roles not only in physical but economic integrations together with the cross-border and transnational infrastructures. In a similar way, cities especially megacities are also growing out of their borders towards regional collaboration, which has given a new role for corridors in the aspects of achieving spatial, economic and social integrations to enhance regional competitiveness.

Especially in the times of global knowledge economies, there has been a prevalence of knowledge corridors considering their great contributions to knowledge-based developments for megacities. With the rise of innovation districts, science and technology clusters have been formed in the forms of corridors in the backgrounds of knowledge economies, which can be exemplified by Silicon Valley, Route 128, London M4 Corridor and

etc. With the announcement of *National Innovation-driven Development Strategy Outlines* in China(State Council of China,2016), great efforts especially in Chinese megacities have been dedicated to developing knowledge corridors aimed at enhancing regional competitiveness through linking themselves with their surrounding cities and towns by a bundle of infrastructures and mainly developing technology-led industries, like Shanghai G60 Corridor, Guangzhou-Shenzhen-Hong Kong-Macau Corridor, Hangzhou West Knowledge Corridor, Hefei Knowledge Corridor and etc.

To achieve regional competitiveness by knowledge-based development, the government of Hubei Province, as one of the major provinces locating in Central China near Yangtze River, has announced at the end of 2018 to develop a knowledge corridor based on one of the largest agglomerations of high technology, primary electronic companies in its territory, known as the Optical Valley which has aimed to be the Chinese version of Silicon Valley. As a provincial development strategy, the Optical Valley Knowledge Corridor (OVKC) is not only supposed to implement the Chinese innovation-driven development strategy, but also to develop a more liveable, sustainable and efficient megacity, which is Wuhan as the capital of Hubei Province, by enhancing the spatial, economic and social integration with its neighbouring cities. Greatly inspired by Silicon Valley, Route 128 and other corridors, the Optical Valley Knowledge Corridor is also an answer to the cluster phenomenon in innovation geography to develop a more competitive innovation economy through technology leapfrogging (Cornell University, INSEAD, WIPO, 2018).

However, despite the general claims of the importance of knowledge corridors, we still know very little about strategic goal-setting in this area. Although there have been a large number of practices concerning corridor development cross administrative borders, studies focused on planning practices of using corridor strategies at an urban scale can be considered relatively scarce. Thus, the aim of this paper is to investigate how to use corridor strategies towards more liveable, sustainable and efficient megacity in the context of China. The Chinese planning system can represent the characters of many top-down counterparts in most developing countries and some developed countries. With the goal to achieve spatial, economic and social integration, the spatial strategies of corridors concern a complex set of economic, social and even political factors, which may be not all applicable to different institutional systems but can be transferrable to other cities which intend to use spatial strategies of knowledge corridors.

The methodological approaches here do not only include the case study investigation of the OVKC as well as science and technology clusters, but also the literature review on corridors. In addition, a set of semi-structural interviews with local governments, representatives from 4 local universities and 17 local enterprises and an online survey concerning the needs of knowledge workers have been conducted. Starting with the literature review on the concept of corridors, the paper will attempt to provide an understanding of the knowledge corridor concept by an investigation of the innovation clusters especially a discussion of the Silicon Valley. Following the interpretations of knowledge corridors in five dimensions, the fourth section will attempt to establish the framework of making spatial strategies of knowledge

corridors. Using the OVKC as an example, strategies have been proposed in correspondence to the interpretations by making it as a loop for innovation systems, a boom for knowledge economies, an attraction for knowledge workers, a highway for innovation flows and a mutual-force for urban governance. Last but not least, the concluding part will discuss the challenge of implementation in policymaking, followed-up work to do and its implications for other cities.

2. Literature Review

Not as a new and univocal one, the corridor concept can be traced back to the linear city models brought up by the Spanish urbanist Soria y Mata(1844-1920) as early as 1882, which has been called the first model fully tailed to the development of transport technology (H Priemus & Zonneveld, 2003). On this basis, the Ciudad Lineal model has been developed and exerted influences on the pattern of urban expansions along with infrastructures especially in regional plans, which was not in the form of unbroken lines but more likely “beads on a string”. Although opposed by many urbanists due to the destruction of ecological environments, the linear or belt developments have taken place on a large scale with the technological progress of transportations. Especially in the 19th century, urban decentralization has been enabled by the widespread use of private cars, which can be exemplified by the Silicon Valley in California, Route 128 near Boston, the Silicon Glen in Scotland and the M4 Corridor in Britain. The Silicon Valley, originated from the Stanford Industrial Park, has undergone the expansion along the Route 101 and Route 280 towards San Francisco and Santa Carla. Meanwhile, Route 128, also benefited from the knowledge spillovers of MIT, has been known as the technology corridor due to the agglomeration of high technology firms. As the United Kingdom’s equivalents to Silicon Valley and Route 128, Silicon Glen running through Edinburgh and Glasgow has been known as the “industrial belt” of Scotland, and the M4 Corridor has also witnessed the high technology growth along the M4 highway. The common features of all the cases mentioned before are not only that they are all originated from the spillover effects of universities but also famous for the agglomerations of technology enterprises along the main roads.

With the constructions of cross-border especially transnational infrastructures and the awareness of economic integration, corridors are leading urban expansion more at regional and interregional scales than at sub-regional and urban scales. As a modern version, the concept of mega corridors has been brought up in the “Project” Europe 1992, which aimed to promote the economic, social and physical integration by enhancing the level of connectives (Priemus & Zonneveld, 2003). Evolving as a multi-faceted concept, the mega corridor has been not only defined as a bundle of infrastructures with heavy flows of traffic linking transnational urban agglomerations, but also an attempt to reconcile regional economic growths and sustainable developments. Thus, the meaning of corridors has been extended to the dimensions of infrastructures, regional economy, urban development and governance(Zonneveld & Trip, 2003).On this basis, the spatial developments of corridors have been focused on establishing the connections between the transportation, economic development, environment and urbanization with the premises that which areas should be designated as corridors and which parts should be defined as development zones and open

spaces (Priemus & Zonneveld, 2003). As an instrument to achieve economic, social and urban integration, the corridor strategies imply overcoming not only physical borders but also social, cultural and institutional barriers which call for co-governance. Thus, strategic spatial planning, which is directed more towards integrated courses beyond traditional planning, concerns that the corridor concept has been elaborated as a physical and network of international infrastructure, and especially the nodal points of corridors have been balancing between the space of flows and the space of places (Albrechts & Coppens, 2003).

Although the concept of corridors has evolved from linear or belts forms to networks, one thing for sure is that the essential characteristic of corridors is the connectivity which enables the free and easy flow of people, goods and information (Chapman, Pratt, Larkham & Ian,2003). Especially in the backgrounds of knowledge economies which calls for efficient flows of financial and intellectual capitals, corridor developments have been considered as important instruments for megacities to achieve economic competitiveness by spreading economic activities from nodal points to the surrounding areas. Greatly inspired by the success of corridor developments especially the Silicon Valley, Route 128, the Silicon Fen and the M40 Corridor, developing countries in Asia Pacific Region have taken on initiatives of knowledge-based urban development especially science and technology clusters in the form of corridors. Amongst the most notable in the past few years are Tokyo-Yokohama-Tsukuba Corridor, Malaysian Multimedia Super Corridor, Shanghai G60 Knowledge Corridors, Guangzhou-Shenzhen-Hong Kong-Macau Corridors in China and etc. Although the concept of knowledge corridors has not been officially defined, the key elements of corridor projects in the backgrounds of knowledge-based urban development focuses on the assembly of knowledge infrastructure(e.g. universities, research and development institutes and etc), technological infrastructure(e.g. ICTs) ,connections to the global economy (e.g. international companies and finance institutions)and concentrations of well-educated and creative people(e.g. knowledge workers) (Winden & Berg, 2004; Carrillo, 2006; Corey & Wilson, 2006, Sarimin & Yigitcanlar,2011). The strategic developments of knowledge corridors in the economic, socio-cultural, enviro-urban and institutional dimensions have been exemplified by the case study of Malaysian Multimedia Super Corridor to be able to achieve economic prosperity, environmental sustainability, socio - spatial order and local institutional competence (Sarimin & Yigitcanlar,2011).

Although there have been examples of corridors towards knowledge-based urban development, the concept of knowledge corridors hasn't been officially proposed yet based on the literature reviews. Thus, before discussing the spatial strategies of knowledge corridors, there are two key questions to be resolved. Firstly, how to understand the concept of knowledge corridors in the new economies driven by science and technological clusters, which do not rely on traditional factors like before. Secondly, how to make spatial strategies of knowledge corridors towards a more liveable, sustainable and efficient megacity based on the local conditions? The next sections will attempt to answer the questions.

3. The Understanding of Knowledge Corridors

On the one hand, what knowledge corridors are different from other corridors is that the former one has an agglomeration of knowledge infrastructures especially and the ability to attract knowledge flow especially intellectual and capital resources constantly. On the other

hand, what corridors can contribute to the knowledge-based developments is that they can use the strength of connectivity to draw more flows into the nodal points and spread them into the surrounding areas so as to increase the regional competence at a larger scale, which will affect the space of places in return. This section will attempt to elaborate on the interpretations of knowledge corridors.

As a complex process, innovation often requires knowledge flow between different kinds of knowledge organizations which establish contact networks and alliance networks by frequent and repeated interactions (Huggins &Thompson, 2015). During the process, local innovation network could be established, which initially catalyzes the intellectual change and knowledge transfer across administrative borders, namely the regional innovation networks which will improve the efficiency and influences of local networks in return. (Pyka & Scharnhorst, 2009). This could be exemplified by the new-emerging trend of science and technology clusters since 2017, which grow beyond urban or regional borders by major transportation systems to achieve collaborations (Cornell University, INSEAD & WIPO, 2018). In the top-ranking list of the science and technology clusters, knowledge corridors have proved to improve their competitiveness of local and regional innovation networks by achieving efficient connections at different scales. Thus, knowledge corridors can be interpreted as a new form of urban and regional spatial structure, which could establish free flows of innovation resources by a bundle of infrastructures linking urban agglomerations, so as to develop local and regional innovation networks. The following five aspects are the major features of knowledge corridors that could be exemplified by case studies.

First of all, there should be a high concentration of different kinds of innovation resources related to the whole process of knowledge production, diffusion and transfer, which act as the foundation of producing innovation flows. In particular, knowledge production sectors include universities as well as their affiliated labs, knowledge transfer sectors like research institutions and related servicing facilities including investment captures and incubators should be all included as the three basic kinds of innovation resources, which keep interacting with each other to form innovation networks of knowledge corridors. Taking the Silicon Valley as an example, Stanford University, Stanford Research Park and Institutional Venture Partner can represent the three typical kinds of innovation resources, which have been interacted with each other frequently and repeatedly and formed the foundations of innovation networks. What's worthy to mention is that key technological infrastructures like national labs, as essential parts of the innovation resources, are playing crucial roles in forming regional innovation networks.

Secondly, the commercial spin-off effects of knowledge production sectors are the roots of innovation networks as well as their dynamics, considering their roles of enhancing expected economic returns of knowledge. For instance, the success of the Silicon Valley does not only repy on the spillover of Stanford University, which has given birth to local leading enterprises but has also benefited from firm neighbourhoods, where leading enterprises play the role of dandelion so as to nurture new start-ups. As essential parts of local innovation networks, firm neighbourhoods and their structures can be depicted as matrix machines, which indicates that distances matters a lot to the way leading enterprises interacting with new start-ups (Pyka & Scharnhorst,2009). This can be exemplified by the case of Hangzhou West Knowledge Corridor, which has witnessed the assembling lots of new start-ups within a 5 kilometre-radius circle centred at the local leading enterprise namely Alibaba.

Thirdly, keeping an attraction for knowledge workers can be considered as catalysts to boom innovation networks, as human capitals have proved to be key flows to improve regional competence. The various demands of knowledge workers should be satisfied by providing not only pleasant environments but also well-established urban amenities. Taking the Silicon Valley again as an example again, its pleasant climate, seashore and mountain landscapes have been known as one of the key factors to keep withdrawing human flows from other places of the world. Besides, there are not only basic urban amenities like schools, gyms, cultural centres and hospitals, but also a high density of the third places besides home and work like coffee shops for knowledge workers to interact with each other face to face, which has also proved to be essential urban amenities especially to creative industries. Thus, it has been proposed in the plan of the Hangzhou West Knowledge Corridor that the density of coffee shops should be improved to 2 per kilometres square, according to the counterparts of the Silicon Valley.

Fourthly, infrastructures which are the backbones of knowledge corridors should be well-equipped, so as to improve the efficiency of innovation flows. On the one hand, transportation hubs like airports, train stations and harbours as nodal points should be well-connected to the regional transit systems, which can not only facilitate the absorption of intellectual and capital flows but also help developing regional innovation networks based on the local networks. On the other hand, the inner transit system including highways, subways as well as bike lanes should be well established to improve the efficiency of inner flows between nodal points. This can also be exemplified by the Silicon Valley which has not only benefited from the Route 101 and 280, but also from the San Francisco International Airport and San Jose International Airport. Thus, it has been proposed in the plan of Shanghai G60 Knowledge Corridor that the network density of highways should be improved 15 percent based on the existing transit system.

Last but not least, smart urban governance to keep urban planning, development and management flexible and adapt to the uncertainty of innovation is the key to keep constant flows in the places of space. The case of the Silicon Valley has not only exemplified the success of market-driven forces but also the smartness of urban governance. Not only the top-bottom approach by governments to regulate the spaces which play necessary roles in the process of innovation but are less-favoured by market, but also the bottom-top approach to improving the initiatives of markets should both be used in the governance of knowledge corridors. Besides, as the boundary of knowledge corridors usually crosses the borders of cities, provinces or even nations, the governing process usually requires the collaborations of vertical governments as well as the participation of universities, enterprises, citizens and etc. As a dynamic participatory process, the co-governance of knowledge corridors will not only need a long-term vision and short-term actions, but also require continuous evaluation and revision according to their own developmental stages and also adapting to new requirements (Sarimin & Yigitcanlar ,2015)

Based on the interpretations of knowledge corridors in five dimensions, the next session will attempt to discuss corridor strategies especially for megacities by the case studies of the OVKC in China, so as to shed some lights on other cities

4. The Knowledge Corridor Spatial Strategies in Megacity Developments: Case of the Optical Valley Knowledge Corridor in China

As the largest knowledge-based urban development initiative in Hubei Province, China, the OVKC covers an area of 1515 kilometres square in Wuhan as well as its neighbouring city namely Ezhou. By benchmarking the progress amongst the prosperous knowledge corridors, it is intended that the OVKC function as a high-tech catalyst to help Wuhan and Ezhou to attract knowledge workers and techno-enterprises and become global international centres, so as to help with the transformation of urban development. The completion of the OVKC is estimated at an approximate 30-year timeframe and the development staged into three phases to allocate the initiatives. The first phase of the OVKC aims at creating a regional innovation hub in the Yangtze River Economic Belt in three years. The main goal of the second phase would be making the OVKC as an essential part of the Chinese innovation communities until 2035. Last but not least, the final goal would be aiming at a world-class innovation cluster, so as to help transform China into a "knowledge nation" till 2050. Towards the goals, adapting to the prevailing social-economic, technological and environmental circumstances in Wuhan, with the principles of producing diversity, prosperity, equity, efficiency and sustainability, a framework of spatial strategies of knowledge corridors based on the five dimensions of interpretations have been established in the aspects of making the OVKC a loop of innovation networks, a boom for knowledge economics, an attraction for knowledge workers, a freeway for innovation flows and a mutual-force for urban governance.

4.1. Making knowledge Corridors a Loop of Innovation Networks

As a type of linear form, knowledge corridors are actually science and technology clusters with a variety of knowledge sectors interacting with each other. The major differences between knowledge corridors and other types of science and technology clusters lie that the former ones with the character of connectivity are easier to develop a loop of innovation networks both locally and globally. Cases like the Silicon Valley show that the development of innovation networks usually go through stages from the agglomeration of knowledge sectors, the formation of local networks, the development of local networks and establishment of regional networks. Although the OVKC has abundant innovation resources including 60 universities, 19 national labs, 121 research institutes and etc, there are still missing ingredients including inter alia, key technology infrastructures, new types of research institutions, venture capitalists to fund the start-ups compared to other knowledge corridors home and aboard. Due to the lack of certain types of innovation resources, the local innovation networks has not been well-established only with local universities, research institutes interacting frequently with enterprises in Wuhan and out of Hubei Province. Let alone the regional innovation network, which has been dominated by three technology clusters centred around megacities like Beijing, Shanghai and Shenzhen. Therefore, the OVKC is at the stage between the formation of local networks and the development of local networks.

Based on the current stage of the OVKC, strategies towards making a loop of innovation networks have been made including bringing more varieties to the types of innovation resources, developing both local and regional innovation networks, so as to improve the

regional roles in the national and international innovation geographies. Firstly, various knowledge sectors have been proposed to be introduced including new types of research institutions and all related servicing sectors like venture capitals and incubators specifically. What's more important is that key technological infrastructures should be encouraged to locate within the OVKC, which would prefer scenery sites. Secondly, networking development is required not only between local universities and industries within Wuhan, but also between all kinds of knowledge sectors in and out of Wuhan as well as Ezhou. Knowledge neighbourhoods have been proposed to be established centring at local universities and research institutes surrounded by venture captures, incubators and new start-ups within 5 kilometres, so as to enhance the transfer of knowledge (Figure 1). On this basis, local innovation networks can be built with four distinctive functional zone designated as key areas to produce, transfer and commercialize knowledge specifically and multiple knowledge neighbourhoods as nodal points to improve the capacity of local networks. Thirdly, the regional networks can be developed with the two airports acting as the innovation hubs to input and output knowledge talents and products. Based on its own strengths, the OVKC will be able to form a regional innovation community with Shanghai and its surrounding cities along the Yangtze River.

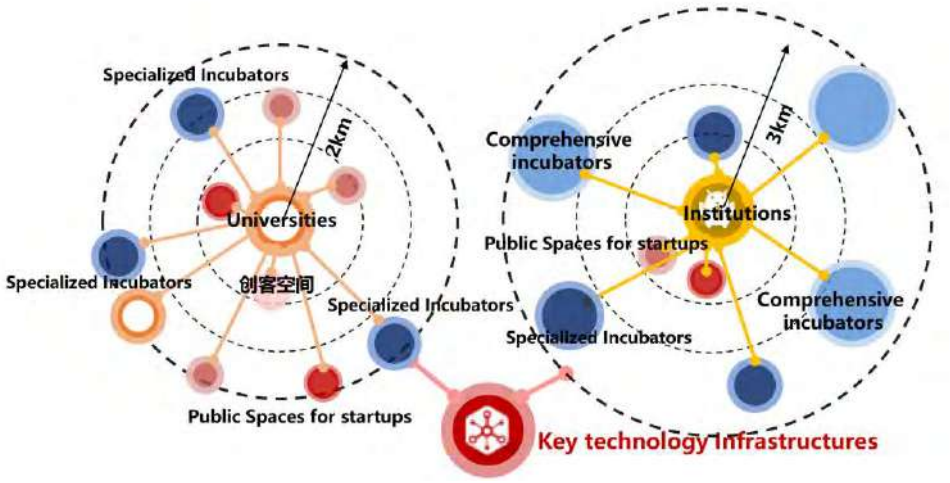

Figure 1 Local Knowledge Neighbourhoods

4.2. Making Knowledge Corridors a Boom for Knowledge Economies

Related to the innovation network is the geographical concentration of technology enterprises, which form industrial clusters and derive the booming of knowledge economies. Thus, the key to making knowledge corridors as a boom for knowledge economies is to incorporate the industrial chain with innovation networks by bridging the gaps between the producing and commercializing knowledge so as to keep nurturing local leading enterprises which could also give birth to new start-ups in the firm neighbourhoods. However, although the OVKC has been well-known for its competitiveness in optoelectronics industries, bio industries and intelligent manufacturing industries, the main reason lies that local leading firms are mostly the branches of national enterprises with their research functions locating in the first-tier cities like Beijing, Shanghai and Shenzhen. This has resulted in the failures of building local firm neighbourhoods, which can be exemplified by the fact that the current

amount of unicorn enterprises ranks behind compared to other knowledge corridors in China. Besides, there is an intriguing fact that high-tech firms have taken account for two-thirds of the total amounts but one-third of all the production value of Hubei Province respectively. Investigations indicate that current high-tech firms are experiencing the threshold of growth due to lack of technical service facilities like pubic semi-works, public data-sharing centres.

Therefore, to boom the knowledge economies of the OVKC, the first thing to do is to build local neighbourhoods of firms and enhance networking possibilities between existing local leading enterprises and start-ups by locating technological service facilities including public semi-works, data-sharing centres and research labs in between, which not only can decrease the cost of growth for start-ups but also can realize the “dandelion” roles of local leading enterprises through face-to-face communications(figure 2). Besides, it is also proposed to introduce new leading enterprises which could locate their research and development sectors locally. To increase the attraction for them, designated zones with specific favourable policies on tax, constructions and etc, have been proposed, which requires deeper discussions furthermore. In this way, the current industrial chains of the OVKC could be incorporated with the innovation networks, which will not only focus on increasing the competence of the existing dominating industries, but also stress the roles of the technological service industries and attempt to expand the boundaries of existing industries towards the future. Especially, stressing the roles of the technological service industries like finances would benefit the building of local innovation networks by enhancing the access of knowledge sectors to venture capitals.

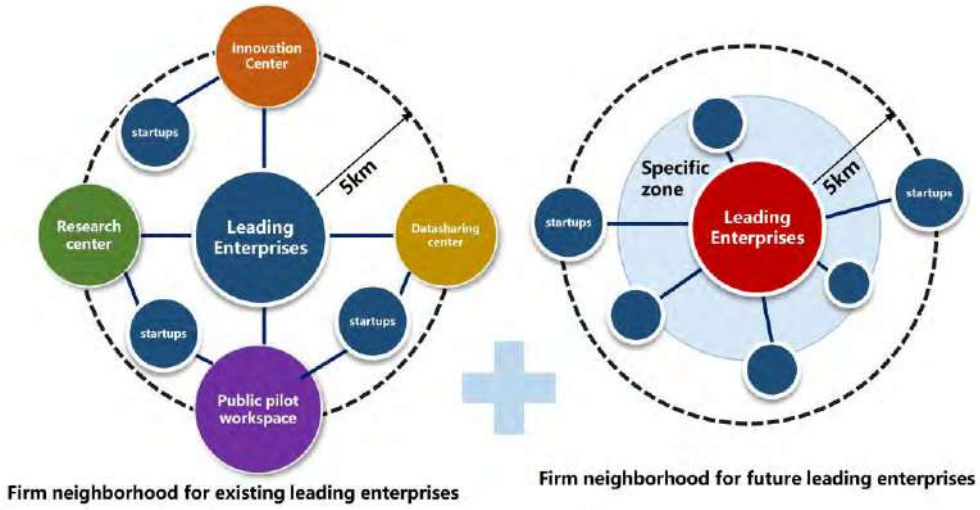

Figure 2 Local Neighbourhoods of Firms

4.3. Making Knowledge Corridors an Attraction for Knowledge Workers

Knowledge workers, with a higher level of education, have been known as one of the most important driving forces behind knowledge-based developments. Together with knowledge, they are sourcing from universities but are free to move anywhere favourable to their living expectations. Pleasant environments and well-established urban amenities have proved to be the major attractions for them. As for the case of Wuhan, it has been known for its

nickname as “the Forest of Campus” but suffering from the loss of undergraduates for a long time due to the lack of attraction for knowledge workers. Although the OVKC is surrounded with mountains, lakes and rivers, there is neither many high-quality city parks with easy access nor greenways linking the surrounding sceneries. Investigations indicate that public space is the most important aspect that the OVKC should be improved at, and the existing urban amenities fail to meet the requirements of knowledge workers. Not only there is a lack of basic urban amenities especially elementary schools and hospitals, but also the third places like coffee shops for knowledge workers to mingle are short-supplied compared to other knowledge corridors. Considering that the number of knowledge workers in the OVKC is increasing at a higher rate than that of local residents, it is necessary to supply with customized urban amenities to meet the requirements of knowledge workers.

Thus, to make the OVKC an attraction for knowledge workers, it is suggested to establish a complex of “green”, “red” and “yellow” infrastructures towards the current problems. Firstly, “green” infrastructures including high-quality urban parks with multi-functions like culture and sports and easy-access pocket parks with communication spaces have been proposed to locate within the corridor, linked by greenways (Figure 3). Secondly, “red” infrastructures which mean basic urban amenities for local residents should not only be supplemented according to the whole evaluation of the current facilities but also be required to be built with high standards. Thirdly, “yellow” infrastructures specifically targeting towards local knowledge workers are suggested to locate around workplaces within 15-minutes walking distances. According to the investigation with knowledge workers, the functions of “yellow” infrastructures are supposed to include not only retails, apartments, sports and so on for basic livings, but also encouraged to provide coffee shops, art galleries, book stores and libraries for knowledge workers to minge between and after work. This complex of “green”, “red” and “yellow” infrastructures will furnish the innovation networks by keeping attracting knowledge workers.

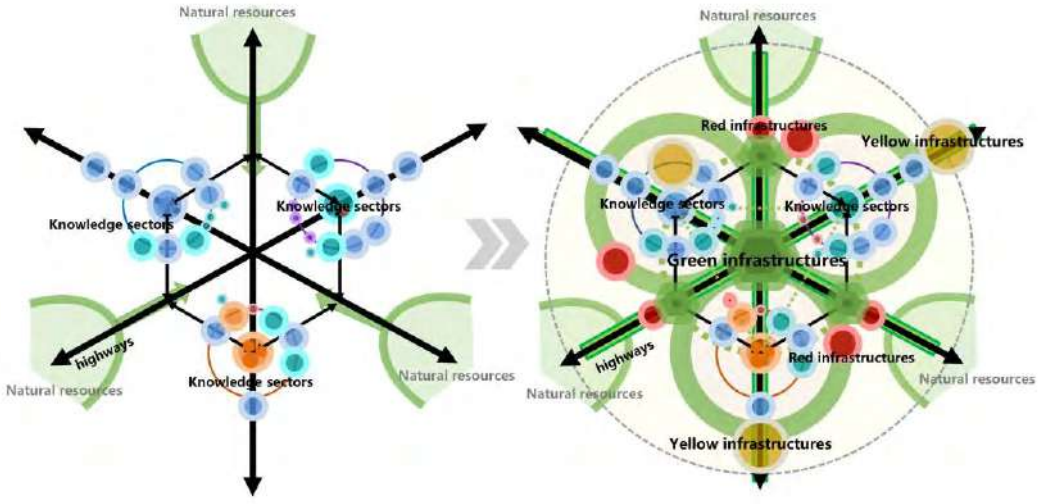

Figure 3 The Complex of “Green”,” Red” and “Yellow” Infrastructures

4.4. Making Knowledge Corridors a Freeway for Innovation Flows

Based on a bundle of infrastructures, knowledge corridors should become a freeway for innovation flows owing to the connectivity. With nodal points equipped with a transportation hubs playing the roles of attracting flows, the infrastructures of corridors could provide a freeway for innovation flows, so as to improve both the local and regional innovation network as a result. Aimed to be the national and international innovation centre, the OVKC still has a long way to go due to its current weak connection locally and regionally. Although with 3 high-speed train stations and 10 intercity train stations, the OVKC has taken the position of transportation hub in Central China, which will be threatened due to the construction of new super highspeed railways in nearby cities. Although there is the Tianhe Airport which is supposed to become the biggest passenger airport in Central China and will be the Shunfeng Airport which aimed at ranking the third among freight airports in Asia, this area is weakly connected to both the airports. Due to the rivers as natural barriers, the transportation system of highways, subways and greenways are all underdeveloped, leading to the traffic jams in rush hours let alone easy access to nodal points.

Therefore, to realize the goals of the national and international innovation centre, the first thing to do would be improving the strategic position in national and international transportation systems by speeding up the construction of the Shunfen Airport and locating super highspeed railway stations within the boundary of the OVKC. Besides, the network density of highway systems is proposed to be improved so as to improve the connection between nodal points especially airports, train stations and other hubs. More efficient public transport systems are also proposed to be built by extending the subway line to link with most nodal points and establishing greenways to connect subway stations with workplaces and housing areas. In particular, a specialized public transport system including subways and bus lines is suggested to establish door to door between universities, research institutions and major knowledge sectors, towards the problems of low efficiency of current public transport. A smart transit system is also suggested to build upon the existing roads, towards the problems of traffic jams in rush hours. In this way, the goal has been set that it will take not more than 60 minutes to reach nodal points especially the airports, train stations and other transportation hubs from anywhere within the boundary of the OVKC.

4.5. Making Knowledge Corridors a Mutual Force for Urban Governance

The tricky parts of governing knowledge corridors lie not only with the uncertainty of innovation but also the cross-bordering issue of linear developments, which is like a dynamic, participatory and strategic process and it requires a careful and delicate orchestration (Sarimin & Yigitcanlar, 2015). As the boundary of the OVKC crosses the borders of two cities, a mutual-force between central governments vertically as well as the two municipalities and the public horizontally has been missing due to the institutional issues. Although the public policies concerning to the innovation activities in the OVKC have been issued at a number of more than 100, only less than 10 percent of the policies are related to the governance of spaces for innovation activities. This has led to the difficulties in the whole process of knowledge-based urban development, due to the lack of flexibilities to adapt to the uncertainty of innovation. For example, the current land use regulation has set up a rigid upper limit for the mixed-use functions while investigations indicate that the requirements of the existing enterprises to improve the proportions of mixed uses are difficult to meet with. This has also increased the institutional cost for enterprises to be engaged more in innovation activities.

To form a mutual-force for urban governance, it is suggested that a “one-stop-agency” for the operational management of the OVKC should be established at first to enhance the organizational capacity, which involves not only the provincial government of Hubei, the municipal governments of Wuhan and Ezhou, but also local universities, enterprises and the public. Besides, the flexibilities of current land use regulations have been proposed to be enhanced by increasing the upper limit of mixed-use functions and adding a new type of land use to the existing system, which could be undefined of land use and applying for specific policies to locate key technological infrastructures, leading enterprises and etc. Beyond this what needed most is not only the adjustment of current public policies but also a continuous policy monitoring system to recognize the current development stage as well as the problems and ensure that the objectives can be achieved. In correspondence to the understanding of knowledge corridors, the system of 36 indexes which can be measured every year and compared with other cities have been established in 5 dimensions corresponding to the interpretations of knowledge corridors (table 1).

Table 2 The Indexes of the Monitoring System

Category	Sub-category	Index
Innovation Resources	Innovation Input	Number of key technology infrastructures
		Number of Incubators
		Number of Public Spaces for Startups
		The percentage of research and development expenses in GDP (%)
	Innovation Output	Valid patents per 10000 people per year
		Number of PCT patents per year
		Number of invented international standards
Industries	Industrial Structure	Percentage of the added value of strategic industries in GDP(%)
		Percentage of the added value of new economies in GDP(%)
		Percentage of high-tech service industries incomes(%)
	Innovative Enterprises	The Increasing rate of gazelle enterprises(%)
		Number of unicorn enterprises
		The Increasing number of high-tech enterprises per year
		Number of enterprises with venture capitals
Physical Environments	Public Spaces	Areas of parks per person(square meters)
		Coverage of urban parks with an area of more than 5000 square meters to residential districts within 500 meters(%)
		Number of urban parks with an area of more than 10 hectares per 10000 people
		Coverage of greenways to residential districts within 5-minute walking distances
	Urban amenities	Number of international schools per 10000 people
		Number of hospital beds per 10000 people
		Number of larger urban amenities(including exhibitions, libraries, art galleries, theaters and etc.) per 10000 people
		Coverage of urban amenities to residential districts(%)
		Areas of the third places(like coffee houses) per person (square meters)
Transport	Accessibility	Coverage of airports within 60-minute travel(%)
		Coverage of train stations within 45-minute travel(%)
		The Density of high-way network(meters per square meters)
	Connectivity	The Density of branch network(meters per square meters)
		Milestones of subways(kilometers)
		Percentage of travel by public transport(%)
		Milestones of public transport per 100000 people(kilometers)

Governance	Spaces	Percentage of increased spaces for innovation activities in office buildings per year(%)
		Percentage of increased apartments for knowledge workers in housings(%)
	Policies	Percentage of policies for innovators (%)
		Percentage of policies for capitals
		Percentage of policies for related issues (%)
		Percentage of policies for coordination(%)

To implement the strategies at local scales, short-term, mid-term and long-term targets for the index system have been made respectively and an action plan for the next year has also been established especially. As a complex of long-term vision, plans and short-term actions together with effective policies, knowledge corridor strategies would require a long span of time to achieve progress. Within the first phase of development, the projects listed in the action plan for the OVKC are about to launch or still in progress though. However, what's obvious right now is that both local governments of Wuhan and Ezhou are preparing to collaborate with each other with the establishment of the strategic plan, which indicates a good start for the implementation of the strategic plans. With the strategies been proposed elevated to national agenda while keeping sinking locally and regionally, this would also improve the competitiveness, sustainability and liveability of the megacity of Wuhan and its metropolitan area.

5. Conclusions

How to understand the concept of knowledge corridors in the new economies driven by science and technological clusters, which do not rely on traditional factors like before? How to make knowledge corridor strategies towards a more liveable, sustainable and efficient megacity based on the local conditions? The two questions above have been answered by the literature review and case studies in this paper. Although the corridor concept, with a long history, has evolved from linear or belt patterns to networks, one thing which has never changed is its character of connectivity. Greatly inspired by the success of the Silicon Valley, M80 and other technology clusters in corridor patterns, there has been a trend of using the spatial instruments of knowledge corridor with its connectivity to improve the regional roles of megacities in developing countries especially like China. Based on the original concepts and case studies, knowledge corridors, as the combination of knowledge-based urban development and corridor development, could be interpreted as corridors with various knowledge resources to establish local and regional innovation networks, clustered leading enterprises which could nurture start-ups to boom knowledge economies, pleasant environments and urban amenities to attract knowledge workers, well-connected transit systems to improve the efficiency of innovation flows and co-governing mechanism to adapt to the uncertainty of innovation. Based on the five dimensions of the understanding, the case study of the OVKC has been used to elaborate the knowledge corridor strategies, which are proposed to be made as a loop for innovation networks, a boom for knowledge economies, an attraction for knowledge workers, a freeway for innovation flows and a mutual force for co-governance, towards a more liveable, sustainable and efficient megacity. As a complex of visions, plans and actions together with effective policies, knowledge corridor strategies should not be phased according to its own circumstances but also require continuous monitoring.

As there will a span of time to access the achievements or failure of the strategic plans of the OVKC, what the case study would like to contribute is the framework in making knowledge corridor strategies rather than the wholesale packages. Like an orchestra, the implementation of knowledge corridor strategies does not only require a conductor to vision, lead, monitor and make adjustments constantly but also a group of music players to collaborate. Although the music books like the framework of the strategies may not change in different theatres, the performances will be not the same with different audiences like the country-specific social, cultural, economic and technological circumstances, which are the key factors to determine the final effects.

Case Study / Project

How to Plan Ahead for an Efficient and Livable Metropolis:

Wuhan Experiences

Wenjing LUO

Abstract

Speakers: Yongdong QIU, Wuhan Planning & Design Institute, China; Yun WANG, Wuhan Planning & Design Institute, China; Haijun LI, Wuhan Planning & Design Institute, China; Wenjing LUO, Wuhan Planning & Design Institute, China The seemingly unlimited growths of metropolises have put great challenges on their efficiency, livability and sustainability. With the rapid emergence of metropolises worldwide, how to best plan ahead for an efficient and livable metropolis has become a global key issue for planners and policy makers. With the rapid developments of megacities in China, policies and guidelines have been published towards making an efficient and livable metropolis recently. Local experiences in China have shown that there are two aspects of strategies that could be spread to the world. On one hand, with the changes in national administrations, there has been a trend of transformation of master plans which tends to focus more on regional collaborations out of the boundaries and urban growths within the boundaries. On the other hand, local governments in lots of Chinese metropolises have realized the benefits of big data and set up online planning platforms for metropolises to upgrade the traditional planning methods.

This session focuses on how to best plan ahead for an efficient and livable megacity by taking the experiences of Wuhan which is a typical growing metropolis and can shed some lights on other cities worldwide. During the first part of the session, Wenjing LUO will introduce the backgrounds of making an efficient and livable metropolis in China, followed by a quick introduction of Wuhan. During the second part, Yun WANG, the head of Master Plan Division of WPDI will give a presentation on the master plan of Wuhan metropolis. Then, Haijung LI, the head of East Lake Branch of WPDI and Wenjing LUO will talk specifically about on how to collaborate out of the boundary and grow within the boundary, with the topic of corridor strategies and boundary defining for metropolitan areas. This is followed by Yongdong QIU, the chief engineer of WPDI, who will give a presentation about Wuhan Planning Lab which helps establishing and implementing master plans by online platforms. The last part of the session will be a moderated round table discussion, open for all interested parties, aiming at summarizing replicable experiences from Wuhan and exploring the effective strategies towards planning ahead for an efficient and livable metropolis.

Research Paper

COMPARATIVE ANALYSIS OF BEIJING-TIANJIN-HEBEI URBAN AGGLOMERATION, YANGTZE RIVER DELTA URBAN AGGLOMERATION, GUANGDONG, HONG KONG AND MACAU BAY AREA BASED ON GRAVITY MODEL

Nan Huihui; Urban Space Architectural Planning & Design Co. LTD.; China
Lu Qing; Urban Space Architectural Planning & Design Co. LTD.; China
Zhao Qian; Urban Space Architectural Planning & Design Co. LTD.; China

Abstract

Beijing-Tianjin-Hebei urban agglomeration, Yangtze River Delta urban agglomeration and the Guangdong, Hong Kong, Macau Greater Bay Area are China's three major urban agglomerations, including China's political, economic, financial and technological centers, which are important engines of the Chinese economy. The purpose of this study is to compare these three urban agglomerations from the economy, government management and spatial interactions. The major methodology of the study is gravity model. Since there are no clear official regulations for the scope of the three major urban agglomerations, we should define the scope and core areas at first, making them at a comparable level. First of all, the economy of the three major urban agglomerations in the wide-area range are similar, while the core area of Beijing-Tianjin-Hebei urban agglomeration is the weakest in per capita GDP. In the perspective of government management, the Beijing-Tianjin-Hebei urban agglomeration is policy-oriented and pays more attention to regional balanced development. The Yangtze River Delta urban agglomeration mainly focus on economic development. Under the policy of reform and opening up, Guangdong, Hong Kong, Macau Bay Area is seeking more regional cooperation with Hong Kong and Macau. In terms of spatial interactions, the Beijing-Tianjin-Hebei urban agglomeration presents a dual-core structure between Beijing and Tianjin. The other urban nodes in Hebei Province are not obvious, and the regional connections are weak, leading to unbalanced development. The Yangtze River Delta urban agglomeration presents the characteristics of a networked structure, and the cities in the entire region are closely connected and have a tendency to be integrated both in economy and transportation. The Guangdong, Hong Kong and Macau Greater Bay Area has formed a strong core composed of cities such as Guangzhou, Shenzhen, Hong Kong, Macau and Dongguan, which are closely linked with each other, but weakly connected with external region.

Keywords

Comparative analysis, urban agglomerations, gravity model

1. Introduction

Due to different translations and personal comprehension, scholars have a variety of understanding of the names of urban agglomerations and related concepts, such as megalopolis (Zhou, 1991), metropolitan interlocking region (Yu & Ning, 1983), and urban agglomerations (Gu, 2011). Although the name is different, most of them indicate that the urban agglomeration is an interconnected whole formed by cities of different grades, types and sizes, with the help of the regional transportation network. In this paper, we use “urban agglomeration” to refer to this phenomenon, and introduce the top three major urban agglomerations in China.

Beijing-Tianjin-Hebei urban agglomeration, Yangtze River Delta urban agglomeration, Guangdong, Hong Kong and Macau Bay Area are the top three urban agglomerations in China. The focus of our study is to introduce them from sizes and formation and development history. Then, we apply gravity model to examine the spatial interactions between cities inside the urban agglomerations, and how they act on the overall operation of the urban agglomeration.

The purpose of this study is to compare these three urban agglomerations from economy, government management and spatial interactions.

2. 2. Theoretical Background of Spatial Interaction Models

Spatial interaction is a movement or transmission over space, which is resulting of a decision process involving different influences (Vobruba, Körner, & Breitenecker, 2016). This paper uses spatial interaction to measure the strength of economic linkages between regions. The spatial connection can reflect the radiation capacity of the central city to the surrounding area, and it can also reflect the acceptance of surrounding areas to central city (Meng, 2009).

Spatial interaction is widely studied in geography, urban science and other disciplines. For example, when determining the relationship between regions, Thünen suggests a concentric structure of crops distributed around urban areas from an agricultural perspective (1986). Weber explores the mechanism of industrial activity distribution from an industrial perspective (2002). Other studies, such as Perroux 's growth pole theory (1950), Hagstrand's spatial innovation diffusion model (1967), Friedmann's "core-edge" theory (1966), etc. are all research and discussion on spatial interactions.

In the quantitative study of spatial interaction, two methods are commonly used: urban flow intensity and gravity model.

Urban flow generally refers to the flow of people, material, information, capital, technology and other elements within urban agglomeration. The formation of urban flow takes the regional transportation network as carrier, and city’s radiation mechanism as the main driving force. Urban flow intensity is used to describe the quantitative impacts of urban outward function. Liang Chen and Zeng Jian (2019) used urban flow intensity model to study

the outward service function of Beijing-Tianjin-Hebei urban agglomeration. Lu Jun and Luo Qi (2017) used the urban flow theory to evaluate the traffic links and economic linkages of cities in Jiangxi Province using Tencent's location big data and traditional statistical data.

Gravity model is based on the gravitational equation of Newton's law of universal gravitation. In the gravitational equation, the gravity between two objects is positively related to mass and negatively related to distance. Henry Charles Carey (1852) first introduced gravity model to spatial connection studies when studying the issue of immigration behavior. Stwewart (Martin, 2008) uses gravity model to describe the magnitude of the population force between two regions. Subsequently, gravity model was widely applied in research on transportation, retail, immigration, and marketing. Since 1990s, Chinese scholars started to use gravity models to measure spatial interaction between cities or regions (Wang & Zhuang, 1996; Miao & Wang, 2006).

3. Methodology and Estimation Strategy

3.1. Construction of gravity model

In the study of spatial interaction, we need to consider the flow of people, logistics, technology, information between cities, which is a complicated process. Due to the poor availability of data such as technology flow and information flow, this paper compares spatial interactions of the three major urban agglomerations from population and economy.

$$G_{ij} = K_1 \frac{E_i E_j}{D_{ij}^b} + K_2 \frac{P_i P_j}{D_{ij}^b}$$

Where G_{ij} represents the gravity between two cities, E_i and E_j are the economic mass of city *i* and city *j*, P_i and $P_i$are population mass of city *i* and city *j*. D_{ij} refers to the distance between the two cities (in this article, we use linear distance). K is gravitational constant of each variable. This paper assumes that the role of the economy and population have equal influence on cities' external connection, so $K_1 = K_2 = 0.5$.. *b* is the coefficient of friction, in this study, and *b=2*. By calculating the gravitational values of each city, we will get a gravitational matrix G_{ij} of three urban agglomerations.

3.2. Determination of the comprehensive influence of cities

Through the comprehensive gravity of the city, we can figure out the comprehensive influence of each city. The higher the gravity of the city, the higher the influence. The formula for the city's overall gravity is:

$$G_m = \sum_{i=1}^{n} G_{mi}$$

G_m represents the comprehensive gravity of city *m*. G_{mi} represents the gravity between city *m* and city *i*.

4. China's Three Urban Agglomeration

In the past 40 years, China's urban population has increased five times. In 2018, China's urbanization rate is close to 60%. China has a new plan to re-plan the national city map. According to the plan, China will promote large-scale urban agglomerations, and urban agglomeration will become the growth pole of economy in the future. At present, Beijing-Tianjin-Hebei urban agglomeration, Yangtze River Delta urban agglomeration and the Guangdong, Hong Kong and Macau Bay Area have become increasingly urbanized, and play very important roles in promoting regional development.

4.1. Defining the boundary of three agglomeration

Since the officially determined urban agglomerations are subjective and related to political strategies, the comparison of the three major urban agglomerations will results in large data bias. In order to ensure that the comparison is fair, we need to redefine the boundaries of the three major urban agglomerations so that they are at a comparable level. Through comprehensive consideration of population, GDP, and area, we finally obtained the scope of the three urban agglomerations (Tab.1), and defined core areas based on the level of urban development and regional influence (Tab. 2).

Table 1 Statistical Data of Urban Agglomerations

		Beijing-Tianjin-Hebei	**Yangtze River Delta**	**Guangdong, Hong Kong and Macau Bay Area**
Total Area	Area (10,000 km^2)	21.8 (Beijing/Tianjin/ Hebei)	21.9 (Shanghai/Jiangsu/ Zhejiang)	18.1 (Guangdong/Hong Kong/Macau)
	GDP (Trillion Yuan)	8.21	17.01	12.49/9.52 (Hong Kong, Macau Not Included)
	Population (10,000)	11159	16090	11980/ 11174 (Hong Kong, Macau Not Included)
	GDP Per Capital (Yuan)	73573	105718	104257/85198 (Hong Kong, Macau Not Included)

Source: Chinese Statistical Yearbook (2017)

Table 2 Statistical Data of Urban Agglomerations

		Beijing-Tianjin-Hebei	**Yangtze River Delta**	**Guangdong, Hong Kong and Macau Bay Area**
Core	Area	6.9 (5 Cities)	10.8 (16 Cities)	5.6 (11 Cities)

Area	(10,000 km^2)			
	GDP (Trillion Yuan)	5.98	11.96	10.55/7.58 (Hong Kong, Macau Not Included)
	Population (10,000)	6025	11154	6956/6150 (Hong Kong, Macau Not Included)
	GDP Per Capital (Yuan)	99268	107193	151719/123265 (Hong Kong, Macau Not Included)

Source: Chinese Statistical Yearbook (2017)

Beijing-Tianjin-Hebei urban agglomeration is the weakest and most immature urban agglomeration among these three urban agglomerations. Although Beijing and Tianjin, two municipalities, are included in this area, the overall GDP is less than Guangdong, Hong Kong and Macau Bay Area without Hong Kong and Macau, and is half of the Yangtze River Delta urban agglomeration. The reason for its poor development is the lag of the integration of Beijing-Tianjin-Hebei, which we will elaborate later.

Yangtze River Delta urban agglomeration is the top one urban agglomeration with largest scale, greatest economy and highest level of integration in China. The development of cities is relatively balanced among three urban agglomerations. Shanghai ranks first in the country with more than 3 trillion yuan of GDP. At the same time, there are 4 cities have more than 1 trillion, and 7 cities have more than 500 billion. In the future, Shanghai will still be the core of this area, together with Nanjing, Hangzhou and Suzhou as the sub-centers. The integration process will keep going on.

In terms of GDP, the economic aggregate of Guangdong, Hong Kong and Macau Bay Area has become the second largest bay area in the world second to San Francisco Bay Area. In 2017, the GDP of Guangdong, Hong Kong and Macau Bay Area reached 12.49 trillion yuan. At the same time, Guangdong, Hong Kong and Macau Bay Area has the highest urbanization rate in China. In 2017, the urbanization rate is close to 85 %.

Figure 1 Beijing-Tianjin-Hebei urban agglomeration

Figure 2 Yangtze River Delta urban agglomeration

Figure 3 Guangdong, Hong Kong and Macau bay area

4.2. Formation and development

The three urban agglomerations are formed and developed under different circumstances, representing the different periods' political characteristics in China.

Beijing-Tianjin-Hebei urban agglomeration was formed with the support of national policies. Since the poverty problem in Hebei Province is very prominent, Chinese government plans to drive backward areas through developed regions, and has tried several regional integrations plans. "Bohai Economic Zone" is the earliest attempt. Initially, Bohai Economic Zone only included Beijing, Tianjin and Tangshan. In 1986, the Economic Union Mayor of the Bohai Economic Zone was established. In 1988, six cities including Beijing, Baoding and Langfang established the "Beijing Economic Cooperation Zone", starting a new attemp. In 2011, the National Development and Reform Commission proposed the establishment of the "Capital Economic Circle", including Beijing, Tianjin and, Baoding, Tangshan, Langfang, Shijiazhuang, Zhangzhou, Qinhuangdao, Zhangjiakou, Chengde, Handan, Xingtai, Hengshui of Hebei Province. Among them, Beijing, Tianjin, Baoding and Langfang are defined as central functional areas, having the prior developing opportunities. In 2015, the "Beijing-Tianjin-Hebei Collaborative Development Program" was approved. The target is to build a world-class urban agglomeration.

Yangtze River Delta urban agglomeration was spontaneously formed under the promotion of the market economy. With its developed land and water transportation conditions and abundant resources, the Yangtze River Delta has already had the prototype of the urban agglomeration in the middle and late period of China's feudal society. After the Opium War, foreign trade started in the Yangtze River Delta region due to its superior geographical position. Shanghai gradually became the trading center and a modern city of the time. After the reform and opening up, Yangtze River Delta seized this new opportunity of development. Shanghai is still the central city of the whole region, and the statuses of cities such as Hangzhou, Nanjing, Suzhou and Ningbo are also becoming increasingly important. It can be seen that the development of the Yangtze River Delta urban agglomeration is based on its

important transportation and trade resources, which makes the whole region open and grows in the market competition.

Guangdong, Hong Kong and Macau Bay Area is a successful work of the Chinese government to carry out reform experiments. From 1978 to 1985, in the early days of reform and opening up, Shenzhen, Zhuhai and Shantou were designated as special zones, directly undertaking industrial transfer in Hong Kong and Macau, forming a development model of "front and back factories" between Guangdong and Hong Kong, driving backward areas through developed regions. At that time, Shenzhen has become the economic center and innovative city of China from the original fishing village, and the urbanization rate has reached 100% recently. The take-off of Shenzhen has also led to the reform and development of the surrounding areas. Until now, Pearl River Delta region keeps exploring the path of innovation and creating a miracle, and becomes the region with the highest degree of openness and the strongest economic vitality in China.

5. Exploring Spatial Interaction of Three Urban Agglomeration

This paper uses the statistical yearbook data of three urban agglomerations in 2017 to establish the gravity model. Through the results of the gravity model, we can not only get the spatial interactions of the three urban agglomerations, but also form a network of connections between cities, which could be presented in the drawing and reflected spatial structures.

5.1. Model results of Beijing-Tianjin-Hebei urban agglomeration

The overall connection of Beijing-Tianjin-Hebei urban agglomeration is weak. Beijing and Tianjin form a strong twin core a radial relationship, affecting surrounding areas. The connection between cities is positively related to the physical distance. The closer the distance, the stronger the connection.

Beijing is closely connected with Tianjin, Langfang and Tangshan, and is weakly connected distant cities, such as Handan, Xingtai and Hengshui. Shijiazhuang, as the capital city of Hebei Province, is a sub-central city in the region. Shijiazhuang only has strong links with the well-developed Baoding, and cannot influence more areas around it.

As China's political, economic, science and technology center, Beijing has gathered resources all around the country. Tianjin has undertaken a series of national strategic projects and projects. The development environment of Beijing and Tianjin is better than Hebei province. However, their influences did not lead to the development of Hebei Province. The Beijing-Tianjin region is still in the agglomeration stage. People, finances and resources keep flowing to Beijing and Tianjin, especially to Beijing. Consequently, Hebei province lost its resources, and the economy of the region is extremely unbalanced. What's worse, the infrastructure such as transportation in Hebei province is also poor, limiting their further development, forming a "poverty belt" around Beijing. There is a huge gap from the goal of "building a world-class urban agglomeration".

With the launch of the national plan of Xiong'an New District, it is expected to help Beijing ease the pressure and promote regional integration of Beijing-Tianjin-Hebei. Xiong'an New District is located in Baoding, Hebei Province, the hinterland of Beijing, Tianjin and Baoding, with obvious location advantages and convenient traffic. The development of Xiong'an New

District will assist on the optimization of the urban layout and spatial structure of Beijing-Tianjin-Hebei urban agglomeration, and complement the shortcomings of Hebei'. In the latest “13th Five-Year Plan”, there has three high-speed rail will layouts from Beijing to Zhangjiakou, Beijing to Shenyang, and Beijing to Shangqiu, helping breaking the blind spots, and increasing the influence of central cities.

Figure 4 Spatial interaction of Beijing-Tianjin-Hebei urban agglomeration

In terms of the city's comprehensive influence, Beijing, Tianjin, Langfang and Tangshan have the greatest influence. These four cities are also well-developed areas in this region. Shijiazhuang’s influence is at a medium level and has not exerted the influence as a provincial capital. Tangshan is an old industrial city of Hebei province, and its GDP is higher than Shijiazhuang. Langfang, located in the central part of Hebei province, has convenient access to the north and south, and its influence on surrounding areas is higher than that of Shijiazhuang. Shijiazhuang is just a small village in history. Due to the construction of railways in modern times, Shijiazhuang has become a “city on the train”, traffic fortress and resource distribution center, and has favorable conditions for development. But compared to the old developed cities, Shijiazhuang's strength is relatively weak.

5.2. Model results of Yangtze River Delta urban agglomeration

Yangtze River Delta urban agglomeration has formed the initial shape of network structure, the internal links between cities are the strongest among the three urban agglomerations. Yangtze River Delta urban agglomeration has formed a high-intensity contact zone with "Shanghai, Nanjing, Hangzhou" as its core, and its regional influence is decreasing toward both sides along the "Shanghai-Nanjing" and "Shanghai-Hangzhou". The connection between Shanghai and Jiangsu is slightly stronger than the link with Hangzhou.

Shanghai is the core city of the region and the largest commuting destination. Suzhou residents are the main source of commuters to Shanghai, so Shanghai has the strongest contact with Suzhou. Also because of commuting, Shanghai has strong links with Nantong, Jiaxing and Zhenjiang. Shanghai's radiation range is almost all over the region, and is only weakly connected with marginal cities, like Lishui, Zhangzhou, Lianyungang, Suqian, Huai'an.

Hangzhou and Nanjing are the provincial capitals of Zhejiang province and Hangzhou province, respectively, and are secondary centers of urban agglomerations. They influence cities inside the province, and their connections with cities close to Shanghai are significantly stronger than those of marginal cities.

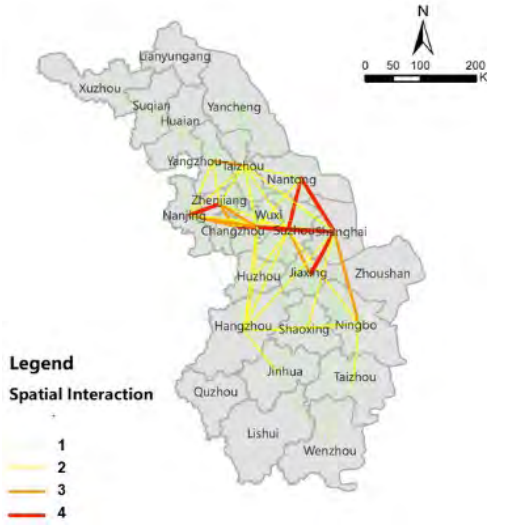

Figure 5 Spatial interaction of Yangtze River Delta urban agglomeration

The comprehensive influence of Shanghai, Suzhou, Wuxi, Changzhou, Nanjing, Nantong, Zhenjiang and Hangzhou in the region is in the high level of the urban agglomeration. Among them, Suzhou, Wuxi and Changzhou are close to Shanghai and have strong regional advantages. They are an important metropolitan area in the Yangtze River Delta urban agglomeration. At the same time, around Nanjing and Hangzhou, regional metropolitan areas have also been formed respectively, which plays a leading role in the surrounding areas.

5.3. Model results of Guangdong, Hong Kong and Macau Bay Area

Guangdong, Hong Kong and Macau Bay Area is the most dynamic and urbanized areas among three urban agglomerations. Shenzhen is the strong core. As the provincial capital of Guangdong Province, Guangzhou relies on political advantages to influence the surrounding areas. Hong Kong and Macau are the core area of the region because of their strong big economic strength and positive influence towards mainland China. Therefore, the spatial connection in the Greater Bay Area are mainly around Guangzhou, Shenzhen, Hong Kong and Macau.

However, uneven development still exists within the urban agglomeration. There is a serious gap between eastern and western sides of the Bay Area. Cities in core areas are closely linked, but cities far from the core area have weak connection. Compared with the Yangtze River Delta urban agglomeration, the radiation capability of the core area is obviously insufficient, and it is unable to provide more resources for the peripheral cities to promote their economy.

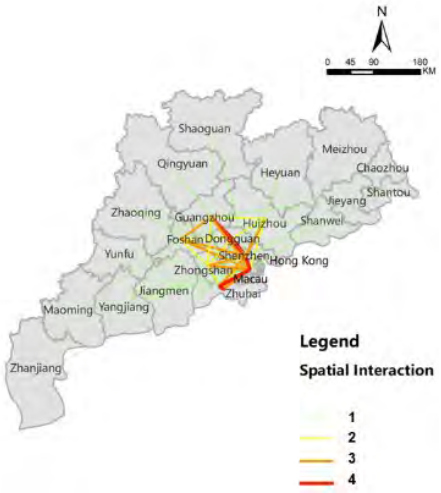

Figure 6 Spatial interaction of Guangdong, Hong Kong and Macau Bay Area

Shenzhen, Hong Kong, Dongguan, Guangzhou, Macau, Zhuhai and Foshan are the most influential cities in the region. In recent years, the integration processes between Shenzhen and Dongguan, Guangzhou and Foshan have been accelerating, and the boundary has become increasingly blurred, which are crucial the growth pole of the region. As an international financial, shipping and trading center, Hong Kong has a very comprehensive and mature international cooperation system, resources and experience, which is irreplaceable by any other citiesy in the Bay Area. Macau is a customs zone that implements low-tax policy. Macau has the superiorities of flexibility, convenience and affordability in finance, and will play an important role in the foreign trade of the Bay Area. Zhuhai is the only city connected with Hong Kong and Macau by Pearl river delta bridge. Zhuhai is a significant node in the cooperation between Hong Kong, Macau and mainland.

6. Conclusion

6.1. Comparison of three urban agglomeration

The integration of the Yangtze River Delta urban agglomeration, and Guangdong, Hong Kong and Macau Bay Area is obvious, and major cities are tightly related to each other. In contrast, the Beijing-Tianjin-Hebei urban agglomeration is concentrated in Beijing and Tianjin, other cities are distributed isolated in the region and rarely connect with outside cities. By comparing the night light indices of the three urban agglomerations, our conclusions are once again confirmed:

In the night light index of the Beijing-Tianjin-Hebei urban agglomeration (Figure 7), we can see more clearly that the Beijing-Tianjin region has a very high light index and is concentrated in central cities. The integration trend is clear and obvious. Most cities in Hebei are scattered around in the form of points and have not been fully developed.

Yangtze River Delta urban agglomeration has the most massive night light coverage (Figure 8). Night lights in the core area are beyond borders of the city and have a tendency to be one part. The brightness of other cities is also higher than that of other urban agglomerations.

Guangdong, Hong Kong and Macau Bay Area has a strong core around Guangzhou, Shenzhen, Hong Kong, Macau, Dongguan and Zhuhai (Figure 9). Like Yangtze River Delta urban agglomeration, it has broken through borders and gradually joined together. The lights in the peripheral cities are obviously dim and scattered.

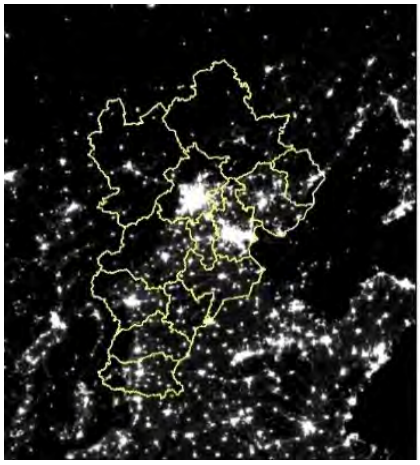

Figure 7 Night light index of Beijing-Tianjin-Hebei urban agglomeration

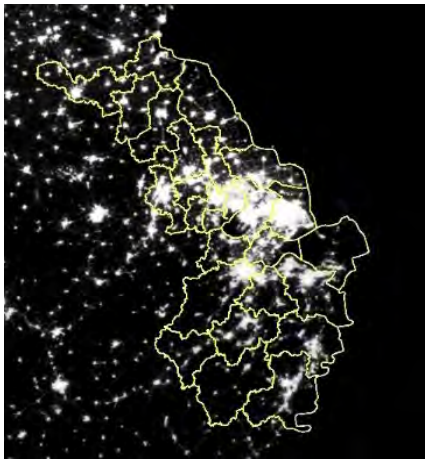

Figure 7 Night light index of Yangtze River Delta urban agglomeration

Figure 7 Night light index of Guangdong, Hong Kong and Macau Bay Area

6.2. Future improvement suggestions

The gravity model of this paper also has room for improvement.

This paper studies the linear distance between cities, and does not consider the situation of attenuation with distance. In the future, distance could be taking into account in the model.

The gap between cities is not only a result of economy and population of the city, but also affected by many factors such as education, medical care, and infrastructure construction. Therefore, more variables can be added in the future to measure the connections between cities.

Case Study Paper

The role of sprawl towards the megacity

Eastern-European sprawl, the case study of Bucharest, Romania

Manuela NEGRILA, UAUIM; Romania

Abstract

Cities nowadays are either growing at a never-before seen rate or shrinking due to technology, globalization and increased mobility. Some of these changes are planned but, most of them are not, thus the quest for a planned and structured megacity can be tedious. Amongst the forces that shape cities, urban sprawl is one of the less analysed but most definitely the least planned. Seeing how the forces that drive this phenomenon are in their majority economic, how can we, as planners integrate this chaotic element into a planned and structured megacity?

Urban sprawl is an issue that has been studied in North America since 1950 due to its environmental, economic and social impact. More recently, this subject has attracted the attention of urban researchers and policy makers all over the world (Ewing et al. 2016; Liu et al. 2018). The phenomenon is even more fascinating because, depending on the geo-political background, it can differ a lot in terms of spatial layout and structure, but the main characteristics are the same. Still, the question remains, why in the last 70 years, urban sprawl has been a phenomenon that has caught on world-wide, even in the face of professionals protesting its downsides? Some evidence can be found in the fact that, from an urban economist's point of view urban sprawl is not a vicious force that disrupts the city, but rather an efficient adjustment to a change in conditions (Lechner & Maier, 2009)

The study aims to better understand the role of urban sprawl towards the megacity by making a comparison between the current development in the northern part of Bucharest, Romania which has obvious urban sprawl features, and the development of the southern area. As Romania tries to align its policies for urban planning to European trends, a study on urban sprawl is necessary. Moreover, in the Bucharest Strategic Concept (local policy), there is a need to rethink the gap between the city and the adjacent areas, defining the limits of Bucharest that no longer fall within the current administrative boundaries and 'regaining the territorial identity of the periurban area' (CSB, Vol.1, pg. 85).

Urban sprawl evidence in Bucharest could only be observed after 1990, when free market and private property were reinstated and has taken effect at first and in larger quantities in the north of the city. With the background of the negative effects the end of the economic and real estate crisis in 2009 left on the northern sprawl and given this part of the metropolitan area is becoming saturated, the current study is based on the precondition, which will have to be validated along the way, that the expansion of Bucharest will take a greater magnitude to the south (Vânau, 2009). It is important to draw attention to the fact that the southern suburbs are in danger of reaching the same situation as the northern suburbs in the next 10 years.

As Bucharest is viewed as a city between the orient and occident (Haroiu, 1997) we believe the study will offer a great insight in both the eastern and western perspective and layout of urban sprawl.

The aim of this research is to understand and better integrate policies towards a metropolis. Even though urban sprawl seems like such an artificial construct, planned design can integrate it in a megacity if we can answer the following questions. How can we, as planners and policy makers integrate the urban sprawl in a megacity? How can this phenomenon, that now is an unplanned mess, help the development of megacities?

Keywords

Urban sprawl, Eastern European cities, keyword 3 (3-5)

1. Introduction

1.1. Context

In the context of the ever growing cities, urban sprawl is one of the phenomenons that draws constant attention to it and gives a deeper meaning to the idea of limitless city. Even when the city has caught up with some previous form of sprawl, a new and more different form of the phenomenon takes shape even further away from the newly developed megacity. It is this snowball effect that is the subject of this study, the correlation between the megacity, urban sprawl and the limitless city. The phenomenon is even more fascinating because, depending on the geo-political background, it can differ a lot in terms of spatial layout and structure, but the main characteristics are the same.

To better illustrate the purpose of this study the first task is to provide a theoretical framework for research. In clarifying the origin and definition of the urban sprawl concept, a brief analysis of the origin and evolution of urban sprawl is necessary.

Furthermore, the case study of urban sprawl in Bucharest and a comparative analysis between the extension of the city to the north and south will be provided in order to demonstrate the effects in an Easter-European city. As Bucharest is viewed as a city between the orient and occident (Haroiu, 1997) we believe the study will offer a great insight in both the eastern and western perspective of the layout of urban sprawl.

1.2. Definitions of urban sprawl

Urban sprawl is an issue that has been studied in North America since 1950 due to its environmental, economic and social impact. More recently, this subject has attracted the attention of urban researchers and policy makers all over the world (Ewing et al. 2016; Liu et al. 2018). Still, the question remains, why in the last 70 years, urban sprawl has been a phenomenon that has caught on world-wide, even in the face of professionals protesting its downsides? To answer this question, a short review of the origin and definitions that were given to urban sprawl along the way is deemed necessary.

In the 1950s and 1960s, suburban expansion was defined as "a contiguous expansion of existing development from a central core" (Self, 1961). Harvey & Clark (1965) saw the sprawl rather as a stage in the development process and not a static state, just as we see it today in the context of the limitless city. It is suggested that some parts of the urban area can go through a stage where they are considered sprawl to evolve and become part of the city. In

the 1970s, sprawl is considered any development outside the "urban core" (Clawson & Hall 1973)

In the early 1990s, especially in North American literature, the term began to be so often used that it does not have a precise meaning, and defining it becomes a challenge for specialists. (Audirac et al, 1990).

Galster et al.(2001) notes that literature confuses the causes, consequences and conditions of sprawl. Thus they note that sprawl is a complex concept that can be defined in many ways (whether positive or negative) and that "sprawl has become the preferred metaphor for the suburban shortcomings and the frustrations of monocentric cities "(Galster et al., 2001, p. 681). Although there are many definitions of sprawl, they all conclude that not all urban development should be considered sprawl. In addition, there are several types of sprawl with different features. „Sprawl (n.) is a pattern of land use in a urban area that exhibits low levels of some combination of eight distinct dimensions: density, continuity, concentration, clustering, centrality, nuclearity, mixed uses, and proximity. ”(Galster et al., 2001, p. 685).

Bruegmann (2006) defines urban sprawl as a type of peripheral growth characterized by low density, mono-functionality, unlimited extension and non-contiguous (leapfrog) away from the city centre, consuming the agricultural space surrounding the city.

Couch et al. (2007) notes that the term urban sprawl is generally used with a negative connotation and describes suburban, inefficient, low-density developments around the outskirts of cities. The authors identify definitions that emphasize the idea that sprawl is a pattern of urbanization and other definitions that see sprawl as a process of urban change. In their work, they claim that sprawl is the process of expanding the city.

But sprawl is not always seen negatively, because "from the economists' point of view, space expansion of the city is not necessarily seen as an unwanted work. It is rather an effective adaptation to changing a condition. "(Lechner & Maier, 2009, pg.3).

After reviewing the different approaches to define urban sprawl over time, it is noted that the term is complex and difficult to define because it encompasses many aspects, and is not just a state of development, but rather a process of evolution of the city. However, the European Environment Agency (2006) definition succeeds in summarizing the main physical characteristics of sprawl observed by different authors over time. In trying to remain objective, the European Environment Agency definition does not take into account the impacts of the sprawl on the environment and the city, nor does it provide any quantification of the phenomenon. In conclusion, it is a comprehensive but general definition, leaving room for interpretation when it comes to defining a limit of sprawl analysis.

2. The case study of Bucharest

2.1. Background

The study aims to better understand the role of urban sprawl towards the megacity by making a comparison between the current development in the northern part of Bucharest, Romania which has obvious urban sprawl features, and the development of the southern area. As Romania tries to align its policies for urban planning to European trends, a study on urban sprawl is necessary. As mentioned in the introduction, depending on the geo-political

background, the phenomenon can differ a lot in terms of spatial layout and structure, yet the main characteristics are the same. Considering these factors, it is important to first understand the geopolitical and administrative context of Bucharest, Romania before proceeding to the analysis of urban sprawl in this city.

The metropolitan area considered for this study has an area of approximately 1,450 km^2 and a population of 2,301,255 in 2018 (Eurostat database). In the current administrative territory, the metropolitan area consists of the major city, the capital of Romania, Bucharest, and other adiecent cities in the Ilfov county: Bragadiru, Chitila, Magurele, Otopeni, Pantelimon, Popeşti-Leordeni and Voluntari. In order understand the territory that will be studied, we must first understand the administrative, geographical and sociological aspects of this metropolis. Further, we will expose some general data, first about Bucharest than about the Ilfov county so that further on we can discuss them together, as an entity.

It is necessary for the purpose of this study to clarify some aspects of the urban planning practice in Romania. According to the territory and urban planning law 350/2001, there are three forms of urban plans that have to be designed by private urban planners and then approved by the administration. These plans are:

- P.U.G. –the general zoning master, it is commissioned by the city council and designed by private urban planners and it used to plan the entire city/town/village and to draw the strategic vision for the next 10 years;
- P.U.Z. –the zoning masterplan, it is used by private investors of commissioned by the city council to justify the need for different developments in an area, sometimes it can be used as a derogatory tool to modify or better define zones already defined by P.U.G. .The changes that can be made by a P.U.Z. are in respect to density, height and overall volume of the future development. These cannot exceed with more than 20% the regulations of P.U.G.;
- P.U.D. –the masterplan for a land plot, it is used by investors as a means to show how their future development respects the norms and regulations of the designated zoning as regulated by P.U.G. and P.U.Z. of the area.

Another aspect to consider is the administrative structure of the city and its surrounding areas. Bucharest is the capital city of Romania and it is governed by a central administration, a mayoralty that takes decisions trough the city council. From an urban planning point of view, the responsibility of the city council is to oversee the general urban plan of the city – including zoning and major infrastructure routes– and to analyse and approve or not the different zoning projects that are submitted by public or private investors. The city is further divided into six districts, each with a local council that is responsible for its zoning masterplans. It is important to note that in order to be installed, a P.U.G. has to be approved by the city council of Bucharest and all the committees involved (infrastructure, parks and recreations, culture), the P.U.Z. has to be approved by the city council of Bucharest and the district local council and the committees, the P.U.D. has to only be approved by and the district local council and some committees if it is the case. The Ilfov county has a similar top down administrative structure, as in the county has a county council and each township has a local council. In this case all masterplans have to be approved by both the county and local council and the committees. Therefore, all planning in the metropolitan area considered for

Bucharest are following top down approval in the administration and are often initiated by private developers.

2.2. Beyond the city, towards metropolis

In order to understand the extent to which urban sprawl exists in Bucharest, a series of spatial, functional and socio-economic analyses of the area are needed. To begin with, a geographical and sociological analysis will be made followed by a historical review of the city's expansion in this context.

Bucharest, the capital of Romania, is located in the south of the country, in the central part of the Romanian Plain. The city has an area of 228 km^2 (0.8% of Romania's surface). The urbanised area consists of more than 70% while the remaining is being made up by green spaces (parks, urban forests), vacant land or patches of agricultural land absorbed by the rapid urban development. According to the last national census, in 2011, the city of Bucharest as defined by the administrative boundaries has 1,883,425 inhabitants (this only refers to the residents of the city), 8.8% of the country's population. As additional data from the census, only 51% of the inhabitants of the city are the active population and of these, 18.5% work in the industrial branch, 18.6% in commerce, 12.3% in construction, 3.4% are civil servants (data provided by The National Institute of Statistics/INSSE). The population density is 8,5 inhabitants/ km^2.

Geographically, Ilfov county is situated in the immediate vicinity of the capital city and encircles the it. This used to be more or less the "green and yellow belt" of the city with mostly agricultural land an forestry, but nowadays this territory is as part of the city as any.

The accessibility of the Bucharest metropolis is very good, the major road axes that penetrate the city are represented by the European class roads, national class roads and radial roads, these, in addition to the outer ring road, which circularly arranged.

Bucharest, being the capital city of Romania, is profoundly linked in its developement with the history of the country. From this consideration, in the interest of this case study, a brief history of the expanion of Bucharest will be provided.

Since its inception in 1459, Bucharest has started to grow further north, having a physical limit in the south, namely the Dambovita river. Gradually, it goes beyond this physical limit, and so the southern expansion begins. Before the First World War, the city begins to develop concentrically until it reaches the next natural limits in 3 directions the lakes in the north and the one in the west. In 1918, the year of the unification of the historical provinces, Bucharest becomes the capital of the Romanian state. This is a period of economic prosperity, which is also reflected in the expansion of the built environment, but also in the administrative perimeter of the city. In the interwar period the major traffic routes (Mogoşoaia Bridge, Brătianu Blvd., Coltea Blvd., Lascăr Catargiu Blvd., and others) are modernised and recalibrated to withstand more traffic. This is the area of transition from manufacturing to industrial economy, tact that can also be observed in the fabric of the city. But as Vânau (2009) observes, the modernization of the city does not follow a specific model of spatial organization but rather has heterogeneous influences (Balkan, French, German, Russian) with a pronounced imbalance between the center and the periphery. Bucharest reaches the natural barrier of the North, the Colentina River and manages to overcome it. This is the period when we start seeing that there is a more pronounced spatial development in the north than in the south.

The 1947-1989 period is marked by centralized planning. This started with administrative reorganization, "Bucharest Municipality becomes an autonomous administrative-territorial unit, and Ilfov county, becomes a distinct territorial-administrative unit with a main focus on agriculture. Forced industrialization and urbanization, as phenomenon specific to the communist era, have also imposed on Bucharest the transformation of the built environment, both in quantitative and qualitative terms. "(Vânau, 2009, p. 40). Thus, Bucharest extends its administrative boundaries to those it has today to accommodate the large population. During the communist era, the city's growth was compact, without exceeding the administrative boundaries of the city, largely following the urban planning principles of the Charta of Athens. The expansion was materialized by the construction of the workers' quarters that were meant to accommodate the growing population. Between 1966 and 1977, the population of Bucharest, including that of Ilfov County, increased from 1,596,457 to 2,094,977 (according to the National Institute of Statistics), which means an increase of 23.8% .

After the fall of the communism regime in 1989, by reactivating the economic circuits of real estate supply and demand a new era of development begins for the city. Changing the political regime, privatization processes, and deepening social disparities influence the city's development. The new landowners are looking for the cheapest properties they find in the localities around Bucharest. Thus, uncontrolled expansion spreads to neighbouring localities, guided largely by changes in user values, land prices, and lack of urban planning. As a result of the privatization of industrial areas, there is a phenomenon of urban renewal of the former factories within Bucharest. But the lack free land and urban planning constraints have led entrepreneurs to investment outside the city.

The first developments outside the city are in the form of individual luxury dwellings, mostly in the northern part of the capital. Then gated communities begin to appear. Most of these are marketed as a house close to nature or nature in your yard and are located at considerable distances from the city but do not have access or basic infrastructure. Real estate speculation and the quality of the natural environment in the north of the capital make this area highly sought after by investors. Thus, from 2000 to the present, there is an uncontrolled expansion of the city, especially in the north, west and east. In addition to residential complexes built at considerable distances from the city, logistics parks and logistics platforms or commercial and industrial clusters also develop. From the point of view of accessibility and utilities infrastructure, local governments rarely provide these facilities before the new residential developments are built. For the most part, this type of facilities appears to be a long way after building the residential complexes. There are cases where some residential districts do not have access to such facilities, such as the Henri Coandă Residential Quarter or portions of the private developments in Mogoşoaia, Bragadiru s.a.

This rapid expansion of Bucharest, in particular residential projects, can be explained by the changing of the political regime and citizens' values but also by an increase in population as a result of migration to the urban environment (Vânau, 2009).

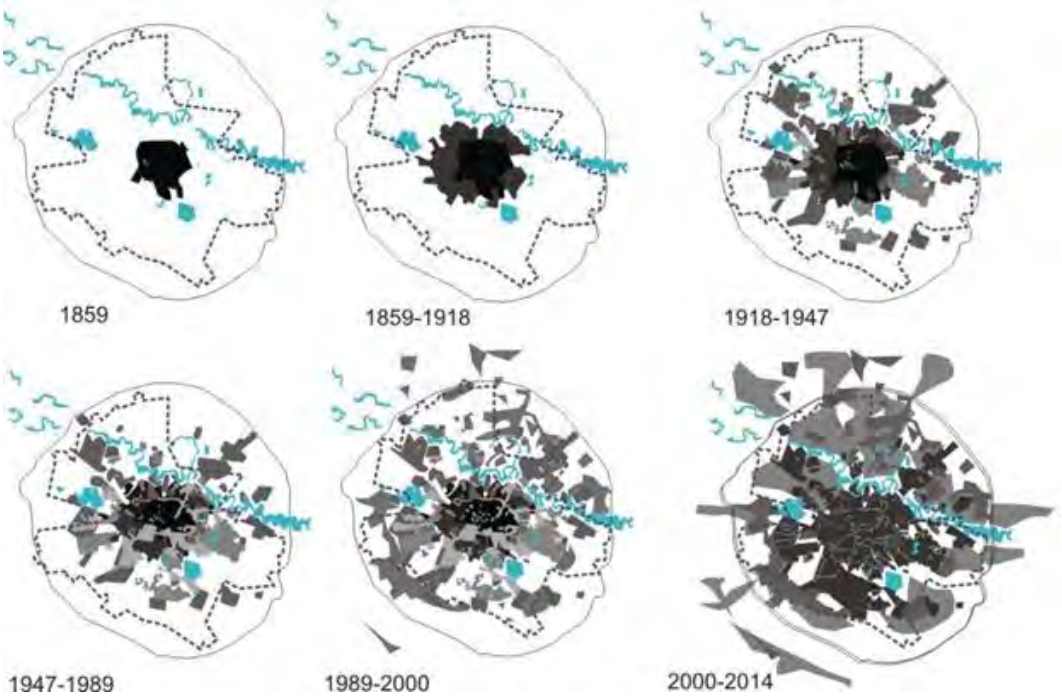

Figure 1 Spatial evolution of Bucharest

The city has extended gradually, sometimes linearly alongside major roads but mostly by fragmentation trough economic speculation. As the analysis progresses, there is clear physical evidence that the north has developed more in density and in the amount of land development.

2.3. Differences in the north and south sprawl

The factors that influence the expansion of urban sprawl in Bucharest are: increased habitation standards (attractiveness), land price, town planning regulations (including the availability of cheap farmland and the possibility of changing their destination), demographic growth, accessibility and access to urban infrastructure. For an analysis of the sprawl situation in Bucharest, these factors need to be taken into account.

Elements of the environment greatly influence the attractiveness of the area. For example, the northern part of Bucharest benefits from several natural elements than the southern part, and this is noticed in the spatial distribution of the sprawl around Bucharest.

There is a strong link between the upward trend in land prices and the area of expansion of the built area (Vânau 2009). In addition, as new residences appear and local governments build or renovate portions of access roads, the price of land increases. As Vânau (2009) remarked, the increase in land price is for developers and individuals is an indicator of the level of attractiveness of an area. Thus "a constructive price-space spiral is established which determines both the price increase and the expansion of the built space" (Vânau, 2009, p. 53).

Considering the discrepancy between the development of the city in the north compared to the south, we consider that a detailed analysis of the differences between the two parts of the city is necessary. This analysis is useful for the study to understand the factors that have led to the development of the north, and how to avoid transforming the southern suburb into an area with the same dysfunctions as the North.

Several natural elements of attraction are present in the northern direction: more than 16 forests (Tunari, Baneasa, Petreşti, Corbeanca, Tamaşi, Andronache, Boldu-Creţuleasca, Ştefăneşti, Bogdana, Moţoc, Costeasca, Mogoşoaia-Chitila, Ileana, Branesti , Pantelimon, Cernica), while in the south these elements are fewer (only 5 forests: Cornetu, Magurele, Jilava, Sinesti and Cretesti and a lake, Mihăileşti lake). In the south, the Glina household waste storage ramp is an unattractive element for potential investors.

Due to the attractive environmental features in the north of the capital and the high demand for land in this part of the metropolitan area, the price of the land in the northern suburbs is higher than in the south. For example, in the Pipera-Tunari area, the average land price is around 250 euro / m2, while in Popesti-Leordeni the average land price does not exceed 110 euro / m2. The discrepancies between the two suburbs are very high in terms of land price.

Residential projects in the northern part of Bucharest are very different from those in the south. First, individual single-family dwellings in the north are built on land generally over 500m2 and have a lower occupancy rate than in the south. This can be observed by comparing the satellite images of the two areas. The lots pattern is clearly different and the density is much lower in the north than in the south.

As for closed communities, the northern ones are developed in the form of parcels meant to save space, but also to suggest a hierarchy of typical houses - from individual dwellings with a larger garden, to coupled dwellings to those that are few in number and have the smallest courtyards. In the south, closed communities are more rare and are usually organized as dormant homes.

Collective dwellings of the gated community in the north of the capital are usually of a very large size (for example, Cosmopolis) and are promoted by being close to nature and having luxurious facilities (swimming pool, sports ground). In the south of the capital, however, collective housing units are smaller in size and have no common outdoors as large as those in the north. Additionally, the distance between buildings is at the minimum allowed by law. Many of these homes are located on Drumul Fermei Street in Popesti-Leordeni. This street has been transformed a lot over the last 10 years, sheltering a lot of real estate investment, not yet fully paved.

As for closed communities, the northern ones are developed in the form of parcels meant to save space, but also to suggest a hierarchy of typical houses - from individual dwellings with a larger garden, to coupled dwellings to those that are few in number and have the smallest courtyards. In the south, closed communities are more rare and are usually organized as dormant homes.

From the observations on the ground, the effects of the economic crisis in the northern suburbs on residential projects are noticed. There are many cases where developer careers have not been fully occupied. For example, the Henri Coandă neighbourhood is inhabited by less than 50% of the rest of the houses being unoccupied even unfinished. This phenomenon is not so common in the southern part of the peripheries since most developments are done through punctual interventions.

The results of field analyses and observations are also supported by the results of the questionnaire conducted for this study. The questionnaire was conducted on a sample of 50 people, of whom 20 lived in the southern outskirts. In terms of habitation, for the northern suburbs, 70% of those surveyed live in a closed residential community - at home or in a block

- while the percentage of those living in a privately-built home is only 28%. However, in the southern part, none of the respondents reside in community-based residential complexes, but 67% live in privately owned houses.

Large commercial projects in the vicinity of Bucharest are located along the major traffic arteries in the northern part of DN1 - Baneasa Shopping Center complex and in the west on the A1 motorway - the Carrefour Militari and Mobexpert complexes and the West Park Militari shopping center the first Designers Outlet in Romania). In the southern suburbs of the capital no such projects were built.

Because of the land price and the attractiveness of the northern area, here are the office parks, such as the North Gate Busines Center on Pipera Boulevard, Voluntari. The southern area, however, is preferred for the development of logistics clusters near the Ring Road, for example in Bragadiru, Popeşti Leordeni, Berceni.

3. Conclusions

The evidence of urban sprawl can also be seen in the data of new development in the city. Since the free market has been established, more and more new housing developments have been pursued. As seen in figure 2, after the economic crisis in 2008, the housing market has taken a fall but in recent years has regained its former glory. A further analysis of the development states that more than 50% of the housing project happened in the sprawled area around the city. This further more highlights the evidence of urban sprawl in Bucharest.

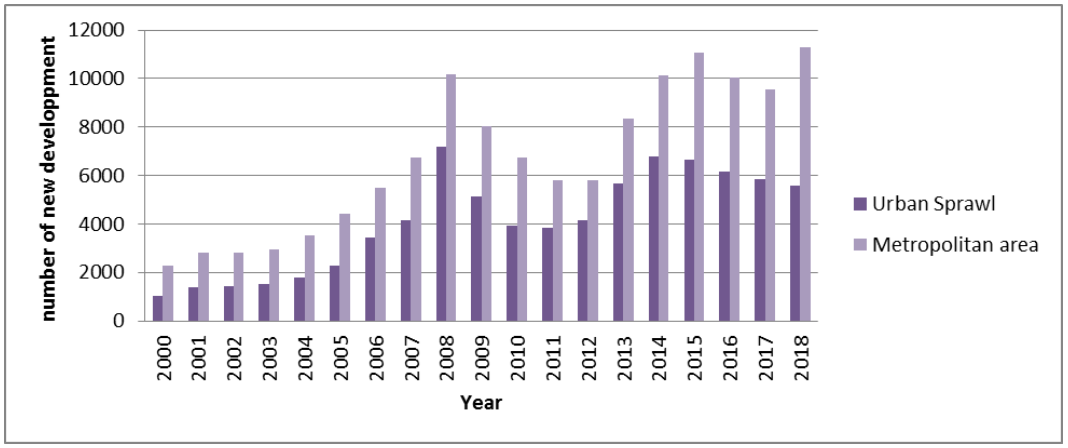

Figure 2 Comparative new development in Bucharest metropolitan area and the sprawled area, data provided by the National Institute of Statistics.

In closing, the research has shown the case of an Eastern-European metropolis and its struggle with the phenomenon of urban sprawl. As we draw the conclusions that this particular metropolis has yet to have coherent policies towards its current chaotic development, some questions still remain for further exploration and for extrapolation to a more global context. How can we, as planners and policy makers integrate the urban sprawl in a megacity? How can this phenomenon, that now is an unplanned mess, help the development of megacities?

Research Paper

BRINGING CREATIVE ECONOMY TO COMMUNITY RESILIENCE TOWARDS BETTER URBAN GOVERNANCE

The Case of Semarang City, Indonesia

Prihadi NUGROHO, Department of Urban and Regional Planning UNDIP; Indonesia

Abstract

As a growing metropolis in the north coast Java region, Semarang City has been transforming from a port city to a multifunctioning city. Mercantilism tradition has brought forward the local economy into trade and service dominance, shifting the city to become an important marketplace beyond the peripheral boundaries. Interestingly, the city's urbanisation growth does not follow 'a common trend' in Indonesia (and many parts of the world) characterized by modernized urban fabrics with mixed land use. The city is suffered from fragmented physical urban transformation and separated formal and informal economy. The urban sprawling forces are scattered around the city outskirt while the inner city's development filled up by discontinued commercial properties. On the other hand, there is 'a new direction' of urban movement based on the bottom-up kampong revitalisation. Instead of encouraging more modernized physical and economic space, these kampong settlements have proposed creative economy from below useful to (re-)organising the economic space of the urban region. This paper aims to examine how the recent urban transformation in Semarang City has been fuelled by creative economy activities through which the kampong settlements promote local community resilience. Desk study method accompanied by focus group discussions and field observations is completed in pursuit of data collection and analysis. The primary data source is taken from the Local Development Planning Authority project on creative kampong development since 2016. The preliminary results show that kampong-based creative economy movement at the urban scale is beneficial to enhancing the informal economy and urban settlement development. Participatory governance has been strengthened following income generation in situ even though their contribution to community resilience in the long-term still requires further explorations.

Keywords

Creative economy, community resilience, kampong revitalisation, Semarang City

1. Introduction

As a growing metropolis in the north coast Java region, Semarang City has been transforming from a port city to a multifunctioning city. Located next to the Java Sea, the early urban transformation originated from seaport development and coastal settlement in Simongan-Bergota area since the sixth century. Until the mid-1500s, this area remained the city's sea

transportation and trading hub when the ruling administration moved the government quarter to the north in Bubakan kampong settlement. For the next half-century, the urban settlements in the northern Semarang developed intensively, occupying the vacant lands resulted from sedimentation towards the Java Sea. This period marked the rise of the city's dual functions of political-economic governance until the present days (Pemerintah Daerah Kotamadya Dati II Semarang, 1979).

The legacy of the Dutch Colonization era (1602-1942) has created social-spatial segregation of urban transformation. A new urban centre built around the former municipal government quarter – currently known as the old city precinct Little Netherlands – and surrounded by well-developed urban settlements for the upper-to-middle class society including the Dutch officials and European nationalities (first class), and the foreign class of Chinese, Arab, and India (second class). Meantime, the lower class society belonged to *pribumi* (indigenous) citizens who lived in slum kampong settlements outside the urban centre and suburbs. Later, a new residential area built for the upper-class citizens in the hilly Candi area of the Upper Semarang, particularly due to cholera and malaria outbreaks for nearly two decades until 1918 and increased population density in the Lower Semarang area (Pemerintah Daerah Kotamadya Dati II Semarang, 1979; Amalia, Purnomo and Shokheh, 2016; Nugroho, 2016).

To date, a mixed urban land-use in the urban centre surrounded by unorganised kampong settlement pattern has featured the contemporary Semarang city landscape. Mercantilism tradition has brought forward the local economy into trade and service dominance, shifting the city to become an important marketplace beyond the peripheral boundaries. Although the manufacturing industry has remained the leading sector in forming Gross Regional Domestic Product (GRDP) with more than 26 percent share, its contribution tends to decline annually. On the contrary, the share of the trading sector (14 percent) and service sector (16 percent) are growing steadily. Together with the population growth rate at 1.6 percent per annum, the local economic change has accelerated urbanisation pressures across the city. Increased growth of population density from 3.343 lives/km^2 (1990) to 4,628 lives/km^2 (2017) has accelerated urban land conversion to built-up area side-by-side with the economic performance growth (Badan Pusat Statistik Kota Semarang, 2018). Therefore, this paper aims to examine how the recent urban transformation in Semarang City has been fuelled by creative economy activities through which the kampong settlements promote local community resilience.

2. Methods

2.1. Data collection

This research collected data primarily from secondary sources of government publications (i.e., policies, regulations, statistics, and project reports), previous studies, and media news using a desk study method. *Badan Perencanaan Pembangunan Daerah* (Local Development Planning Authority/Bappeda) of Semarang City Government was of the key informant in providing those secondary data and facilitating focus group discussion (FGD). The local development policies included for analysis were *Rencana Pembangunan Jangka Panjang Daerah* (Long-term Development Plan/RPJPD) of Semarang City Year 2005-2025, *Rencana Pembangunan Jangka Menengah Daerah* (Mid-term Development Plan/RPJMD) of Semarang City Year 2000-2005, 2005-2010, 2010-2015, 2016-2021 (RPJMD-2000, RPJMD-2005, RPJMD-

2010, RPJMD-2016), *Rencana Induk* (Masterplan) of Semarang City Year 1975-2000 (RIK-1975), *Rencana Tata Ruang Wilayah* (Spatial Plan) of Semarang City Year 1995-2005, 2000-2010, and 2011-2031 (RTRW-1995, RTRW-2000, and RTRW-2011). A number of regulations concerned with kampong improvement/revitalisation, creative economy, and city resilience were examined and triangulated with previous studies and media news as well.

After completing the desk study phase, the acquired knowledge was verified through FGD and field observations. Both were undertaken by involving multiple stakeholders, i.e., the local kampong activists, village leaders, business entrepreneurs, *Kelompok Sadar Wisata* (Tourism Activist Group/Pokdarwis), *Pembinaan Kesejahteraan Keluarga* (Women's Group on Family Welfare Improvement/PKK), youth groups, community-based organisations (CBOs), and government agencies. This phase focused on 10 out of 177 creative kampong development projects initiated by Bappeda since 2016. Such combined data collection was expected to provide a fuller understanding of the creative economy project at the city level.

2.2. Methods of analysis

Content analysis and descriptive statistical analysis were completed to examine all those data collected through desk study method. Both focused on examining the patterns of urbanisation trend in terms of demographic and land-use change, urban sprawling forces, and the government interventions on directing spatial development and controlling the urban development impacts. Policy coordination and consistency were of the important issue during the research so that the implementation of policies and regulations associated with the urban transformation became critical to the rise and persistence of kampong-based creative economy movement. Subsequently, the case study method applied to explore how the kampong communities respond towards the impacts, particularly their initiatives on reforming the urban fabrics. Their struggle and adaptive capacity to maintain the urban kampong livelihood were interesting to feedback the future urban development policies.

3. Results and Discussion

3.1. Demographic profile of the urbanisation trend

Population size in Semarang City has been growing rapidly for the last five decades. The size recorded in population censuses was 646,590 inhabitants (1971) and rose to 1,024,940 (1980), 1,249,230 (1990), 1,348,803 (2000), and 1,555,984 (2010). In 2018, it was 1,668,578 inhabitants and predicted to reach 2,100,000 by 2030 (Biro Pusat Statistik, 1962, 1972; Badan Pusat Statistik Kota Semarang, 1982, 1991, 2001, 2012; Handayani and Rudiarto, 2014; Badan Pusat Statistik Provinsi Jawa Tengah, 2018). As shown in Figure 1, the increasing population trend occurred at declining growth rate from 2.83 percent (1961-1971) to 0.70 percent (2010-2018) annually, with exception to the period of 1971-1980 when it reached 5.25 percent due to territorial extension in 1976. Referring to *Peraturan Pemerintah* (Government Regulation) of the Government of Indonesia No. 16 Year 1976 about Territorial Extension of Semarang City Administrative Boundaries, the city's region was extended to include additional *kecamatan* (subdistrict) and *desa/kelurahan* (village) of the neighboring Kendal Regency (2 subdistricts, 24 villages), Semarang Regency (2 subdistricts, 26 villages), and Demak Regency (1 subdistrict, 16 villages). Consequently, Semarang City extended from 99.41 km^2 (1950) to 364.81 km^2 (1976) and 373.70 km^2 (1990-present) consisting of 16

subdistricts and 177 villages (Pemerintah Republik Indonesia, 1976; Nugroho, 2016; Badan Pusat Statistik Kota Semarang, 2018).

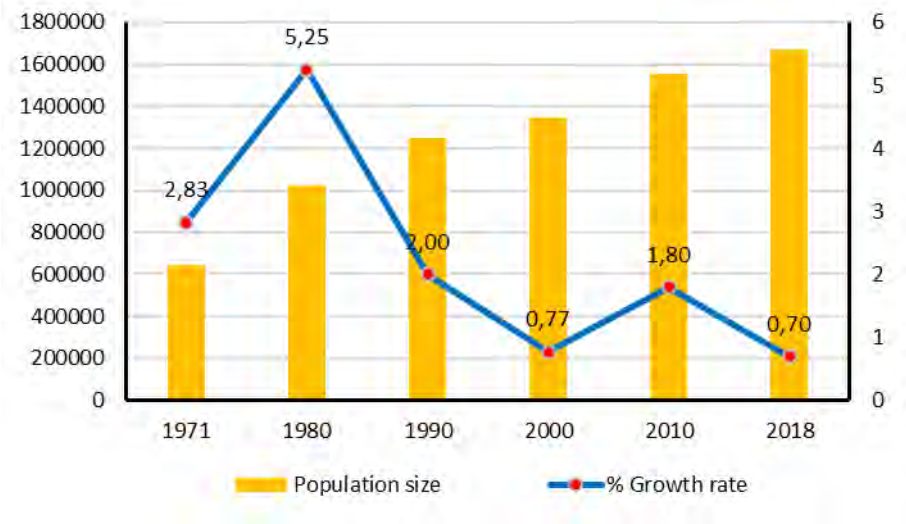

Figure 1 Population size and growth in Semarang City, 1971-2018

Source: Biro Pusat Statistik (1962, 1972), Badan Pusat Statistik Kota Semarang (1982, 1991, 2001, 2012), Badan Pusat Statistik Provinsi Jawa Tengah (2018)

Such territorial extension has led to a significant change of the city's demographic profile. In 1971, the city population lived in an urban area but since territorial extension around 20 percent was living in a rural area (1980-1990), especially in the extended peripheral regions of Semarang City. However, such phenomenon lasted shortly for two decades when the urban population has increased faster to reach more than 90 percent since the 2000s at the lower growth rate (Figure 2).

3.2. Urban land-use change and sprawling phenomenon

Land conversion from agriculture and rural land to the built-up area is an immediate impact of urbanisation trend in Semarang City. Intensified land use change concentrates on the city centre area, started from the former central business district (CBD) growth triangle Johar-Pemuda-Simpang Lima and dispersed towards the urban fringes, i.e., East Semarang, Genuk, and Pedurungan Subdistricts (east-southeast zone), Banyumanik and Tembalang Subdistricts (south-southwest zone), and West Semarang and Tugu Subdistricts (west zone). Typical land-use change of Semarang City represents radial-concentric pattern when the urban growth spreads out along the axial primary roads and new urban settlements and commercial zones which emerged sporadically close to the existing settlements.

Since the late 1990s, the unorganized urban growth pattern has become prominent in the following years. Initially, both RIK-1975 and RTRW-1995 have divided clearly the urban land parcels into different land use zones. The urban growth direction was plotted to the east-west for industrial development zones supported by low-density settlements in Genuk and Tugu Subdistricts, and to the southeast-south for miscellaneous urban services supported by medium-density settlements. The southwestern part of Semarang City was restricted for the built-up area development and preserved for the water catchment area supported by low-density settlements in Gunungpati and Mijen Subdistricts. Meantime, the CBD development remained to concentrate around the city's growth triangle area consisting of the earliest subdistricts, i.e. East Semarang, West Semarang, Central Semarang, North Semarang, and South Semarang Subdistricts, for mixed land use functions of commercial, public services, transportation hubs, and high-density settlements. In practice, the local government policy shift and massive capital investment accelerated land conversion responding the pursuit of the city's long-term vision to become a modernized metropolis underpinned by religious, orderly, and cultured society by 2025. New town development to build a satellite city in the peripheries, new growth centres in the suburbs, large scale housing projects, industrial estate development projects, and commercial building blocks were built across the city scatteredly. The absence of sound zoning regulation and strict law enforcement of building permit made the urban growth uncontrolled, leaving the development control interrupted by the conflicting interests of private investors, neighbourhood communities, and individuals. As a result, the urban sprawling phenomenon has unavoidably occupied the agriculture and rural areas, green open spaces, and vacant or less productive lands.

Figure 3 illustrates the phenomenon clearly where the development of built-up areas in the peripheries is poorly unanticipated, causing the urban discontinuum persistence. Numerous landed housing projects built by private developers and individuals outnumbered the public housing projects. Following the land rent curve law, cheaper landed houses (and commercial buildings) were found in the so-called peri-urban areas. Despite supported by adequate public facilities and infrastructure, such sporadic market-based development has promoted a dual-face urban form portraying a disharmonious mixture of the orderly modernized urban space against the ill-developed peri-urban area and the in-between kampong neighbourhood. Unbalanced public investment has forced population in the peri-urban areas to access the public facilities and infrastructure more expensively. In contrast, the kampong dwellers living around the CBD area have surrendered their livelihood towards poor public goods in the slum neighbourhood. Consequently, the city is suffered from fragmented physical urban transformation and separated formal and informal economy.

3.3. Implementation of the creative kampong development program

To overcome urban poverty and slums, the city government introduced a creative kampong development program in 2016. Under the city's mid-term development program called by *Gerakan Bersama Penanggulangan Kemiskinan dan Pengangguran Melalui Harmonisasi Ekonomi, Edukasi, Ekosistem, and Etos Bersama Masyarakat* (Social Program for Eradicating Poverty and Unemployment through Harmonization of Economic, Education, Ecosystem, and Ethos Aspects of Local Development) – abbreviated with GERBANG HEBAT – the government addressed a kampong-based community empowerment approach to encourage the local residents in designing kampong revitalisation program suitable to the local condition. Hence, each kampong would have a specified thematic kampong development program to promote local uniqueness for household income generation through various social and economic activities such as tourism attraction, local entrepreneurship, and civic engagement.

It was a social innovation program aimed at lowering poverty and unemployment rates, improving slum upgrading, promoting local wisdom for managing potentials and resolving problems at the neighbourhood level, and creating new tourism destinations. The program outputs included the improvement of synergetic collaboration between actors responsible to poverty eradication programs, the integrated implementation of poverty eradication programs, the improved coverage of targeted poverty groups with reference to available poor citizens database, and the achievement of program implementation monitoring. A multidimensional approach was completed to support program implementation through community empowerment of the kampong dwellers to build self-organising groups in coping with the local neighbourhood problems and potentials (social approach); the cultivation of local entrepreneurship atmosphere at the kampong neighbourhood level for stimulating the creation of new business startups (economic approach); beautification of public space in the kampong neighbourhood combined with the improved public facilities and infrastructure

(physical approach); and civic engagement in building the localized identity and social character (cultural approach).

By 2018, a program evaluation conducted by the local Bappeda found that economic reasoning dominated program implementation (53 percent), followed by social (35 percent) and infrastructure (12 percent). The economic reasoning was supported by the facts that there were economic potentials driven by the community-based creative economy group and the availability of natural and human resources in each kampong. On the social dimension, the key indicators included community participation, high poverty rate, and the immediate social problems in kampong neighbourhood. For infrastructure concern, the selected kampong featured slum neighbourhood, unorganized settlement pattern, and less green space occupation. In fact, the evaluation, which administered public perception from multiple stakeholders involved in the program implementation, revealed that the most likely goal achievement of the creative kampong development program was local economic sector generation (42 percent). The social empowerment goal posed the second rank (40 percent) and followed by physical kampong improvement (18 percent). This finding indicates that program implementation has fulfilled public expectation (Badan Perencanaan Pembangunan Daerah Kota Semarang, 2018).

The key actors responsible to the program implementation were local entrepreneurs (45 percent), public servants/retired (26 percent), businesspersons (10 percent), housewives (7 percent), industrial employees (7 percent), and the others (5 percent). Mostly they came from the middle age group 41-55 years (48 percent) and the elderly group above 55 years (40 percent) while the youth group below 40 years participated in the program was only 12 percent. They represented various CBOs, i.e, *Kelompok Swadaya Masyarakat* (Community Self-Organising Group/KSM), PKK, Pokdarwis, small and medium enterprise (SME) group, and youth group with direct support from village and subdistrict government and some external actors from universities, state-owned enterprises, and private companies. Such composition authorised the kampong society to take control of the program implementation from the beginning. Our recent survey has found that the determinants of program implementation are civic engagement (37 percent), business activity (29 percent), public infrastructure provision (22 percent), and external actors' support (12 percent). Surprisingly, the largest budget allocation for realising the program was spent on physical projects. Around 60-75 percent of the program expense was for public facilities and infrastructure upgradings like road access, drainage system, entrance gate, public park and lighting, and mural decoration. The rest expense was for community empowerment projects in forms of various training in business development and entrepreneurship. In fact, the major obstacles that have inhibited the program implementation came from the lack of kampong community capacity in terms of their willingness to participate, knowledge and skills, and technological adaptation. As a result, the program implementation heavily relied on the roles of local champion or smaller community group in driving the overall project planning and implementation from below (Badan Perencanaan Pembangunan Daerah Kota Semarang, 2018).

Of the overall targeted kampongs, 91 kampongs focused on local economic development projects (51 percent), 58 kampongs on environmental conservation projects (33 percent), and 28 kampongs on social development projects (16 percent). The economic projects were generated by the local SMEs and home-based enterprises (HBEs) which produce food and beverages (52 percent), handicraft (28 percent), and service (20 percent). In contrast, more homogeneous projects were found in the environmentally-based kampong development

projects with waste management and urban farming activities, and the social-based projects with children an elderly person caring activities and cultural event attractions. Regardless of thematic focus, all kampongs observed showed social cohesion persistence in daily life. To some extent, they could manage social interactions well but this fact has not contributed directly to their moderate participation in the program implementation. They have realised the importance of civic engagement during the decision-making process from below, but their reluctance to get involved more actively was associated with self-pragmatism to obtain the individual benefits of the program implementation. Hence, the roles of local champion and the elderly group – to whom the kampong society have surrendered the decision-making process – have remained dominant in directing it. In turn, such hierarchical social structure has led the creative economy manifestation was overshadowed by these driving actors' interest. Alternatively, their roles were replaced by village government even though it jeopardised the program's spirit of kampong-based community empowerment into top-down structuralist governance.

3.4. Kampong neighbourhood as an alternative urban space

The rise of creative economy movement within the recent kampong development program in Semarang City Kampung may provide a solution to fix disharmonious urban space. This could be seen as an evolutionary kampong development program. The first generation called as Kampung Improvement Program (KIP) was introduced during the colonial government in the 1920s as a response towards the Dutch Parliament members of the opposition parties who demanded better living conditions for urban populations in the colonies. Surabaya and Semarang were among the first cities which promoted KIP implementation by the municipal government before it was extended to other cities until the next two decades. In 1969, the Government of Indonesia announced a comprehensive KIP under *Rencana Pembangunan Lima Tahun I* (the first Five-Year Development Plan/Repelita I) by introducing participatory approach due to the limited resources that the government had to continue the former top-down KIP implementation. Jakarta was the first city which adopted such participatory KIP implementation. These early KIP forms featured physical improvements in the basic urban infrastructure and services within the kampong neighbourhood and funded by foreign lending. Due to the successful achievement of the first generation of KIP, between the 1980s and 1990s, it was extended to secondary cities and smaller towns ('Kampung Improvement Program: Policy Issues and Local', 1989; World Bank, 1995; Reerink and Gelder, 2010).

Distinguished from the early KIP models, the Semarang case has gone further by embedding place bonding of the kampong dwellers with their settlement, economic activities, and social cohesion. The enhanced public facilities and infrastructure in the kampong settlement are likely to increase the residents' sense of belonging and attachment to their neighbourhood due to the increased quality of life (Amalia, Purnomo and Shokheh, 2016). This could be more intensified because of beautification decorative projects on the kampong's public space from which new tourism spots may exist as well. As the local business growing, many more residents will be interested in doing business from their homes, either as a primary or secondary source of income generation. With the support of social cohesion manifested in the local CBOs' activities, collective awareness for maintaining the improved kampong's physical appearance and urban services as well as the local business sustainability may persist.

Unfortunately, the so-called physical improvement in the kampong's settlement utilities and vibrancy does not fit the economic functionalities that the local business demands for. The

local SMEs and any other home-based enterprises (HBEs) depend on supply chain networks from their close neighbourhood in order to lower their production cost (Harvey, Hawkins and Thomas, 2012; Pratt and Hutton, 2013). They also require specific utilities such as logistic warehouse, workshop, waste treatment unit, parking lots for customers, and marketing gallery, which are commonly attached to their residential homes. In the Semarang case, the program has failed to resolve such basic requirements for the local business. Rather, these issues have remained on the business owners' responsibility to resolve so that in many places this situation has raised social conflicts with the neighbours. The program failure to offset the economic benefits with social amenities could be harmful to community participation and social cohesion. This situation has contributed to lowered or even dysfunctional organisational capacity of the local CBOs to administer the program implementation.

However, the recent creative kampong development program in Semarang City has founded principle approaches to build community resilience in the kampong neighbourhood. Both direct and indirect impacts resulted from place-based local business and tourism attraction have created an alternative urban space to shelter, work, and foster social cohesion within the embedded society at once. Instead of replacing the former kampong appearance with the modernised urban fabrics, the program supports more integrated networks of urban services by preserving the prevailing social cohesion and place bonding. Local wisdom and uniqueness of the kampong settlement are maintained along with the growing economic viability and organisational capacity of the local CBOs to further the program sustainability.

4. Conclusion

Three years of the program implementation are too short to examine the creative kampong development program in Semarang City to come up with such an overarching conclusion regarding its contribution to theoretical building and evidence-based policymaking. It is too early to claim that such renewed KIP model is successful in slum upgrading and poverty eradication in the city. However, the preliminary results have shown that kampong-based creative economy movement at the urban scale is beneficial to enhancing the informal economy and urban settlement development. The kampong residents can continue their local business without being threatened by the extended urbanisation forces across the city. Rather, could have maintained the on-going informal economy side-by-side with the modern urban sectors. In addition, participatory governance encouraged by the program has been strengthened following income generation in situ even though their contribution to community resilience in the long-term still requires further explorations.

Case Study / Project

Metropolitan Management:

Expansion, Governance and Finance

Pedro B. ORTIZ

Abstract

Metro-Urban expansion is challenging world development. Only 3 cities in world history have been one million-plus inhabitants. Now we have 500. These Metro-Cities produce 75% of world GDP. Many are expanding at a 5% annual rate. They double their size every 14 years. Lack of a methodology for expansion is producing an uncontrolled pattern, jeopardizing development and equity. Challenges and alternatives will be discussed.

Research Paper

Chinese Megablock Urbanism

a Tool of Limitless Urbanization at an Unprecedented Speed and Scale

Yixuan PENG, The Hong Kong Polytechnic University; Hong Kong, China
Gerhard BRUYNS, The Hong Kong Polytechnic University; Hong Kong, China
Darren NEL, The Hong Kong Polytechnic University; Hong Kong, China

Abstract

In what way can the study of megablock typologies in the PRD deliver better insight in terms of process and scales of Chinese urbanization?
In the Chinese context, the 'collective' has stood central to its urbanisms and processes of urbanization (Lu, 2006). As a state where ownership and territoriality are retained by a socialist system, the basic elements of this (urban) model have remained the creation of collective housing founded on publicly owned land. From the 'neighbourhood-unit' (邻里单位) and 'working-unit' (单位大院), to 'commodity housing' (商品房) (Lu, 2006), these practices gradually shape Chinese cities in "Socialism with Chinese characteristics" into what can only be termed 'megablock' urban fabrics.
Where, 'Mega' infrastructure in cities, or better yet, megablocks, embody the antithesis of open and transparent entities. Beyond its organization with the physical network (transportation or public service), they impact the urbanization process in terms of speed and scale. The Chinese urban population has risen from 18% in 1978 to 58.5% in 2017 (National Bureau of Statistics of China, 2018). Between 1991 and 2000, 83% of Shanghai's residential compounds became enclaves, with the Guangdong Province alone witnessing the formation of 54,000 closed-off compounds, covering more than 70% of the city surface and housing more than 80% of its population (Miao, 2004).
Broadly speaking, former and ongoing studies of Chinese urbanization are yet to provide a clear perspective of megablock development, both in terms of the unprecedented context and its spatial impact.
This paper aims to address concerns pertaining to the megablock phenomenon: its impacts on urban morphology as well as its prevalent strategies as an urban model. The argument presented here hopes to touch upon the links between planning and the eventual morphological expression of megablock development, and possibly argue for the cultivation of an urbanization practice that needs to become systematic in its sustainable focus and outcomes.

Key words

Chinese megablock urbanism, scale, rapid urbanization

1. Introduction

There is no denying the significance of understanding "scale" in urban studies in China (Miao, 2013). In either daily life or theoretical analysis, the 'mega' scale has become part and parcel of the Chinese context intuitively observed by researchers, citizens or even outsiders as a key and foundational role in all dimensions and formats of urban issues. However, scale, at the same time, is often overly underestimated in many studies of Chinese urbanization.

When examining the form of Chinese urbanism and its spatial organization, one should understand both the meaning and roles of scale and its mechanization in any type of urban development. This brings in its wake other questions that pertain to whether the elements of scale can be fully conceptualized and theorized to act as the basic conceptual framework and analytical tools for analyzing the historical conditions pertaining to Chinese urban form as well as future trajectories of Chinese urbanisms and their evolution processes. In addition, it questions whether it is possible to conduct a secondary level of research that can reveal the opportunities and threats of this 'scalar' model, not only applicable to the Chinese context but also relevant to other urban settings elsewhere. Moreover, what perspectives are implicitly hidden behind the study of Chinese mega scale? The above questions would ultimately lead to the study of the "ultra-large-bigness" as a factor for accessing all formats of Chinese urban forms.

In traditional Western philosophy, relatively, the size of a city or country should be controlled to a reasonable scale. Plato had a thorough discussion about the size of the polis which has been regarded as one of the most classical and influential theoretical frameworks in understanding Western cities. Plato's *The Republic* (380 B.C.) regards the expansion of the city-state as the ultimate cause of the segmentation between the rich and the poor, or political factions within the city. In his view, the polis is suitable to be built in a place that is neither too close nor too far to the port and the population size should be around 20,000. Aristotle further agreed with Plato's opinion that cities should not expand too far away from their designated scale. Therefore, when the size of a polis is too large, some sort of procedure would be required to redistribute the populous to form another secondary polis, so that the size of the city-state can always be kept to an appropriate size.

Inherited with such concepts of social organisms and their limits, the Western perception has difficulty in digesting the material dimensions when observing Chinese city scales. They seem to be unfamiliar with this civilization form, almost equivalent in size to an entire European territory, that has already functioned and operated as a territorial 'unit' for more than a thousand years. This scale challenges the urban philosophy and common sense of Western scholars. As a result, the perception and interpretation of "ultra-large-scale" have emerged.

The majority of existing studies place more emphasis on the challenges and complexity that scale brings to China's urban problems (Wang & Zhang, 2016). When examining and discussing China's super-large scale, many researchers would often state that due to China's huge scale and volume, the urban space remains "big and unreasonable" (Ibid). As such, the basic research paradigm is to appropriate the various criteria of "normative urban morphology" to investigate the challenges and difficulties that are brought about by the "ultra-large-scale" tolerance and function in the conventional spatial scales (Guo, 2019). Based on this typology, a large number of Chinese urban special theories are built upon this or its extension.

The broader framework of this research starts touching upon the question of Chinese 'mega' scale as a discernible scale paradigm. The assumption is based on the following three facts: firstly, the mega scale is inherited from the traditional city-state ideology evident from the historical project; secondly, the socialist public system of the New China has by default had to address the mega phenomena as part of its social-spatial mandate; thirdly, China remains the world's most populated country resulting in the majority of the territorial strategies being mega developments. Collectively these contribute to rethinking the question of scale, more specifically the impact of how and in what terms the 'mega' is utilized in the Chinese context.

Focusing on its radicalness of speed and scale, this paper specifically aims to investigate the formative and material definitions of Chinese mega-development at the urban block scale. Two cases are highlighted of what is defined as Chinese megablock urbanism (CMU), as a model of Pearl River Delta (PRD) urban agglomeration. As such, CMU has become instrumental, as a tool of limitless urbanization, that as yet remains undefined.

2. Background of Chinese Megablock Urbanism

2.1 Definition of "Megablock"

Scale is a fundamental requirement for urban study. Not only is scale essential for conceiving actual proposals and projects, but it remains crucial to inform the diversity of spatial nomenclatures to comprehend and access space itself. The term "Mega" has been widely used in describing spatial forms. In the domain of architecture, *S,M,L,XL* by Rem Koolhaas and Bruce Mau (1995), weaves together OMA projects according to "size", challenging conventional understanding of architecture, scale, and the city. Examples listed within the 'size' category are: small – Villa Dall'Ava, St. Cloud, Paris, 1991; medium – Kunsthall, Rotterdam, 1992; large – Congrexpo (Lille Grand Palais), Lille France, 1994; and extra-large – Bijlmermeer Redevelopment, Amsterdam, 1986 (see Table 1). Koolhaas discusses 'Bigness' in an intriguing way:

> *"Beyond a certain scale, architecture acquires the properties of Bigness. ... Of all possible categories, Bigness does not seem to deserve a manifesto; discredited as an intellectual problem, it is apparently on its way to extinction - like the dinosaur-through clumsiness, slowness, inflexibility, difficulty. But in fact, only bigness instigates the regime of complexity that mobilizes the full intelligence of architecture and its related fields." (Koolhass and Mau, 1995, p495-497).*

Scale	S	M	L	XL
Example	Villa Dall'Ava, St. Cloud, Paris, 1991	Kunsthall, Rotterdam, 1992	Congrexpo (Lille Grand Palais), Lille France, 1994	Bijlmermeer Redevelopment, Amsterdam, 1986
Image				

Table 1. Examples of architectural projects classified by the scale of S,M,L,XL by Rem Koolhaas and Bruce Mau (1995)

Moreover, the use of "mega" as a descriptive term is more commonly associated with overall city definition and not sub-components of what constitutes the city. We trace the origins of the concept of 'mega' to Patrick Geddes (1915). Later the concept was repackaged into the term 'megalopolis' referred to first by Spengler (1918) and later by Lewis Mumford (1938) in Lewis' book *The Culture of Cities*. Lewis uses the megalopolis to describe the excessive development and expansion of cities, and how this has direct bearings on the decline in social quality. Mumford provides six stages in the growth of a city: 1. Eopopis, 2. Polis, 3. Metropolis, 4. Megapolis, 5. Tyrannopolis, and 6. Necropolis. They all refer to single entities as cities operating and functioning under their own operative logic. In more recent definitions, the United Nations (2014) defines each 'megacity' as urban agglomerations that exceed 10 million inhabitants. This essentially shifts the meaning from a single-entity reading

of the mega into a dimension of multiple territories as parts of mega and urban development.

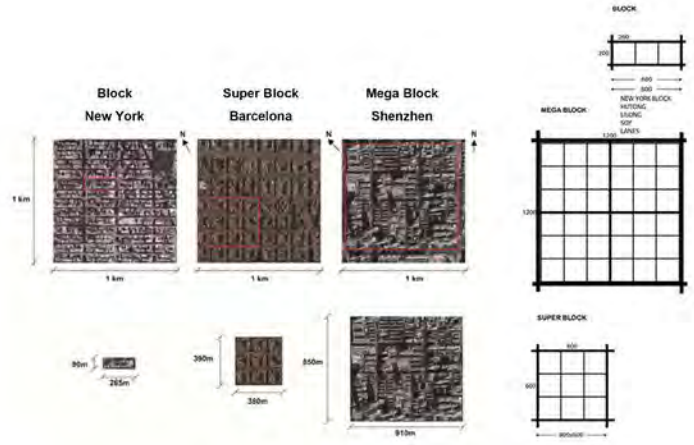

Figure 1. Diagram of a block-superblock-megablock. Left: aerial photos of New York block, Barcelona superblock and Shenzhen megablock. Right: diagram of the block system from Shane 2014. Source: author; Shane (2014)

Shifting focus to the intermediate scale; more specifically, between building and city, at the level of street block; the concept of "mega-block" has been widely mentioned. Still, 'mega' and its relation to the 'block', something we postulate as the 'megablock', remains undefined in its actual properties of morphological characteristics. An urban block can be defined as a plot of land enclosed by streets (definition by for example *Code of Urban Residential Areas Planning & Design* GB50180-2018). A block system is commonly seen as the model that differentiates urbanized from unurbanized area development. Adopting the block principle, urban blocks allow buildings to be located along the perimeter of blocks with entrances facing streets, which attempts to provide ideal social interactions between people (Frey, 1999). Block development is referenced by a variety of scholars. For instance, Alzraikat (2016) indicated a changing capacity and scale of urban organization over time associated with terms such as block, superblock, and megablock. Accompanied with the growth of cities, an urban hierarchy is defined by block sequences. While Siksna (1997) conducted research on the effects of block size and form with samples from North America and Australia. Shane (2014) defined the enlarging and nesting blocks by the city's expansion. He demonstrated

> *"The scale of the block dimensions shifted over time, enlarging its area from its small scale-early beginnings with 1.6acre blocks in grid formations, to 16acre super blocks to 160 acre or more megablocks". (Shane, 2014. see Figure 1).*

2.2 Urbanization at an Unprecedented Speed

In general, urbanization is divisible into three stages according to the level of development: 1. initial period, 2. rapid development period and 3. stable saturated period (Zhu, 2004). Empirical studies in Western urban planning and development processes have demonstrated that the focus of urban planning corresponds to its urbanization level (Tortora et al., 2015). In 1978, accompanied by the economic reformation and opening-up policies, China's first national urban planning guideline emphasized acceleration of the urbanization process. At a global scale this remains unprecedented. In the past four decades, China experienced the largest and fastest industrialization and urbanization process in the history of the world. From 1978 to 2017 (38 years), China's urbanization rate increased from 17.9% in 1978 to 58.5% in 2017 (40.6% growth), with the number of permanent residents in urban areas increasing from 170 million to 810 million (476.47% growth) (National Bureau of Statistics of

China, 2018). Echoed within the urban dimension, this accounts for roughly 40 years of reform that was accompanied by four decades of radical Chinese urbanization (see Figure 2).

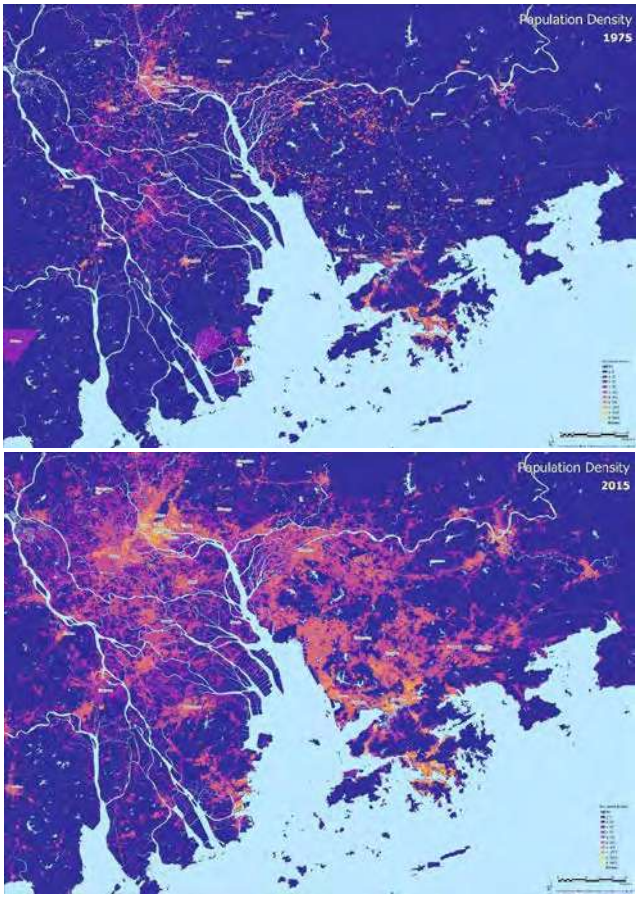

Figure 2. Forty years' urban population density change in the PRD, left: 1975, right: 2015. Source: data from GHS and maps from author.

In a 'modern' sense, radical and mega conditions of Chinese urbanization have emerged with distinct characteristics evident in its spatial and morphological complexes. Rapid urbanization in the Chinese context, starting from the Reform and Opening-up in 1978 has shown levels of urban growth, leaping from 17.9% to 40.5% in 2003. China's 'Great Leap Forward of City' in 25 years, has reached the level of urbanization (from 20% to 40%) equivalent to what The United Kingdom achieved over 120 years, or the United States over an 80-year period (Yin, 2010, p2). After 1992, which is the year the official market economy replaced the former planned economic incentives, Chinese urbanization accelerated to 1.2% per year (three times the world's average in the same period (Ibid)).

2.3 A Tool of limitless Urbanization in Terms of Scale

To achieve this unprecedented rapid urbanization, interventions and new tools are indispensable. Globally, there is a growing phenomenon that is being discussed under the heading of "Big Plans" as stated by Kolson (2001). From the changing nature of urbanization in scale, we witness other qualities emerging in the Chinese context. For example, it has become standard practice for Chinese planning to develop a megacity that is six times larger than Paris or ten times that of London (Li & Li, 2006). Within the framework of big-plan, the development of mega urbanization requires the incorporation of surrounding villages or adjacent cities as part of one administrative boundary. As a consequence, mega-projects entitled 'development districts' (开发区), 'new towns' (新城), 'university towns' (大学城), oversize plazas, lawns, infrastructures, amongst others, courbanize (Yin, 2010), pushing

megablock development as *the* dominant form of planned urbanization. Within the 'Great Leap Forward' context, urbanization relies on a housing model that has shifted from the planned work unit into market-driven real estate. Megablocks claim the titles of the "largest compound in China", and constantly surpass the sizes and scales of conventional planning in a Western sense. For instance, the Clifford Estate (CE) developed in the 1990s captures 100,000 residents within 5 km², with the Huaguoyuan development in the 2010s capturing 420,000 residents in 4 km². If we compare the scale of urban blocks in China with other big cities around the world, the differences are evident (see Figure 3).

Compared to European cities of the same period, Chinese city blocks have always been much larger, in both ancient times (Guo, 2019) and after the 1949 establishment of the People's Republic of China (PRC). Existing models of development easily exceed more than 20 hectares, which is regarded as a tribute to the ancient Lifang (里坊, neighbourhood) system (Sun & Liang, 2003). The adaptation of the Soviet Union's models of 'microdistrict' within the PRC's planning practice, on one hand merged with Chinese traditional collective housing, whilst on the other hand, gradually easing planning into more real estate-driven megablock systems. Morris (2013) pointed out that, in traditional European cities, every small plot of land is orientated along the street to promote a sense of equality to ensure that every resident has a view or access to the street. However, with the limited depth of buildings, the short edge of the street also faces its limit, forming a relatively small scale of blocks. Herein the smallness of plot and block remains the essential planning component.

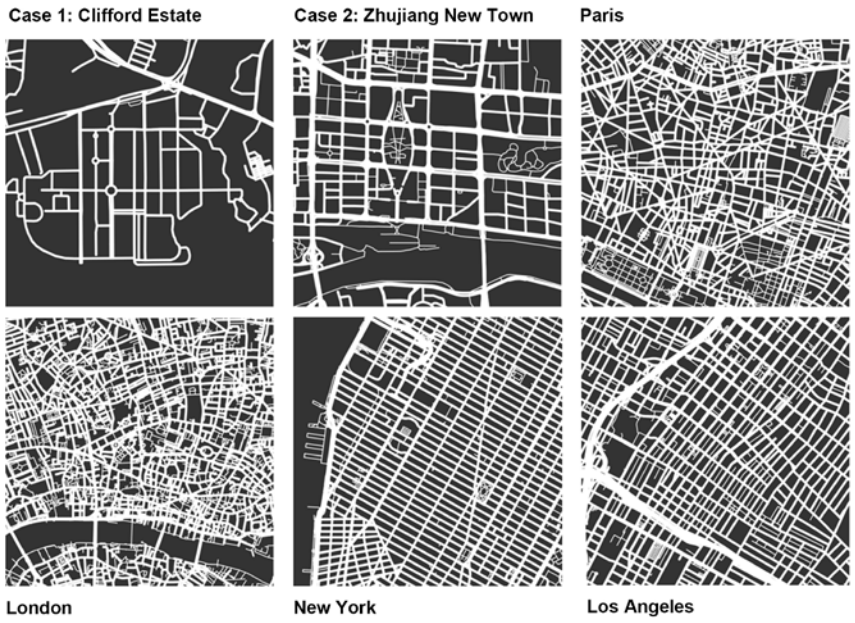

Figure 3. Density of the road-plot within CMU cases versus Paris, London, New York, and Los Angeles. Road width reflects the hierarchy of the road network. Source: author.

According to Table 2, which shows the Chinese planning code for designing residential blocks, and which also exceeds the European standard. This scaling up of block size implies that policies and technical standards have shifted the understanding of planning scale. In February 2016, the State Council and Communist Party's Central Committee adopted new guidelines that call for; (a) compacter cities with denser networks of streets, (b) more pedestrian and cycling lanes, better public transport, mixed-use zoning, and (c) more green space (Normile, 2016). This new planning policy would indicate a conceptual shift in terms of the 'block'. As Table 2 shows, the increase for all spatial dimensions remains a key difference in the new planning codes, currently advocated by the central government to all the planners and planning schools within China.

Distance / Scale	15min Living zone	10min living zone	5min living zone	Living neighbourhood
Walking distance (m)	800-1000	500	300	—
Population	50,000-100,000	15,000-25000	5,000-12,000	1,000-3,000
Dwelling number	17,000-32,000	5,000-8,000	1,500-4,000	300-1000

3 Research Scope and Methodology

3.1 Scope of Study

As a second part to this paper, the main aim here is to set up an operative framework for urban morphological study of Chinese Megablock development. The emphasis to date has concentrated on the PRD region in its newly established Greater Bay Area Framework, which includes the Guangdong-Hong Kong-Macau Greater Bay Area. The two selected cases referred to herein are the Clifford Estate (CE) in Panyu, and the Zhujiang New Town (ZJNT) in Tianhe. This paper attempts to cover the basic characteristics of megablock examples to demonstrate the CMU model, as well as to conduct options of spatial analysis to test certain qualities of megablocks. These aspects derive from a larger body of research related to mega development, that questions:

(1) In what way can the study of megablock typologies in the PRD deliver better insight in terms of processes and scales of Chinese urbanization?

(2) By studying cases in the Pearl River Delta region of south China, would it be possible to deliver other insight that are able to explain how megablock urbanism shapes Chinese cities with the current urbanization practices' unprecedented speed and scale?

3.3 Research Methodology

The research presented herein draws from the discipline of urban morphology to demonstrate the spatial characteristics of the CMU model. By evaluating selected factors and variables, the focus is to understand what CMU actually stands for in urbanization practices.

The CMU empirical methodology takes into account the configurative properties of the urban plot in regard to various factors. As shown in Table 3, megablock properties are expressed using plot dimensions in relation to land use, functional configurations and mobility, each with their distinct variables and measure sets.

Data were collected through multiple sources which included: local government regulatory plans, OpensStreetMaps, open access maps and the statistical data website Map World (https://www.tianditu.gov.cn/), run by China's State Bureau of Surveying and Mapping (SBSM), Google Earth, big data extracted from Baidu Map (map.baidu.com) and real-estate websites including Fang Tianxia (fang.com), Lianjia (lianjia.com), and Centaline Property (centanet.com), field work and proofreading of data conducted during the data collection phase.

Case analysis was conducted using the following steps:

(1) Visualization of the site including building type and 3D model;

(2) Preparing base maps from aerial photos and online maps;

(3) Mapping the main features and facilities of the case;

(4) Calculation of centrality with sDNA in ArcGIS;

(5) Reflection of data analysis leading to the findings of the study.

In combination, the tentative findings relate both formal and spatial findings that combine to form new datasets with variables.

Theme	Concept	Indicator type	Name	Scale	Formula
Land use	Urban form	Intensity	Human density	District /Neigh-bourhood	$\frac{Nb\ of\ People}{surface\ of\ selection\ (m^2)}$
			Building density (FAR)	D/N	$\frac{Floor\ Area\ (m^2)}{Selection\ Area\ (m^2)}$
			Housing density	D/N	$\frac{Nb\ of\ Buildings}{surface\ of\ selection\ (m^2)}$
			Coefficient of land occupancy	D/N	$\frac{Coverage\ Ratio\ (m^2)}{Selection\ Area\ (m^2)}$
		Diversity	Subdivision intensity	D/N	$\frac{Nb\ of\ Subdivisions}{Selection\ Area\ (m^2)}$
			Diversity of subdivision size	D/N	$\frac{1}{Cat}\sum_{i=1}^{Cat}\left[1-\frac{S_{tot\,i}S_i^m}{A}\right]^2$
			Diversity of land use	D/N	$\frac{1}{Cat}\sum_{i=1}^{Cat}\left[1-\frac{S_i}{S_i^{obj}}\right]^2$
Mobility	Urban form	Intensity	Surface occupied by the road network	City/D	$\frac{Road\ Area\ (m^2)}{Selection\ Area\ (m^2)} * 100$
		Connecti-vity	Connectivity of the car grid	D	$\frac{Interesection\ Number\ of\ Car\ Grid}{Selection\ Area\ (m^2)}$
Configuration	Urban form	Centrality	Closeness	C/D	$MGL(x)=\frac{\sum_{y\in R_x} d_M^E(x,y)W(y)P(y)}{\sum_{y\in R_x} W(y)P(y)}$
			Betweenness	C/D	$Betweenness(x)=\sum_{y\in N}\sum_{z\in R_y} W(y)W(z)P(z)OD(y,z,$ $OD(y,z,x)=\begin{cases}1, if\ x\ is\ on\ the\ shortest\ path\ from\ y\ to\ z\\ \frac{1}{2}, if\ x=y\neq z\\ \frac{1}{2}, if\ x=z\neq y\\ \frac{1}{3}, if\ x=y=z\\ 0, otherwise\end{cases}$

4 Case Studies in the PRD

4.1 Case Study 1: Clifford Estate (CE), Panyu

Land use							Mobility		Configuration	
Intensity				Diversity			Intensity	Connectivity	Centrality	
Human density	Building density (FAR)	Housing density	Coefficient of land occupancy (Coverage)	Subdivision intensity	Diversity of subdivision size	Diversity of land use	Surface occupied by the road	Connectivity of the car grid	Closeness	Betweenness
20,000/km^2	0.8-5.3	Figure 4-A/B	Figure 4-A/C	Figure 4-A/C/D	Figure 4-A/C/D	Figure 4-C	Figure 4-A/C/D	Figure-5	Figure 5-left	Figure 5-right

Table 4. Indicator of case study 1: CE

The Clifford Estate (CE) is a residential compound developed by Clifford Group and is situated within the Panyu District, Guangzhou. It is a mega gated community with a low density occupying over 5 km²; the total Floor Area Ratio (FAR) is 0.8 with Green Ratio (GR) of 75%. Its planning strategies include big environment, large supporting facilities and mega transportation (official website). Since its establishment in 1991, it has sold more than 30,000 units, with a permanent population of more than 100,000 people, and 200,000 owners. Facilities include clubs, stadiums, banks, police stations, fire stations, hospital, shopping mall, international schools, and shuttle bus terminals.

Results from mapping and collected data are crosschecked by empirical field work, shown in Figure 4. CE is regarded as a mega residential development with only parts alongside the arterial road open to the public, and with the majority area enclosed and further sub-divided into 26 gated communities. From the analysis of building changes over time, distinctive characteristics include: early phase development (around 1991-2002) has been driven at the most rapid speed and scale on over 60% of its total area, with mainly low-density four storage buildings of 0.8 FAR. After that, project number and intensity drop, occupying less land but elevated building floors and FAR, as high as 5.3 for the Clifford Wonderland built in 2017. The land use map shows that there is a limited mix of functions across the whole mega compound. At the same time, through the mapping of its facilities, the results demonstrate an inequitable spatial distribution of its communal resources, alongside insufficient diversity of jobs and business.

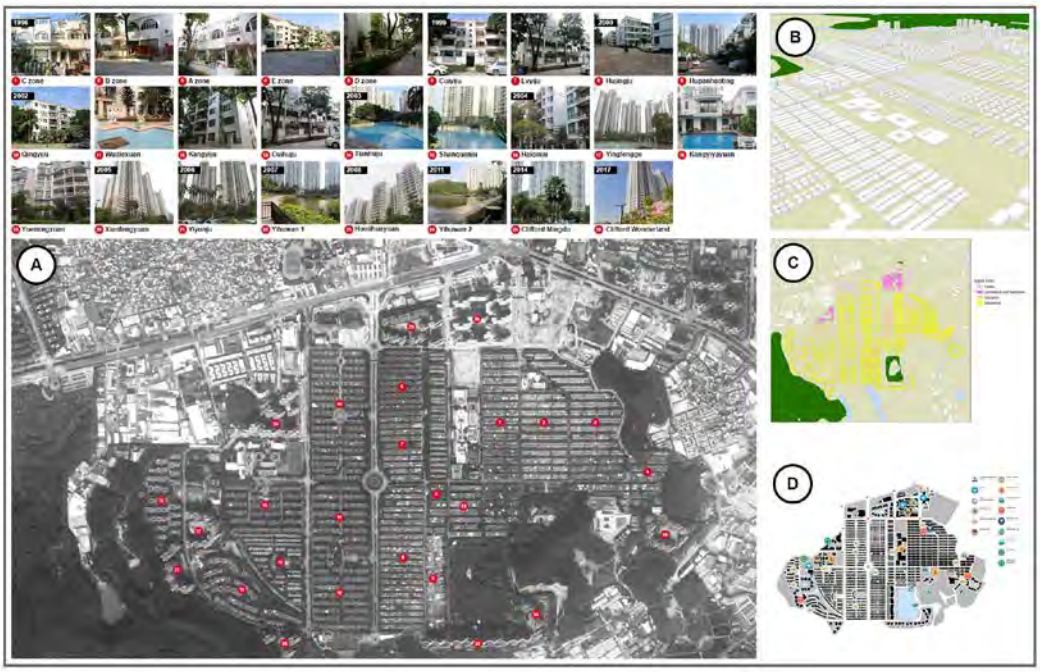

Figure 4. Clifford Estate. A: Aerial photo with building types ordered by constructed year; B: 3D building volume model; C: Land use; D: Main features and facilities. Source: author.

The CMU model's characteristics were further tested by means of other measures. For this effect, we used the Spatial Design Network analysis (sDNA) in ArcGIS to calculate the centrality analysis of closeness (a measure of access) and betweenness (potential flow along a route). The centrality was calculated at two kilometres and ten kilometres network radii, with the former being equivalent to about 25 minutes of walking and the latter to 10 or 20 minutes of driving. Other radii were tested but due to the large size of urban blocks in the region they did not represent the local and mezzo scales well. In the results shown in Case study 1, the closeness within the internal area of CE is relatively high, indicating relative access internally. However, the closeness at the larger scale indicate that CE is isolated from the larger network. Similar results can be seen for betweenness, which future confirms CE isolation from the urban road network.

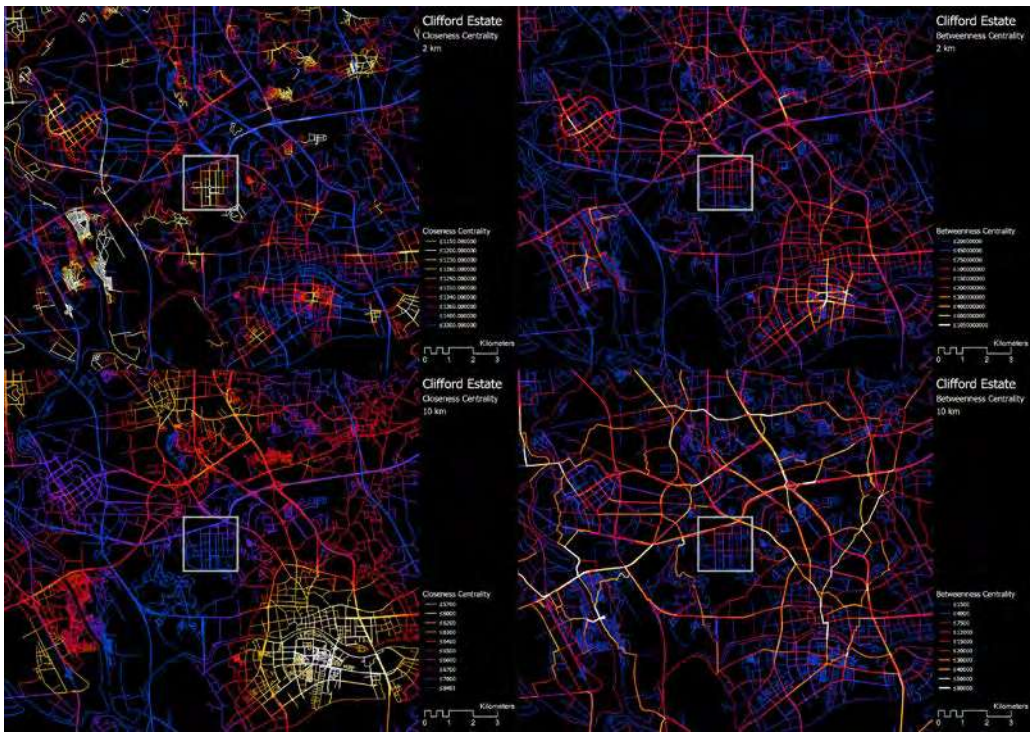

Figure 5. CE centrality analysis of closeness and betweenness in 2/10 km. Source: author.

4.2 Case Study 2: Zhujiang New Town (ZJNT), Tianhe

Land use							Mobility		Configuration	
Intensity				Diversity			Intensity	Connectivity	Centrality	
Human density	Building density (FAR)	Housing density	Coefficient of land occupancy (Coverage)	Subdivision intensity	Diversity of subdivision size	Diversity of land use	Surface occupied by the road	Connectivity of the car grid	Closeness	Betweenness
56,000/km^2	3.4-14.9	Figure 6-A/B	Figure 6-A/C	Figure 6-A/C/D	Figure 6-A/C/D	Figure 6-C	Figure 6-A/C/D	Figure-7	Figure 7-left	Figure 7-right

Table 5. Indicator of case study 2: ZJNT

Zhujiang New Town (ZJNT) is the main component of Guangzhou Tianhe Central Business District (CBD). Tianhe CBD is one of the three national-level CBDs approved by the State Council, and serves the Pearl River Delta Economic Zone. ZJNT has an area of 6.6 square

kilometres and a total floor area of 13 square kilometres (Fang et al., 2009). In 1992, the municipal government decided to develop a regulatory plan for ZJNT based on Thomas Planning Services, Inc.'s proposal. According to this plan, it would reach a residential population of 170,000 to 180,000 and provides nearly 350,000 to 400,000 jobs.

Mappings and analysis of the ZJNT area are shown in Figure 6. In general, this case shows a higher intensity of development in regard to both speed and scale compared to case study 1. Due to the accessibility of data, the focus of the architectural type is residential developments. Despite its initiation from the early 1990s, the earliest commodity housing compound was built in 1999. Mixed with gated and open communities, buildings, in this case, are high-rise with FAR from 3.4 to 14.9, declining from the central axis on both sides. The mix of land use, diversity and intensity equity distribution of facilities all show higher degrees compared to the CE.

Figure 6. ZJNT. A: Aerial photo with building types ordered by constructed year; B: 3D building volume model coloured by FAR; C: Land use; D: Main features and facilities. Source: author.

The centrality test of ZJNT results demonstrate how the megablock differs from the smaller urban block. In two-kilometre centrality tests, the ZJNT internal network placed at a medium level; however, it revealed a separation from the historical core of the city (Yuexiu), while also creating a new urban node at the lower level. The closeness test at the ten kilometres

radii indicated a lower level of proximity between spaces in ZJNT compared to old districts (Yuexiu and Tianhe) and showing the influence of modern planning on access at the mezzo level. In addition, the ten-kilometre betweenness test showed that ZJNT is surrounded by a clear super-grid structure, showing a high dependency on arterial roads.

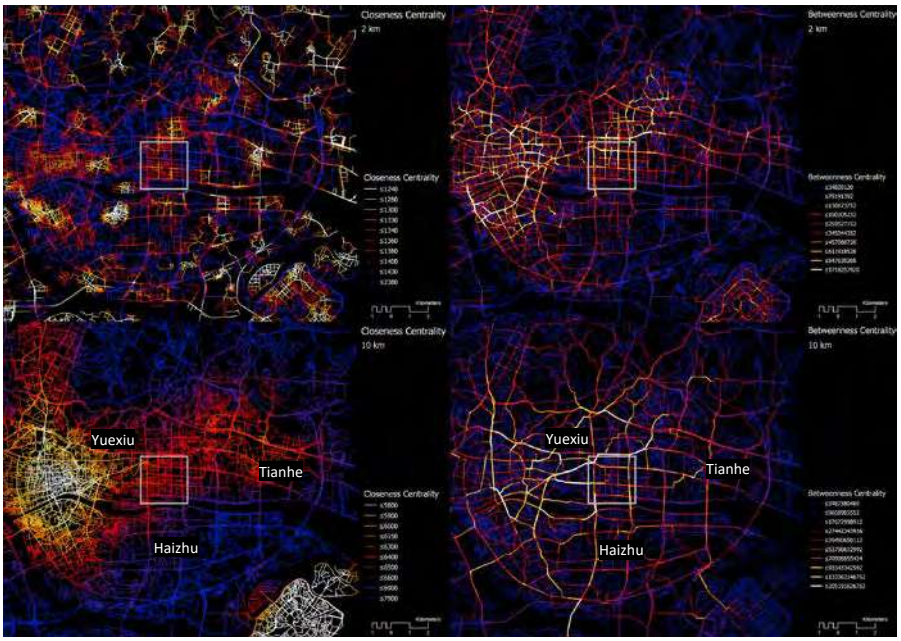

Figure 7. ZJNT centrality analysis of closeness and betweenness in 2/10 km. Source: author.

5 Conclusion and Discussion

The results from both cases show that Chinese rapid urbanization has taken place at an unprecedented speed and scale. Development models and tools differ from other countries, and moreover, the scale of the mega forms a contributing planning factor thanks to radical urban growth. Through the study of its evolutionary tract and the two cases shown, CMU reveals intriguing spatial characteristics and qualities that are worth being further investigated. Adaptations and interventions of analysis tools for CMU are essential for the future study. This requires not only new tools, but also new methods as well as conceptual framing. However, current lessons that we could learn from the Chinese rapid urbanization have not raised enough attention from either Western nor Chinese scholars, especially under the nation's exporting strategies, such as for example, "The Belt and Road" initiatives. Future research will continue to explore the phenomenon of CMU, under the perspective of urban morphology, in a more systematic and sustainable direction.

Research Paper

Integrating Vertical Farming at Scale in Urban Food Planning

Practical Considerations for Planners

Daniel Petrovics, MSc; Hungary/Netherlands

Abstract

At all stages of food production and consumption, resources are utilized in an inefficient manner and at an unprecedented rate, clearly affecting urban food systems. This raises future concerns in terms of climate change, and in terms of long-term food security and availability for growing urban populations. A supply-side solution to these issues - with particular potential in megacities - is Vertical Farming (VF), a high-yield form of controlled environment agriculture with promised potential to produce fruits and vegetables within cities, ultimately reducing their resource intensity. This research builds on an Urban & Regional Planning MSc thesis conducted at the University of Amsterdam. The research aims to provide a practical guide for planners, who aim to integrate Vertical Farming into urban food planning. Through this, an indication of whether and how VF can contribute to reducing the impact of food systems in terms of anthropogenic climate change is provided, and ultimately, it helps to understand if and how VF can be up-scaled for further impact. The research utilized an abductive approach with a qualitative design, where 17 experts working in the field were interviewed. These experts represent academia, consultancy, municipal officers, entrepreneurs, and investors. The findings are particularly applicable to planning with VF in cities in and integrative manner. The findings relate to 26 separate factors, along the lines of categories developed by van Doren et al. (2018). These categories include: Measures for Low-Carbon Urban Development, Operational Arrangements, Policy Context, Market Context, Social-Cultural Context, and Natural and Built Context.

Keywords

Vertical Farming, *Urban Food Systems*, *Up-Scaling*, *Sustainability*, *Low-Carbon Urban Development*

1. Introduction

The growing complexity of global food systems has produced a number of undesired social and environmental externalities in the past. This is particularly true for how food is consumed in urban areas, ultimately building a global network of extensive and resource intense supply chains (Steel, 2013; Ilieva, 2016). The amount of resources consumed in the process, raises future concerns in terms of the climate impact of food systems as well as in terms of availability of staple foods for growing (urban) populations.

Ultimately these problems require the assessment of potential interventions in light of multiple considerations and integrated systems perspectives, whilst keeping the goal of sustainable urban development in mind. To illustrate the wicked nature of this problem, an urban food systems lens can be utilized for assessing a potential technological intervention, which promises to contribute to greening the way food is produced and consumed in cities. This specific intervention is that of Vertical Farming (VF) – a form of closed environment agriculture (CEA), capable of producing fruits, vegetables, and medicinal plants (Despommier, 2010) on multiple physical layers. This technology is particularly suitable for urban environments, as it allows for the efficient use of space, as the surface area of the given farm is not a limiting factor anymore when it comes to food production. Next to this, VF promises to reduce the resource use of global supply chains due to its localized nature, can provide year-round supply of produce, and does not require the use of pesticides (Ibid.). Nevertheless, questions have been raised as to how the high energy demand resulting from the use of aquaponics systems and LED lighting among other unaccounted for externalities should be considered for if one plans for truly sustainable urban food systems (Al-Kodmany, 2018).

This paper outlines, based on the framework developed by van Doren et al. (2018), what practical factors need to be taken into consideration when it comes to successfully planning for the up-scaling of VF, and through this embedding this technology in the city as a Low Carbon Urban Initiative (LCUI). Van Doren et al. (2018) outline two pathways to up-scaling – horizontal and vertical. Horizontal up-scaling entails the spatial reproduction of a given technological intervention, both in terms of quantity, as well as in terms of size. Vertical up-scaling describes the institutional embedding of a technology, be that in terms of policy, culture, or economy among others. In total van Doren et al. (2018) outline 19 factors, which should be considered – these factors have been amended with 7 additional factors, which emerged throughout the data analysis period. This is due to the structuring of the research design through an abductive approach. The principle data collection method was that of semi-structured key informant interviews, with a total of 17 having been conducted with the informants' perspectives representing different geographies as well as constituencies.

This article focuses primarily on practical considerations, which urban planners should consider when planning to apply the technology of VF to transitioning to sustainable urban food systems. The research is based on the data collected as part of an MSc thesis, forming a part of the Urban and Regional Planning MSc degree at the University of Amsterdam. The theoretical findings of the research are presented in a separate publication (Petrovics & Giezen, forthcoming), and for this reason this article should be utilized as a practical guide primarily.

In the following, the article discusses the theoretical framework in more detail, summarizes the methodological approach taken, outlines the practical considerations for planners in detail, and briefly concludes.

2. Theoretical Perspective

In an attempt to accelerate urban development trajectories towards low-carbon pathways, it is essential to understand what pioneers, innovators, and ultimately urban planners need to take into consideration whilst planning for socio-technical interventions. Van Doren et al. (2018) outline that such Low Carbon Urban Developments (LCUDs) are informed by scalable Low Carbon Urban Initiatives (LCUIs). As mentioned in the process of scaling these initiatives, two types of pathways exist: horizontal and vertical. Horizontal pathways entail the spatial reproduction of LCUIs (e.g. through introducing physically larger interventions, or through introducing a higher number of initiatives in a given city). Vertical pathways entail the institutional embedding of these initiatives (e.g. through transitioning the policy landscape, establishing favourable market conditions, or affecting the levels of awareness when it comes to a new innovation).

The linkage and relationship of vertical and horizontal pathways to up-scaling LCUIs does not follow in a linear relationship; rather the two pathways interact in a dialectic manner reinforcing each other in a virtuous cycle. This framework can also be linked to Geels' (2002, 2011) Multi-Level Perspective (MLP) on sociotechnical transitions, in that it describes the specific interactions between *niche* and *regime* level dynamics, and in particular helps one understand the process of scaling *niche* initiatives into a *regime*.

In order to analyse these potential pathways the up-scaling framework of van Doren et al. (2018) has been amended with a set of factors, which emerged throughout the data collection process – marked with an asterisk. In total 6 categories, exploring 26 factors allow for understanding how urban planners should assess LCUIs and in particular work with VF for the sake of sustainable urban food systems. The categories and factors are as follows:

Measures for LCUD

- Financial Advantage
- Reliability
- Low Complexity
- Integrative Functions*

Operational Arrangements

- Leadership
- Stakeholder Involvement
- Resource Mobilization
- Communication
- Logistics*

Policy Context

- Regulatory Policy Instruments
- Financial Policy Instruments
- Informative Policy Instruments
- Political Leadership
- Trust in the Policy Framework

Market Context

- Low Capital and Instalment Costs
- Expertise and Skills of Supply Actors
- Information Availability
- Access to Credit
- Energy Price
- Market Dynamics and Conditions of Peripheral Industries*
- Insurance*

Social-cultural context

- Environmental Awareness and Values
- Consumption Culture*
- Product Qualities*
- Social- and Power Relations*

Natural and Built Context

- Technical Compatibility

3. Methodology

As mentioned, the research is based on the data collected for the completion of the thesis as part of the MSc degree in Urban and Regional Planning, completed at the University of Amsterdam. The research design took an abductive approach, and by this not only produced findings related to VF but also amended the set of factors outlined above. The primary method for data collection was semi-structured key informant interviews. These interviews were conducted with 17 experts working with VF in different geographical regions and capacities. The perspectives of these accounts span academia, consultancy, municipal officers, entrepreneurs, and investors. The anonymized accounts of these interviewees are marked with 3-digit codes. The practical considerations outlined below build on their accounts in combination with the slim literature existing on the applicability of VF as an innovation.

4. Practical Considerations for Urban Planners

The following section outlines the findings based on the amended theoretical framework of van Doren et al. (2018). As mentioned, the findings are based on the 17 interviews conducted in the spring of 2018, which follow three-digit codes for reference. The section outlines, factors falling under measures for LCUD, operational arrangements, the policy context, the market context, the social-cultural context, and the natural and built context.

4.1. Measures for LCUD

Financial Advantage. The financial advantage and profitability of vertical farms is generally dependent on external factors and the business model of the farm. The external factors can be categorized on the lines of real estate and land availability, economic conditions affecting this availability, food scarcity, and the scale at which the operation takes place. As is generally the case with Urban Agriculture (UA), VF is also directly dependent on land availability and is hence receptive in periods of economic downturns, as vacant buildings and lots are more available, and accessible at lower prices in these times (004). This directly affects the viability and profitability of VF as well, especially if the business models consider the availability of vacant space necessary (017). Flipping this logic on its head, economic peeks produce competition in the real estate sector, which makes land less available to UA and VF (e.g. Amsterdam in the recent years) (012, 017). Next to this the scale of the operation also counts, as small-scale installations are not likely to be profitable. This is a typical example of capital expenditure intense industries becoming profitable at scale (011).

The business model related factors can be categorized on the lines of pricing and the ability to charge a premium, the potential for integrating multiple sites within one business, and the potential for integrating functions. Food scarcity and the distance fresh produce has to travel directly impacts the profitability of VF, as this is where premiums can be charged for local and fresh produce (011). If a city is dependent on imports it is sensible to introduce VF and there is potential to charge premiums on the fresh produce. Moreover, dependent on the economic conditions (as is outlined above), business models, which integrate different types of land availability can produce a financial advantage. For example, combining a small-scale, downtown demonstration project, which showcases the technology and produce to consumers, with a large-scale peri-urban

production facility can off-set the incurred financial weight of high land prices in the centres of cities (013). A further type of integration, which can enhance the financial advantage of VF is to integrate functions by for example including some form of hospitality directly linked to the farm (017). This type of integration is explored in detail further below.

Reliability. In terms of horizontal pathways VF is reliable to a certain extent if the installations generally work in self-contained, replicable units or blocks, which allow for easy scalability. This is necessary, as VF is a form of CEA, as is discussed above, which requires tight control over all growth parameters. The production logic of CEA in terms of produce quality directly contributes to the reliability of VF, as the physical aspects of crops are fully controllable, meaning that the visual and aesthetic, the taste, the health and nutritional value, and the shelf life of produce can be directly controlled (010). Due to these factors, the logic of self-contained units has proved successful in the industry on various scales – e.g. InFarm introduced these types of units directly in super markets (InFarm, 2018), CoolFarm utilizes plug-and-play farms (CoolFarm, 2018), while Agrilution has created household level units the size of a small fridge (Agrilution, 2018) (008, 014, 016). The following account from an Innovation Manager from a large tech company working with VF components fittingly describes how this dynamic creates tensions, when one aspires to repurpose vacant space in cities:

> *"I love the whole idea that you take space and transform it into a vertical farm. I love it but I don't believe in it, because with that it's not scalable. I always think you can take an existing old warehouse and build into it another house for vertical farm. But to make it really scalable you need to have always the same set up. […] You need to standardize modules which you can put somewhere, but it always needs to be and in itself an existing ecosystem and not relying on the real infrastructure which the warehouse has given." (016)*

This means that the reuse of vacant spaces is only possible if a self-contained unit is built within the given structure. This way the installation can fulfill the requirements of CEA and can contribute directly to the scalability of the initiative. All these points are however dependent on the knowledge of optimal growth recipes (light, temperature, humidity, nutrition, etc.), which is not yet present in the industry (004). Once these recipes are developed to a sufficient extent, automation and robotization can also enhance the effectiveness of VF (004, 013).

In terms of vertical pathways, the availability of horticultural technolgy and knowledge (e.g. extensive multi-generational knowledge in the Netherlands) can serve as a catalyzer as VF follows many of its principles (008). This being said, a structural restraint persists in terms of staple foods:

crops, such as rice, potatoes, and corn are still difficult to grow in VF (008). Finally an urban planner responsible for green projects in Amsterdam suggested that viable, existing, and functioning examples make municipalities receptive to the technology, as this directly proves it's reliability in the eyes of public authorities. The mentioned example is GROWx in Amsterdam, and the way it is perceived by the municipality as a functioning farm (017).

Low Complexity. As mentioned before the availability of horticultural technology makes the technology utilized in VF available and reliable as well (009). This means that highly developed greenhouse and horticulture industries, such as the Dutch one, can catalyze technological developments as well and can play a great role in ensuring the reduced complexity of VF (015). Nevertheless a key caveat in the industry is that many startups and companies try to develop all of the technology themselves and by this try to reinvent the wheel, ultimately increasing complexity (013). This is unnecessary and risky, as it is better to focus on the core business model of a farm, instead of on developing every single component when such an industry is in the period of innovation (016).

In terms of horizontal up-scaling firstly inefficient practices are common, which reduce the effectiveness of individual plants (e.g. double scissor lifts moving up and down multiple times during harvest) (006), and secondly CEA makes it difficult to make use of vacant spaces due to hygiene considerations (bacteria and plant diseases), if not utilizing the above-outlined self-contained units or blocks (004, 016). Next to this, a further factor that contributes to excessive complexity is that due to the recency of VF, start-ups typically work in silos and wind up developing all the components, which also means that there is no standardization for these components in the industry (e.g. trays, lights, piping etc.) (009, 006, 015). Nevertheless, initiatives are under way to remedy this – the Association for Vertical Farming (AVF) is pushing for industry level standardization (e.g. in components, and dataformats for control systems) (015, 016).

Integrative Functions. This emergent factors is essential, as multiple interviewees outlined that the reliability, viability, and most importantly profitability of VF in this phase of innovation is dependent on integrating food production functions of a farm with other functions (003, 009, 002). These integrative solutions include firstly, functions for marketability (e.g. proximity of the produce and a story) (003), secondly, functions for environmental sustainability (ecosystem services, biodiversity, enclosing nutrient cycles, etc.) (003), thirdly, thermodynamic functions (e.g. cooling water to be used for district heating, or utilizing excess energy and heat from logistical hotspots,

server systems, or airports) (001, 003, 009), and finally, functions for educating the public (e.g. nursery visiting center, VF at public institutions [schools or hospitals] and public space) (010, 002, 007, 014). As a professor working with horticulture explained,

> *"there is an advantage when your are very nearby where the consumers are; I think you should also take the opportunity to make the connection with the citizens, so make some part of your firm or the nursery open for public or that you have sometimes that they can visit so that they can see it. This is because they can't consider it as a factory, and in particular if nobody is allowed to have a look inside how it looks, they might have all types of ideas which are not correct." (010)*

Finally, functions for citizen engagement and community meeting points can also be introduced, in order to re-establish the social aspect of food in cities (009, 010). Such places are considered substantial, as this is "where people meet, discuss about food – this is extremely important for the evolution of community" (009).

In terms of vertical up-scaling this function mixing takes a different dimension. As a respondent outlined, dependent on desired goals, municipalities should directly push for and require function mixing (003). This respondent went on to describe the benefits as

> *"all of a sudden your urban farming is a means to many different ends […] maybe you don't want to optimize for efficiency but for social impact." (003)*

4.2. Operational Arrangements

Leadership. With regards to the role of leadership, the only opportunity outlined by interviewees was by a start-up working in Amsterdam, whose founder mentioned that next to their core three person team it is necessary to partner with visionary and powerful individuals who are vested in the project. He said this is absolutely necessary for the success of such an initiative (008). As he mentioned in explanation for why a tender for a farm was turned down,

> *"You need individuals that are both visionary and powerful. And we had powerful people in that process. I'm not sure if we had some visionary ambassador in that project." (008)*

This account highlights the necessity of fitting leadership qualities not only to the extent of power but also in envisioning what is required for the success of a VF initative. Nevertheless it becomes questionable where such individuals can be found, as an account from a member of the

Amsterdam Economic Board suggests, based on this logic cities would have to rely on "kind of superheroes, super engineers saving the planet" (001).

Stakeholder Involvement. Without conducting an extensive stakeholder mapping exercise, based on the accounts of the interviewees the following can be said. Generally the respondents indicated that the industry is disproportionately focused on engineering and technology, mostly dismissing social elements, which also results in a disproportionate focus on stakeholders in this realm (001). Nonetheless initatives exist, which can be understood as *niche* developments, such as OneFarm in Amsterdam, putting an inclusive approach as a centerpiece to its business model (008). Through engaging local community members in education activities and a volunteering program, they not only aim to open up the black box of the vertical farm to the public, but they also aim at utilizing locally available knowledge and social institutions (OneFarm, 2018). This logic was further extended to a systemic level by a member of the Amsterdam Economic Board. He suggested that outlining a vision for inclusive and participatory approaches to planning by involving all stakeholders from citizens through tech companies to farmers is the way to plan for the success of a food system (001).

In terms of engaging stakeholders necessary for conducting and maintaining operations to a sufficient and successful degree, it has been stated that due to the young nature of the industry, these necessary stakeholders (e.g. light engineers, data scientists, horticulture specialists, entrepreneurs) are not used to collaborating in this manner (015). Next to this there is no framework present yet for establishing this cooperation (015). This being said opportunities do lie in collaboration between *niche* experiments and *regime*-level actors, as was outlined by an Amsterdam based VF entrepreneur, who has set up a business relationship with one of the major lettuce producers in The Netherlands (009). In this sense it is not only resistance that originates from *regime*-level actors, but windows of opportunities also open for collaboration, which ultimately support the up-scaling of VF.

Resource Mobilization. VF carries an advantage in the sense that technical platforms (such as the control systems necessary for handling the production system) can be set up and run by relatively few people (008). This fact is furthered by the tendency of component prices to fall, enabling the per unit output of the VF industry to grow in financial terms. The recurring example for this dynamic is how the prices of LED lighting have decreased due to growing efficiency and broader availability (010, 011). Such developments can reinforce *niche* formation. Next to this due

to the small profit margin there is a general awareness in the industry of the necessity to utilize resources (human, electrical, and spatial) in the most effective and efficient manner (006). Nevertheless, as a sustainability consultant outlined, traditionally in the agricultural sector, there is a race to efficiency rather than quality. This means that there is a serious risk of recreating this dynamic in the VF industry, which could ultimately lead to a race to the bottom, hindering horizontal as well as vertical pathways to up-scaling (003).

Communication. The accounts regarding communication are not clearly categorizable as directly contributing to horizontal and vertical pathways, as they are applicable to individual plants as well as the resulting broader societal dynamics equally, if replicated sufficiently. In general, multiple intervewees suggested that there is a general lack of trust and fear towards new and innovative technologies from the public. The examples mentioned were primarily hydroponic growing systems and soiless cultivation methods (008, 014). Nevertheless with growing interest in local produce, great opportunities lie in communicating the proximity of VF produce (010).

Logistics. Once again, planning for interventions in the supply-side of food systems carries potential, if one thinks in systemic terms, which necessitates a focus on logistic systems as well (003, 006, 017). By looking towards integrated systemic solutions in terms of distribution logistics, and by creating an alternative scaled logistics system for distributing food in cities, the ultimate connection can be made between farmers and consumers. The principle *niche* experiment mentioned as an example for such a system is the FoodLogica experiment, which is a bike-based food delivery system aiming to “clean the last mile’s of Amsterdam’s local food system” (FoodLogica, 2018). If one aims at introducing VF from a sustainable urban food systems perspective, it is essential to conceive of this type of alternative logistic system. Next to this by connecting individual, local producers and end consumers, using such systems can result in "creating an economy of scale without actually needing to scale up yourself" (003). This is especially true as the larger a city, the larger the required logistics operation for scaling, and hence the more difficult it will be for individual plants to scale themselves (006). Next to this, as Steel (2008) outlines in detail, with the lengthy food supply-chains, countries such as the U.K. tend to create bottlenecks in the forms of food distribution centers. Hence, localizing food production and combining it with alternative logistic systems based on more decentralized solutions carries great potential in terms of establishing resilient urban and regional food systems as well.

4.3. Policy Context

Regulatory Policy Instruments. In terms of VF this factor can be understood broadly as the role zoning regulation plays and the way municipal institutions interact with VF in terms of up-scaling. Zoning is generally perceived as a barrier, however progressive municipalities have found ways to accommodate existing zoning codes. Moreover, establishing municipal level authorities responsible for food planning has pushed for more innovative approaches to city-level food planning and has created the *milieu* necessary for up-scaling VF. Nevertheless institutional barriers on the *landscape* level also persist mostly on the lines of bureaucracy, exemplified by difficulties arising from administrative boundaries, stringent health and labor regulation, and lacking harmonization of agricultural regulation across countries. In the following these points are outlined in detail.

First of all, most interviewees regardless of constituency suggested that zoning codes generally do not recognize VF, and do not fit directly in any category. It is not clearly industry, nor food processing, nor agriculture (008, 009, 010, 006, 011, 017). Next to this if vacant space is available, the zoning categorization (e.g. for a space originally intended for commercial use) becomes problematic in a similar fashion (009). Furthermore, the integrated use of electricity and water is a red flag for code enforcement officials, as was suggested by a supplier of horticulture technology components:

> *"you watch the eyes of the officials when you say 'hey I want to run electricity-water-electricity-water'- that's what you're saying right? You want to put irrigation systems and electricity together in a sandwich style" (006)*

Seeing that regulations are not yet ready to accommodate the socio-technical reality of VF it is also essential to take a step back from focusing solely on the codes and regulations, and to look at those resposible for applying them in practice. This same supplier cited above, suggested that the problem is not only with ill-suited and outdated regulation, but with administrators' and clerks' lacking awareness of how to apply them in the context of VF (006).

Despite this, flexible regulators who decide on zoning permits also exist as was outlined by a VF entrepreneur in Amsterdam (008). By utilizing categories of exception, VF can find its space within predefined zoning codes. This claim is further supported by what a municipal officer outlined: certain zoning plans allow for making case-by-case exceptions, as was the case in Amsterdam with GROWx (017). The same officer went on to describe the tendency of UA to gain prominence in zoning plans (017). He furthermore suggested that VF does not directly produce noise or smells that could be problematic for neighbourhoods (017).

In terms of vertical pathways, it has been suggested that the establishment of municipal level food councils can serve as an enabler, as these authorities can create fitting food strategies, where VF can become a key element (002). The primary example for this type of *niche* development mentioned was that of Amsterdam, which established its own council in December 2017 (FoodCouncil MRA, 2018). Next to this municipal level policy initiatives can also catalyze the development of VF. Pushes for sustainability and green agendas, as in the case of Amsterdam (Municipality of Amsterdam, 2015) and Singapore (Building and Construction Authority, 2014) were mentioned (015, 017), alongside the establishment of public food strategies, such as the *Good Food Strategy* in Brussels (Brussels Environment, 2016), or the *Voedselvisie* in The Netherlands (Natuur & Milieu, 2017) (015, 017). However, the key takeaway here is that it is necessary to make urban and vertical farming an explicit goal within public and municipal policies and strategies in order to see a systemic transfer of land to VF, as was outlined by an urban planner working with the Municipality of Amsterdam (017). A key consultant working at building networks within the VF industry fittingly suggested that,

> *"It's not so much about just creating a vertical farm, it's really building a totally different environment with institutions, organizations. […] in the end I hope that you can say there is a better contribution to delivering fresh foods from highly productive, highly sustainable, and circular ways with a very low footprint." (004)*

This being said the reality of the regulatory landscape is one of extensive red tape, which slows and blocks innovation (002). This boils down to the following. Firstly, municipal and administrative boundaries do not always overlap with those necessitated by urban and regional food systems, which ultimately results in lacking communication, influence, and coordination (002). Secondly, stringent health (006) and labor safety (014) regulations also hinder the cause of VF in terms of vertical pathways, and finally, difficulties also arise from the heterogeneity of agriculture related legislation and categorization between different countries, ultimately hindering the up-scaling of an industry already riddled by an inadequate legislative environment (015).

Financial Policy Instruments. Multiple sources of public and private funding exist and are available to VF. This section assesses the public instruments primarily, as the private ones are described in detail further down. Among the public instruments are municipal level subsidies and loans directly targetting urban agriculture (and VF), alongside peripheral subsidies targetting CO_2 reduction, EU level funding through the *Horizon 2020* program, the *SME Funding Instrument*, and potentially the *Common Agriculture Policy* (CAP). Nevertheless the scope of these funds is relatively limited, and in general confusion persists on the accessibility of these instruments.

In terms of municipal finance, the case of Amsterdam is illustrative, as small start-up subsidies targetting urban agriculture purposes, as well as larger loans for green innovation purposes targetting entrepreneurs in this field exist simultaneously (017). On the EU level, the *Horizon 2020* program has been mentioned multiple times as an available instrument (014, 015). Nevertheless it has also been criticized for the slow and inefficient processes, which can generally set back innovation (016). A living example for the success of this funding scheme is InFarm, a Berlin based VF company, which raised €2 million through this program (European Commission, 2017a). Moreover, an interviewee working closely with agriculture policy at the EU level suggested that the CAP is turning towards urban instruments and innovation in the field of agriculture more and more (015). This is exemplified by a Communication Paper published by the European Commission, titled *The Future of Food and Farming*, which mentions VF – for the first time – as an industry with potential for urban applications (European Commission, 2017b). Finally it was also mentioned by an entrepreneur that peripheral subsidies (targetting CO_2 reduction for example) also carry potential for this field and are an active consideration in their business model (009). Nevertheless, most of these subsidies generally target needs-based industry actors – for example the staple crop agriculture sector in the U.S. (006), or the large-scale farmers in the EU through the CAP (015), which can be understood as *landscape* level pressures creating resistance for up-scaling. Finally, the general accessibility of these funding schemes was accounted for as problematic by the same EU agriculture policy specialist (015).

In terms of vertical pathways, general willingness for municipalities to establish green agendas (017), the creation of platforms for knowledge sharing (e.g. Amsterdam Economic Board or the AVF) (003), and simple changes in EU legislation describing minimum acreage for qualifying as a farmer (015) can be mentioned as creating supportive environments for the dissemination of financial instruments.

Informative Policy Instruments. Based on the accounts of the interviewees informative policy instruments are clearly lax in the VF industry. This can be exemplified by the perception that vertical farms are generally seen as black boxes (009), which not only hinders societal acceptance, but also reduces the access to information on how to set-up and operate such an installation successfully. Next to this, simple information on for example the CO_2 reduction capability of VF is also not yet available, as was mentioned by a municipal officer working with the City of Amsterdam as well as multiple entrepreneurs (017, 008, 009).

A further problem arises from the general categorization of produce. There is industry-level confusion on how to categorize the produce, as it does not clearly fall into the pre-established

categories of organic, non-organic, processed foods, and the like. (008). Besides, simple elements such as a label for VF are also not yet existent. As the head of a large tech company working with lighting solutions outlined,

> *"it might be worthwhile seeing if there is a label that could on the one hand side guarantee quality and basically standardize quality a little bit. And on the other side trigger a discussion and explain to the consumers what it is you're doing." (013)*

This lacking label hinders both consumer acceptance as well as the necessary discussions that can push for the development and adjustment of food safety categorization and regulation (013, 014).

Finally, for vertical up-scaling it is essential to have supporting frameworks for initiating business processes. In established industries this would mean that farmers can turn to the ministries responsible for agriculture, and SMEs can go to the business bureau. Yet still, as a policy specialist outlined, VF has no such public contact point, which can setback the initial phase of starting-up vertical farms (015). As the policy specialist outlined,

> *"One of the administrations should take this field and say, 'Okay, you are interested in vertical farming. You want to set up an activity, so come to us and we will advise you on the different stages you have to go through and the different partnerships you can enter into.'" (015)*

Political Leadership. Once again in terms of political leadership, progressive and forward looking municipal officers and institutions are of great importance. City Councils carry the opportunity to enhance VF (004), hence in an ideal scenario such authorities should also focus their work on UA and VF. This also means that food strategies should be outlined by understanding the food related practices of the consumer and citizen (001), as is also outlined by Cohen and Ilieva (2015). This being said it was also mentioned that Urban Agriculture is generally not on the agenda of politicians (003). Closely related, a significant problem of the AVF is that governmental authorities and public figures are not present to a sufficient degree in the industry association (011). Next to this, extensive involvement of public authorities can also hamper developments, as was outlined by an interviewee:

> *"the government tends to want to be involved too much, so it really sometimes also slows processes down because they are so active in promoting it and trying to subsidize it that everything needs to be reported and that you can hardly do any work because you're continuously playing tour guide for the government." (013)*

Hence, political leadership is a necessary and a generally missing element in the VF industry, nevertheless if present it should be conducive to the goal of the farms, and not to the agendas of politicians and public authorities. Finally, the shifting nature from country level food diplomacy to city level food diplomacy was also outlined as a supporting factor (004).

Trust in the Policy Framework. In general, trust in the functioning of existing regulatory instruments is regarded as lax, considering that a fitting policy framework specifically targeting VF does not exist, as was outlined above. This is primarily due to the regulatory barriers that persist, the general policy landscape, and the fact that institutions tend to follow academic and entrepreneurial endeavors with a lag (008, 004). As the Chief Innovation Officer of an Amsterdam based start-up accelerator also working with VF mentioned, "the policy space usually follows the experimental phase" (008). In more systemic terms, this also means that considerations for food security, food planning, and the concept of a food chain generally are not integrated into the political and administrative systems of countries as of yet (002). Nevertheless, exceptions for these dynamics do exist as was explained by a researcher from the University of Wageningen: "There has been the example in the Netherlands for even a ministry on food. You know, not on agriculture but on food" (002). Such an institutional switch may seem of small nature, nevertheless concentrating on food rather than solely agriculture suggests systemic shifts, which could also prove conducive to the cause of VF. Next to shifting institutions it was also discussed that on a case-to-case basis soft-power mechanisms can come in handy exemplified by knowing government officials (013).

4.4. Market Context

Low Capital and Instalment Costs. Virtually all interviewees agreed that VF as the most technology intense form of UA carries high up front costs (001, 005, 008, 010, 002, 016). Seeing that components such as LED lights, trays, pumps, and control systems, among others are essential, costs per m^2 can add up to €2,500 (009). This ties in with the reluctance of traditional lending institutions to support the up-start of VF projects, as well as the emergent Venture Capitalist (VC) funding schemes present on the North American context, as is outlined in more detail below.

Expertise and Skills of Supply Actors. With regards to expertise and the skills of supply actors, it can be said that the VF industry is in the beginning of the innovation cycle. This carries certain defining characteristics, which are also applicable to the field of VF; such as lacking industry-

level integrated and shared knowledge, the development of certain types of partnerships with research institutes, tension with *regime* level industries – especially the greenhouse horticulture industry, multiple individual failures, and the emergence of alternative business models, which challenge the incumbent *regime* from within. These are outlined here-on.

Firstly, multiple interviewees mentioned that there is lacking integrated knowledge, which would be essential to VF. As a Sustainability Consultant working with aquaponics systems outlined, “I'm basically looking for a plumber, farmer, chef” (003) or in other words "in terms of skill sets you need a slightly different set of yet unavailable skills. It needs a rare combination of plant scientist, farmer, data scientists, etc." (008). These accounts highlight two points. On the one hand, integrating this type of diverse knowledge within a multi-disciplinary team can be challenging due to the different backgrounds of the individuals, while on the other hand this set of knowledge is more available and affordable at scale (014, 003). This tension however is being slowly resolved seeing that more and more partnerships are established for knowledge generation at the *niche* level for example, by universities such as the HAS University of Applied Sciences collaborating with companies such as Philips through Public-Private Partnerships (PPPs) (010, 013, 016).

Secondly, it can be said that a great source of resistance comes from the traditional greenhouse and horticulture industries, which carry much of the necessary knowledge, as well as technological components required and suitable for VF (010). As is outlined below, this resistance can be understood as the *regime* maintaining its position, something that is particularly visible in the Netherlands. As a lighting specialist working with both industries outlined,

> *“greenhouse growers are sceptical of vertical farming and they fear that as a kind of destructive instrument. These interest groups are not geared toward helping vertical farming.” (011)*

A potential way forward from this systemic resistance is through the creation of alternative business models, which are on the rise in the VF industry. These models are based on flat hierarchies (016) and partnerships (009), which essentially produce efficient, transparent and innovative workflows, as well as higher levels of aggregate knowledge, which can catalyze changes and progress in the field of VF.

Finally, the role of public authorities should also be outlined, considering conflicting accounts persist. On the one hand, the inherent inexperience of municipalities towards VF combined with an experimental and progressive setting can result in municipal officers being open to experimentation and innovation, and ultimately allowing for the licensing of innovative forms of UA (002). On the other hand, this total lack of public experience with the industry can create

tension seeing that municipalities generally struggle with various types of regulation, as evident from the afore-discussed issue on zoning. (002)

Information Availability. As previously mentioned, the principal problem with regards to information availability lies with the absence of knowledge sharing across the industry. This stems from 1.) entrepreneurs' lacking knowledge - closely linked to the required combination of specific but diverse types of knowledge, 2.) the structural conditions of the political economy, which push for working in silos, and 3.) the technological focus of the industry - rather than the required plant physiology focus. Nonetheless, certain pushes exist for uniting the necessary expertise and personnel, as well as to create a much-needed industry association. The first point – entrepreneurs lax knowledge – has been exhausted above; hence this section discusses the others.

With regards to the structural conditions of the political economy, it can be said that on the one hand, the trend towards neoliberalism has created a political economy geared towards competition, which inherently reduces opportunities for collaboration (001, 004). As a consultant working with business networks outlined, within this *landscape* pressure,

> *"Competition is a great good but if you do it in a collaborative way, you can learn from each other." (004)*

Hence, competitive elements are crucial in such an early stage of an industry; nevertheless certain forms of collaboration are necessary for optimal results. On the other hand, in certain contexts the VC mode of financing also creates silos for R&D on the *niche* level, seeing that this form of financing is geared towards producing and patenting intellectual property (006). As a supplier of horticulture technology described the North American context:

> *"In my experience 99 percent of the decisions made in the industry are about short term profit." (006)*

This account highlights that a pure profit-oriented focus is likely to produce an outcome of short-term returns, and not long-terms transitions, which could benefit the industry as a whole. Next to this, the AVF is still not perceived as a full-fledged functioning industry association, which would be crucial for overcoming these types of barriers for the advancement of the field (011).

Furthermore, the focus of the industry is disbalanced and too concentrated on technological solutions. More focus should be paid to plant physiology (006), as this should guide the development of growth systems and not *vice versa*. As the afore-mentioned supplier of components outlined, "the industry won't ever grow until we focus on the plants" (006). The head

of a lighting supplier company also outlined a misconception from the side of many entrepreneurs, namely that

> *"people think you can just put racks into a warehouse, start growing microgreens and you're in indoor vertical farming, and you're going to solve the world food hunger." (013)*

By failing to develop plant physiology centered knowledge and growth technology simultaneously (013), the process of businesses focusing on building farms solely has been exacerbated. The key point here is that without the fitting operational knowledge, no farm can function optimally and hence the transfer of this knowledge is also necessary (016). An example for how this knowledge transfer can function in a beneficial manner, is the business model adopted by Signify City Farming – Philips City Farming at the time of data collection – which focuses on lighting technology as their core business model, and offers knowledge services after setting up plants in order to maintain the functionality of their business partners' installations.

This being said, pushes for sharing knowledge and integrating and consolidating the necessary information are under way. On the one hand private companies have pushed for business ecosystem approaches to industry-level collaboration. For example, MeetingMoreMinds based in Amsterdam focuses on building business networks, and has initiated such a process in the VF industry as well. Next to this, companies directly working with VF components, as for example Osram, also put building a business network at the core of their business model (004, 015). On the other hand, as previously mentioned, the AVF is gaining more and more traction (009). Sharing knowledge, shaping policy and legislation, pushing for standardization, and providing networking opportunities all fall under their core activities (Association for Vertical Farming, 2018). Nevertheless, certain entrepreneurs are generally sceptical of the AVF due to its young nature and overlapping personnel with private VF initiatives (009, 011). Two explanations can be provided nonetheless. From a structuralist perspective, the inherent competition of industry actors embedded in the landscape of the neoliberal political economy creates a general perception of distrust, which can mean that such an initiative is treated with scepticism. From the perspective of the innovation cycle however, it can be argued that the critical mass of VF initiatives has not been reached yet, which in effect hinders pushes for standardization, knowledge-sharing, and the maturation of the AVF into a full-fledged industry association (006).

Access to Credit. With regards to access to credit and funding schemes external to the above outlined public financial instruments, it can generally be said that traditional lending institutions, such as banks are reluctant to invest in agriculture (006). This is especially true for

Europe, where banks will generally not fund VF due to the high sales price per product (013). In the U.S. the iconic exception to this dynamic is the $200 million investment by Softbank in Plenty, a *niche* VF initiative (Bloomberg, 2017). Despite the reluctance for traditional lending institutions to fund VF, other funding structures, which can be categorized as developments on the *regime* level also exist. Examples for this are large technology companies funding experiments, as is the case with BrightBox in Venlo supported by Philips (013), or start-ups receiving Foreign Direct Investment (FDI) as was the case of GrowX in Amsterdam (002). Next to this it was suggested that there is a growing trend for impact driven investment, which can qualify as a *niche* development (008). This being said in general it is still funding schemes originating in the public sphere that carry the potential to support the industry primarily, as is discussed above.

Energy Price. Energy is the most expensive factor when it comes to the operational costs of VF (009, 006, 002, 014). This means that any kind of dynamic present in the energy sector will affect the operations of a vertical farm to a great extent, and is worth exploring through the accounts of the interviewees. Without conducting an exhaustive review of energy sector market dynamics, those explicitly mentioned can be categorized in two clusters: price volatility and dependence on the energy price, and structural availability of (renewable) energy sources and their relation to the grid. In terms of price volatility, a general *landscape*-level trend of decreasing energy prices is perceived as conducive to the growth of the industry (008). Moreover, the high degree of dependence on local energy prices makes it questionable to what extent VF can be a solution deployable universally regardless of market conditions (010). This fact is further intensified by the conceived opportunity to make case-by-case energy deals in order to enhance the reliability of affordable energy access, however interviewees expressed that it is difficult to strike these case-by-case deals with energy companies (009).

This being said, the structural changes, which the energy sector is undergoing also have to be outlined as respondents highlighted tensions here as well. Firstly, decentralizing tendencies in the energy sector carry decentralizing tendencies for the supply-side of food systems as well (016). With growing availability of power in remote areas – where elements of food crises are also more present – the potential to set-up VF without dependence on centralized supplies of grid-connected power grows. Secondly, it was theoretically outlined that VF could balance energy peeks and dips in grids due to the flexibility of growth cycles by for example reversing the day-night rhythm in a farm to reduce the peek loads on the grid (016). However, this requires careful planning and understanding of the energy infrastructure, as well as the energy up-take requirements of farms, as VF can also put extreme pressure on the grid (002). Thirdly, with regards to renewable energy

sources, a number of entrepreneurs pointed out that in their experience it is not possible to cover energy demand by only renewable energy sources (009, 015). This is mostly due to the fact that most VF facilities are not yet at the scale where they can make use of on-site solar energy (006). Furthermore, utilizing on-site renewable energy sources increases the complexity of the farm, which seeing that the industry is still in the early phases of innovation increases the risk of failure (016).

Market Dynamics and Conditions of Peripheral Industries. This factor is essential to consider as seemingly peripheral industries carry great potential for developments in VF. Changes in other industries can affect the market for the produce and the prices or availability of growth components. The primarily example mentioned for this dynamic can be found in the North American context, where the legalization of cannabis is creating a new and controlled market for plant growers. As was outlined by a growth component supplier, the opening of a regulated market has attracted traditional horti- and floriculturists to grow cannabis, leaving their initial markets with an undersupply. The resulting changes in pricing have produced a market environment, which allows for new industry players to enter the market with more capital-intensive production methods, for example VF (006). This point highlights that seemingly external market dynamics can have a direct impact on one specific industry.

Insurance. The final point that did not fit the categorization of van Doren et al. (2018) is related to the role insurance companies and their requirements play in blocking VF. In general it was suggested that insurance companies set the requirements for extra technical additions from a health and safety perspective, by for example requiring sprinklers above the plants incase of fire, which directly effect profitability in terms of upfront costs (010, 013). Furthermore, the general perception is that insurance companies are sceptical of business models aimed at retrofitting old buildings by for example reducing the maximum floor load when installing piping (013). This factor can seriously hinder the potential for reusing vacant space.

4.5. Social-cultural context

Environmental Awareness and Values. In terms of awareness and values two main clusters should be outlined: 1.) general consumer attitudes towards VF and the surrounding dynamics, and 2.) broader societal developments in terms of food related environmental attitudes.

Most interviewees agreed that there is general perception that that VF is not natural (009, 010, 014, 015, 016). In response to this, an Amsterdam based VF entrepreneur suggested that,

> *"for me it's completely not natural that we have cities with more than 10 million inhabitants. […] I would really like humanity to be established in a way that it is spread equally around the globe; we would be okay with growing everything through organic methods and permaculture. That would be perfect, but is it natural to have cities with more than 10 million people? No."*

In the eyes of those working in the VF industry, these perceptions also stem from opinions based on half-information stemming from the early phase in the innovation cycle (008), and generally lacking awareness of how food is produced (009, 010) and how food systems function (001). As a Dutch interviewee outlined, "we are not aware that food is anything else than a given" (008). In a similar conversation a Germany based VF project manager outlined that their company's existence is legitimized by placing VF at the crossroads of fresh food production and reducing environmental impact. She suggested that this is necessary as "we're all very demanding global citizens that want everything all at once" (014).

Nevertheless, there is a general growth in media attention (010) in the topic on the one hand, while on the other hand it was mentioned that VF specifically carries the same educative potential as traditional soil-based UA when it comes to citizen engagement on the local/neighbourhood level, as was explained by a municipal actor (017). It was also suggested that the general gap in the knowledge about food systems can be potentially addressed by appealing to the tech-savy generation(s) through engaging them with agricultural food production in this manner (015). Next to this, on a more *landscape* level, consumer level pushes to buy more local produce (006), the adjoining (global) sustainability agendas, such as the SDGs (004) or growing discourses on circularity, as for example in The Netherlands (006) carries the potential to support VF in terms of shaping mind-sets and behaviour.

This being said, it is essential to point out that efforts to raise awareness about food systems should also conceive of VF in this context. As the same Germany based project manager suggested,

> *"vertical farming particularly in urban city centres shouldn't be seen as a replacement for a local agriculture system that already exists. It's more about really re-shifting our focus onto regional produce and urban food systems [...] the cities themselves can become self-sufficient in their fruit and vegetable needs." (014)*

In this sense, VF is an element of a larger systemic solution targeting regional and urban food systems as is also outlined by Forster and Escudero (2014). Finally, a key point raised by an

entrepreneur is that the scepticism towards VF in terms of it being natural or not can be a catalyzer to open conversations about food systems at the consumer level (016). By being exposed to food production that is perceived as unnatural, the above-mentioned scepticism and general questions about the origin of food that winds up on the consumers plate can also be asked. Hence the science-fiction-like look of plants growing under purple lights carries the potential to open up larger discussions about factory farming, food-miles, and year-round availability of fresh produce.

Consumption Culture. When discussing any topic related to the supply of produce, the surrounding consumption culture should also be examined. Hence also in the case of food, it is necessary to also explore the dynamics throughout the consumption chain, which is why food culture is a key point. One respondent outlined that when one looks at any type of transformation within a food system, the focus should be on targeting the predominant food culture (001). He went on to describe the problematic nature of fast-food dominant food culture (001, 003). This aspect highlights the persistence of structural and systemic problems, seeing that the continuous presence of cheap and unhealthy foods make it questionable if green values and marketing or communication strategies on sustainable and organic produce are sufficient to change end consumer behaviour, and if at all the presupposed agency is present. In this sense VF in and of itself will not bring society-wide changes in the context of food consumption, as structural barriers persist, and thus should be targeted from a more systemic perspective.

Product Qualities. Seeing that VF is ultimately focused on produce, the qualities of these products should also be explored, as this is one of the competitive advantages arising from VF. Different qualities that carry competitive advantages outlined are as follows: high-end produce, for example edible flowers, herbs, and micro greens can be produced through VF (003, 007, 012), non-edible produce, for example for cosmetics, pharmaceuticals, and pet foods (014) can be produced in these plants, and finally produce that is difficult to ship long distances also carries a competitive advantage (003).

Nevertheless, demand for food is more varied than VF can currently meet (005), which is a major barrier. As two interviewees outlined, “we cannot feed the future cities in this way at least not with the current technology” (006), which means that “vertical farming will definitely not feed the world” (016).

Social- and Power Relations. A key factor, which was preconceived of as missing from the theoretical framework is that of social- and power relations. For this reason, explicit attention was paid to assessing this element of VF as well. This is the key factor when considering the politicizing focus of the critiques of transition theories (Wachsmuth, 2012), and the metabolic conception of cities (Swyngedouw, 2016). In terms of societal problems, the following can be said. Firstly, socio-cultural divides between different groups within a city are apparent in food cultures as well (003). This means that health problems related to food are often grounded in economic standing (003). Secondly, food policy is often too focused on middle-class consumption patterns (004). For VF to be successful these points need to be actively considered by those working in the field, be those entrepreneurs, public officials, or the AVF, as societal acceptance of this type of innovation depends on its accessibility by the wider public.

In terms of problems explicitly mentioned in relation to VF the following can be said. Firstly, the industry has an extractive tendency. A respondent mentioned that certain companies even utilize the up-coming food crisis to market their products with only profit in mind (009). Secondly, VF does not directly and inherently carry an inclusive social dimension, which is common in soil based Urban Agriculture (004). Finally, closely linked to the societal points above, VF produces high-value products that tend to serve the wealthiest strata of society – the top 5% of the consuming public (006). These points are essential to consider when planning for the up-scaling of such a technology, as wide applicability and acceptance depend on considerations for wider societal needs.

4.6. Natural and Built Context

Technical Compatibility. The final point within the predefined theoretical framework developed by van Doren et al. (2018) is that of technical compatibility. The most general result under this factor is that VF solutions always have to take the specific urban context into consideration (003). This means that plug-and-play solutions are theoretically viable, and in terms of yield quantity and quality even more reliable; however, it does not directly guarantee market competitiveness or acceptance in societal terms directly. In this sense, contextual factors to consider are 1.) levels of development, 2.) sunlight hours and growing seasons, 3.) density and fresh produce availability from local/regional sources, 4.) the tension between universal applications and adaptability to already existing built environments, and 5.) the logic demanded by different urban settings when it comes to food systems. These points are discussed hereon.

Firstly, from a technical perspective, due to the unitary logic of CEA, VF is possible anywhere in the world (010). However technical compatibility and advancement is always dependent on the levels

of development where VF is to take place. This means that possibilities to automate for example are dependent on the relationship between capital and labor costs (009). Next to this, compatibility with locally available parts produced by local manufacturers should also be considered from a sustainability perspective, as was outlined by an Amsterdam based VF entrepreneur (009). Nevertheless, viability of a farm is also dependent on natural conditions, namely the general growing seasons and sunlight hours. Environments with ample sunlight do not directly necessitate VF as in these areas greenhouses can suffice (006). It is environments with low sunlight hours and short growing seasons, for example in Scandinavia, which necessitate VF (006, 014). Besides general soil quality should be considered (015), which is an essential point in the context of the global imbalance in the nitrogen and phosphorus cycles (Rockström et al. 2009).

Furthermore, factors specific to the given urban environment, which were mentioned and should be considered, are density (014), the extent to which mega-cities are dependent on long supply-chains, extensive food miles, and imports of fresh food (009, 014), and the land price in city centres (010, 015). This being said there is no perfect recipe for choosing fitting cities. These factors illustrate that multiple points need to be considered when choosing the viable sights for VF, and highlight that the theoretical universal applicability of the technology does not compare to universal viability. A LED lighting provider based in Finland illustrated this, who suggested that,

> *"you have different logic in different cities depending on the geography, the political system, and development." (011)*

He went on to categorize cities on the basis of the different kinds of enabling logics that allow for VF. Firstly, he mentioned Hong Kong and Singapore as cities with limited land availability. Secondly, he suggested that mega-cities such as the urban areas around Shanghai and Beijing have concerns for food safety, which can support VF. Finally, he mentioned North American cities, such as New York and Chicago as having a growing environmentally conscious consumer base, which can similarly be conducive to VF, but from a completely different perspective (011). This theoretical exercise once again highlights that different contextual factors can be conducive to up-scaling from different perspectives, and therefore prove the point that there is not a perfect recipe for the best-case urban environment, when it comes to VF.

5. Conclusion

What emerges from the above accounts is a reaffirmation that there is a need to transition urban food systems to a more sustainable state, and that VF under certain conditions can be an active component of such a transition. Nevertheless, understanding what practical steps need to be taken is a crucial first step in this process, and for this reason the accounts of the 17 interviewees scope 26 factors, which should be considered in this process. The case of VF illustrates that even technologically, and in terms of resource use potentially intense interventions also carry opportunities to transition cities on to more sustainable and green pathways. However, it is essential to reconsider these interventions from a more holistic perspective, which allows for assessing environmental impacts from multiple perspectives, and also allows for understanding the socio-economic structures underlying these interventions, and what this means for planning with this type of transition.

As can be seen from the emerging tensions from the above accounts, one-dimensional promises for any type of sustainability intervention should be treated with a grain of salt. This is due to the fact that without appropriate reflection, and the resulting multi-factor mapping of what has to be considered, introducing complex elements into already complex systems – such as VF into urban food systems - can accelerate the given systems level of complexity to unimaginable and unmanageable levels. Ultimately such interventions can result in unwanted side-affects, such as even higher GHG emissions per kilo of produce, hence, a careful assessment of multiple factors should be the bare minimum when conducting planning exercises. As can be seen, the amended framework of van Doren et al. (2018) can suffice in catering to these needs through the 26 factors outlined above, when considering LCUD in cities. As can be seen from the emergent factors, a predominant focus has been put on social and political factors, and their implications for assessing socio-technical interventions. The reason for this is that the initial framework did not sufficiently cater to these elements, and the accounts of the interviewees highlighted the necessity to amend the initial framework.

All-in-all, having applied an urban food systems lens to a potentially scalable socio-technical intervention – Vertical Farming – has proven that multiple and integrated perspectives need to be considered when assessing the true climate mitigation as well as up-scaling potential of such experiments. Next to this conducting such an exercise, encompassing the amended framework of van Doren et al. (2018), has proven that a handful of factors, previously not considered can also emerge in the process, adding analytical depth to the analysis.

Research Paper

DOES THE IMPLEMENTATION OF SPECIAL ZONES OF SOCIAL INTEREST (ZEIS) ENCOURAGES ADEQUATE HOUSING IN PRECARIOUS SETTLEMENTS?

The Case of Sapé, São Paulo

Mariana REIS SANTOS; Brazil/The Netherlands

Abstract

With the establishment of the Constitution of 1988, a new approach to urban governance emerged in Brazil. The document brought significant changes regarding the right to the city and adequate housing, in particular, for the urban poor. The recognition of these rights triggered the experimentation with inclusionary policies around the country (Rolnik and Santoro, 2013). As a result, informal settlements started to be acknowledged as part of the formal city and were included in zoning and planning laws.

One of the main outcomes of these experiments was the creation of Special Zones of Social Interest (ZEIS), a land and housing policy that linked investments on infrastructure in precarious settlements to land regularisation processes. In 2001, ZEIS was incorporated into the City Statute, a document that established a range of collective rights to guide land use and development. Since then, the instrument has gained popularity in the country as a land regularisation tool. Nevertheless, a considerable share of settlements remains poorly built and addressing informality is still a challenge.

Therefore, this paper evaluated the co-relation between the implementation of ZEIS, land regularisation processes and provision of basic infrastructure in precarious settlements. More specifically, it measured the quality of State interventions supported by the zoning. By focusing on quality, this article aimed to evaluate whether ZEIS has encouraged adequate housing conditions for the urban poor or reinforced precarious patterns of development.

To explore this relationship, a case study was conducted on the performance of ZEIS in Favela of Sapé, a settlement in the West of São Paulo. As a methodology, case studies have become a common option for performing evaluations and analyse what a program, practice or police has achieved (Yin, 2012). Moreover, this research strategy commonly relies on various sources of field-based information (Yin, 2012). Accordingly, this paper comprised mainly primary qualitative data. It also made broad use of content and secondary analysis, with the goal of ensuring validity and reliability.

The performance of ZEIS in Sapé demonstrated that since its implementation, in 2001, tenure security and physical characteristics have enhanced considerably in the area, particularly, when it comes to housing quality and provision of basic

infrastructure. Nevertheless, these accomplishments are being compromised by a strong process of reoccupation which is supported by illegal organisations. In addition, there is a delay of the Municipality in meeting the demands for housing in the area because of governance issues and mismanagement of financial resources.

This scenario, combined with a weak inspection body, has once again permitted the development of precarious housing and infrastructure in the area. It also has compromised the issuance of freehold land titles to the settlement's dwellers. In other words, the site is under a vicious circle where neither the provision of housing and infrastructure is enough to meet the demand nor the land regularisation is completed because of the reoccupations.

In sum, although the implementation of ZEIS seems to have a share of responsibility in Sapé's upgrading process, the local authorities do not have the capacity of reinforcement necessary to maintain these improvements. Furthermore, it is fair to assume that the current legal framework provided by ZEIS is not adequate for the context of São Paulo and requires further adjustments. Not only because of the complex character of the city, but also because in practice, urban norms may be interpreted differently according to political and cultural conditions (Rolnik, 1997).

Keywords

Spatial Justice, Governance, Adequate Housing

1. Introduction

This article was based on the Master Thesis entitled "Does ZEIS encourages adequate housing in precarious settlements? The Case of Sapé, São Paulo", presented at the Institute for Housing and Urban Development Studies (IHS), in October 2018. As the mentioned thesis, this paper evaluates to what extend the implementation of Special Zones of Social Interest (ZEIS) facilitated the development of adequate housing in the Favela of Sapé, a settlement located in the West area of São Paulo. "Adequate" is hereby define as access to basic infrastructure, services and facilities, good location, legal security of tenure, affordability, accessibility, habitability and cultural adequacy.

To conduct this evaluation it was necessary to understand how ZEIS operates. Therefore, legislation, official documents, annual reports, policy documents, and GIS information were extensively analysed. Moreover, previous research was reviewed, with the goal of understanding the trajectory of the instrument and the challenges of design and implementation. In addition, to draw an overview of the current situation of the built environment of Sapé, semi-structured interviews were conducted with professors, government officials, and professionals engaged in the settlement's upgrading process.

The urban interventions in the settlement started in 2012 and are currently on its final stages. Nevertheless, the initial intervention plan suffered many alterations and several aspects were not implemented. In fact, there is no prediction of when or whether or not these aspects will be carried out (Formicki, 2017). Therefore, this article discusses the outcomes of the implementation of ZEIS in Sapé and the performance of the public authorities. Through this discussion, this paper evaluates the effectiveness of ZEIS as an

upgrading tool and establishes whether the instrument has encouraged decent housing conditions or reinforced precarious patterns of development in the settlement.

1.1. Informal development in Brazil

Accommodate the abrupt population growth, caused by the current pace and scale of urbanisation, has been a major challenge for public administrations. On one hand, governance and public policies have a fundamental role on encouraging an equitable spatial development, particularly, when it comes to inclusionary measures and social assistance for vulnerable groups. On the other hand, overregulation and technocratic urban norms commonly difficult the access to the formal land market and, therefore, reinforce informality (Biderman and Smolka, 2009).

The issue of informal land development is acknowledged in Brazilian cities since the end of the XIX century. In fact, since then, informal settlements have been consolidated as the main alternative for low-income families to access the urban land market (Cardoso, 2007). This phenomenon was reinforced not only by historical inequalities and uneven distribution of land and wealth but also by the incapacity of the State of regulating the Real Estate Market. Not to mention the absence or ineffectiveness of housing policies for low-income families in the country.

As a consequence of this scenario, the development of the majority of Brazilian cities happened without planning and with the basic infrastructure following (instead of preceding) the occupation of the land (Cardoso, 2007). Because these occupations often happened in environmentally fragile areas, this pattern of development brought high financial and environmental costs for the public authorities. Furthermore, it shaped the access to basic infrastructure, services and facilities as a luxury, encouraging the speculation with land. In other words, the urban development in Brazil is marked by

"restricted conditions of access to land and housing; high costs of housing production and or urban services, aggravated even further by inflation and unequal (and unfair) patters of income distribution; real property treated as exchange value; extensive hoarding of idle land; and an intense speculation process" (Fernandes, 1993, pp. 213)

It is in this scenario of scarce public resources and high speculation with land that the favelas are formed.

1.2. A shift on the approach to informal development

The approach of the public administration to informal settlements was often inconsistent, varying from efforts of eradication to palliative improvements. Moreover, because there was no legal arrangement to support investments on infrastructure and services these areas, the public interventions were often ineffective. This started to change in the 1980s, with the new Constitution and subsequent implementation of the City Statute[1]. The City Statute brought significant changes to the approach to urban governance in Brazil; particularly, regarding the management of precarious settlements. Through the articulation of several

[1] The Federal law nº. 10.257 of 2001, commonly called the City Statute, was created to regulate the Articles 182 and 183 of the Federal Constitution of Brazil which coordinates urban development policies.

urban instruments, the document created the legal arrangement necessary to regulate and integrate these areas to the formal city.

One of the major instruments instituted were the Special Zones of Social Interest (ZEIS). In the process of building a new urban order based on the principle of the social function of property, ZEIS were consolidated as a unique type of zoning. The main objective of the instrument was to guarantee to low income families the access to urban land served with basic infrastructure, services and facilities. Therefore, ZEIS represented a shift on the approach to informal settlements. Because of the instrument, these areas were for the first time recognised as part of the formal city and included in planning and zoning laws.

2. The case of Sapé

Sapé is a precarious settlement located in the West of São Paulo, under the administration of the Butantã Borough, in the Rio Pequeno District (see Figure 1). The Butantã Borough is one of the wealthiest regions of the city and has significant points of interest such as the Hospital Israelita Albert Einstein, one of the most important private hospitals of the city, the Palácio dos Bandeirantes, seat of the São Paulo state government and the University of São Paulo (USP), one of the biggest universities of the country.

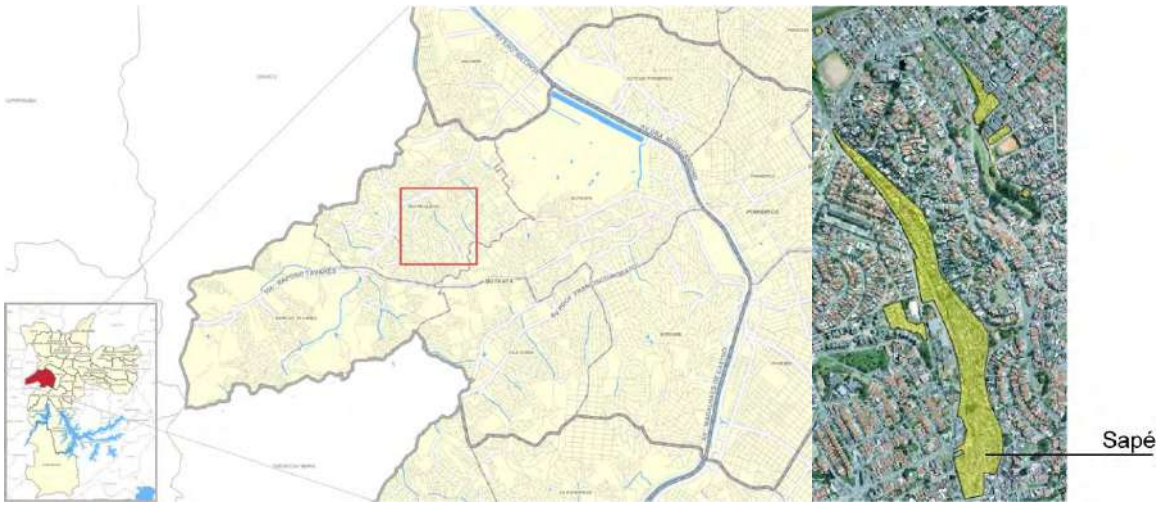

Figure 1 Location of Sapé in São Paulo

Rio Pequeno was mainly formed by pottery, quarry and construction workers, hired to build the university during the 1960's and 1970's, a moment of strong urbanisation in the city. Constructed in public land, the settlement, which started with a few houses along the Stream of Sapé, became a dense and precariously built slum. Because of this densification, the occupation overcame the stream, which led to precarious housing and sanitation conditions (Brandão and Leitão, 2016). Moreover, because of the proximity to the stream, the area went through several episodes of floods over the years, which regularly resulted in great material and human losses.

The public interventions in Sapé occurred in a fragmented way and because of the environmental fragility of the area, the actions towards the depollution of the stream and relocation of dwellers situated in flood-prone areas were fundamental. Therefore, the actions of the public authorities in the area were marked by the tension between environmental demands and housing and urban infrastructure demands.

In 2002, Sapé was regulated as ZEIS by the PDE and incorporated into the Land Regularization Program, resulting in the provision of land titles even before any urban infrastructure arrangement (Grosbaum, 2010). In parallel, the Sapé Stream went through multiple interventions conducted by the Córrego Limpo and 100 Parques Programmes, which were concluded in 2009. The implementation of ZEIS brought about the urbanisation plan of the area. Nevertheless, because of the delay of the public authorities in articulating the necessary arrangements to initiate the construction works, the population in the area had increased and the urbanisation plan had to be readjusted. Finally, in 2010, a public bidding was made and the construction works, which are still running, began.

3. The outcomes of ZEIS

3.1. The effectiveness of ZEIS as an instrument

The demarcation of Sapé as ZEIS ensured the population of the settlement the right to usufruct from the city, in a good location. Therefore, the zoning overcame the “highest and best use” of land, by establishing areas of social interest in prime locations (Borelli and Santoro, 2015). Moreover, the institutional and legal arrangements required to implement the zoning permitted an active and democratic engagement of the community in the urbanisation process.

The intervention plan of Sapé has achieved significant improvements regarding the availability of basic services such as electricity, water, sewage and refusal disposal and, social services and facilities. The removal of dwellings from hazardous areas enabled significant improvements on the quality of the water of the stream. Additionally, it made room for the construction of public spaces, causeways, roads and, cycle paths. Another significant contribution to enlarge the availability of space was the verticalisation of the new housing units. This allowed the allocation of a higher number of people in a smaller area, what is beneficial if you consider the environmental gain to the region and the elevated number of removals conducted along the stream. Nevertheless, the positive outcomes of the urbanisation plan in the area may be at risk because of the strong process of reoccupation of common spaces and hazardous areas.

It is important to highlight that the approach of the Municipality was either to provide infrastructure and do not interfere in the dwelling`s physical characteristics or provide infrastructure and reconstruct the dwellings completely. This indicates an unequal distribution of public resources in the area and favours part of the population instead of benefiting the population as a whole, in an equal manner. The performance of the Municipality demonstrates that the actions of the State often encourage injustice by promoting “private appropriation and accumulation of the commons, the resources, and the collective-created world” (Zárate, 2015, pp.27).

Another approach that disfavoured part of the population was the criteria to select the families that were entitled to these apartments. Because the intervention was made through

a public-private partnership, the financial resources were held by the private sector. Therefore, among their criteria of selection, there was the ability of the family to pay for the new apartments. This is controversial because, through the selection of families with higher financial capability, the opportunity of accessing adequate housing is taken away from the dwellers that need it the most. This illustrates the positioning of Harvey (2015) that profit is commonly prioritised over people's rights, necessities, and well-being. Additionally, this criterion goes against the principle of ZEIS itself, which is to ensure the right to the city and housing to low-income groups.

Nonetheless, in a conflicted manner, the implementation of ZEIS has succeeded in providing legal security of the tenure to the inhabitants of Sapé. The zoning guaranteed to Sapé's dwellers the right to be relocated to the adjacent neighbourhoods and receive financial aid from the government to cover rental expenses. Moreover, the zoning also entitled the inhabitant out of the hazardous areas to remain on-site and, therefore, granted these dwellers the right to the city and subsequent accomplishment of the social function of property, cited by Borelli and Santoro (2015) as one of the positive outcomes of the zoning.

Nonetheless, the issuance of titles did not occur in the area yet because of the reoccupations supported by criminal organisations in the settlement. This demonstrates that perceived tenure security is not only provided to informal dwellers by public investments, as defended by Durand-Lasserve et all (2009), but also by the compliance with the demands of criminal organisations, that often overcome the power of the State in these areas. This confirms the affirmation that cities have become an expression of inequalities and violence (Zárate, 2015).

In Sum, the implementation of ZEIS in Sapé has formed a vicious circle where neither the provision of social housing and infrastructure is enough to attend the demand nor the land regularisation is completed due to the reoccupations that have been contributing to the increase on the population in the settlement. This vicious circle is illustrated below.

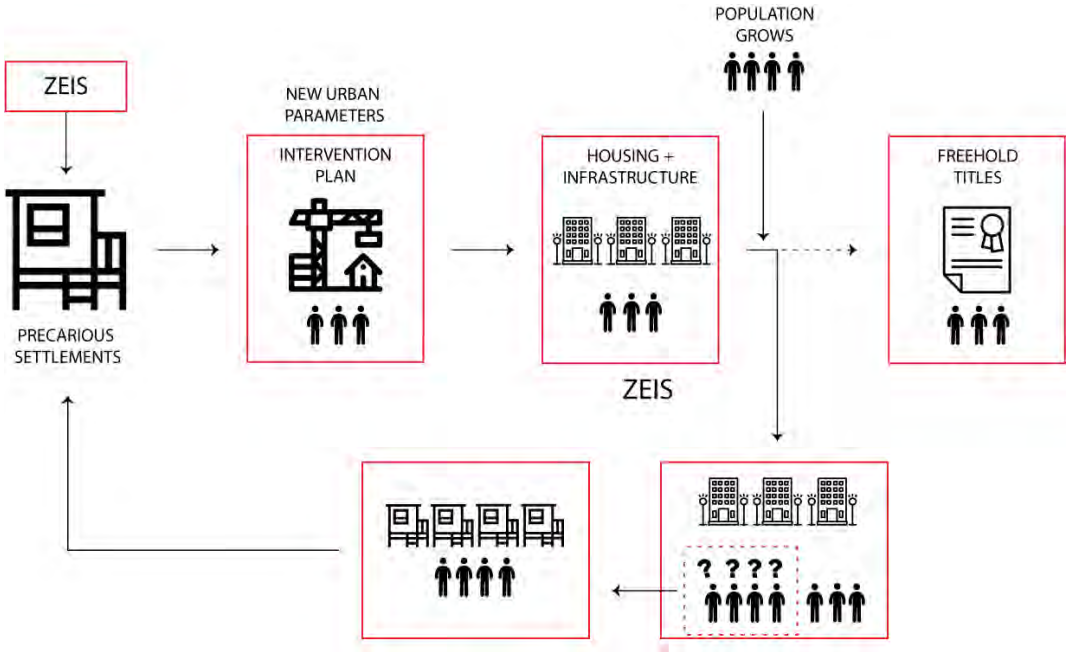

Figure 2 Vicious circle, an outcome of ZEIS in Sapé

3.2. The impact of ZEIS on housing conditions

Housing conditions have changed significantly in Sapé since the institution of ZEIS, particularly since 2011 when the most radical phase of the intervention started to be implemented. Before the zoning, a considerable share of the residential development in the settlement was in hazardous areas, subject to floods and landslides, which was a threat to the life of the dwellers living in these conditions. In addition, the inhabitants that were not in hazardous areas were provided with basic infrastructure and sanitation facilities, which by itself is already a significant advancement considering the precariousness of the settlement before the Public authority intervene. In addition, the area was provided with public spaces, sports facilities, cycle paths, and adequate roads. The construction of these soft services assisted the creation of a socially just space.

The relocation of people from hazardous areas was not only beneficial from a safety and health point of view, considering that most of these dwellers were poorly built and nearby the stream that was an open-air sewage, but also from an environmental perspective. These relocations allowed the depollution of the stream and the provision of sanitation systems to the area, as well as the mitigation of floods. In addition, the inhabitants that were living in precarious conditions around the stream were relocated to newly built apartments, constructed with durable materials an out of hazardous areas. However, a considerable share of dwellers that were relocated did not return to Sapé yet due to the lack of social housing, demonstrating that the demand for housing in the area is still higher than the supply. Furthermore, the actions of criminal organisations in the area have been encouraging the reoccupation of public spaces. This reoccupation process may trigger the precarious development of land in the area once again, considering that the supply of housing is, as mentioned, already insufficient.

3.3. ZEIS and Adequate Housing

When considering the dimensions of adequate housing posed by this paper, the most significant contribution of ZEIS was the provision of legal security of tenure. Although the issuance of titles has not occurred yet, alternative forms of tenure have been granted to the inhabitants of the settlement. Further, legal security of tenure has been ensured also to the inhabitants that were temporarily relocated to the neighbourhoods around Sapé. Nonetheless, the delay of the Municipality on concluding the construction works has been precluding the return of these families to the settlement, which constitutes a violation of their rights. Moreover, the elevated rental costs of the surroundings compromise another dimension of adequate housing that is affordability. This contributes to the criticism of Harvey (2012) and Lefebvre (1996) regarding the neoliberal approach that our cities are managed.

The financial burden of the urbanisation plan is also extended to the families that have remained on-site during the construction works. Although ZEIS is supposed to encourage housing affordability, the provision of public infrastructure and services to Sapé have had the opposite effect in the informal property transactions in the area. This is a common outcome of slum upgrading. Nonetheless, the zoning succeeds in containing the pressures of

the formal Real Estate Market and, indeed, ensures the right to the city to slum dwellers (Borelli and Santoro, 2015). However, in Sapé, it has failed in meeting the demands of the lower income population for housing. This failure resulted mainly from the mechanisms used by the Municipality to finance these interventions, as well as the lack of a unified system to prioritize the demand for housing in the city. Furthermore, the engagement of the private sector in the urbanisation process of Sapé and the incapacity of the local authorities of overcoming the interests of the latest resulted on the selection of families that had a better financial condition over families in hazardous areas. This situation compromises the accessibility of housing in the area. Nonetheless, this scenario is not triggered by the zoning, but for financial and public administration issues.

Regarding the cultural adequacy of the environment constructed in the area, ideally, the new housing should follow features similar to the existing dwellings, what does not occur. By choosing to verticalise the new units, the Municipality contradicts the character of the area. On the other hand, in a megacity like São Paulo where the land is scarce, particularly to produce social housing, this may be a suitable approach. Furthermore, it has ensured to most of the population the right to remain on-site and enjoy a physically safe location, what according to Caldas (2009) is the most adequate approach to intervene in informal areas.

The verticalisation of the housing also promoted significant environmental improvements. A considerable share of these enhancements is a result of the depollution of the Sapé stream and the construction of adequate sanitation systems, which was only possible because of the removal of dwellers from the stream floodplain due to the verticalisation approach. Accordingly, it has also contributed significantly to the habitability of the settlement. Nevertheless, the efforts to clean the stream were a result of the combined actions of the Córrego Limpo and 100 Parques programmes and not of the implementation of the zoning,

Additionally, to ensure such habitability, a high number of removals had to be conducted in the settlement, which violates the right of these dwellers of remain on-site. At the same time, it was necessary because of the precarious and dangerous conditions on which these inhabitants were living. Although these removals are temporary, it may have a negative impact on the livelihood and social connections of Sapé's inhabitants, even with the concern of the Municipality in relocating these dwellers to adjacent neighbourhoods. However, the socioeconomic impact of urban interventions instigated by the implementation of ZEIS, as well as the impact of relocation on the livelihood of dwellers subject to these interventions shall become the object of further research.

Summarizing, the implementation of ZEIS in precarious settlements seems to have a share of responsibility on the adequacy of housing produced in these areas. Particularly, when it comes to ensuring a good location in the city and providing the legal security of tenure necessary to remain in such good location, which guarantees to the inhabitants of these settlements the right to usufruct from serviced land. Nevertheless, the urban parameters permitted by the zoning seems to be distorted to fulfil the private sector requirements, as can be perceived by how the affordability and accessibility of housing were managed in Sapé. In addition, the major advancements on habitability result from the depollution of the stream, which is an outcome of a public-private initiative that is not connected to the zoning, revealing that the implementation of ZEIS was not significant to this process. At the same time, the special urban parameters established by ZEIS permitted a higher use of land, which made room for the construction of public spaces and infrastructure. These were major

improvements to the settlement. And finally, as already mentioned, although verticalisation is not culturally adequate to the profile of Sapé, it enabled important advancements to the area. Accordingly, the overall contribution of the implementation of ZEIS in precarious settlements to the encouragement of adequate housing is summarized in the following scheme.

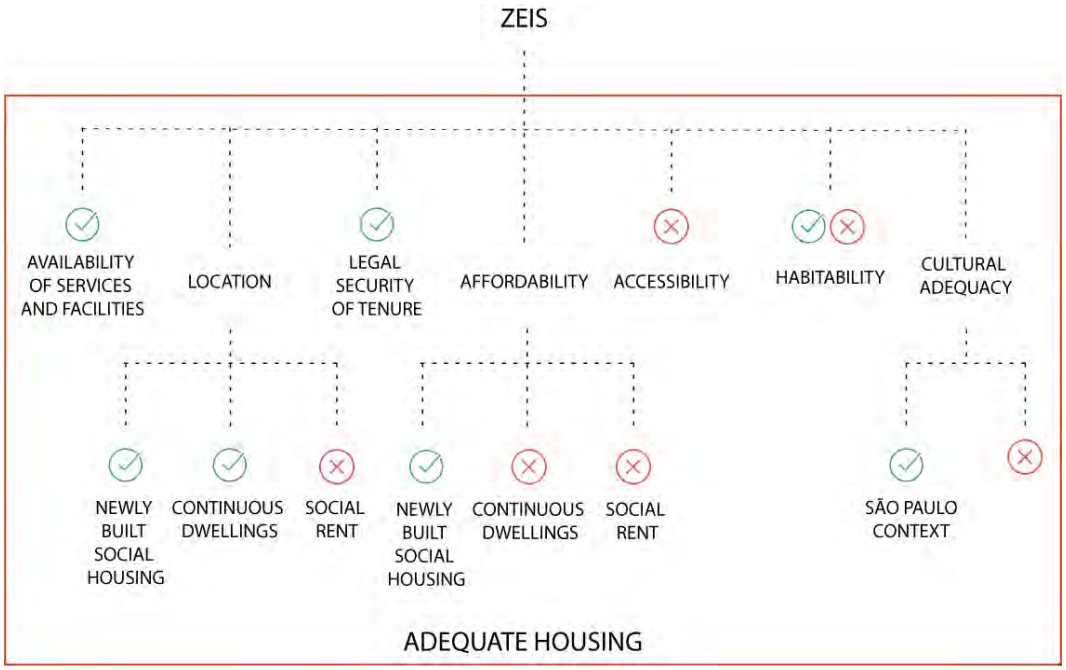

Figure 3 How ZEIS influenced adequate housing in the case of Sapé

4. Conclusion

A considerable share of the negative outcomes of the implementation of ZEIS is related to the lack of financial resources and governance issues. This is illustrated by the case of Sapé, which despite being a ZEIS since 2001, did not suffer significant interventions until 2011, when the financial resources of the central government were made available by the Growth Acceleration Programme (PAC). Besides that, there is a clear delay on the actions of the Land Regularisation Sector (CRF) in reinforcing the interventions made by the Physical-Territorial Sector – CFT (the sector responsible for the coordination and execution of projects). In addition, precarious settlements also face issues caused by changes on administration. For instance, the issuance of CDRU's to Sapé's dwellers even before the implementation of ZEIS and, thereafter, removal of the families that received the concession. Moreover, the instrument seems to be often distorted to attend the demand of the Real Estate Market for profit. In addition, although ZEIS receives financial resources from other urban policies, it seems that in the context of São Paulo, the production of housing has been prioritized over improvements in precarious settlements, again, to satisfy the demand for profit of the private sector.

Research Paper

EVALUATING THE URBAN FORM OF A MOUNTAINOUS CITY FROM THE PERSPECTIVE OF COMPACTNESS CHARACTERISTICS: KIGALI CITY, RWANDA

Ivan RWAMPUNGU, Department of Civil Engineering and Architecture, Saga University; Japan

Prof. Dr. Nobuo MISHIMA, Department of Civil Engineering and architecture, Saga University; Japan

Abstract

A better understanding of the composition and form of cities, and how land use changes throughout a city, can provide helpful insights for city sustainable planning. Many sustainable city models have been studied and the compact city concept has been adopted as one the sustainable model in city planning policies of many countries. However, due to dynamic nature of the city structures around the world, there exists a limited consensus on parameters and dimensions to measure urban compactness especially in the cities developed in unplanned manners. This study aims at analyzing and understanding the urban form in Kigali, the capital city of Rwanda. Two dimensions of spatial organization and spatial distribution of population were measured using GIS functions to objectively evaluate physical compactness. Findings reflected trend of decrease in compact form with absence of sustainable concepts due to lack of regularity authority control and haphazard development. Suggestive measures were provided for future consideration in sustainable urban development of the city.

Keywords

Urban form, compactness, mountainous city

1. Introduction

1.1. Background

The spatial growth of cities is an avoidable fact around the world. In the last 200 years, while the world population has increased six times, the urban population has multiplied 100 times. Today, approximately 50% of the world's population lives in urban areas (Stalker 2000). It has been very significant during last decades mainly in cities of developing counties like Asia and Africa. The expansion is caused by many factors and has been resulting in creation of different city patterns. The first and foremost reason is increase in urban population. The urban population in Africa is expected to triple by 2050 and reach 1.3 billion (UNDESA, 2014). The increase in urban population automatically lead to the increase in density and need for both living space and other activities created by the new population. The resulting spatial pattern will describe its compactness or sprawling. Some cities have been able to

control at some extent this increase by promoting relatively high residential density, thus keeping the population inside its boundaries. On the other hand, cities have expanded its boundaries permitting the new population to live away from the city centre on green spaces leading to an unforeseen urban sprawl. A problem which is currently affecting many cities and being condemned for its negative environmental, economic and social impacts.

With these new urban forms evolving trough urban planning, many studies have tried to find out new urban forms practices and design that are sustainable. However, the debate on most suitable urban form to achieve sustainability is still unresolved. The term "Urban form" can be defined as the physical structure and pattern of urban elements meaning buildings, lots, blocks, streets, intersections, spaces and the way in which these elements are configured and used. In order to achieve urban sustainability, this combination of urban elements and the form need to be understood (Jenks 2000). Jenks, Williams and Burton included the notions of compactness, urban intensification, traditional neighbourhood design, density, mix of uses, housing type and decentralization to define a sustainable urban form. Jenks (2000).

Many sustainable city models have been studied and the compact city concept has been adopted as one the sustainable model in city planning policies of many countries. However, the compact city concept dates back to the early 1970s with the book: "Compact city: Plan for a liveable urban environment" by Dantzing and Saaty (1973). This concept resurged in the United States and later on found more attention in Europe. The rationale being to protect the city for the old compact city, the contemporary concept ensures more efficient use of the land and natural resources as well as achieving better quality of life. Moreover, the compact city concept is based on the process of intensification within city boundaries to increase residential density, centralization and mixed uses while limiting the development beyond the city boundaries (Churchman 1999). The three main components of compact city are high density, mixed land use and intensification. (Burton 2002). Many researches cleared the three components into dense and proximate development pattern, urban areas linked by public transport, and accessibility to local services and jobs. Also, UN-Habitat has recommended five principles of compactness including high density (at least 15,000 inhabitants per square kilometre), mixed land-use, social mix, limited land-use specialization, and efficient street network (UN-Habitat 2014). The benefits of compact city are such as efficient use of land while curtailing sprawl, reduction in transport network and reliance on mass transport, etc. High densities impel less space observed per capita with more land for agriculture and open spaces; public transport serve better in dense settlements with low dependence on private cars; higher densities reduce society's environmental footprint and slow the consumption of non-renewable resources (Ewing 2008).

More than half of the world's population live in urban areas and it is expected that the majority of all future urban growth will occur in Asia, Africa and Latin America. Urban populations in these three parts are expected to double by 2030, while the built-up areas of cities are expected to triple from 200.000 square kilometres to 600.000 square kilometres. (Angel et al., 2005). International policy discourses led by UN-Habitat and the world bank are thus actively exchanging new ideas and best practices on how urban planning can become effective. Within the debate on urban form, the compact city is widely promoted as a sustainable solution to the social, environmental and economic of urban sprawl and other unsustainable patterns of urbanization (UN-Habitat, 2009). However, some cities of three mentioned parts of the world may showcase difficulties to implement the concept as

designed due to different existing composition and form of their cities (Donald B., 2017). Therefore, a better understanding of physical, social and economic characteristics, and how land use changes throughout a city can provide helpful insights for city sustainable planning.

2. Methods

2.1. Case study

Kigali is the capital, commercial and largest city of the Republic of Rwanda. It is located in the centre of the country with a status of a province, one of the five provinces in the country. Kigali is one of the fastest growing cities in Africa (Civco et al., 2005). From its inception since 1907, the city has witnessed a remarkable spatial expansion, population growth and developmental activities such as building, road construction, deforestation and many other anthropogenic activities (REMA, 2013). In 1991, Kigali city only covered an area of 112 km2 with 140,000 inhabitants. In 2012, the city expanded to a total population of 1,135,428 living in an area of 730 km2 (NISR, 2012). This has resulted in increased land consumption and a modification and alterations in the status of land cover/use (REMA, 2013).

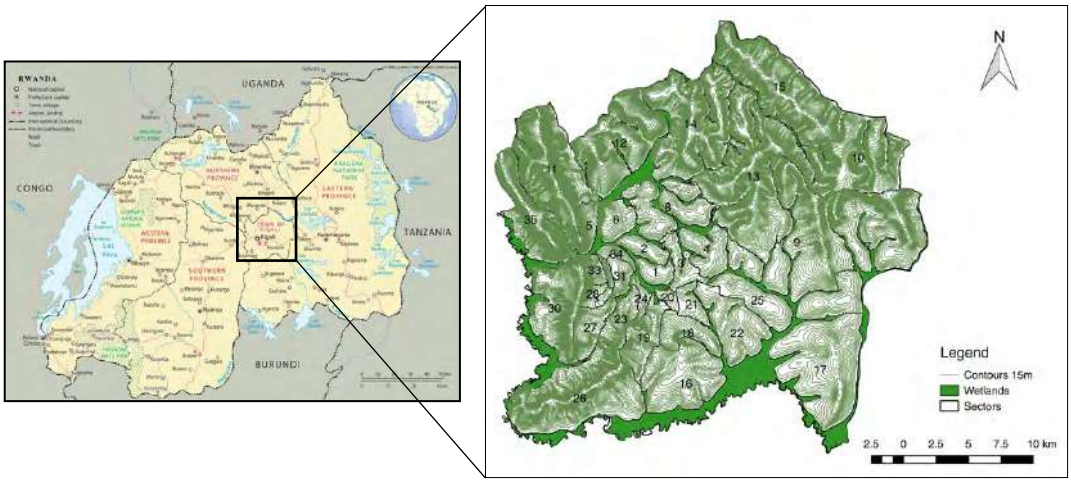

Figure 1 Location of Kigali City and its topographic features. Source:

Kigali is built in hilly landscapes sprawling across ridges and wet valleys in between. Big structures like universities, banks, hotels, international organizations, embassies, government offices, commercial buildings and residential areas of affluent people tend to be built on top of the ridges while the poorer people live down towards the valley. Other poor neighbourhoods are located on the hills which can be seen in the fringes of the city. Wetlands, water bodies, forests, hills with slopes greater than 20 % and other natural constraints to development cover about 50 % of Kigali's area. The city is administratively divided into 3 districts and 35 sub-districts or sectors.

2.2. Aim and objectives

The aim of this study is to measure the urban form of Kigali city, Rwanda through various characteristics of compact form as a sustainable form. The objectives are: (1) to explore trends of urban form expansion; (2) to analyse and evaluate the existing urban form through spatial organization and population distribution measurements and find out whether Kigali city expansion trend generate a compact form, favourable to achieve sustainable urban development.

2.3. Urban form, Compact form and measuring approaches

Urban form is a spatial composition of elements that repeat, and if based on certain sustainable concepts, can lead to the sustainability of cities. The urban form can be monitored on different levels from individual building, street, urban block, neighbourhood to city level (Bertaud, 2013). It is characterized by physical and non-physical characteristics. The physical characteristics are usually stable and easily measurable while non-physical such as density are dynamic. The compact form is conceptually and arguably takin as a sustainable form. Its concept is based on various principles such as intensification, density and mix of uses. This study mainly relates the urban form to the spatial organization and distribution of the population, and land use change trends from natural areas to urban built-up areas. Density and its spatial distribution are basic component of urban form and is used widely for sprawl assessments. Reduction in density over time is considered an indication of urban sprawl and density distribution defines the compactness of urban form.

2.4. Data collection

Data was collected from various government institutions. Various literatures were also reviewed in order to understand spatial organization of urban form and distributions of population. GIS maps representing land use in various year were directly corrected from the urban planning department of the City of Kigali and other data such wetlands data and population census were retrieved from official websites of respective governments institutions. This study is limited to year 2013 due to the availability of data.

2.5. Proposed methodology

Various measures of urban form and compact form are developed by researchers and mainly focus of different aspects such impact of urban form on social, economic, environmental or transport behaviour. In this study, several literatures were reviewed to identify common parameters (Fig.2) that can allow to measure the urban form. In this study, the analysis focused on the spatial organization and spatial distribution of the population. Moreover, some parameters were discussed through literature review and the Kigali Master Plan 2050 which was put in place in 2010.

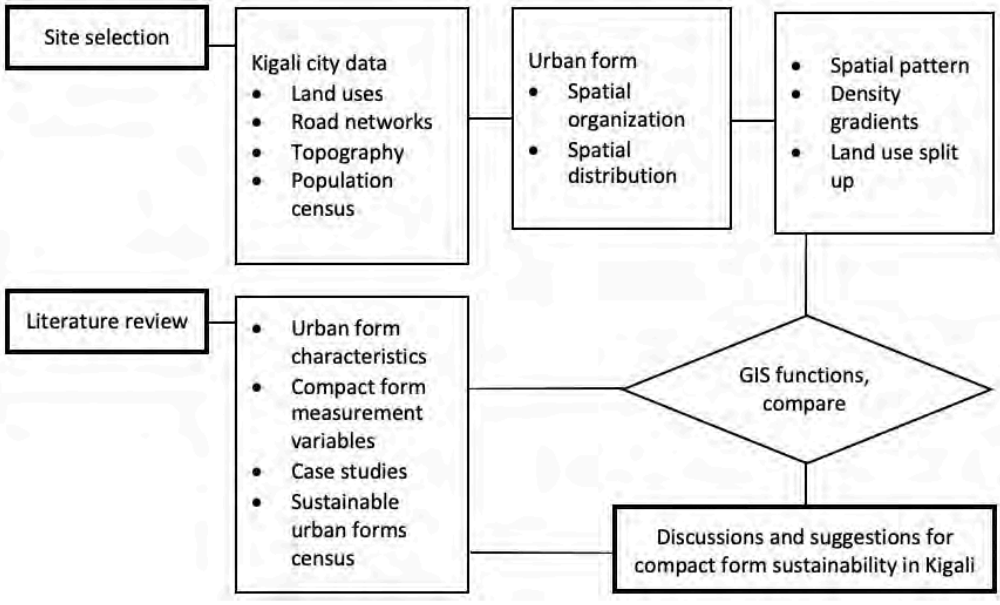

Figure 2 Analysis method. Diagram developed by author

3. Data interpretation

3.1. Spatial organization

The city of Kigali was founded in 1907 but its urban growth started in 1962 after it was declared the capital city. In order to understand the spatial organization of the city we used the method of Bertaud (Bertaud A., 2013). The method uses the concept of superimposing two patterns of the city (1) the spatial pattern of population distribution within the city's built up area when people are at home and (2) the pattern of movement people make around the city during the day. The city of Kigali was found to be predominantly a monocentric model with a dominant CBD and sub-centres. This is mainly a consequence of topography constraints. The CBD, which is taken as the starting point of the city, is located on the top of a hill with gentle slopes and surrounded by wetlands in the northern, eastern and southern sides. On the other hand, the western side is obstructed by mountains with steep slopes. In the process of urbanization, new large to small scale sub-centres were developed creating a multi-centre development with simultaneous radial and random movements of people across the city.

The Central Business District (CBD) is located 6km (Fig. 3) in the western direction from the centre of gravity (CG). The city spatial expansion was always directed to the east. While the eastern part of the city showcases gentler slope, the western part of the CBD is obstructed by Mount Kigali. As par the organic law of the Kigali Master Plan, the developable land should have a slope of less than 20 per cent (KMP, 2013). However, as the master was put in place in 2010, many settlements are located on steep slopes, thus in risky zones to be relocated. Therefore, the spatial distribution and expansion of the city has been mainly influenced by topographical challenges.

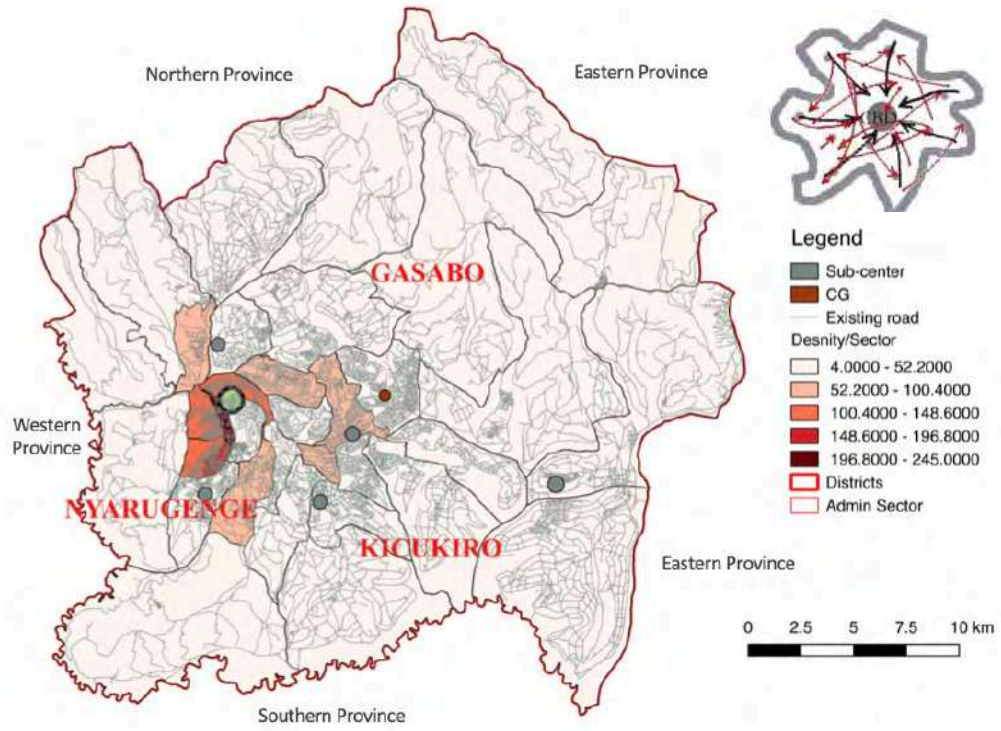

Figure 3 CBD eccentricity and topographical challenges. (Data source: Kigali city urban planning department)

3.2. Spatial distribution

The spatial distribution of the city was analysed through density indicators. The calculations should be based on the built-up area. Four indicators are measured: (1) Average built up area density, (2) Land use split up, (3) Density profile and (4) Population by distance to CBD.

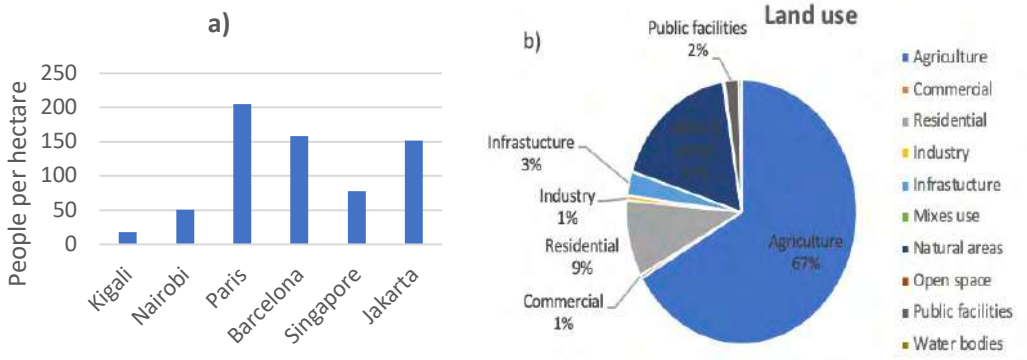

Figure 4 a) Density based on administrative boundaries, b) Land use of Kigali City (2013). (Source: a) Population and area numbers from http://citypopulation.de/, calculations done by author. b) RNRA, 2012)

Figure 4.a illustrates densities of various cities based on their administrative boundaries. As it is visible the density of Kigali is very low compared to other cities. Cities like Barcelona and Paris are classified as compact city due to various reasons including their densification. Figure 4.b showcases the land use occupation in Kigali city in year 2013.

3.2.1. Built up area density

The urban built-up area of Kigali has been growing rapidly since 1962, when it was declared the capital city of Rwanda. In 1990, the administrative area of Kigali was 112 Km2 with 21 Km2 of built up area. Later in 2000, the total area was increased to 349 Km2 with an increase to 47 Km2 of built-up area. It is after 2006 administrative reforms, that the boundaries were expanded to 730 Km2.

In general, the city experienced a relative expansion of built-up areas. Between 1990 and 2010, the city showcases more compactness in the CBD and surrounding built-up areas. The built-up area density has been increasing constantly to reach 147 people per hectare (Figure 5). From 1990 to 2000, the density was primary supported by the densification around the CBD while between 2000 and 2010, however the city area was expanding, the city continued to showcase some more compactness due to a high rate of urban migration compared to settlements. In 2010, the city become more sprawled as the urban density started decreasing. There was a remarkable extension trend in all sides of the city except the western part as depicted in Figure 6. However, the tendency is higher in the eastern and northern sides. The western side was spared to its topography critical for built-up and forests cover.

Furthermore, some new built-up areas appeared in the hinterland of the Southern part. These are smaller and dispersed built-up patches compared to the Northern and Eastern development. Rural lands have been converted into built-up areas due to the increase in urban activities (REMA, 2013). There is a big demand for land by the high number of offices, schools, industries built during last 27years. Moreover, citizens constructed bungalows instead of high-rise apartments.

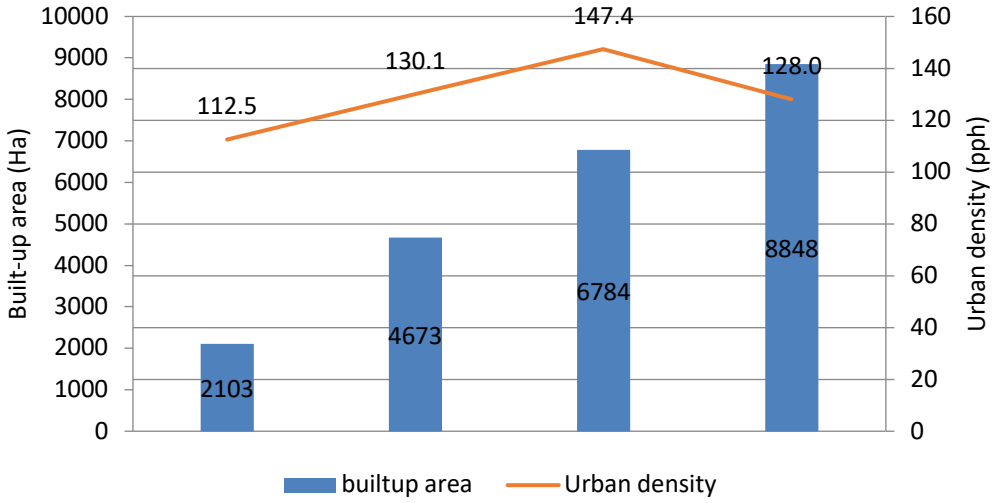

Figure 5 Built up expansion trends from 1990-2013. (Source: Based on KCMP, 2013)

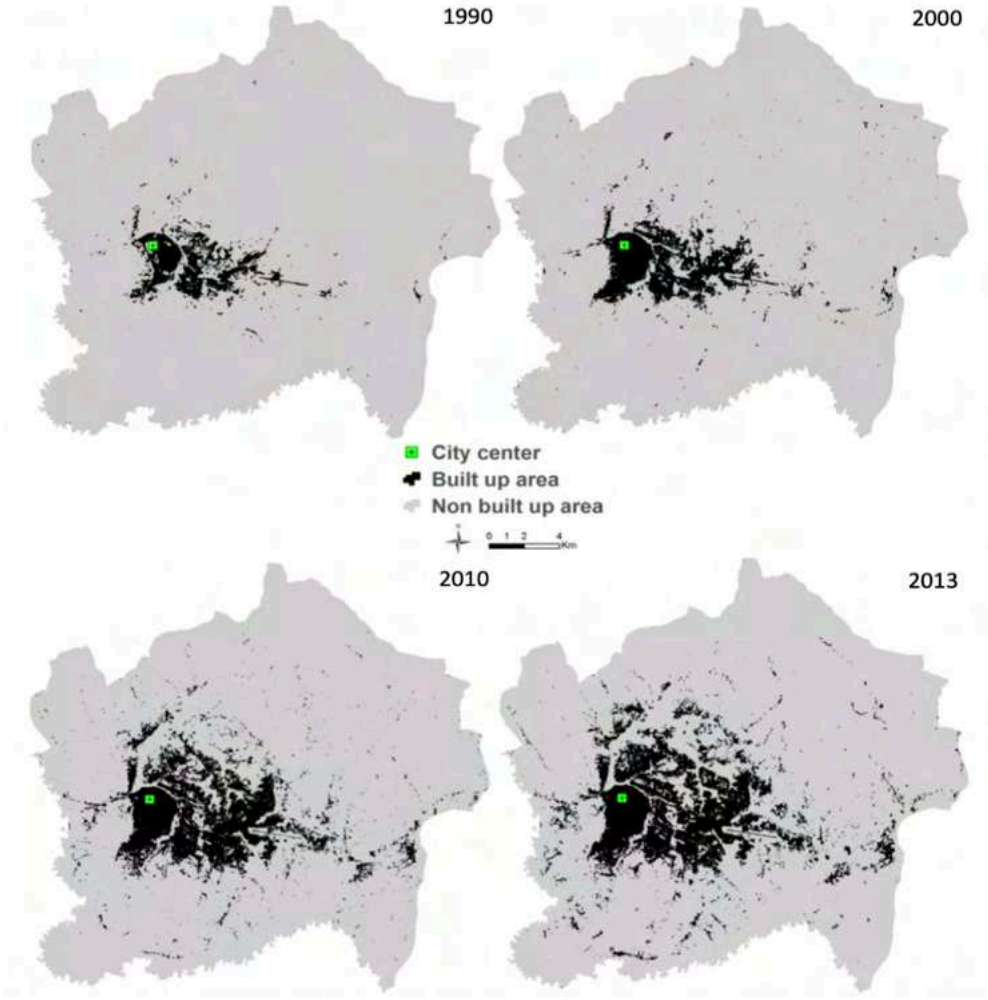

Figure 6 Built up expansion trends from 1990-2013. (Data source: Kigali City Urban planning department)

3.2.2. Land Use split up

The urban land composition has undergone series of land use changes since 1990. As shown Table 1, in 1990, only 2.9% of the total current area of the city was built-up. The agriculture land which includes all green space natural forests excluded, as they are counted in the category of natural areas together with wetlands, has been decreasing with a high decrease during 2001 and 2010. However, the 5.5% decrease in agriculture land was expanded during the 10 years while between 2010 and 2013, only 3 years, a 4.5% decrease is recorded. Although, this category experienced changes and decrease, by 2013, it represented 67% of the total land use. The land used for agriculture is sometimes on steep slopes where any development is typically impossible, thus making it the major land use category within the city.

The built-up area recorded a 341.7% increase over 23 years since 1990. Within the first decade only, the built-up area doubled. The causes are many including the social events such as the end to the genocide in 1994 with many people coming back to settle in the capital as a safer place compared to the surroundings provinces. Although the change rate reduced since 2000, the built-up area is still increasing from changes of other land use categories mainly the agriculture land. A remarkable increase in land used for infrastructure is also noticed during the first and second decades. This is particularly the effect of development and settlement whereby infrastructures such as roads are built to connect different zones of the city.

Land Use name	Land use (in Ha)				Net change (in %)			
	1990	2000	2010	2013	1990-2000	2001-2010	2011-2013	1990-2013
Agriculture	53789	52905	49986	47755	-1.6	-5.5	-4.5	-11.2
Built-up	2103	4673	6784	9288	122.2	45.2	36.9	341.7

Natural areas	13995	11526	10975	12658	-17.4	-4.8	15.4	-9.5

Figure 7 Land use changes in 1990, 2000, 2010 and 2013. (Data source: RNRA, 2012)

In 2013, the built-up area composed 13% of the total area and 18% of the total developable area (not steep slopes or wetlands). As shown in Figure 8 within the built-up area, 67 hectares (76%) are occupied by residential houses mainly scattered and unplanned followed by 14 hectares (16%) occupied by public facilities, 4 hectares (5%) by industries, 3 hectares (3%) by commercial buildings and a relatively small percentage of mixed-use development. On the other hand, public urban open spaces such as squares or parks are almost non-existent in the city. Few roundabouts are sometimes used as public open space. There is need to avail more land for recreational purposes. The Kigali Master Plan 2050 proposed developing and converting wetlands into recreational parks and gardens, thus proving more open spaces while also protecting the environment. Some of the wetlands are currently being occupied by unplanned settlements such as residential buildings or often commercial activities such as car washes.

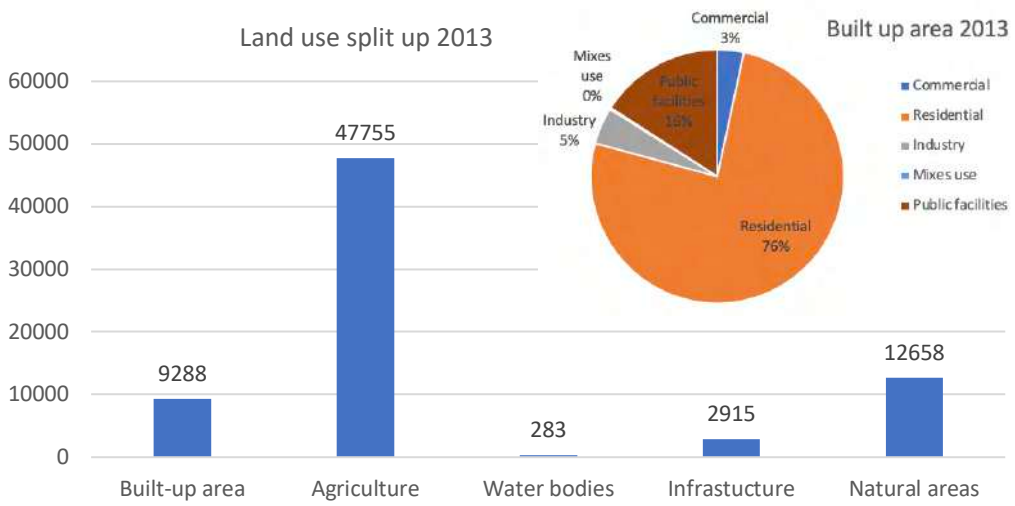

Figure 8 Land use-split up in 2013. (Data source: RNRA, 2012)

3.2.3. Population by distance to CBD/CG

Figure 9 illustrates the population densities residing within a certain distance to the CBD for the year 1990, 2000, 2010 and 2013. IN 2013, the high densities can be noticed near the CBD as they tumble down when going far of the CBD. Within 2km radius of the CBD, the densities are nearly 100 people by hectare. After 5km, the densities are less than 20 people by hectare and remain almost constant. The CBD is located 6km from the western boundary of the city, thus the only the population in the eastern direction is counted.

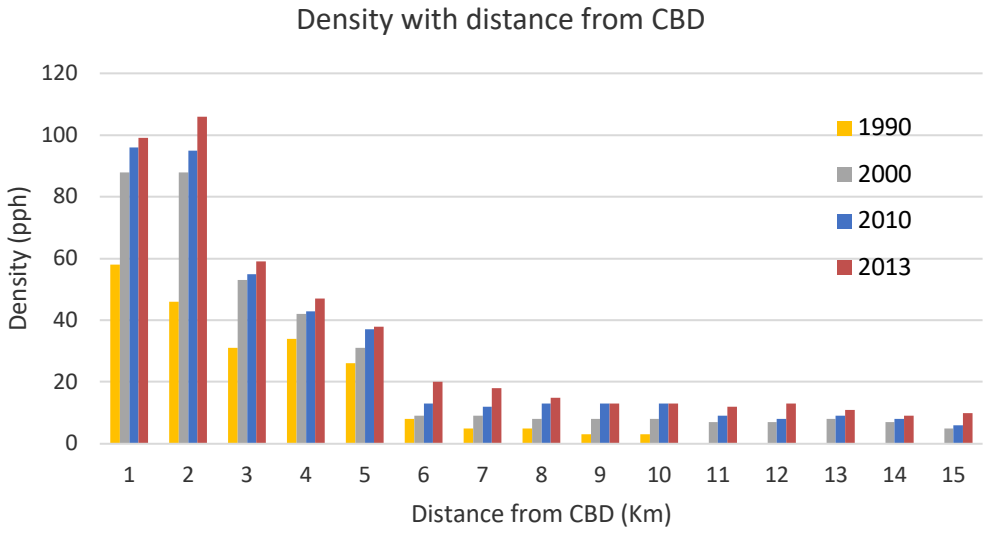

Figure 9 Density variations with distance from CBD. (Data source: RNRA, 2012)

Figure 9 is showing how residential area is spread with distance from the CBD. Despite high densities presents around the CBD, Regular residential land is consistently spread throughout the city. Likewise, as one leaves the city center and moves towards the periphery commercial/industrial land tapers off but does not disappear. This is probably due to the fact that Kigali has no large industrial zone.

4. Discussions

Kigali city is dominantly a monocentric city with various sub-centres spread over the city. The CBD eccentricity is located 6 km from the supposedly centre of Gravity of the city. The spatial growth of the city has been observed directed in the eastern part while in the western part, the expansion is obstructed by steep slopes typically impossible for development. As cited by the law, no development is allowed on slope exceeding 20 per cent. The eccentricity of the city is due to the first modern settlements after the colonization on the top of the hill to ensure security. As the city developed, other commercial services also joined creating the CBD near settlements.

Kigali city showcased an increase in urban built-up area corresponding to its growth of population. From 1990 to 2010, the city has been increasing its urban density creating a more compact city. This was mainly due to intensification of areas surrounding the CBD, whereby in some places, densities exceed 200 people per hectare. With a large percentage of these densities coming from unplanned settlements and eventually located in high risk zones with steep slopes or wetlands. In 2010, the urban density was 147 people per hectare, a value that can be related to that one recommended by UN-Habitat as 150 people per hectare. After 2010, the urban density started decreasing and this is explained by the increase of land consumption, a sign of city sprawl. Kigali population is growing on a rate 4% per annum (2000-2013) and the population is expected to double in 2025 (KCMP, 2013). This increase in urban population has placed considerable pressure on Kigali's housing stock, and resulted in the construction of informal settlements. To meet projected housing demands, Kigali would need to construct roughly 344,000 formal housing units by 2022, but currently less than 1,000 are constructed annually (City of Kigali, 20123).

Kigali city has limited mixed land. Only 19 hectares, representing almost zero percent of built up land, were classified as mixed land use. The biggest percentage with 67% of the total land use is the Agriculture lands. They are followed by natural areas, consisted of natural forests and wetlands, with 17% and built up areas with 13%. Infrastructures are apart with 4% of the total city area. Within the built-up area, 76% is consumed by residential areas, 16% by public facilities, 5% by commercial areas and 3% of the total built-up areas by industries or industrial zones. Although the city is considered green, due to green areas across streets and other areas, only 12 hectares are dedicated to urban open spaces such as parks and gardens. Presently, much of the agriculture land and forest cover is encroached upon and developed as built-up residential sprawl. Since 2010, the built-up densities started decreasing, thus leading to a sprawl tendency. One of the reasons being that since the implementation of the Kigali Master Plan, illegal developments were stopped and policies were adopted making difficult for unplanned settlements. Therefore, land prices in the urban areas started increasing and people objected for settling in the close suburbs whereby land is available on low prices.

The decrease in density as the distance from the CBD increases is a characteristic of the monocentric form of the city. While within 2 kilometres from the CBD, densities are relatively high, there is a detectable drop of density after. On one hand, it can be explained that, the urban built-up area on the western part of the CBD is discontinuous due to topography challenges. Very few developments were made on the steep slopes of mountains located at 2 km western side of the CBD. It is noticeable, that after 5km from the CBD, the density is slightly decreasing. These are new settlements which mainly happened

after the adoption and implementation of the Kigali Master Plan in 2010. They are planned low residential settlements located along main national roads, and they contribute meaningfully in sprawl of the city. Additionally, sub-centres have been created by these settlements.

5. Conclusion and future research

The study illustrated the trends of urban form in different years while understanding whether the city is developing a compact form. To understand it we used two dimensions of urban form which are spatial organization and spatial distribution of the population. Three variables of the spatial distribution were discussed. Furthermore, discussions were related to other compact cities to understand future urban form of Kigali City. Following this study, analysis of spatial organization and density distribution shows that Kigali is dominated by a monocentric compact form which grow in a polycentric dispersing form. In other words, the city compact form is dispersing creating new low densities. The compact form present early was facilitating shorter travels and higher densities within the CBD and its surroundings. Thus, it is necessary to increase density in new sub centres to sustain a more compact form. However, increasing density alone without infrastructure improvement may lead to an adverse impact on sustainability. To achieve a more compact city form, infrastructure upgrade and provision of more amenities and other facilities such as recreational parks, together with transport network is very necessary. An intensification through high density development in existing urban areas and sub centres may lead the city to a compact city.

Though, there is a high consideration of Kigali Master plan, its implementation should consider the trends of city expansion and better urban management, administration and strict regulations are necessary to achieve a more compact form with its benefits. Inclusive planning with more involvement and participation of people in the panning and implementation processes is extremely important and should be adopted to cater for economic and social needs. The existing high percentage of informal development should also be considered as it affects the success of compact city. There is also need to avail more land for recreational purposes and mixed land uses development promotion through various zoning of the city. While the compact city model has been adopted and applied as sustainable model mainly in cities of developed countries, this study suggest that such analysis can be useful for understanding the spatial structure and evolution of the city and thus in future planning and adoption of the compact city policies implementation.

Future research will be focusing on modelling and simulation of future compact urban form basing on trends and characteristics of the existing spatial organization and population distribution. Models may contribute in future urban planning and Kigali Master Plan implementation assessment.

Case Study / Project

Finding Housing Affordability

in MRT Jakarta TOD Areas

Putrikinasih SANTOSO

Abstract

Housing provision and housing affordability are among the most challenging issues to address in most of the urbanized areas in the world, where the lack of provision leads to a massive backlog. The redevelopment of areas within a 700-meter radius from the newly established MRT Jakarta stations is also facing a similar struggle. The implementation of TOD concepts within the 700-meter radius from MRT Jakarta is expected to also encourage urban redevelopment to support its ridership: mixed-use buildings, compact development, high-density buildings. However, the land price, land taxation, and building taxation are following through the transportation and urban mobility infrastructure improvement within the TOD areas. When the redevelopment happens, how to ensure the provision and the affordability of housing in the TOD areas? A study is done in three MRT Jakarta TOD areas: Dukuh Atas, Blok M - Sisingamangaraja, and Cipete Raya. Each of the TOD areas has a distinct context, including a CBD area, an urban center within a heritage district, and a neighborhood center.

The outcome of this study is to determine the implementation strategies for affordable housing provision within MRT Jakarta TOD areas. The main methodology used is research-by-design, with an iteration process between the design outcome and desk-study research, including a review on existing regulation and policies on municipal, provincial, and ministerial level, an overview of the target market for housing provision, as well as a form-based design exercise and iterations to achieve TOD areas design objectives. Among several strategies is the utilization and optimation of existing regulation on the inclusionary zoning regulation.

Research Paper

The Role of Urban Slums in the Evolution of Megacities: A case of Nima and Old Fadama, Accra, Ghana

Eunice YORGRI[1], Department of Urban and Rural Planning, School of Architecture, Harbin Institute of Technology, 92 West Dazhi Street, Harbin, China, 150001

Prof. Leng HONG[2], Department of Urban and Rural Planning, School of Architecture, Harbin Institute of Technology, 92 West Dazhi Street, Harbin, China, 150001

Abstract

Urban areas are contributing unprecedentedly in modelling the social, cultural, economic, environmental and physical development of the globe as they are perceived as basket of opportunities to the poor. This phenomenon has undoubtedly resulted in the influx of poor migrants particularly in the global south and consequently causing the proliferation of slums. This is indirectly influencing the growth of megacities due to increasing population amidst limited infrastructure. So far, limited research has been conducted into the role of poor rural migrants in contributing to the growth of megacities. The study also attempted to propose sustainable planning strategies in guiding future urban planning. The case study used both primary and secondary data collection methods. In all, 304 questionnaires were administered in April 2017 (Nima=146 and Old Fadama=158). From the study, 46% of the respondents in Nima hail from the Northern part of Ghana and 14% from the Volta Region. On the other hand, 49% of the respondents in Old Fadama come from the Northern part of Ghana and 22% from the Volta Region. Both Nima and Old Fadama have high figures on migrant population which means a fair contribution to the growth of Accra as a megacity. Therefore, spatial equality through a comprehensive, integrated and universal national development(UND) covering all sectors should be employed. Also, economic opportunities upgrading which is essential for slum and rural communities in Ghana should be considered. Further research on how cities in Ghana are planning towards becoming megacities is prudent.

Keywords

Megacities, Rural-Urban Migration, Urban Slums, Nima, Old Fadama

1. Introduction

"Across the globe and in a short amount of time, we've given up the tractor for the city bus, the open landscape for one of brick and mortar."

In recent years, world population has grown exponentially including urban population which is said to be first in the history of mankind. Urbanization trends closely mirror the universal patterns of economic development and progress in industrialization. At the beginning of the

20th century, only 13% of the global population lived in cities and only sixteen cities had a population of least one million. Currently, approximately, four hundred cities have populations of more than one million, majority of which are located in the global south(Cohen, 2006). Cities can be places of opportunity, creativity, innovation and of peaceful co-existence across cultural and ethnic divides, thereby generating a high quality of life for residents(Lucci et al., 2015). This basically serves as incentives for rural migrants who try to escape poverty, low levels of development and the impact of climate change. As these poor migrants unprecedentedly influx cities, they also contribute to the rapid growth of cities, albeit sometimes they reside in poor neighbourhoods such as slums. Little attention is given to the impact of poor migrants in the growth of megacities. Therefore, this study considers the role slum plays in the rapid growth of cities by focusing on rural urban migration using two popular slum communities in Accra as case study. The case study is home to majority of migrants in Ghana's capital city. Per the definition by the Ghana Statistical service, a place with a population of more than 5000 residents is termed urban(GSS, 2012). Considering this definition, it means that both Nima and Old Fadama (OF) are urban within the broader urban fabric (city within a city). Assuming, slum populations (majority being migrants) did not exist in cities, then although there maybe megacities, the rate of growth may be significantly low.

1.1 Urbanization and Megacities

Urbanization is commonly associated with economics such as improved job opportunities, a centralized market, better pay and higher individual affluence, attracting people into cities(Cohen, 2006). For the first time in history, more people globally live in cities than in rural areas and this has been attributed to people migrating from rural regions into cities and the reclassification of areas(Habitat, 2016).

Fig.1 Global Mega Cities in 2015, Source:(Institute, 2013, Learner, 2017)

Globally, 55% of the world's population reside in cities and this figure is expected to increase to 68% by 2050(DESA, 2018). In some few years to come, the rural population will almost be approaching its zenith (see figure 2). The black and red arrows as shown in figure 2, visually presents an estimated gap developing between rural and urban population. As the years go by, the rural population is declining whilst the urban population is increasing, gradually resulting in the growth of megacities.

Megacities are considered as cites with a population of ten million and above. In the 1950s, only Tokyo in Japan and New York in the United States of America, were the first known megacities of the world(Munich, 2005, Taubenböck et al., 2012). In 2015, approximately 21 megacities existed globally (see figure 1).

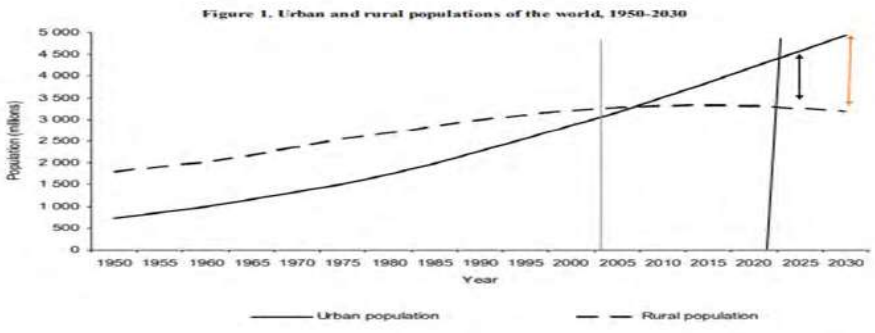

Fig.2 Rural and Urban Growth from 1950-2030, Source; (Nations, 2002)

Currently Africa and Asia host approximately 90% of the world's rural population. Almost half of the global urban population live in areas of less than 500, 000 dwellers. However, one in eight people live in megacities with more than 10milli0n inhabitants. By 2030, it is forecast that there will be approximately 43 megacities in the world, majority of which will be located in the global south(DESA, 2018). Megacities albeit maybe be motivated by urbanization, slum settlements are also the bi-products of unplanned urbanization, which indirectly contribute to the creation of megacities.

1.2 Megacities and Slums

Slum creation has been a dominant characteristic of rapid urbanization in the global South and is expected to continue well into the future(Lucci et al., 2015). UN-Habitat estimated that over 60% of urbanites in Sub-Saharan Africa live in slums as compared with an average of 37% across the global south(UN-Habitat, 2015). Although, no country has achieved middle-income status without urbanizing, the creation of megacities and slums is one of the greatest transformation of the 21st century(Lucci et al., 2015). Slums are massive as megacities and as cities keep experiencing exponential growth, so are urban slums. Slums despite the lack of urban infrastructure, are morphing into mega slums. About 1 billion people currently live in slum settlements, that is, almost a third of the world's urban population (UN DESA, 2013). In the 1970s the United Nations (UN) coined the term "megacity" to designate urban areas with eight million inhabitants and over. In the 1990s, they raised this threshold to ten million. Today, 22 cities and urban regions have reached this population figure, four of them in industrialised countries(Munich, 2005). Around 9% of the world's urban population – about 280 million people – currently live in megacities, and this figure is likely to rise to 350 million over the next ten years(Munich, 2005)

Slums, mostly develop as a result of a combination of factors such as rapid urban population growth, lack of affordable housing and poor governance. In some cases, the pace of urbanization outstrips government's capacity to provide the framework for affordable housing (e.g. land, infrastructure, access to utilities) for an increasing population. Also, governments are unwilling to act as they believe that providing services and better conditions to the poor will attract more people and cause slums to grow further. This means slums actually grow as they remain limitedly serviced for long periods of time (Lucci et al., 2015).

Sub-Saharan Africa is the region with the largest percentage of the urban population residing in slums, that is, over 50%. Implying that, Sub-Saharan Africa is the region where the rate of slum growth has been closer to that of general urban population growth(Lucci et al., 2015).

Ghana amongst the most urbanized and rapidly urbanizing economics in Africa. In the past three decades, the number of city dwellers has risen from 4 to 14 million and about six million people live in slums. Urban growth exerts intense pressure on government and municipal authorities to provide affordable housing, public services and jobs. Statistics from the World Bank shows that, 53% of the population lived in towns and cities in 2014. The urban population increased from 4million to 14million since 1984, with an estimated 6 million (39%) living in slums(Habitat, 2014). Recently, there are approximately 256 slum pockets spread across the country majority of which are located in Accra. This phenomenon has contributed significantly to the growth in population of the Greater Accra Region, although the contribution of natural increase cannot be overlooked.

2. Study Sites and Methodology

2. 1 Study Sites

Ghana had a population of 24.2 million during the last census of which over half of the population lived in urban areas(UN-Habitat, 2011, GSS, 2012). Both Nima and Old Fadama (OF) are slum settlements located in the Greater Accra Region of Ghana. They are amongst the numerous slum pockets (256 slum pockets) spread throughout the country. Nima and OF are peculiar as a result of their long standing history, population of migrants and the continuous influx of migrants into these areas. In details, Nima is located directly north of the ring road and within the Ayawaso East Metropolitan Area of the Accra Metropolitan Assembly (AMA)-figure 3. The low-income residential neighbourhood has a total population of approximately 70,000 and it is settled on 1.59 square kilometers of land(GSS, 2012, Owusu et al., 2008). The population of Nima has increased exponentially considering that in 1960, the average population density in the area was 25, 846 residents per square kilometer and 43, 478 people by the year 2000 respectively(Kang et al., 2010). On the other hand, Old Fadama is located within the Ashiedu Keteke Metropolitan Area of the AMA-figure 3). The slum area occupies a 31.3 hectares of land along the Odaw River and the Korle Lagoon. From the 2009 community enumeration, the community had a population of 79,684 giving a population density of 2424.18 persons per hectare(Settlements, 2010). However, the current population of the area is estimated at 100,000 people, making it densely populated. The now “matured slum” emerged in the 1980s and has become one of the most populous in Accra.

Fig. 3 Location of Nima and Old Fadama on the Map of the AMA

During the colonial period and independence era, urban planning in Accra did not take native and migrant communities into account. They were largely overlooked by the state and left unregulated(Obeng-Odoom, 2010), hence more people settle in the areas but remain unrecognized, particularly migrant communities, thereby leading to population increase and slum formations.

2.2 Methodology

Research is the pursuance of truth through study, observation, comparison and experiment(Kothari, 2004). In order to get an in-depth knowledge on the problem, this study used the case study method and non-probability sampling (purposive and snowball). The main reason for opting for this method of data collection is that, slum residents are difficult to get and their willingness to participate in surveys is minimal (sometimes they feel surveys are a form of mockery to them-more surveys less actions). Therefore, the researcher used non-probability sampling design instead of probability sampling design. The slum areas were selected based on the population of migrants. The researcher is impartial and the data analysis was done without prejudice, without no element of bias. In all, 304 questionnaires were administered to both Nima and OF respondents. Respondents in Nima were administered 146 out of the 150 questionnaires sent to the community, whilst respondents in OF were administered 158 questionnaires out of 160 questionnaires. The reason for the disparity is based on the respective population of the slum community and the willingness of respondents to participate in the survey. Some residents were not willing to participate and also respondents who agreed to participate did not answer the questions satisfactorily, hence were not added in the analysis.

Also, the researcher used secondary data from earlier researches relevant to this study such as journal articles, reports, reviews and unpublished documents from online portals and news, which were duly cited and referenced.

One major limitation of this study is the availability of residents and their willing to participate in the survey.

3. Results and Discussions

Urbanisation is associated with rural–urban migration, as workers move from less productive activities in agriculture to more productive activities in urban areas. But rural–urban migration can also happen as a result of searching for better amenities, to escape rural

poverty (even in the absence of prospects of a formal job in urban areas) or from conflict, natural disasters and social tensions. However, rural–urban migration is actually not the dominant factor behind urban population growth in developing countries, particularly in Sub-Saharan Africa(Lucci et al., 2015). Although the agents of urbanization may be specific to countries, the significant characteristics such as rural urban migration cannot be overemphasized. Therefore, the focus of this study is to examine the role of slums in the growth of megacities through the influx of poor rural migrants.

3.1 Causes of Slums in Accra

The creation of megacities and slum formation can be attributed to multifaceted factors. Slum developments especially in Accra relates to rural-urban migration (lack of jobs at the places of origin) and the lack of affordable housing. Financial and lack of job availability are the internal factors contributing to slum development(Srinivas, 2005). Rapid rural-urban migration, infrastructure inadequacy and economic retrogression are also some of the factors causing slum formation according to the UN-Habitat report in 2007(Habitat, 2006).

3.1.1 Migration

According to the former UN-Secretary General, Ban Ki-moon, migration is an expression of the human aspiration for safety, better future and dignity, forms part of the social fabric and also the very make-up as a human family (2013 High-level Dialogue on International Migration and Development). Migrants constitute more than a billion of the global population and one-seventh of the universal population, with international migrants making up an estimated population of 244million and internal migrants constituting 763million(Tacoli et al., 2015). Migration may occur within a country from urban to rural, urban to urban, rural to rural, or rural to urban. Also, migrants may move willingly to live in a better place and to improve their financial status and this is predominant among rural-urban migrants in Ghana(Awumbila et al., 2014). Table 1 gives an overview of the differences given by respondents of both Nima and Old Fadama between their places of origin and current destination.

Table 1 Differences between Place of Origin and Destination

ORIGIN	DESTINATION
Peaceful	Poor Living Condition
No Tertiary Institutions	High Cost of Living
Cheap Accommodation	Good for Business
Low Level of Development	Great Opportunities
Enough Space	Low Cost of Rent
Lack of Jobs	Good Schools
Good Sanitation	Too Crowded
Different Level of Civilization	

These factors are very important to consider for they significantly form the basis for the movement of rural dwellers to reside in cities. From the survey, 57% of respondents in Nima migrated to Accra in search of jobs whilst 7% moved because of education. Also, 5% of respondents migrated as a result of the low level of development in the area, whilst 6% moved because of marriage. One percent of respondents migrated due to proximity to work, 1% due to the lack of electricity and 1% migrated because of trade. Again, 11% of respondents migrated because of the population of the area, whilst 10% of respondents did not mention the reason for migrating. For OF on the other hand, 64% of respondents migrated to find jobs whilst 7% migrated because of education and 3% because of trade. Furthermore, 1% went for on a visit, whilst 1% migrated due to the death of mother. Added,

eleven percent of respondents migrated due to marriage, whilst 2% as a result of cost of rent. Three percent of the respondents migrated due to the population of the area whilst 8% did not give a specific reason. From the above findings, it's crystal clear that, migrants have diverse and personal reasons for moving and settling at a place (figure 4). To some respondents, the low level of development in the area is no issue, whilst to others it caused them to leave. However, some factors such as good schools (Education), marriage and finding a job are significant reasons for majority as it constitutes a major part of their socio-economic development. Therefore, integrated spatial development should form the pivotal part of government policies, particularly in the global south.

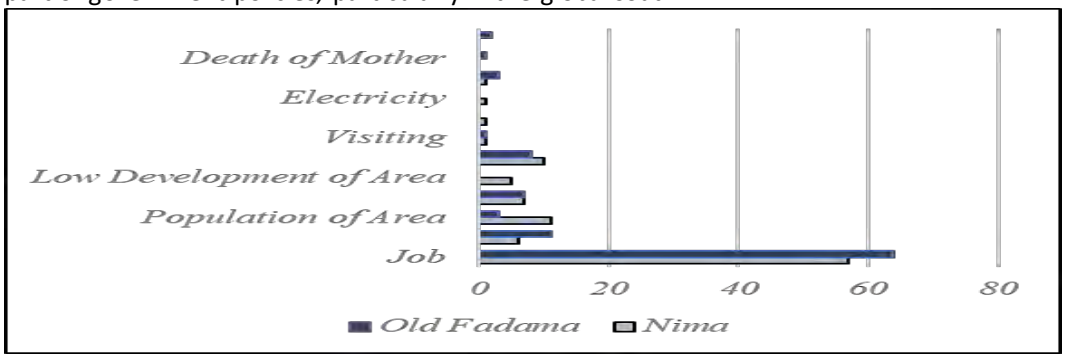

Fig. 4 Respondents' Reasons for Migration

According to the World Economic Forum Report (2017), the push factors of migration include lack of employment opportunities, unsustainable livelihood and rural poverty whist the pull factors include employment opportunities, pursuit of specialized education, better income and prospects for wealth creation, among others(Baffoe and Matsuda, 2017). All the factors are very evident in reasons posit by slum dwellers for migrating from their respective places of origin.

Respondents hailed from different parts of the country including neighbouring countries to settle in Nima or OF. The findings show that, 3% of the respondents in Nima come from the Central region of Ghana, 1% from Western Region, 6% from the Ashanti Region, 21% from the Northern Region, 12% from the Upper East Regions, whilst 6% are indigenes (figure 5). The results for OF also show that, 4% of the respondents, hail from the Central Region, 1% from Western Region, 3% from the Ashanti Region and 35% from the Northern Region (figure 5).

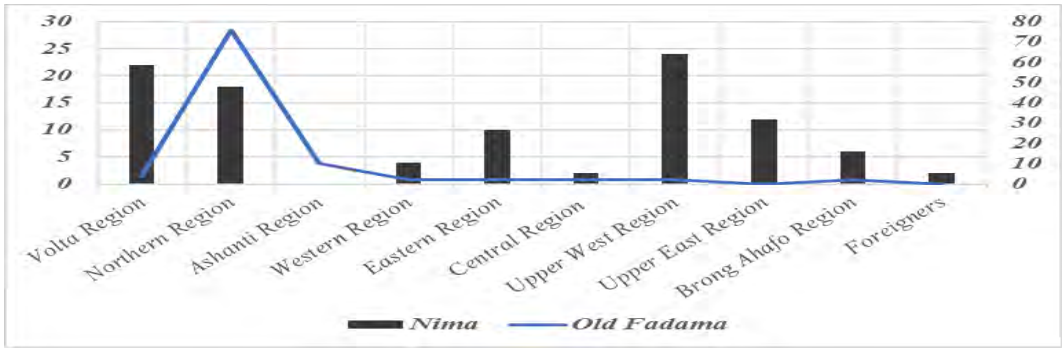

Fig. 5 Respondents' Places of Origin

Despite the fact that respondents migrated from different places, they all hope for good and better living including job acquisition, good schools, hospitals and incredible opportunities. One of the major differences between the place of origin and destination for both

respondents of Nima (78%) and Old Fadama (54%) is the unavailability of jobs and opportunities (push factors). Before deciding to leave the rural area, they feel the abstract beckoning of life in the cities which keeps burgeoning the interest to live in cities which comes as a result of spatial equality. This phenomenon re-iterate that economic improvement for slum dwellers both at the place of origin and destiny can significantly reduce migration, hence decelerating the pace of the growth of megacities, self- sufficient and resilient to forces of poverty. Also, when rural areas are economically empowered, the possibility of abled bodies from the rural areas drifting to cities may be curtailed. Slum dwellers who are young and detest consistent monitory of parents see being away from home and fending for themselves as freedom. Parents must take responsibility of their children and not to push them into child labour and a law restricting child labour should be enacted and stringently and effectively enforced. This has become vital as some respondents in OF are so young to be out on their own. For the girls amongst them, they end up being impregnated, hence contributing to the natural increase in the slum. Most often, they stay in the slums for ages and to some extend start their families in the slums (figure 8). All these account for the creation of mega slums, invariably leading to the creation of megacities. Since the destination provides jobs through the proximity of markets, where they indulge in manual and menial jobs (needing no skill or certificate) such as kayayi, truck pushing, assisting food vendors among others and coupled with the affordable cost of living, they will continue to live there and new entrance will join, gradually leading to the creation of mega slums (mega slums are descendants of megacities, figure 9).

In a nutshell, the responses outlined by respondents were categorised into high impact factors and low impact factors. The high impact factors are the ones relating to government policies and the low impact factors are personal factors (Table 2).

Table 2 Classification of Factors Given by Respondents

PUSH FACTORS	PULL FACTORS	HIGH IMPACT FACTORS	LOW IMPACT FACTORS
Low Level of Development	Job Opportunities	Job Search	Visit
Population of the Area	Education	Education	Marriage
Visits	Trading	Trading	Death of Mother
Death of Mother	Proximity to Work	Low Cost of Rent	Population of the Area
Lack of Social Infrastructure	Low Cost of Rent	Low Level of Development	
		Nearness to Work	

The high impact factors according to this study, are the factors that are relevant and difficult to solve by governments in a short term and are major contributory factors to causing people leave their places of origin whiles the low impact factors according to this study are the factors that also contribute to slum development in infinitesimal cases. The reason for this categorization is to aid in development plans and also present a roadmap in resolving slum challenges from their root causes (For example, 57% and 64% of respondents in both Nima and Old Fadama migrated due to lack of jobs and in search of jobs respectively).

The findings show that 75% of respondents in OF relocated to the area whilst 25% did not relocate to the area. Also, 82% in Nima relocated to the area whilst 18% did not relocate to

the area (figure 6).

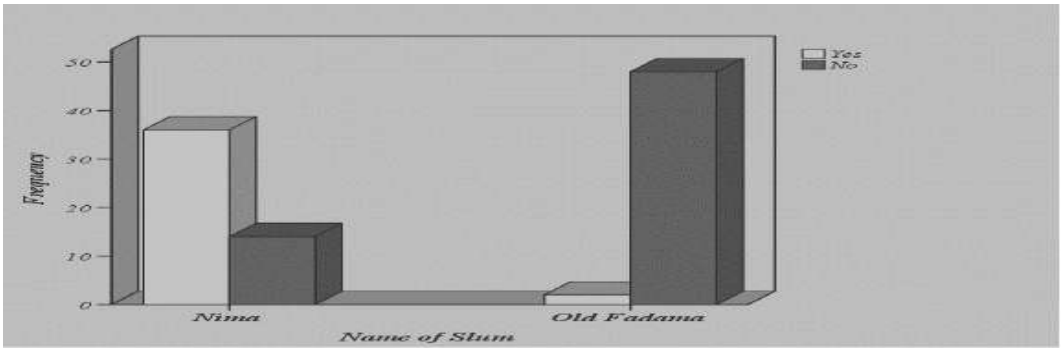

Fig. 6 Respondents Born in the Slum

The place of abode of every individual is paramount, despite the myriad of challenges or no matter how scintillating the place may look. However, even within the city, there are push and push factors that forces slum dwellers move from one slum to another. As already elucidated above, there are other reasons compelling slum dwellers to leave their previous location. Poor rural migrants move to the city for better life but after reaching the city, what they perceive it to be is not what they encounter hence, will continue to move within the city slums until they are capable of finding a decent place (figure 7). The funnel represents the city always welcoming new entrance.

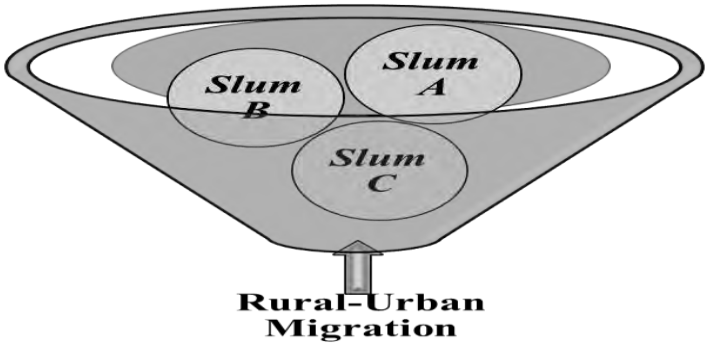

Fig. 7 The Inter-Slums Migration Funnel

The funnel represents the city (figure 7), therefore, slum dwellers will prefer to stay and move within slums until they get what they want within the city, just a few might consider the option of returning to their places of origin. For instance, from the findings of the study, 10% of respondents in Nima mentioned that they left the previous location due to the cost of rent. This means that their first point of call was not directly settling in the slums but due to the high cost of rent they relocated into the slum of Nima. Also, 5% of respondents in Nima mentioned that they had free accommodation, whilst 37% of respondent stated that they preferred this location because of low cost of rent One percent of respondents in Nima also left their previous location due to divorce and eviction respectively. This class of people needed an immediate shelter hence found solace in the slum. Evictions and demolition are mechanisms to eliminate slums in cities but they end up causing more slums, which even grow rather more rapidly since new entrance may take advantage of the condition, leading to urban population growth. The findings of the study in Old Fadama show that 5% of respondents left their previous settlement due to the cost of rent, whilst 1% moved after the divorce with their spouse (table 3). The social implication of this is that dwellers will cease any opportunity that come their way provided they will achieve the reason for which they are in the city and when they achieve it, it may serve as an incentive for new city entrance.

Table 3 Reasons for Respondents Leaving Previous Settlement

	PERCENTAGES	
Reason for Leaving Previous Location	***Nima***	***Old Fadama***
Cost of Rent	10	5
Divorce	1	1
Evicted	1	1
Family Relocation	1	0
Poor Sanitation	1	1
Education	7	7
Marriage	10	18
Work	28	38
Change of Environment	1	1
Demolition	22	2
Proximity to Work	5	2
Trading	1	1
Did Not Relocate	11	20
Not Stated	1	3
Total	100	100

Economically, job availability plays a vital role in elevating not only slum dwellers but the entire citizenry from poverty and conversely boost the economy of the country, of which Ghana is a typically example. Spatial and economic inequality has forced most citizens to move into cities where they end up settling in the slums.

Both Nima and OF have vibrant markets such as the popular Nima market, Agbogboloshie and Konkomba yam markets which often receives people from all parts of the city on daily basis. For instance, most of the young migrants who leave the northern part of Ghana and settle in OF, engage in truck pushing, kayayei (head porters) due to the proximity of the area to these markets and also, both Nima and OF have close proximity to the CBD. From the above analysis, it can vehemently be put forward that the selection of settlement by slum dwellers are based on different informed decisions and choices, some major and others minor but all constituting to the reason for settlement invariable contributing to the creation of megacities. Assumedly, the factors considered by slum dwellers for settling in a neighbourhood varies as compared to high and middle income earners, who not only consider the environment and neighbourhood but also the availability of social amenities and security. Slum formation accelerated as a result of rapid urbanization within the past 20 years particularly in the global south.

3.1.2 The Role of Slums in the Development of Megacities

Slums in cities are seen as the life line of the city depending on the angle from which it is viewed. Predominantly, urban slums come about as a result of rapid urbanization and unfavourable policies. Slums have become inevitable in cities, particularly among prosperous cities of developing countries who lack the strategies of meeting the pressures of urbanization. Most slum dwellers move out of rural areas to escape from the chronic hardships and poverty of the area. Although the rural landscape may well be conducive for living, the lack of economic opportunities and spatial inequality motivates the movement of rural dwellers to cities, where they abstractly perceive or predict the type of life in the city. Sometimes from the evidence gathered by those who are returning from cities and looking "all flashy".

Slum dwellers contribute to the creation of megacities from two main perspectives as concluded by the findings of this research. First is the continuous influx of migrants into cities who find solace in slums (the place they can readily afford). They move in as a result of spatial inequality and lack of jobs. For example, in Old Fadama, more girls avail themselves in the markets as head porters (Kayayei), which needs no degree, certificate or training. The second perspective is the length of state of some migrants (lifetime migrants). They stay in the slums and start their families, who also start their own families (figure 8). Figure 8 assumes each new entrance starting a family and producing about three children, then they eventually become grandparents, creating a slum generational. Adding the new generation to the already existing population coupled with new entrance, will definitely transform the city into a mega city

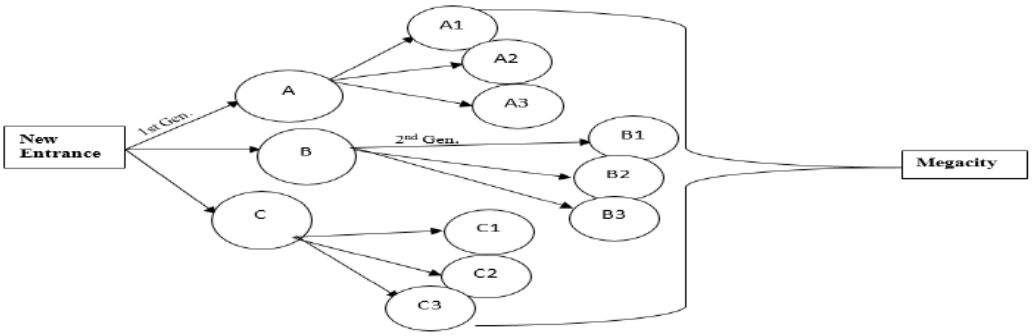

Fig. 8 A model of Generational Increase in Sums

From the statistics, the population of GAR increased from 491,1817, 851,614, 1,431,099, 2,905,726 from 1960, 1970, 1984, and 2000 respectively, to 4,010,054 in 2010(Bentsi-Enchill et al., 2013), with 40% migrating from other regions in the country. No matter how hash and hard the conditions are in the city, slum dwellers still prefer living in the city than to return to the rural area. From the study, both Nima and Old Fadama are migrant communities, therefore any action that will deny them of their source of livelihood will face strong resistance.

Megacities do not just form overnight but have been attributed to numerous factors such as the neglect of infant squatter settlements in cities amongst others as concluded in this study. For instance, slums such as Dharavi (Mumbai, India), Rocinha (Brazil), Lagos (Nigeria) are mega slums in mega cities but did not just form overnight. This means that the existence of slums contributes significantly into the rapid growth of cities (figure 9).

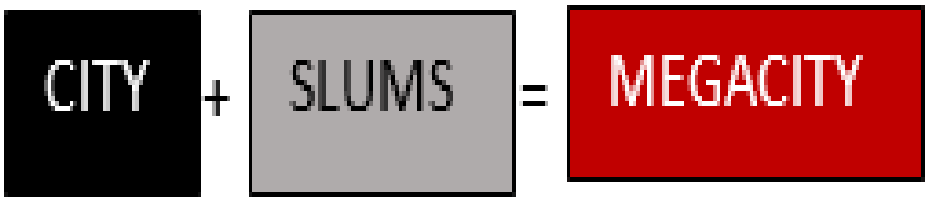

Fig. 9 Basic Urban Mathematical Equation for the growth of Megacities

As presented by some scholars, urbanisation is the increase in the proportion of the national population living in towns and results from a mixture of in-migration from rural areas and natural increase of the urban population. They stated that, the classification of a locality as urban or rural is based on population size in Ghana, that is, localities with five thousand or more people are regarded as urban(Bentsi-Enchill et al., 2013). The proportion of urban population in Greater Accra was 90.5 percent in 2010. Comparatively, GAR has the highest proportion of the population living in urban areas than other regions(Bentsi-Enchill et al., 2013). Also, the population dynamics of the cities in Ghana based on the census data from 1970-2010 show that, the country may possibly create a bipolar urban society, based on lack of proper planning and investment(Owusu and Oteng-Ababio, 2015).

Slums will continue to exist in cities unless the right strategies are put in place. Rural migrants drift into cities for greener pastures and other opportunities in the city. Mega-cities are conceptually different from world cities or global cities because they are defined by population size rather than global functions(Yeung, 2009). Megacities as already defined earlier refers to cities over 10 million. Rural to urban migrants have an enormous number moving to megacities and settling in slums(Crank and Jacoby, 2015). A megacity is a prime example of such a critical stage of development and this is principally true where growth is too rapid(Munich, 2005). Large cities always pull people to it particularly people who are captivated by densely populated areas(Munich, 2005). Urbanization attributed to rural urban migration results in the rise in numbers of poor people living in hazardous conditions(Bolay et al., 2016).

3.1.3 Recommendations

Most cities of the world particularly in developing countries are rapidly urbanizing and morphing into megacities. The euphoria of rural to urban transformation amongst people is considered the global trend. However, uncontrolled movement of people coupled with natural increase is putting pressure on some cities than others. For instance, in Ghana, much pressure is centred on Accra as a result of the heavy concentration of industries, government departments and offices, and the availability of basic services. Basically, a strong political will in addressing the challenges of slums in cities, is pivotal in the planning and implementation of strategies. Granting that, the political will to deal with existing slums through adaptive measures is weak, then the political will to prepare for the future urban expansion through proactive measures will even be weaker(Mehta and Dastur, 2008). It is realistic and prudent for government, policy makers and practitioners from all angles and at all level sought out for affordable and implementable approaches and strategies in resolving challenges of global mega cities and slums. In recent years, urbanization is a global process that makes up the fast development of majority of developing countries therefore also needing prompt attention and important spatial, social and economic sustainable changes.

A comprehensive and integrated planning is clearly needed in Ghana to minimize spatial inequality. Rural areas should not only be seen as agrarian landscape, but areas needing utilities and services. Also, the one size fits all strategy must be eliminated from government policies. The development of respective regions and areas can be made peculiar with the challenges that they are facing. As the law states already, a place with 5000 or people is termed urban in Ghana hence a place ceiling maybe introduced in Ghana controlling the number of people that are permitted to live a particular urban area. Urbanization is inevitable particular within developing countries, therefore strategies for healthy urbanization is prudent especially in cities such as Accra, Kumasi, Tamale and so on.

The quest for education pushed some of the respondents to Accra, therefore, it is imperative for governments and city officials including urban planners to include the construction of schools in rural and deprived areas of the country. Slums are not a novel problem and their challenges have become a global concern, resulting in constant debates both locally and at the international level. Urban planners should provide feasible plans for government to balance efficiency and civil rights. As a matter of civil rights, citizens are to enjoy as their rights basic amenities including proper housing and water. Therefore, a gradual approach in the provision of such amenities can be rolled out. As far as the social needs and poor economic conditions of slum dwellers are not tackled, slums will continue to exist. Therefore, full consideration of civil rights in the entire country is vital. Also, Government should empower youth in the rural areas by building their capacities through skills development and livelihood support such as creating micro-credit avenues. Slum dwellers can also be empowered and sensitized on the need to return to the rural area. This can be possible through a bottom up approach such as community mobilization and sensitization.

A hybrid intervention method is needed particularly in cities to control rural-urban migration, strategies which will not end up creating more challenges in cities such as slum formations. Urban lands, both precarious and habitable lands must be guarded or utilized to prevent encroaching by particular poor rural migrants. Policy regulating rural-urban migration is paramount in reducing and avoiding the growth of megacities. Prioritizing spatial equality as the number one focus of any development agenda is eminent.

Furthermore, the study recommends healthy urban planning, that is, planning for people and putting the needs of people and communities at the heart of the urban planning

process. Finally, the best solution to remedy slums and to prevent the growth of megacities is to prevent them.

3.1.4 Conclusion

Slums are often perceived as a means to an end particularly when a country is urbanizing. However, the influx of rural migrants adds to the already existing high populations of urban areas, who often reside in slums after encountering the hardships of cities and their inability to matchup with the complex conditions of the city. Therefore, this study concludes that provided the systems give room to welcome new entrance into the city, then cities will continue to grow despite the lack of infrastructure and other urban services.

Megacities are mostly categorized by extreme concentrations of people and infrastructure, however, megacities are heterogeneous and complex, just like slums. Seven of the ten most populous cities are located in developing countries(Ali and Sulaiman, 2006). Therefore, in order not to be confronted by the problems of existing in megacities, cities in developing countries must find adaptive and sustainable strategies to prevent the continuous influx of rural migrants. We conclude that, government must recognize that rapid urbanization will continue to hit developing economies and that the impact of Climate change, natural disasters, conflicts and so on, may move people from agrarian into industrialized areas, hence cities must be prepared and work towards it evolution.

Research Paper

Multi-scale Spatial Layout Structure System

Experiences of Shanghai Mega City Spatial Planning

William Zuo, Shanghai Tongji Urban Planning & Design Institute Co.,LTD. China

Abstract

As one of the leading factors of China's economic growth, Shanghai has ranked atop of global metropolitan. Recently, Shanghai has just completed the compilation of a new version of Shanghai 2035 Master plan. Under the guidance of 'outstanding global city' of Shanghai, one of the most remarkable changes is the redefinition of cities and regions. This master plan introduces a five-level spatial layout structure system of 'Central Activity Zone-Main City Zone-Suburban Town Circle-Near Shanghai Collaborative Zone-Yangtze River Delta Regional Urban Agglomerations'. The Central Activity Zone is the core area of the main city, the Main City Zone is the key upgrading area around the main city, the Suburban Town Circle is the suburban development complex composed of the suburban New city-new town-ordinary town and village. the Near Shanghai Collaborative Zone emphasizes the strategic coordination and interactive promotion between Shanghai and its surrounding areas, and the Yangtze River Delta Regional Urban Agglomerations refers to Shanghai driving more than ten cities in the Yangtze River Delta to form a world-class metropolis area. In different spatial scales, this pattern has given a coordinated and unified spatial planning arrangement for urban and rural areas and different regions, which provides a guideline for the world's mega-cities' spatial planning. The disadvantage is that the multi-scale spatial governance system matched with the multi-scale spatial layout structure system has not yet matured in Shanghai and its surrounding areas, resulting in difficulties in planning and implementation. Now, China is commencing a large-scale reform of its spatial planning system, which offers a great opportunity for the implementation of new planning concepts.

Keywords

Spatial Planning, Yangtze River Delta Regional Urban Agglomerations, Planning Integration

1. Introduction

Ever since the definition of mega city was proposed by contemporary urban planners, these regions are steadily growing alongside with influences and challenges. Presumably, many of these challenges such as urban slums, food and energy shortages will bring adversely impact on the long-term development of mega cities. This paper focuses on the regional spatial system invented by the Shanghai Municipal Government. The system has been expected to reshape spatial layout of the emerging Shanghai mega city region and form a compact municipality spatial structure. By introducing this system, the state council of China intends to solve regional development gaps as well as emerging challenges of Shanghai mega city region. This paper also interprets the implementation processes of this spatial system in the field of planning practice.

2. Literature Review

The expansion of metropolitan areas generates influential reciprocal impacts on both the metropolitan and its surrounding districts (Mayer, H. M. 1987). Major treatments for the negative impacts come along with urbanization are categorized into one of the three categories: suburbanization, satellite town development or sub-center development. Each of them has individual advantages and disadvantages. Post-World War II suburbanization in the United States caused a population boost in non-central city sections in 1950s (Tobin, K. A. 2002). Surging population eventually lead to an expansion of suburban and huge amount of expenditure on highway construction. Seoul decided to build the Songdo City to the south of Seoul when facing mega city problems of its own. It is planned to be a modernized and environmentally-friendly satellite city of Seoul with high quality of green open space and affordable housing. The city is qualified with 18.5million square meter LEED certified projects with high standard of sustainability (Poon, L.2018). However, it is common for mega cities and their neighboring cities to form mega city regions which are interconnected to each other in terms of social, economic and environmental impacts. 19 mega city regions have been planned as part of the Belt and Road Initiative proposed by the state council of China. According to the initiative (Preen, M.2018), Yangtze River Delta is considered as hub of the belt and one of the most important regions. Shanghai as the economic center of Yangtze River Delta is adopting a series of planning regulations for sustainable development of Yangtze River Delta as a whole.

2.1. Research Method

The Municipal Government of Shanghai has released the Shanghai Master Plan 2017-2035 (2018) in replace of the existing Shanghai Master Plan 1999-2020. Shanghai has been redefined as a global city of innovation, humanity and sustainability which provides opportunities for the whole community. It introduced a five-level spatial planning hierarchy comprise four urban hierarchies and one regional hierarchy.

By studying major differences between Shanghai Master Plan 2017-2035, Shanghai Master Plan 1999-2020 and other contemporary Master Plans in China, a recognizable pattern change in terms of spatial structure system can be identified. It is the result of a revolutionary reform known as the 'Integration of Various Plans into One Master Plan'. This reform integrates some of the major planning systems in China such as the urban planning system and land use planning system into one ("Shanghai Master Plan 2017-2035",2018). Construction of industrial parks, factories and shipping facilities were addressed by Shanghai Master Plan 1997 as the key factors to regional development. Detailed construction plans were released as guidelines for regional industrial parks. However, none of these factors were scheduled in the Master Plan 2035.The city has adjusted its priorities from economic growth to the creation of a sustainable, ecological and human centered society. It is required by the master plan that all regulatory plans and detail plans in sub-center zones must not neglecting the protection of local environments and heritage sites ("Shanghai Master Plan 2017-2035", 2018).

	Shanghai Master Plan 1999-2020	**Shanghai Master Plan 2017-2035**
National Strategies	Centers of Economy, Finance, Trade and Shipping	Centers of Innovation, Humanity and Sustainability
Residential Population	160million	250million
Total Development Land	1500 km^2	3200km^2
Spatial Planning Layout	Not included	A Five Level hierarchy ranges from center activities zone to the

		Yangtze River Delta Regional Urban Agglomeration Zone
Planning Implementation	Not included	Specific Implementation processes and regulations are included.
Transportation Network	City-wide transportation network	Regional wide transportation network

2.2. Shanghai Mega City Spatial System and Supporting Methods

The hierarchy and functions of networked spatial system introduced by Shanghai Master Plan 2017-2035 are list as following:

- Center Activities Zone： Core bearer of global urban functions such as highly integrated finance, commerce, business, culture, leisure, tourism services and linkages between global network and the entire municipality
- Sub-center of the main city Zone: Also known as the Center of New City, it includes public activity center and public open spaces around the Centre Activities Zone. It partially undertakes specific functions as global activities center. There are five new cities located next to the boundary of Shanghai's urban footprint known as Jiading District, Qingpu District, Songjiang District, Fengxian District and Nanhui District.
- Suburban-Town Zone/Local Centre: It represents public activities centers or new towns which provide public services to the local community.
- Near Shanghai Collaborative Zone or villages: Facilitating integrated urban-rural developments among the five districts create interconnections between Shanghai and its town clusters.
- Yangtze River Delta Regional Urban Agglomeration Zone (YRDUA): The YRDUA is defined as a polycentric mega-city region (PMR) located along the Yangtze River Delta. Shanghai and twenty-five well developed cities are included in this zone. They were chosen by the national government as part of the national stimulus policies to boost Chinese economy (Zhang, M., Xiao, H., Sun, D., & Li, Y.,2018). Shanghai has been identified as the gateway of this agglomeration zone by the master plan. It is expected to promote the economic growth of the entire YRDUA.

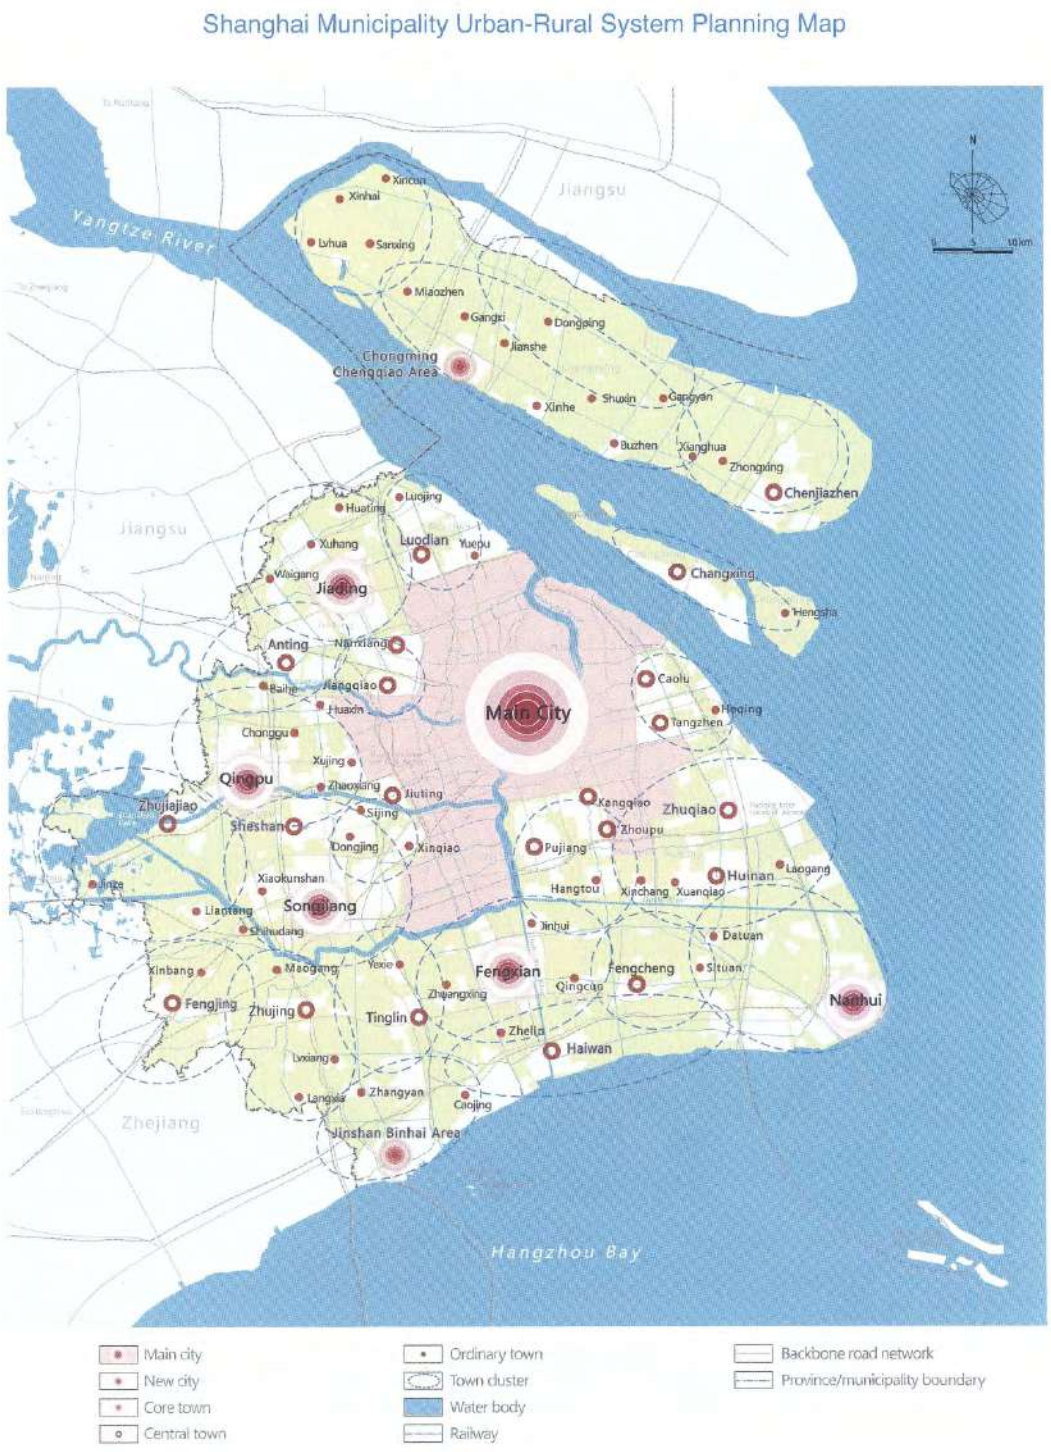

Figure 1: Shanghai Municipality Urban-Rural System Planning Map

Besides the hierarchy, specific land use proposals are introduced by coordinated development plan. Several proposals have been adopted by the Municipal Government of Shanghai to ensure the long-term growth of Shanghai Mega City Region.

- Population Distribution Method: The master plan requires no more than 25 million populations by the end of 2035, which equals to only 0.002% annual growth from 24.15million in 2015. Even as result of increasingly aging population, low-birth-rate and internationalization, this proposed population growth rate is considered extremely low in compare with other mega cities ("Shanghai Master Plan 2017-2035".2018). A concurrent registered residence policy has been frequently used in developing countries to slow down the progression of urban sprawl. As required by this registered residence policy, individuals' social welfare is closely related to their registered residences identified through birthplace. Because of the huge social welfare gap between urban regions and non-urban regions, municipal government like Shanghai and Beijing have strengthened registered residence policies which prevent people from effectively residence changes. As the result of proposed population de-concentration method, Shanghai Government has modified its registered residence policy.

- Urban Footprint Control Method: Before the publish of Shanghai Master Plan 2017-2035, it was common for local governments to adjust urban footprint boundaries in exchange of available land resources. In order to avoid similar uncertainties, 3200 km^2 urban footprint area are chosen as Shanghai's new urban footprint boundary for the next two decades. The five districts identified by Near Shanghai Collaborative Zone are included within development boundary. Regional plan encourages immigration from countryside to regional town centers by compensation (Land compensation standard in Shanghai, 2019). Therefore, local government can transfer inefficient residential land into valuable ecological or agricultural land.

Shanghai Master Plan 2017-2035	
Spatial Structure System	Other Supporting Methods and Plans
Centre Activities Zone	Population Control Method
Sub-Center Zone/New City	Urban Footprint Control Method
Suburban-Town Zone/Local Centre	Ecological Land Management Method
Community Centre	
Yangtze River Delta Regional Urban Agglomeration Zone	City Cluster Development Plans for Yangtze River Delta

- Ecological Land Management Method: Based on the land use structure introduced by the master plan, land resources are divided into three categories: ecological,

agricultural and urban spaces. land uses for the three types of land are clearly separate from each other. In order to prevent inefficient industrial or residential land use, proportions of ecological land and green spaces are strictly limited to no less than 60 percent of the overall land area. It is required by the Master Plan that 23% forest coverage among all the ecological land to ensure environment quality of the emerging mega city region. The figures below demonstrate the proposed location of green corridors across Center Activities Zone and reserved natural inhabits along the Yangtze River. By comparing the distribution of Ecological and Agricultural overlapping areas, we can identify a perfect combination of both form and function in terms of mixed land uses and environmental sustainability. The specific land use purpose is determined by the land use priority identified by local government. For example, if a block of land is suitable for multiple land uses, but surrounded by ecological forest, it is most likely will be classified as ecological land as well.

Figure 2: Shanghai Municipality-wide Eco-Space Planning Map

- Regional Transportation Improvement: In order to improve overall service level as national railway center, Shanghai will strengthen its municipality-wide transit

system by optimizing its quality of existing three level rail transit network. The three level transit network comprises intercity lines, local lines and metro lines. Intercity lines provide express service from Shanghai to other core cities in the city cluster of the Yangtze River Delta such as Nanjing and Suzhou. Local lines shorten the traveling times between Shanghai and its sub centers to no more than 40 minutes ("Shanghai Master Plan 2017-2035", 2018). Metro lines provide direct light railway and subway services within Shanghai

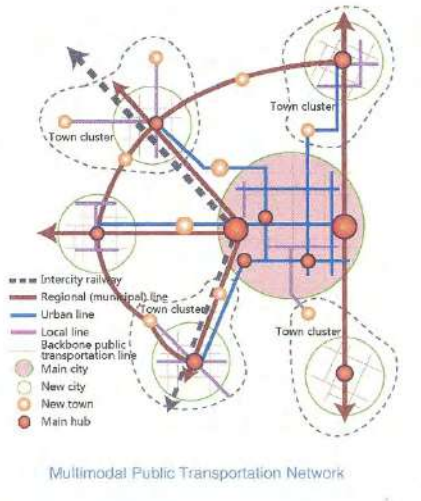

Figure 3: Multimodal Public Transportation Network

2.3. Yangtze River Delta Regional Spatial Structure Reform

The Yangtze River delta urban agglomeration is one of the earliest urban agglomerations formed in China (Chaolin. 2007 as cited in Zheng, Z., & Bohong, Z. 2012). According to Zheng (2012), the YRDUA spatial structure was established based on a single-nucleus and multiply centers model. Shanghai has played an important role as single-nucleus which accelerates the development of the agglomeration through different stages. In early stages, population density of Shanghai and other regional centers such as Hangzhou, Suzhou, Nanjing and Ningbo were growing rapidly based on accumulative effects on urbanization. Local governments have learned the importance of sustainable development and introduced industrial parks around towns and cities (Liuetal.2010).

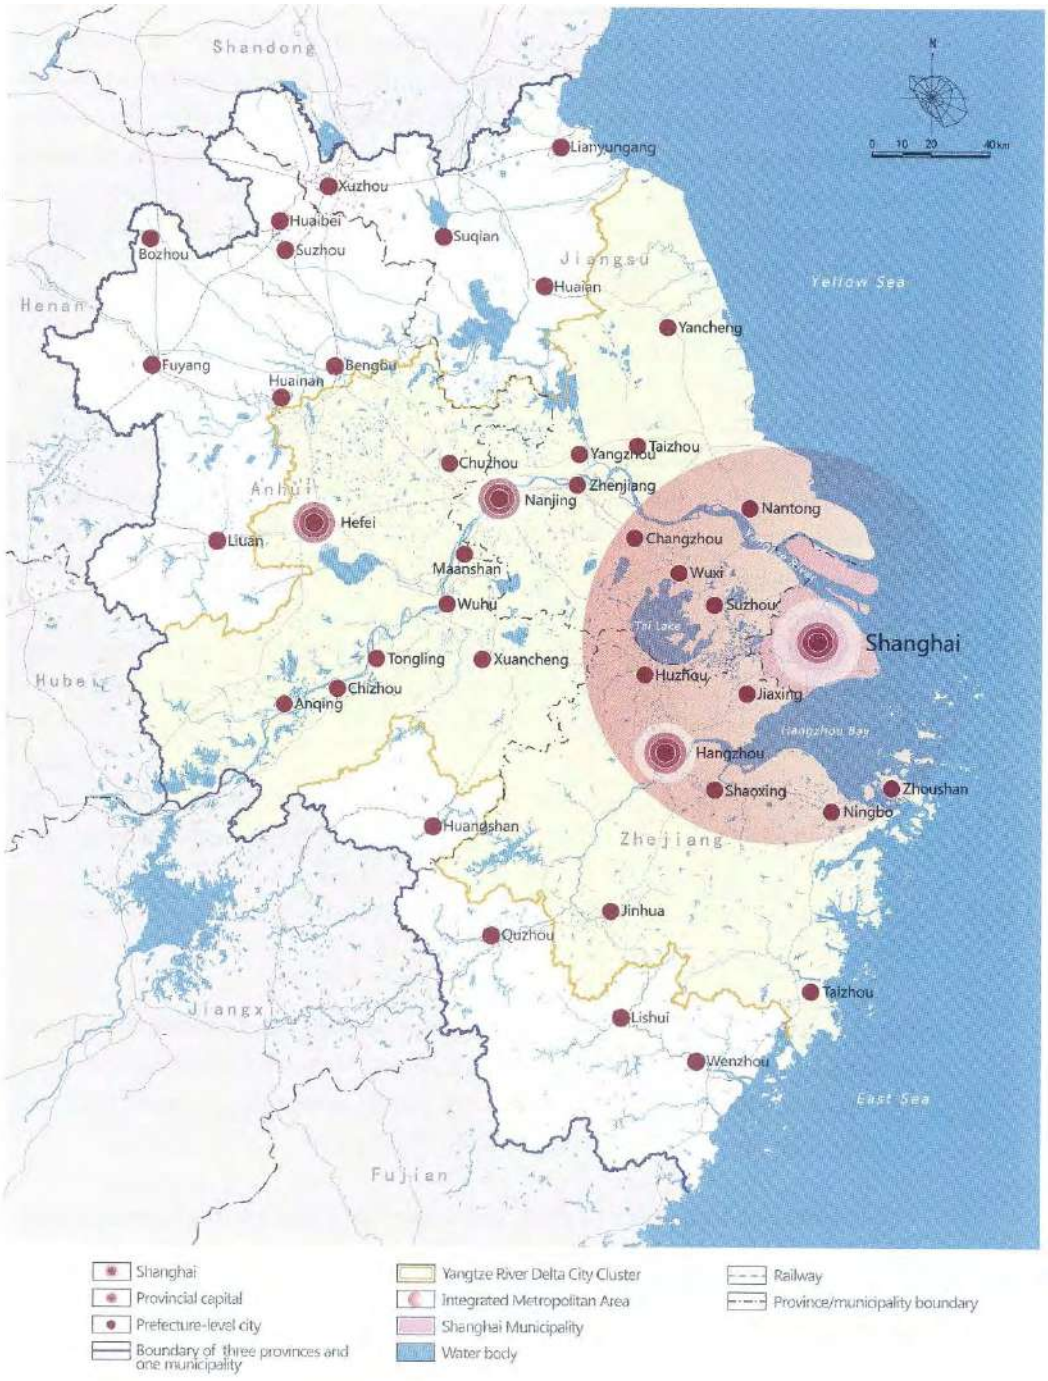

Figure 4: Shanghai Municipality Location Map

The State Council has approved a City Cluster Plan for the long-term development of Yangtze River Delta and other two main city clusters in China (China's City Cluster Plan,

2018). The Yangtze River city cluster includes five development belts stretches from Shanghai as Coastal Development Belt, Hangzhou-Ningbo Development Belt, Shanghai-Nanjing-Hefei-Hangzhou-Ningbo Development Belt, Riverside Development Belt and Shanghai-Hangzhou-Jinhua Development Belt. These five belts connect Hefei, Nanjing, Suzhou, Hangzhou, Ningbo five metropolitan areas to Shanghai. The function of Shanghai as financial and tourism center has been redefined by the 'The Belt and Road Initiative'("The Belt and Road Initiative", 2019) and the Shanghai Master Plan 2035. The original spatial structure has now been shifted from single-nucleus to multiply-nucleus agglomeration. Shanghai is transforming into an innovative, livable and environmental-friendly city rather than an overcrowded economic center. This transformation will most likely bring great opportunities for other cities within the YRDUA by the establishment of Free Trade Zone (FTZ) ("The Belt and Road Initiative",2019.). The free trade zone allows these cities to stockpile imported products first, and collect tariff only by the transaction of these products.

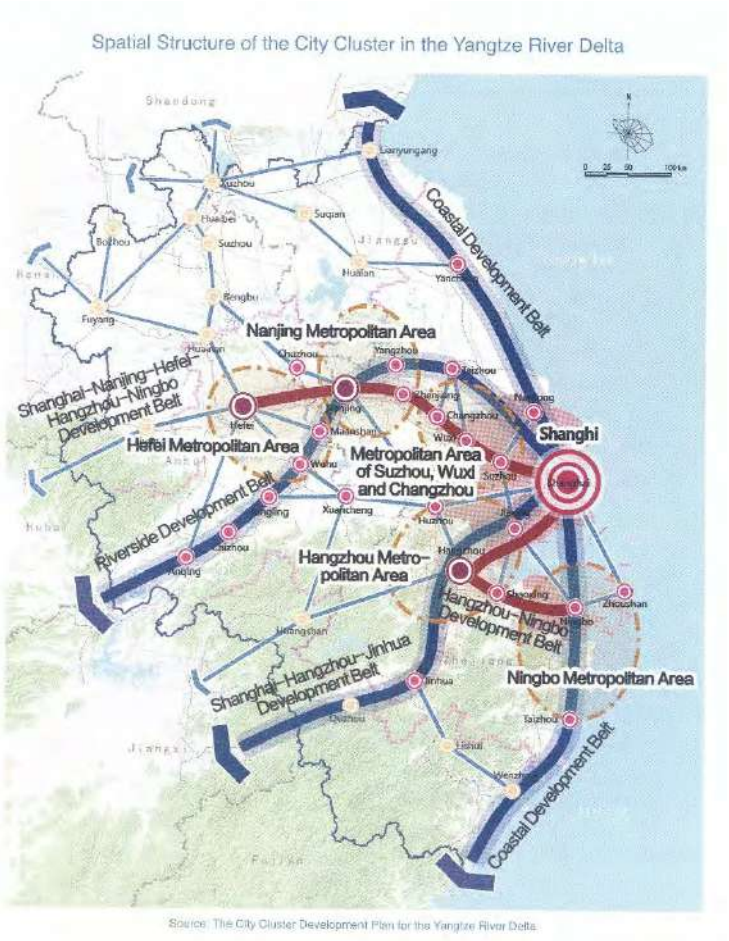

Figure 5 Spatial Structure of the City Cluster in the Yangtze River Delta

3. Planning Implementation Process

An implementation-oriented action planning system has been established based on relevant Unit Plans and Detail Plans. The system requires coordinated development objectives and timetables for population distribution. A variety of planning guidance and outlines will be published in line with the spatial framework of Shanghai Master Plan 2017-2035(“Shanghai Master Plan 2017-2035”.2018).

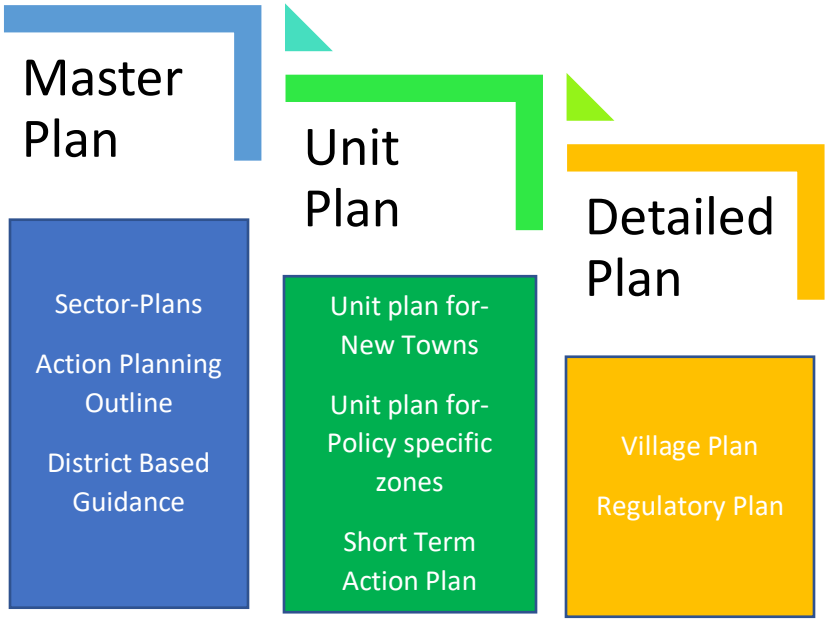

Figure 6: Multi-level plans in planning Implementation process

The overall framework can be classified into three levels

1) Master Plan has defined overall land uses guidance and urban development objectives for all districts. It includes district plans and Sector plans at master plan level.
2) Unit Plan will be prepared by regional government to enhance the support for New towns and Policy specific zones. It guides the construction of short-term projects and local infrastructures with short term action plan.
3) Detailed plan includes regulatory plans, sector plans and village plans. These plans are specific implementation-oriented plans which direct the implementation of urban construction projects. According to the technical standards and specifications proposed by the Shanghai Master Plan 2035 (“Shanghai Master Plan 2017-2035”,2018), Shanghai will refine policies and regulations for better operation management and planning design in key sectors.

4.Conclusion

Mega city problems are caused by many factors. Unfortunately, conflicts between limited land resources and steady growing population is unavoidably one of them. By establishing a spatial structure system, a coordinated development plan and a series of detailed planning implementation processes, the Shanghai Municipal Government has proposed an integrated master plan to strengthen regional interconnections for a sustainable future of Shanghai Mega City Region. As a result of that, the fast-growing city cluster of Yangtze River Delta will be able to offer residential, commercial, industrial and recreational services to Shanghai's cross-city commuters and residents. It will eventually lead to regional population redistribution across the entire city cluster of Yangtze River Delta. Effectiveness of the newly implemented Shanghai Master Plan 2017-2035 may not be revealed in a short term, but shanghai vision and experiences might be considered as a valuable solution to other overcrowded mega city regions.

Research Paper

Building moratorium as a future instrument for tackling unsustainable urban growth

Ivana ANGELOVA, Researcher, Meiji University; Japan

Abstract

We live in times when our planet is overloaded with issues coming from human activities where additional mechanisms to preserve the quality of life are essential. Modern societies experience constant internal dynamics. The uncontrolled urban growth leading to dense and unmanageable environment is a main urban issue cities face today. This is a prevailing problem in the developing countries where the construction industry is booming. Overall, while there is a rush to development there are also some conflicting interests and policies that are leading to unsustainable urban growth.

To regulate a property development a local government can try to impose a moratorium on the issuance of building permits and this can be agreed upon all the interest parties or it may be imposed by operation of law (Lehman and Phelps, 2005). Oftentimes local authorities will impose a building moratorium to tackle development in order to have time to make a satisfactory urban plan or to make some changes and update the regulations. The land use control objective is to promote good planning values supported by the whole community. This is done by regulating the urban growth and it is best implemented on a carefully contemplated comprehensive plan. During a time a new plan is being drafted and growth balance is achieved some construction demand may arise based on an existing outdated, inadequate urban plan. If this demands are met "the ultimate worth of the eventual plan could be undermined" and this where the moratorium comes in place (Coon, 2010).

The resources of academic literature on the case are somewhat in short supply and mainly based on describing specific case scenarios without a critical thought on the tool itself. Based on the resources the paper will look at a few different cases in developed countries using the growth management systems and one southeast european case - the city of Skopje, Macedonia that adopted the building moratorium system in January 2018. The author of this paper was personally involved in the decision making process in that time and will try to elaborate on how the tool was being used.

The validity should be determined by weighing its impact on the affected parties and more comprehensive research in the economic repercussions of the mechanism is needed.

A building moratorium is oftentimes a political decision and it's downside is that political parties would use it merely for their own purposes.

Keywords

Building moratorium, local government, Skopje, sustainable growth, legislation.

1. Introduction

The clustering of human interactions in big urban agglomerations poses a great sustainability challenge on the urban settlements regarding basic services, decent jobs, safety, housing, infrastructure and natural resources. Some of the biggest global implications of the unsustainable urban development are the growing environmental degradation, poverty and inequalities (Caprotti et al., 2017).

To tackle the problems deriving from over-construction in urban environments governments use different growth control mechanisms and other related regulations. Most of the growth controls do not limit development notably but rather they help in generating higher public benefits (Molotch, 1976). In the 80's there was a trend in the USA where the local authorities would use different mechanisms that allow for a systematic growth of their cities in order to balance the need and the supply especially in the housing market. The municipalities used a variety of growth management tools like building permit embargo to fully developed growth management ordinances as to have a control over the private development decisions. From all the growth control tools the outright and vital one is the building moratorium (Rosen and Katz, 1981).

Building moratorium used by the local governments worldwide is the one urban growth management tool that this paper focuses on. The objective of this research paper is to explain the mechanism itself, how and under which circumstances governments can legitimately use it and ultimately this paper will question its repercussions.

In addition, this research presents how and why this tool was used in the case of the city of Skopje, North Macedonia as a representative from the southeastern non EU countries while illustrating cases from other countries namely from the USA and the UK. This is due to the fact that literature provided is limited to examples coming from those regions only. In the case of Skopje the issue of unmanageable environments arises due to poor urban planning, due to corruption in the local and central governments, low public participation, urban plans that do not correspond with the master plan and in return leading to unconstitutional implementation of the urban and construction policies. It is relevant to stress that the urban context and conditions are very similar among many Balkan cities. On the other hand, in the developed countries, the unbalanced building stock growth is mainly due to mismanagement between the supply and demand in the real estate market.

The information provided in academic research papers is focused on describing and analyzing specific case scenarios mainly from the second half of the last century and without a critical thought on the tool itself. There is no holistic overview on the occurrence, meaning the repercussions of using this tool are not yet fully investigated even though academics argue more exploration on the case is needed.

2. Theoretical review

2.1. Definition of the term "Moratorium"

In order to understand how building moratorium is functioning it is crucial to look into its meaning first. Figure 1 shows the synonyms to the term.

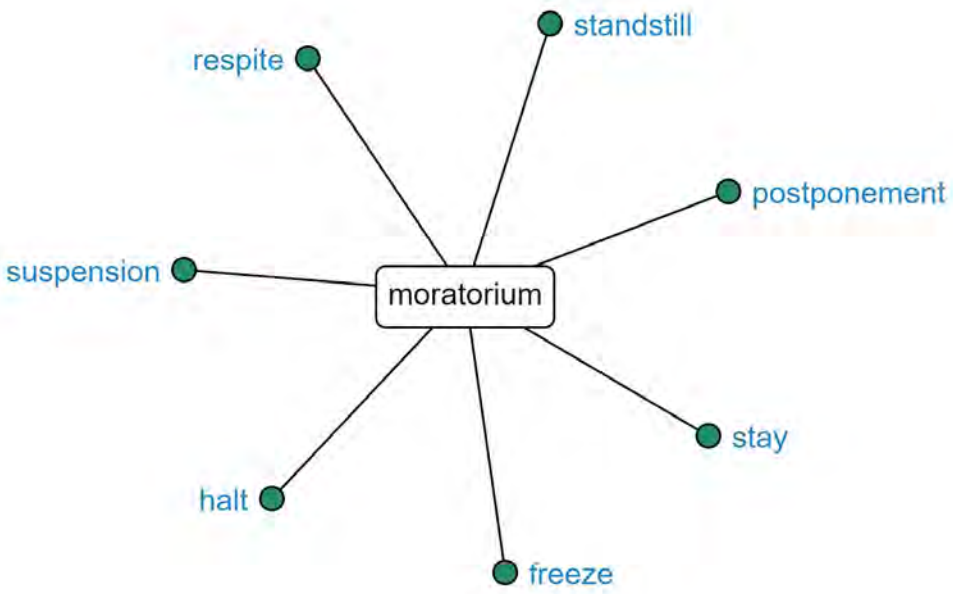

Figure 1. Synonyms for moratorium.

Source: https://www.freethesaurus.com/moratorium

"MO'RATO'RIUM (Neo-Lat., neu. sg. of Lat. *moratorius*, relating to delay, from *mora*, delay). A moratorium is a delay or suspension of an activity or a law. In a legal context, it may refer to the temporary suspension of a law to allow a legal challenge to be carried out "(Gilman et al.,1905).

"A building moratorium halts the construction of a project or projects. Building moratoriums are imposed by cities, towns and the courts, and for a variety of reasons" (Bankrate, 2018).

According to Rosen and Katz (1981) a building moratorium is used to stop the building permits by the local authorities in response to supply deficiency of the most essential public services, particularly the clean water supply, sewage infrastructure and public amenities. In addition, the authors conclude that the building moratorium has become the most common tool for temporary controlling the city growth. Coon (2010) argues that a moratorium on the development should halt the construction temporarily, preserving the status quo while giving time to the government to update the comprehensive plan. In the period when development is pending an adoption and completion of a new more comprehensive and permanent regulations is expected.

The moratorium will last until future events authorise its ending and issues regarding the suspension have been resolved. It is expected that in the time of a suspension of an activity or a low some legal challenges will be resolved (Investopedia, 2018). Only after an evidence of an externality arises governments can regulate development timing under a strict no-takings rule (Turnbull, 2004).

2.2. Circumstances under which a building moratorium is declared and its types

There are varieties of reasons why the governmental bodies may declare moratoria. According to Lehman and Phelps (2005) more often than not when there are concerns within communities connected to environmental degradation and safety an immediate termination of construction activities is seen as the best interest of the jurisdiction and local authorities in urban settlements impose a building moratorium (Bankrate,2018). Coon (2010) explains that governmental bodies will adopt moratoria first and foremost to halt and balance the big demand to development, than to prevent unsuitable and not carefully considered growth and/or to take time in order to raise awareness to a new issue in planning. According to him other reason may be connected to preventing the disadvantaged outcomes that the public and landowners could face in accordance to a construction that might be conflicting with the future plan strategies. In practice those motives are interrelated.

According to time spam a building moratorium can be *short-term*, lasting for several months, typically three months to a year, and *long-term* that last for several years up to a decade depending on the framework set by the local government (Bankrate, 2018). The moratorium can also be *general* referring to all kinds of building permits in one zone or it can be *specific* and pose a ban on a certain land use like a housing moratorium or a commercial moratorium. According to Coon (2010) the most common type is the general land use moratorium that halts the acceptance of new development applications until planning or zoning changes are being made. Passing this law prohibits the landowners right to build by obtaining construction permit until the new comprehensive plan is adopted addressing some new urban issues that has not been previously being dealt with in the planning policies.

2.3. Moratorium in San Francisco Bay Area and in United Kingdom

In the San Francisco Bay Area the issues that led to building moratorium and in this case many other North american cities are coming from speculation in land price and this type of moratorium is specially aiming at the housing construction. “The dynamic economic growth and accompanying rapid housing development of the 1950s and 1960s has evolved into a desire to preserve the status quo and protect the natural and ''economic'' environment from the more damaging aspects of unconstrained suburban development” (Rosen and Katz, 1981). In the late 1970s San Francisco Bay Area housing prices went from being average to the highest in the whole country. In this scenario the residents of the affected area opted for different land use control mechanism like the building moratorium, down zoning, more rigorous environmental regulations and other advanced growth management tools. Among all the most relevant type of growth control was the building moratorium because it showed fastest results in stabilizing the housing prices.

In the case of the local governments in the UK, they use a very typical form of development moratoria- the *moratorium on assets of community value*. Authorities work in cohesion with the residents in order to decide on the list of assets that are of great importance to them and would like to preserve as they are. A form of a public–private partnership is used as a mean to preserve the places listed as public interest. There are however consequences to the asset owners that the government is compliant to make sure they understand. After the official listing of an asset there is a moratorium period in which the interested community members can use their right to bid for the private real estate listed as an asset and buy it. The negotiation period in which the owner is blocked from developing or selling the property to another party rather than interested community group is six months (Localism Act 2011 and the Assets of Community Regulations 2012).

3. Building moratorium in Skopje

3.1. Problems in the urban sphere

The city of Skopje, the capital of North Macedonia is situated in the heart of the Balkan peninsula. In the second half of XX century Skopje faced a rapid urbanisation and has increased its territory immensely. After the fall of Yugoslavia in the beginning of the 1990s the new socio-political system led to some inevitable changes in the way urban planning was practised. Ever since the city is going through changing planning paradigms. Skopje now is experiencing uncontrolled expansion that generates a mixture of various types of urban space with variety of urban issues to deal with, a minimum public space and big environmental problems. “What we face now is urban planning at the most primitive level” (Pencic, 2018). Pencic (2018), an academic and urban planner and also the head of the municipal working group for plans evaluation argues that Skopje was the greenest city in former Yugoslavia after a major earthquake that hit the city in the summer of 1969 opened a chance to literally start planning the city from scratch. Foreign and local experts like Kenzo Tange had the opportunity to create a new city. Skopje was a small town before the catastrophe, but was given the chance to develop in accordance to the latest world-known information at the time. Urbanism in that period was also booming, as experts were to build many cities that were destroyed after World War II. Planners envisioned the physical structures into resilient spatial and organisational patterns adaptable to change. Skopje was and had the chance to be a beautiful city. Land ownership was national, it belonged to the country and was considered a public good while dwellings belonged to the citizens. Today capitalist countries do so, it is not merely a feature of the socialist times. According to her after the country has privatised the national land the city is facing major urban challenges. She addresses the biggest problem in the priority given to the private good while the public is being overturned. Siljanovska and Angelova (2017) would stress that: “The city of Skopje is not in the most desirable condition, it needs a better development and growth strategy. The biggest challenge lies in the lack of transparency in the urban policy making and its inflexibility which makes long-term sustainable solutions almost impossible.”

3.2. First moratorium in the history of the country declared

On the 6th of January 2018, the Council of Centar Municipality in Skopje voted in favour of the decision to halt construction within its legal borders and declared that the urban plans are invalid until their legitimacy is being confirmed.

The DUPs:detailed urban plans for a city quarters (equivalent to the term: comprehensive plans in some countries) are not compatible with the GUP: general urban plan (equivalent to the term: zoning plan or master plan in some countries) of the city. As the renowned architecture and planning magazine Porta 3(2018) puts it, the moratorium is a bold governmental decision. Putting order in the urban chaos and improving the quality of life for the citizens of Municipality of Centar was the pre-election promise in December 2017. Initially a ‘construction blockade’ was demanded by the citizens themselves as they become aware of the continuously endangering conditions and quality of life in their municipality. They have joined to get acquainted with what is planned, what kind of problems can they present to the policy makers and to increase the awareness that as citizens everyone has the right to engage in monitoring the creation of city policies and future spatial development. They asked for more participation and transparency before new plans are being put into power. The moratorium that was implemented in the municipality was as an instrument that helped the new mayor and its bureaucrats providing time to perceive the situation on the ground, to review the planning documents that enable the construction in the previous governmental structure and finally to develop new DUPs that are in line with the GUP. The objective was to review thoroughly the valid plans, as well as the ones in the process of adopting. “The instinctive thinking that something is wrong with urban planning and decision

making for future spatial development is basically derived from the uncomfortable feeling of daily life hardship and the constant increase of pollution problems, traffic collapse, endangered health, lack of place in kindergartens and schools, lack of health facilities in easily accessible locations, loss of greenery, usurped and enclosed spaces and many others" (Pencic, 2018).

On 20th of March 2019 the Constitutional Court ruled in favour of the Chamber of Construction that filed charges on the Municipality of Centar based on the argument that the category of moratorium is not recognised in the legal/constitutional system.

3.2.1. Qualitative analysis of the urban plans

Throughout the first three months of the implementation of moratorium the municipality established a working group of 3 outside members with urban development backgrounds to evaluate the detailed urban plans. The group was intended to establish a methodology for optimal qualitative analysis of the plans based on the building standard law and the masterplan regulations, as shown in Figure 2. The group crucial role was to show its results to the planners and the municipal administration. The group came as a mediator between those two actors and was also involved in the decision making process by giving recommendations for future legislation on planning regulation.

The methodology adopted for analysing the detailed urban plans that the working group provided was:

Analysis of the existing situation: by mapping

- mapping of inventory- of the building stock and streets, due to nonexistent GIS database - outdated database
- Implementation of a previous plan in low (buildings or infrastructure constructed)
- Ownership of empty plots

Comparison of existing conditions with planned conditions:

- 3D visualization comparison
- Shadow analysis: 1.apartment hours under shadow; 2. shadow scope
- Comparable numerical indicators

Analysis of the planned condition

- Comparison of numerical indicators between the GUP and DUP in the procedure
- The area of land aimed for construction and intensity

on the construction

- The need for facilities for public use - education, health and

social protection (schools and kindergartens)

- Green area, public (parks and playgrounds) and private (private gardens, yards)
- Mapping of parcels/plots that do not allow underground parking on -2 levels (4

different ways ways to analysing)

- Number of public parking lots and analysis of street profiles

• mapping objects that do not meet the parameters for the mutual height,

depth and disposition

• Number of population, density and demography (no official population census since 2000)

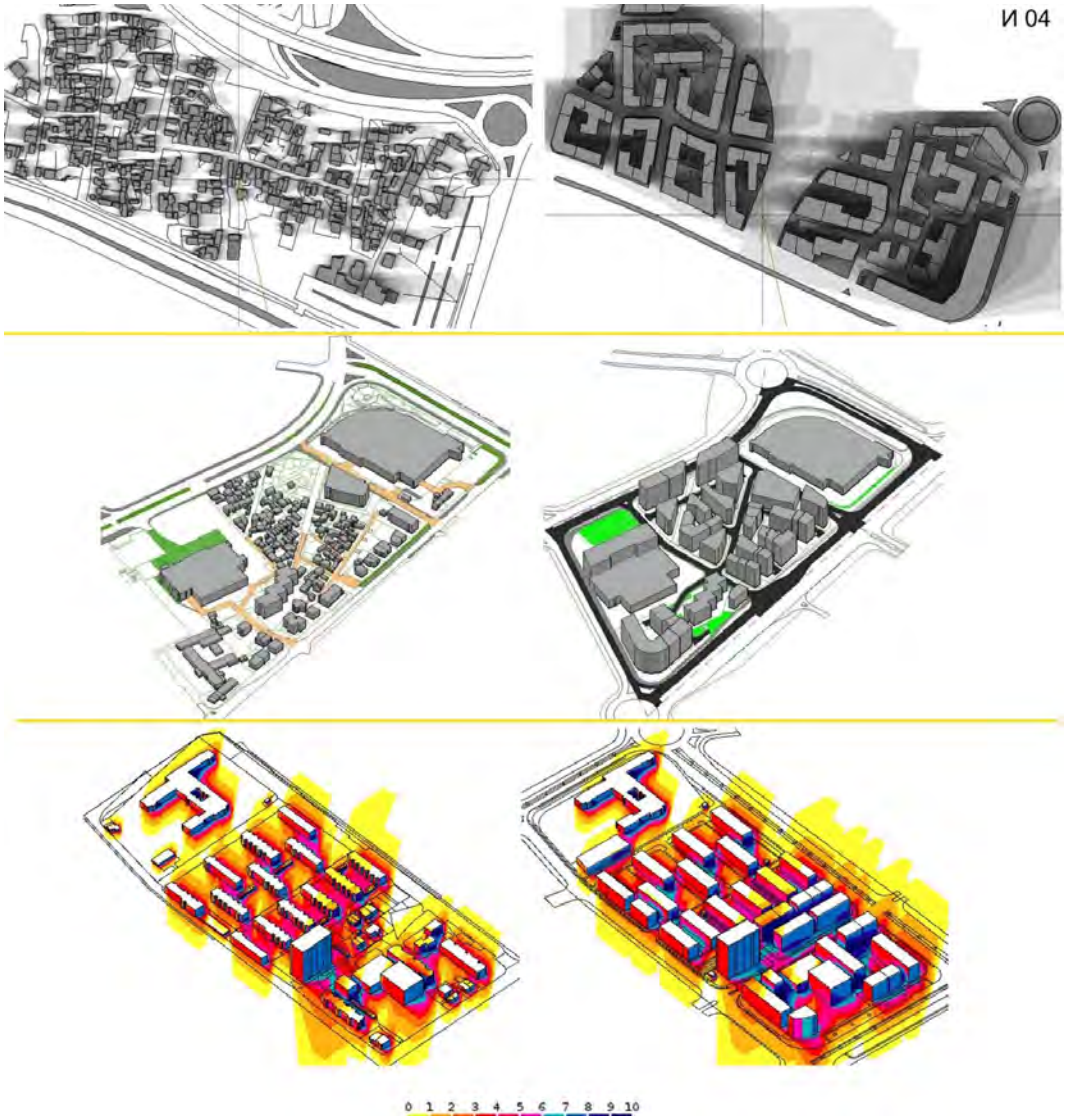

Figure 2. Examples of Qualitative analysis of the urban plans for Municipality of Centar. From top: shadow scope, 3D visualization comparison, apartment hours under shadow.

source: Courtesy of Municipality of Centar

4. The legitimacy of a moratorium

Lehman and Phelps (2005) argued that a validity of a moratorium is determined by weighing its impact on the affected parties. Not in all countries a moratorium is recognized in the constitutional law and in turn local authorities may face big challenges in facing the

troublesome and hardly manageable development. In such case however, there are ways to practice this mechanism. Coon (2010) took the example of The New York zoning enabling laws that did not mention any "moratorium" or "moratoria" but in past cases the New York Court of Appeals indicated that limitation to development and zoning regulations are possible to enforce by law. Landowners could not use a land profitably as long as the community long-term goals in planning are met. On the contrary some other moratoria cases like the Town of Oyster Bay, Texas turned out to be ruled by the supreme court as illegitimate as the town board had no jurisdiction to take such decisions because The Town did not properly refer to the county planning commission, as required by General Municipal Law.

In the case of the city of Skopje, there has been a big media coverage on the local government decision. Affected parties like potential developers and landowners protested against the legitimacy of the decision since the term is not mentioned in the zoning enabling law. However following that the DUPs are outdated and not in compliance with the GUP - a document with a higher legal basis, the municipality of the central zone of the city decided to use this occurrence as a legal basis for the decision to freeze construction (until new synchronised plans are issued). "I know that the decision to halt building construction is something that is being used for the first time in the country but it is stated clearly in the decision the legal grounds on which the moratorium is introduced" (Bogdanovic, 2018). The mayor also backed up the decision relying on the fact that the air quality in the city is among the lowest in the European continent and rapid urban growth would be to blame. "The urban planning documentation for these DUPs is not in accordance with the General Urban Plan (GUP). The detailed urban plans are old and their planning period is over. The stopping of the implementation of the plans will affect the pollution that according to the research based on the UNDP sustainable parameters will decrease by 22 to 25 percent" (Bogdanovic, 2018).

5. The repercussions

The repercussions of stopping the development would affect different actors involved in the process differently. There are many subjects affected by the moratoria in the Municipality of Centar-Skopje: each resident of the municipality, but also every user in that space; anyone who wants to build as the owner of a plot, but also everyone in whose surroundings it will be built; any interested investor, but also anyone who wants to see the benefit of that investment; everyone involved in the preparation of project documentation for future constructions, but also those who need to perform control and give approval; everyone involved in space planning, but also those who need to exercise control and give an opinion. (Pencic,2018). The negative consequence for the local government was the reduced municipal budget due to pending communal service tax form the real estate owners. One of the repercussions of a long-term moratorium is that the municipality with low budget is unable to provide basic necessities for its citizens. When asked about this consequence the mayor answered: "In the past year, we also provided funds from other places ...Today, the Municipality of Centar is a municipality that has no debts.. we managed to provide additional funds in the municipal treasury." (Bogdanovic, 2018). On the other hand there are consequences which should significantly change the development of the city by making it more sustainable and will affect everyone. New urban policies were adopted and the Law on Construction is in its final phase. Bogdanovic (2018) stated that in the coming period the municipality plans to take more decisions that will improve the lives of citizens. In October 2018 in Skopje there was a drop of 31% in the number of building permits

being issued compared to the same month of the previous year (State Statistical Office of the Republic of Macedonia, 2018).

Once a development moratorium is expected anticipatory impacts begin. Large construction companies will rapidly issue building permits so that they can minimize the economic disruptions afterwards. The occurrence is explained by Janczyk and Constance (1980) as: "In the moratorium district , supply should increase as builders rush to get their permits in hand and thus beat the moratorium. Demand should also increase as speculative buyers try to cash in on an expected price increase". Warner and Molotoch (1995) wrote in an article in favour of strict development regulations arguing that the pro-growth regulation group overweights the one against it using the argument of an overburdened planet in need of regional self-sufficiency. However, drawing form four case scenarios where partial or full moratorium was used, the authors noticed some factors that inhibited growth limits from exerting strong influence. Those factors are: *symbolic politics* where policy makers create rules just for the sake of it but without physical output; *episodic intervention* where temporary victories become long-term failures; *countervailing policies* where there are contradictory internal tendencies like restricting development with some policies and encouraging it with others and finally the *initiatives of the regulated* where they may take unexpected advantage form the lax and loopholes.

As to potential hardships to landowners Coon (2010) concludes that the advantages to the municipality must outweigh the negative consequences of a moratoria to potential developers. He concludes that: "The municipality should be prepared to show that the burden imposed by a moratorium is being shared substantially by the public at large, as opposed to being visited upon a minority of landowners". S. Schwartz, et al. in 1979 (cited in Rosen and Katz, 1981) concluded that proponents of the moratorium claimed enablement of a better suburban sprawl control, preservation of neighbourhood character and improved environmental quality. On the other hand Babcock and Bossehnan in 1973 (cited in Rosen and Katz, 1981) argued that growth controls should exclude low and moderate income households and that in the case of housing moratorium the rental prices go substantially higher than usual.

6. Summary

The motive of a building moratorium is to respond to new needs coming from communities by developing new strategies like a comprehensive plan, zoning regulations, site plan regulations, building regulations and improvements to road, water and sewer infrastructure. As a summary a moratorium on construction would be justifiable if: it has a higher purpose like improvement of people's livelihood; there is a rational time frame based on the optimal accomplishment of the goals of the moratorium; have an expiration date; there are protecting measures aimed at the public interest until new policies are put in place; follow jurisdictional procedures by obeying the enabling law.

A topic that needs to be further researched is the economic repercussion of the mechanism. Janczyk and Constance (1980) concludes in their research that governments together with policymakers need to make plans for the long run and foresee growth patterns so that a significant cost on government revenue, jobs in construction sector and consumer surplus can be avoided. Even though the general public supports such decision oftentimes business and welfare elites are not satisfied. Thus a moratorium law should try to accommodate a mechanism to protect to some extent the potential developers and landowners (Coon,2010).

The building moratorium in Skopje can be seen as a trigger to change in the way the city has been growing, saidly unsustainably for the past two decades. Citizens awareness and

participation is growing bigger and a general public interest in understanding and participating in the development of the urban policies that should be aimed not just to serve the market needs but regulate the basic living conditions of the people. On a final note, the tool as a political decision and can be misused to fulfill a hidden political party agenda.

Research Paper

SUSTAINABLE DEVELOPMENT, PLANNING AND POVERTY ALLEVIATION

Jean-Claude BOLAY, CODEV EPFL, Switzerland
Eléonore LABATTUT, CODEV EPFL, Switzerland

Abstract

In 2018, the world population is around 7.6 billion, 4.2 billion in urban settlements and 3.4 billion in rural areas. Of this total, according to UN-Habitat, 3.2 billion of urban inhabitants live in southern countries. Of them, one billion, or nearly a third, live in slums. Urban poverty is therefore an endemic problem that has not been solved despite all initiatives taken to date by public and private sectors.

This global transformation of our contemporary societies is particularly challenging in Asia and Africa, knowing that on these two continents, less than half of the population currently lives in urban areas. In addition, over the next decades, 90% of the urbanization process will take place in these major regions of the world. Urban planning is not an end in itself. It is a way, human and technological, to foresee the future and to act in a consistent and responsible way in order to guarantee the well-being of the populations residing in cities or in their peripheries.

Many writers and urban actors in the South have criticized the inadequacy of urban planning to the problems faced by the cities confronting spatial and demographic growth. For many of them the reproduction of Western models of planning is ineffective when the urban context responds to very different logics. It is therefore a question of reinventing urban planning on different bases. And in order to address the real problems that urban inhabitants and authorities are facing, and offering infrastructures and access to services for all, this with the prospect of reducing poverty, to develop a more inclusive city, with a more efficient organization, in order to make it sustainable, both environmental than social and economic.

The field work carried out during recent years in small and medium-sized cities in Burkina Faso, Brazil, Argentina and Vietnam allows us to focus the attention of specialists and decision makers on intermediate cities that have been little studied but which are home to half of the world's urban population.

From local diagnoses, we come to a first conclusion. Many small and medium-sized cities in the South can be considered as poor cities, from four criteria. They have a relatively large percentage of the population is considered to be poor; the local government and its administration do not have enough money to invest in solving the problems they face; these same authorities lack the human resources to initiate and manage an efficient planning process; urban governance remains little open to democratic participation and poorly integrates social demand into its development plans. Based on this analysis, we consider it is imperative to renovate urban planning as part of a more participatory process that meets the expectations of citizens with more realistic criteria.

This process incorporates different stages: an analysis grounded on the identification of urban investment needed to improve the city; the consideration of the social demands; a realistic assessment of the financial resources to be mobilized (municipal budget, taxes, public and international external grants, public private partnership); a

continuous dialogue between urban actors to determine the urban priorities to be addressed in the coming years.
This protocol serves as a basis for comparative studies between cities in the South and a training program initiated in Argentina for urban actors in small and medium-sized cities, which we wish to extend later to other countries of the South

Keywords

Urban planning, sustainable development, poverty, global South, intermediate cities

1. Urban complexity: Growing cities in developing countries, growing issues ?

The Global South is currently experiencing strong urbanization, particularly demographically and territorially. In parallel, cultural references are changing in terms of lifestyles and the social and economic integration of a growing urban population.
In 2018, the world population reached nearly 7.6 billion, 4.2 billion of which lived in urban areas and 3.4 billion in rural ones. According to UN-Habitat, 3.2 billion urban inhabitants live in South countries. Of these, one billion - or nearly a third - live in slums. Urban poverty is therefore an endemic problem that has not yet been solved, despite the many initiatives taken by the public and private sectors.

To better grasp this debate, we will discuss two distinct issues that have guided our many years of work. These issues could be described as two of the founding elements for urban planning designed to create sustainable, inclusive cities.

The first is urban poverty. Simply knowing that a third of urban dwellers in South countries are poor and live in material and economic precarity on a daily basis very much calls into question the work we do as urban development professionals. We must start thinking of urban planning as a way of fighting poverty.

The second is the focus on small and medium-sized cities, hundreds if not thousands of which (depending on the country) play a decisive role in the exchanges between the countryside and these cities, and serve as regional centers for a multitude of public services. 50% of the world's urban population lives in cities of 10,000 to 500,000 inhabitants. Often unknown outside of their regions, these intermediate cities face enormous challenges, particularly in South countries where they have the highest population growth rate. Over the next decades, 90% of the urbanization process will take place in Asia and Africa.

2. Urban planning in the Global South, occupational hazards

Many critics have voiced their opinions as to the real impact of planning that does not fully addresses the integration issues faced by a large proportion of the population.

Be it in Koudougou in West Africa, Chau Doc in the Vietnamese Mekong Plain, Montes Claros in Brazil or Nuevo de Julio in the Argentinian pampas - example that we will develop further

in this text - (Bolay, 2015; Bolay, 2016; Bolay, 2018) the issue of greatest concern to planners is "How can we beautify cities and make them more attractive to city dwellers and investors," not "What can we do to reduce poverty and better integrate poor people living in precarious conditions?"

Figure 1 Koudougou, Burkina Faso (Photo by J-C Bolay, 2014)

While not diametrically opposed, the thinking behind these two questions is nonetheless divergent. The former avoids delving too deeply into societal complexity and instead seeks technical solutions to improve the city's functionality (infrastructures, networks, communication routes, equipment, etc.), too often forgetting the universal need for accessibility (i.e. for the poor as well). The second makes citizens the focus by recognizing the fact that integrating people socially, economically and culturally fosters sustainable, inclusive urban development. In this sense, urban planning in South cities is too often incomplete at the spatial level, as experts only focus on specific parts of the territory and typically abandon poor, poorly-regulated and outlying neighborhoods. It is also poorly adapted socio-economically speaking, as it tends to focus on business districts and the "select" areas that privileged social actors invest in based on their financial status, relationship to power or even community or ethnicity.

Figure 2 New social settlement in Montes Claros, Brasil (Phot by J-C Bolay, 2018)

Based on a comparative study of nine South cities, Devas (2001) concluded that the standards established for infrastructure, facilities and buildings were completely unsuited to the conditions of the poor, but formed a perfectly workable system of regulation by individuals

with economic and/or political power. This is largely due to the fact that methodological and technical debates are dominated by Europe and North America, and take Western cities - whose characteristics radically differ from those of developing countries - as their point of reference and as experimental sites (Edensor & Jayne, 2012). Reproducing these recipes in different urban contexts is simply nonsensical and can only offer ineffective solutions. The management of public facilities and services is a good example. Today, the privatization of the latter – which in fact are often no longer public! - is a major trend. Hence the profitability of urban investments and their management takes precedence over their "universality."

Figure 3 Informal housing along the river in Chau Doc, Vietnam (Photo by J-C Bolay, 2018)

In many South countries and Western countries as well, the management of basic sectors such as water, energy, transportation, culture and public spaces (to name only the most obvious) is now in the hands of private companies. It is perfectly valid and healthy to worry about the balance of public finances. However, it is untenable to do so at the expense of the working classes, whose economic conditions impede their access to a whole range of amenities and services, the charges for which exceed the spending capacity of modest income households. Therefore, the question is who decides on urban investment priorities, based on which criteria, for whose benefit and according to which cost recovery mechanisms (i.e. from users)? For Watson (2009), demographic and territorial growth in South cities inevitably leads to a concentration of poverty and social, economic and spatial inequalities. Urban planning as applied in many developing countries cannot anticipate or solve the multitude of intertwined problems, between the local needs of each family, community and neighborhood, and the production of planning based on the entire urban territory (but with inexplicit priorities) by specialists.

As the saying goes, "We only lend to the rich." In South cities, the poor know this better than anyone else. Putting aside the social and economic repercussions of urban development, it is normal for companies (public and private) to favor individuals, social groups and, by extension, areas of those city they know will provide a return on their investments. However, they quickly forget that this short-term profitability reinforces social segregation and the fragmenting of the urban territory between rich and poor, and developed and marginalized areas. Though the costs of this are not immediately discernable, they are in the medium and long term. How? Firstly, by creating more and more poor neighborhoods that are in turn neglected by the authorities, with increased insecurity, both real and perceived. Wealthy neighborhoods are equally marginalized and isolated, with gated communities hidden behind walls and protected by private police. The environmental cost is very high, with some parts of the city lacking basic sanitation infrastructure. Natural resources (water, soil and air) are contaminated and impact the health of inhabitants. Again, it is the poor who suffer the most. More indirectly, however, it is society as a whole that pays the price; public schools and public hospitals are reserved for families without sufficient means, savings or social security, while clinics and private schools welcome well-to-do families.

And yet, statistics have long shown that the most dynamic, innovative, richest companies are those that invest in these "social" sectors that benefit all citizens. We must therefore bear in mind the idea of the common good, of going beyond individual dynamics and of rethinking urban planning in a vision of shared urbanity (harmony between the natural/built environment, fighting poverty by favoring social integration, etc.). Though this is feasible and already exists, it is far from being the rule in South cities. Thus, we must reverse the current logic and redefine the priorities of planning.

3. Planning against poverty, a priority for intermediate cities

The question of urban development is particularly critical for intermediate cities as well as small and medium-sized cities of 20,000 to 500,000 individuals (Bolay, Kern, 2019), firstly because they are home to roughly 50% of the world's urban population (United Nations, 2014) and secondly because they are the cities with the greatest urban growth. Despite this, these "ordinary cities" (Robinson, 2006; Parnell & Robinson, 2012) are generally not on the federal government's radar and receive relatively little federal funding to tackle the urgent issues they face or to invest for the future. Investment priorities are not always based on rigorous diagnostics involving long-term planning processes, but rather are often the result of "opportunities" or pressure from powerful stakeholders (from within the city or outsiders). Inhabitants of these cities suffer the consequences in terms social/material precarity, contamination of natural resources, informality of economic activities, and dysfunctional decision-making and governance.

4. Lessons? Learning from what exists and by doing (better)

With this urban context of insecurity and uncertainty about the future of these small and medium-sized cities, we can speak of "poor cities,” not only because many citizens actually live on the edge of poverty but also because the urban authorities cannot afford the investments needed to improve daily life for residents. Reversing this trend would involve changing urban planning by moving away from development models that were designed to comply with standards and rules in completely different contexts (i.e. Western countries) established by specialists with little to no knowledge of the Global South. The major risk here is projecting onto these cities based on criteria that only serve the interests of a minority – in other words, the wealthy – marginalizing the poor living informally in the most underserved neighborhoods. However, it is also an extraordinary opportunity to think about the future based on what exists, taking into account the actual financial and social resources of these cities, to design and implement urban planning that fights against poverty, and to invest in facilities with a sustainable impact on the poor’s living conditions.

Urban planning in developing and emerging countries must be entirely rethought. The essential point, which is too often overlooked, is to start from a participatory diagnosis in which the reality of the city is examined in its various dimensions (demographic, spatial, infrastructural, economic, social and environmental), thus allowing all stakeholders to find their place. This cartographic, documentary and anthropological information should serve as a basis for a database that can then be uploaded with real-time information, thus facilitating the monitoring of "urban development" and a collaborative, up-to-date decision-making process. In parallel remains the question of establishing priorities in terms of lacking

infrastructure, standards, rules and plans that are tailored to the context, the needs identified by specialists, requests from different social actors, and internal and outside financial resources.

Figure 9 Youth in Nueve de Julio, Argentina (Photo JC Bolay, 2018)

Two principles should guide this process: the first is that urban investments should be used to fight poverty either directly or indirectly; the second is a global vision to guide the specific actions in the short, medium and long terms. These precepts can only be applied if the framework conditions are respected: local and regional governments must have the human competencies and financial resources available that will enable them to take action. This is not impossible if the political will is there and is considered legitimate by the population. This inevitably involves consultation frameworks that will open up a dialogue between representatives of the population, public administration, political powers, industry professionals and other special interest groups (private sector; social, religious, and political groups; NGOs; etc.).

5. The city is full of decision makers, so let's train them to be good urban planners

Figures 10-11 Workshop in Pehuajo, Argentina (Photo JC Bolay & E. Labattut, 2019)

Training plays a key role, as does communication and dialogue. These same guidelines should govern implementation. Here, too, there is room for innovation, starting with social practices and human dynamics outside of the formal context at the local and regional levels. Though the technical know-how of urban and business experts (who too often are absent) is indispensable, inhabitants are nonetheless often forced to take matters into their own hands and wind up doing the job (building homes, community facilities, better managing their neighborhoods, etc.) themselves.

These vital forces should be neither overlooked nor set aside, for they are the very heart and soul of a participatory process that includes not only consultation, but conception and action as well. Rather, these forces can be incorporated into the planning process, where they can be useful in the implementation of collective decisions. Communication is also a key issue. How to learn from other cities via the Internet and increasingly frequent global exchanges on urban matters? As Campbell (2012) explains, we learn from both near and far, and no longer unilaterally from North to South but also from South to South and South to North.

6. From research to implementation: A collaboration with a network of Argentinian medium-sized cities

With this urban context of insecurity and uncertainty about the future of these small and medium-sized cities, we can speak of "poor cities,"

The best example of such an approach is what we currently share with the "Colegio de Arquitectos[i]" in District 7 of the province of Buenos Aires in Argentina, where we have created an urban planning training program for professionals in 15 intermediate cities in the northern part of the province.

This program is in line with SDGs (sustainable development goals) and their role in the urban context, as defined by Objective 11 "Sustainable cities and communities"[ii].

Figure 12 Localization of Nueve de Julio, Buenos Aires Province, Argentina (Google map, 2019)

The project was based on an initial collaborative project between the Municipality of Nueve de Julio – a city of 37,000 inhabitants located 260 km from the capital, Buenos Aires - and the CODEV. The collaboration helped us to better identify training needs and to determine the appropriate methods. The first project phase was based on the assumption that the urban planning tools available to the municipality were not adapted to the urban and social needs/reality. Effectively, the city's planning department possesses little data on the city. Moreover, it does not even have an updated plan of the networks or a mapping department; in fact, in 2018, it had a single urban planning unit with only two architects. The reference document is a zoning plan, which is a non-versatile urban planning tool that does not convey a project or a vision of the city's development.

Based on these observations, a collaboration agreement was established between the city of Nueve de Julio and the CODEV (Center for Cooperation and Development, Ecole Polytechnique Fédérale de Lausanne, Switzerland), with the central question: how to create a GIS (Geographic Information System) tool with limited resources? Both agreed that the priority was for the municipality to ensure the production and management of data in order to gain a better understanding of the territory while creating a common tool that would facilitate work between the various municipal services. Among the main findings were:

- A lack of human and material resources for urban planning at the municipal level;
- The lack of a unifying project for the city in terms of urban and territorial planning beyond the urban code (zoning plan);
- Incomplete urban data scattered among the various municipal services;
- A need to include more urban actors, namely residents but also service providers such as the service cooperative, the university sector, etc.

The municipality of Nueve de Julio agreed on the priorities of developing human resources and investing in material and technological resources. In turn, the CODEV agreed to support its effort on planning data acquisition. To do so, a list of 35 essential GIS layers was developed along with an inventory of the availability of this basic data within the municipality (Cortat, 2017). These 35 layers were ranked in order of priority from 1 to 3 depending on their importance (1 being of the highest importance, 2 of medium importance and 3 of minor importance). A synthesis of this work showed that a certain amount of data already existed, even if it sometimes appeared in an inappropriate file format, was not digitized or had not been updated. The conclusion was that half of the basic data existed and the other half needed to be collected.

Three priority actions were then proposed to the municipal planning department: (1) to start building an initial database with existing data after digitizing and converting it to the appropriate formats; (2) to prioritize by assessing the benefits and viability of each production or acquisition of an additional dataset; and (3) to work in collaboration with other actors in order to obtain as much data as possible. It quickly became clear that setting up data collection, even minimal, would prove difficult for the municipality's urban planning department, which has neither the staff, nor the equipment, nor even strong political support from the mayor. To circumvent these issues, the partners envisaged refocusing the project on the Ciudad Nueva neighborhood – an area of 10,000 inhabitants living in precarious living - by developing a participatory citizen mapping process to demonstrate that a lack of financial and human resources could be overcome using simple, inexpensive technologies. But by late 2018, the proposal had run up against political blockage and the project ended in a stalemate.

Figures 13-14 Information on the first training workshop in Argentina (CAPBA, 2019)

The second phase aimed to work with a network of cities in the Northern part of the province of Buenos Aires to overcome such local political blockages. In early 2019, the CODEV launched this phase along with the "Colegio de Arquitectos (CAPBA)," an important and recognized institution in Argentina that is present throughout the country thanks to regional and district representation. The Colegio de Arquitectos of District 7 (CAPBA D7) is setting up a network of cities, the "Red de Desarrollo Urbano Pampeano (ReDUP)," which comprised 15 cities of less than 50,000 inhabitants and includes Nueve de Julio. A first seminar helped highlight the fact that the problems in Nueve de Julio (unplanned urban development, lack of data, inappropriate planning tools, etc.) were in fact common to all the cities in the network. The CAPBA D7 and the CODEV thus established a research agreement in December 2018 to work at this new scale so as to overcome political blockages at the local level and provide support

to municipal staff in high demand. The project is in line with the network's general objectives of promoting knowledge sharing and experimentation at the regional level, pooling resources and developing appropriate tools and training for municipal technicians.

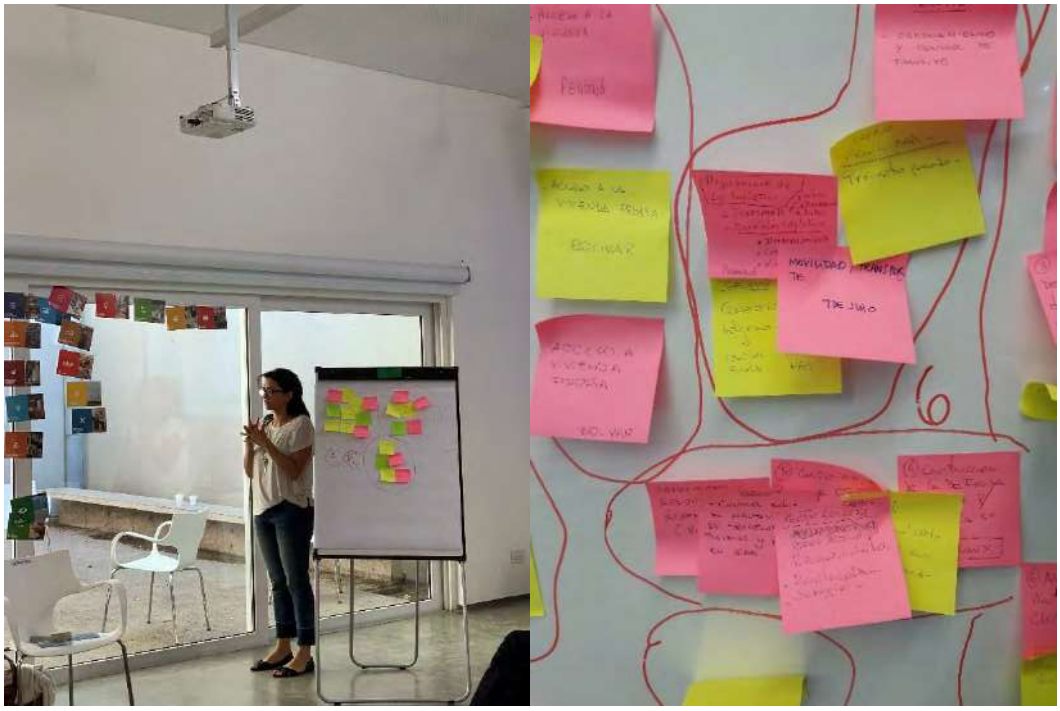

Figure 15 Workshop in Pehuajo, Argentina (Photo JC Bolay & E. Labattut, 2019

This new project phase, which ends in December 2019, will allow for a regional diagnosis of the priorities of each city and the network as a whole in terms of urban planning and the need for GIS tools development.

The working seminars with municipal technicians, the first one organized in March 2019 in Pehuajo and the second one planned for September 2019, will be used to draw up specifications for the construction of a GIS platform that is adapted to the needs of the network as well as for the implementation of a training program, supported by the Colegio and by provincial and national institutional partners who have since joined the initiative.

7. Conclusion: Between crises and urban strategy, the challenges of planning

Our conceptual thinking on the need to quickly find innovative ways to design and develop urban planning in South cities is reinforced by our fieldwork experience as well as the local and regional collaborations that have been set up.

Today we are at a turning point. Having spent a considerable amount of time studying its practical application in African, Latin American and Asian cities that are extremely divergent,

we have now moved into this new training and local capacity-building phase for urban and regional planning.

At the end of a first seminar that brought together municipal technicians from nearly 15 intermediate cities in the province of Buenos Aires, Argentina, some useful lessons were learned for the remainder of the process.

First, in order to define priorities for each city, a shared diagnosis must be established as a first step. This should not only be based on analyses by urban experts - municipal technicians and professionals – but should also include other stakeholder groups. To implement it, cities must have data and analyses at their disposal to observe the major phenomena and dynamics at work in their territory, at the environmental, economic, social and urban levels. But analyzing territories based on data would require a significant change in the municipal work culture, including new skills for technicians, integrating new tools and developing new approaches to interdisciplinary collaboration.

Secondly, for most of these technical experts, planning is first and foremost a task to be managed between planners, engineers and computer scientists. Other communal or regional services - social, health, environmental or cultural - are there to provide data that the former can then process and analyze. Municipal technicians' request is therefore primarily technocratic: to provide them with databases and computer platforms that they can then share, geotag and analyze. This hierarchy of responsibilities and tasks implicitly extends to other urban actors (inhabitants, lobby groups, social or economic groups). At this stage, however, citizen participation is still an abstraction. We still have a lot of work to do together to prove that this dialogue between all of the interested parties is not intended to minimize the work of technicians or their skills, but rather to enrich the database based on social demands. Above all, it should serve to boost urban management by taking collective responsibility for this "common good," this shared urbanity and living environment that is supported and respected by all.

Urban planning is not an end in itself: it is a human and technological way to anticipate the future and act in a coherent, responsible way to guarantee urban and peri-urban residents' well-being. To address the real problems that urban inhabitants and authorities face, planning must create collective infrastructures and access to services that aim to reduce poverty and develop a more inclusive city with better organization, in order for it to be environmentally, socially and economically sustainable.
The field work carried out during recent years in small and medium-sized cities in Burkina Faso, Brazil and Argentina is helping us to attract the attention of specialists and decision makers to intermediate cities that, though they are home to half of the world's urban population, are little studied. All of these small and medium-sized cities face various forms of precarity, with relatively large poor populations, local governments that lack both the financial means to invest in solving the problems they face and the human resources to initiate and manage an efficient planning process. In most of these cities, the governments are still not open to democratic participation processes and do little to incorporate social demands into their development plans.

Based on this analysis, we consider it is imperative to reinvent urban planning as part of a more participatory process that meets the expectations of citizens with more realistic criteria.

This process involves different phases: an analysis phase grounded in the identification of urban investments needed to improve the city; consideration of social demands; a realistic assessment of the financial resources available (municipal budgets, taxes, public/international grants, public-private partnerships), and; a continuous dialogue between urban actors to determine the urban priorities for the coming years.

This protocol shall serve as a basis for the training program initiated in Argentina for urban actors in small and medium-sized cities, which we hope to later extend to other the South countries.

Case Study / Project

Balanced Regional Development through District Planning

- A comparative analysis of Indian and South African planning frameworks

Tathagata CHATTERJI

Abstract

Regional planning literature suggest development of small and medium sized cities to counter balance mega-city-centric growth poles. Yet, implementations of such strategies are problematic, especially in fast growing transitional economies of the Global South. Market driven global economic environment typically favours metropolitan scale, connectivity and human resource talent pool, in channelizing investment generations. Moreover, newly industrializing countries often lack institutional and technical capacities to undertake integrated regional planning.

This paper compare and contrast approach towards balanced regional development through district planning in India and South Africa to draw policy lessons. Employment generation for surplus rural labour has become a crucial developmental challenge for both India and South Africa. Despite achieving impressive GDP growth rates, both the countries are suffering from job crisis. Youth unemployment rate of South Africa is 52.15 percent; while in India, official unemployment rate is 7.2 percent, but under employment is over 30 percent, as millions of people, are stuck in low skill-low wage casual jobs. Rural urban income differentials are high. Rural youth are migrating to big cities, but low skilled jobs are only available at the bottom tier of the urban informal labour market. To redress ruralâóîurban dichotomy, both the countries had sought to undertake regional planning at a district level, and district plans are seen as integrative platform for urban and rural area plans and sectoral agencies of the provincial government. In India District Planning process was institutionalised as part of a wider process of state restructuring and decentralisationunder the74th Constitutional Amendment Acts of 1992. District Planning is a mandatory statutory activity; but its implementation had been slow and uneven. Considerable state-wise variation exists in the planning process as well as its institutional arrangements. In states where properly implemented, District Planning has become an integral part of the participatory planning, gender empowerment, spatial targeting of developmental grants and disaster risk mitigation. India has also undertaken pilot project to develop 30 rurbun clusters to encourage skill development and training for artisans and handicraft sector. Compared to the Indian district planning model's emphasis on social equity through participatory planning, the South Africa's district planning approach is more top-down and has stronger emphasis on economic issues.

South Africa's innovative Spatial Planning and Land Use Management Act (SPLUMA) of 2013 has sought revive rural and small town economies by building logistics networks and product value chains for agro-processing sectors connecting different settlement hierarchies. It has also built in mechanism to harmonize strategic business plan with land use planning and infrastructure development. The comparative analysis of two major transitional economies shows potential of district planning to achieve balanced regional development. It also underscores the need for the regional planning mechanism to combine features of top-down strategic approach and bottom-up participatory approach

Research Paper

The Weak-sided Urban Fringe and the Flexible Planning Approaches

a case study of strategic plan of Yuhuatai District, Nanjing

Zhao CHEN, Urban Planner; China
Chunxiao Huang, Associated Professor; China

Abstract

Although urban fringe is regarded as a unified academic concept, the actual development results present a strong divergence into two categories: the strong-sided urban fringe and the weak-sided urban fringe. This paper starts from basic concept of the weak-sided urban fringe based on existing theory and summarizes the features of the weak-sided urban fringe according to empirical cases, including the low-quality, collage-style land use mode, the structural shortage of both core resources and fundamental facilities, and the fragmented spatial governance. Secondly, differing from the development of strong-sided urban fringe with high investment, urban sprawl and self-replication dominated by growth machines during the rapid urbanization period, this paper proposes the weak-sided urban fringe should adopt a flexible planning approach characterized by precise input, structural optimization and organic growth. Finally, taking the example of Strategic Plan of Yuhuatai District, this paper initially discusses the methodology of flexible planning, including repair of embedded structures, action-oriented organic regeneration and the organizational optimization of multi-governance systems guided by planning.

Keywords

Urban Fringe, Unbalanced Growth, Flexible Planning

1. Unbalanced Growth in Urban Fringe: The Propose of weak-sided Fringe

During the rapid urbanization of China in the past 40 years, the urban fringe area has undergone high-speed dynamic changes and has become the most important growth carrier for China's cities. Studies on China's urban fringe in recent years has achieved fruitful results have construct a preliminary theoretical framework from urban fringe's concepts and characteristics to economic, social, ecological, demographic dynamics and mechanisms, as well as corresponding planning issues and approaches.

When systematically browsing scientific literature on subjects related to China's urban fringe, one main research bias can be identified that more attention is paid to the benchmarking or pilot fringe areas with better development results and more distinctive features. The similarity of this kind of urban fringe is often located in the dominant direction of urban spatial expansion or the main regional traffic corridor, and therefore become the city's key

development area that undertakes core resources, forming a series of successful mode including residential new town, university town, economic development zone and airport city. This paper argues that the growth of urban fringe in most China's cities is unbalanced and despite the above mentioned 'strong-sided' fringe, urban fringe on the 'weak' side should not be ignored. Weak-sided fringe are usually located in the direction that deviated from the main direction of the city and hence incapable to attract high-quality functions and core resources, resulting in a clear gap compared with the strong-sided one. However, both existing researches and planning cases on urban fringe areas are unconsciously concentrated on the strong-side urban fringe while researches on the weak-side urban fringe area are insufficient, and the experiences of strong-side urban fringe cannot be replicated to the weak-sided one.

The conception of urban fringe was first proposed by Hebert Louts in 1936 based on his observation of the urban structure of Berlin. Louts found that the original rural area was gradually occupied by the urban construction and hence became part of the city. Robert Park and E. W. Burges generalized the city into the concentric zone model with CBD at the centre and the transitional urban fringe as the intermediate ring between urban and rural area. Hoyt further modified the concentric zone model account for the impact of transportation systems on accessibility enhancement brought by major transportation routes (e.g. metropolitan expressways and interstate highways). Hoyt theorized that cities would tend to grow in sectors patterns, emanating from the CBD and centred on major transportation routes. Higher levels of access translate to higher land values. Thus, many activities and functions would develop in a wedge surrounding transport routes.

Hoyt's model is also accord with the realties in China's cities. However, the establishment mechanism is slightly different from the spontaneous emerging process as Hoyt observed in U.S., but is formed through active planning regulation. In order to achieve the balance between the growth efficiency and the environmental conservation in the early stage of suburbanization and to avoid the development dissipation and ecological erosion due to the spontaneous sprawl, the municipal government intentionally concentrate the resources and investment in certain part of urban fringe, or the prior development zone, while the rest are regulated as ecological corridor, agricultural zone or restricted development zone. In other words, the emergence of strong-sided/weak-sided fringe is the not only decided by the fringe's relationship with transportation, but also the will of the municipal government.

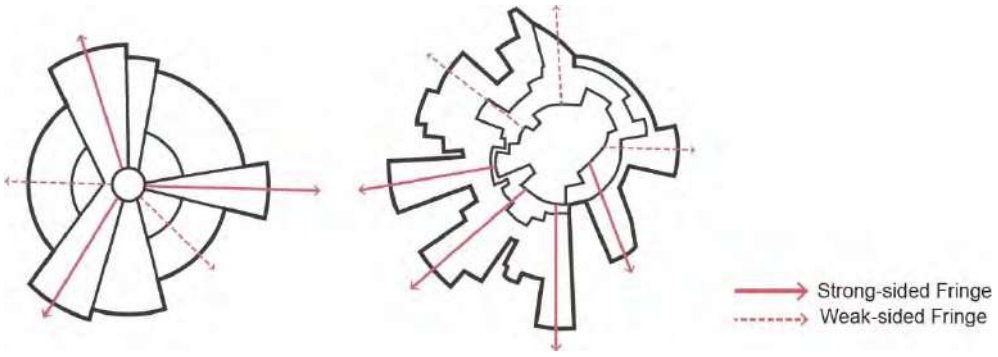

Figure 1 Hyot's sector model(left) and the nonequilibrium growth of urban fringe in Shanghai

2. History and Reality of the Weak-sided urban fringe: evidences from Yuhuatai

2.1. Historic trace: mega-project driven urbanization

As mentioned above, the intention of government played an important role in making the weak-sided fringe. Looking back in history, Yuhuatai District has long been regarded as the periphery outside the city in the government's plan, and therefore presents a typical exogenous urbanization pattern, whose driven power is not the spontaneous agglomeration of citizens, but the implanted mega-project initiated by the government.

After the founding of new China, the central government began to implement the heavy industries leap-forward strategy and anti-urbanism strategy. At that time the state-owned enterprise, or Danwei is more than a productive unit but a self-sufficient, isolated and closed small society for 'the working class', and is usually located away from the cities. As for Yuhuatai, it is firstly recognized in the 1960-70s as the concentration area of giant state-owned steel and mining enterprises for its deep-water harbour and appropriate distance with the city. And it became the initial driving force of the development of Yuhuatai.

After the opening and reform, exogenous industrialization and rapid urbanization process become the engine economic growth in China in the 1990, whose key contents are inter-city competition on attracting FDI and land financing mechanism. In 2000s, Yuhuatai District became the agglomeration of different types of public housing projects for its exploitable land low land price. Most of the housing projects are the removal settlement for the former peasantry whose land and houses in the land expropriation (land financing), and the rest are the indemnificatory housings for the low-income citizens. In 2010, it began to Government-led software Industrial Park for foreign and domestic IT companies, focusing on software outsourcing service, serving companies in Silicon Valley, Israel or Ireland.

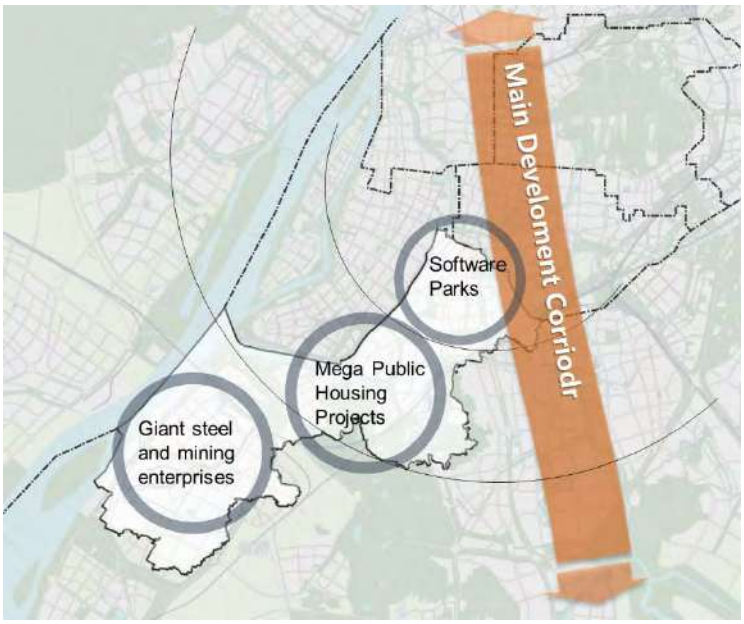

Figure 2 Location and status-quo functional zone of Yuhuatai

2.2. Desakota Land use Pattern and extreme nonequilibrium infrastructure supply

The overall land use of Yuhuatai District is a typical desakota pattern where urban and rural lands coexist and intertwined and strip-shaped sprawl alongside arterial and communication roads. The traffic network of the entire district is not complete, mainly relying on the radial trafficway start from the central city to the fringe, so the newly constructions including the residential areas, industrial areas are distributed on thin layer of the trafficway but lacked in-depth extension. This land use pattern has led to inefficient, fragmented land use. living land are mixed, which has a greater impact on the quality of life of residents. As weak-sided fringe, Yuhuatai District failed to attract the mass investment from the municipal government and public service supply on public transports, schools, hospitals, gyms or cultural facilities are extreme insufficient compared with the central city or strong-sided fringe. However, it become home to NIMBY facilities, such as large indemnificatory housings, large overpasses, building materials markets and cemeteries which occupied lots of land and may have negative impacts on surrounding area.

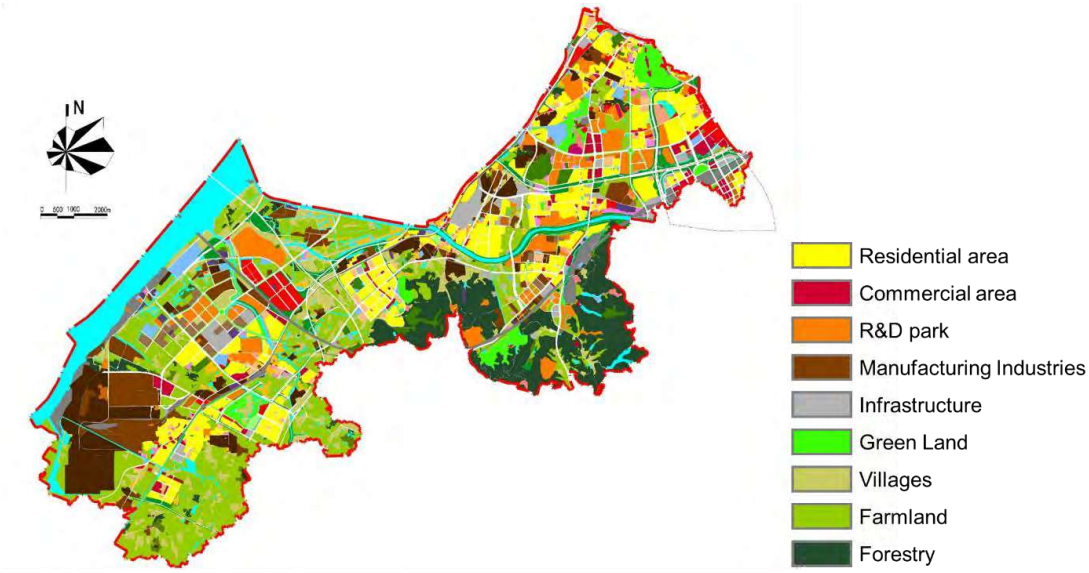

Figure 3 Land use status-quo of Yuhuatai District

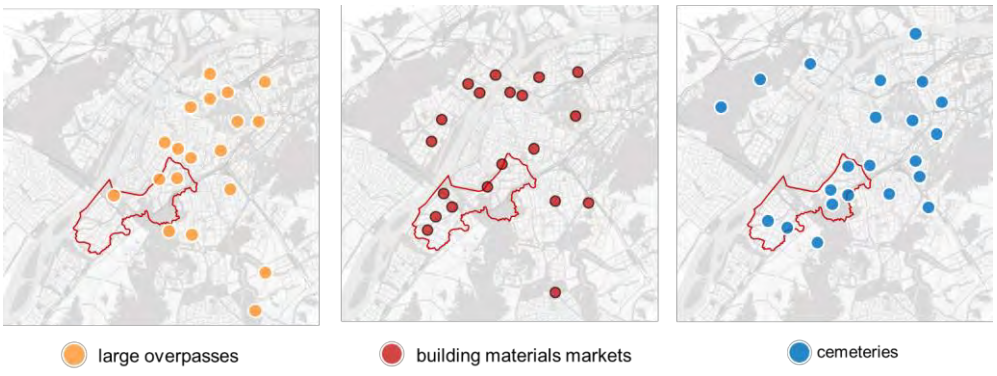

Figure 4 Distribution of the some kind of NIMBY facilities in NANJING

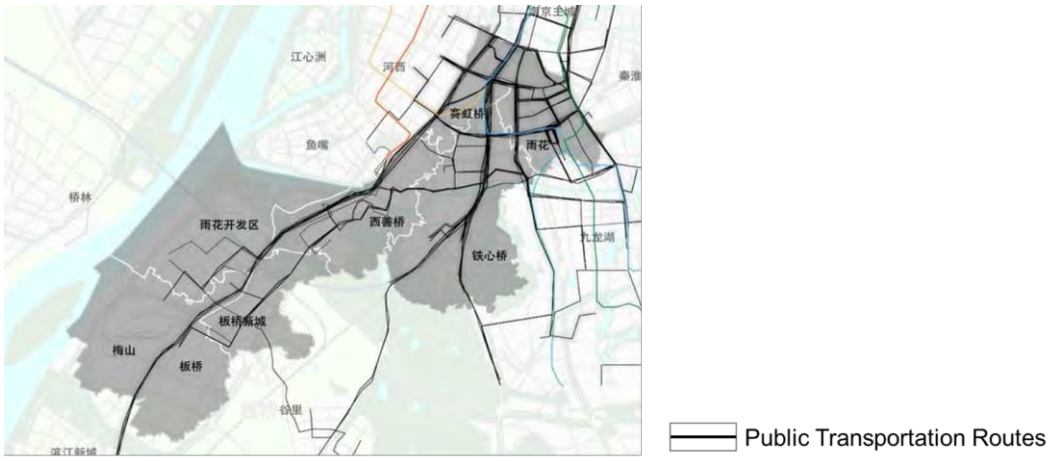

Figure 5 Distribution of the public transport routes of Yuhuatai District

2.3. Adaptive administration strategy and fragmentated governance

Not only the spatial change, but the power structure and governance behind is dynamic. Been regarded as reserve area of central city, Yuhuatai District undergone many administrative division adjustments, making room for the spatial expansion of the central city. To some extent, the 'fringe' should be defined by the dynamic change of the 'central-fringe' relationship, and the former fringe will become the future central city. Corresponding to the rapid urbanization and dynamic 'central-fringe' relationship, an adaptive spatial governance was formed. The adaptive adjustment strategy ensures the consistency of the development of urban fringe, which is an efficiency-first decision-making mechanism. However, the other side of the coin is its fragmentated sub-government power structure, which is caused by the coexistence of the normal government (e.g. town and street government) whose duty is social administration, and the quasi-government entity (e.g. administrative committee of economic development zone and new city) whose duty is economic growth. The two kinds of sub- government overlaps in administrative space but conflicts in the governance objectives and paths, resulting in the low-level redundant construction and disordered policy direction.

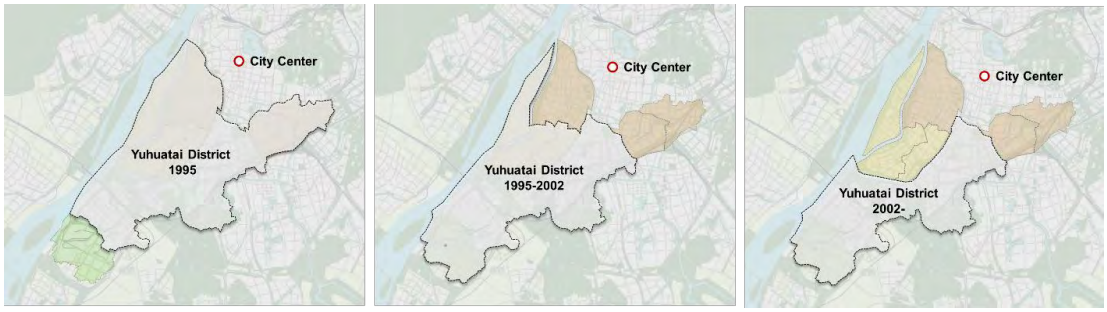

Figure 6 Changing of the administrative division of Yuhuatai District since 1995

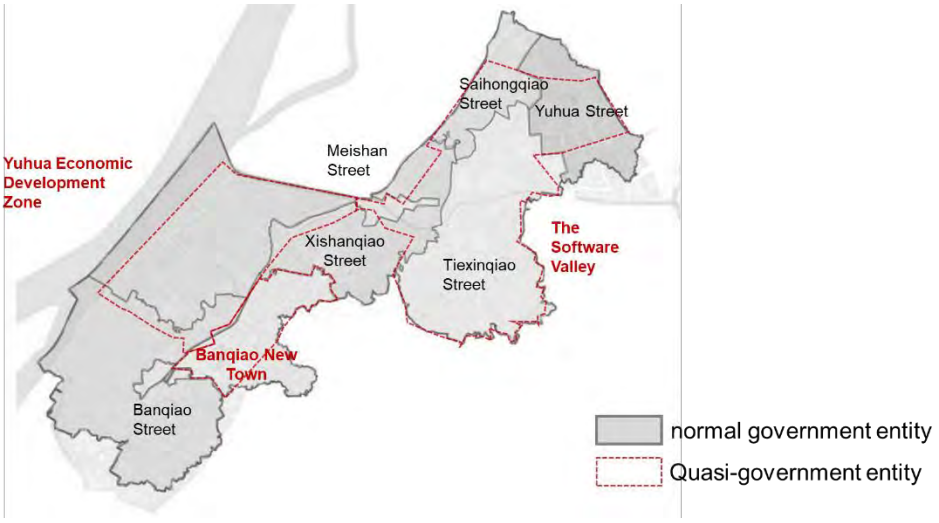

Figure 7 Division of normal government/quasi-government entity in sub-government level

2.4. Leap-forward industrial involution and divided society

Since the whole fringe is collaged by mega-projects or industrial giants in different times, the social structure tends to be polarized which makes the social integration become an important challenge. The two main social groups are the IT employees working in the Software Park and the public housing residents. The IT employees are young, well-educated and can earn higher income. Constantly, the residents in the public housing is aging, and many of them belong to vulnerable group who got unemployed live on the social assistance. The gather of low-income residents brings pressure on elderly care services, re-employment Public security service services. As for young IT employees the work-residence separation is obvious since the living conditions in Yuhuatai District cannot met their demands. Therefore, a large number of young people work here live in other districts, making the lack of urban vitality.

3. Reaffirming the weak-sided urban fringe: new opportunity under new context and the hypothesis of flexible approach

3.1. Paradigm Shift: Modernization 1.0 to 2.0

The characteristics of modernization in the past 40 years of China are quantitative economy and government's enterpriseization. As the economic system reform greatly stimulated the social demand, the 'quantitative economy' strategy is adopted to fill the gap between the demand and the low supply levels of the planned period (as well as the gap between unbalanced regional development) through increasing the productive quantity (e.g. GDP, FDI, etc.), as fast as possible. On the other hand, the GDP competition between cities made the local government set the economic growth as the top priority and the government itself become the biggest 'enterprise', which is described by David Harvey as the 'neoliberalism with Chinese characteristics'. In this way *the modernization 1.0* mode was formed, which is characterized by quantitative-prior industrial development and rapid expansion of urban fringe.

Marked by the global financial crisis in 2008, the global economic structure is undergoing profound changes. After 30 years of rapid industrialization, the demand on quality-prior

development replaced the demand on quantity economy, thus the path dependence of the *modernization 1.0* came to an end, giving way to *the modernization 2.0* or the 'the New Normal' era according to the government discourse. The *modernization 2.0* is distinct with its former version in many aspects, including the oversupply in normal products (rather than shortage in supply), the quality-prior economy (rather than quantity-prior economy), the endogenous development mode (rather than exogenous development mode), the comprehensive competition on both industries and services (rather than single economic competition on manufacturing), the post-Fordism social production (rather than the Fordism standard products) and so on.

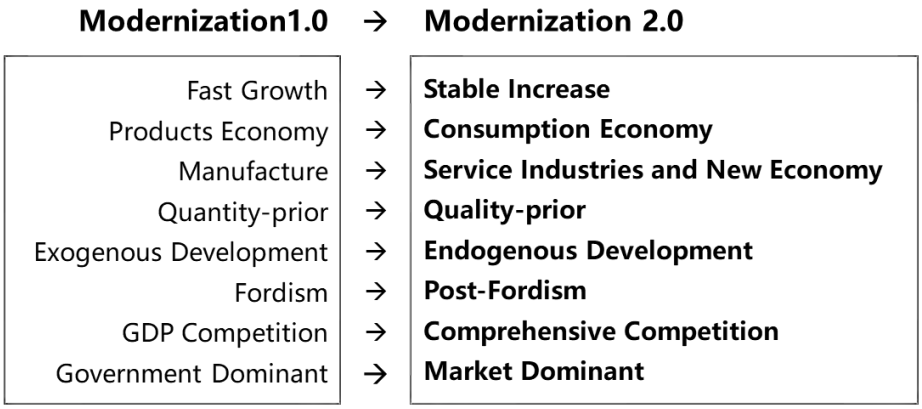

Figure 8 Connotations of the paradigm shift from modernization 1.0 to 2.0

3.2. New opportunities for weak-sided fringe in modernization 2.0

As mentioned above, the differentiation between the strong-sided and the weak-sided urban fringe lies in the different interrelationship with the urban development axis/ corridors, and stemmed from the paradigm of modernization. At present, with the continuous changes and restructuring of the region, the weak-sided urban fringe has also confronted with new development opportunities. On the one hand, with the evolution of transportation and information technology, the city-region has changed from hierarchy system to network, and new regional connections may be formed, thus giving weak-sided fringe like Yuhuatai District the chance to link to the new urban or regional development axis/ corridors. On the other hand, the goals of urban development change from monism to pluralism. In the modernization 1.0, the city emphases on economic growth, therefore mega-projects, large industrial zone and transportation hubs which exert directly affect on the growth of GDP become core resources and be placed in the strong-sided fringe. Under the current new context, the value judgment on resources begun for fringe development to diversify, extending to ecology, innovation, culture, leisure, etc. As a result, the weak-sided fringe faces new opportunities for further development.

3.3. Planning Methodology: flexible reconstruction, structure control and action-oriented approaches

Despite the new development opportunities, it does not mean that the weak-sided fringe can become the strong-sided one at one move. Currently China's urbanization has entered a quality prior, slower speed and market-driven phase after 40 years of rapid, hyper-dynamic and government-driven urbanization, and the general spatial structure and pattern of China's cities tends to be stable, in this way, the weak-sided fringe will remain the status of lacking core resources at least in the initial stage (after the accumulation of development it

is possible to undertake core resources). What is more, in *the modernization 2.0*, due to the deceleration in economic growth, it is impossible to duplicate the growthism-oriented 'rigid' development and planning approach as the strong-sided fringe did in the *modernization 1.0* era. Therefore, a flexible planning approach is required.

"Flexible" means affordable and sustainable, and it differs from the 'rigid' construction in terms of space, function and governance. In terms of spatial development, it will mainly rely on the integration, optimization or redevelopment of old urban space with very few incremental lands. In terms of function, the weak-sided fringe should not be an independent growth pole, but need to cooperate with the central area, to undertake the spill over resources of the central area and final become an indivisible plate of the city-region. And in terms of governance, the strong government dominant is difficult to achieve in the development of the weak-sided fringe, but it still needs the government to carry out limited but precise guidance and integrate existing dispersed entities.

In summary, the context shift of from 'building city upon blank land' to 'building city upon city' requires a different altitude in dealing with the ideal vision and the status-quo, and the key challenge is only not how to active the weak-sided fringe through a restrain but precise planning approach, but how to integrate the weak-sided fringe with the current loose, unordered, modernization characterized strong-sided fringe which formed mass through investment and coherently form a powerful overall structure of the city.

Table 1 Comparison between the rigid construction of strong-sided fringe and the flexible reconstruction of weak-sided fringe

	The Rigid Construction of Strong-sided Fringe	**The Flexible Reconstruction of Weak-sided Fringe**
Space	Highly Urbanized Spawl from the central city Building city upon blank land	Incomplete urbanization; Smart organic growth; Good ecological environment; Based on space renewal and structural optimization
Function	Undertake urban quality industry Compound function	Specialized functional nodes such as ecology, R&D and tourism
Governance	Government dominant; weak bottom-up self-organization	Market dominant; strong bottom-up self-organization

4. Case Study: Strategic Plan of Yuhuatai District

4.1. Ideal Vision: Flexible Specialized Embedded Structure

The methodology of planning is a challenging problem. As for strategic spatial plan there is also a lack of the best or only method of formulation. An important symposium classifies the researches on strategic spatial plan into three categories, thus the institutional, communicative/discourse and interactive approaches, which indicates the mainstream cognition of strategic planning methodology; Albrechts briefly proposed a four-track approach, including long-term vision, long-term and short-term actions, contact with stakeholders and basic process with citizens. Jean Hillier believes that transitional, potential,

and flexible post-structural methodology is a method to solve China's strategic planning. The above combing shows common attempt to make a simple, clear and understandable structure without losing flexibility and systemic. In view of this, this paper considers that a possible strategic planning structure consists of two parts: **structure control and action**.

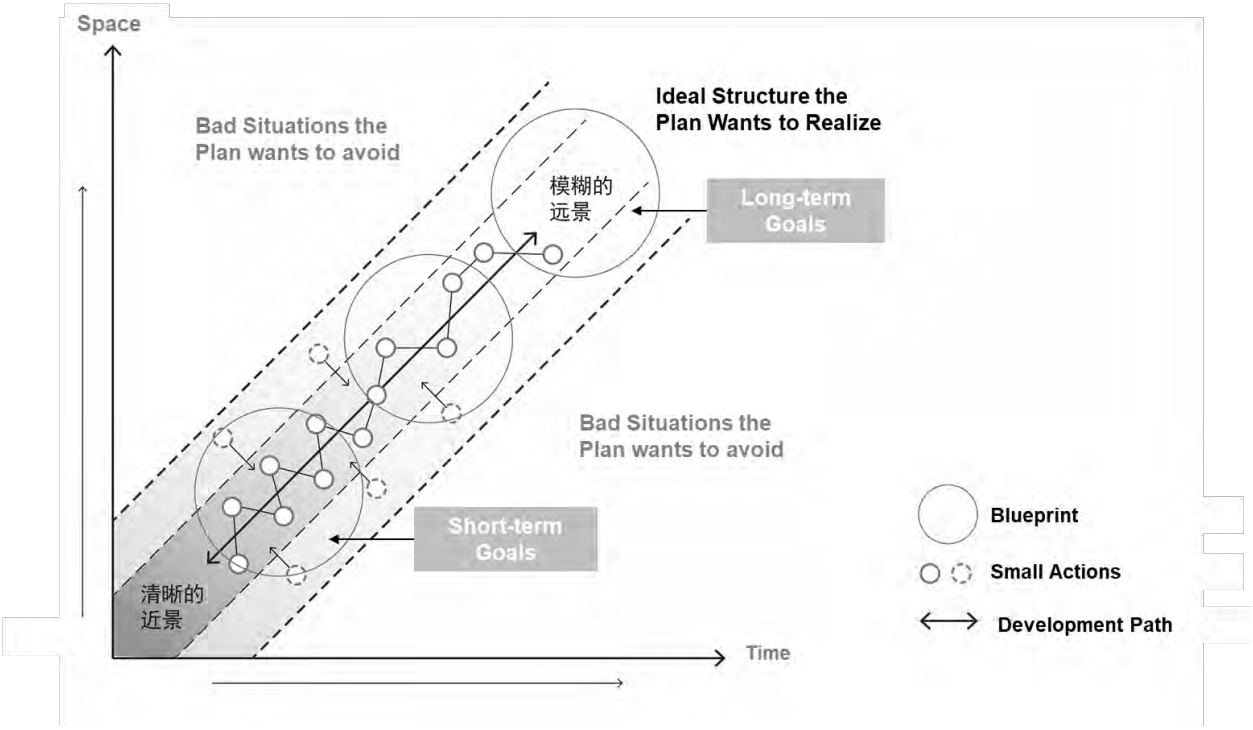

Figure 9 Topography of China's strategic plan

4.2. Structure Control: From Re-create to Re-connect: precise repair to existing socio-spatial structure.

The local Jiangnan Region (means south of the Yangtze River) excellent natural context, history and culture, relatively sustained incremental potential provides another possible solution for the transformation and upgrading of weak-sided fringe in the new macro development stage., the re-connecting solutions. Based on blue network, green network and grey (transportation and infrastructure) network, combined with functional quality organic upgrade and spatial scale shrewd, the plan attempts to constructing high-quality network integrated functional area, and realizing the systematic improvement of the entire structure. With the reconnection of urban space with green/blue/grey Network, the reconnection of social-spatial relationship and the reweaving of the fragmented governance, the plan realizes the restrain but precise intervene to the current space, which lead to the maximum of entire regional effect.

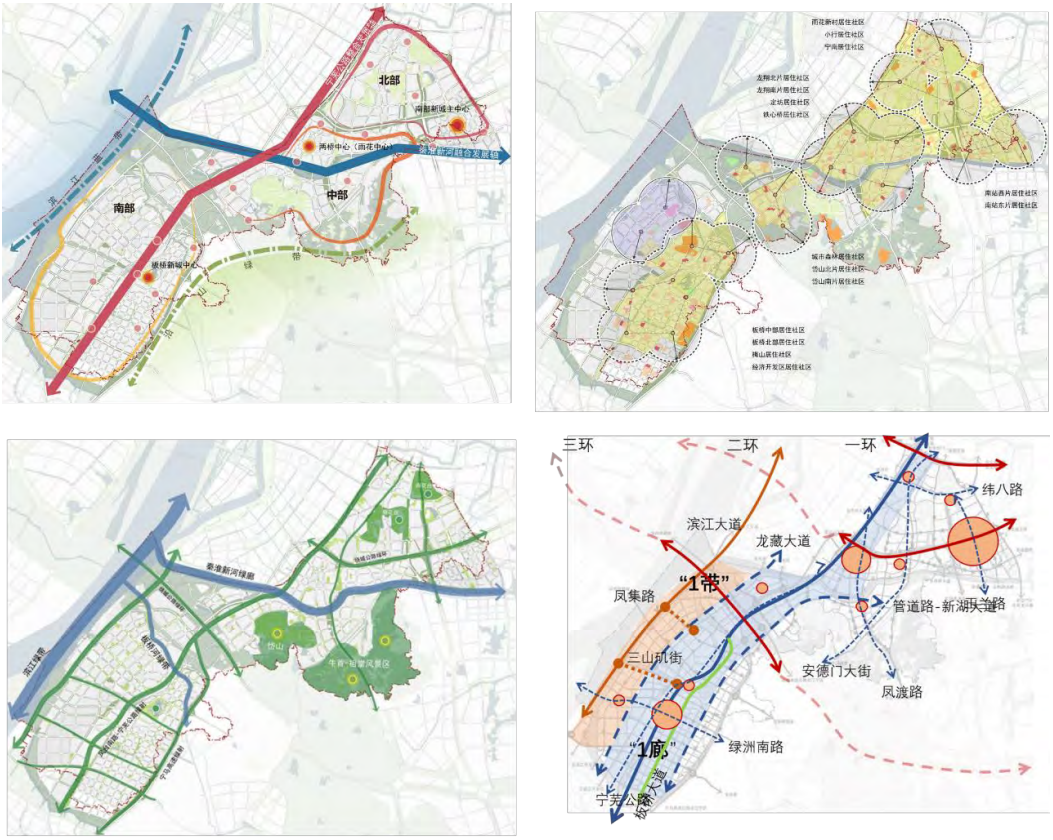

Figure 10 Reconnection and precise repair to existing socio-spatial structure

4.3. Action: Progressive Smart and Organic Growth

The development path of the modernization 1.0 period seems to be self-evident: urban space can be produced and duplicated through a very fast and easy way soon become reality. In this way the only task of strategic plan is the 'blueprint', and it required no attention to think about the action or realization of the plan. However, in the modernization 2.0 era, the plan should focus on helping realizing the blueprint or structure on step by another. In the case of the Yuhuatai, the action logic of strategic planning mainly presents the following characteristics:

Rooted development. Get rid of a single exogenous path dependence, seek to adapt to the new normal macro-development needs, endogenous exogenous compatibility, and develop a local development model by rooting local culture, society, space and other conditions;

Delicate development: Guide the smart growth, build exquisite space and promote lean economic development in the first big situation of large projects. Pay attention to the efficiency and efficiency of input, that is, by investing in key "points", realize self-efficiency and derivative benefits, comprehensive benefits, and maximize system benefits, and guide the rest to self-evolution.

5. Conclusion

As the macro environment enters the “new normal”, strategic planning is also facing transformation and upgrading. Starting from Yuhuatai, we seem to see a new paradigm that differs from traditional strategic planning. Is our goal to create a new paradigm to replace the old paradigm? Not exactly. Paradigm can be seen as a possible approach or solution under a certain period of time or contexts, and the reason why strong-sided fringe development well in the past 40 years is not because of some certain paradigm, but because the paradigm chosen best met the modernization 1.0 context. Therefore, when faced with the macro-transformation of modernization 2.0, the pursuit of good planning and correct knowledge is the only possible eternal paradigm of strategic planning.

HOW TO GRASP THE POWER OF THE PLACE:

The TELLme Project and Metro-dology

Antonella CONTIN, Politecnico di Milano; Italy

Sandy Jiyoon KIM, Politecnico di Milano; South Korea

Abstract

Metropolitanisation processes caused by unplanned urban growth have generated an enormous demand for infrastructure and services, as well as impacts on the environment that can lead to imbalances in social development. In order to promote sustainable growth, it is necessary to plan a fair distribution of services throughout the development of the city with efficient infrastructure system. Our answer is a proactive project, which holds the social and ecological function of the city that restores safe environmental conditions. In the ongoing TELLme Erasmus+ project, we attempt to define a holistic methodology, the Metro-dology; structure a training lab where academia and practitioners can discuss the issues, principles, and gaps of the metropolitan area; and develop mapping tools to comprehend the metropolitan complexity and support the training. We are looking for new relations among the parts of the city through first, mobility project to transform the times of the city; second, identification of suitable places for the production of a modern and clean circular economy; and finally selection of areas for urban regeneration to rediscover and renew the identity of the metropolitan city.

Keywords

metropolis, TELLme, metropolitan complexity, metro-dology

1. The Complexity of Contemporary Metropolitan Issues

1.1. Contemporary Debates on Metropolitan Issues

Rapid urbanisation has been one of the urgent issues across the globe in the past few decades. As a consequence, more and more cities are now becoming part of larger metropolitan areas. As the growth and the environment resemble nothing of the past events, it is essential to distinguish the new metropolis and understand the difference from a traditional city.

In the early 20th century, to describe the extensive urban scale change triggered by the industrial revolution, the word ‘metropolis’ reappeared in the Western world with more modern meaning. It described the urban expansion that had been occurring at different times in different locations around the world over the past two centuries. In this context, the use of the term metropolis emphasised the size of the city that had changed. Otto Wagner and Ludwig Hilberseimer were amongst the first scholars who raised the issue of the Großstadt,

that is the "big city", in reference to the change of measure and scale of the urban settlements in the wake of the industrialisation in the western world.

The phenomenon of the contemporary metropolis, however, differs from the modern industrial "big city". The unrestricted urban growth we are experiencing nowadays has exceeded the timeframe of planning. The nowadays concept of the metropolis is related to a measure and scale which is not associated with human dimensions or commensurate with the urban fabric and the density parameters represented in the concept of proximity. "Metropolitan" as a category is related to a context of mass mobility of people and goods, which implies a different relationship between individuals and groups. The technological utopia, embodied through the spreading of metropolitan infrastructure networks and the overlapping natural universe, has erased previous continuous geographical traces and has disarticulated agricultural and urban historical topological patches. As a result, we may notice a sense of loss of productive and symbolic connotations of the cultivated land.

Moreover, the main drivers of urban development in the past two centuries were not the physical shape of the city but external logic such as economic models, political agenda, and technological optimisation. These growth models focusing on the efficiency of growth demonstrated their limits in addressing the quality of the well-being of the citizens. The prevailing inequality has escalated the conflict amongst groups of people around the globe where existing urban spaces have not been able to accommodate the incoming population. Unplanned occupancy in areas such as main water basins that serve the entire city became a risk for all inhabitants, only exacerbated by the effect of global climate change. The colonial past, on the other hand, has cast long shadows over many of the developing countries to struggle with not only the physical, social, and economic difficulties but also with the cultural identity of the population.

These backgrounds of extreme urbanisation leave us with the big question of how to deal with the metropolitan complexity to realise sustainable growth to reach the well-being of the population in the post-colonial, Anthropocene era. Metropolitan Complexity refers to the issues of the contemporary metropolitan system. Social and economic inequality, the fragility of environmental eco-systems in relation to the global climate change, the emergence of the political idea of the metropolitan dweller as a global citizen, the preservation of cultural heritage; the post-colonial identity, and the governance and policy issues are only a few of these issues framing the Metropolitan Complexity. These issues cannot be addressed with a single, static, and traditional disciplinary approach, but needs a comprehensive and multidisciplinary vision to understand them.

1.2. The TELLme Project and the Metropolitan Approach to Complexity

The TELLme (Training for Education, Learning and Leadership towards a new MEtropolitan discipline) is a three-year Erausmus+ project started in 2017 where the cooperation for innovation and the exchange of good practices are the key actions. The project addresses the urban and architectural disciplines at the higher education level, based on the assumption that cities in the 21st century are the crucial field of complex issues derived by the extreme urbanisation and the HEIs have a social responsibility in providing solutions.

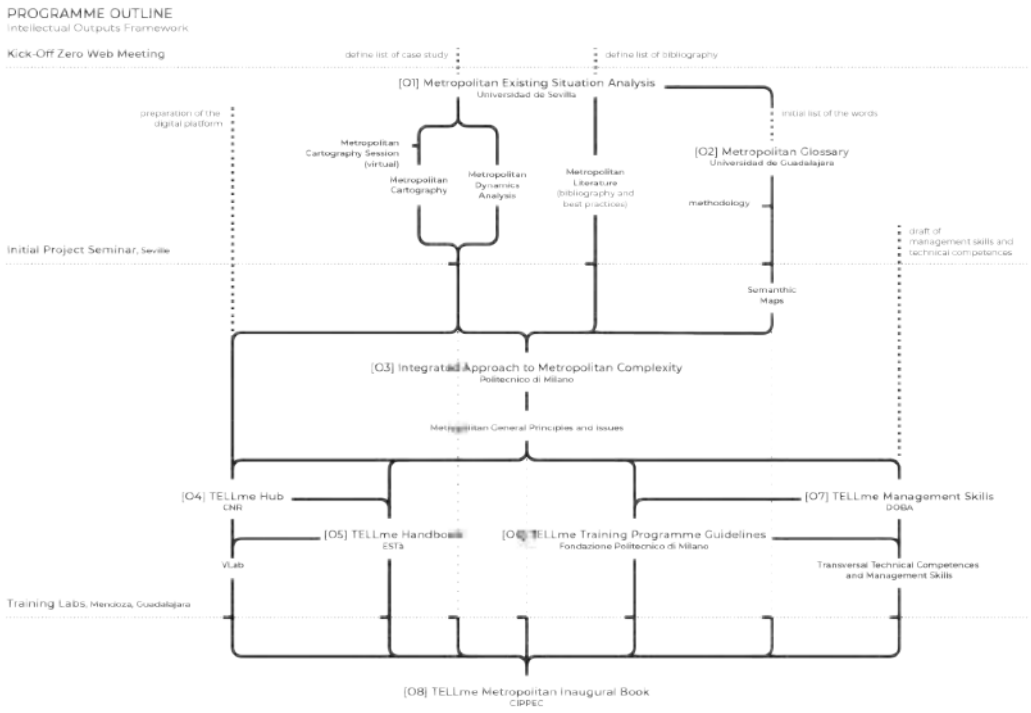

Figure 1 TELLme Intellectual Output Framework

Ten partners and four associate partners from Europe (Italy, Spain, Slovenia) and Latin America (Mexico, Argentina) are working on developing the theoretical framework, methodology, and tools to address the metropolitan complexity holistically. The eight outputs range widely from the theoretical studies to practical training guidelines, yet closely linked to one another through framework and methodology of the Metropolitan Discipline. (Figure 1)

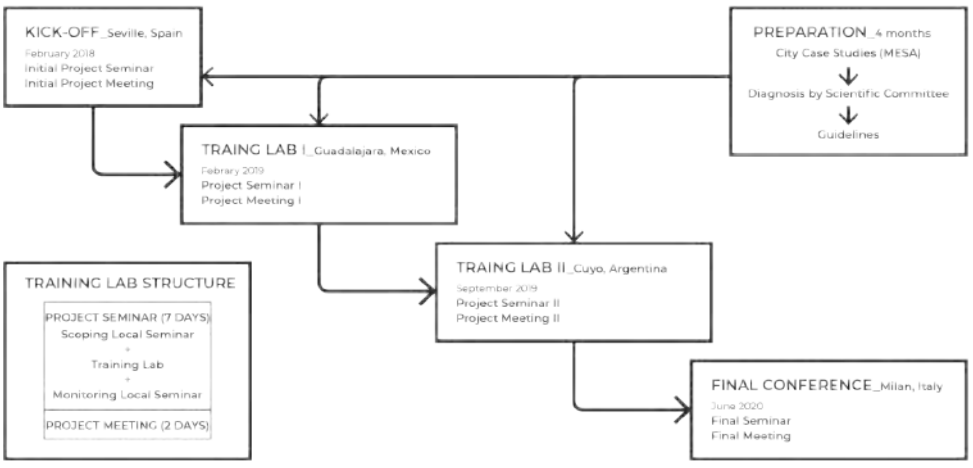

Figure 2 TELLme Training Schedule

In particular, there are two training labs where we test the methodology with actual case studies involving local government and stakeholders. (Figure 2) During the training lab, besides identifying the urgent metropolitan issues of the location, all participants provide feedback and discuss further project developments. The expected impacts of the TELLme project are:

- A multidisciplinary and trans-national collaboration, sharing knowledge, skills and best practises, developing new tools will directly improve the involved HEIs in their capacity to address the Metropolitan Discipline
- Building a community of practice of the discipline amongst higher education institutions through technological innovations that interact with local governments, NGOs

In order to define the metropolitan approach, it is crucial to recognise the paradigm shift from the urban to the metropolitan scale, thus seeing the contemporary metropolis as a “net-city”. According to D. G. Shane, the Net City is “a multi-centred network system” emerged “to handle the apparently chaotic flows of diverse participants in an increasingly global network.” The Net City is essentially a system of cities of different sizes functioning as a whole throughout a network of physical and virtual infrastructures. (Figure 3)

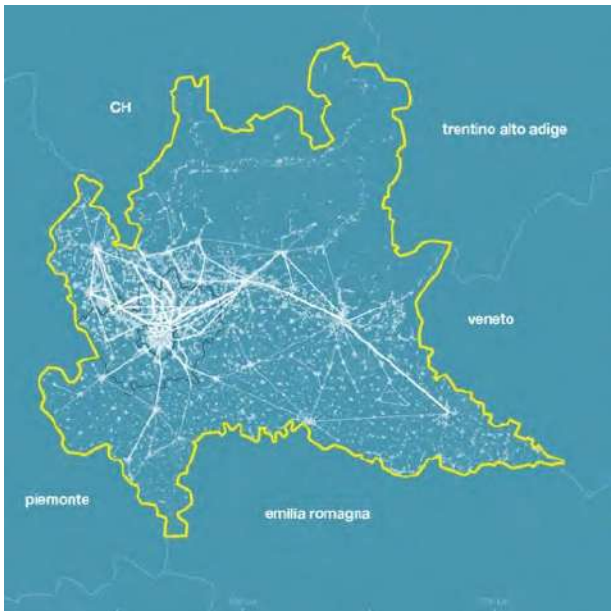

Figure 3 Milan PGT, Metrogramma, 2007

In this polycentric system, however, we are not only dealing with the nodes and edges of the network. According to authors such as Terry McGee, Edward Soja, Neil Brenner, and many more, we are facing a hybrid territory where urban and rural scales define a seamless heterogeneous landscape. This space in-between the network is called “body space”, where the continuity and the connection with the previous system are lost due to metropolitan infrastructure systems. The Body Space needs to be reconceptualised with new meaning and new image in the metropolitan era.

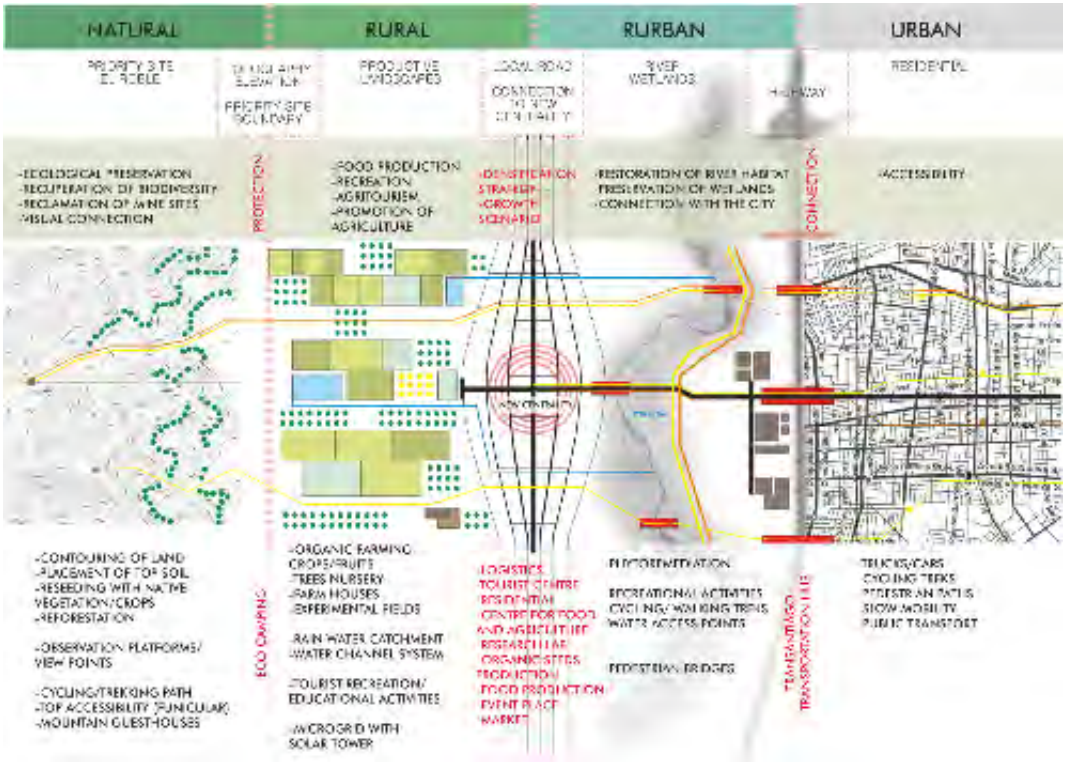

Figure 4 Urban-Rural Linkage Pattern Study, MS Lab 2018

The recognition of "body-space" allowed us to discover new patterns of settlements that are beyond the dichotomy of urban and rural patterns. (Figure 4) It opened the whole new possibilities of shifting between different scales and time that require new spatial practices, social behaviours, and organisational structures. This change also fostered engagements of new spatial agencies such as private and public organisations, universities, families in the interactions amongst global and local forces challenging fixed administrative boundaries at different scales and requiring innovative forms of institutional organisation, and planning.

The necessity of a comprehensive and multidisciplinary approach to the study and practice of metropolis became a common ground for our academic exchange in the past years. The metropolis spatial structure needs a Metropolitan Discipline able to support its construction with organisational, technical expertise, and a big project of urbanity based on a physical and virtual network between the new city shape and the new forms of conviviality. The metropolitan vision will lead to the improvement of the Practice of the Metropolitan Discipline (figure 5) with new competencies.

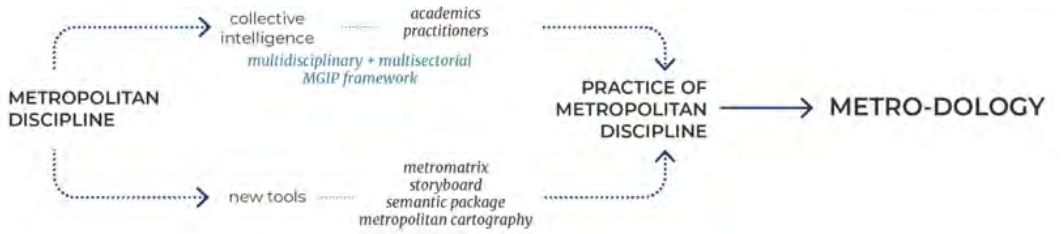

Figure 5 Practice of Metropolitan Discipline

2. The methodology for the Practice of Metropolitan Discipline

2.1. Metropolitan General Issues and Principle (MGIP)

The aim of the Metropolitan General Issues and Principle (MGIP) framework is to create a feedback mechanism where practical experience is reflected in the theoretical work of the Metropolitan Discipline, taking the local environment, community, wealth, governance, and culture dimensions into consideration. Within this basic structure, the collaboration of the collective intelligence yields holistic solutions addressing all dimensions of the metropolis.

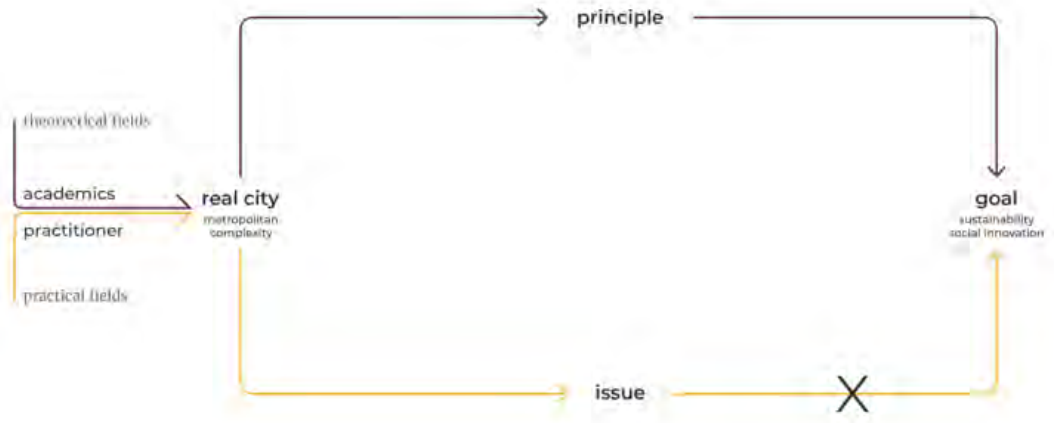

Figure 6 Current Situation in the Metropolitan Practice

The reality indicates the existing situation of a built metropolis. It is the starting point of acknowledging the issues to address, and the principles ruling the specific context. The goal is the ideal objective of a metropolis, which is ultimately the sustainability of the metropolis for the wellbeing of its citizens. From the literature and the case studies, academics set the principles that define what to achieve, how, and why for reaching the goal. On the other hand, practitioners face the issues, which are the undesired outcome of a metropolitan dynamic and often act as a hindrance for meeting a metropolis expectation. (Figure 6)

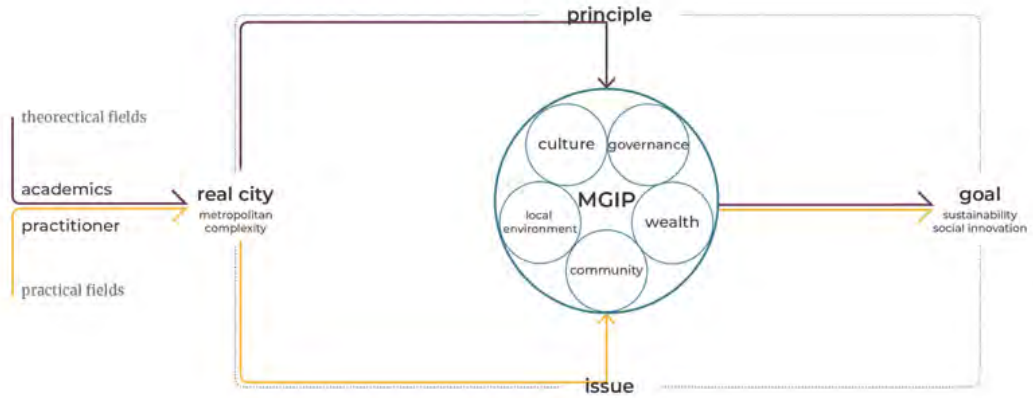

Figure 7 The Proposal of Metropolitan General Issues and Principle (MGIP) Framework

The reconnection of the ideal city with the real built city in the MGIP framework (Figure 7) comes through the process of operator and operation that bring the principles and issues together for finding how to transform, develop, or maintain the existing situation and reach

the goal of sustainability. From this perspective, both the theoretical field of academic knowledge and the practical field of the governance and management of a metropolis are equally acknowledged. The framework attempts to merge the field experience with the theoretical issues of the complex process in Metropolitan Projects by translating the general and theoretical point of view into the more specific practical operations in the metropolitan construction.

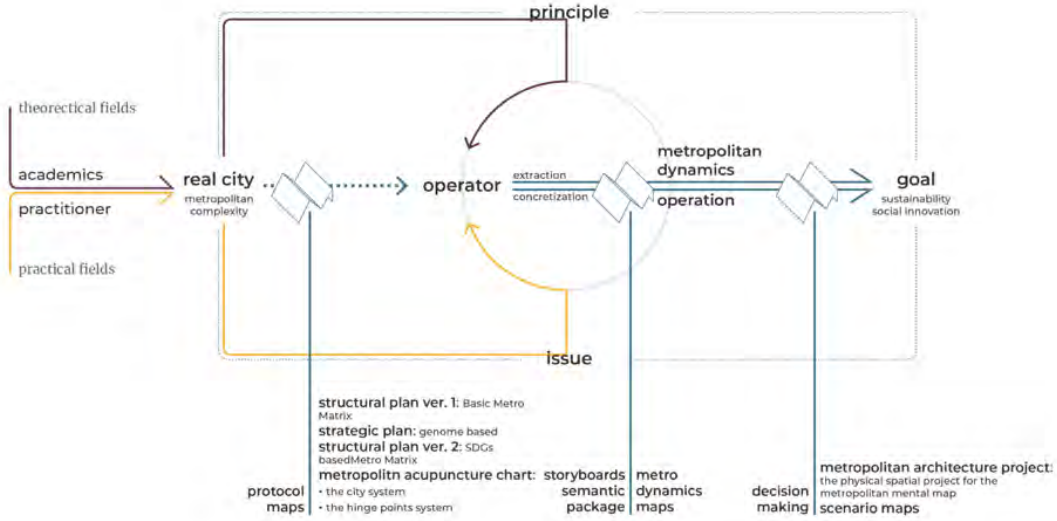

Figure 8 The Tools used in each step of the MGIP Framework

Each step of the framework requires specific tools as part of the methodology and the framework to bridge the gap between the theory and the practice. (Figure 8) Narrative and mapping tools that allow the study of the metropolitan phenomena with a multi-disciplinary and multi-sectoral stakeholder becomes another main pillar of the discipline.

A feedback mechanism follows after the initial establishment of the MGIP framework, where practical experience will be reflected in the theoretical body of the Metropolitan Discipline, taking into consideration the local environment, community, wealth, governance and culture dimension. These categories seek to understand the metropolitan question from a holistic standpoint, in contrary to the traditional methods that have a vision that comes from the sectors in the way which academy and local governments are organized. This gathering of knowledge is the fertile soil that gives place to Metropolitanism: the capacity to give a comprehensive solution rather than a sectoral answer to the problems related to the management of large metropolitan areas.

2.2. Metro-dology

Metro-dology is the collective design process of the Metropolitan Architecture projects based on the MGIP framework. (Figure 9) It is a sequence of phases implemented with specific tools that support the decision-making process of the physical transformations of a metropolis through the building of a metropolitan narrative. The result is a metropolitan narrative, which is not meant to be a linear process, but consists of different phases that relate to each other through a feedback mechanism: Narrative, Interpretation/Diagnosis (Protocol Maps & Metro

Matrix (Ortiz, 2013)), Dynamics, Storyboard, Glossary, Metropolitan acupuncture chart and Metropolitan Project.

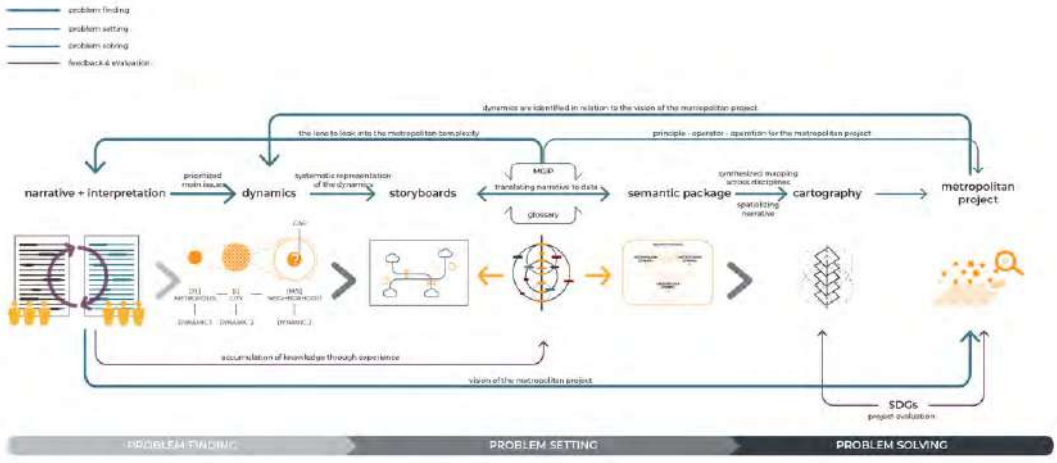

Figure 9 The Metro-dology

The Metro-dology is applied to metropolitan contexts that are a territorial assemblage of rural and urban patterns of settlements; infrastructural networks merging with the natural elements; and the historical traces of places and producing hybrid landscapes that are the new living environment for billions of metropolitan citizens. In order to build a multi-dimensional and multi-scalar narrative of these territories, it is essential to investigate the complexity of a metropolis.

Following the definition of a stakeholder's map, through a workshop dedicated to this phase, we first set up a comparison between a pool of experiences of the different actors of the metropolitan city (Issues) and a reference to principles of general sustainability (Principles) expressed through words and key concepts. Throughout the process, the cartography tool spatially highlights the data that are the premises for orienting metropolitan planning.

Problem Finding

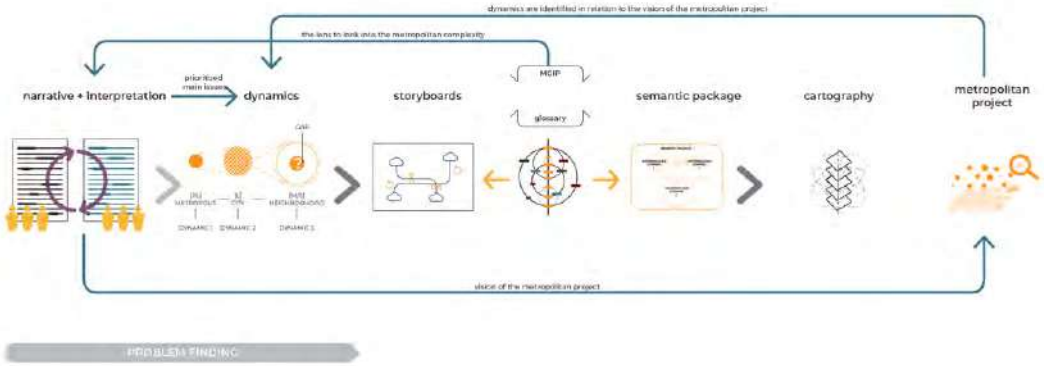

Figure 10 Metro-dology: Problem Finding Phase

Problem or Fact-finding is the first phase of the Metro-dology. (Figure 10) It starts with the narrative of internal experts, namely local decision-makers and civil servants of a metropolis.

They describe the problems, needs, and expectations of their metropolis and the tools available to address them. Metropolitan experts, who are external experts, analyse the storytelling in a constant dialogue with local authorities and have an insight into the problems of the metropolis and of the processes that may produce them.

Simultaneously, a primary study of the metropolis is conducted. By using the global data set, the Metropolitan Cartography tool generates a set of Protocol Maps that become a base for discussions. Protocol Maps are a set of maps showing the fundamental relationship amongst elements constructing the metropolitan system. They reveal the metropolitan structure by layering physical aspects of geographic, historical, and geometrical data. All metropolises have the same set of comparable maps.

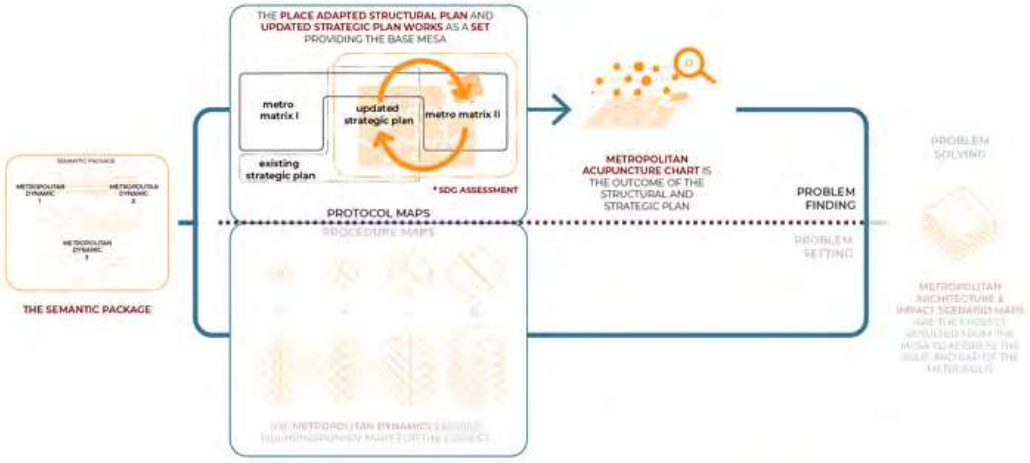

Figure 11 Protocol Maps, Metro-Matrix, and Metropolitan Acupuncture Chart

From the Protocol Maps, the Metro-Matrix is produced. It is a reticular system of axes: few structural geographical axes and some penetrative artificial ones, which first, determine the development of the centre along lines and, second, define hinge points of densification. The matrix assumes its value through the definition of the logic of settlement-distribution, which makes possible the localisation of interchange nodes in peripheral areas. (Figure 11)

Problem Setting

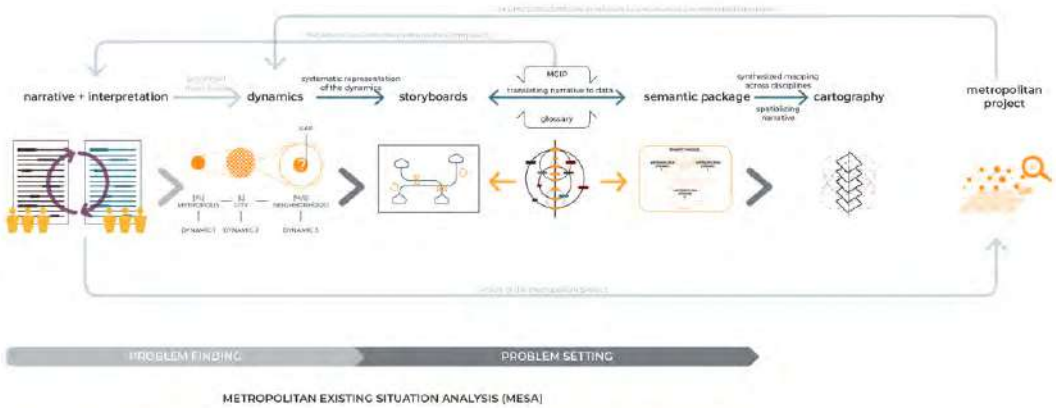

Figure 12 Metro-dology: Problem Setting Phase

The subject of the problem setting is the metropolitan city and its dynamics. (Figure 12) The local actors selected based on their actual involvement in decision-making of a metropolitan area, have chosen a metropolitan transformation, report verbally on the issues (challenges, strengths and weaknesses, gaps and tools used) that affect the expectations of their city and their limits.

The objective of the narrative is to create a complex of observation plane conditions in which data provided exclusively by the local subject are integrated with spatialized data and presented through open source maps. All the data, therefore, are initially observation data, analysed by the metropolitan expert through the general principles agreed upon based on the Metropolitan Genome (Ortiz, 2013).

Once the observation data have been collected, then, through the dialogue conducted in working tables, the process of correlation and interpretation takes place. The metropolitan experts describe the dynamics through a synthesis scheme called a storyboard, an interpretation of the process of the cause of the issue that emerged during the discussion. The storyboard represents the big picture of the issues of a given metropolis and of the dynamics that produce them.

Based on the storyboard and the semantic package, procedure maps are produced. Procedure Maps are a set of maps representing the spatial impact of the process of ongoing metropolitan dynamics identified during problem finding phase. They operate at a large scale and aim at highlighting the dynamics and defining strategies for promoting the sustainable development of the metropolis.

The result of Problem Setting phase is the verification of the hypothesis of the metropolitan dynamics produced with the tools of the TELLme project and identification of further metropolitan project themes and its development hypotheses.

Problem Solving

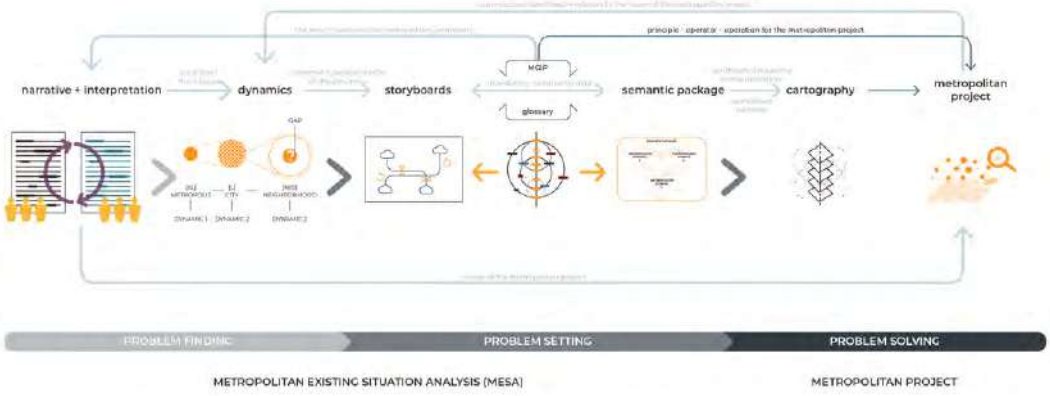

Figure 13 Metro-dology: Problem Solving Phase

In the problem-solving phase, (Figure 13), the metropolitan architecture projects are developed through site-specific operations as a response to the existing gap and in relation to their potential location defined with the metropolitan acupuncture chart. Nevertheless, the latter act as a framework that stresses the value of the metropolitan architecture projects in

building the connections between the big scale of the metropolitan network and the archipelago of the local scale of places to enhance our experience in the space-time of the metropolis.

Maps are also instrumental in the final decision-making act. The use of data enables the production of Impact Scenario Maps that simulate long-term scenarios of metropolitan development to evaluate the impact of Metropolitan Projects on the territory.

The metropolitan dynamics transform existing landscapes, infrastructure networks and city fabrics. The dynamics are processes of transformation of form and map of the urban field on a metropolitan scale. Growth through densification and investment of larger spatial fields change the value of the existing poles and settlement patterns, concerning the new metropolitan paradigm. For this reason, Metropolitan Architecture needs to protect the local value, and also be equipped with "sensitive" infrastructures so that they do not remain or are uprooted or "museumised".

3. Guadalajara Case Study

The case of Mexico offers a unique opportunity to observe how and why drastic change is occurring in migration patterns. The case study of Guadalajara is a result of the TELLme Training Lab held in February 2019. The aim of the training lab was to test the problem finding and setting of the Metro-dology by identifying the issues and dynamics of the metropolitan region with the local government, academia, and local stakeholders, and verifying them with the Metropolitan Cartography tools.

3.1. Problem Finding

The project began with comprehension of the city's geographical position and geopolitical role as an attracting point by identifying possible reasons and directions of migration, and the city's capacity in handling its growing population, land use and ecological footprint. The city's economic growth and social connections are the mechanisms that facilitate migration and determine the scale of impact.

Guadalajara is the second most important city in the centre-west of Mexico, capital of the State of Jalisco. It is also the place of origin of mariachi and tequila, and one of the most important industrial and commercial centres of Mexico: some even call it the Mexican Silicon Valley. The agglomeration that forms the metropolis has around 4.1 million inhabitants. The city of Guadalajara has started to grow again (0.09 %/year), after a period of decline from 2000 to 2014. Today, even though the population growth until the last survey seemed stabilized, the whole metropolitan area shows an expansion in terms of land consumption that has generated sprawl, and illegal occupation of natural and agricultural areas.

The first analysis started with a set of protocol maps to achieve a structural plan of Guadalajara that reveals the relationship between different municipalities and their roles in the metropolitan region. (Figure 14) Guadalajara has a strategic geographical position for the relationship between the two oceans. Today, it is also in a position of the junction between

the axis that connects the city to Mexico City and the axis that connects Guadalajara with the port of Manzanillo. (Scale XL)

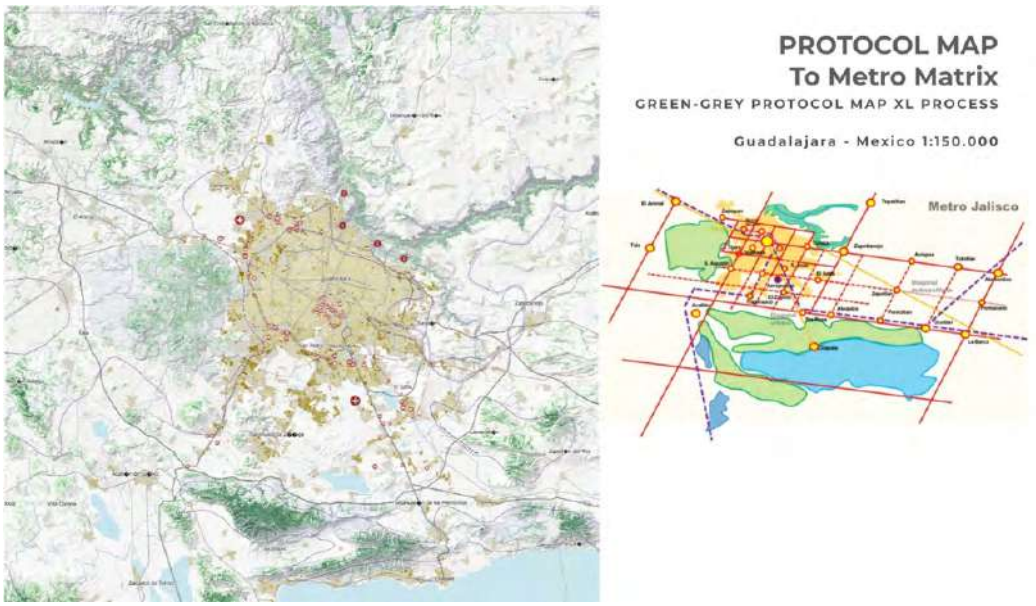

Figure 14 Protocol Map and Metro Matrix of Guadalajara (XL Scale)

After the discussion with local actors such as the universities, municipalities, civil society, and IMEPLAN (Instituto de Planeación y Gestión del Desarrollo del Área Metropolitana de Guadalajara), and based on the Protocol Map and the Metro Matrix, we observed the formation of a metropolitan axis in the metropolitan region of Guadalajara in the L scale (Figure 15): Villa Corona - Acatlán de Juárez - Tlajomulco de Zúñiga. Each municipality has its strong characterization within this axis: Villa Corona is a tourist resort, whereas Acatlán de Juárez has the freight railway that connects Guadalajara to the port of Manzanillo, and Tlajomulco de Zúñiga is an airport city.

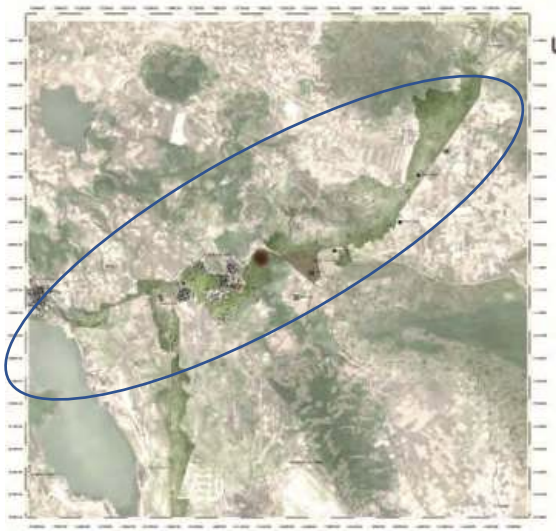

Figure 15 The New Metropolitan Axis of Villa Corona - Acatlan de Juarez - Tlajomulco de Zúñiga (L Scale)

Finally, at the M scale, the area between Villa Corona and Acatlán de Juárez is chosen as a strategic position for the relation with Guadalajara and the Manzanillo Valley. (Figure 16) Since its proximity to the railway station for freights, with a provision of conversion to a passengers station, the area is defined as a buffer zone, that is, the area under tension between three different physical states generating abandoned areas, infrastructural barriers, and informal settlements: City (Guadalajara), Agriculture (Valle del Manzanillo), and Nature (Lagoon). In the area, due to the increasing housing demand from all social levels, there is a planning proposal for mass residential development. The identification of this threshold as an urban-rural linkage landscape that interacts with other existing landscapes, networks and fabrics, encouraged the participants to consider a type of settlement can merge the urban and rural landscape.

Figure 16 The Field of Action between Villa Corona and Acatlan de Juarez (M Scale)

3.2. Problem Setting

After defining inequality and fragility of the territory as the main issues, the participants worked on defining the dynamics causing the issues. The following discussion was focused on answering the following question: Considering the vulnerability of the territory, is it possible to determine sustainable locations for metropolitan residential projects? Based on the initial survey, the TELLme team prepared the procedure maps as a base for discussion. As a result, the participants defined the following dynamics, varying in scale:

- Dynamic 1: The conversion of agricultural land to urban and peri-urban settlements. (Urban-Rural Linkage XL scale)

- Dynamic 2: The expansion of settlements within the valley and the development of small centralities due to a robust localisation of mining centres and productive food processing industries. (Urban-Rural Linkage L and M)

The issue that we started in the Guadalajara-Acatlan de Juárez-Villa Corona area is related to the intensive exploitation of agricultural land due to the presence of red fruit production managed by American multinationals. This production, which has led to a substantial increase in the standard of living of the populations involved in its management, has also caused a significant eutrophication of Lake Chapala with a consequent reduction in the size of the lake, a worsening of the landscape conditions, and now recognised health problems for the indigenous people who lived in the lake (respiratory diseases and malformations).

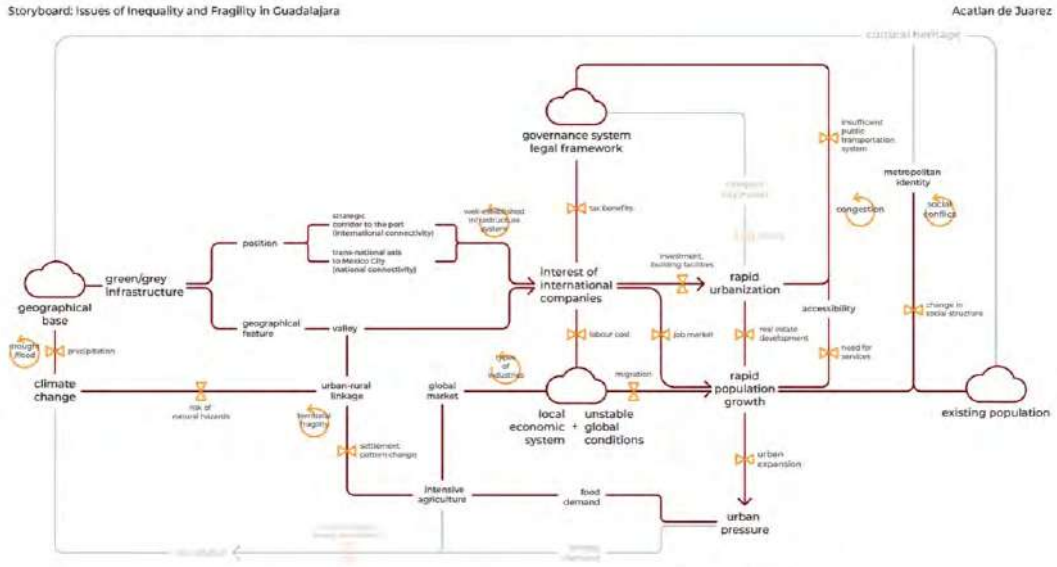

Figure 17 The Storyboard of Dynamic 2: The expansion of settlements within the valley and the development of small centralities due to a robust localisation of mining centres and productive food processing industries

The loss of local markets and knowledge of the cultivation of local products (for example, amaranth) is a possible consequence of having opted for a single international client. From the social point of view, internal and external immigration will focus on an area that is already characterised by the presence of indigenous communities living on the edge of poverty. (Figure 17)

The agricultural vocation of the area is confirmed by the presence of the Metropolitan Trail of Acatlán de Juárez, which had to solve the problems of compliance with the Official Mexican Standard for Treatment of Wastewater Discharges that the municipal rakes did not guarantee to observe. The Metropolitan Trail, which cost 1000 million pesos, however, was only operational for 13 months, due to problems of management and adequate treatment of water; It was the primary source of work for 250 families.

The presence of this plant has caused an increase in demographic pressure in the town of Acatlán de Juárez. This pressure could increase if the hypothesis of implanting the Mexican "Silicon Valley" in Acatlán took shape. The State of Jalisco puts great emphasis on technology. It annually exports the equivalent of 21,000 million dollars in services and technological

devices and, between 2014 and 2016, hundreds of new companies in Guadalajara have received investments -most of US origin- amounting to about 120 million dollars, according to Washington Post. The evident vitality of the territory has also attracted the attention of large companies, and multinationals in the information technology sector, which have decided to open their offices there: Intel, IBM, Hewlett-Packard and Dell are present in Guadalajara and its surroundings.

Based on the storyboard produced by the external expert team after the discussion with stakeholders, the key elements of the dynamic were highlighted in the semantic package. The semantic package is a list of keywords that refers to a set of data, the informative levels, which becomes the legend of the maps describing the phenomena produced by the metropolitan dynamics. To represent a given phenomenon, data within different catalogues are selected through transversal "zone of reading". The storyboard is translated into a Semantic Package by selecting the informative levels representing each element of the storyboard. (Figure 18) Experts in various fields provide the connection amongst the main keyword and the data keywords.

Figure 18 The Semantic Package of Dynamic 2: The expansion of settlements within the valley and the development of small centralities due to a robust localisation of mining centres and productive food processing industries (M Scale)

The Procedure Map reveals the physical dimension of the identified dynamic. Related to the dynamic 2 of Guadalajara, the maps seek to highlight the following aspects (Figure 19):

• Connectivity intercepted by the presence of federal roads, regional roads, municipal roads and rural roads, by rail and by the electricity grid;

• Natural Resources intended as a green system that demonstrates a discontinuity in its extension through a limited number of protected vegetative species, agricultural soils and rural settlements;

• Informal and urban-rural settlements and the relative urban growth understood as the settlement pressure that every single urban centre exerts on the territory: Public services and

the degree of social marginalisation make it possible to give a quantitative and qualitative connotation to the area;

• Water governance through the identification of the main surface and underground water flows (blue system) and water collection points divided according to their use (pastoralism and agriculture, industry, public): The network of telecommunications determines virtual flows that generate networks with interchange points with a high level of accessibility;

• Circular economy of the area represented through land specialisation and land use: Spatialization of agricultural activity is readable through the actual growth of recorded production and the mapping of potential agricultural areas.

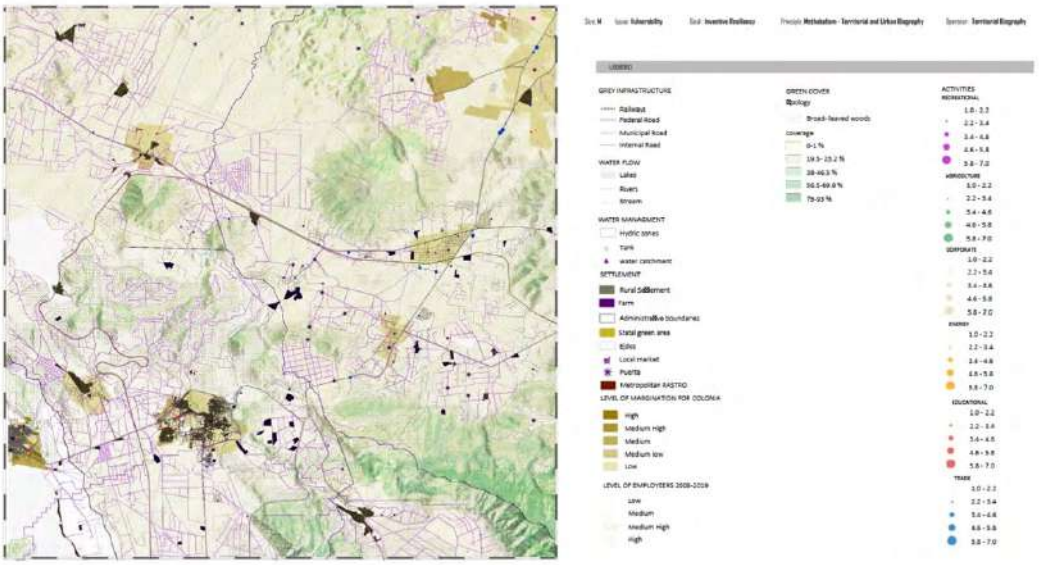

Figure 19 Procedure Map of Dyanmic 2: The expansion of settlements within the valley and the development of small centralities due to a robust localisation of mining centres and productive food processing industries (M Scale)

3.3. Conclusion: Direction for Problem Solving

The main result of the Guadalajara Training Lab was that we identified a metropolitan axis beyond the administrative boundary of the Metropolitan City of Guadalajara. The project needs to be further developed in a sustainable accessibility project that allows the community to experience the environment while avoiding the risk of isolation, and the creation of tourism on which it is possible to invest energy and resources to improve cultural and landscape heritage. The community presence is essential in the area assessments because it reflects the agricultural system of the ejidos, a rural area that can be managed privately or publicly. The lands in common use and the fragmented ones define plots, alignments and geometries as signs that affect the soil and determine the landscape.

4. Conclusion

From the analysis mentioned above, starting from the question about the size of the city, each metropolitan aspect is progressively studied, bonded to a scale and framed throughout the steps of Metro-dology. The necessity for the delineation of fields of action (the bounding box) out of the traditional municipal boundaries emerges as a fundamental step to identify the speed of change produced on the different metropolitan dimensions.

A following step of evaluation needs to be pursued to render territorial criticalities and assets and to help future policy-making processes or ad-hoc interventions. Through a multi-scale integrated approach for assessing metropolis impacts and drivers, the Metro-dology allows us to investigate the relationships among the facets of a city over its surrounding territory.

Case Study Paper

THE CRISALIDE PROJECT:

When innovative planning processes re-balance urban development and create new quality of life using the opportunities provided by the rise of the digital city.

Pietro ELISEI, Eurasia; Romania

Elena BATUNOVA, Southern Urban Planning Centre; Russia

Miruna DRAGHIA, Urbasofia; Romania, Ion Mincu University of Architecture and Urban Planning, Bucharest, Romania

Abstract

CRISALIDE (City Replicable and Integrated Smart Actions Leading Innovation to Develop Urban Economies) is one of the very few projects financed between EU and Russian Federation through the ERA NET RUS PLUS (ENRP) programme. It is the only financed project in ENRP dealing with topics related to urban planning in this current EU programming period (2013-2020). Societal transformation happens in the cities. Cities are the natural habitat for developing innovation. Innovation inherently requires change. Great cities, especially in their golden ages, have been considered as "innovative milieus" or "cradles of civilization" (Hall, P., 1998). The change, as the catalyser of innovation, is embedded in urban life. The change covers different fields, for instance, the demography (e.g. ageing, in-im-emigrations), the citizens' behaviours (e.g. higher mobility, digital literacy, social media addiction), the working patterns (e.g. continuous learning, higher commuting, virtual offices), the use and extension of both public space and sphere (e.g. location-based services, public/private urban spaces as hyper-location, re-use and temporary uses of buildings and brownfields) the modes/means of production (e.g. just in time products, global trade and distribution, effective governance schemes adoption and tools for Public-Private-People Partnerships - PPPP) and so on. Nonetheless, we are in an age of rapid urbanization. In Russia, a polarization of population around major urban areas is evident. This trend led, a few years ago, to the design of a policy facing planning issues related to Russian Urban Agglomerations. Urbanization is a great opportunity for supporting innovative choices and urban solutions. Strategic, smart and integrated urban management is a key tool to promote stable growth and effective processes of innovation. New efforts to modernize the Russian economy and face global issues as well (e.g. climate change, migration, sustainability), have taken on an even greater significance since the implementation of Western sanctions. Cities can be the natural catalyser for promoting innovation, as they contain all strategic elements (e.g. available spaces and infrastructures both public and private, research centres, universities, science parks, creative communities, large industry, SMEs), at a scale of proximity. CRISALIDE is experimenting in Rostov-on-Don, through a collaborative approach involving EU and Russian researchers, the creation of a digital innovative platform aimed at facilitating the renewal and regeneration of brownfields. The platform is abstracting, digitalising and finally creating a replicable and user-friendly tool based on an enlarged participatory planning process grounded on PPPP (Public Private People Partnership) principle. The platform is harmonising the contribution of stakeholders in diverse planning domains and formalize them through KPIs (Key Performance Indicators) providing values at disposal to decision makers linked to

grade of smartness and comprehensive quality of life generated by the triggered regenerative planning process.

Keywords

smart cities, strategic planning, urban policy, urban regeneration, brownfields

1. Linking innovation to the Russian planning context explaining the need for a platform

1.1. The idea of CRISALIDE

The opportunity of designing the project CRISALIDE (**C**ity **R**eplicable and **I**ntegrated **S**mart **A**ctions **L**eading **I**nnovation to **D**evelop Urban **E**conomies) has been given by the opening of the second call of the EU/Russian Federation Programme called ERA.Net RUS Plus. The major objective of ERA.Net RUS Plus is to deepen the transnational collaboration between EU MS/AC and Russia and to reduce the fragmentation of research programmes along national funding lines. Other principal goals of ERA.Net RUS Plus are to further develop the instrumental setting for joint funding activities and thus to provide a solid basis for a cooperative programmatic approach to be pursued in the near future. This programmatic approach will assure the desired and necessary sustainability of the cooperation between EU Member States and Russia and a lasting impact.

The project's name is already a synthesis of the project attitude towards the application of innovative methodologies in the urban realm. The chrysalis (CRISALIDE is the Italian version of the word chrysalis) is a butterfly at the stage of development when it is covered by a hard case, before it becomes an adult insect. It is a metaphor of the translation towards a new state of play characterized by the application of innovative solutions, as innovation is the result of a process that transforms the state of things bringing them to a completely new situation: the chrysalis becoming a butterfly. CRISALIDE through its methodology and participatory activities is developing a stable, engaged stakeholder group, which will assist in the establishment of the innovative development schemes (IDS) tackling aspects related to housing, mobility and infrastructure, public space and services/ facilities, environment, landscape and heritage, as well as urban management and governance. The results and the impacts are organized in three innovation areas:

- organizational innovation (such as new niches for local, city-based private sector to boost R&D and innovation activities, policy impact to reinforce local and national related policies regarding collaboration in the field of R&D and innovation),
- technological innovation and
- social innovation (enhanced Local Identity to improve social capital, increased climate and environmental awareness to favour community's preparedness, increased ICT development awareness to enhance local economics).

1.2. Being innovative in Urban Planning in the EU

We are in an age of rapid urbanization. Nowadays globally, more people live in urban areas than in rural areas, with 55.3 % of the world's population residing in urban areas in 2018 (World Bank Data, 2019). In 1950, 30 % of the world's population was urban, and by 2050, 68% of the world's population is projected to be urban (UN, 2018). Innovation in urban planning covers different fields, for instance,

- the demography (e.g. ageing, in-im-emigrations),
- the citizens' behaviours (e.g. higher mobility, digital literacy, social media addiction),
- the working patterns (e.g. continuous learning, higher commuting, virtual office),
- the use and extension of both public space and sphere (e.g. location-based services, public/private urban spaces as hyper-location, re-use and temporary uses of buildings and brownfields)
- the modes/ means of production (e.g. just in time products, global trade and distribution, effective governance schemes adoption and tools for Public-Private-People Partnerships - PPPP) and so on.

In the European context, especially of urban policies promoted by the EU, in the last few years, the theme of urban innovation has become a mantra that supports various direct financing programs (mainstream funds) and indirect ones (specific initiatives and programs managed directly with the cities or metropolitan areas). The Innovation Union was launched in 2010 as a flagship initiative of the Europe 2020 strategy to build on Europe's strengths and address its weaknesses with respect to innovation and thereby make Europe more competitive in times of budgetary constraints, demographic change and increased global competition. The main achievements under this priority are the implementation of the European Research Area (ERA) and the launch of Horizon 2020, the new research and innovation framework programme, streamlining funding and encouraging cross border and transnational collaboration.

The flagship programme of the EU in this respect is the UIA (Urban Innovative Actions). Cities are going to be financed after proposing innovative ideas co-designed together with a local partnership constituted by key stakeholders, basically following the quadruple helix principle. Urban Innovative Actions test innovative ideas and support urban authorities in their efforts to ensure sustainable urban development. In 2015, urban stakeholders and Member States identified 12 topics which represent common challenges cities are facing: 1) Air quality, 2) Innovation and responsible public procurement, 3) Circular economy, 4) Integration of migrants and refugees, 5) Climate adaptation, 6) Jobs and skills in the local economy, 7) Digital transition, 8) Housing, 9) Energy Transition, 10) Sustainable use of land (nature-based solutions), 11) Urban mobility, 12) Urban Poverty (deprived neighbourhoods).

All over Europe, there are currently 54 projects experimenting urban innovative solutions for current issues faced by EU cities in the above listed challenges (https://uia-initiative.eu/en/uia-cities-map).

Figure 1 Innovative Actions currently financed all over EU

1.3. Being innovative in Urban Planning in the Russian context

Investing with proper methodologies in the urban realm means creating conditions for developing consumer orientated sustainable products and efficient/effective services. In fact, despite the big role of Russia's science and its potential, today the country seems to be lagging behind in cultivating high-tech technologies for innovating the economy of cities. Although it is one of the leaders in developing space, defence and nuclear technologies, Russia is drastically falling behind in producing consumer technologies (Koshkin, P. 2015). Innovations in the contemporary Russian urban planning system are mainly seen in the usage of the new technological tools, such as GIS, but the urban planning system is far from the introduction of organisational or social innovations. Despite the fact that the country' s transition to the new socio-economic model is associated with the introduction of the unknown for the Soviet model conditions, such as private property and private actors, and the creation of the new urban planning system, this system in many aspects replicates the obsolete socialist model of planning. It is still top-down, centralised, comprehensive and does not consider public participation as an important element of decision-making.

CRISALIDE's approach is to build innovative solutions through a dialogue between stakeholders placed before the transformation of a given urban context. A remarkable asset of this project lies in the fact that it is necessary to arrive to the definition of a platform, based on specific urban and territorial indicators, which facilitates decision-making choices in urban transformation and regeneration processes. in this sense both the European and the Russian partners are bound by the concreteness of the real problems connected to the transformation of an urban area. CRISALIDE is currently being implemented, so it has not yet come to define this platform, but concrete hypotheses have been put forward on how to build it. From a strictly urbanistic point of view (there is also in CRISALIDE a translation of qualitative themes into ontologies useful to computer scientists to create the platform, but they are not the main object of this article) the themes (urban functions) on which to work, were identified. Each of these themes is being evaluated based on a set of KPIs (key performance indicators) `based on the following functions:

- The places of living (housing)
- The spaces for production
- The Public space
- Mobility and accessibility
- Governance and participation
- Green infrastructure (NBS, Nature Based Solutions)

2. Applying a participatory based methodology supported by evidence-based planning actions

2.1. Contextualisation of participatory based methodology in CRISALIDE

CRISALIDE project is experimenting a joint EU-Russian research and collaborative approach for the creation of a digital innovative platform, designed to facilitate the renewal and regeneration of abandoned areas and brownfields. As an outcome, the platform is envisioned to become a replicable, user-friendly tool, aligning and harmonising visions from a diverse ecosystem of stakeholders.

In order to achieve its final outcome, CRISALIDE project leverages on the principle of participatory planning, its methodology being guided by a simple vision: to establish a multi-stakeholder group to sustain the collaboration in the field of R&D and innovation through a set of participatory workshops with a two-fold objective: 1) lay the foundation for the platform design by mapping the existing knowledge and gather evidence-based information and 2) design the technical and locally-rooted requirements for the online collaborative platform, the Innovative Decision-Making Tool (IDMT). Based on a set of KPIs (Key Performance Indicators) debated and agreed with the multi-stakeholder group, the IDMT will provide values at disposal to decision makers linked to grade of smartness and comprehensive quality of life generated by the triggered regenerative planning process.

2.2. Participatory based methodology conceptualisation

The conceptualisation of the participatory based methodology is embedded into a theoretical background on participatory planning processes and design thinking methods, in order to design the most suitable workshop scenario for identifying local needs, problems, opportunities and brainstorming potential solutions to the most pressing challenges. One of the main expected outcomes of the participatory based methodology is to boost, strengthen and consolidate the collaboration between multiple stakeholders towards RDI in the city of Rostov-on-Don. By applying a participatory based methodology and approach, the idea of empowerment will provide stakeholders with the ability and capacity to become agents for change in the process of decision-making concerning their own lifestyles and environment (Benson, Roe, 2000). As a natural consequence, the IDMT (Innovative Decision-Making Tool) will be defined in a participative environment and setting, following the core principles of stakeholders' empowerment.

Participatory processes are widely known practices in city planning and development projects. Several methods and practices can achieve certain levels of citizen/ stakeholder

involvement. Research on participatory processes is categorising and classifying practices between four impact levels of participation: information, consultation, collaboration and empowerment (Stelzle, Noennig, 2017). In this context, CRISALIDE project focuses mainly on consultation and collaboration methods, in order to achieve long-term collaboration in the field of RDI among researchers, businesses and companies (technology providers) and the public sector. The engagement and active participation of different local actors is crucial for reaching a successful design and conception of the IDMT. The challenge lies mostly in the process of discovering the diversity of interest and viewpoints and managing to conduct a work of matchmaking until reaching the point of interest alignment and harmonization, without overvaluing certain opinions or excluding too many interests (Healey, 1997).

2.3. Need for evidence-based decision-making

Going beyond the narrative of participatory approaches and stakeholders' empowerment in the process of planning and decision-making, another key challenge lies in the gap between the ideology-based policy making and the more pragmatic evidence-grounded decision-making process (Davoudi, 2006). According to Davies' understanding, the evidence-based policy and decision making represent an approach that „helps people make well informed decisions about policies, programmes and projects by putting the best available evidence from research at the heart of policy development and implementation". Therefore, it is evident that the IDMT should be founded on sound reasoning processes and backed by reliable and actual information and data, leveraging on the evidence-based planning as a rigour and systematic approach to achieve replicable and scalable results (Elisei et al., 2018).

The design and conceptualisation of the IDMT will surely benefit from an evidence-based planning and policy-making approach, considering the following key points: a) better understand the locally rooted needs and challenges from multiple viewpoint; b) demonstrate and amplify the connection between strategic planning and policy-making and political decision-making; c) agree and share a common objective language among the multi-dimensional ecosystem of stakeholders and design a convergent transformation vision; d) open up a transparent communication channel through an open and accessible platform and last, but not least, e) strengthen and consolidate the cooperation between local stakeholders to reach agreements for proceeding towards joint RDI.

2.4. Participatory approach and methodology

The participatory approach and methodology for CRISALIDE project aims at creating the proper framework for developing a shared vision between local authority representatives, researchers/ professionals, businesses, other local stakeholders, civil society and public audience, which enables early stage planning, in order to 'ignite' the collaborative process. In order to select the most suitable tools for participatory approach, we take into account the following five elements: objectives (reasons for stakeholder involvement and expectations/outcome), topic/ planning domain (scope of the issue/ challenge), participants (who is the provider/ beneficiary/ end user), time resource (amount of available time) and financial resource (available budget or funding opportunities).

Figure 2 CRISALIDE Methodological approach

The participatory approach and methodology is clearly linked with the participatory planning cycle, addressing the following steps:

1. Step 1. State-of-play screening, resulting in a set of planning pre-conditions, divided into two main categories: drivers and challenges in respect to the local specificities and the available resources. The first step will take into consideration the following components: defining (local) issues, challenges and needs in relation to (global) challenges; mapping relevant stakeholders (in accordance with the priority planning domains), gathering evidence (collecting relevant data) and mapping resources (opportunities and threats) and assessing the available policy tools.
2. Step 2. Strategic planning, resulting in a set of key priorities, materialised through strategic objectives and intended results for a specific timeframe (short/ medium/ long horizon), which will set the basis for the scenario building and strategic options/ alternative solutions. The second step will have as outcome the selection of the most suitable scenario, taking into consideration the urgencies of the pilot area.
3. Step 3. Action and experimenting, resulting in a list of actions, following a certain prioritisation criterion and allowing for collective brainstorming on the most suitable management structures and organisational logistics for the experimentation. Therefore, the third step will propose a correlation between the actions' repository, the funding opportunities, the implementation timeframe and the monitoring plan. Experimentation should be an intermediary step between action planning and large-scale implementation and it should temporarily test potential solutions (such as the IDMT, to provide room for improvement and preparation for the market uptake).
4. Step 4. Implementation, resulting in the physical implementation of flagship projects and programs, as well as feasibility studies and concrete investment plans. Within this final step, transferability, replicability and up-scaling aspects will be considered.

Within CRISALIDE, the set of participatory workshops is one of the stepping stones for the participatory approach, its objectives being threefold: 1) gathering local stakeholders from

different planning domains and sectors and brokering between diverse interests (main sectors identified so far as being of high interest for the context of Rostov-on-Don: housing; mobility and infrastructure, public space, environment, landscape and heritage, as well as urban management and governance); 2) brainstorming on the IDMT concept and identifying major local issues/ challenges, as well as tool technical requirements and functionalities; 3) debating and discussing further needs, opportunities and possibilities for collaboration.

The methodology for conducting participatory workshops comprises of a toolkit of methods, formats, as well as possible instruments, tools and techniques to be applied within interactive sessions. The following set of recommendations is taken into consideration: a) clear definition of workshop objective (aims and intended outputs/ achievements), b) suitable setting and scene (ice breaking session), c) participants skills and capabilities acknowledgement, d) proper selection of tools and instruments for creative problem/ solution exploration, based on collective intelligence of the entire group for idea generation, e) outputs co-creation (make outputs visual and avoid too-long texts), f) collection of feedback and suggestions/ recommendations and g) evidence and time keeping.

3. The area-based approach and the selected area for experimentation in Rostov-on-Don

3.1. A need for solutions from the bottom

Brownfield redevelopment in Russia is a quite new and challenging issue of urban planning. As such, planners' attention to it has just started to arise, which is being explained by several factors and determinants. Firstly, compared to the highly urbanized territories of the European countries, where the issue has become one of the EU policy's priorities (Science for Environment Policy: Brownfield Regeneration, 2013), Russia has vast greenfield areas near the cities, whose development requires significantly less efforts in terms of economy and legislation. Similar situation is observed in the US, where the interest to brownfield redevelopment is also much lower than in the EU (Meyer, 1998). Secondly, the traditional socialist way of extensive urban growth was not limited by any economic factors and there were not any incentives to recycle land (Bertaud & Renaud, 1997). The following post-socialist construction boom provoked even higher land consumption and urban sprawl due to the high housing demand and interest from both public and private parties to satisfy the population's needs (Stanilov, 2007). However, after three post-socialist decades, the unsustainability of such approach is becoming evident especially in large capital cities, which have been attractive poles for both population migration and investments into housing construction. Traffic, air pollution, lack of social facilities, services and technical infrastructure make new peripheral areas of the large cities less attractive and problematic for the city management. These problems provoked several attempts to reorient urban development inside the existing city territory and consider brownfields as an important development resource, given its intention of appearance in the national policies (Batunova & Trukhachev, 2019).

These first attempts to introduce new approaches in urban development have not yet triggered significant changes, although there are several successful examples in different cities and the request for such changes is rapidly increasing. Recently, a framework for such strategies' implementation has been introduced at the national level programs , however it

is mandatory to be supported from the bottom. At the same time, numerous information systems in Russia that serve to support decision-making processes when creating urban strategic and territorial plans, formulating urban policies, promoting e-government, managing urban infrastructure and housing stock or land use in cities, are often designed and created separately and their integration may be even more difficult than in pre-digital period. In such conditions, participatory and area-based strategies are necessary for better problems' identification and solutions' delivery (Dakin, Burgess & Adamson, 2012). Addressing brownfields redevelopment issue requires a more comprehensive approach that allows understanding the root-causes of the existing problems (Harfst, 2006). The focus on local conditions will also allow to test the CRISALIDE IDMT during the entire process of development and implementation, to put into practice the results of theoretical studies, to receive feedback from users and, in return, to enrich the theoretical work (often desk-based research) with empirical experience (evidence-based system). In addition to technological innovations, the introduction of organizational and social innovations in the spatial planning of the selected city, which will contribute to the reconfiguration of the urban planning process at the local level, will further enhance the set of positive practices of Russian cities.

3.2. Criteria for the city selection

When choosing a city for the implementation of a decision support system, the most important aspect was the presence of a case's characteristics that would allow up-scaling the R&D results and their application in other Russian cities. At the same time, the local peculiarities had to form a set of conditions on the basis of which a wide range of strategic options and planning tasks could be formulated, in search for the solutions of which the CRISALIDE project could be tested. Accordingly, for the city selection we defined nine criteria presented in the table below (tab.1).

Criteria	Relevance and Importance
Administrative status: urban okrug1, capital of the subject of the federation	A status of regional capital and urban okrug provides expanded power of city authorities, an expanded structure of local governments, active interaction of local and regional authorities, the implementation of interests of multiple governmental levels within a city, better representation in statistical databases, in the regional and federal strategic and program documents. Municipal planning is characterized by the presence of approved strategies, territorial planning documents, as well as detailed municipal programs, which makes it possible to get a solid vision of the future urban development

[1] According to the Federal Law #131-FZ of October 6, 2003 On General Principles of the Organization of Local Self-Government in the Russian Federation, as amended by the Federal Law #243-FZ of September 28, 2010

Criteria	Relevance and Importance
Population: more than 500 thousand inhabitants	High concentration of population and economic activities, high population density, buildings and infrastructure, the presence of important educational, scientific, social and administrative institutions, which allows to effectively develop horizontal links between local participants and introduce innovations. Possibility to expand the interaction at the inter-municipal level and to increase the efficiency of the implementation and dissemination of innovative solutions.
Diversified economy with a tendency of growth of the tertiary sector	Request for the transformations of urban areas and presence of potential stakeholders interested in such transformations. Interaction between enterprises of various industries and the activation of the synergic effect of their interaction.
Scientific potential	Involvement of local scientific experts at various stages of the project development and implementation leading to improvement of the quality of decisions made and an opportunity to receive expert assessment.
Positive dynamics of the construction industry	An active construction sector with high competition creates conditions for a variety of products and solutions in urban development. Companies representing the construction sector are among the key participants in the decision-making process for managing the urban environment.
Limited territorial resources for expansive development and internal transformation processes	The limitation in external territorial resources stimulates the search for solutions on the intensive use of urban areas, which is a key component of sustainable development. The presence of implemented redevelopment projects in the city provides the accumulated positive and negative experiences, as well as various management and interaction schemes, the rethinking of which will become the basis for innovative decision-making schemes of the proposed hardware-software complex.
Availability of internal territorial resources that can potentially be used for development	The city planning documentation should identify promising areas for redevelopment. The presence of such decisions in the documentation means the readiness of the local authorities to implement the concept of a “compact city”, as well as the existence of grounds for implementing policies in this direction.
Experience in the development of information systems to support urban management and planning	Experience in the development and implementation of projects, as well as the experience of cooperation of private development companies with government authorities and management allows involvement of representatives of government and business into the project development and implementation, which will further ensure the sustainability of the project.
Participation in federal programs related to priority projects in the field of urban development.	State investments nowadays play an important role in urban development in Russia, therefore, the active participation of the city in state development programs is a prerequisite for the successful implementation of the project, as well as its distribution in the future.

Table 1. Case Study Selection Criteria

In correspondence with the previously described criteria for the CRISALIDE project implementation, the city of Rostov-on-Don has been selected. The city is located in the south of the European part of Russia , being the capital of Rostov region, one of 85 Russian regions. With its population of 1,130,305 people[2], Rostov-on-Don is the 10th city out of 1,113 cities of the Russian Federation. Being an attractive growing pole, the city is characterized by the diversified economic structure with the current prevalence of the industrial production and dynamic development of the tertiary sector. There are 38 institutions of higher education and 40 scientific organizations including the Federal Research Center of the Southern Scientific Center of the Russian Academy of Sciences (FIC SSC RAS), where 400 researchers work (Investment Passport, 2018). The city continues its demographic growth and its housing construction sector expansion, represented by numerous competing companies that together build about 1,100 thousand sqm annually (Investment Passport, 2018). At the same time, Rostov-on-Don is limited in extensive development by its administrative borders and it's forced to seek internal resources for development, which are represented by numerous brownfield sites as a legacy of post-socialist transition and post-industrial development. Those sites are defined as priority areas for redevelopment and housing construction by the Rostov-on-Don General plan (2015) and its Strategy of socioeconomic development (2018), the main long-term municipal planning documents. Several projects of the former industrial areas' redevelopment have been already realized: e.g. the former tobacco factory transformed into the business center 'Tabachka' or a part of the helicopter plant's industrial site Rostvertol, transformed into a business and exhibition center. Rostov actively participates in all national programs and projects. In 2018, the city became one of 36 pilot cities, in the priority project "Smart City". The need for the implementation of intellectual (IQ) solutions in the housing sector of the city of Rostov-on-Don is also stated by the Strategy of the City's Socio-Economic Development (2018), as a measure to reduce the cost of utility resources, improve the safety and quality of housing and communal services, and also to optimize the process of controlling and monitoring the consumption of resources through Internet services.

3.3. A site for experimentation

The site for implementation was selected together with the local administration among several former industrial areas in Rostov-on-Don. It is recommended for redevelopment by the Strategy of Socioeconomic development and attracts high investors' interests. The choice was due to the value of such a significant territorial resource for the development of the city, great prospects for the application of innovative methods and technologies in planning the development of this territory and its development, the potential for creating a high-quality urban environment, creating opportunities for innovative economic development, forming a positive image of the city and attracting investments .Moreover, the large area of the site (about 350 ha) involves a long-term phased implementation of the project.

[2] Federal State Statistic Service (Rosstat), 01.01.2019. http://www.gks.ru/

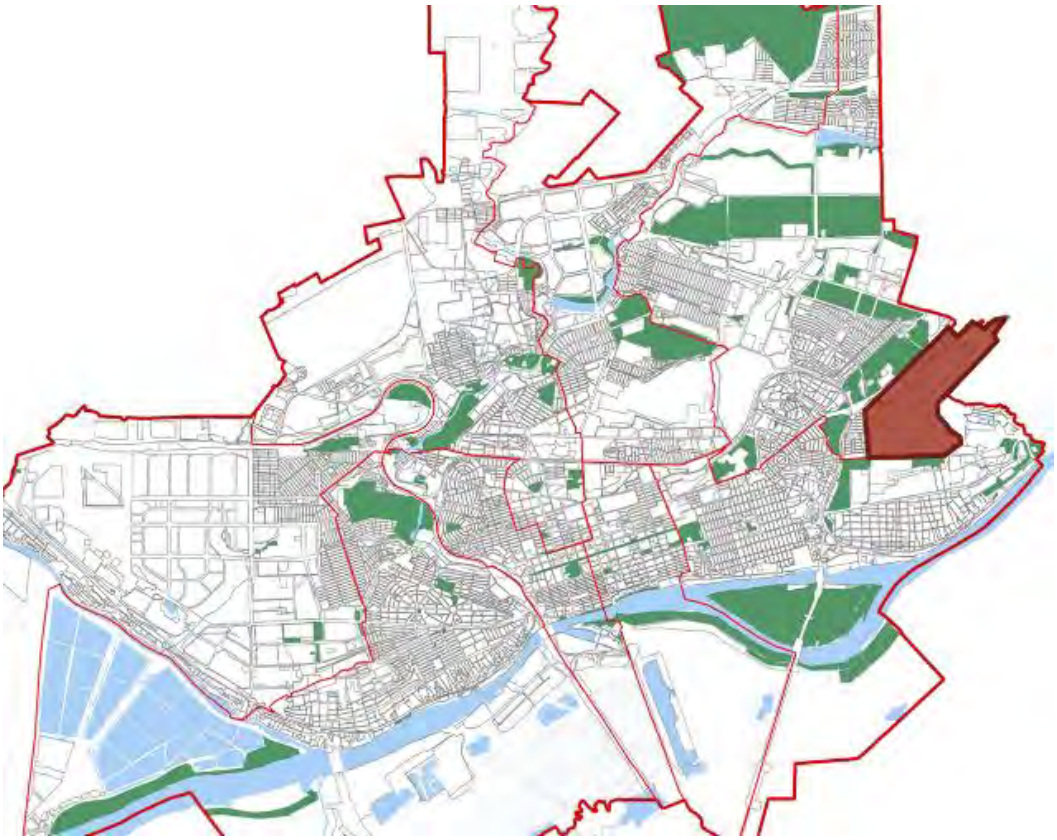

Figure 3 Location of the old airport area and intervention area (old airport) in Rostov on Don

The area of the former airport 'Rostov-on-Don' is located in the eastern part of the city in nine kilometres from the city center, in the Pervomaysky administrative district. The airport stopped its operation in December 2017, when the new international airport was opened - Platov International Airport. In the local planning documents, the old airport's territory was considered as an internal spatial resource for development years before the actual realization. Thus, the city General plan approved in 2015 proposed the construction of 1,596 thousand square meters of housing within the plot of 267 ha until 2035. After the new airport construction, the local authority started to promote the area for redevelopment and several projects have been done, one of which was presented at the Russian Investment Forum in Sochi in 2018. The site is located in the peripheral part of the city, but at the same time in the centre of Rostov-on-Don metropolitan area (named 'Big Rostov') that consists of eight cities and a number of rural settlements and whose population number is estimated at about 2.2 million people. The site is surrounded by the important areas of commercial activities of regional significance: the regional markets and shopping malls with such actors as IKEA or Auchan are operating here. The transport axis on which the site is located, links the city center with the new airport and the very important federal road M4 Don, which connects the national capital Moscow with the Black Sea coast and countries of the Caucasian region.

Conclusions

The CRISALIDE project heralds a way of working on the cities that is very distant from the ordinary practices operated in Russia. The CRISALIDE methodology builds the solutions from

the bottom, works with the stakeholders in identifying the problems to be faced and defines the figure of the planner as that of a mediator and facilitator of complex processes. A methodology that has no a priori solutions, which does not have the innovation package ready to be sold and applied top down.

The CRISALIDE project being oriented to the development of a digital innovative platform, creates an opportunity to introduce social and organizational innovations in urban planning through participatory bottom up approach. The digital dimension is an arrival point of a real participatory planning process. The platform, as a tool that facilitates balanced planning and as a tool that facilitates sustainable decision-making, is born of an advanced dialogic context (IDMS, Innovative Decision Making Scheme). Reducing the complexity of a complex process to an IT tool means losing many nuances, but the advantage of the digital tool (IDMT) is to focus on the essential elements of the planning process, in terms of urban functions and related indicators.

The first results gained from the series of public discussions and CRISALIDE events demonstrated agreement between most local experts on necessity to transform outdated approaches to planning and construction in contemporary Russia. The public opinion demonstrated the need to have an experimental platform for the introduction of new planning methods and practices, advanced construction technologies, organization and management of the urban environment, taking into account such modern challenges as climate change, environmental pollution, demographic problems, socio-economic stratification of society and the rapid development of new technologies. Avoiding the construction of commercial housing, the formation of high-comfort public spaces, the introduction of new forms of mobility and environmentally friendly technologies, the creation of conditions for maintaining the health of the population, the realization of its creative and intellectual potential, the activation of innovative forms of economies. To achieve this, CRISALIDE defined the urban functions listed above in chapter 1.3 as the starting point. For this reason the experimentation underway in Rostov-on-Don, in the area of the old airport, is defining interesting ideas, but also opening up conflicts on the different ways of approaching the problem, on the scale of transformations, on the different way of relating to the use of environmental resources or conceiving innovation in design and use of public space and services. However, in this way, the development of a prototype IDMT in the field of urban planning, based on a real case, is not only the possibility of creating an innovative software and hardware complex for Rostov on Don that meets the principles of the Smart City Concept, but also a real chance to launch socio-cultural and organizational innovations in planning that could be upscaled both in EU member states and in Russian Federation. Finally and definitely, the involvement of pro-active human capital (people, researchers, private actors, administrators…) and scientific potential of the city (university and enterprises…) in the innovation process and experimental activity will contribute to the formation of new products and businesses in the ‘smart city’ sphere, which will strengthen the economic position of Rostov-on-Don and create conditions for the development of new niches of economic activity, especially related to creation of a local new economy building upon the connection Economy of Knowledge <-> Quality of Life <-> Start-ups creation facilitation <-> Sustainable use of Resources.

Research Paper

Research of Traditional Village Conservation and Development Planning in the Perspective of "Multiple-planning"

Taking Liugou Village in Beijing as an Example

Zhengkun GAN, Beijing University of Civil Engineering and Architecture; China
Lingege LONG, Beijing University of Civil Engineering and Architecture; China
Dayu ZHANG, Beijing University of Civil Engineering and Architecture; China

Abstract

As a primary material carrier of Chinese farming civilization, traditional villages have the dual attributes of villages and heritage. The traditional village cannot be regenerated if they were destroyed. Therefore, it is urgent to find a suitable development model and way out in the context of high-speed urbanization. The proper planning of traditional villages mainly covers two aspects of protection and development for a long time. The preparation and management of various types of planning are also intertwined and even contradictory. "Multiple-planning" is an effective way to solve the conflicts between different administrative departments and different types of planning in the current planning process, and also provides a practical planning idea and method for the future of traditional villages. Firstly, the research analyzes the existing planning types of traditional villages and points out that because of the difference of objectives, strategies, and executives, there come three common problems: The protection measures are not easy to implement; The development strategies are unsustainable; The planning and implementation are not connected. These problems directly affected the implementation of planning. They not only hinder the effective conservation of cultural heritage but also restrict the revitalization of the village's economic development. Furthermore, the research discusses the necessity and feasibility of "Multiple-planning" in the conservation and development of traditional villages and proposes a conservation and development planning framework for traditional villages from the perspective of "Multiple-planning." Finally, the research is taking a traditional village conservation and development planning of Liugou in Yanqing District of Beijing as an example. Accomplished valuable planning in the perspective of "Multiple-planning" through objective and systematic status analyzing, exceptional and feasible conservation planning, scientific and sustainable development planning.

Key words

Traditional villages, Conservation and development, Cultural heritage, Multiple-planning

Introduction

Traditional villages, as primary material carriers of China's farming civilization, cannot be regenerated once destroyed. In the era of high-speed urbanization, it is urgent to find a

suitable development model and way out. For a long time, the proper planning of traditional villages mainly covers two aspects of protection and development. The preparation and management of various types of planning are also intertwined and even contradictory. "Multiple-planning" is an effective way to solve the conflicts between different administrative departments and different types of planning in the current planning process and provides a practical planning idea and method for the future of traditional villages. Governments and planners should face many shortcomings in their past work and actively explore to find a scientific and practical way for the planning and construction of traditional villages, keep rural memories and valuable village cultural heritage for future generations.

1 Compilation Model of Relevant Planning for Traditional Chinese Villages

There are many types of planning for traditional Chinese villages. They can be divided into three classes from the purpose of preparation, promotion planning for people's livelihood, industrial development planning, conservation, and remediation planning. Each broad category contains several small planning types (Table 1).

Planning Type	Planning Title	Planning Purposes	Planning Object	Executive Body	Planning Points
Promotion Planning for People's Livelihood	New Rural Beautiful Village Planning	Improving the Quality of the Village	Villages, Buildings	Government	Taking policy as the guidance, improving the basic conditions of village in an all-round way
	Village Environmental Improvement Planning	Improving Environmental Quality	Villages, Buildings	Government	Focusing on infrastructure upgrading
Industrial Development Planning	Tourism Planning	Developing Tourism Industry	Villages	Government, Enterprises, Villagers	Developing tourism resources and expanding village development Market
	Industrial Upgrading Planning	Promoting Economic Development	Industries	Government, Enterprises, Villagers	Build the core industry and enhance the economic strength of the village
Conservation and Remediation Planning	Cultural Relics Conservation Planning	Conserving Important Cultural Relics	Cultural relics Noumenon and Environment	Government	Conserving the core value of cultural heritage
	Conservation Planning of Famous Historical and Cultural Villages	Conserving Village Heritage	Villages, Buildings	Government, Villagers	Conserving the cultural heritage on a large scale
	Traditional Building Renovation Planning	Repairing Important Buildings	Buildings	Government, Villagers	Maintaining the buildings with high value
	Village Landscape Planning	Improving Landscape Quality	Village, Landscape	Government	Design a rural landscape with outstanding characteristics
	Traditional village Conservation and Development Planning	Conserving and Developing at the Same Time	Villages, Industries	Government, Enterprises, Villagers	Establishing archives, analyzing the current situation, conserving heritage, improving people's livelihood, and looking for the characteristics of village development

Table 1 Classification Comparison of Traditional Village Related Planning by Author

1.1 Promotion Planning for People's Livelihood

Objectively speaking, the promotion planning for people's livelihood is usually the most popular type of villagers. The typical representative of such a plan is the Beautiful Village Planning. The planning content does not involve the relocation of villages and the transfer of construction land, with emphasis on the rectification of the village landscape, the construction of infrastructure and public service facilities. Its purpose is to improve the living environment and production conditions through correction and finally promote economic development and social progress. Most of these planning is implemented in a top-down way, which usually ignoring the characteristics of specific villages. Project selection, site selection, and construction scale often do not meet the needs of village development, especially when it comes to heritage conservation and inheritance. It is easy to ignore the repair of traditional buildings and the preservation of classic features, thus resulting in the disappearance of traditional elements in the implementation of planning.

1.2 Industrial Development Planning

The starting point and foothold of industrial development planning are in the market expansion and industrial development of the village. Due to the hollowing and aging of the rural population, most of the traditional villages have a single industrial structure and a small development space. The positioning of the industry is mostly concentrated in the tourism of the tertiary industry. From the perspective of the development of international urbanization, when most people live in cities, rural pastoral scenery and traditional culture will become scarce resources, and the continuous appreciation will attract urban residents to come for sightseeing. Such planning often relies on the core values of traditional villages, led by the government and enterprises, and the villagers participate to a certain extent. However, because there is no sustainable integrated of material and non-material traditional cultural resources, once it is not operated correctly, it will bring irreparable damage to the village.

1.3 Conservation and Remediation Planning

The core of conservation and remediation planning is centered on how to protect the cultural heritage value of traditional villages. The means adopted are often rigid and have a significant positive effect on the conservation of villages in the short term. Due to the attention from the state, most villages in the list of National Traditional Villages have prepared conservation planning, and their control covers village space patterns, traditional buildings, historical relics, and environmental factors. Many of the conservation programs currently in place can technically protect historical buildings and ancient villages as well as intangible cultural heritage. However, how to meet the needs of the residents' living modernization while conservation is a problem that has not been completely solved. For this reason, the state began to require traditional villages to prepare conservation and development planning to handle the relationship between conservation and development.

2 Common Problems in the Planning of Chinese Traditional Villages

Since the objectives, strategies, and executive bodies of traditional village-related planning are different, the following three types of problems have arisen. They directly affected the implementation of the planning and even hindered the effective conservation of cultural heritage. This is also the contradiction that the "Multiple-planning" should strive to improve.

2.1 Conservation Measures are Single and Difficult to Implement

In the conservation-based traditional village planning, the conserving strategy often only pays attention to the object ontology, neglects many objective laws of the village development, and then leads to an inefficiency implementation. In China's urban and rural planning system, the planning and construction of general villages and towns are managed by the Ministry of Natural Resources, the material cultural heritage is governed by the National Cultural Heritage Administration, and the intangible cultural heritage is managed by the Ministry of Culture and Tourism. Traditional villages have a particular cultural status of tangible and intangible cultural heritage, lacking guidance, and coordinating from higher levels of government. For example, because the reduction of construction land can effectively control the population size and alleviate urban diseases, land supply policy in China is generally decreasing. When protecting critical cultural relics units, it is often necessary to vacate some buildings within the scope of conservation, but there is no reasonable area for subsequent resettlement planning. If the conservation and development planning does not combine the land use superior planning, it will not be able to create enough circulation space for conservation. The conservation will eventually not be implemented.

2.2 Development Strategy Is Not Sustainable

With the acceleration of urbanization, traditional villages continue to suffer from "constructive, developmental, and tourism" damages. The relevant planning does not control development in appropriate measures is the root of the problem. Some local governments have neglected the environmental capacity of traditional villages and just compiled industrial planning that caters to the needs of society. Coupled with the spontaneous and decentralized management of the villagers, there has been a severe homogenized phenomenon in the type of industry and structure of the function. The value of "characteristic" in rural areas has not been reflected. Such extensive development strategies continue to impact and erode an accelerated decline of traditional villages.

2.3 Lack of Convergence between Planning and Implementation

The planning implementation of traditional villages is different from another general village planning. The general village planning is characterized by focusing only on the recent construction task, the improvement of infrastructure, and environmental remediation. The planning of traditional villages should pay more attention to the conservation of historical environmental elements and traditional features, which also puts higher requirements on implementation. The reality is that the township-level government, as the main body of the application, lacks professional planning management and supervision and evaluation, and often focuses on project thinking, focusing only on the specific projects in process. There is no macroscopic and systematic overall development thinking, which inability leads to integrate the actual construction of the traditional villages with the planning. As the person in charge of the planning and preparation, the planner only completed the preliminary design work, lacked two-way communication with the villagers, and rarely played the role of dynamic adjustment and feedback during the implementation process. The participation of the villagers as an object of implementation is not high, the information is also asymmetrical, and the acquisition sense of villagers is low, too. In summary, planning is only meaningful if it

plays a role in the process of practice. This is also the key to whether planning can exist and be implemented under the market economic system.

3 The Necessity and Feasibility of "Multiple-planning" in the Development of Traditional Village Conservation

3.1 Necessity

From the international cognition process of heritage conservation, ICOMOS adopted the " The Valletta Principles for the Safeguarding and Management of Historic Cities, Towns and Urban Areas " at the 17th General Assembly in November 2011. It was in a time which politic, economic, culture, and social realm are facing a period of significant change, and it is the necessary revision of the Washington Charter. It proposes that the values of historic towns and their backgrounds should be protected and have integration with the social, cultural, and economic life of our time. It is not difficult to see from the Valletta Principles that in the context of sustainable development over the world, to better conserving the material and intangible historical values of traditional villages, action should be strictly linked to economic and social development. To improve the quality of the environment and life, we must make good use of the "Multiple-planning" model.

Judging from the current situation of the conservation and development of Chinese villages, we are also facing a very severe test. As summarized in the previous article, merely thinking about the future of the village from the safeguarding level is not even keep up with the pace of the times, and it is impossible to restore the decline of the village substantially. At the same time, the previous model faced conflicts between the various departments. The "Multiple-planning" approach is used to coordinate the value orientation of the ideological level, coordinate the planning of the technical method level, and coordinate with the main body of the implementation level. It can provide new ideas for the implementation of traditional village conservation and development. So far, several provinces have issued proposals to strengthen the protection of traditional villages and proposed to prepare of the village "Multiple-planning scientifically."

Also, the state has proposed to adopt the "One Blueprint Strategy" to optimize the urban spatial layout for the new urbanization construction many years ago and promote the "Multiple-planning" used in economic and social development master planning, urban planning and land use planning. This not only provides a clear demonstration of the "Multiple-planning" of the traditional village planning but also emphasizes the necessity of "Multiple-planning" in the future planning of traditional villages from the national level.

3.2 Feasibility

Since 2014, the four ministries and commissions jointly issued the "Notice on Carrying Out the Pilot Work on Multiple-planning in Cities and Counties." Twenty-eight cities and counties across the state have launched the "Multiple-planning" exploration work. Many successful explorations at the town level have provided valuable references for the current "Multiple-planning" transformation of traditional villages, significantly increased confidence.

The sustainable development of traditional villages has also received considerable attention from the Ministry of Housing and Urban-Rural Development. In the basic requirements for

the preparation of the traditional village conservation and development planning (Trial) issued in 2013, it is clearly stated that the conservation and development planning should be formulated, and it is necessary to adhere to the principle of conservation, taking into account development, respecting tradition and living heritage, and conforming to the laws of reality and farmers. The requirements focus on scientific decision-making with multi-disciplinary integration and solicit opinions from the government, experts, and villagers to improve the practicality and quality of planning. Based on satisfying this requirement, the villages meet conditions should further expand the content and depth of the deepening planning according to the actual needs of the village and the circumstances of economic development. This requirement integrates the traditional village planning work, which previously separated from conservation and development. It also integrates the urban and rural planning law, the cultural relics conservation law, the village and town construction management regulations, and other relevant regulations — this laying a sound system for the adaptation of traditional villages to a new era. At the same time, planning of conservation and development and form of project demanding have become a necessary condition for the declaration of the list of traditional Chinese villages and have also created a favorable political environment for the "Multiple-planning" of traditional villages.

3.3 Traditional Village Conservation and Development Planning Framework from the Perspective of "Multiple-planning"

The traditional village conservation and development planning from the perspective of "Multiple-planning" should combine the long-term overall structure with the implementation of recent projects. Seeking to improve the village's long-term development confidence while enhancing the villagers' current sense of acquisition. The planning content needs to fully consider factors such as building style, land use, infrastructure, landscape, street, and industry. The planning content of conservation and development should be coordinated, and the characterization of rural areas needs to be tapped. We must change the pursuit of a single economic value that will make traditional villages a capable carrier of the circular economy. The planning also needs to build a coordination platform for the government, planners, and villagers, strengthen cooperation means at the implementation level and establish a system of responsible planners. Long-term two-way supervision and control should be carried out to implement the planning content and control the quality of each construction project.

4 Preparation of Traditional Village Conservation and Development Planning in Liugou Village, Yanqing District, Beijing

Liugou Village is a well-known rural tourist destination in Beijing north area. The ancient castle in Liugou is formerly known as "Phoenix Castle," which is an important military castle along the Great Wall with a profound cultural connotation. The preparation of the traditional village conservation and development planning fully exploits the advantages of the "Multiple-planning" perspective. The planning systematically and comprehensively integrates the heritage conserving, industrial upgrading, environmental remediation, aiming at promoting the coordinated development of conservation and construction and grasping the new opportunities created by the International Horticultural Exposition and the Winter

Olympics 2022. It is carrying out a tourism quality transformation core on the safeguarding of Liugou ancient castle.

4.1 Analyzing Present Situation with Objective System

Liugou Village is located in the middle of Jingzhuang Town, Yanqing District, with Jiulong Mountain in the west and Yanyu Mountain in the east. Liugou ancient Castle was built in the Ming Dynasty (1551). It is also known as the Phoenix Ancient Castle because it resembles a phoenix that spreads its wings. Its city wall system is a National-Level Cultural Relics Preservation Unit. The nature of the current land within the scope of planning is mainly for construction and agriculture. The village's texture is basically in line with the traditional characteristics which the courtyard is dominated by the Triad Courtyard, and the preserved Quadrangle is less. The road grades in the village are divided into three levels: Main Street, Secondary Street, and House Front Road. The roads in the village are hardened with concrete which does not conform to traditional practices. There are three types of public spaces: squares, nodes, and front houses. The landscape of Liugou Village is generally good, with two listed ancient trees.

One of the most critical aspects of the analysis is the delineation of preservation objects. The principal preservation of heritage objects in Liugou Village is (Figure 1): ground ruins of the earthen Great Wall (National-Level Cultural Relics Preservation Unit) and the Ancient Castle Wall and Gate (as an essential part of the Great Wall defense system, National-Level Cultural Relics Preservation Unit), Chenghuang Temple (District-Level Cultural Relics Preservation Unit), the Ruins of General's Residence, Supply and Marketing Cooperatives (Modern Heritage). Among them, the North Gate and Barbican Entrance have been repaired and preserved in good condition; the Chenghuang Temple and the Supply and Marketing Cooperatives are generally in a reasonable situation. The earthen Great Wall, the Ruins of General's Residence and the rest of the City Walls have been in disrepair for a long time, and

Figure 1 Main preservation heritage objects in Liugou Village by Planning Team

they have suffered severe human-made and natural damage.

The building of Liugou Village is mainly composed of single-story and scattered two-story houses. Due to the long-term disorderly development, many buildings were spontaneously transformed into tofu banquet farmhouses by the villagers, resulting in a severely damaged traditional style (Figure 2). Therefore, the overall appearance of the streets and lanes formed by the building is worrying. Most of the dwelling façades are modified in a vulgar modern style. The walls are painted with white coating or grey cement, some air conditioners and pipelines are exposed, and the billboards are bright and rough (Figure 3). The infrastructure conditions of the village are also relatively backward, lacking basic management and maintenance, especially the insufficient carrying capacity of the drainage pipeline, no separation of rain and sewage, water accumulation will happen during heavy rainfall.

Figure 2 Architectural style evaluation by Planning Team

Throughout the current situation of Liugou Village, it has a specific tourism industry foundation with earthen Great Wall, Ancient Castle, Revolution Culture, Intangible Cultural Resources, Convenient Transportation, and Natural Resources. However, the lack of effective preservation of the wall heritage, the lack of reasonable strategies for cultural exploitation, the weak infrastructure, and the poor village environment have caused the village development hardly to move forward. Therefore, it is necessary to take advantage of the construction of the Great Wall Cultural Belt, the 2019 World Horticultural Exposition, and the 2022 Winter Olympic Games, change the development model of the individual catering and lodging economy, break through the bottleneck and gain new future.

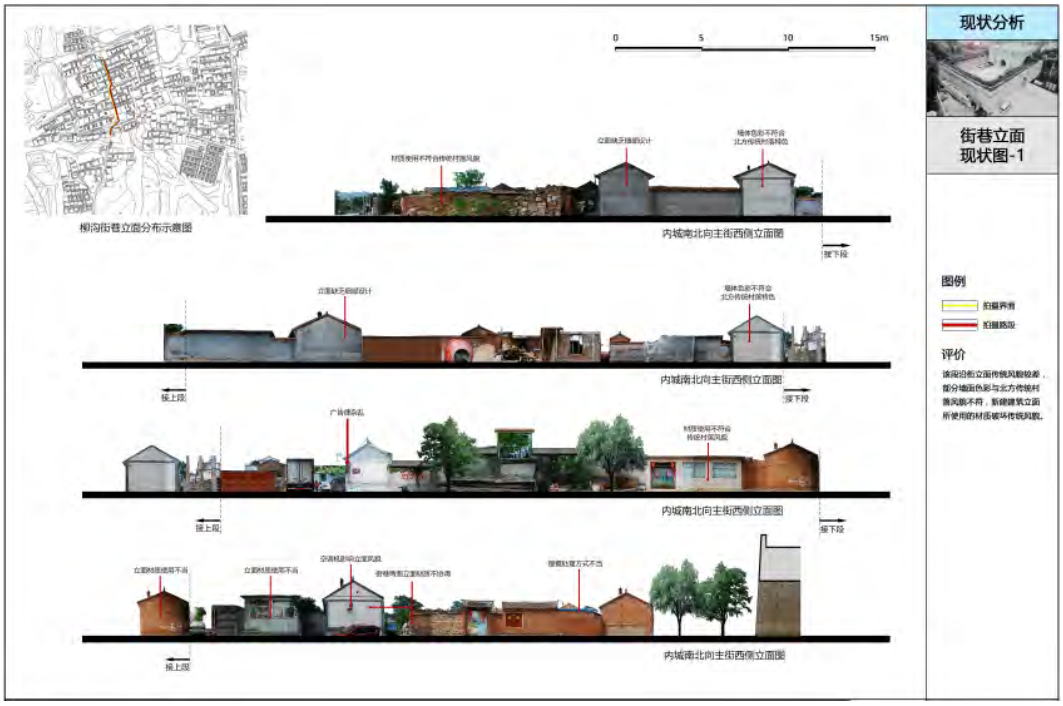

Figure 3 Lane facade status by Planning Team

4.2 Fine and Feasible Conservation Planning

The southwest of Liugou Village Castle connects with the earthen Great Wall; therefore, preserving the Great Wall is the most important principle. Delimiting conservation boundary and construction control zone should also include compliance with the following principles: preserving complete village traditional pattern, keep historical style continuous and cultural relics are authentic.

There is no detail delineated about conservation boundary of Liugou Ancient City in upper-level planning "Great Wall Preservation Scope and Construction Control Zone." This upper-level planning only indicated that 500 meters on both sides of the wall of the Great Wall are the scope of preservation, and 500-3000 meters is the level I construction control zone. Theses cannot solve the practical problems faced nowadays and difficult to guide the future development of the village. Therefore, conservation and development planning of Liugou Village combined upper-level planning regulation with the actual construction condition of the village, put forward specific construction control requirements for non-built areas and built-up areas. Non-built-up areas within the scope of preservation: only greening and fire-fighting passages shall be carried out, and no buildings or above-ground structure could be built. The built-up area within the scope of preservation (Ancient City and surrounding areas): The ancient city and surrounding built-up areas are reserved single-story buildings. The existing buildings in the zone should be maintained in the traditional style. And buildings are not allowed to be rebuilt or added without approval by planning. The ones that have a greater impact on the ancient city are recommended to be retired or demolished. (Figure 4). Peripheral control area: there is a certain distance from the ancient city. It is not allowed to build more than two floors buildings in this area. The height of the building's cornice is no more than 7.2 meters, and rest requirements are the same as the first two areas.

The conservation measures are carried out one by one around the object of preservation, the texture of the village, the characteristic space, the streets, and the buildings. Aiming at the different status quo of the heritage, the planning adopted several technical measures such as cleaning, repairing, and reinforcement, and dismantled all kinds of building or facilities which harm to the heritage. The preservation measures of village texture are divided into three types: control and conservation, carding and repairing, regenerating, and restoration. Control and conservation refer to the preservation of areas with better status quo. Carding and repairing refer to repairing the texture of the area where the current texture is poor. Regenerating and restoration refer to rebuilt to restore the texture were seriously damaged. Establish a three-level feature space system of points, lines, and surfaces. I am using the east-west and the north-south direction main street of the ancient city to form a linear characteristic space skeleton and connect characteristic space nodes such as a village entrance, Chenghuang Temple, green parks.

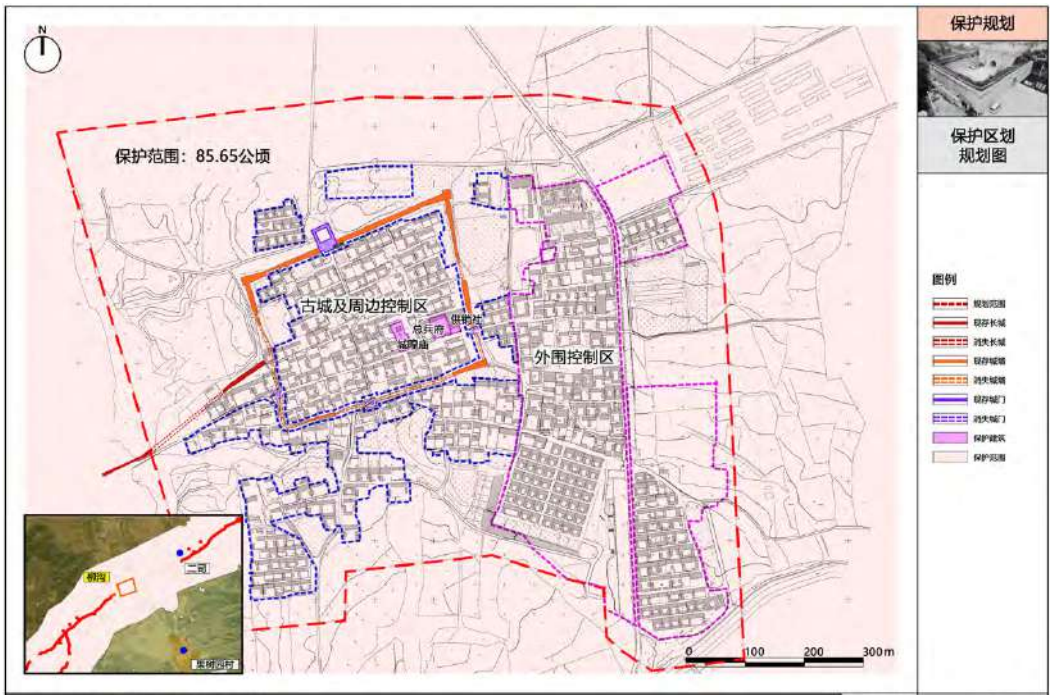

Figure 4 Preservation Zoning by Planning Team

The rectification of the streets and lanes is a key content that Liugou Village needs to focus on, mainly including the two dimensions (Paving and facade). The main street should be changed from cement hardened road surface to tile floor. The pavement should be changed to stone paving or smaller floor tiles in the secondary street and the housing front road. The modern style of doors and windows along the street can be modified according to the traditional style library provided by the planning, and the concrete wall and red brick wall can change into gray brick walls under suitable opportunities. It is necessary to uniformly manage billboards for street-facing shops, to make concealed air conditioners and pipelines outside the building, and to set up green areas along the wall in suitable conditions (Figure 5).

Due to the lack of style management and misunderstanding of the historical environment for years, many buildings to be decorated. It is necessary to control the color of the building in a

warm gray system and use the appropriate building materials recommended in the planning. For dozens of buildings that are within the scope of preservation and hurt heritage, it is recommended to gradually retreat to the demolition and resettlement residential areas that use the newly constructed construction land in the eastern part of the village.

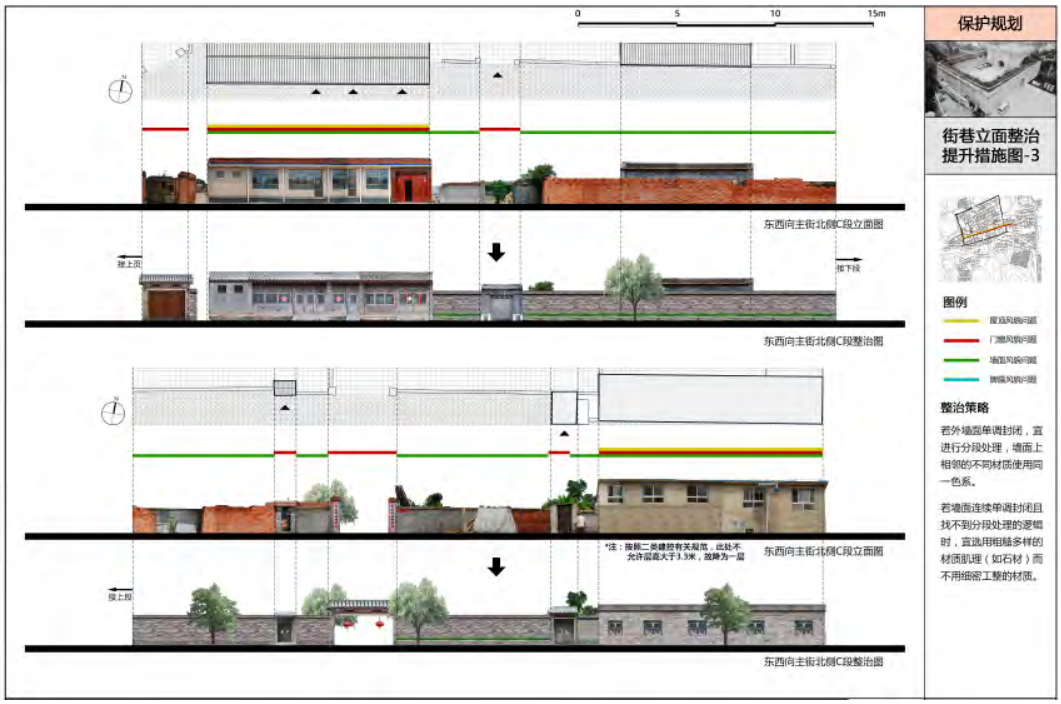

Figure 5 Renovation measures of street façade by Planning Team

4.3 Scientific and Sustainable Development Planning

Compared with other traditional villages with heritage preservation as the primary target, how to develop and upgrade through conservation strategy is the challenge of Liugou Village. Based on in-depth field research, the planning team careful study various related planning, communicate with locals for many times, and have found a clear development orientation for Liugou Village: 1) Vigorously exploring the precious historical and cultural resources of Ancient City, tightly integrate the construction of the Great Wall cultural belt, and create a model for the use of the culture of the city. 2) Using its own and surrounding natural resources, fully integrate and develop particular industries and individual activities to build a famous rural tourism destination in the suburbs of Beijing. 3) Preparing effectively support to the 2019 World Horticultural Exposition and the 2022 Winter Olympics affiliated tourism industry.

The development part of planning creates a general special develop structure of "One Castle, Two Wings, One Belt" which consisted of Liugou Ancient Castle, Jiulong Mountain Sports, and Leisure Park – Yanyu Mountain Forest Park, and Great Wall Cultural Belt (Figure 6). Formulating long-term land use strategies, especially refining the small categories in the Type V village construction land, balance the demolition and construction needs with new construction land supply and increasing the proportion of Type V12 mixed-use residential land to provide support for villagers' business operations.

I am using the cross-shaped main streets of the ancient city to create a skeleton commercial tourism axis and cultural experience axis and at the same time, arranging the tofu experience zone, the traditional Chinese medicine zone, the characteristic commercial zone, the residential zone, and the cultural experience zone throughout the whole village and utilizing excellent natural and historical resources to improve environmental quality and create landscapes and public spaces with local characteristics.

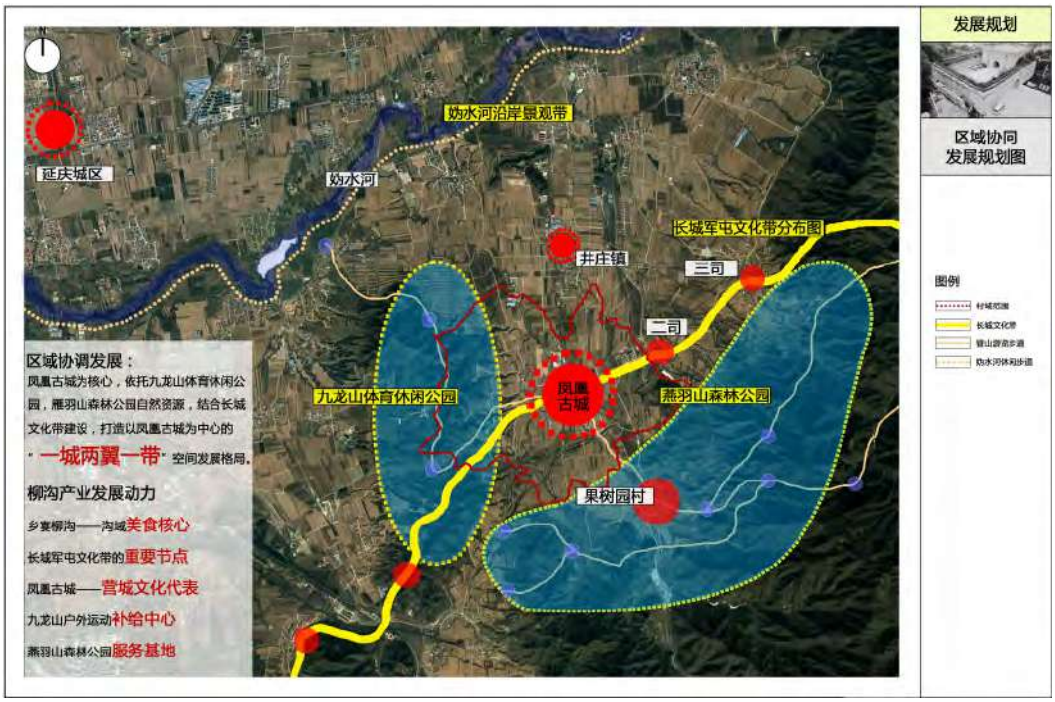

Figure 6 Regional coordinated development planning by Planning Team

The planning will vigorously strengthen the tourism-oriented tertiary industry and expand tourism, including the Great Wall City Tourism, Red Culture Tourism, Folklore Tourism, Agricultural Tourism, and Ecological Agricultural Products Experience. Building a new tour industry structure of Tour (ancient city), Eating (specialty food), Living (high-end B&B), and Purchasing (country specialties), guiding the development of the village from quantitative change to qualitative change. A variety of tourist routes are set up for different cultural landscape nodes, and a guided navigation system with clear levels guides the tourists. Based on conservation and restoration, planning will make rational use of the heritage such as the earthen Great Wall, the ancient city wall and the Chenghuang Temple, so that the value of the heritage can be fully demonstrated in the new era.

At the implementing level, the planning also fully designed the feature space for transformation and utilization, and drafted renovation promotion strategy for typical courtyards (Figure 7). These specific design schemes adopt the typology method, which provides a reference for the future regeneration practice of Liugou Village, such as architectural styles, proportions, materials, colors, and formats. Furthermore, the planning also develops different strategies to meets development needs in terms of safety and disaster prevention, water supply and drainage, power, and gas.

The planning period of the Liugou traditional village conservation and development planning is consistent with the new master plan of Beijing (2016-2035), which is divided into three stages: short term, medium term, and long term. In the coming five years, planning will mainly implement projects that are urgently needed for the development and strengthened the preservation of the ancient city walls. In the eight years of the medium term, planning will gradually improve the overall industrial layout of and tourist facilities of the whole village. In the long-term five years, planning will archive the layout of "One Castle and Two wings" to connect surrounding areas, form a tourism industry development economic belt centered on Liugou Village, and finally realize all the planning goals.

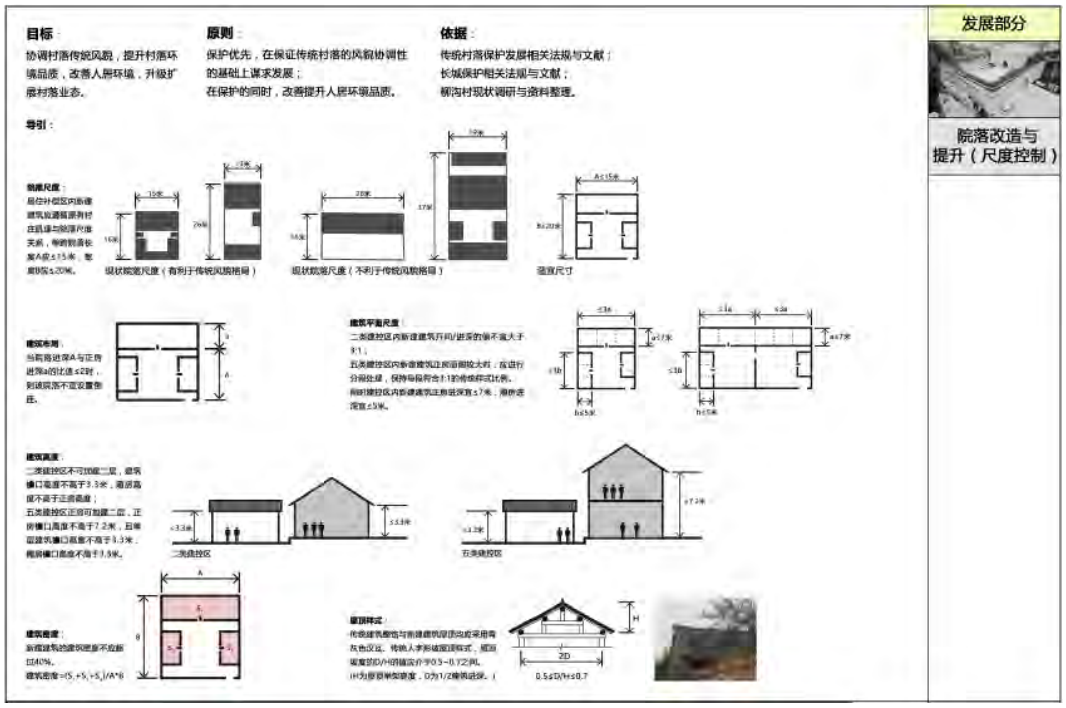

Figure 7 Guideline for courtyard promotion by Planning Team

5 Conclusion

The conservation and development of traditional villages rely on scientific planning to guide, and scientific planning needs constant exploring of new methods from more reasonable and effective perspectives. In the face of the accelerating urbanization process and the unsuccessful rural decay, the planning of traditional villages must adopt a "Multiple-planning" approach. Putting different levels, different goals, and various implementation subjects together through "One Blueprint." At the same time, planning needs to connect the implementing projects that putting the future vision nowadays practice on the same track. These will ensure that the conservation and development planning of traditional villages can play a crucial role in the revitalization of traditional cultural and local economic. As the main responsible person for planning, the government and planners should unify their thinking and act in unison. Continuous supervision of implementation, management of planning, and enthusiasm for public participation will provide diverse and reliable intellectual support for planning.

Research Paper

Two Thousand New, Million-Person Cities by 2050 – We Can Do It!

E. Stephen GOLDIE, RFD, BTP, MPIA, MCNU
City Planning Advisor, Abu Dhabi Department of Urban Planning & Municipalities, UAE

Abstract

In 1950 three quarters of a billion people lived in large towns and cities, or 30% of the total world population of over 2.5 billion. By 2009 this had grown to 3.42 billion, just over half of a total population of over 6.8 billion. The United Nations Secretariat currently forecasts that in 2050 6.4 billion, 67% of a total of almost 9.6 billion people will live in urban areas.

Just over a third of that growth, around one billion people, is expected to be in China, India and Nigeria, but the remaining two billion will be in the countries around those countries: a massive arc stretching across the world from West Africa through the Middle East, across Asia and into the Pacific.

In these other countries, an additional two billion urban residents over thirty years translates into a need to build a new city for a population of one million people, complete with hospitals, schools, workplaces, recreation and all the rest, at a rate of more than four a month: 2000 cities, in countries with little urban planning capability!

In addition, the United Nations' sustainable development goals (SDGs) include goal 11: Sustainable Cities & Communities "Make cities and human settlements inclusive, safe, resilient and sustainable", so these new cities should demonstrate a level of planning competence and city management ability that many towns and cities in the world are struggling to achieve.

Notwithstanding the scale of the problem, the size and cost of the planning effort is demonstrated to be feasible, provided that action is swift and new technologies are developed and applied to the planning and approvals processes.

Of course, taking these plans to construction is a much bigger effort, but the economy of cities is strongly circular, meaning that the initial cash injection generates jobs that pay wages that are spent on rent and goods within the city, which then generate profits that fund developments that generate jobs, etc. However, this requires good governance, a planning consideration that must also be addressed if the full benefits of planning, designing and building 2000 cities in the Third World are to be enjoyed by the citizens of those cities.

Finally, failure is not an option, because "If we don't solve this equation, it is not that people will stop coming to cities. They will come anyhow, but they will live in slums, favelas and informal settlements" (Arevena, 2014), and we know that slums the world over produce crime, refugees and revolution, and then export these problems internationally, one way or another. The world most certainly does not want more refugees or another Syria, so planners must rescue us from that future, before it happens!

Keywords

Rapid massive third-world, urbanisation, RAMTU, SDG 11, transect planning, artificial intelligence

1. Introduction

1.1. The "3S" menace

In Portland, Oregon, on 23 October 2017, the keynote speaker to the ISOCARP-UNESCO Special Event to discuss Sustainable Development Goal 11 - Make cities and human settlements inclusive, safe, resilient and sustainable (SDG 11 - Cities) was Ms. Hawa Deme, co-founder of Umuganda Africa. She highlighted that 95% of future urban expansion will occur in the Third World. The next speaker, Mr. Nicholas You, noted that in the next fifty years, humanity will spend more money on cities than we have cumulatively spent in all of human history, because the quantity of urbanism will double in capacity from 3 billion to 6 billion people (personal notes taken at the event).

The core of the problem is that there will be an additional urban population of 3 billion by 2050. Just over a third of that growth is expected to be in China, India and Nigeria, but the remaining two-thirds will be in the countries around those countries: a great arc of growth stretching from West Africa, through the Middle East, across Asia and into the Pacific. An additional 3 billion urban residents in thirty-three years translates into a need to build a new city for a population of one million people, complete with hospitals, schools, workplaces, recreation and all the rest, at a fantastic rate, and it has to happen in places with low capacity and poor infrastructure. In short, the problem is one of rapid, massive third-world urbanisation (RAMTU). The scale, speed and scarcity of resources required to address this problem are staggering and Chilean architect Alejandro Arevena rightly calls this the "3S Menace":

> *Let's start with the global challenge of urbanization. It's a fact that people are moving towards cities. and even if counterintuitive, it's good news. Evidence shows that people are better off in cities. But there's a problem that I would call the "3S" menace: The scale, speed, and scarcity of means with which we will have to respond to this phenomenon has no precedence in history. For you to have an idea, out of the three billion people living in cities today, one billion are under the line of poverty. By 2030, out of the five billion people that will be living in cities, two billion are going to be under the line of poverty. That means that we will have to build a one million-person city per week with 10,000 dollars per family during the next 15 years. A one million-person city per week with 10,000 dollars per family.* ***If we don't solve this equation, it is not that people will stop coming to cities. They will come anyhow, but they will live in slums, favelas and informal settlements****. [my emphasis] (Arevena, 2014)*

Hence, while diplomats and activists must keep us safe from nuclear war, and scientists and engineers must save us from global warming and species extinction, it falls to urban planners to keep the peace through the provision of healthy and harmonious cities for three billion people by 2050, and - as the Emperor Napoleon reportedly said - "We don't have a moment to lose!"

1.2. Two Thousand New, Million-Person Cities by 2050

When the priority is speed the need for effective planning is even greater than usual, because both the planning process and the plan itself must be first class. So, our first task is a plan for

a program to plan and build new urbanism equivalent to two thousand new, million-person cities by 2050, in countries with little to no capability for this task.

I have written and/or presented on aspects of this problem and of possible solutions before, but have never previously attempted to prescribe a holistic solution. The earlier papers and presentations are here referenced as:

A. **"The Impending Revolution in Urban Planning Practice: Intelligent and automated, but will it be garbage in, garbage out?"** (51st ISOCARP Netherlands, 19-23 October 2015)
B. **"What's So Special About Special Districts?"** (CNU 24, Detroit MI USA, 8-11 June 2016)
C. **"Sustainability and the Revolution in Urban Planning"** (52nd ISOCARP Congress, Durban, South Africa, 12-16 September 2016)
D. **"Smart Planning for Smart Cities"** (PIA National Congress, Sydney, NSW, Australia, 3-5 May 2017).
E. **"The Jobless City – Revolution or Paradise?"** (53rd ISOCARP Joint Congress, Portland, OR, USA, 24-27 October 2017).
F. **"The Periodic Table of Urbanism**" (presented at CNU 26, Savannah, USA, 15-19 May 2018 and at ISOCARP, Bodo, Norway, 1-5 October 2018).

These papers and presentations have all been deliberately leading to this point (although not without some serendipity): the feasibility of solving rapid, massive third-world urbanisation (RAMTU). Therefore, this paper relies heavily on parts of these preceding works, but they will only be further referenced where specifically referred to, in order to better emphasise the references to other author's work than my own.

This paper also assumes that the reader is familiar with the principles and practices of the New Urbanism.

1.3. The New Urbanism

The true impact of the post-Second World War, Brutalist deflowering of cities everywhere took some time to become apparent, but by the early 1960's writers such as Jane Jacobs (Jacobs, 1961), Herbert Gans (Gans, 1968) and Robert Goodman (Goodman, 1972) were exposing the symptoms. In some cases, they also provided insights into the causes and solutions, but it took another thirty years before the more advanced planners, architects and designers banded together and responded to auto-dominated urban sprawl with practical solutions. In the United States this took the name "The New Urbanism".

The New Urbanism has more than a passing similarity to City Beautiful: "Like New Urbanism, the 19th century [City Beautiful] movement redeemed city planning principles whose influence had waned, and recognized that the design of physical space is important to the identity and cohesiveness of a community." (Stueteville, 2004). In the United Kingdom it does not have a clear name, and is perhaps more a loose alliance of the Prince's Foundation for Building Community, English Partnerships, the now superseded Commission for Architecture and the Built Environment (CABE) and the still active Town and Country Planning Association (TCPA), founded in 1899 by Sir Ebenezer Howard himself. New Urbanist practice is also strong in parts of Australia and New Zealand (personal observation).

The New Urbanism, and its overseas cousins, have led a gradual roll back of decades of auto-dependent sprawl while simultaneously (and necessarily) developing a practice that has progressed rapidly from rediscovering the techniques behind the delightful works of past urbanist planners, architects and designers, such as Camillo Sitte, Raymond Unwin and John Nolan, to a body of knowledge and skills that is now well able to plan, design and build sustainable towns and cities: but is it ready for the Digital Revolution?

The description of a whole philosophy of planning is a task requiring many books, not just part of one paper, so I will leave the interested reader to inspect the 1993 Charter of the New Urbanism (Talen, 2013) and then read one of any number of books about the movement. A good place to start is the insightful and witty *The Geography of Nowhere: The Rise and Decline of America's Man-Made Landscape* (Kunstler, 1993), perhaps followed by the *The New Urbanism – Towards an Architecture of Community* (Katz, 1994), which provides an excellent, concise, technical introduction and a comprehensive collection of early examples.

2. Revolution in Urban Planning

2.1. An Additional Three Billion People

Urban planners and designers are faced with the task of housing an additional three billion people in towns and cities by the year 2050 (figure 1). It will be shown later that, not including China, India and Nigeria, this requires the equivalent of 2000 new, one-million person cities to be completed by 2050; the equivalent of building more than six one million-person cities every month for forty years. If climate change displaces another 200 million people, the task will be that much greater (Brown, 2008).

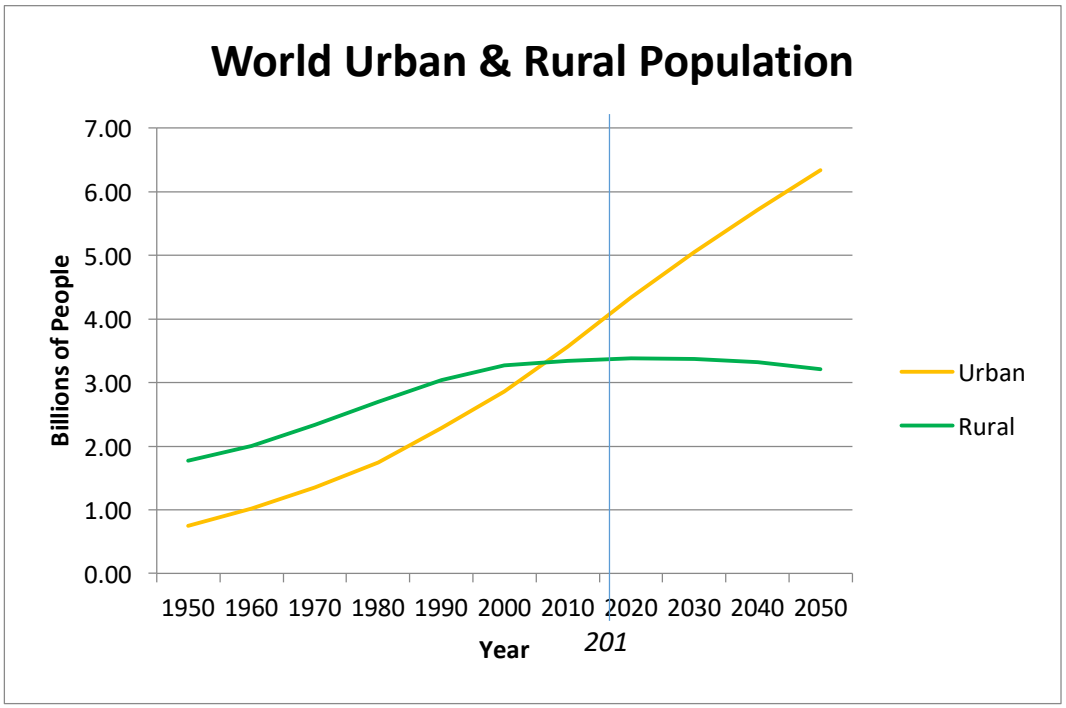

Figure 1: World Urban and Rural Population 1950 to 2015 (United Nations, 2014)

Compounding this problem, but also demonstrating that it might be part of the solution, the developing economies are generating large scale employment in their urban areas, some 900 million jobs in the thirty years from 1980 to 2010 (figure 2), but most of these jobs require the level of education that only a well-designed and managed large town or a city can provide.

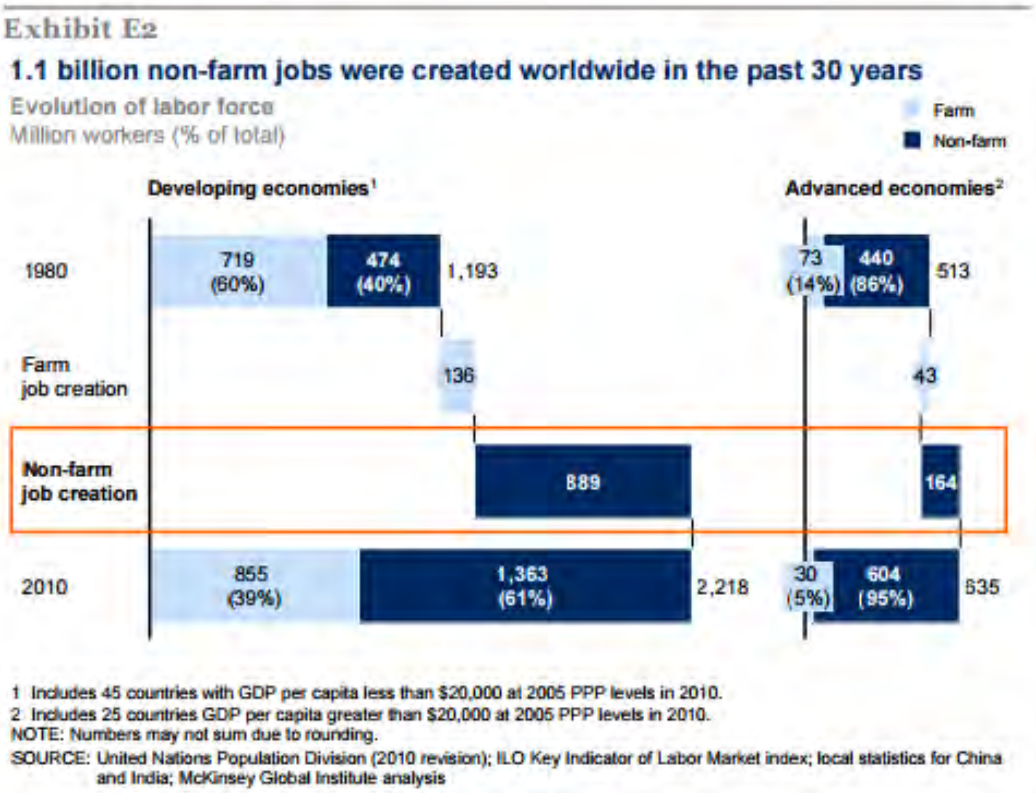

Figure 2: The growth of urban jobs from 1980 to 2010 (Dobbs *et al*, 2012)

China, since the 1980's, and India more recently have recognised this issue and responded with massive city building or urban improvement programs (World Bank, 2014, p. 3; Vikram, 2014), but only one-third of the additional three billion new urban dwellers are expected to be in China, India and Nigeria, the remaining two-thirds will be in the countries around those countries: a great arc of growth stretching from West Africa, through the Middle East, across Asia and into the Pacific.

Clearly, if massive new urban areas are required very quickly, then a plan that previously took the best part of a decade to prepare will now need to be completed in a tenth of that time. The planning process must therefore move from "slow and ponderous" to "fast and reliable", and must be conducted by efficient, well-managed planning agencies and at least equally competent consultants. This requires not only the adoption of all that the new technologies have to offer, but also the development of a plan-making paradigm that optimises the application of that technology in a way that produces good urbanism. In short, a planning paradigm that avoids the possibility of "garbage in, garbage out".

Over the last quarter century, the most significant advances in the understanding of urban areas, the practice of producing good urban planning and sustainable built outcomes, has

come from the practitioners and academics who constitute the movement known as the New Urbanism. Three of these advances, the charrette, form-based codes and transect planning are particularly relevant. Many planners are already familiar with the two-fold improvement in efficiency that a good charrette process provides. Firstly, by shortening the plan making process through simultaneously interactive and iterative plan preparation and secondly by increasing the level of support for the plan across all stakeholders and concerned citizens, thereby shortening the approval process.

However, it is the combination of transect-based planning and form based codes that, in my opinion, gives the opportunity to develop the New Urbanism further towards a systemisation that simultaneously enables localisation, which is, perhaps, the core conundrum of urban planning across the ages. Success will enable automation of the approvals process with the possibility of greater than eighty percent of applications being approved, almost instantaneously, on-line. The development of current transect-based planning practice toward this end is discussed in detail later in this paper.

If it is feasible to shorten the plan making process and the development approvals process then perhaps we can, collectively as a profession, enable from now to the year 2050 an additional three billion people to live, learn, work and play in good, new cities and towns. Perhaps some of these cities will even stand the test of time and become the great cities of the Twenty-first Century!

Of course, "stand the test of time" is on old form of words, the modern equivalent is "to be sustainable". I will briefly address the strengths and failings of "sustainability' later, first it is important to consider the alternate case, unsustainability, particularly, in its worst case scenarios.

2.2. The Limits to Growth

Whether history will refer to our current era as the 4th Industrial Revolution, the Digital Revolution, the Information Age or something else is not the concern of urban planners. What is important is that there will continue to be a civilisation with historians and philosophers who have the time and the inclination to argue about such things, because the alternatives are most likely:

- Mutually assured destruction by nuclear weapons (Caldicott, 2017);
- Mismanagement of the environment, leading to a sixth great extinction that will eventually include homo sapiens sapiens (Kolbert, 2014; Ceballos, Erlich and Dirzo, 2017, p. 7); and/or
- Mass migration, revolution and war through inadequate responses to rapid, massive 3rd World urbanisation.

Collectively, we can refer to these as the “Limits to Growth” which have long been forecast to reach criticality in the middle of this century (Meadows *et al*, 1972), and which, if not overcome will lead to either no human civilization, no humans, or no planet at all. We are all, right now, part of an experiment in survival that is clearly not one that any sane person would want to see played out on their own species and on their own planet.

While the first two of humanity’s limits to growth are well understood, the third, rapid, massive third-world urbanisation (RAMTU), as outlined above, is probably only common knowledge amongst urban planners, and some staff of the United Nations and related agencies.

It is a sorry testimony to the accuracy of the analysis conducted by Donella H. Meadows, Dennis L. Meadows, Jørgen Randers, and William W. Behrens III in *Limits to Growth* (Meadows *et al*, 1972), that 2050, when two-thirds of the people on this planet will live in towns and cities, is our collective date with destiny: the year of the demise of our civilisation that they warned us of almost half a century ago.

There are therefore now only two key questions for our profession:

1. Is it feasible to plan and construct the equivalent to two thousand new, million-person, sustainable cities, in countries with little to no capability for this task, by 2050; and, if the answer is yes,
2. Will we try?

In this paper I will answer the first question in the affirmative, but the second question requires a collective will that I have not previously seen demonstrated by our profession. Clearly, this is our last chance to discover it in ourselves.

3. Sustainability and the Revolution in Urban Planning

3.1. The Triple Bottom Line

Sustainability is usually illustrated by the three-circle 'Triple Bottom Line Model' Venn diagram, representing the three dimensions of sustainability (figure 3). It is a simple, but powerful model that has changed the paradigm and inspired people the world over to strive to create a more sustainable society.

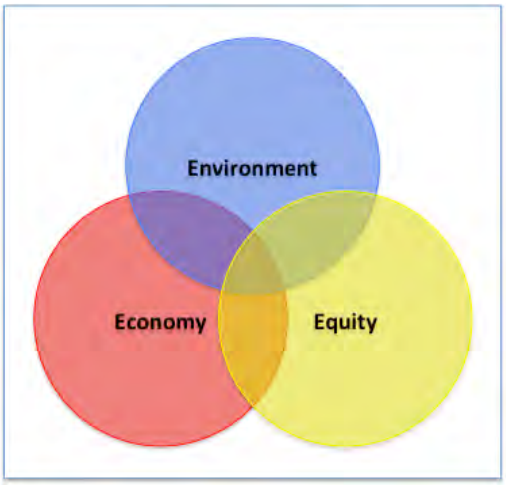

Figure 3: The Sustainability Diagram (Carter and Moir, 2012, p3; Wheeler, 2013).

While the concept of sustainability is vital if humanity is to survive past the middle of this century (Wheeler, 2013, p71) and its diagrammatic representation as three overlapping circles (a.k.a. the Sustainability Model) has been useful in promoting an understanding of what is required, the fact remains that of itself the diagram provides no immediate guidance decision making. In every case the decision maker, or his/er advisers, must analyse the detailed impacts of not only the proposal, but every facet of the proposal.

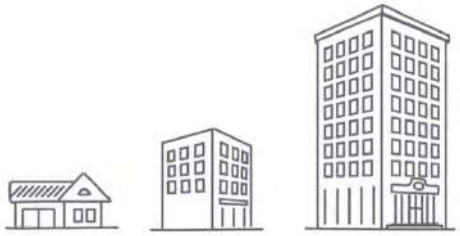

Figure 4: House, Apartment, or high-rise? ©Agatus: Image ID: 343732052

For example, how does the Sustainability Model guide a choice between the options shown in figure 4? The answer, of course is that of itself, it cannot. To make even a simple decision like this recourse must be had to a long list of interrelated factors requiring extensive study and consideration.

However, by mapping sustainability, not as a Venn diagram of concepts, but as real things (figure 5) and then expressing the relationships between these things in an interaction model (figure 6) the inherent tension between the natural and built environments is revealed: **the built environment exploits the natural environment in order to maintain the economy and improve equity for "the people".**

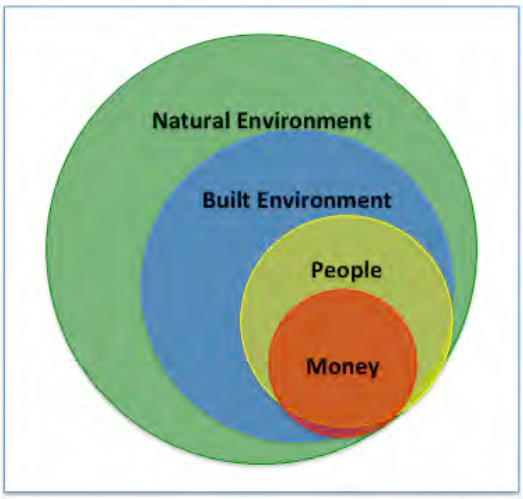

Figure 5: The four factors of sustainability as physical things.

This creates a 'tug of war' between two opposing 'goods' (i.e. it is good to protect the natural environment and it is good to provide for people by way of an economic and equitable built environment), but the difficulty of finding the sustainable middle ground has led to the development of two opposing camps, respectively pro and anti-development. Short term 'wins' for one side over the other encourages the feud to continue, resulting in long-term losses for society as a whole. We need to resolve this conflict, so that we can work together to resolve the existential crisis specified above.

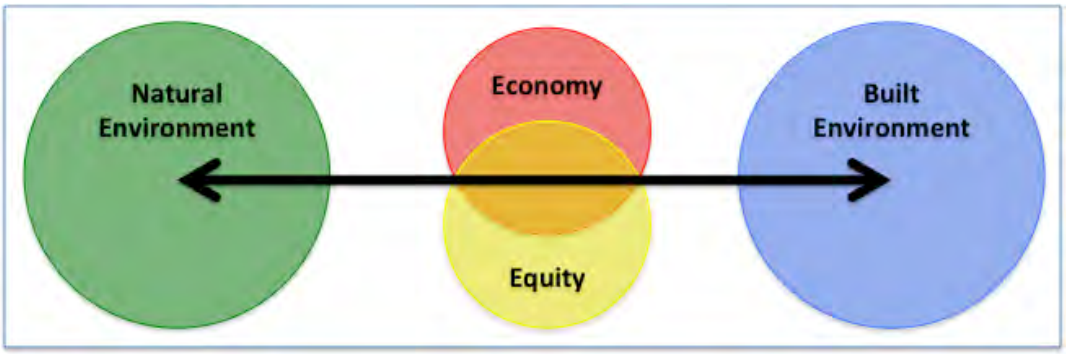

Figure 6: The four factors of sustainability in tension.

Figure 7: The natural and built environmental factors as a transect

The first step is to observe that figure 6 can also be mapped as a cartoon of a transect through an urban region, from watershed to waters' edge (figure 7), demonstrating that an understanding of the urban transect is fundamental to understanding urban sustainability.

3.2. Transect Planning

Many statutory planning systems use land use as their primary organising principle and then control built form by regulations specific to particular land uses. From the town of Seaside (1981, by Andre Duany and Elizabeth Plater-Zyberk of DPZ, Miami, USA for Robert Davis) onwards the New Urbanists have instead regulated built form first and then controlled land use, as necessary, by specific regulations (Katz, 1994).

The form-based code was further developed by adapting to it transect analysis from environmental science (Centre for Applied Transect Studies, 2016). This has resulted in a very useful body of knowledge and related planning and design techniques, including many images that are available on-line, such as figure 8 below, from the latest version of *The SmartCode – Version 9 and Manual* (Duany, Sorlein and Wright, 2008), which comprehensively details the use of transect-based plans and aligns them to the United States statutory planning system.

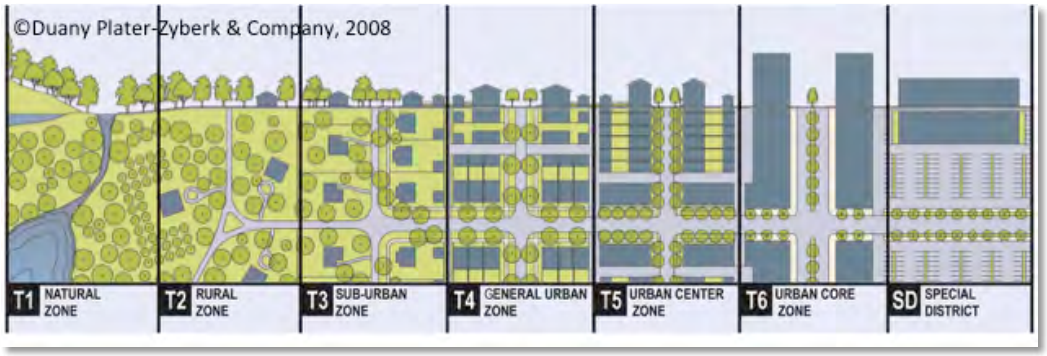

Figure 8: The current standard diagrammatic representation of the prototypical rural-to-urban transect.

It is also important to appreciate that the urban ecological zones designated as T1 to T6 are usually grouped into community units before areas are designed in detail (figure 9). Essentially, the urban structure is formed from these units and their supporting infrastructure.

The standard community units are usually:

- *Clustered Land Development* (CLD), e.g. a hamlet, typically contains T2, T3 & T4;
- *Traditional Neighbourhood Development* (TND), e.g. a village or a neighborhood, typically contains T3, T4 & T5;
- *Transit Oriented Development* (TOD) e.g. a neighborhood or district centre with good transit, it also typically contains T3, T4 & T5; and
- *Regional Centre Development* (RCD), e.g. a regional centre or the central buisiness district (CBD), which typically contains T4, T5 & T6 with good transit.

Notably, a Special District is neither an urban ecological zone, nor a community unit. It is a catch-all category for everything else: "Some types of uses are justified in not fitting neatly into a transect ecozone and therefore must be treated separately. First, it is necessary to include a category (or “district”) for land uses that are either exceedingly large, noxious, or for some other good reason do not fit automatically into an ecozone." (Duany and Talen, 2002, p.256). (Note that in this paper 'urban ecological zone' is preferred to 'ecozone'.)

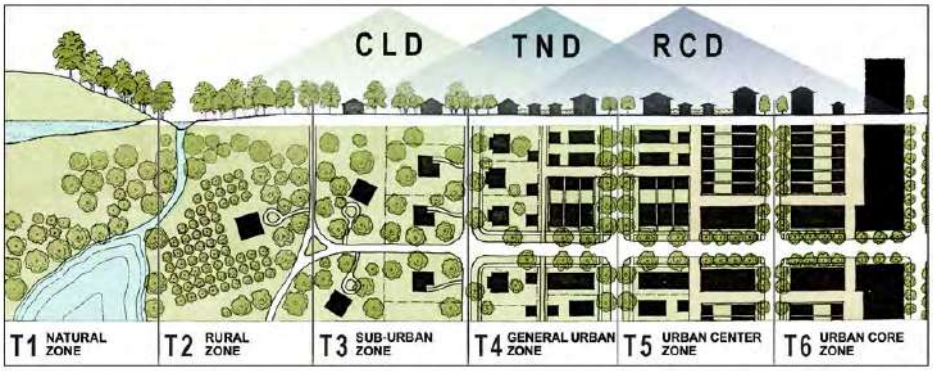

Figure 9: A variation on the transect diagram emphasising the prototypical relationship between transect elements and the community units: CLD, TND and RCD. (Sorlien, 2011)

This simple analysis clearly demonstrates that in urban planning the sustainability factors resolve into the application of a rural-to-urban transect that is already well understood, at least by leading practitioners and some academics. But is that all there is? Can every city plan be reduced to T1 to T6 plus the catch-all "Special Districts"? Clearly, as prototypical elements, T1 to T6 are almost unchallengeable, but perhaps Special Districts requires further examination.

4. What's So Special About Special Districts?

4.1. Boundary Conditions

Surveys of existing conditions and similar planning studies rarely pay attention to the boundary conditions of large areas devoted to a single purpose, but it is key to how such areas relate to the rest of the urban fabric.

Figure 10: A fortified boundary, approx. 250 x 150 metres or 820' x 490', protects the Acropolis

The Acropolis, rising majestically above the central area of Athens, Greece (figure 10) is possibly the archetype of all special districts. It is about the size of three city blocks, so it is not

as large an element as it seems. Clearly, the defining feature is its fortified boundary, a wall designed to add to the natural defensive qualities of the hill on which it sits, while also increasing the area within which people could shelter in time of attack. Over the centuries, defenders of the Acropolis have never been defeated by direct assault, only by encirclement and the threat of starvation.

Figure 11: A secured boundary surrounds Buckingham Palace, part of an irregularly shaped complex approx. 520 x 610 metres or 1,700' x 2,000'

Buckingham Palace in London (figure 11) occupies a much larger area. The site is irregular in shape, but perhaps it could contain around fifteen city blocks. Unlike the Acropolis it has a secured boundary, one designed to be guarded, but not to withstand a heavily armed assault.

Figure 12: A fenced boundary (or in this case, a hedge) demarcating the front garden of this ΣΑΕ Fraternity House's 420' x 200' plot (approximately 130 x 60 metres)

In contrast to the two preceding examples, a fenced boundary is very common. The term 'fence' is used here to indicate a demarcated boundary, as in the magnificent hedge around the ΣAE Fraternity House in figure 12. 'Fenced' also includes ha-has and the wide expanses of 'free-fire zone' lawn and shrubbery used to discourage unregulated pedestrian access to campus style developments, such as a business park. In this context then a "fence" is any form of physical demarcation that is more than a line on a map but less than the sort of fence or wall intended to deter a purposeful intruder.

To complete the set, we need only to add the case where the only demarcation of a boundary is by a few surveyor's pegs or marks. This gives us the simple, but very useful symbols proposed at figure 13, in which the symbols for surveyed and fenced boundaries are standard drawing practice and the symbols for secured and fortified boundaries are standard NATO map-marking practice (respectively a barbed wire fence and a trench line). Finally, when a fenced, secured or fortified boundary encloses an area greater than four hectares (ten acres) drawing these symbols in red will highlight them as potential special districts.

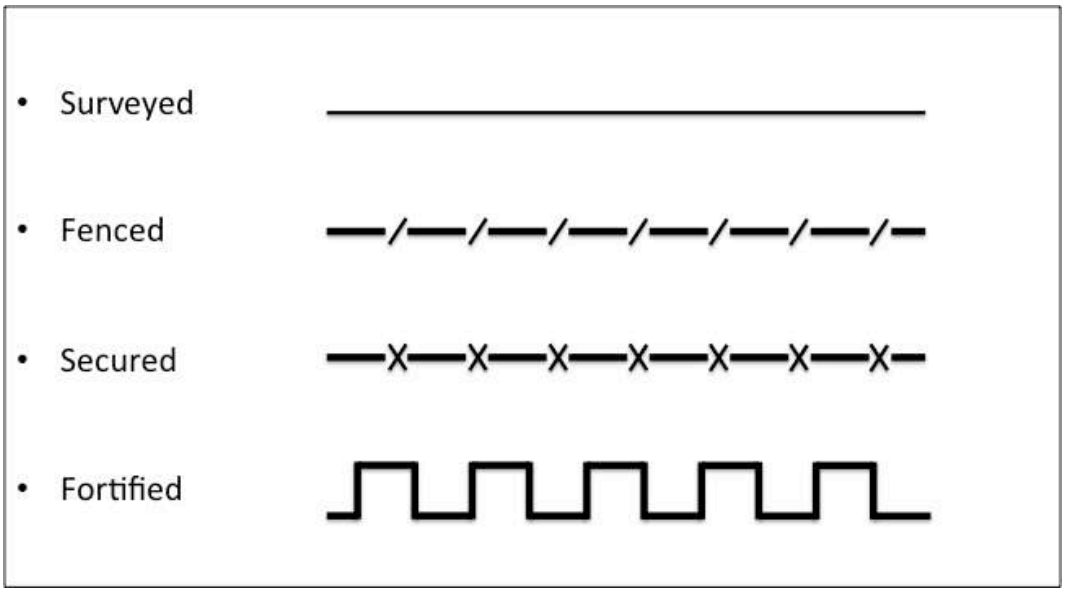

Figure 13: Graphics for boundary conditions

The key point is that physically defined (i.e. fenced, secured or fortified) boundaries constrain movement. The areas outside and inside might be walkable, but the community is prevented or discouraged from walking from one to the other. When these areas are smaller in size than a large city block (say 200 metres or 660 feet square) there is usually little impact on walkability, but when they cover even slightly larger areas than this they have a major impact on the urban fabric. Obviously, the impact is situational, but generally the larger the area enclosed, the greater the impact. This factor allows us to distinguish true special districts from the missing urban-ecological zones and to complete our understanding of the elements of urbanism.

4.2. The Periodic Table of Urbanism

If the prototypical urban transect from watershed to the city centre is expanded to the water's edge, and if, within that transect any special districts, such as a jail, university, boarding school, etc. can be properly identified by a distinct boundary condition, then it is possible to arrange into one 'urban periodic table' (figure 14) the standard rural-to-urban transect extending from watershed to water's edge. This extended transect can now include all of the productive, transport and other uses in the city, the temporary and aberrant types of development, and an expanded range of community units, including special districts as now defined in the section following.

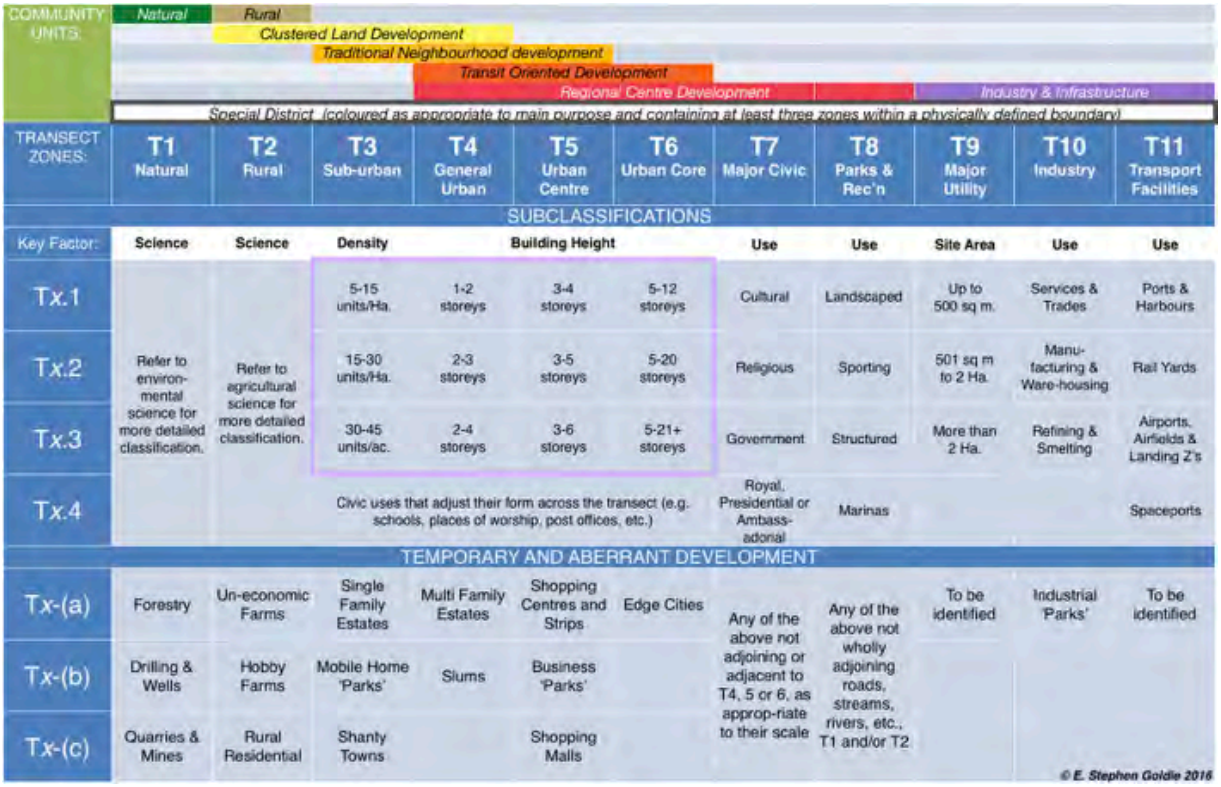

Figure 14: The Periodic Table of Urbanism

Note that within figure 14, in the left hand column, 'x' represents the relevant T-zone in the row headed 'Transect Zone', e.g. T1.1 and so on. Note also that the numerical values given for some transect zones are tentative and require ground-truthing through case studies.

The Periodic Table of the Elements is deliberately arranged to demonstrate the periodicity and grouping of the atoms. Similarly, the columns in the Periodic Table of Urbanism are all grouped by function, while the core box of twelve transect zones (outlined in lilac) demonstrate the urban equivalent of periodicity. These three rows across four columns (T3.1 to T6.3) are typical local transects identifying four distinct, but co-dependent arrangements of built form. For example, suburbs at 5 to 15 units per hectare (2 to 6 units per acre) are only going to support general urban development one to two storeys in height and so on.

Studies and research to identify the mathematical relationships between each transect element, stable and unstable, are currently underway and should form the subject of a future paper.

The simultaneous complexity and simplicity of the Periodic Table of Urbanism hint at a greater order of things, too big to be considered here, but perhaps:

> *This is pretty remarkable evidence that there is a mysterious unity about the patterns found throughout the whole of creation. From the smallest of molecules to the biggest of planetary 'particles;' revolving around the sun, everything depends for its stability upon an incredible simple, very elegant geometric patterning - the grammar of Harmony.* (HRH The Prince of Wales, Juniper and Skelly, 2010, p. 118)

Whether towns of thousands of people and cities of millions are more or less complex than the 118 chemical elements so far discovered is debatable, but as Professor Dmitri Mendeleev is quoted as saying:

> *It is the function of science to discover the existence of a general reign of order in nature and to find the causes governing this order. And this refers in equal measure to the relations of man - social and political - and to the entire universe as a whole.* (Posin, 1948, p. 167)

Just as the Periodic Table of Chemistry identifies the physical components of our universe and is able to predict the relationships between them, the Periodic Table of Urbanism provides a comprehensive framework for describing the "general reign of order" in our towns and cities. It also enables the development of an algorithmic framework for both understanding existing urbanism and for plan making, as a necessary step towards the positive application of artificial intelligence to urban planning.

4.3. Special Districts as a Community Unit

As explained at section 3.2. Transect Planning, the transect zones are usually grouped into community units and the urban structure is formed from these units and their supporting infrastructure. The preceding discussion has now made it clear that the term 'special district' is not required to describe or classify the elements of urban sprawl, nor is it required to provide for the missing transect zones that have been tentatively catalogued above; however, there is a need for a term to describe special groupings of transect elements in circumstances that meet the following proposed definition (see figures 10 to 13 regarding fenced, secured and fortified boundaries). Therefore, I propose that:

> **A Special District is a special purpose community unit containing at least three urban-ecological zones within a physically defined boundary.**

Typical examples include airports, boarding schools, citadels (a heritage feature in many European cities), colleges, convents, hospitals, military bases, monasteries and universities, and would be labelled 'special district—airport', 'special district—boarding school', etc. Along with a defined boundary, these urban elements will also have an internal transect structure, as the examples at figure 15 notionally demonstrate. They are almost cities within cities.

Special District - Jail/Gaol	Special District - Barracks/Fort
Secured boundary (–x–x–)	*Secured boundary (–x–x–)*
T5 Administration, classrooms and theatres	T3 Married quarters
T5 Cell blocks	T4 Town centre
T8 Sports fields	T5 Bachelor quarters & barracks
T10 Workshops & stores	T5 Administration, classrooms and theatres
	T10 Workshops & stores
	T8 Sports fields & firing ranges
	T1 Close training area
Special District - University Campus	**Special District - Hospital Complex**
Fenced boundary (–/–/–)*	*Fenced* boundary (–/–/–)*
T5 Dormitories	T4 Specialist treatment & support facilities
T5 Theatres, lecture halls & seminar rooms	T6 Wards, theatres and administration
T6 Administration & libraries	T8 Gardens
T8 Gardens & sports fields	T10 Workshops & stores
T10 Laboratories, workshops & stores	T9 Incinerator

* 'fenced' means anything intended to demarcate private land, but to a lesser degree than 'secured' or 'fortified'.

Figure 15: Likely transect zones across some typical special districts

Returning to the three examples of boundary conditions given above, the Acropolis (figure 10) can now be classified, in accordance with the Periodic Table of Urbanism at figure 14, as a Special District—Heritage with a fortified boundary and mostly containing the transect zone T7.1 Cultural; Buckingham Palace (figure 11) as Special District—Palace with a secured boundary and dominated by the transect zone T7.4 Royal; while the ΣAE Fraternity House (figure 12) is not a special district, just a very nice element within a T4 urban ecological zone.

So, the answer to the question posed earlier "can every city plan be reduced to T1 to T6 plus Special Districts?" is no, but every city plan can be reduced to T1 to T11, with up to seven sub-classifications, a grid of up to seventy-seven urban ecological zones. As proposed at figure 14 above, the grid currently contains fifty-four defined urban ecological zones, but no doubt some of the blanks will be filled in after practical experience of its application.

It should be clear to all planners and urban geographers that a rural-to-urban transect comprised of the urban ecological zones proposed in the Periodic Table of Urbanism can be mapped across all urban areas. Transect based plans are a subset of form based codes and:

> *As of June 2019, we've tracked 728 codes* [in the United States and Canada] *that meet criteria established by the Form-Based Codes Institute (FBCI), as well as an additional 17 form-based guidelines. 439 of these are adopted, with others in progress. Even though form-based codes are 38 years old, 91% have been adopted since 2001* (Borys, Talen and Lambert, 2019).

So, transect planning has utility as a planning tool, but can it be used in conjunction with some form of artificial intelligence to predictably guide the preparation of plans in at least a partially automated process?

5. Smart Planning for Smart Cities

5.1. Artificial Intelligence Supported Planning

Professor Michael Batty is the Bartlett Professor of Planning at University College London where he is Chair of the Centre for Advanced Spatial Analysis and is a leading researcher in this field. Over two decades ago he wrote that:

> *Computer models of cities either attempt to simulate existing urban form or provide procedures for the design of optimal forms, but rarely both. The mechanisms used to model actual cities usually embody local behavioural descriptions without explicit optimizing,' whereas those that produce idealized forms seek to optimize in a more global fashion, often mirroring the viewpoint of the designer.* (Batty, 1997)

More recently he published *The New Science of Cities* (Batty, 2013) in which he demonstrates a mathematical system where all actors (community, planner and politician) are replaced by algorithms. However, as in all situations involving the application of untested new technologies, it is appropriate to try many different approaches. Sometimes one or the other becomes the preferred standard, but more often than not each new approach encourages improvements in the others, leading to a convergence towards efficiency and effectiveness.

With this in mind, the approach that I propose aims to simultaneously "simulate existing urban form [and] provide procedures for the design of optimal forms", by mapping at the regional scale the following factors:

- Topography (shown by the thick white line in figure 16);
- Travel time to centre (shown as "ta" for travel time by automobile, "tb" for bus and "tt" for train in figure 16);
- Locational rent, in accordance with the work of Johann Heinrich von Thünen (1783–1850) who developed locational rent as a mathematically rigorous theory of marginal productivity (shown as "vr" for value of retail rents, "vm" for manufacturing rents and "vh" for housing rents in figure 16), (Wikipedia, 216a); and

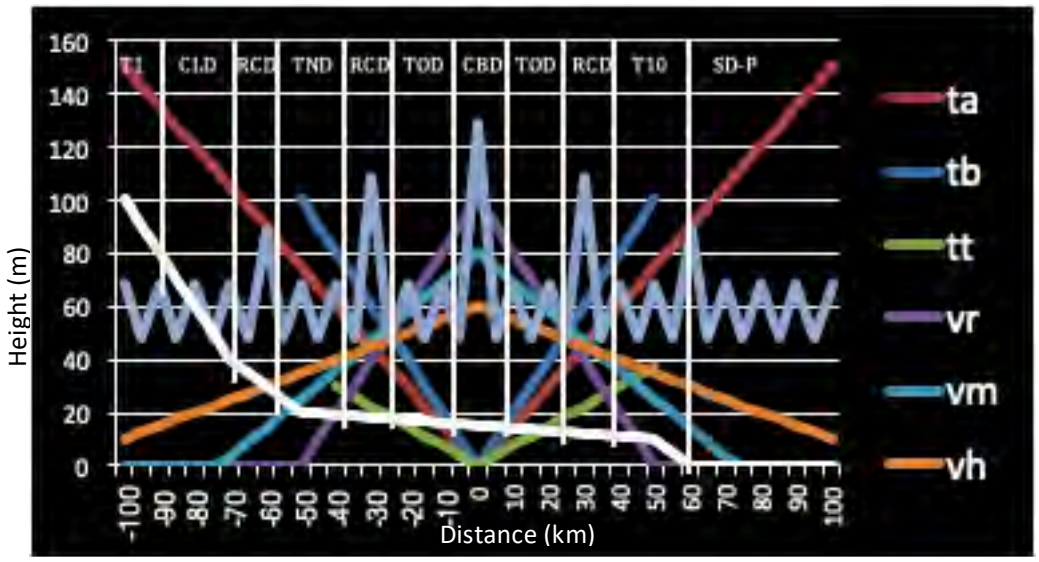

Figure 16: Analysis of urban structure by multiple factors along a theoretical transect.

- Total retail and commercial floor space, in accordance with Central Place Theory as proposed and utilised by the German geographer Walter Christaller (1893–1969), (shown as the light blue line in figure 16), (Wikipedia, 216b).

When these factors are combined into one graph (fig. 16) the results look slightly confusing (even in this fictional example) but when the transect-based planning community units are applied the urban structure is immediately clear: from left to right T1 (i.e. natural), then CLD (e.g. a hamlet), RCD (e.g. a small town on the edge of the urban area), TND (e.g. traditional fine-grained, mixed-use, walkable neighbourhoods), TOD (transit oriented development), CBD (central business district) and so on through to SD-P (e.g. a special district containing a port) on the coast.

Inclusion of additional operational theories of planning, such as the Chicago School models and Reticular Matrix (Ortiz, 2014) improves the reliability of the analysis, but for the purposes of this paper figure 16 is sufficient.

By repeating this exercise with parallel transects across the area to be planned, suitably designed prediction machines (Agrawal, Gans and Goldfarb, 2018) will produce an outline structure plan, as notionally illustrated at figure 17.

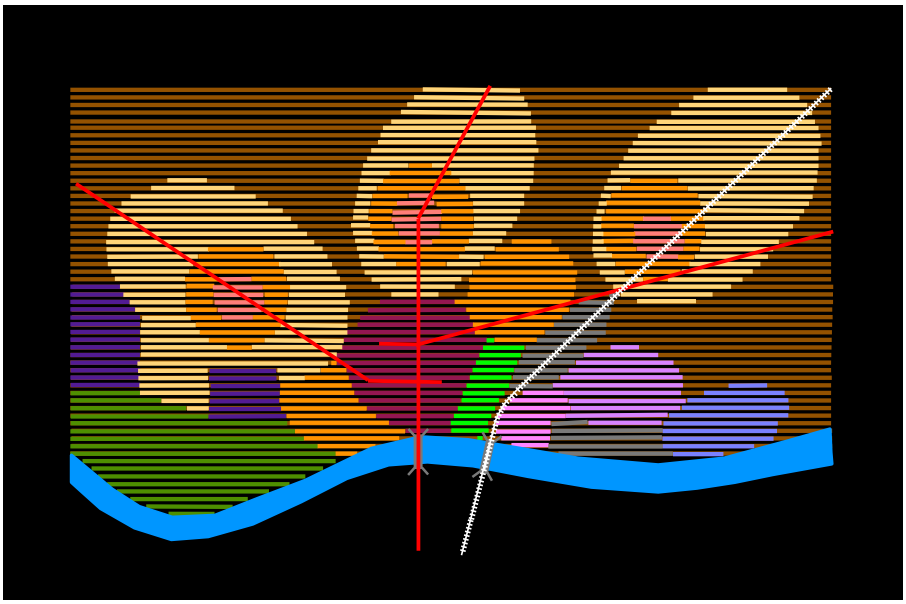

Figure 17: Illustration of how a first draft of a structure plan map might look when developed by an artificial intelligence analysing optimum urban structure along multiple parallel transects.

Applying this analysis to any urban area where the natural areas that are to be retained have been identified, and a transect-based synoptic survey and localising process has been completed, should very quickly produce a 'first-draft' urban structure plan. Refining this plan, checking infrastructure and traffic demand, etc. should follow expeditiously, because it is usually the process of preparing and testing the 'first-draft' many times that is the most time-consuming element. Note that the process of designing the community units in detail is still a professional design process, but this can be done in stages, as required, after the urban structure has been resolved and while the major infrastructure design is underway.

So, it has been demonstrated, using a hypothetical example, that standard urban metrics, applied using well understood theories can be combined with transect-based planning to automate the production of a 'first-draft' urban structure plan. With collective experience this process will become more rigorous and more reliable, producing the first draft of a metropolitan structure plan in hours instead of months and also vastly simplifying scenario testing

However, at the same time that the digital revolution is likely to accelerate urban planning processes, it is also likely to change at least one of the fundamentals of the city: employment. If there are no jobs, will cities cease to exist?

6. The Jobless City – Revolution or Paradise

It is highly likely that over the next two decades there will be a massive loss of industrial and service jobs in the western world, of the order of 80%, (Furman *et al*, 2016; CEDA, 2015) at exactly the same time as the mechanisation of agriculture in the global south is driving rapid, massive 3rd World urbanisation. Issues that humanity must deal with while also preventing nuclear war and avoiding biological annihilation.

Vivek Wadha, writing in the Washington Post[30] (Wadha, 2015) said that "We need a new version of capitalism for the jobless future". Perhaps a revival of co-operative ownership could be part of that model, an economy where:

- The citizens own the city;
- The city consists of all of the usual land uses (residential, schools, hospitals, etc.) renting these out, or operating them itself, as the citizens decide;
- The city owns the land of production (mining, agricultural and industrial);
- The city receives rents from the business owners or in-kind food and products;
- The city maintains itself and provides for the needs of its citizens in the form of food and clothing rations, access to education, health, recreation, entertainment, etc.; and
- The city distributes any surplus income to the citizens as a dividend and/or special purpose grants.

The Digital Revolution increases profits by decreasing labour, but there is no evidence yet that it decreases floor space. What will decrease is the need for worker transport, including parking. Therefore, robotised industrial land requirements might decrease by around 50% as parking areas are turned to more productive uses, but the roads and railways will probably be retained for the movement of raw materials and finished product. As the volume of production rises the value of the land rises and therefore rents can rise. There is no reason why a modern version of Ebenezer Howard's co-operatives could not capture that value (Howard, 1965, p. 58). Equally, urban and indoor agriculture reduces the agricultural hinterland required, thereby reducing land costs for a new city, and transport costs in bringing that produce to town. Areas of saving that could also be captured by a well-planned co-operative.

As explained earlier, "An additional 3 billion urban residents in forty years translates into a need to build a new city for a population of one million people, complete with hospitals, schools, workplaces, recreation and all the rest, at a rate of more than six a month" and clearly,

building one new city of any form will have no impact on a problem of this magnitude. So, perhaps multiple experimental cities are required on each continent, the successes being quickly replicated (in type, not in exact design, which should always be bespoke) and then replicated again, increasing exponentially, until all of humanity that wishes to live in cities can do so in to a satisfactory standard.

So, what are the options: scattered, idyllic rural villages, dense European urbanism or so far untested sci-fi archologies? Letchworth (population 35,000) near London, indicates that while the land ownership model may be relevant, the size is probably much too small, so that probably excludes idyllic rural village as an option, leaving archology, dense European city, or something in-between.

I have previously shown (Goldie, 2017) that both traditional European urbanism or a city-in-a-building archology could provide the physical models for the jobless cities that we should have started to build yesterday. Which of these will work best is likely to be determined by the degree to which each city's planning and design minimises environmental impact, maximises sustainability and, most critically, supports a functioning economic model that will "meet our needs as defined by the bottom two layers of Maslow's hierarchy of needs (physiological and safety) … thereby unleashing the next wave of human innovation and creativity in directions we can never imagine." (CEDA, 2015, p. 46)

7. Global Responses

There have been numerous high-level international meetings, forums and conferences at which the problem of rapid, massive, third-world urbanisation (RAMTU) is notionally addressed by goals, objectives and performance indicators (GOPI). These include the State of the Planet Declaration, the World Urban Forum, Habitat, the New Urban Agenda and the United Nation's sustainable development goals, as outlined below.

7.1. 2012 - The State of The Planet Declaration

The *Planet Under Pressure: New Knowledge Towards Solutions* conference (London, 26-29 March 2012) "... brought together nearly 3000 leading experts and decision-makers to discuss global challenges and offer new solutions." an additional 3000 people participated on-line. The first point in the State of the Planet Declaration is:

> *Research now demonstrates that the continued functioning of the Earth system, as it has supported the well-being of human civilization in recent centuries, is at risk. Without urgent action, we could face threats to water, food, biodiversity and other critical resources: these threats risk intensifying economic, ecological and social crises, creating the potential for a humanitarian emergency on a global scale.* (Brito and Smith, 2012, p. 1)

Unfortunately, the only actions proposed were to "fund and support capacity building in science and education globally ..." and related actions (Brito and Smith, 2012, p. 3).

7.2. 2001 - World Urban Forum

The World Urban Forum (WUF) is the world's premier conference on urban issues. It was established in 2001 by the United Nations to examine one of the most pressing issues facing

the world today: rapid urbanization and its impact on communities, cities, economies, climate change and policies.

Organized and convened by UN-Habitat, the Forum has become one of the most open gatherings on the international arena, for exchanging views and experiences on urban challenges. The inclusive nature of the Forum, combined with high-level participation, makes it a unique United Nations conference and the premier international gathering on urban issues.

The World Urban Forum has the following objectives:

- raise awareness of sustainable urbanization among stakeholders and constituencies, including the general public;
- improve the collective knowledge of sustainable urban development through inclusive open debates, sharing of lessons learned and the exchange of best practices and good policies; and
- increase coordination and cooperation between different stakeholders and constituencies for the advancement and implementation of sustainable urbanization.

The Ninth session of the World Urban Forum (WUF9), was held in Kuala Lumpur, Malaysia in February 2018, and has been recognized by the United Nations General Assembly (resolution 70/210) as the first session to have a thematic focus on the implementation of the New Urban Agenda adopted at the United Nations Conference on Housing and Sustainable Urban Development, Habitat III.

The Tenth session of the World Urban Forum (WUF10) will take place in Abu Dhabi, United Arab Emirates in 2020. It will be the first Forum to be held in the Arab region and it will be another opportunity to review the implementation of the New Urban Agenda.

7.3. 2015 - Sustainable Development Goals

The Sustainable Development Goals (SDGs) are a collection of 17 global goals set by the United Nations. The broad goals are interrelated, though each has its own targets to achieve. The total number of targets is 169. The SDGs cover a broad range of social and economic development issues. These include poverty, hunger, health, education, climate change, gender equality, water, sanitation, energy, environment and social justice. The SDGs are also known as "Transforming our World: the 2030 Agenda for Sustainable Development" or Agenda 2030 in short. The goals were developed to replace the Millennium Development Goals (MDGs) which ended in 2015. Unlike the MDGs, the SDG framework does not distinguish between "developed" and "developing" nations. Instead, the goals apply to all countries.

Paragraph 54 of United Nations Resolution A/RES/70/1 of 25 September 2015 contains the goals and targets. The UN-led process involved its 193 Member States and global civil society. The resolution is a broad intergovernmental agreement that acts as the Post-2015 Development Agenda.

The SDGs build on the principles agreed upon in Resolution A/RES/66/288, entitled "The Future We Want". This was a non-binding document released as a result of Rio+20 Conference held in 2012. (United Nations, 1992, resolution 1, annex I)

The goal most relevant to this discussion is Goal 11: Sustainable Cities & Communities:

Make cities and human settlements inclusive, safe, resilient and sustainable.

7.4. 2016 - Habitat III and the New Urban Agenda

The United Nations Conference on Housing and Sustainable Urban Development, known as Habitat III, concluded on 21 October 2016 in Quito, Ecuador, with delegations adopting the New Urban Agenda – a new framework that that lays out how cities should be planned and managed to best promote sustainable urbanization.

> *"We have analyzed and discussed the challenges that our cities are facing and have [agreed] on a common roadmap for the 20 years to come," Joan Clos, Secretary-General of the conference and Executive Director of the UN Human Settlements Programme (UN-Habitat), told participants at the closing session.* (UN News 2016)

The conference in Quito, lasted one week and drew around 36,000 people from 167 different countries, with a reported 50,000 also visiting the various associated exhibition areas.

Clos said that the document should be seen as an extension of the 2030 Agenda for Sustainable Development, agreed by 193 Member States of the UN in September 2015 (UN News 2016).

The Agenda for Sustainable Development's 17 Sustainable Development Goals (SDGs) recognized the power of cities and towns, which will constitute up to 70 per cent of the world population by 2050, to be the engine for sustainable growth in the future. The New Urban Agenda gives greater emphasis to this concept.

Implementation is covered by paragraphs 23 to 175 of The New Urban Agenda. (United Nations, 2017) Almost every paragraph starts with "We will ...", "We commit to ...", and so on. These statements include:

- "102. We will strive to improve capacity for urban planning and design and the provision of training for urban planners at national, subnational and local levels.",
- "109. We will consider increased allocations of financial and human resources, as appropriate, for the upgrading and, to the extent possible, prevention of slums and informal settlements, with strategies that go beyond physical and environmental improvements to ensure that slums and informal settlements are integrated into the social, economic, cultural and political dimensions of cities."; and
- "126. We recognize that the implementation of the New Urban Agenda requires an enabling environment and a wide range of means of implementation, including access to science, technology and innovation and enhanced knowledge-sharing on mutually agreed terms, as well as capacity development and mobilization of financial resources, taking into account the commitment of developed and developing countries and tapping into all available traditional and innovative sources at the global, regional, national, subnational and local levels, as well as enhanced international cooperation and partnerships among Governments at all levels, the private sector, civil society, the United Nations system and other actors, based on the principles of equality, non-discrimination, accountability, respect for human rights and solidarity, especially for those who are the poorest and most vulnerable."

In response to these points, or for other compelling reasons, there are programs designed to address such issues, for example:

> *From the Federal government's point of view, it is indeed essential to tackle the root causes for irregular migration. This includes improving living conditions and creating better perspectives in countries of origin, notably in Africa. The Federal government has already been very active in this field. This includes projects in education, vocational training, job creation, health, infrastructure or food security, to mention only a few. In the year of 2017, the German government has spent a total of 6.6 billion EUR to this end alone.* (Helmert, 2018)

The question is whether billions of Euros, dollars or dirhams directed piecemeal to education, vocational training, job creation, health, infrastructure, food security, etc. are sufficient to make a difference, or whether it would be better to direct all efforts to the one endeavour that is likely to provide a permanent solution: city building.

As the Germans say, *stadtluft macht frei* (the city makes you free).

7.5. Conclusions Regarding International Responses

While the goals, objectives and performance indicators developed and adopted at these various global meetings, forums and conferences are most worthy, it is notable that while there are many "we will's" there is no mention of 'how' or 'with'. Wars might happen by accident, but great cities do not. Even if they did, such good fortune is very unlikely in the great arc of growth stretching from West Africa through the Middle East, across Asia and into the Pacific, and most certainly not two thousand times in the next thirty years.

Figure 18: Residents line up to receive food in the besieged Palestinian camp of Yarmouk, Damascus, Syria 31 Jan 2014. ©AP/UNRWA

Notably, the most senior public official on the planet has warned that everything that humanity has done so far to address this challenge is not enough:

> *The UN Secretary-General has told a major climate change conference that the world faces a battle for its survival.*
>
> *António Guterres said despite the existential threat, not everyone was confronting the problem with due focus.*
>
> *Speaking in Abu Dhabi on Sunday, Mr Guterres also made an impassioned call for greater support to help develop the green economy.*
>
> *"The world is facing a grave climate emergency – disruption is happening now and faster than top scientists predict," he said.*
>
> *"Every week brings more devastation, floods, drought and…superstorms. All around the world, people are losing their homes and forced to migrate.*
>
> *"The situation only gets worse and we must act now with urgency. We have no time to lose."* (Dennehy, 2019)

Obviously, Franklin's Law is as true today as when the great man first coined it: "If the poor folks are happier at home than they can be abroad, they will not be lightly prevailed with to cross the ocean." (Benjamin Franklin, 1706-1790, from Zolberg, 2006, p. 46), So, not only are the goals discussed above sensible, they are based in long understood common sense, but the questions remain: how, when and where will these goals, objectives and performance indicators actually be implemented in sufficient scale to make a difference? How do we plan and build enough cities, or city expansions, well enough and quickly enough to solve a three-billion-person problem?

8. How to Plan and Build 2000 New, Million-Person Cities by 2050

8.1. Physical Resources – The Planning Staff

Whatever the technologies used to support the planning process they will not (at least not for a generation or two) replace the need for trained urban planners and designers.

At the local government level, such as the planning of a new town or city, the resources applied to planning depend upon many local factors, not least of which are the relevant laws and regulations of the state, but in my experience most of these factors can be subsumed into one constant, the size of community that one local government planer can manage if it is growing at 1% a year. Let us call this population the single planner population (SPP). For example, assume that this factor is constant within any particular state (i.e. emirate, province, nation, state, etc.), then the number of planning staff (S) will be given by the population (P) and the rate of growth, actual or desired, whichever is the greater, (R%) as follows:

$$S = \frac{P \times R}{SPP}$$

Finding the value of the single planner population (SPP) for any jurisdiction is simply a matter of auditing all planning organisations in that jurisdiction and taking the average (of course the audit has to normalise for consultant budgets and professional-to-support staff ratios in order to ensure an accurate comparison). As always there will be special cases and varying preferences for in-house teams over consultants, but in my experience this simple formula gives remarkably consistent results.

So if there is a town of 12,500 people growing at 1%, and the SPP for that state is 12,500 then the number of local government planners required to manage the plan making, plan implementation and administration for that town effectively and efficiently is one, because:

$$S = \frac{12{,}500 \times 1}{12{,}500}$$

$$S = 1$$

Scaling this up to a city of 1,000,000 growing at 1.5%, we get a staff requirement of one hundred and twenty, as follows:

$$S = (1{,}000{,}000 \times 1.5)/12{,}500$$

$$S = 120$$

Clearly, the same city, growing at twice the rate requires twice the staff, because:

$$S = (1{,}000{,}000 \times 3.0)/12{,}500$$

$$S = 240$$

Cities exist because they give economies of scale, but unfortunately, budget makers rarely recognise that in town planning increased size and/or rate of growth creates more problems, not fewer, because human interactions increase exponentially. The fact that this equation increases staff requirements geometrically, not exponentially, demonstrates that there are economies of scale in the planning of a city, but usually not to the degree desired by budget makers.

These same budget makers might also express a tendency to assume that technologies such as automated approvals will allow a reduction in staff. However, if this is done I am confident that the "garbage in, garbage out" rule will quickly assert itself and more planners, rather than fewer, will be required to sort out a mess that we do not have the time to deal with. It would be much more prudent to redeploy statutory planners to planning and urban design, or provide additional training in order to employ them as urban planning technologists, in order to ensure that the plans that are being converted into computer algorithms are sound, and that the outputs are audited for consistency with those plans.

If there is a short-term spare capacity in planning staff, then it would be wise for an agency (or group of agencies) to send them to undertake projects in less privileged jurisdictions. Revising Franklins Law slightly: "If poor people are able to move to nice towns and cities in their own countries, they will not be likely to seek refuge in ours." But, how many should they send? First, we require a likely rate of growth and initial population.

Given a proposed city of one million persons and assuming a density objective of 6,670 p/sq. km (e.g. Wikipedia, 2019 lists San Francisco at 6,226.3 p/sq. km in 2010), an average radius of 6.9 km giving an area of 150 square kilometres (sq. km) and an initial average density of 1 person/sq. km. Then, applying the standard formula for compound interest with A = 1,000,000 P = 150, and n = 30 years, the rate of growth (r) is calculated as follows:

$$r = n[(A/P)^{1/n} - 1]$$

$$r = 30[(1{,}000{,}000/150)^{1/30} - 1]$$

$$r = 30[6{,}666.7^{0.0333} - 1]$$

$$r = 30[1.3411 - 1]$$

$$r = 10.23 \quad \therefore R = 1023\%$$

Applying this growth rate to the staffing problem, and assuming an SPP of 12,500, gives:

$$S = (P \times R)/SPP$$

$$S = (150 \times 1023)/12{,}500$$

$$S = 153{,}450/12{,}500$$

$$S = 12.276$$

Therefore, an initial planning team of 12 full-time equivalent (FTE) urban planners, designers, other specialists (e.g. environmental scientists, urban geographers, surveyors, demographers, transport planners, planning engineers, social planners, planning technologists, etc.) and support staff (geographic information system operators, computer aided design (CAD) operators and administrative personnel) should be sufficient, on average, to produce a master plan for a city, or urban extension, of one million persons in three years. This calculation should be part of the annual budgeting process, because the staffing need will change as the city grows.

Twelve might seem to be a small number for a master plan for the equivalent of a city of one million people, but, counterintuitively perhaps, master planning a new city from scratch requires a smaller team than that required for the physical change management of an existing city with its myriad of issues, conflicts and individual applications for various consents.

In addition to confirming the site selection and preparing the master plan, this team will also be responsible for training the local team to implement the plan. Assuming that the local team have the relevant qualifications, then this should mostly be by on the job training (OJT), so they will be an additional resource, rather than a distraction from the main task.

Of course, the above assumes that the effective application of artificial intelligence to urban planning will not be available for some years, but every effort should be made to advance it, whether in the form described above, or by better approaches, because the task is very big and humanity needs to marshal to the task every resource available.

8.2. The Size of the Task

The next step is to confirm the size of the task

Year	Urban population ($x10^9$)	Total Population ($x10^9$)	%
1950	0.75	2.50	30%
2009	3.42	6.80	50%
2050	6.40	9.60	67%
Increase 2009-2050=	2.98	2.80	106%

Figure 19: Urban Population 1950-2050 (from figure 1 above).

Figure 19 shows the total population increase for all of humanity. Excluding the one billion additional urban population forecast for China, India and Nigeria leaves 1.98 B people to be housed in new urban settlements. If these new settlements are assumed to be, on average, cities, or city extensions of 1,000,000 then the demand is for 1,980 new one-million-person cities, or equivalent urban expansions. If a 1% failure rate is allowed for (i.e. 19.8 projects) then this target can be rounded to 2,000.

Year	Growth Factor	Commencements During the Year	Total Number of MP Commenced	Total Number of MP Completed	% of Target
2020		7	7	0	0%
2021	2	14	21	0	0%
2022	2	28	49	0	0%
2023	4	28	77	7	0%
2024	4	56	133	21	1%
2025	4	112	245	49	2%
2026	4	112	357	77	4%
2027	4	224	581	133	7%
2028	4	448	1029	245	12%
2029	4	448	1477	357	18%
2030	4	523	2000	581	29%
2031				1029	52%
2032				1477	75%
2033				2000	101%

Figure 20: Masterplans required by year

Figure 20 shows that if we assume that, on average, each master plan can be completed within three years, and set up a program to commence seven masterplans in 2020 and grow the number of masterplan commencements by doubling the number of teams in the first two years and quadrupling them annually after that then, 2000 masterplans can be completed by 2033. Assuming twenty years for design and construction then 2000 new cities by 2053 is achievable. If new technologies and lessons learned on the first cities can be applied to speed up the process in later cities then possibly the whole task can be achieved by 2050, or earlier. So, the task is enormous, but feasible. The next question is cost.

8.3. The Cost of Planners and Plans

To estimate the cost, first of planning and then of design and construction of the infrastructure and key buildings, it is assumed that a level of commercial investment, owner-building or citizen labour will provide the majority of the lesser buildings.

As demonstrated at section 8.1 above, a planning team of twelve full-time equivalent (FTE) staff members at any one time should be capable, on average, of site selection and masterplan preparation for a new city for one million people within three years.

No of MP in progress	FTE per Team	Head Office	Total FTE	Wages Growth	Average Cost per FTE per Year	Total Salary Cost ($x10^6)	On costs, operating expenses etc.	Total Cost per Year ($x10^6)
7	12	13	97	1%	$100,000	10	100%	19
21	12	13	265	1%	$101,000	27	100%	54
49	12	13	601	1%	$102,010	61	100%	123
70	12	14	854	1%	$103,030	88	100%	176
112	12	15	1,359	1%	$104,060	141	100%	283
196	12	16	2,368	1%	$105,101	249	100%	498
280	12	18	3,378	1%	$106,152	359	100%	717
448	12	21	5,397	1%	$107,214	579	100%	1,157
784	12	28	9,436	1%	$108,286	1,022	100%	2,044
1120	12	35	13,475	1%	$109,369	1,474	100%	2,947
1419	12	41	17,069	1%	$110,462	1,885	100%	3,771
971	12	32	11,684	1%	$111,567	1,304	100%	2,607
523	12	23	6,299	1%	$112,683	710	100%	1,420
							Total Cost	15,815
							Program Length (Years)	13
							Averaged Yearly Cost	1,217

Figure 21: Planning Costs

At this point some assumptions are required. These are:

- That the definition of precisely what a master plan is in such circumstances is a matter for much discussion, so here "masterplan" is used in a very generic sense.
- That the planning teams require a "head office" team of twelve plus an additional person for every fifty teams, or part thereof.
- That the average salary per FTE is US$100,000.
- That the average employment on-costs (leave, allowances, insurance, training, etc.) plus the operating expenses (office space, furniture, equipment, materials, utilities, etc.) total to an equivalent of 100% of salary cost per FTE.
- That wages and on costs increase due to inflation at 1% per annum for the duration of the project.

If these assumptions are correct, then figure 21 shows that the total cost of the planning program would be US$15.8 T over 13 years, giving an average yearly cost of US$1.2 B, including inflation. Obviously this estimate should be rigorously re-examined before an actual program is initiated, but it is reasonable to expect that a formal actuarial estimate would not differ from this quick estimate by more than plus or minus 15% from the estimate above, giving a range of between US$1.0 B and US$1.4 B.

Project	Country	Designer/ Builder	Projected Population	Estimated Cost (US$M)	Duration (years)	Cost/Year/M Pers (US$M/yr)	Notes
Bahria Town Karachi	Pakistan	Bahria Town (Private)	1,000,000	1000	20	50	Assumed duration
Masdar	UAE	Foster + Partners	47,500	20,000	20	21,053	
Ramciel	South Sudan	Korea Land and Housing Corporation	250,000	940	5	752	Assumed population
New Songdo City	South Korea	Kohn Pedersen Fox	232,000	30,000	20	6,466	
					Average =	7,080	

Figure 22: Construction Cost Examples (from various websites)

Figure 22 shows that the construction cost of a sample of four new cities. Unfortunately, the available data is difficult to find and incomplete. Another complicating factor is that the range is very wide, from a cost per year per million persons of US$50 M for Bahria, a gated community outside of Karachi, to US$21 B for Masdar City, the sustainability demonstration project next to Abu Dhabi International Airport. Considering each of these in turn:

- Bahria is a large project, but it does benefit from proximity to Karachi, a major city with significant (if reportedly inadequate) infrastructure, therefore the total projected cost could be artificially low;
- Masdar has not grown at anything like the initially projected rate and was designed to a very high construction standard, so this cost is probably unrealistically high;
- Ramciel is a totally new city in a remote area in a country typical of the great arc of growth discussed above, but a master plan has not been finalised and the estimate shown is from 2012, so it is possibly a little low; and

- New Songdo City is a high-rise city with a lot of new "smart city" technology and which has reportedly achieved only about one third of its projected occupancy (private site visit, 2018), and is therefore also probably unrealistically high for the type of project discussed here.

Year	Number of MP Completed (cumulative)	Number of Cities In Detailed Design & Construction	Cost/Year (US$M/yr)
2020	0	0	$0
2021	0	0	$0
2022	0	0	$0
2023	7	7	$7,000
2024	21	21	$21,000
2025	49	49	$49,000
2026	77	77	$77,000
2027	133	133	$133,000
2028	245	245	$245,000
2029	357	357	$357,000
2030	581	581	$581,000
2031	1029	1029	$1,029,000
2032	1477	1477	$1,477,000
2033	2000	2000	$2,000,000
2034		2000	$2,000,000
2035		2000	$2,000,000
2036		2000	$2,000,000
2037		2000	$2,000,000
2038		2000	$2,000,000
2039		2000	$2,000,000
2040		2000	$2,000,000
2041		2000	$2,000,000
2042		2000	$2,000,000
2043		1993	$1,993,000
2044		1979	$1,979,000
2045		1951	$1,951,000
2046		1923	$1,923,000
2047		1867	$1,867,000
2048		1755	$1,755,000
2049		1643	$1,643,000
2050		1419	$1,419,000
2051		971	$971,000
2052		523	$523,000
2053		0	$0
30		Total	$40,000,000
		Average	$1,333,333

Figure 23: Construction Cost Calculator based on cost estimates for Ramciel, South Sudan

Considering the above it is proposed that a cost per year per million persons of US$752 M for Ramciel be taken as starting point. Adding 30% as a worst case margin of error gives a tentative US$1 B per year per million persons for the proposed 2000 new cities.

The data on the projected time for detailed design and construction is more reliable, with all but Ramciel proposing a twenty-year program, so this time frame will be adopted for this study.

Given the dearth of reliable, published data on these and other new city projects, a much more extensive and thorough audit by a team that has the resources to visit a much larger sample of new city projects would be necessary before deciding upon an overall project estimate. While a wide margin of error should always be allowed for early estimates of individual project costs (because a completed master plan is required before reliable construction cost estimating is possible), averaging over 2000 projects should be reasonably accurate.

Table 5 shows that, assuming US$1 B per year per million persons, construction costs start in the third year (2023), on completion of the first seven masterplans, at US$7B a year, rising to US$2 T a year in 2032, but deceasing from 2043 as the twenty-year initial city building phase is completed and each city become self-funding.

As anyone familiar with city building would expect, the estimated average planning cost of US$1.4 B p.a. for thirteen years is miniscule compared to the estimated average detailed design and construction cost of US$1.333 T p.a. for thirty years. Combined the total is US$1.3344 T p.a. for thirty years, but this still rounds to US$1.3 T p.a.

8.4. Feasibility

A preliminary cost of US$1.3 T p.a. for thirty years demonstrates that the costs of planning and building 2000 new cities in the great arc of growth from West Africa through the Middle East, across Asia and into the Western Pacific is not beyond the G20 countries and their combined gross domestic product (GDP) of US$78.4 T p.a. (in 2014), as illustrated in figure 24.

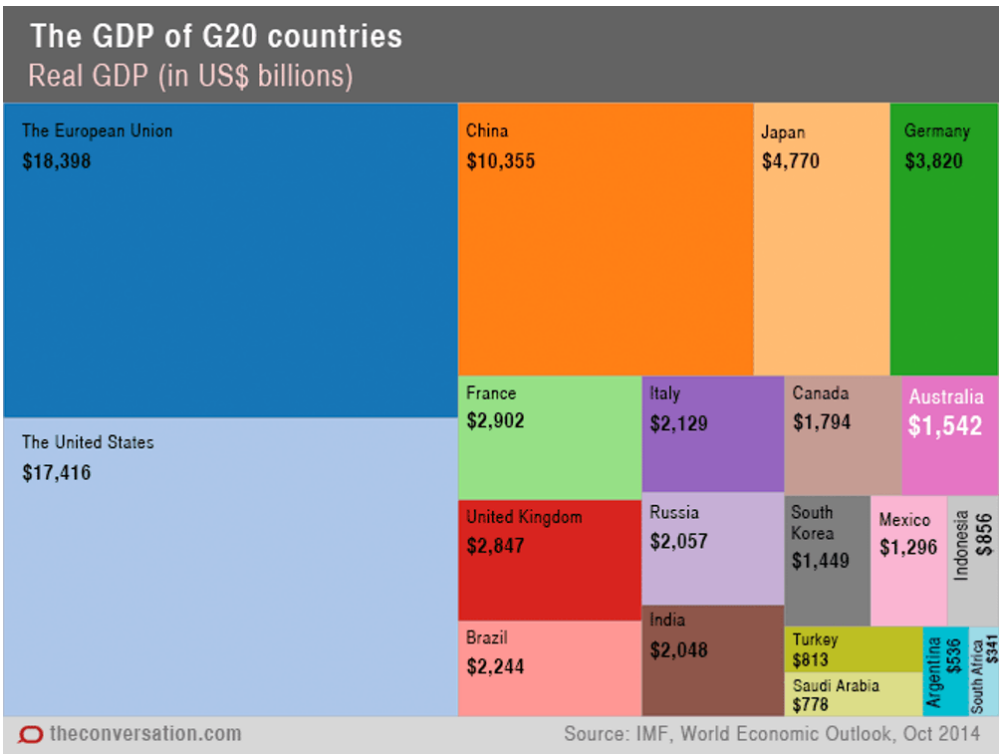

Figure 24: Gross Domestic Product (GDP) of the G20 countries in 2013-14

However, while it is economically feasible for the G20 countries to allocate 1.7% (US$1.3 T out of US$78.4 T) to solving rapid massive third-world urbanisation, it must be recognised that there is little likelihood of a political consensus to deliver that proportion of these countries' wealth in any one year, never mind a consistent policy over more than thirty years. Therefore, some other scenarios should be explored.

For example, if the design and construction costs of Bahria Town are accurate, and can be replicated across the Third World, then the average annual cost reduces to $67 B p.a., which is only 0.085% of the G20's GDP. This is more realistic, but would still require the leadership of a Winston Churchill or Harry Truman to deliver a G20 wide consensus. A further difficulty is that the Bahria development model is premised on the purchase of properties by those with a middle-class income in that market, it will therefore not result in the emptying of dark satanic slums and impoverished shanty towns for a better future in master planned cities "dense with skyscrapers gleaming like the nylon bristles of a brand-new toothbrush". (Blake, 1804; Calvino, 2002, p. 308)

An alternate, free-market plan would require a private consortium to fund the planning effort (US$1.4 B p.a. for thirteen years) and a single donation per city (spread over, say five years) of one billion US dollars (see Bahria Town Karachi in figure 22 above) to provide the initial infrastructure, possibly in return for naming rights. Perhaps the time will come when no self-respecting multi-billionaire would be able to resist the attraction of having a city named after them! The cities would need to be charter cities, meaning that citizens purchase their citizenship with cash or labour. This requires that the master plans provide for the sort of urbanism that is sufficiently dense to create an economically sustainable city, but able to be built with basic building skills and materials, for example the sort of dense urbanism of the older European cities discussed above at section 6.

Of course, all options would benefit from the fact that the economy of cities is strongly circular, meaning that the initial cash injection generates jobs that pay wages that are spent on rent and goods within the city, which then generate profits that fund developments that generate jobs, etc. However, this requires good governance, a planning consideration that must also be addressed if the full benefits of planning, designing and building 2000 cities in the Third World are to be enjoyed by the citizens of those cities. This consideration could possibly benefit the charter cities option, provided that the internal governance of the city is strong enough to resist the interference of a corrupt national government.

Whichever model is adopted (and it could be a combination of one or more approaches) it is absolutely vital that these 2000 new cities provide very high-level triple-bottom-line outcomes. With good master planning they should start with good environmental outcomes and, as they should end migrations of desperation away from home countries, they have a head start in good social outcomes. However, there is little doubt that economic sustainability will require significant advances in the quality of governance in some of the countries in which these cities will be built. The issues raised in this simple statement are well beyond the scope of this paper, but must be addressed as part of this project. Given the time imperative it is necessary that such studies and proposals be conducted concurrently with the initial master planning phase and monitoring of the effectiveness of improvements in governance will, necessarily, last for many decades.

9. Conclusion

Urban planners and designers are faced with the task of housing an additional three billion people in towns and cities by the year 2050. This is the equivalent of building six one million-person cities every month for forty years. If climate change displaces another 200 million people the task will be that much greater. It is truly one of Alejandro Arevena's "3S Problems": a problem that is simultaneously large scale, requires a speedy response and must be dealt with by individuals or teams suffering a scarcity of means.

Compounding this problem, but also demonstrating that it might be part of the solution, the developing economies are generating large scale employment in their urban areas, some 900 million jobs in the thirty years from 1980 to 2010, but most of these jobs require the level of education that only a well-designed and managed large town or a city can provide.

China, since the 1980's, and India more recently have recognised this issue and responded with massive city building or urban improvement programs, but only one-third of the additional three billion new urban dwellers are expected to be in China, India and Nigeria, the remaining two-thirds will be in the countries around those countries: a massive arc stretching from West Africa, through the Middle East, across Asia and into the Pacific.

Clearly, if massive new urban areas are required very quickly, the planning process must be fast and reliable, and conducted within, or for, efficient, well-managed planning agencies. This requires not only the adoption of all that the new technologies have to offer, but also the development of a plan making paradigm that optimises the application of that technology in a way that produces good urbanism. In short a planning paradigm that avoids the possibility of "garbage in, garbage out".

The most significant advances in the understanding of urban areas and in the practice of producing good urban planning, and built outcomes, has been by the movement known as the New Urbanism. Three of these advances, the charrette, form based codes and transect planning are particularly relevant. In particular, the combination of transect-based planning and form based codes gives the opportunity to develop the New Urbanism further towards a systemisation that simultaneously enables localisation (perhaps, the core conundrum of urban planning across the ages). Success will enable automation of the approvals process with the possibility of some eighty percent of applications being approved, on-line, almost in an instant.

However, there is no time to lose waiting for such technological improvements, we need to start right now. The paper has demonstrated that if the funds and resources can be marshalled and fewer than one hundred planners and related professionals and support staff are deployed on seven new city projects within twelve months, then we can plan and build, from now to the year 2050, new urbanism sufficient to enable an additional three billion people to live, learn, work and play in good, new cities and towns.

Research Paper

A 21ST CENTURY NATIONAL ORDINANCE

Planning the physical disposition and use distribution of a Nation

David Green, Perkins&Will and Doug Allen Institute; Unites States
Sulaiman Al Rashad, Kuwait Municipal Authority; Kuwait
Paul Knight, Doug Allen Institute; United States
Nicolò Cammelli, Perkins&Will; Italy

Abstract

This paper outlines the implementation of a National Ordinance across the country of Kuwait. The ordinance is a platform that is based on a seximal system of measurement for spatial and data driven planning. This system simultaneously provides a spatial framework for optimized connectivity as well as an analytical platform for projecting and tracking development across an entire nation.

The national master plan for the country of Kuwait, the Fourth Kuwait Master Plan 2040, utilizes a National Ordinance that serves as the planning and development platform for the country. The ordinance is based on the Land Ordinance of 1785, Jefferson's plan for most of the United States, however, it is restructured to address changes in context, technology and operation. In this case the Ordinance provides parallel Geographic Information Systems for both spatial implementation and data analytics. The intention is to use the Ordinance to address the difficulty in planning for the future of a complex system such as an entire country.

This paper provides 1) a brief introduction to the idea of an Ordinance, 2) the historical context for the idea of a national planning platform, or ordinance, 3) historic examples and analyses, 4) the underlying concepts and methodology for the proposed ordinance, and 5) a detailed analysis of the proposed Kuwait National Ordinance.

1. National Ordinance

1.1. Introduction to the National Ordinance

In the scales of human development, the largest scale tends to have the largest impact. A Nation's constitution affects everyone, while a local ordinance is limited in scope. It is the built-in tenacity at the largest scales that make the influence of broad efforts worthy of more intense study. As such, this paper begins at the scale of the country of Kuwait with the proposed National Ordinance.

In general, a National Ordinance is a regulatory and guiding document to facilitate the distribution of land across an entire country. It is comprehensive by necessity. It comprises methodologies, maps, principles, and policies for subdividing vast territories. While it is prescriptive in its methods, it can materialize incrementally and is typically flexible and adaptable. It has broad impact on the country, but it can also provide guidance and direction for finer details that are to be applied later. Thus, it has the potential to impact everything from the general distribution of uses across a large area to the character of the local

areas that emerge in the development of the country. From a planning perspective, it is a document and methodology that breaks down vast dimensions into manageable and workable units.

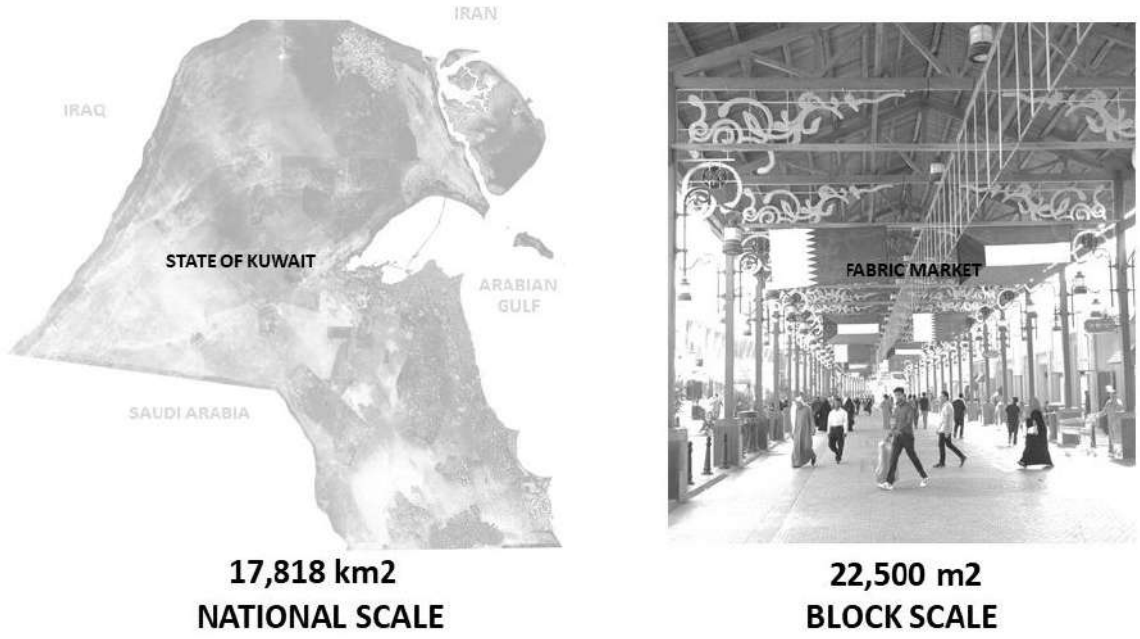

Figure 1 Scales comparison (©Fourth Kuwait Masterplan)

1.2. Introduction to the Kuwait National Ordinance

The national master plan for the country of Kuwait, the Fourth Kuwait Master Plan 2040 (4KMP), utilizes a National Ordinance that serves as the planning and development platform for the country. The ordinance is loosely based on the concepts and applications underpinning the Land Ordinance of 1785, Jefferson's plan for most of the United States, however, it is restructured to address changes in context, technology and operation. In this case, the Ordinance provides two parallel Geographic Information System (GIS) platforms based on a grid system. The first platform is for physical spatial implementation and is structured around a dimensional system that facilitates particular outcomes relative to connectivity and the physical disposition of the public and private realms. The second platform is for the collection, organization and analysis of data to facilitate timely and relevant management of the development and monitoring process. The intention is to use the Ordinance to address the difficulty in planning for the future of a complex system such as an entire country.

Figure 2 demonstrates the parallel platforms, with the grid providing a physical, dimensional structure that precipitates future development that is connected and adaptable, while simultaneously providing an updatable and analytical platform for the distribution of uses and supporting resources for the expanding city and new cities and towns that will emerge in the coming decades.

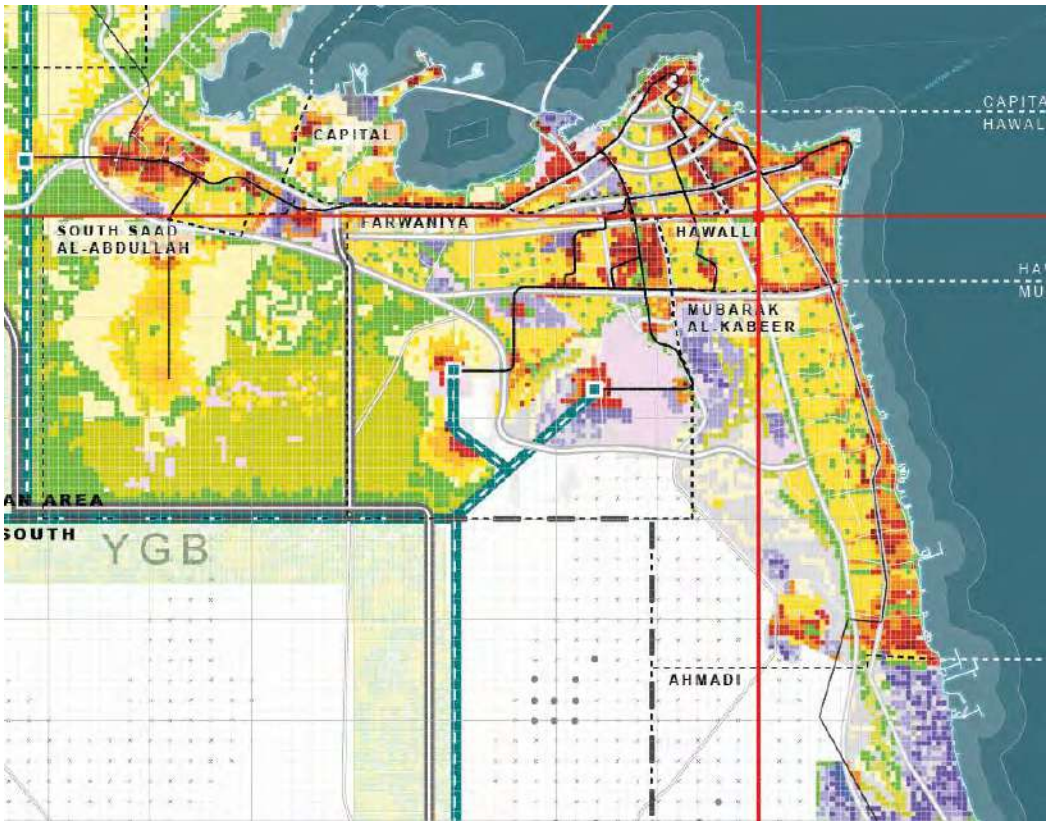

Figure 2 4KMP National Plan (©Fourth Kuwait Masterplan)

2. Historical Context for a National Ordinance

2.1. The evolution towards the 21th Century National Ordinance

A National Ordinance is fundamentally a subdivision program for an entire country. It is a way of organizing the patterns of settlement and development in a growing and changing city, town or other inhabitation. The context and history of these efforts are critical to understanding the opportunities a contemporary national ordinance afford. They are also critical to our understanding of how these efforts evolved over time, and how they were, or were not, successful.

In the process of examining past examples, two scales are discussed, the national (or large-scale) and the city (or small-scale). There is a relationship between the two that is critical to the operation of the Kuwait National Ordinance, and as such, both should be clearly explained.

The examples include, from the ancient world, Miletus (small-scale) and the Roman Centuriation (large-scale), and from the Colonial world, Philadelphia (small-scale) and the U.S. Land Ordinance of 1785 (large-scale).

2.2. The Ancient World

A very early urban planner, Hippodamus of Miletus, was charged with laying out a new Greek settlement along the Aegean Sea in what is today Turkey. To do this, he utilized a grid structure that projected a future city comprised of streets at regular intervals, organized perpendicular to each other. The result was a regular grid pattern that showed public streets and the resulting blocks. In addition, he indicated where specific public buildings and places would be located in the city.

The city plan is shown in Figure 3. It is strikingly simple for a city plan in relation of the complex, multi-volume planning documents that are used to plan cities today, however, it is an early representation of the general way cities would be planned from its inception to the early 20th century. The planning of cities remained little changed for 2500 years, and this simple system produced some of the most liveable, adaptable, sustainable and resilient settlements that we still know and enjoy today.

Miletus is not an example of a successful city, rather an early example of the process of planning cities as simple projections of the public and private realms, devoid of uses, other than the critical public buildings and places that supported the cities. It demonstrates the lasting process more than the lasting city itself. It also represents a structure that provided a backdrop for the emergence of civilization over the past two and a half millennia.

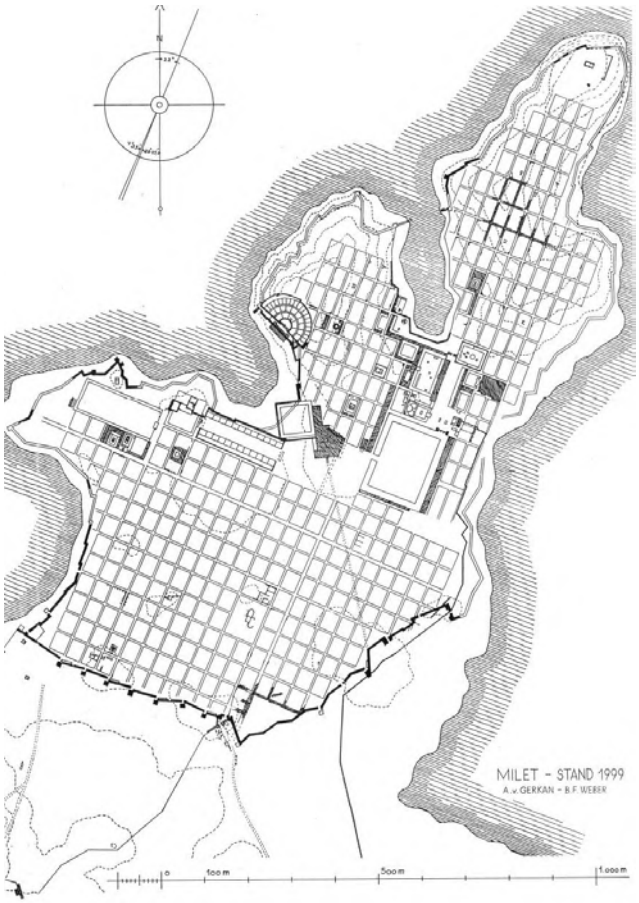

Figure 3 Plan of Miletus around 470 BC (Magli, 2007)

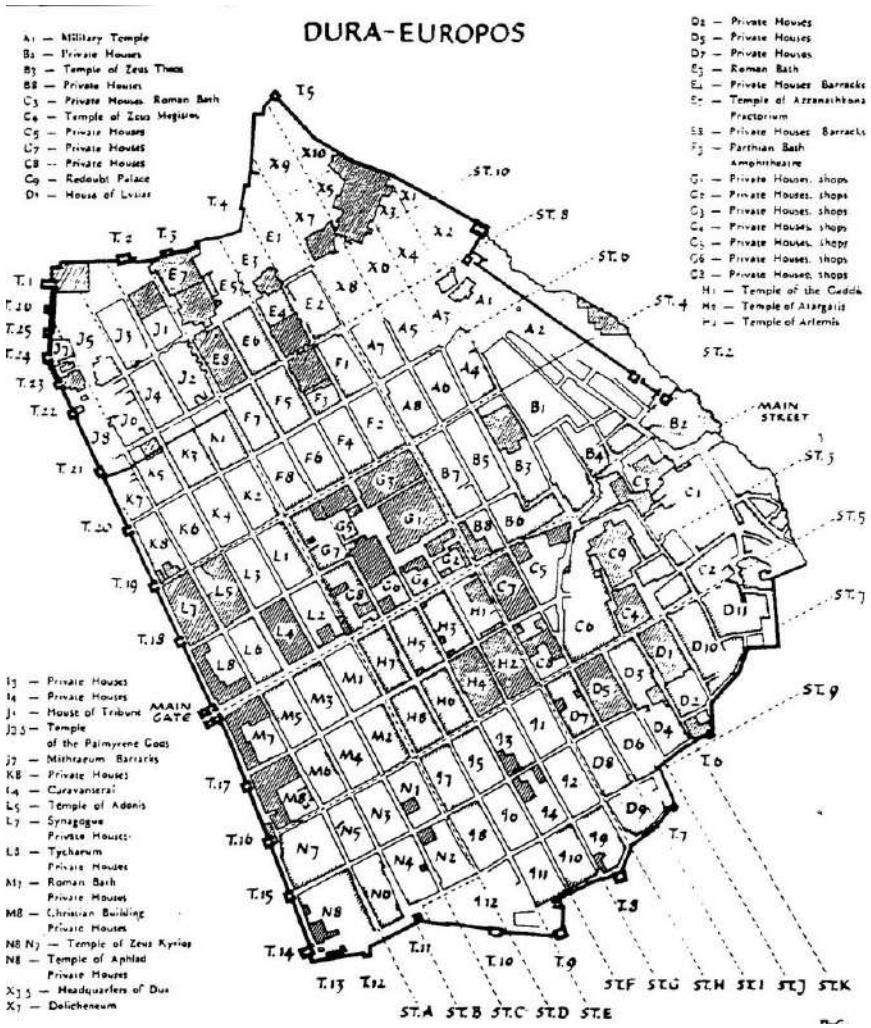

Figure 4 Plan of Dura-Europos (Quadralectic Architecture, 2016)

From Greece, such methodology for city planning and land organisation was taken up by the Romans and their emerging conventions for planning new cities, as evidenced by the diagram below in Figure 5. The city is conceived of with a sacred point of departure, the Axis Mundi, at the intersection of the *cardo* and the *decumanus*, but the execution of the plan is essentially the same as that of Hippodemus at Miletus, a projection of the public realm as streets and the resulting blocks, some of which are identified as important public buildings and places.

The Romans, however, were expanding into an empire, and this necessitated a broader, larger-scale effort to organize land that was both captured and restructured according to Roman principles, but also land that was to be developed as everything from farmland to new urban centers. The key element in this effort was the Roman Centuriation, a system that supported the initial laying out of the two main streets.

Figure 5 Plan of Timgad (Finley, 1977)

The specific process began with the surveyor identifying a central viewpoint, the Umbilicus Agri, through the gates of the city into expansion territory. Two main perpendicular roads, the *cardo maximus* and the *decumanus maximus* were laid out at the designated intersection to form the backbone of the emerging series of streets and roads. In many cases these roads still exist as primary roads linking local villages to main towns, illustrating the lasting presence of public rights of way once they are put in place. The territory would then be subdivided to create a system of parallel and perpendicular streets, *limites quitarii*, dividing the territory into square resultant plots, called saltus and further subdivided into *centuria*. At the most local, granular level, the subdivision process resulted in *heredia*, and further *jugera*. In all this system provided a method for organizing land on a large scale, creating connections between settlements and resulting in highly connected, dense networks of streets and blocks.

As with Miletus, the Roman Grid provided a system of dimensional organization that resulted in boundaries and street centerlines that projected what was public (the streets) and what was private (the resulting parcels of land).

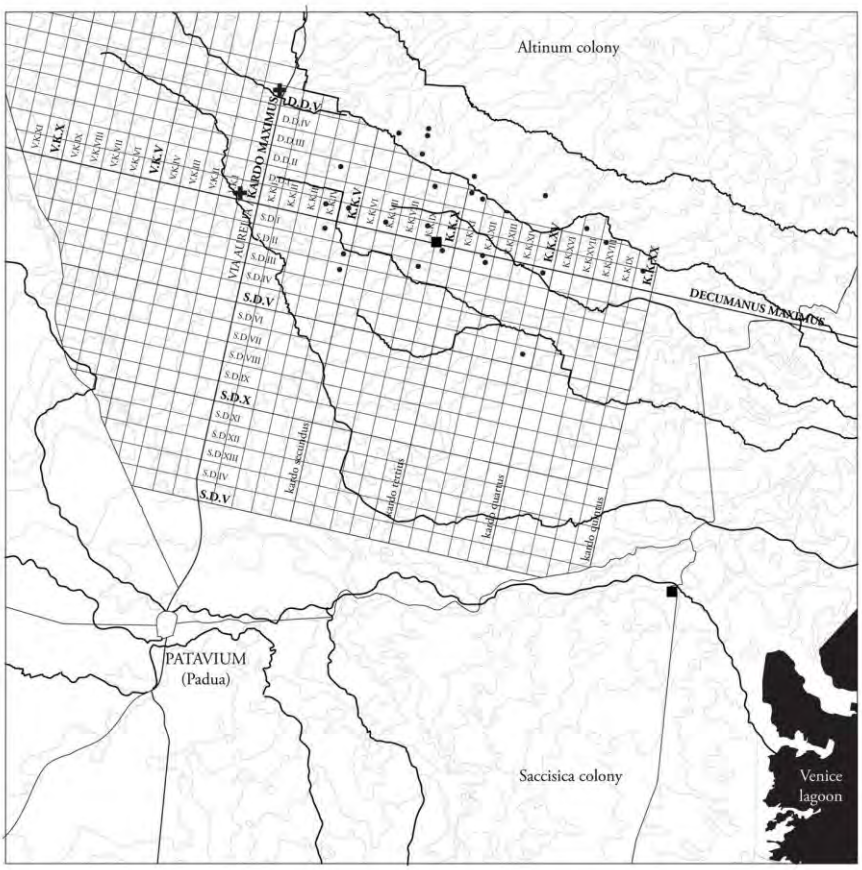

Figure 6 The Roman centuriation between Padua and Venice (Tavone, 2018)

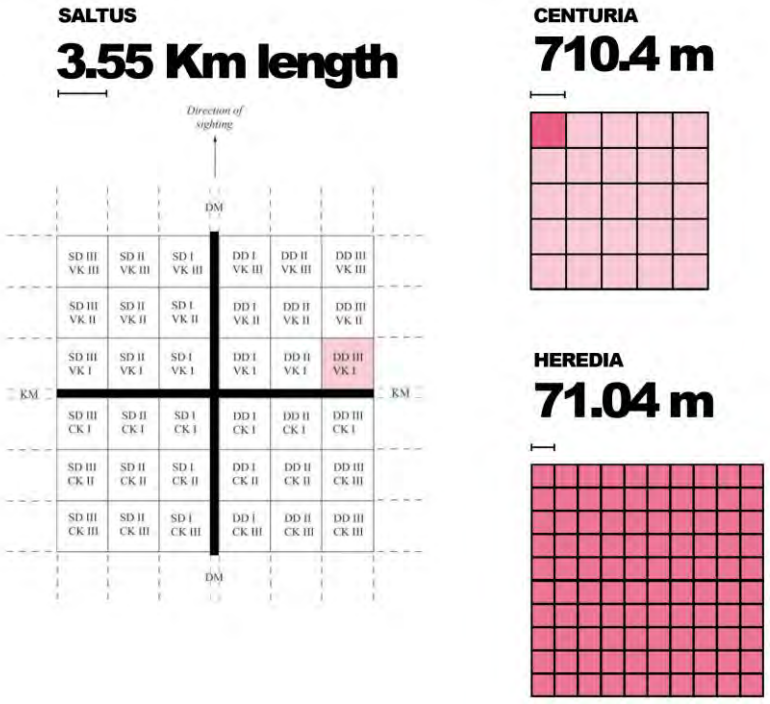

Figure 7 The Roman centuriation between Padua and Venice (Pasquinucci, 2014)

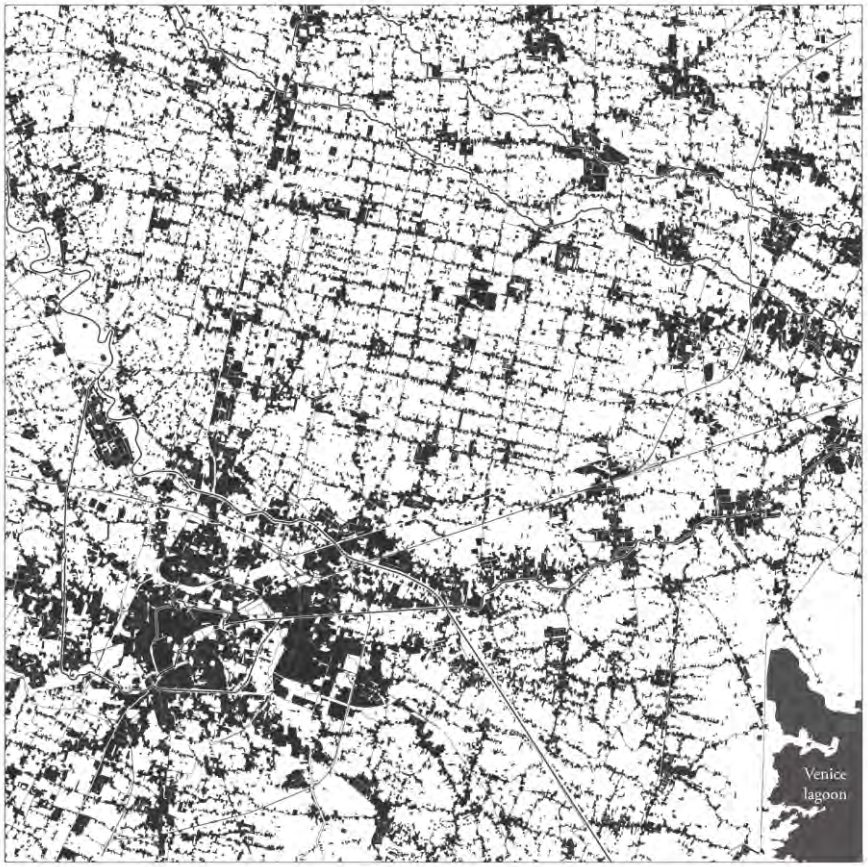

Figure 8 The territory of the Roman Centuriation between Padua and Venice today (Tavone, 2018)

The two preceding examples describe the underlying logic embedded in the subdivision process and the scalar impact of the system. Miletus describes the beginnings of the planned city and the intentional construction of a physical settlement based on the political structure that, spatially at least, balances the obligations of the collective and the rights of the individual. Roman expansion builds on this logic to enact a system that organizes not only the local distribution of land but also the organization of a nation, or an empire.

This methodology continued as the foundation of the subdivision of land throughout the first and second millennia, to a greater or lesser extent, including as it was adopted by the colonies in North America, and then the emerging nation, the United States. These are exemplified by Penn's plan for Philadelphia and the Land Ordinance of 1785, outlined in the following section.

2.3. The Colonial World

While Miletus and the Roman planning process exemplified a logical systemization of land subdivision, the remoteness in time of both belies the impact of the systems. It is difficult to see what the future held for Miletus, or for the Roman systems, because much of the ancient world has been lost. However, through more recent efforts, primarily in the Colonial World, it is possible to track and understand the additional value these systems had on the development of human settlements.

In the case of William Penn's plan for Philadelphia, the underlying logic of Miletus is clear. Penn lays out a very simple plan for the founding of the colonial town, straddling the land between the two rivers. In it, he places a central square, that was originally intended to remain an open space, and is, at least spatially and hierarchically, reminiscent of the Axis Mundi of ancient Rome. It locates a point of departure for the survey and subdivision of land into two distinct categories, public streets and squares, and private blocks and a parcel system for private development.

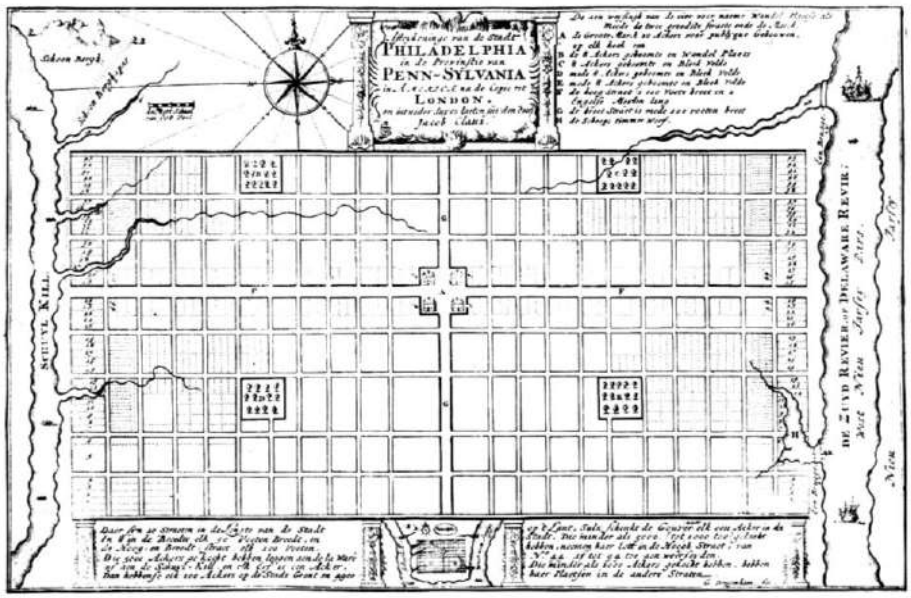

Figure 9 A Portraiture of the city of Philadelphia in the Province of Pennsylvania in America (Penn and Holme, 1684)

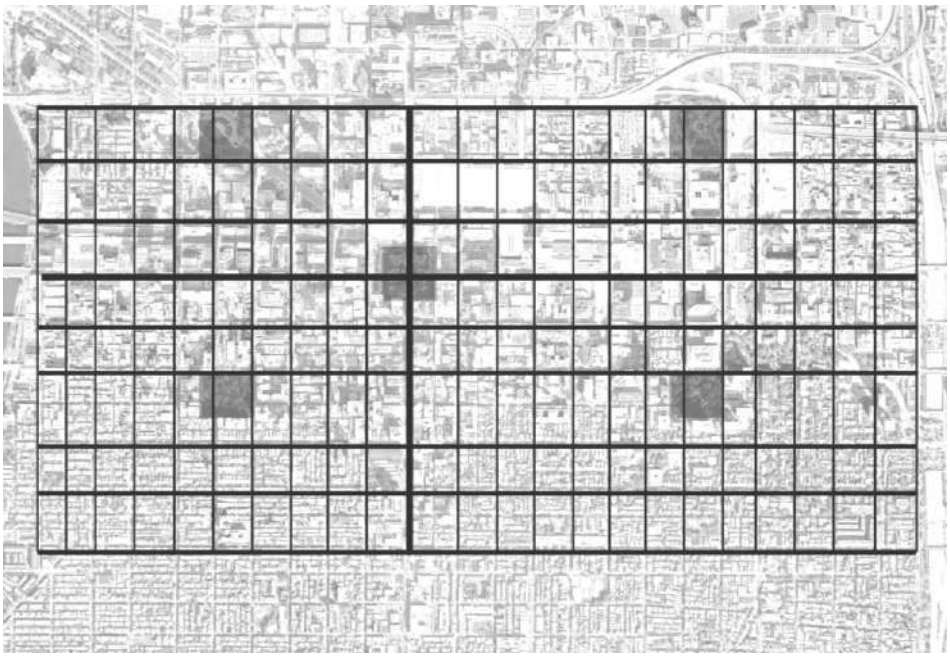

Figure 10 Penn's plan still visible in Philadelphia today (Google Earth, 2019)

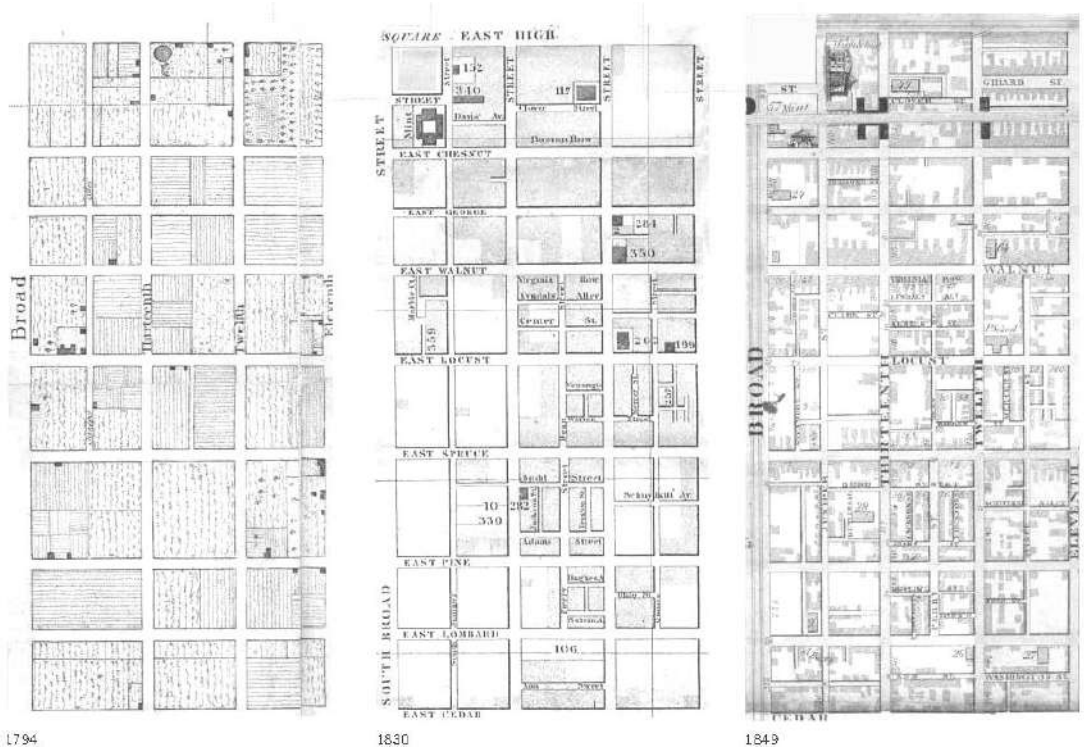
Unlike Miletus and the ancient Roman world, we don't have to speculate to understand the outcome of this planning platform over time. It exists today, in a form that could never have been conceived by Penn at the time of its original implementation. The series of public rights-of-way that his plan laid out are still in existence today; not as excavated ruins but as thriving streets in a large, dense city.

Figure 10 demonstrates the resilience of the simple subdivision plan, and its ability to accommodate, or adapt to, a future that could not have been contemplated at its outset. However, the basic characteristics of the plan remain. The city is a dense network of public rights-of-way that provide an environment that facilitates diversity of projects, walkability and efficiency of resource distribution. The same streets that once carried horse and buggy are now carrying automobiles and, beneath the surface, power, water and other utilities that keep the city running.

Understanding the city as it exists today, and the significant difference in uses and development from its original time is a clear demonstration of the adaptability of the system, but even more demonstrative is the tracking and analysis of the development process over time, understood at intervals, and clearly illustrating not just the ability to adapt to the 21st century, but to adapt to all changes across the more than 330 years since the plan was put to paper.

Figure 11 indicates a series of plans that identify development at different stages of the city's existence. From this, it is possible to understand how the system of subdivision (highly connected streets and small blocks) could originally be occupied as agricultural plots, then move through a series of continued redevelopment from small residential buildings to more dense, more diverse buildings and projects, finally ending up, today, as an extremely dense, high-rise laden city, accommodating far more people, activities and technological advances than could have ever been conceived of at its inception.



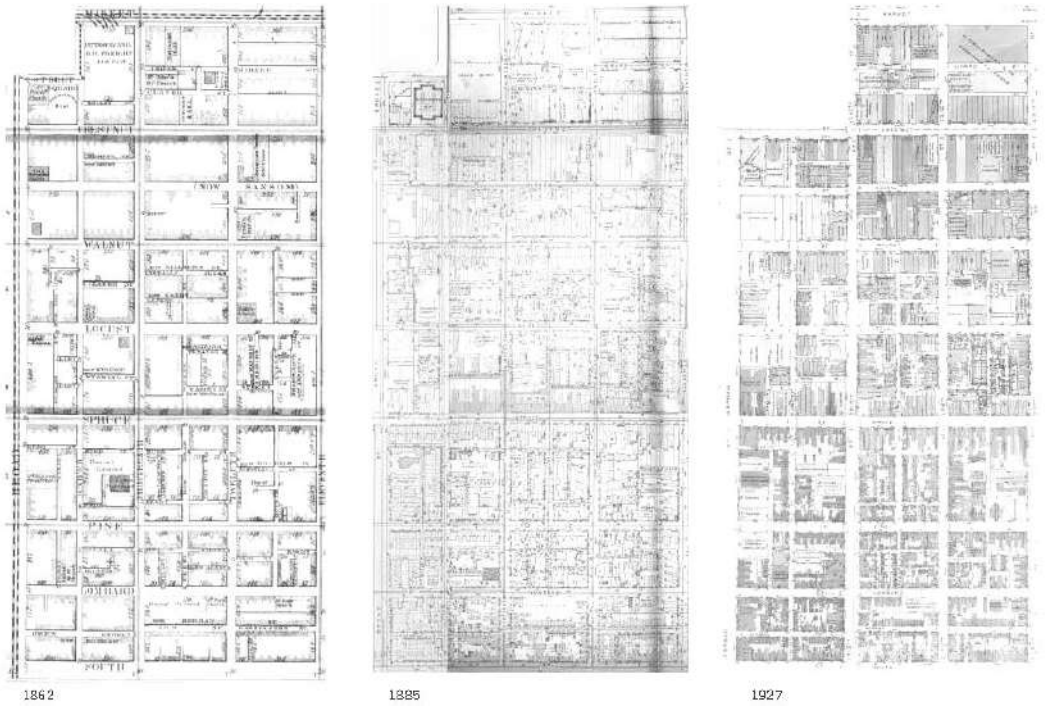


Figure 11 Philadelphia's evolution 1794-1927 (Allen, D., Green, D., Knight, P. 2013)

This series demonstrates the adaptability of the system of subdivision that was the bedrock of city organization and planning for more than two-thousand years. In forms more or less the same, cities such as New York, Buenos Aires, Delhi, Sydney, and Alexandria, Egypt have carried these basic characteristics in their initial conception and execution. But it is the Land Ordinance of 1785 that recaptures the larger-scale intention of the Romans and reconceives of it as a method for large-scale organization and subdivision of land at the national level.

Prior to the Revolutionary War between the United States and England, land in the colonies was allocated through the process of surveying parcels, staking a claim to those parcels, and then working or developing the land. Cities in the colonies, as with other cities at the time, were planned, but the general larger-scale surveying was performed by companies engaged in the speculative selling of staked claims.

After the war however, it was necessary for the nascent federal government to raise money to pay the debts of war, particularly to the soldiers who had fought in it. This resulted in a conceptual leap in terms of the subdivision of land in the country's expansion. Instead of requiring land to be surveyed prior to identification and sale, the Land Ordinance of 1785 and the Northwest Ordinance provided a method for projecting a system of subdivision and organization into territories that had yet to be surveyed. This system was derived from the ancient Roman system discussed above, however the system itself was structured to provide for the particulars of post-colonial America.

The challenge was simple at the time; how does one organize and manage land that had yet to be mapped or occupied. The specific solution was innovative and provided a surveying and organizational method that resulted in a geometric grid to guide the future growth of the nation, which continues today as the major organizational structure for the country.

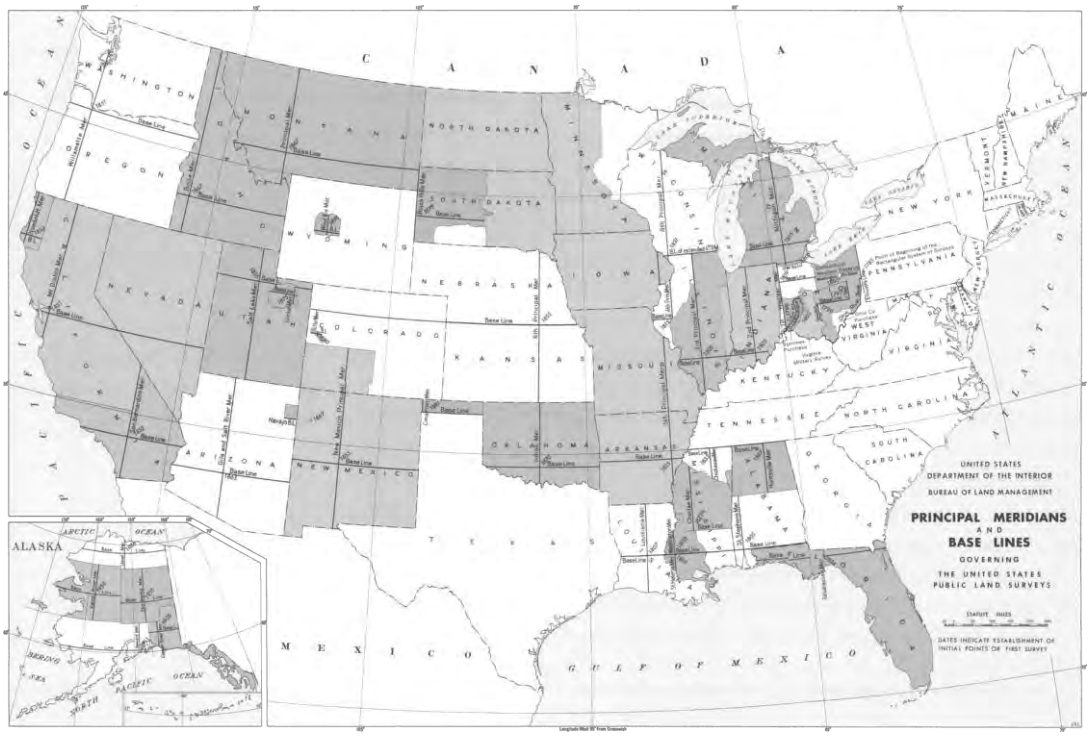

Figure 12 Principal Meridians and Base Lines governing the United States Public Land Survey System (United States Geological Survey, 1988)

One of the primary outcomes from the 1785 Ordinance is its capacity to divide the scale of the country into manageable units. By linking a system of measure with a system of survey, occupation, and development, the Ordinance provided a highly adaptable system for future growth. This resulted in the Public Land Survey System, a system that provided a national framework, the Principal Meridians and Base Lines, townships, sections and subdivisions of land to 2.5 acres.

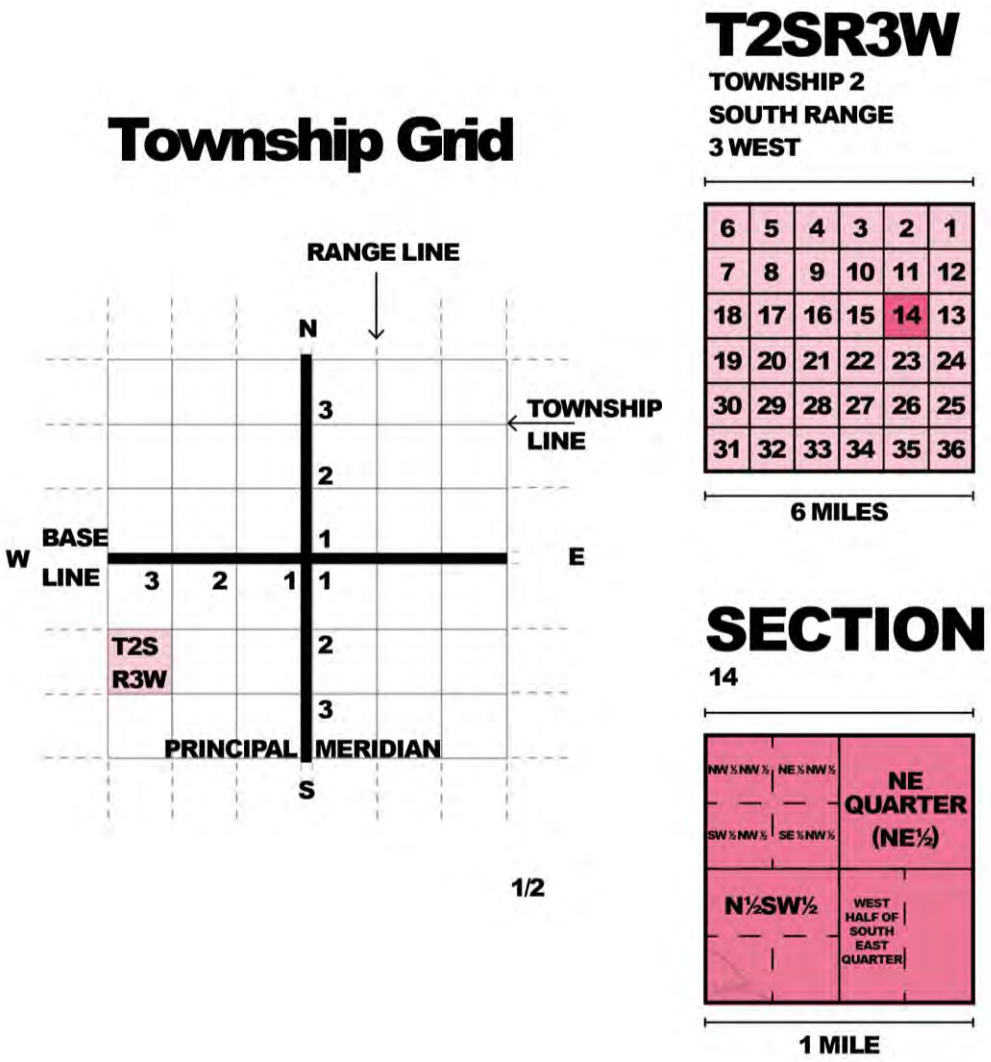

Figure 13 The Public Land Survey System (United States Geological Survey, 1988)

The United States has changed dramatically over the intervening 232 years since, yet the Ordinance still provides an adequate framework. Because its divisions were based on a set of dimensions that have proven to be flexible and useful over time (within the Imperial measurement system), any development that has occurred since the first survey has been successfully accommodated into the framework.

As with Philadelphia, the US Land Ordinances are still present in the development and operation of the nation. And as with Philadelphia, the system can be analysed and understood based on its ability to accommodate change across over more than two hundred years, and its impact can be evaluated based on its implementation.

The system has accommodated and impacted everything from agricultural uses to the form of cities across the country. However, it is important to note that, as with the Roman Grid, the Ordinance had limited discussion of land uses and instead focused on land subdivision. In fact, the only designations of use were tied to the requirement for certain sections of new townships to provide for public places, such as schools and a courthouse, much as Miletus restricted its designation of land uses to those public facilities required for the proper functioning of the city.

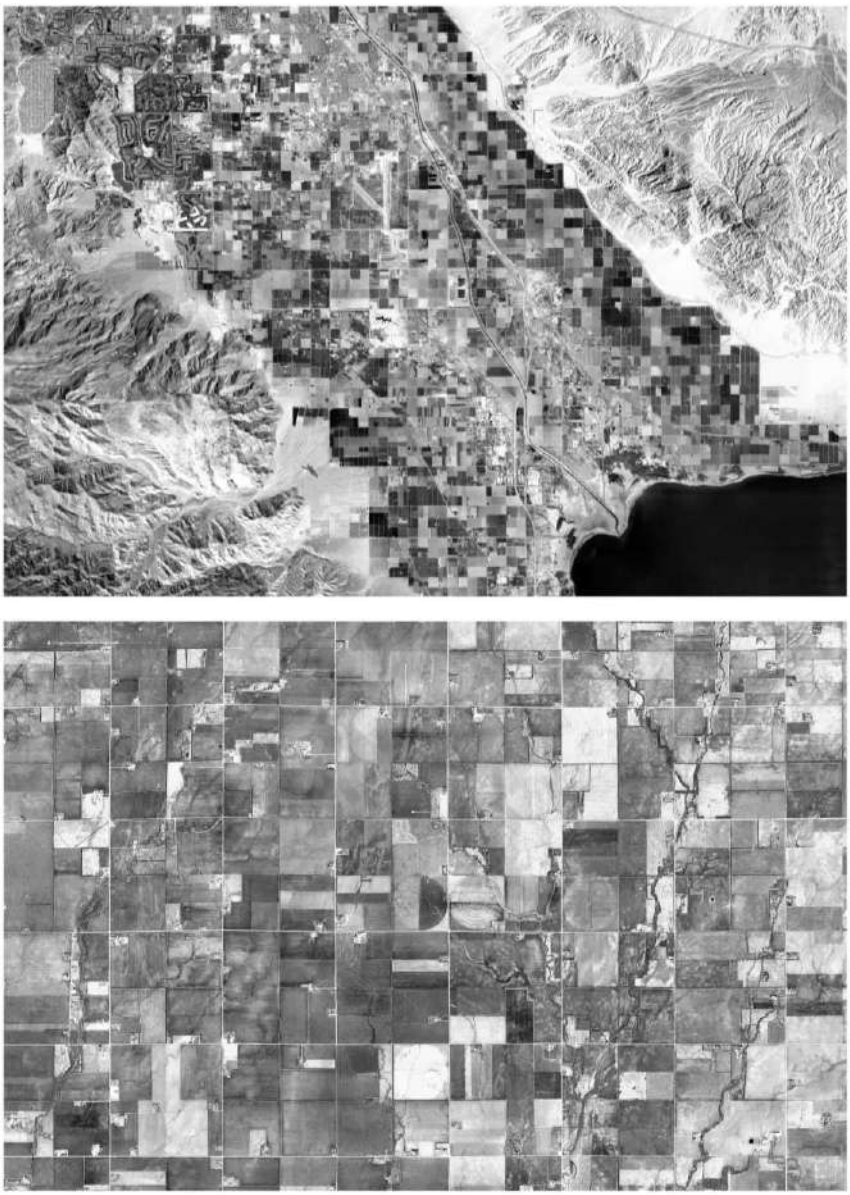

Figure 14 Results of PLSS today (Google Earth, 2019)

In practice, as the Ordinance informed land development and use, the quarter section emerged as the primary dimensional unit, a square a half mile on each side. This had the consequence of providing a development pattern that was connected at least at this scale, from agricultural use to the suburban expansion of cities. This proved beneficial in areas developed within the context of the Ordinance because it reduced the probability of extremely large, disconnected patterns of development that led to the suburbs of the east coast that weren't under the dimensional constraints of the Ordinance.

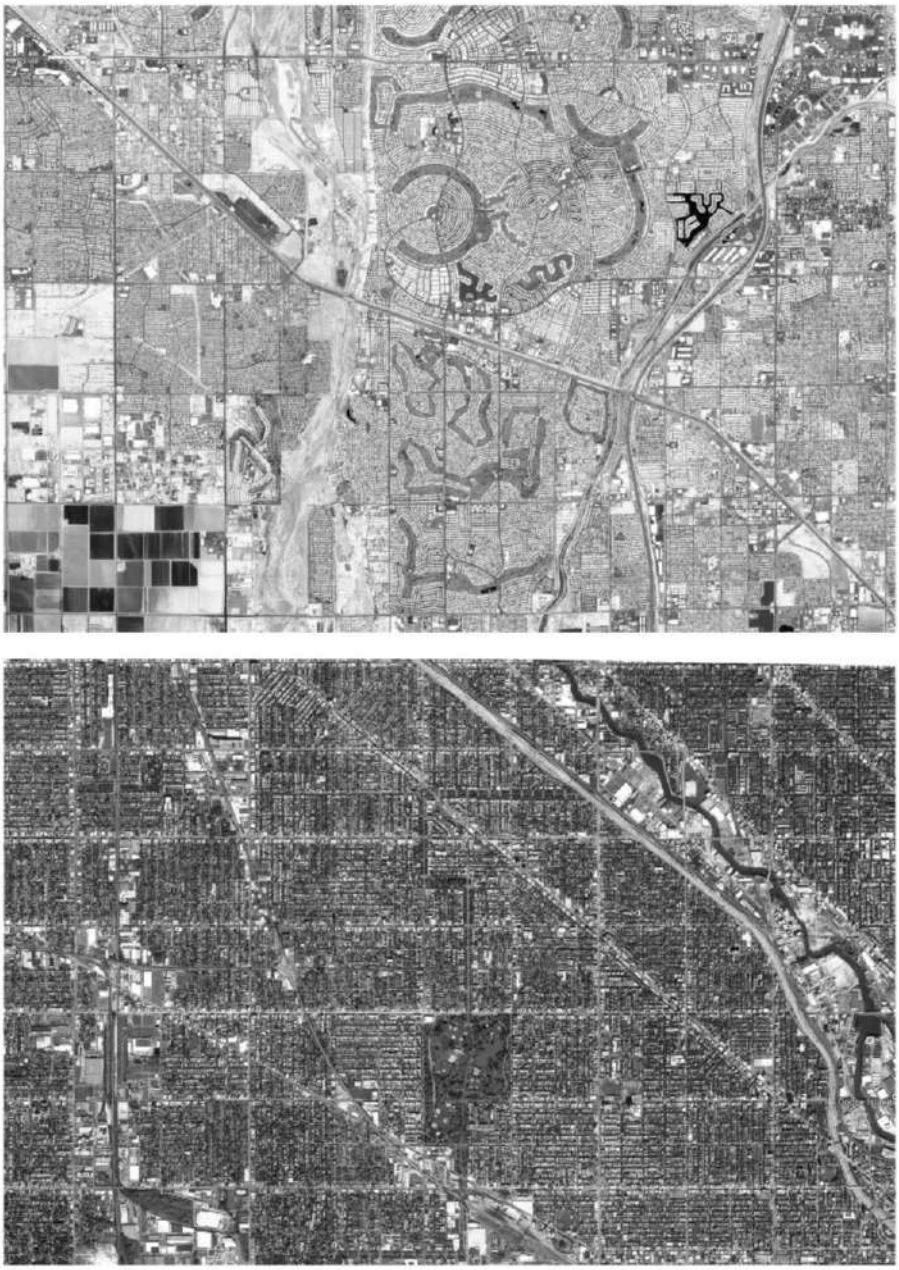

Figure 15 Results of PLSS today (Google Earth, 2019)

Figures 14 and 15 above demonstrate the impact the Ordinance had on development patterns. While the developments internal to the quarter sections are in many cases disconnected developments that follow the twentieth century model of dendritic suburbs, the strength of the section subdivision provides a level of connectivity that would have otherwise been compromised even further, as evidenced in Figure 16.

Figure 16 Suburbs in Georgia today (Google Earth, 2019)

Both Penn's plan for Philadelphia and the Land Ordinance of 1785 had practical applications and benefits to the planning and settlement process. However, they also provide a basic conceptual framework for understanding the methodology and impact of the process, and this is illustrated below.

3. Concept and Methodology for a National Ordinance

3.1. The Concept of Constitutional and Economic Orders

While the notion of a national ordinance seems to pertain to primarily large-scale planning actions it also has its roots in the physical planning of cities. Because of this relationship it is necessary to address the fundamental structure of cities to be able to more fully understand the underlying logic and application of the National Ordinance.

As evidenced in both Miletus and Philadelphia, cities that were planned, prior to the twentieth century were constituted through a simple projection of the streets and blocks that would define the physical attributes of the emerging city. At its core this action provided direction in determining the areas of the city that were to be public (streets, parks, public buildings and other parts of the city that are held by the collective) and those that were to be private (blocks and parcels for houses, offices, shops and other parts of the city that are held by the individual).

In this structure there is further identification of the two orders of land areas that are created with the constitution of a city, town or settlement. The first, aligned with the public realm, is the Constitutional Order, which is political in nature. The second, aligned with the private realm, is the Economic Order.

Every city has this a Constitutional Order and an Economic Order. They are each comprised of certain elements of the city. The Constitutional Order includes boundaries, streets, public gathering places, monuments and other collectively held, public elements of the city. The Economic Order includes development parcels, houses, farms, offices, restaurants, heavy industry, and other privately held elements of the city.

The Constitutional Order brings the collective structure of cities into being with elements that connect the past and future of the city and its inhabitants. These elements are permanent and last through time and through the changes in the city. In most parts of the developed world, the Constitutional Order is controlled by Subdivision Regulation, or some similar regulatory framework.

The Economic Order brings the individual structure of cities into being with elements that provide the operations of the city. These elements are much more transitory and tend to follow market and other external fluctuations. These elements are generally referred to as uses and are controlled by Zoning Regulations, or some similar regulatory framework charged with use allocation and distribution.

This is a series of important distinctions that illustrate the difference between these two basic elements of human settlement.

The figure below describes a diagrammatic interpretation of the two Orders and their relationship. It also demonstrates the need for the Constitutional Order, that which is made up of the permanent elements of the city, to precede the Economic Order.

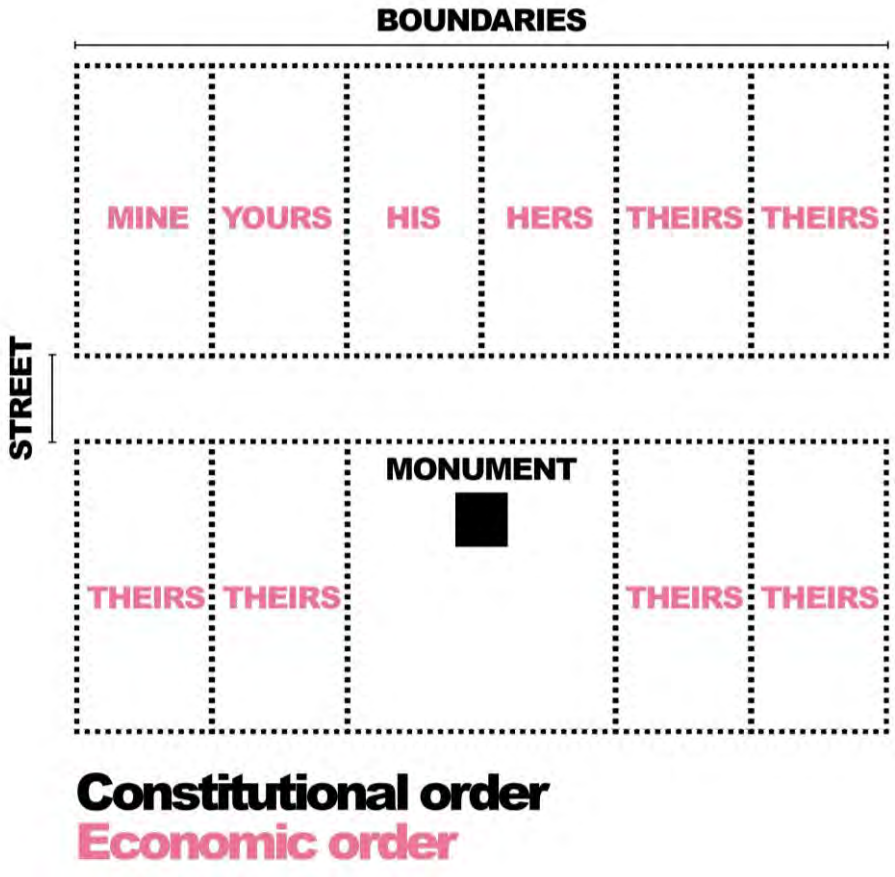

Figure 17 Constitutional and Economic Order of the city (Allen, D., Green, D., Knight, P. 2013)

3.2. Subdivision Dimensional Methodology

The dimensional construct and mathematical logic of a system of subdivision have significant impact on the functionality and efficacy of the system. This is evidenced by the adoption of the Gunther's Chain as the primary tool for surveying from the late sixteenth Century through to the early twentieth century. This simple tool with the parallel 10-based and 4-based measurement system set a course for much of the United States to be subdivided on a 66-foot module (which gives us the dimensional basis for everything from the Public Land Survey System to the Commissioners Plan of 1811 for the city of New York.

As a precursor to adoption of the dimensional construct for the Kuwait National Ordinance, two base numbers were analysed to determine the value of each as the foundation for the Ordinance. Both a 6-base system and a 10-base system were analysed to determine the most highly composite numbers.

Firstly, the number '10' is not as flexible or as fungible as '12'. '10' has four divisors and can only be divided wholly by 1, 2, 5, and 10. Any and all other divisions will result in a remainder. '12', on the other hand, has six divisors and can be divided wholly by 1, 2, 3, 4, 6, and 12. Because of these additional divisors, '12' is a more workable and fungible number than '10'; '12' has more utility than '10'. More divisors result in a number that is able to adapt to more situations, making it easier to respond to a range of needs.

Figure 18 below outlines the spatial implications of the analysis.

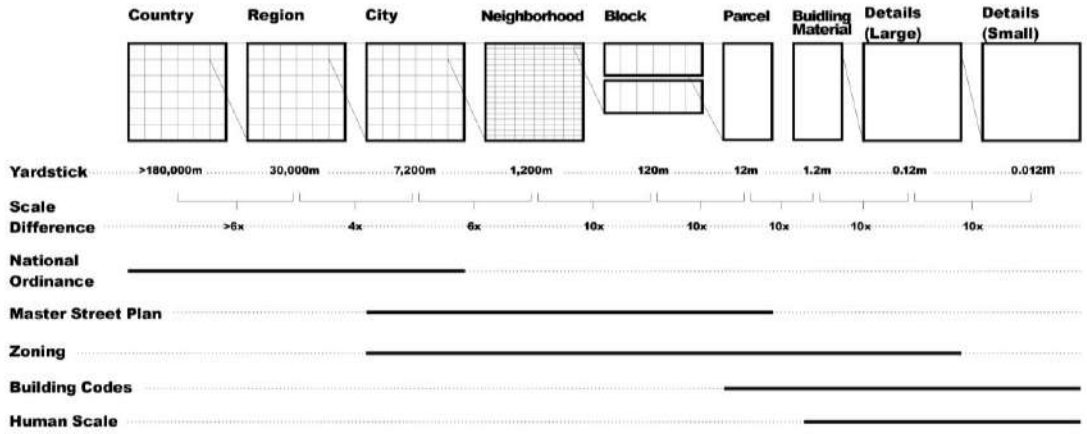

Figure 18 Theoretical subdivision based on the logic of 12 (©Knight, P.)

Numbers are repeatedly subjected to multiple subdivisions. Halving, for example, is perhaps most common; in fact, it is embedded in our own DNA. Twelve-hundred and its resultants can be halved four times before encountering fractions (1200 to 600 to 300 to 150 and finally to 75) while 1000 can be halved only three times (1000 to 500 to 250 to 125). But halving is not the only common method of subdivision. Thirds and fourths make frequent appearances throughout our daily lives. With this in mind, the numbers have been analyzed to determine their behavior when subjected to successive iterations of subdivisions by quarters, thirds, and halves. That exercise is shown in the two diagrams below (note that the "censor bars" are covering fractional numbers; only whole numbers are counted in this exercise).

COMMON DIVISIONS	1/4	1/3	1/2	2/3	3/4
1,000	250	-	500	-	750
750	-	250	375	500	-
500	125	-	250	-	375
375	-	125	-	250	-
250	-	-	125	-	-
125	-	-	-	-	-

COMMON DIVISIONS	1/4	1/3	1/2	2/3	3/4
1,200	300	400	600	800	900
900	225	300	450	600	675
800	200	-	400	-	600
675	-	225	-	450	-
600	150	200	300	400	450
450	-	150	225	300	-
400	100	-	200	-	300
300	75	100	150	200	225
225	-	75	-	150	-
200	50	-	100	-	150
150	-	50	75	100	-
100	25	-	50	-	75
75	-	25	-	50	-
50	-	-	25	-	-
25	-	-	-	-	-

Figure 19 Generational subdivision (Allen, D., Green, D., Knight, P. 2013)

Generational subdivision is defined here as subsequent divisions of both a number and its resultant "offspring" (e.g., 600 is an offspring of 1,200, being half of 1200; 600 itself can then be subdivided further). The diagrams above reveal the superiority of 1200 over that of 1000: 1000 only has 5 generations of subdivisions, while 1200 has 14 (i.e., 1200 is almost three times more flexible than 1000). Additionally, the "offspring" of 1200 are themselves superior to the "offspring" of 1000. The numerical fungibility of "twelveness" passes from generation to generation. This is a simple observation and characteristic of mathematics and nothing more; however, it can be readily utilized in planning.

4. The 21st Century Kuwait National Ordinance

4.1. The Vision for Kuwait

Livable places are those where people want to live, work, visit and are attractive for development. The most livable countries in the world are ones that people are drawn to because of economic opportunity

and the high quality of the living environment. Livable cities are vibrant and diverse and they have evolved over time to create complex and compelling environments rich with economic and cultural interactions and expansion. Livable places are more prosperous and their populations happier.

To deliver the vision for Kuwait's future, creating livable places in Kuwait is fundamental and the challenge is to move away from a lifestyle that has become internalized and embrace the external spaces between the buildings.

In order to realize the full potential of the country, the urban areas must be more livable using the rich cultural and urban history, diverse and complex population, strong economic foundation, and collective desire to foster transformation. Kuwait as a country has a strong foundation upon which to build this future vision. The metropolitan area of Kuwait is already a diverse and vibrant place, and by 2040 it will have a higher quality built environment with a human-focused public realm and improved connectivity.

Locating jobs close to where people live is an important part of the 4KMP vision for a livable Kuwait. To this end new settlements outside of the KMA are planned to have economic activities and drivers to support local populations and to give each area an identity and individual character.

To create livable places, the Plan will promote a higher mix of activities in our urban areas generating higher levels of street activity and increase development density around transport nodes. More optimal use of the land will occur, with the many undeveloped plots within the metropolitan area being prioritized for development. As we grow outwards from the metropolitan area into new settlements in the north and south there will be a greater emphasis on placemaking – that is, creating places where people want to live and work.

The National Ordinance is a critical component to the 4KMP2040 because it is the mechanism through which the State can ensure that future development is highly connected and adaptable, as well as to ensure that resources and efforts are being directed in the most efficient and beneficial way possible. In order to do this, it must operate within two parallel constructs. The first is the spatial construct which is concerned with the physical disposition of the subdivision of land while the second is the analytical construct, which is concerned with the management and analysis of data across the country as it develops and redevelops.

4.2. The Spatial Construct

From a spatial perspective, the entire country has been organized around a GIS-based grid set on a 6-kilometer square pattern. This specific dimensional pattern allows for subdivision to 1.2 x 1.2, .6 x .6, .3 x .3 and .15 x .15 kilometer cells that provide a spatial construct down to the scale of the individual block.

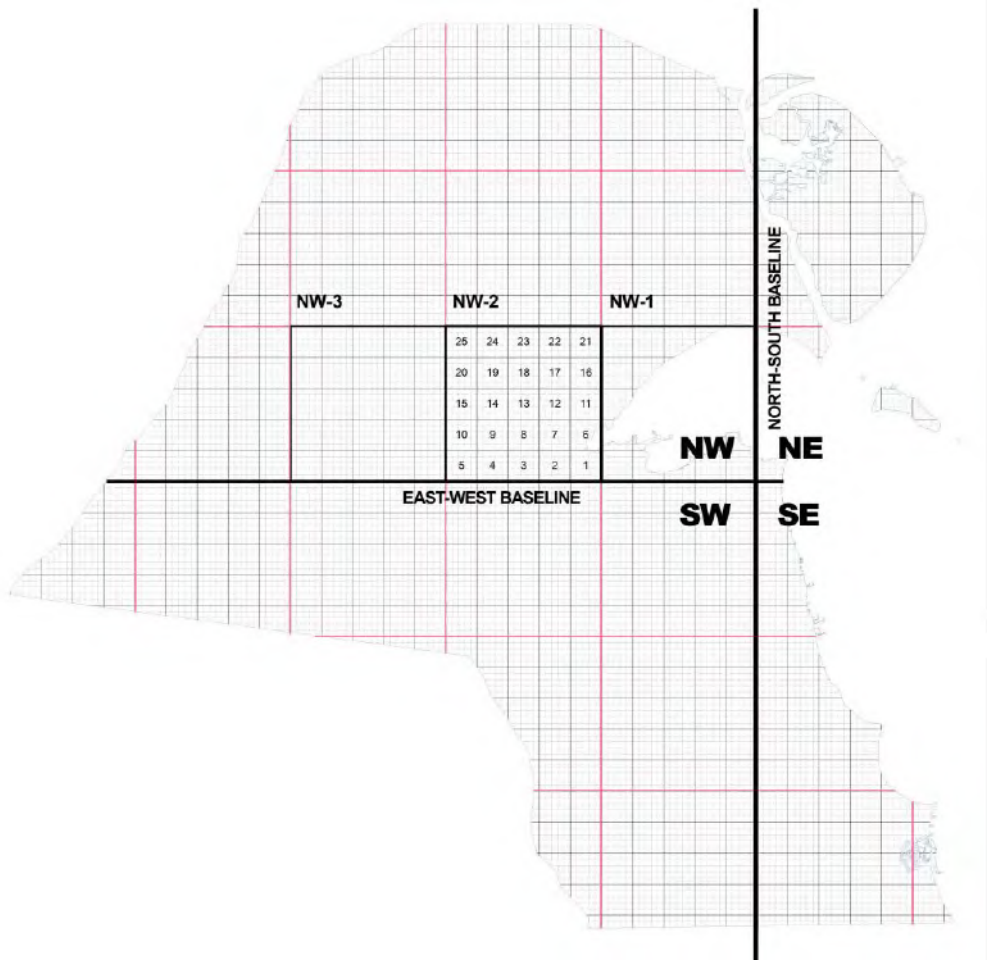

Figure 20 Kuwait National Ordinance and Coordinate System (©Fourth Kuwait Master Plan)

Figure 21 Kuwait National Ordinance – Planning Scales (©Fourth Kuwait Master Plan)

In terms of the spatial structuring of future development, the National Ordinance projects a grid across the entire land area of the country, with the smallest cells in the grid structure set at 150 meters square. The notion behind this is that the grid is a projection of future street centrelines that, when implemented in this fashion, result in development patterns that are highly connected and produce block sizes that are dictated by the Zoning Code. It is not the intention that all new planning and development follow this specific spatial pattern, rather that the logic with which the spatial pattern is structured should be incorporated into all new development. And, to the greatest extent possible, new development should follow the grid pattern, without compromising the quality of the places resulting from future planning processes.

It is incumbent upon future planners and designers to make the case for breaking the logic of the National Ordinance, and this should only be done when it can be shown to more successfully support the Principles upon which this Plan is based, primarily connectivity and adaptability. It is also necessary that future plans support the National Ordinance as the vehicle through which a consistent development pattern across the entirety of the country will emerge.

The series of diagrams below explain the planning structure in terms of its scalar implications and the resultant physical disposition in the planned areas.

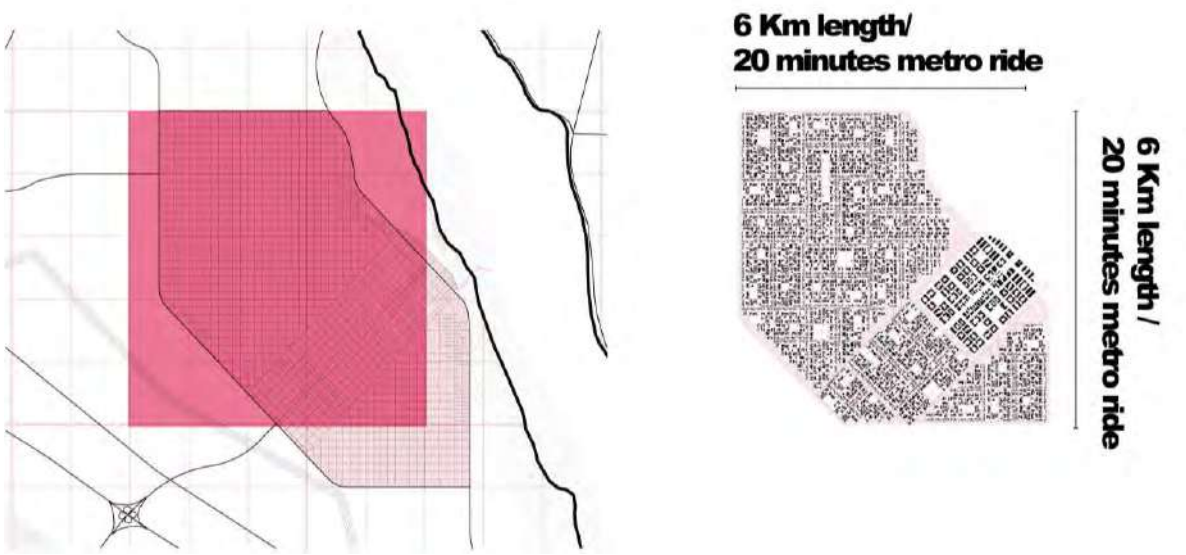

Figure 22 6Km x 6Km grid (©Fourth Kuwait Master Plan)

Figure 22 demonstrates the six-kilometer scale that is used to plan larger areas such as new towns and cities and larger areas of agricultural or other broad uses. The plan indicates a general conformance to the underlying grid, while also providing an example of discontinuity to foreground a contextual issue, in this case alignment with the coast.

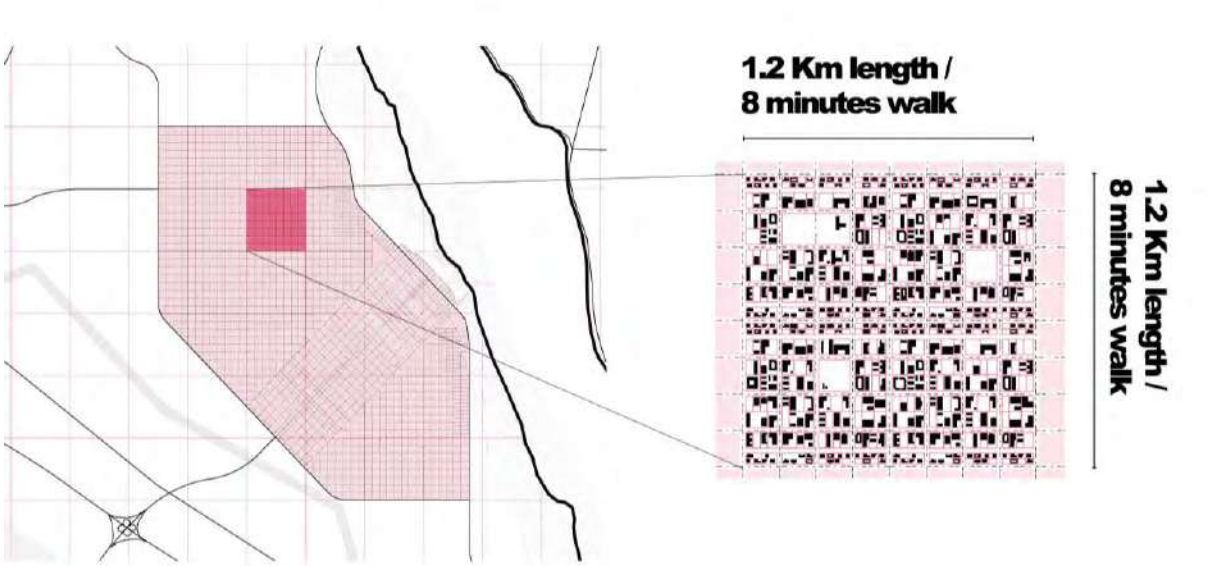

Figure 23 1.2Km x 1.2Km grid (©Fourth Kuwait Master Plan)

Figure 23 demonstrates the district level planning framework at the 1.2 x 1.2 kilometer scale. This scale is generally aligned with the maximum walkable distances to perform daily tasks as well as reaching the limits of walkability to a transport stop.

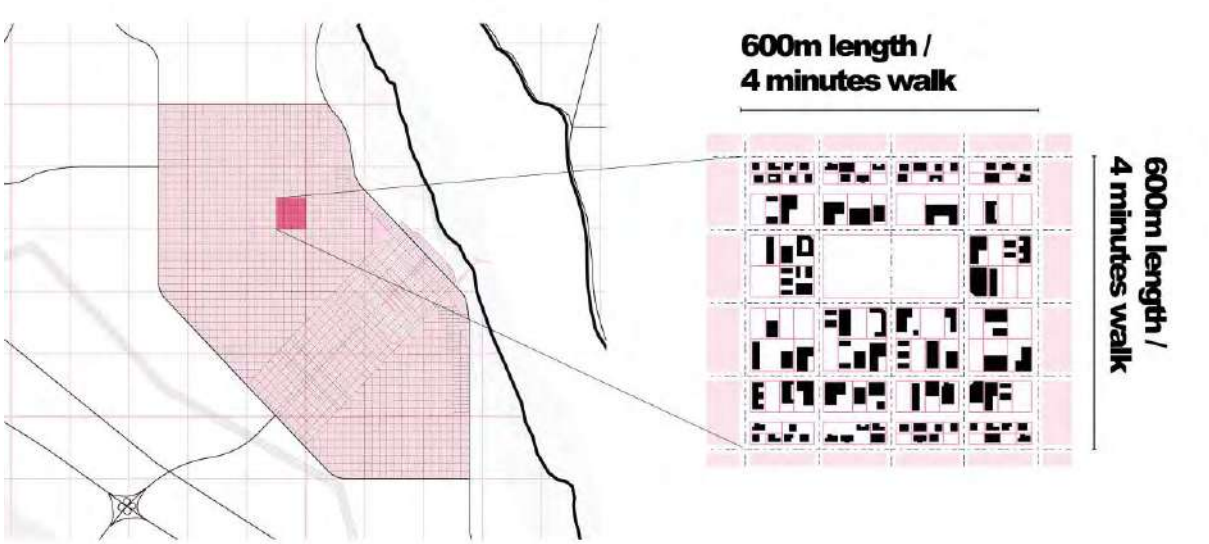

Figure 24 1.2Km x 1.2Km grid (©Fourth Kuwait Master Plan)

Figure 24 demonstrates the small neighbourhood level planning framework at the 600 x 600 meter scale. This scale is generally aligned with comfortable and convenient walking throughout the neighbourhood and to reach transport stops.

Figure 25 150m x 150m grid (©Fourth Kuwait Master Plan)

Figure 25 demonstrates the most granular scale, 150 x 150 meter cell size, which also correlates directly to city blocks. It provides an opportunity to follow the dimensional criteria of the Ordinance, utilizing the cell lines as centrelines of projected future streets. The resulting block size has a perimeter that is generally in the range of +/- 480 meters, or 120 meters on each side. This block size is adaptable, walkable and in line with benchmark cities that are described in section 2.

The series above clearly demonstrates the nested dimensional logic of the system. Whether working from a broad regional strategy at the 6 kilometer scale planning for a small neighbourhood, or even the individual block, the system facilitates consistent planning to ensure that decisions made at one scale do not adversely affect the planning structure at either larger or smaller scales.

4.3. The Analytical Structure

In terms of data analytics and management, the National Ordinance provides a neutral platform to objectively evaluate characteristics and indicators across various scales throughout Kuwait. The scalar structure is parallel to the structure of the spatial planning construct.

For analytical purposes, the same grid that is superimposed over the country for spatial subdivision is also used for data management. All accessible data is incorporated into the GIS database and grid platform upon which the National Ordinance is structured. The data is aggregated and disaggregated at scales from 6 kilometer square cells to 150 meter square cells. The data is then used for analysis and management of development according to the information and outputs required in the processes. This process allows for a much more rigorous analysis of decisions regarding all aspects of the planning and development process, ensuring appropriateness of planning actions.

It is also critical to the parallel system outlined in sections 3.1 and 3.2 that provide a platform for both spatial distribution as well as analytical analysis; management of assets across the country and projections and tracking of future development. Figure 26 below is a projection of the future development in a new town in the northern part of the country (Subiyah). The cells represent both the projected physical structure of the new town as well as the use types and intensity distribution in the initial projections. In this scenario the entire new town is highly connected, but the distribution of

residential, commercial, green spaces and industrial uses are spread throughout the area, indicating nodes of highly intense development and areas of less intense development.

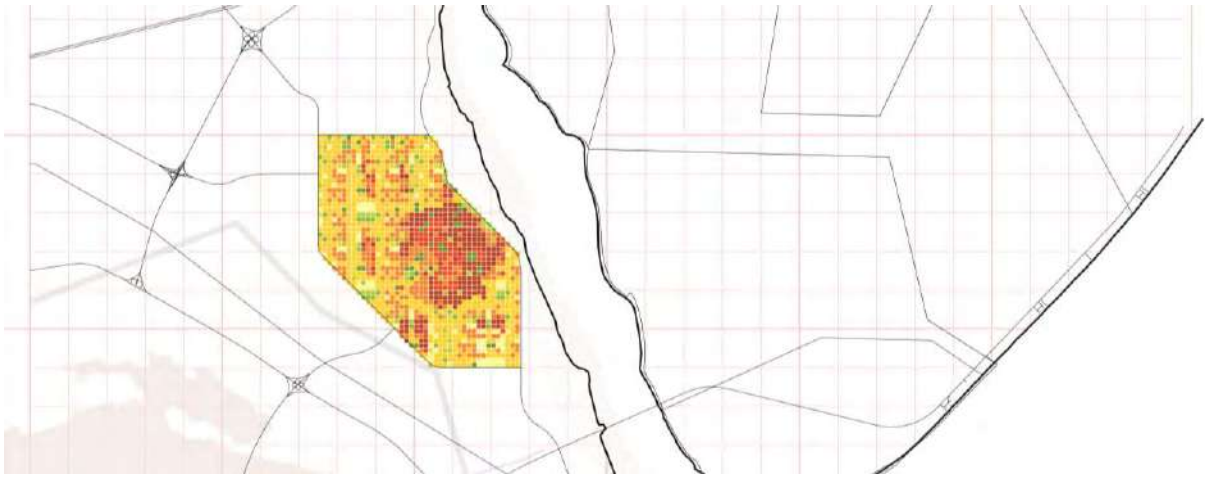

Figure 26 Example of Data Aggregation at Block Scale 150m x 150m (©Fourth Kuwait Master Plan)

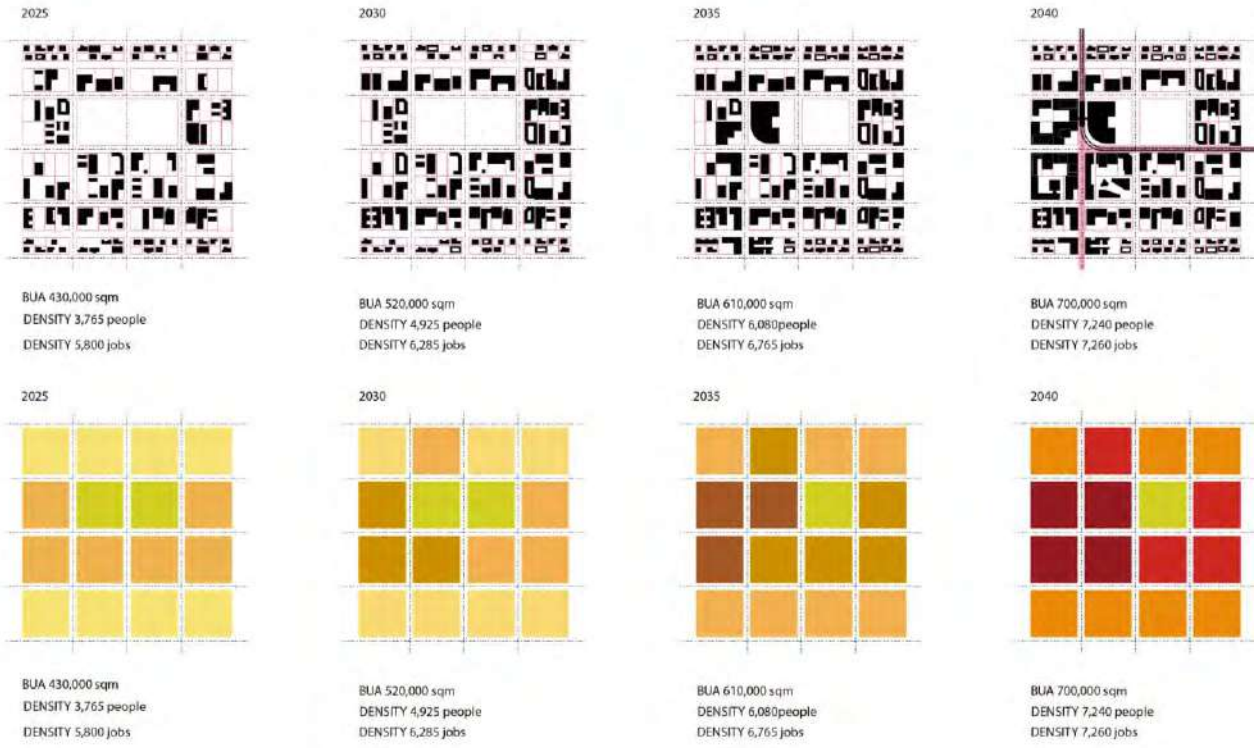

Figure 27 Example of neighbourhood performance and trackability, 5 years interval targets (©Fourth Kuwait Master Plan)

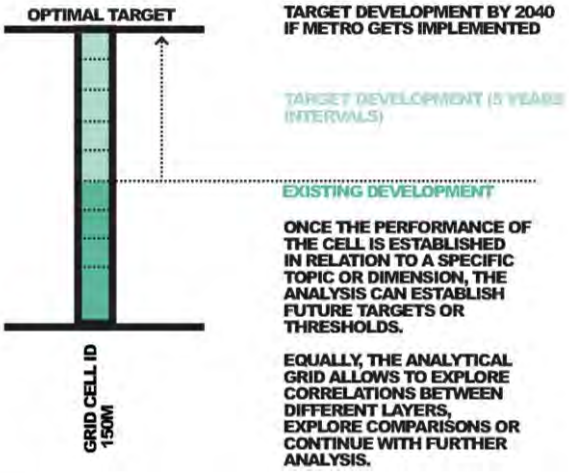
Figure 28 below introduces the format for communicating data around the key indicators for connectivity, although there are also similar formats for economic activity, place development and supporting systems (utilities, legal, resources). The charts provide specific data around modes of transportation, including auto, metro, bus, cycle and pedestrian trips. These data are derived from an existing conditions analysis that sets the current gross number and percentage of trips that can be attributed to each mode. The lower charts show the same information, in matrix format, for each 600 meter x 600 meter cell, or portion of cell that is included within the area boundary. In each cell the current quantum is indicated as a percentage of overall projected, targeted quantum at year 2040.

This demonstrates both the quantum needed to fulfil the projections as well as the relative percent increase across all cells. The intent is to identify those modes of transport, in this case, that require the highest level of additional investment, or those that have otherwise increased in the baseline indicator data. This system works as both a detailed projecting and tracking platform for indicators across all sectors as well as a graphic representation to clarity intensity of existing and projected conditions. It further allows for analysis at both the study area scale as well as across larger municipal or metropolitan areas.

Finally, it provides a system to balance the relative successes and failures to attain targets across sectors and draw correlations between sector projects and initiatives that are tending to drive change consistent with the overall master plan and those that are performing counter to the projections.



2040		NW-25-15-2	NW-25-15-1	NW-26-6-3	NW-25-10-4	NW-25-10-3	NW-25-9-4
MODAL SPLIT	Walking Trips	70	135	28	697	972	34
	Bus Trips	187	361	73	1,857	2,592	92
	Cycle Trips	47	90	18	464	648	23

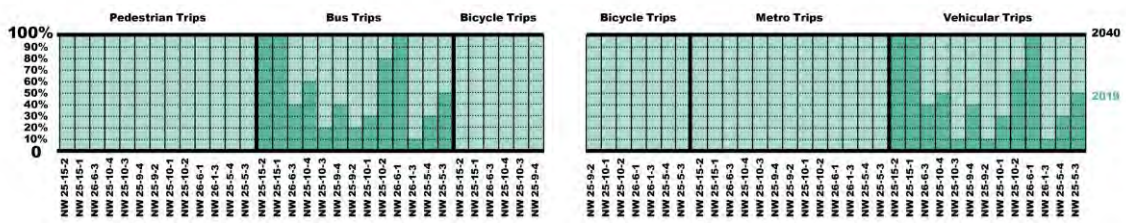

Figure 28 Data and Graphic Indication at 600 meter scale (©Fourth Kuwait Master Plan)

Figures 29-31 below increases the scale of analysis to 150 x 150 meters. The specific area is selected due to the projection of a future metro station which is critical to the overall performance of area and is set up as the key trigger for development in the area. In this scenario, a specific connectivity methodology for identifying metro catchment areas was used to determine the area of impact due to construction of the metro station. This area will have a significantly higher level of both gross trips as well as percentage of metro trips due to its proximity to the station. While the remainder of the Action Area can be evaluated at the broader, 600 meter x 600 meter scale, it is critical to understand a more granular distribution of trips and movements to more accurately plan for the future metro and to manage development in the catchment area to ensure it positively supports the performance of the metro station and broader public transportation system. This area will have the biggest impact and as such should have the highest level of accuracy in analysis. This also demonstrates the capacity of the system to operate at the national and extremely local levels simultaneously.

5. Conclusion and Next Steps

The world is currently facing challenges that are significantly more complex than at any time in its history. The impact of the decisions that the planning and affiliated professions make in the coming decade have the potential fundamentally alter for the better the current course the planet is following. However, this can only succeed with a shift to a more objective and cross-sectoral planning and analysis process. Effects of these decisions on climate change, public health, resource management, and myriad other elements of human inhabitation must be considered within a balanced and interrelated platform. Planning must move closer to the dispassionate practices of the scientific community.

The research and work demonstrated above is represents a significant move in this direction. The underlying analytical and spatial platforms are agnostic towards outcomes and supportive of a rigorous methodology in determining existing conditions and resultant projections stemming from future targets, themselves derived through a deep analytical process.

Further, the platform provides an opportunity to move beyond static regulatory practices and implement a much more progressive, adaptable and updatable system that is highly responsive to changes occurring across all sectors. The notion that a master plan, or more accurately, a comprehensive plan, should be a static document and set of regulations is no longer tenable. Looking to guidance from twenty or thirty

years, or even longer, ago will not provide planners today with the information required to make necessary and accurate decisions.

Figure 32 above represents the balanced spatial and analytical information and projections for an entire country, as is most beneficial at the current time. However, built into this plan is the necessity for modifying the projections as new information emerges.

As we plan for the future of the planet, and the cities we inhabit, one thing is certain. In the coming decades much of the information we have, and the decisions based on that information, will be found to be inaccurate. The Fourth Kuwait Master Plan demonstrates a clear path to addressing this circumstance and providing direction for future planning and development.

Case Study / Project

From one-way to interactivity - difficulties and strategies in the planning of adjacent areas of metropolis

Liang HE

Abstract

The Yangtze River Delta metropolitan region is one of the six largest urban agglomerations in the world. Its regional integration development is a key point of the Chinese government's regional coordination strategy. And also, establishing the Yangtze River Delta integration model zone has become a national strategy. There are a high degree of urbanization, huge population and large economy by nominal GDP in this area. The core area of the Yangtze River Delta is headed to the north and south with Shanghai as the leader. The two regions have been unbalanced for a long time. Among them, the urban agglomeration represented by southern Jiangsu in the north wing region is a traditional rich land in the south of the Yangtze River. The development level and scale are much higher than those in the south wing region, especially the Kunshan Huaqiao. Under the guidance of Rail Transit Line, The level of development is relatively high, and it is closely related to the central city of Shanghai, and it plays the function of the residence of the employed population in Shanghai. In contrast, in the south wing area, the development is relatively slow. From the perspective of the scale and level of urban construction, compared with Jiading and Huaqiao in the north wing, Songjiang, Jinshan and Zhejiang Jiashan in the south wing are currently less connected, and there is no rail transit and other great luck. The amount of commuter transportation is only traditional railway transportation, such as railways and highways. Achieving high-degree coordination between different cities, especially in cross-administrative regions, is the focus of planning and related academic research.

Based on a practical project, this study focuses on the adjacent area of Shanghai. According to the history, culture, ecological space and urban development of Fengjing Town of Shanghai and Jiashan County of Zhejiang Province, the study-from a micro-perspective-analyzed the functional coordination, infrastructure connectivity,conservation of ecosystem and administrative barrier in the process of regional coordination and proposed the following planning strategies: first, preserving Fengjing Ancient Town cooperatively to promote the image of both cities-jointly protect ecological resources such as the water environment; then, building international schools, hospitals, high-quality residential areas and some other projects to enhance the area's vitality , and attract working-age population from Shanghai; finally, replanning the regional traffic, connecting the impasses and improving the infrastructure and service of transit transfer ,such as the intercity railway transfer. Based on the project, this study summarized three major difficulties in a regional cross-border coordination planning: First, a cross-administrative planning involves multiple administrative subjects and usually causes huge costs due to poor communication; secondly, there are conflicts of interest between the two administrative subjects in adjacent areas, increasing the difficulty of planning implementation; thirdly - it is difficult to do a cross-border management and the technical standards are also different.How to solve these problems, the future needs to be further explored and coordinated by multi-participation including urban managers, planners and the public.

Case Study / Project

Rural Revolution

leveraging emerging infrastructures

Jason HILGEFORT

Abstract

There has been a global issue facing the rural, from Italy, USA, to now SEAsia, that has left them behind their rapidly expanding urban centers. Within South East Asia a new model is emerging. In key rural areas, new infrastructures are being leveraged to allow for new opportunities for countryside places within the larger constellation networks of cities. Within China a new model 'Taobao Villages' have emerged. Perhaps the original model is Shaji in Jiangsu Province, China. The origin story of Shaji had a humble beginning. A few local entrepreneurs that learned from production models in urban coastal China and Ikea started their own taoboa shop. Working with local carpenters, they made the first version of the hacked furniture, photographed it and put it on their Taobao shop. They sold a few in the first week and continued to get more demand and business was booming. Very soon, they were fixing up their houses and getting new cars and the whole village was curious about how they made money. As business expanded, they recruit villagers to join their operations and the knowledge of the e-commerce and the business of flat pack furniture spread. Their employees and relatives started to open up their own e-commerce shops. With the low barrier of entry to e-commerce and simple furniture, the village flourished with rapid multiplications of shops and factories making flat pack furniture to be distributed all across China.

The taoboa village model was initiated in a bottom up manner, but in many ways has been supported by the Chinese government. Initially the Chinese government developed a 'how to guide' for rural villages to learn from the model in Shaji. Now, the government is using this mature model to link outside of China. Recently the Chinese government has been working with the Thailand government and locally based on entrepreneurs to evolve this model abroad. Later, in Ningde, Fujian Province, China, an technology entrepreneur from Shanghai has used his patents for high spectral technology [satellite/drone imagery systems for observing plants/soils] to develop a new form of High Tech food villages. The private company worked in association with the local government to identify a few key areas for new villages in a valley outside of Ningde. The villages have been developed to both allow for food production, visitors, and office researchers to reside within.

These 'factories for food' were designed to allow for a mix of living, working and recreation. The developer, thanks to China's current plans to link to eastern Europe and Africa, has plans to repeat this model in other locations. In all of these cases, new technologies [e-commerce, satellite imagery, drones, 4 axis cnc machines] are being used to offer new opportunities to rural communities. Instead of focusing on the nostalgia for the development of rural areas, new systems are being deployed. These focus not on traditional forms of urban planning, but on new technologies to provide new employment models. Some argue they represent the 'industrialization of the rural'. Others point to them more as an embracing of a global reality. Both are true. The rural is no longer 'the other' to the city. In order to survive, they need to use their existing characters to provide and gain from the global network.

Research Paper

Whole-region Tourism Greenway Network Organization Mechanism Based on Gravity Model Flow Measurement

Xue JIANG, School of Architecture, Harbin Institute of Technology; Key Laboratory of Cold Region Urban and Rural Human Settlement Environment Science and Technology, Ministry of Industry and Information Technology; China

Tianyu ZHAO; School of Architecture, Harbin Institute of Technology; Key Laboratory of Cold Region Urban and Rural Human Settlement Environment Science and Technology, Ministry of Industry and Information Technology; China

Abstract

The structure and organization of greenway network is the core stone of greenway planning. Generally, the relevant between point elements and line elements in the network is taken as the focus of quantitative structure evaluation. In this study, the evaluation and organization method of greenway network is based on gravity model flow measurement. Ningan city is taken as an example because of its rich tourism resources and ecological resources. The cost distance formula has been improved in the process. Network flow is allocated to each path in the gravitational model to enhance the scientific evaluation. Firstly, the existing greenway network structure is sorted out and summarized. Minimum cost path method is used to form potential greenway network structure. This structure is divided into two parts, one is based on comprehensive elements and the other is based on general elements. The existing structure and potential structure are combined to form a preliminary abstract network structure. Gravity model is used to measure and classify the traffic among abstract network nodes. Two kinds of greenway network structures are compared and analyzed. On this basis, the greenway network is optimized and verified through field research. It provides a basis for the further planning and implementation of the actual greenway network in small towns

Keywords

small town planning, greenway network, Whole-region tourism, gravity model, flow measurement

1. Introduction

Greenway construction and development has entered a relatively rapid stage of development in China since 2010. It is an inevitable trend for the networking of greenways. In the rapid construction of Greenway network, more attention should be paid to the construction of greenway network structure. The quantification of greenway network planning and construction is of great significance to the scientific construction of greenway system.

At present, the organization methods of greenway network are mostly based on graph theory, Euclidean distance, connectivity and probability theory. It is neglected for the bearing capacity of the elements themselves and the flow rate of the line elements. Meanwhile, China's Whole-region tourism has developed rapidly since 2016. For the greenway of small tourism towns, the carrying capacity of greenway needs to be further considered the impact of leisure tourism. Taking the above factors into account, the view of flow and demand is put forward as the function synthesis in the construction of greenway structure, so as to meet the planning and development of greenway network in small tourism towns.

2. Analysis of existing greenway network structure in Ningan

2.1. Research Background

Located in the southeast of Heilongjiang Province, Ningan is famous for Jingbo Lake Tourism Scenic Area (Fig.1). From 2012, the rapid development of tourism industry has also led to the development of tertiary industry. By 2017, a total of 1.77 million visitors were received, with an annual increase of 26.1%.

Figure 1 Distribution of major resources in Ningan City

Figure sources: drawn by author

There are abundant resources and various land use types in Ningan. The types of tourism resources are comprehensive, covering eight categories in the Classified Investigation and Evaluation of Tourism Resources (GBT18972-2003). There are 3 nature reserves, 4 ecological townships and 25 Provincial Ecological Villages in the city. The main ecological resources include characteristic water resources such as Jingbo Lake and Mudanjiang River, abundant mountain forest resources and various agricultural resources. They have all kinds of resource bases for developing greenway network from the perspective of Whole-region tourism.

2.2. Element Screening of Greenway Network

Taking the Whole-region tourism service value as the evaluation index, combining with national standards, provincial and municipal standards, village and town standards, Ningan's Whole-region resources of ecology, humanities, industry and recreation were screened through field research.

A total of 24 green paths and 23 important resource nodes were screened out (Fig.2).

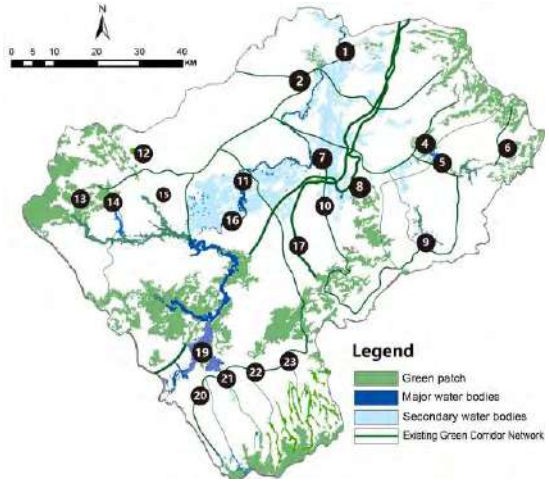

Figure 2 Green path and node distribution

Figure sources: drawn by author

(1) Green corridor: From the spatial distribution, most of the corridors are distributed along major rivers, large lakes and mountains, especially along the vertical green corridor along the Mudan River and Jingbo Lake, as well as the horizontal green corridor along the Mudan River and Xiaobeihu Lake, which constitute the main framework of the existing green corridor in Ningan City. On the west side of the city, a small-scale greenway network with Jingbo Lake Scenic Area as the core has been formed, which combines the surrounding woodland, park green space and so on. In the southeast of the city, large areas of woodland, cultivated land and types of green space are relatively dense. The main roads and railways with vertical distribution in the city are regarded as the main axle belts for the development of green industry. It forms a green channel for industry, and there are many alternative paths in the process of connecting and spreading with other patches in the city. Due to the dispersed distribution of green patches and the absence of a system of existing greenways, the tourism greenway network is divided into five parts scattered in the city. The network connection is not close enough to activate the overall greenway network to play the role of sustaining the benefits of leisure economy and ecological vitality.

(2) Important resource nodes: Important resource nodes are mainly divided into recreational resource nodes, humanistic resource nodes, ecological and industrial resource nodes. Important resource nodes are distributed along the north-south axis and east-west axis of the city as a whole. Because urban settlements play an important role in the Whole-region tourism development of the greenway network, in order to make the formed greenway network benefit more urban residents, strengthen the participation and utilization of the greenway network, urban settlements are listed as the secondary nodes of the network and the important priority choice of network intersection nodes. In addition, the distribution of forestry resources in Ningan has formed its ecological environment matrix, and forestry resources can be used as node resources in the development of tourism to analyse its role in promoting Whole-region tourism. With the further development of forestry resources combined with leisure trails and eco-tourism, a large area of forestry green patches will become the basis of the development of the tertiary industry. Therefore, important forest farm resources are extracted in the form of node resources, so as to facilitate the pertinence and implementation of subsequent planning.

2.3. Existing abstract structure of Greenway Network

(1) Abstraction and analysis of current network corridors

In order to analyse the present situation and future structure of greenway network more clearly and clearly, the existing elements are abstracted to form the abstract structure of Greenway network. The network corridor between resource nodes is connected according to the degree of close connection between traffic function, landscape function and ecological function.

Through the abstract results, there are 109 corridors in the existing greenway network, connecting 81 nodes (Fig.3).

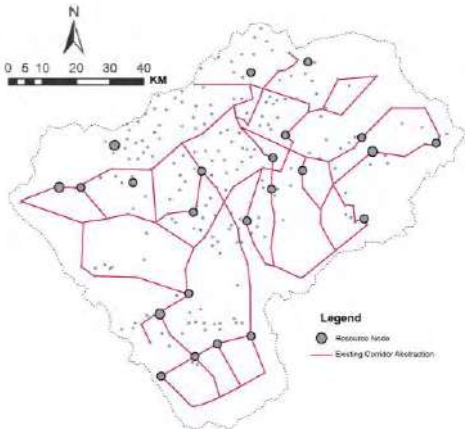

Figure 3 Analysis of network node factor domination area

Figure sources: drawn by author

At present, four key resource points are not connected into the network by corridors. The αindex of existing networks is 0.18. It shows that the number of loops in the corridor network is relatively small, which makes the greenway network show the characteristics of higher linear connection and lower replacement connection. The β index of network corridor is 1.35. It shows a lower level. It shows that the existing greenway network nodes have the problems of relative isolation, punctuation and smoothness. The network corridor γ index is 0.46. It shows that the network connectivity of the whole network structure is not strong. It does not form a relatively effective connection channel. The main reason for the characteristics of the network corridor is the lack of overall planning for the greenway network in the development of the county and municipality. Urban landscape fragmentation has been aggravated. The effective connections of Greenway nodes are gradually reduced.

(2) Streamlining and analysis of current network structure

Through actual investigation, the corridor structure is simplified and reorganized according to the logical relationship (Fig. 4). The current network structure includes 23 network nodes and 30 network corridors. According to the importance of resources, it can be divided into primary network, secondary network and tertiary network. Among them, the primary network structure is used as the basis of network construction. Ningan city's important tourism resources and ecological resources are connected by the first-level network. It is the main network skeleton at present. Major residential areas, industrial parks and Jingbo Lake scenic spots are connected in the North-South direction. It extends to the west to connect the Xiaobeihu scenic area and to the east to connect the birch River Scenic area. The

secondary network structure is regarded as the connectivity and perfection of the primary network. The three-level network mainly reflects the contact line at the site level. At present, it is not perfect, and cannot play a good role in expanding the network. It needs to be further optimized and upgraded.

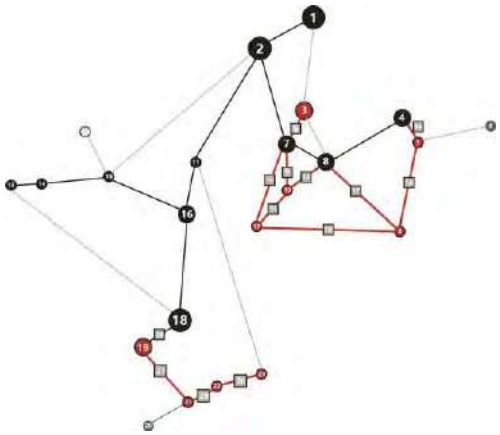

Figure 4 Existing abstract network structure

Figure sources: drawn by author

3. Network traffic measurement based on Gravity Model

3.1. Factor Resistance Value Assignment

In the measurement of network traffic, the interaction force between the elements of each node is determined by gravitational model. Firstly, the resistance value assignment of each factor needs to be determined in the flow measurement [6] [9]. In order to compare and analyse the differences of Whole-region tourism greenway network schemes, two comparative structures were proposed based on the differences of comparative corridors when Whole-region tourism integration was included or not accepted.

Firstly, each factor is assigned according to the influence degree of Whole-region tourism resistance（Fig.5）. It integrates three factors to be judged and calculated, including resource type, vegetation coverage and tourism sensitivity. Because of the emphasis of this study on the Whole-region tourism impact, the proportion of resource types is 0.35, the vegetation coverage is 0.20, and the tourism sensitivity is 0.45. The comprehensive resistance of Whole-region tourism reflects the difficulty of energy flowing between different node units, including "ecology, production and life". In the greenway network organization based on general basic elements, only resource type resistance and vegetation coverage resistance are considered. In this case, the proportion of resource types is 0.64 and the vegetation coverage is 0.36.

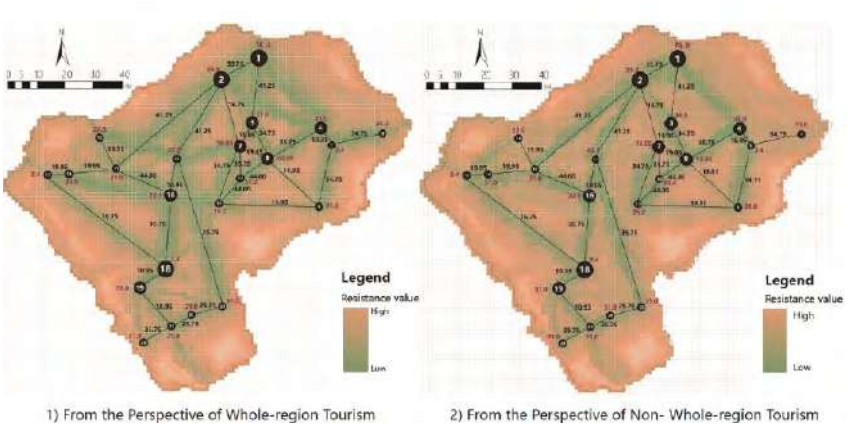

Figure 5 Comparison of two cumulative cost surface

Figure sources: drawn by author

3.2. Flow Measurement

The flow measurement formula is improved according to the gravitational formula. Generally, the distance cost between node i and node j is expressed as $D_{ij} = L_{ij} / L_{max}$. L_{ij} is the cumulative cost of functions between nodes I and j, and the maximum cost of all functions in the L_{max} research area. In this study, cumulative function cost is regarded as the inverse ratio of the mutual attractiveness between two nodes, that is, the greater the mutual attractiveness between two nodes, the smaller the cumulative function cost (Table 1). Therefore, gravity formula can be defined as $L_{ij} = 1/(r^2/ L_iL_j) = r2/ L_iL_j$, which L_i and L_j are the element resistance values of node i and node j respectively, and R is the minimum distance between node i and node j. Therefore, the flow matrix can be generated based on the nodal mutual attractiveness of the comprehensive resistance value of Greenway elements and the resistance value of general elements. Based on the calculation of mutual attractiveness, the traffic among the greenway network nodes is further calculated. Inter-source corridors with high interaction intensity were extracted as main corridors and other potential corridors were supplemented.

Table 1 Cost matrix of attractiveness of abstract greenway network nodes

1	2	3	4	…	21	22	23	
0	0.13	0.22	0.46	…	5.91	5.71	4.59	1
0.13	0	0.53	2.04	…	13.16	14.67	9.77	2
0.22	0.22	0	0.88	…	11.52	12.84	14.49	3
0.46	2.04	0.88	0	…	11.65	13.05	14.46	4
…	…	…	…	…	…	…	…	…
5.91	13.16	11.52	11.65	…	0	0.07	0.41	21
5.71	14.67	12.84	13.05	…	0.07	0	0.14	22
4.59	9.77	14.49	14.46	…	0.41	0.14	0	23

3.3. Measure Result

The difference of mutual attractiveness among different resource points is taken as an important judgment basis in the extraction of potential greenway structure. However, the resistance value of the Whole-region tourism greenway network is different from that of the general greenway network. In both cases, nodes with mutual attractiveness greater than

70% are structurally connected. It generates two kinds of network structures respectively. The Cumulative Cost Surface is shown in Fig.5. The network structure based on the measured results of network flow can be seen from Fig.6. A-type network structure is extracted from the cumulative cost surface formed from the perspective of Whole-region tourism. The B-type network structure is formed on the basis of the cumulative cost surface from the perspective of non-Whole-region tourism.

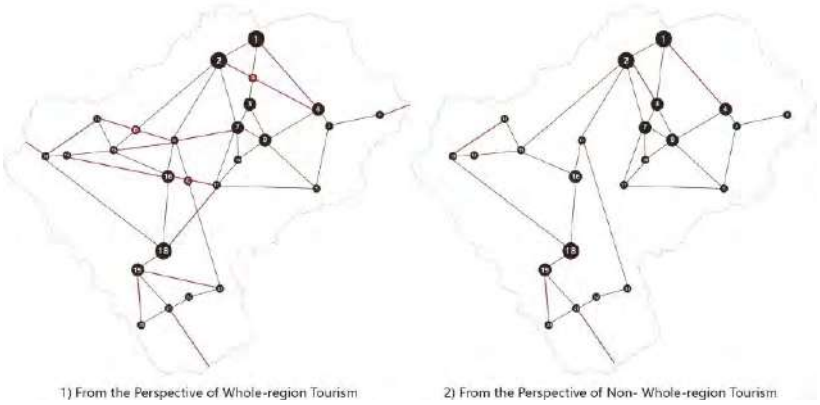

Figure 6 Comparison of two measurement results

Figure sources: drawn by author

From the result of generation, the potential greenway composition in the network structure based on the resistance value of comprehensive greenway elements is more abundant. More nodes have the possibility of connecting. Nodes related to tourism resources play a more important role, making the construction of the whole greenway network more prominent. The overall structure also has more possibilities to expand to the periphery of the city. The B-type structure lacks certain extensibility. It is weakly connected with the outside of the city. At the same time, its internal potential greenway and the current greenway have a strong consistency. If only the network structure based on general natural ecological factors can not satisfy the further optimization of its network development.

4. Evaluation and revision of abstract greenway network

4.1. Grading calculation of Greenway based on structural optimization

The greater the attraction between the nodes in the greenway network, the greater the flow between them and the stronger the function of the corridor. For the corridors in this study, there are corridors that can be reused [10]. Therefore, the final cumulative frequency flow of a single corridor is obtained and calculated by superposition of the functional flow of the corridor.、

The function flow matrix can be obtained by superimposing the function flow of Greenway connected by different nodes. The higher the flow rate, the higher the frequency of corridors used. In order to make the evaluation results clearer, the functional flow corridors of the greenway network are also divided into three levels in this analysis (Fig. 7).

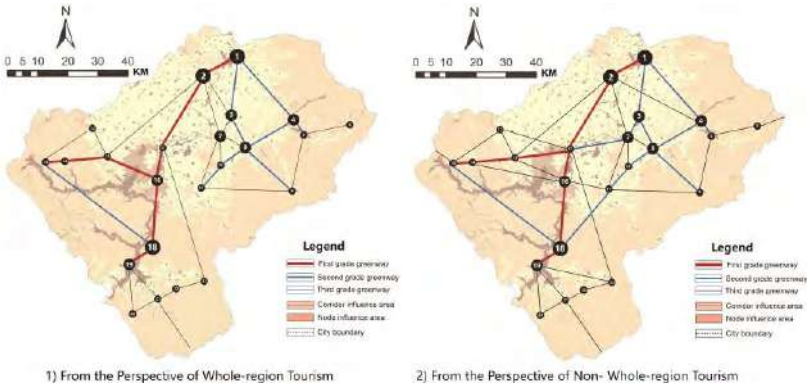

Figure 7 Evaluation chart of corridor comprehensive function flow

Figure sources: drawn by author

Compared with the existing corridor system, the first-class corridor of A-type structure and B-type structure lays more emphasis on the main line running through the north and south, and the two lines of tourism from the central to the western Jingpo Lake natural scenic spot. Because of the slow development of the eastern part, the functional flow is less. At the same time, more three-level network corridors are formed through the concept of functional flow to avoid the deterioration of the ecological patch island effect in the original network.

Compared with B-type corridor, A-type corridor brings about the improvement of secondary corridor structure based on the integration of forest farms, reservoirs and farms with the development of Whole-region tourism. Secondary function flow is no longer only concentrated in the eastern and central part of Ningan, but based on the eastern and central part of Ningan. It runs through the whole network framework and plays a transitional role of better connection between the first-level corridor and the third-level corridor. In the east-central part, the radiation structure is formed with Huashuchuan Reservoir Nature Reserve as the core. In the west, the secondary functional flow corridor connects Xiaobeihu Nature Reserve and Jingbo Lake Nature Reserve, which makes all the important tourism, production and living nodes in Ningan City connect in an orderly way. Therefore, the structure of the Whole-region tourism function corridor has certain operability and structure optimization ability.

4.2. Greenway Network Certification Based on Field Research

The revision of the greenway network structure mainly considers two aspects: the coverage of the network and the possibility of the actual formation of the network. First, the greenway network should basically cover all existing residential areas and tourist areas, so as to promote the development of Whole-region tourism more efficiently. Secondly, the construction of greenway network is closely related to the production and life of citizens. After the construction and evaluation based on theory, the possibility of network formation is determined through field research, and some of its structures are renovated to ensure the reliability and validity of the greenway network architecture.

The influence area of the greenway is generally buffered by 15 minutes' walking, cycling and driving distance outside the corridor and nodes [1]. This buffer is a more convenient and frequently used area for its node and corridor accessibility. From the perspective of Whole-region tourism, the influence scope of Greenway should be expanded correspondingly because of the scale benefit brought by tourism. According to the relevant requirements of

the National Garden City standard, the service radius of general park green space is 500 meters. However, due to the large spacing of urban resource points and the lower degree of resource concentration compared with cities, the service and impact capacity of patches in the greenway network in this study are affected by many factors. According to the field survey results of 500 residents in the city, residents within 10 kilometres from the resource point are all positively affected by the resource point (Fig.8). Therefore, combined with relevant research, the influence range of primary corridor is 10 km, secondary corridor is 5 km and the tertiary corridor is 2.5 km.

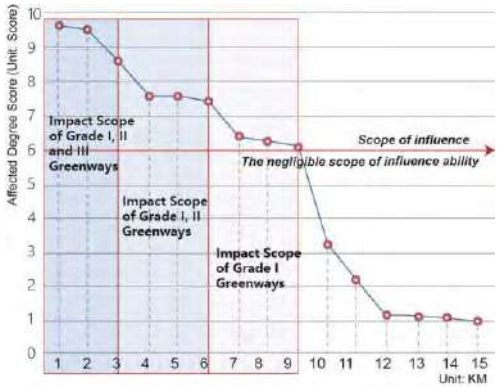

Figure 8 Resource point impact scope survey

Figure sources: drawn by author

According to the overall situation of the current greenway network structure coverage (Fig.9), type A based on the Whole-region tourism perspective has certain structural advantages. Firstly, compared with the current situation, the greenway network structure has more balanced coverage for the whole city. It breaks the current situation of relying on the western side of the city mirror Lake Scenic Area of the single focus of development. Two new development cores have been formed on the East and south sides of the city area, and the multi-level structure has been expanded outward depending on the original trend of the first-level network. Secondly, compared with B-type network structure, the density of secondary corridor and tertiary corridor of A-type network is higher, the influence scope of the whole network is wider and the connection between different levels of network is smoother.

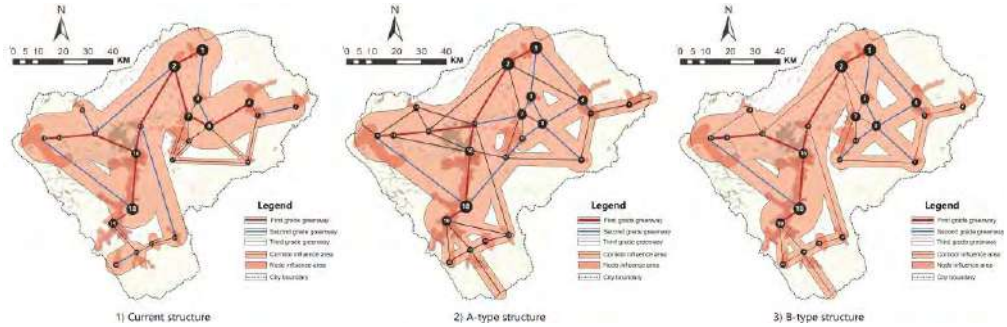

Figure 9 Greenway network structure coverage area

Figure sources: drawn by author

However, as far as the structure of the current A-type network itself is concerned, there is still room for further optimization. First of all, the third level corridor structure can still

further cover the southwest side of the city. The network structure makes insufficient use of forest farms on the southern side of the city. According to the field investigation, the three-level corridors on the southeast side of the city can be further improved, mainly the possibility of connection between 6, 9 and 23 corridors, and the possibility of connection between 1 and 6 corridors on the northeast side of the city. Secondly, the primary corridor composed of nodes 1, 2, 7, 8 and 4 is not reflected in the A-type structure, mainly because the mutual attraction between patches is relatively weak from the perspective of Whole-region development. However, according to the field investigation, the possibility of the formation of the first-class corridor in the west can be further explored, so as to improve the first-class corridor structure in the A-type structure.

Important nodes in primary and secondary networks are mainly investigated. A questionnaire survey and interviews were conducted among 500 citizens and tourists (Table 2). The network certification work was carried out in combination with the opinions of six planning experts. Questionnaire is mainly about the way of scoring between two nodes in the existing structure and corridors with certain possibilities in the above analysis.

Table 2 Survey Scores for the possibility of corridor formation in type A structure

The total score of the questionnaire is 10. A score of more than 6 points is the basis for the formation of corridors. A score of more than 8 points or 7 points is the basis for the formation of a first-class corridor and a second-class corridor. From the evaluation results, synthesizing various opinions, it is possible to form corridors between nodes 6, 9 and 23 between nodes 1 and 6. The original first-class corridor in the west can be further extended. Accordingly, the final structure of Ningan Greenway Network is formed. The GIS tool is used to simulate the greenway, combining with the network structure (Fig. 10).

5. Conclusion

The comprehensive construction of greenway network organized from the perspective of Whole-region tourism reflects the basic demands of the comprehensive resources' endowment of regional greenway network and the comprehensive promotion of the integration of greenway network resources. The construction of greenway network structure based on gravity model studies the idea of resource flow allocation through network in the evaluation of corridors. It embodies the mutual attraction of elements and explores the

source corridor with strong interaction as the main corridor. This study obtains a more scientific greenway structure based on traffic measurement, and makes a comparative analysis of the two types of network structure from the perspective of Whole-region tourism. It determines that the overall planning of resources is the optimal path for the network development of Greenway system. Through the research, the influence scope of Greenway at all levels in the Whole-region tourism greenway network is determined, and the actual form of greenway network is formed with the help of GIS. It lays a foundation for the construction and actual construction of county and municipal greenway network.

Research Paper

The Informal Syndicate Raj:

Emerging urban governance challenges in newly incorporated villages of Bidhan Nagar Municipal Corporation, West Bengal

Dr. Ratoola KUNDU, Assistant Professor, Centre for Urban Policy and Governance, TISS Mumbai, India

Abstract

*Peri-urban spaces in the Global South are regarded as sites of radical and often violent of transformation of social and spatial structures, of brutal dispossessions of lives and livelihoods to make way for speculative real estate development and the accumulation of capital through the expropriation and commodification of land. What kinds of politics and governance configurations emerge in the peri-urban areas of mega-cities? A host of state and non-state actors such as developers, aspiring middle-class urban dwellers are reimagining these sites. This paper investigates the complex governance and livelihood transformations following the upgradation of Bidhan Municipality to a Corporation in 2015 through the state driven merger of the existing planned satellite township of Salt Lake with the surrounding unplanned rural and urban areas. The paper argues that a new politics of unsteady alliances characterises the messy, unsettled and restless territories of the newly formed Municipal Corporation. A highly contingent, informalised and powerful configuration of non-state actors – locally known as **Syndicates** control the development dynamics and political fortunes of the periphery.*

Keywords

Informal sovereign, periurban governance, land acquisition, political party

1. Introduction: The conflicting stakes in governing the fragmented urban periphery

The frontiers of urban areas are particularly volatile and dynamic where urbanisation is posited as the primary driver of economic growth and the harbinger of socio-spatial transformation from rural to urban (Roy). Contestation and violence against people and their habitats is central to this process whether it is carried out in a planned manner by the state and market or through informal means wherein land is subdivided into layouts and its use is converted from agricultural to non-agricultural with the active collusion of state and non-state actors. Along with the displacement and dispossession of the erstwhile peasants and other groups of people living and working in the urban fringes, peripheral urbanisation processes hasten the erasure of histories of people – their identities, their economy, their social ties, kinship and caste networks, collective associations and institutions, their common property resources, and their built and lived habitats. It leads also to an incredible socio-spatial churning, as groups continue to be simultaneously settled and unsettled, often clashing with

one another over control of territories, access to resources and cultures (Gururani). The resulting territory is therefore characterised by uneven urban development, splintered, fragmented, incomplete geographies of being and becoming urban or resisting urbanisation (Cowan, Gururani).

While studies have highlighted the different trajectories of peripheral urbanisation, or examined the drivers of peri-urbanisation (particularly the role of the state and the market), and the impact of socio-spatial transformations on the original inhabitants of these areas, there has been little work on the ways in which different sets of actors struggle to a) reassert, or consolidate their power, authority, collectively mobilise access and claims to the emerging urban periphery through different and perhaps new regimes of territorial governance arrangements and b) assert their agency in reclaiming and remaking one's identity and making sense of the changed reality through varied, incremental, contested strategies of place-making.

However given the dynamic and emerging nature of the periphery, there is very little understanding of what kind of relationships and mediations emerge between different groups that live and work here. What kind of relationships, strategic yet unstable alliances are forged between these new and old actors – particularly between erstwhile (internally displaced) farmers and the new migrants? How is the relationship between land and labour reconstituted through new circuits of capital accumulation and regimes of governance? How is the shifting terrain of the periphery mediated, structured and governed? How are inhabitants making sense and attaching meaning to these spaces and in turn being influenced by the dynamic shifts in the landscape? What kind of power structures and locally contingent assemblages have been carved out to influence and control these processes of large scale transformations and the limits of such influence? And finally, what can the study of these relationships, everyday practices, contestation and negotiations reveal about the future of urban peripheries as viable and livable places?

2. Theoretical and Conceptual Frameworks: Informal sovereigns and everyday governance

Urban governance in the periphery, particularly the formal institutional mechanism is characterised by multiple authorities, overlapping jurisdictions, lack of coordination and fragmentation that lead to further problems in articulating decisions as there might be internal contradictions and conflicts (Dupont, Cowan). Thus while the merger reflects a political decision to bring in more votes or consolidate control over a particular territory by reconfiguring the existing political boundaries, it may also lead to emerging fractions and conflicts as a result of the fallout of the new power sharing arrangements. Moreover, while the rationale for the merger is to attract central government funds in order to undertake large scale policy driven infrastructure improvement projects, the governance situation in the context of a newly cobbled local body presents multiple challenges as interests and stakes are at cross purposes. This is exacerbated by the socio-economic divergence, cultures, aspirations for development and widely divergent political mobilisation across the three localities. Thus while there are elected members and elite, politically connected middle class lobbies in Salt Lake, based on the idea of tax paying propertied citizens, the governance of the gram panchayat areas is often under the control of big men, or party leaders with particular elite

caste/class backgrounds or land owning privileges, or the ability to use muscle power, and/or lend money and negotiate with state level functionaries.

Given that the peri urban area is characterized by fragmented and overlapping governance arrangements and conflicting interests of locally elected representatives, infrastructure and services continue to develop in an uneven and unequal manner, creating archipelagos of well serviced areas (Graham and Marvin). Therefore, new actors emerge in the interstices of service provisions, trying to bridge the gap in terms of service provisioning (Simone) and also staking out an opportunity to control new territories (Lund, Hansen and Seputtat). In return of these services/infrastructure/resources, these powerful local entities are able to extend their control over the locality, or command votes and allegiance (Lund, Cornea). In this case, there are powerful syndicates which have emerged in the area who control the pattern of urbanisation in the area, and the local economy by exerting their influence over labour, construction material supply and the negotiated arrangements they carve out with the new and powerful urban institutions that dot the landscape – from parastatals and development agencies, to newly elected ward councillors in the newly formed corporation. These informal sovereigns (Lund) could take the form of Syndicates or local clubs (Cornea) and often overlap with the local political parties and yet are also important intermediaries. They are critical to the everyday governance of these dynamic frontier urban areas and specific to the political economic context of West Bengal.

The paper is based upon my dissertation fieldwork in 2008 and 2009, followed by subsequent research projects through ethnographic fieldwork by Masters and MPhil students in 2013, 2015. In 2017, in depth, semi structured interviews with key person residents (6 total) and elected councilors (9 total) from the three merged spatial units were carried out by a PhD student to understand the dynamics and the impacts of the merger. In addition to the field level primary data collection, newspaper archives, government reports and documents were also studied in detail for secondary data.

3. Introduction to the Case study area: Bidhannagar Municipal Corporation and its surrounding areas

The North eastern periphery of Kolkata has been shaped through multiple and highly contested state driven attempts at urbanising rural agricultural and ecologically sensitive areas. In the early sixties a planned new satellite township called Salt Lake was created to decongest the city of Kolkata. A strong regulatory regime controlled the supply, subdivision, and sale or transfer of lands in these planned townships, and the entry of private players was strictly regulated by the state (Sengupta, 2013). As this township began to get populated, spurred by the setting up of the Special Economic Zone in Sector V of the township, the villages around the township began to be transformed in an unplanned and haphazard fashion. In the mid 90s, the Left Front Government decided on urbanization as a strategy to attract businesses and investments into the state. The rural areas adjoining Salt Lake city (Bidhan Nagar Municipality) was chosen as the site for the setting up of the Rajarhat New Township, three times the size of Salt Lake. Massive displacements and dispossessions of farmers, share croppers, fisherfolk and others dependent on the rural economy were hushed up by the State to enable the acquisition and development of Rajarhat New Town. These processes in turn created a ripple effect in the peripheries with private developers, big and small, buying up

villages, converting ponds and wetlands to gated urban complexes through speculative urban development. Eventually, the discontent of the erstwhile villagers led to a political denouncement of the LFG and the Trinamul Congress (TMC) came to power in West Bengal in 2011 with promises of protecting the rights of farmers and villagers from predatory capitalists.

In May 2015, the West Bengal government headed by TMC formed the Bidhannagar Municipal Corporation (BMC) through the official merger of three territorially distinct, socio-economically diverse, administratively separate settlements - Salt Lake City (a planned satellite township and a municipality), Rajarhat-Gopalpur town (an older, unplanned peripheral urban area and municipality) and parts of Mahishbathan (a rural Gram Panchayat area on the fringes of Salt Lake). This was ostensibly a top down, state driven strategy to enable the sustainable development of these extremely disparate and unevenly developed areas. The state government also argued that it would be easier to access central government schemes such as Smart Cities Mission, AMRUT etc. due to the changed administrative status to a Corporation.

It resulted in the delimitation of the geographical area into 41 wards through a process of violent territorial reshuffling – administrative boundaries being redrawn, territorial mergers and divisions that have had far reaching socio-political consequences in terms of reconfiguring existing power structures and institutional arrangements of decision making across state and non-state actors. Accompanying these shifts in power relations, alliances and alignments as well as notion of territoriality are the emerging conflicts, aspirations and claims over the control, management and distribution of resources and urban services, particularly land, water and labour. Given that the area under the newly formed Corporation is undergoing rapid urbanisation, fuelled by the construction industry and the IT sector, vacant lands, common areas, and shared natural resources are under threat as is the sustainability of the area as a whole. The urban peripheral region is likely to be affected by the transposition of new power structures and hierarchies on to existing, contingent and locally negotiated and tenuous institutional arrangements around power sharing.

The diversity of social backgrounds, occupational status and interest politics in three different locations and the socio-spatial transformations that accompany the merger leads us to question the process of evolution of governing institutions themselves – will the new institutional arrangement be exclusionary, unjust? Will it be co-opted by elite actors and middle class interests that are concentrated in Salt Lake? Will the newly elected local government be captured by vested interests of developers working in the fringes? Or, will the local government carve out new opportunities for more just and sustainable, people-friendly and industry friendly mechanisms of governance? On the other hand, how does the socio-spatial merger affect the transformation of social institutions given the changes in values, norms, preferences, class relations, and aspirations and in turn influence the politics and governance processes?

In the next section I discuss the emerging relationships between these new and old actors, the reconstitution of the relation between land and labour and between older structures of power and new emerging centres of power and influence that simultaneously reinforce and challenge the status quo.

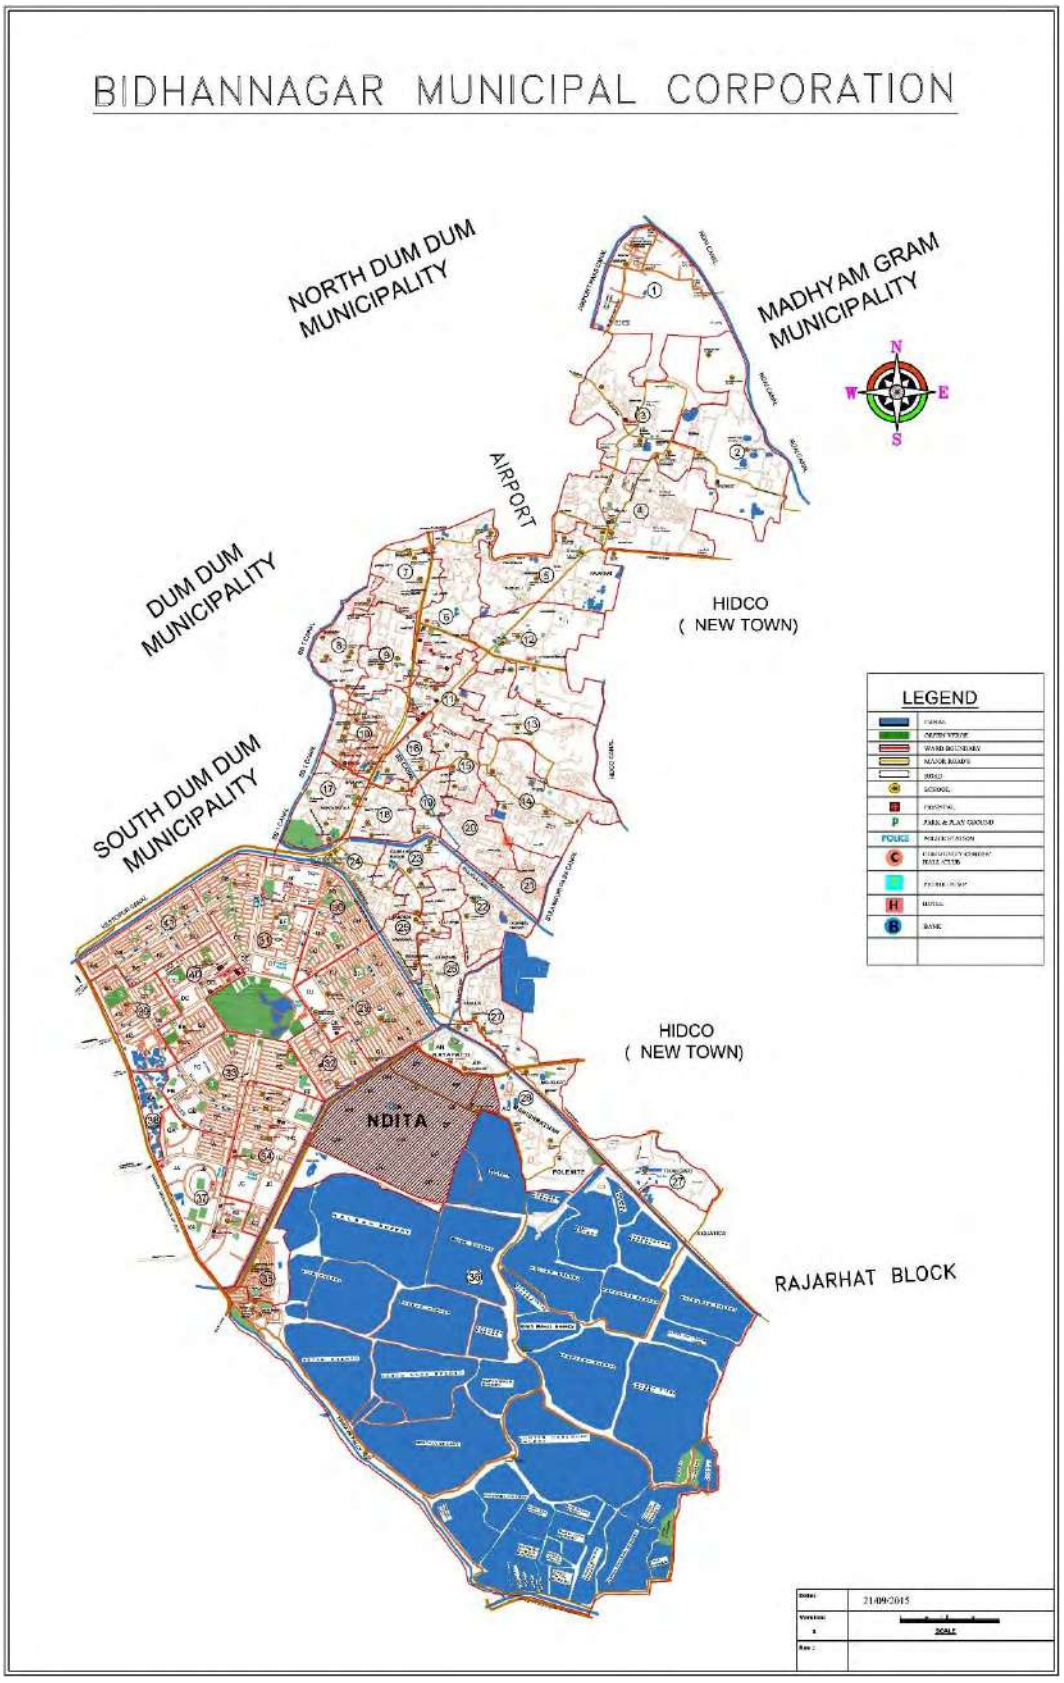

Figure 1 Map of Bidhannagar Municipal Corporation. Source: BMC website

4. Findings

4.1 The Village in the City

Prior to 1995, Mahishbathan was part of a larger fertile agricultural region dotted with dense villages with long histories of settlement, ponds, orchards and substantial waterbodies. Inhabited by farmers and fishermen, two thirds of who were from marginalised socio-economic groups - either the Muslim community or Dalit community, the locality was connected to Kolkata through the exchange of fresh produce, goods and services (Dey, Samaddar and Sen 2013). Landholdings were typically small and there were multiple tenure structures that enabled some to work as share croppers, as tenants, and even as farm labourers. Many inhabitants were engaged in fishing and in the trade and transport of fresh produce and fish. With the formation of Salt Lake city, Mahishbathan began to transform through a spillover effect as those unable to afford rents in Salt Lake moved into these adjacent villages. Villages received electricity connections, upgraded primary schools, and access to water (though filled with impurities), irrigation facilities and roads. Given that this area was already informally urbanized, there was little protest from the villagers to the proposal of the merger. In fact, for most villagers, this was welcomed given that they felt they would now be treated at par and get more money for development works and not be seen as the poorer cousin of Salt Lake city.

This facilitated new circuits of rent extraction and capital accumulation that mediated the relationship between older village inhabitants and the new migrants. Some villagers with extended and pucca houses became land lords, renting out rooms to the new migrants, often distant relatives, asserting new forms of social and economic power in the process. Residual lands along the wetlands and canals are being deliberately occupied by political force in order to settle the new migrants for a steep price, in exchange of the right to stay in those areas and access water and other urban infrastructures, away from the gaze of the state.

Hiru Ganguly (name changed) lives in Mahishbathan. He has a house with an orchard and with the transformation of the surrounding villages, he too built up his house to two floors, along with a row of small rooms in the orchard which he lets out. Though a landlord, he has worked as a driver in a logistics company for 25 years. The past two years, he has taken up the job as a private driver to a family living in the gated complex nearby as the hours are more relaxed. His distant cousins have rented rooms in the orchard. Hiru has also taken a hefty commission from his cousin's wife who has secured employment as a domestic help in the same family he is employed with. Hiru's wife does not work and his children are studying in English medium schools that have opened in Rajarhat. When asked about his choice to work as a driver, he articulated "*it is not out of a necessity. I am quite comfortable financially because of the steady rent I get. For a long time, I have not practiced agriculture though our family had a lot of land. It was increasingly difficult to find good agricultural labour. The New Town project changed this as my agricultural land was acquired and with the money I built the rooms for renting. I rent out to only known but distant relatives and*

they also benefit from this association. I choose to drive because I like to be out of the house. I am respectable person in the village and I ensure that I maintain my status".

The families with larger land holdings (often belonging to higher castes or influential families with political clout) in these villages have also been able to sell of portions of their land to private developers to construct apartment complexes given that the regulatory regime is weaker in the village pockets and the gram panchayat colludes with private players to approve the building plans. While some villagers have rented out the extra space to new migrants, others have opened up small grocery shops, cable TV shops, mobile repair shops, tea shops, etc., revealing a changing village economy. Many of these products and services sold in the villages are extended to the residents of the adjacent gated communities. These new livelihood practices, entrepreneurial spirit, moving away from subsistence economy, an emerging sense of private wealth and competition and constant efforts to improve one's property permeate the village atmosphere. Thus investing in rental property has become a strategy for villagers to enter the informal land market in Rajarhat.

However, not all residents are able to seize these new opportunities, leading to a deepening of social and spatial inequalities in the villages. While the new urban economy is dependent upon the labour of non-skilled informal workers and have absorbed the migrant labourers as security guards, maids, drivers, construction labourers but many erstwhile farmers in the villages are skeptical about these kinds of jobs, which they consider undignified and underpaid and thus prefer not to these jobs (Basak 2013).

One newly elected local councilor said "*we have been here since our forefathers came here and made the land habitable. With the rapid urbanization, many have lost access to livelihoods. It is true some have improved their houses, but where do we go now? What do we do? Where will our cows graze? The big buildings will soon stifle us. Every inch of land now is up for grabs.*"

For some of the villagers, there is no choice however but to engage in menial jobs such as rag picking – these are usually the low caste and the most marginalised sections of the village population who worked as agricultural labourers, share croppers or fishermen in the wetlands that are fast being engulfed by urbanisation. Their huts are visibly in a dilapidated kuccha state and their families impoverished. They have also lost access to the commons which were essential to their daily life for feeding their livestock, or cultivating vegetables, or for their children to play, leaving these families in an extremely vulnerable state.

The social fabric of these villages, thus far from being insulated, are now sites of emerging conflicts over resources between original residents and new migrants and original residents, further disembodying the experience of place (Kundu 2017). These villages are actually very much at the centre of the constant processes of settling and unsettling that is remaking the urbanising landscape of New Town though in highly uneven, unequal ways and often by exploiting migrants and the most disadvantaged. As Gururani (2017) has argued, "*they sustain and accommodate the everyday life of an unfolding urbanism. These rural enclaves challenge the standard narrative of urbanization and urge us to consider how in the postcolonial context unlike the post-*

industrialized world, the urban is constituted materially and symbolically, by what lies outside of it or excluded from it".

4.2 People as Infrastructure

Simone has posited that in the extremely marginalised and neglected inner city areas such as that of Johannesburg, there exist an incredible capacity for inhabitants of limited means to co-create spontaneously, very flexible and fleeting social arrangements that enhance the potential for economic and cultural operations. This conjunction – "*complex combinations of objects, spaces, persons, and practices" is what Simone refers to as "people as infrastructure*" – at once provisional and mobile, operating without clearly delineated notions of how the city is to be lived or used – and yet managing to bring together very different skills, resources, practices that enable them to reproduce life in the city with the only certainty that the outcomes are flexible and radically open ended. He posits this idea of a highly urbanised social infrastructure in contrast to the dominant idea of infrastructure as a physical entity – the provision of which through networks places people, objects and territories in a city in a way that it increase the idea of efficiency (Simone).

In the frontiers of urban Kolkata, which is marked by its distinctive lack of such complete and efficient systems of networked infrastructure (whether it is water pipelines, electricity supply, or roads) and population is scattered, density is low, and there is no distinct urban feel to the place, the concept of people as infrastructure takes on a different meaning. The Bidhan Nagar Corporation is still in the process of becoming an integrated functioning unit. This state of administrative limbo has led to a splintering of the geography and has impeded how inhabitants make sense of their surroundings and access basic infrastructure such as transport, water, electricity and garbage collection, particularly in the fringes of the Corporation.

Erstwhile farmers have become bridges for the apartment dwellers by providing services that are absent in the New Town. There is a vibrant network of informal autorickshaws that ply in New Town area responding to the needs of residents to access markets, schools, offices in the absence of public transport. Apartment dwellers in the periphery highlighted their dependency on the villagers for a number of their daily requirements. Mr. B. Poddar, a long-time resident of Greenfield Heights says, "*…the Atharotala market continues to exist because we (meaning the residents) protected it from being evicted by HIDCO. They are illegally occupying land and they charge us more for fresh vegetables and fish. But without the market, we would have had to go to Salt Lake which is 5 or 6 km away. In the absence of transport, how do you expect a retiree like me to go that far?"*

Debolina, a resident of an apartment complex in the peripheries, sums up the uneven and complicated nature of this dependence, shot through with class inequality and social tensions, "*The surrounding area of the village is basically dominated by Muslims. We have never heard of any communal issues in this region. They are very helpful in nature in fact all the service providers like drinking water, paper wala, milk provider, flower wala, maids etc. are from their community. Somehow we are dependent on them. As it was their land they keep on reminding us about the matter that we are living on their land*". Thus the dependence is simultaneously built on an

economic transaction and an act of social "othering", which distinguishes apartment dwellers from the villagers (Kundu 2017).

From the formation of local informal markets selling fresh produce collected from neighbouring ponds and fields, to informal tea stalls feeding the formal white collar workers to the construction labourer, to the supply of drinking water in housing complexes, the intricate web of autorickshaws that ply through the rural-urban divide, infrastructural gaps are being filled in by the village people (original residents and new migrants) who see an opportunity opening post the phase of being dispossessed of their lands and identities during the course of land acquisitions. In the absence of adequate physical urban infrastructure, people across the rural-urban divide have become part of the interconnecting infrastructure, filling in the gaps, through uneasy, temporary collaborations with unlikely partners born out of need in an unfamiliar territory. Much of these arrangements belie the confines of territoriality and involve potential economic risks as many of these arrangements are considered illegal – particularly hawking, illegal tapping of water and electricity.

Najimuddin, a hawker opposite DLF II in the Unitech area says, "*This shop that we have built here. HIDCO and the police obstructed us. We got around 3000 people out on the street and blocked the main road connecting DLF. The police came and but they ended up cooperating with us*". Eviction threats are all too real and the administration sometimes destroys all the goods while at other times, the police and the administration may reach a certain agreement for the hawkers to operate their food stalls in these very visible spaces of Rajarhat New Town. For Najimuddin however, the risks associated with hawking brings back memories of being forcefully evicted from his family's agricultural lands in the very same DLFII area. Yet at the same time, it also reveals a spirit of making new connections to survive – not only with the customers, but with the police and the HIDCO administration as well as collectively mobilising through the city wide Hawker Sangram Committee's network.

Yet, people invest in these risky ventures based on an implicit trust and not always necessarily on traditional identities of belonging to the same religious community, village, kin or caste networks. Yet these are tactics of surviving a harsh environment that has in many ways refused to formally accommodate the erstwhile village populations into the emerging urban economy, expropriating their control over land and the means of production and stripping them of spaces to voice their grievances. The economic ventures people create are fraught with tensions, are extremely fragile and tenuous in nature and are dependent on their ability to flexibly negotiate changing regimes of rule and administration, be attentive to changing demands of customers and to mobilise themselves on more broad based social platforms to alleviate their risks.

4.3 The rise of the Syndicate Raj in Rajarhat New Town

The analysis of the changing social relationship between the different groups in Rajarhat New Town and its surrounding areas is incomplete without an examination of the ways in which it is governed, who are the actors that mediate access to votes, voters as well as infrastructure, open up informal spaces of deliberation and resolve territorial conflicts, and control the complex and dynamic logics of settling and unsettling populations over the periphery? Given the deep socio-economic divides

and fragmentation of political authority in the periphery, the pervasive fear and terror that accompanied the accumulation of capital through the expropriation of land, the emergence of a mixed rural and urban population with various competing claims and differentiated subjectivities of citizenship, as well as the presence of a surplus population facing expulsion from the circuits of corporate capital accumulation – it is important to understand how these tensions are being managed in the present day.

Historically, the social production of the eastern periphery of Kolkata is premised on unimaginable violence committed against farmers, sharecroppers, CPI(M) party workers, activists, women and others by a combination of politicians – administrators – police – criminal strong men from the late 80's onwards. For instance, Ruis Mandal, a strong man in the Thaakdari, Mahishbathan area, was nominated as an election candidate for CPI(M)from the area. In spite of being a history sheeter, with charges of murder and arson against him, he was made to win the election, thus paving the way for a reign of terror where oppositional voices were swiftly stifled. During his rule, the civil society organisations such as the farmers association and the *bhery* workers association from the area, who had struggled against the atrocities and exploitation of the landed gentry in the area, were dismantled. Internal opposition to the Party's collusion with powerful private players trying to assemble land chunks of land, was also quashed through violent means – thus making way for a "peaceful" land acquisition process in 1996.

The formation of extra-legal land procurement committees and neighbourhood committees that made it possible to co-opt opposition parties and have them coerce and convince the farmers to give up their land at prices which were priced at far lesser rates than the market and the government rates supplemented the actions of the "strong-men" cum politicians who used their capacity for violence to exude control over territories, dispense their own justice, and make decisions with respect to life and death. Political fortunes and positions in these coveted extra-legal structures of mediation became the vehicles to consolidate power as well as immense personal fortunes.

For example, the MLA of CPI(M), Rabin Mandal held on to his seat for close to two decades, and used his political clout to become the Chairman of a Special Purpose Vehicle called Bhangar Rajarhat Area Development Authority, through which he controlled the power to control private developers access to urbanisable land. At the time, TMC MLA Tanmay Mandal was also made a member of the LPC and this further dampened chances of popular protest over large scale land acquisition. Tanmay Mandal was later sacked by Party president Mamata Banerjee for his alleged involvement in the Vedic Village land scam in the area which exposed the complicity and deep imbrications between the then ruling party, the opposition party, the district administration, private players, the local police and criminals in the use of violence to grab land from farmers. Hansen and Seputtat have thus argued that "*The gangster, the underworld, or the informal sovereign who has become "a law onto himself" are, in other words, central to the endeavors of governments and police forces to produce legitimacy, and to perform the sovereignty of the state."* In many ways, we see that the rule of individual 'big men' subsumes the state and the rule of law, highlighting how the distinction between state and market is increasingly blurred.

The nature of governance regime in Rajarhat shifts post 2011 when the TMC won the state elections with a resounding victory over the Left Front Government. Land and anti-land acquisition were the central plans of TMC's bid to overthrow the regime of Left rule. While BRADA was dissolved on charges of appeasing private interests in land, there emerged a political vacuum in New Town area which was being administered by parastatals (HIDCO and NKDA) but had no urban elected local body. Although it appeared as if these Special Purpose Vehicles were empowered to bypass the local elected bodies at the village level, especially regarding land acquisition and land development and planning decisions, this period saw the rise and consolidation of the power (and personal fortunes) of the panchayat leaders from TMC. Jehanara Bibi is one such powerful figure from Patherghata who acts as a formidable leader and a mediator between the multiple stakeholders and their conflicting claims to the periphery. She proudly proclaims, on being asked about her role in the area, "*I stand as the most approachable person in this case. HIDCO approaches me to empty lands and villagers also approach me negotiate with HIDCO. So I am everywhere. Panchayat is a good governance in Rajarhat where matters are resolved within hours and which benefits all."*

Jehanara begum is a strong woman in her own right and has a long association with the area. She was elected to the Patherghata gram panchayat as the Pradhan in 1989 from TMC. She went on to consolidate her political clout by becoming the Rajarhat Panchayat Samity Savapati in 2003. She will be completing two full terms at the Zilla Parishad covering Bishnupur, Chandpur and Patherghata. She confidently responds that she takes decisions on behalf on the Panchayat as well given her long years of experience. While sceptical of the possibility of the formation of an urban local body in Rajarhat New Town, she maintains that she is integral part of the decision making processes in the area – from settling hawkers by negotiating with HIDCO, to deciding what slab of rents they should pay in the newly constructed hawker's market, to convince farmers to give up their lands for development, to listening to the issues faced by migrants and helping them access services. Jehnara Begum however thinks that the current regime of rule is one that is markedly more peaceful that the strong-men dominated CPI(M) era- "*CPM used to send bouncers wearing red turbans and young boys on motorbikes to capture lands, once upon a time. Now, it is negotiated. TMC rule is peaceful"* reflecting a broader party strategy to consolidate its power base and move away from oppositional politics to one that is more grounded in the question of governance.

Informal sovereigns are certain non-state actors, with a capacity for violence, who act as vote aggregators for the party in power but also have some autonomy within their own territories with respect to rule-making, providing housing and services to 'informal' residents, facilitating real estate/ infrastructure deals or becoming real estate developers themselves. Their public authority is constituted by making public decisions and providing services as non-state actors but while referencing the state (Lund 2006). Instead of individual sovereigns who sustain the rule of the regime, Rajarhat New Town is governed through a complex, ever shifting alliance of different Syndicates – both labour based and material supply based. Though seeded during the CPI(m) era in a bid to appease land losers in the area, today the Syndicates act as informal structures that not only provide muscle and money power to elected

representatives but they also help to marshal political forces in support of local political leaders and to protect their political and economic turf. It is a complex assemblage of hydra-headed organisations – blurring significantly with land losers collectives, local "para" clubs, and lower level of party workers. In exchange of their ability to collect money, the labor and the materials supply syndicates get privileged access to construction projects, contracts, etc.

Figure 3 The political nexus with Syndicates. Source: Newspaper

These Syndicates are shown to have significant decision making powers in the governance of the highly uneven fringe areas of the Corporation: (i) control over labour and material requirements of the periurban economy (ii) ability to mobilise large numbers of people and votes (iii) influence decision making with respect to the development of urban infrastructure networks in and through villages where real estate developers are flocking to.

Some of the elected representatives who were interviewed professed widely varying opinions about the Syndicates. One of the elected councilors from the Salt Lake area complained that the Syndicates had become a menace and were supplying inferior quality material for a premium. They were able to wield this power over the construction business because they were armed, violent and often had the support of some party leaders. For an elected representative from erstwhile Mahishbathan panchayat area, who is also actively involved in the local social club, syndicates are nothing but peoples collectives that were formed during the state driven land acquisition drive by the LFG. These state sanctioned bodies were formed so that land losers could be rehabilitated through skilled training and by gaining a foothold in the changing economy through contracts for supplying building materials or labour. This representative insisted that the media had wrongly portrayed this "peoples collective" as a criminal and violent mode of organizing the local unemployed youth. This view was publicly corroborated by the Mayor of Salt Lake, Sabyasachi Dutta, who said, "*I am simply looking out for the underprivileged in my area. They look to the construction business for employment*."

Figure 2 Photograph of a banner showing the Syndicate's support for Mayor Sabyasachi Dutta. Source: Newspaper

With strong infighting and regular territorial clashes erupting regularly between TMC factions in the Rajarhat area, the gradual institutionalization of syndicates raises the question whether this will ultimately challenge the authority of established leaders and ultimately the rule of TMC, or will their continued presence consolidate TMC's presence in a fractured, volatile, and highly differentiated urban periphery. These multiple sovereigns thus point to the constant blurring between the business of politics and the politics of doing business in a regime of rule onto themselves and evokes close connections to the state to gain legitimacy in the eyes of other stakeholders.

4.4 The Unsettled City

For the planned township of erstwhile Bidhan Nagar Municipality, which is largely populated by an urban middle and urban middle class population, it means being clubbed together with areas which are underserviced in terms of basic infrastructure – piped water supply, underground drainage networks, sewerage networks, etc. An uneven property and land use regime plays out across the three territorial units – Salt Lake has lease hold properties only, with strict laws about transferring of property and even in terms of land use conversions. However the other two areas have freehold property regimes. There is an underlying unease amongst the city dwellers of Salt Lake city that their needs will be overlooked in favour of the more pressing concerns and political pressure from the added areas. There are also claims that the direct, face to face contact and access to the local elected officials will change once the delimitation takes place and thus people will be removed from the decentralised governance of the urban local area. "This is vote bank politics. The demography of the

three areas is vastly different and it would be disastrous to merge them" said a lawyer from the Salt Lake area.

In the checkered development politics of the periphery, Salt Lake city has been deliberately left out and neglected in the past four years since the merger. This is particularly a sentiment that is voiced by middle and upper class propertied citizens who feel that they have been central to the growth of Salt Lake, its identity as a peaceful urban area with excellent amenities. Their ties to the place has been cemented not only through their social and cultural bonds that have developed over time in the neighborhoods, but also through the municipal taxes they have diligently paid to the urban local body in exchange of services.

Retired bank official Soumen Chatterjee, who lives in AG Block of Salt Lake, is uneasy about law and order. "*All funds are likely to go to Rajarhat-Gopalpur because that area has more voters. Problems like syndicate wars might spill over.... It's a lose-lose situation for us*," he said. "*Salt Lake and Rajarhat (Gopalpur) have two separate characteristics in all aspects. They also have socioeconomic and cultural difference. We are very apprehensive and doubtful as to how these two areas with separate identities could function together*" said Kumar Shankar Shadhu, Secretary, Bidhanagar Welfare Association.

The fears are not misguided given the political undertones of the merger. Krishna Chakraborty, the last chairperson of the erstwhile Bidhannagar Municipality (TMC) said her party would develop the backward areas without neglecting the rest. "*Families grow. Everyone has to work together for the whole family to prosper. For the next five years, Rajarhat-Gopalpur will be our focus, but not at the cost of Salt Lake.*"

4.5 Red to Green to Saffron: The shifting politics of the periphery

Some political commentators have astutely observed that it was a deliberate political strategy to add Mahishbathan (II) and Rajarhat Gopalpur Municipality areas to Bidhan Nagar Municipality in order to regain control over the urban area in the Lok Sabha elections of 2016. Elections were delayed for a considerable time to enable the merger of the three areas and the formation of the Corporation. However, Opposition parties to TMC (particularly the Bharatiya Janata Party) have been gaining ground in the Bidhan Nagar urban area with the increasing dissatisfaction that the urban populace of Salt Lake city have faced with the urban local governance. Residents and businesses have developed a fear the Syndicate Raj that now mediates development activities and offers "informal protection" to businesses in Salt Lake, and whips up votes for the party in return of the political patronage they receive. Though these informal power brokers were somewhat more controlled during the era of the LFG rule, given the total penetration and control of the party machinery over the bureaucratic and administrative structures of governance, there is a distinct shift in their operations under the TMC rule. Given that the TMC as a party lacks the organizational structure of the LFG, it has also been at the mercy of these informal power brokers at the local and regional level to ensure control over voters. "Syndicate, as is being imagined, is not a centralised network. The local power brokers under the patronage of regional strongman form the mainstay of the syndicate. The regional strongman could be a political leader of any party, not just TMC's" (The Wire,2016). And even within the TMC, party leaders from adjoining or overlapping

territories in rapidly urbanizing areas such as Rajarhat, are competing against each other to curry favours with the Syndicates. Severe infighting within the party, particularly between the Mayor and the Deputy Mayor who respectively control syndicates from Rajarhat Newtown and Rajarhat Gopalpur areas, have led to policy paralysis and deteriorating services in the newly merged Corporation. Bidhanagar Corporation area has also been embroiled in the most bitter and violent clashes across rival factions of TMC supported syndicates given the real estate boom in the area. However, in a recent turn of events, TMC has demanded the resignation of Salt Lake Mayor, Sabyasachi Dutta, who also happens to be the MLA for New Town Rajarhat. Sabyasachi's growing closeness to the BJP and his openly anti-TMC statements led to the party stripping him of his powers.

5. Conclusions

The paper attempted to explore the different contours of relationships that are emerging between the different groups of actors in the periphery of Salt Lake city – particularly between the erstwhile villagers, the new migrants to the erstwhile villages, and the citizens of Salt Lake city. Migrants remain largely invisible and immensely vulnerable – they are kept in a state of permanent impermanence as they are selectively handed documents and ID proofs to consolidate their claims to land, housing, services, jobs etc. They are not allowed to collectivize although they are encouraged to support the local powerbrokers during elections.

The erstwhile villagers on the other hand, have a graduated and differentiated access to the new economy jobs or the option to rent out land. They lack skills or the drive to get involved in some of these new forms of informal labour – but are part of the circuit in other ways – as middle men or intermediaries brokering information, land deals, renting houses, creating connections to local political strong men and parties, getting connections to services, connecting to government agents who will provide an identity or documentation proof to new migrants. "Here having the right information and building fluid, provisional relationships with powerful builders and political actors is key to social mobility" (Kamath and Raj).

The fragile ecosystem of syndicates, local intermediaries, para statals and party functionaries belie any definite forms of institutionalization of governance structures but remain powerfully open ended, a highly contested field, where each actor tries to influence the other or subvert the other, or negotiate the terms of trade-off between political allegiance and economic gains, straddling the urban and rural divide. The powerful Syndicates are open in their support for heavyweight party functionaries such as the Mayor of Bidhan Nagar Municipal Corporation, which was manifest in their show of strength in numbers during the filing of his nomination and also in the public display of congratulations upon his victory in 2016.

The urbanising landscape is one that is patchy, fragmented and extremely volatile. There are elements of the village that seep into, sustain and change the dynamics of urbanisation. The circulation of capital happens through the calculated informality that creates differentiated spatial values and the control over labouring bodies.

Case Study / Project

Anticipation Strategy for Urban Conurbation

in Semarang- Surabaya Corridor

Dwitantri Rezkiandini LESTARI ,
Latifah LATIFAH

Abstract

Semarang-Surabaya corridor is the backbone for economic growth of Central Java and East Java. This corridor also plays a role in national economic growth. Semarang-Surabaya corridor development is expected to create positive externalities, such as creating spillovers in urban areas along the corridor. The spillovers in an urban area along the corridor happen in Jakarta-Cipularang corridor. Besides creating positive externalities, the development of Jakarta-Cipularang corridor as the backbone for economic growth of Jakarta-Bandung also create uncontrolled urban conurbation. Weak spatial control is the trigger for this phenomenon. Based on the phenomenon that occurs in Jakarta-Cipularang corridor, Semarang-Surabaya corridor development should pay attention not only in the infrastructure development plan but also in the spatial control strategy. This project applies the concept of economic corridor development, which produces outputs such as urban cluster plans along the corridor, anticipation strategies, infrastructure development programs, and spatial control along Semarang-Surabaya corridor.

Research Paper

Response Path Adapted to the Unbalanced Shrinkage of Small Towns in Metropolitan Areas

A case study of Wuhan in China

Yanqun LI, Huazhong University of Science and Technology; China
Hong GENG, Huazhong University of Science and Technology; China (Corresponding author)
Erpeng SHI, Huazhong University of Science and Technology;

Abstract

Along with the global wave of urbanization, urban agglomerations with megacities as the core have become the main form of urbanization in various countries. The polarization effect around the metropolis leads to the centripetal flow of capital, labour, land and other resource elements in the surrounding small towns, which causes the shrinkage of small towns in the metropolis, such as population reduction, economic recession, idle housing and dilapidated space. The shrinkage of small towns in the metropolis has become a global issue. However, as an important spatial unit in the spectrum of urbanization that serves, connects and couples urban and rural areas, the shrinking phenomenon faced by small towns has an important influence on the healthy development of urbanization. Exploring the development path of adaptive shrinkage for small towns has become an important part of the healthy urbanization of metropolises.

Based on the public data of population, land and economy in Wuhan, China from 2004 to 2014, this paper uses GIS and other spatial analysis technologies to comprehensively measure the relevant characteristics of the shrinkage of small towns. The results showed that the small towns in Wuhan are in the form of "unbalanced shrinkage" under a local growth. And the towns present a spatial pattern of "circle increasing shrinkage" around the boundary of main downtown. With a further exploration of the formation mechanism of "unbalanced shrinkage", it is found that this shrinkage pattern is caused by a combination function of various factors, such as downtown deprivation in the policies supply, centripetal delivery of social capital and reconstruction of regional division of labour network. Based on this, this paper tries to propose some response paths for small towns in metropolitan areas to adapt to the "unbalanced shrinkage". First of all, the small towns should integrate into the regional differential development pattern and strive for the institutional dividend. Secondly, the small towns should promote an industrial transformation, and then attract the market release of social capital. Thirdly, the small towns should improve the living environment and promote intensive use of land. Through these paths, we can stabilize the three-level structure system of "urban-township-village", and ensure the healthy urbanization of metropolitan areas.

Keywords

Small towns, Unbalanced shrinkage, Circle increasing pattern, Formation mechanism, Wuhan

1. Introduction

Along with the global wave of urbanization, urban agglomerations with megacities as the core have become the main form of urbanization in various countries. More than 55 percent of the world's population live in the urban agglomerations. The polarization effect around the metropolis leads to the centripetal flow of capital, labour, land and other resource elements in the surrounding small towns, which causes the shrinkage of small towns in the metropolis, such as population reduction, economic recession, idle housing and dilapidated space. Countries such as the United States, Germany, France, Japan and the Netherlands are generally facing the shrinking plight of the development momentum of small towns (Oswalt 2006, Johnson 2006, Glock 2004, Ortiz-Moya 2015 & Bontje 2012). The shrinkage of small towns in the metropolis has become a global issue. A comprehensive comparison of the development characteristics shows that there are significant differences in the types, characteristics and mechanisms of the shrinkage of small towns in different countries. For example, the shrinking small towns in both the United States and Japan are located in suburban, but the United States shows the phenomenon of poverty agglomeration and middle class outflow, while Japan shows the phenomenon of functional decline (Downs 1997 & Saori and Polivka 2008). The shrinking small towns in Germany are mainly concentrated in East Germany, showing the phenomenon of continuous decrease in population and employment rate, and spreading to West Germany (CHEN, et al. 2018).

In the context of China's localized development, it is found that the general growth and local shrinkage in China's rapid urbanization process have become the normal, with the economy entering the new normal (DU and LI 2018). For small towns in metropolitan areas, it shows local shrinkage under the overall urban growth. Specifically, Chinese metropolises are still showing a strong growth trend, and small towns still have a strong development potential on the whole. However, on the one hand, the outflow of labour force, the hollowing out of families and the aging of population have reduced the population vitality of small towns, while the convenient urban transportation network has provided the opportunity for township residents to go to the city for over-consumption, which has compressed the local consumption market and business service level of small towns. On the other hand, the government finance and social capital traditionally invested in small towns turn to the central supply driven by the value-added in the central city, leading to the market risk of small town businesses facing the transfer, withdrawal and withdrawal of business entities (GAO, et al 2019). Under the combined action of internal and external forces, some small towns in China's metropolitan areas show multi-dimensional shrinkage of population, space, economy and ecology, including the outflow and aging of labour force in the population dimension, hollowness and index deprivation in the spatial dimension, imperfect industrial development in the economic dimension, systematic low-level consumption in the ecological dimension and other external manifestations (DU and LI 2017, LIU and YANG 2017, LI and GENG 2018). Public and micro survey data show that more than 45% of the small towns in China's metropolitan areas have a new spatial pattern of "growth and shrinkage" co-existing

in a certain degree (LI, et al 2019). However, as an important spatial unit in the spectrum of urbanization that serves, connects and couples urban and rural areas, the shrinking phenomenon faced by small towns has an important influence on the healthy development of urbanization. Exploring the development path of adaptive shrinkage for small towns has become an important part of the healthy urbanization of metropolises.

Located in central China, Wuhan is the central city of Wuhan city circle, with a population of more than 12 million and a total area of 8,848 km^2. Over the past 20 years, Wuhan has become a typical metropolitan area in China, relying on its strong absorption capacity of population and economic resources. However, during the development, the small towns in Wuhan metropolitan area is faced with the simultaneous competition of Yangtze River Delta Urban Agglomeration and Pearl River Delta, and also faced with the challenge of resource backflow under the strategy of rural vitalization. It leads to irregular flow of urban and rural resources such as population and capital. As a typical area that has experienced the "collapse of the central region" and "rise of the central region", and also experienced frequent population migration, the small towns in Wuhan metropolitan area show remarkable logic of growth and shrinkage.

Based on the above, by taking small towns in Wuhan metropolitan area as the research object, this research uses the government open statistical data, supplemented by some micro survey data, to identify the growth and shrinkage pattern of small towns in Wuhan metropolitan area. Then the research analyses the phenomenon and formation mechanism of the growth and shrinkage of small towns in Wuhan metropolitan area, and puts forward the adaptive planning response path to promote the healthy development of small towns in metropolitan area.

2. Methodology

2.1. Analytical Framework

Population change is widely used internationally as the main criterion to measure whether the towns shrink or not (Oswalt, et al. 2006). The Shrinking City International Research Network (SCIRN) defines shrinking towns as "areas with a population of at least 10,000, most of which should experience population decline for more than two years, accompanied by structural economic transformation and crisis" (Wiechmann 2008; Hollander, et al. 2009). However, as a complex system with overlapping factors of population, land and economy, it is limited to evaluate the shrinkage of small towns simply by population index. If the development of small towns is regarded as the flow and agglomeration of capital, labour and other production factors in the built space (Bertinelli et al. 2004), then the shrinkage of small towns should be understood as the spatial decay caused by the outflow and relocation of capital, labour and other mobile production factors (Du, et al. 2017). It is proposed in relevant studies that town's shrinkage has economic, population and spatial dimensions, which can be used to emphasize multidimensional processes and effects (Martez-fernandez et al. 2012). Based on the above, population, economy and land are selected as the index dimensions to evaluate the shrinkage of small towns in this study, with a view to systematically explain the phenomenon of shrinkage of small towns.

2.2. Research Method

Based on the above, a three-dimensional comprehensive index system of population, economy and land was firstly established. The comprehensive index system includes eight indexes, which are: total population, urbanization rate, regional GDP, total fixed asset investments, local fiscal revenue, built-up area, population density, and area of public green space. Then, all the indexes are standardized, and the weight of indexes is determined by means of "Standard Deviation Decision" (Wang 1999), so as to avoid the influence of each index dimension and subjective assignment (formula (1)). And then, the comprehensive development index of small towns is calculated according to the formula (2), and the shrinkage degree of small towns is characterized according to the change of the comprehensive development index of small towns in different years, seen in formula (3).

$$W_j = \sigma(Index_j) / \sum_{j=1}^{m} \sigma(Index_j) \quad (1)$$

$$Index_i = \sum_{j=1}^{m} X_{ij} W_j \quad (2)$$

$$\text{Shrinkage} = \Delta_{Index} = Index_{it1} - Index_{it2} \quad (3)$$

2.3. Data Source

This research takes all the small towns in the six remote districts of Wuhan except the Chengguan Towns as the research objects, with a total of 58. The six districts are as Huangpi district (located in the north of Wuhan, contains 16 towns), Xinzhou district (located in the northeast of Wuhan, contains 13 towns), Jiangxia district (located in the south of Wuhan, contains 10 towns), Dongxihu district (located in the west of Wuhan, contains 6 towns), Caidian district (located in the west of Wuhan, contains 10 towns), and Hannan district (located in the southwest of Wuhan, contains 3 towns). With a comprehensive consideration of the urbanization process and characteristics of both China and Wuhan, this research selects the year of 2004, 2009 and 2014 as the time points of indicator measurement. The demographic and economic data of research evaluation indexes are all directly or indirectly derived from the statistical yearbook of Wuhan and six districts, supplemented by relevant data obtained from field observation and questionnaire survey. The land data are derived from the built-up area patches downloaded from the Google map.

3. Result

3.1. Comprehensive Development Index of Small Towns

Through the use of population, economy, land and other relevant data of the year 2004, 2009 and 2014, the comprehensive development index of small towns in Wuhan was measured, and the spatial distribution map of the comprehensive development index of small towns in corresponding years was drawn (Fig.1). The results show that the overall difference of the comprehensive development index of small towns in Wuhan in 2004 is small, with a spatial pattern of "high in the north and low in the south". The small towns with high comprehensive development index are mainly concentrated in the north of Wuhan, including Yangluo and Xinchong in Xinzhou district, and Shekou, Tianhe, Hengdian in Huangpi district. In 2009, the north-south difference in the comprehensive development index of small towns in Wuhan gradually weakened. Small towns with high comprehensive development index are concentrated in the north of Wuhan. Especially Yangluo and Shekou have become the significant growth poles. However, the comprehensive development index of small towns far

away from the main downtown have showed a decreasing trend, such as Mulan, Xiaosi, Sandian, Jiujie and so on. By 2014, the comprehensive development index of small towns in wuhan has formed a spatial structure of "decline of circle layer" which rings the main downtown, that is, the closer to the main downtown, the higher the comprehensive development index is; the farther away you are from the main downtown, the lower the composite development index. The first circle layer consists small towns surrounding the main downtown, including Yangluo, Wuhu, Shekou, Tianhe, Jinghe, Zoumaling, Zhashan, Zhengdian, etc. The second circle layer refers to the small towns located in the middle of six districts, including small towns such as Shuangliu, Wangji, Cangbu, Liuzhi, Qijiawan, Yuxian, Jinkou, Dazhi and so on. The third circle layer is located at the edge of Wuhan. And the small towns present continuous spatial pattern with small comprehensive development index, mainly concentrated in the north of Huangpi district, the north of Xinzhou district, the south of Jiangxia district and the west of Caidian district.

At the district level, the differences in the comprehensive development index of small towns in six districts of Wuhan were relatively small in the early days. However, by 2009, the comprehensive development index of small towns in various districts showed a polarization trend and the differences were significantly enlarged. Till 2014, the differences in the comprehensive development index of small towns among different districts gradually narrowed. But there were significant polarizations in the small towns within the six districts, which was manifested as the spatial pattern of the declining circle layer of the comprehensive development index of small towns from the main downtown to the outside.

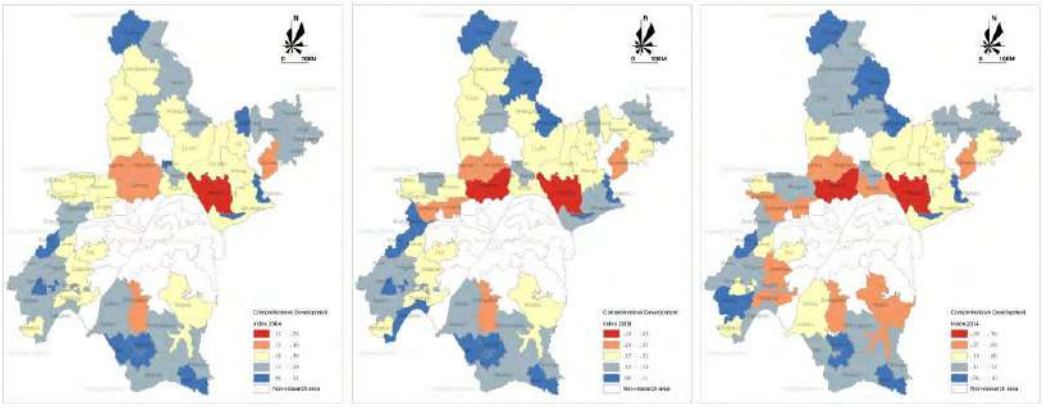

Figure 1 Spatial difference of comprehensive development index of small towns in Wuhan

By comparing the calculated results of the comprehensive development index of small towns with the spatial distribution characteristics of retail business in Wuhan (FIG.2), it is found that the calculated results of the comprehensive development index of small towns are highly consistent with the spatial distribution characteristics of economic industry, so as to further verify the authenticity of the comprehensive development index

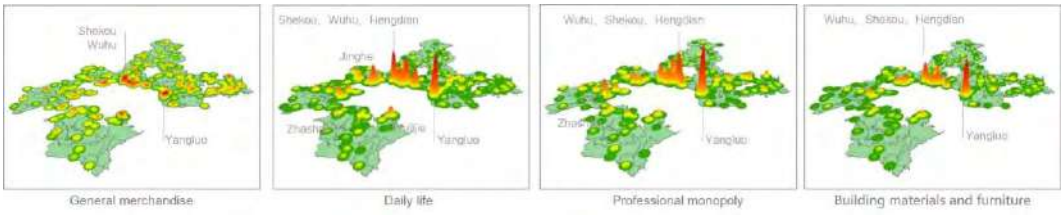

Figure 2 Spatial distribution pattern of entity retail business in small towns in Wuhan(2014)

3.2. Unbalanced Shrinkage of Small Towns

The change of comprehensive development index is used to measure the growth and shrinkage of small towns. If the comprehensive development index declines, it can be defined as the shrinkage of small towns, and vice versa. This research measured the shrinkage degree of small towns in Wuhan in three periods: 2004-2009, 2009-2014 and 2004-2014. The results show that from 2004 to 2009, there was a large area of shrinkage of small towns in Wuhan (FIG.3). More than 50 small towns showed varying degrees of shrinkage, but most of them showed small extent of shrinkage. Only Yangluo, Tianhe, Dongshan, Zhengdian and other small towns, concentrated in the northern part of the main downtown, showed relatively high degree of shrinkage. From 2009 to 2014, small towns in Wuhan showed an overall growth trend. But there were still 17 small towns which were far away from the main downtown got a shrinkage, such as Changxuanling, Xinchong, Baiquan, Caijiacha, Yuxian, Xiaosi and other small towns, mainly concentrated in the northern Huangpi district and the western Caidian district. Small towns near the main downtown showed a significant growth pattern, especially small towns such as Yangluo, Wuhu, Jinkou and Zhashan, which showed an increase of more than 0.1. On the whole, during the period of 2004-2014, small towns in Wuhan have showed a pattern of "unbalanced shrinkage" which coexists with significant growth and shrinkage. The shrinking small towns were mainly concentrated in Huangpi district, Dongxihu district, the west of Caidian district and the middle of Xinzhou district. The growing small towns are concentrated in the first circle layer outside the main downtown and some small towns in the south of Jiangxia district and the east of Xinzhou district.

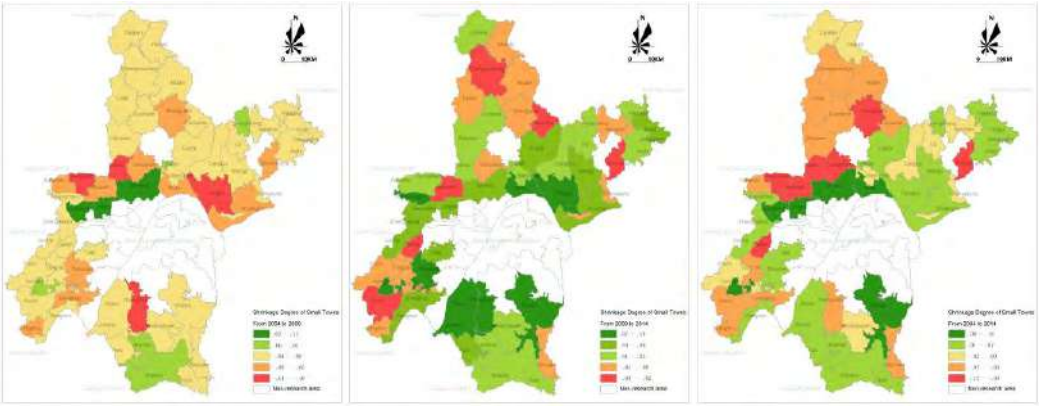

Figure 3 Shrinkage degree of small towns in Wuhan (2004-2009, 2009-2014, 2004-2014)

At the same time, the research measured the shrinkage degree of small towns from the single dimension of population (FIG.4). The results show that from 2004 to 2009, 45 small towns in Wuhan experienced population shrinkage, covering all six districts. The population shrinkage of Huangpi district is the most serious, especially the small towns like Shekou, Liuzhi, Qijiawan, Luohansi, Hengdian, Yaojiaji and Caidian, whose population fell by more than 7,000. From 2009 to 2014, only 10 small towns experienced population decline, which was quite different from the previous stage in terms of population evolution space. Based on a ten-year investigation from 2004 to 2014, it is found that the population of small towns in Wuhan has a development pattern of "shrinkage in the north, growth in the west, growth and shrinkage coexists in the south and east", and presents a circle structure of "shrinkage in the periphery towns and growth in the main downtown". Further analysis from the district level shows that the population of six remote districts in Wuhan are all decreased from 2004

to 2014 (FIG.5), but the decrements are significantly different. Xinzhou district and huangpi district had the largest total population reduction, with 217,000 and 154,000 respectively. While in Caidian district, Dongxihu district and Hannan district, the population decline was no more than 30,000, among which Caidian district has the smallest decline, only 13,000. In terms of the shrinkage degree of population, the most severe one is Dongxihu district, reaching 0.41, followed by Xinzhou district (0.35) and Jiangxia district (0.37), and the least significant one is Caidian district (0.17).

By comparing the above two calculation results, it is found that there is a significant difference between the two methods of measuring the shrinkage degree of small towns. Although population is the most direct variable to measure the shrinkage of small towns, as a complex multi-dimensional feature, the "unbalanced shrinkage" of small towns cannot be measured independently by a single index, and a multi-dimensional evaluation system must be established to scientifically identify the growth and shrinkage of small towns.

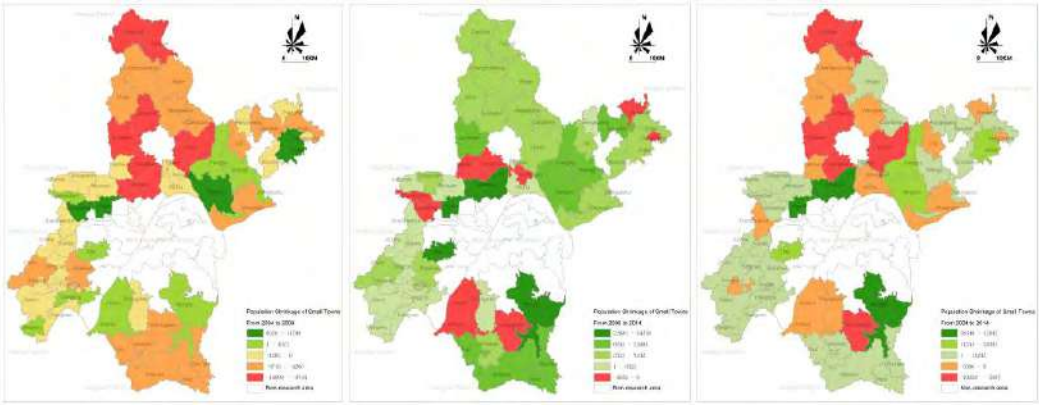

Figure 4 Population shrinkage of small towns in Wuhan (2004-2009, 2009-2014, 2004-2014)

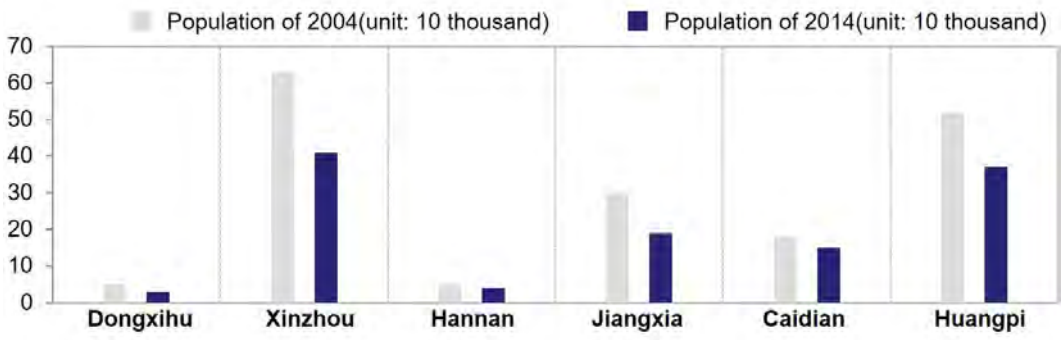

Figure 5 Population of six districts of Wuhan in the year of 2004 and 2014

4. Discussion and Conclusion

4.1. Formation Mechanism of the “Unbalanced Shrinkage”

The above results show that the small towns in Wuhan have shown a certain trend of unbalanced shrinkage, with a regional unbalanced spatial characteristic. A comprehensive interpretation of the internal characteristics of regional unbalanced shrinkage found that the formation of this shrinkage pattern lies in the unbalanced supply of city institutions,

centripetal delivery of social capital and reconstruction of regional division of labour network.

(1) Unbalanced supply of institutions

The effective supply of upper institutions will significantly affect the social and economic development and space construction process of small towns. Since 2004, Wuhan has issued a series of policies to support the development of its peripheral small towns (Table 1). Due to the bias and preference of the government-led institutional supply, the small towns present regional unbalanced institutional environment. It has become the general trend of Wuhan's development to put public resources and social capital into orderly groups around key towns, central towns and new towns. Especially since 2010, according to the development strategy of "upgrading the main city and expanding the new city", Wuhan has further increased the investment and construction in the new city, formulated the regional employment and housing balance plan, and supported the gradient transfer and agglomeration distribution of urban population and industries. The new towns such as Zhashan, Shekou, Wuhu, Yangluo, with the aid of regional public service facilities, further enhance their industrial development and economic strength, leading to the further intensification of the polarization trend of regional development. On this basis, the regional growth poles have gradually formed, such as Yangluo, Zhashan, Wuhu, etc. For example, Wuhu, the new town in the north, is in a leading position in Huangpi district with the construction of transportation facilities such as new Huangwu Highway, Hankou north road, the fourth ring road and regional functional facilities such as Hankou north market group and Taichuang zone (FIG. 6).

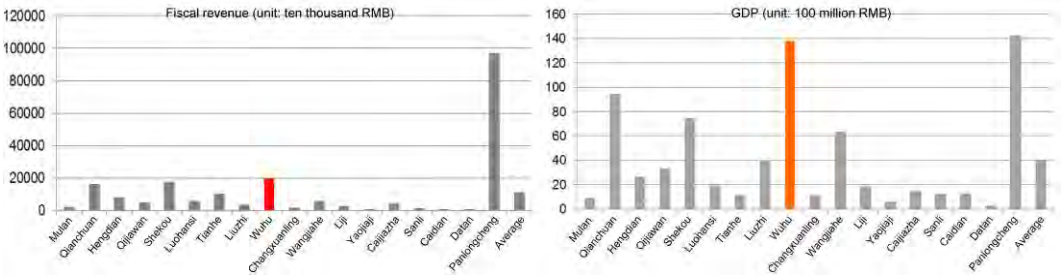

Figure 6 Comparison of fiscal revenue and GDP between Wuhu and other towns in Huangpi district in 2014

Table 1 Evolution of policy and institutional supply of small towns in Wuhan from 2004 to 2014

Time	Policy/ institution	Content	Effect
2004	Opinions on speeding up the construction of small towns	Developing key towns, accelerating investment in infrastructure and public service facilities and guiding the injection of social capital	Effectively promoting the construction and development of Yangluo, Wuhu, Zoumaling, Xingou, Xiangkou, ZuoLing, Shekou and other key towns
2006	Urban agriculture development planning of Wuhan	Promoting the construction of urban agricultural industrial zones	Six industrial parks have been formed, including Wuhu to Shuangliu, Dongxihu, Caidian to Hannan, Huangpi to Xinzhou and Jiangxia

2008	11th five-year plan of city spatial layout in Wuhan	Delimiting six new town clusters and six ecological green wedges	Promoting the rapid growth of towns within the new town cluster and limiting the development of towns within the ecological green wedge;
2010	Master plan of Wuhan	Determine the four-level town system of "main city - new town - central town - general town"	Strengthening the supporting facilities of the new town and the central town and improve the construction scale of the central town
2011	Opinions on accelerating the implementation of new urbanization	Cultivating the development of central town, characteristic town as a strategy to promote new urbanization	Further strengthening the development level of the central town. And show policy preference on land indicators, financial supply, and public facilities construction
2012	Notice on the pilot reform of the administrative system of economically developed towns	Carrying out a reform of strengthening the administrative system of expanding the power of economically developed towns	Three regional growth cores have been formed, including Zhashan and Wuhu

(2) Centripetal delivery of social capital

The Neo-Marxist theory holds that the spatial production of urban construction environment is the result of social capital control and action (ZHANG and CAI 2006). The effective allocation of government and social capital has become the main driving force for the social and economic development of small towns. Before 2004, with a small agglomeration effect of the central downtown of Wuhan, the capital investment in small towns remained relatively stable, which effectively promoted the construction of facilities in small towns. But with the rapid development of the central downtown of Wuhan since 2005, the capital appreciation effect and effective recovery rate of the central downtown are much higher than the peripheral small towns, causing the government finance and social capital of the traditional small towns to turn to the central supply. Especially the industrial capital, mainly concentrated in the industrial parks in urban development areas, which leads to the general lack of industrial support and vitality in peripheral small towns. At the end of 2010, the "Industrial doubling plan" of Wuhan has put forward that the layout of industrial project and allocation of development factors would mainly located in nine key blocks, which only covers three small towns, which are Yangluo, Shekou and Zhashan. In 2014, the comprehensive planning of the four major blocks of Wuhan proposed that industrial enterprises should be centrally distributed, new town centres should be centrally built, supporting infrastructure should be centrally built, and "industrial agglomeration, spatial concentration and land use intensification" should be strengthened. At the same time, the establishment of industrial parks in peripheral small towns is prohibited, especially those located in efficient and characteristic agricultural circles. These requirements directly make it difficult for the peripheral street towns with a certain development foundation to play their important carrier role in the urbanization process due to a lack of proper support, and the local

industrial development of the towns and villages is limited, and the towns and villages all show the trend of decline. Statistics show that during 2004-2014, the new construction lands of the small towns, with an area of 175.1 square kilometres, are mainly located in the first circle around the main city, such as Yangluo, Shekou, Tianhe, Wuhu, Zhashan, Jinkou and other towns (Fig.7). While the area of construction lands for small towns outside the first circle has only increased by square kilometres. Due to a lack of injection of social capital, the peripheral small towns generally face the dilemma of slow space growth and sluggish development.

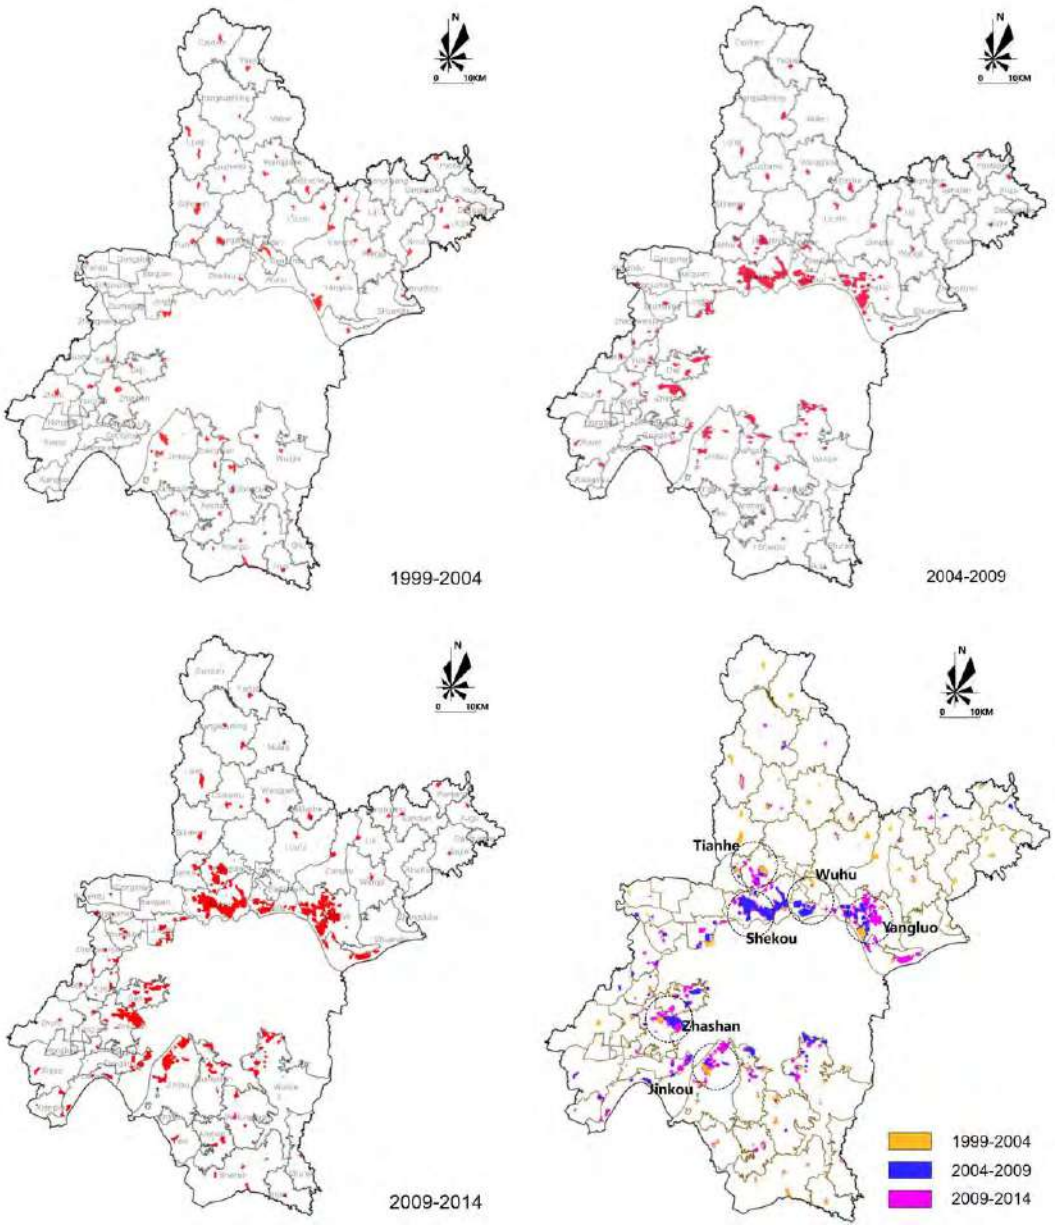

Figure 7 Distribution of new construction land in small towns from 1999 to 2014

(3) Reconstruction of regional division of labour network

According to social network theory, urban and rural social and economic development is attributed to the spatial flow effect of material resources, in which material resources are

mobile elements and social and economic network is the connection bridge of element circulation. Since 1978, Wuhan has long valued urban areas over rural areas, leading to the solidification of the urban-rural dual structure. Small towns become the connection bridge and transfer station connecting the circulation of material resources between "urban area" and "rural area", thus gradually forming a stable "city-town-village" three-level division of labour network within the scope of the city. However, with the introduction of policies in China such as the new socialist countryside in 2005, the beautiful countryside in 2009 and the rural revitalization in 2017, Wuhan has made great efforts to improve rural construction and promote the overall planning and integrated development of urban and rural areas. After more than ten years of rural construction, Wuhan has basically achieved the integration of urban and rural facilities, which has weakened the public service function of small towns to the countryside. At the same time, the industrial capacity of small towns declines, and the functions of small towns fade as a result of transmission. There is a phenomenon of "city-village" cross-level factor flow between urban and rural areas in Wuhan city, and the service shrinkage of function decline generally occurs in small towns.

In addition, Wuhan has focused on the development of rural tourism industry since 2010, and formed a number of unique tourist towns relying on their own landscape resources and tourist attractions, such as Caidian, Yaoji, Changxuanling, Mulan, Liji, Wangjiahe, Daoguanhe, Suohe, Yong'an, Fasi and other towns. In accordance with the idea of key transformation and upgrading, 74 beautiful villages and 15 central villages (communities) have been built successively by adopting four models, including the mode of combining agriculture with tourism, the mode of combining poverty alleviation with development, the mode of building new countryside and the mode of developing characteristic agricultural products. The villages gradually get rid of the dependence on towns, which leads to the significant weakening of township functions.

4.2. Response Path Adapted to the “Unbalanced Shrinkage”

As mentioned above, under the influence of institution, capital and network, the development of small towns in Wuhan city shows a significant feature of "unbalanced shrinkage". In spite of the regional integration development, the shrinkage of small towns has its inevitability and rationality. However, this kind of shrinkage also adversely affects the healthy development of social economy in small towns. Therefore, it is necessary to adjust the development mode of small towns, explore the development path of small towns adapted to the unbalanced shrinkage, so as to promote the healthy development of small towns and urban division of labour network.

(1) Integrating into the regional differential development pattern and striving for the institutional dividend

To cope with the influence of regionalization, the self-cognition initiative of small towns should be exerted firstly. On the one hand, small towns need to seek differentiated and characteristic development in regional competition, give full play to their advantages in region, culture, resources and location, and seek a breakthrough in development based on characteristics and advantages, so as to eliminate the adverse impact of contractive elements. On the other hand, small towns should extend the industrial chain and form linkage development with surrounding industries to integrate into regional development pattern and improve regional competitiveness based on their own characteristics, development capabilities and regional development requirements.

On this basis, small towns should actively strive for institutional dividends. In the process of institutional supply, the government always gives priority to the overall development efficiency of the city, while lacks independent thinking of individual small towns. Therefore, small towns must actively acquire the preference of urban institution to better support their own development. To be specific, on the one hand, during the process of regionalization development, small towns should face up to the reasonable shrinkage under the influence of regional environment, and effectively adjust, restructure or streamline the regional and internal functions of small towns according to the changes of regional environment. And then they should pay attention to the reallocation and selection of resources after shrinkage and expansion, so as to meet the needs of regional development. On the other hand, small towns should change the development mode from the self-centred mode to the regional cooperation and become the important node of the network town cluster with multi-centre connection. In the meantime, the city government need to targeted put forward the strategies adapted to the "shrinkage" for the small towns in the overall urban planning, including regional economic collaboration, urban and rural public service facilities sharing, town and country information interaction between urban and rural areas, ecological network and other dimensions, with a view to improve the precision of unbalanced resource allocation and delivery, scientific nature and rationality.

(2) Promoting an industrial transformation and attracting the market release of social capital

The low level industrial structure and low efficiency industrial type are the important factors that cause the sluggish industrial development and economic shrinkage of small towns. For small towns in Wuhan, due to the spatial attenuation and selective orientation of radiation from the main downtown, most of them still mainly rely on agriculture and traditional industry, while the tertiary industry is weak. However, the production benefits of agricultural products gradually tend to be saturated, and the development of traditional industries is mostly in a state of small scale, low level, poor benefits and short industrial chain. It is not only unable to support local residents' jobs, but also difficult to effectively realize industrial agglomeration and driving effect. These small towns supported by traditional industries are prone to economic shrinkage due to their difficulty in adapting to the requirements of economic development in the post-industrial era in regional competition.

Therefore, small towns must adjust the industrial structure, reorganize and make full use of internal factor resources, strengthen and expand the industrial chain, and improve the industrial system to form an industrial development model of agglomeration and linkage. At the same time, we should abandon the unsustainable resource-consuming industries in the adjustment of industrial structure, and realize the intensive transformation, so as to lay a good foundation for the healthy and sustainable development of small towns. In addition, the injection of social capital also provides a new opportunity for the renewal of urban built environment and space reproduction. According to David Harvey's secondary circuit theory, the effective delivery of capital plays a significant role in stimulating the social and economic development of cities and towns. Therefore, in the shrinking small towns, we should return to the capital market, use urban industrial transformation to attract capital backflow and stimulate urban space reproduction.

(3) Improving the living environment and promoting intensive use of land

In 2019, China's urban and rural planning has officially entered the era of spatial planning. Land improvement oriented by intensive utilization of land resources has become an important part of space governance. However, the construction of small towns is blindly expanded with a widespread use and waste of land for a long time under the stimulation of land finance. Although the Wuhan government has restricted the construction scale of small towns in terms of land transfer index, the lack of forward-looking spatial planning has led to the lack of orderly guidance for the construction of small towns, and the phenomena of land waste, environmental pollution and farmland occupation still exist. Along with the phenomenon of population outflow and economic deactivation, the living space, commercial space, public space and industrial space in small towns are all in the state of vacant and decaying to varying degrees, which further worsens the dirty and poor urban environment in small towns. Therefore, it is particularly important to promote the intensive use of land and improve the living environment of small towns.

For shrinking small towns, the increment of urban land should be reduced, the existing land stock should be used for follow-up land development as much as possible, and the idle urban construction land caused by the sluggish economy should be revitalized. And the government should weaken the concept of land finance, strengthen the improvement of urban living environment, supply urban environmental sanitation facilities, and strengthen the supervision of urban land development, utilization and construction with the goal of creating a good urban living environment.

For small towns that have not shrunk, we must adhere to the development principle of intensive use of land and efficient use of space in small towns, and carry out appropriate incremental development on the basis of not reducing the development efficiency of urban stock land, so as to avoid the decline of energy efficiency of urban land and enter the shrinkage trap of "land overdraft". At the same time, urban living environment should also be improved, and the supervision mechanism of urban living space protection should be done well, to avoid population loss and urban deactivation caused by uninhabitable urban.

(4) Building a stable regional division of labour network

While facing up to the shrinkage of small towns, China's unique "semi-urbanization" phenomenon cannot be ignored. The basic social security function of small towns is still an important link in the relationship between towns and villages. Especially for the small towns in the outer suburbs of Wuhan, most of them are not highly urbanized, and also not completely divorced from the leading mode of agricultural production. Those small towns still have the structural function of linking urban and rural relations, promoting the flow of factors and serving rural revitalization. A healthy relationship among city, towns and villages is still an important problem in the process of urbanization. Therefore, small towns should not only optimize their service functions, social functions and ecological and cultural functions, but also further strengthen the linkage development relationship in the "city, town and village", "town and town" and "village and village", so as to build a network city-town-village hierarchical model. Small towns also need to integrate scattered elements of regions and grass-roots units, form a network of industrial interaction, service sharing and transportation interconnection supporting system, and build a networked and flat multi-dimensional city-town-village space system, in order to realize the interconnection of elements and resource sharing in the overall shrinkage process. In this way, the service efficiency of grassroots public service facilities can be strengthened, and the relationship

between towns and villages can be reshaped to prevent the rupture of the single linear hierarchy relationship formed by shrinkage and to resolve the inertia of dependence on the original linear hierarchy system and its negative impact.

Research Paper

Rural revitalization under the background of balancing urban and rural development:

A case study of Batang village, Guangdong province, China

Weihong GUO*, South China University of Technology; China
Bin LI*, South China University of Technology; China

Abstract

Since reform and opening up, the development of Chinese urban and rural areas has shown an evolution of integration from isolation. The government promulgated national policies and related planning strategies, aiming at realizing the goal of rural revitalization through the system reform and planning adjustment of balancing urban and rural development. In the complex process of social development, there are many problems with rural areas, such as lack of infrastructure, unbalanced economic development, dilapidated living environment and insufficient sharing between urban and rural areas. On the premise of meeting the requirements of national laws and policies, this paper takes the planning of Batang village in Yunfu city of Guangdong province as an example. Combine with ReBAM theory to make sure Batang village is suit for developing tourism. And based on field survey made a Batang plan by planning knowledge. Through literature review and field survey to explore how to realize the revitalization of the rural areas under the development mode of balancing urban and rural development. The conclusion of the research took rural tourism as the breakthrough point, and formed complementary and dislocation development mode with the city. In living aspect, the research optimized infrastructure and improved people's living environment as well as summarized cultural elements to inherit rural civilization. In production aspect, it exploited rural commercial potential and income-generating path, and completed the transformation from passive development to active revitalization to achieve prosperity industry and life. In ecology aspect, it combined with sustainable development model to create an ecological and livable rural landscape. At last, the research established urban and rural co-management system and shared rural information platform to achieve effective governance, to ensure that tourism mode as a starting point for rural revitalization planning can be sustainable development. The research of this paper practiced the national experience of rural revitalization as a pilot project, facilitated the implementation of relevant policies and supported planning for rural revitalization, and explored the methods of rural revitalization under the background of balancing urban and rural development. Based on the acceptance of the plan by local villagers, the approval of Guangdong Postgraduate Education Innovation Project in 2018 and got the third prize of National Competition for Ecological Wisdom Inspired Urban and Rural Practice in 2019, it is hoped that the research will contribute to the rural revitalization under the background of balancing urban and rural development.

Keywords

Rural revitalization, plan, tourism, balance urban and rural development

1. Introduction

Since reform and opening up in 1978, China has taken a series of strategies to balance urban and rural development. In 1980s, Shenzhen firstly took into an economic zone for achieve the urban development in Pearl River Delta. In 1990s, Pudong area in Shanghai of Yangtze River Delta developed rapidly (Suh, 2007). In the early 2000s, Binhai New District started to establish in the area around Bohai Sea Area. In 2017, the country sets the development strategy of Xiongan new district (Li et al., 2017). With the fast development of urban areas in China. More and more rural people have moved to big cities for living. Thus the urbanization level is rapidly catching up from 10.6％ in 1949 to 56.1％ in 2015 (Gu et al., 2017). Villagers abandoned their houses and lands and turned their villages into ghost towns (Gao and Wu, 2017). The development of urban and rural is unbalanced.

In fact, since the founding of the PRC in 1949, rural revitalization has been the important step for national development (Zhu,1999; Zhang, LeGates, & Zhao, 2016). In recent years, with the vigorous development of industry in China's cities, it is time for industry nurturing agriculture (Zacharias and Tang, 2010; Wang et al., 2019). Rural revitalization has been more focused of people's attention in China now. It aimed to break through the urban and rural binary system and reduced the disparity between cities and countrysides to realize the urban-rural integration (Li, 2015).

In 2017, the party's report on the Nineteenth Congress placed the issue of rural revitalization (Sun, 2018). Rural revitalization is a theoretical system and strategic guidance aimed at achieving comprehensive rural development with strong agriculture, beautiful countryside and rich farmers, aiming to accelerate the modernization of agriculture and rural areas, narrow the development gap between urban and rural areas and realize the construction of a well-off society in an all-round way (Zhou et al., 2018). As for rural planning strategies, Chinese focus extended from the function and economy to the cultural, aesthetic perspectives and other relative aspects (Chen, 2011).

But up to now, with the unbalanced development of urban and rural development in past few decades, there are lots of problems took into rural in China. Here takes the Batang village as an example to analyze.

2. Problems

2.1. Lack of infrastructure

In living aspect, lack the infrastructure of sewage system, public transportation system, public restroom, garbage disposal and relative service facilities are common problems in the rural of China. Even more and more villages have been established sewage system but imperfect infrastructures for using caused the problem of living environment. And the public transportation system hasn't established perfect in most of the villages. Incomplete traffic system will take harmful influence on rural revitalization (ChengBo, 2018; Zheng and Iop, 2018).

As the Figure 1 shows, the sewage system in Batang village doesn't wonderful for local villagers use. The restroom on the lake not only polluted the local living environment, but also affected the mood of the view. And Figure 2 shows the only public station in this village. There is no identification to show this is a bus station. The public transportation system doesn't perfect.

Figure 1 Restroom without sewage system

Figure 2 Unrecognized bus station

2.2. Unbalanced economic development

In production aspect, the economic gap between urban and rural areas is widening. The urban-rural income ratio had increased from 1.86:1 in 1986 to 3.33:1 in 2009, even though it's reduced to 2.7:1 nowadays (Chen et al., 2019). But the unbalanced economic development had been led to widening the gap between rich and poor people, for the harmonious development of the overall society had a negative impact (Chen et al., 2018). As Figure 3 and Figure 4 show, rural production mainly rely on primary industry in Batang village. And the articles for daily use made by old people of hand weaving.

Figure 3 Primary industry

Figure 4 Hand weaving

2.3. Dilapidated living environment

In ecology aspect, China's cities have attracted more and more people from rural to urban for living. By contrast, less and less people living in rural (Li et al., 2017). As the Figure 5 shows, Batang village is one of the villages in Xinxing county. And the population of Xinxing county is gradually decreasing.

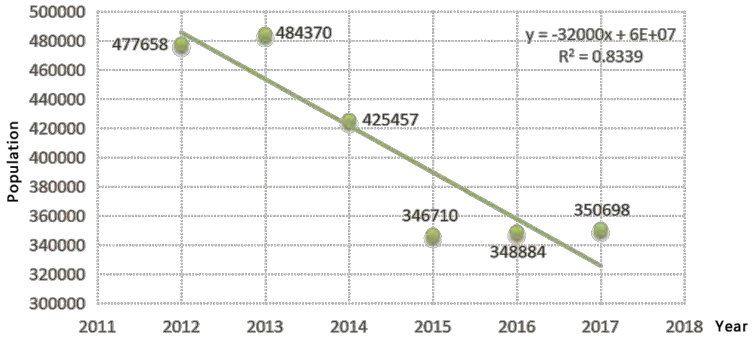

Figure 5 Population trends of Xinxing county

Less population means less people for living and producing in rural areas (Li et al., 2014). With the time goes, the rural left dilapidated living environment. And the left people for agricultural production, they had to use more pesticides for high levels of agricultural output. This took the problem of soil pollution, food safety issue and other environmental problems (Fan et al., 2009; Chen and Zhang, 2019). All of these makes the ecology environment decadent.

2.4. Insufficient sharing between urban and rural areas

In governance aspect, insufficient sharing between urban and rural areas is a historical issue. In order to develop the national economy from 1949, China had implemented a series of policies to support industry priority development. As the Introduction mentioned, the big city rapidly development is under this historical background. Since the 21st century, rural governance recognized and reformed to establish long-term mechanism of industry nurturing agriculture and cities supporting countrysides (Wang and Jin, 2014; Fang, 2017). With the process of rural revitalization in recent years, rural tourism became the main way to implement (Li et al., 2018). But just with the support of government is not enough, insufficient sharing between urban and rural areas needs bottom-up initiatives of local people to achieve rural revitalization (Li et al., 2016).

3. Methods

3.1. ReBAM theory

With the development of rural revitalization of tourism model, this paper focus on ReBAM (Recreational Belt Around Metropolis) theory try to find a reasonable way for revitalizing Batang village in Xinxing county. ReBAM theory firstly offered by Prof Bihu WU in 1998. This theory has been applied and developed in Xiamen (Dong, 2010), Chongqing (Zhou et al., 2013), Kunming (Baohong et al., 2011), Shanghai (Wu and Cai, 2006), Wuhan (Li et al., 2016), and Beijing city (Guo et al., 2010). It's an effective method for rural revitalization which includes three determinants, they are the growth of domestic demand, transportation networks, and policy-driven supply.

As the Figure 6 shows, the travelling population more than sevenfold increased in Xinxing county form 2005 to 2017. The demand of tourism is rapidly developing. This is one of the three determinants underlying the formation of ReBAM theory.

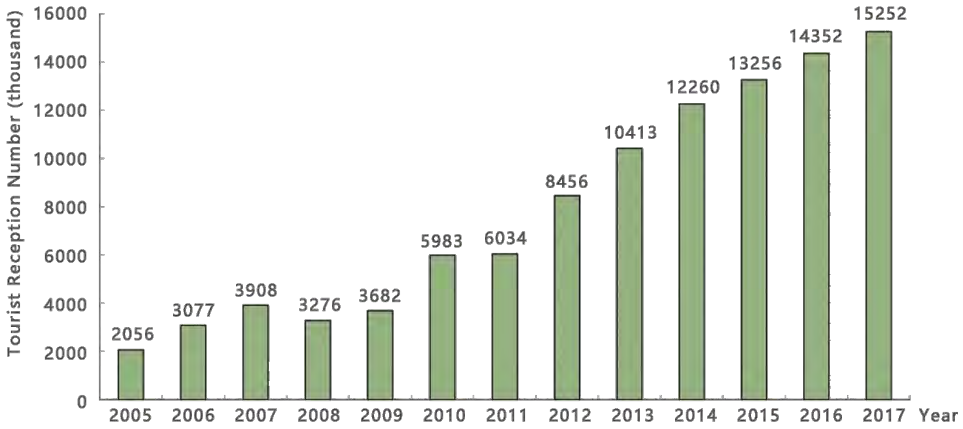

Figure 6 Travelling population trends of Xinxing county

3.2. Field survey

Through field survey we can see Batang village is located in Xinxing county, Yufun city, Guangdong province (Fig. 7). The traffic system of Batang village is convenient that include

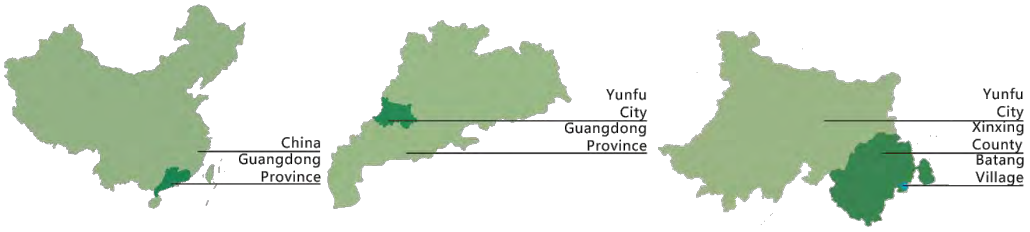

Figure 7 Batang village location

No.534 county highway to connect surrounding cities (Fig. 8). There are 5 cities can be arrived within 2 hours transit time (Fig. 9). And the total population of these cities are around 12.4 million that provide great potential tourists. The convenience traffic network support the ReBAM theory of rural revitalization for rural tourism.

Figure 8 Traffic network of Batang

Figure 9 Transit time of Batang

3.3. Literature review

Besides reference ReBAM theory to analyze the demand of tourism for Batang village is sufficient, and through field survey to verify the transportation network is convenience for travelling, this research also took literature review to find the policy-driven supply to further support the rural revitalization of Batang village is suitable for tourism model.

Chinese Central Rural Work Leading Group published *Strategic Planning for Rural Revitalization (2018-2022)* in 2018. It aimed to develop rural revitalization in national macro level. This policy document mentioned rural revitalization ways based on balancing of urban and rural development. And it emphasized tourism development way should combine with rural in living, production, ecology and governance aspect.

Department of Natural Resources of Guangdong Province and Department of Agriculture and Rural Affairs of Guangdong Province joint released *Land Use Policies and Measures to Implement the Strategy of Rural Revitalization* in 2019. The Chapter 10 clearly stated that to increase land use support for rural tourism.

Yunfu City Master Plan (2012-2020) and *Xinxing County Master Plan (2013-2035)* show Batang village in Promote Development Zone (Fig. 9 and Fig. 10). It means the urban planning of this area is supported by relative urban planning departments and policies.

Thus tourism model can be concluded as a method that rural revitalization in Batang village is suitable whatever from ReBAM theory, filed survey and literature review.

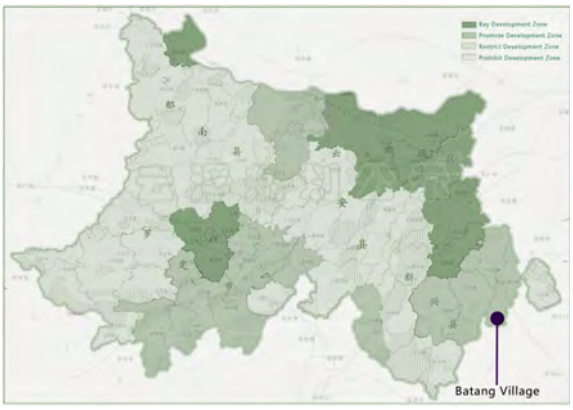

Figure 9 Yunfu city function plan

Figure 10 Xinxing county function plan

4. Results

4.1. Living aspect

Based on tourism model of rural revitalization, the research combined with planning knowledge to plan Batang village from four aspects.

In living aspect, as above analyzed there are lack of infrastructure such as garbage disposal, public restroom and public transportation system. So the plan designed facilities system and traffic system. As Figure 11 shows, the facilities system include public service facility, plaza and park, public restroom and garbage collection point according to the current situation of Batang village. And Figure 12 shows the traffic system include county high way, main village road, secondary village road and car parking. Even though the transportation network is convenience to Batang village, but the original traffic system needs to be optimizing inside of

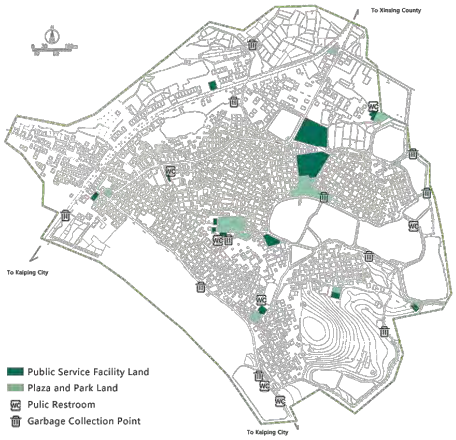

Figure 11 Facilities system

Figure 12 Traffic system

the village. These will give local residents a better living condition. Then more and more local people will be willing to live in here. It's also better for servicing tourists and inheriting rural civilization.

4.2. Production aspect

In production aspect, this plan classified land use nature firstly. The land use of Batang village divided into 6 categories. They are water land, agroforestry land, residential land, public service land, industrial land and transportation facility land. These land use coordinated with the design of living aspect (Fig. 13). According to unbalanced economic development problem analyzed above, the plan tried to mix some new industries in Batang village. Based on field survey, on both sides of the county highway has been existed some workshops. So it will be better to plan industrial development zone in these areas. The plan considered the local hand waving industries to plan handicraft development zone. And it complement business development zone for people trading in here (Fig. 14). The land use and industrial layout will

Figure 13 Land use

Figure 14 Industrial layout

offer more opportunities for improving local economy, and this will support the tourism development of Batang village.

4.3. Ecology aspect

In ecology aspect, the design planed landscape structure and landscape conservation areas based on field survey (Fig. 15 and Fig. 16). Not only considered the tourism model for rural

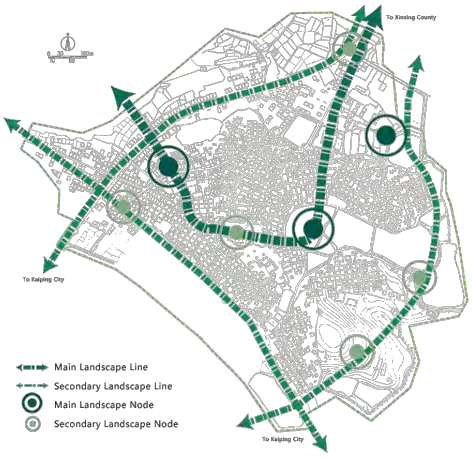

Figure 15 Landscape structure

Figure 16 Landscape conservation areas

revitalization, but it also attended to balance the relationship of natural landscape and cultural landscape. From different kinds of landscape levels, such as landscape nodes, landscape lines and different areas, the plan tried to integrate ecological landscape as a whole and to achieve harmony between man and nature. Even though existing population of Batang village is decreasing, but the better ecological environment will support rural revitalization.

4.4. Governance aspect

In governance aspect, even though a series of national policies has been inclined to rural areas since the 21st century. But just rely on the strategies conducted by country is not enough. It should be also taken an action from bottom to up. Especially for rural revitalization is based on tourism model. The support by government is limited, the better life need local villagers strive for that. So on the basis of government support, the plan also emphasized to found local organizations for rural revitalization. National governance coordinate with local autonomy will form a co-management system for rural revitalization. Even if the governance consist of government and local villagers can not be drawing as a blueprint, but this governance system is almost the most important link of rural revitalization chain.

5. Discussion and conclusion

The research focused on rural problems of China, found four main problems such as lack of infrastructure, unbalanced economic development, dilapidated living environment and insufficient sharing between urban and rural areas. Combined with ReBAM theory, field survey and literature review analyzed tourism model for rural revitalization is a good way especially for Batang village. Based on planning knowledge from living, production, ecology and governance aspects designed a new way for rural revitalization as well as try to solve the existing problems.

Based on the guide of School of Architecture, South China University of Technology, PB Design and relative organizations support, the research started from August, 2018 through field survey (Fig. 17), workshop study (Fig. 18), finally got the acceptance by local villagers and approval of Guangdong Postgraduate Education Innovation Project (Fig. 19). And recently, this research got the third prize of National Competition for Ecological Wisdom Inspired Urban and Rural Practice in July, 2019.

Figure 17 Field survey

Figure 18 Workshop study

Figure 19 Awarding ceremony

Up to now almost one year past, Batang village is developing well. The problem of restroom on the lake to pollute the living environment has been solved (Fig. 20). New plaza and excellent sewage system is gradually constructing (Fig. 21).

The ReBAM method based on three determinants of the growth of domestic demand, transportation networks, and policy-driven supply. It's also need to explored diversely for different villages (Van et al., 2008). Even though Batang village meets the requirements of these. This research creatively found the rural revitalization way combine with the existing theory and current problems. Not only is it just for tourism model of ReBAM, but it solves current problems too.

Figure 20 One year ago before research

Figure 21 Present view after plan

Under the background of balancing urban and rural development, the research found a feasible way based on tourism model for rural revitalization. Hope this research will be useful whatever in practice or academic field.

Research Paper

Short Analysis of the stakeholders' benefit and satisfaction about Rural Land Share Cooperatives of the Southern Jiangsu Province

- A Case Study of Jinxi Town, Kunshan City

Yi LI*, Shanghai Tongji Urban Planning& Design Institute Co.Ltd; China

Xihua ZHU, Jinxi Town government; China

Abstract

The agricultural land around Shanghai is famous for its huge population and intensive cultivation. With the expansion of the metropolis, a large number of agricultural people have entered the city to work, and rural land has been abandoned[1,2]. In 2009, Kunshan City implemented a land transfer system, and 99% of the cultivated land was packaged for large-scale farmers, and initially realized large-scale operation[3]. However, the large-scale business model has gradually experienced problems such as predatory management, ecological destruction, and no sense of social responsibility. Through the establishment of agricultural land share cooperatives, Changyun Village took the lead in realizing the collective management of agricultural land, taking shares in the land, giving priority to paying dividends to the land, and paying wages to the farmers working in the cooperative. The peasants' enthusiasm for entering the city has become an important buffer for the migrants to work in Shanghai and surrounding villages[4]. It has increased the employment rate. At the same time, it has supplied green agricultural products to the city, passed on agricultural technology, and activated local communities.

This article intends to analyse the correlation between several village share cooperative models based on Changyun Village and the large family farm contracting model of more than ten villages, and the satisfaction of villagers, combined with property rights theory, scale economy theory, and accounting cooperatives. Cost-benefit, evaluate the effect of "long cloud-style" collectivization on revitalizing the surrounding villages of metropolises and assess the satisfaction of governments at all levels. Through field interviews and questionnaire surveys, the correlation analysis of village cadres and villagers' satisfaction was conducted.

The government is optimistic about the role of the "long cloud model" in grassroots management and improvement of people's livelihood. Even if public finances are required to invest a large amount of money, it is necessary to strengthen the medical and social security of the villagers. The government is also quite satisfied with the Changyun model. At present, the economic benefits of the stock cooperatives have steadily increased. Although the growth rate is not large, the villagers have a strong sense of well-being, and the village's ecological environment has been improved. In the future, the cost of the village will be reduced after the large-scale operation, and the overall economic benefits will be improved. The

future research direction will be how to solve the specific problems that plague the cooperative's production and operation, such as low rice prices and lack of high value-added finishing facilities to continue to activate the surrounding areas of the metropolis and improve the satisfaction of the government and villagers.

Countryside around metropolis, Rural revitalization, Large-scale agriculture, Collective management

1. Agricultural land cooperatives

1.1. The definition of land cooperative

Agricultural land joint-stock cooperative is made by who enjoy the right to the contracted management of rural land and farmers engaged in agricultural production and operation of collective organizations, such as the management of land investment, entrust DaiGeng circulation mode of centralized and unified planning, unified management of the rural mutual cooperative economic organizations (hereinafter referred to as land cooperative). Since the household contract responsibility system, China's agricultural land is mostly decentralized management. In 1987, China put forward that where conditions permit, land management on an appropriate scale can be steadily promoted. In October 2008, the communist party of China (CPC) stated: "farmers are allowed to transfer their contracted land management rights in the form of subcontracting, leasing, exchanging, transferring and joint-stock cooperation in accordance with the principle of voluntary compensation in order to develop diversified scale operations." This provides a theoretical basis for the establishment of specialized farmer cooperatives based on the pricing of land contracting and management rights. The land transfer began to speed up after China made it clear that "farmers are allowed to transfer their contracted land management rights".

1.1. The causes of land cooperatives

Rural land joint-stock system reform comes into being in accordance with the development conditions of rural economy and society. With the development of China's industrialization and urbanization, the household land equalization system based on the land contract responsibility system is facing more and more problems.

In economically developed areas, rural labor transfer to the town and non-agricultural industry, farmers farming will reduce, even some villages have per capita arable land area is small, low degree of intensive land use, the efficiency is not obvious, and some are willing to engage in farming the land farmers and foreign individuals and enterprises need enough land scale management, land circulation strong demand, so the government issued documents, encouragement policy and related supporting policies to promote land scale. As an innovative mode of land transfer, rural land stock cooperative system has been actively responded and promoted by farmers and the government. The reform experiment of rural land joint-stock cooperative system was first carried out in Nanhai, Guangdong province in the 1980s, and then developed to a certain extent in Jiangsu and other places. The south China sea model and Kunshan model came into being in the actual work.

2. Basic information of Jinxi town and Changyun village

2.1. Subheading 2.1

Kunshan is located in the Southern Jiangsu, which is economically developed, highly urbanized and has a leading land transfer speed in China. With the expansion of the metropolis, a large number of agricultural population have been to cities for work and rural land is facing the risk of being abandoned. In 2009, Kunshan city implemented the land transfer system. The transfer land is up to more than 200,000 mu. All villages in Jinxi town have set up land joint-stock cooperatives, which have contracted out 15,315 mu of farmland to 127 large professional farmers, covering 99% of the town's total farmland . The large-scale farmland operation has been initially realized, which has solved the problems of land fragmentation and small-scale agriculture to some extent, and promoted the land intensification and agricultural mechanization degree.

Changyun village is a typical agricultural village, located in the north of Jinxi town. It has thousands of mu of farmland, and a large number of fish ponds. It has 6 natural villages, with 530 residents and 1,780 registered population, covering an area of 3.5 square kilometres. The disposable income of permanent residents is 29,000 yuan per person (2019).

Figure 1 Area of Jinxi Town

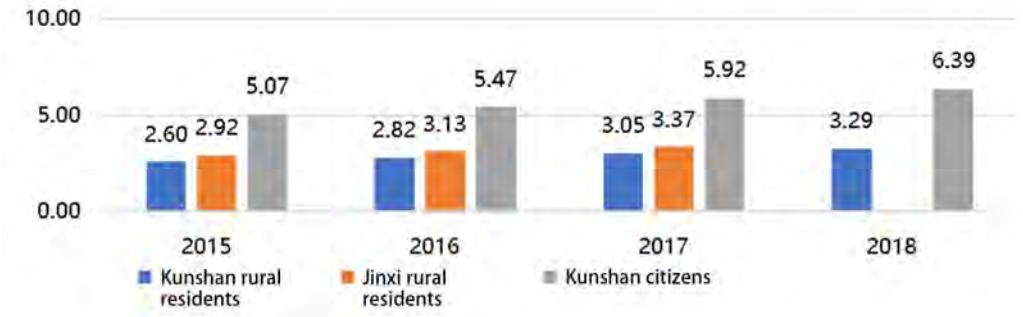

Figure 2 Kunshan urban and rural residents and Jinxi rural per capita disposable income from 2015 to 2017 (ten thousand yuan)

2.2. Subheading 2.2

In this research on Jinxi town, we found that the aging degree of rural population in Jinxi town is relatively serious. There is income gap between urban and rural areas. Young adults gather in cities and old people stay in villages. The elderly account for about 30 percent of the farmers surveyed, which is higher than the aging level of the surrounding urban population. The average age of the sampled changyun villagers was 55. Among the rural elderly interviewed in Jinxi town, 50% live alone or live with their spouses, while half of the surveyed families are 3-6 people, and the younger generation lives in other places. Most of the young and middle-aged people working in the area are outsiders. The population engaged in agriculture is aging.

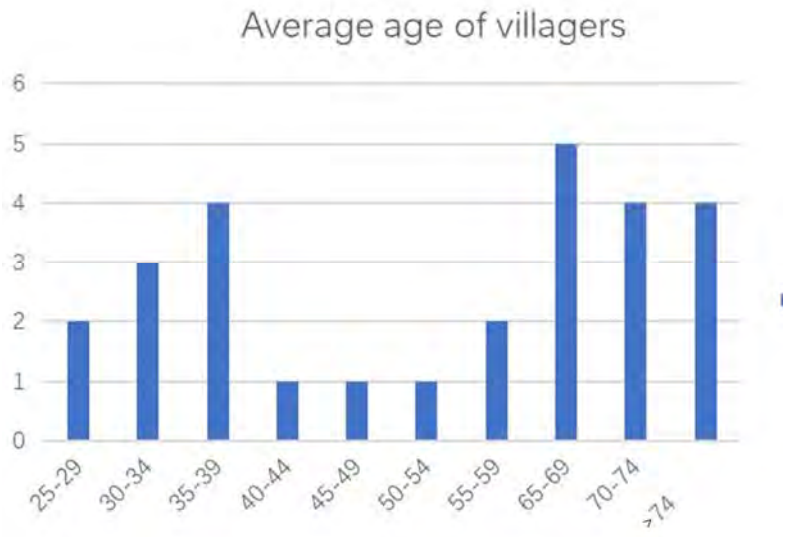

Figure 3 Average age of villagers

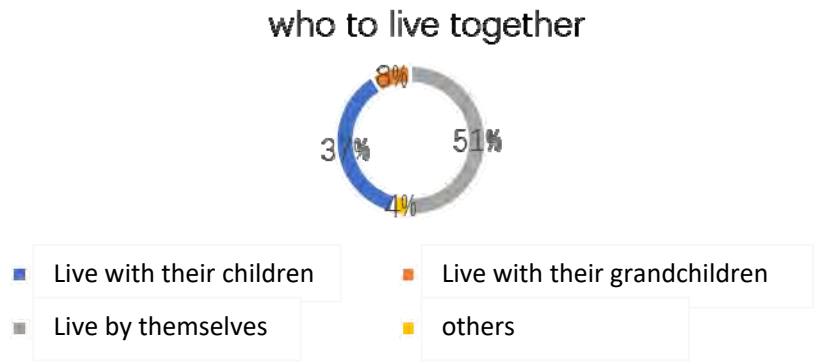

Figure 4 who to live together with villagers

3. Changyun Agricultural land cooperative

3.1. Subheading 3.1

In 2009, Changyun village gave land to 8 large farmers, and the rest farmers received a circulation income of 700 yuan/mu. Problems such as predatory operation, ecological destruction and no sense of social responsibility gradually appear in the large family management model, which leads to the widening gap between the rich and poor in the village. The government's subsidies to farmers for growing grain have risen gradually, to the point that they are equivalent to rental payments, while farmers who have transferred their land have not received dividends. Many large farmers sublet their farmland to earn the price difference. Large families disregard social responsibility, and perfunctory or even resistance to instructions such as pesticide safety, environmental protection, water conservancy and other, Leading to the pesticides disorderly and ecological damage.

Changyun village takes villages and towns as units and turns the traditional large contract into the farmland stock cooperative. In 2009, it established the Changyun agricultural land share professional cooperative (hereinafter referred to as the agricultural land cooperative). The agricultural land cooperative has been registered for industry and commerce, engaged in agriculture, forestry, its registered capital is 7.31 million yuan (2019). Cooperatives adopt the corporate system of operation and management, and farmers become shareholders with their contracted farmland rights and enjoy dividends. Changyun village tries to "co-own, co-manage and co-enjoy", and adopts the new mode of "cooperative farm" such as collective operation, contract labour and fixed production. Farmers' income mainly comes from dividends and labour in cooperatives.

Currently, about 1900 mu of rice is planted in Changyun village. In 2019, the farmland cooperative cultivated 1,850 mu. As a pilot project of collective agricultural cooperative operation in the town, Changyun farm launched innovative practice and promoted agricultural modernization and intensification in combination with Jinxi town's "10,000 mu of good farmland" project. At the same time, the development of ecological agriculture, raising rice paddy duck, rice paddy crab.

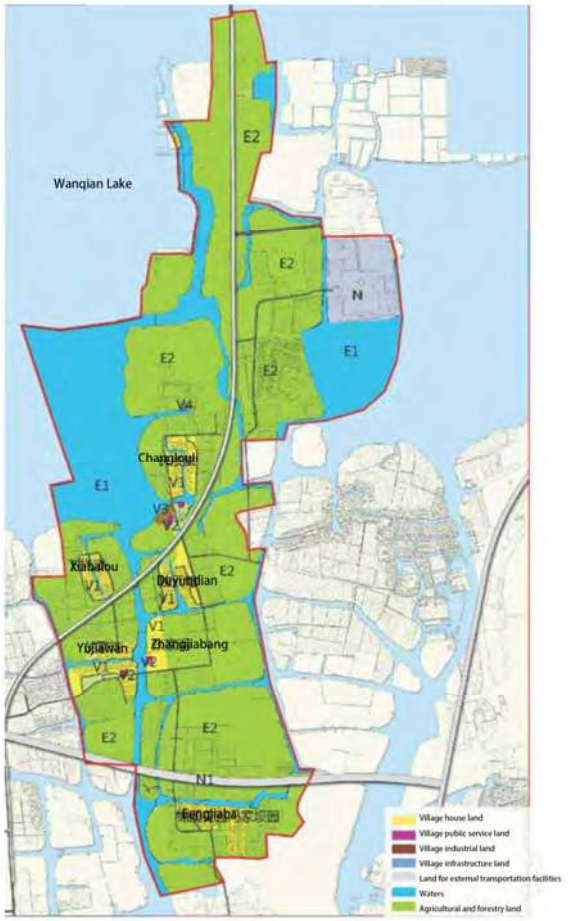

Figure 5 Agricultural Land of Jinxi Town

4. The model of Changyun land cooperative

4.1. Profit distribution of agricultural land cooperative

Cooperative dividends include two parts： Guaranteed income + dividend income. The form of guaranteed minimum income is the most suitable distribution form of land joint-stock cooperatives.

The first dividend is the farmland guaranteed income distributed to the shareholders at the beginning of the year, which is 900 yuan per mu per year. The second dividend is paid at the end of the year, which is no less than 100 yuan per share.

4.1. Production mode of agricultural land cooperative

1) scale and standardization

The cooperative carried out reclamation, building contiguous high-standard farmland. Improve soil quality through fallow cultivation and ecological transformation. With rice, oilseed rape、wheat, barley, highland barley and other crops as the key, the planting structure is optimized.

Farmland joint-stock cooperatives coordinate the allocation of capital, technology, labor force, land and other production factors, realize centralized support of agricultural technology services, unified seed supply, unified fertilizer use, unified disease prevention and pest control, unified field management, and unified settlement; We will implement centralized management of agricultural production, and settle production costs, operating expenses, subsidies for policy funds and production benefits.

2) Contractor's Scheduled Production Village collective and experienced farmers signed a contract production responsibility, every 100-200 mu to hire experienced farmers as administrators, awards for overproduction and compensation for reduced production. If more workers are required, the cooperative arrange villagers to do farm work. At the end of the year, farmers receive their wages by work record.

5. The cost-benefit analysis of stakeholders

5.1. Cost-benefit analysis of Jinxi town, Kunshan city

Tangible cost of government:

The cost of Jinxi town and Kunshan city mainly comes from land subsidies, water conservancy investment, agricultural tools support, technical support and so on.

Local government finance has supported land transfer. Since the 21st century, the investment of modern agriculture at Suzhou and county levels has been more than 2 billion yuan every year. Land about 15,400 hectares, equivalent to 231,000 mu, an average of 26.58 million yuan per mu. Changyun village irrigated area is a key construction project of Jinxi irrigation and water conservancy, which has invested 28 million yuan to transform the irrigated area of 5,000 mu of farmland. Now the village has formed a contiguous irrigated area, and the mechanization degree has been further improved. Jinxi Changyun irrigation district has built "one body and two wings" water conservancy technology information application platform. Jinxi has established a long-term water management and protection mechanism for small farmers. At the same time, the higher government needs to carry out technical promotion and scientific research support. These constitute tangible costs.

Intangible benefits of government:

The government's grass-roots construction income is the largest intangible income. It is reported that Changyun village's cadre and mass communication is closer, the degree of mass participation in management is strengthened, and party members' sense of responsibility is also increased. Villages have increased farmland and increased the balance of occupied and subsidized land. The government promoted agricultural techniques and trained more talents familiar with practical agricultural techniques. Provide members with free technical and professional training. The governments of Kunshan city and Jinxi town think highly of the role of "Changyun model" in grass-roots management and improvement of people's livelihood, and take it as a model to promote.

5.1. Cost-benefit analysis of Changyun Village

Tangible benefits:

Total village income has increased.

At the village collective level, the costs include land transfer payment, agricultural labor settlement compensation, and the purchase of tools and tools seeds. Expenditure: 1.87 million yuan for rice and 450,000 yuan for wheat. Before 2012, the total income of Changyun village was less than 1 million yuan, which is a relatively weak village in jinxi town of Kunshan. Cultivated land area: 1,850 mu. Jinxi ecological rice planted in the irrigated area was rated as "the ten most popular real estate rice by Suzhou people". It was mainly sold to Jinxi town and Kunshan city with a market price of 9.8 yuan/kg.

In terms of income, the total revenue was 2.9 million yuan, based on the per mu yield of 1,000 jin of rice and 600 jin of wheat. In terms of expenditure, the planting cost of rice and wheat, the service fee of labor and agricultural technology per mu and the payment of circulating gold amount amount to about 1 million yuan. Total revenue minus total cost, the net balance is about 500,000 yuan. If the contract is contracted by a large family, 300 yuan/mu will be paid according to the contract, which is only 100.2 million yuan. By contrast, the net operating income of "cooperative farm" has increased by 194,100 yuan.

The intangible benefit is the improvement of ecological environment. The sanitary environment of changyun village has been improved, the village capacity environment, the appearance of farmland has been increased, and pesticide has been applied.

5.1. Cost-benefit analysis of Villagers

Intangible costs:

Opportunity cost of farmer: working income is measured and calculated.

Land is not only a means of production, but also a means of living. After the transfer of land, farmers cannot grow their own vegetable seasonings, but need to buy them. Field research found that many people were growing vegetables at the head of the village. Manpower liberation: expand the scale of operation, farmland concentration area is conducive to mechanized operation, is conducive to the efficient use and liberation of labour force, help farmers go out to work.

The increase of cooperative income can bring the income of farmers who have become shareholders. The land transfer fund increased from 750 yuan per mu in 2012 to 1050 yuan per mu in 2015, an increase of 40%. Farmers transfer income steadily. Before 2012, the village's per capita income was less than 20,000 yuan. Some 50, 60 personnel, through participating in the demonstration of agricultural labour settlement compensation, the annual salary can increase about 20,000 yuan. The per capita income of villagers increased from 21,000 yuan/person in 2012 to 29,000 yuan/person in 2015, an increase of 36%.

6. The satisfaction of villagers

6.1. The fieldwork analysis to satisfaction of Changyun's villagers

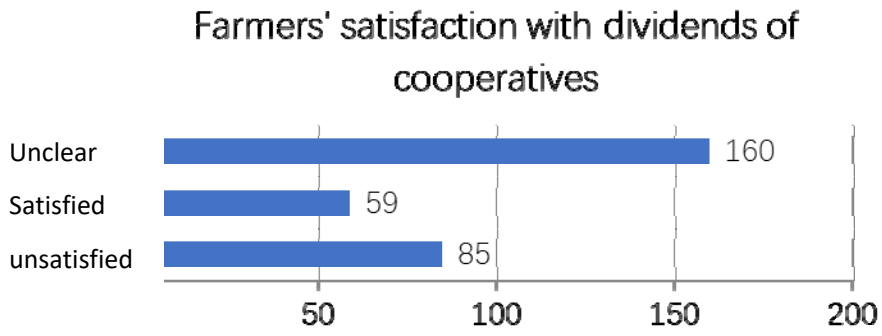

Figure 6 Farmers' satisfaction with dividends of cooperatives

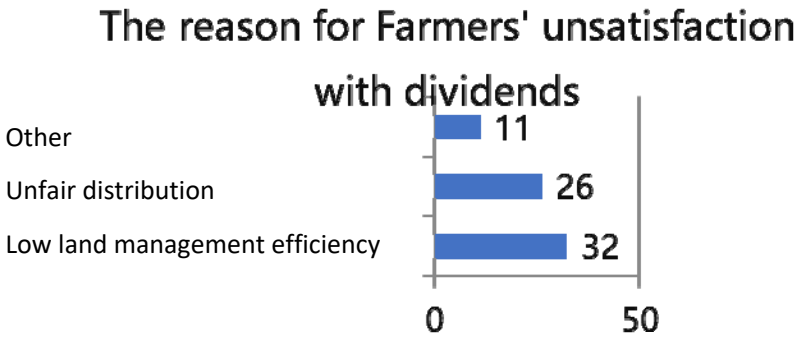

Figure 7 The reason for Farmers' unsatisfaction with dividends

Farmers in Changyun village are more satisfied with the dividends of the cooperative than those in Kunshan city. 18% are dissatisfied with the dividends of the cooperative, 19% are satisfied, 52% avoid answering questions directly and choose unclear, and the remaining 11% do not choose.

The main reasons for low satisfaction are the land management efficiency and distribution fairness. The villagers also suggested improving the quality of their produce.

6.2. How to increase returns

Jinxi agricultural products sales market is small in number and scale, and no well-known consumption place has been established. Comparing with the surrounding areas of Yangcheng lake, it can be found that the professional market and comprehensive market in Jinxi town, as well as the catering places for consuming agricultural products, are far less than Yangcheng lake area. The high value-added industrial chain did not come into being in this town. Most of the primary industries in Jinxi village produce raw materials with less primary processing and lower added value.

In the main functional area planning, Jinxi town belongs to east China grain and oil production area, so it can develop characteristic aquatic products. Changyun cooperative is

also doing shrimp farming in rice paddies and crab farming in rice paddies. Increase the added value of farmland. Deep processing of grain can be considered to explore the value of farmland. Build your own rice processing plant, but no land and no money. Village officials hope to build a centralized rice processing plant in Jinxi. The cooperative develops rice paddies to raise fish, shrimp and crabs, and resells them after processing outside. It needs technical guidance and training.

6.3. A brief analysis of the risks associated with earnings:

Increased risk of scale operation

With the deepening of land circulation and the concentration of agricultural production factors including land, capital, technology and labor, the rights and interests of village collectives and farmers have also entered the production and operation entities of agricultural enterprises in the form of shares. However, agricultural production faces the dual pressure of natural risk and market risk. Cooperatives should enable farmers to participate more actively in management and be more aware of risks.

Production risks faced by Changyun cooperative include: low quality and low price of rice brand. Second, although agricultural products have brands, there is still room for improvement in quality. We hope to give priority to improving the quality of agricultural products. Changyun village also faces management risks. The Changyun model relies on strong village cadres. The management sustainability of the Changyun model still needs to be explored. The long-term disadvantages of agricultural land cooperatives have not been shown yet, but the risks in the future are also worth paying attention to. Precedent has been set in Nanhai, Guangdong, and equity distribution has solidified and caused conflicts. The village committee and the joint stock company are identical, the financial income and expenditure lacks the supervision. Villagers lack information and professional experience, making it difficult to express their demands

7. Conclusions

The land stock cooperative system imitates a company, but its nature is different from that of a company. The people who make up the joint-stock system of land are local villagers. But also assume the function of food security, social harmony and stability resettlement of farmers, rural construction function. As can be seen from Changyun cooperative, rural migrant workers in cities have volatility. The cooperative has become an important buffer for migrant workers in Shanghai and surrounding villages, increasing the employment rate, providing green agricultural products, inheriting agricultural technologies and activating local communities. The advantage of cooperative is that it is convenient to introduce capital and profit distribution, which can promote the large-scale operation of agricultural land, and it is suitable for areas with deep industrialization and urbanization. In terms of equity distribution and agricultural production efficiency, cooperatives still need to be improved. Faced with fierce market competition, cooperatives mainly composed of middle-aged and elderly people left behind are not profitable, but they have their applicability and advantages, which can bring certain benefits to grass-roots governments, villages and villagers, and need to be promoted according to local conditions.

Research Paper

Out-migrate Elites as Rural-Urban Link

An Innovative Pathway Toward Rural Development Around Metropolis

Tianzhu LIU, China
Jingsheng LI, Tongji University, China

Abstract

Urbanization has caused the outflow of rural population, leading to the depression in rural areas. However, out-migrate elites (OMEs) are found involving in rural affairs in China's coastal areas and contributing to the rural development. This paper questions what is the role OMEs play in rural development. We undertake the research with the participatory research method: taking the practice of village planning as the opportunity to conduct in-depth interviews, questionnaires, and observations in the planning processes. The analysis concludes the binary nature that OMEs have: both "rural" and "urban". OMEs' kin, geographical and economic relations with the village derived from their rural experience, are the motivation of their participation in rural affairs, while their urban life experience contributes to the significant human, physical and social resources that the village is lack of. On this basis, OMEs deliver resources to the village in the process of participating in rural development. Through the delivery of knowledge and physical resource, they provide diversified ideas and funds for the village. Meanwhile, they bring long-term influence to the villagers by affecting their values and building endogenous capacity for the village. Furthermore, OMEs help expanding the social network of the village by introducing their personal social resources from cities into the village, bringing developing opportunities for the village.

Keywords

Out-migrate elites, Rural-urban link, Rural development, Village planning

1. Introduction

The rapid growth of urbanization and industrialization in China in recent decades has brought about the prosperity of the whole nation, but also accompanied by the large population flowing into the city from rural areas. The proportion of rural population to total population decreased from 82.1% in 1978 to 41.5% in 2017 (National Bureau of Statistics, 2018). Most of the rural population who have moved to the city are young and middle-aged people aged from 15 to 50 years old with greater ability. In such way, urbanization has caused the outflow of rural population, as well as the productivity, capital, and knowledge resource, leading to the depression in rural areas. Thus, unbalanced urban and rural development come to be a significant problem around metropolis in this era. On the other hand, however, diverse subjects in cities are involved in rural areas in different ways as the rural villages are increasingly open, which could be seen as the rural urban interaction, supplying the rural endogenous power (Douglass,1988; Sabet and Shahryar, 2017). Especially

in coastal metropolitan areas where cities are in high degree of aggregation with strong economy, with the increasing integration of urban and rural areas, individuals and organizations from cities participated in the development of the rural villages and affected them. In this rural-urban interaction, we recognized a type of people and we call them "out-migrate elites" (OMEs). They were born in the village and now live in the cities, but till keep contact to the village and bring opportunities to the village.

There have been some discussions about this group of people. It's found that new generation of rural elites who go out to work have improvement their abilities and insights in the process of earning a living and employment, thus making up for the lack of resources, projects and leaders in the village (Chen, 2015). It is also concluded in the study that more than half of the "County sage" had experience in migrant work, contributing to their "elites" property (Xu, 2015). Having a strong sense of self is an important attribute of the village elite, which is related to the experience of having more education and working and living outside (He, 2000). These researches further proof the value of OMEs, but they simply discuss the elite attributes of the persons who are out of the village. The value of OMEs in village development has not been systematically studied. What is the role OMEs play in rural development? Specifically, what characteristics do OMEs have? Why do they keep contact with the villages? And on those basis, in what way do they affect the rural villages? These are the questions we are going to explore in this research.

2. Definition and methodology

2.1. Definition of Out-Migrate Elites

In order to carry out the research, we need to have a preliminary definition of the OMEs. Though there is no generic concept and title accepted by academia, scholars have recognized the existence and value of this group of people. Luo described them "the third force", representing people who went out from villages and work in administrations and enterprises but still care about village development and try to deliver resources for the village (Luo, 2002). Ren (Ren, 2003) named these former villagers who were seeking development outside the village but participate in the village life crossing space barriers as "outflow elites", with the meaning of the potential of elites' return and the long last contact with the village.

Learning from the above literature, we use the term "out-migrate elites" here, aiming to directly express the identity of our research objects, especially the attributes comparing to the normal villagers who live inside the village. "Out-migrate" describes the status of grown up in the village but going out to study or work, and often living outside the village. "Elite" means that he or she can help the village public affairs because of the resource advantages. Actually "out-migrate" determines the attribute of "elite": the small-scale peasant economy situation in China determines that it is difficult for the rural areas to achieve the affluence of most people simply through traditional agriculture. Those who come to the town and city through employment, business, military participation, and further studies have the ability to make a living in the city through their efforts, gradually escaping from the way of relying on land to survive. In conclusion, OMEs in this paper are defined as "the original villagers who migrate to cities to make a living but still care about the development of the village and have

the ability to provide certain resources to the village". This includes, but is not limited to, civil servants, entrepreneurs, engineers, and the alike who works outside the village.

2.2. Participatory research method

In order to answer the questions mentioned before, we undertook the research with the participatory research method, with the opportunities provided by the village planning projects in coastal areas of China. Village planning aims to promote rural socio-economic development through industry planning and spatial strategies, based on the investigation and communication with villagers (Li, 2019). As a part of public policy of rural areas, the planning compilation is normally authorized by government and is always supported positively by villagers. With the support of village planning projects, we have little difficulty to get access to the village and to contact villagers and OMEs, being able to gain trust with them so as to collect information and to conduct in-depth interviews and questionnaires. Moreover, as a typical tool to promote village development, the planning process reflects the OMEs' participation in rural development. Thus, we got the chance to organize meetings and discussions so that it was possible to make observations in the planning processes of initiation, design, decision-making, and implementation (see figure 1).

Figure 1 Group meeting of village planning process in case study villages

2.3. Case study villages

Figure 2 The location of case study villages (left: in China, middle: in Fujian, right: in Zhejiang)

Explicitly, three rural villages (figure 2) in the coastal areas of China, Leishan Village (L village), Pucheng Village (P village), and Tangxi Village (T village), were studied as example, from 2014 to 2017. They belong to Ningbo (L village and T village) and Fuzhou (P village), two well developed large municipalities, at the administrative level. Though through different ways, OMEs in those villages participated in the planning process in diverse forms. Besides to the basic information like geographical and cultural resources of the villages, we collected data through the observation in group meetings and semi-structure interviews and questionnaires with OMEs. Different village planning projects were initiated for different

reasons and therefore were accompanied by different participants, so the research method applied in those cases were not exactly the same.

T village belongs to Yuyao, Ningbo, with the distance of 86 km to Ningbo city centre, 71 km to Yuyao city centre and 11 km to the town, with around 1280 people in 2014. Its village planning was initiated in the 2014 by the villagers, looking for an avenue to better village industry to improve the villagers' income. So that the funding of planning was shared by the village and government. The village has very proactive leaders, who recognized the value of those people "*who has quite good status in cities but always contact the village as well*" and thus organized a series of activities attached to the village planning to enrol them in the process. In addition, a Wechat (a social media app) group was built for the instant communication between villagers, OMEs and planners. In T village, we mainly collect information about OMEs via the village head and through the observation in the planning discussion meetings and the group discussion via social media.

P village is located on the southwest of Fuzhou, with the distance of 80km to Fuzhou city centre and 22km to Yongtai county centre. It is composed of three administrative villages with continuous built-up area and with the villagers sharing same ancestors so that they treat the villages a whole from a cultural identical perspective. P village is very large because of the mentioned reason with around 7000 villagers, 49% of whom migrated to the large cities, mainly being in business. The village planning project started in 2016 because of the OMEs' willing to improve the living environment of the aged and the project fund was shared by OMEs and government. While the main initiator of the planning project was the OMEs group and the amount the the OMEs is considerable, we did semi-structured interview with some OMEs and did a questionnaire through the internet with the help of an OME who was the main contact of the project.

L village is located in Fenghua, Ningbo, with the distance of only 32 km to Ningbo city centre. Different from the former two villages, the planning of L village started in 2017 was not actually an official statutory planning but was a voluntary project attached to the activity "nostalgia economy +" organized by city government which aimed to improve the rural village development though community building. Because the village is very close to the city, many people still lived within the village. The village head didn't realize the value of OMEs, but she accepted our suggestions and contacted the OMEs to participate in the planning discussion, which was the main channel for the data collection.

3. Profile of Out-Migrate Elites

3.1. Basic characteristics of OMEs

In terms of age, OMEs are mainly young and middle-aged people. In P village, the average age of OMEs is 44 years old, and the average age when they migrate is 19 years old. The OMEs who are older than 60 years old often have weaker physical capacity and the less desire for struggling due to their age, and they miss the village life and choose to return to the village. As Lin S, OME in P village stated: "*The first generation of villagers who came to Shanghai to make a living have been in Shanghai for 30 years. Take my parents as an*

example, they came to Shanghai in 1988 and now they chose to go back to live in the village. My father and mother have returned to the village, and they are not willing to work so hard here. (In the city) Although they don't have to do much thing, they feel bored. In the village, the circle of communication is bigger, while in the city they can only share a small family. My mom lived very close to her sister in Shanghai, but they meet at most two times a month. However, in the village, friends meet everyday".

Different from the occupational status in village where people mainly work in agriculture, the professions of OMEs are diversified because of the opportunities provided by the city. In P village, the professions of OMEs include at least civil servant, entrepreneur, engineer, university teacher, middle school teacher, and bank staff. In T village, more than 54 OMEs own the leading positions in their working area.

As for the geographical distribution, most of the OMEs live in cities not far from the village, normally in the same metropolitan area. As shown in figure 3, OMEs in P Village and T Village are mostly located in the county-level cities (Yongtai County/Yuyao City) and municipal-level cities (Fuzhou/Ningbo City) where the village belongs to in the administrative level and mega cities like Shanghai.

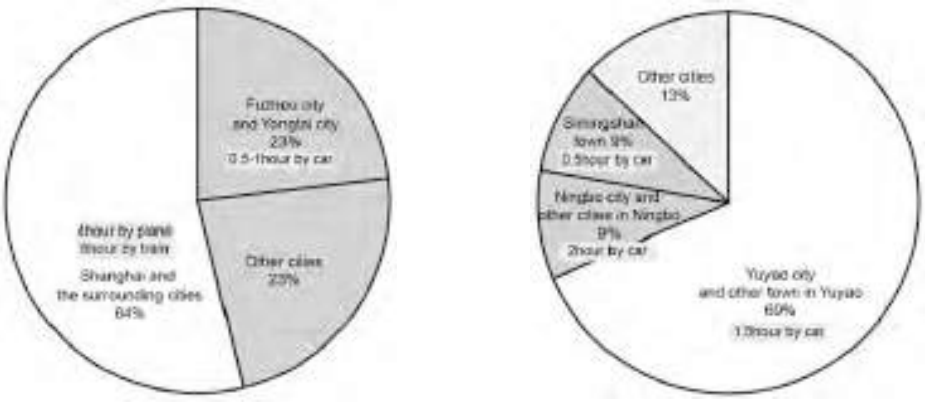

Figure 3 OMEs geographical distribution and time distance (left: P village; right: T village)

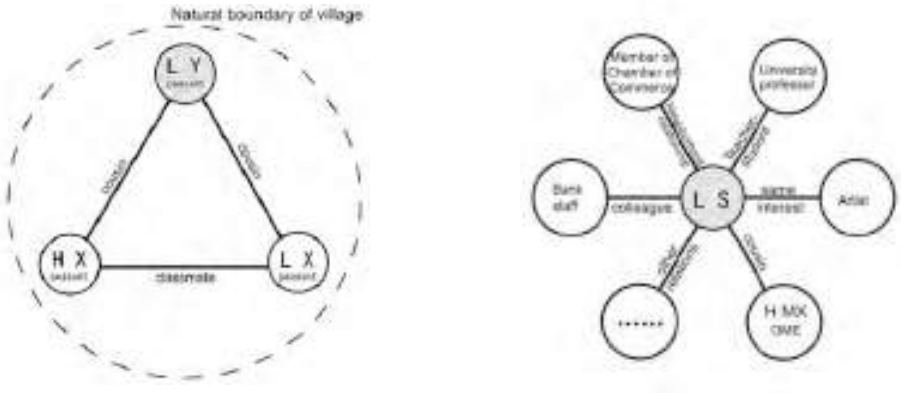
3.2. Resource characteristics of OMEs: based on the comparison of villagers

The above information about OMEs provides us with a view to understand their resource characteristics, especially with the comparison of villagers who stays inside the village. This characteristic will be described from the human resource, physical resource and social resource (Lin, 2005). In terms of human and physical resource, generally the most labour intensive age and the ability to set up a career in a more developed city are the support of OMEs' richness in resources, as well as the broad vision and ideas gained from the experience in the city. While many OMEs have also achieved business success, most of the people in the village are still peasants with an annual income of 7,500 yuan in average, relying on the economic support of the OMEs. Moreover, occupation, especially occupational status, is more indicative of the OMEs' rich resources. They have obtained professional skills and organizational skills related to their professions, and accumulated corresponding physical resources due to those skills. A considerable number of OMEs are leaders of government departments or management personnel of the company, which means relatively higher wealth, power and prestige resources (Lin, 2005).

As for the social resource, figure 3 presents the comparison of the social network of a typical villager and an OME: the ability to access a wider range of resources. The village is a “society of acquaintance” which means that people are familiar with each other and have similar job occupation. Therefore, social relations are limited to small-scale primary relations and people's interactions are often repeated with homogeneous resources, as shown in figure 2a. On the contrary, OMEs live in towns and cities and have developed various secondary relationships in social interactions. Thus, the social network is open and wide with rich heterogeneous resources, as shown in figure 2b. The latter may acquire a wider range of resources due to the opening of social networks (Lin, 2005).



a：villagers’ close social network **b：OMEs’ open social network**

Figure 4. Comparison of social network of villagers and OME in P village

3.3. OMEs’ Participation in rural affairs

In the era when transportation and internet infrastructure are not well developed, the OMEs keep in touch with the village by sending money to the family (Li and Xue, 2014). With the improvement of those infrastructure, the contact between those who migrated out and the village comes to be easier. 44% of the OMEs in P village keep contact with the village every week, while the remaining 36% keep monthly contact with the village. The frequency of visiting the village is determined by the geographical location. OMEs living in the county area always visit the village 20-30 times a year, while those who live in municipal-level cities go to the village about 10 times a year, and those who live in other cities return to the village 1-8 times a year. In the village planning projects, though in different ways, there are OMEs involved in the all those villages. OMEs in P village gathered together spontaneously with the consensus goal of making the village better for living. 44 OMEs in Shanghai and more than 20 OMEs in Fujian province were involved in the settlement of “Beautiful Village Committee” and were distributed with tasks by each person’s advantages. In T and L village, more than half of OMEs came to attend the village planning discussion after the call from the village head.

Other than the actual participation, the willingness of OMEs also reflects their possibility of participation in village affairs. In P village, 68% of OMEs are willing to give suggestions for the village development; 36% of them would donate for the village construction if needed; 32% of them would like to get policy and funding for village with their social resources; and 16% of them are willing to bring friends to consume in the village. OME in L village who was doing business in Ningbo believes that the development of the village still depends on young OMEs.

He was not likely to return to the village to make a living and work, but he could invest money to the village.

4. Social Relationship: the motivation of OMEs' participation in rural areas

The participation of OMEs to the village has been presented, further, it's necessary to understand why they are involved in the village issues. When we treat OMEs as a kind of exterior resource of the village, the social capital theory is helpful to explain their participation. In the theory, social relation, resource and action are the components of social capital (Lin, 2005). We have discussed the action and resources of the OMEs, so we try to explain the motivation of their behavior through their social relationship with the village.

4.1. Kinship: rooted relationship of OMEs and the village

There is a strong "family" concept in Chinese culture especially in rural areas. Fei described it as "the differential mode of association", which means that the most intimate relationship is with relatives such as parents, and as the kinship goes weaker, the social tie becomes weaker (Fei, 2006). Many young and middle-aged OMEs have parents who still live in village because of the difficulties in adapting the lifestyle in cities, which is the reason why OMEs have intimate contact with the village. In P village, 76% of the OMEs visit the village for their parents and relatives, composing the main reason for why visiting the village. For those OMEs, they care about the living environment of village because the infrastructure and environment is strongly related to the living quality of their parents and relatives.

In addition, OMEs have clan relations with the village, which is derived from the sense of belongings based on kinship, and 60% of the OMEs expressed that they will visit the village for ancestors' worship festival. Ancestral halls and activities are active till now, for which hundreds of OMEs came back to the village in the worship festival day in 2016 even though it was not in vacation.

4.2. Geographical relationship: OMEs' willingness to return to the village in the future

While the kin relationship leads to the connection between OMEs and the individual villagers, the geographical relationship brings the connection between OMEs and the village itself. 80% of the OMEs in P village indicated that they would like to return to the village for vacation or after retirement.

The natural environment, cultural environment and friendly social interaction atmosphere in the village are important parts of the OMEs growth, composing the beautiful memory and the nostalgia of their life. In P Village, the OME Zhang MH introduced the traditional house with deep emotion as "*I always dream of this place.*" Zhang ML expressed his love for hometown as "*The landscape and scenes of the village have always been a beautiful thing for us. We should keep those good memories.*" Lin JY, the OME who was doing business in the county, expressed her emotion for the village through the willingness to repair the ancestral home: "*I come back here three to four times a year. My best memories are about here. I want to come back and repair the old house…Then I can bring my child here to live and for vacation.*" Tang YJ in T village and Lin S in P village expressed most OMEs' willing to return to the village after retirement that "*I will go back to the village within five years in the*

future. My wish is to have a room to stay in the village." Though qualified to migrate Hukou to cities, some people chose not to do so just for keeping his land property in the village.

4.3. Economic relationship: property relations and industry opportunities

Most of OMEs have property related to house and land in village. In terms of land and house property, due to the collective ownership of village land in China, the property distribution of the village is closely related to the household registration (Hukou). The OMEs with their Hukou in the village still have the property of farmland, homestead, and cooperative shares. Moreover, there are some situations that OMEs still owns property in village though their Hukou migrated out. In general, almost every OME have property rights inherited from their parents and other relatives. For example, Lin JY, the OME of P village has been working in the city for decades with her Hukou in the city, will inherit a traditional house owned by his uncle. Further, if the land property has been confirmed before the migration of OMEs' Hukou, OMEs will have farmland property for a certain number of years. For example, P village has already done land rights confirmation about 30 years ago and the OMEs who moved out of his Hukou to the city after the confirmation still has a homestead and farmland. For another scene which can be seen in T village, with the permission of villagers, some OMEs have the shareholding of the cooperative whatever his/her Hukou is in the village or not. These are strong and long lasting ties between OMEs and the village, promoting OMEs paying attention to the village issues, which are related to their private property.

Another aspect of economic relation is about the industrial development. For those OMEs who want to operate a company, there is an advantage in the low cost of both land price and human labour for developing industry (a farm or a resort for example) in the hometown village. In addition, due to the demand for social network in business, people who go out to do business often operate industries that are related to the village and gather in neighbouring cities. For example, P Village has a traditional industry that produces dried fruit, and later OMEs who went out for business are mainly engaged in the food industry and gathered in Shanghai and surrounding cities for mutual support. This kind of link promotes OMEs to link each other closely so that they always have a sense of belongings of the hometown village.

4.4. The binary "rural" and "urban" nature of OMEs

Based on the description of the resources and social relationships of OMEs, a diagram depicting the social relations of OMEs and the village is drawn as shown in Figure 5, from which we conclude the binary nature of OMEs: the "urban" characteristic and "rural" characteristic. The "urban" characteristic presents the resource heterogeneity due to OMEs' occupational and workplace differentiation from their city living experience. This can be seen from the comparison outside and inside the natural boundary in figure 5. The latter "rural" property is reflected from the strong social link between OMEs and the village as well as within the OMEs group, which can be seen as "strong tie" because those are within the cultural boundary of the village shown in figure 5.

The social capital theory refers to the relationship between the strength of the relationship and the acquisition of resources. The weak tie theory believes that infrequent contact "weak tie" brings heterogeneous resources that are not easy to get in normal life (Granovetter, 1973), emphasizing the importance of heterogeneity of resources, though meaning the difficulty of the access of the resources. On the other hand, Chinese scholar Bian proposes that China is a strong relation-based society and the success of action depends not on the

breadth of information that weak ties can bring but on the certain help that strong ties can provide (Bian, 1998), underlining the importance of strong ties, though accompanied with less resources. However, when we talk about OMEs, this group could be treated as the combination of "strong tie" and "heterogeneous resources", thanks to the binary nature it contains. This characteristic indicates the convenience of getting diversified resources from OMEs. Especially when OMEs gather together, they cooperate and deliver integrated resources gained from the city to the rural village.

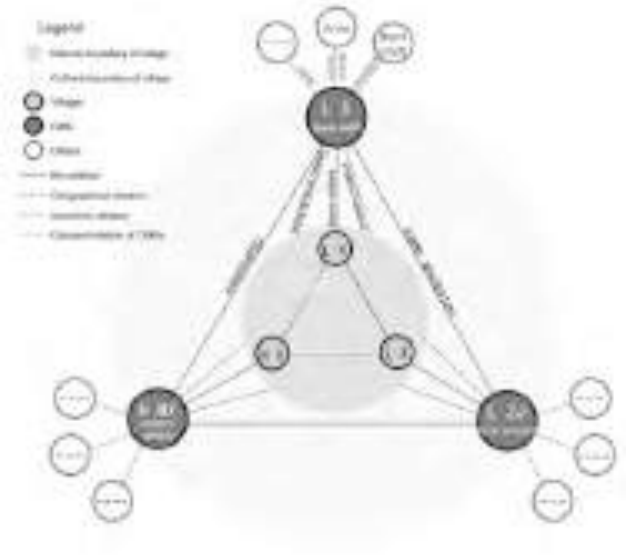


Figure 5 Diagram of the social relation network between OMEs and village (P Village)

5. OMEs' contribution to rural development: the delivery of urban resources to rural community

5.1. Delivery of information, knowledge and physical resource

Based on their own professional knowledge and long-term experience in cities, OMEs have developed diversified ideas for the village development. For example, in the discussion of industrial development in T Village, the OME Tang W working in the county government department proposed the idea to produce of agricultural and handicraft products in the coming years and to develop sports and health related projects in the long run, based on his knowledge of policy environment and economic situation in the county; while entrepreneur Tang ZG, based on his business management experience, recommended that the village could diversify its financing forms such as attracting private capital, crowdfunding, and shareholding. In terms of living facilities improvement, because OMEs have experience in the city and also have their own actual needs for the village facilities, they have put forward very specific ideas and suggestions for the improvement of the living environment, such as "*constructing the waterfront road with the roadway 6 meters wide and the sidewalk 2 meters wide, along with the houses with shops on the ground floor...*" and the OME who has gained training about urban planning even drew the section of the waterfront road to guide the construction. Those are ideas not be recognized by villagers and could be good opportunities for the village.

Moreover, those ideas are able to be achieved because of OMEs' involvement and operation in the project. For individual behaviour, this is reflected in the investment of funds and human labour by OME individuals. Based on the improvement of village environment and the development of individual industry, they provided funds by themselves for village construction and development. For instance, Lin Z, OME in P village devoted money for the construction of village pavilion and main road. In T village, Tang ZY wanted to invest in the hotel located in the village and was in the process of negotiation. Chen SH came up with the idea of developing local specialty for the village and has put it in practice with the result of well designed tea product, using the village's name as its brand name. For the village construction fundraising, the OME representative Lin ZJ expressed the general idea of OMEs as: "*We are obliged to pay for the village construction...The people living outside of the village are wealthier and ought to do something for the village.*" As for the public projects which requires large amount of funding, programs are more implementable with the OMEs' participation. Taking the waterfront road project of P village as example, the project's proposal, initiation, design, and implementation fundraising were all driven by the operation of the OMEs. They planned the project based on their own expertise, estimated the budget, and contacted the design company. In the fundraising phase, they apply government funds through their channel and invest their own money and goods for the project. Lin Z ， entrepreneur who was in charge of the fundraising told us how the money raising was planned: "*how to gather more than 9 million yuan for this project? First of all, we should apply for the money from government in the name of the 'beautiful village construction', which could get about 2 million yuan, and then it is not difficult for us to raise 1 or 2 million from individuals*". In those ways, OMEs introduces information, knowledge and physical resources into the village to provide ideas and development conditions for village development.

5.2. Delivery of values and capacity building

In their experience in large cities, OMEs have cultivated the values to understand the precious value of traditional culture and natural environment of rural areas. In the process of participating in the development of the village, the values were imported into the village and affected villagers. Taking the traditional landscape conservation as an example, in all those three villages, when the villagers proposed to demolish the traditional buildings and build the European-style houses, OMEs emphasized the preciousness of the tradition and proposed the necessity to protect traditional features. They suggest that the buildings should keep old style and should not use cement and steel in construction. As the authorized elites, they have influenced villagers and led their value orientation in the process.

In addition, as OMEs have broaden their horizons, accumulated knowledge, and fostered the consciousness of modern citizenship (Yang, 2008), combined with the authority of their elite roles and the ability to integrate village interests (Luo, 2002), they bring about the consciousness of modern governance to the rural village and promote the capacity building by encouraging the villagers through directly participating in village management and the organization of public activities. Research on rural social information dissemination points out that when information sources are homogenous to recipients, that is, when they have the same intention, subculture, language, and personal and social characteristics, the effect of communication to gain knowledge or change attitude is obvious (Rogers and Berger, 1988). The OMEs act as the "source of information" – comparing to the external subjects such as planners and government, the same cultural and linguistic background of OMEs and

the villagers determines the efficiency of communication with the villagers. At the same time, because of knowledge and occupation, they have prestige and authority among the villagers, thus being more effective in delivering information to the villagers. Taking L village for example, the new head of Chen SH, also as the senior executive of a big company in Ningbo, introduced the "5S Management Rule" into the village. He invited the old authorized villagers to give suggestions and make decisions and regulated the reimbursement system of the collective expenditure, modifying the governance model. Based on the introduction of those values and the consciousness of modern governance, the villagers have been fundamentally promoted, thus affecting the development of the village in the long run.

5.3. Expanding social network of the village: bringing developing opportunities for the village

The OMEs' participation has also expanded the social network for villages, through their own social resources, to attract more attention and development possibilities. These social resources include top-down government resources, potential investment subject resources, related technical organizational resources, and so on. In L Village, OME believed that the village had potential to attract investment, so he organized social media group with the entrepreneurs he made friends in business to introduce potential investors to the village. In P village, civil servants (those who were retired and who were serving in the occupation), entrepreneurs, teachers and other OMEs working in the local or other cities were organized as a committee. The civil servants and the member of the chamber of commerce usually have the social relations with government officials so that they were in charge of the contact with the government officials to gain policies, funds, and information support from the special bureaus such as traditional village conservation office. OMEs in the enterprise have social relations with the local propaganda company so that they are required to contact local TV station to film the tourism video for the village. OMEs brings more attention to the village and more development possibilities by introducing their social resources to the countryside.

6. Conclusion and discussion

We conclude the "binary" nature that OMEs have. To the standpoint of OMEs' relation with cities, the experience of working and living in the city contributes to the significant human, physical and social resources of OMEs. From the perspective of OMEs' tie with villages, the kin, geographical and economic relationship is found as the fundamental connections. The "binary" characteristics and the development of metropolitan area, especially the construction of highway and internet infrastructure, make it possible for OMEs to maintain close contact with the village. Meanwhile, OMEs' appeal to the countryside, which is based on their relationship with the village, and the environmental thrust from the cities, prompts them to participate in village affairs. It is in this process that OMEs deliver resources from urban to rural areas, promoting village development. Taking the rural planning process as the example, OMEs serve as the rural-urban link and provide a novel way for rural development by building endogenous capacity for the village. Through participating in public issues, OMEs bring the values and information from city into the village, diversifying ideas to the village development, and exchanging information with villagers to enhance their abilities. Furthermore, OMEs help expanding the social network of the village by introducing their personal social resources from cities into the village.

There are still some issues that need further discussion. First of all, as an important resource of the village, what kind of ways can promote the participation of OMEs in rural development? In addition, what kind of organization can strengthen the role of OMEs? As a link between urban and rural areas, in addition to playing a positive role in the countryside, can OMEs' actions in the countryside also have a positive impact on the city, so that this link is reciprocal? These are issues that need to be explored in the future.

Case Study / Project

The Shrinkage and revitalization of villages

in metropolitan area of mega cities

Zhengyin LU, Xiaoyi WEN

Abstract

The megacities are a double-edged sword for the surrounding rural areas: while providing opportunities, they are also 'draining' the surrounding areas. The meaning of Water-related spaces of the rural area in South Jiangsu Province - China - are the cradle for the economy in history, and are also where lies its social, ecological and cultural characteristics. But rural and water-related activities in southern Jiangsu are weakening. Many rivers have been silted up or turned into arable land, and traffic has been reduced. The former studies focus more on space design and less on their network with different agencies and actors. And there lacks small to medium scale spatial economic network quantitative analysis and data visualizations among villages, towns, and cities. Meanwhile, an argument has been raised that developing real characteristics will help the villages to revitalize. How to find and revitalize the villages by reconstructing the center of the villages? Does this method work for the Chinese metropolitan villages and towns?

The paper focuses on studying the significant network of villages in metropolitan areas from ecological, cultural and economic perspectives.has a positive effect on how to preserve the cultural context of water towns. In this paper, the characteristics of hydrology, atmosphere and vegetation cover are analyzed at the regional level by remote sensing satellite image data analysis and field survey, the connectivity of main industries in rural areas is described. And the result network is coupling with economic, social and ecological network (e.g., fishery, aquaculture, tourism network etc.) and its influence scope. Finally, by comparing the industrial network characteristics of the towns and villages with better tourism towns such as Zhouzhuang and Wuzhen in Zhejiang Province, it is concluded that the coupling relationship between industry and ecological system should be well handled.

Case Study / Project

Defining the Rurban

- a case of Hyderabad

Sohini MAITI, Satyajit MAL

Abstract

Large parts of rural areas in India are not stand-alone settlements but part of a cluster of settlements, which are relatively proximate to each other. These clusters typically illustrate potential for growth, have economic drivers and derive locational and competitive advantages. Hence, making a case for concerted policy directives for such clusters. These clusters once developed can then be classified as 'Rurban'. (SPMRM, National Rurban Mission Ministry of Rural Development, Govt. of India). Is it possible to preserve the essence of rural community life with focus on equity & inclusiveness while providing urban facilities? As the word rural by definition means non-urban, is the Rurban model more applicable for the secondary cities or suburban towns? Hyderbad presents us with a situation where an Outer Ring Road (ORR) is created to contain the urban development but placement of Information Technology Investment Regions (ITIR) along the ORR and even in areas nearby the river Musi possess serious threats to the existing villages in this area. The paper aims to take a real life situation along the ORR and derive the forces of growth and a possible ideal model for the Rurban. The age old transect from natural zone to the urban core zone is to be questioned in this current era urbanisation and we are definitely in need of an answer that balances the extremities of rural and urban. Between 2000 and 2014, the proportion of the global urban population living in slums dropped from 28.4 per cent to 22.8 per cent. However, the actual number of people living in slums increased from 807 million to 883 million. They can become the target population for suburban towns or secondary cities if these are equipped to provide a sustainable model with more production, more employment more equitable distribution of income and focussing the poor. Development is, ultimately, the progress of human freedom and capability to lead the kind of lives that people has reason to value. (Sen & Dreze, 2013) A rurban model appropriate for today's context can be a tool to generate that value for the public.

Research Paper

THE ROLE OF FOOD IN RE-IMAGINING THE CITY

From the neighbourhood to the region

Teresa MARAT-MENDES, Instituto Universitário de Lisboa - ISCTE-IUL, DINÂMIA'CET-IUL; Portugal

João CUNHA BORGES, Instituto Universitário de Lisboa - ISCTE-IUL, DINÂMIA'CET-IUL; Portugal

Abstract

Humanity is now believed to live in a new geological epoch, the Anthropocene, as changes have been reported on the atmosphere, air, water, and soil, but also on societal perceptions of these issues. This presentation departs from the theoretical assumption that the impact of the abovementioned changes on culture and the environment have not yet found a stable influence on urban planning. This presentation overviews the implications of the food system within urban planning while considering it as a socio-technical system which integrates production, distribution, transformation, consumption and disposal patterns. The production phase of the food system in particular, emerges as a fundamental planning challenge, extending to urban form solutions, individual behaviours, dietary regimes, inequalities in foodsheds planning, and the cultural capital of food. Accordingly, the food system emerges here as an opportunity to identify how current urban fabrics of cities and their rural and regional hinterlands can be transformed in terms of their metabolic function and respond to the needs of people and the environment. To do so, this presentation introduces the preliminary results of an analysis conducted by an ongoing research project SPLACH – Spatial Planning for Change, at two particular scales: the region and the neighbourhood. Thus, while focusing in the Lisbon Metropolitan Area (LMA), in Portugal, we provide an analysis of the Regional Plan as well as of specific residential neighbourhoods located in LMA, regarding the relationship between the food system functioning and urban planning approaches. The analysis includes a comparative number of case studies which differ in urban form solutions, socio-economic conditions, but also geographical location. The results support the request for a stronger integration of the above-identified underexplored topics of the food system within urban planning, which will be fundamental to inform a new theory of the city that makes any serious contribution towards a sustainability transition.

Keywords

Urban Planning, Urban Agriculture, Sustainability Transition, Region, Neighbourhood

1. Introduction

Planning for a sustainable humanized environment requires the equilibrium between the social, the economic but also the physical systems. At a time when 55% of world population lives in urban areas and is expected to increase to 68% by 2050 (UN, 2015, 2016), it is important to disclose how cities socio-metabolism behave today accordingly and could be changed into a sustainable one.

Urban metabolism was first explored by Wolman (1965) who proposed to quantify the flows and stocks of materials and energy in given environments, thus understanding the city as a functioning organism. Later, advancing towards a different concept, that of socio-ecological metabolism, the work of the Vienna School of Social Ecology articulated the physical analysis of materials and energy with social activities, amounting to couple the socio-ecological systems (Fischer-Kowalski and Weisz, 2016). This approach allowed, among other possibilities, significant contributions on the transition processes between different metabolic eras (Krausmann et al, 2016) as well as on the deepening the environmental history of particular places (Winiwarter et al, 2016).

In the planning sphere, the metabolism would be acknowledged through its Circular perspective, while making effective use of waste, which was then regarded as a fundamental goal for urbanism (Rogers, 1997). The notion of Circular Metabolism would gain greater attention by academics, and the urban system was expected to work while making use of its own waste. However, this call for circular metabolism of cities found a difficult relationship with current planning in many countries. In some cases, this tension reveals the limitations of planning structures focused on 'management' rather than 'planning', which ensure relative liberty for urban development projects on the private sector, but often delay the necessary transition of urban systems to more sustainable models.

The project 'SPLACH – Spatial Planning for Change' aims to inform future public policies for such transition to sustainability, including the fundamental role of urban socio-ecological metabolism while reinforcing its spatial dimension, through the understanding of its implications on urban form. The research team of DINÂMIA'CET-IUL for SPLACH project is focusing its analysis on Lisbon Metropolitan Area (LMA), which includes 18 municipalities and is the most densely populated metropolitan area in Portugal.

Fundamental for an effective metabolism is the access to basic human needs, which all cities must ensure in order to be liveable: housing, water, electricity, transportation, internet and food. While some of these are widely acknowledged in Portuguese planning instruments, others, particularly water and food, are relatively absent.

The food system – the pattern across which food is produced, transformed, distributed, commercialized, consumed and disposed (Pothukuchi and Kaufman, 2000; Steel, 2008) – has inherent spatial implications, as it relates to land-use systems, infrastructure and both the built and natural environments of cities.

Although some studies have been developed to diagnose the LMA food system and its metabolic impact (Oliveira et al, 2017) this is still not reflected in the central documents of spatial planning in Portugal – the municipal Masterplans, as well as on urban design scale. Although some Portuguese municipalities have ventured into food-related programs, including refurbishing of municipal markets, urban allotment gardens and pedagogical farms, these are not yet included in the general strategies for the development of LMA municipalities (Cabannes and Raposo, 2013; Oliveira et al, 2017; Marat-Mendes et al, 2018).

On the other hand, many grassroots initiatives can be observed in the actual territory that are also invisible in planning documents, and which seem to have deserved little attention or interest from planners. Initiatives of urban agriculture have been subsidized by municipalities in the LMA, but these municipal programs are very different from Guerrilla Gardens in many of the same municipalities, which attest to how communities have appropriated vacant and even private spaces for food-production purposes. Nevertheless, it should be noted that such grassroots initiatives have already received the attention of a number of researchers, former members of FAO and UN organizations, such as Cabannes and Raposo (2013)

This paper aims to observe 'invisible' food-related initiatives, particularly at the production phase of the food system, emphasizing the potential role of urban agriculture in improving the socio-ecological metabolism of the LMA, and confronting it with the approach to the territory comprised in spatial planning. Two planning scales will be central here: the regional and the municipal. The former allows an observation of how the territory of the LMA is envisioned in public policy, while the latter allows a more direct confrontation between particular places and their treatment in planning, inclunding the design solutions which have guided them.

1.1. Literature review

The study of the relation between the food system and urban planning has deserved greater attention in recent years. A succinct description of the food system would present it as the system of activities across which food is produced, processed, distributed, cooked, eaten and disposed of (Pothukuchi, Kaufman, 2000; Steel, 2008). This includes not only the activities themselves but also the institutions (Pothukuchi, Kaufman, 2000) and the power relations (Wekerle, Classens, 2015) implicated in those activities.

Although nearly two decades ago, Pothukuchi and Kaufman (2000) presented the food system as a 'stranger' to the planning field, this situation seems to have changed meanwhile. Brinkley (2013) comprehensive account about the research in this area, concludes that most aspects of the food system have already entered into the concerns of urban planning studies, while emphasizing that the waste-disposal phase of the system, as well as the cultural capital of food remain however underexplored. Steel (2008) analysed the relations between food production and the structure and distribution of activities in specific cities, while Parham (2016) explored the role of food in relations of urban conviviality and concluded that this plays a fundamental role in a future sustainable development.

Notably, most authors interpret the food system as a holistic and multi-scale system, which comprise aspects related to the political economy, public health, environmental impact and cultural issues (Reynolds, 2009; Steel, 2008; Viljoen and Bohn, 2012; Reisch et al, 2013; Brinkley, 2013; Cohen and Ilieva, 2015; Sonnino, 2019). Reisch et al (2013) have used the term 'integrative paradigm' to define an adequate methodology towards the food system. This entails creating integrative, cross-sectoral, population-wide food policies extending to the entire food system in order to ensure its overall sustainability.

However, this definition is already enough to point out some problems arising from the food system and its study. One major problem has to do with the fact that the food industry is highly fragmented (Reisch et al, 2013) with inquiries usually struggling to establish inter-disciplinary links between fields of study and planning (Brinkley, 2013). This problem applies not only to the urban food system, but to the urban systems in general, particularly with

respect to sustainability issues (Webb et al, 2018). Analysing urban systems – including the food system – for their institutional role will then imply accepting that not only policies are fragmented, but also that several institutional forces may prove to be a barrier to integrated and large-scale change (Webb et al, 2018).

In a sense, this situation may be specific of our times, as neoliberalism, social inequality, the domain of the private market over cities (Drago, 2018) and sustainability threats (Cohen and Ilieva, 2015; Fischer-Kowalski and Weisz, 2016) call into question the institutional structures and power distribution underlying urban systems. With respect to the importance of neoliberal economics in the food system, Steel (2013:59) points out that agribusiness has created a situation in which food supplies are determined not by local cultures but by economies of scale. More recent accounts (Sonnino, 2019) have emphasized a shift of food system approach with public entities increasingly acknowledging their own participation as actors in the food system.

As such, we may accept that ours is a time when we have outgrown the institutions we have and are struggling to design new ones (Bartlett, 2017, p.194). As such, urban systems – insofar as they are deeply implicated in the division of society in space – and food systems – as they ensure a human basic need – may provide the basis for new conceptual frameworks which allow us to imagine different institutions able to respond more effectively and closely to the population and environment demands, across a variety of scales of space and governance (Webb et al, 2017:69).

The relation of this with urban form is also a critical point for the food system, although in many papers, the spatial dimension is under-stressed or even entirely overlooked. Urban form, understood as the configuration of fixed metropolitan elements, comprises several important features of cities, including density, compactness and land-use (Lo, 2016), the importance of which is very considerable within the food system.

With respect to urban agriculture, and specifically to the practices of guerrilla gardening, Richard Reynolds' handbook 'On Guerrilla Gardening – A hand book for gardening without boundaries' (2008) presents an overview of this movement, as well as several important notions – both theoretical and practical – of these illegal proactive actions.

Although urban agriculture is also being studied by itself as a social and even political movement, there are many reasons why it would be so stressed in food system literature. One important aspect is that the production phase of the food system is where most environmental implications are located, including land-use, soil degradation, water consumption and pollution, eutrophication, biodiversity loss, and introduction of hazardous chemicals (Reisch et al, 2013). Furthermore, it is also at the production phase of the food system where most of the financial implications are located, in particular in what concerns the land which is needs for such activity. This is mostly depended on land values which greatly depends on the speculative market.

On the other hand, industrial agriculture itself is a problem in terms of metabolism, as it is mostly dependant on non-renewable energy sources (Erb et al, 2016) with deep implication in Net Primary Production – energy fixed by autotrophic organisms – which is at the basis of heterotrophic food chains and accumulation of carbon stocks in soil (Erb et al, 2016). Discussions of urban agriculture are usually considered for themselves, with livestock being usually left out of any perspective for urban space (Reish et al, 2013; Brinkley, 2013). Furthermore, the general absence of the food system and urban agriculture from urban land

physically segregates consumption from production, leaving populations dependent on private-market food-outlets, and often adding to other social problems of poverty and access to land or housing (Purcell and Tyman, 2015; Cabannes and Raposo, 2013; Wekerle and Classens, 2015).

Moreover, from the perspective of labour challenges, since the 1970s, agricultural labour has been decreasing, to the point of near disappearance (Fischer-Kowalski, Haas, 2014). And with respect to architecture and urban planning, Viljoen and Bohn (2012) advance a new model for sustainable urbanism which prioritizes the creation of a 'productive multifunctional landscape' with spatial, social and environmental implications.

1.2. Methodology and structure of the article

This paper aims to clarify the important role which urban agriculture plays within the LMA. To do so, it confronts some of the problems stated in the Municipal Plans of the municipalities of LMA with actual initiatives that can be found on the territory. Our present analysis focus on three specific municipalities of LMA, namely Lisbon, Oeiras and Almada. For each municipality, we will analyse a specific urban agriculture initiative and identify what particular contributions they may provide for both improvement of urban structure and of urban socio-metabolism.

To do so, this paper is divided in four parts. After this introduction, section 2 presents a brief overview of Portuguese spatial planning, specifying the roles of the municipal and regional scales and observing how the food system is or is not present at these planning scales. The third section details the case-study of urban agriculture, confronting initiatives with spatial plans, but also with the issues identified in the above literature review. Section 4 includes the concluding remarks, as well as suggestions for how to acknowledge and incentivize the already existing initiatives analysed in the previous section.

2. Urban planning in Portugal

The current structure of spatial planning in Portugal has been fundamentally determined since the 1974 Revolution which overthrew a conservative dictatorship that had been in power since 1933. However, municipalities under the dictatorship had also produced spatial planning documents.

After the Revolution, the 1982 Law of Soils attributed to municipalities responsibility over their spatial planning, and two further Ground-Basis Laws for Spatial Planning were issued since, in 1998 and 2014. Within the structure of Portuguese spatial planning, the municipal level has a singular importance, since it is mandatory for each municipality to have an approved Municipal Plan, a *Plano Director Municipal* (PDM). This has been required since the first Portuguese Law of Soils was published in 1982. Since then, other planning scales such as the National, Regional, Intermunicipal and Interregional are also foreseen within the Ground Basis Law for Spatial Planning, but their preparation of approval is not systematic and sometimes are never fulfilled.

2.1. The Lisbon Metropolitan Area and its food system

The territory of the LMA comprises 18 municipalities – Mafra, Vila Franca de Xira, Sintra, Amadora, Lisbon, Odivelas, Loures, Oeiras and Cascais in the Northern Bank of Tagus river and Almada, Barreiro, Alcochete, Sesimbra, Seixal, Moita, Palmela, Setúbal and Montijo in

the Southern Bank of Tagus river. The Metropolitan Area is an administrative delimitation which was established in the early 1990s, extending for the Lisbon Region. Together, these municipalities totalize 3 015,24 km² and are home to 2 812 678 people, amounting to a population density of 935,8 hab/km². The Ground-Basis Law on Spatial Planning determines which soils must be classified as urban but also those that are rural. From the 18 municipalities of LMA, 17 include those both classifications of soil, while the Lisbon municipality comprises only the urban one.

In the transition from the 19th to the 20th century, the Lisbon municipality concentrated more than half of the population of the Lisbon Region, and at least 40% of its territory was agrarian, while the built environment amounted to only 16% (Niza et al, 2016). This territorial organization was not symmetrical to the social division of labour, as only 4% of the Lisbon population worked in agriculture, versus 17,3% who worked industrial jobs, and only 1% of Lisbon's food was produced within the city (Niza et al, 2016). Cereals, wine and olive oil, all important foodstaples of the Mediterranean diet, were all brought into the Portuguese capital from its surrounding municipalities (Niza et al, 2016). Also, within the Lisbon Region, about 1000 farms and about 200 gardens ensured the production of fruit and vegetables (Marat-Mendes et al, 2015).

The formation of the Municipal Plans dates back to the 1930s, when the Portuguese Government ordered new General Plans of Urbanization to organize the growth of cities with more than 2500 inhabitants. Nevertheless, a number of cities under such conditions, never witnessed the development of their plans. Furthermore, some regional plans would soon be drawn but not approved. A particularly important exception was the *Plano de Urbanização da Costa do Sol* (PUCS), a sub-regional plan which sought to develop the urban planning of the coast area located between Lisbon and Cascais. The PUCS infrastructure was designed by the French urbanist Alfred-Donat Agache in 1935-1936, including the first motorway built in Portugal, but it was Étienne de Gröer who would conclude the PUCS and design the Urban Plans for the urban centres along Costa do Sol, which would be concluded in 1946 and approved by the Portuguese Government in 1948 (Marat-Mendes, 2009). The PUCS remained active until the early 1990s (Pereira, 2009).

The strong relation between Lisbon and the remaining municipalities through the food distribution was indirectly acknowledged in the plans by Étienne de Gröer, within PUCS in particularly, at the neighbourhood scale, where Gröer applied the Garden City principles as proposed in England by the social reformer Ebenezer Howard (1902). The PUCS included urban settlements separated by rural belts, which included gardens and farms, all linked through a three-layered mobility system with motorway, highway and train (Marat-Mendes, 2009). Moreover, in his Masterplan for Lisbon, the *Plano Director de Urbanização da Cidade de Lisboa* (PDUCL), Gröer predicted the construction of council housing neighbourhoods, all designed by other architects and mostly inspired by the Garden City, but also by the Garden Suburbs designed by Raymond Unwin. In these Lisbon neighbourhoods, the preferred building type was the single-family detached house with a small front-lawn and a larger backyard meant for leisure and food-production (Marat-Mendes and Borges, 2019).

Although the PDUCL failed to be approved by the Portuguese Central State, a new Masterplan was prepared but also shared its unapproved fate. Such situation left Lisbon without an overall Planning instrument and driven by sporadic urban plans, for specific delimited isolated areas would govern Lisbon urban growth in a random manner (Marat-

Mendes and Borges, 2019). In the case of Lisbon, the 1950s and 1960s are a period of legal void in terms of planning, and the plans for further council housing start embracing the need for construction at a greater scale and with greater density. To this period correspond the urbanization plans for the Olivais area and for the Chelas Valley, both large-scale agrarian zones, converted into urbanized land (Marat-Mendes and Borges, 2019). Although all urbanization plans predicted the creation of green areas, these did not respond to any productive proposes, as they meant especially for landscaping and leisure of communities.

In the transition from the 20th to the 21st century, this situation changed dramatically, with a very significative increase of the urbanized land. This is closely related to the post-Revolution spatial planning structure, which established municipal planning, but left unresolved tensions between land-use regulations and private property rights (Mourão and Marat-Mendes, 2016). This has led to massive – and often unplanned – land-use conversions which translated into a significant loss of rural soils and a construction boom that eventually led to housing surplus and uncontrolled speculation (Mourão and Marat-Mendes, 2016). However, the LMA still comprises a significant amount of rural soil, and 740 000 tons of foodstuff were produced within it in 2015, against 3,7 million tons which are exported from other parts of Portugal and 5,4 million tons from other countries, mostly in Europe (Niza, 2017). To this, one may add that the LMA exports 4,7 million tons of foodstuffs for other parts of the country and 1,8 million tons for other countries (Niza, 2017). As such, the LMA is still a highly productive metropolitan area.

The dichotomy between productive and unproductive land has grown more polarized throughout, as green productive areas are classified as rural, but urban land in Lisbon can only comprise urban parks – essentially non-productive. This tendency responds to the paradigm inherent to the Ground-Basis Laws, which establish that urban land cannot be productive. As such, although urban agriculture has always existed within urban perimeters, including in Lisbon itself, its role is underacknowledged and its presence in urban planning is scant and difficult. Although most municipalities are creating urban agriculture parks, these are all small-scale and oriented towards leisure and landscaping, with few acknowledgements for its productive aspect (Marat-Mendes et al, 2018). Beyond these municipal initiatives, there are several examples of Guerrilla Gardens – both productive and unproductive gardens located in areas non designated for such activities (Reynolds, 2008) – in all LMA municipalities, the majority of which differ significantly from the municipal allotment gardens both in what regards their goals but also the design, showing that the role of agriculture within the urban land of the LMA may still be greater than previously acknowledged.

2.2. The municipal level

The PDM coordinates two lower scales for planning purposes, namely the Urbanization Plan, *Plano de Urbanização* (PU) and the Detailed Plan, *Plano de Pormenor* (PP). These lower scales must abide by the sets and rules of the PDM and are employed regularly for several kinds of construction work.

The PDM synthesizes the economic and social strategy for the development of a municipality in their spatial dimension. As such, it defines land-use partitions, areas for special programming, infrastructures and territorial management.

Although the PDM's were of strategic importance for the urban growth of Portuguese municipalities, the evolution of their implementation proved to be a difficult task. Although

each PDM should be rewritten every ten years, within the LMA, half of the current PDMs date back to the year 2000 and have not yet been revised. Moreover, contradictory interpretations of the relation between land-use regulations and private property have long allowed unplanned development in many Portuguese municipalities, the LMA included (Mourão and Marat-Mendes, 2016).

In spite of the Ground-Basis Law for Spatial Planning, PDMs in the LMA have been written throughout a wide timeframe, and thus they are meant to tackle local, territorial and socio-economic problems which may have changed greatly since their writing. Eight of the 18 PDMs are prior to the first Ground Basis Law (1998), five were approved in 2015, one year after the second Ground-Basis Law, leaving however unclear which Ground Basis Law have indeed guided them. Only one PDM was approved afterwards. While all municipalities include urban land, with the exception of Lisbon municipality, all include also other classes of land ranging from 'rural land' to other specifications such as agriculture, forestry, agroforestry, green protection and natural spaces.

Our analysis of the PDM's of the Municipalities has concluded that the food system is never directly mentioned in these planning instruments, although it is often implicit on dispositions related to rural land. Notably, most PDMs include agriculture where construction is not allowed; and natural spaces are placed in urban land, but essentially as a non-productive one.

In many PDMs, urban agriculture initiatives could be incepted into programmed reconversion of industrial facilities. Urban farms or gardens are mentioned in the PDM's of Lisbon, Cascais, Odivelas and Oeiras, but their value is never acknowledged as a productive one. Instead, it is regarded as a leisure outdoor activity.

The PDM of Oeiras indicates the allocation of spaces for biomass production in its Ecological Structure. In turn, the Vila Franca de Xira PDM, allows "industrial facilities for production, transformation and commerce of produces of agriculture, livestock and forestry" in some of its agricultural spaces. Commercial activities are usually allowed in urban land and often in industrial and forestry land. However, food-commerce is not distinguished from other types, although accounting for food-outlets would help municipalities keep track of food-access (Moudon et al, 2013) and identify where deficiencies are located.

Generally, urban farms are unacknowledged as opportunities for kickstarting a local short food-supply chain. Finally, there are abundant regulations for maintaining ecological balance and controlling the effects of automobility in public space, but no attention is given to the environmental benefits that could be drawn from such public and vacant spaces.

2.3. The regional level

As stated above, the regional level is predicted in the Portuguese spatial planning structure, but it is not mandatory. A further difference between the PDM and the *Programa Regional de Ordenamento do Território* (PROT) is that the former is binding for both public and private entities, while the latter only includes public entities. The first PROT for the LMA (PROT-AML) was written in 2002, but its revision never came to be approved.

Written in the early 2000s, PROT-AML aims to give the LMA an European and Iberian capital, taking advantage of the potentials of its geographic location for Euro Atlantic business (DGT, 2002), a goal which may have been interrupted by shifting political and financial conditions within the country from 2007 on.

The territorial strategy of the PROT-AML is based on reaffirming the central role of Lisbon within the metropolitan area, using its recently increased access to the Southern Bank of Tagus river to revitalize its critical areas. In the Northern Bank of Tagus river, the situation is more polarized, with the Amadora-Lisbon-Loures-Vila Franca de Xira belt in critical urban condition and the Lisbon-Oeiras-Cascais (former PUCS territory) in optimistic development. Extensive green areas are located in the more peripheral areas of Mafra, Sesimbra, Palmela and Montijo, countering the more densely urbanized areas (DGT, 2002). The PROT-AML also includes an Environmental Strategy, which acknowledges the quality of the metropolitan agrarian and forestry spaces, which are meant to be protected as a feature of local character against excessive urbanization or infrastructure needs (DGT, 2002). One way to ensure this protection is the Metropolitan Structure of Environmental Protection and Recovery, which must map and manage specific parts of the territory, but also promote adequate activities to integrate these areas into the remaining urban structure.

2.4. Food and urban planning – some questions

Despite the central importance of food in cities, its presence in spatial planning at both the regional and the municipal levels in LMA is indeed scant. Many municipalities have published specific programs which relate to the urban food system, including networks of urban allotment gardens, but these are not predicted in the PDMs and neither in the PROT for the LMA.

Given such absence, we submit that the best way to understand the role of the food system on a potential sustainable transition of the LMA territory is to ascertain how it relates to the needs and desires of local communities, many of whom have shown great resourcefulness and willingness to participate in food-production activities. Furthermore, we call for a recognition of the historical role of food in the territory and of how 20th century planning has determined the relations between urban spaces of consumption and rural spaces of production. As this polarization between urban and rural is implied in all PDMs of the LMA, but also on its PROT, we seek to confirm if this same polarization can be confirmed in particular places.

3. Urban agriculture

3.1. The Chelas Valley and the Condado Estate

The Chelas valley area, located in the Easter area of Lisbon Municipality, comprises a total of 510 ha of a territory, which was an agrarian area until the 1960s. At this point, the acute housing shortage felt in the city led the municipality to start an urbanization plan, whose final version would be coordinated by architect Francisco Silva Dias and concluded in 1964. This plan would be subject of a revision process throughout its implementation process, yet aspects such as infrastructure and public equipment came rather late and different from what had been originally planned, thus compromising its success (Heitor, 2001). Divided into six zones (two of which were subdivided in two), only Zones I, J and N2 were implemented according to the original plan, and the first two were occupied in the aftermath of the 1974 Revolution. Most occupants were immigrants from the former Portuguese colonies in Africa, and the Democratic State came to legalize their presence. However, without predicting the difficult social conditions that would result from fundamentally poor communities, instead of the mixed communities envisioned in the urbanization plan (Heitor, 2001).

From all the Zones in Chelas, Zone J was by far the most ill-reputed, associated with the anathemas of crime, unemployment and drug-trafficking (Heitor, 2001). The planners, Silva Dias and J.A. Lobo de Carvalho, conceived Zone J as a 'building-city', a megastructure based on a continuous plateau with services and commerce, above which housing slabs rose, designed by architects Tomás Taveira and Vítor Consiglieri. The whole estate included service areas, linked by pedestrian decks, which ensured a circulation system detached from the motorways.

Recently renamed as Condado Estate, the area underwent a rehabilitation project whose most important aspect was the demolition of the central slab in 2009. In the Chelas Valley, another important change was the creation in 2010 of the Chelas Valley Horticultural Park, which occupies an urban park between Zones N2 and N1. However, this Horticultural Park is much smaller than the large extensions of Guerrilla Gardens that remain within the Chelas territory.

The Condado Estate is surrounded by Guerrilla Gardens in its southwestern and north-eastern limits. They occupy the vacant areas meant to counterbalance the high-density of the housing slabs. With plots of varying size and generally structured in a very privatized and individualized manner, most are accessible from the outside, and there is very scant use of gated shared pathways between different plots. Limits between plots are very well established, including through wooden fences and walls constituted by recycled materials. Some fruit trees are scattered on the terrain, but they are not a dominant cultivation type here. Although some of the plots are generally abandoned, most of them are still in use, and their cultivation is especially of edibles.

The Condado Estate includes some commercial areas which sell foodstuffs, and it is nearby Zone O, which comprises the planned 'central area of equipment', also has supermarkets and other food venues. However, the Condado Estate is surrounded by large motorways with very few crossings and often without sidewalks. Pedestrian circulation is very difficult within Chelas itself, and also to the rest of the city. Moreover, given its high-density dynamics, the estate comprises a significant amount of public open space, but this is often used as parking space. Despite the presence of the gardens, and their proximity to some of the most difficult parts of the estate, urban agriculture was not contained in any rehabilitation programs.

Figure 1 The Condado Estate and its surrounding Guerrilla Gardens

3.2. Laveiras – multifunctionality, transportation

The Laveiras Housing Estate area is located in the Municipality of Oeiras. Its design was initiated in 1987 by Architects Pedro Viana Botelho and Nuno Teotónio Pereira and its construction ending dates from 1990. Comprising fifteen housing slabs with terraces on the ground- and first-floors, this neighbourhood was further on added to another estate, a set of seven housing towers designed by other group of architects. Separating the slabs from the towers is a commercial gallery on the ground floor of the eastern limit of the original estate. The whole neighbourhood is barely accessible from its western limit, where it is limited by a motorway with no sidewalk. Indeed, the only pedestrian link between Laveiras and the Oeiras centre (on the eastern side) is a single road cutting across neighbourhoods of single detached houses. The most acute problems with the Laveiras Estate are not related to the quality of housing or public space, but rather to accessibility issues. Inhabitants have no option but to move using car or bus, which links it only to the Oeiras municipality.

Furthermore, on its eastern and western limits, Laveiras is surrounded by green or vacant areas. It was in these free areas located in the western but mostly the eastern limit of Laveiras that Guerrilla Gardens have emerged. On the eastern limit, behind the south set of towers lies and defined by Estrada de Laveiras is the second and third set of gardens. The second comprises 12 metres wide plots which run until the creek further east. Plots are explored individually by families who live in Laveiras and are all cultivated and relatively dense. Separation between plots is mostly ensured through vegetation (sugar canes in

particular) and with reed skirting, sugar canes and assemblages of recycled wood and metal. Production is mostly for self-consumption and the land is owned by the Caxias Sports Association.

Another larger set of allotments starts behind the northern set of towers, with varied sized of plots, which are also explored by residents of Laveiras. Most plots are of rectangular form, perpendicular to the creek, but others have used the space located between the circulation pathway and the creek, which is usually narrow and long. Only a few plots are not cultivated, and most are cultivated with vegetables but also with fruit trees, especially in larger plots. Production is mostly for self-consumption and the land is privately owned and paid yearly between all the farmers/ gardeners who use it.

Figure 2 The Laveiras neighbourhood and its Guerrilla Gardens

3.3. Almada – access and renovation of the ecological structure

Almada is one of the LMA municipalities whose PDM was written prior to the Ground Basis Law, in this case in 1997. Although the next version of the PDM, which is currently under revision, is expected to devote an entire section to urban agriculture (Marat-Mendes et al, 2018), the current one does not mention urban agriculture at all. Specifically, the PDM is protective of Almada's green-fields but not attentive to agriculture.

Hortas de São João are a municipal allotment garden, implemented on land classified as channel-space for infrastructure. Around it, it has many housing blocks and detached houses

with gardens and yards of varying size. In all cases, these buildings are privately owned, as this is not a designated area for council housing. Also nearby is a large vacant space. As such, Hortas de São João are located in a very diversified urban context, ranging from high- to low-density, and in proximity to commercial activities and motorways. The allotments are owned and managed by the municipality, and the access of gardeners to such allotment requires a registration for a selection process. Then, each gardener whom have been granted authorization to work the allotment will be in charge to maintain its plot. Only biological agriculture is allowed, and the municipality provides workshops to inform about it. Fruit trees are not allowed in the plots, as these provoke shades. Therefore, a specific plot is designated for the cultivation of trees of all gardeners. Most gardeners are retired or unemployed, and the park includes some convivial areas and leisure spaces, meant for activities relatively dependant on the agricultural aspect of the initiative, like barbecues and picnics.

Unlike Guerrilla Gardens analysed so far, these plots are organized according to an orthogonal grid, a standardised composition unit and a properly installed irrigation network. The proximity to some housing blocks of different scales, from towers to cottages, has no particular impact in the design, although most farmers do live nearby.

However, it must be noted that plots here have varying size, ranging from 25 m2 and 125 m2, perhaps because a lot of them are attributed not to individuals but to families (Marat-Mendes et al, 2018). The rental value paid for each plot depends on its size, and plots are distributed firstly between candidates with financial difficulties. But, there are waiting lists of people wanting access to a plot that the municipality has not yet been able to respond to. However, the access conditions promote food security by prioritizing those whose access to food may decrease, but also promote socioeconomic variety by placing the park close to middle-class neighbourhoods. Almada has a long history of cooperative organizations, and the Municipality was run by a communist-leaning coalition between 1976 and 2013, which may explain the sensitivity of the municipality to the social role of urban agriculture.

Figure 3 – The São João Municipal Allotments in Almada

4. Discussion and concluding remarks

Planning instruments in Portugal generally understand agricultural activities as being rural ones, an idea which underlies the regional and all municipal plans within the LMA. The case-studies which we have here showed are only three of numerous examples within the urban perimeters of the LMA, many of which have already been documented (Cabannes and Raposo, 2013; Oliveira et al, 2017; Delgado, 2018; Dias, 2018; Marat-Mendes et al, 2018). Municipal initiatives have created horticultural parks whose focus is predominantly based on a leisure dimension, but which still provide a contribution for the recovery of productive space within cities. In the case of the examples we have here detailed, the productive activities are taking place on land where, less than a century ago, was of agricultural or forestry use.

Guerrilla gardens distinguish themselves for more adaptive and individualized appropriation of space, but they seem to play a particularly important role on social housing neighbourhoods whose regeneration is acknowledged in the PDMs, but also in general by the PROT-AML (Cabannes and Raposo, 2013; Marat-Mendes and Borges, 2019). The examples of the Condado Estate and the Laveiras neighbourhood do both refer to council housing areas, and even if the Guerrilla Gardens are a direct response to a sense of urban isolation and poor access to food, they still denote how citizens appropriate available space and, in doing so, may contribute to the sustainability and productivity role of the territory. In these areas, knowledge and practices typically associated with the rural realm re-emerge in

an urban context, changing the physical landscape. Furthermore, such knowledge and practices also change the social landscape, for they help inhabitants assessing their needs and struggling to be capable managers of urban space (Purcell and Tyman, 2015) and of the food system.

Such initiatives must also be acknowledged in terms of their environmental advantages, as they obviously bring people closer to the land and to the food production, a reality that has been long segregated from cities (Steel, 2008). They also help decrease dependency on the agri-food business and the access to fresh vegetables and fruit cultivated according to different knowledges (Cabannes and Raposo, 2013).

Urban agriculture examples must inform planning strategies, but more attention is needed to the productive dimension, rather than to the dominant leisure one, potential of it, as they bring advantages in terms of a more varied and food-secure city (Viljoen and Bohn, 2012). The existence of urban agriculture in the LMA, particularly considering the role of Guerrilla Gardens, must however be taken further, as a unique opportunity to conceive new conceptual frameworks that allow planning to come closer to societal demands (Webb et al, 2017).

In the LMA, there are several aspects of planning that can be changed towards a more sustainable model. In terms of metropolitan organization, the PROT-AML envisions a polycentric metropolitan area with compact centres. Agricultural and forestry activities are included in a Metropolitan Environmental Protection Structure, which despite its complexity presents no challenge to the urban-rural divide in most municipal plans – at the time and now. And while it proposes multimodal transportation systems, efforts are mostly directed at automobility.

Thus, despite its briefly stated commitment to sustainability, the PROT-AML seeks to develop the territory without calling into question the very opposition between urban and rural land. This however assumes an horizontal metabolism, with biomass entering urban perimeters from outside and with no use for waste agricultural activities. Our literature review (particularly Steel, 2008; Viljoen and Bohn, 2012; Reisch et al, 2013; Parham, 2016) would further suggest that a more sustainable approach (social and ecological one) would be indeed needed for cities to shorten their food systems and for production activities to move closer to urban areas, closing the gap between urban and rural. But so, would the three case-studies have described above. All are located in different contexts within the PROT – while the Chelas Valley is considered a critical urban area, both Oeiras and Almada are mover spaces of the region, indeed closer to the centre. Yet, the interest in urban agriculture in these three municipalities attest to an important degree of demand on the part of population who either rent an allotment from the municipality or create one for their own.

At the municipal level, a greater recognition is still needed for urban agriculture. Although many municipalities have advanced horticulture gardens programs, solutions are needed in terms of a greater variety of urban design solutions and land-use policy to optimize them and make more allotments available, but also to understand the role of Guerrilla Gardens play within specific urban areas. In isolated council housing neighbourhoods, they show a constructive approach from local communities to make better use of available space, while improving their own access to quality food. Policy on this subject must beware of the dubious implications of charging the urban poor with their own food security while

recognizing the contribution of urban agriculture to the sustainability of the territory by countering urbanization excess and adding new functionalities to specific areas.

There seems to be a gap between the aims and of Portuguese spatial planning instruments and some aspects of societal demand in the territory of the LMA. While PDMs and the PROT-AML all acknowledge the need for sustainable development, this seems to be only possible within a set of a-priori conditions. These include the maintenance of the urban-rural divide, by increasing density in already urbanized areas and controlling growth in rural peripheries who concentrate the majority of food-production activities. By finding ways to include food-production in urban perimeters, spatial planning would not only be responding to a societal demand, but also taking one step further into shortening the metropolitan food-supply chain, thus improving its social-ecological metabolism.

Case Study Paper

URBAN POPULATION GROWTH AND THE GROWTH OF TOWNS AND CITIES IN INDONESIA

The Challenge of Non-Statutory Town Development

Fadjar Hari MARDIANSJAH, Department of Urban and Regional Planning, Universitas Diponegoro; Semarang, Indonesia

Paramita RAHAYU, Department of Urban and Regional Planning, Universitas Sebelas Maret; Surakarta, Indonesia

Deden RUKMANA, Department of Urban Studies, Savannah State University; Georgia, the USA

Abstract

This study examines the emergence of new tendencies in the current Indonesian urbanization process. The process is characterized by not only the development of large cities and mega-urban but also rapid development of many smaller cities and urban concentration. The latter includes the non-statutory towns in the territory of kabupaten. The rapid growth of towns and population, in addition to the huge number of accumulated urban population in kabupaten suggest that this type of urban concentration will play a more significant role in the future of urbanization and urban development in Indonesia. The development of these small towns and cities will also bring significant implications and challenges for central as well as local governments, including the government of the urbanized kabupaten, especially in improving the capacity to manage such emerging characteristics of development.

Keywords

Urban Growth, Urbanization, Non Statutory Town, Indonesia

1. Introduction

Urban population growth in developing countries has been one of the most important phenomena that bring very big challenges since the second half of the twentieth century (Cohen, 2004; McGranahan & Satterthwaite, 2014; UN, 2014; Jedwaba, et al., 2017). Very earlier study urbanization, suggest that the analysis of the urban population growth lead to the analysis on the process of urban concentration and development (Tisdale , 1942). Later, the study of urbanization became larger as the analysis of concentration then moved into regional or national development context (Friedmann, 1973).

Urbanization is favored because urban status tends to poses higher economic development potential and investment opportunity (Sircar, 2017; see also Ye and Xie, 2012). Urbanization has offered opportunities for economic development, welfare and quality of life for cities and regions, since the process play roles as transformative processes that brings about higher productivity to cities and strengthen the spatial structure of cities and regions in both internal and external context (UN-Habitat, 2016).

Some scholars argue that due to this positive affect of urbanization, this process is often established by government policies (Fan, 2013; Ye and Xie, 2012; Anderson and Ge, 2004). For example, rapid urbanization in India is claimed influenced by how the government intensively defined area as urban. In addition to statutory town like municipal cities that possess governing body, there are outgrowth or a dense settlements growing outside the boundary of statutory town; and census town (CT) or urban area on the basis of three criteria: total population, density, and percentage of male workforce in non-agricultural sector (Sircar, 2017). Census Town (CT) boosts the number of urban areas in India (Sircar, 2017).

Through different perspective, rapid urban growth, such as extended urbanization brings in social, economic, ecological, and governance conflict due to disparity of those aspects appear between the core city and the extended urban areas (Shatkin, 2019). Urban population growth particularly in the South has been also associated with concerns such as unemployment, poverty, disparities, inadequate infrastructure and housing. Obtaining a transformative role of the process requires a good capacity to manage the process, not only at the local level, but also regional and national level (Center for Strategic and International Studies/CSIS, 2015). With this regard, regional urbanization is argued as one way to understand regional disparity (Zhang and Han, 2009).

One of the problem of disparity between the core and the peripheral or extended urban areas is due to directive urbanization or urbanization because of re-classification. It is explained by the phenomenon of Census Town in Indian context (Pradhan, 2013). The conflict is due to the CT is governed by the rural government that possess different characters with the CT. Linking the CT with their urban core is proposed solution to deal with the disparity problems (Pradhan, 2013).

To benefit from such process, in-depth analysis is required. Furthermore, Soja (2011) also emphasized the importance of regional analysis of urbanization especially in recognizing the challenge of reconfiguration of metropolitan and regional modes of urbanization process, including their intercity connectivity and integrations to the global activities. Such analysis is also important to understand the spatial influence of regional urbanization to increase equal opportunities for the cities and the inhabitants. In this context, the study of urbanization has also linked to efforts in improving the roles of cities and other urban concentrations in creating welfares, better quality of life and performing sustainable development (UN-Habitat, 2016).

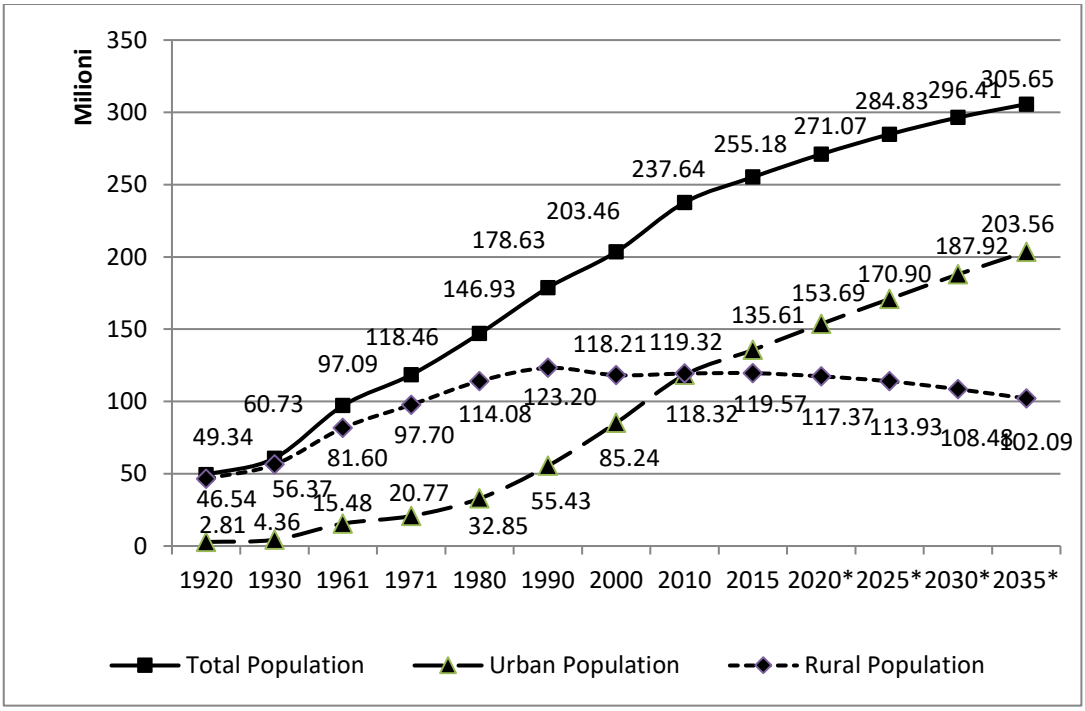
Similar to the global trend of urban population exceed 50% of the global population for the first time in history (UN, 2015), Indonesia experienced the same milestone in 2012 (Jones and Mulyana, 2015). Indonesian society has started predominantly urban. Today, the Intercensal-census 2015 shows that Indonesia is predicted to have 136.44 million urban populations that represent 53.1% of urbanization level (BPS, 2016). The number is about 50 times higher than 100 years ago. In the future, urban population in Indonesia is expected to increase rapidly with more than 203 million urban populations in 2035 with the level of urbanization about 66.6% (BPS, 2013).

Indonesia has also become a member of group of countries that have more than a hundred millions of urban population since the early year of the 21st century, with China, India and Japan in Asia(see UN, 2015). These figures show the great challenges in the future of urbanization processes in Indonesia. This article aims at examining urban population growth in Indonesia and its implication to Indonesian urbanization challenges. The analysis emphasizes on the urban population growth and its distribution among regions as well as among types of cities in Indonesia. The study applies statistical descriptive analysis, with statistical data withdrawn from national censuses. In doing so, the Indonesian territory will be divided into macro regions: Java, Sumatra and other regions.

The paper consists of five parts. Following the introduction, the concept of urbanization and global urban process as well as their challenges and implications will be discussed. The third part will discuss urban population growth in Indonesia as the case study. Subsequently, the important challenges of Indonesian urbanization process will elaborated. This section will be divided into four subsections: the rapid and significant increase, the spatial distribution, the increasing number of small towns and cities, and the increasing roles of non-statutory towns and cities in *kabupaten*. Finally, the paper will provide some conclusions.

2. Urban Population Growth in Indonesia and its Challenging Issues

Indonesia has experienced significant population growth since the last century. Between 1920, the first census in the Dutch colonial era in 1920, and 1961, the first national population census in the independence era, the population in Indonesia has been double from 40.34 million to 97.07. Later, according to the result of the 2000 national census, the population has been double again to 203.46 million. The last national population census in 2010 shows that the population was about 237.64 million and today according to the result of the 2015 intercensus population survey it is predicted to be 255.18 million with about 135.61 million urban populations in 2015 (see Figure 1). The latest number represents 53.1% of Indonesian population. definition, Indonesia is now an urbanized country (Poston and Bouvier's , 2010). With 3.5% annul urban population growth, Indonesia has experienced a much more rapid urban population growth than the world, Asia and Southeast Asia which have 2.05%, 2.50% and 2.53% of annual urban population growth rate respectively in 2010-2015 (UN, 2014). Bappenas (the National Development Planning Board of Indonesia), BPS (Biro Pusat Statistik or the National Bureau of Statistics of Indonesia) and the UNFPA have also projected that Indonesian will have more than 200 million urban population in 2035 (BPS, 2013).



Sources: Calculated from census data.

*Note: * = Calculated based on the results of Bappenas, BPS and UNFPA Population Projection in BPS, 2013*

Figure 1 Total urban and rural populations in Indonesia, 1920-2010 and 2015

Zhang and Deng (2016) argue that the Indonesian urbanization process has exceeded its peak after 1980s by defining the period of 1980s as the stage of extraordinary urbanization and the period of 1990s as the stage of urbanization adjustment. This paper argues that the period after 1980s and the later periods, after 1990s is more complicated considering the absolute number of urban dwellers will reach to nearly 3.5 million in 2000s and between 2010 and 2015. It is predicted that the period of 2010s is the decade when Indonesia will have the biggest number of additional urban population annually with more than 3.5 million per year from 2011 to 2020.

Indonesia will be expected to experience to have an average of 2.69 million of additional urban populations annually from 2010 to 2050 (UN, 2014). In this context, it can be considered that urban population growth and urbanization process in Indonesia is distinct and very important, since there are not many countries that have more than a million new urban populations annually, especially for decades. Indonesia places the fourth of thirteen countries, after India, China, and Nigeria, which have the kind of pressure at least until 2050.

The enormous number of additional urban inhabitants that need to be taken care of, has made Indonesia seems to have to build a large metropolitan every year in the coming decades. Certainly, Indonesia needs to develop urban infrastructure and services for its cities that most of them are still lacking. The development is not only important to respond the growing needs of the additional urban population, but also for the present and the future urban population and activities. The failure in responding these consequences will not only creates constraints in providing effective service deliveries as well as in performing economic growth (Lewis,

2014), but also will increase the slum formation in the rapid urbanization process that is not associated with economic growth and development (Quintana, 2016).

2.1. Uneven Spatial Distribution of Population Growth in Indonesia: The dominant concentration in Java

The population in Indonesia is not distributed evenly throughout the country. The results of the SUPAS or *Survey Penduduk Antar Sensus* (Inter-census Population Survey) in 2015 shows that Java remains the main concentration of the population. According to the latest census, there were 136.6 million or nearly 60% of the total populations live in Java. Sumatra and the other regions represents only about 20% of the total population. In terms of density, with an average of 136.8 people per square kilometer in 2015, Indonesia also has a high degree of heterogeneity too. Java has become the densest populated island with and an average population density of 1,120.3 people/km^2, while Papua has the lowest density with a density of 9.6 people/km^2. The second densest populated region is the Islands of Bali and Nusa Tenggara, with 717.7 people/km^2 as the density of Bali and 192.8 people/km^2 as the average density of the region. Meanwhile Sumatra, the second largest concentration in Indonesia, is only counted as the third densest populated region with an average density of 114.8 people/km^2. This considerable imbalance of spatial pattern of Indonesian population density shows that the magnitude of Indonesian population strongly remains in Java Island.

Province	Area (km2)	Urban Population	Urb. Pop Share	Total Population	% Urban	Pop. Density (inhab./km^2)
Java	129,438	90,825,696	67.0%	145,013,573	62.6%	1,120.3
Sumatra	480,793	22,848,775	16.8%	55,198,752	41.4%	114.8
Sulawesi	188,522	6,892,367	5.1%	18,702,298	36.9%	99.2

Indonesia	***1,965,709***	***135,613,086***	***100%***	***255,182,144***	***53.1%***	***129.8***

Sources: Calculated from SUPAS data, 2015

Table 2. Distribution of urban and total populations in Indonesia, 2015

Java keeps its share of 66 % of Indonesian urban population as it has been since four decades ago (see Table 5). What had been changed for Java is that the very rapid urbanization process in 1970s and 1980s increased the urbanization level of Java from merely 18 % to 25 % and it keeps on increasing afterwards. . The result of the 2000 population census indicated that Java has 49% for its urbanization level in 2000, while the other regions were still less than 35% at the time. Java is much more urbanized than other regions with a 62.6% of urbanization level in 2015 as the highest among regions in the country A more detailed comparison of Java and other island is shown in Table 2

Year	Java	Sumatra	Other Region	Indonesia

Table 4. Distribution of new urban dwellers in three macro regions in Indonesia, 1971-2010

These situations have lead Java can still keep its major share of urban population in Indonesia. It also could be predicted that Java will still got million new urban populations annually for the near future.

2.2. The Increasing Number of Cities, especially small size cities

The urbanization process in Indonesia has also increases the number of cities and towns. Table X indicates that the number of cities has increased from 50 cities in 1980 to 94 cities in 2010, while Table Y shows the order of cities more than 500,000 populations in Indonesia according to their inhabitants. The cities with less than 500,000 populations are not included in the Table Y since they are very dynamic and have many members. It is interesting to recognize that the increasing number of cities has been occurred especially after 2000. It influenced by to the opportunities introduced by the implementation of new decentralization scheme brought by the local government law no. 22/1999.

Type of cities	Number of cities and their population				Additional Population	Annual Growth
	1980	1990	2000	2010		
Large cities of 5 million or more	1 cities 6,503,449	1 cities 8,259,266	1 cities 8,384,853	1 cities 9,588,198	3,084,749	*1.30%*

Sources: Calculated from census data of 1980, 1990, 2000 and 2010.

Table 5. Number of cities and their population in Indonesia, 1980 to 2010

All of the cities in the list, except the DKI Jakarta, the largest city in Indonesia that has a status of a province of special region, are the cities with a status of *daerah kota*, the Indonesian term for cities with decentralized authorities. *Daerah kota*, which often call just as *kota* in daily practices in Indonesia, is one of the two Indonesian administrative divisions as the local autonomous regions at the lowest level, i.e. *daerah kota* and *daerah kabupaten* (or *kabupaten*). *Kota* is an Indonesian word which normally has the meaning of "city". Nonetheless, in the sense of the administrative division of Indonesian territory, it also has the meaning of "municipality", that is to say as the local Indonesian regions designated for the urban area. As an autonomous region, *daerah kota* that is ruled by *walikota*, or mayor, who is elected by the inhabitants of the city for five years, also has local parliament called the DPRD Kota (*Dewan Perwakilan Rakyat Kota*) whose members are also elected by the inhabitants for five years as well. Meanwhile, *kabupaten* is another local Indonesian region designated for non-urban constituencies, as most of their territory is non-urban land. The *kabupaten* is ruled by the *bupati* or the head of *kabupaten*, who is also elected by the inhabitants of the *kabupaten* for five years. As the local representatives, the *kabupaten* has an elected parliament, called the DPRD *Kabupaten* (*Dewan Perwakilan Rakyat Kabupaten*), whose members are also elected by the inhabitants for five years too. Yet, even if the *kabupaten* is designated for a non-urban area, there are many *kabupaten* who also have towns in some particular areas in their territory, as the result of development and urbanization process in their area.

Thus, in terms of urbanization discourse, both *kota* and *kabupaten* have their urban populations and activities reside in their territory. However, in contrast to the *kota* that has their own government institutions in order to take care of their authorities, including in dealing with the needs of urban development management, the towns in the *kabupaten* can be considered as non-statutory towns since they do not have any authorities as well as any institutions as their own, including the urban development institutions. So their need for urban development management is provided by any institutions belong to the government of the *kabupaten*. It is a pity that we do not have any supported data that can show the development of the number of the towns in the *kabupaten*, especially in a time serial manner, so the development of such number could not be figured out precisely as the development of cities that is presented in the Table 5.

One important feature of the Indonesian *kota* is that most of them could be categorized as small or medium size cities. Among 94 *kota* in 2010, there were only 11 cities categorized as cities with more than one million, and 16 cities of 500,000 to one million populations. Eight out of the eleven millionaire cities are located in Java, including five of them: Jakarta, Bekasi, Tangerang, Depok and Tangerang Selatan (plus Bogor that nearly have one million populations) are located in the Jabodetabek or Megaurban Jakarta, while six out 16 cities in the next size are located in Java.

The increasing number of cities, in terms of the creation of new *kota* (newborn cities) as new local governments is considered as an administrative and political process that is also part of the country's democratization process (Fitrani et. al., 2005). This reason is also happen for the new *kabupaten*. Therefore most of the new *kabupaten* and *kota* are created after 2000, the starting year of new decentralization era and democratization process in Indonesia. Meanwhile for towns it is mostly influenced by the Indonesian urbanization process that has been taking place at the regional level.

The process of the creation is known as *pemekaran* that is literally means 'blossoming' (Fitrani et. al., 2005), but Anne Booth (2011) prefers to call it as 'splitting' since the creation of new *kota* or *kabupaten* can be considered as a 'splitting' the new *kabupaten* or *kota* from their *kabupaten induk* ('mother kabupaten'). The number of local government in Indonesia increase from 259 consisted 49 *kota* and 210 *kabupaten* (exclude Irian Jaya or Papua) in 1961 to to 292 in 1998, and 434 in the end of 2004. In 2009, the number has become 495 consisted 98 *kota* and 397 *kabupaten* (Booth, 2011), and today the number has increased to 514 consisting 98 *kota* and 416 *kabupaten*. Most of the new local governments are located outside Java. Java has the least significant increase of the number of *kota*, from 20 in 1971 to 30 in 2010, while Sumatra from 20 became 34 in the same period. The outer region (the region outside Java and Sumatra) was the region that experienced the most rapid increase, from 10 to 30.

In Java, most of new *kota* created were big cities with more than 500 thousands and even more than 1 million population at the time they are initially created. Then, it is also interesting to know that all of the big and cities are located in western part of Java, surrounding the Jakarta area, the densest populated region, which consists of the Provinces of DKI Jakarta, Jawa Barat and Banten. In contrast, most of the new *kota* outside Java consist of less than 200 thousands populations cities, when they were created. These phenomena have also shown the high influence of Java, especially Jakarta, into the characteristic of urbanization process in Indonesia that creates uneven urban growth among Java and the rest of the islands in Indonesia.

Table 6. List of Cities of more than 500 populations in Indonesia from 1980 to 2010

Among the six types of Indonesia cities according to their population, the cities of 500,000 to one million, cities of 1 to 5 million and cities of 100,000 to 500,000 populations seem to be the types of cities that have rapid growth of their population (see Table X). The first type of cities has grown from four cities in 1980 into ten cities in 2010 with nearly 13 million additional populations and an average rate growth of 3.94% annually. In fact, among the six new member of this type of cities, there were only Palembang and Makasar (see Table Y) that have grown and promoted from the cities of less than 1 million in the previous period, while the other four cities were newborn cities that are created from the *pemekaran* from its *kabupaten*, i.e. Kota Bekasi from the part of *Kabupaten* Bekasi in 1997, Kota Tangerang and Tangerang Selatan from *Kabupaten* Tangerang in 1993 and 2008 respectively, and Kota Depok from *Kabupaten* Bogor in 1999. All of these cities created from the main urban areas of their *kabupaten*. One important feature of these *pemekaran* is all of the newborn cities were cities of more than 1 million populations just when the cities created. So, their influence to the population growth as well as the additional population to the type of cities were very important, as if the influence of the newborn cities is excluded from the calculation then the annual population growth of this type of cities will only become 1.35% per year and the additional dwellers only about 2.9 million urban population, a similar level to those of the large city of Jakarta in the same period. Similarly, the type of cities of 500,000 to 1 million has also influence from the creation of newborn cities (see Table Y), as Kota Batam was created in 1999, Denpasar in 1992, Tasikmalaya in 2001, Serang in 2007 and Cimahi in 2001, and only nine cities that have grown from the cities of less than 500,000 populations. In this regards, their urban population growth was only 1.98% annually without the influence of these newborn cities.

The same influence of the presence of newborn cities has also happen in other types of cities. Even the cities of 100,000 to 300,000 populations has the biggest number with 25 newborn cities, while the cities of 300,000 to 500,000 have only four newborn cities, and the cities with less than 100,000 populations have only six newborn cities. Therefore if we do not count the influence of the presence of the newborn cities, we will have different figures of which type of cities that have more rapid urban population growth than others. The analysis shows that the cities of 100,000 to 300,000 population is the type of cities with the most rapid growth with an average rate of 2.77% per year, and the cities with less than 100,000 populations is the next with an average of 2.65% per year, while the cities of 300,000 to 500,000 is the slowest grown with an average of 1.18% per year. These figures show that the small cities with less than 300,000 populations could be said as the type of cities that grown fastest.

3. The Formation of Urban Region

In addition to increase the number of cities, particularly the smaller size of cities, urban population growth in Indonesia has also triggered complex spatial processes that lead into the formation of urban regions. In Java, the most densely populated region that also the place where Indonesian urbanization process is concentrated, the formations are not only occurred in the very big cities like Jakarta, Bandung and Surabaya as the main urban concentration in the island. The formations are also happened in some much smaller cities, as is shown by the Table 7 and Table 8. In addition to the very big urban region of Megaurban Jabodetabek that has nearly 30 million urban populations today, Java has also some large metropolitan, i.e., Metropolitan of Bandung Raya and Metropolitan Surabaya that has more than five million urban populations each, four metropolitans with 2 to 5 million urban populations each (Semarang, Malang, Surakarta and Yogyakarta), four metropolitans with 1 to 2 million urban populations, five urban regions with 500,000 to 1 million urban populations, and two urban regions with less than 500,000 urban populations

Table 8. Urban population growth in smaller urban regions in Java from 1980 to 2010

Firman (2016) argues that the period of 1980s to 2000s are the period of mega-urbanization of Java with the phenomena of development of the Megaurban Jakarta, Bandung and Surabaya. The high population density that make the concentrated urbanization possible to be happened in Java and the enormous annual absolute increase bring fundamental basis for

the occurrence of the development of urban region formation that have based on not only in big cities in the form of megaurban or large metropolitan formation, but also in some much smaller cities in the form of small and medium size metropolitan. The development of urban region formation has shift many of urban activities, especially residential, manufacturing and services, from the cores into the fringe areas that brought a great expansion of the urban areas, that later also brought some urban environmental and also issues like traffic jams, flood problems, high intention of ground water utilizations, the appearance of urban heat problems, as well as crimes, poverties, social exclusions and other inequalities in the urban life of every urban region.

Most of the processes are influenced by the limited ability of the core areas in providing space for activities to the growing population and urban activities in these urban areas. The limited provision of spaces in the core areas resulted in high prices of land in the areas, which encouraged many growing activities, especially housing and industrial activities, tend to move out of the city to find cheaper land prices. In the small city-based urban region formation, the development of these formations are also influenced by the narrowness of the administrative area of the city that play as the urban core, which is supported by the availability of regional roads that provide good access for the growing activities outside the city boundaries. As the result, the urban areas expanded beyond the city's boundaries into the peripheries, which are usually the jurisdiction of neighborhood *kabupaten*, which is followed by the formation of small towns and cities in the territory of the *kabupaten*. Even, in the case of Jakarta and Bandung, the process has also created newborn big or millionaire municipalities. In this regard, thus, the formation process of urban region could also be seen as one of the influential factor for the urbanization process in many *kabupaten*.

It is also interesting to know that the development of urban region formation outside Java is not strong as its appearance in Java yet, as today they are only appear in Medan Metropolitan Region in North Sumatera, Metropolitan Makassar in South Sulawesi, and Metropolitan Denpasar in Bali. Meanwhile in Java, their emergence is relatively evenly distributed, as the two largest urban regions, i.e. Jabodetabek and Bandung, are located in western part of Java, and the third and fifth largest, i.e., Surabaya and Malang, are located in eastern part, and the other three large metropolitan, i.e., Semarang, Surakarta and Yogyakarta, are located in central part of Java. In addition, in term of coastal and inland area, even though two out of the three largest, i.e. Jabodetabek and Surabaya, are located in the coastal area, there is Bandung that is located in an inland area. Moreover, three out of four other large urban regions (Malang, Surakarta and Yogyakarta) are located in inland areas, and six out of eleven smaller urban regions are also not in coastal areas.

4. The Increasing Roles of Non Statutory Towns and Cities in *Kabupaten*

Another important feature in recent Indonesian urbanization process is the increasing roles of the *kabupaten* in welcoming urban population growth. As shown in Table 9, the high increase of the number of *kota* or municipalities was not followed by the increase of their share in accommodating urban population in their areas. Instead of increasing, the role of municipalities has declined. The role has decreased from 71.5% of the national urban population in 1971 to only 44.2% in 2010, even though the number of *kota* or municipalities has been double in the periods and the number of urban population of municipalities has also

increased from 15.9 million to 52.3 million. The decreasing role of the municipalities was, in fact, due to the more rapid increase of the urban population in *kabupaten, which* increased from 5.9 million (28.5%) in 1971 to 66.1 million (55.8%) in 2010 (see Table 4). In this context, it indicates that the process of urbanization in Indonesia brings urban areas in *kabupaten* have become the main place for urban population growth in Indonesia.

Year	*Kabupaten*	Share (%)	Kota	Share (%)	Total	Number of Kota	% Urban
1971	5,912,294	**28.5**	14,852,978	**71.5**	20,765,272	**50**	**17.5**
1980	14,048,324	**42.8**	18,797,505	**57.2**	32,845,829	**50**	**22.3**
1990	29,267,080	**52.8**	26,122,091	**47.2**	55,389,171	**51**	**30.9**

2010	66,059,240	**55.8**	52,261,016	**44.2**	118,320,256	**94**	**49.8**

Source : Calculated from census data of 1971, 1980, 1990, 2000 and 2010

Table 9. Distribution of urban population and among kabupaten and kota, 1971 – 2010

The increasing urban population in *kabupaten* has led to the increasing the number of urbanized *kabupaten*. According to the result of the national census 2010, there were 33 *kabupaten* in Indonesia that more than half of their populations reside in their urban places that consist of 21 *kabupaten* in Java and 12 *kabupaten* outside Java. Moreover, there were also three *kabupaten* (Garut of West Java, and Malang and Jember of East Java) that have more than one million urban population although their urbanization level were still less than 50%. Kabupaten Bogor could be considered as the biggest urbanized kabupaten since it has more 3.8 million urban population in 2010, followed by *Kabupaten* Bandung (2.7 million), Tangerang (2.3 million), Bekasi (2.1 million), Sidoarjo (1.7 million), Cirebon (1.6 million), Deli Serdang of North Sumatra (1.4 million), Karawang (1.3 million), and so on. The existence of the very big number urban population in their territories could be seen as important reason that makes them, as well as other urbanized *kabupaten*, need to have good effort in managing their urbanization process.

It is also interesting to know that there were 11 *kabupaten* that have very high urbanization level with more than 75% of urbanization level that consist of nine *kabupaten* in Java and two *kabupaten* outside Java. The western part of Java, which consists of the DKI Jakarta, West Java, and Banten Provinces, is the micro region where the urbanization process has much more been concentrated. This region has biggest number of very high urbanization level *kabupaten* with more than one million urban populations, i.e., Bogor, Bekasi and Tangerang that play as the peripheries of DKI Jakarta, and Bandung and Bandung Barat that play as the peripheries of Metropolitan Bandung. In fact, these *kabupaten* have spawned newborn big or even millionaire municipalities. Moreover, this region has also other *kabupaten* Cirebon, Karawang and Garut that have also more than one million urban populations each. Kabupaten Karawang could be regarded as part of the large corona in the Megaurban Jabodetabek, since it is located adjacent to *Kabupaten* Bekasi that is being a part of the peripheries in the megaurban. Meanwhile, Kabupaten Garut is part of the large corona in the Metropolitan Bandung as its location adjacent to *Kabupaten* Bandung, the peripheries in the metropolitan, and *Kabupaten* Cirebon is the periphery of *Kota* Cirebon, in which both of them form Cirebon Metropolitan.

Note : The asterisk indicates that the kabupaten is not adjacent of any city.

Table 10. Urban population and it concentrations in urbanized kabupaten in Java, 2010

The regional urbanization process taken place into the *kabupaten* has also triggered many town formations in the territory of *kabupaten*, as results of the population densification as well as the nonagricultural activities development that lead to rural-to-urban reclassification process of villages in the *kabupaten*. Although Firman (2003) argued that the growth of the urban population in Indonesia has strongly influenced by the growth of large cities in the predominantly agricultural regions in the corridors of the regional roads that connect the large cities of Java, the rural to urban reclassification processes are not only happened in villages of the *kabupaten* located in adjacent to large cities but also in villages in the *kabupaten* around

much smaller size of cities, including in those that are not adjacent to any cities like in Karawang, Garut and Purwakarta of West Java Province, in Banyumas, Jepara, Pemalang and Kudus of Central Java Province, and Jombang of East Java Province. The densification process as well as the development of urban activities changed the previously rural areas into more urbanized areas and form urban areas in the *kabupaten*'s territory, in both small and large size. Firman (2016) said that in Java alone, the number of villages classified as urban village has increased from 7510 villages in 2000 to 9239 villages in 2010.

Source : Calculated from result of 2010 census.

Table 11. Urban population and it concentrations in urbanized kabupaten outside Java, 2010

In terms of town formation, a detail study using three rapidly urbanized *kabupaten*, i.e., Kabupaten Tegal, Malang and Purwakarta show that all of the urban villages in a *kabupaten* will not agglomerate into single urban area (Mardiansjah, 2013). The wide area of the *kabupaten*'s territory, where the agricultural land is often still dominating the land have made the reclassification process only occurred in some particular villages that mostly are influenced by two factors, i.e., the history of the villages as service centers and the potential of the villages as the place of development. Most of the villages that reclassified as the initial urban villages are the villages that play role as the place of service center like the market place or other services like educational or health services. Meanwhile, the availability of regional road that connecting the villages to the surrounding urban centers as well as its distance, and the availability of potential economic activities are parts of the potential of the villages as the place of development. Therefore, instead of to be agglomerated into single urban area, in most cases, urban villages of the *kabupaten* agglomerated into some town (urban areas) with varying sizes of tows.

Table 10 and Table 11 show the number of urbanized *kecamatan*, a territorial subdivision of kabupaten, with the range of population size in every urbanized *kecamatan* for every urbanized *kabupaten*. In fact, the number of urbanized *kecamatan* is not the same with the number of town formed in the *kabupaten*. For example *Kabupaten* Tegal that has 10 urbanized

kecamatan (see Table 10) has five towns in the territory, since six *kecamatan* agglomerated into two relatively big towns with a population of about 200,000 and 300,000 respectively, and other two other *kecamatan* agglomerated into one town with 80,000 populations and the rest two *kecamatan* form their own town; *Kabupaten* Malang that has 14 urbanized *kecamatan* has nine small and medium sized towns (30,000 to 200,000 dwellers); and *Kabupaten* Purwakarta that has six urbanized *kecamatan* has two small and medium sized tows ((60,000 and 210,000 respectively). Nevertheless, the number of urbanized *kecamatan* could be seen as an indicator that most of urbanized *kabupaten* have several towns formed in their territory with varying size but significantly comparable to the population of many cities in Indonesia.

4.1. Some Important Challenges of Urbanization of *Kabupaten* in Indonesia

Previous discussion argues that urban population and urbanization process in Indonesia has not only intensified the urban challenges in large cities but also emerge the in much smaller size town and cities. The challenge in the small and medium cities is coming from the rapid growth of its population as well as increasing number of the type of cites, in both types: cities of 100,000 to 300,000 populations and cities with less than 100,000 populations. Especially for those located in Java, these type of cities has also experienced a process of urban region formation, in which the urban population growth take place beyond the city's border and go to the surrounding *kabupaten* that lead into a rural-to-urban reclassification process in some particular villages where the urban population growth of *kabupaten* took place. In these regards, Firman (2016) argues the process is a kind of urban conurbation process of the large cities that has led the urban population growth occurred not only in the city core area but also extended to the peripheries, the territory of *kabupaten*. Firman (2016) also argued that the rapid growth of urban population in the *kabupaten* was the part of the mega-urbanization process in Indonesia (or in Java) that similar to other large cities in Asian countries. However, the presence of the rural to urban reclassification process has not only occurred in some *kabupaten* adjacent to large cities, but also in many *kabupaten* adjacent to much smaller cities and even in some *kabupaten* that are not adjacent to any cities, in Java and outside Java.

The different characteristic of Java to other regions, i.e., a very high population density, has led into different characteristics of urbanization processes from those outside Java. In Java, the urban conurbation processes have been occurred in both small and large cities, and even happened in some particular not-adjacent-to-any-cities *kabupaten*. These phenomena have also shown the different characteristics of urbanization in Java as an urbanization process that has been appeared in a regional level, which then brought significant differences in the number of urbanized *kabupaten* as well as in the urban population size among urbanized *kabupaten* among in Java and in other regions. In Java, the number of urbanized *kabupaten* is much bigger than those outside Java; and also the urban population size (see Table 10 and Table 11).

In these phenomena, later the role of cities in accommodating urban population growth has been decreasing. Their role that was receiving more than 70% of urban population until 1971 has decreased into less than 50% in the late of 1980s. In the opposite, the role of *kabupaten* in accepting urban population has increased from less than 30% in 1971 to more than 50% starting 1990, even though it was slightly deceased from 2000 to 2010 as there were some *pemekaran* some *kabupaten* into *kota* that also reclassified some urban dwellers of *kabupaten* into those of *kota*. Today, there are more than 66 million people live in towns in *kabupaten*, while about 52 million people reside in cities in Indonesia.

The increasing role of *kabupaten* is considered to bring some important challenges in the urbanization process. The first challenge is coming from the large number of urban population involved in urbanization process in the *kabupaten*, which is not only in terms of the total number of urban population living in *kabupaten*, but also in terms of the number of urban population in some particular *kabupaten*. According to the result of the 2010 census, there are ten *kabupaten* (nine *kabupaten* in Java and one *kabupaten* in Sumatra), which have more than one million urban inhabitants. Some of them have more than two million urban inhabitants, like *Kabupaten* Bogor with 3.8 million urban dwellers, *Kabupaten* Bandung (2.7 million), Kabupaten Tangerang (2.3 million), and Kabupaten Bekasi (2.1 million). There are also 21 *kabupaten* that have around 500.000 to one million urban inhabitants in their territory. These figures indicate that many *kabupaten*, especially those located in Java, could also have big challenges in dealing with their urbanization process in their territory in order to respond their urban population growth.

The second challenge comes from the spatial characteristic of urban population concentration in *kabupaten* that is different from urban concentration in municipalities. Urban population in most *kabupaten* rarely concentrated in a single urban concentration, but commonly in more than one urban concentration with varying size that each of them is significantly comparable to that of the municipality. Most of them consist of the capital of the *kabupaten* and other urban concentrations, which are developed from existed rural centers (Mardiansjah, 2013). The large number of urban concentrations in *kabupaten* will also bring challenges for the *kabupaten's* institutions since they should take care of many towns in their territory in addition to their obligation in managing their regional as well as rural development processes.

The last important challenge comes from the nature of *kabupaten* that is designated as the local government for non-urban region as the complementarity of *kota* (municipality) that is designated for the urban region. As the implication, most of the government of *kabupaten* is not well prepared to implement well management of urban development processes as well as their implications. It is indicated by the absent of some institutions or services that specifically dedicated for managing urban development process such as city planning department/services, building control and supervision institution, and fire department in many *kabupaten* including in the urbanized *kabupaten*. Usually the functions of the absent institutions are performed by a division or even a section of certain institution. Thus, most of the functions are not run well since they are implemented by a lower echelon that means with smaller staffs, smaller financial resources, smaller technical capacities and also smaller decision powers.

These challenges come from the nature of towns in *kabupaten* that can be classified as non-statutory ones. Since towns in *kabupaten* are the part of the *kabupaten*, they do not have their own authorities as well as their own resources, including human, financial, tools as well as decision powers, as all of the resources and authorities belong to the *kabupaten*. Therefore, all of the towns highly depend on the *kabupaten*'s institutions that should also take care of the *kabupaten*'s regional development as well as the rural development as most of *kabupaten* have non-urban areas as the majority of their administrative territory.

5. Conclusion

Located in the place where global urbanization grows rapidly, the Indonesian urban population growth and urbanization process become one of the significant processes that should be better understood and managed in order to take benefit from the inevitable process. The approach developed in this study provides insights into the importance of Indonesian urbanization process that has potential to be experienced by other developing countries in the south: the significant number of urban population involved, the spatial concentration of urban growth that remains to be concentrated in the main region, and the small towns and cities, including those the non-statutory, that should be given more serious attention in order to bring better management in their urban development process.

Although the pace has eased in the last few decades, the challenges brought by the urbanization process in Indonesia could not be considered to have diminished as well. Instead, the challenges will be greater in the future, since the number of annual number of new urban population involved continues to increase until the next decade and will only slightly decrease in the next few decades. This will bring some important changes in the country, as it has changed the population of the country into a predominantly urban society and has led Indonesia to become a member of group of countries that have more than one hundred million urban populations.

In addition to increase the size of some main urban agglomerations, like Jakarta that has grown as the Jabodetabek or the Jakarta Metropolitan Region (JMR), the megacity with a population of more than 25 million of urban inhabitants, including in both in the core and in the peripheries, there is a great tendency that urbanization process in Indonesia takes also place in much smaller town and cities that also developing, reforming, and reproducing small towns in the territory of *kabupaten*. These phenomena will lead into new challenges in urban future in Indonesia, as the phenomena do not only involve enormous number of population, but also large number of *kabupaten* as well as the number of the towns. The solution is considered will not only involve a capacity building for the *kabupaten* in managing their urban development process, but also need a fundamental political will for political and administrative rearrangement that provide better authorities, tools and mechanisms, especially for the urbanized *kabupaten*, in dealing with their urbanization process and urban growth. Furthermore, the solution is considered to need spatial affirmative policies that can accelerate a more balance development and urbanization processes throughout regions in Indonesia.

Case Study / Project

The Smaller Town

as Component of an Urban Settlement Cluster

Derry O'CONNELL

Abstract

In Ireland rejuvenated town clusters gather together interactive settlements in a rapidly emerging metropolitan alternative to either the city or the rural lifestyle. A similar trend is observable in many countries where quality of life in a settlement of smaller scale can exceed that in the city. The concept of nucleated settlement has made planning sense for centuries, but where unique individual settlements can be related and co-ordinated with efficient connection, by recent advancements in rapid sustainable transportation, there may now be a clear role for the smaller settlement and its defined hinterland. Traditional settlements carry the advantage of place-rich heritage, identity, proximity to the natural environment and human scale. Modern transportation systems now give them connection to the essential shared services of other places. While the traditional town which serves this cluster concept brings the stability of established place, evidence now shows however that it must adjust to develop a different operational structure in the service of its role within a broader settlement framework.

This paper draws on a five-year study of sixty-six urban settlements in Ireland illustrating how the structure, layout and operation of the traditional settlement is adjusting to become a modern part of a semi-dispersed settlement network. Each town is taking a place in this route-linked strategy, each having a function and identity in a composite framework which is now bonded across distance by an emerging hierarchy of efficient connections. Reworking of the fabric of towns towards a new role has introduced a range of new relationships between modern operational structures and traditional urban frameworks. Findings have revealed such details as the inverting relationship between street and block, as towns collectively adjust to new scales of use, particularly in a changing global retail interface. The research has taken a morphological approach using such techniques as cartographic regression (Kropf 2017) and review of development activity, relating towns to each other by comparing their timelines of change (Field and Morse 1985). The work has also embraced significant engagement with municipal authorities.

Abstract

Istanbul is a unique part of the world because of not only its history, but also its function as a bridge from the point of economic, social and cultural interrelations. There are many cities, which are settled near a water source; however, Istanbul is the only city that is settled between two continents and two seas. All these features create some opportunities and threats for the city in terms of hinterland relations and the spatial structure.

This paper aims to find out the economic, social and cultural impact of globalization on the spatial structure and the hinterland relations of Istanbul while discussing the city's contradictory positions as an edge of Europe and as a bridge between the East and the West. Within this scope, we made a multiscale analysis considering inter-regional and inter-urban relations and their socio-spatial imprints within the boundaries of the city. Firstly, we made a comparative analysis to understand the changing position of Istanbul in the world in the 21st century by using global and regional indexes. Secondly we examined the change in the hinterland relations of the city by investigating the flows of people, goods, services and ideas between other regions / cities and the city of Istanbul in time. Thirdly, we traced the spatial imprints of these flows and interactions within the city in terms of relocations and displacements.

Our study shows the growing importance of the city not only as a part of Europe but also as a node and bridge for the globalized world while emphasising socio-cultural and socio-economic tensions within the city as a result of this process.

Keywords

Istanbul, globalization, global city indexes, spatial structure, hinterland relations.

1. Introduction

Istanbul is one of the fastest-growing metropolitan areas not only in its region but also in the world. It functions as a bridge in terms of social, economic and cultural flows and transitions between continents as well as the cradle of human civilization.

Despite the changing of the capital from Istanbul to Ankara in 1923, Istanbul achieved to sustain its role as "the nation's industrial and business centre, greatest port, the focus of transportation network and the centre of cultural and intellectual life" (Göymen, 2008). For

the last decades, Istanbul attracts millions of people from different regions in Turkey as well as from the other near and far countries from Asia to Africa (Table 1).

Table 1: Population change in Istanbul, the Marmara Region and Turkey from 2000 to 2018 (TurkStat, 2019).

	2000	2005	2010	2015	2018
Istanbul	11,076,840	12,128,577	13,255,685	14,657,434	15,067,724
Marmara Region	17,829,639	19,467,417	21,285,696	23,403,950	25,034,570
Turkey	64,729,501	68,860,539	73,722,988	78,741,053	82,003,882

Istanbul is located in the middle of the Asia, Africa and Europa. Just in a three hours flight, it could be reached 1.5 billion people. Besides Turkish Airlines (THY) widens its hinterland and starts to flight more than 350 destinations in the world. This makes Istanbul more accessible from any point of the world.

On one hand, Istanbul is an *"avantgarde"* city for Turkey and its region. Economic impact of Istanbul is very high. According to the Turkish Statistical Institute (TurkStat), 43% of the total taxes are collected and 55% of economic activities are produced in Istanbul. Together with adjacent cities (Kocaeli and Tekirdağ) in the metropolitan region, this ratio reaches more than 50% of taxes and 65% of economic activities in Turkey. Additionally, more than 13 million tourists visited the city in 2018.

On the other hand, not only the city of Istanbul and the rural towns within the boundaries of the city, but also other cities in Turkey and near countries such as Balkan and Middle East as well as Africans, which play an essential role supporting and providing resources of foods, labour, industrial activities, raw materials and so on to the city of Istanbul.

As well as economic situation, social and cultural transition between the different groups makes the city unpredictable core of the region. Different ethnic/religious groups and immigrants live in the city together. Beyond all that, Istanbul is a big exporter of the Turkish TV series to the neighbours of the country especially in the Middle East and the Balkans.

In this paper, we examined how globalization process affected the city's socio-economic and socio-political position within the world, and how this change influenced socio-spatial processes within the city. In the second chapter following the introduction, the most popular global city indices including Istanbul were picked and the changing position of Istanbul in the world has been scrutinized. In the third chapter, changing hinterland relations of the city in terms of flows of people, capital, goods, services and ideas/cultures; and their socio-spatial imprint within the city were discussed.

2. The Changing Position of Istanbul in the World

Istanbul is included in almost all international studies comparing world cities. The main cities where Istanbul is compared in various categories in the Global City Indices are New York, London, Tokyo, Paris, Frankfurt, Zurich, Dubai, Beijing, Seoul, Hong Kong, Bangkok, Singapore, Sydney, Vancouver and Los Angeles. These cities both share and compete with each other in the world city network.

Istanbul attracts people from almost every point of the world. The recognition of a global city encourages international organizations to think and produce new projects in that city. According to the Global Power City Index (2018), cities like Doha, Dubai, Beijing and Bangkok make great efforts to attract people's attention, while Istanbul can naturally attract people without special effort. Istanbul is the 34th most powerful city in the world, with high global accessibility and a preferred stopping point for international travel (MMF, 2018). Istanbul is an advantageous transfer and maintenance point in terms of location for both air passengers and airline companies in long-distance transfer flights in the east-west and north-south axis in the world. Istanbul has a strong transportation and communication infrastructure. Ongoing and planned large-scale regional transport projects strengthen the infrastructure and renewal of Istanbul and neighbouring cities. The city has something to appeal to everyone in the world. According to Kearney's Global Cities 2019 Report, Istanbul ranks 26th among 135 most influential global cities (Kearney, 2019).

The business world in Istanbul is very active and lively. The indices reveal that Istanbul can attract qualified people from Turkey and abroad. This is a very important feature for Istanbul, because the performance of global cities is rapidly increasing when it can attract a qualified young population from the world to live and work. According to the JLL Global 300 Cities Index, Istanbul ranks 17th in terms of population, 13th in terms of economic size and 19th in terms of commercial attractiveness among 300 global cities (JLL, 2019).

Istanbul's foreign trade volume is around 195 billion dollars (TurkStat, 2016). According to the data of the Ministry of Commerce, Istanbul exported USD 34 billion and imported USD 57 billion in 2018 (Ministry of Commerce, 2018). With these characteristics, Istanbul is one of the 20 most important business and trade cities in the world according to the 2016 Commercial Attraction Index. In addition, for many years, Istanbul has been shown as one of the leading investment cities by all credit rating agencies. According to World Bank 2015 data, with an economic size of 349 billion dollars, Istanbul has a larger economy than 130 countries in the world (for example, Pakistan, Chile, Ireland, Finland, Portugal and Greece). Having a stock exchange in global city indices is shown as an element that reveals the economic impact power of a global city. In this context, the presence of BORSA İSTANBUL adds a great strength to the economic attractiveness and image of the city. The cost of living in Istanbul is relatively low compared to many global cities (eg Dubai, New York, etc.). In the 2018 survey of the Mercer company, which ranked 209 global cities according to the high cost of living, Istanbul was ranked 154th. According to UN Habitat Urban Data 2016 data, food and clothing prices, urban transportation costs, urban utility bill costs and leisure time costs are among the factors that reduce the cost of living.

The quality, speed and environment of hospital services in Istanbul are better than all other global cities (Numbeo, 2019). The number of visitors to the city to receive qualified health services and treatment has increased in recent years. Compared to many global cities, there are many historical and natural areas to visit in Istanbul (and nearby neighbouring cities). These features make Istanbul stand out in the global competition and make it strong.

According to the global city index data, there are two important issues that have left Istanbul weaker in global competition. First, Istanbul is not yet able to produce sufficiently effective projects and projects on environment, energy and waste. There is a need to make strong moves in the city in terms of clean energy, environment and recycling, not only in order to

be ahead of the economic race, but also to make Istanbul a liveable place for both people and other living things. Evaporation increases, scarce ground and surface water resources decrease, water quality decreases, vegetation cover changes, and seasonal imbalances in temperature and rainfall amounts occur due to global climate change and global warming. Like many other world cities, Istanbul is also affected from changing environmental conditions. Protecting natural resources and nature should be kept on the agenda as much as economic development in Istanbul in order to prevent Istanbul from being affected by climatic changes and global warming in a longer term. Turkey has its signature under the international agreement on global climate change. Therefore, the country must adopt a strong attitude on this issue. The lack of open and green spaces in the city and the intense structuring in Istanbul are the major factors that downgrade Istanbul in global city indices.

Second, Istanbul (including patent, utility model, trademark, industrial design and registration) is unable to produce enough original information and manage the global flow of information. According to the Networked Society City Index 2016, which researches the sustainable development of global cities in the information and communication sector, Istanbul is the 22nd most integrated city in the global network and its performance in this area is rapidly increasing (Ericsson, 2016). The inability to keep the circulation of useful information around the world is the biggest obstacle for Istanbul to become a leading and efficient city in the world in terms of R & D studies and patents.

Istanbul, whose transportation and communication infrastructure has been renewed, strengthened and expanded year after year, has the potential to be a central city that manages all global flows between the three continents. Anatolia and Turkey's European territory of the new road, sea, rail and air are connected with the new projects. This facilitates and accelerates the flows of people, goods, services, information and finance between Europe, Asia and Africa.

Not only in terms of land transportation, but also in terms of air transportation, Istanbul has a great importance both at national and international level (Eren, 2018). Turkey's air cargo operations are mainly carried out via Istanbul and Marmara region. Istanbul Atatürk Airport ranks 30th in the airport rankings according to cargo traffic in the world. Due to its location, Istanbul can reach most of the continents of Asia, Europe and Africa within a short flight distance of three hours. Istanbul New Airport will make Istanbul the centre of both the country and the region in terms of air cargo logistics. With an annual cargo capacity of 6 million tons, the new airport crosses Hong Kong, Memphis, Shanghai, Seoul, Dubai, Tokyo and Frankfurt airports in terms of volume. The fast connection of the new airport by road and sea, and the strong integration of transportation in the city are of great importance in terms of the international competitiveness of the new airport.

There are many large-scale transportation and infrastructure investments in Istanbul. These investments increase the interaction and trade relations of Turkey with Asia, Middle East, Mediterranean and the European countries and relieve Istanbul's urban transport and traffic. Istanbul is a consumption and distribution focus where 53% of the production of logistics activities occurs in Turkey. These activities contribute 32 billion TL annually to the national economy (IBB, 2017). Therefore, Istanbul is the most important locomotive city in the development of trade, industry, finance and tourism sectors.

With the Istanbul Stock Exchange, Istanbul is Turkey's main financial centre. However, the city aims to become an international financial centre. This objective is clearly emphasized in the 2009 Strategy and Action Plan, the Vision 2023 document and the 10th Development Plan. In line with this objective, the international financial centre, which has a physical infrastructure in Ataşehir, is expected to provide new jobs for 30,000 people. In 2016, 104,000 people are employed in finance and insurance activities in Istanbul. Therefore, there are 7 jobs per 1000 people in the financial sector in Istanbul. This ratio is below the average standard in international financial centres. Therefore, the financial sector in the city needs to be expanded by following a special strategy. If the financial and insurance sector in Istanbul grows by 4.7% each year, in 2036 a total of 261,000 people will become employable in the sector. When Istanbul's capacity in the financial sector increases, this will also help the growth of other sectors in the country.

Istanbul has the potential to become a headquarters for financial investors in the Arabian Peninsula, the European Union and Russia. This can be achieved by creating the most advanced technological infrastructure in Istanbul, facilitating access to innovative technology and reducing costs.

For foreign investors, Turkey is considered as a country that is difficult to do business. The World Bank Ease of Doing Business Index based on 2017 data, Turkey is ranked 69 among 190 countries. Unfortunately, the new investment incentive system does not include incentives for the rapid growth and internationalization of high value added sectors such as finance and IT in Istanbul.

Istanbul is a national and international trade centre. 69 out of every 1000 people in the city are employed in wholesale and retail trade sector. This ratio shows that Istanbul is behind Dubai (94) but ahead of Hong Kong (68) and Singapore (63) to become a global commercial centre. Istanbul is also very close to its competitors in the food and beverage sector. In 2016, 284,000 people are employed in this sector in Istanbul. Therefore, 19 out of every 1000 people work in this sector. 25 out of every 1000 people in Singapore and 29 out of 1000 people in Dubai are employed in this sector. Istanbul has the potential to attract many more international students in the higher education sector. Today, 25,000 teaching staff is employed in this sector.

To sum up, Istanbul has a number of strong points/advantages to compete with other global cities such as its location, transport infrastructure, young population, and lower costs of living while it has some weaknesses to eliminate such as its environmental conditions, quality of life and lack of innovations to lead the world.

3. The changing hinterland relations and socio-spatial organization

3.1. Flows of people: Demographic transition

Turkey was mostly “a country of emigration” during the second half of the 20th century. From the beginning of the 21st century, the country has become a cross-road point not only for irregular migrants from Asian countries such as Afghanistan, Pakistan, Bangladesh, Iraq, Iran but also for EU specialist and retirees and regular/irregular migrants from the former Soviet Bloc countries.

Turkey signed Convention Relating to the Status of Refugees in 1951. Today, Turkey, known as migration and asylum country for many years due to policies, are faced with difficulties. However, Turkey's traditional immigration policy nowadays, nation-building concerns, and maintaining a homogeneous national identity was largely shaped by efforts. Turkey's immigration policy in recent years, necessitate the replacement of traditional policies (Kirişçi, 2007).

In 1923 (the proclamation date of the Turkish Republic) the city of Istanbul had a nearly 700.000 population. Its growth continued relatively until the 1970s, when it reached about two million (TurkStat, 2018). After that, accelerated economic development, which fuelled strong internal migration especially from the middle and eastern Black Sea and Eastern Anatolia regions of Turkey, led to a rapid expansion of both population and built-up area. By the end of 2018, the city had a population of more than 15 million on a territory that covers 5.461 km^2. Currently, about two-thirds of the population (9 million) live on the European side, and one-third (6 million) across the Bosporus on the Anatolian side (TurkStat, 2018).

While there were 20 universities and 198.612 students (associate-bachelor-master-doctorate) in Istanbul in the 2000-2001 education period, the number of universities increased to 57 and the number of university students to 774.350 in 2018-2019 (YOK, 2019). The number of university students in Istanbul corresponds to 41% of the total number of university students in Turkey (1.888.557 in total). In the 2017-2018 period, the number of foreign students studying at the universities in Istanbul is 35,735 which refers the 28.5% of all foreign students in Turkey (YOK, 2019).

According to the TurkStat, 46.509.314 tourists and sojourners have visited Turkey in 2018. Of these, 18.643.175 visited Istanbul as a tourist/visitor (TurkStat, 2019a). There are 1.013.618 foreigners with a residence permit in Turkey, and 517.997 foreigners (51.1% of total foreigners) are located in Istanbul (DGMM, 2019a). Similarly, there are 3.62 million Syrians under temporary protection in Turkey; and 547.535 Syrians (15% of total Syrians in Turkey) are settled in Istanbul (DGMM, 2019b).

While the number of international immigrants migrating to Istanbul in 2000 was 54.644, as of the end of 2017, this number reached 166.044. Of the 166.044 people who came to Istanbul in 2017 by international migration, 148.722 were foreign nationals. In 2017, international net migration to Istanbul was 90.195 (TurkStat, 2019b). As it is seen, Istanbul has attracted 35% of all international immigrants (466.333 all over Turkey) in 2017. In addition, 42.4% of international net migration was realized in Istanbul.

In terms of internal migration, the opposite is the case. In 2015-2018, the emigration from Istanbul is higher than immigration to the city. In this period, net migration was realized as -287.600 (TurkStat, 2019b).

Table 2: The population / visits and the share of Istanbul in Turkey

	(Year, Source)	Istanbul	Turkey	%
Population	(2018, TurkStat)	15067724	82003882	**18,37**
University Students	(2018-2019, YOK)	774350	1888557	**41,00**
International Tourists / Sojourners	(2018, TurkStat)	18643175	46509314	**40,08**
Temporary residents	(2019, DGMM)	517997	1013618	**51,10**

International Immigrants	(2017, TurkStat)	166044	466333	**35,61**
International Net Migration	(2017, TurkStat)	90195	212693	**42,41**
Temporary Protection (Syrians)	(2019, DGMM)	547535	3626820	**15,10**
Domestic Passengers (Airports)	(2018, DHMI)	41795577	112911108	**37,02**
International Passengers (Airports)	(2018, DHMI)	60780029	97587056	**62,28**

As can be seen from the Table 2, the gravity of Istanbul, which hosts 18% of Turkey's population, is much higher than its population. The city has become a centre of attraction for university students, tourists, sojourners, international immigrants and refugees. This attraction has dramatically changed the demographic structure of the city. In the central areas of the city, some of the dwellings inhabited by local residents have been converted into motels / pensions / dormitories, and some have been converted into dwellings where students and refugees reside. The fact that housing stock in the central areas of the city is older than the peripheral areas while the rental and sales values are higher in addition to the parking and security problems in these areas influenced the preferences of the local people, who can find new apartment buildings or reside in gated communities in the peripheral areas. As a result, the demographic structure that emerges in the central areas of the city causes the alienation of the citizen to the city.

The number of universities in the city has increased rapidly in the last 15 years and most of the new universities are concentrated in Fatih, Beyoğlu, Beşiktaş, Şişli, Üsküdar, Kadıköy districts, where can be described as the historical core of the city (Figure 1). Fatih district is also the most preferred area for international immigrants and Syrians under temporary protection. Fatih and Beyoğlu are also the centres of touristic activities.

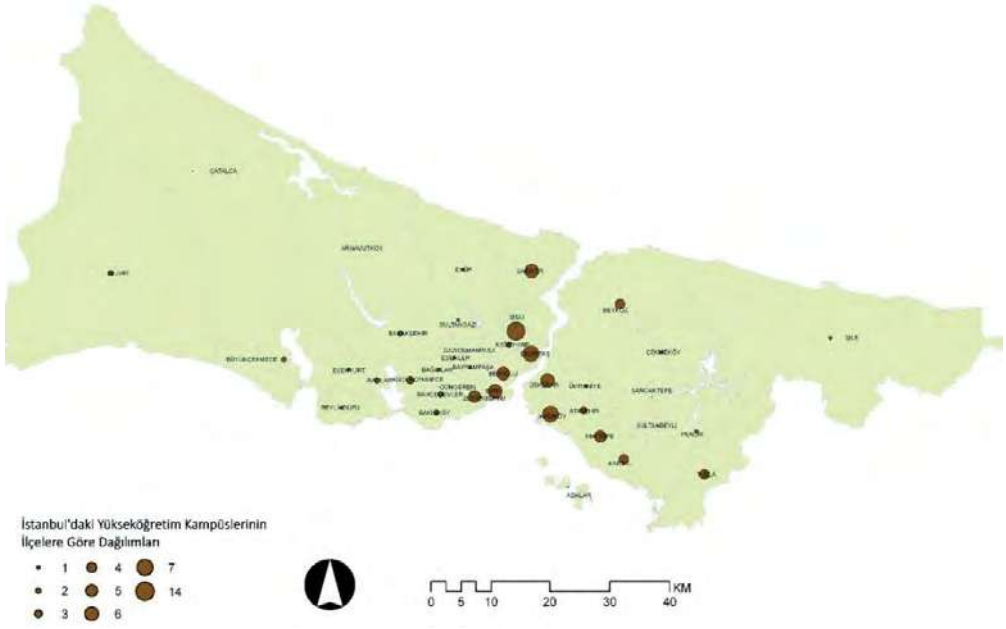

Figure 1: Distribution of Higher Education Campuses in Istanbul by District-2015 (Arlı, 2016a).

In addition, gentrification zones have started to be formed in the central areas of the city, especially in some districts of Beyoğlu, Şişli and Beşiktaş. The transformation in these regions also resulted in the displacement of the old inhabitants of the city.

In summary, Istanbul's adventure of being a centre of attraction and a global city on an international level has led to a change in the demographic structure of the city. The movement of the city dwellers from the centre to the periphery and out of the city, increasing visibility of tourists, students, expats, intellectuals, single white-collar employees in the central areas of the city. In addition, low-quality houses in the central areas of the city, where have not yet been transformed, has become a shelter for the Syrians under temporary protection.

3.2. Flows of capital, goods and services: spatial re-organization

Despite numerous headwinds, unsuccessful military coup and adverse shocks, "Turkey's real GDP has grown by more than 34% over the past 5 years, faster than any other OECD country except for Ireland and only slightly less than China and India"(OECD, 2019). Turkey's business sector showed one of the highest investment rates in the OECD countries. However, even there is a big economic fluctuation in the second part of 2018, which triggered a recession in the second half of the year (Figure 2), strong fiscal and quasi-fiscal stimulus have moderated the contraction in early 2019.

Istanbul is the capital of economy in Turkey informally. All financial centres, banks, insurance companies etc. are located in the city. It has provided more than 40% of Turkish taxes and nearly 55% of economic activities in Turkey (IBB, 2017).

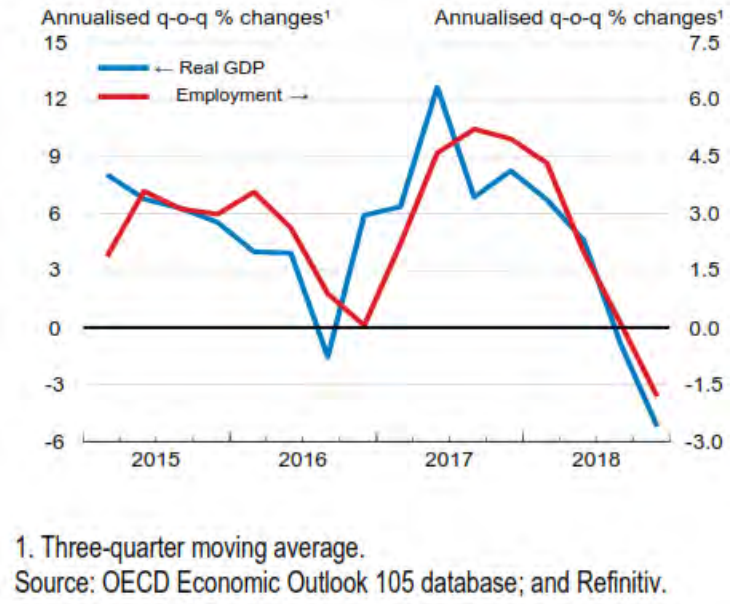

Figure 2: Turkeys' real GDP and employment distribution between 2015 and 2018.

Thanks to rapid economic growth, numbers of immigrants from all parts of Turkey and from neighbour countries migrated to Istanbul in one of the world's fastest migration rate. This flow of migrants put the physical infrastructure of the city under great pressure and caused great congestion costs. As Göymen points out in his study, the generally unqualified waves of migrants continued to come to Istanbul, putting pressure on housing stocks and physical and social infrastructure; Increased congestion forces the environmental bearing capacity to its limits. (Göymen, 2008).

Istanbul is also one of the main cities of media and cinema industries in Turkey. The ongoing boom period, which remains largely unknown to the majority of casual viewers in the West,

began in 1999. Since then, Turkish drama serials have been seen across the rest of the world by billions of people. To put this surge into context, in 2004 Turkish TV exports were worth $10,000. That figure grew to $350 million by 2017. The aim is to hit the eye-watering sum of $2 billion by 2023 with TV dramas expected to make up over half that total (Looch, 2019).

Human movements and demographic changes in the city have progressed in parallel with goods, services and capital flows. These trends have led to significant changes in the spatial organization of the city.

The traditional business centre of the city (Historic Peninsula-Beyoğlu) first expanded northward (Şişli-Levent-Maslak); later, a financial centre was established on the Anatolian side of Kadıköy-Ataşehir-Kozyatağı axis. As a result of the expansion of the traditional centre and the formation of new centres, the number of skyscrapers has started to increase rapidly in the central areas of the city and sub-centre areas. On one hand, newly constructed skyscrapers have an impact that strengthens Istanbul's global urban image. On the other hand, they have been criticized for their negative impact on the city's historical skyline, as well as the traffic load it brings to the city and deepening the socio-spatial differentiation in the city. The rapid increase in the number of skyscrapers brought about the Dubaization / Manhattanization discussions.

Global brand chains spread from the centre to the peripheral areas thanks to the rapidly increasing number of shopping malls in the city. The number of shopping centres in the city, which was 25 in 2004, reached 80 in 2014. Şişli, Beylikdüzü and Esenyurt on the European side, Ataşehir and Ümraniye on the Anatolian side were the most preferred districts of the new shopping malls (Çakır Zeytinoğlu et al., 2016).

The fact that this trend and increasing land values in the city started to put pressure on the industrial areas within the city resulted in the decentralization of the industry in the east-west direction (Kocaeli-Bursa-Tekirdağ). As an important industrial axis of the city, Basin Ekspress Road today is mostly used with services such as shopping centres, hotels, offices and residences.

The symbols of change and transformation in the integration process of Istanbul to the global world appear as “mega projects”. Yavuz Sultan Selim Bridge (the 3rd Bosporus Bridge), which was completed in 2016, the Istanbul Airport, which was put into service in 2018, and Kanal Istanbul (the waterway project) planned to be constructed as an alternative to the Bosporus are the three most important and most debated mega projects in this period. All three projects were supported by advocates of economic integration with the global world and criticized for increasing the pressure on the city's natural resources and shifting the direction of development towards forest areas in the north. These projects have become important platforms in which socio-political tensions in the city have come to light (Baş et al., 2018).

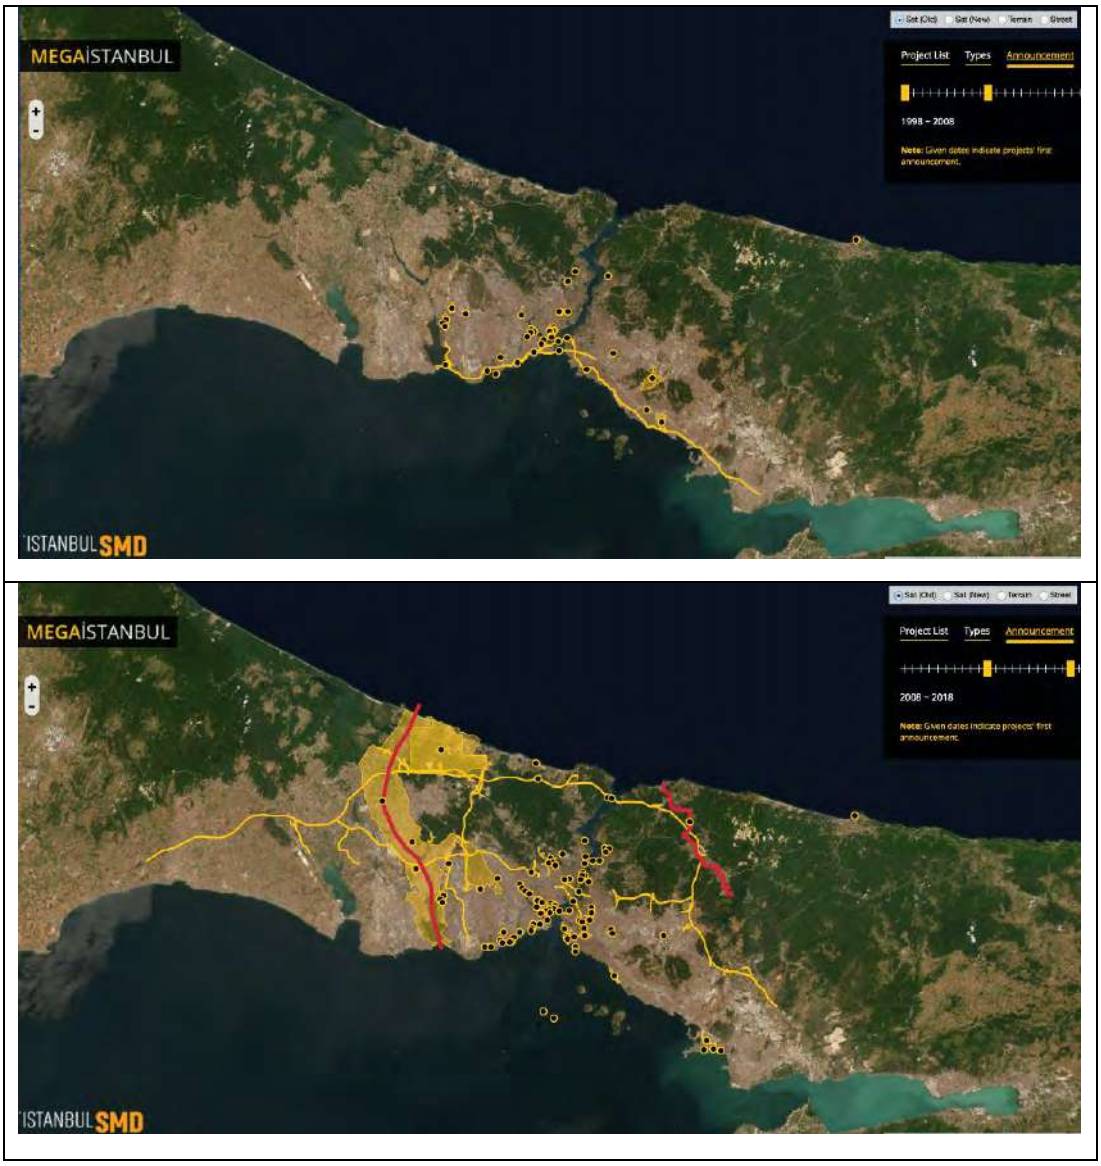

Figure 3: Planned / Announced mega projects in Istanbul between 1998-2008 (above) and 2008-2018 (below) (IstanbulSMD, 2019).

The mega projects announced to the public between 1998 and 2018 are shown on the map of Istanbul (Figure 3). In the first decade, mega projects envisaged both in the centre of the city and on the east-west axis. However, the number of these projects has boomed as the integration process into the global world has accelerated; and the location of these projects, both growing in number and area, shows that the direction of development of the city has also changed.

It is also possible to follow the rapid development and change of the city through the land use data of CORINE (Coordination of Information on the Environment) shared by the Ministry of Agriculture and Forestry. It can be read from the 2018 data that mobility started with the new airport and highways / bridges in the north of the city (Figure 4).

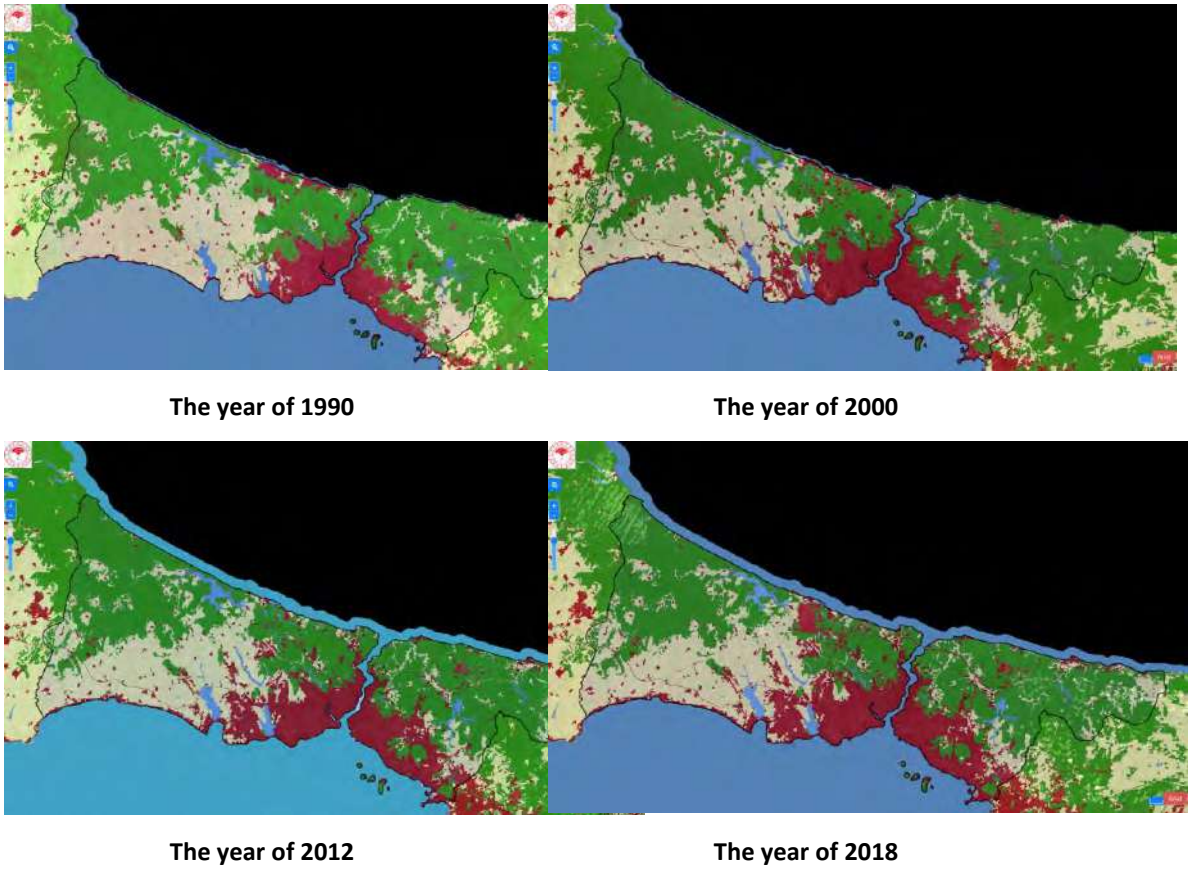

Figure 4: The changing land use of Istanbul between 1990 and 2008 (CORINE Land Use Data) (TOB, 2019).

To sum up, Istanbul's integration with the global world has led to socio-spatial transformations in the central areas of the city, and to the expansion of the city in the east-west and north directions and forcing natural thresholds.

3.3. Flow of cultures and images: socio-cultural transition

In addition to the flows of people, goods, capital and services, it is seen that Istanbul is on its way to becoming the centre of the cultural industry and expanding its area of influence. Cultural interaction has occurred in two ways. First, a mutual cultural exchange has become possible through numerous cultural events, exhibitions, festivals and congresses; and second, thanks to the Turkish TV series, a cultural hinterland has been formed in a wide geography especially in the Balkans, the Middle East and Latin America.

Turkish TV series have created a cultural hinterland in the geographies where they are exported, and the interest and curiosity of the audience watching the series has increased. According to Ozcan and Anaz, Turkish TV series and films have positively impacted Turkey's visibility abroad (Ozcan and Anaz, 2016). Moreover, there are some touristic organizations organized only to visit the sets (Melamed, 2019; Gürmen, 2016; Sobecki, 2010).

Turkish TV series are also very effective in the Middle East and the Asian countries. For instance, A study conducted in Pakistan revealed that exposure to foreign culture by watching its series and programs, had a profound impact on Pakistani youth, thus affecting cultural identity, norms and values. (Raza, 2015).

Magnificent Century (Muhteşem Yüzyıl), an epic historical drama launched in 2011, that found audiences beyond Latin America and the Middle East. At its peak the series, which tells the story of 16th century Ottoman sultans, was broadcast in over 40 countries with more than 200 million viewers worldwide (Looch, 2019). Ertugrul Resurrection (Diriliş Ertuğrul) is one of the most popular Turkish TV series all over the world. It has shown in more than 50 countries as well as in Netflix.

The city was selected as the European Capital of Culture in 2010. According to the International Congress and Convention Association (ICCA), Istanbul is one of the most important destinations that host international congresses. Although Istanbul, one of the top 10 cities hosting the most international community in the world in 2008-2012, declined by ten places as a result of the terrorist incidents and coup attempt in 2013-2017 period, the city has still an important attraction power (Table 3).

4. Conclusion

Istanbul is a city with high recognition in the world. Today, Istanbul has a certain positive brand value that has naturally emerged in the fields of geography, finance, services, trade and tourism. The city has some important advantages and disadvantages compared with other global cities. The main advantages of the city are its location/accessibility, historical background, cultural heritage, transport infrastructure, young population, cost of living, and healthcare services. The main disadvantages of the city are environmental conditions, lack of open spaces and green areas, and insufficient R&D studies and patents. In addition, the most obvious realities of the city, overcrowded construction, crowded population and traffic congestion create a very strong negative image and perception among the people who look at the city from outside and make the city's many positive features and beauty unnoticeable.

> *Istanbul after the year of 2000 is a city whose global integration tendencies are getting stronger but consequently its internal tensions increase* (Arlı, 2016b).

These internal tensions are leading to the dichotomy of global integration/local segregation. Human mobility in Istanbul is a good example of these tensions, and it shows social relocation and displacements within the city. While domestic immigrations to the city have always been higher than emigration from the city until 2015, there has been a reverse trend since 2015. In the last three years, the city's residents tend to migrate to other metropolises and cities in the country. However the city remains a point of attraction for students, international immigrants, tourists, sojourners and refugees.

The presence of international immigrants means for Istanbul to hold global labour power. The fact that international immigrants prefer Istanbul is a positive contribution to the global attractiveness of the city. It is useful to consider in detail how global labour power can be exploited in the upper and lower levels of Istanbul. While establishing a population policy for Istanbul, it should be taken into consideration that the city would always be a point of attraction for international immigrants. In this context, regular scientific researches/measurements on the qualifications and capabilities of permanent/temporary refugees should be carried out and the social integration policies pursued in the city should be sustained. Following such an approach on international migrants will bring about improvement in the socio-economic structure of the city.

As pointed in the previous chapters, Istanbul's efforts to be integrated with the global world have also triggered socio-spatial transformations in the central areas of the city, and to the expansion of the city in the east-west and north directions towards natural thresholds. The city needs to empower its position among other global cities without destroying its social fabric and transcending its natural thresholds.

Case Study / Project

Settlement Development Analysis of Malang City peri Urban Area

and Its Conformity with the Regional Spatial Plan

Mirza PERMANA

Abstract

The development of Malang City has consequently led to an upturn of new residential, trade and industrial centers in the suburbs area. Settlements rise massively in a number of suburban areas due to attractions of economic centers and accessibility easiness. This study, locating in Malang City. The research aims are: (1) to determine the characteristics of settlements in peri-urban area, (2) to analyze conformity to the regional spatial plan (RTRW), and (3) to establish development direction. Descriptive and comparative analysis were used through both qualitative and quantitative approaches. Settlement intensiveness ranges from low to moderate. The densest is in Pakishaji District (57 percent) while the lowest one is in Tumpang District (17 percent).

The result of visual analysis on land use map in 2018 shows that 70 percent of settlements close to city grew following the main road network in the pattern of ribbon development. The biggest increase of settlement in peri-urban region indicated by the highest number of population, is seen in Singosari District. The farther from the city, settlement spread formed leapfrog pattern by 30 percent. During period of 2008-2018, built-up land increase by 12 percent while agricultural land in a declining trend. Significant changes occurred in Singosari, Pakishaji, and Karangploso Districts, especially in 2008-2013. Based on overlay between suitability map of residential areas and current spatial plan of the city (RTRW) of 2010-2030, 208 hectares or 0.5 percent of settlements is not in accordance with the RTRW. Such settlement areas were mostly built on the land designated for agriculture either wetland or dryland. Directions for the development of settlement in peri urban areas following the regional spatial plan without conversion of agricultural land.

Research Paper

Analysis on Integration Path of Urban and Rural Industries Based on Economic Data Model

A Case Study of Strategy Planning of Taiyuan Rural Revitalization

Huimin QI, Shanghai Tongji Urban Planning & Design Institute Co., LTD. ; China

Abstract

In the background of ongoing urbanization in China and prominent "dualistic" contradiction between urban and rural areas, rural revitalization is extremely urgent. Currently, common problems concerning industry, ecology and humanities exist in rural areas. This paper attempts to figure out the causes for differences in industrial development in rural areas on the basis of macro data analysis and industrial spatial distribution.

Given the lack of quantitative analysis of the relationship between urban and rural development and industrial structure, this paper adopts SPSS statistical software to conduct regression analysis on the statistical data of Taiyuan City in the past ten years. Based on the relationship between industrial proportion and urban-rural income ratio, this paper proposes how the adjustment of urban industrial structure promotes the industrial development in surrounding rural areas and the narrowing of urban-rural income gap.

From the perspective of rural industry undertaking or complementation with urban industry, this paper then puts forward the idea of undertaking the transfer industry within the scope of ensuring the aggregation effect of the city center and the carrying capacity of the ecological environment, proposing an industrial development path from agriculture to processing industry and then to culture, tourism and recreation industry for the villages in Taiyuan.

Keywords

Regression analysis, Industrial structure, Urban-rural integration, Taiyuan path

1. Introduction

1.1. Urban-rural dual system

Under the past 40 years of reform and opening up policy, China's industry has developed rapidly. The population gathering brought about by the spatial clustering of the industry has caused the rapid expansion of the city. Rapid urbanization has led to a prominent problem of urban-rural dual structure. Since ancient times, urban and rural areas have been born out of a relationship of natural conditions and economic structure. A series of urban-rural dual policies, such as industrial priority development in the planned economy of New China, have

led to a strict separation of urban and rural social and economic structures (Yifu Lin, 2002), resulting in severe restrictions on the flow of production factors between urban and rural areas. It was not until the implementation of the reform and opening up policy that the urban-rural dual structure was loosened. Engels said: "All urban problems are caused by poverty in the countryside." Therefore, the common development of urban and rural areas is the mission of an era. The development of urban and rural integration is inseparable from the economic development driven by industry. The development of industry cannot be separated from the support of construction space.

1.2. Urbanization

Since World War II, Western scholars have begun a lot of research on urbanization, and international scholars have never stopped discussing urban-rural relations. Since the 1980s, with the acceleration of the globalization process, the theory of coordinated urban and rural development has become the main direction of discussion. The proliferation of large cities from the top down, the rural industrialization from the bottom up and foreign direct investment drive the development of rural to semi-urban. There is a lack of management in the semi-urbanized areas in rural areas (Ruoxiang Jia et al., 2002; Shenghe Liu et al., 2004). The global capital allocation, market, talents, technology recombination and allocation caused by economic globalization have brought in a large influx of foreign capital. With the rapid development of processing and manufacturing, a large number of rural semi-urban areas have been created. With the acceleration of China's urbanization process, China's urbanization rate has reached 60% by 2017. Industrialization since the 1980s has accelerated the disappearance of rural areas, and a large number of small and medium-sized cities and small towns have developed. The growth of GDP has a significant correlation with urbanization, and the development of the economy has driven the development of urbanization. In the early days of reform and opening up, the development of industrialization accelerated urbanization and brought about a significant improvement in the national economy. In the 20th century, China's economic development entered a period of transition. The agglomeration of industry led to the difference of space economy, accompanied by a large number of labor pools, which led to the typical urban dual structure problem. What followed was the central government's proposal to build a series of financial support policies, such as characteristic small towns, urban-rural integration, and beautiful villages, in an attempt to narrow the gap between urban and rural areas through urban reincarnation. In 2003, Professor Xie elaborated on a series of urban problems brought about by the development of urbanization, and proposed the road of new urbanization 4 (Zhiqiang Xie, 2003), which triggered the thinking of urban scholars, sociologists and politicians. . Scholars in economics believe that cities should be aggregated and cannot reverse the laws of industrial, labor, capital and other factors. With the development of industrialization, China began a large-scale land development process. Since the 1990s, large-scale development zones, industrial parks, and high-tech parks have been built. The following picture shows the urban and rural development trends of Chinese cities from 2004 to 2017. The data of Figure 1 as bellow was missing urban area data in 2004-2007, and noted that the urban area is the area of the city proper before 2006

(Source from National Bureau of Statistic of China).

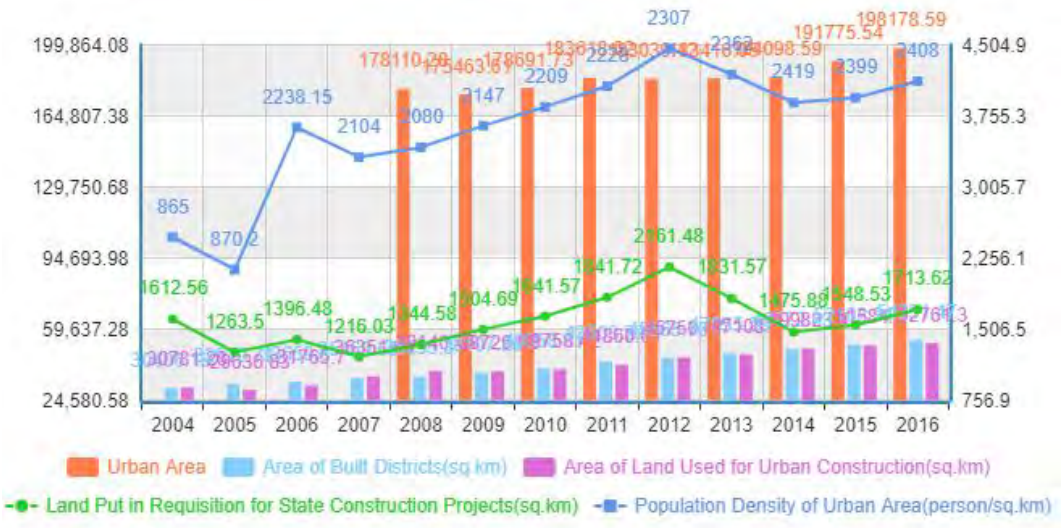

Figure 1 China's urban expansion trend chart

It can be seen from the table that the speed of urban construction area expansion in China has been positively correlated with the rate of population agglomeration, and there is no significant increase in urban population density. A series of urban and rural development issues that followed have entered the vision of the planning industry, academic circles and political circles. The expansion of industrial land has led to the spread of construction land, and the economic development and urbanization brought about by industrialization have allowed China to develop rapidly. Under the background of the gradual disappearance of the demographic dividend, Zhao Min and other scholars proposed that the development of rural space should adhere to the "smart contraction" view. 5 Zhang Li discussed the deterioration of the demographic dividend and the qualitative transformation of urbanization. The land expansion brought about by rapid urbanization has led to the local government's high dependence on land finance. How should China's urbanization and construction land development develop in the context of the current transformation of development mode? Does industrial development, which is a pillar of the national economy, play a major role in promoting urbanization? What is the strategic guiding significance of the relationship between urbanization and industrial development and the development of land use for its rural development? How to develop the industrial economy of Taiyuan's countryside in the context of industrial transformation and development?

2. Methodology

2.1. Objective

This paper attempts to use the econometric method to conduct regression analysis on historical statistical data. The research goal is to use quantitative methods to find out the relevant factors affecting urban agglomeration in urban and rural development, and to use satellite remote sensing images of land construction and expansion to Taiyuan. An objective analysis of land use in the past 15 years. In the 40 years of reform and opening up, China's urbanization rate has doubled (Figure 2), which is nearly double the time of the UK's urbanization rate (Figure 3).

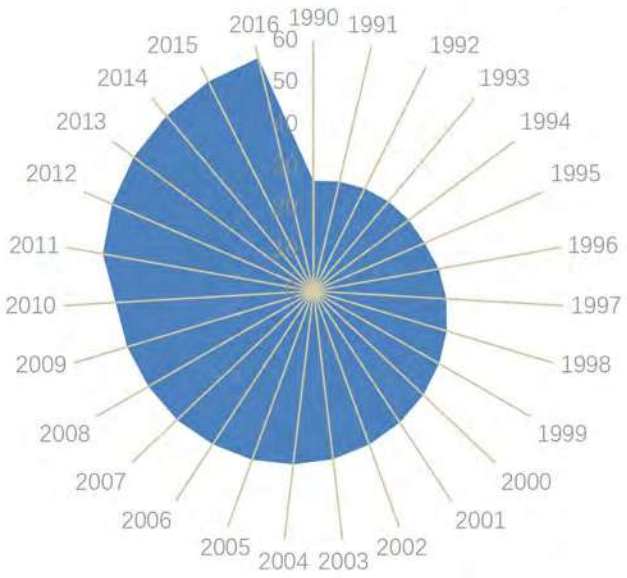

Figure 2 Mainland-China's average urbanization rate

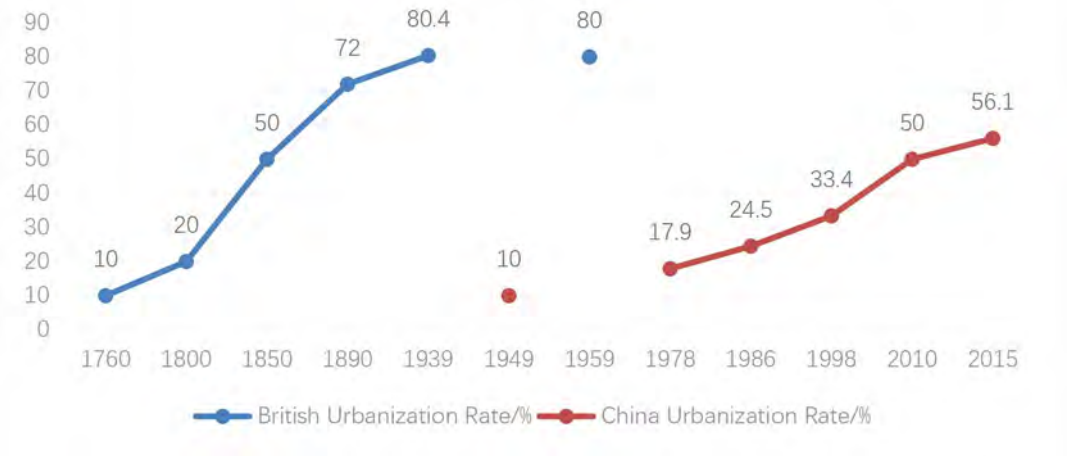

Figure 3 Time-varying chart of urbanization rate between British and China

In economic geography, the spatial aggregation index system was extensively studied by Western scholars in the 1970s. So far, no ideal spatial aggregation index system has been established (Masahisa Fujit et al., 2005; Pierre-Pilippe Combes et al.,2008). According to years of data collection and observational research, the factors that cause population aggregation to form spatial imbalance development are labor productivity, transportation costs, and trade costs. Based on the degree of data acquisition, this paper establishes an incomplete model of urbanization rate research model, showing in Figure 4 as bellow.

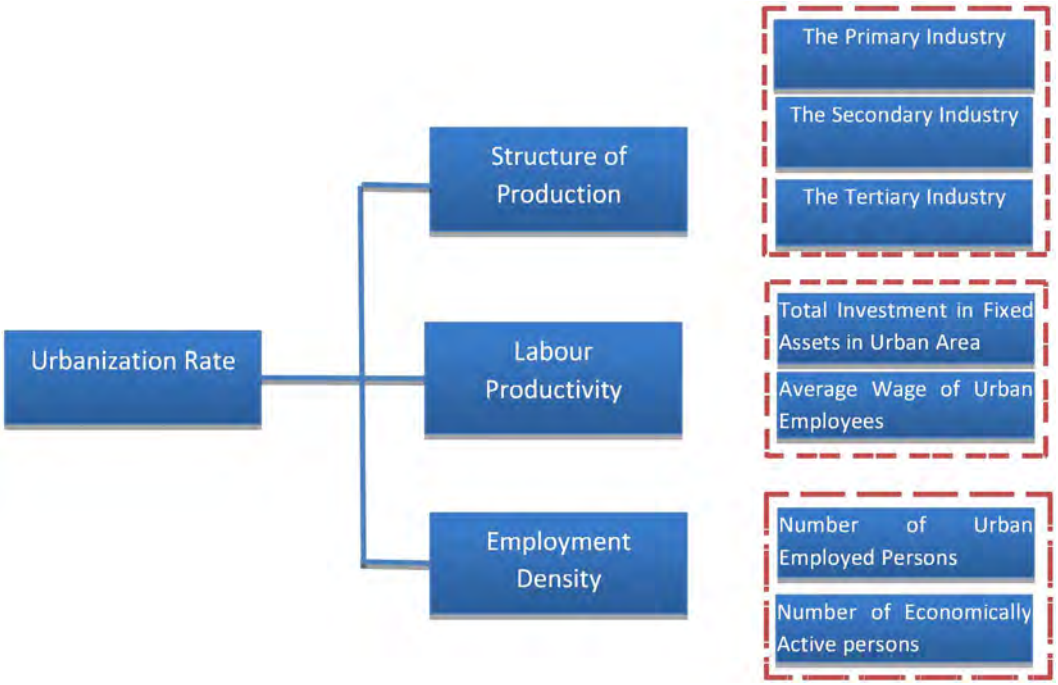

Figure 4 Research framework model (the author self-painting)

2.2. Model hypothesis

The SPSS software was used to analyze the urbanization rate and independent variables of the dependent variables. Before doing the regression analysis, the relationship between the independent variable and the dependent variable is depicted in a scatter plot (Fig 5) to find the relationship between each dependents. According to the observation analysis, the general linear regression model is established as follows:

$y = \alpha_i + \Sigma\beta_i x_i + \varepsilon$ (Equation 1)

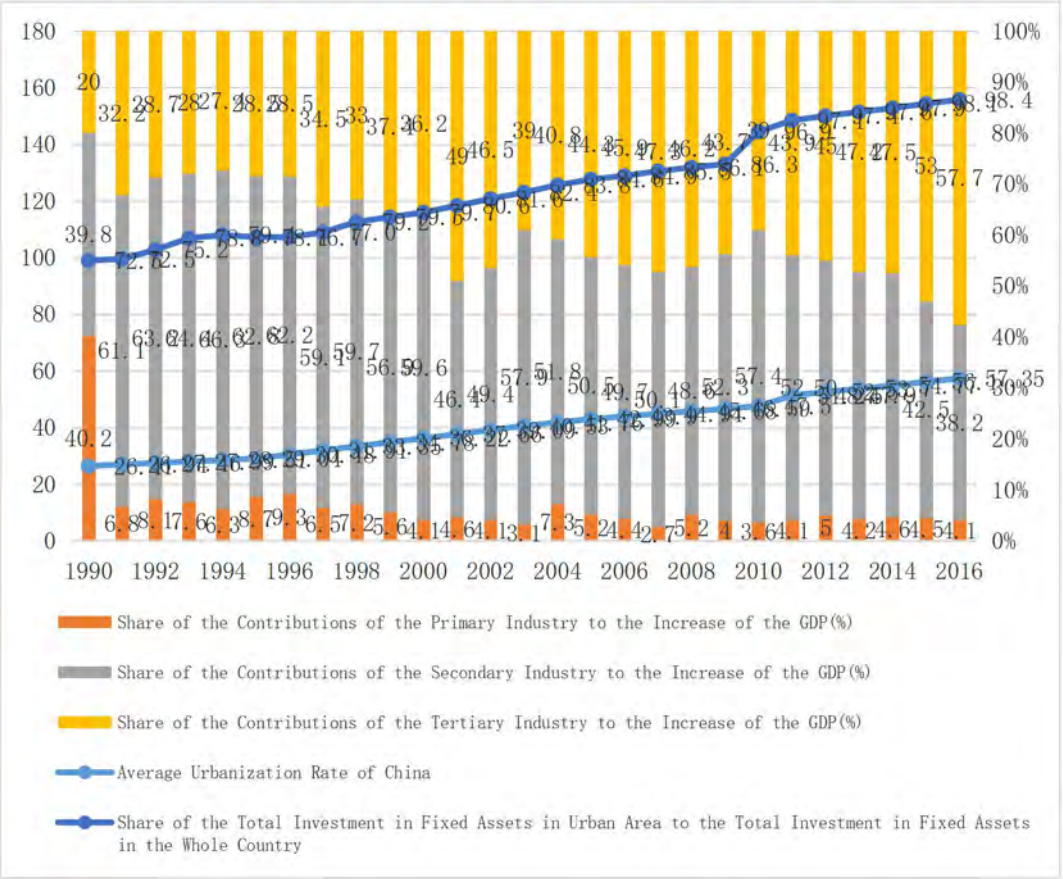

Figure 5 Urbanization rate related variable icon

2.3. Data selection and processing

According to the research framework established in the research method, the whole country is studied as the whole geospatial target, and each city is where the space gathers. Therefore, the data indicators corresponding to the elements in the corresponding research framework are searched, and the data model is established by SPSS software for regression analysis (Xiaojun Huang et al., 2008; Chenggu Li et al., 2004). Looking for statistics from 1990 to 2016 from the China City Statistical Yearbook, the year was chosen in 1990 because the implementation of the 1989 reform and opening up policy promoted the development of the market economy. By the year 2016, it was considered the international trade elements in the latest year data available, and also 2016 is the year in which US sanctions against China's international trade began. The data indicators were selected: the national average urbanization rate, the contribution of the primary industry to GDP, the contribution of the secondary industry to GDP, the contribution of the tertiary industry to GDP, the gross domestic product (nominal GDP), and the investment in fixed assets of the whole society (100 million yuan), urban fixed assets investment (100 million yuan), employed persons (10,000 people), primary industry employed persons (10,000 people), secondary industry employed persons (10,000 people), tertiary industry employed persons (10,000 people), Fourteen data indicators for urban employed persons (10,000 people), rural employed persons (10,000 people), and economically active population (10,000 people).

Considering the magnitude of the data and the homogeneity of the samples, I processed some of the data. The specific treatment method is: calculating the ratio of the contribution of the primary industry to GDP, the contribution ratio of the secondary industry to GDP, the contribution ratio of the tertiary industry to GDP, the ratio of urban fixed assets investment to the fixed investment of the whole society, and the first production. The ratio of employed persons, the ratio of employed persons in the secondary industry, the ratio of employed persons in the tertiary industry, the ratio of employed persons in urban areas, the ratio of employed persons in rural areas, and the proportion of employed persons in economically active population. There are 10 independent variables entering the regression equation in the model.

3. Model analysis

3.1. Data out-put

General linear regression was performed using SPSS, and a stepwise regression method was used to establish the model. The modeling path given by the stepwise regression modeling method is shown in Figure 6. The coefficient is as shown in the table column “B”: the proportion of urban employment is a variable that significantly affects the urbanization rate, followed by the tertiary industry to urbanization. The rate plays a small positive effect. In the second model, the independent variable of the tertiary industry's GDP is tested by the reliability coefficient of 0.01, and the three coefficients of the model are all tested by the reliability coefficient of 0.05. However, in Model 3, which is the most stable one, the proportion of second-employed workers is obviously a negative correlation to the urbanization rate. Bring the regression coefficient into Equation 1, and get the general linear regression equation: $Y=3.045+113.305X_1+0.12X_2-39.071X_3+\varepsilon$ (Equation 2), where X_1 is the independent variable urban employment ratio, X_2 is the independent variable third. The contribution rate of industry to GDP, X_3 is the proportion of employed persons in the secondary industry of independent variables, ε is the error term, and Y is the urbanization rate of the dependent variable.

Figure 8 Model summary table

From the bellowing figure 7, the stability of the model is shown. The residual coefficient of Model 3 is the smallest, the stability is gradually increased, and the P values are all less than 0.01, so the model is statistically significant.

The autocorrelation analysis of the model is carried out, and the residual histogram and scatter plot are drawn. The distribution of residuals does not show obvious regularity, indicating that there is no autocorrelation in the data of this problem.

3.2. Model analysis

From the regression analysis of statistical data from the year 1990 to 2016, it is concluded that increasing the proportion of urban employed population is a positive factor in the process of urbanization. The proportion of employed persons in the secondary industry is negatively related to urbanization. The industry has moved beyond urban areas to non-urban areas. Therefore, in today's urban-rural integration development, how to promote the development of rural areas is not to increase the number of jobs in the countryside, but to take advantage of the advantages of the countryside to promote the development of rural characteristics. There should be a concentrated central city and regional economy to promote the common development of surrounding towns and villages, stop the rough development of the construction of land for large-scale demolition and construction, and

turn to intensive and efficient development. The accumulation of urban population and industry is an inevitable trend of economic development.

4. Case study of Taiyuan

4.1. Analysis of industry and urbanization

Taiyuan belongs to the capital city of central China. In recent years, the economic aggregate has increased steadily. In 2017, the city's GDP reached 338.218 billion yuan, accounting for 22.6% of the province's GDP, a year-on-year increase of 14.43%, and a three-product structure ratio of 1.2:37.6:61.8 (Source from the city Statistical bulletin). However, due to the geographical location and development conditions, the development of districts and counties is uneven. Compared with the six districts of Taiyuan City, Gujiao, Loufan, Qingxu and Yangqu are the suburbs of Taiyuan City. The rural characteristics are obvious. In 2017, the total GDP of the three counties and one city was only 23.553 billion yuan, accounting for only Taiyuan City. The total economic output is 7%, of which Loufan County has a minimum of 2.11 billion yuan.

As of 2017, the city's permanent population in the city of Taiyuan reached 4.38 million, of which the rural population was 670,000, the overall urbanization rate has reached 84.7%, ranking third in the provincial capital cities (data from local cities' statistics bulletin). However, the level of urbanization development in districts and counties is obviously different. The average level of urbanization in Liucheng District is above 90%, and the highest is 97.57% in Wanbai District. The average level of urbanization in the three counties and one city is only 45%. The lowest is Qing. Xu County 33.55%.

According to the China Urbanization Quality Report (2013) jointly issued by the Chinese Academy of Social Sciences and the China Economic Weekly, the total urbanization quality of Taiyuan City is 0.52, ranking 80th in the country and 4th in the six central provinces. The disposable income of GDP and urban residents is second to last and the first in the six provincial capitals of the central region. As a heavy industrial city, Taiyuan has long been a high-energy, high-pollution extensive industry as its economic development path, and its resource environment has been severely challenged (Yongzhen Duan, 2017). The master plan of the city of the year 2004, showing that Taiyuan's is going to transform into a high-tech and technology-intensive industrial city.

4.2. Analysis of land use

According to recent pictures of Taiyuan city remote sensing satellites, land use data is extracted. The land use in 1999, 2004 and 2011 was classified and the land use type was analyzed by satellite remote sensing images as the year of 1999, 2004 and 2011.

By collecting and sorting the land area of different land types according to the year, the table 1: statistical classification table of land use is obtained. The data from 1999 and 2004 were from the land use analysis and identification of satellite remote sensing images. It can be seen from the analysis that after years of land use control and industrial structure adjustment, the area of industrial land and the land area of the mining industry have been effectively controlled, and the scope of living and residential land is constantly expanding.

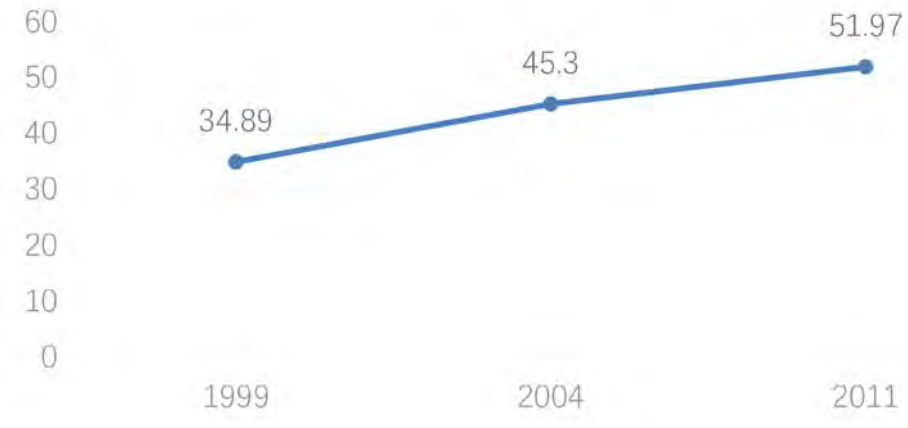

Figure 9 Industrial land share as the year 1999, 2004, 2011

Indicators	Year of 1999 (Remote sensing images) KM²	Year of 2004 (Remote sensing images) KM²	Year of 2011 (Remote sensing images) KM²
Industrial Area	34.87	45.3	51.97
Living Area	634.38	783.85	838.85
Mining sites	38.07	33.14	33.34
Total area(industrial land, residential land, etc..)	1428.09	1928.40	3527.66

Table 1 Statistics of land use table

After the remote sensing image is processed by the GIS software, the data and visualization of the classified land are analyzed. In this article, I use yellow plots as living and habitat area, brown for industrial use, and blue for mining. From this point of view of time evolution, mining land is gradually decreasing, and distributed in the periphery of the mining area, and after the adjustment of industrial structure, part of the mining land has been converted into industrial land. Through the ecological restoration work in mining subsidence areas in recent decades, the ecology of the mining area has been greatly restored.

From the perspective of the layout of urban industrial land, it is mainly distributed along the Weihe River and the main traffic trunks. The distribution of living and residential land is relatively scattered. The urban area is mainly concentrated in the plain area of the central part of the Weihe River, and the land is continuously spreading to the surrounding areas, and the rural residential areas are scattered. Among them, the land surrounding the mining area has been converted from mining land to industrial land, and a large amount of residential land is distributed around the industrial land. With the transformation of heavy industry and the adjustment of industrial structure, combined with the increase in the area of urban land development and construction, the economic benefits of urban land are at the

bottom. At present, the per capita land area of Taiyuan City is higher than that of other big cities in China. The main reason is that the skeleton is large, the layout is scattered, and the national defense industry is more. The industrial, warehouse and protective land accounts for 50% of the total land area, while the main land in urban land. Part of the living and residential land is only 30%.

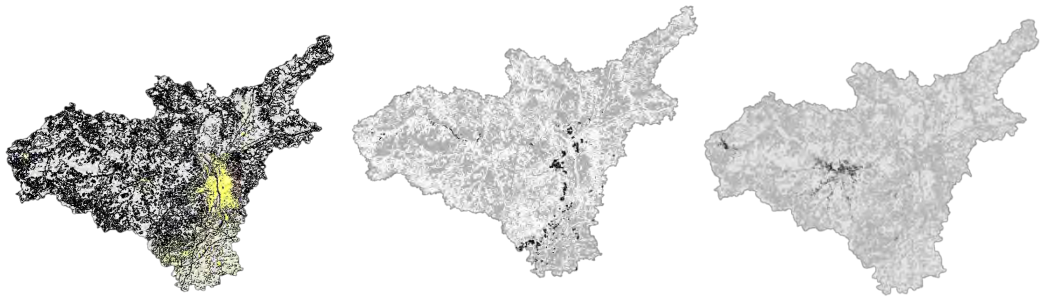

Figure 10 Distribution map of residential land, industrial land and mining land in Taiyuan City in 1999

Figure 11 Distribution map of residential land, industrial land and mining land in Taiyuan City in 2004

Figure 12 Distribution map of residential land, industrial land and mining land in Taiyuan City in 2011

4.3. Summary

The total construction land of Taiyuan City has an average annual growth rate of 587.6 hectares, with a small average annual growth rate, which is equivalent to that of Shijiazhuang, far smaller than cities such as Hohhot, Zhengzhou, Xi'an and Hangzhou.

The demand for construction land in Taiyuan City is spatially different, among which Xiaodian District and Qingxu County are growing rapidly. Among all types of construction land, the growth of independent industrial and mining land is the fastest, the growth of urban construction land is slow, and the land for rural settlements is not decreasing.

From 1998 to 2006, the total construction land in Taiyuan's central urban area showed a growing trend, with an average annual growth rate of 11 square kilometers, and the growth rate increased year by year. From 2001 to 2006, the annual construction land in Taiyuan City increased by 3.92 square kilometers, far less than the annual growth of construction land in the central city. It shows that the future growth of urban construction land in Taiyuan City is mainly due to the construction land demand in the central city.

Taiyuan is the city that in the stage of centralized urbanization now. And the central city tends to be excessively intensive. The marginal area is extensively used. The urban expands strictly big with low efficient land use. In the future, through the transformation of the old city and the increase of investment in the new district, the main urban area will be promoted from excessive intensive to rational and intensive development, while promoting the peripheral area from extensive to intensive use.

Based on the land price perspective, the evaluation of the current residential, industrial and commercial land will promote the central position of the urban area. As the same time, it should demonstrate the land rent benefit of the urban land to fully exploit and realize the economic value of the land, in order to optimize the spatial structure of the city, and revitalize the old city. About 321 hectares of residential land and 267 hectares of industrial land do not meet the location and land rent conditions, and propose adjustments.

5. Research enlightenment

5.1. Economy of Industrial

Development ideas and objectives adhere to the general principle of “taking the town with the township”, guide the development of the “small town group”, and build a “central city-small town group-township-village” linkage development situation to realize the “City Belt Township and Township Belt”. The organic linkage development system of villages and villages (Big villages) with villages (Small villages) will complement the short-term economic development of districts and counties, guide the development direction of towns and villages. Sorting out and improving the urban and rural spatial development strategy, and strengthen the equalization of urban and rural service facilities. Promote rural revitalization and development by region, sub-type and echelon. The village should retain its own characteristics, such as the distinctive culture, the social structure of “acquaintances”, the unique way of life, and the characteristic buildings and production tools left over from history, to develop the rural cultural tourism industry. Protect the ecology, support the scale of agriculture and industrial cluster development.

5.2. Land use efficiency

The urban growth boundary should be strictly controlled to improve the economic benefits of urban production space and ensure the aggregation effect of large and medium-sized cities. Let the tertiary industry with high efficiency in land production such as innovation and technology and productive services return to the city center to lead the city's new round of economic development. Through rural revitalization, we will promote a more rational distribution of production factors in urban and rural areas and large areas, and improve the efficiency of the use of economic resources. The government-led land development path should be transformed to allow more market economies to participate in rural revitalization. Considering that not all rural areas can participate in the division of labor in the market

economy, rural revitalization should have a focus. In China, where resources are scarce, what is more needed is to adopt a smart growth strategy in areas with outstanding development advantages.

Taiyuan City has entered the mature period stage of urbanization. Now the land use of the central urban area tends to be excessively intensive, the marginal area uses extensive land, and the city expands rapidly. In the future, through the transformation of the old city and the increase of investment in the new district, the main urban area will be promoted from excessive intensive to rational and intensive development, while promoting the peripheral area from extensive to intensive use.

5.3. Labor

From the perspective of urbanization rate, the urbanization rate under the resident population statistics is much higher than the urbanization rate under the household registration population. To a certain extent, the household registration system has hindered the free flow of labor across regions. Due to the regional differences in rents and the continuous migration of industries to the periphery of the city, the labor force from rural to urban areas mainly gathers outside the city center to make a living. With the continuous development and changes of the market and technology, the existing labor force needs to constantly update the knowledge structure to adapt to changes in market demand and to have a place to live in the city. Therefore, the development of science, technology, transportation and the rising cost of urban living are also factors that limit the increase in urbanization rate.

5.4. Future research

In the middle of this paper, the study of urbanization rate is analyzed from the perspective of national urban data. While the provincial-level super-large city as the growth pole of regional development, Gucheng Li and etc. have carried out the economic support model for the regional economy of China's urbanization. The analysis made a qualitative analysis from the aspects of urbanization rate, built-up area, urban economic density and regional economy, and found out the data represented by each development factor. In the follow-up study, the provincial cities will be separated from the megacities such as Beijing, Shanghai, Shenzhen and Guangzhou according to the type of international cities, and they will be studied as independent urbanization processes in large and medium-sized inland cities. The agglomeration of industry leads to the difference of space economy, accompanied by a large number of labor gathering, which leads to the typical urban dual structure problem.

Research Paper

Deciding Where to Live in The Suburb:

Linking Utility-Maximization and Residential Mobility in Polycentric Urban Region Context

Abstract

In a polycentric urban structure, the commuting pattern which was traditionally directed from the suburban to CBD, is becoming more complex with increasing reverse- and cross-commuting activities. This paper is aimed to provide empirical evidence which validating the importance of utility-maximizing parameters, derived from the monocentric model, in the context of post-suburbanized polycentric urban region. It questioning to which extent of different residential mobility between municipalities could be linked to the variation of such parameters. Focusing on the frontier areas of Jakarta Metropolitan Area (JMA), Indonesia, each municipality within the region is treated as a Decision-Making Unit which intend to maximizing co-location between residential and employment uses. Using the data from the 2017 National Socio-Economic Survey (SUSENAS), the analysis was simply taken by comparing the aggregative-mean of income, housing-cost and transportation cost data from each municipal in JMAs periphery. The Data Envelope Analysis (DEA) was used for measure how these utility-maximizing parameters related with inter-suburban migration flows. The results show that housing cost is the only utility which still has significant impact in polycentric setting. Moreover, the area with lowest utility value tends to be the most efficient in attracting in-migrant. It implies that residential mobility within suburban areas does not motivated by lower housing or transportation cost, nor to get near to major employment location. Thus, workers heterogeneity and behavioral aspect may have played bigger role in residential mobility of polycentric urban setting.

Keywords

residential mobility, polycentric, suburban, utility-maximization, Data Envelope Analysis

1. Introduction

Globalization has transformed what previously known as suburban into some new different urban forms. The decentralization of employment to suburb has created multiple attractive

sub-centers, where residential and economic activities were mixed together. This process, termed as post-suburbanization, could be found globally with some variation between countries (Phelps and Wu, 2011). In the United States, post-suburbanization mainly involving the decentralization of service, driven by private sectors (Fishman, 1987; Kling, Olin and Poster, 1995). In The Continental European region, the decentralization of service is strongly controlled by government's policy and planning (Bontje, 2004). In China, government control become the most prominent trait, especially on manufacturing sectors de-concentration from its main metropolis (Wu and Phelps, 2008). In Indonesia, economic decentralization was largely occurred in manufacturing sectors, marked by the establishment of several industrial complexes (Hudalah and Firman, 2012). Lack of government control has been used by private sectors to took the control of new independent settlement development outside the urban core to support the industrial complex, creating post-suburbia (Firman and Fahmi, 2017). Post-suburbanization could be used to explain the variety of urban transformation process in global metropolitan periphery. Nevertheless, distinguishing feature between different regional outcome, may laid on how variety economics base and institutional background affected their urban development.

Different post-suburbanization pattern would create differ urban forms and population consequences. In the United States, declining suburban out-commuting has been followed by the decrease on its population (Lucy and Phillips, 1997). Increasing suburban economies has stimulate inter-suburban commuting dominance (Lee, Seo and Webster, 2006). In Continental Europe, post-suburbanization marked by balanced core to suburban migration (Tzaninis and Boterman, 2018) and high non-urban population growth (Champion, 2001). Post-suburbia served as a reverse and cross-commuting destination, while many suburbanites still made traditional commuting to the urban core (Bontje, 2004). In China, the liberalization in housing market has encouraging the middle class to relocate to the periphery, as well as increasing long distance traditional commuting volume (Zhao, Lü and de Roo, 2010; Hu, Sun and Wang, 2018). In Indonesia, peripheral urban transformation was reflected in the massive growth of urban localities in the outskirt, and the rise of reverse-commuting volume (Firman, 2011). The existence of some new sub-center has attracted industrial workers from adjacent municipal area (Permatasari and Hudalah, 2013). Nevertheless, recent evidence in Jakarta Metropolitan Area has shown that the growing metropolitan transportation problems was not only involving reverse-, but also cross-commuting problems (Sadewo and Syabri, 2018). The emergence of post-suburbanization and its polycentric spatial structure has been argued to have double spatial implications: changes in commuting patterns and population mixing.

To some degrees, the commuting pattern is particularly affected by the individual residential strategies (Baccaïni, 1997). The evidence from Catalonia, Spain, has shown that commuting decision influenced the migration decision, vice versa (Romaní, Suriñach and Artiís, 2003). The suburbanization of employment to peripheral areas could bring positive impact to travel distances, if the workers choose to reside close to their job location (Ingram, 1998). The emergence of complex commuting phenomenon is showing that employment suburbanization process, did not followed by workers residential adjustment. The experience from French has indicate that majority suburban jobs has been taken by the workers from another suburbs (Aguiléra, 2005). While the motivation for doing reverse commuting could be explained by amenities-related factors (Aguiléra, Wenglenski and Proulhac, 2009), or socio economic disparity between home and work location (Davidson and Ryerson, 2018), the existence of cross-commuting pattern have not been well comprehended. While several

attempt has linked cross-commuting to household characteristics (Tscharaktschiew and Hirte, 2010), many were still presumed utility-maximization related factors as a major cause of the phenomenon (Berliant and Tabuchi, 2015; Viguié, 2015; Wrede, 2015). Despite of indicating the monocentric model influences, to the best of our knowledge, no empirical evidence of utility maximization influences on the residential mobility within the polycentric urban settings has been provided. Thus, question arises whether utility-maximization factors was also involved in a residential adjustment problem within polycentric urban region?

This study took the case study of Jakarta Metropolitan Area (JMA), a vast growing polycentric urban region in Indonesia. Post-suburbanization has been evident on its eight peripheral municipal areas. Driven by the private sectors, the development in the suburbs has been growing fast in the last several decades. Phelps and Wood (2011) argued that general post-suburbanization process would lead to the formation of a new town, as it was also expected by Hudalah and Firman (2012) in the case of JMA. Yet, recent evidence shows that amplifying polycentric form of JMA peripheral areas is dominated by manufacturing sectors, pushing back retail and service to agglomerate in the urban core (Sadewo, Syabri and Pradono, 2018). To date, the spatial implication of such distinct process to the population mobility have not been comprehend well. Despite the polycentric spatial structure being an important feature in the post-suburbanization process, several evidences from the post-suburbanized region, especially in Asia, still indicate a tendency toward monocentric land value pattern (Tsutsumi, Shimada and Murakami, 2011; Fang, Logan and Pal, 2015; Elmanisa *et al.*, 2016). Therefore, an empirical evidence of the interplay between utility-maximization and residential mobility in the region would not only contribute to the urban economics debate, but also to the post-suburbanization discussion.

2. Literature Review

2.1. *Urban Structure and Residential mobility*

The terms of residential mobility denote as an intra-urban moves within the same region, typically in a relative short distance (Howley, 2009). In a monocentric urban model, residential location selection was determined from one's ability to make a trade-off between land rent and transportation cost. The workers live in a concentric ring of a particular distance from the central business district (CBD) forming distance decay pattern of residential density. Given the assumption of perfect information, zero transaction cost, and zero moving cost, the residential location consumption for every household is frictionless and static. Quigley and Weinberg (1977) argue that in the equilibrium state of monocentric model, no household has an incentive to move, unless there are some changes in the parameter which defines their utility-maximizing behavior: housing prices; income or other demand determinants; and transportation cost. However, when employment is decentralized within the monocentric city, Dubin (1991) suggests that workers should adjust their residential location closer to their job to minimizing commuting cost. However, many evidences show that pure form of monocentric model has been increasingly difficult to find throughout the world. The emergence of multiple urban subcenter creates more complexity on worker's residential location selection.

Theoretical residential selection discussion in a multi-centered urban economics framework were built upon utility-maximization consideration. Using an inter-connected two cities

setting, Suh (1988) derived several scenarios of equilibrium with intercity commuting. The distance between cities, urban size, cost of moving, commuting cost, and the wage difference, were identified as important heterogeneities for generate the intercity commuting. Depending on the location of CBD, in a decentralized employment, wage rate is crucial to determine workers residential location (White, 1988). Wrede (2015) proposed three probabilistic properties of urban equilibrium. First, workers residential segregation of different subcenter is theoretically incomplete, thus, generates substantial excess commuting. Secondly, land rents are generally asymmetric around subcenters. And third, only a fraction of the available land in the outer urban areas were utilized, whereas the land rent is already equal to the land opportunity costs and therefor it is invariant with the distance to the CBD. When a commuting subsidy is given, it could create a welfare enhancing transfers which stimulate the decision of moving or commuting (Borck and Wrede, 2009). A further contribution was made by Viguié (2015), by adding the moving cost and housing-search imperfection variables in the canonical urban economics model, which lead to the coexistence of people working in different employment centers. Shortly, the basic assumption of distance decay housing price gradient from the monocentric model were still confirmed in the multi-nodal version.

The evidence from the several polycentric urban regions have also showing some consistency with the classic urban bid-rent theories. The existence of multi urban center is found to have a significant impact on housing prices both in developed and developing countries context (Heikkila *et al.*, 1989; Wen and Tao, 2015). Yet, each center shows different effect on housing prices, whereas new CBD has a higher impact than the traditional ones. Other studies using the multi-centered framework in Glasgow by Osland and Pryce (2012) found that the relationship between housing price and employment center in is non-monotonic. It is tended to rise initially to some distance from the employment (sub) center, and then gradually decline. With respect to commuting activities, more attractive employment (sub)center seems to played substantial role on affecting housing price gradient. Using a bi-centric examples, the study of Yiu and Tam (2007) find that the a closer location to more frequently traveled employment center have relatively higher housing prices. Huge amount of commuting activities between two similar employment centers would flatten housing price gradient from one to another, vice versa (Yiu, 2008). In San Francisco, the displacement between job-housing location is influenced by such high housing prices around employment centers (Cervero and Wu, 1997). Nevertheless, high waged workers in the outlying centers does not seems to follows the rule, as they choose nearest housing with high price. With respect to transportation cost, the study from 28 metropolitan areas in the US have shown that in many areas, transportation cost is as high or higher as housing, whereas low-income household tend to live in such high transportation cost areas (Haas *et al.*, 2006). Hence, the finding is also confirmed the influence of workers financial capacity which reflected on wage rate in determining the residential location selection.

2.2. *Urban Development and Mobility in Indonesia*

As commonly found in other developing countries, land development has been the subject of one of the main problems for many urbanites. While reviewing urban land development policy in developing countries, Firman (2004a) described some of the recognized problems: including the use of land resources; land regulation and legal frameworks; institutional land management and coordination; land pricing and taxation; inadequate data, information, and infrastructure capacity; and the lack of tenure security. In Jakarta Metropolitan Area, such

land policy perplexity has escalating land-price in the CBD and land banking practice by private sectors in the outskirts (Firman, 2004a, 2004b; Elmanisa *et al.*, 2016; Firman and Fahmi, 2017). Several consequences emerge in the peripheral areas. New town development has created spatial segregation and the rising tension between land owners, developers, and the local government (Firman, 2004b). Indeed, the housing expenditure in Indonesia were found to be strongly with income (Monkkonen, 2013). Thus, the mismatch between housing supply and demand in the peripheral areas has put a bigger challenge to the social segregation problems (Cahyadi and Surtiari, 2016).

Jakarta's future has argued to accommodate the middle class, while decreasing of affordable housing has displaced the marginalized farther on the outer periphery (Kusno, 2012). The influence of the urban structure transformation in JMA was showed by the increase of average number of daily trips and trips length in JMA between 1985 and 2000 (Susilo *et al.*, 2007). In terms of mobility, the segregation is clearly visible from the commuting mode preference. Earlier study from Sugiarto et al (2014) in JMA have shown that there is some tendency where increasing income followed by the rise in their transportation cost. Nevertheless, different from most developed country, up to 56 percent of commuting travel in region is conducted by motorcycle (Sadewo and Syabri, 2018). While the automobile commuters growth have been stagnant between 2000-2010, the use of motorcycle has increased of 27,5 percent (Susantono, Santosa and Budiyono, 2011). Among many reason, recent evidence from the college student travel in Semarang, Indonesia have revealed that motorcycle travel cost only half than public transportation (Nasruddin and Ratnasari, 2014). The rapid use of motorcycle to facilitate transportation cost-maximization seems to have encourage many people to commuting.

3. Data and Method

This study compares utility-maximizing parameters value between those eight suburban municipalities. Recently, Dewita et al (2018) have been highlighted the limited availability of publicly available and accessible data on housing costs, transport costs, and household income. Here, the value was obtained by analyzing the data from the National Socio-Economic Survey (SUSENAS). It is one of the most reliable cost of living survey in Indonesia, and have been used by several studies of housing (Monkkonen, 2013). The SUSENAS was a household expenditure-based survey. Unlike other surveys in Indonesia, it includes housing and transportation expenditure along with income and recent migration experience. The survey held twice a year in March and September, whereas the former intended for municipal level estimation needs, while the later used only for provincial level estimation. The March 2017's SUSENAS consist of 12,694 household in the whole JMA, of which 7,869 household located in the suburb is used for the modelling purpose.

For measuring household income, total monthly household expenditure was used for proxy by assuming of zero saving. The housing cost (HC) was approached using monthly residential expenditure, distinguished by type of tenure: tenured housing (TH) and rented housing (RH). While the rented housing cost shows actual paid price, the tenured housing cost is an owner equivalent rent (OER) for their current house, in which they willing to pay in a competitive market. Similar concept has also been used by US Bureau of Labor Statistics to measure Consumer Price Index. It was more efficient to measure user cost directly, thus preferably both theoretical and empirical (Gillingham, 1983). There had been some concern of several

drawbacks when using OER as a housing-cost proxy. Díaz and Luengo-Prado (2008) have been highlighted the possible bias of OER with the actual cost of housing, mainly comes from tax advantages from housing service. Dewita et al (2018) have also emphasize of the hardship for the respondent to accurately provide the estimation. Yet, they added that it is more suitable in Indonesian context for providing "aggregated and ground-truthed" information.

The differences of residential expenditure between municipal could also depict the moving cost, as it describes the potential amount that would be gained/loss if one's decided to move. While the transportation cost (TC) comprises of total monthly expenditure for the use of private vehicle and public transportation by all household member, including fare, fuel, taxes, maintenance, parking, and other operational cost excluding the purchase. The monetary aspect reported in this paper was obtained on the similar manner with Dewita et al (2018). Finally, the residential mobility refers to the number of households who made a residential move among the suburban areas within the region in the last five years (recent migration). The household who move within the same municipalities, or move from TH to RH vice versa did not covered by this paper.

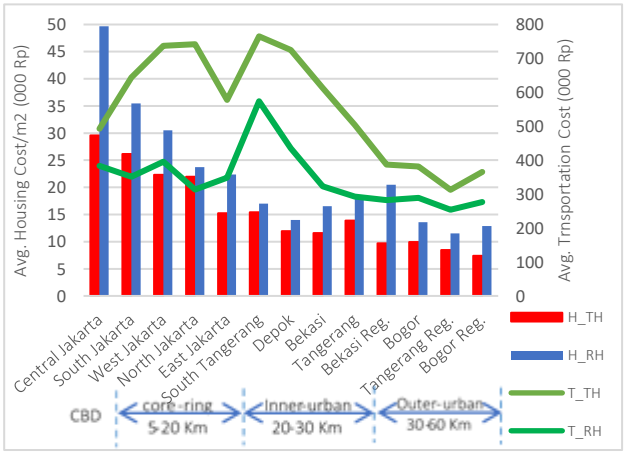
The analysis was simply taken by comparing the aggregative-mean of income, housing cost and transportation cost data from each municipal in JMA. Owing to the use of municipal level areas as an analysis unit, the spatial insight was given by divided the region into four concentric rings, based on their distance to the CBD. The core areas consist of the CBD (0-5 Km) and the core-ring (5-20 Km), while the suburb consist of the inner urban (20-30 Km), and the outer urban areas (30-60 Km). Furthermore, Data Envelope Analysis (DEA) was used for measure how these utility-maximizing parameters relate with in- and out- migration flows on suburban areas. DEA is a non-parametric based method, which originally designed to measuring the relative efficiency between units who performing similar task. It offers more objective ways for ranks the units itself in a best way without have any prior information of data distribution, nor the weight of each variables. In the calculation, each municipal in the JMA peripheral areas was treated as Decision Making Unit (DMU) which maximizing employment for their own citizen. Thus, they should provide a competitive environment to attract residential movement, rather than commuters. Given of particular input and output, DMU with the best combination (score of 1.00) were chosen as the most efficient location in doing the task, relative to other.

4. Findings

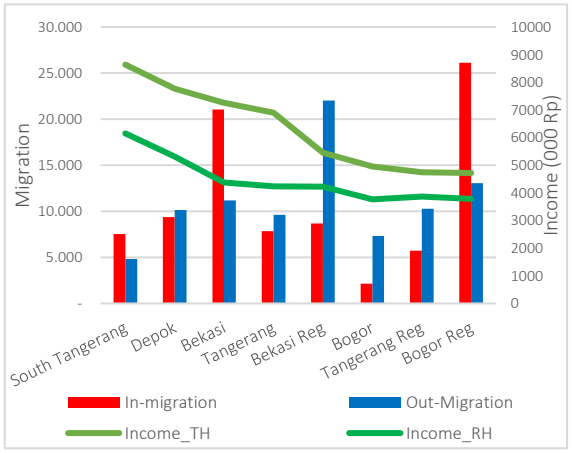
The comparative housing cost (HC) for the whole JMA shows some congruity with distance decay pattern (Figure 1.a). Highest HC was found in Central Jakarta, where the CBD (metropolitan core) located. It was decreased from 12 to 48 percent for tenured housing, and 28 to 55 percent for RH in the core-ring. The HC increased again in the inner urban areas, especially in the east and western parts of the inner urban areas. The HC tends to decrease as it goes further to the outer urban areas, except for rented housing (RH) in Bekasi Regency, where the recognized post-suburbia lies (Hudalah and Firman, 2012). The overall cost of having a tenured housing (TH) in JMA is 28 to 29 percent less than RH. This value was at the same rate between core areas and the suburb. Nevertheless, having whether TH or RH in the core areas will cost the workers doubled rather than in the suburb. Furthermore, moving from the inner- to outer-urban areas means that worker could save almost 33 percent from its HC spending if they choose to made a TH, and only 12 percent if they choose to rent.

For the transportation cost (TC) aspect, different pattern was found in the core-ring areas. While there was a tendency of decreasing TC for those who have RH, the TH travelers experienced the opposite. Their TC was increasing from 17 to 50 percent. Increasing TC cost was also found in several suburban areas, most notably showed on South Tangerang in the inner urban. South Tangerang's citizen TC was the highest compared to whole JMA areas, both for TH and RH. Their Adjacent neighbor's Depok was ranked the second, and overall inner urban ring TC was 14 percent higher than the regional's average. In contrast with the HC, the TC for permanent tenure was 38 percent higher than for those who rent. Living in core areas would cost TC respectively 11 and 5 percent higher for each TH and RH compared to the core area. Shall the workers choose to move farther from inner- to outer-urban areas, they could have saves 45 percent for TH and 32 percent for RH.

Average JMA household's income in 2017 was 6.2 million Rupiah. Those who live in the suburb have 23 percent less income compared to the core areas households. Figure 1.b. shows that while the municipalities with highest income could be found in South Tangerang, an inner-urban area, municipalities with lowest average income lays within the west and southern parts of the outer-urban. The disparity was even higher when we distinguished between TH and RH. Overall renters in JMA has 37 percent less of income compared to those who have tenured. Interestingly, RH household in the inner-urban areas have a higher income, compared to TH household in core, and RH household in core areas. If this finding be seen together with TC pattern, it could show that RH household have their income by commuting to another municipalities. Thus, the income aspects on selected residential location seems to be more related with TC rather than HC.



(a) Housing and Transportation Cost Comparison in JMA by Type of Tenure



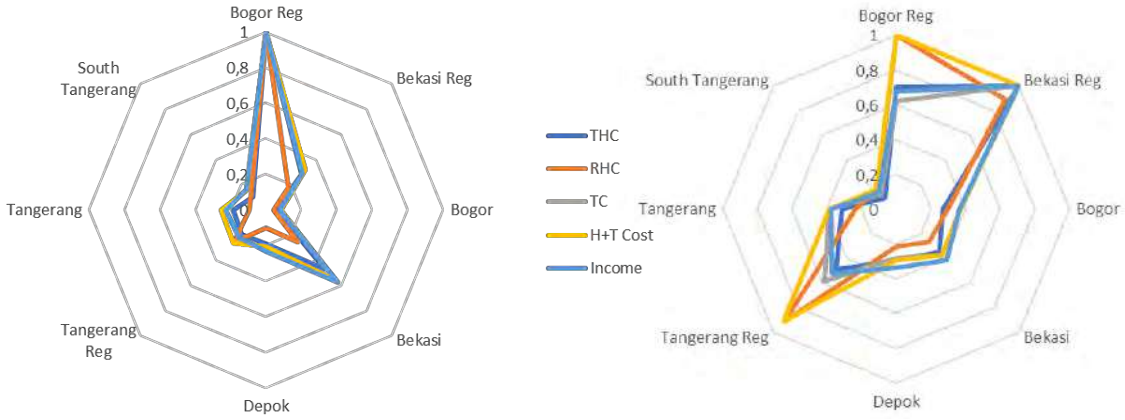
(b) Income Disparity and Migration Pattern in JMA's Suburban

Figure 1. Some Comparison of Utility Value in JMA

Inter-suburban moving events in JMA was actually inconsiderable. In 2017 the number of intra-suburban migrating household was less than 1.6 percent from the total. Highest in-migrant was found in Bogor Regency, municipalities which has the lowest HC and income. Migrant in this municipality mainly came from their adjacent inner-urban such as Depok, but many also came from another outer-urban areas like Bogor City, and Tangerang Regency. On a contrary, the in-migration flows seem to be reversing in Bekasi city. Located in the Inner-urban areas and being the second place of in-migration location, the majority of its migrant is

coming from the neighboring outer-urban, especially Bekasi Regency. The situation reciprocally experienced by Bekasi Regency. Almost 76 percent of Bekasi Regency's movers choosing Bekasi City in the inner urban areas, whereas 70 percent of the numbers, is moving for a TH. Such massive flows made Bekasi Regency the highest out-migrant holder. In brief, either in- or out-migration in JMA suburban seems to have no particular pattern.

For DEA analysis, recent migration experience between suburban areas was set as an output. The result showed a confirmation of how each TH cost, RH cost, TC, the combination of transport and housing cost (T+H cost), and income were efficient to attracted in-migration to Bogor Regency (Table 2.a). On the other hand, RH cost and T+H cost was showed a strong influence to pushing households moves out from Bogor Regency (Table 2.b). Considering that only 18 percent of the housing is rented, it means that most of out-migrant is renters and they moved for better opportunity in others suburb. The migrant which came to Bogor Regency pays as same as the average of existing household for TH cost and TC, but must pay one-third higher for RH. Similar situation of housing renters could also find in Tangerang Regency. The household moving to this place has a below average income and TH, but must pay tripled from the existing household. Interestingly, Bekasi Regency which was a major employment location was placed in the top rank for pushing people's moving out. The fact that the majority of their out-migrant move to a costly place in inner-urban areas indicate that utility-maximization was not the main reason behind this decision. The movers to Bekasi City have an average for income and HC, but pays 41 percent higher for TC indicates that they did not move closer to their job and hence creating more commuting. Other municipalities utility characteristics was far from ideal to attract inter-suburban migration. Thus, this municipal will continue to be the destination of movers from other suburban.



(a) In-migration (b) Out-migration

Figure 2. The Relation of Utility Parameters and Migration in JMA's Suburban

5. Conclusion

This paper comes with two conclusions. First, monocentric model utility-maximization parameters, were still consistent to be used in polycentric setting, but limited only for HC. For TC, inner-urbanites tend to have the highest expenses, imply that they have the longest journey, or maybe they were the most severely exposed with congestion. While less average TC in outer-urban areas shows that they were co-located better. In polycentric structure, the

trade-off between HC and TC does not merely depend on location. Tenurial status was also playing an important role on residential location decision. Despite of having much lower income, household which decide to choose RH were burdened with high HC cost but relatively lower TC. On contrary, selecting TH would cost less for housing, but charge more on TC. Secondly, suburban municipal with lowest utility value like Bogor Regency tends to be most efficient in attracting in-migrant. Surprisingly, they also produce some high score on pushing migrants out. Meanwhile location with similar utility value such as Bogor City does not display the same manner. Instead, developing post-suburbia, a significant major employment location as it could find in Bekasi Regency creating a numerous out-migration flows to their inner-urban area. This phenomenon shows that residential mobility within suburban areas occurs not for a lower HC and TC, nor to get near to major employment location. Further research on urban mobility within a polycentric setting should move beyond utility-maximization approach, and tried to identify the heterogeneity and behavioral aspect of mobile workers.

Abstract

For so long, urban studies in developing regions such as Indonesia has been trapped into a single view of global value and capital as the main, powerfull forces of the process. The result is therefore, a global, universal form or urbanization and the production of urban spaces. The fact that cities each have different histories, heritage, and resources show that there are local variations in response to global-economic pressures.With a case study of the transformation of the desa-kota in Bali, Indonesia, this paper shows and argues that in the dynamics process of urbanization, local actors and forces have play a significant roles in the production of urban spaces. Further, it argues that the existing centralized-Indonesia 'formal/legal' urban policy and planning system does not fit with the existing dynamics of local-cultural variations of urbanization – the roles of adat institutions and nomrs are significant and therefore should be supported and facilitated.

Keywords

desa-kota, transformation, local-global dynamics, adat institution, Bali

1.Introduction

1.1 Urbanization and Urban Growth in Indonesia: Questioning the Desa-Kota Idea

With the rapid level of urbanization and urban growth, the sustainability and the quality lives of the majority of the Indonesian population will depend on the quality of the urban environment. Based on the data of the Central Bureau of Statistics Indonesia (BPS, 2013), in 2010, the rate of urbanization in Indonesia is 49.8 percent. Recently, more than half the residents of Indonesia (53,3%) reside in urban areas. In 2025, with the total population of around 273 million, approximately 68 percent of them will be living in urban areas. Such rapid urbanization rate which is then manisfestated in the rapid growth of the city should be

anticipated with good planning and appropriate management in order to guarantee its sustainability.

This current status and future projection of urbanization in Indonesia brings two related aspects. First, urbanization and urban growth will facilitate the improvement of the quality of life and the environment of a large part of Indonesia society – something that we all hope. Second, however, this rapid urbanization phenomenon could increasingly perpetuate many problems that are already exist, and even leads to the worsening quality of the urban environment and urban communities – the sustainability of the city and its residents is questioned. There is a crucially need for a better and appropriate planning effort to guide rapid urbanization and urban groiwth in Indonesia.

The theory and the concept of the kota-desa were firstly promoted by McGee (1991). It was to explain the phenomenon of the development of suburban areas of Asian countries, including Indonesia. The basic argument is that the process and the product of urbanization in Asian countries is not similar to that in Western countries. In particular, this concept refers to the processes, forms and characteristics of the sub-urban settlements. It describes that such area has already some urban characteristics, but at the same time, still retain the characteristics of the rural environment and life. Further, this concept explains the stages of the development of urban areas on the sub-urban or outskirts of the city that are not entirely planned and managed, and tend to be organic. Physicaly, the concept of desa-kota manifestated in the form spatial transformation, a complexd and dynamic mix between urban and rural elements. Socially, culturally, and economically, the concept also explains an interesting, complex, and dynamic mixed and interaction between urban and rural activities, between modern and traditional institutions, and between formal and informal mechanisms.

Since its birth, the desa-kota concept tends to be used to describe the phenomenon or development model of Indonesian cities and also Southeast Asian cities – it is a kind of descriptive model. In spite of some criticisms, the concept is increasingly accepted as a relevant concept to understand the processes, forms and characteristics of the development of Indonesian cities. Under the challenges and the need for a more better and appropriate planning approach to guide urban development in Indonesia, it would be very challenging to explore the possibilities of such concept for a more prescriptif ones. A preliminary study done in Yogyakarta in 2014 (Harmen et.all. 2014) shows that the desa-kota in Yogyakarta has a range of distinctive characteristics and contains aspects that in accordance with the principles and indicators of sustainability.

1.2 Urbanization and Urban Grwoth in Bali: Problems or Challenges

Up to now, various studies and writings have been done on Bali, the paradise island, famous as the largest tourist destination in Indonesia. With the beauty of nature, traditions, culture, and history, Bali is called as the island of the gods, that offers exceptional beauty. Traditional settlements in Bali, for example, has very clear concepts and principles that are a balance and harmonious interactions between man and nature (Budiharjo, 1987). The very rapid development of tourism, however, is increasingly brought pressures and problems to the beauty of Bali. As have been documented by several studies, various environmental, social, and economic problems have appeared in Bali and threatening her sustainability (Martopo and Mitchell, 1995).

According to data from BPS (2013), the level of urbanization in Bali is currently around 56 percent. This means that about 1.7 million inhabitants of Bali resided in urban areas. It is also already projected that by 2025, the urban population will increase to about 2 millions.

Such significant increase should be appropriatelly respond to make sure the sustainability of Bali.

Geographically, the urbanization in Bali is concentrated in the city of Denpasar, which has more access to various economic centers and tourism attractions in Bali. In 2013, the city of Denpasar has only 789,000, population, and it is projected that it will become 1.2 million in the year 2020. This figure includes the whole urbanized areas of Denpasar, known as metropolitan of Sarbagita, consists of Denpasar, some parts of Badung and Gianyar. This rapid development has penetrated the villages on the outskirts of Denpasar which some are traditional Balinese villages. The expansions of urban areas in the tradional Balinese villages are crucially important phenomena which should be explored and documented. It is with the assumptions that such case may constitute best practices of rural-urban settlements, which can be learned and then further develop as a descriptif model of rural-urban settlements in the future.

1.3 The Objectives of the Paper

Based on the background presented above, this goal of this research is to explore and document the desa-kota phenomena in Bali, which is belived to be a unique and may contains some important elements and principles of sustainable urban settlement. Such general goal could then be elaborated into three objectives, which are: 1) To document the best practices of three types of rural-urban settlements in Bali;
2) To examine their sustainability as well as the factors that determine the sustainability;
and 3) to develop a planning model to guide the future development of the desa-kota settlement in Bali.

This research was conducted with deskritif analytical approach, whereby the three cases studied were explored and analyzed with a set of indicators. The indicator used is determined through a review of the literature and discussed with stakeholders in the three cases examined. From here, the level of sustainability can be measured in three cases. Further, it then analyzed factors that determine the sustainability of the three cases. From such process then, lessons learned could be then generated. In order to achieve such objectives severalmethods were used in the reserach which included: field surveys, interviews, as well as FGD with stakeholders in three villages. Further, secondary data were also collected, particularly related to aspects of sustainability in three cases.

2.Revisiting The Desa-Kota Ideas

The concepts and terminology of the desa-kota, firstly promoted by Terry Mc. Gee, an expert on urbanization and urban areas in Asia, in the mid 1980s (McGee, 1987). McGee used the term kotadesasi, to explain the phenomenon of the development of the city in the Asian country, particularly the Southeast Asia countries, which shows difference process and products compare to that of cities in Western countries. This concept specifically describes the process, form, and character development in the suburb area which was originally a rural area. The developmental process of the city that are not fully planned and managed resulted in a mixture of between urban and rural environments. Such unique spatial formation is complicated with a dynamic mix between urban and rural activities. Such processes then produces a distinctive settlement characteristic.

Although Gottman already explained the unnique phenomena of a megalopolis city in 1960s, McGee argues that the concept of kotadesasi is not the same as a Megalopolis concept. He stated that: "The megalopolis is a region dominated by the activities of the central urban system. In many Asian countries, the process of Kotadesasi is somewhat different, for it is occuring in many different locations often in areas adjacent to fairy-giants of the urbans cities and sometimes in the form of corridor development adjacent to main roads or railways that link reasonably close, large cities."

Further, he explained that the growth of megalopolis will form special elements namely: 1) a big city; 2) suburban areas; 3) rural-urban; 4) high population density village; 5) low population density village; and 6) small town. This process is characterized by the change of the village became a city, which was accompanied by a shift in economic activity into the formal informal. Example of a megalopolis in Indonesia, among others, is Jabodetabekjur (Jakarta, Bogor, Depok, Bekasi, Cianjur). He, however, also explained how the entire Java island can also be referred to as a series of large megalopolis. The ide of kotadesasi is then used to explain the development of metropolitan cities like Jabodetabekjur, referred to as the Extended Metropolitan Region – EMR. Some characteristics of EMR are: 1) high population density); 2) most of the population depends on agriculture; 3) undergoes transformation activities from agriculture to non farm activities (trade, transport and industry); 4) the intensity of a high population mobility possible availability of transportation is cheap; 5) high interaction between rural and urban activity; and 6) mixing of intensive land use between settlements and economic activities, such as agricultural, industrial, household and industrial areas.

Later, the concept of kotadesasi was then used by many researchers to investigate the phenomenon of urbanization and urban growth in various Asian countries. These studies confirm this concept (Guldin, 1997; The Desakota Study Team, 2008; Moench and Gyawali, 2008). One among studies concerning the desa-kota idea has resulted in nine parameters of to be used to asess the desa-kota, as can be seen in the Table below.

Table 1. The Desa-Kota Parameter

No	Parameter	General Condition of Three Cases
1.	Access to the city	This network enables connectivity between villages and cities, either to support the activities of the economic and social
2.	Job opportunities in second and tertiary sector	Allow the villagers, including woman to acess job and income, without having to leave her village/familly
3.	Access to outside world	The network of communication that allow villagers associated with the outside society actively, both national and global
4.	Most household engage in both farming and non-farming activities/labour	The villagers have a double income from farming activities and non-agriculture
5.	There is still local/traditional group	Provide opportunities to maintain traditional norms, including a spirit of social works and togetherness; strong social capital

6.	Access to Modern technology	Enable local communities to respond global/modern opportunities; Start available modern technologies for processing agricultural and non-agricultural products
7.	Contractual works is exist	Direct wages/cash economy quite dominant, though still tend to be informal sector
8.	Mixed on rural and urban institution	Enable local communities to maintain both traditional and modern activities
9.	Link to global market	Getting connected with the global economy

3.Description Of Research Area

Bali represents the most important tourist destination of Indonesia (Cole, 2012). Located eight degree of equator, Bali has warm temperatures which draws more than 3.5 million tourists in 2014 Tourism in Bali has been relying on the cultural activities and beaches (Rajendra and Nicholls, 2014). Hindu is the main religion in Bali. Its culture is strongly embodied in ceremonies, everyday rites, and temple festivals (Tang, 2004). Natural resources have been very important for this 5,636.66 km2 island, for example coastal resources, agriculture, mining, and forest (Rajendra and Nicholls, 2014). Bali's main concept of development in 1970s was culture-based tourism development supported by agricultural activities (Sudaratmaja, 2010). Having relatively small area combined with high number of population, for about 4 million people in 2015, land conversions have been unbearable to occur. Land conversion has been a high demand for tourism development, mainly at Badung Regency, Gianyar Regency, and Denpasar City.

Land conversion in Bali has been occurred in average 380-400 ha per year in the last 12 years (Bali Environmental Agency, 2015). The highest record was set during 1987-2003. In average 1,000 ha open land per year was converted into built-up land. The number has actually declined in 2010-2014 that was 338 ha per year land conversion. Paddy field is relatively more in favor for investor than dry land because its equipped infrastructure, for example irrigation canal, street, bridge, market, and information system (Sudaratmaja, 2010).

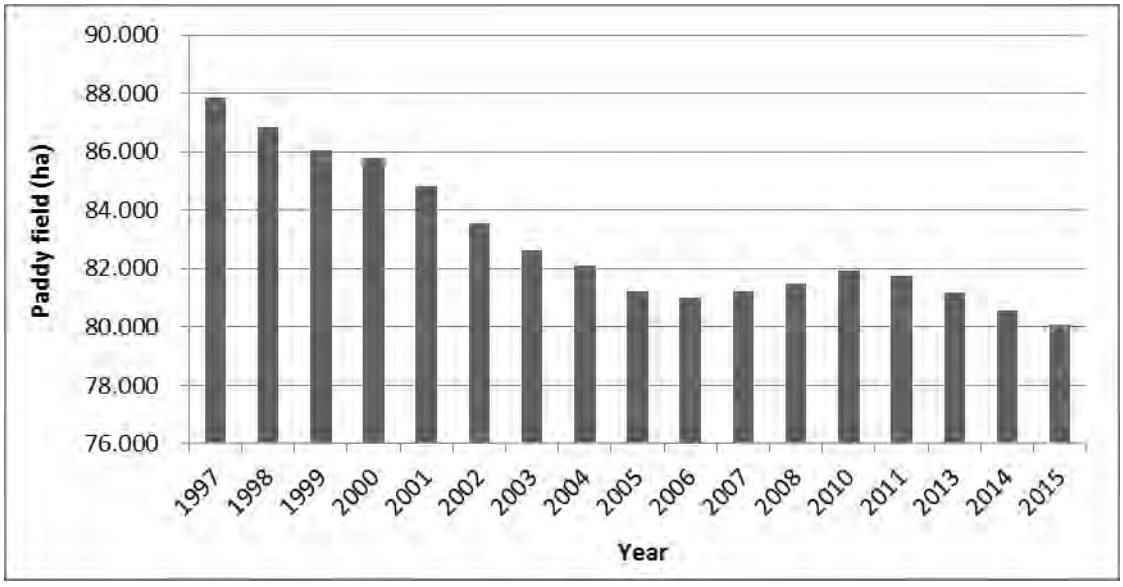

Figure 1. Land Conversion in Bali 1997-2015

Source: Bali Environmental Agency (2015) and Sudaratmaja (2010)

Bali Employment Statistic (2016) stated that in 2015, 56.12% employee in Bali works in service sector, and followed by 24.43% and 24.02% of agricultural sector and manufacture. In Denpasar City, tertiary sector has absorbed major employment, that are trading-hotel-restaurant (39.55%), service sector (24.02%), and industry (13.29%). Work opportunities in Denpasar City have drawn people from other regions, particularly rural area. The good quality of road infrastructures has made Denpasar accessible and relatively close to commute every day. Three cases of desa-kota, that are Lebih Village, Jagapati Village, and Pejaten Village, have different distances and traveling times.

Table 1. Distance from Three Villages to Denpasar City

Village	Distance to Denpasar	Traveling time to Denpasar
1. Lebih	20 km	45 minutes
2. Jagapati	15 km	33 minutes
3. Pejaten	30 km	1 hour and 4 minutes

Descriptions of Three Case Studies/Villages

The reserach has been able to identify several characteristics of the three villages that distinguishes one with the other. This characteristic is important to be understood and documented because it will be the basis of the development of three villages in the future. The following table summarizes the characteristics of the three villages that were examined.

Table 2. Description of Three Villages

DIMENSION	Village: Lebih, Gianyar	Village: Jagapati, Badung	Village: Pejaten, Tabanan
Physic/ environmental dimensions	• Unique landscape, a combination of hilly areas and coastal areas • Under pressures of new regional road/bypass: land conversion; • Traditional settlements and housing is still preserve, including agricultural lands	• Environmentally sensitive, yet fertile areas in between two rivers; • Paddy fields still dominant and preserved; • Divided by regional road, but not significantly give pressures; • Traditional settlement is still preserved	• A fertile geographical unit • Paddy fields, which are spacious and dominant, mixed with clay industry are tourism potential.
Socio-cultural	• Traditional practices are still strong; • New urban/tourism activities	• Traditional practices are still strong; • New/modern activities exist in limited ways	• Traditional practices are still strong; • Some villagers engage in tourism sectors/activities; • Start to become small tourism destination
Economy	• Mostly still depends on agricultural and fishery sectors; • Local economy is still dominant; • Tourism sector is increasing	• Mostly still depends on agricultural sector; • Increasing number of villagers work in modern sectors (public and private)	• Mostly depends on SMEs; • Increasing number of villagers engage in modern sectors.

Source: analysis (2016)

It can be summarized from the study that the three villages have characteristics that are fairly typical, although not too special. From physical point of views, for example, each village has its own unique which could be developed into a beautiful and unique residential and landscape. It particularly has an interesting blend of natural and human-made environment. It could then appreciated as a unique and interesting cultural landscape.

However, despite their uniquesness, the study also documented transformation processes that happen slowly. Such transformations, if not guided, could slowly erode and undermine the values landscape of the villages. As will be further expalin in this paper, the changing landscape of these villages have caused by some modern/government projcests, including, bypass, embankment of the beach along the waterfront, as well as the construction of a variety of commercial and tourist facilities. In the case of the village of Jagapati, the existing

landscape has not occurred in large scales, except for the case of the construction of a new residential complex by developer which then adding elements of the urban landscape in the village setting. In the case of Pejaten, the changes happened due to the exploitation of clay for the raw material of tile and pottery which is quite massive. This process is even triggered some landslides in several areas, caused some casualties.

4.Research Finding And Discussions

4.1 Three cases based on Desa-kota Parameters

As has been stated in the previous section, McGee has stated that desa-kota settlement could be evaluated through at least nine parameters, consists of physical, social, and economic dimessions. An assessment of the three cases studied in this research reveals that these three cases meeting the parameters and criteria stated in the literature. As can be seen in the Table 3 below, with a slightly different conditions, all three cases meeting the criterias as desa-kota settlements according to Mc.Gee.

From spatial points of views, these three cases have relativelly good and efficient access to the at least two cities. All three cases have access to the main/major city in the region, Denpasar. Case 1, Lebih also has access to the nearby city of Gianyar, Jagapati also has access to a famous town of Ubud, while Pejaten has also access to a growing city of Tabanan. Such good and efficent access to these three cities, open local communities in three villages to commute daily from their village for many economic, social, and even cultural activities.

Table 3. The Three Case According to the Desa-Kota Parameters

No	Parameter	General Condition of Three Cases
1.	Access to the city	All three villages have good access to the city and other urban/economic centers
2.	Job opportunities in second and tertiary sector	All three villages offer job opportunities in primary, secondary, and tertiary sector – mixed of job opportunities open for village residents;
3.	Access to outside world	All three villages have a good access to outside world, through many kinds of IT
4.	Most household engage in both farming and non-farming activities/labour	Most of village residents in three cases have a mixed-income/jobs, farming and non-farming
5.	There is still local/traditional group	Traditional institution (Adat) is still exist and strong/effective in three villages
6.	Access to Modern technology	Tend to uses traditional technology (in farming, industry, and trading
7.	Contractual works is exist	cash economy tends to be dominant, sector informal is still important
8.	Mixed on rural and urban institution	Balance mixed between traditional and modern institution (desa dinas and desa adat; bank etc.)

9.	Link to global market	More connected to global market, particularly Lebih village

Source: analysis (2016)

4.2 Sustainability Assesssment

A qualitative assessment based on FGD and various other informations has revelead that in general, the three villages could be categorized as those which shows some elements of sustainability. As can be seen in the Table 4 below, the sustainability prospect of the three villages is quite good. This general conclusion is very important because it can be used as the basis for further efforts to enhance the prospect of sustainability of the three villages.

Table 4. The Sustainability of Three Villages

Main Indicators	Lebih	Jagapati	Pejaten
1. Food Security And Sovereignty	+++	+++	+
2. Poverty/Vulnerability	+	+	+
3. Welfare/Happiness	+++	++	+++
4. The Role of Traditional Institutions	++++	++++	++++
5. Identity/Proudness	+++	+++	+++
6. Quality of Landscape	++	++	+++

Source: qualitatif assessment from FGD, interviews, and secondary information (2016)

The above table indicates that there are quite a lot of positive factors that play a role in ensuring sustainability of the three villages. Of the three pillars of sustainable development that are physical/environmental, social, and economic, all three villages have generally had a positive factors to maintain the condition and prospects of sustainability in three villages.

4.3 Factors Contributed to Sustainability of Three Villages

The study also identify factors that affect the condition and prospects of sustainability. Through a qualitatif assessment based on FGD, interviews with stakeholders, as well as the data collected, it can be summarised in the following table. The following table summarizes the various factors according to three pillars of sustainable concepts that are physical aspect/environment, social, and economic issues.

Table 5. Factors Contributed to Sustainability of Three Villages

DIMENSION	Village: Lebih, Gianyar	Village: Jagapati, Badung	Village: Pejaten, Tabanan
Physical/ Environment	• Fertile land; • Water availability; • Open access to sea; • Topograhy/steep slope.	• Clear settlement pattern; • Fertile land; • Good water supply; • Paddy field still preserved; • Housing density still	• . Clear settlement pattern; • Unique settlement pattern (SMEs village) • Good water supply; • Housing density still fine/ok.

		fine/oke.	
Social	• Strong traditional institutions; • Good local leadership; • Good social capital; • Relatively small number of poor/vulnerable villagers. • Community's tolerance.	• Strong traditional institutions; • Good local leadership; • Good social capital; • Community's tolerance.	• Strong traditional institutions; • Good local leadership; • Good social capital; • Community's tolerance; • Relatively small number of poor/vulnerable villagers.
Economy	• Strong local economy/agriculture and fishery; • Mixed economy; Tourism opportunities	• Job Opportunities from urban sectors; • Mixed economy.	• Sustainability of traditional roof tile industry – its comparativeness; • Mixed economy.

Source: Qualitative assessment from FGD, interviews, and secondary information

4.4 Problems and Challenges faced by Three Villages

As mentioned earlier, the three villages also face some pressures that threaten their sustainability. The following table summaries the pressures and challenges faced by the three villages. Such pressures and challenges, for sure, should be understood and appropriatelly respond as they would guarantee the future sustainability of the three villages.

Table 6. Problems and Challenges faced by Three Villages

DIMENSION	Village: Lebih	Village: Jagapati	Village: Pejaten
Physical/ environmental	• Urban development: road and tourism facilities, • Seawall construction; • New housing development by developer; • Agricultural land conversion; • Increasing housing density; • Changing of traditional pattern of housing; • Air and water pollution.	• New housing development by developers; • Agricultural land conversion • More uses of pestisida; • Increasing housing density; • Changing of traditional pattern of housing;	• New housing development by developers; • Increasing housing density; • Changing of traditional pattern of housing; • Soil degradation; • Agricultural land conversion.

Socio-cultural	• Social changes; • New migrants; • New job opportunities; • Social inequality; • HRD.	• Job opportunities; • HRD; • New consumerism	• Job opportunities; • HRD.
Economy	• Economy gap • Tourism opportunities; • More cash economy.	• Local economy; • Access to credit; • Economic value of agricultural sectors.	• Competition with modern roof tile industry; • Market fluctuation

Source: qualitatif assessment from FGD, Interviews, and secondary information

5.Conclusion: Desa-kota: An Alternatif for Sustainable Settlement?

This research concludes four main findings. The first is that, as assumed in this research, the idea of desa-kota, firstly promoted by McGee in the early 1990s, is also existed in Bali. In this paradise island, the urban and rural tissue are strongly intertwined in a dynamic and complex system. Two settlement typologies exist in a very close proximity, the Desa (village) and the Kota (city) – The Desa-Kota. It is a mixture of agricultural and urban landscapes/fabrics which then can be appreciated as an interesting and unique cultural landscape. The Desa-Kota has urban densities, but a highly green quality. Functionally, urban settlement and rural landscape are intertwined in a dynamic and synergetic cooperation.

The second conlusion could be drawn from this research is that the Desa-Kota in Bali has some positive aspects in terms of its sustainability. There are at least six aspects of sustainability explored in this research, which includes: 1) food security; 2) poverty/vulnerability; 3) welfare and happines; 4) identitiy/proudness; 5) quality of landscape; and 6) the role of traditional institution. Although each village has differnt level of quality among these six aspects, in general, however, all have some that kind of quality. In other words, this researach has founded that those three cases have a relatively sustainability condition and prospects.

Further, the researach also found several positive factors which significantly contribute for the sustainability of cultural landscape of the desa-kota in Bali which are: 1) strong adat/traditional institution; 2) government policies; and 3) local/community leadership. These three factors are dynamically play together. Efforts to guarantee future sustainability would depend very much on how we could support such three important factors. The fact that the role of traditional institutions is very strong and significant in three cases is actually not surprising as many studies have already argued that such aspect is crucial for the whole of Balinese culture.

In addition to such positive findings, however, the researach also recognize several problems and challenges faced by the desa-kota in Bali. Among three dimensions of sustainability, economic dimention is the most challenges and problematic aspect. As far as these three villages able to appropriatelly respond such problematic and challenging aspect, their sustainability would be more guaranteed. This, in particular, relates to the idea of whether they could develop an alternative local economic resources, managed by local communities,

and tapping the growing global market opportunities. If that condition could be achieved, the desa-kota settlement in Bali could be further develop into an alternative model for resilient and sustainable settlement.

Research Paper

A Study on the Approach of Sustainable Development on Traditional Cultural Landscapes Surrounding Metropolitan Shanghai

Ding SHI, Department of Cultural Heritage and Museology, Fudan University; China
Dianhong ZHAO, Shanghai Tongji Urban Planning & Design Institute CO.,LTD; China

This work was supported by Youth program of
Shanghai Planning Office of Philosophy and Social Science (2016ECK002)

Abstract

At present, the area of urban built-up areas in Shanghai has been effectively controlled, and the once neglected rural landscape has attracted much attention. This study focuses on the methodology of effectively utilizing cultural landscape resources and promoting further harmonious development of urban-rural relations in Shanghai. As a category of cultural heritage, cultural landscape is an indispensable resource for urban development. During the process of urban and rural planning, local cultural landscapes need to be regarded as the driving source of urban development. For a long time, Shanghai, as an international metropolis, has lain particular emphasis on historical relics in the built-up areas of the city. However, since the cultural landscape resources surrounding the built-up areas have been neglected, the image of Shanghai lacks an echo with nature and the countryside. This study examines features of cultural landscapes in Shanghai and puts forward several issues in the conservation and sustainable development of cultural landscape resources, so as to provide the basis for heritage protection, urban and rural planning and tourism planning in Shanghai in the future.

Keywords

cultural landscape, metropolitan Shanghai, conservation, sustainable development, Methodology

1. Shanghai: The Paris of the East?

Shanghai used to be the largest metropolis in the East. It was regarded as the Paris of the East, the city of opportunities and the paradise for adventurers. On mentioning the urban image of Shanghai, what would you think of? The answers may vary. The 20th century Shanghai is usually marked with European-style historical buildings left during the Concession Era, shikumen-style residences or large areas of industrial heritage when the banks of the Huangpu River and the Suzhou River underwent a period of industrialization.

Meanwhile, the 21st century Shanghai may consist of groups of skyscrapers, an advanced underground system, complex highways, and a futuristic new urban area built after the 2010 Shanghai Expo. It can be concluded that Shanghai is an Asian metropolis with a large scale, a complex urban structure, cultural diversity, and an active economy. It is also a complex of urban heritage left during particular historical periods. Therefore, it is hard to summarize in one sentence the value system which Shanghai represents.

What impresses people most is in fact the large number of buildings and the historical neighbourhood, brought by the art of architecture and urban and rural planning as well as a tremendous amount of capital investment during the development of Shanghai. From a chronological perspective, the most impressive urban image of Shanghai is largely related to the urban history after Shanghai became a foreign treaty port in 1843. Therefore, the origin of Shanghai's urban culture has become a bewildering question. Has Western commercialism contributed to the prosperity of Shanghai in recent history? Is Shanghai the Paris of the East?

2. Where is "the rural Shanghai"?

The image of urban Shanghai is regarded as the representative of contemporary Shanghai because it is characteristic and highly-recognizable. However, Shanghai is not made solely from various building groups. Apart from highly concentrated built-up areas, Shanghai owns extensive rural areas. With traditional Chinese gardens scattering in the city, natural landscapes account for a large proportion of urban areas. Shanghai is not a city without history. Before it became a foreign treaty port, it was not a fishing village, but a county. Therefore, the history of Shanghai started before 1840.

The choice of the location of a city and its construction should take natural and geographical features into consideration. Shanghai is located on the west coast of the Pacific Ocean and on the east of the Asian continent. It is a part of the alluvial plain of the Yangtze River Delta. With an average elevation of 4 meters, the majority of Shanghai is situated on a flat terrain except for several hills and mountains in the south-western region (with the highest altitude of 103.4 meters). Approximately 6000 years ago, the present west part of Shanghai already became a land. The present eastern region has also become a land for 2000 years. According to statistics published at the end of 2017, Shanghai enjoys 6340.5 square kilometers of land area, accounting for 0.06% of the total land area of China (SMPG 2019).

The following part is contributed to a brief history of Shanghai. In the Spring and Autumn Period and the Warring States Period, Shanghai was named as "shen" (申) as it belonged to Huang Xie, Lord Chunshen (春申君) of the Kingdom of Chu. In the Jin Dynasty (4th -5th century), the inhabitants who lived on fishing made a bamboo fishing tool named "hu" (扈). Since the estuary was called "du" (渎), the lower reaches of the Song River was first named as "hu du" (扈渎). Later, the character "hu" (扈) was replaced by "hu" (沪), the present abbreviation of Shanghai. In the tenth year of the Tianbao Years of the Tang Dynasty (751 AD), Shanghai belonged to Huating County (the present Songjiang District). In the second year of the Chunhua Years of the Northern Song Dynasty (991 AD), as the upper reaches of the Song River gradually became shallower, the coastline moved eastward, which caused inconvenience for large ships entering and leaving the harbour. As a result, non-local ships could only dock at Shanghaipu (the present Huangpu River from the Bund to Shiliupu), a

branch of the Song River. In the third year of Xianchun Years of the Southern Song Dynasty (1267 AD), a town was established on the west coast of Shanghaipu, named "Shanghai Town". In the 29th year of the Zhiyuan Years of the Yuan Dynasty (1292 AD), the central government ruled out Shanghai Town from Huating County and established Shanghai County, which marked the beginning of Shanghai as a city. In the middle of Ming Dynasty (the 16th century), Shanghai became the national center of cotton, textile and handicraft industry. In the 24th year of the Kangxi Years of the Qing Dynasty (1685 AD), the Qing government established the customs in Shanghai. In the middle of the 19th century, Shanghai became a prosperous business port. After the founding of the People's Republic of China in 1949, Shanghai underwent tremendous economic and social transformation. In particular, it has deepened reform and opening up since 1987. Since the beginning of the 21st century, Shanghai has striven to create an international center of economy, finance, trade, shipping, and technological innovation (SMPG 2019, ESEC 2010).

Due to the massive migration into the city and a rapid increase in floating population from other regions, the total population of Shanghai has been gradually accumulating. The population was under 100 thousand when Shanghai became a foreign treaty port. By the end of 1949, the household registration population was 5.2 million. By the end of 2017, the permanent residential population was 24.1833 million, with 9.7268 million permanent living migrants from other cities and 14.4565 million permanent household registration residents. By the end of 2017, Shanghai had 16 districts, 107 towns, 2 villages, 4253 resident's committees and 1590 villager's committees (SMPG 2019).

The above statistics demonstrate that Shanghai enjoys distinctive natural environments and a long history of human interaction with nature. Shanghai is in fact surrounded by large areas of villages, towns and rural areas, which witnessed human activities before the city became a foreign treaty port. If Shanghai is compared to a painting, these rural areas are its color base. Therefore, a study of the more extensive natural environment and a longer history of Shanghai needs to take into consideration of these "color bases", which can be termed as "the rural Shanghai".

How to display the key elements of the rural Shanghai? From the perspective of landscape heritage conservation and urban and rural planning, the idea of cultural landscape needs to be introduced.

3. How to understand the cultural landscape of Shanghai?

"Cultural landscape" is a concept from cultural geography and a type of world heritage. It can also be viewed as a holistic methodology for heritage conservation (Han 2010). For urban and rural planners, whether they can comprehensively understand the idea of cultural landscape is significant to the future realization of the sustainable development of natural resources and culture.

3.1. The concept of cultural landscape

The founder of cultural geography, Carl Ortwin Sauer (1889-1975), proposes the concept of "cultural landscape" in his 1925 paper "The Morphology of Landscape", which has exerted a profound influence on later studies of landscape. According to Sauer's definition, cultural landscape is "fashioned from a natural landscape by a culture group", among which "culture is the agent, the natural area is the medium, the cultural landscape the result" (Sauer 1925).

In 1992, cultural landscape was listed as a category of world heritage. According to *The Operational Guidelines for the Implementation of the World Heritage Convention*, cultural landscape belongs to the category of cultural heritage and it represents "combined works of nature and of man". In addition, cultural landscape is further classified into three sub-categories: landscape designed and created intentionally by man, organically evolved landscape (relict or fossil landscape, continuing landscape), and associative cultural landscape (UNESCO 2017).

The purpose of creating these sub-categories is to promote deeper understanding of various ways of human interaction with nature and to look for cultural landscape heritage sites with "outstanding universal value" worldwide. In China, classic examples of cultural landscape include the following world heritage sites: Hani Terrance of Yunnan province, the West Lake of Hangzhou, a city of Zhejiang province, and Huashan rock painting of Guangxi province (UNESCO 2019).

Some cultural landscapes gather attention worldwide because they are selected as world heritage sites. However, this does not mean that only cultural landscapes with special value need conservation. Since the selection of world heritage is choosing the best from the good, some ordinary cultural landscapes are destined to remain off the list, which should not diminish their value. On the contrary, these ordinary cultural landscapes are closely connected with people's daily life. In urban Shanghai, what are the characteristics of cultural landscapes?

3.2. Cultural landscape as a platform for interaction between human and nature

To examine cultural landscapes of Shanghai as a platform for interaction between human and nature, the focus should switch from architecture heritage to a more extensive area with a consideration of diverse natural features.

Types and features

To examine cultural landscapes in urban Shanghai as "combined works of nature and of man", there are several types of classic cultural landscapes: gardens and green spaces (including traditional-style gardens and modern public gardens, which are highly-integrated works of nature and humanity), riverside landscapes (especially referring to the combination of waterways, ships, trees on both sides of the bank, bridges, architecture heritage closely related to shipping, and industrial heritage), rural areas (including villages, large areas of fields, and crisscrossed canals), and water towns (business and handicraft industry towns emerged around the intersection of water and land for convenient transportation during ancient times).

In terms of spatial features, the above types of cultural landscapes are closely related to the water system. Most of them can be interconnected through the spiderweb of the water system, which forms an interconnected web when viewed from a flat space. Meanwhile, as waterways extend linearly, landscapes along the bank form a particular sequence. For instance, the Suzhou River, one of the main water systems of Shanghai, originates from the Taihu water system to the west of Shanghai. It travels across villages in Suzhou and rural areas in Shanghai and enters the central area of Shanghai through water towns. It connects several urban public gardens, industrial heritage sites and architecture heritage areas when

it flows under numerous bridges with various shapes and designs. Finally, it joins the Huangpu River around the north of the Bund. From west to east, the wider Huangpu River connects a number of traditional and modern areas, including villages, rural-urban fringes, industrial heritage groups, harbors and ports, historical building clusters in the Bund, business circle in Lujiazui and urban parks, before it finally joins the Yangtze River northward. Therefore, the main waterways in Shanghai have broken their barriers and have respectively connected landscapes emerged from different eras together, which helps to form a way of understanding the geographical features, history and value of Shanghai (XI 2019).

Value

The value of cultural landscapes is rather obvious for Shanghai. To begin with, cultural landscapes contain ecological value. From an ecological perspective, in central Shanghai, public gardens and green spaces along both sides of river banks have made tremendous contribution to biological diversity in the urban area. From the perspective of cultural ecology, those areas provide citizens with spaces for communication, leisure and entertainment, which are important to the mental health of urban residents.

Secondly, cultural landscapes can bring economic value. Since the ancient times, rural areas around urban Shanghai have provided the city with agricultural goods, handicraft goods, industrial raw materials, labour forces and intellectual resources. Rural areas have also been the market for industrial products from urban Shanghai. The urban and rural areas have basically maintained a healthy relationship, complementary to and interacting with each other.

The next is historical and cultural value. Like the large number of architecture heritage sites and industrial heritage sites, cultural landscapes also witness the history of Shanghai. A number of Ming-style and Qing-style gardens locate in urban areas of Shanghai and its surrounding water towns. Shanghai also has the first public urban garden in China. Water towns surrounding the urban area has enjoyed numerous famous figures and literature talents.

It is those clearly-ordered, spiderweb-like waterways and water systems that bring ecological, economic, historical and cultural value together. Most of the water systems are not naturally formed, but are dependent on the canal system of natural main river channels, such as the Suzhou River (old name: Wusong River) and the Huangpu River. They reflect how residents of Shanghai have effectively utilized water resources through their interaction with natural environments during hundreds and thousands of years. Their wisdom can be found in various kinds of water-related activities, such as flood discharging, shipping, irrigation, farming, and planting. This giant water web not only creates a connection between the agricultural, industrial and commercial society during the same era, but also forms a tie between the past and the present (Hartog 2019).

3.3. Challenges and opportunities

However, it is a pity that Shanghai did not fully utilize and promote the value of cultural landscapes during the process of urbanization and industrialization in the past. As an international metropolis, Shanghai has been attracting domestic and foreign capital. Consequently, the land prices of Shanghai have remained high, which has popularized investment in commercial real estate properties. Although capital-led urban development can boost modernization of basic infrastructure, it does not reserve large areas of ecological,

cultural and historical spaces, which, from a profit-oriented perspective, is not worthwhile. Therefore, lack of large areas of high-quality waterfront green spaces and outdoor spaces for sports and leisure becomes an obstacle in promoting the living environment of urban Shanghai. On the other hand, from the perspective of urban and rural relationship, the development of urban Shanghai is based on incorporating its surrounding rural areas. Rapid urbanization and industrialization forces the surrounding rural fields to transform into living areas and industrial areas. Therefore, lands in the countryside also become targets for capital investment. Thus, the ecological and cultural value of the countryside are devalued or neglected.

The values of a city can determine its destiny. Shanghai has begun its introspection and transformation. In 2018, Shanghai Master Plan (2017-2035) was officially published. Till 2035, Shanghai aims to become an excellent global city, a desirable innovation city, a humanistic city, an eco-city, and a modern socialist international metropolis with world influence. Based on the requirement on "Negative Growth" of total land planned for construction, the total area shall be controlled within 3,200 square kilometers. Shanghai shall prioritize ecological requirements, making them the bottom line and the red line for urban development. It shall also strengthen the urban ecological basis and increase the area of ecological lands. Specifically, urban and rural planning shall guard four bottom lines, including ecological conservation red line, permanent prime cropland conservation red line, urban development boundary and cultural protection control line (Tu 2019, Meyer 2019). Therefore, the Plan is a great opportunity for the understanding and conservation of cultural landscapes in urban Shanghai as well as sustainable development.

4. Conservation and Sustainable Development: planning for balance

How should areas with highly-concentrated cultural landscapes be planned if large projects of demolition and construction are not available in Shanghai? In terms of natural elements, compared with built-up urban areas, rural areas around the city have a higher possibility to be re-planned. The following sections will illustrate several ways for cultural landscape conservation and sustainable development.

4.1. The water system: rebirth and revival

During the process of urbanization, Shanghai used to depend on the shipping function of water systems, but neglect their ecological functions. Since the establishment of modern road traffic system, the shipping function of waterways has been abandoned, except for main waterways. Consequently, a number of water systems were filled. It is necessary to rediscover the possible ecological functions of the remaining waterways and irrigation water systems that extend to villages, towns and rural fields. Waterways that have been filled can be unfilled. For existent water systems, apart from upgrading their shipping functions, exploring the possibility of creating ribbon-like landscapes is also necessary. During ancient times, creating landscapes and building irrigation facilities used to work together. For example, there have been blooming peach blossoms and fluttering willows on the Bai Causeway of the West Lake, which have formed a beautiful landscape with traditional Chinese style. Planting scenic tress along water systems can not only revive the beauty of

traditional Jiangnan style, but can also provide routes for birds and other animal migration, which, from a landscape ecology perspective, carries significant ecological value.

4.2. The countryside: a pastoral life at home

Due to convenient transportation, residents of Shanghai usually choose to spend their weekends to the beautiful countrysides in nearby Suzhou or Hangzhou. Although Shanghai enjoys large areas of countryside, most of them are used for productive and functional reasons and lack interaction with urban culture. Therefore, "urban Shanghai" and "rural Shanghai" seem to have been two independent worlds without cultural connections. How rural and pastoral landscape can comfort people of Shanghai is yet to be explored and the wisdom of traditional pastoral lifestyle has not been brought to modern society. As a result, representing the past pastoral life at home, apart from increasing productivity, the countryside needs to create high-quality rural landscapes with a traditional Jiangnan style and thrives to become the charming and attractive countryside at home. In terms of building rural industry, it can also actively explore the connection between pastoral life and pension industry. To conclude, urban and rural planners should view the countryside as a kind of cultural resource and should discover value from production and lifestyle in the countryside, which can later be put into practice and popularized.

4.3. The water town: a poetic habitation

Water towns are connected with water systems and the countryside. Water towns emerged because villagers gathered to exchange goods, which played a significant role in the ancient agricultural society. At the same time, in ancient times, water towns used to be cultural centers of Shanghai where a number of intellectuals had lived. Water towns in Shanghai are culturally and geographically connected with those in the south of Jiangsu province and the north of Zhejiang province (Nolf 2019). While water towns around Shanghai, such as Zhouzhuang, Tongli and Wuzhen, have had high-quality tourism industry, water towns in Shanghai generally lack development in tourism. It is not because Shanghai is short of good water town resources, but because it does not fully understand and promote lifestyles and aesthetics of water towns.

Water towns in Shanghai are the most complex and important cultural landscape areas as they possess both urban and rural features, thus connecting the urban area with the countryside. In recent years, with the development of infrastructures, people can not only enjoy a convenient modern lifestyle in water towns, but also the comfort of streets and alleys in water towns while developing an intimate relationship with nature. Therefore, more and more youngsters have been attracted to live in water towns and start their business there. From the perspective of non-local residents, water towns create a perfect combination of modern technology and traditional architectural spaces and possess huge potential in becoming "poetic habitations", a project which is now under exploration and implementation in towns around Shanghai. Water towns in Shanghai prospered during ancient times, became wasted during the age of modernization and industrialization, and now have been revived under the new age to create new values for the city. As an example of traditional habitation culture, water towns are worthy of careful study in urban and rural planning, tourism planning and conservation planning.

5. Conclusion and suggestions

Shanghai is not the Paris of the East. It is rooted in the rich soil of Jiangnan culture and enjoys characteristic geographical and cultural features. Therefore, it is meaningless to decorate Shanghai with European style. The spirit of Shanghai should be viewed with a larger scope which takes the city's history and geography into consideration. The cultural landscapes surrounding the built-up areas of Shanghai emerge from the city's natural and cultural basis, known as "the base color" of the city. The development of Shanghai cannot proceed without its background and base color. Otherwise, it would become water without a source, and a tree without roots.

The countryside and water towns are the largest cultural landscapes in Shanghai and are interconnected with a huge network of water systems. These landscapes bear wisdom of traditional production and lifestyle and are a key to understanding "the rural Shanghai". Although these cultural landscapes were once neglected and damaged during the process of rapid modernization, they are still the important foundation for ecological protection and cultural development in the future and can shed light on building future human habitations. Therefore, the wisdom and value of these cultural landscapes are worthy of deeper exploration and study.

Cultural landscapes are indispensable resources for a city. In order to "plan for balance" in Shanghai, several types of unbalance need to be tackled with, including unbalance of the city and the countryside, unbalance of conservation and development, unbalance of men and nature, and unbalance of history and modernity. Since conservation and sustainable development of cultural landscapes can greatly help in solving these issues, it is necessary to rediscover the value of cultural landscapes. This can help to incorporate historical, natural and cultural elements into people's daily life, to create a charming "rural Shanghai" and to revive the countryside. During this process, cultural landscapes can be viewed as a holistic methodology of heritage conservation and of sustainable development of urban ecology and culture.

Abstract

High urbanization rate in Indonesia become a huge challenge for Indonesia nowadays. It is predicted that in 2025, 68% of Indonesia's population will live in urban area. Jakarta is the most challenging city for controlling urbanization. As the Capital City of Indonesia, nowadays Jakarta has 11 million population, and almost 30 milions population in Jakarta greater area makes Jakarta became the world's second largest urban area.

As cities become more crowded, many cannot support inhabitants' basic needs like housing. The township development outside Jakarta becoming a huge project for the government of Indonesia and private sector. Today, in Greater Jakarta area itself, there are 33 township development project since early 80's, which is mostly developed by private sector. Township development become a new resident area and center of economic growth. This is why high urbanization rate in Indonesia is also followed by a historic transformation of Indonesia economy. From rural – agriculture to urban – services economy.

Township development outside Jakarta is also creates a more challenging development phase: connectivity between Jakarta and township at greater Jakarta and also a public – private partnership in developing new township.

Keywords*:*

Township Development, Urbanization, Greater Jakarta Area

1. Introduction

High urbanization rate in Indonesia increased tremendously following the country's rapid development by rural – urban migration. In 1950, 15% of Indonesia's population lived in urban areas, in the next 40 years in 1990, later this number is doubled to 30%. The latest report in 2015, The Central Bureau of Statistics (BPS) reported that Indonesian people in urban areas has increased from 49% in 2010 to 53% in 2015. It is also projected by The Ministry of National Development Planning that in 2035, 66% Indonesian will be living in urban areas (PPN/Bappenas, 2015). This circumstance leads to socio-economic and cultural shifts and changes. Moreover, it has an impact on national and urban policies, including housing and settlement sectors.

Table 1 Population Distribution in Urban and Rural Area

Source: Central Bureau of Statistics (2018)

YEAR	POPULATION LIVED IN URBAN AREAS (%)	POPULATION LIVED IN RURAL AREAS (%)
2010	49,80%	50,20%
2015	53,60%	46,40%
2035	66,60%	33,40%

Jakarta is the most challenging city for controlling urbanization. As the Capital City of Indonesia, Jakarta holds some pivotal roles for the country as well as region. The city is the centre of Indonesian national government, transportation system, and the heart of some activities such as economy, education, healthcare, culture, and tourism. As a centre of national activity, Jakarta also has been attracting many people from other areas of Indonesia to migrate to the city. According to the Central Bureau of Statistics, the rate of population growth in Jakarta during 2000-2010 was 1.41%, and in 2010 the population in Jakarta reached 9,607,787 with a density of 14,506 people/km^2, making Jakarta the densest province in Indonesia. Nowadays Jakarta has 11 million population, and almost 30-millions population in Jakarta greater area makes Jakarta became the world's second largest urban area.

Based on Globalization and World Cities Research Network (Globalization and World Cities Research Network, 2018), research conducted by University of Borough, UK, Jakarta is categorized as the Alpha World Cities, compatible to Amsterdam, Beijing, Milan, Frankfurt, and also Seoul. It means that Jakarta is an important world cities that link major economic regions and states into global economy. Jakarta is also promoted as Global City. According to A.T Kearney Global Cities Index in 2012, Jakarta ranks at 54th position among world's global cities.

As the largest city in Indonesia where urbanization is growing rapidly, people are seeking for a place to live in or at least near the city. When Jakarta itself has been fully occupied, and the land prices are getting hard to be controlled, people tend to move outside the city, which causes urban sprawl.

The overall population of the megacity of Jakarta grew in the 20th Century, from about 150.000 in 1900 to about 32 million in 2019. The megacity of Jakarta is also called Jakarta Greater Area or *Jabodetabek,* a name formed by combining the initial syllables of Jakarta, Bogor, Depok, Tangerang, and Bekasi areas.

Table 3 Regional Profile of Jakarta Greater Area

Cities	Population	Areas (km^2)	Density (people /km^2)	Population Growth (%)
DKI Jakarta	10.374.235	662,33	15.663	0,94

Based of the research conducted by World Bank, Indonesia can benefit more from urbanization. I assumed that why Indonesia's benefit from urbanization is still low because Indonesia has only a little number of cities that acts as urbanization target city.

Other countries have gained higher economic growth through formal employment and better labor productivity that result from urbanization. Every 1% growth in urban

population correlated with per capita GDP increase of 13% for India, 10% for China, and 7% for Thailand. But Indonesia is gaining only 4% GDP growth for every 1% of urbanization.

Moreover, the rate of urbanization in Indonesia is negatively correlated with the supply of housing, transportation, and infrastructure. Population growth encourages fulfillment of basic infrastructure and services for all groups of people living in urban areas. Housing ownership as a basic need must be affordable for all levels of society. Uneven or unplanned provision of residential housing will cause sprawl in peri-urban areas and cause green areas to convert to urban areas, which in turn can have a negative impact on food security and the emergence of slums.

To support their daily activities, urban communities' accesibility can burden the transportation system and cause negative externalities such as congestion and pollution. The high ownership of private vehicles due to the failure to fulfill public transportation services for the community can lead to heavy traffic and causes economic loss for such city. According to the Governor of DKI Jakarta, in January 2019 there has been a Rp100 trillion pounding every year. Although there have been many government efforts to overcome traffic congestion in Jakarta, from motorcycle restrictions, odd-even license plate policies, to the development of transit oriented development (TOD) but none of these efforts has directly touched the main causes of congestion in Jakarta, namely the increase of motorized vehicles every year, not including the flow of transportation around the city of Greater Jakarta Area in and out of the city of Jakarta in the morning and evening, or during office hours.

The fulfilment of othe basic infrastructure needs causes high-financing burden for the government. Infrastructure needs such as hospitals, schools, parks, highways, flood and fire disaster management facilities, and other government supporting installations. Moreover, due to urbanization, the provision of basic infrastructure must meet certain quality standards, accommodate the needs for the elderly and persons with disabilities, and in proximity of the settlement's areas.

2. Urbanization Challenge in Greater Jakarta Area

Jakarta as a Megapolitan City involves the city/provincial governments of the surrounding areas in dividing the burden Jakarta has to bear, forming Jabodetabek as the largest urbanization destination in Indonesia. Besides accommodating a total population of 32 million in 2019, it is also home to 26 million vehicles, based on the Jabodetabek Transportation Management Agency (BPTJ) in 2019. The total number of people traveling to-and-from the Greater Jakarta Area area increases from year to year, at least 49.5 million people commute per day in 2018. Of that number, 23.4 million people commute within the city of Jakarta, 4.67 million people commute from areas other than Greater Jakarta Area, while the other 20.02 million are Bodetabek (Bogor, Depok, Tangerang, Bekasi) residents who commutes into Jakarta city per day. With the proportion of vehicles dominated by motorbikes (75%), private vehicles (23%) and public vehicles (2%) per day puts great pressure on Jakarta and the surrounding area.

Bearing a huge burden to the city, the Jakarta Greater Area is also a hub for various activities. According to the Central Bureau of Statistics, the City of Jakarta and the surrounding area have a very large GRDP level of Rp 2,249 trillion in 2017, where DKI Jakarta Province alone contributes half of that value, in the sum of Rp 1,286 Trillion. The average GDP growth per-annum reaches 9.89%, making Jabodetabek a large economic agglomeration in Indonesia. The value of GDP produced should be sufficient in providing the resources needed for the City of Jakarta and its surroundings to solve urbanization problems and fulfill the basic needs of its people.

Table 4 Gross Domestic Product of Region (GDPR) of Jabodetabek Region in Rp Million

Jakarta Greater Area	Gross Domestic Product Of Region (GDPR) (Rp Million)	GDPR Growth (%)
DKI Jakarta	1.286.668.000,00	10,29
Kota Bogor	38.506,50	26,51
Kota Tangerang	149.420.370,00	5,91

The level of income per capita or the average income of the population in Jabodetabek Region is Rp. 145.49 million based on 2017 BPS data. The largest per capita GRDP is owned by Central Jakarta City, Rp. 641 million or 11.05 times greater than Indonesia's per capita GDP in the same year. While the lowest per capita GRDP is owned by the City of Depok with Rp. 25.88 million. The per capita GRDP in the Jabodetabek area, which is above the national average, is mostly the contribution of the DKI Jakarta province, while the contribution from surrounding cities is only a small portion of the proceeds obtained by the Jakarta Province.

Table 5 Gross Domestic Product of Region (GDPR) per capita of Jabodetabek Region in Rp Million

Jakarta Greater Area	GDP Per Capita (Rp Million)
Kep Seribu	303,10

In comparison to the degree of inequality of population distribution or gini ratio in Jabodetabek, seen from the table 6, DKI Jakarta and Banten provinces have low level of inequality, which is below 0.4. Gini ratio is a measure of inequality or aggregate inequality whose numbers range from zero (perfect income equality) to one (perfect income inequality), and classified in 3 categories, namely low (<0.4), medium (0.4-0.5) and high (> 0.5). In contrast to West Java Province which has a moderate level of inequality or above 0.4. Thus, it can be said that Jabodetabek's ability to face the challenges of urbanization is at a sufficient level. Although these capabilities are on the borderline of land capacity and financial capacity in meeting the daily needs of the community.

Table 6 Gini ratio of Jabodetabek Region

PROVINCE	URBAN-RURAL GINI RATIO
DKI Jakarta	**0.390**
Jawa Barat	**0.405**
Kab. Bekasi	0,336
Kab. Bogor	0,384
Kota Bekasi	0,351
Kota Bogor	0,410
Kota Depok	0,352
Banten	**0.367**

Source: Central Bureau of Statistics, Various Year

Compared to other countries, based on research conducted by UN Habitat in measuring the welfare level of a city in the City Prosperty Initiative (CPI), the welfare level of Jakarta is relatively low. The CPI is based on the aspects that make up a city, starting from the ability to meet the basic needs of the population, the use of economic benefits for the welfare of the population, the quality of the environment, the implementation of policies, and the capability of government institutions. Based on a scale of 0 - 100, Jakarta was ranked 40th out of 60 cities studied by UN Habitat. In comparison to other Asean countries, Jakarta's CPI ranking is above the cities of Manila and Bangkok.

Table 7 City Prospertity Index of Jakarta

GLOBAL RANK	ASIA AND OCEANIA COUNTRY	CPI	PROSPERITY INDEX QULITY
7	Melbourne	80,30	Very Solid
10	Sydney	79,77	Solid
15	Tokyo	77,82	Solid
19	Osaka	76,99	Solid
24	Hong Kong	73,35	Solid
33	Almaty	67,44	Moderately Solid
40	**JAKARTA**	**57,23**	**MODERATELY WEAK**
41	Bangkok	56,71	Moderately Weak
42	Ulaanbaatar	56,58	Moderately Weak
44	Manila	55,81	Moderately Weak
46	Abha	54,25	Moderately Weak
47	Yerevan	53,23	Moderately Weak
51	Kathmandu	46,98	Weak and Very Weak
57	Karachi	37,00	Weak and Very Weak

Based on another research conducted by the Indonesian Planners Association (IAP) in the Indonesia Most Livable City Index for cities in Indonesia, when compared to the surrounding area, Jakarta scored an average level. Most Livable City Index tries to

measure from two aspects, namely the physical (such as infrastructure, infrastructure and spatial planning) and non-physical (such as the level of community participation and economic activity) in order to score the comfort level of the city as a place to settle and work. Jakarta is rated above the cities of Depok and Tangerang, but Jakarta is rateds under the City of South Tangerang which is categorized in Upper tier of the most livable city group. In conclusion, the pace of urbanization is driving cities around Jakarta to help improve the level of service in order to reduce the burden on the City of Jakarta. Including occupancy expenses that Jakarta can no longer fulfill due to the scarcity and high-price of land.

Table 8 Most Livable City Index of Jakarta Greater Area

Source: Indonesia Most Livable City Index Report, 2017

JABODETABEK	MLCI 2017	TIER 2017
DKI Jakarta	62,6	Average
Kota Bogor	63,2	Average
Kota Tangerang	61,1	Bottom
Kota Tangerang Selatan	65,4	Top
Kota Depok	61,8	Bottom

3. Housing Needs in Jakarta Greater Area

According to Jones Lang LaSalle (JLL) Research Report (2018) regarding Jakarta Property Market Review Q4-2108, the availability of apartments in Jakarta is abundant, judging from the completion of several apartment towers in the Jakarta CBD area and apartments around the LRT and MRT projects which are in the marketing phase. The construction of apartments around the transportation corridor is to support the fulfillment of transit-based housing. Meanwhile, according to the Q4 2018 Market Report in Jakarta issued by Colliers International, the conditions for fulfilling occupancy in Jakarta also showed the same outcome. It is estimated that 41,677 units from 79 projects in 2019-2021 will increase the total supply to 21% over the next 3 years to reach 243,495 units. The available stock of apartments in Jakarta will also be dominated by the middle and middle-to-lower classes, with various stimulant policies from the government, it is estimated that the apartment occupancy will be well-maintained.

However, the diversity of people who come or settle in Jakarta as a result is different from one another, such as the diversity of the population's purchasing capability to own a house. Based on 2017 Susenas data analysis, only half of the population of DKI Jakarta (51.67%) owns property, where residents who does not own a home are concentrated in 40% of the poor. This is caused by several factors, in addition to the rate of population urbanization into the capital, limited land availability, high land prices in Jakarta, and wage of Jakarta workers whose growth does not parallel land prices. The percentage of families living in a house owned by another family or individual and does not own another house in the DKI Jakarta province, is highest when compared with other provinces, which is 43.60% (Susenas, 2017). This number is an indication of the backlog or lack of housing for residents of Jakarta. The low quality of settlements in a particular area leads to slums, a problem in the destination cities of urbanization. With such challenges, the only solution

in order for people to have permanent and habitable occupancy is, to provide new habitable housing outside the city of Jakarta.

The challenge of ownership backlogs and uninhabitable homes in Jakarta, is still major. Based on the 2015 data from the Central Statistics Agency, there are 1.276 million Jakarta residents who does not own a home. Residential needs will continue to be a challenge in the future. Estimated by 2020, there will still be a housing deficit with a backlog of 7.63 million and 2.38 million non-habitable homes nationally. Not including the addition of new families to reach 700,000 units per year.

The limited development of housing to meet the housing backlog is due to the scarcity of land and high land prices. The density of land that has been built in cities and the high price of land in urban centers ultimates to the development of settlements that convert land on the outskirts of the city from green areas to settlements, and the limited land to support settlements because it is far from water and electricity services. The average increase in land prices from 2010 to 2014 reached 24.54% in the Jabodetabek region. Map of land prices in Jabodetabek are shown in the following figure, where relatively cheap land prices are in cities around Jakarta. This has led to the development of township development to reduce the occupancy burden in Jakarta.

Figure 2 Land Price Map in Jabodetabek

4. Township Development as an Innovative Solution

At the early stages of the development of Jabodetabek, Indonesia experienced a large economic development with growth in 1995 and 1997 reaching an average of 5.2 percent (Stern, 2003) and even reached 7 percent per year for more than a decade (Hill, 1996). This situation encouraged the development of land on a large scale and became one of the causes for Jakarta to develop into very large metropolitan. (Winarso, 1999; Winarso, 2002; Cybriwsky and Ford, 2001). Large-scale land development or township development, also known as the development of a "new city", united Jakarta with its periphery which became known as Jabodetabek, a very large urban area, or "megacity" (Winarso et al. 2015).

At a time when the Indonesian economy was booming, or in the 10-year period since 1986, large-scale land development has led to 20 new cities in the area of Jabodetabek (Winarso, 1999). As of now, in 2019, according to research conducted by JLL there are 33 new cities that develop large-scale housing. The total area of the new cities now amounts to 50,388 hectares in the Jabodetabek area which is mapped in the table below.

Table 9 New Cities in the Greater Jakarta Area

NO	TOWNSHIP	LOCATION	AREA (Ha)
1	Alam Sutera	Tangerang	700
2	Bintaro Jaya	Bintaro, Tangerang	2.321
3	BSD City	Tangerang Selatan	6.000
4	Citra Garden City	Jakarta	451
5	Citra Grand Cibubur	Cibubur	220
6	Citra Indah City	Bogor	825
7	Citra Maja Raya	Maja	2.600
8	Citra Raya	Tangerang	2.760
9	Citraland Cibubur	Cibubur	200

Source: Analysis, 2019

The development of new cities provides new housing opportunity for people who work or live in Jakarta and the surrounding areas. The approach to the construction of a new city is very strategic in triggering the emergence of new hubs that may potentially distribute the burden of Jakarta in meeting the needs of the community. The new cities were built by the private sector to assist the government in meeting shelter needs. In the figure below, the distribution of the 33 new cities in the Jakarta Greater Area is mapped based on the location and scale of the development. It is seen that, connectivity between the township and the city of Jakarta encourages the development of public transportation infrastructure, such as trains or inter-city buses that pass-through toll roads. Township must also be well planned, both in terms of technical planning, infrastructure and finance and connectivity with its hinterland, Jakarta. With the establishment of an effective new city, it will create a new growth center that can generate collective regional growth. Thus, it can be said that township development is a solution to the challenges of urbanization in the city of Jakarta by distributing the burden with new cities around it.

5. Government and Private Roles in Township Development

5.1. Government Role

The government as the policy-maker, formulate strategic programs and development plan. In urban development, the Indonesian government has compiled the 2015-2045 national urban development policy and strategy (Kebijakan Strategis Pembangunan Perkotaan Nasional/KSPPN) which sets a national urban development vision to realize "Sustainable Cities and Competitiveness for Community Welfare" which are described in the following 6 missions:

1. Increasing equitable development of cities according to their roles and functions in order to reduce inequality between cities, between regions and between villages
2. Speed up the fulfillment of minimum urban service standards based on the typology and characteristics of the city
3. Build decent, safe and comfortable city dwellings, which are environmentally, societally and culturally based
4. Controlling space and urban development activities, by maintaining the capability and capacity of the city environment, as well as being responsive and adaptive to climate change and disasters
5. Build economic activities, government, and urban communities that are productive, creative and innovative, efficient and IT-based
6. Improve the quality of the implementation of urban governance that is transparent, accountable, participatory and professional

The government plays a major role in setting policies, strategies, plans and programs, both in development planning and budgeting or in preparing spatial plans. Plans for the construction of township must be accommodated in spatial plans with structures and patterns that has legal strength so as to provide long term legal certainty. The government must also provide various incentives in the form of easy business processes and permits that are fast, transparent and free of extortion.

In order to achieve the vision and mission and to put the urban development plan into realization, the government is not independently capable due to budget constraints. Therefore, the government budget allocation must be placed on strategic allocations, namely on allocations that will trigger the growth of regional development, and allocate budget for development where the private sector cannot or is not interested for taking part. In this case, the government can play a role in the construction of basic infrastructure such as roads, clean water, electricity and the construction of public facilities such as mass transportation, or in some cases in providing land for the development of the township area which can be cooperated with the private sector.

Due to the limitations of the government in terms of budgeting and technical capabilities, the government must involve urban stakeholders especially those who have access to financing and proven technical capabilities. The main stakeholders that must be involved by the government are the private sector, because the private sector has sufficient

financial resources and technical capabilities that have been tested in the construction of dozens of new cities around the Jakarta area.

5.2. Role of Private Sector

The private sector has access to funding both in the form of company internal capital funds, banking funds and public funds through the stock exchange. The technical capabilities of private developers have also been proven in building township of world-class quality, in which some has received international awards such as Bumi Serpong Damai and Alam Sutera. With these various factors, the private sector is very strategic to become a partner of the government in the construction of new cities.

The private sector has a role as the party that provides the land and create masterplan and siteplan, which must be in aligned with spatial plan set by the government. Furthermore, the private sector also has the role to find and provide funding needs for the development process. After the development funds are available, the private sector will carry out the development process in staging phases in accordance with the planned development staging. Furthermore, the private sector must also build various public facilities and social facilities in accordance with the minimum standards of service facilities. After the new city is built and has been inhabited by residents with various activities in it, the private sector must provide good management of the area in order to create a quality urban environment.

Table 11 Role of Government and Private Sectors in Township Development

Government Role	Private Role
1. Planning Strategic National Policy Planning	1. Land Provision
2. Compiling National-Reguional-Lokal Spatial Planning	2. Creating Masterplan and siteplan
3. Provide incentives; Ease of Business Process, Hasten License and Permits	3. Funding the development
4. Build basic infrastructure needs: Roads, Bridges, Water Supply, Energy Supply	4. Development Process
5. Provide Public Facilities: Public Transportation, Waste Management Facilities etc.	5. Build Public and Social Facilities: Mosques, Green Areas, etc
6. Providing Land (in some partnership scheme)	6. Estate Management

Sumber: Analysis, 2019

5.3. Future Challenges: Public and Private Partnership in Township Development

Township development has been carried out by the private sector in a dominant manner, starting from initial initiatives, ideas, concepts of planning, financing, development and estate management of the township region. The government's role is only as a regulator. Along with the increase of the urbanization and difficult urban challenges, the Indonesian government currently plans to build 10 new cities, where initial initiatives, ideas, concepts of planning, financing, development and estate management are carried out by the

government. This is certainly a challenge and raises a big question, will the government be able to realize the development of new world-class city quality independently?

Based on the experience of private developers over the past 4 decades, building new cities is a long-term project that requires large funds and long-term commitments. Without intending to undermine the government's capability, it doesn't seem appropriate if the government moves independently to build 10 new cities. Synergy and collaboration with the private sector that has the ability, experience and tested is certainly a wiser step. The government can become a regulator, enabler and in certain cases act as a provider of land for the construction of new cities. This public-private partnership can work well by mirroring and learning from previous experiences.

Nowadays, the Indonesian government plans to move capital to a new location which has yet to be determined, although based on various studies, the possibility of an alternative location is the Kalimantan Island, namely in East Kalimantan, Central Kalimantan or South Kalimantan. With an estimated budget requirement of around Rp. 466 trillion (USD 30 Billion), the budget provided by the government is around Rp. 30 trillion. The rest of these budget is realized from the cooperation of the government and the private sector as much as Rp. 340 trillion, and Rp. 95 trillion from the private sector. In this case, the government has stated that it will involve the private sector through the public private partnership scheme and pure private investment scheme. Of course, with a long history of township development experiences around megapolitan Jakarta, experienced private developers can become a strategic partner of the government in building the new capital city of Indonesia.

Case Study / Project

FACTORS INLFUENCING of LAND USE CONFLICTS

IN PATIMBAN SEAPORT INDONESIA

Roni SUSMAN, Thomas WEITH

Abstract

Coastal areas are globally under pressure during the last centuries. It often results in land use conflicts which are affected by the diverse composition of stakeholders and interest as well as lack of governance. Our study from Patimban Indonesia explores the influencing factors of large scale land transformation for seaport development resulting in land use conflicts and options for governance in the future. We realized interviews and standardized survey to investigate drivers of changes and landowners' decision making processes to uncover different dimension of the relationship between land use changes between 2010 and 2018. Additionally, those GIS maps are utilized to identify the physical and spatial changes. We valuate that coastal land management in Northern of Subang shows poor performance of land governance, which undermines or hamper the efforts to create sustainable development, environment, and agriculture. One option for the future could be to enforce a stronger coherence between land use planning and land tenure towards an integrated land governance process. Additionally, it will be necessary to discuss and redefine the role of government in coastal land-use development at all levels, especially to raise the capacity of local government in land management.

Research Paper

The City of the Future

A new paradigm, a new vocabulary

Esther Vlaswinkel, Urban designer MSc and director of SVP; The Netherlands

Abstract

THE CITY IN WHICH EVERYTHING IS CONNECTED TO EVERYTHING

To design the city of the future, we have to stop extrapolating the problems of today. This is why team Stadsvrijheid developed a new conceptual framework, a new paradigm for the future. On the basis of this paradigm, the team argues back to the here and now. This approach requires different ordering principles and new design tools, in short: the development of a completely new vocabulary.

Current ordering principles such as density and functions will no longer be applicable in the future, which will centre on length of residence, production potential and the intricacy of the urban fabric. Combinations of these factors determine the DNA of an area. The team's conceptual framework for the future sketches a new world in which everything is connected to everything; people as well as things. Technology plays an important role in this. In the resulting circular economy, everything is productive.

The test site for this new paradigm was Utrecht's eastern fringe. This promising location allows the interweaving of landscape and city in the context of today's urbanization pressure. It is precisely in the monofunctional and fragmented urban fringes that a new type of urban character can emerge by connecting new developments in the field of mobility and technology.

Anyone who wants the city to be liveable and healthy has to move towards a city in which walking is the norm and therefore away from 'radial thinking' of the traditional city. The outskirts of Utrecht will become gateways to the city or even the Randstad, with the Sciencepark as the global attractor and the Lunetten hub as the global connector.

The team translated the contours of the conceptual framework into ordering principles and balanced these using a 'mixing console'. Important principles are: the intricacy of the urban fabric (everything is connected), travel time (everything is proximate), length of residence (everything takes its own time) and varied production (everything is productive). The mixing console allows an alternative method of organizing areas according to functions or density. A specific mix determines the DNA of a region.

The team devised new design tools to create the city of the future. The 'armature', for example, is a tool that can be used to redefine the current road infrastructure. Development along the Z axis, for example, is based on the principles of urban stratigraphy and builds on the strata of the existing city. This allows densification and the current physical barriers such as the motorways will transform into layered landscapes that will act as hubs connecting future centres.

In 2040, city dwellers travel by foot and motorized transport between cities will be connected collectively or individually. The resulting city is a continuous city for pedestrians that not only allows more density, but in which there is more room for greenery as well. Functions such as

roads and housing are layered, stackable, connectable entities linked to new energy and transport networks. They create a productive and endlessly connected urban landscape.

In this layered city everything, including waste, produces something. Everything is designed to last a certain period of time, for example based on length of residence. In this city, the cost of space is the driving force behind change. This comes with new investment models in which the relationship between interest and involvement play a part.

Team Stadsvrijheid consists of designers and specialists of SVP, OKRA landschapsarchitecten, Cross Architecture, Advier, Thefutureinstitute, Info.nl, BPD and The Missing Link

Keywords

Future city, new vocabulary

1. The Landscape as the Basis for an Intensive and Healthy City

1.0. Situation

The outskirts in the east of Utrecht are fragmented. Office locations, residential neighbourhoods of all kinds and recreational functions typical of urban fringes, such as sports fields and a stadium, determine the atmosphere. In addition, substantial infrastructure bundles such as roads, the new tram line and the railway track cut across the area.

Waterlinieweg, which is part of the Dutch Water Line, traditionally bounds the area to the west and guards the border between city and surrounding landscape. The New Dutch Water Line is of high spatial and cultural-historical value. Utrecht's eastern outskirts contain perfectly beautiful forts and defences, which currently go largely unnoticed. In the years that new construction in the area has been permitted – which it previously was not because of its military significance – some scattered locations have been developed. The ambition is to give the area more cohesion and to link its transformation to the improvement of the existing green structures.

1.1. Spearheads: intensive and inclusive utility value and new mobility systems

Utrecht is growing, the use of the city centre is increasingly intensive and there is growing pressure on its scarce open spaces. Stadsrand Oost's green basis can potentially change from a monofunctional to an intensively used and socially inclusive area that meets the conditions of healthy urbanization. The eastern outskirts of Utrecht can accommodate urban functions and will therefore allow the densifying city some breathing space.

In addition, the quest is on for new mobility systems that are light and adaptable and will improve access to the fragmented area and connect it with the city and the region. The existing infrastructure of car lanes, train tracks and the soon to be opened new Uithof Line are obstacles as well as connections. What will this area look like in the distant future? Is light rail the solution or will the system have to become more and less radially-oriented? And what role can Waterlinieweg play in this development?

1.2. Challenge

The growth of Utrecht and the densification of the existing city create opportunities to transform Oostelijke Stadsrand into a metropolitan living, working and recreational landscape. A well-proportioned landscape design can bring back coherence and make the cultural-historical layers experienceable. The challenge is to combine this with more intensive use, densification and accessibility. How can the city achieve this while maintaining a good spatial, social and economic balance?

Healthy urbanization is the starting point every time. This means the focus is on exercise, well-being and sustainability and on living, employment and education. This calls for a living environment that is designed to actually have positive effects on health and that encourages healthy behaviour.

2 New paradigm, new vocabulary

Figure 1 Test plan 'Stadsvrijheid' (urban freedom): The term stadsvrijheid, which denoted the area outside the city walls in the Middle Ages, today once again denotes space in which there is room for experiment.

To design the city of the future, we have to stop extrapolating the problems of today. This is why team Stadsvrijheid developed a new conceptual framework, a new paradigm for the future. On the basis of this paradigm, the team argues back to the here and now. This approach requires different ordering principles and new design tools, in short: the development of a completely new vocabulary.

Current ordering principles such as density and functions will no longer be applicable in the future, which will centre on length of residence, production potential and the intricacy of the urban fabric. Combinations of these factors determine the DNA of an area. The team developed these ordering principles on a test site.

The team's conceptual framework for the future sketches a new world in which everything is connected to everything; people as well as things. Technology plays an important role in this. In the resulting circular economy, everything is productive.

The test site for this new paradigm was Utrecht's eastern fringe. This promising location allows the interweaving of landscape and city in the context of today's urbanization pressure. It is precisely in the monofunctional and fragmented urban fringes that a new type of urban character can emerge by connecting new developments in the field of mobility and technology.

Figure 2A
Movement is everywhere
Mobility will be a commodity. Design will not take existing forms of infrastructure into account.

Figure 2B
Everything is connected
In addition to people, objects are also part of the network, connected to it and operating independently.

Figure 2C
Everything produces something
In the circular economy, everything produces something. Waste is raw material and health clubs generate energy.

Figure 2D
People's perception of time is layered. We no longer build for 'as long as possible', but for 'long enough'.

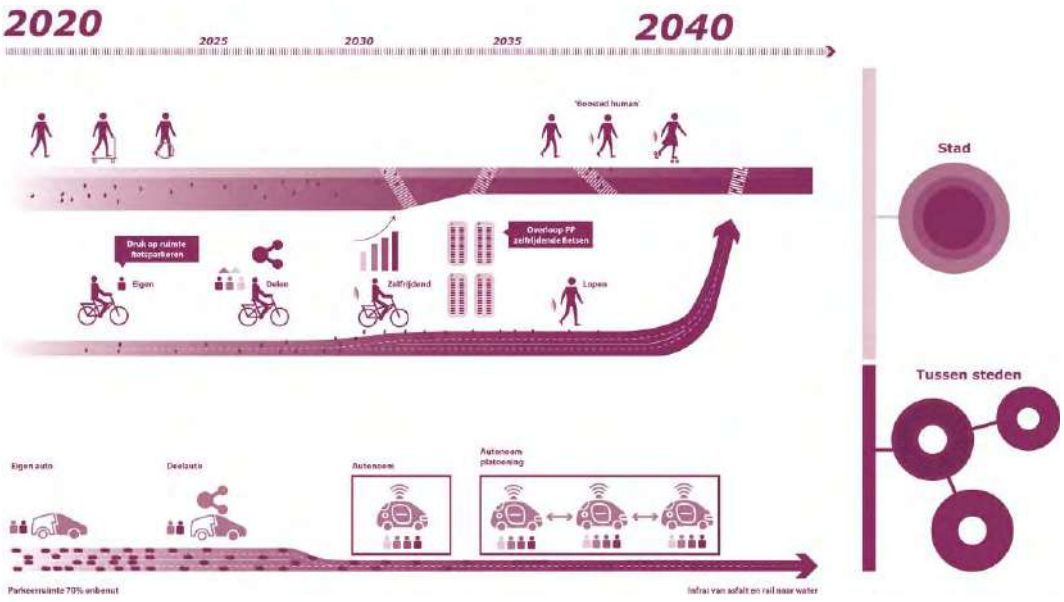

Figure 3 The cost of space is the driving force behind change: human dimensions are the most efficient. By 2040, the test site no longer needs any large-scale transport. The Lunetten and Science Park hubs and the intricate urban fabric ensure that every destination in the area is within walking distance.

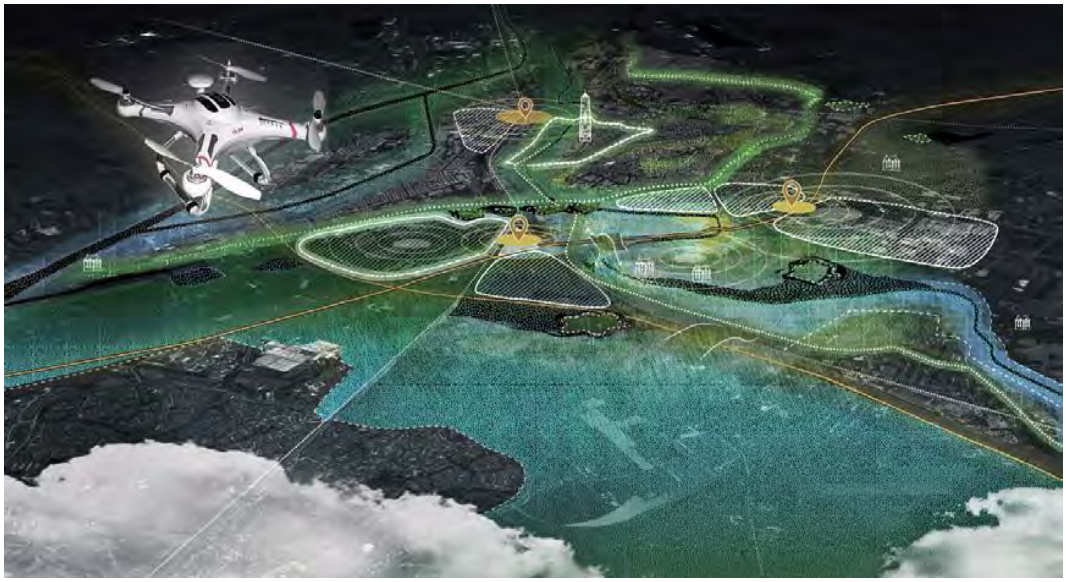

Figure 4 West to east transformation: from back of the city to front of the city (Lunetten, Sciencepark and Kromme Rijn landscape).

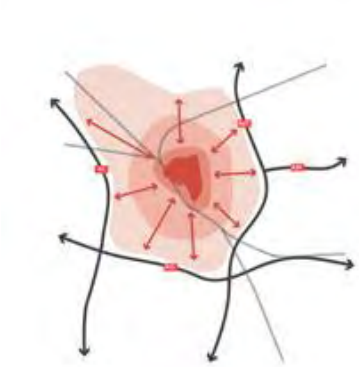

Figure 5A/B/C
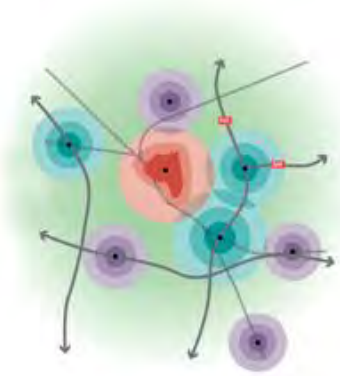
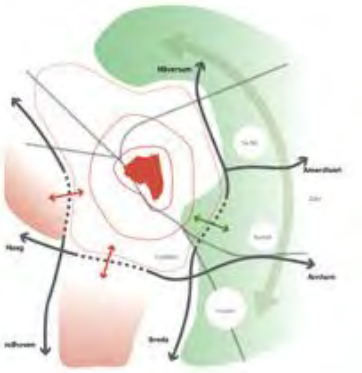
Utrecht today: radial thinking



Utrecht 2040: Complementary centres



Utrecht 2040: #030 integration

2.1 Complementary Centres

Team Stadsvrijheid wants to create a healthy city with a large variety of living environments in which the human dimension is the starting point for every intervention. The team also considers connecting the existing city with its outskirts as an important task. After all, the infrastructure that is intended to ensure accessibility also cuts the city into segments and often creates barriers that stand in the way of good connections.

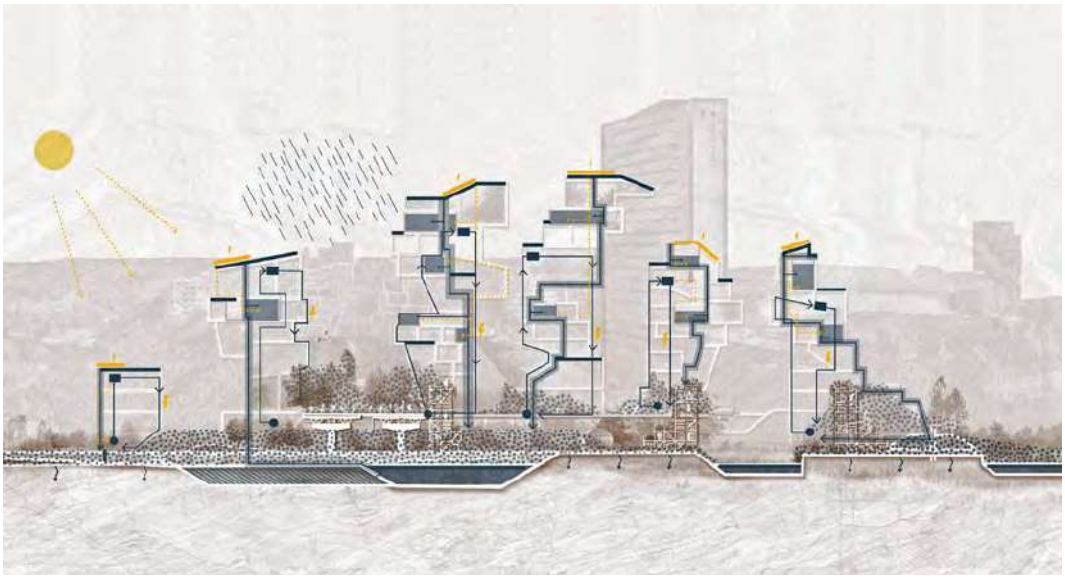


Figure 6 The landscape as a valve that controls the flow of water to the city: 70 per cent of the water in the canal system originates from the Kromme Rijn River. In 2040, the meandering 'water machine' will result in a stronger current, less sedimentation, cleaner water and new ecological connections to the city. Locally, the river will become important as a climate-adaptive production and recreational landscape and as the Arcadian backdrop of the city's new front.

Figure 7A Science Park: 'global attractor'

Figure 7B Lunetten: 'global connector'

Anyone who wants the city to be liveable and healthy has to move towards a city in which walking is the norm and therefore away from 'radial thinking'. By looking at Utrecht as a city with several complementary centres rather than a single centre-oriented city, specific places in the outskirts of Utrecht that can serve as hubs of connections with the region and the rest of the world catch the eye. The outskirts of the city will become gateways to Utrecht or even the Randstad, with the Sciencepark as the global attractor and the Lunetten hub as the global connector, and thus change from the B-side of the city to its A-side.

Figure 8 Transformation Kromhoutkazerne: adaptive campus for 'new arrivals'. Self-built top-up community from locally produced bamboo (light, biobased and adaptable).

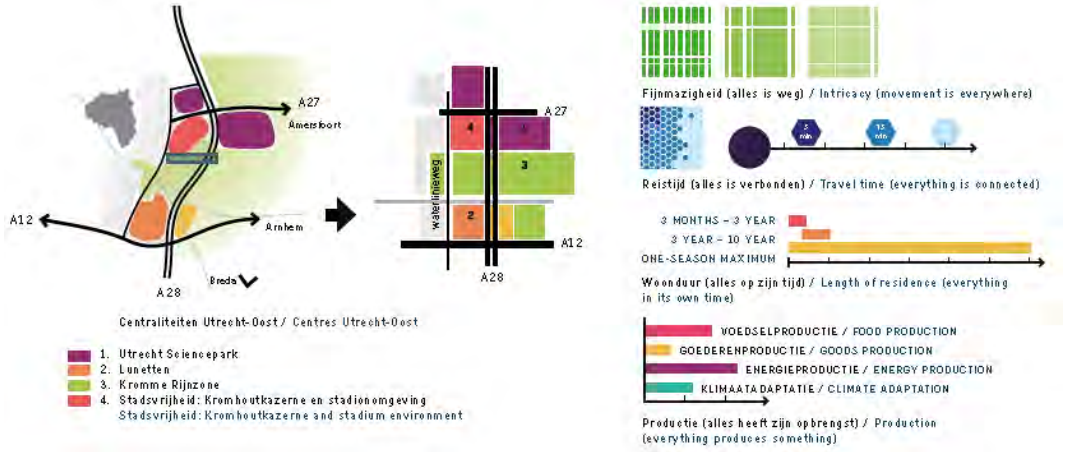

Figure 9

2.2 Area Mixing Console

The team translated the contours of the conceptual framework into ordering principles and balanced these using a 'mixing console'. Important principles are: the intricacy of the urban fabric (everything is connected), travel time (everything is proximate), length of residence (everything takes its own time) and varied production (everything is productive). The mixing console allows an alternative method of organizing areas according to functions or density.

A specific mix determines the DNA of a region. The team developed these principles for different locations on the test site. The Kromme Rijn zone, for example, offers space to green pioneers who live and work in a nature-friendly way. No fixed energy network is provided for them, but rather an autarkic system that matches their nomadic lifestyle. In Utrecht Science Park, a higher density of housing and business activity is appropriate.

Living here means using a service, which will suit the lifestyle of temporary residents such as expats and students.

Figure 10 Transformation stadium environment: the high-density heart of Stadsvrijheid with ground floors at various levels. As the crow flies, the area is 100 per cent wadeable and therefore 100 per cent passable.

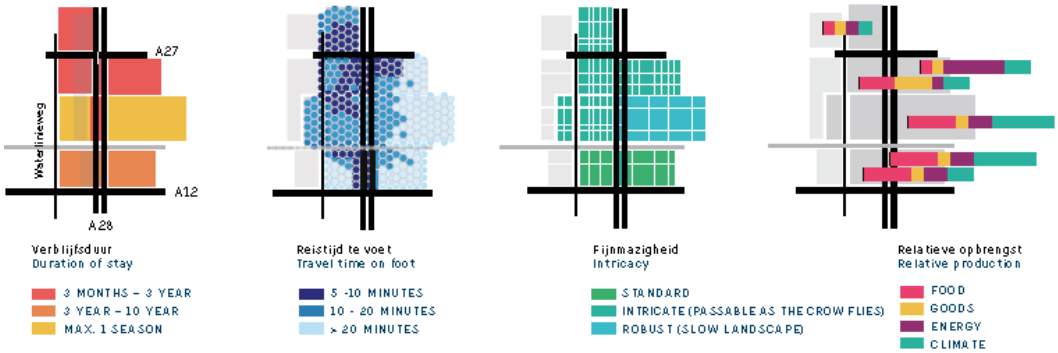

Figure 11 Mixing console for the area (theme maps).

Noun[1] **{ar•ma•ture}** The	*meaning* housing of infrastructure, such as utility bundles, data, energy, waste, goods [2] layered support structure for what has not yet been built [3] carrier of urbanization [4] *origin* arma: equipment [5] *synonym* setting, support structure [6] *example* Armature 27; interurban armature located on former A27 motorway.
Noun **{cen•tra•li•ty}** the	[1] *meaning* source of activity and exchange in urban landscape [2] multifunctional and dense [3] sometimes coincides with mobipoint (see list) [4] *synonym* community.
Noun **{food•board}** the	[1] *meaning* body that promotes the impor tance of circularity [2] local administrative body [3] origin food forest; production based on the ecological food cycle in an area.
Noun **{he•ri•tage deal}** the	[1] *meaning* investment vehicle developed in connection with the nomination of the New Dutch Waterline for the World Heritage List for creative petit projects by local heritage corporations.
Noun **{me•an•der}** the	[1] *meaning* dynamic climate-adaptive landscape [2] *origin* winding course of a river.
Noun **{mobi•point}** the	[1] *meaning* point that links routes with mobility-related service providers [2] where supply and demand is largely determined by market forces [3] social safety and experience are important synonym site.
Noun **{nolli 2.0}** the	[1] *meaning* design principle for the walkable city [2] movement as the crow flies through an intricate network of third places [3] *origin* map that distinguishes between public and private space.
Noun **{turn}** the	[1] *meaning* shif t in economic and spatial focus from west to east in the twenty-first centur y [2] *origin* shif t in power relations.
Verb **{to un•bun•dle}**	[1] *meaning* deconstruction of the transport system: infrastructure of transpor t, mobility objects, people, services based on data, curators, users [2] this leads to the walkable city (see nolli 2.0).
Noun **{ur•ban•stra•ti•gra•phy}** the	[1] *meaning* urban densification by developing via the Z-axis [2] dense construction near armatures [3] physical barriers are removed without compromising on the amount of greenery.
Noun **{Utrecht hash•tag}** the	[1] *meaning* system of main armatures around the city of Utrecht [2] the armatures form the development axes of the city [3] the #hashtag is rooted in the past, and shapes the future [4] carries the development and is the grid along which people reflect [5] *synonym* fence; grid [6] *origin* graphic symbol used on Twit ter to mark keywords in a message; word or sentence prefixed with the # symbol.
Noun **{wa•ter ma•chi•ne}** the	[1] *meaning* landscape system that purifies water and meets the power requirements for the urban system. Improves quality of life.

Figure 12 Vocabulary design tools

2.3 Design Tools

The team devised new design tools to create the city of the future. 'The armature', for example, is a tool that can be used to redefine the current road infrastructure. Development along the Z axis, for example, is based on the principles of urban stratigraphy and builds on the strata of the existing city. This allows densification and the lifting of the physical barriers of Waterlinieweg and the A27 motorway; the landscape can be layered and brought into the city.

The test site shows the possibilities of the new ordering principles. Embracing change and a variety of governance practices can never produce a clear-cut final picture. That is why the team presents an imagined atmosphere that includes the dynamics of gradual development – with tempting vistas that provide insight into the functioning of the city of the future, but that also raise questions.

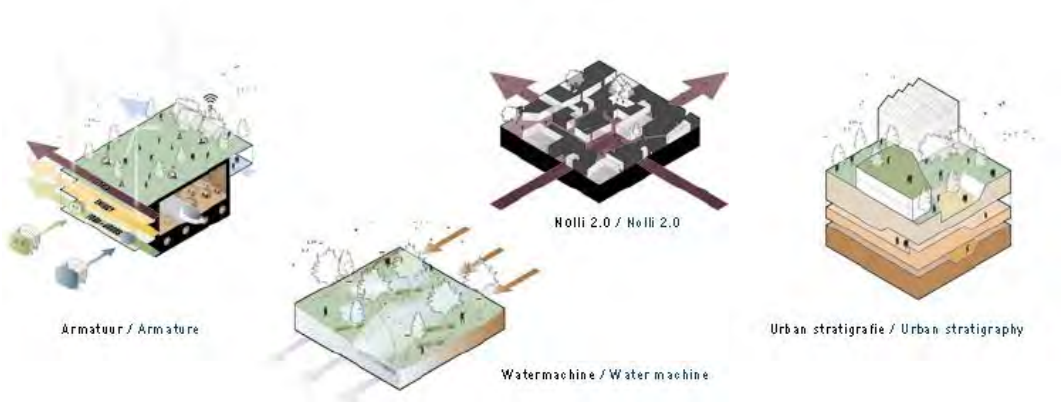

Figure 13

2.4 A continuous city for pedestrians

In 2040, city dwellers travel by foot and motorized transport between cities will be connected collectively or individually. Current barriers such as Waterlinieweg and the A27 motorway are hubs that connect Utrecht's future centres. The resulting city is a continuous city for pedestrians that not only allows more density, but in which there is more room for greenery as well. Functions such as roads and housing are layered, stackable, connectable entities linked to new energy and transport networks. They create a productive and endlessly connected urban landscape.

In this layered city everything, including waste, produces something. Everything is designed to last a certain period of time, for example based on length of residence. In this city, the cost of space is the driving force behind change. This comes with new investment models in which the relationship between interest and involvement play a part. The team distinguishes different models for each housing type. The interests and returns of the one housing type can accrue to a residents' collective, for example; other target groups can decide to use housing services, in which case the return and interest are in the hands of owners and investors.

Research Paper

The Anti-city

Gurgaon and its villages

Soumya S Warrier, School of Planning and Architecture Delhi; India

Abstract

Today is a time of unprecedented growth — of shaping newer and ever changing environments around. Issues and shortcomings of rapid urbanisation offer opportunity grounds for architecture and planning, in this changing maze of activities. The paradigm shifts in the way how people see spaces, and how professionals see the same, are exposing and challenging the architect and urban designer to current harsh realities.

India has been home to the earliest of civilisations and growth. Its intense engagement with the other continents have shaped and reshaped its culture and political ideas. With ginormous populations, extraordinary cultural mixes and rising economies, some of its regions are sites of intense action. This stage of intense fluctuation and turbulence demands reflection on how they have shaped (or are shaping) our relationships, societies and human exchanges. One is also forced to ask questions as to whether the existing knowledge capacities are enough to help manage and intervene these situations. It's time we decoded our development trajectory and identified the fault lines so as to aim for a favourable projected future.

Keywords

Liberalisation, privatisation, service villages, anti-city

1. Introduction

Serpentine flyovers, glazy facades, sky-kissing towers — who knows the history to this 'millennium city' of Gurgaon? For a region that belongs to a country that was home to some of the most urban ancient civilisations as compared with its contemporaries, how is it that the impression of it, left on its rampant modern versions shrank down to a negligible?

The late twentieth century urbanisation that spread (in India) was in complete disconnect to its past centuries (McNeill, 2000). Never had humankind (all over the world) left behind what existed before this much, and never had it impacted such a wide spectrum of both animate and inanimate matter as it did starting from the late 1900's. As patrons kept changing, what the land saw was the rise and fall of cultures and power forces, thereby giving in to dystopia. Liberalisation and globalisation gave birth to 'world cities' (coined by Patrick Geddes in 1915) that brazenly allowed transnational business interests to eat them up. Such 'New York, London and Tokyo models' infected our cities and social styles to change in an uncurbed manner. The new urban landscape has fallen prey to late global capitalism with zero connect to context or people. We are thus in and around *anti-cities* that highlight the differences and not similarities among its lot.

The consumerist trait was effortlessly transferred overseas to a subcontinent that was in thirst for this postmodern drift. One would wonder how such control exertions could ever be so powerful. The backward or the East (with reference to orientalism) is subtly convinced that this is the only best thing that could ever happen to them – through literature, education and media (Gramsci, 1930's). The images of America, Shanghai and Dubai thus haunt our bigger cities – the watered down version of which will soon start hitting the smaller ones. The over emphasis on universalisation of what 'living' or 'habitat' means has gotten us mind blocked, so much so that they shy away from the truth that none of this will make any sense unless grounded in a specific locality. The cultural (il)logic of late capitalism as explained by Fredric (Jameson, 1991) is a kick-starter to the postmodern catastrophe that hit (or will hit) all areas alike.

The 'culture of congestion' (Koolhaas, 1978) engulfed the East almost a century later than it did in the West. Cities, its people and its architecture followed the image of an image – simulacrum[1]. It could be thought of as an era of hyper-reality which took away from the originality or genuineness of a place. In semiotics this stage is considered as an inability of one's conscience to differentiate reality from a simulation of the reality – where one is surrounded wholly by pseudo-reality. There is thus a comfortable existence of the self in a constructed (though temporary) 'new real'. Cities today, have conveniently absorbed this concept for their growth. Nehru's vision for modern India could be read under similar lines; history and environment took a backseat while capital intensive strategies were welcomed with the backing of a large group of deeply patriotic men (Guha, 1995). The planning of the capital city of New Delhi and the dream city of Chandigarh were on-ground realisations of this vision which initiated a new wave of city planning and development in the country. The act of mimicry they followed is clearly evident from how our cities are being viewed since then with a top down approach, blanketed by master plans.

Design and development of many contemporary cities in India are active examples of this phase of liminality[2]; Gurgaon being a perfect case for investigation. The name Gur*gaon* (*gaon* meaning village) with its added note of being the 'millennium city' is a striking contradiction in itself. Its history is splendid and eventful – references in the *Mahabharata;* oldest agrarian settlements in the area; along early important trade routes; base of early British units — all vocabulated contextually through either history, art or architecture.

2. Pre-liberalisation Gurgaon

2.1. Early history

The oldest record of Gurgaon is in Mahabharata (the ancient Hindu mythology), where it is believed to have been an area granted by the eldest Pandava king Yudhishthira to Dronacharya. Around 900 BCE, this area had been under the effective control of Maurya Empire. The area of Gurgaon also formed a part of Harsha's empire in the 7th CE, and then of the Gurjara-Pratiharas. From 763CE to 1156, it was under the Tomara and Chauhan dynasty. In 1192 during the rule of Delhi Sulatanate, people were forced to convert to Islam, creating

[1] A blind imitation of a person or thing; *image of an image*.
[2] The idea of threshold. An in-between mental stage; interstitial space/phase.

years of Hindu-Muslim unrest. During early 1700s the area was under Rajput rule, and in the late 1700s it was conquered by French generals.

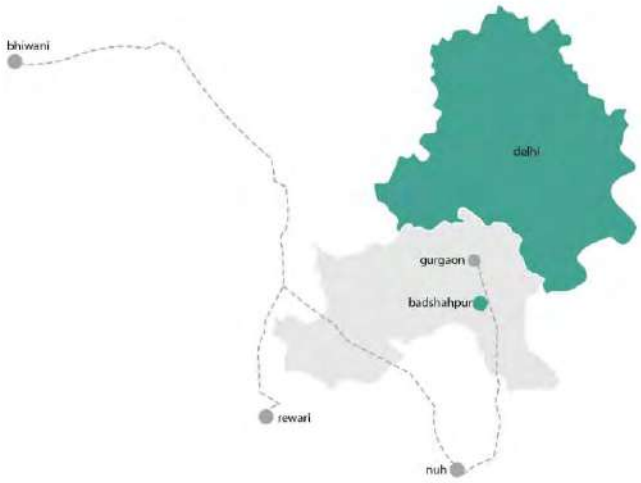

Figure 1 Gurgaon and its surroundings, Source: Author

2.2. The British influence

The proximity of Gurgaon to the imperial capital (Delhi) played a major role in shaping its destiny. In 1803 The East India Company took control over Gurgaon, and in 1816 the town became its administrative headquarters. The feudatory races continued to engage in agriculture while the higher castes were involved in trade or British service.

The 1857 uprising created huge unrest in Gurgaon, due to the constant fights between the Nawabs and the British. There was a considerable loss of life and built, and no steps were taken to develop Gurgaon educationally or economically. After the World War I, the policy of ignorance was slightly modified as the people of the district contributed liberally in men and money for the war.

With the strengthening of Muslim League in 1940, communal tension increased in the following years. Following independence in 1947, the Punjab Province was bifurcated to East Punjab (India) and West Punjab (Pakistan). Members of the minority community on either sides fled for their life in large numbers leaving everything behind.

2.3. Urban rehabilitation

The government distributed land to employ all the displaced farmers, where all of them who owned land or were cultivating it in Pakistan were declared eligible for temporary allotments. Each family was given a plough unit of 10 acres (or 4 hectares). Because of this, despite the shattered economy during the post partition years, agricultural production in the state did not remain low for very long.

With majority of the displaced persons settling in urban areas, the trade and industrial sectors saw a development, initiating an industrial economy in the district.

2.4. Contemporary phase

In 1966 when the state of Haryana was formulated Gurgaon was designated as one of its districts, with an agro-based economy. Planned urban development of Gurgaon started in 1966 with the Urban Estates Department Haryana. 1970s marks the beginning of the city's growth and development journey.

The potential evolutionary prospects of Gurgaon were noted by the authorities during the preparation of the first master plan of Delhi. Gurgaon remained a small farming village while Delhi emerged as the political capital of India.

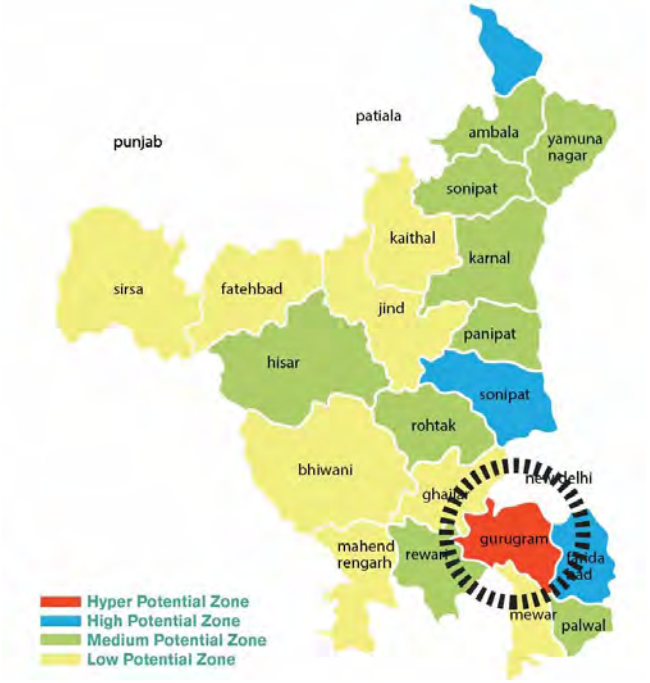

Figure 2 Map of Haryana showing growth potential zones, Source: Government of Haryana, Graphics: Author

In the 1970s the town of Gurgaon expanded initially juxtaposed to the old colonies of Gurgaon. Later, residential and industrial sectors were realised. Gradually the expansion started encroaching upon the agricultural land of the villages surrounding Gurgaon.

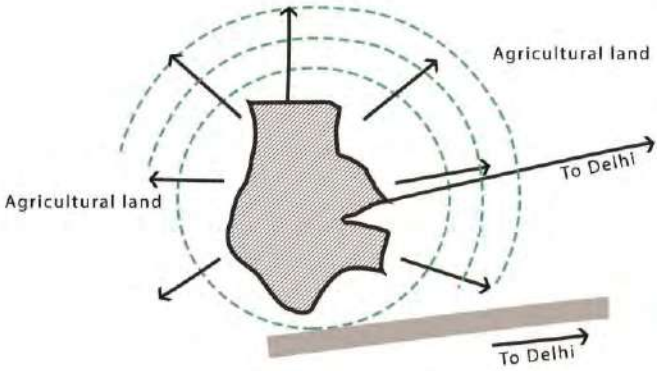

Figure 3 Growth expanding to agricultural lands by early 1970's, Source: Author

With the establishment of HUDA (Haryana Urban Development Authority) the growth and development gained momentum. More villages were acquired and converted to residential sectors in the 1980s. The implementation of Haryana Urban Development Act in 1981 was a gateway to the entry of private developer groups like DLF and Ansals. The coming up of Maruti Suzuki plant in 1983 triggered a new industrial fabric thereby making Gurgaon a priority town in the metropolitan area. These developers transformed the growth trajectory of Gurgaon.

The old colonies and the adjacent sectors located to the right of NH8 were largely built by the government authorities prior to 1990s and these constitute the Old Gurgaon. The areas built to the left of NH8 were built by private developers from 1990 onwards to form New Gurgaon. The small villages that exist till date and have become urbanised in the process of the city's growth spread in both Old and New Gurgaon are the Urban Villages.

3. Post liberalisation Gurgaon

The sectors built after 1990 were largely built by private developers. New Gurgaon experienced a job centre boom in late 1990s which resulted in more people moving into the city. Several multi-national companies like American express, IBM, Microsoft, Infosys, Ericson, Oracle, Bank of America, Nokia, The Coca-Cola Company, and many more chose to locate their offices in Gurgaon during the late 1990s. The sudden demographic changes and cultural changes gave the city a new identity.

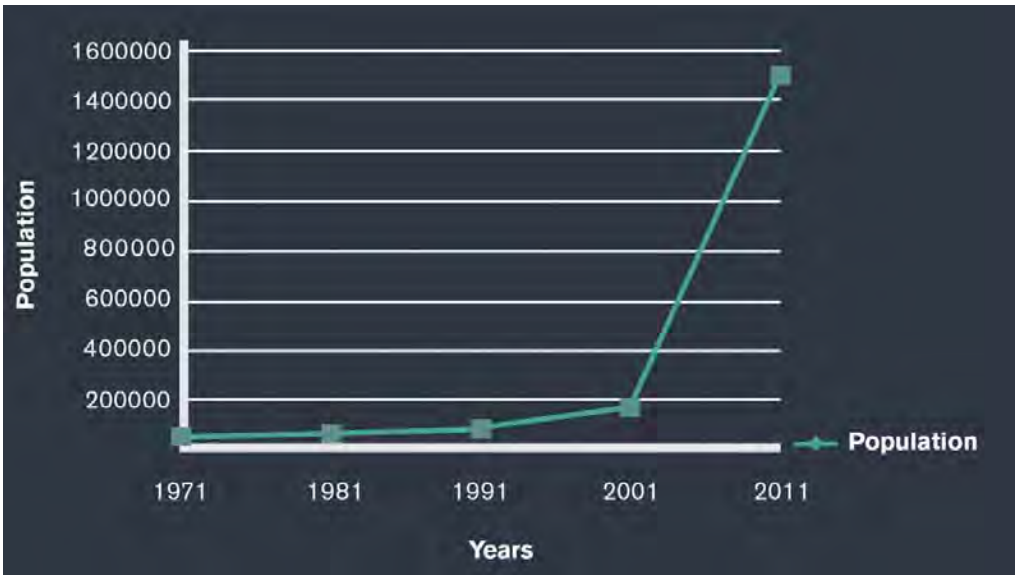

Figure 4 Population influx post liberalisation
Source: Census 2011, Graphics: Author

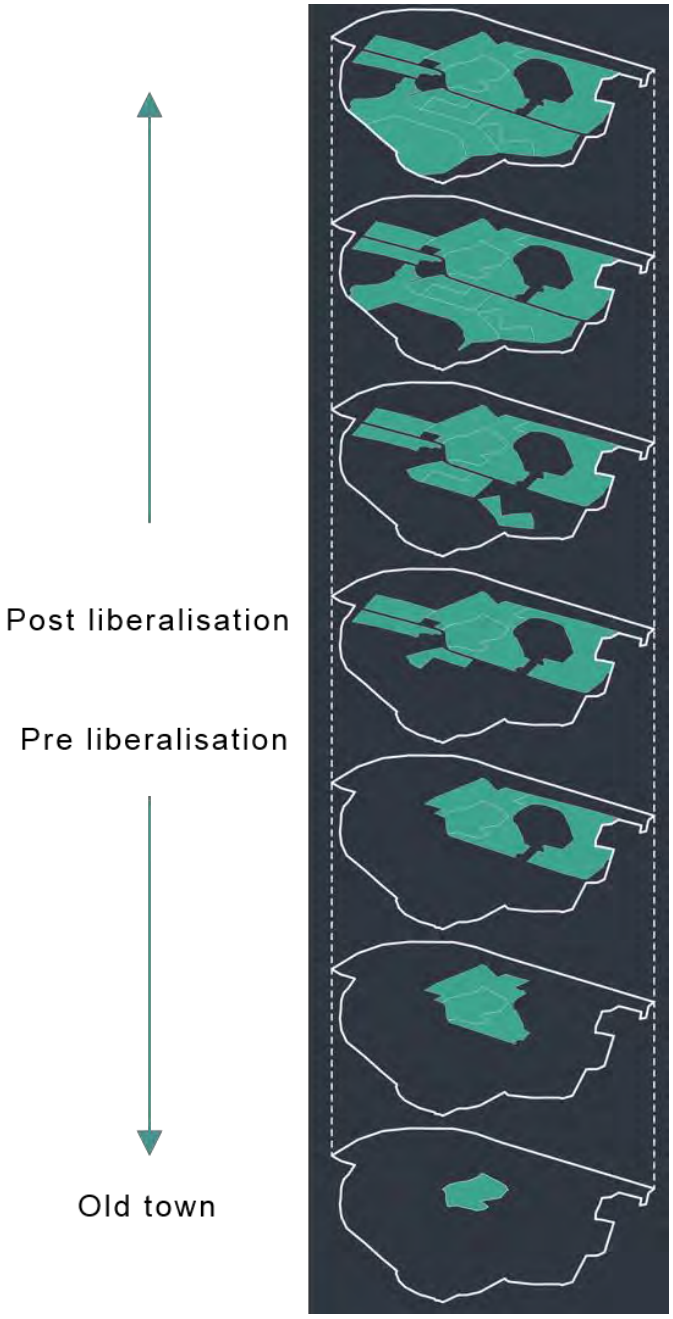

Figure 5 Growth of Gurgaon, Source: www.shodhganga.com, Graphics: Author

Various jurisdictional changes were also seen in the period of 1991-2001, where many rural villages merged to form municipal corporations or tehsils in and around Gurgaon. The 2018 September *Hindustan Times* newspaper reported an incident where 46 villages in Gurgaon decided not to pay property tax to the Municipal Corporation of Gurgaon (MCG). The villagers claimed that the land was rightfully owned by them and were transferred illegally to MCG. It was also mentioned that since the inception of MCG in 2008, all their lands were brought under the jurisdiction of MCG, all local panchayats were disbanded, and plot lands worth crores of rupees were transferred illegally.

4. Urban village/city?

Post-independence, Gurgaon – along with other cities/towns in and around Delhi – (unfortunately) got absorbed into the 'new plan wave for future cities'. Migration (both in and out) created unsettling environments for a while but the emphasis, as priorly planned, was more on the urban agenda of creating a new face to the city. The 1970's saw Gurgaon falling on the track of accelerated urban growth and development – enormous population influx post liberalisation caused the growth rates to shoot up in the 1990's. Gurgaon was no more a village, but a rapidly growing city.

Land values and land ownerships juggled in the years that followed – owing to sectorisation and privatisation of land. There was a rapid flow of people into the sectors of Gurgaon, small and big – from villages (to the former) and *New* Delhi (to the latter). The 'surburbia' concept that was tested (and which had failed) in the West, was thus tweaked and appropriated to Gurgaon where the new city was advertised as a better liveable one as compared to the congested city of New Delhi. The way in which Gurgaon started pulling in people like a hungry magnet is a marker to a subtle new trend of city growth dominated by private players – a trend that was borrowed from the West and which was comparatively new in India. The spatial ideas though remained the same (as the West) with zero considerations to site history/context. Sector plans proudly adorned the plots where once (probably) stood native agrarian community neighbourhoods which were probably sent away to some inner villages nearby. Many villages in Gurgaon saw shifts in their built landscapes due to this.

4.1. Villages of Gurgaon

The villages Jharsa, Sukhrali and Sarhol were studied for an understanding of the trends (Source: Author, Ashin Thomas, Venna Sri Hari Kanth – M.UD Batch 2019, SPA Delhi), which revealed a fascinating picture of the past and present conditions of these villages.

The 1848 East India company map of Delhi district shows the prominence of a place called *Jharsuh* along the trade route between Delhi and Ajmer. *Jharsuh* and *Sookralee* are amongst the oldest settlements of Gurgaon district. As evident from the map, *Jharsuh*, or modern day

Jharsa village was more important than Gurgaon for trading and agriculture. As the traders always preferred routes which were safe from natural obstacles such as mountains, deserts and deep forests, and which had easy access to supply centres, Jharsa was a much convenient option for being a halt point.

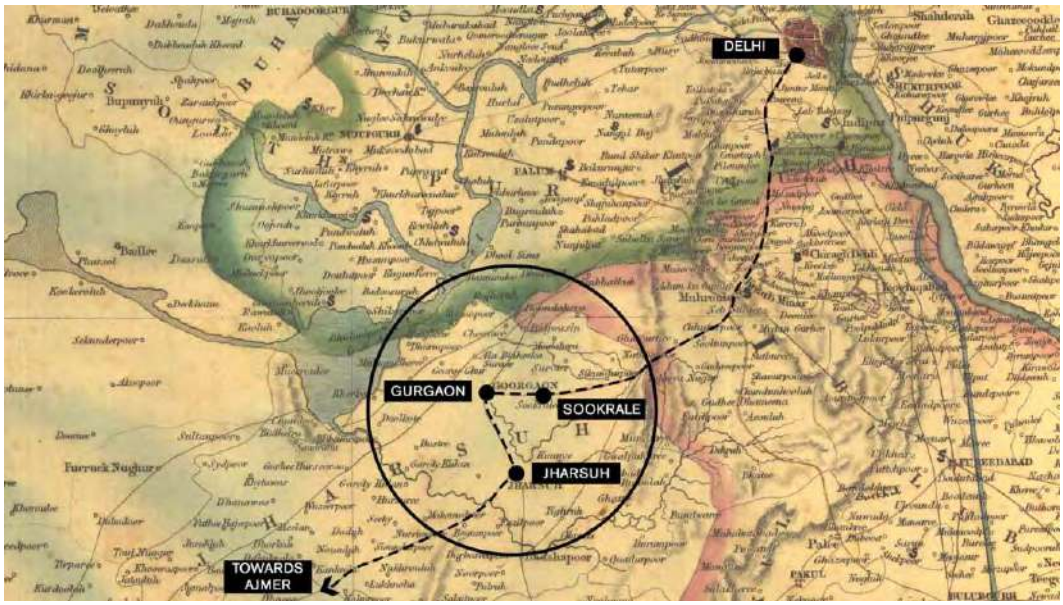

Figure 7 The 1848 East India Company map

What blew away the economy of Jharsa was the partition of India in 1945 when the trading communities migrated to the Muslim dominant country of Pakistan. The village witnessed influx and outflow of people leading to changes in settlement patterns and housing typologies. Changes in the community profile and occupation were observed as the new immigrants were either absorbed in the field of agriculture or were accommodated in the newer markets formed near the core city area. There was thus a major shift from agriculture to service sector during the 1960s. When HUDA acquired land in the core city, people started moving to outer villages like Jharsa, Sukhrali, Patel Nagar, Dhankot and the like. As the city had more and more to offer to its people and outsiders, many more in-migrated to the city and surrounding villages.

Sectored developments appeared around Jharsa, especially in 2004 when the Cyber Park was opened and the construction of Medicity Hospital was initiated. It was approached by workers and migrants, which marked the beginning of a new real estate market. The village witnessed the emergence of a new service/working class population. With Medicity hospital and Cyber Park fully operational by 2008, huge migrant population from other cities and states approached Jharsa for cheap and affordable housing. This led to construction of newer floors and buildings to appropriate the village to absorb the migrant working class. By 2014 this trend became stronger and the peripheries of the village began to change to include newer requirements of the working population. Jharsa today is primarily populated by these migrant workers with small groups of natives also living in it.

The work flow patterns were observed to find out that majority of the people who lived in Jharsa were migrant labour groups (of various economic classes) who worked in the nearby city areas.

Figure 8 Live-work patterns, Source: Author

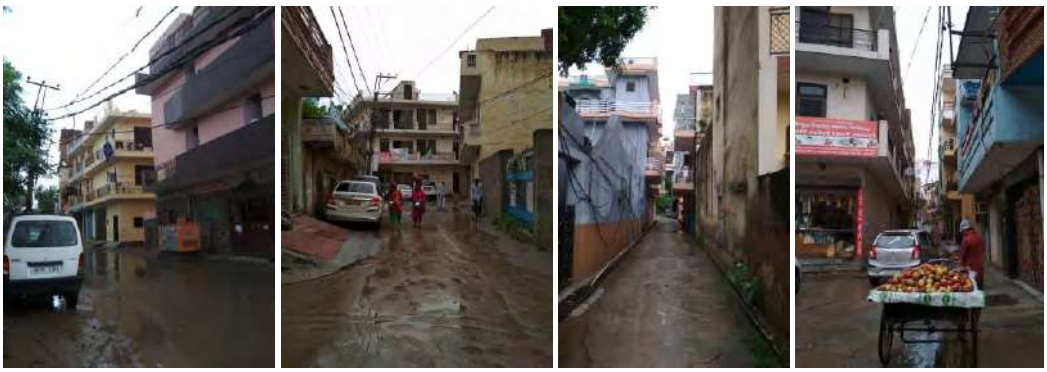
The present community fabric of Jharsa could be understood as follows:

Residents of old village Jharsa	Property owners in Jharsa village	Workers of Cyber Park	Workers of Medicity	Other residents
• They constitute the native population of Jharsa village • People are involved in cattle rearing and such local jobs • Significant presence of unemployed population • Isolated from the outside city as there are no major job/other connections to and from the village	• Major property owners are Jats – they have strong community feeling and dominance in the area – they rent out their floors for the working population • Presence of Pandits and muslims who also rent out their homes to the various working population there • No new buying/selling of property – high demand for land and space – great opportunity for rental business	• Stay on rental basis in Jharsa – cheaper rents and convenient accessibility • Do not have a sense of belonging to the place – they see Jharsa as merely a place of residence • No community unions or associations	• Doctors and nurses of Medicity form a significant population of Jharsa due to easy accessibility and cheap rents • Dominant presence of Malayali and Afghani population – small stores and restaurants that cater to them present in the area • Start of cultural identification to the place – the Syro Malabar Prayer centre in Jharsa	• The population working in other areas of Gurgaon find cheap accommodation in Jharsa • No significantly visible cultural associations to the place

Figure 9 Community fabric of Jharsa, Source: Author

The fact that Jharsa is rapidly becoming home to more of migrants and less of natives is thus very evident. The question that rises is, if this trend continues, what would be the identity of Jharsa tomorrow when the identity of it today bears no relation to its past?

Images from the inside of Jharsa village



Images from the periphery of Jharsa village

The villages Sukhrali and Sarhol were also studied, and the comparison presents striking similarities in the present character of these 3 villages.

Attribute	Urban Village		
	Jharsa	Sukhrali	Sarhol
Place of residence	• Most prominent attribute • Huge rental business run by Jat communities that accommodate the service and working population • Mix of cultures and ethnicities	• Most prominent attribute • Natives have appropriated their houses to accommodate the rental floors • Huge student and working population – proximity to cyber city • Mix of cultures and ethnicities	• Lesser native resident population and dominance of service class population – trend of natives moving to the sectors for better facilities • Mix of cultures and ethnicities
Commercial space	• No major commercial magnets – therefore does not entertain outside population	• Main roads are lined with small to medium scale commercial stores and eateries – entertains both resident and outside population (to a small extent)	• Most prominent attribute • Earlier ground floor residences converted into small shops – on rental basis • Entertains outside population due to its commercial nature
Cultural node	• Living population has little cultural association to the place • Resident population unaware of the history of the place • No major festivals or procession routes in the village – culturally passive zone	• People display no significant cultural association to the place • Resident population unaware of the history of the place	• Lack of cultural prominence due to lesser residing population
Industrial area	• No major industries in the village and therefore do not provide any job/service opportunities to the outsiders	• No major industries – though small scale industrial outlets are present along the main roads – does not entertain any significant outside population	• Industries in close vicinity – entertains huge service class population
Institutional area	• Medicity in close vicinity – provides job for various working classes	• Minor management institutes in close vicinity – entertains student population	• No major institutions in close vicinity

4.2. Emergence of a new village type?

It is interesting to observe how the growth of Gurgaon into a millennium city has given way to a new trend of development of *service villages* around it.

Cities normally grow outward from the inner (historic) core forming a nucleus type of development. In most cases, the core remains intact with high historic prominence manifested through its architecture (and/or function). The cities of Old Delhi and New Delhi are the nearest examples to this. *Service villages* on the other hand follow a different growth pattern. These (urban) villages are generally the ones that surround huge magnet cities. The edges of these villages are approached by magnets that induce a gradual ripple of inward transformation in them. This inward growth is found to eat up the inner core thereby completely transforming the village into a new type bearing no relations to its past.

Figure 11 Service villages: understanding the anit-growth, Source: Author

All of the villages studied here, though have their respective history and evolution patterns, however today fall perfectly into the category of such **service villages** that could be identified with a common equation. The lack of connections they have with their past identities, and the similarities in their current profiles and growth trajectories presents us with a plausible future where each of these villages could be replaced in space and context with any other, and it wouldn't make much of a difference. These 'cities of non-cityness' further strengthens the argument that our cities today are traversing a path of *anti-growth*.

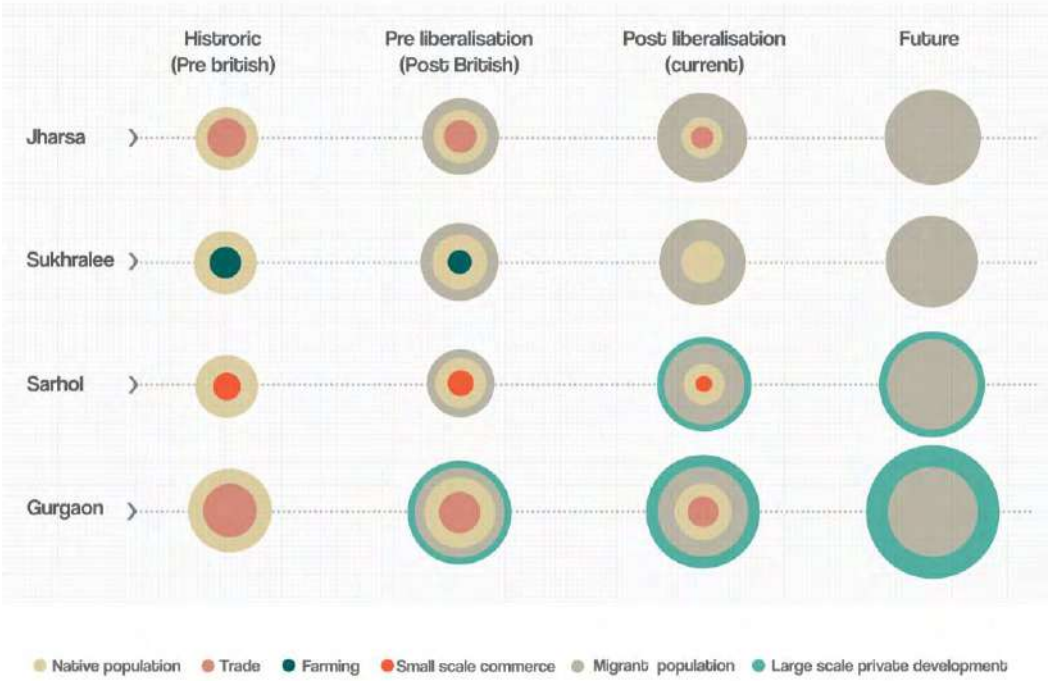

Figure 12 Comparison of villages, Source: Author

Thus, what one sees here is the rise of an era of capitalist prone, privately planned *anti-cities* that serve a select few. Transformations have in every step, challenged the urban landscape – unfortunately in no good way – and have embraced and lived up to the concept of delirium yet again; of places, cultures and people too. The focus lies on a much larger agenda – of the so called 'growth' and 'development' that gravitates around the nucleus of a small yet powerful group. In no time, Gurgaon has become this monstrosity that engulfed anything related to context, spitting out replicas of the US - Dubai - Shanghai models. The origin and growth of service villages is the perfect example as to how the surroundings of megacities have also adapted to better suit this new model of development, thereby becoming replicas of one another. The hyperactivity of Gurgaon (and other cities of the kind) may tend to a state of rupture or redundancy in near future.

5. Conclusion

The story of Gurgaon traced through its migrants, presents one with the layered history of the city. Of religious infusions and strong trade routes, of British Raj and changing community profiles, of transforming sectors and shifting loci of urban centres — this land has been one with constant flow of activity flux. With neo liberal policies lined up for the country, and the state propagating a new wave of growth and development, one however is left with the question of 'what from the past was left behind in the run?' A new phase to the city, or an interstice of uncertainty – one is pushed into a state of indecisiveness to judge the newness that Gurgaon and its surroundings is today.

The developments in Gurgaon post the millennial year have been disturbingly absurd as they in no way relate to the history, architecture or urban form of the old city or its villages. The

engulfment by the private was so fast that one is unable to evaluate the way in which the villages around it have changed. These transformations have added a new layer to the 'urban fabric' of these so called 'urban villages'. Today, being in Gurgaon means something. The picture that an outsider has of the city is of flashy building facades, sky-high flyovers and high end living. The fabric – both built and social – has changed and is in a constant phase of experimentation and exploration. The outsider is no longer an outsider, neither is a villager any more a villager; both have access to something that previously they have not had, which brings them to a common platform under the large umbrella of the new global city that Gurgaon is today. The cosmopolitanism that the shifts have brought to these villages is worth mentioning; whether it is or not by choice is however a point of further discussion and debate.

The transforming neighbourhoods due to accelerated urbanisation in Chiang Mai (Thailand), the historical urban patterns and socio-cultural identities challenged by development pressures in Ho Chi Minh (Vietnam), the contingent socio-urban reforms giving way to gentrification in Philippines — are all indicators to the emergence of such privately planned cities all over the world. (The Southeast Asia Neighborhoods Network)

The seduction of this colonial language could be escaped only through agency[3] or autonomy. The approach should primarily be bottom up – using the lessons from ground reality rather than from constructed imagery. Urbanism and architecture – like art and cinema – should engagingly explore the idea of subjectivity[4] and self-empowerment. Concepts like local area planning (LAP) which directly communicate with the context and people should be extended to the master planning bodies of all areas. UDRI, a Mumbai-focused organisation has all of its members from Mumbai who know the city well; organisations like these could be studied to develop similar context-specific groups in other cities. COSTFORD, a non-profit voluntary organisation set up in 1984 by Center for Developmental Studies in Kerala, works with alternative design philosophies and materials developed by Laurie Baker. With the involvement of The Department of Science and Technology and The Department of Rural Development of the Government of India, The Department of Local Self Government of the Government of Kerala, Housing and Urban Development Corporation (HUDCO), and numerous experienced and young professionals, COSTFORD has over the years worked on remarkable rural development projects and schemes at both the Centre and the State. Turning 50 this year, the Aurovillian thought of an alternative, universal town to realise human unity, was an experimental step towards autonomy. One could learn from these narratives. Our profession needs to re-invent itself to cultivate meaningful and efficient patronage for now and the future. One should be able to address his city and its people, and should be able to wade his way out of social inequity and corporate fascism.

Is the projected future of redundancy of such cities and villages a fact; or a mere perception, too adamant to accept the new base layer these cities have become for newer divergent layers to be added on and grow forward? Nevertheless, it's high time we withdraw ourselves from layering the incompatibilities of environment and growth that create toxi**cities**.

[3] Ability to act or perform an action; the facility to do in a political scenario.

[4] Subjectivity or the idea of self; as explained by French philosopher René Descartes - "I think therefore I am". The concept could also be linked to Marxist way of how to construct individuals or how to be, as opposed to capitalist hegemony of domination by consent.

Case Study / Project

Just Schwerin

Balanced urban-rural development?

Thomas WEITH, Meike FIENITZ

Abstract

The study uses the case of the German city Schwerin and its surroundings to analyse current challenges, conflicts and approaches to solutions regarding an integrative urban-rural development. The focus is on the question in how far solutions for conflicts between city, surroundings, and rural areas can be just. Additionally, the project discusses how regional justice can be defined in the context of spatial and landscape development, and how it can be implemented in practice. This approach promises to generate new solutions for balanced urban-rural development because it recognizes that land use systems and land use governance are strongly influenced by values and norms (Seidl et al. 2012, Davy 2012). Yet up to now a broader discussion about theoretical approaches and conceptual consequences in land use contexts is missing. Important discourses reflect the ethical dimension of justice, especially about environmental justice and spatial justice (e.g. Basta 2016, Edwards/Reid/Hunter 2015). In order to create applicable solutions, the project uses an approach which from the very beginning brings together research and practice. Thanks to transdisciplinary collaboration, the different actors and their perspectives are included early on in the development and testing of solutions for land use conflicts. Thus the case study of the Schwerin region will encourages regions to discuss interrelations and to engage in questions regarding regional justice.

Case Study Paper

Planning Practice in Areas Beyond Megacities under the Rural Revitalisation Strategy in China

Case Study of the New Jijiadun Village

--A Concept of "Co-Creation Community for Rural Life"

Xiaoyi Wen, Shanghai Tongji Urban Planning & Design Institute CO.,LTD.; CHINA

Ye Liu, Shanghai Tongji Urban Planning & Design Institute CO.,LTD.,; CHINA

Abstract

Under the global trends of urbanisation, rural development has posed a global challenge. As the Chinese government has continued to take invested in its rural areas, the Chinese urban and regional planners have also been presented with a series of questions: How to avoid the withering of rural communities due to urbanisation? How to build rural brands and form a new focus? How to maximize the utilisation of resources and regenerate the "hollow" villages? How to create the new ecosystem and change the rural outlook?

Based on the theories indicated in the books by Piro and Ganser (2016) and Scott, et al. (2019) regarding the rural community planning, this paper uses a qualitative approach by conducting a case study of the new Jijiadun Village, describing an emerging pattern of rural life in areas around Shanghai, under the background of the Chinese Rural Revitalisation Strategy. With reference to the theories, the paper establishes the concept of "Co-Creation Community for Rural Life (乡村生活共创集群)", which refers to a new type of rural community formed by rural life enthusiasts and investors in an existing village, integrating multiple dimensions like rural homestay industry, cultural business, catering industry, organic agriculture, and family activities based on a platform built, planned and operated by an operating company.

Particularly, the paper explains how the Chinese planners have created the impetus for the rural industrial development based on the rural homestay industry. And it focuses on how these planners have broken the boundaries between the urban and rural areas, taking the city dwellers back to the rural and natural life while bringing vitality to the rural areas, which means to build a new path to rural innovation and urbanisation equilibrium with Chinese characteristics. Furthermore, combined with the authors' practical experience in the field of rural planning, the paper shares the models and approaches available for rural regeneration, which are applicable to rural areas and/or urban fringe seeking innovative development beyond megacities.

Keywords

Rural Revitalisation, Rural Community, Development Model, Urban-rural Rebalance

1. Background

With the development of industrialization and urbanization in China, the rural population is constantly shifting to cities, and the rural land is constantly swallowed up by cities. As the carrier of China's five thousand years of agricultural civilization, rural areas cannot catch up with China's modern development. As the carrier of traditional civilization, rural areas will fall into ruin in the process of urbanization, which is a foreseeable outcome.

As of 2017, the number of villages in China was about 2.45 million, while in 2000 there were about 3.6 million, which means a decrease by nearly 1.15 million in merely 17 years. About 185 natural villages are disappearing each day. By the end of 2018, China's urbanization rate reached 59.58 %, and China has entered a stage of integrated urban and rural development. On the one hand, rural culture is withering, and "hollow villages" keep appearing. In the meantime, the population surge has brought more stressors to human society, such as urban air pollution and living cost, making the urban living environment increasingly worse. How to revitalize the countryside, motivate people to return to the countryside, and relieve the pressure of the city, has presented a universal challenge.

In September 2018, the Chinese government released the "Strategic Plan for Rural Revitalization (2018-2022)", which indicated that "the rural area is a complex of natural, social, and economic features, involving multiple functions such as producing, living, as well as ecology and culture, which interacts and co-exists with the urban area, to constitute a main space for human activities together". The proposal of this strategy puts forward the requirements of implementing the rural revitalization strategy, particularly for the planning managers, practitioners and planners throughout the country, and clarifies the direction and focus of rural revitalization in China in the future.

Prior to this, the Chinese planners and cultural tourism companies had already gone deep into the rural area. In the past few decades, through rural design and construction practices, they have sought ways and methods of rural revitalization. These successful practices and cases have then been integrated into rural revitalization. Under the background of such times, it will provide a reference for the rural areas in need of development in the future.

2. Observation: *From Minshuku Design to Rural Revitalization*

From the historical perspective, the urban-rural relations have been constantly changing with the development of modern civilization. Having gone through the stages of opposition, balance and integration, the ideal urban-rural relationship should be the integration with each other, namely, the urbanization of the rural area and the ruralisation of the urban area. The cultural penetration that occurs between the rural and the urban areas can bring the two even closer. Driven by this, rural tourism developed around the metropolis has experienced rapid growth. As these tourists come and go, the urban trends, lifestyles and public resources are gradually brought to the rural areas. In this sense, rural tourism has presented an important opportunity to promote the coordinated development of urban-rural relations.

2.1. Moganshan Program

The keen planners took the lead in investing in the rural life. In 2001, they created an ideal minshuku in a beautiful countryside in the Moganshan area of Zhejiang, China. On the basis of the existing empty houses and old buildings in the local communities, their program has managed not to destroy the original village structure and created a comfortable rural community with low-density buildings. After creating Minshuku (homestay or guesthouse) brands such as the Lost Villa and Yuanshe (Fig. 1-2), the planners have set up the Minshuku Alliance and launched the “Moganshan program”. More designers, artists, cultural scholars, and green life advocates have begun to take part in the program which has gathered a variety of themes and formats during the process. They worked together to renovate the abandoned rural public buildings in Moganshan and include more significant functions such as cultural display and art parks, rural education and training, catering facilities, and art hotels, to create China's first cultural marketplace, the “Yucun1932”, which aimed to rebuild the rural areas (Fig. 3-6). Since its launch, this innovative cultural marketplace has been attracting tourists and culture enthusiasts from major cities in the Yangtze River Delta as well as other regions of China. This program has become a symbol and benchmark in the field of cultural creation and the Minshuku or guesthouse industry in rural China; moreover, it has practically facilitated the interactions between the rural and urban areas, creating a sense of belonging for both rural and urban populations.

2.2. Songtsam Model

Along the Dian-Zang line (Yunnan-Tibet line) in China, there has been an innovative tourism model, namely, the "hotels+tourism" model by the Songtsam Hotel, which integrate varied themed hotels into the tourist spots. In 2000, Pema Dorje, a TV producer, established the Songtsam Hotel after he left Beijing and returned to his hometown, a rural region in Tibet. Since then, he introduced a modern model of hospitality operations, designing and creating more comfortable hotels based on the traditional Tibetan buildings in the rural Tibet. In the past ten years, dozens of Tibetan-style hotels have been created along the the Yunnan-Tibet line (Fig. 7). Geographically, each hotel is connected to the fields, canyons, snow mountains, lakes and forests on the Tibetan Plateau (Fig. 8-9); Culturally, each of them is connected to Tibetan temples, villages, arts and crafts, as well as the local cuisine. These hotels can be set as separate tourist destinations; or they can be integrated into a travel loop.

Songtsam will continue to build more hotels along the Dian-Zang line, known as the world's most beautiful road. It intends to rebuild the "the Ancient Tea Horse Road", and form a world-class tourist route. The Songtsam Series Hotels have not only attracted more tourists to come to the rural Tibet, but also put a focus on maintaining the local cultures and traditions by recruiting local employees. Trip Advisor has ranked Songtsam as the top 25 hotels in China for nine consecutive years. The attraction of cultural tourism comes from the culture itself, and the rural revitalisation will be enabled with the cultural revitalisation in the rural areas.

Fig. 7 The map of Songtsam Yunnan-Tibet line, https://www.songtsam.com/

Fig. 8 Songtsam in Tacheng, Tibet , https://www.songtsam.com/

Fig. 9 Songtsam in Shangri-la, Yunnan , https://www.songtsam.com/

The success of the Moganshan program is due to the professional sense of the planners; and the success of the Songtsam model cannot be separated from its respect for culture. What is common is that they both have initiated urban-rural interactions and introduced the urban civilization and industrialization into the rural areas. While recreating the rural life, the rural spirit will also relieve the increasing pressure of the urban areas. They put forward the concept of rural ecological circle and promotes a model integrating production, life and business that can be a virtuous circle and create value.

3. **Experience:** *"Co-Creation Community for Rural Life (乡村生活共创集群)"*

Rural tourism is changing because of the involvement of cultural creation and guesthouse development. Specifically, rural tourism has been shifting its focus from traveling to vacationing, featured with scale development, ecological environment protection, emerging business mode and rural construction. However, these forms of business are fragmented and scattered. So the question is how to integrate them as a whole and present a replicable model of rural revitalisation.

In February 2017, the Chinese government released the concept of "ecological pastoral complex", which can be expressed by a formula, namely: "agricultural science and technology + agricultural production + agricultural tourism + agricultural culture". The

ecological pastoral complex includes three industrial sectors of agriculture, cultural tourism and real estate.

Based on the successful experience of the Moganshan program and the support of national policies, the XBAND Group (xband.club) has been trying to explore new ways of rural cultural tourism development. As an operator of rural pastoral complex, it has tried to renovate the traditional villages in rural or suburban areas where the residents have mostly migrated to the urban areas, by developing the boutique homestay clusters that are well equipped with facilities like amusement park or playground for children, coffee shops, restaurants, handicraft workshops, outdoor sports, specialized retail stores. In the meantime, the surrounding environments like farmlands, forests and waters are undisturbed while developing these vacation destinations in the suburbs to serve tourists from the urban areas. Such an idyllic complex project usually covers an area of several hundred acres and has a business area of 5,000 to 50,000 square meters. It is positioned as a Co-Creation Community for Rural Life (乡村生活共创集群), also known as the “ideal village”.

3.1. Project Overview

As the first practice of the “ideal village”, the Jijiadun Village has the outstanding geographic advantages with convenient transportation since it is east to Shanghai, the most famous international metropolis in China, and west to Suzhou, the famous historic and cultural city. As the first “ideal village” practice place, Jijiadun Village has convenient transportation and obvious location advantages. It is east to the international metropolis Shanghai and west to the historical and cultural city of Suzhou. It is a scarce resource due to its connection with Shanghai, since the transportation from Jijiadun to Shanghai takes less than one hour (Fig 10). The Jijiadun Village has taken a typical pattern of Jiangnan Water Township, with abundant natural resources and tourism resources (Fig. 11-12).

The Jijiadun Administrative Village covers an area of 1.7 square kilometres and consists of two natural villages. To be specific, there are 142 houses in the Jijiadun Natural Village, with a construction land area of 5.7 hectares. Since most of the residents in the village moved to towns and cities, the village was nearly empty. The government has relocated the remaining households at the end of 2014 upon their consent, and the land of the village has been state-owned. Instead of adopting the traditional approach of returning farmland to the forestry, the local government decided to develop the village with limited capital by collectively using the land, focusing on cultural tourism and attracting people to the village, so as to revitalise the village and the neighbouring areas.

Fig. 10 The Location Map of Jijiadun Village

Fig. 11 The Micro-location Map of Jijiadun Village

Fig. 12 Aerial view of Jijiadun Village, Xband.club

3.2. Project Planning

As for the "Planning of Jijiadun New Rural Life Project in Jinxi, Kunshan", at the level of overall planning, it has integrated the existing conditions and the regional resources, to maintain the existing water township pattern and pastoral landscape as well as present the unique local features. According to the plan, the Jijiadun Village will be the core area, around

which there are eight functional areas, including: the rural industrial demonstration area, the sightseeing agriculture demonstration area, the theme ecological park, the residential area, the Zhangnan Featured Village and the ecological agriculture demonstration area (Fig. 13).

residential area, the Zhangnan Featured village and the Eco agriculture demonstration area. The local government undertakes the infrastructure construction of the surrounding supporting sections and core areas, and the township accompanying cultural brigade conducts overall planning and design, project investment, investment construction and operation management for the core area (Jijiadun Village). The local government is responsible for the construction of supporting infrastructure in the core area as well as the surrounding functional areas, while the XBAND Group is responsible for the overall design and planning of the core area (namely the Jijiadun Village), attracting businesses and investment for the project, as well as operations management.

The project has adopted an innovative model that consists of entering with scattered capital, development of rural complex, and reconstruction of the cluster community. It tries to integrate and reuse the collective assets and resources in the rural area; in the meanwhile, it also tries to integrate the abundant social resources, absorbs the intellectuals and technologies from the urban areas. Based on the capability in planning and development, the professional operations management, and the diverse financing channels, the project aims to realize the coordination of investment, construction, and operations.

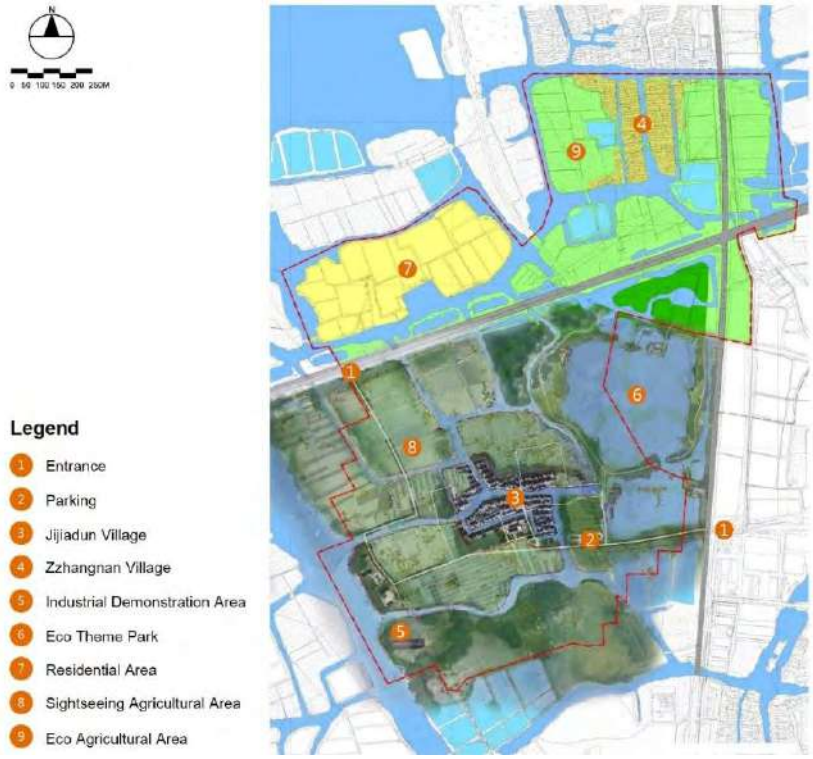

Fig. 13 Master Plan of Jijiadun Village, Planning of Jijiadun New Rural Life Project in Jinxi, Kunshan

In the core area (Jijiadun Village), through the analysis and calculation of the current situation, 121 households were retained on the basis of the 142 houses, and the other 21 households were returned for agricultural land. The planned construction land area is 4.92 hectares (Fig. 14-15).

The planning has comprehensively evaluated the houses retained in the core area, and make overall arrangements according to the needs of the construction stage and the development needs of the resident business. The houses that basically meet the development needs of the layout are reserved, while structural reinforcement and decoration are planned as needed. For houses that do not meet the needs, renovations will be carried out within the scope of their original house sites.

Fig. 14 Homestead Utilization Analysis Diagram, Planning of Jijiadun New Rural Life *Project in* Jinxi, Kunshan

Fig. 15 Core Area Plan of Jijiadun Village, Planning of Jijiadun New Rural Life Project in Jinxi, Kunshan

3.3. Business Model

An innovative model, namely the "1+X" cultural and rural model of the Jijiadun Co-Creation Community (Fig. 16) has been developed:

1: Taking the business of the hotel as the core, it has integrated varied functions such as the cultural business, themed restaurants, leisure experience, organic agriculture and other functions of cultural tourism, so as to form a complete cluster of cultural tourism.

X: It stands for a specific theme related to the rural cultural tourism, such as education and training, exhibitions, art performances, etc.

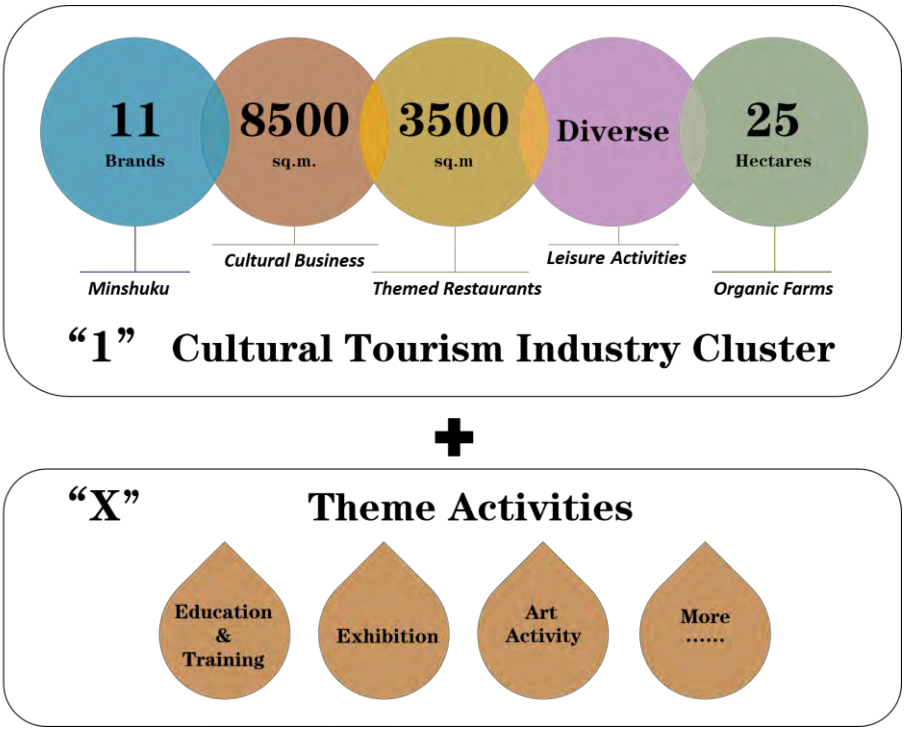

Fig. 16 Model Canvas of the Jijiadun Co-Creation Community

On the basis of revitalizing the rural collective stock assets, this model introduces the cultural tourism of diverse features to redevelop the Jijiadun Village and reuse its resources, so as to improve the living environments and infrastructure in the rural area, which would again attract and guide the local residents to return and invest themselves into the construction and operations management of the rural tourism. At the same time, the project can upgrade the rural tourism industry from the three basic stages of agritainment (rural entertainment), sightseeing tour and family trip; the upgraded rural tourism is also known as the rural tourism 4.0, namely, the Co-Creation Community for Rural Life. Further, the project has a purpose of attracting attention to the rural areas and attracting people to return, which tries to facilitate those aware of the new rural lifestyle concept to invest in the rural areas, and enrich the operations of the Co-Creation Community for Rural Life, ultimately revitalise the rural areas.

3.4. Development Status

At present, the first phase of Jijiadun Village has been completed and has operated 7 branded homestays with 180 rooms in total. Successively, it has attracted the entrance of varied businesses, such as pottery, woodworking, handmade ships, café, restaurants and natural farms. In the village (Fig. 17), there have been a series of themed activities successfully held, such as the Rural Life Festival, the Field Music Festival, the Parent-Child Summer Camp, and the Water Market, which have attracted abundant new villages from Shanghai and its surrounding areas.

With the continuous improvement of the infrastructure and the continuous construction of the village, the Jijiadun Co-Creation Community is expected to have a maximum flow of 3,000 people per day after the completion of the overall development, including 500 hotel guests. Generally, the annual number of tourists is expected to achieve 300,000。

As part of the exploration in rural revitalisation, it has made adequate achievement. The XBAND Group regards the Co-Creation Community for Rural Life as the ideal village, which has been promoted in many rural areas in China as a replicable, promotable and sustainable rural development mode.

4. Conclusion Rural Revitalisation Outlook

From the Moganshan Program to the Jijiadun Co-Creation Community for Rural Life, the emerging industrial and business modes like Minshuku, rural tourism, cultural creation and others have blurred the boundary between the rural and urban areas. The urban and rural lifestyles and cultures have integrated with each other, which are not limited by their

geographical features. The exploration of the emerging modes will influence and inspire the planning for the rural revitalisation in the future. The planning for rural areas should not be limited to traditional landscaping, but take more perspectives, to focus on the local environments and conditions. According to the practices and cases demonstrated above, there are several recommendations for rural revitalisation.

1) Cultural Reconstruction and Rural-Urban Integration

Focus on culture and explore the distinctive features of the local area, to maintain the strengths and overcome the weaknesses. Establish the cultural creation platform, to attract external talents and young labourers to return to the rural areas and form their new rural cultures. Facilitate interactions and bonds between the original residents and new incomers as well as the integration between the urban and rural lifestyles, so as to gradually shorten the distance between the urban and rural areas.

2) Spatial Planning with Rural and Pastoral Landscape Maintained

The uniqueness of a rural area from its spatial dimension and arrangement carries the humanity and memory of the local rural life. The planning should abandon the external biases and respect the originality of each rural area. On the basis of the unique rural and pastoral landscape of a specific rural area, it is recommended to use low-density buildings to maintain the intimacy and affinity of the rural area, and create a rural community of ecological vitality.

3) Resources Integration and Modular Development

Integrate internal and external resources and establish the industrial platform of rural recreation to motivate the development of the tertiary industry and promote the overall value of the rural lands. Meanwhile, the rural areas can facilitate modular development of the rural cultural tourism, to rapidly revitalise the rural areas with the well-developed operation modes and customer groups.

4) Planning Oriented, and Multi-party Coordination

Use planning as a means of regulation, to comprehensively integrate the industries and establish feasible models of rural development featured with scientific layout and orderly construction, as well as optimized rural environments. Establish an interactive mechanism that involves the government, enterprises, planners and local residents, using the quality platform and advanced concepts from the external parties to satisfy the local needs and guide the local development with characteristic industries.

Abstract

China's urban and rural development has entered a new stage of comprehensive transformation. The advent of the era of metropolitan development and the strategy of Rural Revitalization are two important national strategic backgrounds of this study. As the highest urbanization rate in Southern Jiangsu, rural and urban development needs synchronous resonance. Rural areas, as an important role in the integration of the Yangtze River Delta and the development of Shanghai Metropolitan Area, play an important role in regional cohesion and complementary functions, and are an important part in the overall construction of the metropolitan area. Jinxi Town is located in the southern end of Jiangsu Province, bordering Qingpu District of Shanghai, and between Suzhou and Shanghai. In ancient China, Jinxi was a traditional town of fish and rice and water culture. During the period of reform and opening-up, Jinxi worked closely with surrounding cities to create a brilliant chapter of "Sunan Model" and "Kunshan Model". In the new stage of development, Jinxi Town shoulders the heavy responsibility of more ecological functions and reduction of construction land indicators. It is not only more responsible for ensuring food production safety and protecting ecological functions, but also more demanding for rural revitalization. It is also more urgent to study its development path and strategy. Firstly, this paper takes Jinxi's contemporary mission as the starting point, secondly, through the analysis of Jinxi's function orientation, population, industry and space, and then puts forward the general strategic requirements of Rural Revitalization according to these four aspects. Thirdly, it demonstrates several different types of villages in Jinxi town, respectively. The cases of upgrading agriculture, industrial integration and development, demonstration of rural community and industrial retreat to build Jinxi Town to revitalize villages in the countryside. Finally, through the follow-up revision and improvement of planning formulation, to help the effective implementation of Jinxi Town's Rural Revitalization strategic planning.

Through this study on the Rural Revitalization of Jinxi Town, on the one hand, it comprehensively implements the national deployment and the task of Jiangsu as a benchmark; on the other hand, it earnestly follows the law of rural self-development, and in the theoretical category of regional economy, it is based on the development of metropolitan area and the background of Rural Revitalization era, with Chinese characteristics, Shanghai. The road of Rural Revitalization in metropolitan area. At the same time, this paper expects to provide ideas and

methods for the compilation of strategic planning for Rural Revitalization in metropolitan areas.

Keywords

rural revitalization, Shanghai metropolitan area, Kunshan Jinxi

1. Basic overview

Jinxi is in the Core Hinterland of Yangtze River Delta Metropolitan Circle——Shanghai Metropolitan Circle, arounding dian Shanhu Strategic Cooperative Zone.As an important role in the integration development of the Yangtze River Delta and the development of Shanghai Metropolitan Area, rural areas play an important role in linking up and complementing each other's functions. They are also an important part in promoting the overall construction of the Metropolitan Area.

Therefore, on the basis of clarifying the future development direction of Jinxi, how to strengthen the regional interaction and connection with the metropolitan area and strengthen the integration of urban and rural areas is of great significance for activating the vitality of the countryside, promoting the realization of the goal of eliminating urban-rural dualization in the metropolitan area, and how to take the step of Jinxi rural revitalization.

Figure 1: Location Map of Jinxi Town

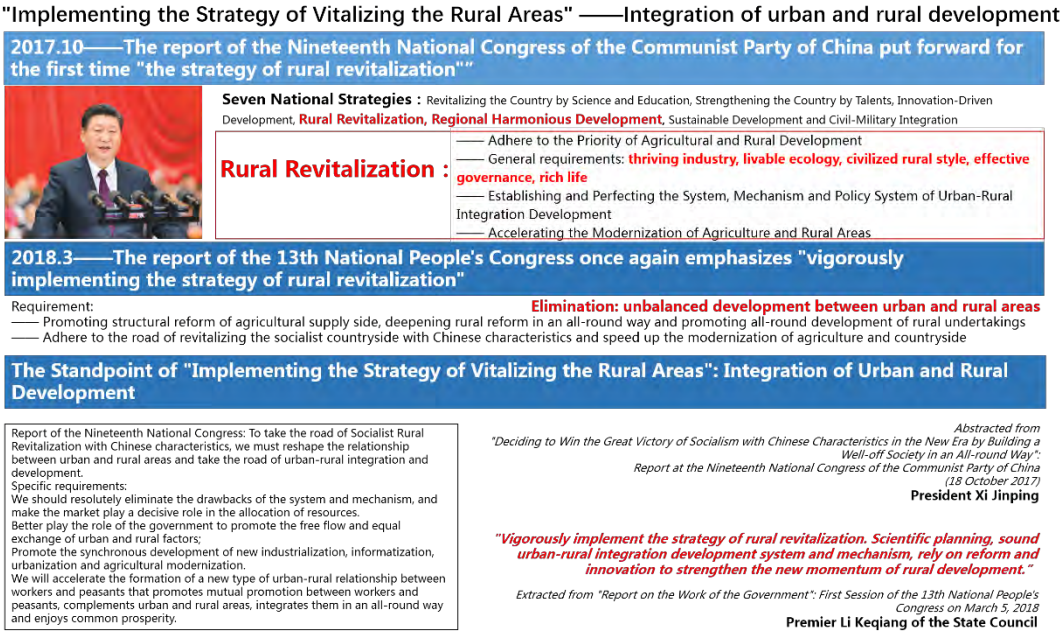

Figure 2: Overall requirements of national strategy

2. Mission

2.1. Historical Review

Jinxi Town is located in Kunshan City, between Shanghai and Suzhou, belonging Jiangsu Province. Jinxi Town has a total area of 90.69 square kilometers. It has Unique Humanistic Landscape, and be famous of Folk Museums. When we talk about the word”canal”, then we think about The most biggest and greatest Canal in China. The China’s earliest national space strategy : It is (the Beijing-Hangzhou Grand Canal) ,as much important as the Great Wall.

In the Spring and Autumn Period, the State of Wu dug a canal from Yangzhou to Huai'an, Later on, the canal had been successively restored and expanded in several dynasties to the existing Beijing-Hangzhou Grand Canal. At that time, the southern part of the Yangtze River was the economic center of the empire, with the most abundant sources of wealth and food. One of the purposes of the construction of the Grand Canal is to transfer food and wealth from the south of the Yangtze River to the political center in the north of China, to provide economic support and food supply. The reason for choosing canal transportation is that it costed less and saved more time than land transportation. This project takes many years and it worded. Because of Jinxi is close to Chenghu Lake and has abundant rainfall and water resources, People worked hard and kept digging, the nature small lakes had been dug into lardge ones ,in Local language which called ”Dang”. and people dug canal to their homes, which called”bang”, so they used family names plus “bang” as villages’names. Such as zhujia bang , gujiabang, These village names are still in use today, until now, jinxi also Retains the typical " bridge, water, house” of the traditional Jiangnan water village style.

The canal created Jinxi: High-quality ecological background, traditional land of fish and rice: fertile land fit for farming. So in the past, In the National Land Planning of the Beijing-Hangzhou Grand Canal, Jinxi thrives in response to water. The most important responsibility
