From the perspective of equity, this kind of differentiated spatial agglomeration means that the opportunities for accessing the resources of the elderly nursing institutions in different regions are different. The elderly in the low-value clusters have unfair spatial access to the services resources of the elderly nursing institutions.

It can be seen that as of 2017, from the perspective of demand, there is still a certain gap in the realization of the spatial distribution of the resources of Shanghai's elderly nursing institutions. From the point of view of population distribution, the high-accessible street-town unit carries a relatively reasonable number of elderly people, but from the perspective of spatial distribution, this difference is gradually increasing, which means low-reachability gathering area. The elderly population within the group bears more inequity in the services of the aged care institutions.

Relative to the description of the phenomenon itself, the local Moran's I calculation clearly defines the range of high-aggregation and low-aggregation areas with different search radius options. At present, the service of Shanghai's elderly nursing institutions is relatively fair in the distribution of people, but the spatial flatness is particularly significant. With the increase of the search radius, the suburban elderly space can obtain more resources for the aged institutions, but the elderly in the central city is difficult to achieve the same effect.

4.2. The development of the equity caused by the location: study in elderly nursing institutions from Shanghai

From a development perspective, the emergence of spatial phenomena in cities is associated with specific historical periods, especially for public services. In urban development environments, there is a dynamic match between the growth of the total and the demand population. Relationships, diachronic comparisons help to help planners grasp the changes in the matching relationship between public service facilities and the demanding population during the construction process, and lay the foundation for further layout optimization in the future.

By comparing the equity of the spatial layout of the Shanghai elderly nursing institutions in d0=18000 meters in 2000, 2010 and 2014, the data of the population and elderly nursing institutions at the same time were matched to reflect the equity of Shanghai's elderly nursing institutions in different periods. Development.

From the perspective of the accessibility development in different periods (Figure.6), in 2000, the spatial differentiation of Shanghai's accessibility has begun to appear. The accessibility of the elderly nursing institutions has gradually changed from the central city to the suburbs. In terms of total volume, from 2000 to 2017, the accessibility of the elderly nursing institutions in Shanghai is increasing, and the total number of elderly nursing institutions in the high-accessibility range is increasing (Figure.7).

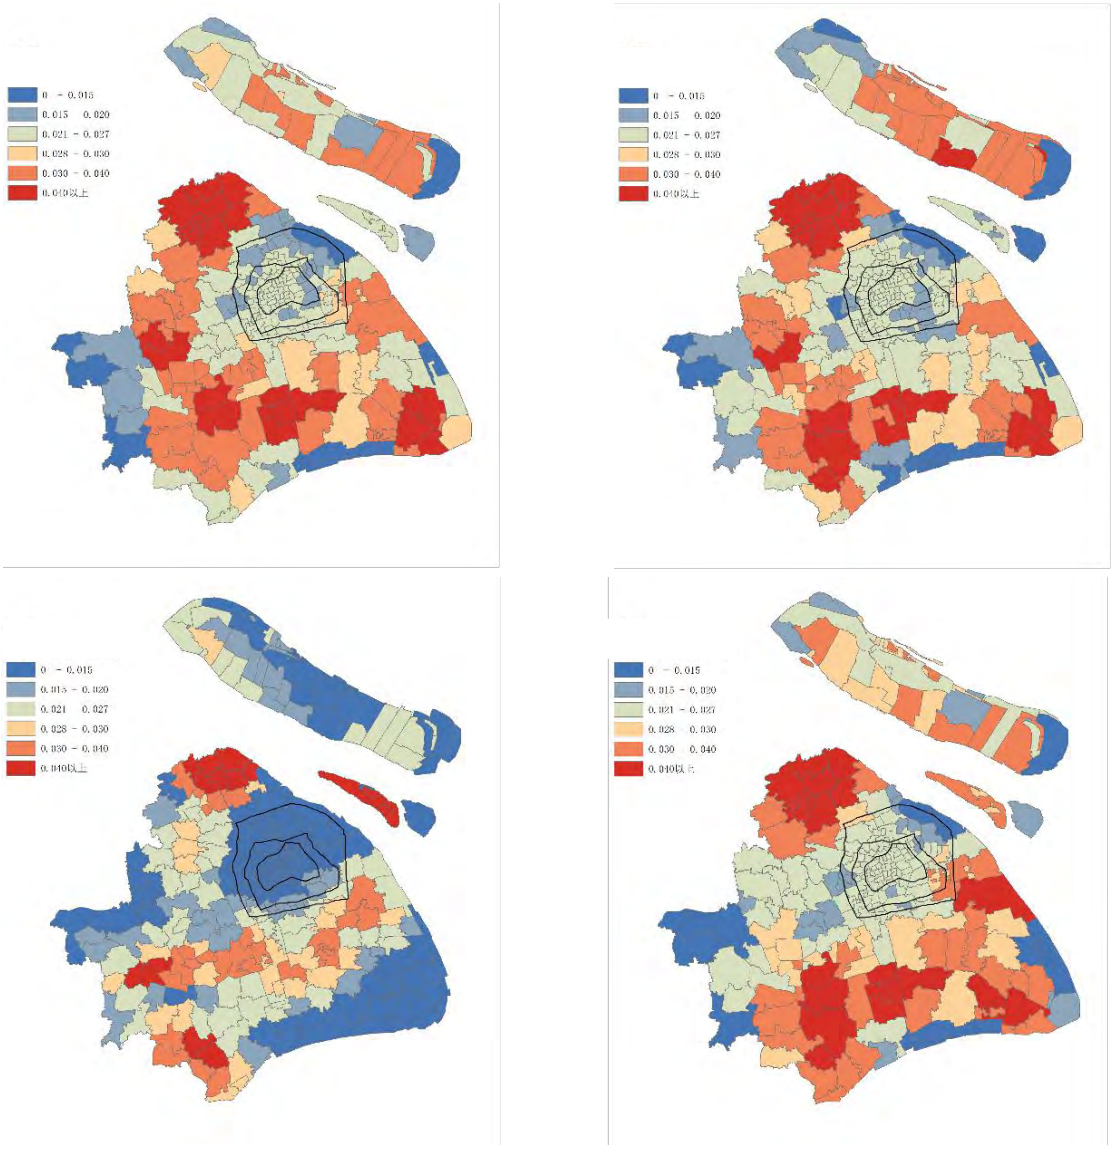

Figure 6 t=2000 Shanghai elderly nursing institutions' Accessibility (Top left), t=2010 Shanghai elderly nursing institutions' Accessibility (Top right) ,t=2014 Shanghai elderly nursing institutions' accessibility (bottom left) t=2017 Shanghai elderly nursing institutions' Accessibility (bottom right)

Accessibility can only represent the existence of inequity from the phenomenon . The result is the relative magnitude of population and resources, and it's difficult to describe the specific inequity in general. Therefore, Gini coefficient and Lorenz curve are used to analyze the degree of equity about the different service provided by the elderly nursing institutions, which is caused by the location, among the elderly (Figure.6). Although the distribution of accessibility between different research years showed a similar trend, from the perspective of the equity of the distribution of service population (Figure.3), Judging from the Gini coefficient of accessibility of Shanghai's elderly nursing institutions, in 2000, the Gini coefficient of the accessibility of different intervals in Shanghai reached 0.43. In the "big gap" interval, the number of elderly people in high-accessible streets is too low, and the inequity of population distribution is significant, but since 2010, this situation has improved.

The Gini coefficient of accessibility distribution gradually returns to the normal interval, which indicates that the coupling between the growth of the resources of the elderly nursing institutions and the changes of the distribution of the elderly is gradually increasing in recent years, and the limited supply of resources has achieved the role of promoting the equity of the distribution of the population.

d0=18000 meters	2000	2010	2014
Gini Coefficient	0.43	0.21	0.26
Lorenz curve			global Moran's I	I=0.68, Z=27.4, p-value: 0.001	I=0.61, Z=15.7, p-value: 0.001	I=0.65, Z=16.3, p-value: 0.001
Global Moran's I scatter plot			
Figure7 Comparison of the degree of equity with different years

Different from the improvement of the equity of the population distribution, in recent years, the improvement of the equity of the spatial distribution of the elderly nursing institutions has been minimal. The global Moran's I (Figure.7) is at a significant interval at each time ($p<0.001$, $Z>2.56$), and both are positive, indicating that at any time, at 18,000 search radius, Shanghai's elderly nursing institutions are reachable. The sexual distributions all show spatial positive correlation, the similarity units of the similarity show agglomeration in space, and the overall effect of agglomeration is similar, indicating that the spatial distribution of the accessibility values is not random, and the clustering of the research units The growth is

proportional, and the inequity of this spatial distribution is not only accidental, but the result of the long-term development of Shanghai's elderly nursing institutions and the elderly.

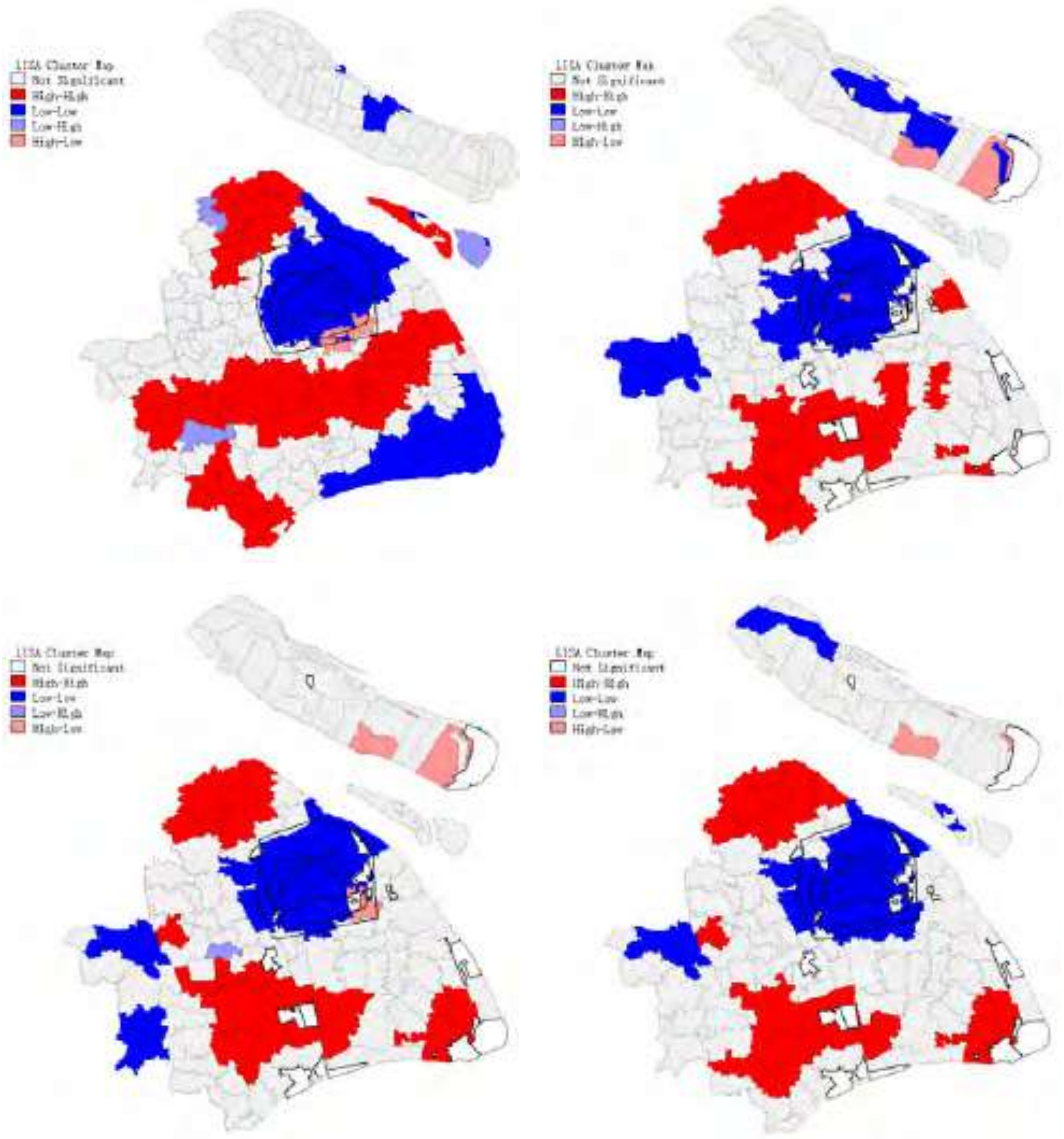

Figure8 Local Moran I of different search years, t=2000 (Top left), t=2010 (Top right) ,t=2014 (bottom left) t=2017 (bottom right)

This trend is analyzed by local Moran's I. From 2000 to 2014 (Figure.8), the overall trend is the trend of low-accessibility units concentrated in the central city and high-accessibility units concentrated in the suburbs. At the same time, it can be found that the distance of the high-accessible agglomeration area from the outer ring line boundary is gradually increasing, and gradually concentrated in the suburbs. Relatively speaking, the central city area has been in a low-accessibility gathering area, and the change is relatively low. Service has always existed. However, there are exceptions to the development of equity in service space. In 2000, the low-accessibility agglomeration space in the southern part of Shanghai gradually turned into a high-value clustering unit, indicating that the resource input of the elderly nursing institutions in this area is relative to the population. The growth is faster, the

investment in resources has achieved certain results, and it has reached a higher level of service in Shanghai. It can be seen that although the increment of the elderly nursing institutions in the city area is increasing, the inequity of the distribution of the service space of the elderly nursing institutions is also easing, but there are still areas where the equity and growth are faster than the increase in the demand population. The development of equity cannot completely replace the changes in local areas.

overall, from 2000 to 2014 (Figure.8), the inequity of the spatial layout of elderly nursing institutions showed a general trend of mitigation, and the differences in the distribution of services among the elderly groups were weakening, while the spatial distribution was inequity. But it is constantly focusing. The development of past elderly nursing institutions was based entirely on the lack of spatial planning. During this period, the formulation of public policies for elderly nursing institutions promoted the equity of their services in population distribution, which is common to market and policy supply. As a result, it is also inseparable from the cross-regional recommendations of the elderly population. Another convenience, this shows that the intervention of spatial planning has a high necessity to promote the equity of the redistribution process of public service resources. Per capita indicators and market mechanisms can follow the changes in demand to a certain extent, thus achieving the easing of inequity attributes of the distribution of service groups in the elderly nursing institutions, but this lack of analysis on the spatial level is difficult to optimize and solve strategies at sunrise, even It will aggravate the existence of inequity distribution of relative supply in the space. The latter not only exacerbates the inequity of the layout of public service facilities, but even causes waste of resources.

At the same time, it should be noted that from 2010 to 2014 (Figure.8), the inequity of the distribution of people in Shanghai's elderly nursing institutions and the inequity of spatial distribution have fluctuated slightly. The trend, on the one hand, shows that in recent years, the equity of the distribution of the services provided by the elderly nursing institutions has been well maintained, but the equity of the spatial distribution has not been well adjusted, and the overall pattern of the high and low accessibility spaces is On the other hand, this kind of volatility also reflects the instability of the equity pattern. Under the dual dimensions of time and space, the goal of building a new public service facility should not only make up for the gap in the low-service space unit, but We must also pay attention to the changes in overall spatial equity from a dynamic and global perspective.

5. Conclusion

At present, within the search radius of d0=18000 meters, Shanghai's elderly nursing institutions generally show a lower central urban accessibility and a higher suburban trend, but the distribution of old-age care services among the population is in a fair and reasonable range, but In terms of space, there is a significant agglomeration trend. The central urban area is a typical low-accessibility gathering area, while the suburbs form three high-level areas with Jiading Baoshan junction area, Songjiang Fengxian and Jinshan junction area, and Pudong Da Tuan town as the core. Daren gathering area.

From the perspective of development, compared with 2000, the distribution trend of the accessibility of the elderly nursing institutions in Shanghai has not changed much in recent years. In general, it still shows the characteristics of low suburban high in the central city, but

with the population. With the dynamic development of facilities, the equity of the distribution of old-age care services in the elderly has been significantly improved, and the disparity in 2000 has gradually turned to a relatively reasonable space. However, the inequity of spatial distribution has not been significantly improved, but it has become more focused on the scope. From the perspective of the migration of different agglomeration spaces, the southern part of Pudong New Area has been transformed from a remarkable low-accessibility cluster in 2000 to a high-accessibility cluster, indicating that the construction of the elderly nursing institutions has achieved remarkable results relative to the population growth. .

Compared with the overall elderly nursing institutions, the inequity of the population distribution and spatial distribution of the basic elderly nursing institutions is more significant, and this part of the content has not been effectively reflected in the existing planning, which can explain the disadvantages of the elderly population. For the group, it is more difficult to obtain fair resources for the elderly nursing institutions. They are at a more unfair interval in the provision of services for the aged care institutions at the basic demand level.

The evaluation method of accessibility can reflect the existence of inequity of resource distribution, and its high and low range can clearly reflect the spatial distribution difference of relative supply. Under the traditionally equal allocation of ideas, relying on administrative units as the basic statistical unit, it is difficult to take into account the complementary roles between the streets, so the actual service level of some streets will be too low or too high (Figure 3.9-3.10) , which in turn will cause interference to further spatial layout optimization. It can be seen that the choice of evaluation methods affects the accuracy of the understanding of the supply of public resources on the status quo. On the one hand, it is necessary to combine the characteristics of data to adopt a more accurate research method to reflect the status quo; at the same time, to study the layout of different types of public service facilities. In the middle, we should rationally and objectively analyze the characteristics of various facilities, and pay attention to the rigor in the choice of methods and parameters. At present, under the condition that the goal of the elderly nursing institutions in all streets of Shanghai has been basically completed, the accessibility can explain the matching relationship between supply and demand more accurately, and has more effective guiding significance for reflecting the supply situation of the facility.

Although accessibility helps to guide the further supply optimization of public service facilities, it cannot reflect the degree of inequity at the global scale, and it is difficult to clearly define the global distribution of limited resources. The existing equity evaluation of public service facilities can be divided into two aspects: population orientation and spatial orientation. The former reflects the differences in access to public services by different groups of people, while the latter reflects the agglomeration of public services in spatial distribution. The equity of public services in the distribution of people reflects the degree of overall matching between supply and demand, while the equity of spatial distribution can reflect the preference between

resource supply policies in different regions. The emergence of agglomeration areas of public service resources should attract the attention of planners. Based on a comprehensive analysis of future population, economic and industrial development trends, suggestions for further optimization and allocation should be made.

Abstract

Cities and towns account for more than two-thirds of world energy consumption, a significant proportion of which is spent on operating buildings. Ambitious national energy and emission reduction targets necessitate that energy demand due to buildings is considered as an important measure when any future evolution of a district or city is planned. Energy consumption of buildings in cities is influenced by their immediate local environment. Factors such as local temperatures, wind speed (street-canyon effect), air pollution levels, human activities, access to daylight, etc. Indeed, in order to reduce energy consumption and associated carbon emissions globally, more attention should be focused on urban-scale energy analysis of the built environment. Nowadays, with the rise of the scientific paradigm shift and model theory, and the development of the spatial data, the use of the complex model of urban-system analysis become one of the important research of urban theory. Under this circumstance, this research will focus in the research stream, the application of a new integrated agent-based and spatial analysis modeling for energy prediction and energy-saving policy analysis in Urban Planning. The basis of the research will be to develop new, general purpose, computer models that can be used to assess the distribution of energy demand according to the spatial scale of the evaluated policy (e.g. local, city level). These models will look not only at the individual building level, but also at the district and city scales, in order to be able to assess the impact of urban planning policy and practice in land economy and spatial building pattern or design interventions on the energy demand of the wider scale.

Keywords

Spatial analysis, District energy efficiency, Urban planning.

1. Introduction

Cities and towns account for more than two-thirds of world energy consumption, a significant proportion of which is spent on operating buildings(Bose, 2013); (Robinson, 2011). Ambitious national energy and emission reduction targets necessitate that energy demand due to buildings is considered as an important measure when any future evolution of a district or city is planned. Not only the accounting of present-day energy consumption of

the built environment by regions and by sectors, but also the prediction of achievable reductions to meet relevant emissions targets. (Keirstead, 2012). Indeed, in order to reduce energy consumption and associated carbon emissions globally, more attention should be focused on urban-scale energy analysis of the built environment (Heo and Choudhary, 2012).

Energy consumption of buildings in cities is influenced by their immediate local environment. Factors such as local temperatures, wind speed (street-canyon effect), air pollution levels, human activities, access to daylight, etc. Typically referred as micro-climatic factors, these are largely anthropogenic, resulting from local agglomerations of density of buildings and population, equipment, land-cover, activities of a city or region. In addition, many studies have proven that human behavior has a significant role in energy consumption patterns of buildings in urban settings (Frayssinet and Merlier, 2018). It is very likely behavior factors affecting energy use have positive spatial autocorrelation in city context. Therefore, it is important to consider spatial effects as well as occupants' behaviours in analysing energy consumption patterns of buildings in urban settings. However, there are still many limitations in current research technology and methodology, especially the interaction between energy consumption and occupant behavior in daily activities should be further discussed. Nowadays, with the rise of the scientific paradigm shift and model theory, and the development of the spatial data, the use of the complex model of urban-system analysis become one of the important researches of urban theory (Choudhary and Tian, 2014). Under this circumstance, the paper follows the technical waves, application of a new integrated agent-based and spatial analysis modeling for energy prediction and energy-saving policy analysis in Urban Planning. The basis of the research will be to develop new, general purpose, computer models that can be used to assess the distribution of energy demand according to the spatial scale of the evaluated policy (e.g. local, city level). The new integrated energy model that can be used to analyses energy consumption patterns due to buildings at the district scale, which also enables a technological innovation by ABM for behavior modeling.

We named the new integrated analysis environment: IUBEA from the initial letters of Integrated Urban Building Energy Analysis. The data used in the IUBEA includes physical features of buildings (e.g., size, volume) per use type and per district, demographics, economics (e.g., cost of land), and energy data at various spatial scales in cities. Another important feature of this computer model is that it is programmed within an open-source software (Netlogo), which allows other users to access it easily. In addition to being open-source, Netlogo (Tisue and Wilensky, 2004) is chosen in this project because it has many functions, such as scenario-based analysis, GIS environment, and agent-based modelling. Furthermore, it has several extensions to link with other programs, such as statistical program R and numerical computing environment MATLAB.

In IUBEA, we implemented the model methods and validations through a case study of London. Agent-based modeling (ABM) in the integrated analysis environment (IUBEA) is a technique for bottom-up simulation, providing an alternative perspective to those that can be attained by using optimization or general-equilibrium approaches(Zhao and Wang, 2010) . This paper explores techniques to integrate a spatial analysis environment in the field of urban building energy assessment in cites to make full use of current spatial data relevant to urban-building energy consumption and energy efficiency policies. So, users of the model are able to easily relate building and spatial characteristics parameters to policy or utility

figures, which can lead to an efficient energy model, which contributes the body of knowledge of energy modeling beyond the single building scale.

2. The framework of the Integrated Agent-based and Spatial Analysis Modelling

The main purpose of the research on urban scale building energy model is analysis the relationships and key factors affecting energy use in spatial autocorrelation in city context. Ensure that the planner can make reliable decision-making solutions based on system analysis of the mechanism of energy use and urban development. Techniques for extending building models to quantify energy consumption of a district, or city region have come into closer scrutiny as policy-implementers are under pressure to take large-scale actions for reducing energy consumed by regions, districts (Choudhary, 2012). In order to provide the reliable techniques for the low-carbon urban planning, researchers should use qualitative and quantitative analysis to evaluate the design of energy-saving policies before the implementation of energy-saving policy. On the one hand, to quantify the implementation effect of energy-saving strategies in different object's spatial position and scale. On the other hand, by comparing the environmental and socio-economic (include occupant behavior) impacts in spatial context, choose a more effective planning strategy that reduces the energy demand of district or city level. Therefore the typical steps for energy-efficiency analysis in urban planning as shown in Figure 1.

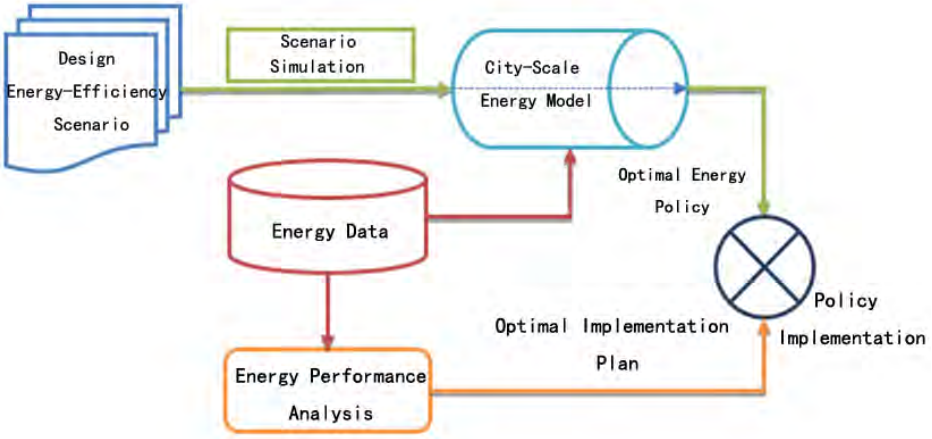

Figure 1 Composite relation of energy effectivity research

In addition, there are interactions and influence mechanisms of energy consumption and various spatial factors in built environment, named "spatial heterogeneity" (behaviour uncertainty caused by spatial position differences). By the influence the space phenomenon, policy-implementers should come into closer observation the energy-efficient in spatial to adopt different policies and implementation efforts in different regions to achieve the energy-saving purposes in the most economical way. Based on the above simulation key features, the systematic framework for the study of the integrated spatial analysis modelling for energy-efficiency and demand analysis in urban planning is constructed as shown in section3.

3. Contents and Methods in the Integrated Model Environment

The analyses in IUEBA are implemented through four functions. The first displays the data spatially and can be used for data query at different spatial levels in cities. The second is to explore the relationship between various factors and energy consumption using correlation and regression analysis and create statistical energy models. The third is to study the effects of different scenarios on building energy use, named “scenario analysis”. The fourth is to investigate the optimization zones using mixed-use method based on energy use intensity of districts. This section will describe these four main functions in detail.

3.1. Spatial distribution analysis of the energy consumption in city scale in IUEBA

These spreads (or distributions) can be used for estimating the probability distribution of the gross energy consumption per local authority in Greater London. The work is driven by the need to quantify future energy demand of buildings in their urban context as a function of projected growth of buildings and populations, refurbishments, policies incentivizing energy efficiency measures, and changes in building operation.

when predicting the energy consumption of a district in a city level, the actual value can vary significantly from the prediction, due to the different spatial contexts in which each district has its own unique characteristics that influence the energy consumption in various manners. The influence of the immediate environment and climate change on energy consumption or carbon emission in urban environment by the robust mathematical modeling method has been explored before (Cheng and Steemers, 2011). Geo-computation of existing distribution of energy consumption for an analysis of policy scenarios of energy use abatement is a case, where the context of the urban planning can be assessed and understood in detail, by gathering geospatial data, energy bill data and information using methods such as GIS and survey. Besides, advanced Geo-modeling methodologies of spatial analysis of energy consumption need be developed to improve the way in which observed data is used to spatial statistical test and validate models.

In this study the energy consumption of a set of uniform buildings within an area is normalized and expressed as kWh/m2/year. The total energy consumption of buildings in a district can be expressed as the sum of energy consumption of its constituent buildings in the following form:

$$E_k = \sum_{i=1}^{N} EUI(i) \cdot PA(i,k) \qquad (1)$$

where, E_k is the energy consumption of a district k in kWh/m2/ year, normalized by its total building floor area. $EUI(i)$ is the energy use intensity of a building type i in kWh/m2/year, $PA(i,k)$ is the percentage of built floor area of building type i in district k, and N is the total number of building types.

A common feature in EUI studies is that even in the same type building, the difference of EUI is existence due to the varies in building age, sub-functions, and equipment performance. The hypothetical model does not fully reflect the actual energy consumption. So the energy density of

different types of buildings is more appropriately expressed in the form of probability distribution show as （2）.

$$G_k \sim N(E_k, \sigma^2), \quad \text{for k=1,2,3,...,D} \qquad (2)$$

where, G_k is the observed energy consumption of a district k in kWh/m^2/ year, D is the number of all observation points. σ^2 is the variance of the distribution, which represents the error in the measurement process, accommodating any differences between the recorded gross energy consumption of a district and that of its individual buildings. These errors may be systematic, owing to how energy consumption is recorded or due to other reasons in the observations.

There is also an external spatial influence value of building energy consumption in each district. Spatial analysis techniques of SAR and GWR is used to quantify spatial influence in energy consumption of a neighbourhood, district level.

We first use spatial autoregressive methods to incorporate spatial influences into the calculation of building energy density. The spatial feature quantity b(k) is used to characterize the spatial characteristics of energy consumption in different regions as show in （3）

$$E_k = \sum_{j=1}^{N} I_j P_{k,j} + b(k) + \alpha, \quad \text{for k=1,2,3,} \cdots \text{,D} \qquad (3)$$

Where α is a constant term; however, the spatially distributed intercept α is varies in different regions, it is assumed that it satisfies a stable uniform distribution; *b(k)* is a spatial feature of a certain district; It is expressed as the follow:

$$b_k | b_{k-1} \sim N\left(\frac{1}{n_k}\sum_{j=1}^{n_k} b_j, \tau^2\right), \quad \text{for k=1,2,3, } \cdots \text{,D} \qquad (4)$$

Where n_k is the number of adjacent areas affected by the area *k;* τ represents the accuracy of the distribution and is expressed in the model as follows:

$$\tau = \frac{1}{\varphi^2}, \quad \varphi \sim uniform(0,100) \text{D} \qquad (5)$$

Where ϕ is the variance parameter obeys the uniform distribution ：Uniform (0,100).

A common feature in these studies is that the energy consumption of a set of uniform buildings within an area is normalized and expressed as kWh/m2/year. This value, referred as energy use intensity (EUI), is derived from published standards of typical building consumption patterns, or from auditing energy consumption of a representative sample of buildings, or computed using statistical or physics-based energy models of representative buildings. It is a standard normalization because it enables scaling-up energy consumption of a large set of buildings into gross energy use of a district, and likewise, allows delegating total energy use of a district to its consumers (buildings).

3.2. Spatial factors analysis of the energy consumption in city scale in IUEBA

The immediate local environment has important influence on energy consumption of buildings which has been explored before. Such as local temperatures, wind, access to daylight, pollution, noise levels, etc. These spatial factors result in significant differences in the amount of energy use such heating, cooling, ventilation and lighting required to maintain a building at acceptable conditions. How to identify spatial influence factors, improve the accuracy of key factors, and eliminate the interference of non-critical factors on model predictions, is still a problem to be solved in the integrated environment. In this paper we use spatial statistical methods to quantify the influencing factors in the energy simulation.

The regression analysis in this project has two main aims: interpretation and prediction. The interoperation is to understand the spatial relationship between energy and independent variables. For instance, how population number or floor area can influence the energy consumption and whether the floor area or population has more significant effects on energy consumption. The prediction is to investigate the effect of changed independent variables on energy consumption. Note that this regression analysis can deal with one or multiple independent variables. The regression analysis can be used for interpretation to understand the relative importance of independent variables on energy consumption. This analysis can also be very helpful to determine the variations of energy consumption explained by the independent variables in the regression.

The spatial form factors is shown as example how the regression analysis is implemented in IUBEA environment, as shown：

$$\hat{E}_t = Constant + \beta_{building} \times S_t^{building} + \beta_{road} \times S_t^{road} + \cdots + \varepsilon \quad (6)$$

where: $\hat{E}_t$ is estimated energy consumption of a given area, $\beta_{building}$, β_{road}, etc. are the coefficients of building, road, etc. $S_t^{building}$, S_t^{road}, etc. are the area of building, road, etc. ε is the random error term.

Implement of correlation analysis on spatial socio-economic features with energy consumption. Normative building energy model has many parameters that may not be sensitive to analysis the Socio-economic features impact EUI distribution in spatial. The procedure of the Correlation and regression analysis is to apply a sensitivity analysis to a set of parameters to reveal the relations of distribution of Socio-source features with energy consumption in spatial.

The influence of the local environment on energy consumption of buildings has been explored Anthropogenic factor, such as local agglomerations of buildings and population types, equipment , activities, across various parts of a city as well as socio-economic features such as income levels, wealth, and demographics have also been shown to influence the energy consumption patterns in buildings. Given the feasible ranges of model variables, the next step is to generate data samples and retrieve the corresponding model outcomes for variable sensitivity analysis with the distribution of Socio-economic features. The method for sensitivity analysis is the same in different types of application in building energy analysis as show in Figure. 2 (Tian, 2013).

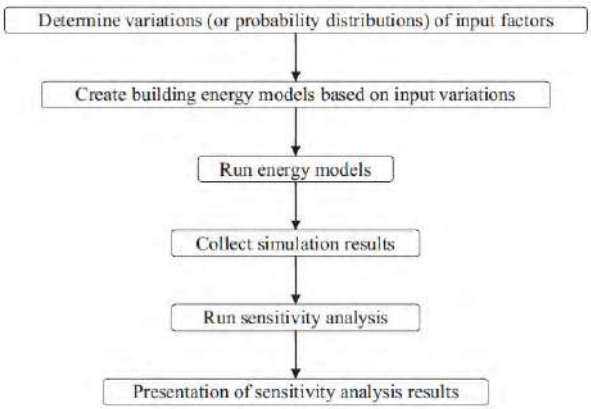

Figure 2 Flow diagram for sensitivity analysis in building performance analysis

3.3. Energy prediction and scenario analysis in city scale in IUEBA

1. Energy prediction

Based on the analysis in section 3.1 and 3.2, the prediction analysis can be implemented if the independent variables can be used to explain most of variations of energy consumption. Then the regression model is used to predict the change of energy consumption due to the variations of independent variables. The total energy consumption of buildings in a district can be expressed as the sum of energy consumption of its constituent buildings in the following form

$$E_k = \sum_{i=1}^{N} EUI(i) \cdot PA(i,k) \quad (1)$$

The results from formula above should be verified with actual energy data to make sure that both energy use intensity and area data are reasonable at a given spatial scale. Then analysts can change energy use intensity or floor area to explore the possible effects of these changes on energy consumption in the same or different spatial scales in cities.

2. Scenario analysis

Baseline Scenario:

Scenario analysis is used for what-if analysis. The function in this section is different from "regression analysis", as explained in Section 3.3. Scenario analysis does not implement regression method, but it depends on only independent variables. Therefore, this method is more flexible compared to regression analysis because it is suitable for the situation where energy consumption data are unavailable in some spatial scales or some areas of a city. To implement the scenario analysis, analysts should have good knowledge on the effects of these independent variables on energy consumption. Furthermore, some form of validation of energy calculations is necessary to confirm that the prior assumptions in the model are appropriate.

New Scenario design:

This section will describe three new scenarios to explore the possible change of energy consumption in cities.

(1) Electrification Scenario: It seems there are more benefits for electrification in building sector if grid electricity can become gradually carbon intensive. As an example, electricity emission factors in the UK have been reduced around 35% from 1990 to 2010 (UK Defra & DECC, 2012). This energy scenario is to explore how the total energy would change if building sector would use electricity instead of gas for heating.

(2) Building type conversion scenario: In urban environment, it may have some reasons to change building types due to economic or social reasons. Then, it may be of interest to investigate change of building types on total energy consumption in cities.

(3) Energy efficient Scenario: In order to reduce carbon emission, it is important to understand how the improvement of energy use efficiency may influence total energy consumption in cities. Thus, this scenario allows analysts studying the influences of change of energy use intensities for different building types.

3.4. Optimal simulation of energy consumption based on ABM model in IUEBA

Implement Agent based model for energy efficiency and human behaviour simulation

The application of this section will facilitate deployment of energy efficient buildings, socio-economic impacts and energy supply technologies in city design, by developing quantifiable, system-level models that assess their feasibility and implementation in the wider context of socio-economic, and regulatory characteristics of the city. The system-level model will not only enable a more robust scaling-up of the impact of technological innovations up to the city level, but also allow trade-offs between their environment, societal, and economic impacts to inform regulations and policy scenarios.

1. Initiate model environment

In this agent model we apply

- Energy Consumption Source:

lighting, HVAC(heating, ventilation, air-condition, cooling), Equipment,

- Energy Sources:

Gas, (Oil), Electricity, Renewable Energy(Solar, Wind, Biogas, Bio-diesel)

- Environment Sources

Residential, Commercial, Industrial, Transport

In this mobility model we consider people like household employment consumption is the main part of energy consumption of a city People migrate to cities for the following reasons: For better employment, education, treatment, amenities and thus an increased quality of life.

2. Formulation & Methodology of model simulation

$$EUI_{msoa} = \alpha \times e^{\frac{N_{population}}{c_p \times \sum_{j=1}^{M} S_{building}}} + \beta \times e^{\frac{N_{employment}}{c_e \times \sum_{j=1}^{M} S_{building}}} \quad (7)$$

Where $\mathrm{EUI_{msoa}}$ is the energy use intensity of middle super output area (MSOA). $\mathrm{N_{population}}$ and $\mathrm{N_{employment}}$ are number of population and employment respectively in MSOA. $\mathrm{S_{building}}$ is the floor area of each building type, and M is the number of building types. $\mathrm{c_p}$ and $\mathrm{c_e}$ adjust the strength of population and Employment that can be determined before regression controlling weights of population and employment.

4. Results analysis

4.1. A case study of London

London has been used as a case study to explore its building energy patterns with this new integrated IUBEA model environment. In this case-study, London has three spatial scales: LA (local authority), MSOA (middle layer super output area), and LSOA (lower layer super output area). London has 32 local authorities and the city of London is also regarded as a special LA in this study. According to UK census 2001, London has 983 MSOAs and 4765 LSOAs. MSOA and LSOA areas are created based on population and household number.

Note that there is a change of these MSOA and LSOA areas in 2011 census due to population and household changes.

Theme	Data set	Reference
Energy	Electricity /Gas at borough level	(DECC, 2013c)
	Electricity/gas at MSOA and LSOA	(DECC, 2013b) (DECC, 2013a)
	EPC (energy performance certificate) & DEC (Display energy certificate) in London	(UK DCLG, 2013)
Area	Land use area from UKmap	(UKMap, 2011)
	Floor area	(UKMap, 2011) (Choudhary, 2012)
Social economy	Population	(London datastore, 2013)
	Household	

Table 1. Date source used in this analysis

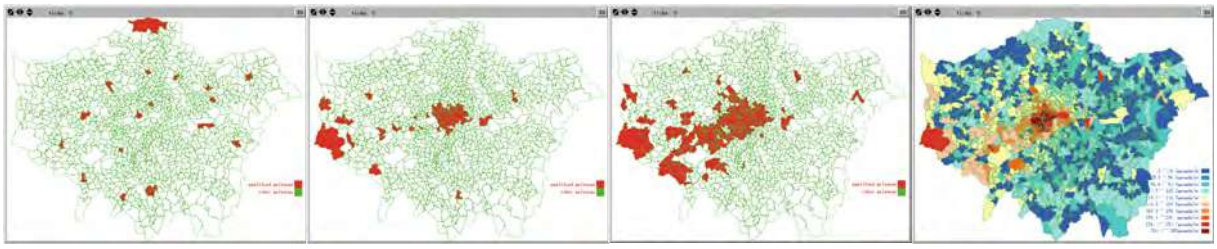
Table 1 lists the data sets used in this paper. These data can be divided into three categories: energy, area, and social economic factors.The energy data used in this analysis includes regional data and point energy data in London. The regional energy data means the total energy in a specific spatial scale, while the point energy data is the energy data for individual buildings. Both electricity and gas data in domestic buildings in London has good quality from LA to MSOA levels although the energy data in a few number of MSOA areas is unavailable (DECC, 2013a, b, c). For non-domestic energy data, there are full data at LA level from UK DECC. For MSOA gas data in London non-domestic sector, the data quality is also fine except for a small numbers of MSOA areas, whereas the electricity data at MSOA level is almost impossible to use since most of data are unavailable due to disclosure issues (DECC, 2013b) . The point energy data in this paper is from UK DCLG, including DEC (display energy certificate) and EPC (energy performance certificate) (UK DCLG, 2013).

4.2. Results

As described in section 3, many types of analysis can be implemented. In this section, we only show some results of corresponding the main functions described in section 3.

1 Spatial factors analysis

To show the area percentage of school and offices at MSOA levels in London. Figures 2 present the descriptions of the visualization cases. Cases a and b calculated by two modes absolute/relative only, are used to analyse the scaled /absolute distribution Area of Offices



(a) (b) (c) (d)

Figure 3 (a) Retail floor area of MSOA more than 20% in Greater London. (b) Office floor area of MSOA more than 20% in Greater London. (c) Office cost of MSOA more than 50% of 983 polygons in Greater London. (d) Office cost distribution of 983 MLSOA in Greater London

and Schools per MLSOA in London in London. It refers to the operation between properties in polygons, which is very important to quantify the change of some variables per-district.

Figures 4 Figure4 (a) (b)the non-domestic electricity is replaced by domestic electricity and the results presents the regression with residential floor area and population. We attempt to explain whether; floor area or employment can explain more on the variations of non-domestic electricity based on R^2.

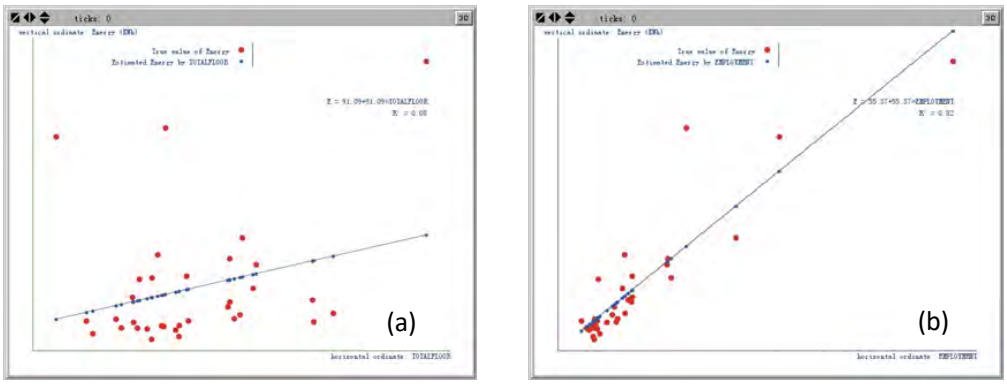


Figure 4 a) regression of domestic-electric/floor-area; b) domestic-electric/population

2 Spatial distribution analysis

In the "I-UBEA" combined with GenBUGS software to process the spatial statistical based on Bayes analysis, the model runs 20,000 times, of which "Burn-in Period" is 2000 times. Based on the distribution of the energy density of 13 different types of non-residential buildings in London, this section selects the main proportion of community buildings in London to show the model application. Based on the distribution of the energy density of 13 different types of non-residential buildings in London, this section selects the main proportion of community buildings in London to show the model application. By comparing the density distribution results of 13 building types, the distribution of building energy consumption shows obvious spatial polarization characteristics, and some spatial forms have obvious polarization. Figure 5 shows the distribution of the mean of the posterior distribution of community buildings in the tested 953 MLSOAs. Among them, the high-energy buildings obviously have a concentrated trend, but they do not form a group distribution pattern. Instead, they form a concentrated high-energy-consuming area near the center of the city, and shows distinctly different from the multi-center patterns compare with other types of buildings

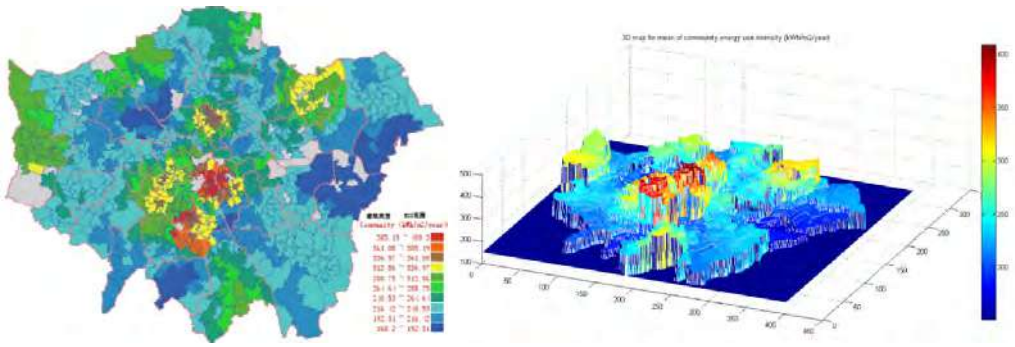

Figure 5 Posterior distributions of calculated area weighted EUIs of community building in MLSOAs of London

3 Scenarios analysis

The input data are included all local geography data and historical energy consumption records of recent years. In this section figures 5 presents the comparison results between three scenarios due to electrification in London building sector. The results are based on the distributions of EUI from both DEC and EPC data. Then the results from both base case and electrification scenario distributed in Figure 6.

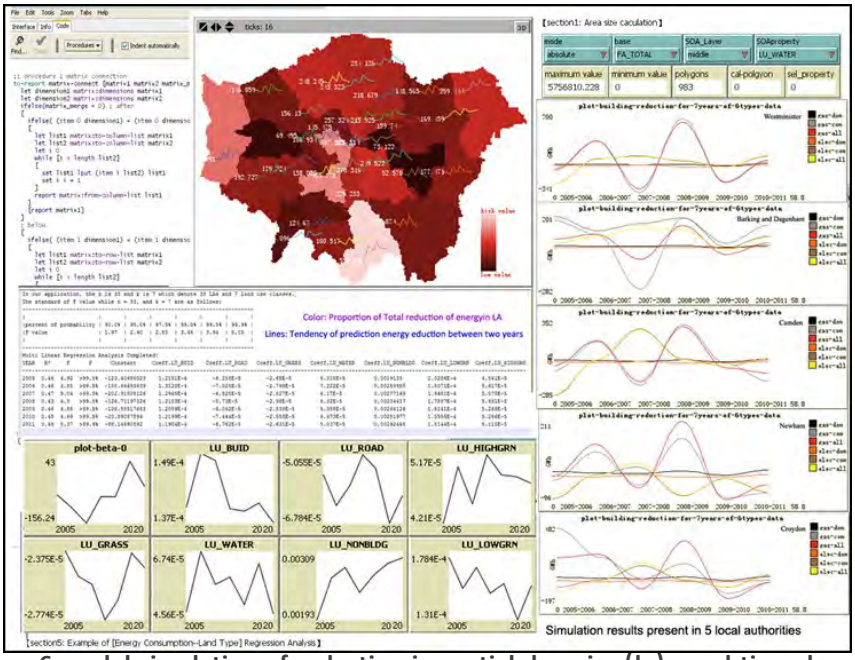

Figure 6 model simulation of reduction in spatial domain（la） and time domain（ 2005-2020）

4 Agent-based energy models

Figure 8 shows the people migrates to neighboring MSOA according to accumulation of different energy sources. Weights of each energy source can be set, thus denoting different policies. From the results each MLSOA has its own distribution of resources and population , thus energy use intensity (EUI) in there. Some polygons have higher EUI than others. Statics plots in figure 7 show how the interaction between energy consumptions, socio-demographic characteristics, environmental conditions and human behaviour which all combine in unique ways to create very different energy saving opportunities for each local authority.

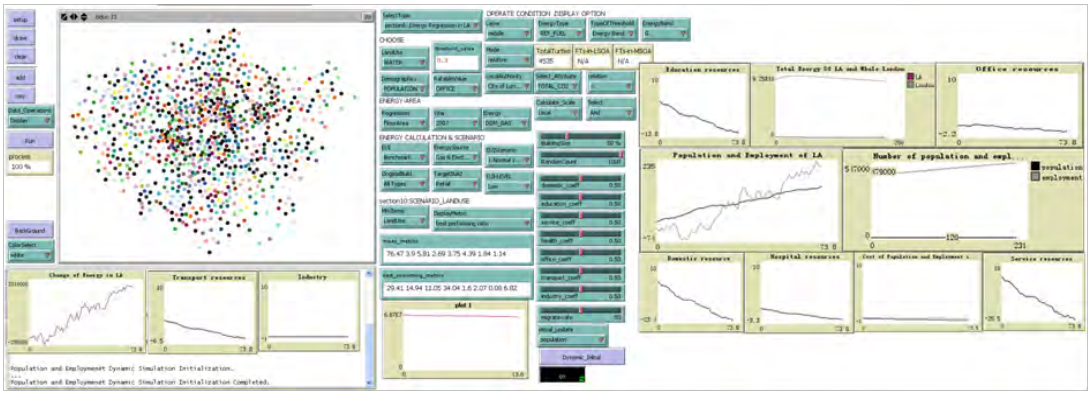

Figure 7 Agent based model for energy prediction in terms of population mobility generated from IUBEA results

5. Conclusion

This paper has described a new integrated GIS environment to make thorough analysis of energy performance in city buildings. This energy analysis environment can be used for multiple functions, including spatial data visualization, data query, regression analysis, scenario analysis, energy optimization, and agent-based energy analysis. London has been used as a case study to illustrate its main functions.

The following conclusion also can be drawn from this research:

- Urban scale energy models should consider the effects of spatial dependence when dealing with energy use at urban scale. Or at least, the immediate local environment factors should be analyzed whether there is significant spatial correlation.
- ABM (Agent-based-model) can be a feasible tool to tackle intellectual challenges (uncertainties) in energy modeling. The uncertainty that is caused by occupant behaviors accounts for a significant discrepancy between the predicted and actual energy usage that typically have strong interactions.
- As a result, the research proved the possibility of the integrated approach in simulation, and the analysis of energy-efficiency which is influenced by comprehensive factors including spatial context and human interventions. The final adoption example of London demonstrated that the integrated analysis environment as a feasible tool for building energy consumption have unique advantages and wide applicability.

Case Study Paper

Why We Need Participatory Mapping ?

Amandus Jong Tallo, Urban and Regional Planning Department Agung Podomoro University; Indonesia

Abstract

More than 50% Kapuas Hulu regency conservation area, where forests are the world's buffer zone in the face of global warming. The availability of conservation areas causes social inequality for Dayak people in Mensuai village, Kapuas Hulu Regency, West Kalimantan Province, Indonesia. This study aims to delineate management boundaries area palm oil between community forest, which were carried out for two years, using participatory action research involving related stakeholders. FPIC (Free, Prior, Inform, Consent) are principles in this research process. Free; in which the community is given an understanding of conservation areas and the constraints of management space that are provided at the beginning without coercion, and the choice of rejecting activities (prior) understood by society through shared social learning), consent ends in people who do it (participatory principles are actually implemented) through several stages including, mapping of stakeholders (functions & authority), making mental maps, spatial learning (learning using tools in the form of Global Positioning System/GPS and arc gis training for village communities), and public consultation. The results of this study indicate that the community consciously feels it has its own area through participatory mapping activities carried out. The resulting map is in the form of a village boundary map that has been communicated with boundary villages and companies, land use maps with existing uses, tenure maps containing types of land ownership (communities, companies, government), village spatial maps (structure and spatial patterns). The success of the mapping process is supported. The output produced is not only a map, but also a very complete village product, by calculating the lack of food security of the local community, in terms of carrying capacity of the land. Participatory mapping addresses the spatial challenges of land tenure rights and land history, spatial layout, and various the interests of sustainable village development.

Keywords

conservation,map, sustainable.

1. Introduction

Spatial problem is how to place humans and activities in a fixed area (Tallo, 2016). The dynamics of development in Indonesia are not accompanied by a planning process, so that open space arrangements are interpreted as laws and guidelines for development, only in the form of spatial planning in the licensing process. Spatial problems in Indonesia are caused by the top-down planning process, not bottom-up (Nurdin, 2017).

The process of spatial planning as a political process in development causes a crisis of spatial information (Brandusescu and Sieber, 2018). The smallest administrative spatial unit in Indonesia is a village, where the presence of a village law requires the village to have a map and village profile (Indonesia, 2014). The map needed is a coordinated map with clear village

boundaries, but village boundaries cannot explain the potential of the area, so a land use map is needed. Village maps are a mandate from the state for villages to develop the area (Fisiko, 2015).

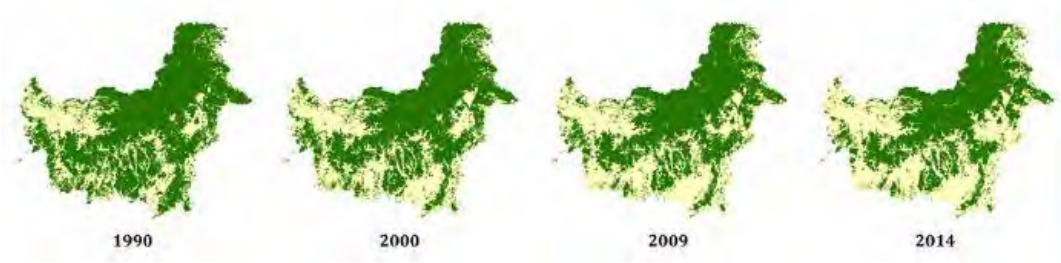

Figure 1 Degradation Rate of Forest Areas in Kalimantan Province (Ruhyat Hardansyah, 2016)

Every village has the potential, both the potential for natural resources in the form of land, water, climate, geographical environment, livestock, agriculture, mining, fisheries, and the potential of Human Resources (HR) in the form of communities with diverse cultures, and interactions (Koto, 2017). Kalimantan Island as one of the lungs of the world, experiences land conversion (forest to cultivation area) approaching 50% of 60% land area (Ruhyat Hardansyah, 2016).

The spatial system in Indonesia is likened to a human body, where there is a sensory center with a network system and also a body part that needs to be maintained and can help the body's motor system. Spatial planning is a manifestation of the structure and pattern of spatial use (Umum, 2007).

The author's view from an academic point of view, Indonesian spatial planning still speaks technically, positivistically, regardless of the social aspect as the basis for forming space. The unit of space is actually formed from the smallest element is land, so that the use of land in carrying capacity is a challenge in planning. The ability of the land to accommodate activities and support for elements of land units as part of the land needs is spatially delineated so that spatial clarity of location becomes a measure of land use.

Villages in Indonesia are formed from traditional settlements, where a group of families (father, mother and child) occupy a location. Families form a village based on genealogical similarity, marriage and so on, and eventually form a village administrative unit. The experience of the author when entered the village, did not yet have clarity on the boundaries of the territory, even the boundaries of the agricultural area were not spatially determined because the community assumed that the agricultural boundary was the extent to which a resident could cultivate agricultural land, thus requiring a social approach.

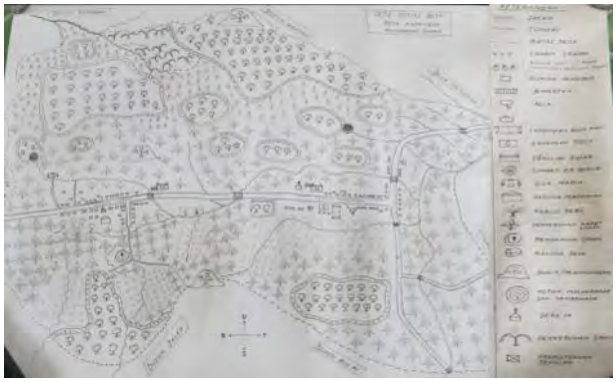

Figure 2 Sketch of Kerengas Village, Suhaid Sub-district, Kapuas Hulu Regency, West Kalimantan Province Indonesia

Starting from the need for a map as a spatial picture and a technocratic spatial system that requires community participation as a solution in spatial planning. Making maps in eliminating the imaginary boundaries of each region is the basis of thinking in spatial land tenure studies based on community participation (Masschelein and Quaghebeur, 2006). This paper talks about the author's experience of approximately 5 years accompanying several communities in mapping the territory.

2. Methodology

This study activity used an inductive method, where researchers carried out discussions with the community in producing coordinate maps. The basis for the mapping process is the FPIC (Free, Prior Inform and Consent) approach, where community rights are upheld in every decision (Colchester and Ferrari, 2007). According to (Joko Waluyo, Andi Kiki, 2015), descriptions of FPIC are as follows:

a. Free means that decisions must be achieved through processes that respect the interests of each party, without violence, intimidation, threats, or bribery and coercion, and there should be no fake or deceptive results.

b. Prior means that the negotiation must take place before the government, investor, or company decides what they will do. This means that before the government, investors, companies enter and start doing something within the territory of indigenous peoples

c. Prior means that negotiations must take place before the government, investors, or companies decide what they will do. This means that before the government, investors, companies enter and start doing something within the territory of indigenous peoples.

d. Consent means that every decision or agreement reached must be carried out through an open and gradual process that respects customary law and selected community authorities. The parties must build a dialogue that opens the opportunity for the community to find the right solution and is useful in an atmosphere of mutual respect, full and fair participation, with sufficient time to reach a decision.

In the process of making maps, there are several stages, including; (1) request for permission from the parties, (2) confirmation of approval and rejection from the community, (3) establishment of a mapping team, (4) data collection and verification, (5) public consultation. The five stages in this paper are explained in 3 major stages, namely the preparation of mapping and making village sketches, the mapping and verification process, and public consultation. The duration in each stage varies depending on the conditions in each field.

3. Results & Discussion

3.1. Community organization as Success Key of Activity

The key to the whole mapping process is communication. The formation of the communication process must be built by a facilitator with the soul of a community

organizer/CO (Tonn, Zambrano and Moore, 2001). Being a big question, in building a social process in the context of participatory mapping, is it a CO or a facilitator? The facilitator can be understood as someone who understands the technical implementation of mapping in the field (use of mapping tools; drones, compasses, gps/global positioning systems, retrieval of coordinate points, digitization processes, so that maps can be displayed according to mapping rules). A CO, must be able to have a positive continuity of curiosity towards the goals to be achieved (Murphy, 1990).

Figure 3 Communication process with Mensusai Village Community, Suhaid Sub-District, Kapuas Hulu Regency, West Kalimantan Province Indonesia

CO itself is a person or group of people from a particular organization sent to the community in carrying out the tasks of an organization in building a social movement in a better direction. CO is present in the community to build social awareness. A CO in relation to participatory mapping must be equipped with standard (general) skills and spatial abilities (understand about mapping problems). CO works in the midst of society in accordance with the interests or issues mandated. So facilitators are more directed at technical matters, while CO plays a role in the process of social communication. The process of building social communication will be ideal if there is a division of roles between CO and facilitator, but it would be better if a facilitator must be able to have the spirit of CO.

Inland communities in Indonesia, are very friendly and open to outsiders. Openness will get closer, if a CO presents the intent and purpose in the activity at the beginning. Introductions in the middle of the village/region, of course, become foreign to a CO, especially to traditional communities

Figure 4 Process of Team Teaching in the Field When Mapping in Mensusai Village

Introductions do not have to discuss what we are going to do together, there are many alternatives that can be done, including discussions about village potential, such as: arwana fish (siluk), or declining rubber prices (2015 personal survey, Rp.5,500 / kg) , or the potential of rice. Diplomatic creativity must be built on the initial process. The importance of the process will affect the next process. It is expected that a CO can hear more, while asking critical questions. CO can play a role in cases of advocacy, arbitration, monitoring and evaluation, identification and various social cases in a spatial framework.

In general Friedmann, 1992 develops 4 stages that CO is doing in facilitating an activity including Perception, Summarization, Authorization, Impelentation. The four stages are detailed in the following points:

a. Perception (perception on community)

   The presence of CO in society at this stage aims to study fragmented and unsystematic ideas. This understanding will refer to actor relations, social factors in general that affect the living system of the local community. The results of the investigation are in the form of mapping problems and individual relations in the community. The main themes are the existing social relations. Don't pretend to be the most indigenous, a CO feels the most expert at knowing, and looking for problems in the field.

b. Summarization

   Summary is a brief and clear field record, accurate and easy to understand. Reports are written based on the observations obtained, but are still focused on the issue. Written facts based on community relations, without giving intervention. The report will be given to the organization that sent the CO in the community, from the report all the actions and movements carried out can be documented.

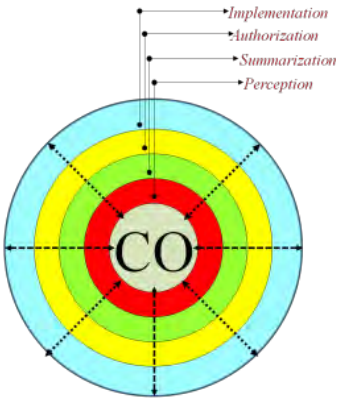

Figure 5 Four stages of CO (developed by author adopted by Friedmann, 1992)

c. Authorization (Communication with Authority)

Communicate each movement to the highest organization. At this stage, field progress updates are carried out, related to the availability of citizens, when the initial meeting/socialization meeting will begin, the availability of village sketches. The purpose of co-ordination is that CO can work in accordance with the mandate given, and comply with the normative requirements of the organization. The process of communication with the community must still be maintained, not to reduce the social relations that have been built. Communication was also carried out by CO with the local government (Head of Sub-District/Regency), so that the legality of CO's presence would not become alienated in the community.

d. Implementation

The results of communication with tertiary organizations are communicated back to the community, becoming an agreement belonging to the community. It is intended that the proposals and suggestions of the community be accommodated, so that the agreement is a community agreement. This stage is the initial stage of starting socialization with the community.

3.2. Participatory Mapping in Mensusai Village

Mensusai Village is located in Suhaid Sub-district, Kapuas Regency, West Kalimantan Province, Indonesia. An area; 4259.77 hectares, which are divided into 3 hamlets namely Langsat, Rambai and Mawang. Topographically, the area includes hilly areas, where there are 12 hills including; Baderi Hill, Sungai Muntik Hill, Sangkap Hill, Merbai Hill, Jeluti Hill, Sebendung Hill, Telujung Hill, Budu/Untut Hill, Linang Hill, Tembesuk Hill, Rimbak Besar Hill and Penunduk Hill.

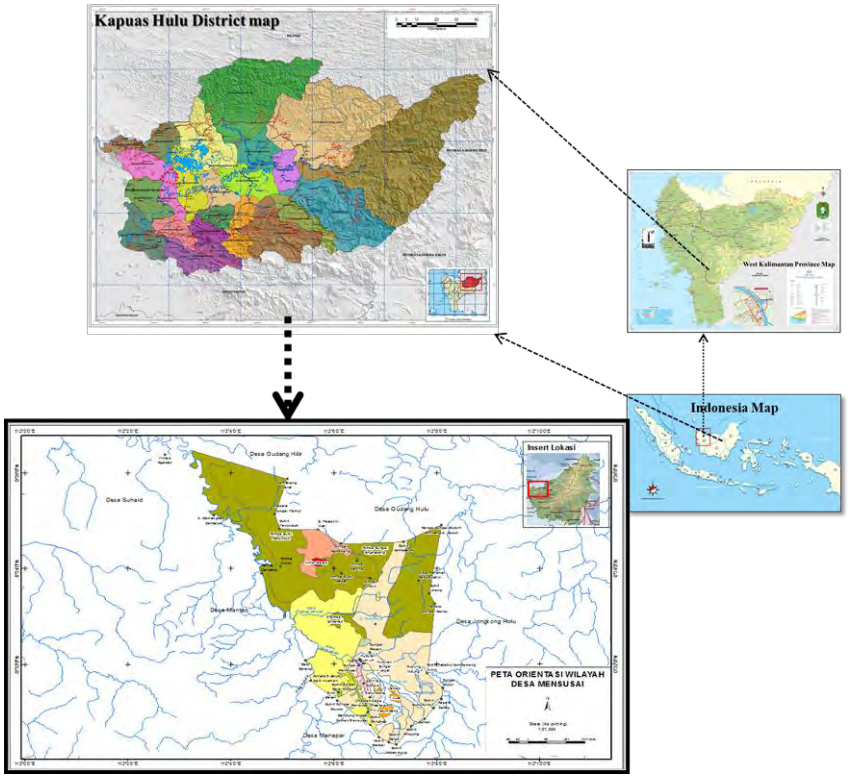

Figure 6 Orientation of Mensusai Village

The distance from Mensusai Village to the Subdistrict Capital City (Suhaid Sub-District) requires 1 hour trip (25 km), if it goes to the Capital City of Regency it takes around 5 hours with a distance of about 120 km, and to the Provincial Capital City takes around 12 hours distance of about 300 km. In general, to access the location, people use motorbikes, especially to go to the Sub-District and Regency capitals, while going to the Provincial Capital City by car.

Figure 7 Decree of the Village Mapping Team

Demographically, the population of the village of Mensusai is dominated by women, of which 60% of the population is in Langsat Hamlet. 70% of the village community has elementary school education, with a livelihood of 85% being farmers. This village is very unique, because it borders on oil palm plantations, the area is still maintained, so there is no conversion of land to oil palm.

3.2.1 Formation of Team and Village Sketch

The preparation of the mapping process was preceded by the presentation of the intent and purpose by the author to the village head, and the village community agreed. The agreement was then carried out by the village administrator, by making a decision letter from the village mapping team. Related to village boundaries have been resolved with limited villages in the previous process.

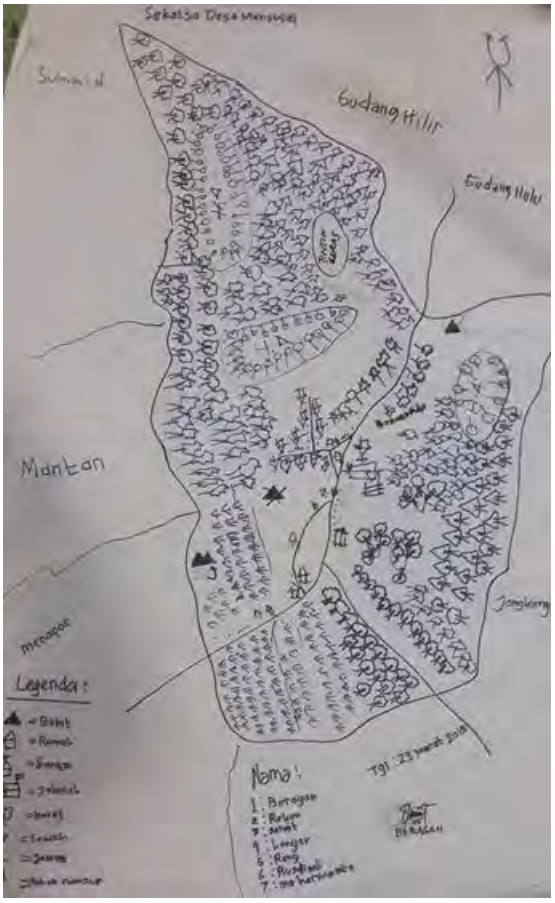

Figure 8 Mensuai Village Sketch

The next process is determining the timing of the implementation and the number of teams that depart. The obstacle faced is that the map needs to be sketched into a village so that it becomes a guide in the process of taking coordinates in the field. The team that was formed then discussed with the author to carry out the process of making a village sketch.

The sketching begins with the making of a duplicate of the Mensusai Village Map which contains some basic information, including village boundaries, village roads and rivers, then from the basic information, participants fill in and describe some of the land uses in the village, such as where settlements, yards, gardens, rice fields, mine sites, customary land and

others. The final goal in the village sketch is that the community has a mental map in the work process in the field, besides that it also becomes a guideline for the community in dividing the team and the location to be mapped..

3.2.2 Mapping Process

The team was divided into 4 groups, based on the number of GPS available. Each team consists of 5 people. The time of data collection was carried out on March 27-28 2015. The mapping location was quite challenging, because there were many large rivers and ± 5 m deep peat areas.

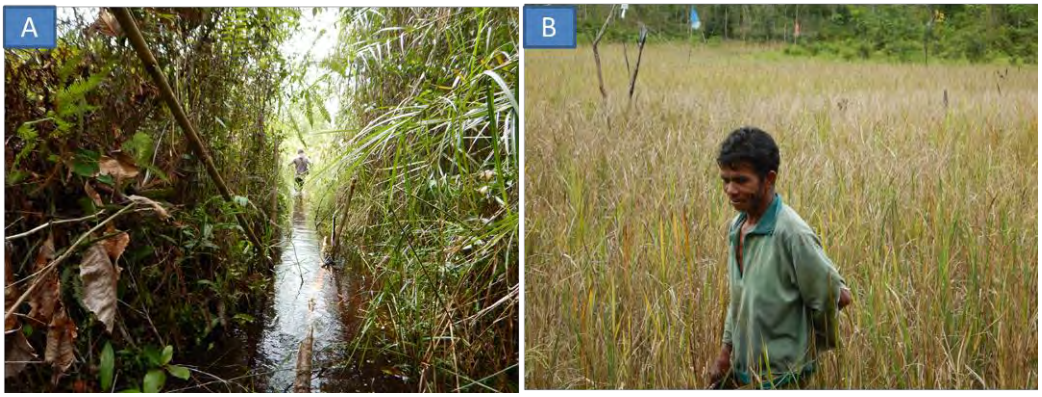

Figure 9 Condition of Swamp (A), and Community Field (B) in Mensuai Village

Land use is the focus of taking coordinates. Point collection is carried out every 100 m using GPS. Mapped locations include settlements, paddy fields, rubber gardens, graves, reserves and tembawang. According to the head of tribe, this village is an old village, where the first start was the Mayan Dayak tribe, who lived around the Mayan river. This is the author got when entering the sacred forest (Gupung Nibung) with an area of 2 hectares. There are many ancient pottery that can still be seen around Gupung Nibung.

Figure 10 Map of Sacred Place and Traditional Pottery in Gupung Nibung

Every night the author and the team conduct a review related to mapped locations. The purpose of the review is the spatial learning to the public on field information that has been

mapped (fulfilling the inform consent aspect). The verification process must involve cross gender and age, so that aspects of representation in the participatory process can work.

Figure 11 Verification of Mapping Results.

The verification process was carried out in two stages, namely daily verification and final verification. Daily verification was performed at night after returning from the field. Final verification was performed at the end after the map is ready to be printed in the size requested and ready to be ratified by the village government and tribe. During the verification process, one of the team members coordinated with the village administrator, to create a village profile. The division of tasks, in order to speed up the mapping process in the field.

3.2.2 Public Consulatation Forum; Spatial Discussion

The consultation forum was held during a public consultation activity on May 21, 2015. The purpose of the public consultation activities was as a discussion room between the village community and the mapping team. This activity begins with remarks from stakeholders (head of village/sub-district), followed by exposure from the facilitator to convey the entire mapping process, and the results of mapping to the community.

Figure12 Public Consultation Process

The presence of stakeholders helped the team in the mapping process. Stakeholders were present: (i) representatives of the Suhaid Sub-District Government, (ii) Representatives from the Suhaid Sector Police, (iii) Bordering villages such as Mantan Village, Jongkonghulu Village, (iv) community representatives such as community leaders, tribe leaders, youth leaders, teachers, representatives of the PKK.

There are several products produced from the mapping process including: land use maps, spatial interactions, boundary maps, structures and spatial patterns, tenurial maps and village profiles. The maps were generated from 450 coordinate points assisted by village teams and CO.

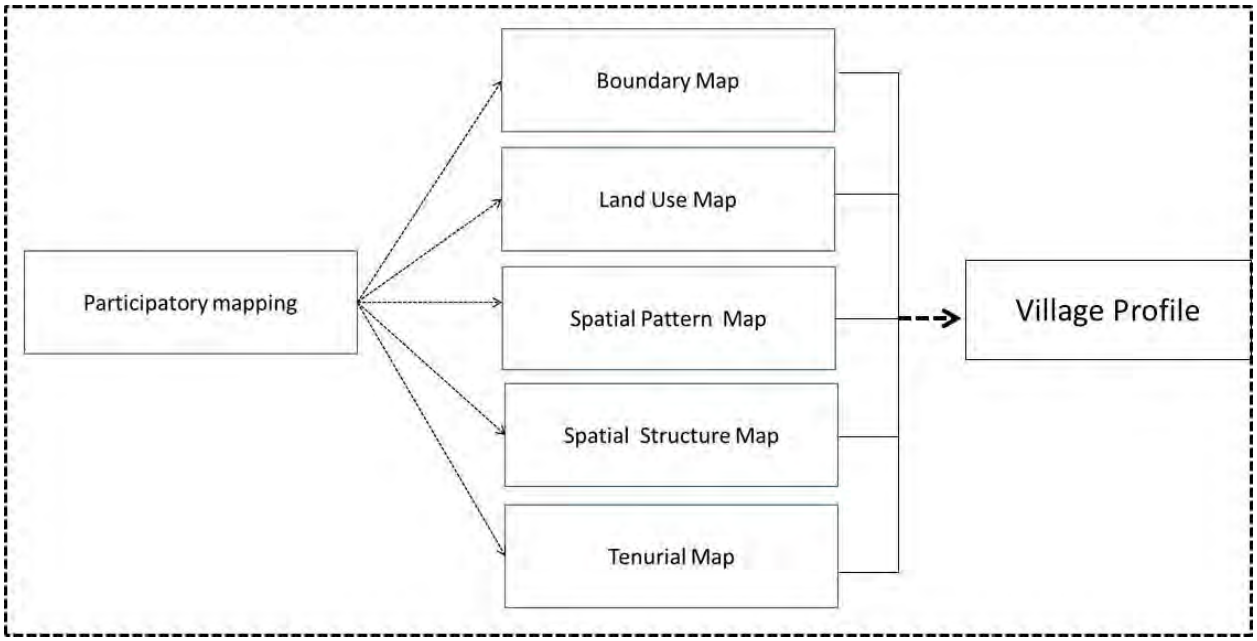

Figure 13 Results of Participatory Mapping

From the picture above explains that participatory mapping can help villages capture areas, plan areas and document spatial information. Participatory mapping also talks about how to protect the area through a map of spatial patterns (areas that need to be maintained), looking at patterns of ownership of individuals, communities, villages (government) and participatory mapping that will explain the history of the village (Amandus Jong Tallo, 2018).

3.3. Prai Ijing Traditional Village

Prai Ijing Traditional Village is located in Tebara Village, Waikabubak Sub-District, West Sumba Regency, East Nusa Tenggara Province, Indonesia. Village inhabited by ± 10 family heads are still very traditional. The mapping process was carried out on the basis of the request of Tebara village head, Marthen R. Bira in early 2019. The biggest challenge for the writer is that the community in the village is still very traditional in maintaining culture, with 90% of education being elementary school graduates and many still not completing education.

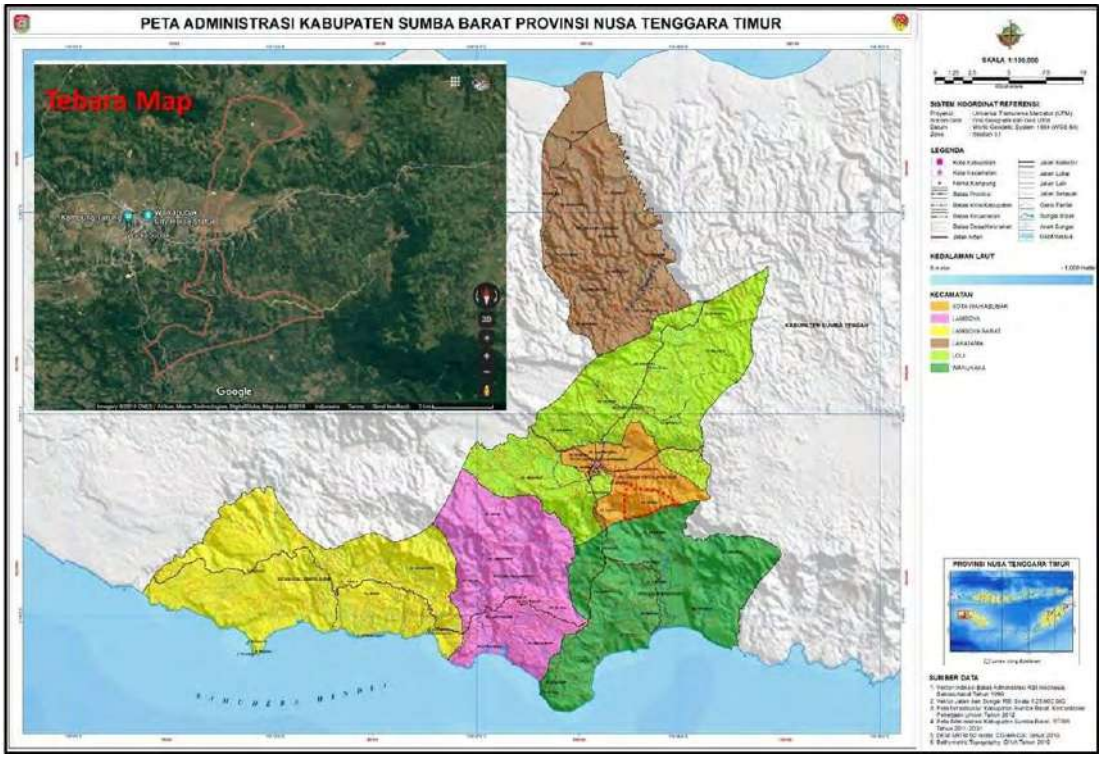

Figure 14 Orientation Map of Prai Ijing Traditional Village

Prai Ijing itself means Ambarella Village. This village adheres to the marapu belief system (Local Religion). Marapu itself means sacred objects that are worshiped by the local community, there are still sacred spaces inside the house, and inside the house. On the inside of the house in the upper part of the attic as a place to store superior seeds and ancestral heirlooms. In the middle of the house there is space separated by male and female gender. The bottom of the house is an animal cage.

The mapping process was carried out on 14-17 July 2019. The author's technique was easily performed because the village location is still accessible to cellphone networks and there are not many trees as a barrier. The author taught how to use the Android-based SW Map application to the village community. Previously, a basic map of Google Earth 2009 was installed on each handphone before the learning process began. The process of mapping and finalization is still ongoing

Figure 15 The training process with the community

The community jointly carried out the exercises and mapped every point of the house, the cemetery, the number of residents, belonged to certain tribes, and village infrastructure such as toilets, water reservoirs, customary graves. Each house has 1 grave which is the most important point in the unit of the Prai Ijing Traditional Village community unit. The village structure is divided into three parts, the bottom, the middle and the top, where the northern part is the first place for this village to stand, the middle and the south.

Figure 16 Digitized Results Map of the Prai Ijing Traditional Village community

From this process there is a learning that participatory mapping can answer cultural-based spatial systems (gender, ritual space, sacred and profane space), water fulfillment spaces and accessibility. As well as being a suggestion for the development of tourist routes when going to visit.

4. Conclusion

Participatory mapping is key in describing spatial information. Planning that starts from the community level is carried out based on community spatial information. The communication process as a CO is also key in mapping activities. Many participatory studies are very long and time-consuming, but with the help of technology and village resources, they can be optimized so that the time efficiency in implementing activities can be completed. Learning from Mensuaia village shows that the map from the participatory process will raise community rights to the area to produce boundaries, land use, history of land ownership, so that participatory mapping activities strongly support civil policy in the effort of one map policy. Lessons from the Prai Ijin Traditional Village show that the map can show the spatial relations, ritual relations and history of the region based on local wisdom.

Research Paper

Habitat 5.0 – Towards affordable and sustainable housing in the developing world

"Brick-Chain" – a pattern- and blockchain-based approach to build communities

Silja Tillner, Architekten Tillner & Willinger ZT GmbH, Austria
Eva Maria Kuehn, TU Wien, Faculty of Informatics, Austria

Abstract

"Habitat 5.0 – Towards affordable and sustainable housing in the developing world" strives to build communities by following urban design patterns for sustainable settlements and goes beyond the mere production of individual housing structures. It is a blockchain-based approach that leads to "disruptive innovations" in order to achieve "quality good enough"[1] to upgrade informal settlements. The key approach relies on the secure and verifiable transfer of existing, qualified know-how that enables residents to participate in the process. The self-building of houses with ecological materials is safer, cheaper, faster, sustainable, and supports the vision of "Glocalization."

Habitat 5.0 is a need-based approach: The need is the lack of affordable and adequate housing which leads to the surge in informal settlements. The idea is to improve informal housing in situ.

This need is aggravated when disasters strike, as informal settlements are the most vulnerable when heavy rainfall, floods, storms or earthquakes hit unstable land and unsafe structures. Apart from informal housing, many other cheaply built structures are usually affected and destroyed by natural disasters. Therefore, disaster relief housing is another major potential of this approach.

Keywords

Affordable housing, sustainable and secure structures, informal settlements, urban design patterns, blockchain

[1] "Quality good enough" comes from Clayton Christensen of the Harvard Business School, who coined this term and the related concept/theory—based on insights stemming from real world cases—starting in the nineties (*The Innovator's Dilemma*, *Seeing What's Next*, *The Innovator's Solution*, *The Innovator's DNA*, *Competing against Luck*). In this case, it refers to providing adequate, safe and sanitary housing, but avoiding exaggerated levels of quality and excessive provisions to save costs and assure affordability.

1. Introduction

1.1. Urgency of addressing housing crisis & improving informal settlements

Informal settlements are a problem, as they are unecological, unsafe and lack adequate social and technical infrastructure. Through the absence of planning and architectural expertise, land is densely built-up with no public spaces and proper streets. As a result of continuous urbanization, this problem will keep growing.

The UN Special Rapporteur Leilani Farha stated in her 2018 report[2] to the General Assembly: "Currently nearly one-quarter of the world's urban population lives in informal settlements or encampments, most in developing countries but increasingly also in the most affluent countries. Living conditions are shocking and intolerable. In many cities in Africa, more than half of the population lives in informal settlements. In Asia, there are 520 million residents of informal settlements."

The urgency of this problem has been known since a generation. In his iconic book, *Architecture for the Poor*, Hassan Fathy writes that "at least one billion people will die early deaths because of unsanitary, uneconomic and ugly housing" (Fathy 1989). The situation of the world's poor population has worsened dramatically in the last 30 years due to continuous urbanization and growing inequality.

The need for sanitary and safe housing is aggravated when disasters strike, as informal settlements are the most vulnerable when heavy rainfall, floods, storms or earthquakes hit unstable land and unsafe structures. Apart from informal housing, many other cheaply built structures are usually affected and destroyed by natural disasters. Therefore, disaster relief housing is another major target of this approach. The situation is exacerbated by the climate change which leads to more frequent occurrences of natural disasters.

1.2. Problem classification

The following is an attempt towards a classification of the major problems of informal settlements that will be addressed with the Habitat 5.0 approach. Therefore, this is not a complete list of all the numerous problems that occur in these areas devoid of planning, regulations or administration, but a focus on the most urgent ones:

Illegality and exploitation: Often, settlements are built illegally on land not zoned for construction, e.g., unsafe slopes, waste dumps, etc. Other settlements are built illegally on agricultural land with permission of the land owner, who makes a profit through the arrangement. This is detrimental to the environment, as natural resources are diminished, agricultural land is reduced and the built-up surface is increased.

Dangerous hygienic and sanitary conditions: The aforementioned lack of appropriate zoning means inadequate or missing infrastructure, water, sewer, electricity, etc., which causes dangerous hygienic and sanitary conditions. This has negative consequences on the environment due to pollution and illegal waste dumps.

Missing structural safety: Existing informal settlements are increasingly densified either by extensions or additions to already unsafe buildings and therefore further reduce the

[2] "UN Special Rapporteur on the Right to Housing." http://www.unhousingrapp.org/.

structural safety of the original construction, which was never calculated in the first place. Rooftop additions are often only accessible via dangerous stairs.

Vulnerability to disasters: These conditions make these settlements particularly vulnerable to natural disasters. Heavy rainfall causes landslides that wipe unsafely built structures away. In general, the terrain and the morphology of the land underneath are not stable enough to withstand unexpected or extraordinary climatological occurrences.

Endangering women: The absence of infrastructure makes densely built-up settlements without public spaces and safe streets particularly dangerous for women, who have to walk long distances when public transport does not serve the area. Gender mainstreaming goals appear utopian under these conditions.

Lack of public transport: This forces people to commute by car and encourages environmentally damaging forms of transport that are also a big burden for the household budget of low-income families.

Low quality of life: Far away from their workplaces and their social network, people become isolated and cannot participate in city life. This is especially disadvantageous for the children who need access to schools, libraries and recreational facilities.

1.3. The megacity Cairo as a demonstrative example

The megacity Cairo can serve as a case study and illustrate the various forms and building types of informal settlements. 7 percent of Cairo's inhabitants cannot afford to live in an apartment, based on the supply of the official housing market, but have to refer to the informal market with all its negative consequences. This market bases its supply on illegal land or construction, following three different strategies: (1) Farmers transform their land zoned for agricultural use into building sites without providing adequate infrastructure, i.e., public transport and utilities (sewers, water, electricity, etc.). (2) Already densely-built up residential areas are further densified with illegal buildings or additions. (3) Illegal structures are added onto the roofs of historic buildings (mainly on buildings from the late 19th and early 20th century in Downtown Cairo) without structural reinforcement or safe access.

Figure 1: Illegal construction in existing residential neighborhoods[3]

The government and nearly all private developers, in contrast, focus on the development of new towns in the desert (Sims, 2012) on the outskirts of Cairo to accommodate numbers that have more than tripled since the 1970s, far from public transit and current living quarters. New town developments in the desert are negative for the environment, because the desert is a place difficult to inhabit. Previously undeveloped open spaces are built-up and

[3] http://www.mei.edu/content/informal-areas-cairos-silent-urban-revolution

large efforts are needed to provide the desert with appropriate infrastructure, especially water. Moreover, the peripheral locations encourage unecological commuting patterns, reduce the quality of life and have a negative impact on the household economy of the workforce and their families, who are separated from their workplaces and social contacts. That is the reason why many of these new housing developments have failed to be accepted and are struggling with high levels of vacancy.

1.4. The effect of climate change on housing

In his keynote speech at ISOCARP,[4] Jeremy Rifkin focused on climate change: "Real-time climate change is not only affecting the way of life in the industrial world, but threatening the livelihood of millions of people in the developing world. [...] We need to arrest the climate crisis quickly; we need to be completely off the carbon deposits [...] in order to avoid the abyss [...] Three defining technologies will emerge across the civilization and converge to create a general purpose technology platform and infrastructure that fundamentally changes how society manages, powers and moves economic and social life and governance."

The three mentioned technological revolutions are: information and communication technologies, new sources of energy, and new modes of mobility in transportation and logistics. Rifkin encouraged participating planners and architects to take swift action and apply all the innovations of the digital world—especially blockchains. He argued that instead of individual pioneering projects, the entire planning and construction industry should be adapted to the requirements of climate protection. A special focus should thereby be set on the retrofitting of the entire existing building stock. Concluding, he showed the path from globalization to glocalization through decentralization.

1.5. Structure of the paper

The paper is structured as follows: Part 1, 1.1-1.4 focuses on the problem description. Part 2, 2-1-2.2 gives an international background of goals, declarations and efforts so far. Part 3, 3-4 offers potential solutions with the proposed "Habitat 5.0" approach.

2. Background and related work

2.1. International declarations and future commitments give direction

Following the initiative of UN Habitat,[5] states have committed under Goal 11 of the Agenda for Sustainable Development to upgrade all informal settlements and ensure adequate housing for everyone by 2030. The Agenda aims to build upon the inherent capacities of informal settlement communities and recommends supporting and enabling residents to participate in the upgrading processes. Goal 11.1: *By 2030, ensure access for all to adequate, safe and affordable housing and basic service and upgrade slums. Proportion of urban population living in slums, informal settlements, or inadequate housing*.

The UN Habitat Goal 11 serves as a guideline and as an inspiration of our approach.

2.2. "Best practice" so far to support residents in situ

Some positive efforts have been made, but they always rely on individual initiatives by NGOs or socially responsible architects and planners. Selected examples are the work of Alejandro

[4] https://isocarp.org/2018congress
[5] http://habitat3.org

Aravena/Elemental in South America, who created intelligent design solutions for building new and better houses in situ, and the work of Balkrishna Doshi, India's architect for the poor. They both succeeded in activating the residents and engaging them in a participatory way to create and upgrade their homes while at the same time achieving excellent design standards. Aravena realized that in order to significantly ameliorate the world-wide housing crisis of the poor, much higher numbers of quality housing need to be produced and people have to be activated to build themselves. His concept of building only "half a house" took a large step in that direction. Aravena was convinced that when faced with a limited budget, it would be better to build only half a good house and leave the other half for the residents to be completed at a later point themselves. The first half contained all of the necessary infrastructure, the kitchen, the bathroom and the structurally safe shell. The second half would contain additional bedrooms on an upper level or in a carefully calculated gap adjacent to the neighboring building. Afterwards he even offered his designs for free so they could be replicated by housing developers or governmental authorities without a sufficient budget for hiring architects.

Figure 2: Quinta Monroy Concept, Elemental[6]

ELEMENTAL is a Chilean based architecture practice that focuses on architecture work of public interest and social impact. They became well-known through Quinta Monroy, a social housing project on a valuable, centrally located site in Iquique, Chile that had been illegally occupied. After the land had been purchased, the budget was nearly used up. Thanks to an intelligent plan by Elemental, it became possible to rehouse the 97 families on the same site by building only half a house for each family, consisting of the basic infrastructure, which provided residents with a shell they could later add to themselves.

ELEMENTAL's director, Alejandro Aravena, was awarded the Pritzker Prize[7] in 2016 for ELEMENTAL's social and humanistic approach to architecture, which shows how architecture at its best can improve people's lives. Following the honor, he released several of his low-cost "incremental" housing plans free to the public as open source designs to provide the material to government agencies and developers to help tackle the global affordable housing crisis.[8] Although this is a most laudable effort, there are no reports yet of the designs having

[6] http://arquittetando.com.br/wp-content/uploads/2018/03/5.jpg
[7] https://www.pritzkerprize.com/
[8] http://www.elementalchile.cl/en/

been replicated. As the director of the Venice Architecture Biennale in 2016, he focused on projects that engage citizens in poor communities world-wide and on affordable housing for the most disadvantaged.

Figure 3: Settlement in Aranya by architect Doshi, for which he was awarded the Pritzker Prize[9]

The internationally noted champion of housing for Indian's poor, Balkrishna Doshi, was awarded the Pritzker Prize[7] in 2018, in large part for the Aranya low-cost housing project in Indore. It accommodates 80,000 people with houses and courtyards linked by a maze of pathways in the city of Indore. Architect Doshi believes that a large part of Aranya's success lies in the fact that instead of presenting those who would live there—often in a purpose-built house for the first time—with a ready-made design, the development allows residents the space and opportunity to adapt and improve their homes. Beyond aesthetics, Doshi argued that architecture and urban design—done right—can and should be socially transformative for the world's poor.[10]

2.3. Summary

These laudable efforts nonetheless remain hand-tailored, one-time solutions that cannot be easily replicated elsewhere—not even in their own countries, because they were created for specific situations and user groups. In general, these one-time solutions fall short because they cannot become parametric and be broken down into individual components and rearranged in different situations. This means the designs are a complete oeuvre that cannot be taken apart, separated into individual components, organized by theme and rearranged in other circumstances. But they could be used and developed further to fulfill these requirements in the process of developing "Habitat 5.02.

3. Our vision to improve the situation is termed "Habitat 5.0"

The UN Habitat Agenda recommendations serve as a foundation for our strategy entitled "Habitat 5.0," an approach with social aspects comprising the appropriate urban development, design, planning and construction processes. The major goals include: affordable living for everyone; using existing strengths, infrastructures and buildings; inclusion of current technologies; regard for world-wide expertise; consideration of ecological aspects (CO_2 emissions and energy self-sufficiency); flexibility to enable future adaptations by the users; and gender equality. The guiding principles to achieve these goals are:

[9] https://www.architectureindevelopment.org/project.php?id=401#!prettyPhoto

[10] https://www.theguardian.com/global-development/2018/mar/12/low-cost-housing-needs-dignity-indian-architect-balkrishna-doshi

- The recognition of the right to remain in situ, so that residents retain their social connections.
- Access to serviced land.
- The self-construction of homes by inspiring residents to get actively involved in upgrading their neighborhoods and dwellings and providing them qualified know-how for that.
- Usage of economical building materials, preferably from the local region.
- The participation of residents at all stages by integrating their skills and labor capital into upgrading programs.
- A scalable and replicable approach that can be easily adapted to new situations.
- A sustainable business model that supports all these social aspects.

The uniqueness of our approach lies in its potential for further development, adaptation and replication. The repeated use of a "flexible toolkit" creates multiple benefits and makes it economically attractive to a large group of potential beneficiaries.

4. Proposed approach for Habitat 5.0 based on digital transformation, design patterns and blockchain

Habitat 5.0 foresees a close integration of the digital and real worlds. The latter refers to spaces for housing, resources and involved communities. The former refers to the employment of digitalization concepts to disseminate and reuse existing architectural expertise in a practical way, in near-time, in a fair and secure fashion, and free of corruption. The know-how shall be collected and structured in so-called "design patterns" that include designs, required skills, experience reports and useful solutions. The approach relies on an organically growing infrastructure where architecture and planning experts all over the world are motivated to contribute.

Hannah Arendt writes: "Basically we are always educating for a world that is or is becoming out of joint […] To preserve the world against the mortality of its creators and inhabitants it must be constantly set right anew. The problem is simply to educate in such a way that a setting-right remains actually possible, even though it can, of course, never be assured. Our hope always hangs on the new which every generation brings; but precisely because we can base our hope only on this, we destroy everything if we so try to control the new that we, the old, can dictate how it will look" (Arendt, 2000).

Habitat 5.0 aims to address the shortcomings of the previous efforts and take the next step building upon the experiences of Doshi and Aravena. The reasons why this approach makes a difference are the wider range of its applicability and the world-wide network of people who shall become involved. It follows the ethics of sharing knowledge and experiences in a fair and transparent manner and avoiding corruption. The cornerstones are:

- The housing projects would stay in-situ so that the residents can remain within their existing social networks.
- A democratic participatory process enables their equal and fair participation.
- The affordability of the new or upgraded homes shall be guaranteed and gentrification prevented through the participation of the residents who work on the improvements of their community and thereby gain a right to remain there.

- Ecological responsiveness is regarded through the use of local materials and labor.
- Know-how is transferred in a fair way to other countries and communities, authorities, NGOs, experts and laypersons.
- Collective intelligence leads to innovative and unexpected solutions. There will be an open call for interested experts, so that people who want to contribute to this effort with their knowledge and experience as well as potential beneficiaries have a chance to participate.

4.1. Urban design pattern language

"Patterns" are a recognized approach that promotes learning from proven solutions in a highly usable way. Especially in the described setting we do not assume that the involved stakeholders, especially the inhabitants of informal settlements, have the respective knowy how to build their "cities" and not to be "fooled" by corrupt exploiters. This indeed is a core root of the problems described in Section 1.2.

Each successful, welly used public space, regardless of its time of creation, has specific, inherent qualities. These can be abstracted so they obtain a less specific and more general meaning. Christopher Alexander was the pioneer in that respect (Alexander et al., 1977). This knowy how shall be identified and generalized in the form of such parameterizable patterns, leading to a global, open knowledge base of architectural expertise, including expertise about (new) materials and their gray energy. The starting point is, therefore, the identification, selection, collection and provision of patterns for the design of urban spaces. This objective refers to "learning from" a multitude of comparable projects and from tested and proven solutions, including those mentioned in Section 2.2. The patterns provide design modules that allow different combinations and ensure future flexibility and adaptability.

The idea is that the building of public spaces relies on such prey defined design patterns created by professional planners and architects. Such patterns are developed based on proven experiences and quality solutions. They form a kit of parts that laypersons can use without detailed knowledge. On one hand, they allow these laypersons to create functioning and aesthetic solutions by reassembling, enhancing and transforming existing urban design patterns in different ways. On the other hand, they shall leave enough freedom for individual parametrization and creativity. The art is to nevertheless guarantee good and "quality enough"[1] solutions.

The result is a "pattern language" with examples and rules for different applications that we are currently developing based on our experiences in rey using designs in Architecture (Silja Tillner and Sabine Pollak developed a pattern language for selfy build projects (Tillner, Pollak, 2017)) and Informatics (Kuehn, 2016). As the name "language" suggests, it has a highly usable interface that allows even nony experts to query and navigate through the patterns using simple language artifacts. The solutions are presented in an understandable and comprehensive way and are illustrated with practice reports. The language also encourages the giving of feedback so that the quality can be continuously improved.

The pattern language serves to collect and generalize the patterns and their solutions in the form of a "handbook" with a respective set of rules that can be applied in different situations. This means that the pattern language also includes process patterns beyond the mentioned design patterns. Sharing and reusing processes implies a better usage of resources. Professional planners and architects provide knowy how about urban design strategies and methods for the urban spaces, as well as information on sustainable building

materials through patterns. Besides the conscientious and saving use of materials and the reduction of waste, there will be a pedagogical benefit, too. The verification that the patterns are ecological shall alleviate the climate problem. In addition, the patterns will be verified consensually to support gender mainstreaming and the mentioned striving for qualities like fairness, etc. All patterns shall be digitized so that they can be easily disseminated, developed further, combined in various ways, shared and licensed.

Clearly, the coordination of all these activities and processes requires a respective IT platform. We propose a new kind of blockchain termed “Bricky Chain” (see Section 4.2) for this.

4.2. The “Bricku Chain” toolkit

The “Bricky Chain” concept introduces transparent, decentralized and cooperative processes. It is inspired by the principles of blockchain. The notion of a blockchain was introduced in the seminal article about Bitcoin (Nakamoto, 2008), a blockchainy based cryptocurrency. Since then, the idea of a blockchain has been proposed for many different business applications. A blockchain pursues a radically new philosophy beyond current IT approaches. It relies on a “distributed ledger technology” (Kuehn, 2019) without any central “many iny they middle.” Instead, the trust is achieved and the rules for cooperation are agreed upon in a consensual way by equal, distributed “peers.” Data and transactions are replicated to all peers, who independently verify their accuracy. Business processes become automated and thus faster, tampery proof and transparent. The peers do not have to trust each other, but can still enter into secure business relationships.

As the paradigm of a blockchain fits the principles of Habitat 5.0, we propose the usage of a new blockchainy based infrastructure called “Bricky Chain,” which allows the participative, selfy organized collection of patterns and their distribution in a fair and decentralized manner. The digitalization of patterns facilitates further and flexible development, combinations, sharing, community building and licensing models via the Bricky Chain. The proposition is to create a toolkit of consistent quality that consists of proven, generic design elements and plans that can be used firstly by NGOs, local authorities and experts to produce welly functioning layouts of the settlements and, secondly, by the people for building iny place. Residents use a pattern languagey based interface to search for the most suitable solutions and for realy time collaboration with experts. The distribution of the patterny based designs as well as all interactions is accomplished by the “Bricky Chain.” The Bricky Chain infrastructure provides licensable pattern toolkits including the respective support, incentive and donation models. The pattern toolkits themselves will be provided to the end users, who can be NGOs, citizens, etc.

Following the blockchain philosophy, the kit for parts, as well as for the entire infrastructure, shall be open source. The patterns can be adapted and expanded for the different continents to respond to the different climatic conditions and support environmental protection. Examples for further developments contain ecological qualities such as information on the preferred use of local materials and building techniques, the length of transport and the gray energy of the building materials.

As a consequence of applying the Bricky Chain toolkit, a worldy wide network of creative people, practitioners, local authorities, NGOs and end users who support the exchange of knowledge and ideas will continue to grow naturally. The modular nature of the approach allows for flexibility and extensibility. Such a flexible and adaptable toolkit shall offer quick

solutions to local authorities and NGOs, especially for disaster relief housing after cyclical catastrophes.

4.3. Long-term perspectives

In addition to the digitalization and dissemination of expertise in the form of pattern-based toolkits, industrial 3-D printing technology will be used. By combining the design patterns with 3-D printing utilizing high-performance 3-D printers, a “design and build” situation will be supported without the need of experts. The pattern language software would enable end consumers to download a building kit and 3-D print certain parts for the house. Since 3-D printing is still a fairly slow process, the goal is to combine it with local building expertise so that the simpler forms of assemblage can still be performed manually while the more complicated connecting links and complex joints will be 3-D printed. Following an “IKEA” type of assembly, untrained people will be able to use prefabricated corner elements and joints and connect them with wooden beams or other locally available building materials. Each form of implementation shall use the resources at-hand most efficiently and effectively.

On the other hand, the modular and digitized approach provides the end customers, designers and builders with enormous flexibility in terms of design and materials used—enabling the use of locally sourced and environmentally friendly building materials. The main modular building blocks could be universal across the international network. Multiple uses of proven and certified modules would offer substantial cost savings as well as better designs. A potential combination of the 3-D printers with robots offers another level of technical accuracy and efficiency.

5. Evaluation of the approach

5.1. Support of the Habitat III goals

The claims of Habitat 5.0 are aligned with the Habitat III New Urban Agenda. Its main impacts comprise: new forms of know-how and IPR licensing in the form of patterns of architects and planners; new, gender-sensitive processes for collaboration and sharing models; verification of process and design patterns to conform to the Gendered Innovations methods of the EU; collaboratively designed urban spaces that contribute to the health and well-being of people and foster nature-based approaches.

Through the use of predefined yet developable patterns, citizens will be enabled to engage themselves in a meaningful way. The patterns distributed by the Brick-Chain will serve as “tools” that complement the citizens’ lack of expertise, thereby balancing the role of experts and laypersons. This ensures sustainability of the approach because the newly gained skills will be applied by the empowered citizens in the future.

5.2. Contribution to alleviate the problems of informal settlements

The Brick-Chain could contribute in the following ways to alleviate the problems of informal settlements (see section 1.2):

Illegality and exploitation: The transparent process of planning and building and the traceability through the blockchain will prevent illegal land transactions and speculation.

Dangerous hygienic and sanitary conditions, missing structural safety and endangering women: Since these conditions are caused by the absence of responsible planning and illegal constructions, the provision of technically correct design patterns will allow authorities, NGOs and laypeople to create urban design plans with safe streets and public spaces, adequate infrastructure and building plans with sufficient technical equipment.

Vulnerability to disasters: The construction on unstable land in combination with unsafely built structures causes the high levels of risk. These risks will be reduced by the same transparent processes that help to prevent illegality and exploitation.

Lack of public transport: Although the Brick-Chain cannot substitute a public bus service the blockchain technology will support the planning these services as well as stimulate self-organized ride-sharing and shuttles.

Low quality of life: The participation in the design and build process will plant the seeds for a resilient social network. People will get to know their neighbors and more actively participate in city life. The blockchain technology could support learning networks, e.g. the creation of study groups, book-sharing etc.

6. Conclusion

The advantage of the suggested pattern-based approach is to reach beneficiaries on a large scale and therefore make a bigger impact than previous, isolated initiatives by applying "disruptive innovations." The patterns lift the concept of modular design to a higher level: They transfer modular design principles to public urban spaces through parametrizable design and planning, which is cheaper and more effective than tailoring. Patterns enable a replication of know-how and selling of IPRs in an emerging market. Environmental protection patterns will inform the citizens and also ensure sustainable processes in the future thanks to their replicability.

The motto is "quality good enough"[1] to encourage the self-building of houses with appropriate ecological materials—safer, cheaper, faster and sustainable, supporting the greater vision of "Glocalization." The secure, fair and fast distribution of the know-how is guaranteed by the application of a blockchain-based IT platform called "Brick-Chain." Through the flexibility and reusability of this approach, substantial cost-savings compared to traditional, one-time aid efforts are offered. Owing to the geographically dispersed applications of an easy-to-use pattern language, the system can also be applied directly by the end users, providing not only additional cost savings, but also a further education aspect.

The following facets of the approach make it unique from a business and innovation perspective: The long-term perspective is to develop a "business venture with a social aspect, which would be based on a modular approach, leveraging modern, industrial 3-D printing technology and a unique design pattern approach in order to enable the use of local, sustainable materials for the rapid replacement of inadequate housing with new, safe, and sanitary dwellings." The pattern language is an answer to establishing validated and tested modules that encourage laypersons to get creatively involved and can be rearranged and re-used in numerous ways, which is unfeasible with traditional design techniques, and then applied elsewhere. Habitat 5.0 is a flexible model that can be transformed and developed continuously, as the needs of the citizens and the conditions of the cities vary.

The main goal and the ethics of the project are to achieve affordability in "housing for all" in the developing world in a sustainable way, namely to achieve a resilient ecological city with active and engaged citizens who are part of the process and therefore feel responsible for safeguarding the environment. On one hand, this means the application of innovative knowledge and practices related to social inclusion and participatory self-regulating processes. On the other hand, the efficient use of resources, technological innovation and community services guarantee a lasting impact. All development processes shall be understandable and transparent.

Abstract

With the development of urbanization and the continuous development, construction and renewal of the city, the living environment of human beings has also undergone tremendous changes, such as residential community environment and service facilities, urban roads and street spaces, and urban public service formats. And the layout of the facilities, etc., and these are the real needs of people in urban life, but the characteristics of these needs or their problems will inevitably have a certain impact on the user's psychological feelings, thus affecting people's use needs. Then, studying the ways in which urban residents perceive changes in the living environment and how they perceive changes in psychology and emotions will have practical significance and can effectively assist urban management and builders to optimize the living environment of residents. This is also the long-term. One of the topics of greatest interest to urban researchers since then.

In the theory of demand hierarchy proposed by American psychologist Abraham Maslow, safety is the basic requirement second only to physiological needs. So safety, especially psychological security, has become one of the basic needs of people in the urban environment. People's perception of the psychological security of the urban environment is also one of the most important indicators in urban environmental assessment.

In the past, due to the influence of technical means, the study of urban environmental psychological security often relied on the limited investigation of a small number of respondents. Low-density data is difficult to measure the perceptual results of universality. With the leaping development of the mobile Internet, Internet image data has grown geometrically over time. And with the development of artificial intelligence technology in recent years, image recognition and perception analysis based on machine learning has become possible. The maturity of these technical conditions provides a basis for the study of the urban renewal index evaluation system based on psychological security.

In addition to the existing urban visual street furniture data obtained through urban big data collection combined with artificial intelligence image analysis, this paper also proposes a large number of urban living environment psychological assessment data collection strategies. These data are derived from crowdsourcing, and the collection method is limited by the development of cost and technology. At present,

the psychological security preference of a large number of users on urban street images is collected by forced selection method, and then obtained by statistical data fitting to obtain urban environmental psychology. Security sense training set. In the future, when the conditions are mature, the brainwave feedback data in the virtual reality scene can be used to carry out the machine learning of psychological security, so as to improve the accuracy of the psychological security data.

Keywords

urban environment, psychological feeling, artificial intelligence, method research

1. Problems arising under the policy of wall-up planning in China's demolition shop

Urban planning in China has always been based on government decision-making. Although some factors such as cultural economy and resources are also taken into account in the design process, social and psychological factors are often ignored, resulting in certain differences between government investment and the feelings of the masses after the implementation of the plan.

For example, in response to the new round of overall land planning and wall repair policies in Beijing and Shanghai, Beijing and Shanghai have concentrated on renovating residential shops along the street, Yongkang Road and Changshou Road in Shanghai, as well as various shops in the east-west urban areas of Beijing and Chaoyang in recent years, with the intention of restoring the style and appearance of streets and alleys. In 2017 alone, Beijing has demolished 1496 shops in Xicheng District, covering an area of 13297.4 square meters. As an open block model, Shanghai has also carried out block renovation work, Yuyuan Road, Fuxing Road, Yongkang Road and other commercial along the street have also been demolished. However, a series of social reactions have been praised and demoralized. It's different. Many people feel that the move has damaged the living environment and feelings of the local population, and lost the original vitality of the street.

2. The importance of psychological safety to the community

First, human is a socialized animal, and communication is one of the important links of social psychology. The communication provides the information resources necessary for the physical and mental development of the people, and the people exchange information and establish and maintain contact with each other. Communication is the way of self-concept formation, and is an important means to meet the demand and maintain the psychological balance. As the end user of the street space--in the case of the masses, our little street is not only a convenient means of living, but also a channel of more social interaction and emotional release.

There is a lack of communication between the modern community and the old neighborhood and the neighborhood. Along the street, it is different from the community greening and the community space, and people will consume a certain degree of time (such

as shopping, dining, etc.) along the street, and this kind of space provides some degree of space for the masses.

At the same time, the inconvenience and the change of the environment caused by the demolition and repair of the wall have not improved the public security of the audience in nature, and the lack of the lively neighbourhood commerce has reduced the public's natural supervision of the street to some extent. After the demolition, the traffic of the block is obviously reduced, especially at night, the open street is easy to cause a certain potential safety hazard, and the sense of feeling also makes the person feel insecure.

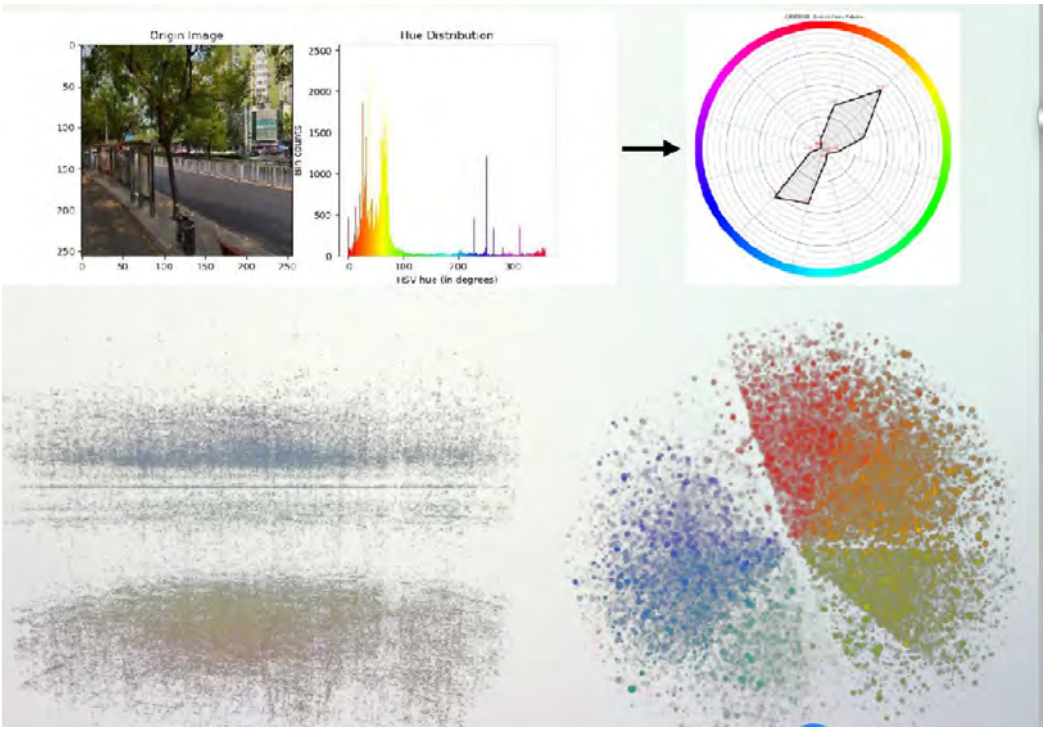
The "gas field" referred to in the traditional "Fengshui" of our country is either popular or the "energy field" is to some extent to describe the distance comfort between the human and the person in life. In the planning standard, the standard of the 5-minute life cycle and the 10-minute life cycle is also mentioned. However, after a large number of street shops have been removed, the existing environment does not provide the residents with the necessary public supporting commercial facilities. That's why a lot of people don't feel the smell of life and culture.

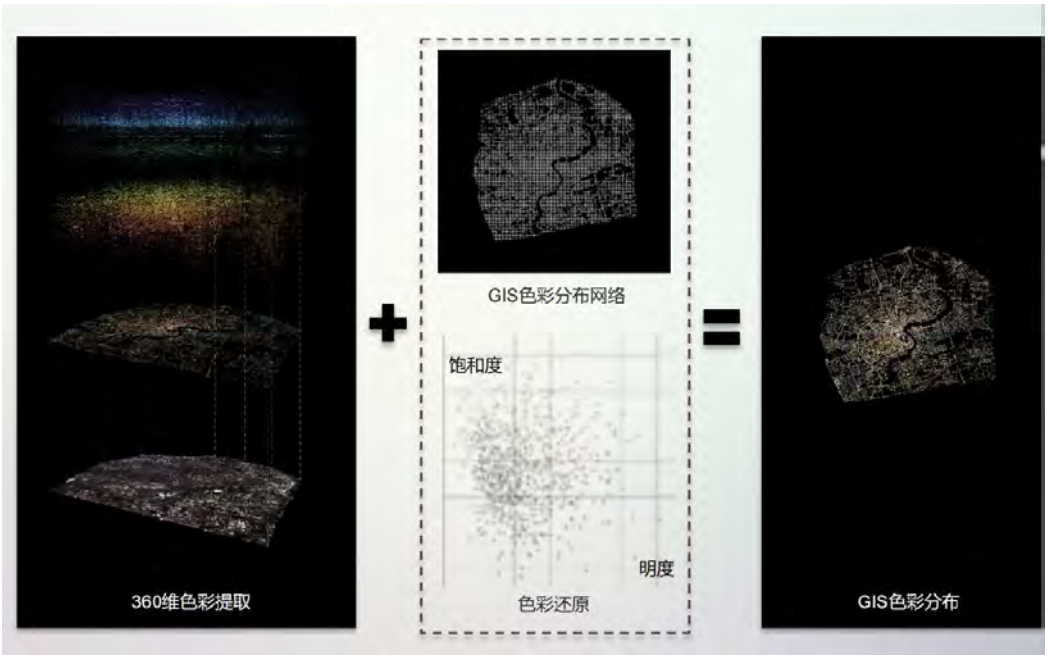
3. Selection criteria and methods of Urban Color in Psychological sense of security comfort in Planning

Our research found that. Urban color perception is one of the main ways for human beings to recognize their own urban environment. Environmental color also has a great impact on human behavior. For example, the choice of soft colors in the living area to give people a warm and safe feeling, for the business district, often with brighter colors to give people a vibrant feeling.

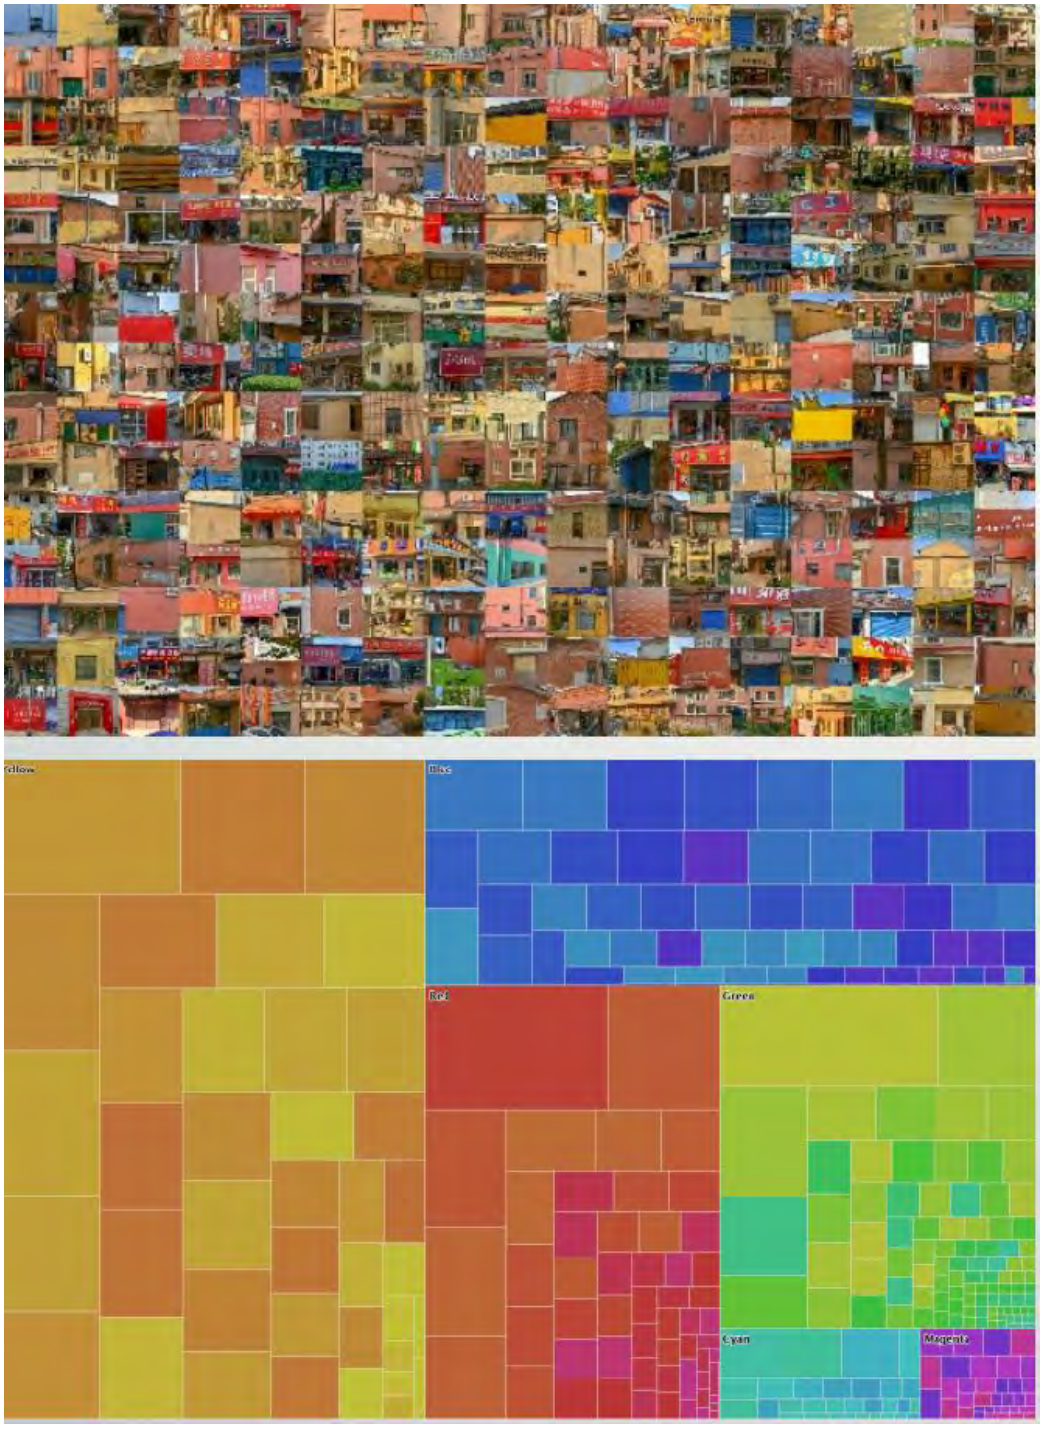
We extract the main architectural colors from the city-related photo data and define their architectural color genes, and use the color reduction principle (SHV) color space and AWB algorithm to process. A 360 degree high definition, 3 D data set was obtained. Analyze the color of the city. (see the extraction and comparison process below for details)

Step 1. get the color

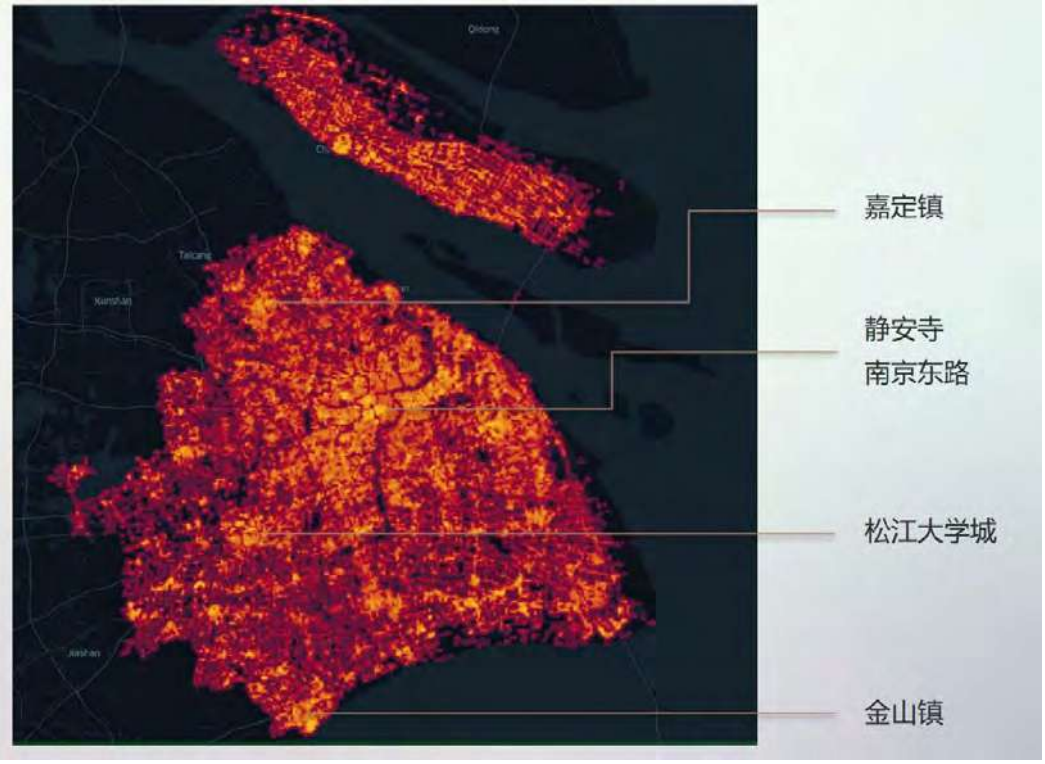




Step 2.compare the colour



Step3. compare the area

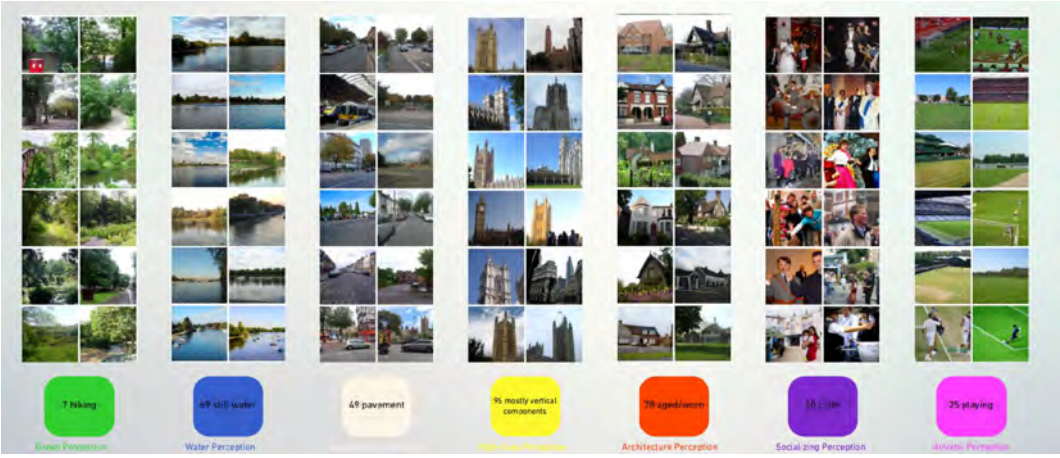


We can see that the colors of the different regions of Shanghai are completely different, and the commercial area and the residential or university, the suburban area is obviously different. However, in other cities, the color change of cities is not obvious in many times in different functional areas.

When we extract these color analysis, the next step is to analyze the human perception of the environment, what is the most comfortable standard. We divide perception into three parts: urban intention, artificial intelligence and new city perception. The image of the city, first from the Massachusetts Institute of Technology in the United States. They put forward the appearance of the city, combined with the five elements of the city (roads, boundaries, areas, nodes, markers) to fully demonstrate the importance and variability of the city. The landscape of the city, in many roles of the city, is also a visible, memorable and gratifying source. Giving urban visual form is a special and quite new design question.

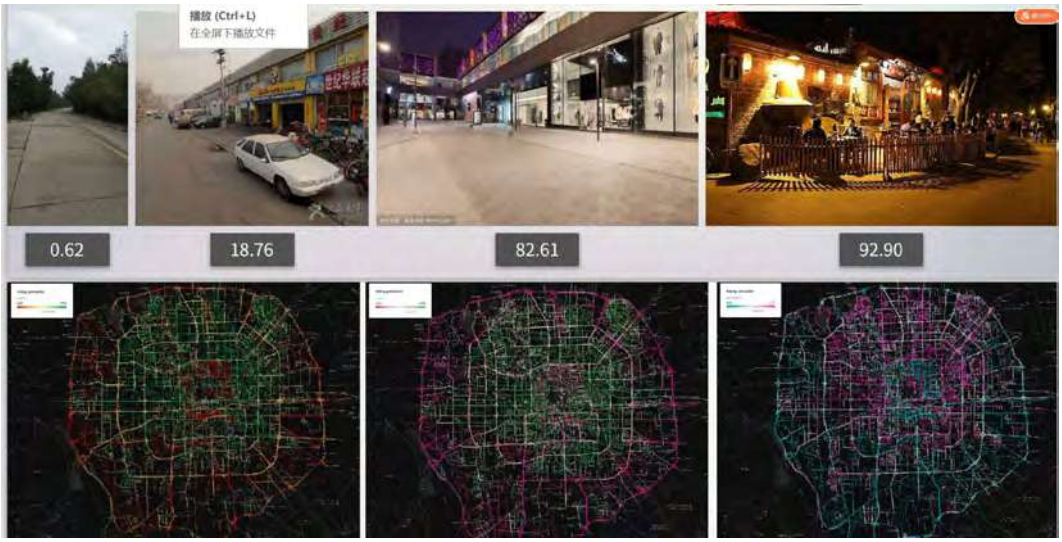
Title

Liu's C-image spatial research method uses GIS to obtain public uploaded photos with a large number of location information combined with artificial intelligence to obtain what is the best or worst public evaluation of the environment. Element extraction and recognition are carried out. Thus, after comparison.



Take greening as an example, although there are mandatory requirements for the proportion of greening in many parts of China, but in fact, after the implementation of the public perception is not good. The reason is that the public perception of the environment deviates from the cognition of the government or related departments. In the process of urban color analysis, we get a part of the perceived evaluation criteria for greening. (as shown in figure, 5 is the highest score for perception)

And for the street renovation perception mentioned at the beginning of the article, we also established a street public cognitive system, which is based on the same principle (see figure below: the street sense of security and comfort rating is the highest on the right).



The above conclusion is that not all policy making or expert assessment of the environment is the most beautiful and comfortable environment in the public perception. And the beautiful and comfortable environment is not the most sense of security environment. Through our only perceptual technology, we can avoid the discomfort of the end-user experience in our planning. It also increases the humanization and rationality of planning and design.

conclusion

Finally, for urban renewal and community transformation to improve their social satisfaction, the real intervention of public participation is also a means to improve satisfaction. In addition to actually obtaining the demands of the masses, it can enhance the individual sense of participation and belonging. Of course, it is also an effective means to guide the conformity psychology of the masses by combining the appropriate media publicity before the implementation.

In a word, in the process of urban transformation in China, the government has to take into account social and psychological factors, in addition to the need to consider the traditional development and positioning, and the function of the community is to provide the people with comfortable and reasonable living and working environment. The unharmonious social psychological contradiction can also bring negative potential influence to the stability and development of the whole society, and how to improve the satisfaction of the masses and to avoid a certain social psychological problem is the important basis of the "improve that level of people's living and the governance of new society" in the 19-big report of the Party.

Case Study / Project

Cities and Digitization

Perspectives and Challenges of the Smart City Technologies on Urban Planning and Design

Junyan YANG, Yi ZHENG, Simon MARVIN

Abstract

Cities have recently witnessed the emergence of connected objected and advanced technologies that are going to have an increasing influence on city planning and design as well as urban studies. Cities are mostly defined by their complexity. Megacities are characterized by millions of daily human flows and activities driven by individual and collective decision-making. From this approach, how can urban environment be improved for people's daily life? And how can healthier and smarter services for citizens and public space users be provided and be translated into urban planning and design applications? Based on the outcomes of the international digital urban design workshop happening in June 2019 (co-organized by Southeast University of China and ISOCARP), the session will put in perspective the future challenges of urban planning and design disciplines under the angle of digitization. Three professors will be invited to present their research on the topic and the outcomes of the digital design week in Nanjing. An interactive discussion with the public will follow then. During the first part of the session, Mr. Yi Zheng will introduce the session topic and present the results of the Nanjing International Digital Urban Design Week. Pr. Junyan Yang (Southeast University of China) will then speak about the relation between digitization, public space and urban design.

The session will highlight the impacts of the digital transition on emerging urban planning and design approaches, and illustrate how our understanding of the city is changing with big data. The question on how to make cities healthier and more sustainable through smart technologies will be raised, taking a few cities and megacities as references and Nanjing as a case study. Several digital urban design samples will be shared to the public in order to inspire its participation in the last part of the session. Pr Simon Marvin (Director of the Urban Institute, University of Sheffield) will give a presentation about robotization of production, smart city services in our urban environment, applied to digitization and AI (Artificial Intelligence) and daily life of people in the city. The question on how the urban environment could be (re-) designed to match with smart objects and applications will be introduced at the end of its presentation.

Pr Michael Tomeldan (University of the Philippines) will present then a general view on urban issues in Southeast Asian megacities, in relation with digitization and its perspectives in the region. The public will be invited to discuss the current transformations of traditional urban lifestyles and potential responses by urban planners, considering the challenges brought by big data and digital technologies.

Research Paper

Measuring Visual Quality of Street Space Based on Deep Learning and Street View Picture :

Pilot in The Lilong Area in Shanghai

Qinglai Zhang, Tongji University; China
Jiatian Bu, Tongji University; China
Yifan Yu, Tongji University; China

Abstract

Built environment indicates of street space quality have been carried out in a profound influence on the image of city， human behavior and public health. A street that is considered as a fundamental element in urban studies. Of the 5 elements of the image of a city, i.e. landmarks, paths, nodes, districts and edges, suggested that the paths are the most dominant elements, the research of which would provide a basis for the clustering and organization of the meanings and associations of the other four elements and the city as a whole. Additionally, taking a quantitative measurement of the visual appearance of street space has proven to be challenging because visual information is inherently ambiguous and semantically impoverished. Recent developed image semantic segmentation techniques and Street View Picture dataset make it possible to eliminate the previous restrictions, Furthermore, bringing forward a research paradigm shift. Lilong, which typically represent for historical street space in Shanghai, are selected for empirical study .This paper attempts to measure subjective qualities of the Lilong environment comprehensively and objectively. By employing Street View Picture, pictorial information is the proxy for street physical appearance, which utilizes the image semantic segmentation techniques (The model used in this study is Deep lab V3 which can achieve a 85.7% pixelwise accuracy when classifying 150 categories of objects) to parse an street scene into scene elements, such as buildings, roads, pavement, trees, cars, pedestrians, and bicycles. Then, the elements corresponding to each street point in the two directions of spatial coordinate are summarized and the average value is calculated. The potential factors were calculated based on 3-dimensional composition calculation of greenery, openness, enclosure and motorization may serve as indicators for inferring. The outcomes were used to evaluate the street types, functionality, quality, time, status, and human activities of a street. The result indicates that visual quality of Lilongs are barely satisfactory, while some regeneration projects in the historical protection block is better. A lot of Lilongs are in shortage of visual green, relative more continuous but with low vertical diversity. In the most recent 6 years, less than 2.74 million square meters Lilongs are not regenerated which are mainly slow building renovation. A series of quantitative analyses demonstrates the ability and great potential of auto-calculation method useful for auditing street environments.

Keywords

Visual quality Quantitative evaluation Street View Picture Deep learning Lilong

1. Introduction

Street space is an important part of urban public space, the quality of street space affects the behavior of users, public health level, the shaping of urban culture. In its report "Streets as Public Spaces Promote Urban Prosperity", UN-Habitat states that streets have an important impact on the social productivity, quality of life and amenities of cities. The past several years have seen a rapid expansion of research on the health implications of street environment features such as aesthetics, traffic， physical disorder, social interaction, and pedestrian safety（Hoehner, C.M. et al,2005;Boehmer, T. K. et al ,2007; Middleton, J. 2018). Admittedly, good street environment can promote social interaction, form friendly neighborhoods, and also affect the healthy behavior of residents, improve the output of individual healthy behavior. Therefore, designing human-oriented street space has become one of the vital environmental improvement strategies for competitive cities. Many countries and regions have proposed street design guidelines to improve the environmental quality of the streets. In China, Shanghai has proposed street design guidelines. The widespread street policies and platforms indicate that people begin to pay more attention to the refined design based on the human-oriented scale.

In the past, the traditional measurement of street space quality adopted two-dimensional plane analysis or small-scale subjective research method, it is difficult to measure the level of urban three-dimensional street space quality on a large scale. With the development of image segmentation technology and street view acquisition technology, the research on street space has obtained a new method breakthrough. In this paper, in order to improve the quality of the street space environment, we introduce Baidu Street View pictures and machine learning techniques to quantitatively evaluate the indicators of street space environment. This paper selects the street view picture of Lilong area in Shanghai as research object, identifying the elements of the street environment and carrying out the evaluation of street space environment, which provides support for the transformation and quality improvement of the street during the urban renewal process.

2. Literature review

2.1. Visual quality of street space

"Space quality" usually refers to people's perception and experience of the space environment, which is highly correlated with the material spatial elements and service level of the built environment, and is an important index to measure street environment in urban design theory. There have been many classical studies on the quality of space. The pioneers, represented by Jacobs(1961) and Lefebvre(1962), reflecton on the functionally dominated modernist urban planning and design, and discuss the spatial characteristics of human-based scale and its social and economic effects. Young Gale(1971), William White(1980), Kevin Lynch(1984) discussed how the characteristics of urban space can better enhance the quality and vitality of the city. These studies have proven physical space and street form are the cornerstones of street activities.

The past several years have witnessed a considerable number of studies have measured the multisensory qualities of street space, including auditory quality (Easteal et al., 2014; Aletta et al., 2016; Herranz-Pascual et al.,2019) and the visual streetscape(Griew et al.,2013; Lun Liu et al.,2017; Jian Kang et al.,2018). In this paper, we concentrate on measuring the visual quality of street space. It objectively depends on physical components of street space. There are plenty of research discussing the spatial elements on street scale， such as greenery, enclosures, openness, connectivity, street wall continuity, density, accessibility, cross-sectional proportion, scale, tidiness and so on (Montgomery,1998; Sallis et al.,2003; Harvey et al.,2015).The spatial elements can bring better perception of visual perception and also play an important role in social interaction.

2.2. Methods for measuring visual quality of street space

Currently, there are many studies on street analysis and evaluation. Studies have been conducted to identify important factors in identifying important factors in the building environment that affect human mobility by assessing respondents' perceptions of the chosen building environment through different types of interviews or face-to-face questionnaires （Appleyard et al.,1972; Sallis et al.,1998）. Ewing and Clemente (2013) made a quantitative evaluation of the five important factors of street perimeter, humanization scale, permeability, cleanliness and imagery by analyzing the respondents' ratings of street images. This kind of qualitative research is still instructive to the current research, but due to the lack of quantitative data and evaluation index in-depth study, it is not conducive to further assist the refined design practice and control.

The development of big data, artificial intelligence and other technologies can help solve the relatively vague and subjective evaluation of urban spatial quality in the past. With the widespread use of open data in urban spatial analysis, street view pictures are becoming an important complement to multi-source urban data. Google, Baidu, Tencent and other Street View image data can allow users to use 360-degree panoramic views to quickly access street space reality information, is suitable for street-scale research(Liu,2015). For example， Google Street view data has been used to the construction of urban three-dimensional models(TORII et al.,2009), the evaluation of street security(NAIK et al.,2014), and the quantitative analysis of street view green visibility(Yu Ye et al.,2018).

With the development of artificial intelligence, through machine learning algorithms in the computer field, using deep convolution neural network architecture to achieve the deep processing of accurate street view pictures, it has become possible to effectively identify various elements of street space. Image semantic segmentation-based models have developed rapidly in recent years, such as FCN networks, SegNet networks, DeepLab, PSPNet ,image recognition accuracy is getting higher and higher, and can be replaced to handle the complex built environments(YAMAGATA et al.,2017). The model used in this study, DeepLab V3 (Chen et al., 2017), can achieve a 85.7% pixelwise accuracy when classifying objects.

3. Method

3.1. Study area and data collection

3.1.1 Study area

Our research is conducted within lilong area in Shanghai central area, which has a history of more than one hundred years. According to official statistics, by the end of 2016, the lilong area covers 7 million m^2 , including Shikumen Lilong, and Guangli Lilong , Garden Lilong (Figure1). As the main residential building in modern Shanghai, lilong spatial layout coincides with the direction of the urban development of modern Shanghai, which reflects the microcosm of the modern Shanghai urban development, and has very important historical humanistic value and historical landscape value. However, with the development of the city, the Lilong area has appeared old houses and crowded living situation, and its facilities are not complete, which results in mismatch between Lilong and modern urban function. In this paper, the streets of the Lilong area are selected as the research object (Figure 2), we try to provide a strategy for the protection and renewal of the city's historical and cultural history through the study of the street quality of Lilong area.

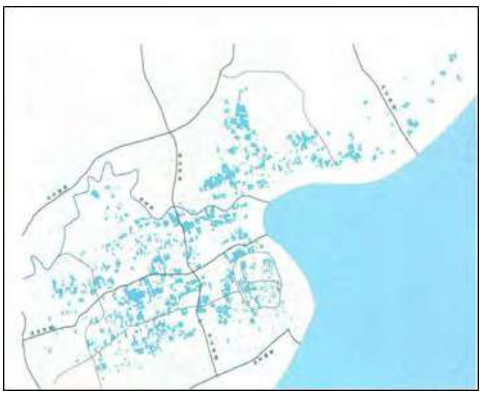

Figure 1 The distribution of Lilong area in Shnghai Source: Zhang Chenjie

Figure 2 The distribution of street in Lilong area

3.1.2 Lilong

As the largest and most widely distributed building type in modern times, lilong has dismantled a considerable part in the transformation of the Old City, but in terms of the current stock, it is still an important part of the historical space of central Shanghai. Lilong is a combination of East and West architectural characteristics of the residential type, its layout takes the form of the early Western town-style housing, the building monolith plane and structure is born out of the traditional Chinese courtyard-style housing.The main types of lilong, mainly include old-style, new-style, park-style, apartment-style, and wide-style.(Figure3) At present, the core Lilong area of Shanghai's central city mainly includes: Laochengxiang area, Xiamen Road -Suzhou River area, Hengshan Road -Revival Road area, Changle Road- Changshu Road area, Huaihai Zhong road- Sinan Road area, West Nanjing Road- North Maoming Road area, Wuyi Road area, the southern part of Old North Station area, Shanyin Road -Dolun road area, and Tilanqiao area (Zhang,2012).(Figure4) In a nutshell, Lilong typically represent the fabric of historical streets and are of significant importance to Shanghai. From the perspective of historical value, there is an urgency for a technical recognition and interpretation of the characteristics of traditional street forms. The restoration, regeneration and transformation

of Lilong spaces are key to historical protection in Shanghai, and need continuous scientific observation.

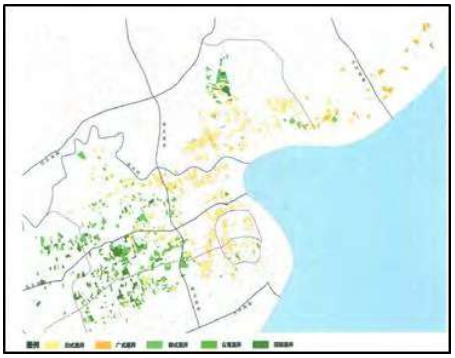

Figure 3 The distribution of different types of Lilong Source: Zhang Chenjie

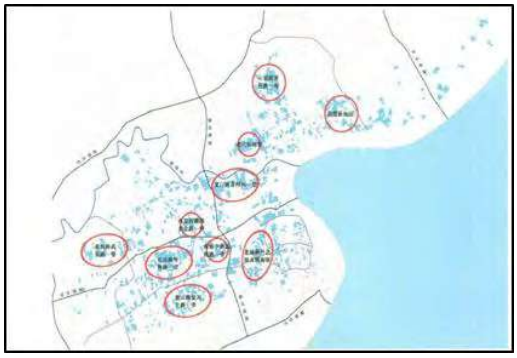

Figure 4 The spatial structure of the distribution Source: Zhang Chenjie

3.1.3 Street View Picture

This paper uses Baidu map street view picture data set to study the quality of street space. Street image data acquisition is obtained through API from Baidu Panorama static map service. The sampling point has an average spacing of 30m and generates the sampling position along the centerline of the road. Each sampling point has longitude and latitude parameters to facilitate the following scrawling process in GIS. In order to prevent the deformation of obtained Street View images, combined with the road centerline data obtained by OSM and the calculation of the sampling point based on the network topology before climbing the data by GIS, the Street View image is guaranteed to be parallel to the long axis direction of the street. And then, we input the angle of the horizontal and vertical direction and the sample point coordinate data to obtain street view picture by using Python and the request Key. (In our this research,: picture size: 1024 * 512; pitch: 0; heading: 0, 180 for two directional SVPs). The study obtained a total of 16,431 sampling points, 32862 street view pictures

3.1.3 Other data

The 2018 Point of interests data was crawled through the network including catering, shopping, and life services. The data format is point data of the shpefile in ArcGIS, which is used to calculate the functional diversity of the street.

3.2. Method

This study makes an objective evaluation of street features by machine learning to extract the characteristics of street scene pictures. A scene of deep full convolution neural network architecture segmentation technology analysis of images through semantic segmentation of picture pixels has been studied(Kendall et al.,2015). Using the Deep Lab V3 model, this paper uses the Deep Lab V3 model to semantically divide the street images of the Shanghai area, identifying 18 elements such as roads, sidewalks, buildings, walls, fences, columns, beacons, signs, vegetation, terrain, sky, pedestrians, bicycles, cars, trucks, trains, buses, motorcycles, etc(Figure5). Then, the elements corresponding to each street point in the two directions of spatial coordinate are summarized and the average value is calculated. The potential factors were calculated based on 3-dimensional composition calculation of greenery, openness, enclosure, motorization, walkability and functional diversity may serve as indicators for inferring. The outcomes were used to evaluate the street types, functionality, quality, time, status, and human activities of a street. The greenery is measured by the proportion of trees

at the sampling point, the openness is measured by the sky ratio, the enclosure is taken by the sum of buildings, columns and trees, and the motorization is used as an indicator of the degree of mobility and the walkability is measured by pedestrian and pedestrian paving. Through the POI data, measure the street functional diversity in the 15m buffer zone of the street centreline.

Thus, several indicators (a temporary six in this research) have been formed to comprehensively evaluate the physical visual quality of street space, the values of which a_i are normalized to the values e_i based on the deviation standardization Eq.(1)

$$e_i = \frac{a_i - \min(a_i)}{\max(a_i) - \min(a_i)} \quad (1)$$

i = greenery, openness, enclosure, motorization, walkability, functional diversity and so on.

Following this, these six normalization values are summarized into one Index $Y_{quality}$ according to Eq. (2), below, which represents the overall physical visual quality of street space. The indicators are simplified into six and the coefficients of each are equally distributed for the convenience of discussion. Accurate coefficients still require further quantitative research based on large-sample surveying and theoretical literature reviews.

$$Y_{quality} = \sum_i \alpha_i e_i \quad (2)$$

α_i are the weighting coefficients, awaiting further detailed research for improvement.

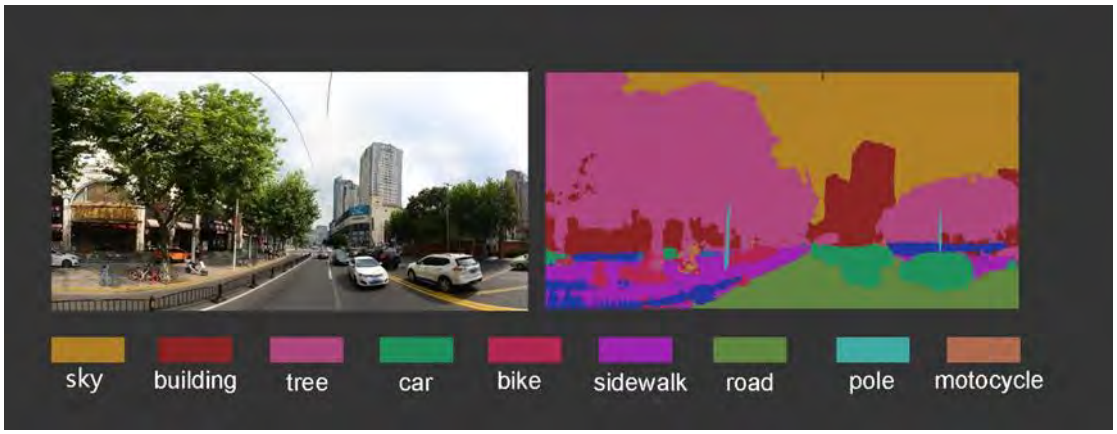

Figure 5 A segmentation demo by Deeplab V3

4. Results

4.1. Identify different street types

This study makes an objective evaluation of street features by machine learning to extract the characteristics of street scene pictures. Calculate the elements of 32,862 images in the study area and determine the main road types in the study area based on the proportion of the various elements. Figure 6 shows the seven most common dimensions of street features in each road type, namely buildings, roads, skies, sidewalks, cars, trees, and walls. For each dimension, the length of the axis represents the average ratio of each feature within the horizontal perspective. For example, green streets generally 50% green rate, 30% of buildings. In different historical periods, the elements of the streets are quite different, and the streets in the old Shikumen area are mainly based on buildings and higher degree of openness, and

the green rate is low. There are some areas that have been updated through the city, with buildings accounting for 40% of the view and about 26% of motorways, and these streets have higher traffic. The garden is more green and the enclosure is high.

The semantic division of the features of the street shows that the various scene features of the street will change due to the change of different road levels, so we can identify different types of roads by identifying the proportion of various elements in the street. With the continuous construction and development of the city, the function and role of Lilong area's streets will change with the changes of urban heterogeneity and urban renewal. Lilong is a gathering area of the history and architecture of the central city of Shanghai. Different time span and different construction types show its unique style of urban style. Updates and protections also need to be treated according to their characteristics .From this point of view, according to the results of the above analysis, according to the composition of the design elements of the street to determine the real function and function of the street, and further the renewal and protection of the streets in Lilong area put forward a more scientific and clear update strategy.

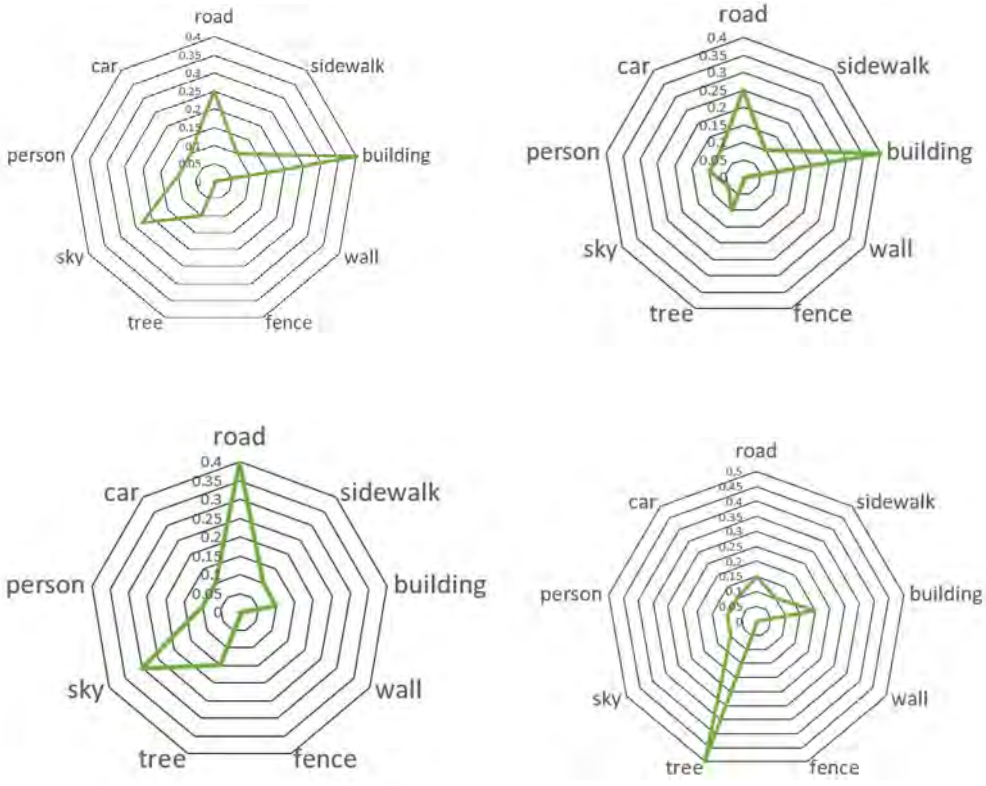

Figure 6 Percentage of different types of street elements

4.2. Spatial distribution of street features

After identifying the proportion of various elements of the street, the evaluation index of street quality is summarized. The average green viewing rate on streets in the Lilong area was 23.4%, which is nearly 5 percentage points higher than the average green viewing rate of 19.8% in Beijing Hutong(Tang et al.,2018) which typically represent for historical street space in Beijing.The average openness of streets was 22.8%, the average enclosure was 56.1 % and the average degree of mobility was 12.8%. The spatial distribution of greening in the study area was uneven, and the degree of greening was quite different in different construction

periods. The street scale in Lilong area is more suitable for human-based scale, and the incidence of automobileises is much higher than that of bicycles. The walking conditions are suitable for walking activities.

4.2.1 The spatial distribution characteristics of street greenery

Due to the influence of urban construction in the historical period, the degree of greenery of the streets is obviously different. The old town area is the early old-style construction area, its greenery degree is the lowest in the Lilong area, the average street greenery rate of 13.2%, far below the greenery level of the whole study area. Though it is a relatively complete area of Shanghai's old city texture, but its level of greenery landscape needs to be greatly improved. Huaihai Zhong road -Sinan Road area, Changle Road Changshu Road area, Hengshan Road - Revival Road, West Nanjing Road- North Maoming Road area is a new style of Lilong, garden and apartment gathering distribution area, its greenery degree is better, some areas of green view as high as 60%. In Xiamen Road, Suzhou River area, the south of the old North Station the southern part of Old North Station area and Tilanqiao area and other areas are wide-style distribution area, have low level of greenery.

4.2.2 The spatial distribution characteristics of street openness

Contrary to the spatial distribution characteristics of street green vision rate, the higher areas of street opening are the Laochengxiang area, Suzhou Road area, the southern part of the Old North Station and Tilanqiao area. The area with lower street opening is Huaihai Middle Road- Sinan Road, Changle Road, Changshu Road, Hengshan Road, Fuxing Middle Road. Although the height of the building is not high, the street is green and the street is directly blocked by trees because of the small scale of the street. The degree of opening is lower, and the street green vision is higher.

4.2.3 The spatial distribution characteristics of street enclosure

The street enclosure characteristics of the street are generally better, and a higher enclosure can form different levels of space. The areas with relatively high degree of street interface are the Laochengxiang area, the Huainhai Middle Road- Sinan Road, the Changle Road- Changshu Road area, and the Hengshan Road- Revival Middle Road area. These areas have dense urban textures, and the ratio of the height of the buildings on both sides of the streets is high. It can reflect the characteristics of the old Shanghai city. The area of the the southern part of the old North Station and the Tilanqiao area is relatively low.

4.2.4 The spatial distribution characteristics of street motorization and walkability

The degree of motorization in the study area increases with the level of the road network, and the degree of motorization is higher. The average car's appearance rate is 8.2% higher than the bicycle's appearance rate of 1.2%. It shows that the way of traveling in Shanghai is still characterized by car. The street scale of the Lilong area is relatively small, giving people a better sense of space and being more suitable for walking. With the process of urban renewal, the development of the city in the past focused on the development of traffic-oriented transportation. The Lilong area is also the main way to consider the car dealership, Ignore the way to walk. In the Laochengxiang area, Tilanqiao area ,the street sidewalks are relatively small and poorly walked. The renewal and construction of the future should focus on people's feelings and need to create a systematic walking space.

4.2.4 The characteristics of street functional diversity

The diversity of street functions in the study area increases with the level of the road network, and the degree of diversity becomes higher. There are differences in the diversity of streets in the Lilong area in different historical periods. The areas with low levels of street function diversity include the Laochengxiang area, the Tilanqiao area, and the Changshu Road-Changle Road area. The areas with high degree of street functional diversity include the Suzhou Road-Xiamen Road area, Huaihai Middle Road- Sinan Road, the Hengshan Road-Revival Middle Road area. With the development of the city, the function of some areas can not adapt to the mode of modern urban development. The development of its single function has led to the reduction of urban vitality. In the process of urban renewal, it is necessary to inject a variety of functions to arouse the original Vitality.

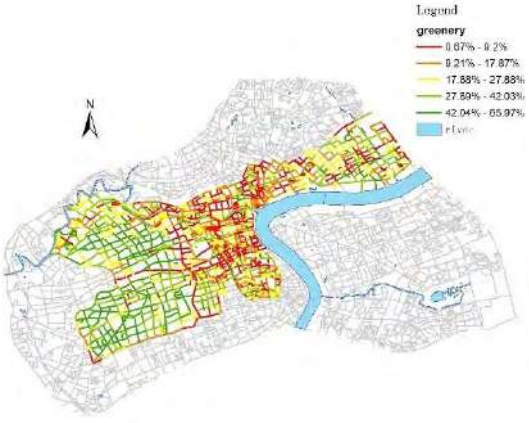

Figure 7 Greenery

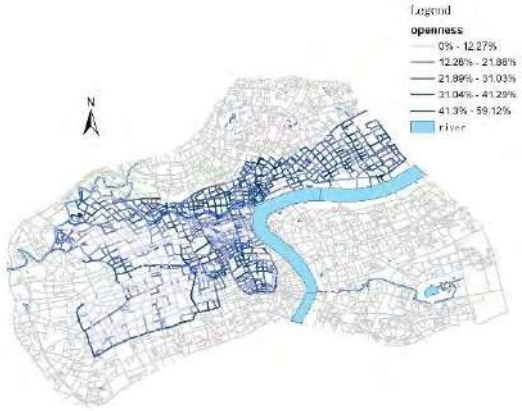

Figure 8 Openness

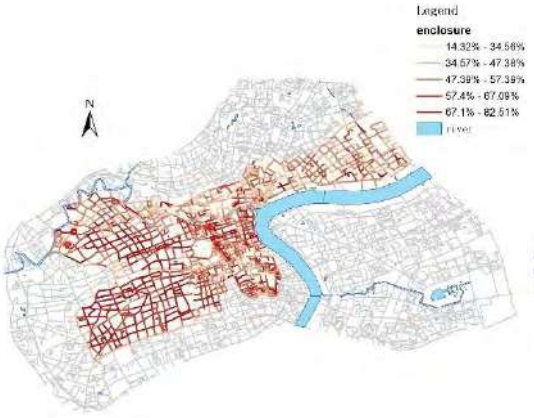

Figure 8 Enclosure

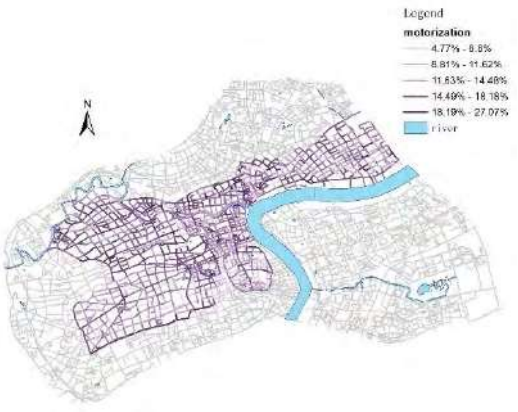

Figure 9 Motoriazation

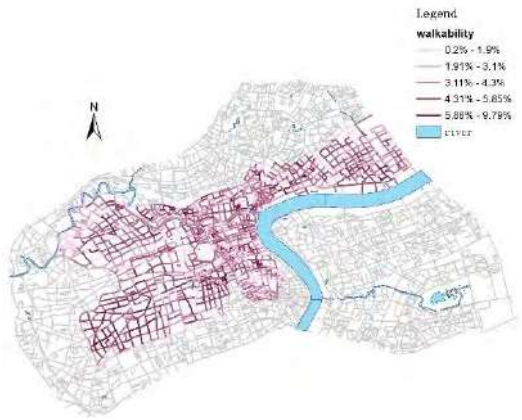

Figure 10 Walkability

Figure 11 Functional diversity

4.3. Visual quality of Lilong

Figure 12 shows the final six-aspect physical visual quality of Lilong index result. The average physical quality index score is 2.35. From the calculation results, We can see that the areas with high street quality and quality scores include Hengshan Road- Revival Middle Road area, Huaihai Zhong road-Sinan Road area, Changle Road- Changshu Road area, and West Nanjing Road - North Maoming Road area. The areas with low street quality scores include Laochengxiang area, Suzhou Road -Xiamen Road area, the southern part of Old North Station area, and Tilanqiao area.

It can be concluded that Lilong on the south side have better skeletons than those on the north, especially Lilong in the historical protection areas. The reason for this phenomenon may be the management factors in the historical period. The blocks with higher scores are mainly distributed in the French Concession, the management is unified and perfect, and the lower scores in the public concessions are not well managed. It is not difficult to observe that some regeneration projects take full consideration of the historical forms , keeping the original architectural features, while some partially change in spatial scale due to the need for modern transportation. In addition, with the continuous development of the city, the street texture of the Lilong area has been affected by motorization, and these areas have a high degree of openness. It can be seen from the various visual space elements that high-quality streets tend to have high greenness, diversity and spatial envelopment (ie, inverse contrast of sky visibility), while street greening can enhance the shelter of the street and strengthen the space. It also reduces the visibility of the sky. It can be seen that in the street renewal and renovation of the case area, improving the street green rate, strengthening the space enclosure and diversity should be the main strategies to improve the space quality.

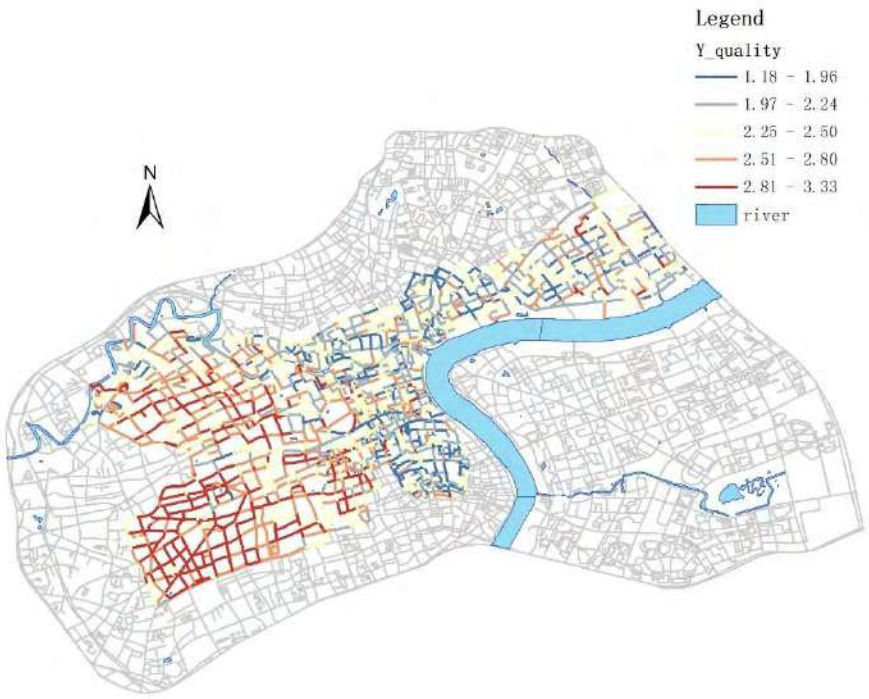

Figure 12 Physical Visual quality of Lilong Index

5. Conclusion

This paper examines the application of space quality evaluation in street urban design environment assessment for the Lilong area in the central area of Shanghai. The empirical research on Lilong shows that although the central city of Shanghai is famous for its culture, history and architectural layout, the quality of the street environment cannot meet the needs of current urban development and needs to be improved. A lot of Lilongs are in shortage of visual green, relative more continuous but with low vertical diversity. In addition, due to the low levels of street function diversity single function ,it has led to the reduction of urban vitality In the most recent 6 years, less than 2.74 million square meters Lilongs are not regenerated which are mainly slow building renovation The current urban design concept lacks the concept of refinement, the difference in street space is small, lack of recognizability and regional characteristics, and the safety, convenience, comfort and visual pleasure of slow-moving activists are not considered enough. The objective elements of this paper quantitatively measure the green visibility, openness, enclosure, motorization and walkability of the street. The research shows that the spatial distribution of greenery in the study area is uneven. The greening degree of the different types of construction in different areas is different. The construction scale of Lilong area is small, so the spatial opening degree and interface enclosing degree are suitable. In addition, many traditional styles and features are challenged by rapid urbanization. The development of vehicle-oriented traffic ignores people's feelings, and future development should focus on meeting the diversity needs of people.

Case Study / Project

Improving Space Structure of Traditional Resources

-Based Citie`s Transformation in a Background of Supply-Side reform: a Case Study of Yantai City of Shandong Province

Dianhong ZHAO

Abstract

Supply side structural reform aims to adjust the economic structure, promote industrial restructuring and optimization, to achieve the optimal allocation of resources. Eliminating excess capacity and improving effective supply are two important vehicles for maintaining the medium-high economic development under the new normal economy. At present, the resource-dependent cities` transformation in China is not only faced with the threat of traditional 'Urban Disease' , but also faced with the dilemma of 'Resource Curse' . Insufficient system guarantee, serious industry rigidity and inadequate factors innovation have become major bottlenecks in the resource-dependent cities transformation.

This report puts forward to build optimization model of compact spatial structure by regarding spatial restructing of resource-dependent cities as cutting point, and takes Yantai city as an example to explore the optimize model and mode of gold-resource city`s improving space structure. Under the background of supply-side structural reformation, first of all, this article combines the overall analysis thinking of macro view, medium view and micro view to create three ideas of the traditional resource-dependent cities transformation, which are:

1. According to the development grade and endowment conditions, traditional resource-dependent cities turned to take the 'Human-centere' urbanization development idea.

2. Traditional resource-dependent cities should build a complete urbanization financing system and establish a new circulation mode of local balance of payments.

3. Narrowing the welfare gap between residents to realize the 'people of urbanization' and the transformation of development mode.

In addition, focusing on the optimization model of spatial structure of the traditional resource-dependent cities transformation. Firstly, improving spatial structure should respond to the transformation of innovation driven government method, and emphasize physical transformation of socialization idea. For example, inventory optimization, urban renewal, reconstruction of new industrial district, bridging the relationship between the old space and social economic development. The Second optimize spatial structure is to establish inclusive and service-oriented soft space by focusing on the factor of 'people'. The third optimize spatial structure intends to serve in the increase driven by innovation and builds creative and intellectual city. Finally, improving spatial structure refers to the design of system and mechanism, which means to combine the transformation of space, system and mechanism of the optimization model of spatial structure of traditional resource-dependent cities. This way provides a theoretical reference to achieve the optimization model of spatial structure of the traditional resource-dependent cities transformation.

Case Study / Project

Participatory and Good Governance

The role of stakeholders in increasing the adaptive capacity of the poor to cope the impact of climate change. Case studies: Surakarta and Yogyakarta, Indonesia

Andie ARIF WICAKSONO

Abstract

Poverty and climate change considered a global problem. Meanwhile, adaptation to climate change and poverty reduction are context-specific and vary per case. The urban poor is vulnerable to flooding, especially flash floods because most of them live in flood-prone riverbanks. they are also prone to disasters and diseases outbreak. On the other hand, urban poor also have an important role to address the city's vulnerability to climate change. Some of the urban poor of Yogyakarta who cares about river conservation movement formed the riverside community-based organizations (CBOs). In Yogyakarta and Surakarta, some evidence indicates that the pro-poor approach is used to build the adaptive capacity of the poor. Together with the government's task force for poverty alleviation (TKPKD), these CBOs provided medium for participation on the local level in Yogyakarta. The same also happened in Surakarta. These stakeholders initiated supplemental programs acted as the pro-poor approach on the riverside settlement. It consists of in and ex-situ planning at both policies and management at the local level. The in-situ measures consist of addressing the socio-cultural aspect of poverty, improving coverage, efficiency, and sustainability of basic services, and addressing economic poverty. They also included adequate safety net in education and healthcare system through PKMS-BPMKS in Surakarta and KMS in Yogyakarta, while empowering the poor to protect the environment. However, the ex-situ measures consist of micro (sectorial) policy in construction, such as the relocation of the Riverside housing and the improvement of the physical infrastructures' of the poor. The CBOs responded to the innovative collaboration of these stakeholders by delivering discussions and collective action movements, since it was done through transparency, accountability, responsibility, independence, and democracy. These processes are the implementations of good governance on the local level. The collaboration provides cost incentives on government-owned rental housing buildings and generates active participation among stakeholders. Furthermore, the CBOs initiated the M3K-flood free housing program. Logically, this M3K reduces the heat island effect in the city, consequently reducing the impact of climate change and the vulnerability of the poor to disaster. This in-depth case studies research is parts of the researcher's Ph.D. trajectory and uses the empirical exploratory approach with purposive sampling derived from a list of related participants: local government officers, city leaders, NGO person, local academia, and riverside communities. The primary data is collected using interviews with snowball sampling, while secondary data is collected from policies and reports to understand the approaches and setting of multi-stakeholders' collaboration. The finding indicates that the role of stakeholders is to create a medium through active collaboration. While poses in different situations for each case, this collaboration is important to form the foundation of a pro-poor approach. This approach could enhance the adaptive capacity of the poor to cope with the impact of climate change. Using Yogyakarta and Surakarta as Indonesian case studies, this paper contributes to the knowledge of adaptation strategies in developing countries.

NGUY Thi Khanh-Green Innovation and Development Centre; Vietnam

Abstract

Climate change is an existential threat to all life on Earth. Humans are at the helm of emission controls and the underlying political mechanisms to avert worst case scenarios. As nations shift their policies and planning around this reality; there is an opportunity to redefine incentives across industries that promote clean energy and lower emissions in building, transportation and land use systems. In turn, workforce training and education across a broad international network can help ensure a just distribution of benefits as incentives kick in and markets transition. The Vietnam Oregon Initiative (VOI) officially launched in 2015 by Oregon's Governor Kate Brown and the Ministry of Foreign Affairs as a formalized partnership to advance mutual benefits through multi-sector exchange and capacity development. The Vietnam Oregon Initiative Climate Agenda (Attachment I) builds on this network to promote public policy solutions that enhance Oregon and Vietnam's market-based transition to clean energy and climate resilience.

Keywords

Climate change, Network Governance and Sustainability

1. Comparative Policy Background and Network Governance

1.1. Oregon and Vietnam Climate Policy and Methodology

Oregon has a legacy of environmental leadership starting with the passage of the first bottle bill in the U.S. in 1971. In 2018, after an updated bill passed doubling the deposit fee paid at time of purchase from 5 to 10 cents, Oregon hit a 90% redemption rate (4). Oregon Senate Bill 100 passed in 1973 marking establishment of the regulatory structure necessary for local and statewide land use planning and protections for farm and forest lands. In the 1990's land use coordination programs were integrated across state agencies to meet 19 state land use goals starting with the imperative of citizen involvement as well as maximizing density on lands within the urban growth boundary backed by data from mandatory studies to assess land use demands (economic opportunity analysis and 20 year population and housing demand studies). In 1993, Portland was the first city in the U.S. to create a local plan for reducing carbon emissions, now known as the Climate Action Plan. In the Plan's 2017 progress report that 83% of the identified 170 actions were on track and in fact translating

to a 21% carbon emission reduction to date. In 2016, Oregon passed the Clean Electricity and Coal Transition Act, a first-of-its-kind law to transition completely off of polluting coal-fired power while doubling the state's commitment to clean electricity -- like solar and wind -- to 50% new, renewable energy by 2040. Further, in 2018, Oregon's Climate Agenda was developed to strengthen the link between climate goals and work force opportunities and economic benefits in the transition to clean energy. The Portland Clean Energy Community Benefits Initiative passed as well in 2019 to invest money from a corporate tax into local projects communities of color who are disproportionately impacted by climate change. In 2020, if HB2020 passed it would have set emission limits to 80% below 1990 levels by 2050 and generated funds to aid in the disproportionate impacts of climate change.

In 2020, Vietnam will officially launch its power development plan and like Oregon work to advance renewable energy infrastructure (to 20% of the power mix by 2030) and transition away from fossil fuels in order to protect ecosystems which support clean water, air and soil. To promote these shifts in investment; ngo's are working at the household scale in rural communities to provide training and cost-effective strategies to increase energy access and efficiency and the knowledge to install and utilize renewable resources of energy. For example by 2030, the Million Green Homes program championed by ngo Green Innovation and Development (GreenID) aims to have one million buildings in Vietnam with solar PV rooftop systems paired with energy efficiency and other green solutions that benefit vulnerable populations and small and medium enterprises.

Building on Vietnam's recent climate initiatives to invest in renewables and transition to a greener economy and the State of Oregon's Climate Agenda emerges a chance to strengthen the Vietnam Oregon Initiative network, learn together and test mutual benefits.

1.2 Methodology

The shared climate agenda is a network governance approach to informal multi-sector partnerships that can nimbly respond to market incentives to leverage political, economic and educational resources. Collaborating through this unique state to country partnership aims to maximize market-based solutions to expand clean energy by broadening access to workforce training, low carbon lifestyles and amenities.

1.3 Vietnam Oregon Initiative Shared Climate Agenda

Promote Climate Change Policy and Build Up Leadership: Establish programs that build up Vietnam's leadership capacity and the scientific basis to implement climate adaptation and mitigation strategies. Work with members of the National Assembly, provincial governments, and line ministries such as the Ministry of Construction, Ministry of Planning and Investment and Ministry of Natural Environment and Ministry of Science and Technology to integrate policies into local planning, administration and investment strategies.

Action Areas

• Public sector training for climate leaders including decision-making and policy development which reduce coal dependency in power generation and align market-based programs to transition to renewable energy sources.

• Engage Vietnam national and local governments to improve economic governance to advance community-based participation and investment in emerging carbon markets and technology that supports renewable energy power generation and storage.

Develop Clean Energy Workforce through Training and Education: Prepare Vietnam's workforce for the transition to a greener economy through training and education programs aligned with clean technologies and less carbon-intensive construction and production models.

Actions Areas
• University partnership development to host technical trainings and workshops for emerging technologies.
• Share renewable energy technology production and application models for large and small-scale installations of solar and wind power.
• Build private sector partnerships to promote knowledge transfer for integration of energy efficiency, green building science, automation and robotics.
• Share smart city applications for building and land use that promote quality of life and reduce environmental impacts on vulnerable populations.
Expand Sustainable Product Development: Improve the performance and quality of businesses in Vietnam and Oregon to compete globally in sustainable product development.
Action Areas
• Expand the application of life cycle assessment and financing tools to promote viable clean technology products and services across multiple sectors including manufacturing, agriculture and forestry.
• Increase market access to energy efficient appliances for residential and commercial use.
• Advance sustainable transportation system models that increase smart, multi-modal transportation options including electric vehicles and bicycle infrastructure.

2. Oregon Case Studies; Emerging Green Markets Tied to Urban Resilience and Rural Working Lands

2.1. Oregon Renewable Energy Policies

Oregon Renewable Energy policies for utilities paired with energy efficiency in Oregon are some of the most aggressive standards for cutting greenhouse gas emissions in the U.S. Since the 1980's (following passage of the Northwest Power Act), energy efficiency was identified as a cost-effective priority for the region. Paired with SB 1149 passed in 1999, Oregon's largest utilities were required to invest in energy efficiency, using utility revenues collected through a public purpose charge. By mandating that utilities supply 50 percent of customer demand with renewable energy by 2040, Oregon created one of the first renewable portfolio standards in the U.S. Unfortunately, Oregon undermined that target by classifying a number of "dirty" energy sources as renewable such as sewage gas and manure digesters and allowing the use of a compliance mechanism to purchase credits with no monitoring oversight (2). Despite these shortcomings, by 2019 more than 55,000 workers in the clean energy sector, 50 times as many as of those employed by fossil fuel industries, and this number is growing 11% annually – faster than Oregon's statewide average. These jobs typically can't be outsourced, are often accessible with a technical degree, and 11,000 of them are located in rural communities.

Oregon has invested significantly in energy efficiency programs, in recognition of the need to promote lower energy bills, protect public health and safety, improve environmental benefits, stimulate sustainable economic development, create new employment opportunities and reduce reliance on imported fuels. Oregon's ngo Energy Trust, stands outs for its return on investments in energy efficiency programs which have shown to provide $3 in cost savings for every $1 in program fees. Since its inception in 2002, Energy Trust has led over 700,000 home and building improvements from improvements in insulation and heating and cooling efficiency. Through this work utility customers have saved over $7.6 billion on utility bills, installed 13,000 renewable energy systems and saved or generated enough energy to fuel a clean energy power plant. $6.3 billion of that funding has been directly added to the economy with 22.8 million tons of carbon dioxide avoided equal to removing 4 million cars from the roads for a year (3).

There is a workforce development component which has proven valuable in retrofitting homes and commercial buildings for energy efficiency. Clean Energy Works (now Enhabit) was a collaborative effort to align energy efficiency outcomes with low-income households who needed the savings most and retooling an underutilized workforce to implement the plan. Clean Energy Works saw the following results:

- Over 20,000 families were served with results of more than 30% energy savings per household
- Energy retrofits were increased by eight times, from less than 200 per year to about 1,600 per year.
- Accessible to 82% of the Oregon population; the program significantly increased capacity to respond to local needs throughout the state.
- There was a high return on investment, over $100 million in economic activity and the creation of 500 new jobs

Governor Kate Brown further elevated Oregon's leadership on energy initiatives when she signed an executive order which required new state-owned buildings to be carbon neutral in 2022; all new buildings to be solar ready by 2022; and new residential buildings to "zero energy ready" starting in 2023.

2.2. Oregon Agriculture Policy

Oregon Agricultural policies are grounded in a state-mandated approach to protecting high-value farm and forest "working lands" through a scientific suitability analysis of soils. Oregon has some of the most productive soils in the world both due to natural (geologic conditions) and now because of strict classification system to keep these soils in use. The State of Oregon requires rigorous testing in order to determine appropriate land use designation to ensure areas contained by urban growth boundaries for high-density development are often on degraded soils and or soils with low agricultural or forestry values (5). Not only does this protect natural carbon sinks (trees, plants and soil), it also promotes density for compact communities increasing access to basic amenities (transit, water, sewer, etc). In Western Oregon alone, scientists predict that Oregon's urban growth boundary and scientific approach to land use has contributed to carbon storage equivalent to a reduction of 1.7 million metric tons of carbon dioxide (CO2) emissions per year (6).

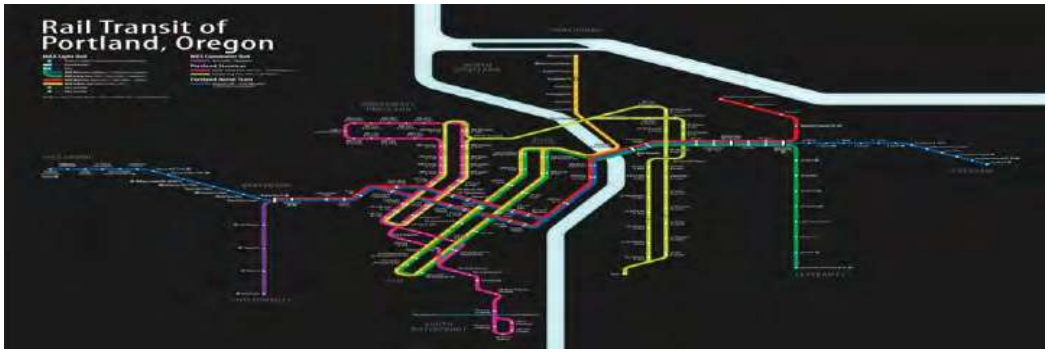
Further, these productive soils contribute to a robust local food economy. "Oregon's location quotient for food production is 2.6, meaning the concentration of agricultural jobs is two and a half times what it is nationwide. This is primarily driven by crops (grains, fruits, vegetables, etc.) and fishing. Oregon's location quotient for food processing is 1.5 meaning the local concentration 50% larger than in the average state." Knowing rural communities especially with resource-dependent economics are especially sensitive to the effects of climate change and increases in fuel prices—expanding the use of soil testing as a basis for local land use controls across the U.S. and Vietnam could rapidly and significantly expand carbon sequestration.

Picture 1 Oregon's Urban Growth Boundary has protected productive soils from being paved over by inefficient development

2.3. Oregon Transportation Policy

Oregon Transportation policies have targeted systemic reductions in fuel emissions resulting in over 1 million tons of carbon emissions reduced since the passage of Keep Oregon Moving (HB2017). Transportation remains the number one contributor to greenhouse gas emissions (about 20%) primarily from trucks and single-passenger vehicles in Oregon despite major investments in clean fuel standards and electric vehicle rebates. Compact communities that increase the density of neighborhoods within the urban growth boundary and require developments to be transit-oriented best support fewer vehicle miles traveled and improve walkability, bikeability and transit ridership rates. The next phase for transportation policy is to curb emissions in urban areas with be congestion pricing to minimize commuting times, traffic delays and idling.

Nationally, studies show that investment in public transit not only contributes to local quality of life; it also supports tens of thousands of manufacturing jobs through its supply cahin. There are over 2,700 manufacturing companies producing parts for public transit systems nationwide. The American Public Transportation Association found that 15,000 jobs are tied to every billion dollars invested in transit capital from construction to upgrading level of service (8).



Picture 2 Map of Portland's efficient light rail system, one of the most developed in the U.S.

3. Vietnam Case Studies; Emerging Green Markets with Value Chain and Green Job Creation.

3.1. Vietnam Land Use and Development Policy

Context: Existing green policies and real estate market development

Picture 3 Solar energy used for aquaculture farm in Phu Lac.

In the last decade, the multi-function buildings are becoming popular in the cities and their growth is proportional to the fast urbanization, especially the outstanding thriving of leading

real estate investment companies including Vingroup, Novaland group, Dat Xanh Company, Vihajico Company, FLC group etc. with the larger-scale real estate projects like Tay Mo smart city, Time city, Ecopark, etc. in the Northern and Sunrise city view, Lakeview city, Aquacity, Palm marina etc. in the Southern. These mixed housing and hospitality projects provoke the increasing demands of energy, water and waste treatment resulted from the blooms of their commercial retails, housing, food centers while the public infrastructure presents the poor capabilities due to the low investment and inadequate planning.

The concept of Green building (GB) embraces the principles of low environmental impact through greater energy efficiency, low energy demand, reduce water usage, improve indoor quality and minimise construction waste [1]. Green buildings with green certificates have been implemented in many countries around the world. The green building certificate has been implemented by 6 countries and the LOTUS green building certificate has been provided by the Vietnam Green Building Council with an increasing number of buildings getting LOTUS certificates so far. Beside of LOTUS certificate, the Vietnam Green Building Council provides the certificate of LEED (Leadership in Energy and Environmental Design) for building projects in Vietnam [2].

In nearly 10 years of development, the number of buildings registered to get LOTUS certificate increased with 50 building projects in 2018 including different types like mixed use, hospitality, retails, residential buildings, office, industrial, school [3;4]. This number still is behind of the growth of buildings provided by the current market. The Green Buildings has been mainly grown in two big cities, Hanoi and Ho Chi Minh City, and currently tend to expand to other cities where the tourism activities and services are growing with high rate. For example, the Novaland group planned to provide to market in 2019 the new big hospitality and building projects in Phan Thiet, Nha Trang, Vung Tau, Bien Hoa etc. [5]

Beside of the initial development of green building certificates like LOTUS, LEED, the renewable energy, especially solar energy, has been strongly promoting by the Vietnamese government in responding to the national contribution commitment of the reduction of greenhouse gas emissions under United Nations Framework Convention on Climate Change 2015. The national legal framework to promote the development of renewable energy has been approved by Prime Minister with Decision 02/2019 / QD-TTg to enable the solar rooftop power solar power, Decision 11/2017 / QD-TTg to enable the mechanisms of investment of solar power plants. The regulation on prices of buying solar energy by regions has been drafting and finalizing to promulgate soon [6]. The promotion of green energy in different industries also supported by two other top legislations including Decision 1393/QĐ-TTg on endorsement of National Green growth strategies and Law of National Environment Protection No 55/2014/QH13 promulgated by National Assembly which implies the significant use of energy efficiency and renewable energy in the economic leverage as the key feature to protect the environment.

This national legislative framework created a breakthrough to boost the development of solar energy market in Vietnam, opening up many potentials for the use of solar power and energy efficiency for buildings and infrastructure utilities in mixed retail and residential projects. The small and medium cities are considering as the emerging markets with smaller scale of real estate which are mostly the hospitality and retail projects.

In reality, even the increasing number of LOTUS/LEED registrations of building projects, the motivation of using the green building certificates in the real estate market is not noticeable in bringing the benefits to the investors. The use of those green certificates faces several challenges such as entailing the upfront cost in the total investment when adopting the green certificates and then increasing the price of units which is always unlikely for the customers, lack of environmental awareness of residential results the absence of pressure to adopt those certificates and regulation enforcement at grassroot level.

Market driver: the inter-connected benefits among green building certificates and value chain and community health.

The wider application of green building certificates for mixed housing and hospitality projects will generate the business opportunities for services and products used in constructing the green buildings such as using the natural materials and designs to minimize the energy use of building, the high-performance electrical devices and smart monitoring devices to optimize the building's energy consumption, the green mobilities for residential buildings in moving to their offices, shops and supermarkets etc. Using the green input resource spurs the opportunities of minimizing the on grid electricity consumption of building amenities and increasing the use of green energy.

In the context of transition of electricity production market with the increasing participation of the private sector with focus on the renewable energy, the electricity price is being strongly adjusted by the Vietnamese government in the direction of market based pricing of power. The meaning of resource efficiency is becoming significant for all of activities and outputs of enterprises. The buildings with green services and facilities with green inputs resources will bring the meaningful benefits to the building owners. The real estate investors could get better public and customer trust through improvement of environmental performance of buildings against certain targets, lower operational costs by conserving input materials and energy efficiency, minimize waste and enhance their compatibility with high standards related to health and safety for buildings. The adoption of green certificates with healthy and safety standards contributes to diminish the risk of liabilities and health insurance claims for residential living in the buildings.

The typical instance of Ecopark, one of biggest mixed retails and residential township, recognizes the significance of eco values and is trying to improve their eco township through doing the valuable actions like as the campaign to zero waste, use eco buses and electric car for internal and external transportation, and digital technology application for township infrastructure management etc. which aims to use the green standards to bring more and more eco values to their residential communities. [7].

It’s time of the maturing opportunities for real estate companies to consider the benefits of high investment costs and low operation costs with friendly environment impacts instead of low investment with damaged environmental impacts. Breaking the financial barriers with the conflict between investment cost and environment values also contributes to this driving development of the green building market.

Potentials of green jobs generated from value chains of real estate market

The obviously current impacts of climate change and air quality in the major cities are clearly showing the signs of degradation and boosting the real estate investors to consider their vision of eco friendly products and services in the market segment of housing, commercial building and hospitality projects to improve their competitiveness. Promoting the development of green buildings and non- fuel infrastructure facilities or seriously considering the green values created in the process of operation will bring the insights for development of green jobs and green technical skills.

Even there are many business opportunities for this green building market but it exists the huge gaps of resources. As emerging markets in the world, the important driving resource is the skillful workforce who contributes as qualified inputs to the services or products of enterprises. In this workforce market, the improvement and enhancement of green skills is critical factor to produce the green buildings with green certificate adoption. The green skills of this market relate to the areas of technical design, engineering, procurement, management, material manufacture and supplies, efficient equipment and appliance manufacture and installation etc.

The value chain of services and products generating from the development of green buildings are significant element that enhancing the development of green labor market in Vietnam. In nearly a decade of green building development, the green skill labor market has still under developed and fragmented then can not play as a driving actor.

The fundamental reason which explain this low development of green workforce comes from the intrinsic issues of education of universities which are still developed behind of market growth and needs [8]. Green knowledge and skills of vocational training programs are scattered in the most of industries.

The second reason comes from the gap of local green technologies which always concentrate in the big companies and in big cities where there is always providing a high incomes and job opportunities for this high labor market. Small and medium local suppliers are almost unskilled and knowledgeable about green technologies due to their inability to invest to those technologies and hire those qualified labors. In addition, small local suppliers are unable to access the green technologies and materials which only reach their low prices once importing the huge bulks.

Finally, the dissemination of green knowledge only aims to improve the awareness of energy saving, reduce energy energy consumption, use high energy efficiency devices, monitor energy consumption but not yet targets to the objective of identify the career direction and education of young generation. The communication programs are focus on short-term implementation and have not really improved the attitude and made consensus among residents and communities. In reality, most of students and their parents could not reach any information and perceive about the green career market when identifying their career education even they could collect those career information through consultancy education centers.

Recommendations to develop green skills for greening real estate development project

Building the green workforce resource to respond to the market demands is not easy and should be approached and implemented by different inclusive pathways. In vertical

direction, they should be enhanced through the comprehensive curriculas from vocational training programs to undergraduate and graduate education programs and frequently update the professional training programs for targeted officials of local governments and company staff. The integration of green values into the education schools needs to be addressed through vague projects for students to improve their awareness and changing their routines. At the grassroot of policy making and implementation, the improvement of abilities of policy makers should be taken frequently with incentives to create their self motivation and innovative ideas. In horizontal direction, the knowledge and skill improvement needs to undertake in cross relevant sectors from material manufacture, engineering and services to banks and financial institutions. The inclusive campaigns with demonstration projects are necessary and bring the impacts and public influences to the residential to improve their awareness of green values for environment protection and change their routines from using the low efficiency to high efficiency appliances and mobilities, from using the polluted products to eco-friendly products (for example phasing out the plastic products in the habits of shopping and food storage).

Picture 4 Ecofarm greenhouse in Tan Thanh commune, Thanh Binh district, Dong Thap province.

3.2. Vietnam Agricultural Policy

Context: Mekong Delta region, the biggest agricultural market in transition process.

Mekong Delta of Vietnam includes 13 provinces (Long An, Tien Giang, Dong Thap, Vinh Long, Tra Vinh, Hau Giang, Soc Trang, Ben Tre, An Giang, Kien Giang, Bac Lieu, Ca Mau, Can Tho) in which their overall agriculture sector plays a role of key driving economic actor of the region. In period of 2016-2018, the total agricultural production value accounts for 34.6% GDP of national agricultural production [1]. The agricultural transition towards to join the global value chain of high quality products is realising as the long-term vision of Vietnam Government which attempts to marginalise the economic gains and attract the great investment for Mekong Delta region. Strategies with actions to promote this agricultural transition are built on the involvement of key actors including the state, enterprises, farmers and scientists for the production, processing, packaging and market consumption [2]. The production steps including the breeding development, cultivation and processing stages (preliminary processing or finished products) are improving through the supports of enterprises and scientists in order to response to the international and local market standards. At the national level, the Prime Minister's Decision 80/QD-TTg on promoting

consumption of agricultural products through signing a wholesale contract has made a big step forward the promotion of agricultural products in the new markets. In addition, land pooling policies for agricultural land enables the farmers in expending their farm and production scale.

The regional agricultural extension policies of the provincial governments in the Mekong Delta region aim to improve the knowledge and knowhow of farmers and enable the provision of materials and accessibility to financial resources when upscaling their business and production.

The edging insight is visible in the Mekong Delta agriculture with the remarkable and very active partnership involvement of the leading research institutes and universities such as Can Tho university, Cuu long Delta Rice research Institute, Institute of Agriculture Science for Southern of Vietnam etc. in all steps from breeding stage to cultivation and harvest through transferring the technologies and knowhow to improve the quality, reduce the use of fertilizers and water.

Besides, Mekong Delta provincial governments are improving step by step the legislative framework and investment environment to engage the private sector and foreign investors into the agriculture transition and the region's agricultural development.

Market driving actor, Agriculture 4.0 is the combination amongst ICT technology and renewable energy and energy efficiency for processing and cultivation to reach the high quality market based agricultural products. [3]

The development and maturity of ICT 4.0 and bio-agricultural technologies from advanced countries such as Israel, Japan etc. and those technologies are expanding in Vietnam's agriculture and especially in the Mekong Delta region. The ICT application plays a significant role as the actor no 5 in driving the agricultural growth. This actor is bringing the efficiency for the agricultural production in responding to the healthy and safety standards like Vietgap, BMP, ASC, BAP etc. and also allows to reach the high yield due to minimize their dependence on the season, climate and nature. The of greenhouse cultivation technology, solar energy and energy efficiency (LED lamps, pumps), and ICT tools of monitoring the quality of water, soil, fertilizers and agricultural waste now is popular in the Mekong Delta provinces. The successful story of organic agricultural farms of Ecofarm represents the new trend in the agriculture sector with significant projects of 84 ha of organic vegetable farm in Kien Luong district of Kien Giang province, and 8000 m2 of organic vegetable farm in Thanh Binh district, Dong Thap province [4]. Other story is the farms of My Dong Agricultural Coop No2, the farmers use smart fertilisers together with other harmless biological product and water level measuring equipments which use the electricity generated from solar energy to monitor the rice plants at each stage of growth [5]. The use of clean energy for the entire system allows the inclusive changes and use of resource efficiency for agriculture through saving manpower, materials, electricity and water.

Regard to the environment conservation, the system of collecting agricultural waste to produce the biogas and re-use in the process of livestock cultivation also studied and implemented in some small farms in Mekong region but still need to improve in term of technology. The biogas production and broad use in the agriculture allows to complete the

closed circle from livestock, fruit and vegetables cultivation and aquacultural production in Mekong region.

There still exist a great potential market for exploring the renewable energy use in the process of packaging and storaging stages to improve the supply of products for the domestic market through prolonging the freshness of the product without use of preservative chemicals.

Mekong Delta region is also the region which is favorite the development of numerous solar energy plants since they reach around 2200 – 2500 hours of sun per year [6]. In this regard, marginalising the land use in the both sectors including agriculture and energy is important to avoid the conflict of land use. Recently several international organizations and companies have begun to study the dual use renewable energy and cultivation both for rice and vegetable crop or aquacultural farm [7-8]. This dual use aims get the two-in-one effect, offgrid electricity for agricultural development with high productivity while curving off the high electricity demand on the national grid.

Potentials of green jobs from value chain of eco agriculture development

The agriculture 4.0 is the new trend and emerging market in Mekong Delta region. This emerging market demands a range of energy services which need to tailor with the different types of agricultural farm. The local leading universities and research institutes mostly are focusing on the edging technologies to support the agriculture activities like the breeding, cultivation and harvest but still not address yet to supplementary services like energy and ICT application.

Meanwhile the abilities of local energy service companies are still restricted. Especially it exists the wide gap of information dissemination of the potential benefits of solar energy use for cultivation and the lack of training programs for farmers. Except the relatively large companies, most of famers still keep their cautious to invest the solar energy for their own farms.

Recommendations of green education for agriculture 4.0 development:

Again, the inclusive pathways to enhance the fundamental education of universities and vocational schools are the key elements to bridge the gap of green skillful labor force in the agriculture market. The local universities and vocational schools need to address to the integration of green technology curriculas and broadly comprehensive training programs which combine the greenhouse technology, energy services and ICT application for agricultural sector in Mekong Delta region. Moreover, the development of community based agriculture education programs and productions with the own and share model of green energy investment (solar and biogas energy) contributes to build up a community based branding of clean agriculture while maintaining a water management and minimizing the agriculture waste for the environment.

Together, the VOI Climate Agenda promotes a package of policy mechanisms and industry practices to build a learning and implementation network across diverse sectors and networks. It will take shared leverage through the Vietnam Oregon Initiative to move political strategies, investments and education towards a more prosperous future.

Research Paper

RESEARCH ON STRATEGIES OF LOW-IMPACT URBAN DESIGN IN CHINA

Take Beijing waterfront urban design evaluation as an example

Cong CAO[1,2], Suning XU[1,2]

[1] School of Architecture, Harbin Institute of Technology, China

[2] Key Laboratory of Cold Region Urban and Rural Human Settlement Environment Science and Technology, Ministry of Industry and Information Technology, China

Abstract

This paper aims to provide theoretical method support and practical experience for creating environment friendly urban space by low-impact urban design methods, and discussed on two aspects of theory and practice.

Firstly, the definition of low-impact urban design in the context of Chinese cities is expounded by combing the development stage of urban design environment view and analysing the development needs of Chinese cities. Then, it discusses the framework content and evolution process of low-impact urban design in China, and puts forward the view that low-impact development elements and low-impact design control elements are mutually dependent and mutually reinforcing. Next, the objects and related characteristics of low-impact urban design are explained from multiple perspectives, as object system, object composition and basic characteristics. Relevant strategy formulation is the focus of this paper. First, it is necessary to establish a low-impact urban design system in coordination with legal planning, so as to help implement the low-impact design concept with the seriousness and execution of legal planning. Secondly, the framework of low-impact urban design control elements including 5 different layers is established, which can effectively evaluate and optimize the impact of design results on the city. Thirdly, the value evaluation mechanism of dynamic cycle is proposed, which is helpful to the implementation of low-impact urban design and the restoration of design intention. Finally, the paper takes Beijing waterfront urban design evaluation as an example to apply the low impact evaluation model proposed in this paper, and satisfactory results were obtained.

Keywords

Low-impact urban design, urban design, strategy, China

In recent years, global climate change had brought severe test to the living environment development, the city both responsible for climate change, but also slow down the crisis. China is one of the world's most active countries on the exploration and construction of low-impact urban design. Low-impact construction represents China's commitments to international community about energy-saving and carbon emission reduction, also in line with the national strategy of ecological civilization construction and urban development

trend in the future. In the context of such research, the innovation need for method and theory of Low-impact urban design was even more necessary and urgent.

Low-impact urban design described in this study is based on the ecological urban design strategies, to address the complexity and uncertainty issues, which generated in the process of construction and development of Chinese cities. And build the pattern framework with sustainable characteristics based on the view of flexibility and adaptability, which does not adhere to the traditional urban design processes or programming, instead combining flexibility with sustainable design actions to be applied to different urban spaces.

1. The definition of low-impact urban design

1.1. The evolution of environmental view of urban design

The definition of "environment" here refers to the totality of various natural and social factors surrounding the space of people and which can directly or indirectly affect human life and development. While "environmental view" refers to the sum of people's views and concepts on the environment itself. Stern & Dietz divides environmental values into three levels as self-centred values, human-centred values and ecology-centred values. There is a progressive relationship among the three different levels, the ecology-centred values are the most advanced and most in line with the development concept of low-impact urban design. In the course of its development, the environmental view on space, nature and human value of urban design are constantly changing, and different views have been generated along with this process. Based on the principle of time division, the evolution process of environmental value of urban design is summarized below. (Figure 1)

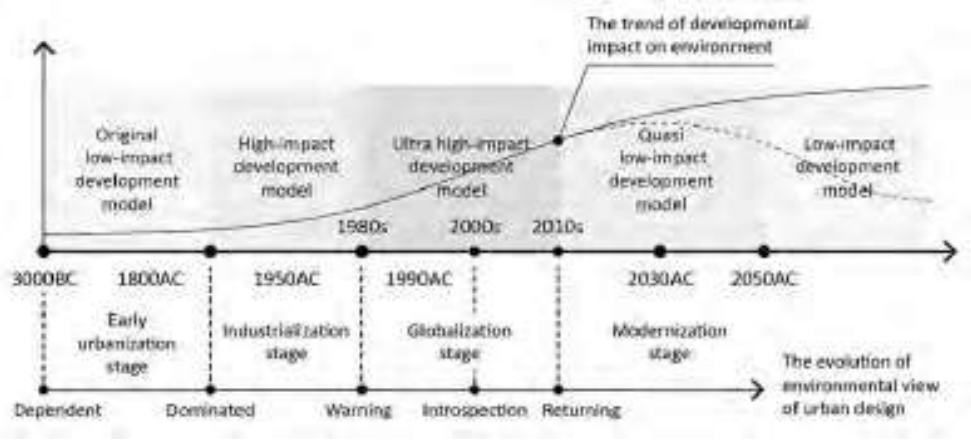

Figure 1 The evolution process of environmental value of urban design

It can be seen from the figure that the environmental view of urban design has gone through four stages: original low-impact development model, high-impact development model, ultrahigh-impact development model and quasi low-impact development model. In the early urbanization stage, the city adopted a simple and primitive low-impact development mode, which was under the control of social productivity. Subsequently, the rapid development of industrialization led to the high-impact urban development mode. At this stage, the environmental view was mainly manifested as the dominant use of natural environment and resources. At this time, the theoretical circle had begun to sound warnings about the adverse impact of urban development on the natural environment. After the city into the

stage of globalization, as a result of the social productive forces rapid ascension, urban development impact on natural environment reached unprecedented heights, the emergence of a large number of urban problems prompted scholars and urban managers a reflection, exploration eco-friendly concept of urban development and urban design theory is urgently needed. At the beginning of the 20th century, the urban development mode represented by low-impact development has been recognized globally. Specifically, the impact curve of urban development on the natural environment has been moderated and decreased, providing a good expectation for the ultimate realization of low-impact urban development mode.

1.2. The definition of low-impact urban design in China

In the past 30 years, China has experienced an unprecedented process of rapid urbanization, realizing the development achievements of developed countries that took nearly a century to achieve. On the one hand, rapid urbanization has greatly improved China's social economy and people's living standards. On the other hand, the high-impact development mode represented by serious irreversible damage to the natural environment is also constantly interrogating the conscience of urban managers. Therefore, in recent years, the low-impact urban design concept represented by green urban design and eco-oriented urban design has been widely recognized and applied in China, and has accumulated considerable theoretical and practical experience.

Low-impact urban design is a new urban design concept with green urban development theory as the background, natural ecological system as the support, human behaviour as the leading, spatial form design as the means, advanced technology as the support, implementation and evaluation as the guarantee, and spatiotemporal continuation as the purpose.

Specifically, low-impact urban design is under the background of global climate change, and to the environment, energy, ecology and other related disciplines theory as a guide, in-depth study of urban space environment and the internal interaction between urban construction activities, and in view of the urban form evolution and low impact development issues, the relationship between dimensional specified in the theoretical basis and practical level of strategies, methods and evaluation system. So as to promote the formation of ideal low-impact urban development mode, and creates a social practice process of urban space environment in harmony with the climate environment protection, ecological system growth and high-quality public life.

2. The connotation interpretation of low-impact urban design

2.1. The framework of low-impact urban design

"The interaction between human and environment" has always been the focus of urban design and the practical basis of low-impact urban design. The so-called "environment" refers to the overall space of people and various natural and social factors that can directly and indirectly affect human life and development. As a realistic system and basic framework of citizen life, urban physical space environment should include artificial environment, natural environment and the interaction between the two parts.

Low-impact urban design is based on the understanding that urban space environment can support and guide human behaviour. "Natural environment -- human activities – artificial environment" has also become the main line of methodological framework to exert the values of low-impact urban design. It should be noted that since city is a complex giant system, the structural mitigation effect of urban design on the impact of urban construction on the natural environment is often difficult to be quantified and ignored as an indirect path. But in fact, urban design can achieve the goal of comprehensively reducing the impact of urban development on the natural ecology from the perspective of reducing the overall space energy consumption demand, improving the overall space ecological quality, and promoting the human activities efficiency.

Therefore, follow the main line, low impact urban design research should further to the relationship among human, artificial and natural elements under the background of climate change. (Figure 2) As well as its mechanism of integrated influence on urban system.

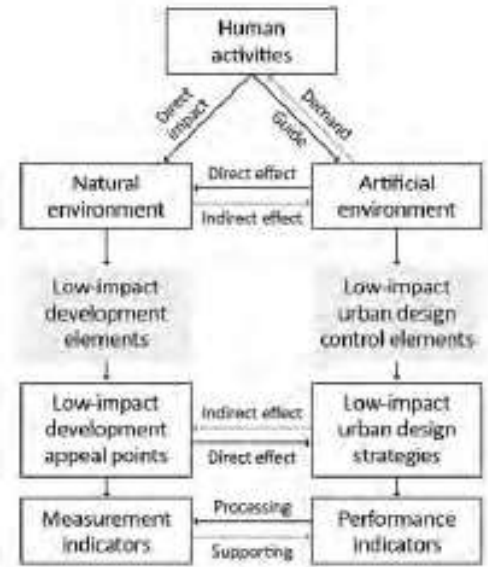

Figure 2 The evolution process of environmental value of urban design

2.2. The objectives of low-impact urban design

The establishment of the objective framework of low-impact urban design plays an important guiding role in the practice process and is the internal power throughout the whole process of urban design. The following will be discussed on the strategic level of the goal composition.

The strategic level goal of low-impact urban design is to help mitigate climate change and promote sustainable development of human settlements. Sub-goals are decomposed into three aspects:

(1) Promote the development of low-impact economic structure: urban design can combine new economic structure, logic of green development, ecological security pattern, energy-saving building technology, clean and efficient energy to create opportunities for new growth points of low-impact economy.

(2) Promote the formation of low-impact social order: urban design can create an environment and opportunities for residents to change their lifestyle through form design

and public participation, so as to facilitate the formation of a low-impact economy-oriented consumer society.

(3) Promote the coexistence of human and nature: urban design can protect natural resources and environment by exploring the development of settlements with the lowest energy intensive lifestyle.

2.3. The basic characteristics of low-impact urban design

Low-impact urban design is built on the basis of ecological civilization. Its essence is to integrate various natural elements and urban system components into the overall environmental system, and discuss how to achieve the liveability of urban environment and the efficiency of urban operation under different resource endowment conditions. Its basic characteristics mainly include four aspects as following.

(1) Systematic features Low-impact urban design advocates to re-examine the traditional linear planning mode, pay equal attention to the material and non-material attributes of the environment, and grasp the overall relationship of the system from the mutual connection of various components. The integral control of urban design on spatial form is not a simple superposition of various low-impact design elements. Instead, it aims to improve the operation efficiency of urban systems, reduce urban internal consumption and environmental damage, and ultimately achieve the symbiosis between human and nature.

(2) Operational features Low impact urban design has stronger target orientation and operability, and the related concepts are easier to be implemented and put into place. It has high operability that can be copied and promoted. The concept of "low impact" is permeated into various spatial scales and operational levels to test the effectiveness of the design results. Specific performance for the stage development expectations, measurable technical indicators, verifiable evaluation system.

(**3) High efficiency features** Low energy consumption, low pollution, low emissions and high performance, high efficiency and high benefit are the characteristics and direction of urban development in China, the Chinese academy of sciences points out in its China's sustainable development strategy report. To some extent, low-impact urban design is essentially a kind of "high-efficiency urban design", which follows the principle of minimum loss and minimum impact, improves the urban physical environment through natural regulation, pays attention to the climate protection effect of the ecosystem, and reduces the negative impact of human activities on the environment as much as possible. In short, one of the important features of low-impact urban design is to attach importance to the rationality of resource utilization, and to obtain the maximum economic, social and environmental benefits with the minimum input.

(4) Circularity features Circularity is the internal mechanism of natural ecosystem with strong vitality. Low-impact urban design should also combine the "circulation law" of the ecosystem to establish the feedback mechanism and material exchange mode between urban space and environment, so as to reduce the impact of construction activities on the natural environment to the smallest extent possible. It includes reduction of resource input, reuse of process maintenance and recycling of resource output. It can be seen that the focus of low-impact urban design should shift from functional design to resource-oriented design to reduce the adverse impact of urban activities on the natural environment and improve the self-sufficiency of the city.

3. The strategies of low-impact urban design

3.1. Compilation process in line with the statutory planning system

In the relationship between low-impact urban design and statutory urban planning, urban planning focuses on studying the functional combination of urban land use, comprehensively coordinating the development of economy, society and engineering technology, and seeking the comprehensive balance of social, economic and environmental benefits. The research field of low-impact urban design focuses on the interaction effect between urban natural environment and artificial environment, mainly to solve the disturbance of urban physical space and human activities on the natural environment, and its core content is to use the theoretical methods of related disciplines to create an efficient and high-quality urban environmental space.

Low impact urban design because of its lack of legal status, cannot be directly used to guide the implementation and planning management work, but as a research method and analysis process can also be throughout the whole process of urban planning. (Figure 3) It is coordinated with all levels of planning in time axis and space scale, which provides a model foundation for constructing a collaborative platform. Judging from the revision process of urban and rural planning laws and regulations in China and the implementation of local regulations, it is difficult to solve the demand of urban design legal status and regulatory effectiveness in a short term by means of legislative approach. Therefore, it is a reasonable choice to translate low-impact urban design achievements into legal planning system by means of "planning translation". By compiling multi-level urban design results to comply with the statutory planning system. The core control elements in the design results are reflected in the planning provisions, restrictive descriptions, prescriptive or guiding indicators at the certain level and taken as the basic conditions for the preparation of the sub-level, so as to strengthen the guiding and regulating role of urban design in the city construction project.

3.2. Establish low-impact urban design control elements framework

The element is the essential factor that makes up the thing, also is the basic unit that makes up the system. Combining with the low-impact urban design factors affect the mechanism of decomposition is analysed and related reference, this paper presents the "low-impact urban design control elements 5 layers framework" composed of the ecological impact layer, space impact layer, demand impact layer, economic impact layer and the aesthetic impact layer. It should be noted that the control elements of low-impact urban design are the selection and reconstruction of traditional urban design elements from the perspective of promoting urban operation efficiency in the context of climate change. Irrelevant or weakly correlated elements are not considered in this paper. (Figure 4)

(1) Ecological impact layer The impact of urban construction and human activities on the natural environment and natural resources was emphasized, and more attention was paid to the content of low impact on the macro-ecological security system and the original structural characteristics.

(2) Space impact layer This layer focuses on the physical form and spatial quality of urban physical space, and how to reduce the impact on urban operation state under the premise of developing corresponding contents, including urban infrastructure sub-layer, road traffic network sub-layer, urban block and open space sub-layer.

(3) Demand impact layer As the decision-maker and executor of urban construction behaviour, human is the ultimate decisive force of low-impact development. How to realize the vision of low-impact urban design under the premise of meeting the usage demand and spiritual demand of the citizen is the focus of this layer.

(4) Economic impact layer Economic development is one of the fundamental missions of cities, and low-impact urban design also needs to pay attention to this aspect. It includes the adjustment of urban economic structure, the improvement of comprehensive land value and the improvement of urban operation efficiency, and the supply of resources and services.

(5) Aesthetic impact layer The aesthetic demand of city is an inevitable product of urban development to a specific stage. As a new urban development concept, low-impact urban design inevitably contains the content of aesthetic thinking, which also proves from the side that the spiritual appeal of urban activity participants is one of the fundamental driving forces of urban evolution.

Figure 3 Coordination mechanism between low-impact urban design with statutory planning

Figure 4 Low-impact urban design control elements framework

Specifically, in order to ensure the integrity and effectiveness of the proposed framework structure, it should have the following characteristics.

(1) Hierarchy The framework of low-impact assessment elements deconstructs the influencing elements according to the progressive collection of elements, and each layer is composed of its own sub-elements to form a hierarchical element system framework.

(2) Structural Refers to the system independent of each other in proportion to a certain structure, and to a large extent determine the nature of the system. The levels of low-impact elements are complete and independent. After superimposed, the links among subsystems are emphasized to form a tower-like element correlation structure together with human activities, which determines the comprehensive performance of low-impact urban design as a whole.

(3) Heterogeneity Refers to the different status and function of the same element in different subsystems. Each level of the low-impact evaluation system has its own emphasis on the impact of the city, and the evaluation period is also different. The layered setting is convenient to discuss the effect and potential of each level more clearly, and also helpful to provide reference basis for the design organization, management and maintenance.

3.3. Dynamic evaluation mechanism of low-impact urban design

City itself come from the continuous accumulation of urban design implementation. The results of implementation at this time must be updated at a future point by the ongoing impact of human activities. However, the results accumulated through the passage of time will gradually accumulate into the urban design gene of the city, which will lead the iteration of the city development for a long time. In addition, the mutual attraction and consciousness between people and cities can be established by this gene, and eventually become part of the public values of the city.

The practice of low-impact urban design in China has long been focused on design but neglected implementation. This static urban design system is unable to timely and effectively foresee and adjust the unreasonable aspects in the design results due to the characteristics that its action factors are difficult to be separated. After its implementation and operation in the physical space, it will be modified postemptively and passively, resulting in multiple wastes of planning resources, construction resources and development time.

The logic of circular evaluation of low-impact urban design refers to by the whole cycle process is decomposed into preparation sub circulation as decision-making, implementation, evaluation, adjustment. Then the connotation behaviour of each sub circulation is logically disassembled, and the implementation effect of the sub-cycle is continuously evaluated and monitored. The obtained results are injected into the starting point of each sub-cycle to determine whether there is an update or adjustment demand, so as to realize the dynamic optimization goal of the whole process of low-impact urban design results. (Figure 5)

Figure 5 Dynamic evaluation mechanism of low-impact urban design

From a neutral perspective, resource effectiveness, internal and external effectiveness and ecological effectiveness are the evaluation conditions of the implementation vision of low-impact urban design. In addition, it tries to reach a relative consensus under the background of multi-value subjects of the government, the market and the people, so as to guide and adjust the action plan and connotation of urban design, generate sensible spatial results, and conclude the "reincarnation way" of low-impact urban design through deduction.

4. Exploration on low-impact urban design application

4.1. Introduction of Beijing waterfront space

As a world-famous ancient cultural capital, Beijing has a history of over 3,000 years, the water conservancy construction in Beijing is closely related to urban construction. And its waterfront urban design research is also an important part of the implementation of Beijing's overall low-impact urban design, which has a high research value.

Beijing water system was constructed in the Jin Dynasty and then completed in the Yuan Dynasty. After the utilization and development of Ming and Qing dynasties, a complete system and complete function water network was formed. Since the founding of the People's Republic of China, the urban functions of Beijing water system has gradually degraded in the context of large-scale city expansion. A large number of water system has lost their original functions of grain transport, irrigation and defence, and even the royal river channels supplying water for imperial gardens were not entitled to special status any more. Many natural river channels and ponds were straightened with curves cut off, and thus formed into artificial drainage river channels during this period. (Figure 6, 7)

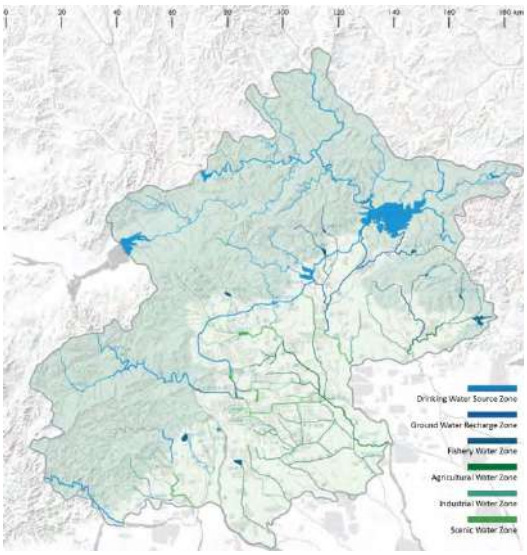

Figure 6 Water function layout plan of Beijing waterfront space

Figure 7 Satellite data of Beijing central city waterfront network

It can be seen that the development course of Beijing water system in recent years is not in line with the concept of low-impact urban development. Excessive intervention of artificial behaviour has greatly damaged and weakened the original form and natural properties of urban water body, which remains to be solved. Therefore, the research on low-impact urban design of Beijing waterfront area is helpful to restore the natural properties and functions of water bodies to some extent, alleviate various problems caused by urban construction activities, and improve the ecological elasticity of space and the value of natural supply.

4.2. Evaluation of Beijing waterfront space

The core objective of Beijing waterfront space urban design is, based on the relationship of city and river, to analyse how water impacts ecological environment, urban space and public life in the circular and metabolic process. The project will be developed from the following research perspectives and evaluation framework with synthetic weight. (Table 1)

(1) Landscape pattern perspective Geographical position and topography precipitation in Beijing is characterized by uneven space-time distribution, and dry and wet seasonal alternation. Given hydrological features and distribution of hydraulic facilities, an ecological design principle of regulating the dry and wet season is provided to guide the low-impact oriented waterfront space design.

(2) Behavioural requirements perspective Due to the water supply security as the main function of the water network in Beijing, there is little room for public activities within the river channels. According to people's utilization requirements of the waterfront space in different seasons, space for urban water utilization and public activity is integrated, and regulation suggestions are proposed in order to improve environmental quality of waterfront space.

(3) Administrative implementation perspective According to impacts of city evolution on the water system distribution in modern times, multi-department coordination and management mechanism and pertinent design guideline are proposed based on the duty of each relevant urban administrative and institutional body.

Table 1 Evaluation elements and synthetic weight of Beijing waterfront urban design

FIRST CLASS	SECOND CLASS	SYNTHETIC WEIGHT	INDEX LEVEL	WEIGHT
ECOLOGICAL IMPACT LAYER	WATER	0.388	WATER QUALITY	0.118

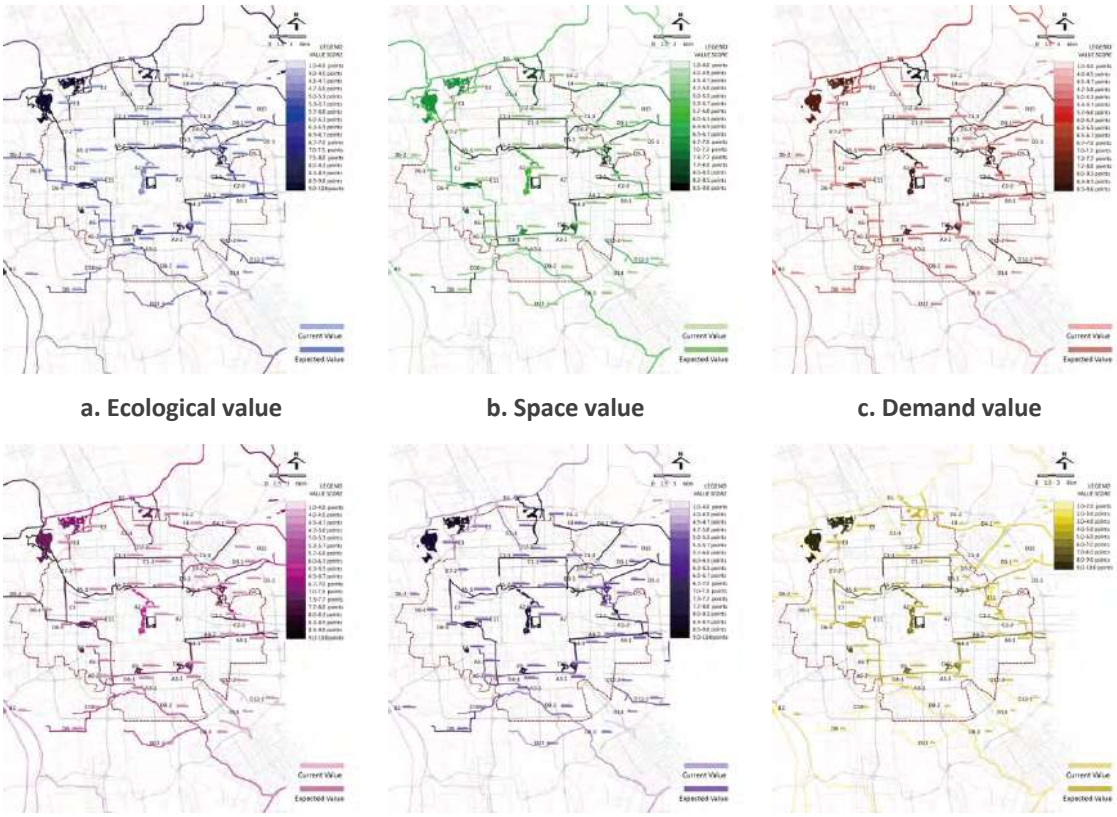
			FACILITY CHARACTERISTIC	0.300

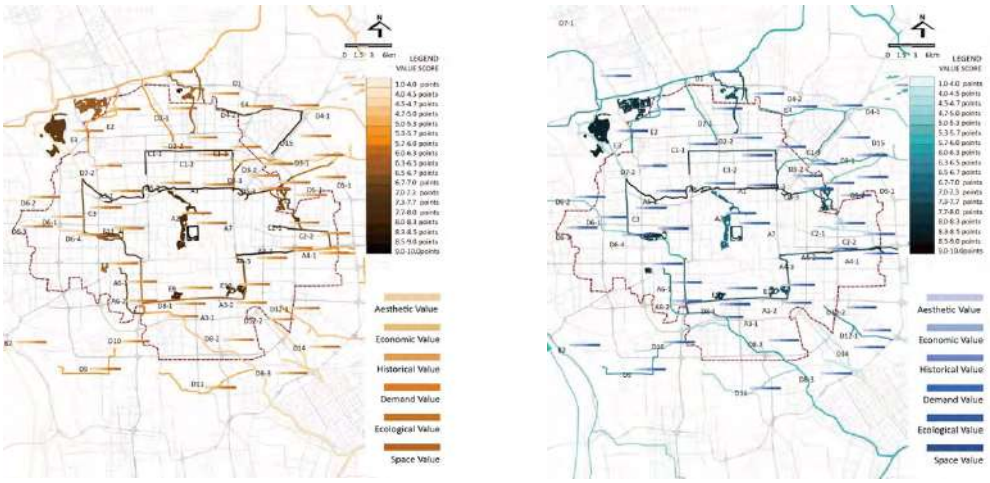
Combine the related survey data with the low-impact design vision, at the same time, based on the evaluation layer system and weight factors listed in table 1. The ecological value, space value, demand value, economic value, aesthetic value, historical value of Beijing waterfront space urban design has carried on the quantitative analysis, the result is shown in figure 8 and figure 9. The information shown in the figure relatively objectively shows the current situation, characteristics, needs and other content characteristics of Beijing waterfront space, and can effectively guide the following low-impact urban design work.



a. Ecological value b. Space value c. Demand value

d. Economic value e. Aesthetic value f. Historical value

Figure 8 Evaluation of sub-layer of Beijing waterfront space



a. Current comprehensive value b. Expected comprehensive value

Figure 9 Current and expected comprehensive value of Beijing waterfront space

5. Conclusion

In the development process of low-impact urban design, the interactive extension of ideas, entities, time and people makes the city in constant evolution, showing colourful vitality in a flexible way. Admittedly, this direction is still in the exploratory stage in China, and a set of universal experience and methods have not been summarized yet. Although the multi-dimensional integration concept and mode framework described in this paper does not become a common value orientation and criterion in the field of low-impact urban design, it can also be regarded as a positive attempt.

Case Study / Project

Building Unique Cities:
an Imperative for Sustainability and Liveability in the Global South

Olga CHEPELIANSKAIA

Abstract

Cities face an unprecedented urbanization pressure, which led cities of the Global South to building infrastructure hurriedly, compromising on their natural ecosystems, cultural distinctiveness, human scale, wellbeing and liveability. As a result, many cities in developing countries are characÂ¬terized by overcrowded, poor quality and insufficient infrastructure services, low-quality building stock and a uniform cityscape. Negative consequences related to building uniform go far beyond a cultural loss and severely compromise urban sustainability, economic vibrancy and quality of life: - Urban development often happens at the expense of natural ecosystems rather than in line with them. The standardised way of designing blocks coupled with unplanned city expansions have led to massive encroachments over water bodies and green areas, water pollution, and even flattening of hillsides. Loss of unique natural ecosystems makes cities simultaneously prone to floods, heat waves, droughts and scarcity of natural resources. - Standardised materials and construction styles have high carbon footprints owing to higher embodied and operational energies.

Modern buildings deteriorate relatively quickly, shortening the lifecycle for new building stocks. This leads to even more energy consumption and carbon emissions resulting in increasing climate vulnerabilities. - Lack of unique visual identity affects the city's economic competitiveness through lost tourism opportunities and a loss of quality of life, liveability and wellbeing that results from depriving citizens of sufficient green and blue areas, and weakening their sense of belonging. Building unique cities is an imperative to achieve sustainability and resilience. And it can be done in two interconnected ways: - First, it is critically important to revive the existing natural and built heritage. Heritage buildings using vernacular materials and styles are a repository of knowledge that reflects how cities have traditionally responded to their local context.

Bangkok had developed around numerous canals and vernacular stilt houses protected dwellings from floods. Low-rise highly dense clusters in Jaisalmer minimised heat gain while internal courtyards allowed cooling airflows. Similarly, natural heritage plays a critical role in sustainability, climate resilience and provides unique landscapes. - Second, it is equally important to build unique today. Contemporary urban developments have much to learn from the growth patterns of heritage cities, their connection with nature, culture, society and context. New kinds of sustainable building stock need to be developed bringing together localized vernacular approaches and technological innovations. Multiple stand-alone or small scale innovative solutions already exist: Earthships in New Mexico, Laurie Baker's brick houses in Kerala or the town of Ksar Tafilelt in Algeria for example.

Upscaling these solutions however remains a challenge to discuss. The proposed session will take a shape of a working group and build upon the work initiated by the program Sustainable Cities through Heritage Revival (SEHER Asia) and UNICITI - an international think tank consultancy - with knowledge support of the Cities Alliance, the Indian National Trust for

Art and Cultural Heritage (INTACH), the Future Institute as well as selected individual world renowned architects and urban practitioners.

The session will be divided into three parts:

1. A keynote presentation (20 minutes) will highlight the importance of rapidly coming up with a new way of building Asian cities today and share directions for solutions identified so far;
2. A moderated working session (45 minutes) will follow, gathering participants around one or two round tables depending on their number. The objective is to learn from each other and identify break-through alternative approaches to urban development;
3.Conclusions (15 minutes) and possible ways of continuing this joint work will be discussed and summarised in a statement to share at the concluding plenary or to circulate electronically to ISOCARP members.

Research Paper

Transdisciplinary planning approaches towards resilience

Elizelle Juanee CILLIERS, North-West University, South Africa

Abstract

Urban functions are no longer separated spatially or socially, and the contest between diverse land-uses is reaching a peak due to growing populations and increasing urbanization that inflates the pressure on already strained resources within the urban fabric. The trend of depletion of green spaces is an increasing global phenomenon, intensifying the growing carbon footprint, impairing water quality and compromising health and overall quality of life, ultimately leading to cities that are far removed from the safe, clean, and livable environments, as envisioned in planning theory. Green spaces are often viewed as a "luxury good", despite the comprehensive literature on the extensive benefits of such spaces to their host cities and communities. Misconceptions relating to the notion of green spaces are reflected in the undervaluation of these spaces, under-prioritization in the budgeting process and ultimate negligence in terms of broader spatial planning approaches. The lack of function and ownership further exacerbate the social- and economic value of these green spaces, especially within the South African context, apparent by the disproval of the compensation hypothesis and rejection of the proximity principle. Much effort will be needed to change perceptions and sensitize decision-makers to understand green spaces as a "public good" and "economic asset". Resilience thinking could pose solutions in this regard, drawing on transdisciplinary planning approaches to manage change and steer Spatial Planning towards the era of transurbanism. It would however, require the emancipation of the disciplinary identity of Spatial Planning as crucial driver towards resilience, departing from theoretical and methodological frames of supplementary disciplines, as well as the indigenous knowledge and living experiences of communities, to co-produce urban innovations. Conveying strategic and lateral thinking, contemporary Planners would need to become generative leaders, with socio-emotional intelligence, to generate innovation and co-create solutions for strained social contexts, for depleting scare resources, for managing change of contemporary urban landscapes.

Keywords

Trans-disciplinary planning, green spaces, resilience

1. The contemporary urban landscape

The world population of today is growing by an average of 162,600 persons per day. Almost every spatial planning-orientated paper references the increasing world population in arguing the complexity of the planning profession to create a sustainable future. The planning profession has evolved from a designing art, to a social science (Zhang, 2006:12), to a management and applied science (Zhang, 2006:12; Cilliers & Cilliers, 2016). Contemporary

Spatial Planning is now confronted with "the management of change", to resolve conflicting political and social demands on space, while protecting the earth's generative capacity (Campbell, 1996:296; Cilliers & Cilliers, 2016). Spatial change is at a peak within the urban landscape, as 4.2 billion of the world's 7.6 billion people (55%) currently reside in cities (UN DESA, 2018). Projections show that urbanisation, the gradual shift from rural to urban areas, combined with the overall growth of the world's population could add another 2.5 billion people to urban areas by 2050 (reaching 68% urbanisation), and reaching full global urbanisation in the following decades, intensifying the challenges of the contemporary urban landscape.

The four urban functions of working, living, leisure and transport which Le Corbusier (1929) once so elegantly deployed in his model of the city can no longer be separated from each other either spatially or socially (Mulder, 2002). The contemporary urban landscape deploys a picture where formal data (land-use, functions and zonings) are now distorted by informal data (activities and interaction) that precedes planning structures, as illustrated in Figure 1.

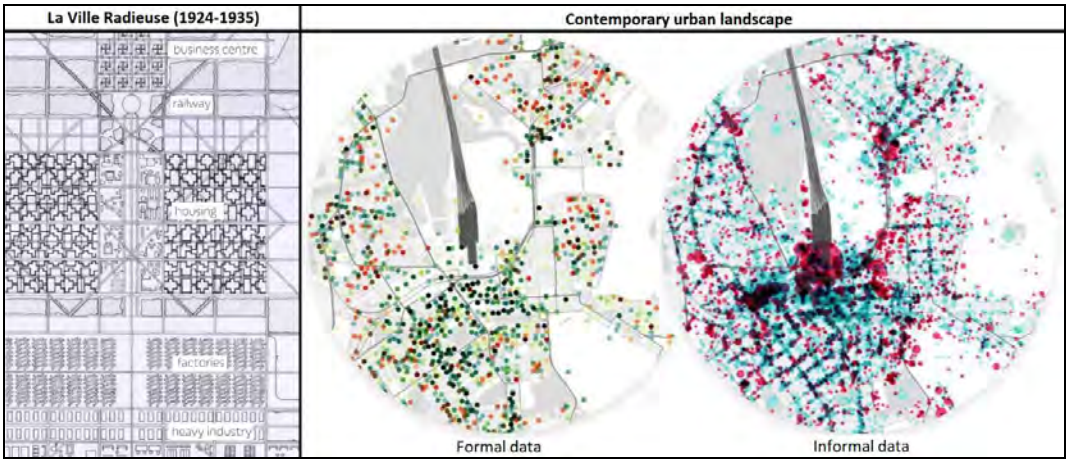

Figure 1: From La Ville Radieuse to the contemporary urban landscape
Source: Based on Le Corbusier (1929) and Danin (2019)

In Africa, the expected rate of urbanisation poses a further concern in light of potential negative environmental impacts (Kestermont et al., 2011) that could lead to unprecedented changes, especially within a soon to be urbanised landscape, where informality and sustainability collide. Africa is in a unique position to embrace informality as a contributing factor to the realisation of broader sustainable development objectives, as argued by Lategan (2017) in reference to South Africa's informal backyard rental sector and its contribution to structuring sustainable urban landscapes. But, for Africa to lead this discourse on informality and sustainability, the African space economy should be reconsidered from a Spatial Planning perspective (Okeke, Cilliers and Schoeman, 2018), to facilitate ways to host growing populations, accommodate urbanisation and changing urban landscapes and social dynamics, while recognising land as a scarce resource, and as a force of global importance in the quest towards sustainable development (Sustainable Cities Institute, 2012; Cilliers & Cilliers, 2015).

2. Land as a scarce resource of the contemporary urban landscape

Land was once plenteous and resources were abundant. With the predictions of full global urbanisation within the next half century (McArthy, 2016), urgent action is needed to recognise land as a scarce resource of the contemporary urban landscape. Spatial planning has a key role to play in this regard, shaping the contemporary urban landscape in line with the universal ambition for sustainability, embedded in the global sustainable development goals (United Nations, 2017). In the search for "inclusive, safe, resilient and sustainable cities and human settlements" (United Nations, 2017), the interrelated role of the environment as catalyst to realises the objectives of sustainability (Anderson & Elmqvist, 2012) is becoming more prominent. There is now an expanded scientific understanding that green spaces are substantially beneficial to urban communities and cities (Llausas & Roe, 2012; Thomas & Littlewood, 2010; Wright, 2011), and that ecological principles are a sine qua non for sustainable cities (Forman, 2013, Lui et al., 2007; Stigsdotter, 2008; Cilliers & Cilliers, 2015).

However, despite theoretical and methodological frameworks in support of green spaces within the urban landscape, the reality suggests of a depletion of urban green spaces across the globe. Statistics illustrate, amongst others, a depletion of green spaces in 25 European cities (European Environmental Agency, 200), in 274 metropolitan areas in the United States of America (McDonald et al., 2010) and to an even greater extent in Africa (Cilliers et al., 2013; Kestermont et al., 2011). In South Africa, for example, green spaces occupy less than 10% of urban land (McConnachie et al., 2008). The lack of green spaces in high-density urban landscapes are in most cases a result of their susceptibility to urban development pressures (More et al., 1988:141; Luttik, 2000) and the under prioritisation of green spaces in the decision-making process (Bertaud, 2010). As a result, cities are being further removed from the safe, clean, and livable environments, envisioned in planning theory (Van den Berg et al., 2007).

Data from the Global Carbon Project (2018) illustrate that land-use changes, especially the depletion of green spaces and deforestation, comprised 11% of total emissions produced in 2017. Land as a scarce resource is thus becoming a force of global importance, as changes in land-use contribute to the growing carbon footprint (Global Carbon Project, 2018). Spatial Planning could influence both the release and uptake of carbon, by considering industry planning and emission of fossil fuels, emissions from land-use changes, protection of carbon sinks such as the oceans and land, and recognising planning as either catalyst, or inhibitor, of changes in atmospheric concentrations of CO2 (Global Carbon Project, 2018), as indicated in Figure 2.

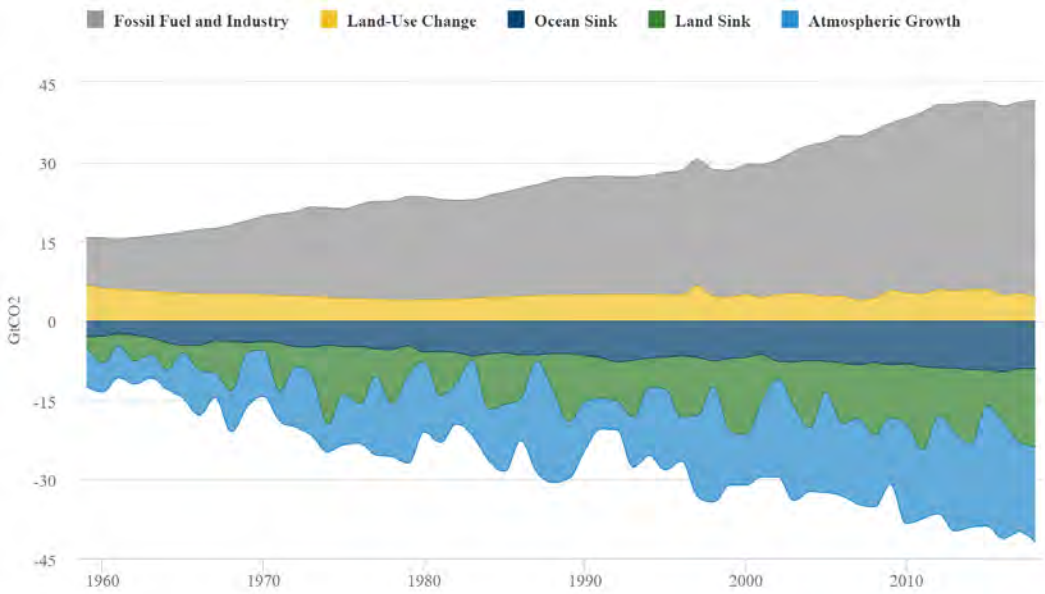

Figure 2: Annual global carbon budget of sources and sinks from 1959-2017
Source: Global Carbon Project (2018)

Cities have become a central nexus in the relationship between people and nature (Elmqvist, 2014), where the provision of green spaces results in a range of supplementary ecosystem services supporting humanity, including provisioning, regulating, supporting and cultural services (Cornelius, 2016:86; Cilliers et al., 2018), but concurrently, where the lack of green spaces, trigger other negative impacts, known as ecosystem disservices (Shackleton et al., 2016). These impacts relate to, but are not limited to, the intensified urban heat-island effect, increased energy consumption (Akbari, 2005), impaired water quality (James, 2002) and ultimately compromised human health and comfort (Centre for Disease Control and Prevention, 2006; EPA, 2019, Timmermans et al., 2017).

In the African urban landscape these impacts are magnified due to proportionally higher pressure on land use and loss of biodiversity per unit of wealth produced, compared to Europe (Cilliers et al., 2013). The prioritisation of green spaces in this context is also more complex, as strained social contexts often overshadow community needs. In many cases development-decisions precedes environmental concerns (Cilliers & Cilliers, 2016; Thysse, 2017), in support of growing societies. Despite comprehensive evidence from literature and best practices pertaining to the value of green spaces as 'public goods', articulated in terms of ecological-, social-, and economic values (Cilliers & Cilliers, 2016), green spaces are often considered a 'luxury good' in the African context and not a necessity or a sine qua non for sustainability (Cilliers and Cilliers, 2015; du Toit et al., 2018).

As a result, the "more pressing needs", such as eradicating poverty, providing basic services and addressing the growing housing backlog (Cilliers & Cilliers, 2015; Soares et al., 2011; Cilliers & Cilliers, 2016) take precedence in municipal and national budgets, only further constraining the planning and provision of green spaces in areas where it is often most needed (Cilliers & Cilliers, 2016; Huston, 2016). The reluctance to budget and plan for green spaces should, however, not be confused with the community need in search of such spaces. Previous findings by Cilliers et al. (2013) demonstrated how the valuation of green spaces

fluctuate against different socio-economic gradients, as poorer communities put a higher demand on provisioning services (food, lawn, medicinal, shade), while more affluent communities put a higher demand on cultural ecosystem services (aesthetics and ornamentals). More recent research suggests of a growing need for green spaces amongst local communities within the South African context (Lategan & Cilliers, 2014).

The need of such green spaces are however, due to misconceptions and the lack of budgets and planning, not being met in practice. Research by Lategan and Cilliers (2014) considered the value of public green spaces and the informal backyard rental sector of Bridgton and Bongolethu (Oudtshoorn, South Africa) and concluded that green spaces in these areas are not providing any specific service to the communities and therefore, despite the need expressed for green spaces, not used by most individuals. The compensation hypothesis, which departed from the understanding that communities with limited access to private green space will seek compensation elsewhere, was disproved in the Bridgton and Bongolethu case study (N=708), further supporting the impact of impractical spaces. Such spaces do not provide a service to communities and do not entice users, who do not have access to ample domestic green space, to seek compensation in these public spaces (Lategan & Cilliers, 2017; Maat & De Vries, 2006; Lin et al., 2015).

The majority of local research suggest that green spaces in South Africa are not on par with international standards in terms of quality and function, strengthening the false perception that these spaces are not valuable or valued (Cilliers & Cilliers, 2016). It is further posited that the lack of quality and function related to these green spaces explains for most part, why these green spaces do not increase property values in accordance with the internationally accepted green proximity principle which states that residential property prices increase as proximity to green space increases. This results and disproval of the green proximity principle, was derived from a local case study conducted in Potchefstroom (JB Marks Municipality, South Africa) where statistical analysis of variance (ANOVA) was applied to the property values of five residential areas to determine the significant difference between the means of properties located at different distances from an urban green space (Cilliers & Cilliers, 2017). The collective results of the Potchefstroom Case study (N=188) illustrated a statistical difference between zones located further from the green space ($p=0.76$), thus rejecting the null hypothesis and disproving the proximity principle. Ecosystem disservices associated with crime in green spaces (Konijnendijk et al., 2013: 22) and the perception of green spaces as crime hotspots (Perry et al., 2010), were identified as possible contributing factors why residential properties located adjacent to green spaces exhibited a lower price per square meter than properties located further away. Cilliers and Cilliers (2016) identified a lack of function and ownership connected to green spaces, as contributing factor for negligence and failure of green spaces in local context.

In an attempt to steer the national vision towards realising the importance of green spaces within the urban landscape, the South African Cities Network (SACN) appointed Cilliers and Cilliers (2016) as authors of the publication “Planning for Green Infrastructure: Options for South African Cities”

This research introduced the notion of green infrastructure (GI) as a long-term strategic approach to plan green spaces as a network of supportive infrastructure. It contributed to the discourse on the valuation of public green spaces from different social and cultural gradients, as well as the discourse on user-values and valuation from a local perspective. It

called for the integration of green infrastructure as part of mainstream Spatial Planning, recognising that much effort will be needed to change perceptions about the necessity of green spaces in both urban and rural landscapes in South Africa. To sensitise decision-makers to grasp the value and role of green spaces as a 'public good' and 'economic asset', more practical guidance is needed (Cilliers et al. 2018) with a proactive and deliberate response to address contemporary challenges (Folke, 2006).

It mandates a shift towards resilience thinking in planning (Schoeman, 2017), where Spatial Planning response to the increasing economic, social and spatial vulnerabilities in cities, and halt the rapid depletion of natural resources and environmental degradation (Harrison et al., 2014). It implies planning structures and systems that will allow communities to endure change (Spacey, 2016) and for methods to explore the dynamics of the city and spatial systems in different ways (Schoeman, 2018). It calls upon a systems approach to planning contemporary urban landscapes, inclusive of learning and innovation (Schoeman, 2018). Such structures and systems demand transdisciplinary planning.

3. Transdisciplinary planning towards resilience

Transdisciplinary planning goes beyond the ''primacy of science'' (laypersons inputs in scientific research) as well as the ''primacy of practice'' (provision of classical decision support), establishing a third epistemic way (Wiek 2007; Jahn 2008; Bergmann et al. 2005) where experience-based guidelines find mutual grounds between all stakeholders (Cash et al. 2003). Transdisciplinary planning brings academic knowledge and non-academic knowledge, as illustrated in Figure 3.

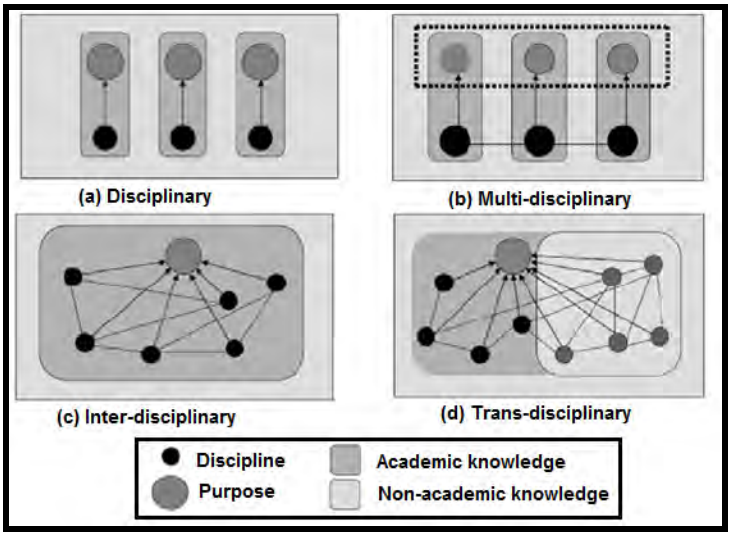

Figure 3: Scope of disciplinary approaches in promoting the interface between disciplines Source: Fry et al (2007)

Transdisciplinary planning could strengthen the spatial meaning of resilience in the contemporary urban landscape, by capturing metabolic flows (production, supply and consumption chains), social dynamics (demographics, human capital and inequality), governance networks (institutional structures and organisation) and the built environment (ecosystem services in the urban landscape) (Harrison et al., 2014, Schoeman, 2018).

Transdisciplinary planning provides a platform to explore the socially and spatially integrated dynamics of the urban landscape in different ways, as it calls upon a 'planning with' approach as referred to by Cilliers and Victor (2018). Such approach is grounded in anthropological understandings of space and cities as 'meshworks' (Ingold, 2016:10), which simultaneously draw on literature and concepts in spatial planning, in an attempt to make the argument for a 'planning with' approach 'policy relevant' (Spiegel, et al., 1999:182-186).

A 'planning with' approach draw on the expertise of transdisciplinary stakeholders, including the indigenous knowledge and lived experiences of local communities as agents of urban change. It contributes to realising the potential of integrative planning as it challenging professionals, scientists, authorities, policy-makers and local communities to take collective ownership of the direct environment (Cilliers & Victor, 2018). It will align with trans-urbanism approaches that redefine urban life and introduces new politics of the urban landscape (Thrift, 2013), in relying on multiple stakeholders to collectively reorganise the urban landscape as a living structure, informed by the urban landscape itself (Mulder, 2002).

Such a transdisciplinary 'planning with' approach could place public green spaces as the common denominator for aligning informality and sustainability, when green spaces are perceived as a 'public good' and an 'economic asset' that can benefit both communities and their environment through the ecosystem services they provide. The valuation, and prioritization of green spaces in this sense, would not only advance supporting ecosystem services such as enhanced biodiversity (Cilliers et al., 2013), habitat provision (Stiles, 2006), and the provision of refuge to species that are disappearing from urban areas (Hodgkison & Hero, 2007) but also regulating ecosystem services such as reduced atmospheric carbon dioxide (Cilliers et al., 2010) enhanced air quality (Bolund & Hunhammer, 1999), countering heat island effects (Akbari et al., 2001), limiting noise pollution (Bolund & Hunhammar, 1999) , but would also result in multiple cultural ecosystem services (social benefits) such as physical (Kuo, 2003, Roger, 2003) and psychological restoration evident from the mediational analyses by Van den Berg et al. (2007), as well as increased levels of physical activity (Owen et al., 2004), stress relief (Hansmann et al., 2007), happiness (Chiesura, 2004) and better neighbour relationships (Roger, 2003). It would further entail cultural ecosystem services with economic benefits relating to increased tourism (Wooley et al., 2003), enhanced local investment in the area (Cabe Space, 2009), increased property values (Luttik, 2000) and overall improvements in quality of life (Schultz and King, 2001; Smith et al., 2002).

Spatial Planning will still be confronted with the management of change, but the emphasis will shift from land-use, towards managing interaction between space, activities, and values (Danin, 2019). Interaction planning might soon become the new axiom (Danin, 2019) of the contemporary urban landscape as transdisciplinary research feeds into values to inform smart spatial data towards informed decision-making and good governance.

Finally, in agreement with Pinson (2004), disciplinary identity should remain as a precondition of transdisciplinary collaboration. Thus, while other mature sciences may, and should, contribute to the urban dialog, Spatial Planning should emancipate itself from these theoretical and methodological frames to further construct its own identity (Pinson, 2004) as a global scarce skill and national priority, to give spatial meaning to supplementary disciplines. Conveying such strategic and lateral thinking, Planners would need to become generative leaders. Moving away from adaptive leadership that is motivated by challenges or problems (Senge, 1990) and moving towards generative leadership, that recognizes and

taps into collective intelligence and energy to generate effective solutions (Klimek et al., 2008:2). Such leaders have courage and an acute level of socio-emotional intelligence to identify the core issues to be addressed, and to frame these issues in a manner that will motivate a variety of stakeholders to engage in creating urban innovations (Bushe, 2019).

Such Planners would be able to co-produce innovation to address the great questions of our time: How to embedded resilience thinking in managing change of contemporary urban landscapes by also asking the questions of resilience for whom, resilience from what to what, and resilience when, where and why (Meerow & Newell, 2017). How to transform and decolonize planning in Africa to be inclusive. How to find sustainability within informality? Academia stand central to developing socio-emotional intelligence as a soft skill for contemporary and future planners and generative leaders. that would require a greater emphasis on experiential learning, a methodology within social constructivism, to learn through experience, and "learn through reflection on doing" (Felicia, 2011) embracing also a "safe to fail" approach in urban planning and design (Ahern et al., 2014). It is through such inquiry-based approaches that we can collectively become co-producers of knowledge (Tengo et al., 2014) and agents of future change, needed to collectively, build the city.

"We have one half century left to get urbanisation right".
The time for generative Planners to rise, is now.

Stakeholders perspective on resilience building in the City of Rotterdam

Theresa Audrey O. ESTEBAN, Erasmus University Rotterdam, Graduate School of Social Science and the Humanities; The Philippines

Abstract

In 2016 the City of Rotterdam joined the 100 Resilient Cities of The Rockefeller Foundation. The 100 Resilient Cities is an initiative emphasizing the need for cities to build resilience. Rotterdam was one of the first to heed the call of the 100 Resilient Cities highlighting the city's position as a frontrunner in addressing climate adaptive urban planning projects and innovative means in dealing with flood risks and vulnerabilities. Learning from the great North Sea flood of 1953 disaster experience, the Netherlands ensured strong preventive measures making the country safe from flooding. The City of Rotterdam benefits from these strong preventive measures as this safeguards the city and the biggest and most important port in Europe from any disaster. However, these strong preventive measure have also muted the concept of resilience on the stakeholders. This is also further weighed down by the many different initiatives present in the city. The paper seeks to investigate the institutional and non-institutional actors perspective on resilience and the environmental threats in the City of Rotterdam. The research assumes that knowledge and experience on Rotterdam's environmental vulnerabilities and threats lead to better collaboration between and among stakeholders in making the city resilient. This knowledge and experience also leads to the mutual adaptation of roles between the government and other stakeholders of the city such as the citizens, businesses, academe, civil society organizations among others. The research explores questions related to stakeholders perception on risk and vulnerability of the city to disasters, disaster awareness and concern, and their definition of resilience and a resilient city.

Keywords

Resilience, Resilient city, Collective engagement, Flood risk, Netherlands

1. Introduction

One of the most significant flooding disaster that occurred in the Netherlands is the 1953 North Sea Flood. The flood which hit the South of Holland on 01 February 1953 'breached approximately 180 kms of coastal-defense dikes' (Watson and Finkl, 1990: 740). This inundated 160,000 hectares of polderland and left a total of 1,835 dead (Watson and Finkl, 1990: 740). The North Sea Flood disaster impacted the way the Dutch managed flood risk, stressing that the great flood of 1953 should never happen again.

Five years after the Great North Sea Flood the Dutch carried out the Delta Plan prioritizing the implementation of the Deltaworks project which is composed of a network of dams, sluices,

storm surge barriers throughout the multi-river delta created by the Rhine, Meuse and Scheldt located in the South of Holland. The project entailed the strengthening of dikes in Holandsche Ijssel and construction of advance engineering design and technology for the coastal and flood defense such as the Maestlankering storm surge barrier. The project called for raising existing dikes, storm closure of main tidal estuaries and inlets, except the waterway link between Rotterdam and Antwerp to give access to both ports as such dikes in those areas were strengthened (Watson and Finkl, 1990; Wesselink, 2007). This extensive and elaborate flood defense system have successfully safeguarded the country and cities like Rotterdam from any impending flood risk.

However, in 1993 and 1995 the feeling of safety and security was challenged when an extreme high river discharge in the Meuse and Rhine rivers happened (Lu and Stead, 2013; Wesselink, 2007). This has prompted the Dutch to rethink their relationship with water by proposing a more adaptive strategy, Room for the River, to allow more space for water. The threat of changing climatic condition have increased the vulnerability of delta cities to rising sea levels and extreme water discharge in rivers to the sea. The City of Rotterdam has been active in addressing these issues through the various plans, programs and projects around the city. The review of planning and policy documents from 2004 to 2010 conducted by Lu and Stead (2013) showed impacts of climate-related flood risks and vulnerabilities existed since the mid-2000s. The study related this to the concept of resilience in Rotterdam's spatial planning and policy-making where they found that in the city the notion of resilience is considered by local planners as a term of enhancing the city's image, and promoting development in places outside the protective dikes and as a synonym for adaptation (Lu and Stead, 2013). The term resilience then covers different ideas among policy-makers and technocrats alike and remains an abstract concept for many stakeholders.

In 2013 the Rockefeller Foundation launched the 100 Resilient City initiative to help more cities build resilience to physical, social and economic challenges that are a growing part of the 21st century (The Rockefeller Foundation, 2017). Cities under this initiative are provided access to resilience-building tools and services supplied by a carefully selected platform partners from the private, public, academic, and non-profit sectors. The City of Rotterdam was one of the first to apply to the program and in 2016 released its Resilience Strategy targeting a 100% climate proof city by 2025. The Strategy likewise drew attention to engagement and collaboration of the stakeholders in meeting its action plans. While this initiative is not the first to spearhead resilience programming in the city it is the only initiative that highlight Rotterdam as a "resilient city". Many stakeholders however remain oblivious to the meaning of "resilience".

In this light, this paper assumes that knowledge and experience on Rotterdam's environmental vulnerabilities and threats lead to better collaboration between and among stakeholders in making the city resilient. This knowledge and experience also leads to the mutual adaptation of roles between the government and other stakeholders of the city such as the citizens, businesses, academe, civil society organizations among others. The paper focuses on awareness as an important thematic area being investigated by the author in her dissertation research. It explores questions related to stakeholders perception on the city's risk and vulnerability to disasters, awareness, concern and response to disasters, and their definition of resilience and a resilient city.

Following this introduction, the paper proceeds with a review of the definition of resilience and the varying conception of resilience. Then the concept of collective engagement urban

resilience framework as a conceptual tool explaining the complexity of resilience building in the urban context will be introduced. The framework likewise identifies two approaches in urban resilience and the main actors involved which is imperative in the methodology of the empirical study. Thereafter primary data gathered from the face-to-face interviews of the various stakeholders of the City of Rotterdam will be discussed. Finally, the research findings and discussions will be outlined including its implication to future research.

2. Different perspectives of resilience

Originally a concept used in ecology, resilience was first defined by C.S. Holling as a "measure of the persistence of systems and their ability to absorb change and disturbance and still maintain the same relationships between populations or state variables" (Holling, 1973: 14). He later redefined this as the magnitude of the disturbance that can be absorbed before a system changes its structure by changing the variables and processes that control behavior (Holling, et al., 1997; Mayunga, 1995; Berry, 2013). In this second definition, resilience is understood as the capacity of a system to absorb disturbance and maintain its equilibrium. This ecological perspective of resilience means that the system has an ability to cope with disturbances and return to its functioning state. It assumes that a system undergoes multiple levels of equilibrium but still retain its structure and function (Gunderson, 2010; Mehmood, 2015; Wagner, et al., 2014; Sharifi and Yamagata, 2016; Holling, 1973; Folke, 2006). Holling asserted that resilience should be interpreted as having multiple-equilibria rather than seen as a single-equilibrium (Holling, et al., 1997; Sharifi and Yamagata, 2016). While Elmqvist (2014) offered to extend the resilience concept by stating that resilience is not just recovering from a single disturbance but also refers to the capacity of a system to adapt and transform.

Apart from the earlier mentioned ecological perspective of resilience there are different perspectives on the term resilience. Engineering resilience which interprets resilience to having a single-equilibrium where a system bounces back to its pre-disaster phase after a disaster (Gunderson and Holling, 2002; Andavarapu and Arefi, 2016). This implies that 'equilibrium' or stability only refers to reverting to the pre-disaster phase through recovery (Gall, 2013). Engineering resilience assumes that disturbances or disasters are predictable and forecasting methods are reliable sources of information (Sharifi and Yamagata, 2016).

The socio-ecological resilience perspective recognizes that systems have multiple equilibria facilitating the systems' ability to absorb and adapt to disturbances. This resilience perspective interprets resilience as having multi-equilibrium where the system has the capacity to reorganize and transform to another state (equilibrium) after a disturbance. Socio-ecological resilience is also known as adaptive resilience which stemmed from recognizing cities as complex and dynamic socio-ecological systems (Sharifi and Yamagata, 2016). Two other perspectives on resilience following the multi-equilibrium interpretation are social resilience and community resilience. Social resilience is the ability of groups or communities to cope with external stresses and disturbances as a result of social, political, and environmental change (Adger, 2000). Most of the work on social resilience were based on prevention, preparation and response to natural disasters and the management of natural resources (Keck and Sakdapolrak, 2013; Takeuchi et al., 2014; Mehmood, 2015). While community resilience refers to the ability of the community to bounce back using its own resources. This terminology is often used in disaster management work specifically in rebuilding and reconstruction.

The resilience concept assumes the dynamic and complex adaptive systems across temporal and spatial scales (Folke, 2006). It is a multidisciplinary concept that explores persistence, recovery, and the adaptive transformative capacities of interlinked social and ecological systems and subsystems Elmqvist (2014: 5). The different perspectives of resilience magnify its multidisciplinary and complex nature.

3. Transformation, adaptability and resilience building

The terms adaptability and transformation are key in creating resilient cities. Adaptability refers to the ability of the stakeholders to influence resilience (Folke, et al., 2010). It is the 'collective capacity of the human actors in the socio-ecological system to manage resilience' (Walker, et al., 2004: 7). Transformation, on the other hand, is the ability of the system to shift from its current normal state to another development or improved state (Sharifi and Yamagata, 2016). Transformation is necessary in building resilience through spatial and temporal scales. Transformation, similar to adaptation, requires an understanding of the roles each stakeholders contribute to the city's overall function. It is the result of the improvements done during the adaptation process

The city is a complex, multidimensional socio-ecological system that continuously undergo changes. Disasters such as flooding elicit these changes and adds on to a city's already complex behavior. The city's collective engagement to address these changes at various levels and scales determines its ability to become resilient. One key element in building resilience are the stakeholders, particularly their capacity, awareness, and understanding of resilience in order for them to collectively take part in building resilience. But in order for stakeholders to participate in building resilience there is a need to expand their knowledge and awareness. This knowledge does not only focus on how to build resilience but also why it is needed. The awareness and concern on risks and vulnerabilities of the city are important to bring this into focus.

There are two sides in approaching urban resilience, one the approach taken by the government and the other by the citizens. These two approaches interlace into what collective engagement is all about. That is "a collaborative process participated in by multiple stakeholders to arrive at a solution or decision to increase urban resilience through both formal and informal means" (Esteban, 2018). This means that both approaches of the government and the citizens should be on the same level. Obviously the technical, technological, and scientific interpretations cannot be equal between the government and the citizens but there should be a leveled understanding on what resilience is. Understanding resilience and building urban resilience requires public concern and awareness.

The collective engagement urban resilience framework (Figure 1) incorporated the two approaches into a conceptual framework that emphasizes that the government and the citizen (self-organization) approach to urban resilience can be two different ways. Both still go through the same four dimensions of collective engagement - concern, action, efficacy and security - in order to reach resilience. This can be assessed in terms of the collaborative capacities of the institutional actors (government) and the non-institutional actors (citizens and citizen groups). It meets in the middle when both actors increase their capacities and collaboration to achieve their common goal of building resilience (mutual adaptation of roles).

The framework looks at the two approaches and in so doing understand the different perspectives on resilience and how both lead to the common denominator which is concern for their city. In the succeeding section, the methodology for the empirical study will be outlined.

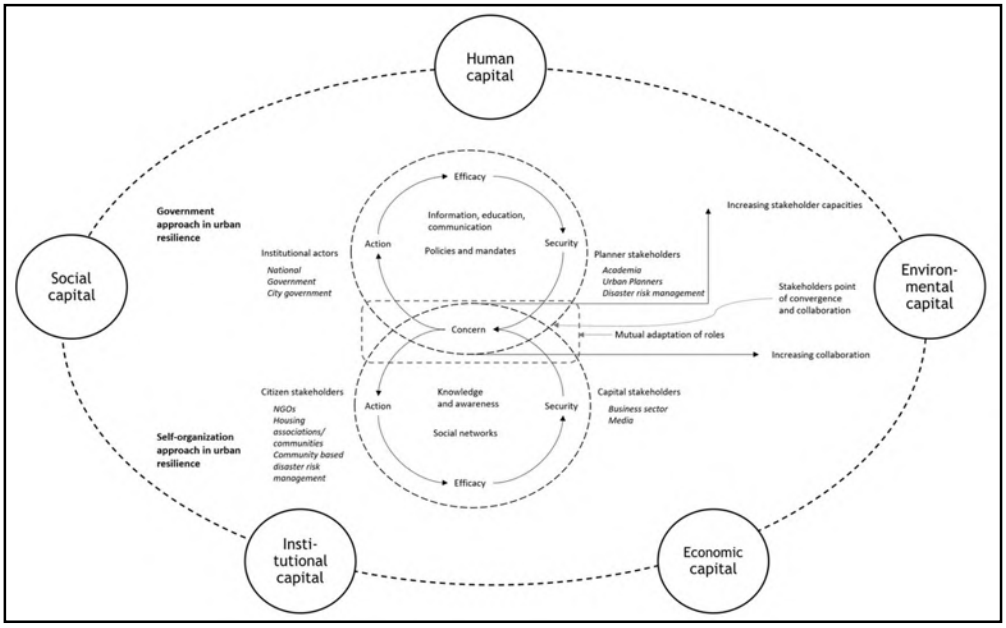

Figure 1 Collective engagement urban resilience framework (Source: Author, 2018)

3.1. Methodology

This paper is based on the initial findings of the author's fieldwork under the thematic areas awareness, key threats and resilience for the dissertation project 'Collective engagement: from disaster-prone city to disaster-resilient city'. These thematic areas are three of the ten thematic areas in the semi-structured interview guide used in the fieldwork done from November 2018 to February 2019.

Using the concept of the collective engagement urban resilience framework, the paper focused on the stakeholders involved in the government and the self-organization approach to urban resilience. The government stakeholders identified for the study are the institutional actors (government workers and the water board) and the planners (academics). Under the self-organization approach stakeholders identified are citizens (non-government organizations, community council, housing associations, private citizens) and the capital stakeholders (architectural firm and the port authority). Key informant interviews were conducted using a semi-structured interview guide containing open-ended questions on perception on risks and vulnerabilities in the city, awareness and concern of the general population on flood risks, and definition of resilience and resilient city.

3.2. Sampling Methodology

The key informant interviews targeted key knowledgeable persons in city development and planning, and disaster risk management in the City of Rotterdam. An initial list of 10 persons were identified (5 institutional, 1 planner, 2 citizens, and 2 capital stakeholders) using the snowball sampling each responded were asked to recommend one to two persons to be

interviewed until a target of at least 13 respondents were reached. In total 19 interviews were done for the case study (9 institutional, 2 planners, 6 citizens and 2 capital stakeholders).

3.3. Processing

The qualitative data gathered through the interviews were transcribed, collated, reviewed and processed using the Atlasti software. Based on the main line of inquiry: (1) awareness and concern on flood risks, (2) perception of risk and vulnerabilities, and (3) definition and perception of resilience, the qualitative data were allocated general codes, i.e. disaster experience, awareness, resilience with subsequent sub-codes at it emerged in the review. Memoing was done as insights arose.

4. Primary key findings

The results of the key informants interview were categorized into the three main line of inquiries: (1) awareness and concern on flood risks, (2) perception of risk and vulnerabilities, and (3) definition and perception of resilience. Memoing was done as insights rose from the interviews.

4.1. Awareness and concern to flood risks

There is a general perception among the interviewees on the low level of awareness of the stakeholders in Rotterdam on flood risks and vulnerabilities. Most of the interviewees asserted that people feel safe and secure in terms of flooding. One interviewee even pointed out the low level of awareness in the country because "disasters always happen somewhere else, you see it on tv but not in your neighborhood" (Citizen stakeholder, male), while another wondered on the awareness of people that they live below sea level (Citizen stakeholder, female).

The big issue in the Netherlands is that people are unaware of the threats . . . in the Netherlands we have no disasters, we have no floods, so people are not aware but in fact we are very vulnerable. (Planner stakeholder, male)

I wonder how many people really feel that they live below sea level because we didn't have any disasters. The only disaster we have is our bank account because we have to pay for that every year we receive an amount and we have to pay it. (Citizen stakeholder, female)

Most of the interviewees attribute the low level of awareness and concern on the risks due to the high safety and preventive measures of the Netherlands (Planner stakeholder, male (2); Institutional stakeholder, male (6); Institutional stakeholder, female (3); Citizen stakeholder, female; Citizen stakeholder, male (2); Capital stakeholder, male (2)). Many of the interviewees often quoted the probability '1 in 10,000 years' of a flood disaster in the country which gives security to the general population (Planner stakeholder, male (2); Capital stakeholder, male; Citizen stakeholder, male; Institutional stakeholder, male). One asserted that the 1953 flooding disaster happened so long ago that,

The new generation is used to the fact that it is arranged that okay nothing bad happened so far [ ] when the Delta program was built they felt safe. So this whole new generation they never had anything to do with it. You see what I mean? So it's not in their psyche, it's not in their minds that they should be afraid of anything. (Planner stakeholder, male)

Some of the interviewees say that there is a level of awareness among the people but it varies (Planner stakeholder, male; Institutional stakeholder, male; Citizen stakeholder, male; Capital

stakeholder). An interviewee asserted that the Dutch are aware because they learn it from school and everybody knows about the Delta Works (Planner stakeholder, male). Interviewees mentioned that people have an idea on threats because they can see it on the television but the idea of this happening in the future is not present nor do they know what to do about it (Institutional stakeholder, female (2); Citizen stakeholder, male (2); Capital stakeholder, male; Institutional stakeholder, male).

I think most Dutch are aware because they learn it in school, and of course everybody knows about the Delta Works and the Maesland barrier, but I think most people don't know about that website where you know how the elevation of your residence whether you are below sea level. So I think they are not aware of the urgency and also not so much on the threats. (Planner stakeholder, male)

Interviewees pointed out that a certain level of awareness is present for people who live in areas where it usually gets flooded and/or where most people have a higher level of education and income (Institutional stakeholder, female (3); Planner stakeholder, male (2); Institutional stakeholder, male (3); Citizen stakeholder, male; Capital stakeholder, male). Many of the interviewees identified the Nordereiland as the only place where most people are aware of flooding and know what to do when there is a flood (Institutional stakeholder, female (3); Planner stakeholder, male; Institutional stakeholder, male (2); Citizen stakeholder, male (3)). The location of the residents of Rotterdam also has to do with the socio-economic and educational status. Interviewees from the institutional actors mentioned that people living in the north have a higher education and higher income compared to the south. In these cases interviewees view that there are other concerns that stakeholders feel are more important than thinking about flooding (Institutional stakeholder, female (2); Planner stakeholder, male; Citizen stakeholder, male (2); Citizen stakeholder, female; Capital stakeholder, male).

So I would say in terms of awareness I would say there is a difference. But maybe also secondly if your main concern is how to make it through the month, then maybe that is actually what you are really aimed at and not so much actually about the other stuff. (Capital stakeholder, male).

4.2. Perceived key threats

The perceived threats of the interviewees vary from environmental threats to social threats. Environmental threats can be classified as having too much water and too little water. Interviewees who fall under the categories of institutional actors and planners stakeholders identified flooding coming from four directions of water 'from the river, from the sea, from rain and groundwater'. There is also a problem on too little water especially during the summer periods. Too little water according to the interviewees affects the wooden piles where most old houses are built on since it rots. Interviewees also mentioned that too little water also affects the strength of the polders.

It's the flooding because I always say water comes from four [sides] here. You have water from the river, from the sea, from rain, and also groundwater is coming up. So in four ways the water is coming. (Institutional stakeholder, male)

We have in our street a simple association and they come together one or two times a year but here in this street the problem is the opposite, the water level in the ground is too low. And for that reason the wooden piles under the old houses, they only stay intact when they are below water, wooden pile stays intact when they are below water levels. And when the water

levels get more down the top of the piles they get rotten so when you walk on the street you see at the moment they are working on the foundations. So the opposite problem. The water level is too low in the ground. The ground water is too low. (Citizen stakeholder, male)

Social related threats have also cropped up in the interview as a bigger threat than the risk of flooding. Several interviewees mentioned that 'there are so many nationalities living' in Rotterdam (Institutional stakeholder, female; Citizen stakeholder, male) and not a lot of people have high education due to people working in the harbor (Institutional stakeholder, female; Institutional stakeholder, male). Some see the big social and economic gap that one interviewee said,

If you have that in your world you cannot really focus on energy transition and sustainability, stuff like that. I think there is too big of a gap between those people and those people who can actually look forward because they are privileged in that kind of sense. (Institutional stakeholder, female)

This social and economic gap is also seen by one interviewee that hinders people from 'joining society' (Institutional stakeholder, female). The same interviewee also mentioned that there is an aging population in Rotterdam where most are concentrated in the south.

4.3. Perception and definition of resilience

The interviewees were asked to define resilience and describe what a resilient city is. Interviewees with a more technical background defined resilience in terms of their technical knowledge, referring to 'a system is able to bounce back in the state it was before' (Institutional stakeholder, female; Planner stakeholder, male (2); Citizen stakeholder, male (2); Institutional stakeholder, male (2)). Some referred to concepts of the Rockefeller Foundation.

I have always in my mind the definition of Rockefeller Foundation about urban resilience as a way to handle shocks and stresses in the best way. . . So we work, the Rockefeller Foundation had sort of a definition and also all kinds of resilience qualities, like robustness, flexibility, redundancy, integration. (Institutional stakeholder, male)

While one interviewee defined it holistically.

When I make a definition of a resilient city and that is also for the whole town planning. It is strong as it is complex. When it is simple, it is also simple to destroy. So the whole network of the city has to be not only one or two or three but ten different layers of mentality, of physical structures, of maintenance of the city, of all the those things, make it to a strong environment. (Citizen stakeholder, male)

While some also asserted that 'it should bounce back into a system where it has a higher level of resilience than it had before' (Planner stakeholder, male; Institutional stakeholder, male). Some interviewees also found the term 'resilience' as abstract (Citizen stakeholder, male) preferring other terms as robustness, preparedness, flexibility, or simply using the Dutch word 'veerkracht' (Institutional stakeholder female; Capital stakeholder, male; Institutional stakeholder, male; Citizen stakeholder, male). Some interviewees defined resilience and resilient city with a social orientation (Citizen stakeholder, male (2); Citizen stakeholder, female; Institutional stakeholder, female). The interviewees view the ability of the people to connect with each other as a way to make the city resilient.

When asked what factors contribute to making a resilient city, interviewees found social and institutional factors as the most important (Institutional stakeholder, female (3); Planner stakeholder, male; Institutional stakeholder, male (2); Citizen stakeholder, male (3); Citizen stakeholder, female; Capital stakeholder, male). Interviewees identified strong social networks, working together with the community and awareness as important to bring this idea of resilience (Institutional stakeholder, female (3); Planner stakeholder, male; Institutional stakeholder, male (2); Citizen stakeholder, male (3); Citizen stakeholder, female; Capital stakeholder, male). Some also pointed out to the ability to maintain this resilience through ensuring that there is a budget for maintenance and not just implementation (Citizen stakeholder, male; Citizen stakeholder, female). While some mainly point out the importance of people in general as factor in resilience.

But resilient city is all technical things but it also has to do with the people who live here, we all have to bring that up, we have to pay for it. It can only be done by the people who are themselves are one, aware of it, and two, they have to have the money and the knowledge. So the city can only be flexible if people want to pay for it and people can work together. It's the only way. So it starts at the bottom with people who are willing to cooperate. (Citizen stakeholder, female)

Well, I think that people in disaster context they rely on their networks. And there are a lot of examples in Rotterdam where there are stronger communities that people know their neighbors, that they work together, that they do workshops, that they cook together and those ties are very important within a disaster context. I also know that there are certain areas that people don't know their neighbors, that they are very distant from each other and I think that will be a problem whenever there is a disaster if you don't know where to go or where to search for help. I mean then you are by yourself and in a disaster context you always need other people. (Institutional stakeholder, female)

How Rotterdam is, I think. Rotterdam is a city that was bombed in the war. My father was living in the area where it was bombed in the war. Then my father and his brother and their mother, the three of them the house was gone and they went to live in the West in a house without anything, they started to build a new life. And many people did in Rotterdam, and the immigrants came from everywhere and they had nothing. Now [there are] many [ ] they started to work very hard in the harbor. That is resilience. Incredible, you know. So we are a very resilient city. It is really incredible how people survived the war and started with nothing and people came from everywhere and with nothing and they have a house and many children and grandchildren. Incredible. Sometimes they are sick because of the work, and they built their own life. That is resilience. People. (Citizen stakeholder, male)

5. Analysis and conclusion

The results of the interview indicate that the stakeholders see that there is a level of awareness on flood risk in Rotterdam. This level of awareness can be attributed to Dutch history lessons which is part of the educational curriculum. Since the 1953 Great North Sea Flood and Deltaworks project is part and parcel of the Dutch history this is also discussed in school. This means that there is a general understanding on the history of the Dutch way of managing water and preventing disasters. However, from the time of the 1953 flood the rarity of any disaster occurring have affected the level of awareness of the stakeholders specifically on flood risk. This time and experiential gap between 1953 and the present time have made

the population least concerned about flood risk. This is also exacerbated by a growing generation gap among the population who never witnessed the 1953 flooding or have ever experienced any type of flooding.

Interviewees with a more technical background recognize the vulnerability of the city to disasters including the possibility of a disaster from happening. However, this is not often translated to the non-technical stakeholders or the laymen. The government has instilled the feeling of safety and security among the citizens with the repetitive mention of risk being 1 in 10,000 years, a number calculated by scientists and engineers on the possibility of another disaster such as the 1953 flooding ever happening. In fact, most if not everyone knows the ratio '1 in 10,000 years' in the Netherlands but many people do not realize that the 1 in that ratio is a possibility that can happen anytime – today, tomorrow, next week or in the 10,000th year. Many interpret this as happening not in their lifetime. This perhaps is the second gap that can be recognized in the study.

In Rotterdam most of the people aware of the flood risk are those who live in Nordereiland which is outside the dike. Residents in Nordereiland are most of the time subjected to flooding during the storm season. This brings up the question whether awareness and concern on the risks of flooding depends on the location. It was raised by the interviewees that while location can be a contributing factor in the level of awareness of the stakeholders, as in the case of Nordereiland, it is also mainly due to the type of community existing in terms of social and economic status. People with lower income will be more concerned about their daily living expenses than the possibility of flooding or more so climate change. Those with higher income and higher education have a wider network in the city, pay higher income tax, and may have a stronger stance on government and/or political issues that may affect them and their community. This social and economic gap among the city stakeholders is also seen as a threat by the interviewees because it impedes on the ability of those belonging in the lower income from integrating in the city. Esteban (2017) noted strong stakeholders tied to the community as one of the contributing factors in collective engagement and rapid recovery after a disaster. Relating this to resilience building, citizens who do not fit into a community nor the city will have a much more difficult time seeing themselves as part of the city. Integration is important in resilience building because this makes citizens feel that they are connected to the city, that they are valued, and that they can contribute to its growth.

A fourth gap that can be seen from the interview is the way stakeholders define resilience. Stakeholders defined resilience in two perspectives, one is more technical attributing resilience to the city's physical make up. It is how the city is planned to adapt to the changing climatic conditions as well as ensure that the city can bounce back from any disaster. The strong preventive measures play a role in making the city resilient. Interviewees see the importance of continuous improvement of these preventive measures to incorporate climate change adaptation as a factor in creating a resilient city. This suggests a more structural, engineering, and spatial design element. The other perspective is mainly focused on the social aspect of resilience, in particular the role of the people of Rotterdam. The interviewees see that the people and their social networks are equally important to create a resilient city.

The last gap that can be drawn from the interviews is the translation of the word 'resilience' itself. Some interviewees perceive resilience as an abstract concept. The concept of resilience and resilient city is still lost in translation for some of the interviewees including some institutional actors who would rather use words such as robustness, preparedness and flexibility. The Dutch term veerkracht is more acceptable for many interviewees since it hits

the local language. In this way, it can be said that the acceptability of the concept of resilience may be better achieved if it is relatable, such as using the local language to draw the general population towards the vision of the city.

The collective engagement urban resilience framework shows that the mutual adaptation of roles of all stakeholders help in building resilience. If the level of awareness and concern on disasters, risks and vulnerabilities is low among the stakeholders, how then will stakeholders engage to address these risks and vulnerabilities. The gap between strong preventive measures and preparatory measures can be narrowed down by raising awareness on flood risk management, climate change adaptation, and resilience building. It will also help to make the concept of resilience more identifiable to all stakeholders. The goal is not exactly to make a unified definition of resilience and a resilient city but a definition that is more engaging.

6. Acknowledgements

I would like to thank the interviewees from the City of Rotterdam for their willingness to be interviewed and their honesty in sharing their views. I am especially thankful to my PhD promotor Dr. Jurian Edelenbos of the Erasmus University Rotterdam who has supported me from the beginning of my PhD journey, provided extensive feedback on my dissertation project, and continues to guide me in the direction that would most help me succeed.

Research Paper

Living with water

How memory and experience can help build community resilience in Dordrecht

Theresa Audrey O. ESTEBAN, Erasmus University Rotterdam, Graduate School of Social Science and the Humanities; The Philippines

Abstract

In 2021, Dordrecht, the oldest city in the Netherlands, will be commemorating the 600th anniversary of the St. Elizabeth flood. This disaster flood event inundated the entire Dordrecht and separated the city from Geertruidenberg. After the flood Dordrecht was left with only the old city center that the city had to reclaim their land. To date Dordrecht has remained an island surrounded by water. The city's vulnerability to flooding have prompted the city to actively participate in climate adaptation strategies and innovative design methodologies to help the island city cope with changing climatic conditions. Dordrecht is one of the cities participating in the Room for the River project which allows vast tracks of land to be flooded in the event of a big flood. The city is also surrounded by dikes that protect parts of the city from any impending flood danger. Still the historic city center which lies in the unembanked area occasionally experience flooding. Every two to five years residents of Dordrecht especially in the old city center experience some low level flooding due to high waters and heavy rainfall. Yearly the city conducts a drill in the city center to train people on how to place flood barriers and sandbags in front of their homes. However, there is also a sense of complacency especially for the areas in the city where the structural measures were heavily constructed (those that are within the dike). This feeling of complacency may have been placed due to their strong belief that the city is indeed safe due to the structural measures that have been carefully integrated to ensure that flooding will never happen again.

Memory-based disaster experience can be the starting point in building knowledge on disasters. Most often people who have experienced a disaster can provide experiential knowledge in dealing with disasters in the future. Further people who experience disasters on a more regular basis have more built in memory and knowledge. Using interviews from key stakeholders of Dordrecht, the paper will draw out how this memory-based disaster experience and living with water helps Dordrecht towards its vision to become a self-reliant island.

Keywords

Resilience, Collective engagement, Collective engagement urban resilience framework, Memory-based disaster experience, Netherlands

1. Introduction

The profound impact of the Sint Elizabeth flood is apparent in Dutch history. The Rijks Museum holds a piece of beautifully painted depiction of the Sint Elizabeth flood in four panels which "serve as a powerful illustration of the traditional narrative describing the fight against floods that shaped Dutch national identity" (van Asperen, 2019: 36). History, including the artistic representation of the flood disaster, impacted the collective memory of the Dutch that many understood the Sint Elizabeth flood as an apocalyptic event most especially in Dordrecht.

The impact of the flood in Dordrecht was huge that it wiped out 17 villages (Waals, et al., 2011) and separated Dordrecht from Geertruidenberg. Land was slowly reclaimed after the big flood through compartments where each compartment is protected by dikes (Waals, et al., 2011). Centuries of land reclamation and diking in Dordrecht have shaped the city into what it is now, an island city that lies between the Rhine and Meuse two large and important rivers not just in the Netherlands but the entire Europe.

Figure 1 The Saint Elizabeth's Day Flood 1490 by Master of the St Elizabeth Panels (Source: https://useum.org)

While the Sint Elizabeth flood was the biggest flood that made an impact on the physical and economic landscape of Dordrecht, the 1953 Great North Sea flood made a pivotal role in constructing a long-term flood preventive measure in the entire country through technology and engineering. The hardest hit area in the Netherlands was Zeeland where water levels reached NAP +4.55 (Rijkswaterstraat, 2019) still Dordrecht was not spared as water level reached NAP +3.70 (Hinborch, 2011) and inundated the city specifically the historic city center. In 1993 and 1995 extreme river discharge from the Meuse caused flooding in Zuid Holland. Also, in 1995 the threat of a flood event due to problems in the Rhine resulted to an evacuation of 200,000 people for a week (Jak and Kok, 2000). These flood events have resulted to not just preventive measures but adaptation measures such as the Room for the River project that allows vast tracks of land to be flooded in the event of a flood.

The City of Dordrecht like many other cities in the Netherlands are divided between the *binnen de dijk* (within the dike) and *buiten de dijk* (outside the dike). As a result of the compartmentalization, a large part of the island is *binnen de dijk*, while the historic city center, the area of the Staart, the inland seaport, and the green area near Hollands Diep and Nieuwe Merwede are *buiten de dijk*. Every two to five years Dordrecht residents most especially those living in the historic city center experience low level flooding due to high waters coming from the river. Such many of the residents in the unembanked areas are aware of the risks and vulnerabilities they are facing. For those in the embanked areas the residents rarely experience such flooding that the notion of risks and vulnerabilities is low.

Figure 2 Map of Dordrecht showing the embanked and unembanked areas (Source: Risicokaart.nl)

This paper focuses on memory-based disaster experience which is one of the thematic areas being investigated in the author's dissertation research 'Collective engagement: from disaster-prone city to disaster-resilient city'. Disaster experience provide some experiential knowledge in dealing with future disasters. Most often people who experience disasters on a regular basis have more built in memory and knowledge. Using interviews from key stakeholders of Dordrecht, the paper will draw out how this memory-based disaster experience and living with water helps Dordrecht towards its vision to become a self-reliant island. The paper proceeds with a discussion on memory-based disaster experience and how this can be the starting point in building community resilience. Thereafter, the empirical study will be presented with a brief discussion on the methodology. Finally, the analysis and conclusions will be discussed.

2. Memory-based disaster experience and resilience building

Cities are complex socio-ecological systems that grow in different pathways and timescales. The path to resilience is a dynamic process that goes through several dimensions. There is no one size fits all strategy in building resilience. The city's complexity in terms of not just the physical attributes but also social and cultural attributes require different approaches. One thing remains the same for most cities, in a disaster context experience results in a steep learning curve for the community, the government and many other city stakeholders to adapt to the situation. Hooli (2016) found that 'those who regarded themselves better prepared are those who have experienced and learned what the floods are like' (p. 702).

Memory-based disaster experience allows those who experience it to develop coping strategies (Pfister, 2011). This does not usually mean though that the learning is sustained through a long period. Pfister (2011) pointed out that a "disaster gap, the rare occurrence of severe hazards during almost a century, is a significant element in explaining the loss of functional disaster memory" (p. 17). Nevertheless, memory-based disaster experience play a significant role for groups, communities, cities and even nations to develop not just coping mechanisms but disaster mitigating infrastructures to ensure their safety and security. The Netherlands is a good example on this having ensured that the 1953 Great North Sea flood will never happen again, the Dutch implemented the Deltaworks project in 1958. The continuing research and improvements on water management and climate change adaptation showcase the stronghold of that flood memory.

Memory and learning are important in building resilience. In fact, the panarchy framework, an expanded concept of resilience, use the terms 'revolt' and 'remember' period to illustrate the adaptive cycles present in socio-ecological systems (Gunderson and Holling, 2002; Berkes, et al., 2008). The 'revolt' period causes the critical change (such as a disaster) while the 'remember' period "facilitates renewal and reorganization by drawing on the memory that has been accumulated" (Berkes, et al., 2008: 18). Specifically, Folke (2006) referred to memory as the "accumulated experience and history of the system, and it provides context and sources for renewal, recombination, innovation, novelty and self-organization following disturbance" (p. 259). Interestingly, the word "accumulated" is used in both context which means that it is a growing experience that builds capacity to renew and reorganize. Cook (2018) seconds this by presenting "collective memory as the accumulation of individual recollections" and "shared public memory becomes a dynamic force that shapes and transforms the narrative of what is remembered" (p. 329). If flooding incidents repeat overtime the chances of retaining memory and learning from it increases. But of course a flooding disaster is not something that many desire to happen in order for the city and its stakeholders to learn.

Trainings, narratives, and information that is widely disseminated to the general population help retain learnings derived from the experience. Repetition of these types of knowledge building activities and information reinforce awareness. A well-informed and aware

stakeholders helps the city in building urban resilience because it lessens the surprise a disturbance such as a disaster would bring. It increases their adaptive capacity.

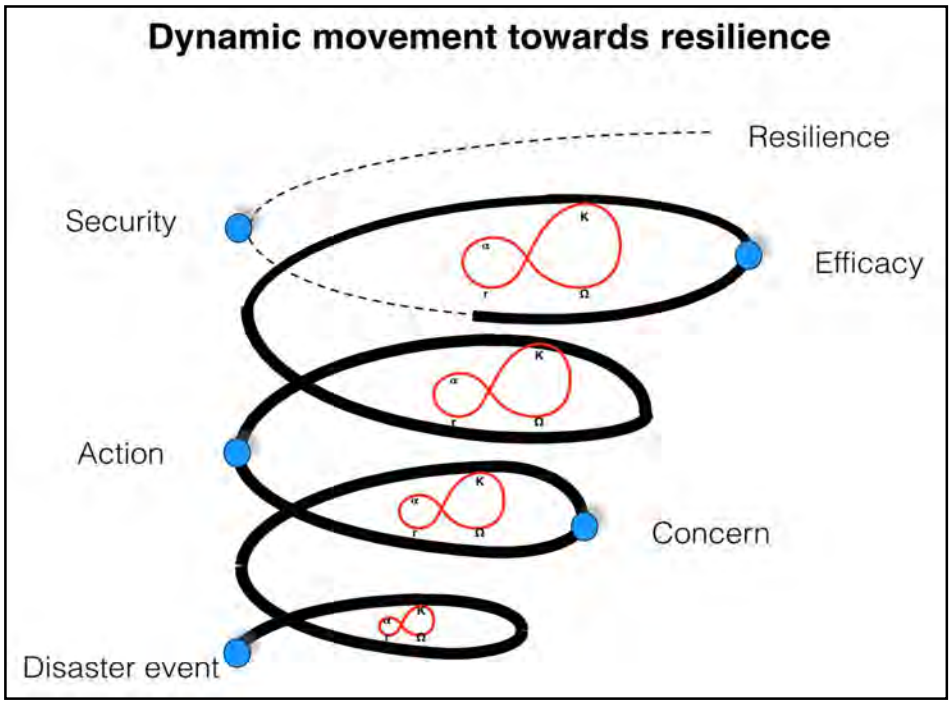

Figure 3 Dynamic movement towards resilience from the disaster event (Source: Esteban, 2018)

Esteban (2018) illustrated in Figure 3 that a disaster event, whether this was a recent or distant past experience, provoke city stakeholders to behave or act on this experience to improve their situation. In order for cities to build resilience cities go through a dynamic process of change through several dimensions (Esteban, 2018). Resilience is not the end of the process rather it should be understood as a continuous process of maintaining a level of stability. These dimensions follow an adaptive cycle of stability and change within the collective engagement urban resilience framework (Figure 4). The framework has two approaches in building urban resilience, the government and the self-organization approaches. Both approaches start from a collective concern where institutional and non-institutional stakeholders remember and learn from past disaster events. Stakeholders in this dimension have a shared vision and concern in building urban resilience. Collective action facilitates the exchange of information, knowledge and experiences to help in creating solutions (Esteban, 2018). Collective efficacy is the point where stakeholders with their knowledge strengthened by the exchange of information and experiences in their various networks actively engage. The last dimension is collective security, which can be seen in Figure 4 converges back to concern. Collective security is the dimension where stakeholders reach a high level of awareness. This means that the stakeholders are equipped with the knowledge and information on risks and vulnerabilities as well as how to prepare and act once a disaster happens.

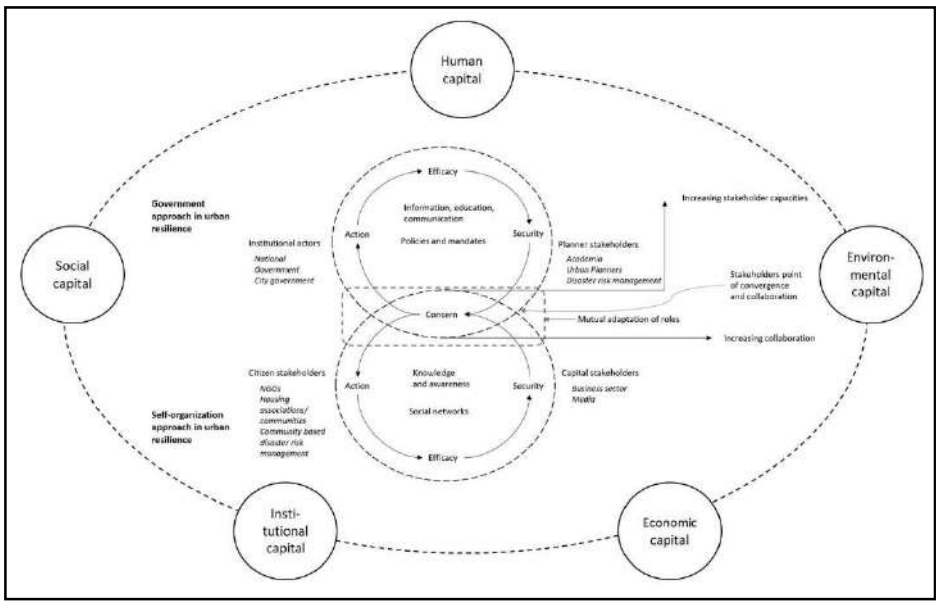

Figure 4 Collective engagement urban resilience framework (Source: Esteban, 2018)

How a city progress from one dimension to another depends on the domains of change that leads to its transformation state. Figure 5 shows the domains of change within the collective engagement urban resilience framework which influence the dynamic movement to urban resilience. Stakeholders are part of the domains of change and are in fact critical in the formation of either a formal or informal organization that can be the bridge between the government approach and the self-organization approach towards urban resilience. The bridge within this domain of change facilitate the translation of issues affecting the city as a whole into opportunities for change and renewal. This bridge is similar to the bridging social capital which is the inter-relationship with other groups and stakeholders within the city (Esteban, 2017). Strong social capital helps in establishing 'trust and reciprocity within and between networks' of stakeholders and actors (Esteban, 2017: 223).

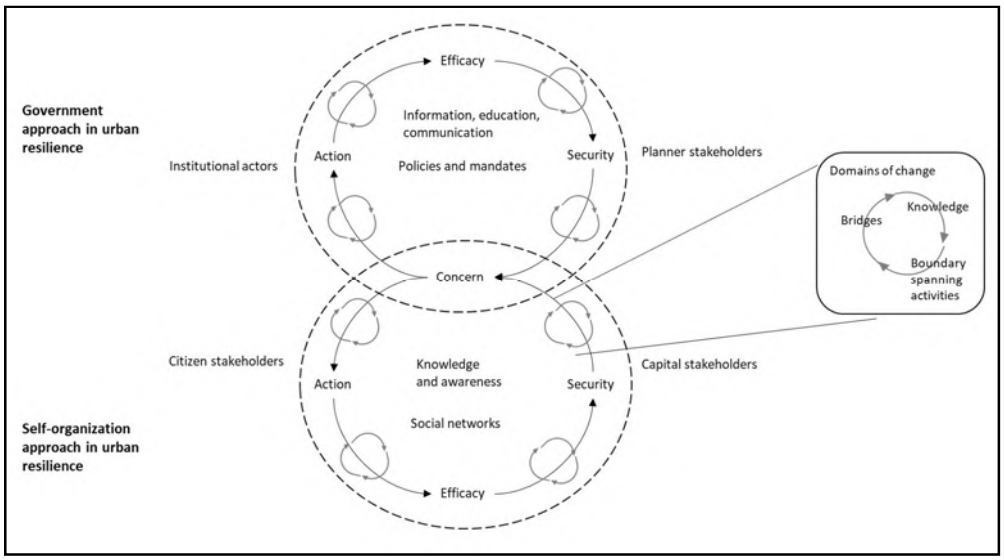

Figure 5 The domains of change within the collective engagement urban resilience framework (Source: Esteban, 2018)

3. Empirical study: living with water in Dordrecht

The paper used a qualitative approach through face-to-face interviews of key informants. Following the collective engagement urban resilience framework the key informants come from the institutional actors, planners stakeholders, citizen stakeholders and capital stakeholders. An initial list of three targeted informants were interviewed. Succeeding interviewees came recommended by the initial list creating a snowball until 15 interviewees were reached. The interviews were carried out by the author from November 2018 to February 2019 and forms part of the dissertation research. The questions asked during the interview ranged from the disaster experience, collaboration with stakeholders, awareness and concern, disaster risk management, resilience and resilient city. In this paper the objective is to draw out the memory-based disaster experience of the stakeholders in the City of Dordrecht and assess the level of awareness on the risks and vulnerabilities in living with water between areas in the city that are frequently flooded and those that rarely experience this. For that matter, the results of the interview on questions particular to disaster experience and awareness and concern is considered. This is also because there is a current limitation in the time for coding and analyzing all aspects of the interviews. However, this paper forms an important contribution to the overall analysis for the Dordrecht case in the dissertation project.

The qualitative data derived from the interviews were transcribed and processed using the Atlasti software. For the thematic areas disaster experience and awareness and concern a total of 14 themes emerged from the interviews. These were further coded using the three domains of change, bridges, knowledge and boundary spanning activities. A separate code memory-based disaster experience was used to draw out salient points on this specific topic. The findings presented below will begin with the memory-based disaster experience, followed by each domains of change.

3.1. Memory-based disaster experience

There is a collective memory on how Dordrecht was shaped by the 1421 Sint Elizabeth flood among the interviewees. The 1421 Sint Elizabeth flood "drowned 17 villages roughly in the hinterland" (Institutional stakeholder, male) and changed the entire landscape of Dordrecht. There was "a very large inland sea, then the island was gradually reclaimed from that sea" (Planner stakeholder, male) making "Dordrecht an island which is still is today" (Institutional stakeholder, male). The Sint Elizabeth flood affected the economic situation of Dordrecht that one interviewee even said, "if that flood would not have happened Dordrecht would probably be the Amsterdam of the Netherlands" (Institutional stakeholder, male).

The other big flood that the interviewees remember is the 1953 Great North Sea flood. However, interviewees noted that while the 1953 flood was a big flooding disaster for the country, in Dordrecht the effect was not as big. Interviewees noted that it was the province of Zeeland that was gravely affected and that it was the dike ring opposite of Dordrecht that got flooded (Institutional stakeholder, male (2); Planner stakeholder, male). The interviewees noted a minor flooding in the city center but acknowledge that the 1953 flood have had an impact on the collective memory of the country. Interviewees recalled that the national government vowed that the flood of 1953 should never happen again which resulted to how the Dutch deal with flood risk management through the Deltaworks project.

Interviewees recalled that the 1993 and 1995 riverine threat changed the water management strategy of the Dutch from responding to a disaster through preventive measures to adapting to disasters (Institutional stakeholder, male; Planner stakeholder, male). However, interviewees shared that since the 1953 Great North Sea flood no other disasters have happened in Dordrecht or in the country that in general people feel safe. Interviewees mentioned that flooding has been calculated to happen 1 in 10,000 years that people translate this to "not going to happen" and they have other "more urgent calamities to worry about so it is not in their priority" (Institutional stakeholder, male; Planner stakeholder, male). An institutional stakeholder interviewee opined that, "Perhaps some say we have done it too well because they don't see any risk anymore. . . The attention is fading and fading away. That's what happened in the Netherlands." (Institutional stakeholder, male). This is supported by the statement of another interviewee, "We are in Holland we feel so safe and well-protected. We don't have the experience of a real flood, only in '53 but there are not so many people that are really experiencing that. What other disaster have we faced not so many. So we don't have the experience and we don't know what will overcome us when it really happens, we don't know." The previous institutional stakeholder interviewee also pointed out that the older generation know about the 1953 flood because they experienced it. He said that the older generation are more concerned to the point that they will call the *waterschap* to check if the water pumps are working because they don't hear the pumps anymore.

3.2. Bridges

There are a lot of public organizations in Dordrecht that are interested in the city. The city government itself make efforts in making people more conscious of the risk of water (Planner stakeholder, male). Three of the planner stakeholder interviewees all come from academic institutions who have themselves done a number of studies on Dordrecht that range from technical engineering to social science related studies on public participation and governance.

Interviewees named the *veiligsheidsregio* (safety region) in Dordrecht as an organization that work together with the *waterschap* (waterboards) to improve awareness in the city on flood

risk. The national government and Dordrecht "as a city itself are working on awareness" (Institutional stakeholder, male). Institutional stakeholder interviewees noted the communication strategies that they conduct to the general population. An interviewee noted that awareness is improving in Dordrecht but also admit that there are still no studies on awareness or on what level of awareness the population has (Institutional stakeholder, male; Planner stakeholder, male).

3.3. Knowledge

The interviewees asserted that the people in general are not concerned about flooding since they trust the government and the flooding disaster happened long ago. But the interviewees also noted that the people in Dordrecht are more conscious of the flood risk than elsewhere in the Netherlands because people see the water bodies (Planner stakeholder, male (2); Planner stakeholder, female; Institutional stakeholder, male). One interviewee said that Dodrecht is "one of the few cities, especially the old town [that] is more or less in the river . . .you see some of the houses [ ] standing [on] the river so from centuries it is quite normal to live with the water" (Institutional stakeholder, male). He asserted that this has allowed them to adapt to changing water conditions and that this is not new to them.

Interviewees mostly refer to people living *buiten de dijk* as more aware compared to those living *binnen de dijk* because "they have regular elevated levels on the quays . . . the awareness there is bigger than behind the embankments" (Planner stakeholder, male). Comparing this to the people living within the dike rings an interviewee remarked "People inside the dike rings, they say 'a disaster will occur once in every ten thousand years, well it will not happen today and it will not happen tomorrow, but maybe several hundred years,' so it is much harder to make them aware that the situation can be tomorrow," (Institutional stakeholder, male). According to the interviewee this mindset makes it harder to communicate to people living within the dike to invest in their house in case of a flood because people will say "then make strong dikes and make sure that it will not happen" (Institutional stakeholder, male).

The higher level of awareness of people living *buiten de dijk* can also be attributed to the amount of information that is given to them. Yearly the people receive letters on high water levels and remind them on what to do in case of high water levels. One interviewee remarked, "I think that around the big rivers there is a lot of educational workshops and teaching moments for the citizens to be aware of what is happening and the government is really helping and making sure that every citizen actually knows about it," (Planner stakeholder, female).

3.4. Boundary spanning activities

There are ways to communicate flood risks one is through the website overstroming.nl however one institutional stakeholder interviewee shared that not a lot of people are aware of this. He said that even his colleague did not know about the website. Media (television and newspapers) and social media (Facebook) have been used to increase the communication and awareness among all stakeholders but interviewees also mentioned that it is really difficult to measure if these medium really reach the people (Institutional stakeholder, male (2)). One interviewee mentioned the TV series "Als de dijken breken" that actually brought "the consciousness on why we should evacuate" (Citizen stakeholder, male). The same interviewee also pointed out that after that show ". . two days later everyone forgot it. Goes back to normal life. And did anything change after this series? No. Apparently not."

In Dordrecht there is a yearly exercise where people in the old city center put *vloedschotten* (flood barriers) in front of their houses (Institutional stakeholder, male (2)). This is an exercise that the City of Dordrecht do together with the *waterschap* (Institutional stakeholder, male). There were also some exercise on how to evacuate within your house. Interviewees see the yearly *vloedschotten* exercise as a good way to make people aware of the flood risk and also to prepare themselves. Candidly an interviewee mentioned that, "It is a very good thing that there is a high water situation every two years because if it is once every thousand years people won't believe it or they will say it will not happen in my time," (Institutional stakeholder, male). The same interviewee opined that "there is a correlation with the last [experience], the period between the two flooding and the awareness." He made the example of the high water level they experienced in 2012 and 2013 where people 'reacted more accurately' in 2013 because with the flood in 2012 'it was 8 years ago [from] the last flooding.' He also shared that the city government have also made instruction films on how to use the flood barriers and the sandbags.

Interviewees shared that there are a lot of activities being done in Dordrecht to improve the awareness of people (Institutional stakeholder, male; Planner stakeholder, male). These activities are also being done together with other cities and even in schools. One of the more successful projects they have done in Dordrecht are the experimental projects on floating houses. "Experiments are rather a safe place to do different things but when you start working with each other for quite a while you get to know each other and know why, what their responsibilities are, what their problems are and when you know their problems and responsibilities you can make it also your own and combine it with your own urban development," (Institutional stakeholder, male). The interviewee see this as a way to keep the people's relationships and each others interests to make an integrated plan. Another interviewee mentioned that they plan to commemorate the Sint Elizabeth flood in 2021 by doing a number of activities every year until that time (Planner stakeholder, male). He said that there are two main things that they will do to make people more aware of rainfall flooding, one is to have open garden days in spring to showcase how they have 'greened their gardens'. The other is an open attic evening in autumn 'where people invite each other to their attic and they have a dinner there and play a game [ ] with the neighbors'. He further explained that the latter is 'to raise awareness about sheltering, that they have to [make a] shelter in their attic.'

4. Analysis: collective memory in Dordrecht

Results of the interviews reveal a collective memory on the flooding disasters that happened in Dordrecht and in the Netherlands. Much of these collective memory can be attributed to the ever present narratives depicted in art works and the landscape of Dordrecht which serve as a constant reminder on how the city was formed. There is a level of consciousness on flood risk that is present in Dordrecht with the fact that the city is an island surrounded by water. There is also a regular occurrence of high water levels in the old historic city center. While the 1953 Great North Sea flood did not have a big effect on Dordrecht its occurrence and the result thereafter (the implementation of the Deltaworks project) is in the collective memory of the Dutch in general.

It can be said that both the Sint Elizabeth and North Sea flooding disasters resulted to the natural movement of people to protect themselves from any impending danger. After the Sint

Elizabeth flood people reclaimed land from the sea to rebuild Dordrecht, and after the North Sea flood the Dutch vowed the flood disaster will never happen again by strengthening existing dikes, constructing flood barriers, among others. Through these engineering feats the Dutch have ensured the security of the population which as one interviewee has said "we have done it too well because they don't see any risk anymore." It is common knowledge for the people in the Netherlands that it is 'safe and well-protected' from floods. While these two flooding disasters are well within the collective memory, the disaster gap is wide that the level of awareness and concern for any flood risk is fading.

From the interviews it is quite apparent that Dordrecht is actively engaging with different stakeholders. The City of Dordrecht work closely with the *veiligsheidsregio* and *waterschap* on various activities in relation to prevention from as well as preparation for disasters. As formal bridges to city stakeholders the boundary spanning activities they conduct, such as the yearly *vloedschotten* exercise in the old historic city center, equips the residents with knowledge as well as a reminder on what can happen and how one should prepare for flooding. Yet, it can be noted in the interviews that the level of awareness on flood risk is stronger among people living *buiten de dijk* because of these regular exercises. Also, there is regular information on high water levels communicated to the residents in these areas. Such that even if with the glaring presence of the water in Dordrecht and the collective memory of the flooding disasters one cannot say that the risk of flooding is within the collective consciousness of all the people.

Dordrecht is working towards their vision to be a "self-reliant island" and improving the awareness of the people is an important facet of this. Quoting one institutional stakeholder interviewee, "The philosophy [is] *zelfredzaam*, self-reliant island, and that vision is still valid it's a bit undermined by the recent intervention but I think that vision to be self-reliant is I think a promising way." Planned activities specified in the interviews to increase awareness on flood risk, climate adaptation, and flood preparation is supported by planners and institutional stakeholders. This paves the way for opportunities to learn, remember, discuss, and experience that in turn will help in the transformation of Dordrecht into becoming *zelfredzaam*.

5. Conclusion: Three watermarks

Memory-based disaster experience. Memory-based disaster experience can help stir a shared experience to work towards a shared vision. History has shown that after the 1421 Sint Elizabeth flood and 1953 Great North Sea flood physical measures were done to secure the population from flood risk. In this case, the experience have left an indelible watermark on the manner of response the Dutch has with regards to flood risk – "never to happen again." While the narratives and the collective memory is still present the disaster gap that has emanated due to the strong preventive measures of the Deltaworks project after the 1953 flood have caused flood risk awareness to wane.

Living with water. The regularity of the high water levels and flood risk management activities *buiten de dijk* residents are trained and equipped with knowledge. This places them in line with the City of Dordrecht's vision to become a self-reliant island. Activities such as the proposed commemoration of the 600th Sint Elizabeth flood anniversary will help remind people of the rich history of the city as well as an opportunity to showcase projects such as the Room for the River which can be considered a high watermark on innovative climate change adaptation strategy.

Collective memory. Halbwachs (1980) differentiated collective memory from history by stating that collective memory "is a current of continuous thought whose continuity is not at all artificial, for it retains from the past only what still lives or is capable of living in the consciousness of the groups keeping the memory alive." Therefore, if the rest of the population of Dordrecht *binnen de dijk* continue to have a distant attitude towards flood risk then commemorations, remembrance, communication and information will remain a watermark visible only when held towards the light.

6. Acknowledgements

I would like to thank the interviewees from the City of Dordrecht for their willingness to be interviewed and their honesty in sharing their views. I am especially thankful to my PhD promotor Dr. Jurian Edelenbos of the Erasmus University Rotterdam who has supported me from the beginning of my PhD journey, provided extensive feedback on my dissertation project, and continues to guide me in the direction that would most help me succeed. I also would like to thank my colleagues Gerjan and Petra for candidly sharing with me their "flood memory" knowledge and childhood learnings one morning as I disturbed them in their office. Hoping they will not get tired of me talking about floods and disasters.

Case Study / Project

Promoting Water Resilience in Semarang:

Building a Coalition through the Water as Leverage (WaL) Program

Wiwandari HANDAYANI, Barry BEAGEN, Santy Paulla DEWI

Abstract

Like many cities in the region, Semarang faces mounting challenges related to climate change and rapid urbanization. In the past decade, Semarang has been engaging in a range of national and international networks to promote resiliency - from community programs to large scale infrastructure. This attention and engagement from local and global network of actors, collaborators, and donors cumulatively contribute to Semarang's strategic role in Indonesia as well as a leader in urban climate change mitigation and adaptation practice. More recently, Semarang is chosen as one of the three cities in Asia for the Water as Leverage program initiated by the Government of Netherlands in 2018 - a new opportunity for the city to not only tackle water-related issues and climate change, but also its various urbanization challenges. Semarang is compounded by a range of interrelated water issues from river and tidal floods, lack of clean water supply, drought and land subsidence. Government efforts tend to be responsive and partial, primarily focusing on mitigating tidal inundation occurring in coastal areas. However, with rapid urbanization along the watershed, its hilly catchment areas are also experiencing floods and intensifying downstream risks. The lack of comprehensive efforts from upstream to downstream is a result of complex institutional structures involving city, province and the national government. Indeed, collaboration and good cooperation amongst all stakeholders are key in realizing integrated water management from upland to coast.

This paper documents and examines the Water as Leverage program as an opportunity to build a coalition amongst disparate stakeholders to promote water resilience in Semarang. Some key questions to be addressed are: (1) how has the cumulative experience of resiliency building in Semarang contributed to the success (or at least so far) of the program? (2) how has the proactive role of the government contributed? (3) how the alignment of research and engagement between international teams and city vision was critical? This study uses qualitative methods to unpack the problems and issues faced by each stakeholder, more importantly, the actions taken and yet to be done to create institutional alignments. Methodologies include stakeholder mapping, institutional capacity analysis, and assessment of opportunities for collaboration.

As the process is ongoing, interim results have demonstrated that there are opportunities to build a strong coalition. The intensive research and engagement from the design teams and knowledge partners have resulted in a good commitment of the government in local, provincial, and national levels - further supported by the active involvement of local stakeholders, the including Semarang Advisory Councils consist of Professors of local Universities, various local community groups, and local NGOs.

Research Paper

Green Roof: An approach to repair the climate of Dhaka city

Ferdous Farhana HUQ, Rajshahi University of Engineering & Technology; Bangladesh
Nidalia ISLAM, Bangladesh University of Engineering & Technology; Bangladesh
Sakib ZUBAYER, Rajshahi University of Engineering & Technology; Bangladesh
Nessar Uddin Ahmed, Development Design Consultants Limited, Bangladesh

Abstract

Dhaka the capital of Bangladesh looks no better than a piece of hardscape from aerial view which justifies the swelling concern of replacing green areas with built up areas to fulfill the demand of briskly growing urban population. Increasing air temperature, changing rainfall pattern and 'unhealthy' air bears the proof of Dhaka city being an urban heat island created by the present development trend. Unrecoverable damage has already been done to the green spaces of this city which has turned this city as the most polluted city in the world. At the edge of the collapse of sustainability of this city new approaches such as 'green roof' can be used to repair its lungs. Although rooftop gardening has been a traditional concept in Bangladesh, in city-wide scale a very few buildings can be seen with green space in roof or balconies. This study employs satellite image analysis and GIS technology to identify the buildings with a green roof. This study uses a questionnaire survey to explore the commonly used green roof method, motivation benefits and challenges behind the implementation of the green roof. This research presents the global scenario of green roof and explores the possibilities of developing the green roof approach in city scale in Dhaka city.

Keywords

Green roof, Rooftop gardening, Urban Heat Island, Climate change, Satellite image analysis

1. Introduction

The world is going through a trend of migration, Poor infrastructure design, social and economic challenges are pushing people towards cities. Study shows that by 2050 the level of world's urbanization will be up to 69% whereas 86 % people of the developed nation and 66% people from less developed nations will be urban dwellers (Hui, 2011). Dhaka, the capital of Bangladesh is the home of 18 million people and has ranked as the densest city in the world with 47,400 people per square mile (Amin, 2019). Such rapid urbanization imposes excessive development pressure as any land is lucrative for physical development and construction due to heavy demand for it. As a result, Dhaka has lost its wetland areas significantly and this city occupies only 1% of its total land for parks and open spaces whereas in many modern metropolises this percentage is almost 20%-30% (RAJUK, 2015). Maheng et al (2019) mention Dhaka suffering from Urban Heat Island Effect (UHIE) along with other megacities of the world. UHIE is mainly generated when urban green space is replaced by thermal materials that store solar energy which lead to the increase of surrounding air temperature once it is re-emitted (Maheng et.al, 2019), Parvin and Adubu

(2017) addressed the UHI of Dhaka city from 2002 to 2014 by using remote sensing technique. Their study presents from 2002 to 2014 the built-up area of the city increased from 74.12 to 135.36 square kilometers. By these 12 years, the average yearly temperature has increased by 5 degree Celsius and this study suggested to focus on urban greening to curb the heating effect (Parvin and Adubu (2017). At present context, green roof, rooftop gardening, rooftop farming has become a new trend in many countries to utilize the built-up areas for greening as well as a source of urban food production (Safayet et al, 2017, green roof policies incentives and guidelines, 2014, Rahman et al, 2014, Patnaik et al, 2014, Sam and Hui, 2014, Rowe, 2010, Vazhacharickal, 2014, Shuvo and Hakim, 2013). This idea has not been adequately practiced in Dhaka city whereas that most of the roofs of Dhaka city are suitable for gardening and do not require major improvement work rather need some modifications (Islam, 2004 in Safayet et al 2017). Based on the discussed context this study aims at identifying the rooftop gardens of the research area, hardscape- softscape ratio of the research area, overall scenario of rooftop gardening practice, challenges and how this practice can be promoted widely from planning perspectives.

2. Gardening, Rooftop gardening, and Green roof

The root of the gardening lies in the ancient culture where a garden was seen not only as a source of food but also a sign of prestige and affluence especially which were extensively ornamental and associated with villas and palace of wealthy (Carroll, 2003). Gardening originated in Egypt continuing and evolving through the civilization of Mesopotamia, Greek, Roman, Medieval to reach the contemporary age and has given birth to the idea of formal landscaping (Lambert, 2019, Managbanang, 2013 Carroll, 2003). The origin of Green roof or rooftop gardening lies in the terrace garden from an ancient culture. The earliest known record of terrace garden is the ancient Ziggurat from Ur city of Mesopotamia. Hanging garden of Babylon by King Nebuchadnezzar is another example of a terrace garden which is considered as one of the seven wonders from the ancient world (Cartwright, 2018; Shamim, 2013). The formal definition of a rooftop garden says that it is a technique of growing plants on the roof of a building by using containers (Chicago dept. of Environment n.d; Spacey, 2016). Whereas Green roof is a technique of growing plants on the rooftop of a building over a protective waterproof membrane that separate hard roof from the soil (Rowe, 2011, Spacey, 2016). Generally, two types of a green roof are constructed which are extensive and intensive.

Extensive	**Intensive**
Height: 6-15 cm weight: 60-150 kg/sqm vegetation: Moss, herb, grass Retains water: 70-130 l/sqm Minimal irrigation, nutrient, and maintenance	Height: 15 cm->1m weight: 180-500 kg/sqm vegetation: Shrubs, perennials, small trees Retains water: 22-451 l/sqm More irrigation, fertigation, and maintenance required

Source: Hossain et al 2019; Jafari et.al, 2015

Although Rooftop gardening is the umbrella concept of the green roof there is a major benefit of a green roof over RTG which is, a green roof can retain stormwater where RTG does not provide this facility.

3. Green roof adaptation example and prospects in Bangladesh

The evidence from the study on the 'Secret garden located at the rooftop of a shopping complex in Malaysia suggest that having greenery element such as a green roof helps in regenerating and revitalizing the commercial setting in urban area and it helped people to be aware of green roof and its benefits (Rahman et.al, 2015). Singapore set an example of establishing a hydroponics green roof in 1988 in Changi general hospital (Jafari et al,2018; Mastura et. al 2017). Laski in Bangkok is a good example of rooftop gardening where this project intended to grow healthy vegetables for household consumption of the city and enhancing the green of the city (Hui, 2011; Jafari et al 2018). Hui (2011) in his study summarized different cases on green roof and RTG from all over the world. He discussed one case about 'Santropol Roulant' an NGO run by young people that supports RTG to ensure good health and food security of the senior citizen. RTG is now being commercially practiced in few areas of USA. The UK has undertaken low carbon policy and to implement this policy they are using RTG as a tool and now 14% of residents of London grow some foods in their gardens. Tokyo has passed an ordinance where it has been made mandatory for the buildings to keep green in 20% of its rooftops. Roppongi Hills at the center of Tokyo has RTG where paddy and vegetables are grown. Another great example of encouraging RTG is the law amendment by Taiwan government in 1995 declaring the rooftop as the public space so that tenants of the buildings can access the roof to use fully for storing things, plantations and drying clothes. These initiatives have enhanced RTG in the cities of Taiwan (Hui, 2014). Vazhacharickal (2014) in his study presented some exemplary cases of terrace garden as well as balcony gardens from Mumbai. In this study, he figured out major actors such as Marathi Vidnyan Parishad, Urban leaves, Mumbai port trust and Vidya Vaaridhi Trust who give advice, training, and awareness to people to set urban farms, terrace gardens and kitchen gardens (Vazhacharickal, 2014). Poddat et al (2017) scientifically proved the effectiveness of green vegetation on reducing heat gain and heat loss through the walls during summer and winter respectively.

Several types of research have been conducted on green roof practice in Bangladesh. Roy et.al (2016) presented homestead and rooftop gardening as one of the major techniques of enhancing urban forestry and urban greening for sustainable development in Dhaka city. Department of Agriculture Extension (DAE), Bangladesh launched "Integrated Quality Horticulture development projects enlisted 68 people from different parts of Dhaka city whom they train them to conduct rooftop gardening (Mastura et al, 2017). Many studies have mentioned about lack of initiatives from the government as the major reason for not practicing RTG. Therefore, such types of initiative from the government, as well as NGOs, are needed in higher numbers to repair the climate of the city. Shuvo and Hakim (2014) designed a compensative greening framework targeting rooftop gardening and apartment surface landscaping for reviving the green of Dhaka city.

4. Method of the Study

4.1. Study area

Ward 20 from the Zone 3 of Dhaka north city corporation is selected as the research area (Dhaka North City Corporation, 2016; Mediabangladesh.Net, N.D). The official ward name of this area is Mohakhali Niketon. This area is comprised of Mohakhali Shantiniketon residential

area and Gulshan Niketon housing area and located at the heart of Dhaka north city corporation. In this area primarily four types of land uses are observed which are residential, commercial, mixed-use and administrative. Among the land uses, the residential area comprises 72% and other land uses occupy 28%. Mohakhali slum occupies 25.8%, Gulshan Niketon area Occupies 26% and Mohakhali Shantiniketon residential cover 48.2% of the total residential area of the selected study area (RAJUK, 2004).

Figure 1 Research Area

Source: Prepared by Author by using Dhaka North City Corporation, 2016 and RAJUK 2004 data

4.2. Satellite Image analysis

WorldView-3 Satellite Mono 4 band (Red, Green, Blue, NIR) Image has been used in this study. The image was taken on 04th August 2018. The resolution of the image was 40 cm and it was clear enough to avoid any noise and cloud reduction operation. The satellite image was projected using Universal Transverse Mercator (UTM) within Zone 46 N– Datum World Geodetic System (WGS) 84. Training samples were developed in Geographic Information System (GIS) to create a signature file for supervised classification. Training sites are manually taken polygons from each type of land cover that identify and represent that particular type of and cover and the statistical characterization of these land cover using training sites is called the signature file (Good child, 2009). Maximum Likelihood Supervised Classification, using training sample and signature file, has been performed in order to classify the land cover and identify the rooftop vegetation as well. The land cover was divided into 4 classes such as Built up area including buildings and roads, rooftop vegetation, regular vegetation, and water body. Accuracy of the performed classification was assessed using Kappa Coefficient. In this regard, 280 ground truth points (70 from each class) have been taken from Google earth image of the study area of August 2018. Converting to raster pixels in the same resolution of the image, these random reference points have been compared to the classified image to calculate total accuracy and Kappa Coefficient. The value of the Kappa Coefficient varies from 0 to 1.00, while value over 0.7 is considered as acceptable (Daniel and Montero, 2011). The calculated value of the Kappa Coefficient was 0.87 which means the accuracy was acceptable.

4.3. Field Survey

Rooftop garden owner or the caretaker from 30 selected buildings from the research area was surveyed with a structured questionnaire. Survey findings were analyzed by using statistical tools.

5. Results and Discussions

5.1. Vegetation Condition of the research area

Satellite image analysis figured out that the rooftop vegetation covers almost 10% of the research area which proves the ongoing practices of rooftop gardening in ward 20 as well as justifies RTG's prospects to be practiced in city scale. Except rooftop gardening, other vegetations cover 26% of the study area whereas the built-up area covers 64% of the research area. At the current scenario hardscape vs softscape ratio is 1.8:1. If the percentage of RTG is omitted hardscape vs softscape ratio becomes 2.8:1. Therefore it is evident that RTG can significantly overshadow the hardscape ratio and contribute to enhancing the total softscape amount of the city.

5.2. Motivation and Purpose of RTG

People living in Mohakhali Shantiniketon residential area and Gulshan Niketan housing share the same interest and enthusiasm towards roof gardening although the two areas have different aspects from a spatial point of view and urban facilities. Along with hobby working as the primary motivation for roof gardening, family members inspiration is also another important drive as in many case studies more than one family members are involved in gardening and they also inspire each other. The percentage of paid personnel is greater in Gulshan Niketan whereas the involvement of owner and caretaker are almost equal in Mohakhali residential area. Recreation is found to be the primary reason behind RTG whereas Organic food production for the family in this city life become the secondary pleasure in roof gardening.

5.3. Plants and Plantation technique

50 % of the respondents produce vegetables, fruits, and flower altogether in their gardens. Whereas rests of the respondents produce either of the plant type or any combination of them. In most cases, people have used two types of technique-Planter type (large drum and pot) or extensive type (permanent masonry planter box). 78% of respondents use planter technique for rooftop gardening. 17% of the respondents use both planter and extensive rooftop gardening technique whereas only one case found who use planter and intensive gardening method for rooftop gardening. People use the large drum, plastic containers and soil pots as planters for growing different types of. Among the thirty respondents, two respondents mentioned using only large drum planter as they only grow fruits. For creating extensive rooftop garden people of the study area construct a base with brick and concrete covered with a plastic sheet. Above it, they place soil with a depth varying from 1 foot to 3 feet. The soil layer is walled with brick and concrete. This is the general method they use for the extensive or intensive type of gardening.

Figure 3 Roof Top Gardening Scenario in Research Area

Source Field survey, 2019

5.4. Collection of Gardening equipment

People of the study area collects their gardening equipment i.e. plats, seeds, fertilizer, soil, pesticide from nursery but they also followed other methods too i.e. random collection of seedlings (village house, , etc.). Two cases were found where the garden owner started gardening with the own seedbed and plant collection. They collect gardening equipment from random spots. The nearest nursery of the area is BRAC nursery which is <500m from

the Gulshan Niketan area and 500m-1km from Mohakhali area. Four cases were found who collect their equipment from the nursery that is located >1km.

5.5. Costing of RTG

40% of the respondents mentioned that they spend < 5ooo take for starting the rooftop garden. 28% spend 5000tk to 20,000 takes as an initial cost of rooftop gardening. Rest 32% spent more than 20000 takas.

5.6. Challenges of RTG

The survey finds that 99% of the people who has roof garden do not face any structural error for roof gardening in their building. Only 1% respondent showed concern about the dampness. 45% of the respondent didn't find any difficulties for roof gardening. 22% of respondents think lifting goods to the rooftop and maintenance are challenges for a rooftop garden. The other 23% responds that watering, bugs, insects, and problems are a hindrance for roof gardening.

5.7. Impact of RTG on urban heat reduction

32% of respondent suggested that they didn't find any benefits in heat reduction. If we analyze the square fit of the plantation, we see that the percentage of green with the total floor area is below 30%. It indicates that if a good amount of floor area is not covered then we are not going to get the full benefit of roof plantation. The respondent also suggested that if they move from the current location, they will continue gardening in their new home too. Only 18% wasn't sure or reluctant to continue gardening. Those who are tenant complained that sometimes landlord doesn't allow them to use the roof for gardening. But if they are given opportunity, they are very enthusiastic about the rooftop garden.

6. Recommendations

The respondents of the survey area recommend many suggestions to inspire roof gardening. Creating social awareness is the most recommended, government incentive – in forms of tax reduction, supplying plants and seeds are the second highest suggestion. Few respondents suggested that training and workshop from the government can be arranged to encourage roof gardening. One respondent suggested that government certified paid personnel from City Corporation can visit and help in the development and maintenance of RTG. Some respondents emphasized ensuring the access of the tenants for the purpose of gardening. This recommendation section of this research has been developed based on recommendations suggested by users and the best practices from worldwide.

6.1. Ensuring the place of RTG in Bangladesh National Building Code

The best practices from the world show that different countries have made green roof mandatory by adding policy in their building code (Inhabitect LLC (2014); Hui, 2014, Mastura, 2017). The current BNBC mentions about mandatory green around the building at the ground but does not mention anything regarding green on the rooftop (BNBC, 2012). A few design guidelines can be added to our BNBC code so that any structural hassles can be maintained easily. The "Imarat Nirman Bidhimaa-2008" already have a rule which excludes the water fountain, pergola roof, green/open to sky terrace and veranda from FAR included

area to encourage people to design a building with more openness. The inclusion of green roof can increase the percentage of the extensive plantation. Design of the green roof can exempt construction area from the FAR included area. This research recommends reviewing current BNBC and adds a new policy on the green roof so that the builders, Architects, and engineers incorporate this policy into their design.

6.2. Ensuring access to the roof

Majority of the people living in the study area are either tenant or own one or multiple flats. People who live as a tenant in multi-storied buildings most often lack access to use the roof. This research has found some cases in the study area where the roof has been used for gardening by multiple flat owners or tenants who have access to the roof. This is a good example of developing rooftop gardens in a cooperative way. An initiative from Government is needed to ensure the free access of the tenants to use the roof for storing, drying clothes or gardening purpose. Such example has already been set by the Government o Taiwan (Hui, 2014). Government associations or NGOs can encourage the landlord, frat owner and tenants to develop rooftop garden in a cooperative manner.

6.3. Property tax reduction

Property tax reduction is currently a popular initiative taken in different states including New Yorkton inspire green in the building (Inhabitect LLC, 2014). Such tax incentive programs can be taken by the Bangladesh government which will surely encourage residents to develop gardens at roofs.

6.4. Encouragement from Government and NGO's

Survey findings indicate that regardless of urban facility and amenities dwellers of the overall city are very enthusiastic and carries a positive thought on roof gardening. The cost and hurdle ship don't discourage them rather arranging training and awareness program from the government can increase the percentage of proactive people who loves gardening. Making people aware of the benefits of rooftop gardening through mass media can be another way of informing people about RTG. Government or NGOs can launch programs aiming at encouraging people for RTG. They can provide free soil, seeds, fertilizers, plants to people as a part of the encouragement for developing rooftop gardens. They also can initiate small loans programs to encourage RTG.

7. Conclusions

Although Gulshan Niketon Housing area and Mohakhali Shantiniketon residential area are located in the same ward, they differ in both planning and spatial characteristics. Nevertheless, the positive feedback and enthusiasm are almost the same from both the areas. People living in planned Gulshan Niketon housing area and organically developed Mohakhali residential area try to establish a rooftop garden according to their ability. The research findings acknowledge that there is a huge scope of making people encouraged at vast scale on developing rooftop gardens at residential areas. Many people have hidden wish to have a garden at home but they lack inspirations, proper guidance, and scope to use the hard surface of the building. It suggests that using the current crush for rooftop gardening to reduce the hardscape of Dhaka city will not be challenging form user point of view. Most

of the users are indifferent of the challenges of developing a rooftop garden as they hold a very positive attitude towards RTG. Furthermore, maximum users believe that RTG helps to cool down the microclimate of the roof. This research has found out that large scale RTG contributes significantly to cool down the temperature of the top floor of the building rather than small scale RTG. It is the responsibility of professional and policymaker to start a positive ripple of roof gardening in an urban scale. RTG at urban scale will not only benefit to reduce UHI effect but also bless the city with aesthetical and psychological benefits.

Research Paper

Urban Design Study of Resilient City in Greater Bay Area[1]

Peijun LU, South China University of Technology; China

Yimin SUN, South China University of Technology, State Key Laboratory of Subtropical Building Science; China

Bilin CHEN, South China University of Technology; China

Sheng XIA, South China University of Technology; China

Abstract

With the increasing climate change, the contradiction between the vulnerable natural conditions and rapid urbanization in Guangdong-Hong Kong-Macao Greater Bay Area becomes much more prominent. Urban security is threatened by various severe natural disasters, such as rising sea level, storm surges, and intensified floods, etc. To solve this problem, based on the theory of resilient city, this paper develops three resilient urban design principles: 1) integrated city principle; 2) adaptive technology principle; 3) flexible design principle, and build a research-design-feedback loop pattern. In the research and prediction stage, we quantitatively calculate the influence of natural disasters that may happen in the future in the Greater Bay Area and map the disaster influence in the natural basement layer, urban infrastructure network layer and urban settlement layer by Geographic Information System(GIS) through scenario stimulation. Based on this, the most severely affected areas in the future will be defined as key design areas. In the urban design stage, we focus on one of the key design areas – Pazhou and stimulate multiple scenarios to assess the urban resilient risk. We propose different integrated urban design strategies to balance the urban development and risk, select the adaptive hydraulic engineering technology to realize a more sustainable green infrastructure and build a flexible development framework to face the future uncertainty. In the evaluation and feedback stage, we develop a time series model of heavy rainfall to evaluate urban resilience in different design and quantify the impact of natural disasters through a set of urban resilience indicators in various layers, in order to pick up more resilient design to optimize. The practice experience shows that the resilient city is a long-term process, which requires an interdisciplinary cooperation mode, among research, design and feedback and a great management and control platform and a multi-objective evaluation index system so as to achieve real-time monitoring, regular evaluation, and dynamic control. This study attempts to make up for the lack of resilience city research in planning and design practice, to provide practical experience for the next stage of urban building.

Resilience, Greater Bay Area, Planning and Building, Design and feedback

[1] International Cooperation and Exchanges National Natural Science Foundation of China (Cooperation Project of China, Netherlands and Britain) : Adaptive Urban Transformation (AUT) - Territorial governance, spatial strategy and urban landscape dynamics for a more resilient Pearl River Delta (No:51761135025) ;

1. Background: Urban Resilience in Greater Bay Area facing severe challenges

The Pearl River is the second largest river in terms of stream flow. Guangdong-Hong Kong-Macao Greater Bay is located in the complex area in the Pearl River which is formed by the three main river Xijiang, Beijing, and Dongjiang (Liang Xiong, 2019). The Greater Bay is one of the most quickly developing region in the field of urban expansion in the world for the past four decades. The built-up area emerged at an average speed of 122.25 km2/year between 2000 and 2016 (Yang Zhiwei, 2018), while the GDP increased over 1000 folds from 1980 to 2016 and the population grow explosively from 20.1 million to 61.46 million between 1982 and 2016. However, on the one hand, the Greater Bay Area belongs to the estuary alluvial plain, which located in low altitude and sea-land boundary that determined its own ecological vulnerability (Meyer & Nijhuis, 2014). On the other hand, the frequent natural disasters led by climate change, rapid urban expansion and an increasing number of the population have caused serious damage to the ecological environment of Greater Bay Area, weakening the urban resilience to natural disasters and shortening the life cycle of sustainable development (Dai Wei, 2019). According to historical statistics, from Qin Dynasty to Qing Dynasty (over 2100 years), more than 100 floods have occurred in the Guangzhou section of the Pearl River, with an average of 20 years per flood (Qingzhou, 2009). Since the 20th century, Since the 20th century, there have been two major floods causing more than 100,000 deaths and injuries (Qingzhou, 2002). Therefore, as the Greater Bay Area has risen to be a national strategy, it is more urgent to improve the urban resilience by urban study, plan, and design, and propose a systematic framework to make resilience cities.

Both foreign and domestic scholars have achieved preliminary results on the resilience city in the Greater Bay Area. Liang Xiong and Steffen Nijhuis mapped the landscape formation, water infrastructure network and urbanization in the Pearl River District from 4000 BC to 2015 AD, to show the different dynamics of the delta and understand the interaction among the tangible and intangible components of the delta system (Liang Xiong, 2019). Based on the study of the post-disaster spatial resilience planning and design in Delta city such as Rotterdam in the Netherlands, New York and New Orleans in the United States, Dai Wei had built a systematic spatial plan framework for Delta city and try to apply into urban design in Pazhou West District (Dai Wei, 2019; Dai Wei, 2018). South China University of Technology has carried out a series of historical studies on the theme of the water system. Liu Wei had studied on the urban canal-system of ancient Guangzhou (Wei, 2015). Li Jiahao research on evolution and dynamic mechanism of the water system in Shunde, Foshan.

Next, in the first part, this study firstly proposes three resilient urban design principles: 1) integrated city principle; 2) adaptive technology principle; 3) flexible design principle, and presents a research-design-feedback loop pattern adapted to the current situation of the Greater Bay Area. In the second part, this study evaluates the comprehensive influence of the natural disaster may happen in the future in the Greater Bay Area by scenario analysis and define the key design area. In the third part, this study takes Pazhou as an example to apply the resilience urban design. On the basis of the assessment on multi-scenario risk, the design propose different development model to balance the benefit between the urban development and urban risk, apply the mix land use principle to deal with the uncertainty in the future and pick up a suitable, adaptive and ecological engineering technology to achieve a public, sustainable infrastructure. In the fourth part, this study builds a time series model of

heavy rainfall to assess the urban resilience of different design. In the last part, we point out the limitation of the evaluation system and discuss the tendency in the future that urban planning and design will toward integration and interdisciplinary, so we suggest to build a management platform to control the implementation.

2. Strategy: Resilient Urban Design Principle

Resilient cities are defined as the ability of the urban system to digest and absorb external disturbances, maintain the original structure and the key functions (Resilience Alliance, 2007). Its basic structure can be summarized into four aspects: economy, engineering, environment and society (Chen Li, 2017). Therefore, based on the Layer-cake model by Ian McHarg (IL McHarg, 1969), Dutch scholars developed the vertical stratification research methods in the 1980s. Meyer studied the Delta City resilient evolution law of urban system and decomposed the evolution of urban system into three layers based on spatial flow: 1) the first layer is the natural basement, mainly dealing with the natural environment, including the agriculture system, water system, and ecological system; 2) The second layer is the urban infrastructure network, which consists of subsystems such as transportation system, water conservancy system and municipal engineering system. 3) The third layer is the urban settlement, which mainly reflects the social and economic status of the city. This layer is composed of some subsystems such as land use system and industrial development system. Mayer's research team also used Geographic Information System (GIS) to mapping the development of different layers of Delta Cities around the world, revealing the evolution rate change of different layers and the restriction relationship between different layers (Meyer & Nijhuis, 2014). On the basis of this research, Dai Wei proposed the delta spatial planning principle based on the resilience system, emphasizing that the planning goal of improving urban resilience is based on the inherent evolution law of the urban system, the collaborative planning as the means and scenario stimulation as the planning guidance. Through case analysis (Dai Wei, 2019).

In view of the current situation of urban development in the Greater Bay Area, the author proposes three resilient urban design principle:

1) Integrated city principle: Taking the phenomenon about “individually in the process of construction” into account, the author thinks that the city should be considered as an entirety and the solution of the urban problem should be considered as a comprehensive and interdisciplinary process.
2) Adaptive technology principle: In view of the current situation that engineering technology tends to be a large-scale transformation of nature. The author believes that we should deepen the grasp of the engineering technology and emphasize to adopt the appropriate, ecological and sustainable engineering techniques to achieve a high-quality and high-resilience green infrastructure system.
3) Flexible design principle: in order to address the uncertainty of policy and the variability of natural disasters in the future. The author emphasizes the method for responding to dynamic demand, using the scenario simulation to explore the flexibility and adaptability of land use and building the dynamic management and control system to implement.

Based on the above principles, the author develops a research-design-feedback loop pattern for the actual situation in the Greater Bay Area. Starting from the macroscopic natural basement research, planning and designing the urban infrastructure network to guide the urban social and economic development.

1) Research Forecasting: Studying other professional research results and similar cases, some of the most probable and most demanding scenarios in the future are derived as planning simulation scenarios to increase the proactive prevention strategy for uncertainty.
2) Systematical Design: Focus on the scenarios analysis result, identify the key to constrain the future development, propose the urban design integrate development framework to determine the spatial layout, rationally select the land use model to cope with the uncertainty of future development, and select appropriate engineering techniques based on construction needs.
3) Evaluation Feedback: It belongs to a part of design control. Builds a quantitative indicator system to correct the design direction and implementation direction through feedback. When there is a large deviation between the evaluation result and the expected goal, feedback is given in various forms such as qualitative, quantitative, grading and shaping.

3. Research Forecasting: Scenario Analysis Delineating Key Design Areas

Greater Bay Area is selected as the macro-level scenario simulation. As shown in Figure 1, it is the urban agglomeration of Guangzhou(GZ), Shenzhen(SZ), Foshan(FS), Dongguan(DG), Zhongshan(ZS), Zhuhai(ZH), Huizhou(HZ), Jiangmen(JM), Zhaoqing(ZQ), and two Special Administrative Regions of Hong Kong(HK) and Macao(MC), which is planned to be constructed as a world-class urban agglomeration and the forth Bay Area in the word.

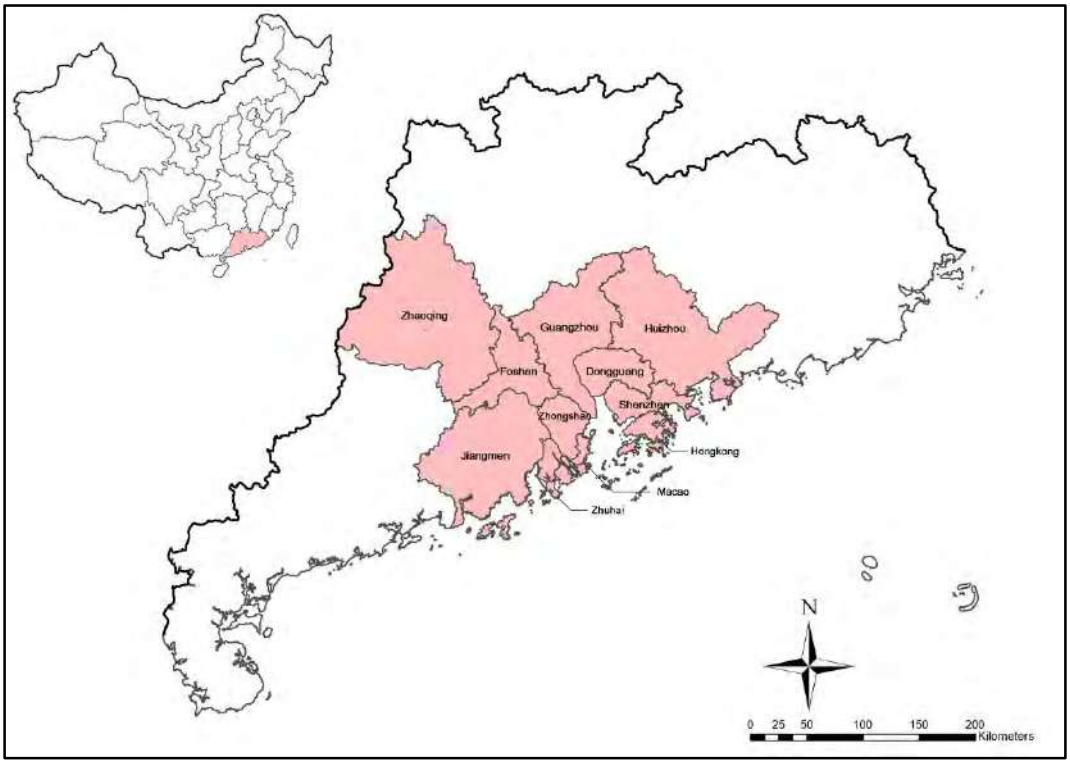

Figure 1 regional scale (Source: by author)

The research data includes the 2017 urban Land-Use and Land-Cover Change (grid resolution of 30m) describing the natural basement of the Greater Bay Area, and the urban road space distribution data and urban elevation data (DEM) demonstrating the urban infrastructure network. All the data is provided by the Resource and Environment Data Cloud Platform (http://www.resdc.cn/Default.aspx). In addition, the economic and population data of the street units of the Greater Bay Area are mainly from the statistical yearbooks of each city (Table 1). The research data also includes boundary vector data for the street (town) unit of Greater Bay Area, which is obtained from the open source map data platform OpenStreetMap (https://planet.openstreetmap.org/). In order to ensure the unification of the data, the study uses the ArcGIS platform to convert all data into a horizontal Mercator projection.

City	Area (km^2)	Population (million)	Population Density (persons/km^2)	GDP (billion dollar)	GDP per km^2 (million dollar/km^2)
GZ	7436	14.4984	1949.76	321.26	43.20

3.1. Assessment of the Impact of Disasters on the Natural Environment and Urban Construction on a Macro Scale

Considering that storm surges and sea level rise will become one of the main natural disasters in Greater Bay Area, the study adopts a spatial overlaying method to extract land data of 3 layers of natural basement, urban infrastructure network and urban settlement, which are affected by storm surges under different scenarios. Among them, the estimation of sea level rise is based on the research results of Li Guangsheng research group specifically for sea level change in the Pearl River Delta: in consideration of sea level rise and storm surge superposition, the optimal condition of the Pearl River sea level elevation in 2050 is estimated to be 3.3m, and the worst situation is estimated to be 4.5m (Li Guosheng, 2013).

Therefore, without considering the protection capability of the seawall, supported by GIS spatial analysis technology and based on the DEM data of the Pearl River Delta region, we first analyze the various types of land areas that are submerged at different heights of sea level rise, and then draw the impact of sea level rise superimposed storm surges on the natural basement and urban infrastructure network in Greater Bay Area under different scenarios in 2050, and point out the possible impacts of farmland, green space, constructed land and roads in different cities. Then we estimate in detail the impact of sea level rise superimposed storm surges on street-scale urban construction.

Figure 2 illustrated the impact of sea level rise on the natural environment and urban construction under different scenarios. With the increase of sea level and storm surge water level, the flooded area ranks first of farmlands and constructed lands in the Greater Bay Area, which is followed by the water areas and the tidal flats around it, while the flooded area of grasslands and woodlands are growing very little. Specifically, under the best estimate of sea level rise and storm surge water increase in 2050, the total area of submerged farmland is 734.01 km², and the total constructed land area is 835.28 km², accounting for 36.88% and 41.97% of the total area inundated, respectively. Under the worst estimate in2050, the total area of submerged farmland is 1054.12 km², and the total constructed land area is 1054.12 km², with respectively 36.99% and 42.30% of the total inundated area.

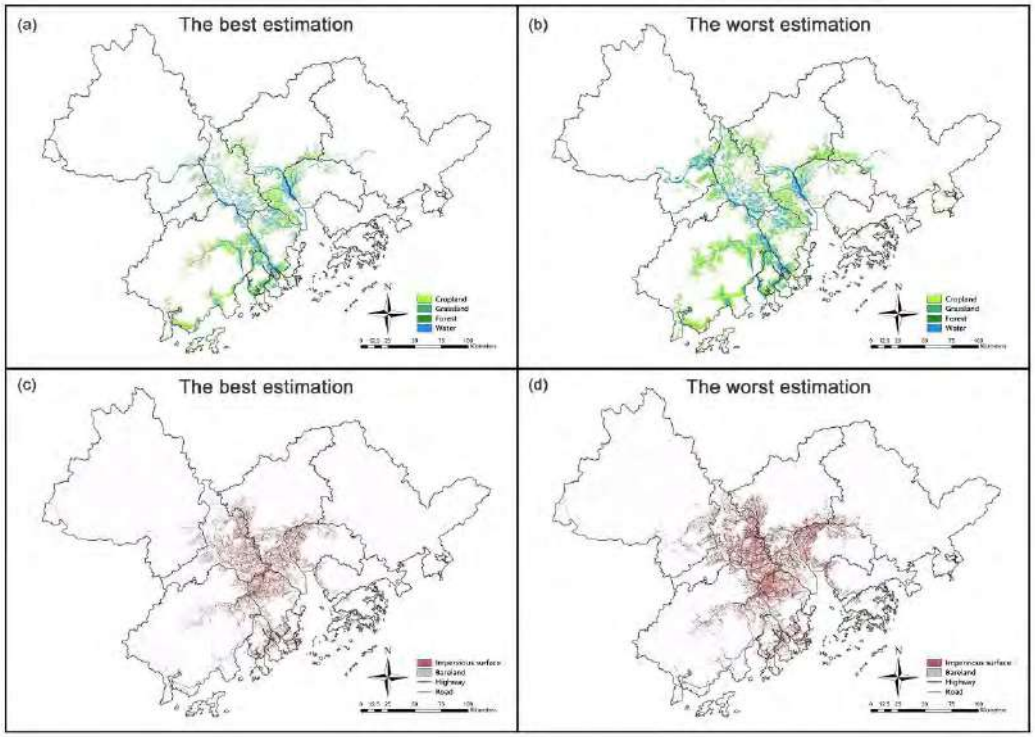

Figure 2 Different estimation of rising sea level on the natural environment and urban construction (Source: by author)

Specific to each city (Table 2), in the estimation of the impact of sea level rise and superimposed storm surges under different scenarios from the perspective of the natural system, Foshan has the greatest impact, followed by Zhongshan and Zhuhai. Specifically, under the optimal estimation scenario, Foshan is flooded with 15.30% of farmland and 19.03% of grassland, and under the worst one, it is flooded with 25.08% of farmland and 28.70% of grassland. From the perspective of the urban system, Zhongshan and Foshan are seriously affected, and Zhuhai and Jiangmen go next. That is, the impact on the west bank of the Pearl River was greater than that on the east coast.

city	Cropland		Grassland		Construction Land		Urban Network	
	Best	Worst	Best	Worst	Best	Worst	Best	Worst
GZ	5.75%	9.39%	4.90%	8.26%	8.56%	14.55%	7.88%	13.53%

Table 2 Different estimation of rising sea level on various land use in each city (Source: by author)

3.2. Assessment of the Impact of Disasters on the Socio-economy on a Medium Scale

The above research reveals the impacts of natural disasters on the layers of the natural basement and urban infrastructure network, and in this part, we consider the impact of natural disasters on the city's socio-economy. We take the area of the inundated built-up area/the area of the built-up area of the city to measure the degree of disaster in the streets, and the GDP per street unit in 2017 to measure the degree of economic development. Figure 3(a) and (b) illustrate the scatter plot of these two variables. At the meanwhile, we define the built-up area of more than 12% submerged (average of the best and worst estimate) and the degree of economic development exceeds 2×108CNY/km² (median) as the vulnerable street unit, and we respectively display them in Figure 3c and Figure 3d.

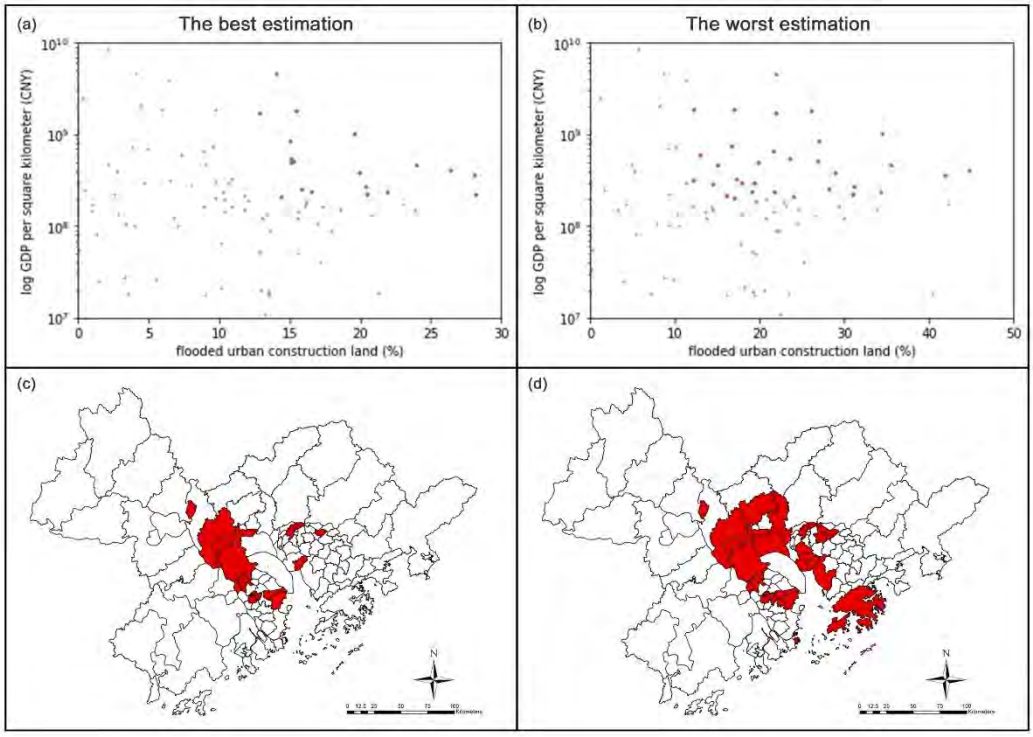

Figure 3 Different estimation of rising sea level on economics in each district (Source: by author)

The analysis shows that under the best estimation scenario, sea level rise and storm surge disasters mainly threaten the urban areas on the west bank of the Pearl River Estuary, mainly in Foshan, Guangzhou, and Zhongshan. In the worst-case scenario, the threat of disaster will spread to most of Guangzhou and Dongguan and Hong Kong on the east bank of the Pearl River.

3.3. Delineate Key Design Areas Based on Research Results

On the basis of the research, we use the spatial superposition method to integrate the impact of natural disasters on layers of urban infrastructure network and urban settlement, to make a resilient urban design in the key areas, key control areas and general control areas of the

Greater Bay Area (Figure 4). Among them, the key areas refer to those where resilient urban design is urgently needed to cope with natural disasters that are likely to come, and to avoid major impacts on the city's socio-economy; the key control areas refer to the development of resilient urban planning to cope with possible natural disasters and to reduce the corresponding socio-economic losses; the general control areas refer to natural disasters that can carry out relevant tough urban studies to cope with accidents. The Central and Eastern Pazhou, which is in the key control area, is selected as the design area for further planning.

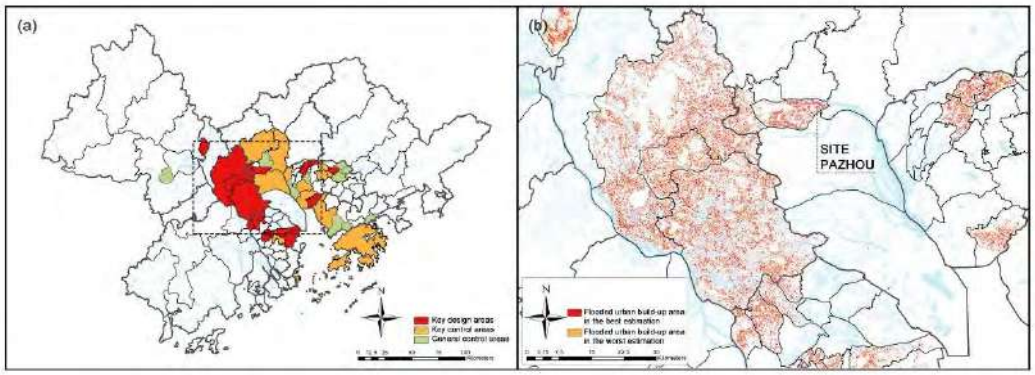

Figure 4 Key Design Areas and Pazhou (Source: by author)

4. Systematical Design: Taking Urban Design of Central and Eastern Pazhou in Guangzhou as an Example

Pazhou Island, Guangzhou, which is located at the junction of the eastern and the central waterways of Pearl River, has a low terrain and has been affected by typhoons and floods. In Junuary 2019, South China University of Technology (SCUT) and the University of California, Berkeley (UC-Berkeley) held a joint design workshop based on the central and eastern Pazhou, trying to explore the design methods for urban resilience in Pearl River Delta cities from the perspective of rainwater management, urban integration and compact development.

4.1. Risk Simulation and Assessment of Pazhou Island under Multiple Scenarios

Pazhou Island is located in Haizhu District of Guangzhou, surrounded by water, at the eastern junction of the front and rear channel of the Pearl River, and its southwest side is Huangpu Canal. It is the alluvial island, the terrain is low and the coastline is about 10km. At present, the elevation of the east side of the island is about 8.05m, and the elevation of the top of the southeast side is 6.95m. The average annual tidal level of the Pearl River recorded at the hydrological station (Sun Yat-sun University Station) near the east side is 8.227m (2018), and that recorded at the Huangpu Station near the southwest side is 6.94m (Figure 5).

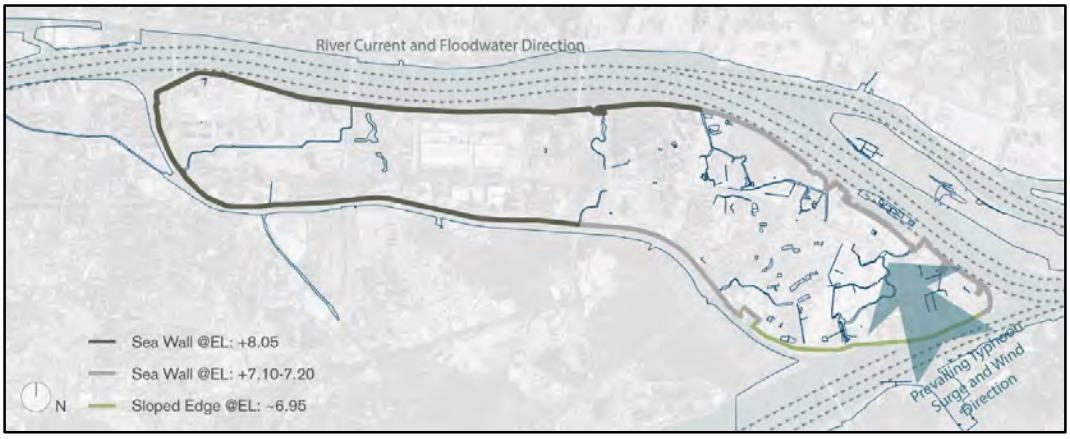

Figure 5 Hydrologic regime and water conservancy facilities (Source: UCB-SCUT workshop)

According to the universal risk of sea level rise that is likely to be faced in the Greater Bay Area, and the possible heavy rainfall and storm surges that may be caused by typhoons, in this workshop, a model for analyzing the elevation of Pazhou Island and its different heavy precipitation conditions (Figure 6) was established based on the topography of the island, without considering existing embankments, sluices and other water conservancy facilities, so as to simulate strong precipitation in 50 mm, 100 mm and 200mm (2018 Typhoon Mangosteen).

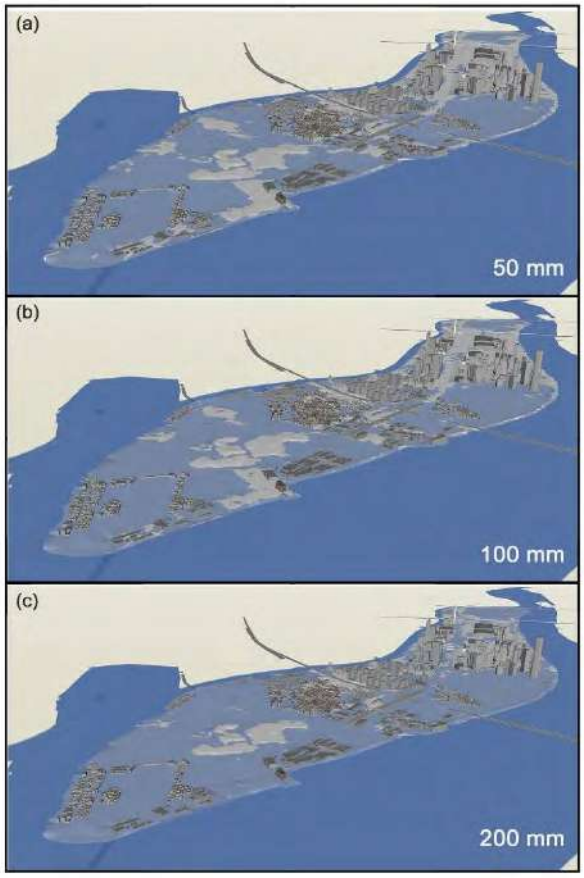

Figure 6 Flood risk scenarios (Source: UCB-SCUT workshop)

4.2. Overall Resilient Urban Design of Central and Eastern Pazhou

Resilient Urban Design emphasizes the adaptability and learning ability of urban systems, to build a stable, diverse, redundant, integrated, flexible, and interconnected urban infrastructure and environment that is resistant to risks and adapts to interferences. Therefore, in view of the above risk simulation and assessment of the island, corresponding feedbacks and overall design strategies (Table 3) are proposed, which involve interdisciplinary aspects such as urban planning, water conservancy engineering and ecological design.

Risk	Related Majors and Feedbacks	Specific Design Strategies
Low-lying alluvial island	1） urban planning: classification of land development based on the terrain	①Land developments of higher intensity are concentrated in the highlands; ②Residential areas are arranged at high points, followed by commercial, business areas and major transport facilities, and finally green space, farmland, and other submersible areas.
	2） water conservancy engineering: artificially adjust the site elevation according to the current land shape and extreme water lever	①The height of parts of the embankments is adjusted, which is a hardened waterfront area with a narrow scale; ②The low-lying ground of residential areas are to be lifted up.
	3） ecological design: maintain continuity in low-lying habitats	①The current broken water system and green space are to be connected. ②Blue-green infrastructure connecting with the external ones are reserved in the newly built areas.
Threats of storm surges and floods	1） urban planning: integrate land use and urban transportation according to base terrain	①The mix-use land pattern is advocated to promoted the diversity of urban space and mitigate the degree of damage to the same area by the risk of storms and floods; ②A low-carbon redundant traffic space is to be established guided by public transportation, and the redundancy is increased by constructing pedestrian bridges on low-lying lands.
	2） water conservancy engineering: combine rigid engineering tools with resilient green infrastructure	①Rigid measures are taken to reinforce dikes in places which lack buffers and where is with large urban construction; ②Decentralized rainwater storage design is adopted in combination with green infrastructure, and the existing farmland and

		wetlands are preserved in low-lying areas to improve the adaptability to storm threats.
	3） ecological design: establish natural floodplain combining low-lying lands	①Water squares, rain gardens, undercut or sloped green spaces are established according to different functional parts of the city; ②Recreational and other facilities are introduced to the natural floodplain in order to create multi-purpose space.

Table 3 Urban design strategy of Central and Eastern Pazhou (by author)

The workshop adopted two different holistic development models (Figure 7) to explore how to strike a balance between urban development and adaptability to stormwater hazards. Two different development visions were presented through design: one is to achieve intensive land development, which needs to invest in higher flood control facilities; the other one is to preserve existing farmland, vegetated areas and other open spaces, so that the constructed area and the green infrastructure system are organically integrated, and the cost of flood control is relatively low.

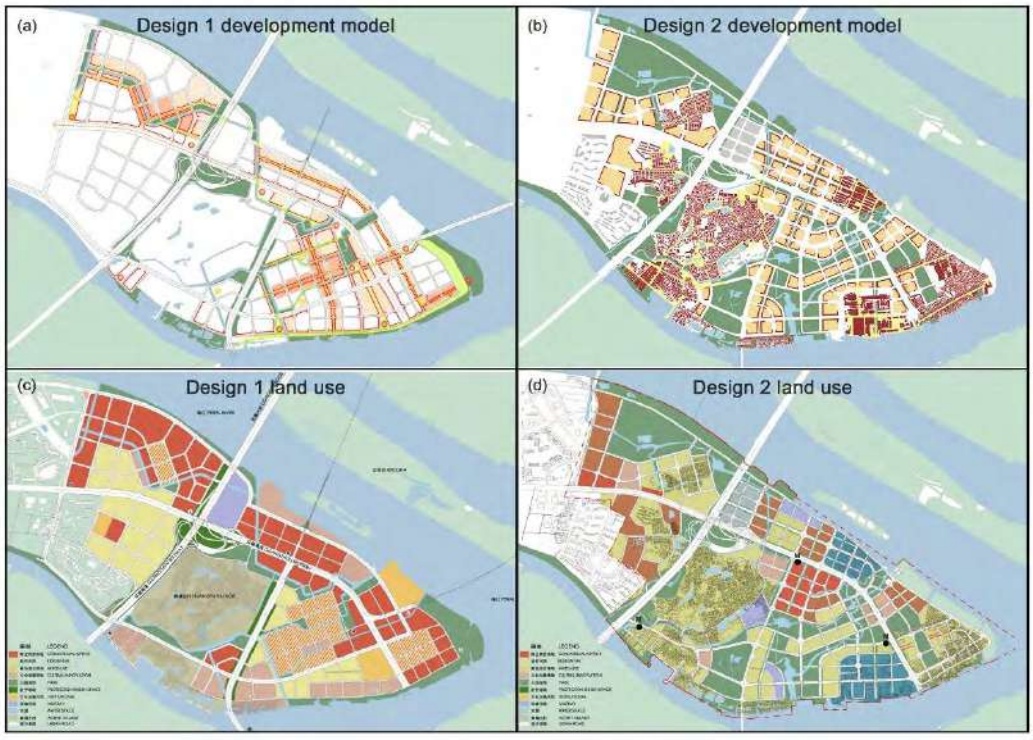

Figure 7 Development model and land use of two urban design (Source: UCB-SCUT workshop)

4.3. Engineering Means Selection and Adaptability Evaluation

Due to the relatively heavy rainfall in Pazhou Island, it is likely to face the threat of heavy storm surges and floods, if the rainwater is not properly stored, but only removed by engineering means. The workshop proposed three possible hydraulic engineering design strategies and evaluated them: First, to prevent flooding by increasing the elevation of the base. This strategy is relatively straightforward, but involves huge earthworks; Second, to establish a flood defense system, such as dikes, sluice, etc. and centralized flood discharge

facilities, such as flood drainage channels and intercepting ditches, etc. This Strategy is more effective in a short period of time, but the centralized drainage facilities may lead to land subsidence; Third, to bring together the water conservancy and ecosystem to create a decentralized rainwater storage system to store, manage and reuse rainwater on site.

The first two strategies are rigid static water conservancy engineering methods, and often do not have the adaptability and learning ability in storm disasters. Once the future climate change makes the flood exceed the engineering design standards, the water inflow will still occur in this island. The last method is more flexible and sustainable, but it requires a certain amount of land. In summary, appropriate technical means should be selected in combination with the different situations of the site.

4.4. Application of the Principles of Flexibility in Design

The principles of flexibility in specific design is embodied in a smart and compact urban growth and a mixed-function block design. A mix-use zone is created within a walkable scale, and multiple zones are connected by constructing multiple levels of public space, so as to further enhance the interconnectivity and redundancy of urban resilience.

To achieve the resilient open space design of the above-mentioned combining urban planning, water conservancy engineering design and ecological landscape, and to meet the current development capacity, it is necessary to carry out appropriate high-density development in the constructed area of the central and eastern Pazhou, pre-planning spaces for green infrastructure. Combined with the walkable scale of “small blocks and dense road network”, mix-use block design is proposed (Figure 8), according to the needs of development intensity of different regions. Besides, the urban public services are considered, to achieve a certain degree of the balance between occupation and residence in order to reduce carbon emissions. What’s more, the adaptability of climate in south China is considered in the block design, such as the street interface in the form of an arcade, the ventilation openings and courtyards in the blocks, and the square design, and so on.

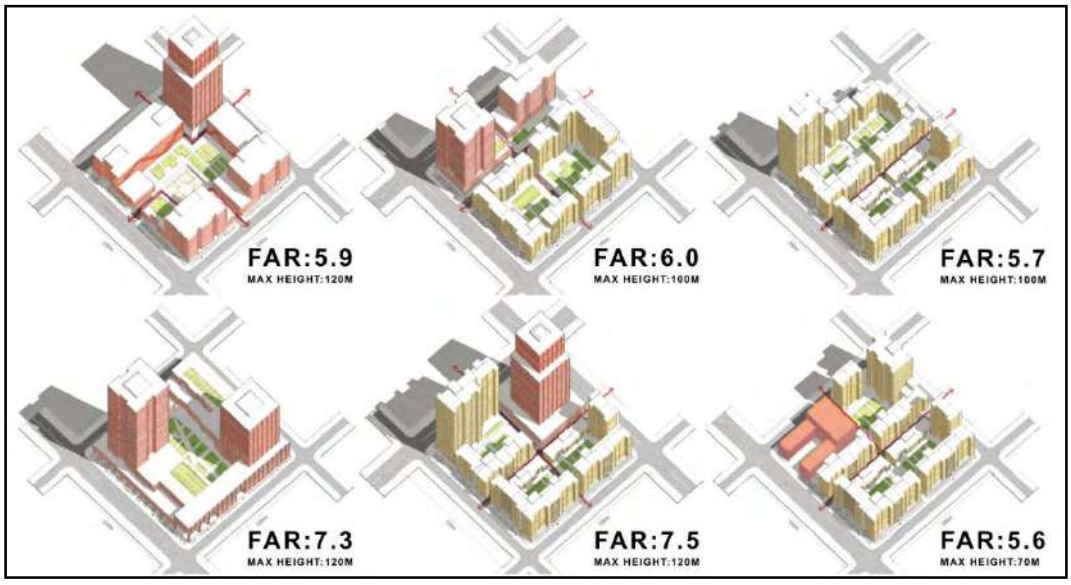

Figure 8 Block design of mix land use (Source: UCB-SCUT workshop)

5. Evaluation Feedback: Multi-program Quantitative Assessment of the Resilience

Based on the initial formation of the urban design, we design a set of resilience indicators to evaluate the resilience of different urban design plans and feedback to the urban design stage. The purpose of the evaluation feedback is to introduce the theory of resilient city in the early stage of design, to form a comprehensive consideration of urban ecology, urban design and water conservancy. Through early scientific decision-making, the repeated planning and design modifications during the constructing phase are to be reduced, which may hopefully save time and resources.

5.1. Time Series Model for Urban Resilience Assessment of Heavy Rainfall

Not considering existing embankments, sluice gates and other water conservancy facilities and assuming that the urban drainage system runs smoothly and the water level of Pearl River remains constant (7m), we construct a time-varying model for analyzing different rainfalls in Pazhou to simulate the impact of quantity of the rainfall on various urban systems. Input data includes different elevation areas for each design (Figure 9) and their corresponding land use type. The set scenarios are 50mm, 100mm, 200mm precipitation, and the precipitation time is 3h. The quantified indicators of output include the height of the rise in stagnant water and the temporal changes in the various types of land that are submerged.

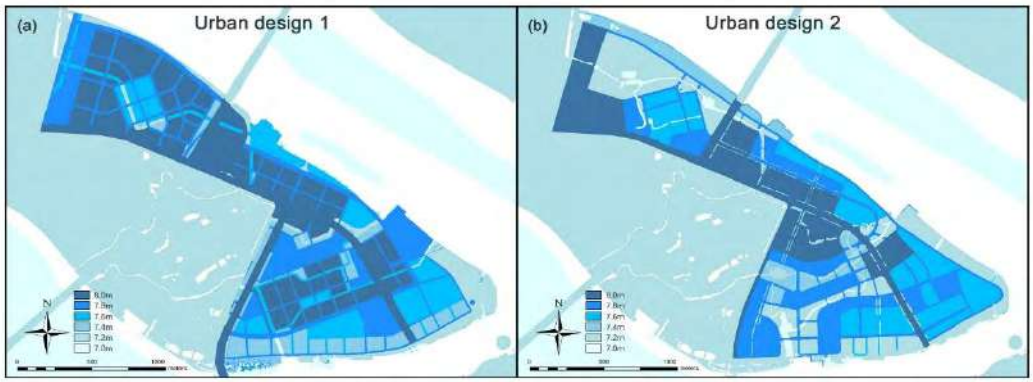

Figure 9 Elevation of two urban design (Source: UCB-SCUT workshop)

Figure 10 illustrates the temporal variation of the water surface height along the rainfall process in different scenarios. Overall, the water lever of urban design 1 has increased rapidly. The maximum height of the accumulated water is close to 0.7m. The speed of the stagnant water is also fast. The water level is maintained at 0.05m within 9 hours after the precipitation. In urban design 2, the increase in the height of the accumulated water is relatively flat. The maximum height of the accumulated water is about 0.6m, but the speed of the whole water volume is also slower. It stays at about 0.1m for a long time, so the time of water accumulation is longer.

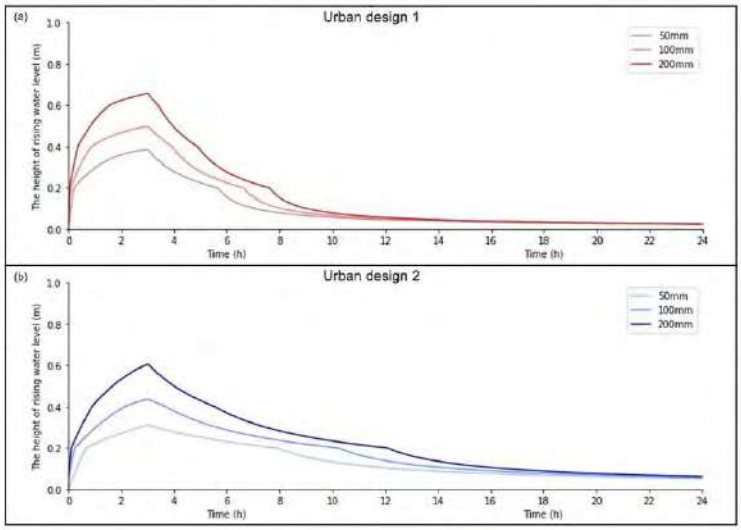

Figure 10 The temporal variation of height of rising water level in different scenarios in two urban design (by author)

Specifically, urban design 1 and 2 perform well in heavy rainfall facing 50 mm of rainfall, and the natural basement absorbs most of the precipitation and protects the urban system from precipitation. However, in the face of 100mm heavy rainfall, there is a difference in the performance of the two. The natural basement of urban design 1 is difficult to absorb a sufficient amount of rainfall, but the urban infrastructure network is well protected because of the urban design, so precipitation directly affects commercial land on the layer of the urban settlement. Urban design 2 retains sufficient natural ecological land and green space, and the city has strong resilience. The difference in resilience between the two schemes is that: when facing with serious natural disasters, the overall recovery of urban design 1 is strong, but the capacity for disaster response is insufficient. About 10% of urban constructed land (commercial and residential land) is flooded. Although the recovery rate is slower in urban design 2, the disaster preparedness is sufficient. Only 4% of the urban land is inundated, and the late stage of disaster recovery mainly through the water system on the layer of the natural basement which does not affect the urban operation.

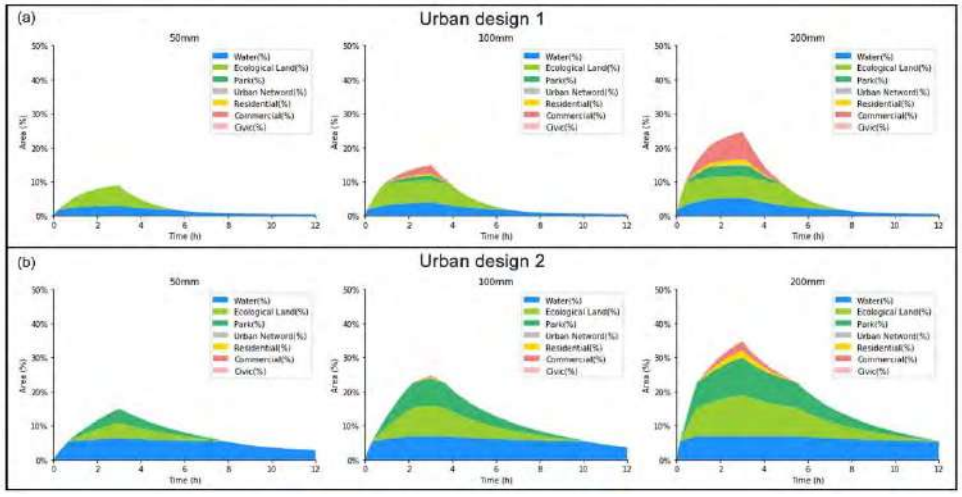

Figure 11 The temporal variation of area of various land use in different scenarios in two urban design (by author)

5.2. Feedbacks Based on the Results of the Assessment

Based on the evaluation results, we put forward 3 feedbacks on the next stage of urban design to enhance urban resilience.

Appropriately increase the covering area of the natural basement and adjust its elevation to meet the urban water conservancy project implementation to achieve the 100-year construction standard, which can be continuously measured through the feedback model.

In residential and commercial areas that may be submerged, it is recommended that the ground floor be overhead and designed as a semi-public space to enhance the quality of the space and to cope with sudden precipitation.

The underground public space should be set up to consider the extent of flooding, and the underground public space entrance in the flooded area should be specially designed to protect the normal operation of the underground public space.

6. Discussion

6.1. Interdisciplinary cooperation mode: integration of research, design and feedback

The city is a complex giant system. Each city's challenges require multiple disciplines in collaboration to propose solutions. The natural disasters caused by climate change in cities also require urban planning, water conservancy projects, and ecological design to build an interdisciplinary platform. In this process, urban planning is responsible for formulating urban development frameworks from the perspective of urban systems and balancing the interests of each system. Ecological design is responsible for regulating the relationship between urban artificial systems and ecological natural systems, and adjusting the development framework to ensure sustainable urban growth. Urban design is responsible for shaping urban public spaces and urban blocks within the development framework and maintaining flexibility to face the future uncertainties. The water conservancy project is responsible for assessing and selecting appropriate engineering techniques to achieve sustainable goals. In this interdisciplinary exchange and cooperation process, it is indispensable to break through the traditional academic constraints of “architectural-planning-landscape” and to explore from a broader interdisciplinary field. It is the key to establish a cooperation mechanism between the urban study and other professions.

6.2. Management and control platform: evaluation indicator, real-time monitoring and dynamic maintenance

The evaluation feedback process can effectively adjust the design optimization direction and implementation direction, but the strength of the adjustment depends on the perfection of the evaluation index system. Through reflection on the evaluation index system in the design process, we understand that the above evaluation system is limited to the short-term impact on the urban system when natural disasters occur, and fails to show the strength of the urban reconstruction ability after encountering natural disasters. Moreover, the existing evaluation system is limited to a single target, and it fails to evaluate the impact of disasters on urban infrastructure (such as medical and municipal facilities) and urban population economic development. This is also part of the next work.

It is important for a management and control platform to do real-time monitoring, regular assessment, and dynamic maintenance. In the planning and design phase, the platform can quantify the urban resilience of the design and guide to select excellent solutions. During the design implementation phase, the platform can supervise the implementation progress in real time, assess the urban resilience periodically, and compare design and implementation to find and correct the deviation. Besides, through the dynamic maintenance of the platform, the first-hand data of each system in the city can be obtained, which is beneficial to enriching the knowledge library of urban evolution and development, and further analyzing the law of urban evolution.

7. Conclusion

Resilient cities are not only the inevitable requirement of the development of the world city, especially the coastal cities, but also the practical need for the Greater Bay Area to realize leap-forward development. Based on the theory of resilient city, this paper proposed three resilient urban design principle and a research-design-feedback loop pattern and applied from the Greater Bay Area to urban zone-Pazhou. The practice process shows that the design research (the analysis of previous designs and patterns) and research-by-design (testing different possibilities for an area) both play an important role in resilience urban design. And these create a complete design closed-loop. The experience also points out the limitation of the evaluation index, suggests that the resilient city evaluation indicator needs to move from short-term to long-term and from a single goal to multiple goals, so as to improve the quality and efficiency of resilient cities.

Case Study / Project

Effects of ongoing infrastructure improvements in relation to planning policy

for flood resilience and historic urban morphological development in Jakarta

David MATHEWSON

Abstract

This paper explores historic institutional responses to flooding and the influences of such planning policies on the spatial development of Jakarta within the context of pressures from severe flooding and rapid urban development set against a background of significant recent institutional change from the national to the local level in recent years. This study will focus on the local and city scales, considering recent changes to patterns of urban spatial development across Jakarta as new flood defences and mitigation measures have been incorporated in various parts of the city which form part of a wider network of flood and water management infrastructure currently being implemented by local and national government. Several sites will be analysed using urban morphology with GIS-based mapping and satellite imagery to understand the impact of this new infrastructure on existing communities in different parts of Jakarta and the relationship between typology, context and decision-making at the local and national governmental levels.

While this article will study spatial impacts at the local scale, it will examine how these disparate sites form part of a wider trend at the extent of the city-region, because the nature of flooding means that both upstream and downstream areas are affected and the origins of problems can arise far from visible disasters. Using document analysis, newspaper articles and historic maps and satellite images, a historic institutionalist approach will be used to understand the policy context and decision-making process involved with the practical realisation of flood-resiliency in the city, which has resulted in a number of side-effects, including displacement of local residents, problems of land tenure, access to affordable housing, severance of social networks and interruption of local livelihoods.

Case Study / Project

Earthquake Post-disaster Relocation Identification

in Meuredu Pidie Jaya Nangroe Aceh Darussalam

Dani MUTTAQIN

Abstract

Indonesia's geographical position was crossed by the world's active fault lines which are prone to earthquake. Physically and non physically was affected by earthquake. Growing trend of disaster was induced displacement to reduce risk by relocation, adaptation and protection were means mitigation. High risk of earthquake disasters area was identified to reducing the impact of earthquake risk by the government and stakeholders. Through micro zonation mapping of earthquake-prone areas known to areas that have a high risk of earthquakes. The determination of the areas that are in active fault becomes a protected area for fault lines was the regulation by Indonesia Government. The existence of settlements around active faults can improve settlement development and population density. Restrictions on the development of settlements around active faults are as far as 20 meters from active faults. Land management can be an effort in reducing disaster risk through land consolidation and land pooling. Identification of land requirements and conformity to spatial planning in determining locations for regional relocation in efforts to reduce disaster risk.

The purpose of this study is to identify suitable locations in the relocation in terms of physical and spatial plan. Through the GIS analysis method by combining micro zonation and active faults against spatial regulation. The results of the analysis show that there are 78 building units in active faults, 1 unit of public facilities, and buildings that have a high risk for collapsing a total of 179 units. The total land requirement in Meuredu District is needed for the relocation location which is 3.62 ha and the availability of land is 23 ha.

Research Paper

CHANGED PRECIPITATION PATTERNS AND THE NEED FOR A NOVEL APPROACH TO BUILDING PLOT PLANNING

The lessons learnt in the sub-alpine climate zone of Slovenia

Dr. Matej NIKŠIČ, Urban Planning Institute of the Republic of Slovenia; Slovenia
Jernej ČERVEK, Ministry of the Environment and Spatial Planning & University of Ljubljana; SI

Abstract

The events related to climate change are recently challenging the Slovenian urban planning. One of them are the floods in urbanised areas that call for a radically new approaches to how the urban built structure is organised and managed. The continental (and largest) part of Slovenia has a subalpine climate which has been traditionally characterised by a moderate precipitation throughout the year. This is now being changed as the larger amounts of water fall on the ground in a shorter period. As the current urban structure is not shaped in accordance with these new circumstances, parts of the cities are getting flooded more often. Some mitigation measures have been implemented, however to address the issue comprehensively new urban planning approaches are needed too. The paper will present one of the tools that has been developed within the endeavours of the national Ministry of Spatial Planning to reform the urban planning system to better reflect the changes posed by the climate change. It is related to the urban design criteria for building plots planning. To allow the rainfall to penetrate the soil as soon as the precipitation reaches the ground, new measures in organisation of the building plots will be provided. The current system defines the percentage of the built-up area within the plot but does not consider the permitted percentage of the paved open spaces (which do not allow the water to penetrate into the grounds), therefor it will be supplemented by the new measures based on the ability of the plots to allow the penetration of the water. The paper firstly presents the current system of building plots regulation within the Slovenian planning system. It then reports the results of the extensive analyses that focused on the existing characteristics of building plots for different building typologies across the country (housing, production, trade, public services) with the aim to map the state of the art in terms of the potential of the existing building plots to allow the water to flow into the grounds. The third part explains the methodological framework for the new approach to the building plots regulation. The last part presents the newly proposed approach and relates it to other urban design tools that need to support the implementation in practice. The concluding section relates the lessons learnt in Slovenian case to the similar situations elsewhere and stress the responsibilities that the urban planning and design have in providing future urban environments that will ensure the environmentally just living conditions for all.

Keywords

urban environments, precipitation, building plot, urban design, urban planning regulation

1. Introduction

1.1. The changing climate conditions in Slovenia

Slovenia is a Central European country, measuring 20.271 km2 and positioned between three distinctive geographical regions: the Alps, the Pannonian Plain and the Adriatic Sea. Most of the country is characterised by the hills and valleys with water streams (Melik, 1963). Even if the territory of the country is small, its geographical diversity results in a great variability of weather and climate conditions – the influences of the Mediterranean (coastal), Alpine (mountainous) and continental climate all meet and intervene in Slovenia.

As observed in many other parts of Europe, the climate conditions are quickly changing in Slovenia too. According to the national environment agency at the Ministry of the environment and spatial planning "climate change represents an increasing threat to environmental, social and economic development and requires rapid intervention" (internet source 1). The changes include the rising of the average temperatures in the last 20 years, the changed air currents, weather patterns and distribution of precipitation. The hazardous weather phenomena are rising too. An outstanding issue are the changes in the precipitation distribution which cause either floods or droughts. The changed precipitation distribution comes also due to the increased number of severe storms. This has very severe consequences for both rural and urban areas (Kajfež-Bogataj, 2008).

In the urbanised areas the excessive rainfall and short-term strong downpours are the climate change driven events that cause some of the major problems. Due to the relatively high percentage of the covering of the ground by an impermeable material in the urbanised areas the amount of the water that falls to the ground cannot directly leak through the soil. Additionally, the soil sealing is contributing to the increased heat-island effect, which in turn results in more thunderstorms and increased precipitation.

According to IPCC (2007) Slovenia can expect the average temperatures to increase for up to 3.5 °C by the end of the century. This means that the uprising issues need to be addressed systematically, also by challenging the existing and finding new future practices of planning and design of urban areas. This paper investigates the possibilities and opportunities offered by the introduction of the new spatial law in Slovenia which foresees the introduction of the so-called building plot as a basic tool for organisation of the built-up areas.

1.2. Building plots regulation

In 2017 Slovenia adopted a new spatial planning law, so called *Zurep-2* (Official Gazette of the Republic of Slovenia, 2017). The three main topics covered by the law are the spatial planning, land policy and monitoring and control. It sets the basic rules of spatial planning and management at the national level, while it also foresees the adoption of more detailed rules and regulations in the additional legally biding documents. One of these detailed regulations will be the National spatial order (in Slovenian: *Državni prostorski red*), which will replace the existing Spatial order of Slovenia (in Slovenian: *Prostorski red Slovenije*, abbreviated as PRS) (Internet source 2).

The still valid PRS defines the general planning rules at the national level. By the time of its adoption (2004) the climate change processes had not been accelerated to the extent as we know them today, therefor the adaptation and mitigation measures were not deliberately addressed. PRS covers the issues of changed precipitation patterns indirectly by defining the

approaches to channel the rainfall into the sewage system. E.g. it defines that the water from the roofs of the objects as a rule shall be drained within the object's building plot via the infrastructure such as drifting devices, sinking ditches or drainage pipes in accordance with the environmental protection regulations. At the same time, it stays rather flexible in terms of the regulation of the percentage of the surface of a building plot that can be sealed – this is regulated through the footprint index only which varies in accordance to the dedicated land use, however it does not regulate the character of the parts of the building plot that are not built-up. In practice this means that the open spaces within the building plots in theory can be either hundred percent sealed or hundred percent green surfaces. In practice this percentage greatly varies. Accordingly, the ability of the building plots to sink the rainfall directly into the ground varies too.

The aim of the study presented in this paper was to firstly analyse the state of the art in Slovenia in terms of the (un)sealed surfaces within the building plots for various types of developments, and secondly, to propose a new planning approach that would at the national level regulate the percentage of the sealed surface within the building plots. The study was undertaken under a leadership of the main national research institution in the field of urban planning, i.e. Urban Planning Institute of the Republic of Slovenia, in cooperation with LUZ Urban institute of Ljubljana and BD projektiranje Ltd in 2018 and 2019.

2. Analyses of existing building plots for different building typologies

2.1. The context

Reckien et al (2018) who made a comprehensive analysis of local climate planning to date and classified the alignment of climate change plans with spatial (local, national and international) plans in European Union report that cities of central and northern Europe in general have more elaborated approaches to adaptation and mitigation to climate change through planning documentation than cities in other parts of Europe. The endeavours of Slovenia in this field are largely related to some international documents and protocol, e.g. Kyoto Protocol and the related Operational Programme to Reduce GHG Emissions (internet source 1). This document lists many environment-oriented goals as a response to a climate change, such as savings of end-use energy, increasing the proportion of electricity generated from renewable energy sources, increasing the share of biofuels and increasing the renewable energy sources in energy end-use. However, these goals do not address the need to rethink the way how the planning of the cities most detailed land-use elements (i.e. building plots) shall be adapted to better meet the changed climatic circumstances. Some efforts have been made within other region-based international policies such as the Alpine Convention (AC) which sets the (sustainable) development goals for eight Alpine countries of Europe while protecting the nature (Morandini and Roblek, 2011) and was adopted by Slovenia in 1995 (Bogataj et al, 2011). One of the clear objectives of AC is to reduce the damage of the soil, among others via the restriction of soil sealing. AC as a guiding document does not define which tools each signatory country of the convention shall use to reach the objective in practice - this depends on the planning and other regulatory systems in each of the AC countries.

Slovenian Ministry of the environment and spatial planning has recognised an opportunity to develop such a tool within the preparation of the new National spatial order. However, the state of the art had to be revealed first in order to get an insight on the amount of the sealed soil within Slovenian cities and other settlements as described further below.

2.2. Analitical framework

The project brief clearly structured the research into two phases: the analytical phase (phase one) and the guidance-defining phase (phase two).

The analytical phase had the objective to identify relevant case studies across the country and reveal the following:

- the minimum, the maximum and the average size of building plots for each of the most common building typologies (housing, public services, trade and production);
- the percentage of the built-up surface of the plot;
- and the percentage of the sealed part of the open space within the building plot.

The task of the analytical phase was also to reveal the level to which each studied case is in compliance with the demands set in the local spatial development plans in terms of the above-mentioned criteria.

Due to the great variety of landscape conditions (and related climatic conditions) around the country the project brief demanded to choose the case studies in different parts of the country, i.e. in all statistical regions as well as in all architectural regions of Slovenia that have been defined previously in the study commissioned by the Ministry (Fister, 1993). It was also demanded that in each architectural region one urban settlement and one non-urban settlements are analysed. The third demand of the brief was that the chosen case studies shall represent a wide array of settlements by size (big, medium and small size settlements).

The brief also defined that in each of the settlements a number of typical morphological unit has to been chosen (so called distinctive morphological pattern) reflecting each of the main building typologies (housing, production, trade and public services).

Based on the demands of the project brief the following urban settlements have been included as case studies (the number of inhabitants is indicated in brackets): Ljubljana (> 100.000); Velenje, Novo mesto, Koper (10.000 – 20.000); Trbovlje, Ptuj (10.000 – 20.000); Idrija, Radovljica (5.000 – 10.000); Sevnica, Cerknica (3.000 – 5.000); Črna na Koroškem and Radenci (< 3.000). While among other (non-urban) settlements the following were chosen (the corresponding statistical region is indicated in brackets) Moravske toplice, Martjanci, Tešanovci (Pomurska); Lormanje, Šetarova, Zg. Voličina (Podravska); Podgorje, Šmartno pri Slovenj Gradcu (Koroška); Topolšica, Zavodnje, Bele vode (Savinjska); Čemšenik, Razbor pri Čemšeniku, Jesenovo (Zasavska); Kostanjevica na Krki, Orehovec (Posavska); Dolenjske toplice, Dolen. Sušice, Selišče (JV Slovenija); Dobrova, Polhov Gradec (Osrednja Slovenija); Begunje, Dobrova vas, Rodine, Smokuč (Gorenjska); Nova vas, Nemška vas na Blokah, Veliki vrh (Primorsko-Notranjska); Kozana, Dobrovo, Biljana (Goriška); Šared, Malija (Obalno-Kraška).

The more demanding step of the sampling was choosing the morphological units to be studied within each case study settlement. The research team decided to use a combination

of orto-photo analyses and on-site visits to choose the most relevant units. Once they had been selected a clear boundary was defined to enable a technical (GIS) part of the analyses.

The technical part of the analyses was done in the Arc-GIS environment on the following order (see Figure 1):

1. preparation of the dataset; the cadastre and other information from geodetic and other relevant state-datasets for each case study has been uploaded. This included the ortho-photo images, polygons of built structures, plot-division and road network for each case study;

2. digitalisation of the boundary of each morphological unit that has been studied;

3. based on the information from steps 1 and 2, the overlapping of relevant data gave precise numbers on the size of building plots, the percentage of the built-up surface of the plot and the percentage of the sealed part of the open space within the building plot.

Figure 1 An example from the Arc-GIS database showing the analysed morphological unit for the case of family-housing typology (red – boundary of studied morphological unit, blue – buildings, yellow and grey - private and public traffic surfaces, green – private gardens).

The analyses of the level that each studied case meets the requirements of these criteria as set in the local spatial development plans had were done by on-line or physical review of these plans.

2.3. Results of analytical step

As shown in the Table 1 below, the share of the type of surfaces greatly varies depending on the land use and the building typology. In the majority of non-housing typologies, the greatest share goes to sealed open spaces, with the exception of schools, kindergartens and family farming where the greatest share goes to unsealed open spaces. The unsealed open spaces are unsurprisingly also the most common type of surfaces within all building plots dedicated to housing typologies.

Table 1 The share between the built-up surfaces, sealed open spaces and unsealed open spaces for different land-use and building typologies

Type of surface:		Built-up surfaces (%)	Sealed open space (%)	Unsealed open space (%)
Land use / Building typology:*				
Trade	Shopping centres	35	50	15
	Local shops	26	54	20
Public services	Mixed use	29	56	15
	Fire-brigade	27	42	31
	School	23	15	62
	Kindergarten	25	18	57
	Healthcare centre	25	38	37
Production	Industry	40	43	17
	Small production and warehousing	36	47	17
	Large scale farming	28	39	33
	Family farms within settlements	22	16	62
	Remote family farms	18	24	58
Housing	Deteched houses	21	14	65
	Semi-deteched houses	29	9	62
	Row houses	31	14	55
	Smaller blocks of flats	20	28	52
	Large-scale housing	24	28	48

** For each land use and related building typology many concrete case-studies were analysed, the table shows the average values.*

These results show that some types of building plots have greater ability to sink the rainfall water directly into the ground then the others - in Slovenian case among the types shown in Table 1 the following have the highest ability: detached houses, semi-detached houses, schools and family farms within settlements. While the lowest ability has been detected mainly among the production-related typologies, such as industry, large scale farming, small scale production and warehousing.

The study also showed that in some studied cases the demands set in the local spatial development plans were not met. Out of all 246 studied cases, in 15 cases the footprint index was exceeded, in 21 cases the floorspace index was exceeded, in 13 cases the green-space index was exceeded and in 10 cases the open-living-area index was exceeded. The size of the building plot was exceeded in 16 cases, while the heights of the buildings were exceeded in 13 cases.

3. New approach to the building plots regulation in Slovenia

3.1. Methodological framework

Based on the results of the analytical phase and in accordance with the project brief, the second part of the project dealt with the development of the new regulation of the

organisation of the building plots in Slovenia. The main goal of such an endeavour was to improve the capacity of the urbanised areas to sink the water directly into the grounds by leaving appropriate amount of building plot's surface unsealed. At the same time, it was equally important to bear in mind the functional demands of each building type - to provide enough appropriate surfaces that allow the functioning of each building type, e.g. allowing enough open paved surfaces for the motorised traffic manipulation around warehousing etc.

One of not many Slovenian studies of the relation between the climatic conditions and the morphological patterns in the cities revealed that "the key parameters with the cooling effect are: green areas and their placement and the lack of traffic areas, particularly stationary traffic (i.e., parking)" (Fikfak, 2017, p. 18/20). The own analyses of the research team showed that while the built-up surfaces of the building plots stay within the very comparable limits (between 18% and 40% of the total surface of the building plot, as shown in Table 1) there are greater differences when it comes to the share of (un)sealed surfaces of the open spaces within the building plot: the sealed vary from as low as 14% up to 56%, while unsealed from 15% to 65%.

All these insights directed the project team into rethinking of the existing system that defines the organisation of the building plots. It is based on the distinction between the built-up and open space within the building plot, while there is a need to clearly define also the relation between the sealed and unsealed surface.

A new model was therefor based on the distinction between these two basic categories:

- the sealed area (in Slovenian: *neprekriti del*). The built-up area and all paved open spaces account into this category. The decisive criterion is that within sealed area the water cannot freely penetrate into the soils;
- the unsealed area (in Slovenian: *raščen teren*). The green spaces without underground construction account into this category. The decisive criterion is that within unsealed area the water can freely penetrate into the soils.

As shown in Figure 2 the category of sealed area is then subdivided further into the 1st sealed open space dedicated to motorised traffic, and 2nd sealed open space not dedicated to motorised traffic and 3rd the built-up area. While the category of unsealed area includes the green areas only in the part where there is no underground construction which would block the water enter the soils (e.g. cellars etc.). The open living area (marked with dashed grey line in Figure 2) extends across both new basic categories – it includes the unsealed surfaces in total while only a part of the sealed surface (the one that does not hold motorised traffic) – keeping this category as a part of the new system too was seen as important to continue the legacy of the existing system where the open-living-area index was introduced to assure enough surfaces for the non-motorised users of the open spaces surrounding the buildings.

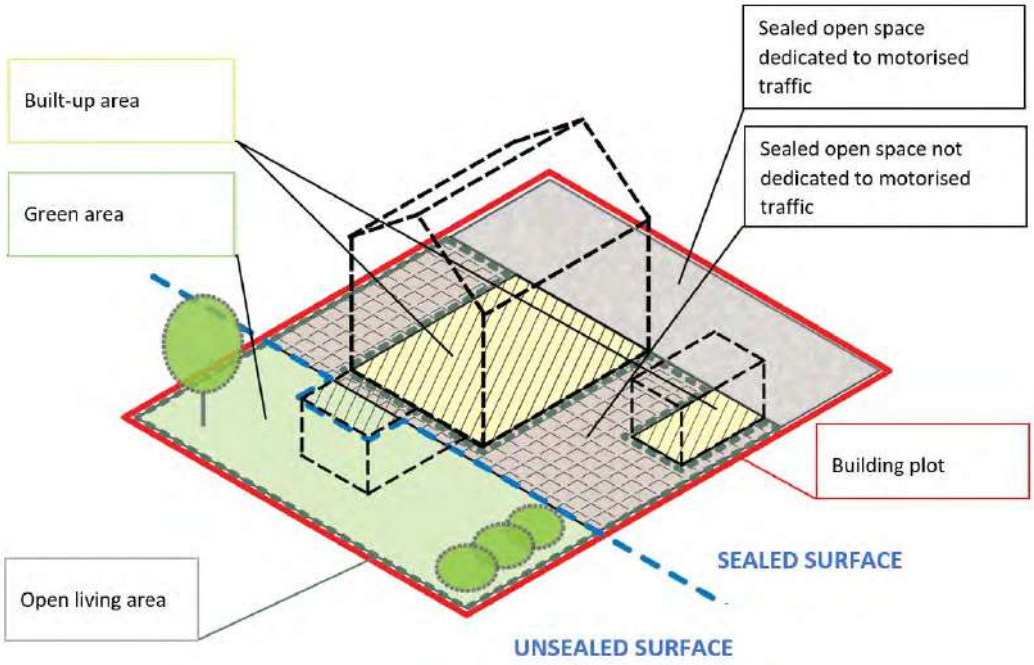

Figure 2 The organisation of the building plot into two basic categories (sealed surface and unsealed surface) with sub-categories

In order to regulate the permitted percentage of the sealed surface within the building plot, a new urban planning index was introduced: sealed surface index (in Slovene: *faktor prekritih površin* – FPP), which defines the maximum percentage of the sealed surfaces and must not be exceeded.

3.2. Defining the building plot regulation by types

In order to achieve the appropriate extent of the unsealed surfaces in practice, each of the building plot types (reflecting the land use and its building typology as shown in Table 1) had to be defined by the percentage each of the categories defined in Figure 2 can cover. As shown in Figure 3 four aspects were defined for each of the land uses and related building typologies:

- A) the percentage of built-up area (maximum allowed),
- B) the percentage of sealed open space dedicated to motorised traffic (maximum allowed),
- C) the percentage of sealed open space not dedicated to motorised traffic (minimum required),
- D) and the percentage of unsealed surface (minimum required).

Nevertheless, the land use and related building typology could not be the only decisive factor. In some cases, it was important to consider the location of the building plot within the urbanised area. Many Slovenian cities follow the policy of densification of the urban areas nowadays in order to avoid the greenfield developments (Cotič et al, 2017). Therefor for those housing typologies that can appear in both densely built up as well as in the more suburban (lower densities) zones this distinction has been made. Similarly, the distinction between the farmhouses within the settlements and the farm houses standing alone in the

landscapes was made in the new system too. In some cases (see Shopping centres in Table 2) it was also defined how much of the unsealed area must be defined in one larger piece (and not scattered around in many smaller pieces).

Table 2 The share between the built-up, sealed and unsealed surfaces within the building plot for different land land-use and building typologies, as proposed for the new Slovenian National spatial order

	Built-up area	Sealed surfaces		Unsealed surfaces
		For motorised traffic	Not for motorised traffic	
	Max (%)	Max (%)	Min (%)	Min (%)
Housing				
Detached houses	central: **40** non-central: **30**	central: **20** non-central: **30**		**40**
Villas	**20**	**20**		**60**
Semi-detached houses	central: **40** non-central: **35**	central: **30** non-central: **35**		**30**
Row houses	**50**	**20**	**10**	**20**
Smaller blocks of flats	central: **40** non-central: **35**	**25**	**15**	central: **20** non-central: **25**
Large housing estates	**35**	**20**	**15**	**30**
Public services				
Kindergartens	**30**	**20**	**15**	**35**
Schools	**30**	**20**	**15**	**35**
Healthcare centres	**50**	**25**	**5**	**20**
Trade				
Smaller local shops	**50**	**15**	**5**	**30**
Larger local shops	**40**	**30**	**10**	**20**
Shopping centres	**40**	**20**	**10**	**30** (out of which at least 50% in one unit)
Agriculture				
Farms	within settlement: **50** out of settlement: **60**	within settlement: **30** out of settlement: **20**		within settlement: **20** out of settlement: **20**
Production				
Industry and warehousing	**60**	**25**		**15**

4. Soil sealing as one of the considerations in building plots organisation

Soil sealing is however only one aspect of the organisation of the building plots and may not stay the only one if the high-quality urban environments are to be achieved. Therefor the proposed new regulation addressed some other aspects of the plot organisation too.

4.1. Integration of soil sealing measures and urban design measures

To make a clear guidance for the future decision makers at the local levels of spatial planning in Slovenia (local authorities, local planning offices, urban planning bureaus etc.) the guidance has been prepared in a form of the Manual (Nikšič et al, 2019). The introductory pages give some general approaches to the organisation of the building plots, such as explain main terminology and definitions, list the general objectives of building plot organisation (functioning of the building, environmental footprint, relation to the existing context, sanitary and technical requirements and above all the assurance of quality living standards), and then explains the division of the building plot into two main categories (sealed and unsealed surface) and their sub-categories. As shown in Figure 3, the requirements for the organisation of the building plot for each of the building typologies is presented in a textual and graphical manner.

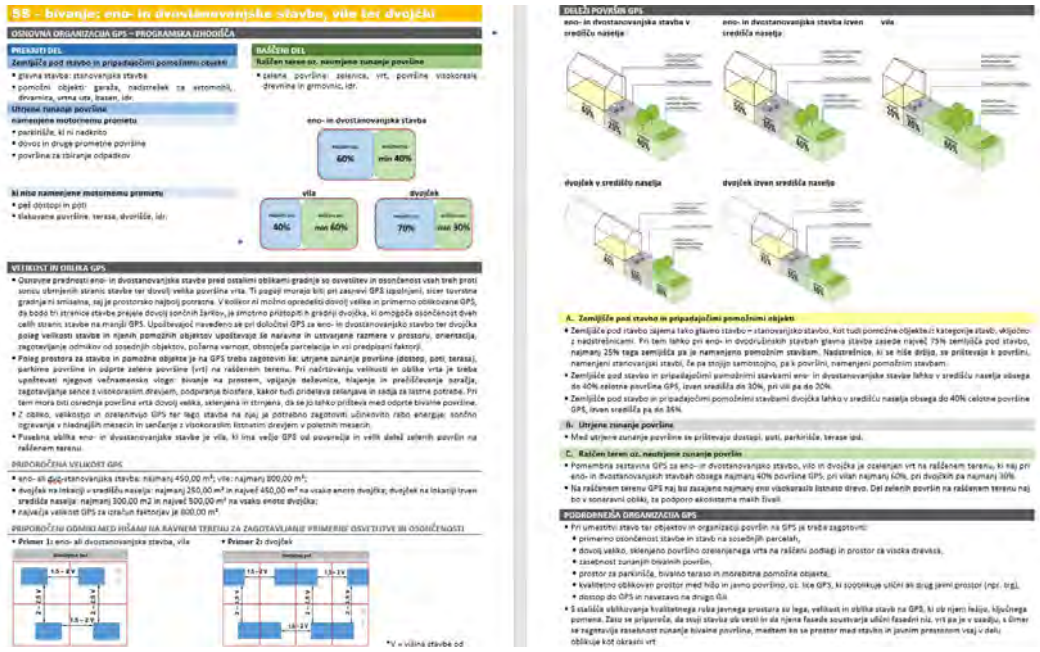

Figure 3 An example of the textual and graphical guidance for the organisation of a building plot in the manual for building-plot organisation (the case of Detached housing)

4.2. Implementation issues

The preparation of the Manual is only the first step in the process of changes aiming to introduce a new practice of building plots planning in Slovenia. The important further steps must be done. Firstly, the new approach has to be translated into a legally biding form within the new National spatial order. If this will not be done and the new guidance will stay only at the level of the recommendation it is less likely that the long-term goals (i.e. the ability of plots within urbanised areas to directly sink the rainfall into the soil) will be reached. And secondly, a new approach (and Manual) has to be promoted to the decision

makers and any other potential user, preferably via short face-to-face teaching or video lectures that would explain a rational behind the new approach as well as detail the information how to use and implement the new regulation for each of the addressed typologies.

5. Concluding thoughts

The climate change with the changed precipitation patterns is forcing the city authorities, planners and other stakeholders in urban development to rethink the long-established practices of city making. One of the basic elements and tools of the regulation of the urban areas is the regulation of the building plots. As this study showed on the case of Slovenian planning system, the current approach to building-plot organisation must be reformed to address the fact that it is important to regulate the amount of the surfaces that stay unsealed – not only by regulating the footprint and open-living-area index, but also the sealed surface index. It is of a great importance to raise the awareness that the capacity of the city to sink the rainfall greatly depends on the amount of the open space that is (not) sealed. In order to rise this awareness, the combination of soft (manual, educational activities) and hard measures (translation of recommendation into a legally binding rules) must be followed.

Acknowledgments: The authors of the paper acknowledge the important contributions to the project *Manual on urban design criteria for building plots planning* (which was the base of the paper) of the following experts (abc order): Bernarda Bevc Šekoranja, Nina Bizjak Komatar, Boštjan Cotič, Simona Čeh, Bogdana Dražič, Zala Jerman, Matic Klun, Zala Koleša, Katarina Konda, Barbara Mušič, Simona Peršak Cvar, Janja Solomun and Mojca Strbad.

Case Study Paper

Embodied Carbon Emission Analysis of Industrial Sector Based on Input-Output Analysis : Case Study in Bitung City, Indonesia

Sani NURAINI, Bandung Islamic University (UNISBA), Indonesia
Imam INDRATNO, Bandung Islamic University (UNISBA), Indoensia

Abstract

Bitung has the status of Special Economic Zones (SEZ) for the field of fisheries, oil industry, and other logistical support in the eastern region of Indonesia by the Indonesian government gazette of 2014. Based on Bitung City in Figures received from the Statistics of Bitung City (BPS), the Gross Domestic Regional Product (GDRP) at current prices in Bitung City in 2017 worth 14.09 trillion Rupiah still experiencing an increase compared to 2016 worth 12.68 trillion Rupiah. The largest share of GDRP in Bitung City in 2017 was the manufacturing of 33.63 per cent. Despite the advantages, Bitung City is experienced environmental degradation, even though economic growth continued to increase. This study aims to build a model of environment-economy linkages through Input-Output (I-O) Environment and to calculate the impacts of the economic sector in Bitung City. The paper presents the conceptual and analytical framework of the Input-Output approach of the Bitung City. The I-O Model is based on the Bitung City I-O tables and the methodology developed by Wassily Leontief. The model databases use the 2017 I-O tables and data series provided by BPS. The analysis conducted leads to two main conclusions: first, three groups of key industries for the economy was identified; second, while an increase GDRP growth, it has an impact on the environment.

Keywords

Input-Output Model, Economic Growth, Carbon Emissions

1. Introduction

As the largest archipelago nation in the world, Indonesia is one of the countries that are most vulnerable to the negative impacts of climate change. Generally, the global climate change model has predicted that Indonesia will experience an increase in temperature, intensity of rainfall that will increase the risk of floods and droughts, and extended dry seasons. The impact of climate change will among others take the following forms : increased frequency of extreme climate occurrences, that affect community health and sources of living, degrade biodiversity, and instability of the economy (Ministry of National Development Planning, 2014).

Ample scientific evidence has substantiated that climate change is already occurring and felt by the entire global community. In Indonesia, the economic impact of climate change is estimated to be very significant even though it is still difficult for being accurately estimated (Indonesia Ministry of National Development Planning, 2014). Nevertheless, several studies have shown that economic losses that are directly as well as indirectly attributed to climate change in Indonesia in 2100 could reach 2.5 percent, namely four times the average global GDP loss due to climate change (The World Bank, 2010). In fact, if the probability of a disaster occurring due to climate change is also take into account then the economic losses could reach 7 percent of GDP (The World Bank, 2010).

Nowadays, Indonesia has the opportunity to improve the economy through the manufacturing industry. Consequently, Indonesia needs to anticipate the potential risks of negative impacts on the environment and natural resources (United Nations Environment Programme, 2005). As climate change becomes a reality, Indonesia continues to seek a balance between its current and future development. In 2010 the Government of Indonesia pledged to reduce emissions by 26% (41% with international support) against the business as usual scenario by 2020 (Indonesia Ministry of National Development Planning, 2014 p. 2). North Sulawesi needs to reduce emissions by 15,3% and Bitung City at least 7,3% by 2020 (Indonesia Ministry of National Development Planning, 2014 p. 128).

The manufacturing industry is a key sector in many national economies and is involved in creating sustainable economic growth (Behun et al., 2018, p. 23). At the same time, industrial processes can have negative environmental impacts, causing climate change, loss of natural resources, air and water pollution and extinction of species. These threaten the global environment as well as economic and social welfare (European Commission, 2006).

North Sulawesi is a province with it is capital Manado, has 15 regencies/cities which is divided to 11 regencies and four cities (Kristiningsih, et al., 2018, p. 7). The land areas of Bitung are 33.279,10 hectares or 2,9% out of North Sulawesi land area (Statistics of Bitung City, 2018, p. 9). Based on Government Regulation No.32/2014 on Bitung SEZ (Special Economy Zones), SEZ with the total area of 534 hectares (BPIW Kementrian PUPR, 2018, p. 7).

Figure 1 Special Economy Zones (SEZ) Bitung City
Source: Authors, 2018

Based on data from Statistics of Bitung City (BPS), Gross Domestic Regional Product (GDRP) at Current Prices in Bitung City in 2017 worth 14.09 trillion Rupiah, experiencing an increase compared to 2013 worth 9,54 trillion Rupiah (Figure 2). The largest share of GDRP according to successive business fields in Bitung City in 2017 was the Manufacturing 33.63 per cent. Bitung City is known as an industrial city and one of the largest fish producing cities in North Sulawesi (Statistics of Bitung City, 2018, p. 400).

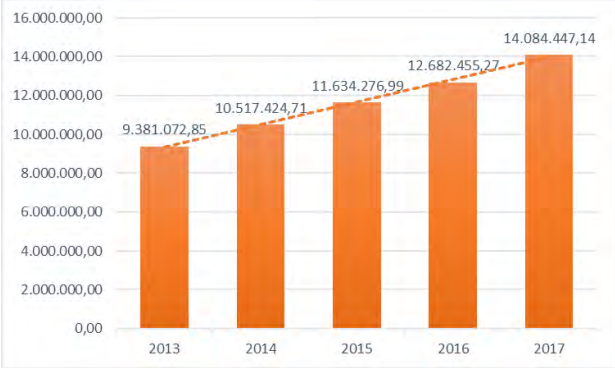

Figure 2 GDRP of Bitung City 2013-2017
Source: Statistics of Bitung City, 2018

Despite the advantages, including the purpose of establishing SEZs is to encourage and enhance internal competitiveness, growth, job creation, and foreign exchange earnings. SEZs have a mixed record. Moreover, SEZs today operate in an ever more challenging environment. However, based on data received from the World Input-Output Data (WIOD) in 2017, three biggest sectors have an impact on emissions to the environment in Bitung City, which: manufacturing sector, agriculture, forestry and fishing sector, and the transportation and storage sector. The three sectors show the condition of the last 3 years in Bitung City has decreased from 2015 to 2017 about 8.58 per cent. Means, that experienced environmental degradation, even though economic growth continued to increase.

This study aims to build a model of environment-economy linkages through Input-Output (I-O) Environment and to calculate the impacts of the economic sector in Bitung City.In Section 2, the findings are presented and discussed in relation to relevant GHG and green economy theory, to assess the necessity of information resources for a pro-active approach to gas emission in the industrial sector. Section 3, data and methodologies. Section 4, the main findings of the study. Then Section 5, summarised the study and gave some recommendations.

2. Literature review

2.1. National Action Plan for Green House Gas Emission Reduction

The National Action Plan for Green House Gas Reduction (RAN-GRK) is a follow up from the Indonesian commitment to dealing with climate change issues. To follow up the GHG emission reduction commitment, the RAN-GRK was developed to provide a policy framework for the central government, local governments, prívate sectors, and other key stakeholders in implementing actions related directly and indirectly to GHG emission reduction efforts during the period of 2010-2020 according to the Long-Term Development Plan (RPJP 2005-2025) and the Mid-Term Development Plan (RPJM). The RAN-GRK was approved in a Presidential Regulation No. 61 Year 2011.

The RAN-GRK proposes mitigation actions in five priority sectors (Agriculture, Forestry and Peatland, Energy and Transport, Industry, Waste Management) as well as other supporting actions that are an integral part to the national development planning which supports the principles of economic growth, poverty alleviation and sustainable development (Thamrin, et al., 2011)

2.2. Green Economy

The industrial revolutions that have unfolded across different world regions since the end of the C18th liberated economic growth by unlocking and harnessing vast reserves of fossil energy. They freed millions of people from laboring on the land, produced the conditions for the growth of cities, and fueled the growth in welfare and well-being experienced the world over. There were many social costs as well, and societies have found responses to these such as the rise of social security provisions from taxation.

There have also been deep-seated environmental costs of industrialization which have been revealed through science, piece-by-piece. Brown, gray, and green environmental problems, related to local pollution, and later to nature protection and global issues like ozone depletion and climate change, have emerged as prominent issues in parallel with industrializations across different regions and countries.

The green economy is not about maximizing production or consumption. It is about improving the well-being of individuals in an environmentally-friendly and sustainable manner. Therefore, the way we measure progress in a green economy is critical to the success of transforming societies towards a green economy. The present indicator used to measure progress, the gross domestic product (GDP), which measures an economies products and services, is ill-suited for the purpose (IHDP, 2012)

2.3. The Green Industrial Policy Turn

Green Industrial Policy can provide an instrument to facilitate structural change and accelerate a country's transition towards an Inclusive Green Economy. Green industrial policy tools can be broadly understood as 'sector-targeted policies that affect the economic production structure with the aim of generating environmental benefits (World Bank, 2013). A green industrial policy is therefore 'an industrial policy that is meant to trigger and facilitate structural changes as entailed, or required, both to respond to environmental conditions or situations, and to develop a green, circular economy (UNIDO, 2016)

3. Methodology

Before outlining the methodologies for analyzing the input-output matrices used in the study, let us first introduce the data and a few useful notations that will help us present the intuitions behind each methodology.

BIMINDO is the center of economic growth in the North Sulawesi Province and has huge potential in the maritime, fisheries, agriculture and tourism sectors. Metropolitan BIMINDO (Bitung-Minahasa Utara-Manado) has the potential to build a low-carbon city and resilience to climate change. Bimindo is the center of economic growth in the maritime industry, urban economics through Bitung SEZ. Bitung as SEZ based on Government Regulation No.32/2014, can support the development of ports and supporting infrastructure, development of commodity export and import, and human resource capacity building. Bitung's rapid urbanization is increasing pressure on the physical environment not only in terms of population increases, but also in the economy, including the fishing industry (ICCTF, 2018, p. 2).

In introduction, there is a statement that Bitung's economic development reduce environmental quality, as understood that economic development is spread across various

sectors. Each sector has a different production technology and it produces a difference in the amount of environmental impact. Differences in the types and quantities of inputs and technologies used by each economic sector and have different impacts on the environment. therefore it needs to be identified, which sector has a large impact and which sector has a small impact on the environment? Economic and environmental activities show a systematic relationship, economic involves the production, distribution, and consumption that is accommodated by the environment, thus raising questions about how to analyze economic linkages with the environment.

3.1. Data Sources

The data used are based on the Gross Domestic Regional Product (GDRP) of Bitung City 2017, the input-output tables of North Sulawesi Province 2014, which were published in 2014 respectively. The main data sources are the 2014 input-output tables of North Sulawesi Province. These tables are published by Statistics of North Sulawesi Province (BPS – Badan Pusat Statistik). We use Indonesia's sectoral energy use by energy commodity is collected from the World Input-Output Database (WIOD).

3.2. Methods

The methodological approach in this study is to use the input-output approach of analysis. Now input-output methods are usually used to calculate the energy consumption and can be easily applied to all sectors regardless of the length and complexity of their production process.

The table for the year 2014 built by the researcher depending on the actual data, while the table for the year 2017 built by the researcher by updating the 2014 table using the RAS method. According to Indonesia's standard industrial classification system, we aggregated the North Sulawesi Province input-output tables into 17 sectors to satisfy the study efficiency.

Input-Output Fundamentals

The basic Leontief input-output model is generally constructed from observed economic data for a specific geographic region (nation, state, county, etc.), concerning the activity of a group of industries that both produce goods (outputs) and consume goods from other industries (inputs) in the process of producing each industry's own output – interindustry consumption. The data required to fulfil the input-output model consists in flows of products from each of the producing sectors to each of the purchasing sectors. These interindustry flows (or intersectoral) are measured for a particular period (usually a year) and in monetary terms. Basically, an input-output model consists of three basic tables, which are analysed in the following sections: the transaction or flow table, the technical coefficients table and the direct requirements table (Alexandra, 2001, p. 9).

Technical Coefficients Table

The technical coefficients show the value of inputs purchased from all sectors in the economy per monetary unit of output in a particular sector, in other words, they show the production function for each production sector. For instance, for a given sector A, technical coefficients represent the value of purchases from each sector in the economy that must be made by the sector A in order for it to produce one monetary unit worth of output. Therefore, technical coefficients can be derived by dividing all entries in each sector's column by the total outlay of that sector. If, from the transaction table, x_{ij} symbolise the value of sales from sector i to sector j and x_j the total output of sector j, the technical

coefficients (described by the symbol a_{ij}) for each sector are calculated using the following equation (Alexandra, 2001, p. 12) :

$$a_{ij} = \frac{X_{ij}}{X_i}$$

With this table for the economy as a whole, it is possible to calculate the secondary demand on the output of the industries that supply a specific industry's suppliers and so on through successive outputs until the effect of the final demand has been traced (Miller & Blair, 2009). The effect of an event at any point is transmitted to the rest of the economy step by step via the chain of transactions that links the whole system together.

Backward Linkages

Backwards linkages measured by using coefficient matrices (A), it is summation of the elements of the column for the target sector (Osama et al., 2013, p. 36), by using the data of I-O of the Bitung economic we have been reached results as shown in table 1.

$$BL(d)_j = \sum_i^n a_{ij}$$

In its simplest form, a measure of the strength of the backward linkage of sector *j*– the amount by which sector *j* production depends on interindustry inputs – is given by the sum of the elements in the *j*th column of the direct input coefficients matrix $\sum_i^n a_{ij}$. Since the coefficients in A are measures of direct effects only, this is called the direct backward linkage (Miller & Blair, 2009, p. 556)

Forward Linkages

The focal idea for forwarding linkages is to study the impact of increased output that occurs or may occur in the used sectors when there is a change in its provider sector of production inputs. (Osama et al., 2013, p. 37). Where $FL(d)_i$: the ration of intermediate demand to total demand X_i for a particular sector.

$$FL(d)_i = \sum_j^n \frac{X_{ij}}{x_j} = \sum_j a_{ij}$$

Also it measures the impact of forward linkages sectors dependency to other sectors when production of this sector is used as inputs production in other sectors, high impact of these linkages to a particular sector that includes the expansion in this sector will generate the power stimulate all sectors to enlargement. In other words, the impact of forward linkages happens when particular sector products used as inputs in production one sector or more from other sectors which generate an incentive to do new activity or increase production for specific sector which means these linkages stimulate new investment through creation excess supply (Zahran, 1968).

Environmental Input-Output Analysis

A straightforward approach to calculate pollution generation is by using generalised input-output analysis Assume a matrix of poluution output or direct impact coefficients, which here is called D^p, and $D^p = [d_{kj}^p]$. The elements of this matrix are the amount of pollutant abatement per dollars' worth of industry. Meanwhile, we have a vector of total outputs, which we call X^{p*}. The level of pollution associated with the total output can be seen as :

$$x^{p*} = [D^p(1 - A)^{-1}]\, f$$

Forcesting

Exponential smoothing (ETS) methods are the most widely used forecasting methods. ETS an intuitive forecasting method that weights the observed time series unequally (Ostertag & Ostertagova, 2012, p. 62). Forecasting methods are used to produce emissions data in 2017. The data available from the World Input-Output Data (WIOD) is until 2009. Specifically in this study using *forecasting.ets* using the latest version, AAA from the ETS algorithm in Excel on the Ms.office 2016 formula as follows:

xlfn.FORECAST.ETS (x,Known_Y's, Known_X's, 1, 1)

Information :
x = Year used
Y's = Data range (value)
X's = Data range (Year)

Simulation

A simulation is an approximate imitation of the operation of a process or system (Banks, et al., 2010). The simulation used in this study aims to assume a model scenario. The scenario assumes an increase in GDRP for 17 sectors simultaneously. It can be seen as :

$$\Delta X = \frac{1}{(1 - A)^{-1}} \Delta Y$$

ΔY = $\Delta Y_{2016}.trend\ Y_{2010-2016}$

Where *ΔX* shows changes in economic output and *ΔY* indicates changes in final demand.

$$\Delta D = \Delta X.\frac{E_i}{TI_i}$$

Information :
ΔX = Output of all sectors
ΔY = Final request
ΔD = Impact of emissions
E_i = Emissions in sector i
TI_i = Total Input in sector i

4. Results

4.1. Linkages Analysis

The result of the study show that between economic sectors in Bitung City are related to one sector on other sectors. The result of the study, show that between economic sectors in the Bitung City are related to each other. The linkages analysis is to identify "key" or "leading" sectors in that economy (those sectors that are most connected and therefore, in some sense, most "important") in Bitung City. Means, if there is an increase in the final demand in a sector is one rupiah, it will cause of increased final demand in all sectors is one rupiah.

Backward Linkage (BL)

The main suppliers of inputs are business activities sector (0.0588), electricity and gas sector (0.0486), and the manufacturing sector (0.0401). Highest backward spread index is business activities sector (1.4929), accommodation and food service activities sector (1.2218), and electricity and gas sector (1.2018), table 1. Means, if spread index (α>1) is an indication that

the sectors have the ability to develop other sectors as a provider of inputs for the production activities in the sector.

Sector	BL	Index
Agriculture, Forestry, and Fishing	0.0134	0.6710
Mining and Quarrying	0.0116	0.6740
Manufacturing	0.0401	1.1482
Electricity and Gas	0.0486	1.2018
Water supply, Sewerage, Waste Management and Remediation Activities	0.0288	0.9655
Construction	0.0398	1.1830
Wholesale and Retail Trade; Repair of Motor Vehicles and Motorcycles	0.0258	0.9119
Transportation and Storage	0.0366	1.1904
Accommodation and Food Service Activities	0.0396	1.2218
Information and Communication	0.0191	0.8187
Financial and Insurance Activities	0.0335	1.0807
Real Estate Activities	0.0097	0.6683
Business Activities	0.0588	1.4929
Public Administration	0.0227	0.9026
Defence and Compulsory Social Security	0.0240	0.8839
Human Health and Social Work Activities	0.0356	1.1109
Othe Services Activities	0.0237	0.8746

Table 1 Backward Linkage of Bitung City
Source: Input-output tables of Bitung City, Updating 2017, the results of data processing

Forward Linkage

In table 2 In table 2 shows that the highest of forward linkage is manufacturing sector is equal to 0.1267 this figure means that if there is an increase in the output by one unit then output these sectors will provide additional output in other sectors amounted to 0.1267. Means that the output manufacturing sector is widely consumed and used as inputs for production activities in other production sectors.

Highest forward linkages are manufacturing (0.1267), wholesale and retail trade sector (0.0736), and transportation and storage (0.0591). Highest forward spread index are manufacturing sector (2.8484), wholesale and retail trade sector (1.8257), and agriculture, forestry, and fishing sector (1.7424), table 2. Means, if the spread index forward linkages to more than one (β>1), it indicates that the sector has the power thrust against other sectors. Improvement on the output produced will greatly affect the production process of other sectors. However, if the index is less than 1, which mean the sector is less able to provide a thrust force in the production process of other sector.

Sector	FL	Index
Agriculture, Forestry, and Fishing	0.0554	1.7424
Mining and Quarrying	0.0062	0.5720
Manufacturing	0.1267	2.8484
Electricity and Gas	0.0043	0.5332

Water supply, Sewerage, Waste Management and Remediation Activities	0.0002	0.4934
Construction	0.0315	0.9237
Wholesale and Retail Trade; Repair of Motor Vehicles and Motorcycles	0.0736	1.8257

Source: Input-output tables of Bitung City, Updating 2017, the results of data processing

4.2. Multiplier Effects

A multiplier coefficient measures the increase in the total output of the economy in response to one unit of the initial increase in final demand in industry. If a one rupiah initial increase in the final demand of a given industry induces a three rupiah increase in the total output of the economy, then the output multiplier is three.

The result shows that the impact (multiplier) have an influence on the development of the economic sector in Bitung City. Based on the results, the three sectors have the highest multiplier value, including : business activities sector (3.0532), accommodation and food service activities sector (2.4988), and electricity and gas sector (2.4580). These three sectors have the ability or potential to increase GRDP.

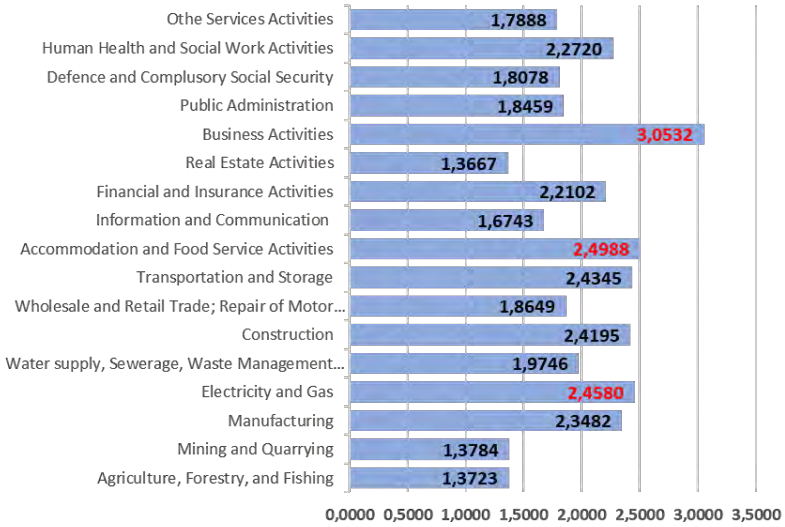

Figure 3 Multiplier Effect Input-Output Table of Bitung City, Updating 2017.
Source: Input-output tables of Bitung City, Updating 2017, the results of data processing

4.3. Simulation Results

Input-output simulation : when the economy rises considering changes in the final demand of 17 sectors. The simulation is shown, the economy rises considering changes in the final demand of 17 sectors, and the increase in GRDP is assumed by calculating the GRDP per sector over the past five years.

Simultaneous change of 17 sectors can increase GRDP worth 1 760 110 million rupiah. The amount equals the GDRP growth is 13.37 percent. Simultaneous changes in 17 sectors that have an impact on the environment, in addition to increasing GDRP growth rate, the influence of the 17 sectors increased the emissions of 3 109 million tons. The amount is 6.43 percent.

Sector	GRDP			
	GRDP	Shock	Million Rp	Percent
Agriculture, Forestry, and Fishing	2.769.194	115.254	269.687	9,74

5. Conclusions

The paper presents the conceptual and analytical framework of the Input-Output approach to Bitung City. The model uses annual Input-Output (I-O) tables, support estimation equations for technical coefficients, macro indicators and other variables. The I-O Model is based on the Bitung City I-O tables and the methodology developed by Wassily Leontief. The Model databases uses the 2017 I-O tables and data series provided by Statistics of Bitung City (BPS) for 58 sectors of the economy, which are aggregated into seventeen sectors.

Hence, this study firstly explores by using forward and backward linkages methods, we have identified three groups of key industries for the economy : (i) business activities sector (0.0588), electricity and gas sector (0.0486), and manufacturing sector (0.0401); and (ii) manufacturing (0.1267), wholesale and retail trade sector (0.0736), and transportation and storage (0.0591). Results show that the production of manufacturing sectors does have a strong capacity to stimulate the domestic economy. Then, Multiplier effects three sectors have the ability or potential to increase GRDP, which : business activities sector, accommodation and food service activities sector, and electricity and gas sector.

Based on simulation results show that the environmental impact from economic growth, considering changes in final demand of 17 sectors in Bitung City. The simultaneous change of 17 sectors can increase GDRP worth 1 760 110 million rupiah. The amount equals the GDRP growth is 13.37 percent. It has an impact on the environment which increased the emissions of 3 109 million tons. Particularly manufactuing sector, we found that while an increase GDRP growth in the manufacturing sector, at the same time it has an impact on the environment which increased the emission is 27,16 percent.

Case Study / Project

An assessment and delineation of Socio-economic Resilience Landscapes of the Region

based on the inherent latent factors of vulnerabilities

Shivangi Singh PARMAR, Joy SEN, Arkopal GOSWAMI

Abstract

In this era of climate change and rapid urbanization, it is important to understand the metabolism of the regional system to achieve socio-economic resilience. The concept of socio-economic resilience of the region is used to refer the capacity of systems of the region to absorb or adapt shock and vulnerabilities. Broadly, the overall socio-economic resilience of the system is affected by sudden external shocks and inherent latent weak conditions. Latent weak conditions slowly make the regional system weak and more susceptible to vulnerabilities. It is difficult to directly observe the latent factors of socio-economic resilience since these constructs are unobserved or hidden. However, the possible method of measuring the latent factors of socio-economic resilience have been done from the data collected on related variables that can be directly observed and measured. The development of sustainable cities and region by providing a socio-economic resilience measurement framework in terms of latent factors of vulnerability and dimensions of resilience could be the major contribution of the study and it will aid policy-makers in the planning of socio-economically resilient region. The following paper focuses on the determination of factors of the inherent latent weak conditions of socio-economic vulnerabilities and their relationships.

The main objective of the paper is to assess socio-economic resilience based on the interrelationship between the levels of vulnerability of susceptible regions and indicators of socio-economic resilience. In the first part of the study, identification and extraction of the determining factors have been done in following two categories äóñ adaptive capacity and sensitivity factors, followed by the study of principal components and dispersion analysis of following two categories. Then in the second part of the study, income-inequality measurement and nesting-shift-share analysis of the susceptible regions has been done to understand the income and employment scenario of the 19 districts of West Bengal, India. Using extracted secondary data, under the two category, factors were determined and its nesting is analyzed in the following 19 districts of West Bengal, India to assess the interrelationships of levels of vulnerability and indicators of socio-economic resilience. Later using GIS, Temporal analysis has been done to visualize the spatial relationships of levels of vulnerability and Socio-economic Resilience. Delineation of levels of socio-economic vulnerability of the region based on inherent latent weak factors of socio-economic vulnerabilities would give a platform to policy-makers for a better understanding of the metabolism of the region through identified latent weak areas contributing to the susceptibility to vulnerabilities of the region.

Case Study / Project

Identifying climate resilience challenges in Vietnamese cities.

Case studies of Can Tho and Da Nang

Thai Son PHAM

Abstract

This paper aims to identify and discuss major issues regarding urban climate resilience in urban areas in Vietnam, through an investigation on the Can Tho and Da Nang, two medium-size cities located in the Southwest and Centre regions of the country. It starts with a short introduction on the concept and framework of urban resilience and a quick investigation on the understanding and application of the concept in the context of Vietnam. After that, using official figures sources from the technical departments and Climate Change Office of the two cities, the paper comparatively points out the urban resilience challenges coming from natural conditions, urbanization patterns, climate change related conditions and risks of the two cities. Subsequently, data collected from the direct observation, interviews and consultation with various stakeholders in Can Tho and Da Nang, including experts working for organizations, technical departments, districts and wards as well as selected residents from vulnerable areas, show that resilience capacity of the two cities is still limited with weak coordination mechanism and plans, uncomprehensive understanding of risks due to the absence of data and empirical analysis and lack of financial resources. Besides, although being the main beneficiary of development projects, the participation of citizens is limited, and community resilience are not sufficiently addressed and promptly guided. To address the resilience issues above, in the conclusion some policy implications for Vietnamese cities will be discussed and prospective research directions on resilience topic in Vietnam will be proposed.

Case Study Paper

Role of Women Self Help Groups in Disaster Resilience and Livelihood Regeneration: Post Flood Experience from Kerala

Dr. Priyanjali Prabhakaran, Associate Professor, CET, India
Prof. Suja Kartha, Professor, MCAP, India

Abstract

The Indian state of Kerala witnessed one of the worst floods in nearly a century in August 2018. More than 400 lives were lost and more than a million persons had to move to relief camps. The government and the civic society together overcame the disaster with great effort. The disaster management plans in place required a revisit and a rethink. A study of the revival efforts of one of the worst affected villages was conducted in September 2018. The study pointed out the need for a detailed spatial plan for disaster resilience, and recovery. Also it showed the power of women self help groups in mitigating the effects on flood and reconstructing their livelihood. The case of a severely affected village is examined. The methods used include, sectoral studies, observation and interviews. The village's experience in facing and mitigating the floods gives rise to the need for a spatial planning strategy to address the disaster during its occurrence and the recovery to be followed. Critical infrastructure were affected during the floods, parts of the major connecting roads (State highways) were submerged in water, closing evacuation routes. Many Agricultural and fishing farms were submerged in addition to a lot of houses. Many small scale traders lost everything they had. After the flood waters receded many roads including major state highways could be used with minor repair. Women self help groups called "Kudumbasree" units came forward to restart cooperative farming in the paddy, plantain and fish farms with the help of agriculture department of the state government. The floods proved to be devastating. However normal life could restart with great effort. If the village had a proper plan in place to discourage building activity in flood plains and a recovery plan in place the extent of damages could be reduced. Living under the threat of more floods and droughts expected in near future, this study proposes a resilience action plan using the social capital of women self help groups.

Keywords

Flood Resilience, Livelihood Regeneration, Women Self Help Groups, Gender Mainstreaming

This paper is part of a larger study of flood resilience conducted at College of Engineering Trivandrum. The authors wish to express their gratitude to the 2017-19 batch of M.Planning (Housing) students

1. Flood Resilience

Many studies have predicted more floods and droughts in many regions of the world in the context of climate change. The frequency of occurrence of floods and related climate hazards is likely to increase in near future. Large scale land use conversion and increase in anthropogenic activities lead to greater risks during disasters. Kerala experienced the worst

flood in last 94 years, in August 2018, often compared to the devastating floods of 1924. The flood has left many lessons of to be learnt for planners and disaster management experts. Even with all disaster management and risk zonation plans in place Kerala had to suffer the effect of flood leaving deep marks in the physical and social fabric. The highly literate community of Kerala rose to the occasion and took the lead role in rescue, relief and rebuild activities.

Kerala the southernmost state of India is often classified as an Extended Metropolitan Region- An area of 38863 square kilometres with 44 rivers and 590 km of coastline showing widespread urban characteristics. According to Disaster management plan of Kerala, 14.52% of the state is vulnerable to floods. Flooding during Monsoon and drought during summer is being witnessed more frequently in recent years. Many attribute this to widespread land use conversion including reclaiming of paddy and wetlands for dry crops and building activities. Flood resilience is the ability of a community to face a hazard and come back to normal life with minimum damage. A proper management plan can aid the community to get to safe place, cause minimum damage to assets and to recover to normal life in a short span of time.

2. Community participation in risk reduction

Local community can play a vital role in disaster risk reduction and mitigation. Community is the first responder at the time of a disaster. Community level capacity building can reduce the vulnerabilities and increase resilience. Community can play a great role in rescue, rehabilitation and mitigation phase. However it requires coordinated efforts and proper leadership to put a preparedness plan in place.

While flood waters started rising in Kerala, the community was the first to respond. Fisherfolk who are skilled in dealing with deep waters came forward with their boats and started rescuing the stranded people. In addition to the relief camps opened by the state administration, private persons, families, NGOs, and religious organizations also came forward to start relief camps. The youth, especially students came forward to volunteer work in the relief camps. Relief materials were collected from all over the state and truck loads of relief materials were transported to relief camps.

Community volunteering should be utilised with a proper plan so as to ensure that relief material and personnel reach all shelters. In many cases inaccessibility caused delay in receiving relief materials.

A major hurdle faced by relief workers was the reluctance of affected people to shift to relief camps. A lot of persuasion was required for convincing the people to move to relief camps.

2.1. Flooding in Karumalloor

Karumalloor is a village under the jurisdiction of a “Village Panchayath” (the smallest self governance unit in a three tire system). The elected Governing Body of the Village Panchayath is responsible for ensuring people participation in all aspects of Planning. 50% of the elected representatives are women. The village has an area of 21.05 Sq. Km. and a population of 36,078 as per Census 2011. The northern boundary of the village is the river

Periyar, the longest river in Kerala which flows from the Western Ghats on the East towards the Arabian Sea on the west. Majority of the population is depended on agriculture. Paddy is a major crop cultivated here. Vegetables, plantain and some dry crops are also cultivated.

Figure: Immediate context of Karumalloor Village

Paddy was a major crop cultivated all over Kerala. In the past three decades this has drastically reduced due to the increasing cost of Labour. Largescale paddy field reclamation has resulted in ground water depletion and more surface runoff. In Karumalloor many women self help groups have started paddy cultivation on leased fields. This new initiative has increased paddy production and curtailed wetland reclamation. Kerala Paddy and Wetland conservation act (2008) prohibits reclamation of paddy fields.

In August 2018, excessive rain and poor reservoir management resulted in the river overflowing into the paddy fields and most of the low lying area. Water has risen upto 10-11 m from the riverbed. Many houses and roads also were submerged. Even critical infrastructure, like roads and bridges, community health centre and Village Panchayath office were also flooded.

Housing

The village has 13,928 houses as per the development report of the Panchayat (2017). Since the village is near the town Aluva, the development pressure has resulted in many apartments buildings being built near the river bank. Some of these apartments were submerged upto two storeyes during the floods.

There are 19 low income housing areas (housing colonies) in the village. These housing units are mostly government funded within 150-200 Sq. m. Plots. Many of the housing colonies are located in low lying land as land value is low in these areas. 80% of these houses were affected by floods and had to be relocated to relief camps. There were 7 relief camps which were opened in five schools, one college and one church.

50% of the population depended on tapped water from treated source for drinking water and another of 29% on uncovered well. Both the local water supply sources and wells were s largely affected and contaminated by flood waters. Solid waste management also was a major issue after the flood waters receded. Most of the households had cattle and poultry,

only a part of which could be rescued during floods. Post floods', removing the carcases of cattle was a major task. The Panchayath with the help of local community carried out it properly. Timely removal and disposal could prevent major outbreak of diseases. However burning was considered as an effective method which resulted in atmospheric pollution.

3. Women self help groups in Kerala

"Kudumbashree" is a major network of women self help groups all over the state. Started in 1997, it is considered as a major poverty alleviation scheme in the state. The self help groups are active in many areas of self employment starting from small scale production, marketing, waste management, provision of domestic services and farming. State government initiatives have helped to provide low interest loans to the groups as capital. It has resulted in increasing female workforce participation among rural and urban poor and better living condition.

Karumalloor village also had a strong network of Kudumbashree groups. They were active in paddy cultivation, poultry and cattle rearing, fish farming, small scale high tech farming etc. Floods damaged many of their assets and affected their operation.

4. Kudumbashree and Livelihood restoration

4.1. Subheading 3.1

With the active participation of community and state agriculture department, Kudumbashree has spearheaded the fast recovery of this sector. Within a month of the flood when the study was being conducted, framers had already started the next crop season. Kudumbashree groups were seen preparing farm land, transporting farming materials in small pickup vans and setting up poultry farms. Without waiting for any government agency or external aid they started their rehabilitation work.

However lack of proper insurance has increased the economic loss in both agriculture and animal husbandry. Creating more local markets can help in the development of dry cultivation.

After the flood the change in soil condition has affected the cultivation. There has also been a reduction in the water table level. The existing ponds are filled with mud and clay which has reduced the availability of water. Uncertainty of how the crop will react to the new soil condition has generated concern within the farmers.

There has also been a reduction in the milk production by the cows, This has affected the milk distribution by the societies.Also there are No compensation fixed for shed ,Feed loss and machinery damage.

Most of these Kudumbashree women come from economically weaker sections. They require small scale assistance and training to continue their livelihoods. Village level local authorities can train them in reducing the vulnerability and increasing their capacity for resilience. Local leaders from Kudumbashree could be encouraged to lead disaster

management, rescue and restoration teams. Local level planning can reduce livelihood vulnerability and help in long germ Nation Bulding.

Case Study Paper

Flood resilience planning for Disaster prone Panchayats.

A case of Karumalloor panchayat in Ernakulam District,Kerala

SUJA KARTHA, Professor, MCAP; INDIA

DR.PRIYANJALI PRABHAKAR, Associate Professor,CET;INDIA

Abstract

Major parts of Kerala in South India experienced one of the worst floods in nearly a century during the monsoons of 2018.More than 400 people lost their lives, one million people were displaced and the extent of damage culminated in rebuilding the State of Kerala.Kerala is one among the best governed states with a very strong local governance network.The floods and the aftermath did prove that people of Kerala could bounce back in no time though could roll back decades of development thus such a disaster could be a threat to the economy and very existence of the community.Karumallooris a Panchayat(an institution of self government in rural areas) in Ernakulam district located along the Periyar the longest river in kerala and one of the severly affected areas in the district with 75% of the area inundated during the floods in . The aim of this paper is to explore the issues in such panchayats and to identify the need and strategies for developing flood resilient communities. The methodology includes a very intensive background study of the panchayat selected as a special case leading to development of a vision and mission and finally a resilient plan for that community. The panchayat has the presence of natural drainage channels,unused and undeveloped land parcels,community cohesion, thus with high potentials of developing a proper resilient framework which includes institutions, systems and infrastructure to combat the vagaories of nature in the coming years.

Floods, Local self-governance ,Planning, Resilience

1. INTRODUCTION

1.1. FLOODS

Flood has been considered as one of the most frequent disaster in the world. The economic loss and life damage due to flood has put more burdens on economy than any other natural disaster. It is defined as “High-water stages in which water over flows its natural or artificial banks onto normally dry land, such as a river inundating its floodplain.” When the hazards caused by flood, run over the coping capabilities of the affected population it become disaster. India also has continuously suffered by many flood events which claimed huge loss of life and economy. Flood occurs in some parts of India, particularly during the monsoon season that runs from July to September each year. Gujarat, Assam, Uttarakhand, Bihar Maharashtra, Kerala are the major states in India that are frequently affected by flood disasters.Floods occurred in Kerala during August 2018 due to the unprecedented rainfall and has been widely described as the worst in the last century, with notable comparisons to the catastrophic floods of 1924. 14 districts among 29 in the state had been put on red alert and 35 dams were opened. The flood and landslides have engulfed human lives, households

and farmlands. A large majority of the people died due to landslides caused by the floods. Further major issues faced were lack of basic necessities like drinking water, medical supplies and roads were impassable in certain areas for a long period of time.

Figure- 1 Kerala floods (Source: Generated (www.khaleej times .com 18.08.2018)

1.2.KERALA

Kerala is a state situated in the southernmost tip of India with an area of 38 sq km bordered by Karnataka in the North, Tamil Nadu to the East and South and Arabian Sea on the West and is known as Gods Own Country. The average annual precipitation in Kerala is about 3000mm.The state is blessed with two monsoons namely the south west monsoon from June to September and the North east monsoon from November to February. The maximum rainfall is during the monsoons as a result of which the heavy precipitation reaches the main rivers through various water channels.

Kerala experienced an abnormally high rainfall from the start of the south west monsoon in June 2018 to last week of August 2018.The state received almost 2500 mm of rainfall during this period. Reservoirs had reached their almost full capacity level due to the continuous rains lashing the state. Water had to be released from the dams due to heavy rainfall in the catchment areas. This led to flooding of 13 districts out of 14 in that area.35 out of the 54 dams had to be opened for the first time in the history of the state. The state was placed on a red alert by the Kerala State Disaster Management Authority as a result of the severe flooding. A number of relief camps were in operation accommodating thousands of families with the co ordination of the State government machinery, Central government and several NGOs.

1.3.KARUMALLOOR-THE STUDY AREA

Karumalloor is a panchayat located in the severely affected Ernakulam district of Kerala state, India. The Panchayath is bounded by the distributaries of Periyar River. Periyar(meaning-big river) is the longest river with the largest discharge potential in the Indian State of Kerala. Periyar is termed as the Life line of Kerala due to several reasons like it generates a significant proportion of Kerala's electrical power via Idukki Dam, flows along a region rich in industrial and commercial activity, supports a rich fishery, provides water for irrigation and domestic use throughout its course .

Majority of the areas were waterlogged and the inundation level went up to 13m from the Mean Sea Level .73 % of the panchayat area was flooded. Trucks, boats and choppers were

used for rescue as normal vehicular transportation was affected during the flood . The village consists of large tracts of paddy fields and the panchayat is mainly a rice-based agrarian economy. Flood had also caused a large amount of loss to the crops and yields. This significantly affected the livelihoods of the population depending on agriculture for their income. Hence the study on the impacts of flood and planning for the resilience of Karumalloor Panchayat is very relevant.

Fig 2 (Source: Generated from Primary survey (23-26 September 2018) based on Google maps 2018)

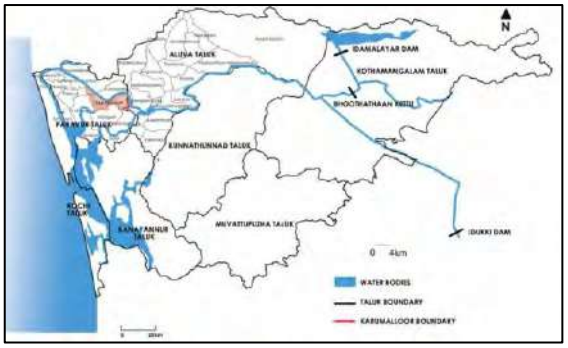

Fig 3 (Source: Generated from Primary survey (23-26 September 2018) based on Google maps 2018)

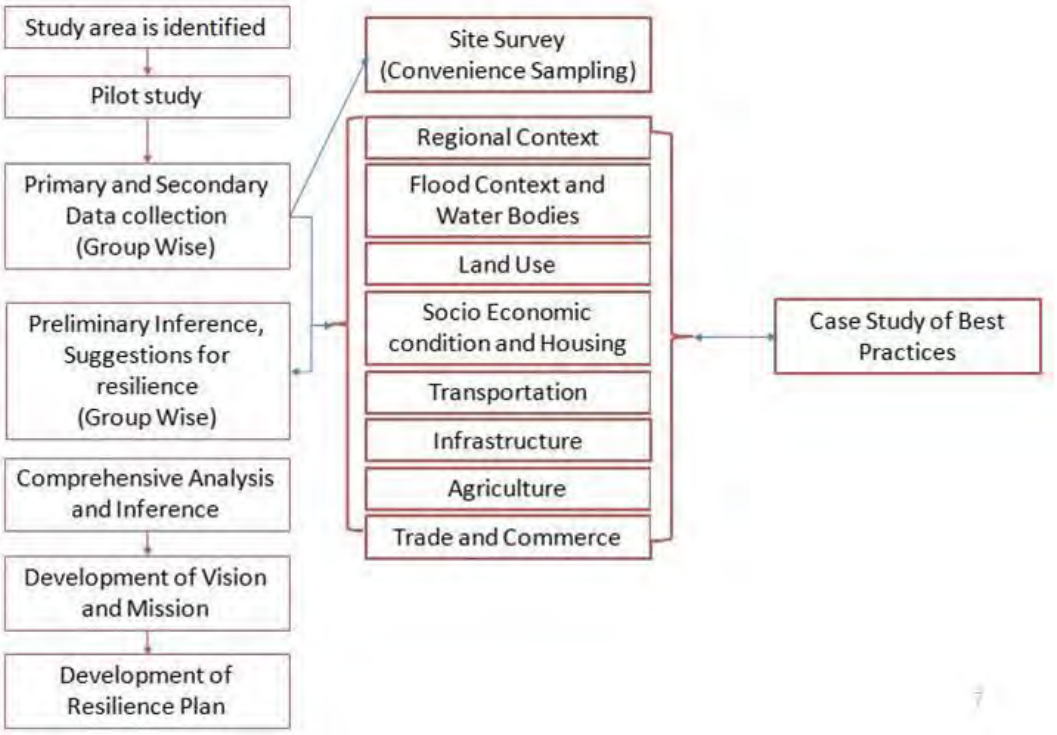
2. Research Methodology



This framework elaborates on the steps taken to develop a vision and mission to provide a structure for the proposed interventions , identifies and prioritises those solutions that will help to prepare strategies to improve the community as a flood resilient model addressing in an integrated way with environmental, social and economic objectives.

3.Regional Context of Karumalloor Panchayat

3.1 Location

Karumalloor Panchayath is located in Ernakulam district, Kerala. The area of Panchayat falls under two taluks (Aluva and Paravur taluk) of Ernakulam district. The panchayath was formed in 1953.As per Census 2011, the Panchayat is divided into 20 wards. The area of Panchayat is 21.05sq.km with a total population of 36,078. The village consists of large tracts of paddy fields. Karumalloor occupies an area of 0.7% of the total area of Ernakulam district

(3068sq.km) in which 2.25% of paddy cultivation is contributed by this panchayat.

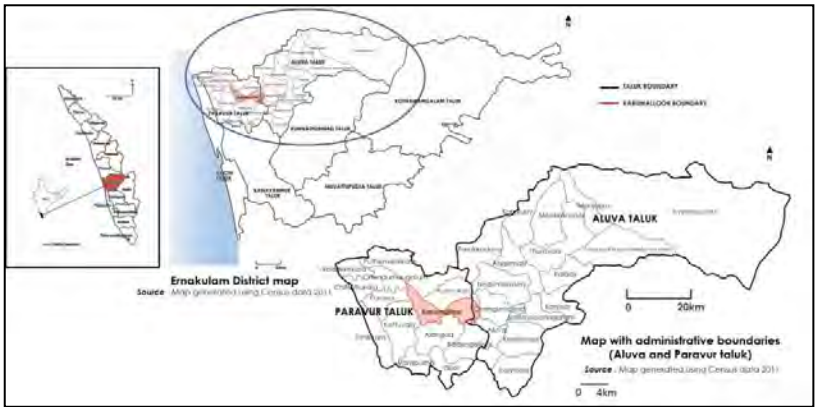


Figure 4 Location map (Source: Generated from Primary survey (23-26 September 2018) based on Google maps 2018)

3.2 Significance of Aluva town with respect to Karumalloor panchayat

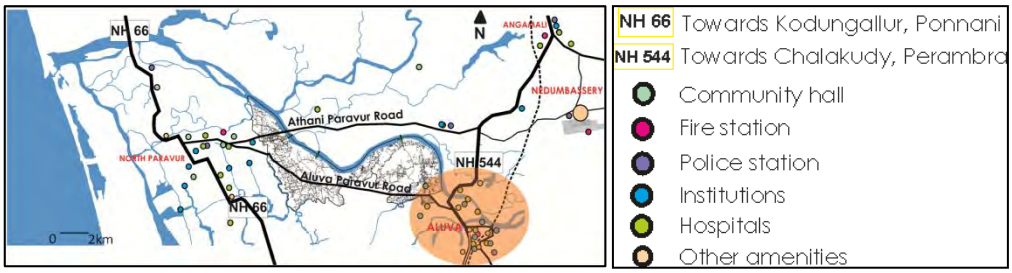

Figure 5 Importance of Aluva town with Karumalloor (Source: Generated from Primary survey on (23-26 September 2018) based on Google maps 2018)

Aluva is a municipality situated on the eastern side of Karumalloor panchayat and one of the major industrial centres of the state.It has become a key transportation hub with connection to all major forms of transportation. Based on the observations from Primary and secondary study, concentration of facilities and infrastructure is seen in Aluva as compared to North paravur on the western side. Aluva is well known for its large river banks of Periyar River.The international Nedumbasserry airport, national highway 544 and Periyar river flowing along the region are contributing to the development of the region. All the above factors in and around Aluva can trigger developmental growth thus creating increased land value, unplanned developments and high demand in Karumalloor panchayat. It is also observed that pressure is exerted on eastern side of Karumalloor panchayath as part of development. Thus Aluva an important commercial town in Ernakulam District, Kerala is set to play a pivotal role in deciding the future of Karumalloor and its precinct

3.3 Accessibility to the Panchayat.

Karumalloor Panchayath can be accessed through two national highways, NH66 towards Kodungaloor and NH544 towards Chalakudy. Two major roads pass through Karumalloor panchayath, Paravur-Aluva road and Paravur Athani Road connecting the national highways. Karumalloor is taken as Fifth Order settlement based on the parameters considered for classification in District Urbanisation report (2011) which includes Educational facilities,Health Facilities , Market , Physical infrastructure facilities , Transportation facilities ,Facilities in Agriculture and allied sector

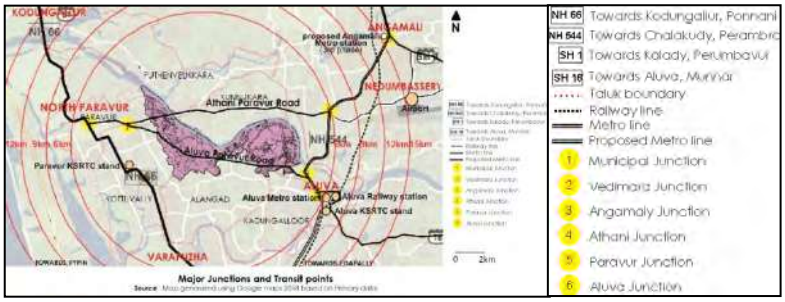

Figure 6-Junctions of Karumalloor Panchayat(Source: Generated from primary survey on(23-26 September 2018) based on Google maps 2018

4. Analysis of Physical features of the Panchayat

4.1 Demography

The total population of Karumalloor panchayat as per census 2011 is 36078 persons.According to the census 2011, the child population of Karumalloor panchayat is 10%, which is similar to the composition of state and district.The old population in panchayat is 11%. If the growth trend continues, overall work participation rate will tend to decrease. Thus the community should be prepared for self sustenance.

4.2 Land Use

The existing land use map of Karumallur (which is prepared based on the Google map data and primary site study) shows a prominent residential settlement with agrarian economic base.It can be observed that more than half of the geographical area is covered by residential land use (51.92%) followed by agricultural land use (36.15 %) including both paddy fields and dry cultivation.The residential areas and commercial areas constituting 1.11 % are developed mostly along the transportation routes and around the agricultural fields. The industrial land use constitutes only 0.46 % of the total area and is widely dispersed in the panchayath area. The public and semi-public land use constitutes 1.63 % of the total area.0.45% of the total area comes under open spaces which includes school grounds and other open play areas, parking areas and plots belonging to religious buildings. Water bodies share 8.29% of the total area including Periyar river along the boundary, private and public ponds, canals etc. The land use pattern has undergone a drastic change in terms of built up land from 2002 to 2018. The change can be also seen in the distribution of agricultural land and water bodies within the area and major development along the transportation corridors.

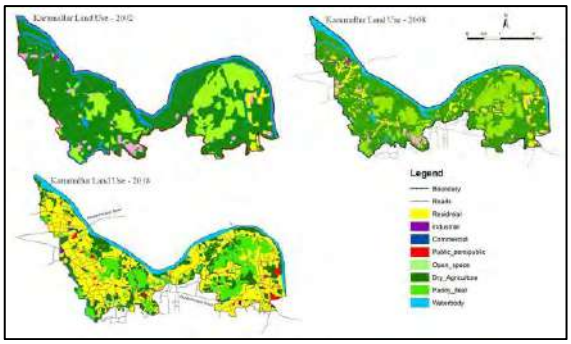

Figure 7 Change in Land Use over the years, 2002-2018(Source: Adapted from LRIS(2002), State Land use board(2008)and Generated using Google Maps ,Arcmap and primary site study)

4.3.Topography

Low lying flat land covers major portion of Karumalloor panchayat. Though periyar is flowing through the northern parts of the panchayath the area is prone to drought like situation during summer. Ground water level in many areas has come down drastically over time. The prime reason for the depletion of the ground water is assumed to be due to refrainment from traditional agricultural pratices and excessive consumption which has disturbed the ecological balance. Uncontrolled sand mining from the river bed and also the reduced precipitation in the area due to climatic changes are also identified as the reasons for the lowering of the water table in the area. Irrigation is highly dependent on the Periyar River.

4.4 Soil Permeability

Land use, topography and soil type present in an area are dependent on each other and act together in intensifying the impact and damage due to flood. Soil permeability is the important characteristic which has contributed to flood impact. Sometimes, the change in land use can indirectly cause the change in the characteristics of soil present in an area. Sand was the most common soil type in the area which had high permeability followed by sandy clay and silty loam with comparatively low permeability.

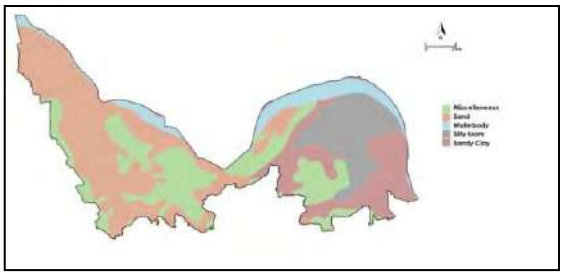

Figure 8 Change in Land Use over the years, 2002-2018(Source: http://kslublris.com/LRIS/Kerala/district.php accessed on 12th September 2018)

5.1 Analysis of Infrastructural features of the Panchayat

5.1.1 Housing

Karumalloor Panchayat has 51% of residential land use. There are 8390 census houses within the panchayath as per Census 2011. One of the main characteristics of the housing in the panchayath is the 19 housing colonies developed under Government housing schemes for the economically backward people. Government schemes like Lakshamveedu colony built under the one lakh housing scheme and four cent colony, with an average of 20 houses in each colony are the prominent ones.

5.1.2 Typology

A shift in real estate investment is visible within the panchayat between 2012 -18.The panchayat that had a predominant typology of individual houses has witnessed the development of high rise residential projects that raise the density and increase the land value.The developments of these buildings are observed on locations with an aesthetic view of Periyar river.

5.1.3 Water supply

50 %of the population are dependent on tap water from treated source for drinking water and another majority of 29% on uncovered wells. The sources were largely affected in all cases during the floods**.**

5.1.4 Roads

The roads are made with no storm water drainage system. There is reduced rainwater percolation due to bad surface treatment practices. There is total absence of rainwater harvesting facilities and culverts are blocked due to waste dumping and silting with sludge deposit on roads. Natural drainage channels are blocked due to unplanned construction of roads and buildings.

5.1.5 Drainage

48% of houses in panchayat do not have drainage connectivity for the waste water. Surveys identify issues like absence of septic tank. Lack of maintenance of the existing septic tanks is a serious threat and leads to water contamination during and after floods.

5.1.6 Solid waste management

Organic and Non-organic waste is largely being treated within individual household level. Kudumbashree a community organization of Neighborhood Groups (NHGs) of women in Kerala is involved in collection of solid waste collection in few wards where density is high while panchayath has a mechanism to collect plastic from the same wards. Post-flood, the debris and sludge were cleaned on a personal initiative basis while all household waste was collected by panchayat. The waste in areas where the panchayat had not collected was dumped into the drains or on the sides of the access roads.

5.1.7 Electricity

The entrie panchayat is electrified.During flood, the supply was affected with loss of electricity for approximately 9 days during which the residents were moved to relief camps.

Most relief camps faced power loss which made the situations worse and relief works more difficult.

5.1.8 Telecommunications

Telecommunication systems were unavailable during flood. Landline was available in few houses but mobile network was completely cut off. So the rescue operations couldn't be coordinated or managed which made the whole process delayed and difficult. The major reasons for the breakdown were the flooding of the telephone exchanges and mobile towers located in flooded areas.

5.2. Analysis of reasons of the flooding in the study region

5.2.1 **Flood inundation**

Kerala received 42% higher rainfall than average in the months of July and August 2018.2346mm of rain that poured over the state during the flood is considered to be the major reason for the flooding in several districts in Kerala (Kerala Food of August 2018).Periyar river basin which is spread over an area of 5389 sq km has received maximum rainfall in the recent times which is the prime reason for the flooding of the periyar downstream.

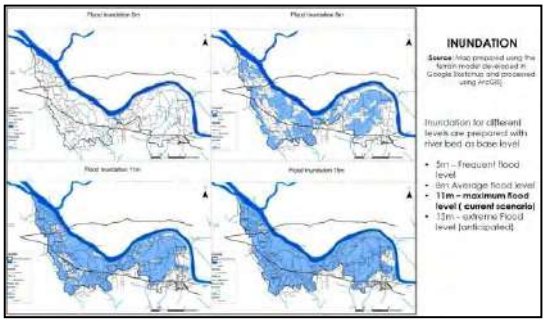

Figure 9 Change in Land Use over the years, 2002-2018-(Source: Generated using ARCGIS)

Majority of the area in the panchayath is vulnerable to flood. Flood inundation levels in the site are studied based on the site visits done and data collected on the flood water levels. From the observation and data collected from the site it is observed that the water level has risen 10.5 – 11 meters from the river bed.5m inundation scenario helps to identify the areas and infrastructure that are affected due to more frequent low risk floods**.**

5.2.2 Dams opening to Periyar River and its operation during Kerala Floods, August 2018.

Periyar sub-basin consists of about 50% of the total live storage of the State that is about 2.92 BCM. The reservoirs with substantial live storage capacity in Periyar sub-basin are Idukki, Idamalyar and Mulla Periyar.Several dams are built in the Periyar drainage basin for

power generation and irrigation purposes and most of the dams in the state were opened due to the extremely large inflow of water to the reservoirs. As per reports of Kerala Floods August 2018 , floods in Kerala was due to severe storm occurrences during the days from 8th to 9th August 2018 and later 15th to 17th August 2018.

5.3 Analysis of Social Infrastructure

Karumalloor Panchayath is dependent on Aluva and Paravur Taluk for specialised social Infrastructure which is more developed and caters to a wider segment of the population. The Panchayat provides all basic facilities for its people including primary health centre,educational institutions, banks etc.The facilities present in the panchayat has ensured the maximum aid to its people during the flood converting most of the infrastructure to act as relief camps and collection centres. During flood these offices were majorly flooded including the Grama panchayat and village office.Though few of the buildings were unaffected, these were completely isolated or were inaccessible by the authorities which made the loss more severe.During flood most of the hospitals were badly affected. Patients had to be moved to various other medical centres in safer areas. Most hospitals had high loss in terms of machinery and equipments. Karumalloor has numerous schools which are under government and also few private educational institutions including colleges and higher schools.The panchayat includes 34 anganawadis of which 18 were affected by the flood. Most schools located in safer areas were relief camps which stayed unaffected throughout the flood scenario.

5.3.1 Housing Finance

The wards with higher SC(officially designated groups of historically disadvantaged people in India) population indicate that they are located in floodplains. This conveys that the finance invested in uplifting the standard of living of the vulnerable by facilitating finance for housing has been into a flood plain. Insurance for any category of risk cover including health insurance is absent.

5.3.2 Agriculture

The conversion of paddy and wetlands to other uses had a huge impact in flood as these areas usually act as natural water storages during heavy rain. In Karumalloor, till 2008 trend for converting paddy land was prominent but after the enforcement of Kerala Paddy and Wetland Conservation Act, the area of paddy cultivation is observed to be doubled. This shows the importance of agriculture sector in the Panchayat.The active participation of community and agencies like Krishibhavan which is a government body under department of Agriculture and kudumbashree has helped in fast recovery of this sector with farmers starting the next crop in a about a weeks time after the floods. However lack of proper insurance has increased the economic loss in both agriculture and animal husbandry. Large scale female participation in farming and animal husbandry has also been observed. There is a serious change in the soil condition after the floods which have a very severe impact on the cultivation. There has also been a reduction in the water table level. The existing ponds are filled with mud and clay which has reduced the availability of water. Uncertainty of how the crop will react to the new soil condition has generated concern among the farmers.

5.4 Analysis of Precautions taken and Damage assessment

5.4.1 Warning Mechanisms

The early warning for disaster was received through announcements made by panchayat authorities for evacuation. This was conducted around 10 hours prior to the extreme flood

scenario.Warnings were given through media announcements.90% of the population affected by flood evacuated on self-initiatives. The remaining 10% who refused to move or remained isolated were evacuated in later stages or were provided with food and other supplies. Power supply could be restored only after 9 days and telecommunication was partially restored in 5 days.

5.4.2 Damage Assessment

The houses are affected in different manners in different parts of the panchayat due to varying topography.The major losses were damage to interiors, loss of furniture,appliances,structural damages etc .Few houses were unfit for occuopation after flood waters recede. Damage is being assessed on the basis of claims made by the owners.
Unfortunately no Standard tool for assessment is being used and there are no categorization of their social and economical back ground for assessing the capacity of the beneficiary.No defined time frame was also made for assessment.The relief camps that where active in the panchayat for the displaced did not meet the relief camp guidelines of NDMA(National Disaster Management Agency). The transportation network was severely affected. Connectivity was lost for almost 4 days. Majority of the areas where waterlogged and the inundation level went up to 13m from the Mean Sea Level. Trucks, boats and choppers were used for rescue as normal vehicular transportation was blocked during the flood. Bridges in the panchayat however were all safe.

5.4.3-SWOT ANALYSIS

6. THE WAY FORWARD - DEVELOPMENT OF A VISION

To develop Karumalloor as a model for flood resilient community through regional and local planning interventions in participatory/inclusive/integrated manner. Resilience is a capacity to recover from difficulties at the earliest thus building up a capability to anticipate, prepare for, respond to, and recover with minimum damage to life and property, the economy, and the environment.Specific local landuse policy options need to be worked representing the varying geographic areas in the panchayat.Some of the most important aspects include Allowing the Right to river,consideration of vulnerable settlements,identifying safer areas for

planned development/rehabilitation,proper watershed management thus empowering the panchayat to face future flood situations of any magnitude.

6.1 General strategies

Regional Context: Planned/Regulated development due to the developmental pressure exerted in Karumalloor by the neighbouring towns/cities like Aluva,Kochi etc

River Corridor: Allowing the right of way thus protecting and preserving Periyar River and rejuvenating water bodies of the panchayat by adopting water management techniques.

Land use: Redefining the land use in order to adapt for flood resilience by integrating different sectors and thus reducing the damages.

Demography and Habitat assessment: Developing sustainable housing through resilience technology and vulnerability zoning to reduce loss of people and property

Infrastructure: Developing a network that ensures external and internal connectivity and accessibility to critical infrastructure even at the time of a disaster.

Agriculture and Livelihood: Making Karumalloor a Model self-sustained agrarian community by improving agriculture practices and conserving the existing paddy fields.

Trade Commerce and Industry: Developing self-sustaining resilient community by promoting markets at local level with the help of joint actions by the residents and administrative bodies

6.2 ECO SYSTEM CONSERVATION

Promoting natural and indigenous vegetation that reduce soil erosion with water holding capacity. Wetlands present in the panchayat need to be conserved so that it can act as water storage areas during flood. No conversion of existing paddy fields to be allowed under the legal framework of paddy and wetland conservation act, 2008.No change in the soil characteristic in flood plain by further change in landuse or crops being cultivated.Land parcels areas that can help to retain water and increase the percolation of water and thus reduce run off to the Periyar River are identified to convert them into public spaces. Areas that have higher drain density and which lies near to the river edge is identified for creation of water ponds. These ponds will help to reduce out flow of water from the panchayat and increase the water retention ability of the land. This will help to increase the ground water level and it can act as a source of water for irrigation. These ponds can also be used for practices like aquaculture etc. The increasing residential density in and around the panchayat pushes a need for public spaces. These areas if properly planned can offer scenic view of Periyar river on one side and lush green paddy and other farm lands on the other side. Another major intervention is the largest watershed present in the panchayat. Network of drains and ponds could be created along with revival of existing ponds to improve the water retention capability of the land. Farm lands have to be considered as wide drainages at the time of flood and therefore creating culverts merely on the drains are not enough. Culverts have to be planned at frequent intervals so that flow of water is not obstructed in the event of a flood. Roads constructed across the drains have to be provided with culverts

to allow easy flow of water.Edges of the water bodies may be treated with proposals like Xeriscape to improve the quality of water and landscape elements like Bio-swales to concentrate or remove debris and pollution out of surface runoff water.

6.3 Roads and Internal connectivity

As the roads are spread in all zones, zone-wise strategies cannot be made in the case of transportation. So strategies are formulated for different stages of disaster management.
Elevated roads wherever necessary, improved drainage system and preventing rainwater discharge from residences to roads are few proposals that needs to be carefully planned. Improved rainwater percolation in streets and proposals to include Rain gardens, Soft edges etc. Permeable roads and collection ponds must be planned and designed to avoid water retention on roads allowing water to infiltrate through the layers into the underlying road below which will help to maintain the natural drainage flow

6.4 Strategies for response

Efficient warning system- Warning and monitoring systems that can alert crisis management agencies .
Vulnerability mapping-Assess the vulnerability of existing infrastructure, undertake measures to prevent damage and develop long-term capital investments to retrofit and/or replace the most critical emergency lifelines
Response team-Forming a response team is very crucial in emergency response planning The team leader should be able to prioritise the activities, monitor and update as and when needed to counteract situations leading to strategic decisions. A strong communication system must be included to ensure effective supervision, directives, and response controls.
Trained volunteers-Panchayat can adequately prepare/train volunteers with essential tips to assist relief machinery that is in action .
Maintaining connectivity-Telecommunication and road connectivity has to be restored as early as possible to evacuate affected people, to provide medical assistance and food supplies.
Sequential evacuation-A planned evacuation process has to be worked out to minimise loss to human as well as animal lives. A proper vulnerable area mapping, road connectivity mapping can identify possible evacuation routes, priortise and help in execution of the same in a phased manner

6.5 Strategies for Resilience

Land use management strategies are very important in planning for flood resilience. Any unplanned changes in land use pattern can intensify the impact of floods in any area. Zoning is one among the the first measure taken in order to adapt with the impact of flood.The strategy adopted for this panchayat is a proposal to divide entire area into five zones based on the present flood level, CRZ regulates areas and topography.

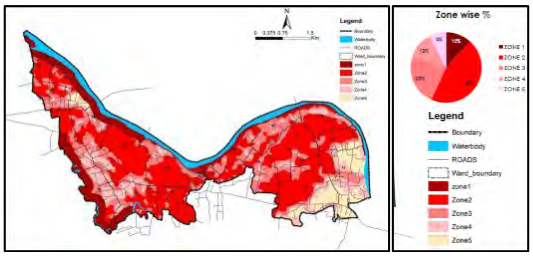

Figure 10 Zoning (Source: Generated in ARCGIS 2018 using data on flood level, topography and CRZ regulations.)

Figure 11 (Source: Generated using ARCGIS, 2018)

Flood Level 0 -5 m –It is proposed as a No development Area- Where development should be avoided due to environmental or safety concerns. Zone 1 is constituted by high risk areas which are frequently affected by flood (prone to risk in 5m flood level). This zone also includes all areas under CRZ regulation, which are 200m from river line with saline water and 25 m from other water bodies. Almost all area along the river comprising of 12% of the total panchayat area is classified under this zone.No new construction to be allowed in this zone and Coastal zone regulations (CRZ III) areto be strictly followed .Embankments like dykes/leaves can be constructed but require proper geographical or hydrological study.All natural embankments in zone I are to be retained. Area under this zone shall be developed to have landscape elements like green spaces or xeriscape/softscape with natural perennial plants that tolerate stagnated water and flooding.Encroachments of any kind are not to be allowed in this zone.

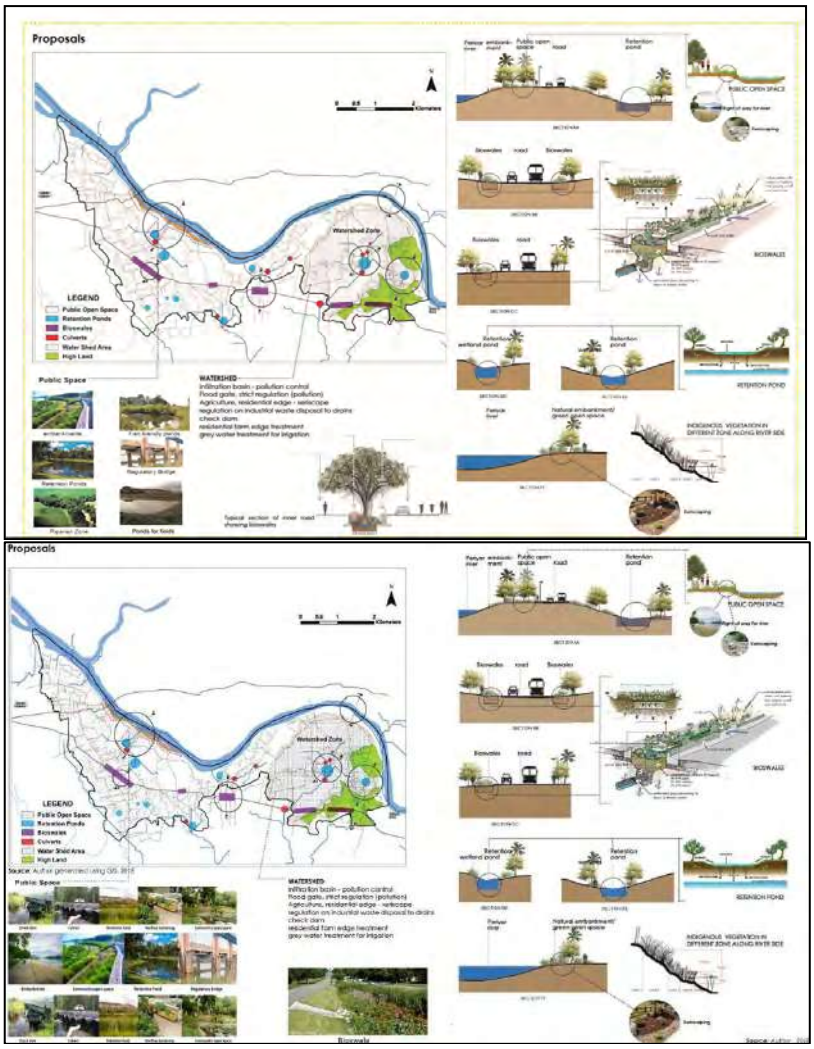

Figure 12-(Source:Author)

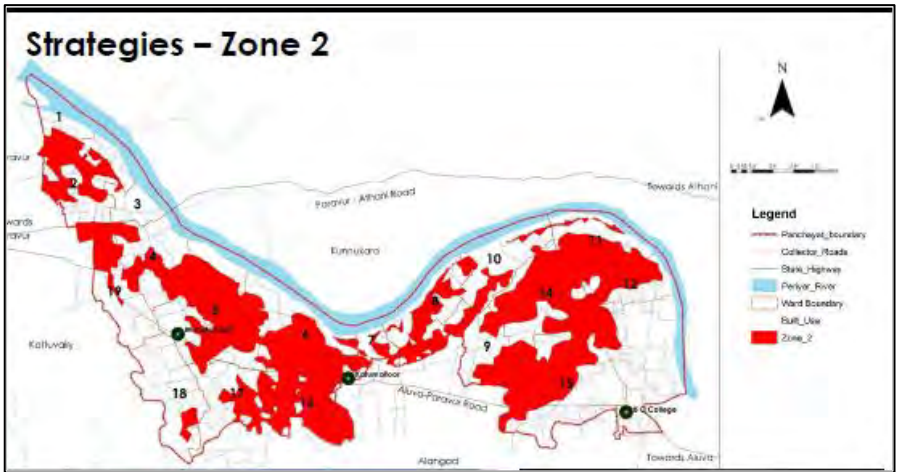

Figure 13(Source: Generated using ARCGIS, 2018)

Flood Level 5 - 8 m- Constrained area- Where development is possible, but natural features limit use of the land.

Major portion of the total area, that is approximately covering 45 % of the panchayat comes under Zone 2 which is comprised of agricultural land, both paddy cultivation and dry cultivation, and residential and industries associated with it. All areas that can be affected in flood level between 5m to 8m and topographically low lying areas comes under this zone. These areas can be categorised as moderate risk areas. Karumalloor panchayat office is an important control point which comes in this zone.Flood resilient crop cultivation are to be practiced so as to reduce the loss.Traditional/indigenous agriculture practices are to be followed strictly, which are very important for water retention.No existing agricultural plots are to be converted and further agricultural practice are to be promoted.No Relocation instead Retrofitting strategies for Resilient housing to be adopted with Incentives for affordability of retrofitting. Usage of flood damage-resistant materials for the houses can be identified and proposed.Shops need not to be relocated but should have portable water proof storage spaces to keep the goods safe during flood and for easier shifting when needed.The building structures should be made resilient to withstand flood conditions.Existing local Industries located in Zone 2(brick manufacturing units) should have transportation facilities for the movement of machineries at the time of flood .No further industrial constructions to be allowed in this zone.

ZONE 3- Flood Level 8 – 11 m -Constrained area

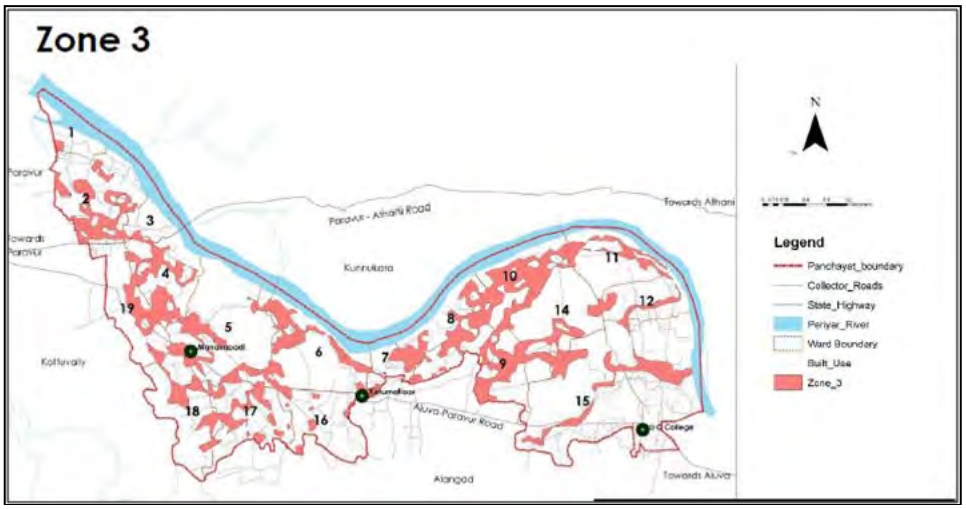

Figure 14(Source: Generated using ARCGIS, 2018)

Zone 3 is constituted by 23 % of the total area of the panchatat. Areas that can be affected in 8 – 11m flood level (which is the present flood level condition:11 m). Major land use in the zone is residential and the risk factor is low compared to zone 1 &2. Existing wells for households must be constructed with proper concrete surface casing. Rain water harvesting must be practised. Ground water infiltration techniques like bio swales along the roadside are to be constructed. Each household must have proper solid waste management and sewage treatment.

ZONE 4- Flood Level 11 – 15 m -Targeted Growth Area- Most suitable for various types of development.

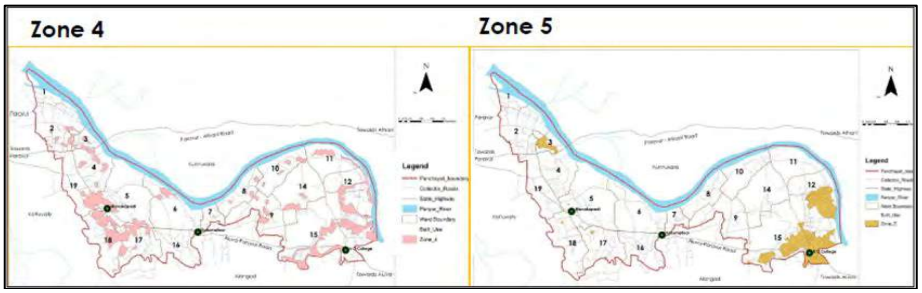

Figure 15 (Source: Generated using ARCGIS, 2018)

Zone 4 includes areas that can be affected in a situation (predicted) 11-15 m flood level which is categorised as very low risk area in case of a flood situation. Compared to Zone 1,2 & 3, this zone shows mixed land use pattern with medium to high dense development. All major control points and critical infrastructure can be relocated to this zone.Common storage space for consumables can be accomodated at every high points in this zone. Movement of goods/machineries from the flood affected areas may be shifted to these zones at the time of disaster. These storage spaces should be placed near to the relief shelters and these stored goods can be used by the people in the relief camps at the time of disaster.

Zone 5- Above 15 m Safe area- Very less possibility of getting affected in flood.

Zone 5 is the most safest area in the panchayat, in high land, which includes Manjalikunnu and UC College wards. The zone is again dense with mainly public and semi-public land use. No restrictions need to be enforced for development. Dense development is proposed to be permitted .The proximity to critical infrastructure will raise the land value in general.This zone can be considered for inclusive development for relocating the vulnerable from the flood prone area .Higher consumption of FAR in this zone needs to be encouraged.

Hazard Zoning

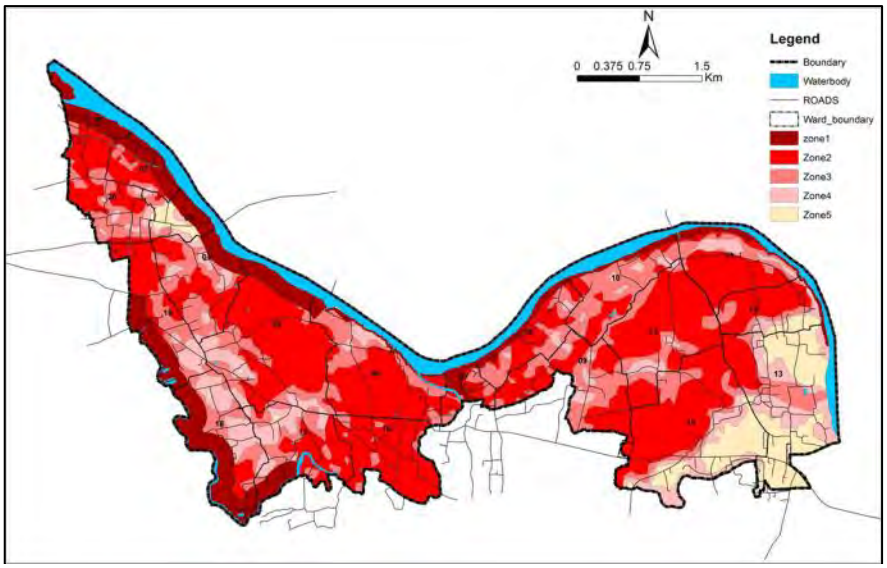

Figure 16(Source: Generated in ArcGIS using data on flood level, topography and CRZ regulations.)

Based on hazard zoning, a safe route that ensures access to critical infrastructure and relief camps is to be prepared.When the warning that the water will rise above 5m is issued, evacuation of Zone 2 should start as early as possible. Evacuation should also include the households that belongs to Zone 3 which will get isolated in this stage .Evacuation should start as soon as the warning that the inundation level will go beyond 8m is received. Remaining people from Zone 3 need to be evacuated including people from Zone 4 who will be isolated in next stage.Evacuation starts when warning that inundation level will go beyond 8m. Remaining people from Zone 4 need be evacuated.Once the inundation level crosses 15m , the only places left will be Manjali,Kottappuram and UC College-the highest areas in Zone 5. So the relief camps in other areas should be shifted to safer areas.Further development of all critical infrastructure is recommended to be in this zone including a Helipad facility to be accommodated for emergency evacuation.

7.CONCLUSION

The theoretical concept of resilience suggests the potential to enhance expectation of, preparation for, and mitigation of natural disasters. In practice however the challenges are often unpredictable. It is not always a bouncing back but more of an adaptive capacity by the affected community.Community resilience will need to build up on the existing knowledge about floods and be aware of the disastrous impact of human interventions in flood prone areas.Land use planning is one of the measures that could contribute to resilience. Building resilience and long term sustainability should be the key to a framework adopted in long term strategic planning proposal. Landuse policy decisions can be a very effective practical measure to increase the resilience of the community in a flood prone area Communities are engaged and empowered to take part in the land use planning process, so that they can effectively contribute to reducing their own risks before and after a disaster.

Local landuse decisions may have to be incorporated which are guided by State policies and decisions. Such changes/development may happen over time and incrementally but may enhance the resilience capacity and assure safer growth for the community. Communities can actively involve in strategies for risk reduction through increased awareness of their civic

responsibilities, protecting the environment, boosting up economy through indigenous traditional agricultural practices, adopting engineering/new solutions for risk reductions etc.
Unlike disaster preparedness resilient planning can go a long way in empowering the community to manage any disaster that may occur. It actually helps in reaping multiple benefits, sharing both risks and responsibility and completely help in a rethinking process.

Abstract

Sumba Iconic Island is a collective program established by the national government through the Ministry of Energy and Mineral Resources (ESDM) with various governmental and international institutions such as the National Electricity Company (PLN), Hivos, Norwegian Embassy in Jakarta, Asian Development Bank, and all level of local government from provincial, regency, municipality, district, and village level. This paper focuses on using qualitative data gained through interviews with stakeholders to find out the various operation and maintenance models of renewable energy power plants that are currently in practice in Sumba Island.

This study shows that currently there are four models of operation and maintenance for systems throughout numerous villages in Sumba. The first one describes O&M being handled by trained locals, second one is handled by the village cooperative (Koperasi), the third one is collaboration between PLN and local government units or private sector, and the last one is collaboration with the private sector and village-own company (BUMDes). The first one mentioned is the weakest one, and faced many constraints such as lack of technical skill and the local peoples' limited understanding. The other three models succeeded, to a certain extent, in sustaining the renewable energy system in the particular village.

Keywords

Operation and maintenance, renewable energy, power plant, Sumba Island

1. Introduction and Aim

Sumba island is one of the least-developed regions in Indonesia with issues revolve around poverty, minimum infrastructure as well as lack of social services. Located in the impoverished Province of Nusa Tenggara Timur (NTT), more than 30% of the island's population are in poverty according to 2016 statistical data documented by Indonesia Statistical Bureau. Transportation infrastructure and facilities are still very limited in terms of

quantity, quality and frequency of flights. Village access roads are often in poor condition, with loose stones and potholes. Roads are not all paved, or sometimes only paved with sand and stones. Roads between sub-villages are generally unpaved. Markets are generally further away and there are fewer kiosks in villages. Next, the regencies in Sumba (specifically in West Sumba) has the highest number of neglected children under 5 years old (Indonesia Statistical Bureau, 2016) which indicates the severe absence of social services there. Limited numbers of schools contributed to the high rate of illiterate particularly among women. Health facilities are mainly found in sub-district towns, due to limited availability of doctors.

One of the barriers of development in Sumba is the lack of electricity. More than up to 60% of the families in Sumba live without electricity (Indonesia Statistical Bureau, 2017). A Study conducted by Craine (2013) reported that at the national level, while 72% of the country has grid electricity from PLN, only 6% of the country is using kerosene lighting. Surprisingly, half of this 6% population are situated in NTT with approximate numbers of 50.000 – 60.000 households. Sumba has two main grid systems, Waikabubak and Waingapu. The peak load of the Waingapu and Waikabubak systems combined amount to about 5.5 MW with a 2.5MW base load. The energy demand on this sparsely electrified island is increasing in line with regional economic development and population growth. Based on PLN information, the electricity demand in Waingapu and Waikabubak has grown with 6% and 8% per year respectively.

Due to its poor condition, the island has been one of the main development agendas for the Government of Indonesia (GoI) in the last 5 years. As a way to respond to the needs for energy and electricity many entities including government institutions have tried to harness renewable energy technology as alternatives. Overall, Sumba poses as the ideal candidate for the 'fossil fuel independent pilot island.' Important renewable energy resources, such as Hydro, solar, wind and biogas are present on the island and have high potential in terms of becoming the primary energy sources for the island. The GoI through its National Electricity Company (PLN) has provided a huge number of solar lighting sets for villagers that currently do not have access to the main power grid. The villagers pay a small fee to participate in the programme and in return PLN maintains and repairs the lighting sets.

A more integrated initiative has been started involving multi background stakeholders from the government to NGO in a program called Sumba Iconic Island (SII). This program is coordinated by the Indonesian Ministry of Energy and Mineral Resources (MEMR), together with Hivos, since 2010. By maximizing the potential of renewable energy particularly on biogas, biomass, solar, hydro, and wind energy in Sumba; to date, the program has successfully produce RE installation that contributes to 20.9% out of the total of 50.9% of Sumba's current electrification ratio, covering electricity access to 4158 households and 14.868 solar powered plants (Herdiani, 2018).

The SII targeted that Sumba Island is going to be 100% electrified by 2020. However, to date, the electrification ratio has only reached 50.9% (EBTKE, 2018), from all types of systems. This number is actually has been doubled since the project started in 2010. The problem that frequently faced by the RE system installed in Sumba villages are happened in the Operation and Maintenance phase. Therefore, this paper aims to identify the O&M mechanisms

existed in RE system in Sumba, and also tries to understand the stakeholders' role, particularly in the O&M phase

2. Methodology

The method used in this paper is descriptive qualitative, we attempted to describe various O&M processes in the off-grid renewable energy systems in Sumba Island. The organizational structures for maintenance work is described chronologically based on the stakeholders' role. In particular, we focused on issues relating to the operation and maintenance of various off-grid renewable energy systems in rural areas and whether any level of synergy exists, or should exist, between public and private actors.

The field survey employed a qualitative approach as the primary means of collecting and analyzing the data. In order to gain a deep and thorough understanding of the various models of operation and maintenance in off-grid RE power plants in Sumba Island, data was gained through in-depth key informant interviews and focus group discussions, where respondents were subject to semi-structured interviews and discussions, with questions that were framed to consider about their experience and invite them to reflect on additional information that they find pertinent. Respondents include technicians, village leaders, community members, representatives of NGO/INGOs in the region, and public officials. The recorded interviews and conversations were transcribed and underwent content and descriptive analyses. The list of interviewees are further described in Table 1.

Table 1 List of Interviewees in Sumba Island

Village Name	NGOs	INGOs	Government Agencies	Private Business
Ndinjo	IBEKA	Hivos	Regional Planning and Development Agency	PT. RESCO Sumba Terang
Analewe			State Electrical Company (PLN)	
Dangga Mango				
Weepaboba				
Odi Praurata				
Weelimbu				
Kanilu				
Lete Kamauna				
Tebara				
Djela Manu				
Rada Loko				
Ramadana				

The contents of the table shows that most of the key informants are village leaders from 12 villages in West and Southwest Sumba. The village leaders were able to give us firsthand

details regarding renewable energy power plants that were constructed in their village, based on their own experiences, observations, or correspondence with other locals. Due to the close proximity between the villagers and the power plants, village leaders often converse with outside technicians or volunteers that operate or maintain the power plant. NGO/INGOs interviewees are from IBEKA and Hivos respectively. IBEKA and Hivos are responsible for developing and constructing renewable energy technology power plants throughout Sumba, including wind farms, micro hydro plants, and solar PV farms, as well as each of their corresponding off-grid power lines. Officials from the Regional Planning and Development Agency (Bappeda) and State Electrical Company (PLN) were interviewed to gain information on the inner workings of managing a renewable energy power plant and whether any regulation or statutes exist that governs or constrains such activities. Lastly, PT. RESCO Sumba Terang is a private company that has also been involved in the construction and design of several solar PV power plants, in collaboration with Hivos and BIRU among others.

3. Results and Analysis

The results of our field data collection indicates that there are four operation and maintenance (O&M) models currently in practice by multiple off-grid renewable energy plants spread throughout Sumba Island. This information was gained primarily from our focus group discussion held in the Regional Planning and Development Agency in East Sumba, attended by public officials, representatives of INGOs that play a role in the renewable energy development in the region, as well as representatives from academia and communities.

The four O&M models that are currently in place are distinguished based on who operates and maintains the power plant, as follows: (1) the local community where the power plant is located and to whom it serves; (2) locally organized cooperative, in which members of the community band together to manage the power plant as a locally owned enterprise; (3) the State Electricity Company (PLN), the state-owned enterprise that serves and provides on-grid electricity for the region; (4) private sector/developer model, which take form as national or international NGOs (Gah, 2018). The results suggest that despite the ubiquity of renewable energy power plants in the island, there currently isn't a mutually agreed policy or structure that governs the process of maintenance for the disparate models. The stakeholders for the power plants in each respective O&M model are then tasked with determining the best maintenance process for their power plants based on the assets that are accessible to them.

3.1. Operation and Maintenance by the local community

There are several local communities who operate and maintain the renewable energy power plant, namely the communities in Ndinjo, Analewe, Dangga Mango, Weepaboba, Odi Praurata, Weelimbu, Kanilu, and Lete Kamauna Villages. These villages have two accessible sources of electricity which are on-grid, connected to the state electrical grid from PLN; and off-grid, that is connected to the solar PV. The solar PV serves as an auxiliary electrical source provided through the joint efforts of the local government, village government, and

PLN. However, the same actors decided in unison that the technology is used and operated by the community, hence once the handover was completed, the process of operation and maintenance are handled by the community.

Based on our observation, there are at least two sub-models of operation and maintenance practiced by the communities. First, the sub-model in which maintenance processes were directly conducted by the solar PV end-user. Second, the sub-model in which maintenance processes are handled by an appointed local that was subsequently trained as a technician by PLN staff and aided by a local handyman that serve to repair the solar PV of the village. However, the case of village technician or local handyman that handle the O&M process is only implemented in 2 out of 8 villages that we visited, namely in Odi Praurata and Kanilu Villages. There were 2 O&M technicians in Odi Praurata, these technicians were trained by PLN staffs when they handed over the solar PV to the community (Yulius, 2018). Meanwhile in Kanilu village, the 2 local handymen were chosen due to their experiences (Wilem, 2018).

There are both similarities and differences of O&M process between the villages that have the first and second sub-model of O&M. The similarity between these two O&M sub-models is that the end users operate and maintain the solar PV independently on their own during its average lifespan of 2 years. Meanwhile, the difference lies on the maintenance aspect when the solar PV is damaged. The maintenance processes of the two sub-models community O&M, when the solar PV is damaged, are different. The maintenance process of the first sub-type of community O&M is handled by the end-users themselves. Meanwhile, the community relies on the technician's assistance on the second sub-type of community O&M. The community tends to bring the damaged solar PV to the technicians or local handymen to be fixed.

These two sub-models of community O&M have similar problems since most of the O&M process is handled by the end-users. These problems are (i) the lack of local community's capacity; (ii) the financial issues; and (iii) the lack of security (Gah, 2018). First, the lack of local capacity leads to the unsustainable O&M process within the community. As an example, the community directly utilizes and connects the solar PV into the phone battery. Because of that, there lies the possibilities for the phone battery to explode, be damaged, and harm the solar PV itself. Another example, especially in the first sub-model of O&M, a tendency to either leave the damaged solar PV alone or fix the damaged solar PV without appropriate knowledge of the end-users is high. Therefore, the damaged solar PV can't be fixed properly and further increase the problems within the solar PV. In consequence, the community tends to abandon then throw away the damaged solar PV and decide to re-use the Pelita. Second, the financial issue also affects the community not to repair any damaged solar PV because the community should pay for the service that is provided by the technicians. The community has not been able to structure and manage the budgeting. Last, the problem regarding the security. Several parts of the power plants are found missing because there is a lack of security. As the renewable energy power plant is managed by the community, the possibility that the power plant is being left without any monitoring system is high. Therefore, it could increase the possibilities that lead to the theft of the power plant (Gah, 2018).

3.2. Operation and Maintenance by Cooperative

Cooperative acts as the entity that operates and maintains the renewable energy power plant. Based on our interview with IBEKA, one of the cooperatives that manages to work on the O&M process is Kenyulururi Cooperative. Kenyulururi Cooperative is in charge for the daily operation of Kamanjara Micro Hydro Power Plant (MHPP) in Moubokul. This MHPP was constructed on November 12, 2017 by Ibeka (Institut Bisnis dan Ekonomi Kerakyatan), a social business entity with engineering focus. It has been operated for 9-10 months (per March 2019). The installed capacity of this MHPP is 95kW (65kW based on Ibeka website) and it supplies electricity for 106 households in Moubokul Village. The daily operation of this MHPP is handled by the Kenyulururi Cooperative as it hires the operator to ensure the daily operation of the MHPP. However, shall any part of this MHPP is damaged, the operator will report to Ibeka and Ibeka will further replace the broken part. Ibeka still holds the responsibility for the MHPP as the asset has not fully transferred to the village government (Petrus, 2018).

Regarding the information from Bappeda, the O&M process that is controlled by the collaboration with the cooperative could be classified as quite successful. One of the reasons of the quite successful O&M Process is the cooperative conducted the training support in collaboration with the Ministry for the technician to operate and maintain the renewable energy power plant. Hence, in the event that the transfer assets has been conducted and the cooperative has to manage the whole O&M process, the cooperative has already been prepared, through the training, to handle the O&M process (Gah, 2018).

3.3. Operation and Maintenance by PLN

The third model of O&M is handled by PLN, a state electricity company in Indonesia. PLN is the main actor that administers the electricity supply business in adequate amount and quality. PLN could provide the electricity supply from renewable energy power plant for the end-users by constructing the power plant or transferring the assets from the previous holder. Subsequent to the ownership of renewable energy power plant by PLN, PLN will control the O&M process of its assets. Besides that, PLN had run the assets belonged to third parties such as MHPP in Waekelo Sawah, MHPP in Kamanggih, Billa Cenge Solar Power Plant (SPP), and Bodohula Biomass Power Plant (BPP) (DAGI Consulting, 2018).

MHPP in Kamanggih could be referred to as one of the examples how PLN manages the O&M process. MHPP in Kamanggih was built in 2011 by Ibeka in cooperation with Hivos. Once the power plant was officially operating, the O&M process was handled by Jasa Peduli Kasih Cooperative. Subsequent to the 2 years O&M process handled by the cooperative, in 2013, the management of this MHPP was handed over to PLN after the interconnection cooperation agreement was being signed. The cooperative is now selling the electricity not to the end-users directly, but to the PLN with the rate of Rp475/kWh. PLN handles the management of MHPP including the maintenance, distribution of electricity, and bills due from household users. PLN is also hiring technicians to operate the MHPP in Kamanggih. Every month, the cooperative will submit the billing to PLN in relevance with the electricity usage per month and will earn the income from the electricity sales (Bakti Foundation, 2016). Despite of the existing collaboration, there is one big challenge occurs in the O&M process, namely the transfer of assets between the asset owner and PLN. If the transfer of

assets hampers the whole process of cooperation, there might be possibilities that PLN will stop the O&M process, as happened in the case of MHPP Wakaleo Sawah (DAGI Consulting, 2018). But overall, based on the statement from Bappeda, PLN has conducted the O&M process well in the professional way (Gah, 2018).

3.4. Operation and Maintenance by Private Sectors

The last model of O&M is handled by the private sector in collaboration with BUMDes. In the case of East Sumba, the solar PV installation, with 11 microgrid solar panels, has electrified 5 villages, namely Tawui, Lailunggi, Praimadita, Tandula Jangga, and Praiwitu Village since April 2018. The solar PV has the total capacity of 492 kWp and be able to supply the electricity for 852 households and 57 public facilities (MCA-Indonesia, 2018). The project is funded by the United States of America under the grant from MCA-I.

The collaboration between the private sector and BUMDes is working under the certain scheme, (i) the BUMDes in each village establish the joint BUMDes (BUMADes), (ii) the joint BUMDes creates a company in the form of PT (Perseroan Terbatas/Limited Liability Company, (iii) the company owned by these BUMDes is collaborating with the project developer, PT. Mikro Kisi Sumba (MKS). The profit sharing from the scheme is 51% for the BUMDes and 49% for the project developer (Gah, 2018). In order to ensure the sustainability aspect of this project, the 5 established BUMDes in the villages (52 management members) had received the management and entrepreneurship training (MCA-Indonesia, 2018). PT. Mikro Kisi Sumba acts as the holder of WUPTL (Wilayah Usaha Penyediaan Tenaga Listrik). For the O&M process and main distribution network are handled by PT. Listrik Vine Industri, meanwhile the minor O&M is handled by the BUMDes. Besides that, Hivos has also established a renewable energy service company, PT. RESCO Sumba Terang that is focusing on the O&M process for the renewable energy facilities built by Hivos and funded by MCA-I (DAGI Consulting, 2018). Based on the statement of Bappeda, the private sector O&M process is well conducted by developer. It has also increased the participation rate of BUMDes, village government, and the community to preserve the renewable energy power plant (Gah, 2018).

4. Discussion and Concluding Remarks

Based on the information gathered through interviews, focus group discussion, and direct observation, there are currently four O&M models existed for communal renewable energy system in Sumba Island. The first model which solely relies on the local community, both the end user and the appointed local technician, faced huge challenges in maintaining the system. The lack of capacity of the local community and financial issues are consistently came up in the models that use local community for the system's O&M. Whereas the other three models are able to sustain their O&M phase up until present time.

It is worth pointing out several limitations in our study, particularly those that are present in the methodology. Firstly, the analysis is limited in both scope and time. The number of respondents through whom we were able to acquire data were not sufficient to represent all off-grid renewable power plants in Sumba Island and their respective technologies. The time they were afforded was also limited due to their other obligations at the time. Secondly, due

to the disproportionate number of technologies represented by the respondents, we therefore contrived to categorize all manner of RE technologies like solar, wind farms, micro hydro, and biogas, among others, under one umbrella term: renewable energy power plants. We recognize that by doing so, we inadvertently generalized issues or complexities unique to a certain set of technologies for the sake of simplicity.

This early study has shown that in order to sustain the O&M phase of renewable energy system in Sumba, the involvement of the third party is still needed. Furthermore, since the capacity of the local community is relatively low, the regular training is not sufficient to enhance their skill. There is a need for a more intensive training to prepare the locals for this phase. The result also shown that it is possible for the local community to do the O&M phase for sustaining the RE systems in their village as long as that the collaboration with other party is well established.

Research Paper

GREEN AND BLUE INFRASTRUCTURE TO REGULATE THERMAL COMFORT IN HIGH DENSITY CITY PLANNING- A CASE OF NAVI MUMBAI, INDIA

ADINARAYANANE RAMAMURTHY, Associate Professor and Head- Department of Planning, School of Planning and Architecture Vijayawada, Andhra Pradesh; India

ANUSHA ROY, Master in Environmental Planning and Management- Department of Planning, School of Planning and Architecture Vijayawada, Andhra Pradesh; India

Abstract

Cities create an environment that is clearly distinct from their surrounding areas. Urban structures alter the surface energy budget, modify the vertical profile of various atmospheric properties, interact with both local and regional circulation, and introduce anthropogenic heat. As a result, the climate conditions in the urban environment significantly differ from their rural system. Sustainability in planning is a topic of high interest among urban planners, urbanist and policy makers yet lack of scientific knowledge in the field leads to low impact in evolving urban planning decisions. Urban climatic map, as a tool provides a visual and spatial information platform using Geographic Information System (GIS). Increase in vegetation and water surfaces, known as green and blue infrastructure (GBI), is of particular interest due to their multiple functionality and benefits for the urban environment, such as increasing urban biodiversity and improving air quality in case of urban vegetation.

The urban climatic, environmental and planning parameters, as well as their impact, are considered to synthesize and comprehensively evaluate the physical urban environment with regard to thermal load and dynamic potential. The parameters considered to evaluate Thermal load include: Topography; Population Density; Land Surface Temperature; Air Temperature and Dynamic potential are: Normalized difference Built up Index; Normalized difference Vegetation Index; Normalized difference Water Index and Prevailing Wind of the study region. Study concludes with planning decisions to develop urban climatology-based map for GBI to enhance cooling effects and thereby undertaking measures to regulate thermal comfort in the city through green and blue infrastructure.

Keywords

Urbanization; GBI; Thermal load; Dynamic Potential; Urban Climatic Map; Sustainable Built Environment

1. Introduction

1.1. Background

World has seen an increased gathering of its population in urban areas, since 1990. This trend is not new, but relentless and has been marked by a remarkable increase in the

absolute numbers of urban dwellers from a yearly average of 57 million, between 1990-2000 to 82 million by 2018. In 1990, 43 per cent (2.3 billion) of the world's population lived in urban areas; by 2015, this had grown to 54 per cent (4 billion) (UN Habitat, 2016). By 2050, global population is projected to increase to around 9.8 billion. It's estimated that more than twice as many people in the world will be living in urban (6.7 billion) than in rural settings (3.1 billion). It's projected that 68 percent of the world's population will live in urban areas (Roser, 2018).

Such urban expansion is not only wasteful in terms of land and energy consumption, but increases greenhouse gas emissions. It has also led to the alteration of ecological systems in many cities over the past two decades (UN Habitat, 2016). Urbanization directly contributes to deforestation of large chunks of tree cover for accommodating the ever-increasing population. This leads to decrease in the services provided by the natural system. Urban structures alter the surface energy budget, modify the vertical profile of various atmospheric properties, interact with both local and regional circulation, and introduce additional sources of heat (e.g. anthropogenic heat). As a result, the climate conditions in the urban environment significantly differ from their rural counterparts (Di Luca, 2015).

In view of above it is inevitable to have a sustainable planning strategy for high density cities. Sustainability in planning is a topic of high interest among planners yet lack of scientific knowledge in the field leads to low impact urban planning decisions. Urban climatic map (UC map) as a tool provides the visual and spatial information platform using GIS (Ar. Ebin Horrison, 2011). Increase in vegetation and water surfaces, known as green and blue infrastructure, is of particular interest due to their multiple functionality and benefits for the urban environment, such as increasing urban biodiversity and improving air quality in case of urban vegetation (Früh, 2016).

1.2. Research Concern

The high-density cities contribute by various factors in increasing the thermal stress in the city. For a sustainable built environment, it is important for planners to strategize the city planning to achieve thermal comfort. At the same time, climatic conditions at city level have to be collaborated with plan making. Climatic concerns in urban planning and design can impact on the thermal performance of urban areas, help reduce energy consumption and dependency on fossil fuels, decrease emissions, provide energy and cost efficiency, and contribute to cleaner and more comfortable environments(GEDİKLİ, 2018).This research is an attempt to understand how urban climate maps can be operational to arrive at plausible decisions in urban planning, thereby undertaking measures to regulate thermal comfort in the city through green and blue infrastructure.

Keeping the aforesaid knowledge in mind, the researchers have chosen Navi Mumbai as study area for further investigation.

2. Urban Climate Dynamics

2.1. Urban Climate Dynamics

There is a general understanding that — "A different climate is produced by the built environment in urban areas – the urban climate". Today, the term "urban climate" also encompasses the change in the natural composition of the air through anthropological

influences. Every structure has an influence upon the individual climatic elements. Large built-up areas divorce themselves in a climatic sense from their surrounding landscape. The significant causes contributing to the production of a separate urban climate lie in the far-reaching alteration of the heat budget and the local wind field. This heat can be either stored or emitted from any urban area from the building volume, topography, population density and land uses. The intra-urban air temperature variations due to the urban forms and surfaces can be termed as Thermal Load. A key problem of urbanization is the Thermal Load it generates due to buildings and artificial/man made surfaces (ARUP, 2006). This thermal load can be minimized with the availability of wind and cold air mass exchange in particular localities of urban areas. The availability of green and blue spaces in any city can catalyse the cooling effect which can thereby reduce the thermal load of the city (K.R. Gunawardena, 2016).

2.2. Physical Criterion for Developing Urban Climatic Map

The urban climate of the city can be characterized with a balanced consideration of —negative effects, i.e. the Thermal Load (e.g. building bulks) and —positive effects, i.e. mitigation factors to reduce Thermal Load (e.g. green spaces) and promote Dynamic Potential (e.g. air ventilation). Table 1 depicts the all the input layers required to generate the Therma Load and Dynamic Potential of the study area.

Table No. 1 Overview of GIS layers for Urban Climate Analysis Map

S.No	PHYSICAL CRITERION	EFFECT ON TEMPERATURE	INPUT LAYERS
1	Thermal Load	Positive	1. Topography 2. Population Density 3. Land Surface Temperature 4. Air Temperature 5. Normalized difference Built up Index (NDBI)
2	Dynamic Potential	Negative	1. Normalized difference Vegetation Index (NDVI) 2. Normalized difference Water Index (NDWI) 3. Prevailing Wind

Source: Compiled by the researcher based on literature review, 2019.

2.3. Thermal Load Map

By adding the specific classification values of the above 6 layers based on weightages given to each parameter determined by the regression and correlations with respect to Land Surface Temperature (Topography, Population Density, Land Surface Temperature, Air Temperature, Normalized difference Built up Index (NDBI)). The classification values for the composite layer of Thermal Load are derived and the result generated is presented in figure 1, which indicates the rank wise temperature values in the system. The Higher ranks shows areas with low temperature.

It has been observed that darker shades of red and orange shows the higher intensity of thermal load in certain location of the study area. It can be clearly seen how the areas near to the water body and green spaces are relatively having lesser thermal load compared to

the other areas. Further, Figure 1 reveals that areas with higher built up show shades of darker yellow and orange which is comparatively warmer.

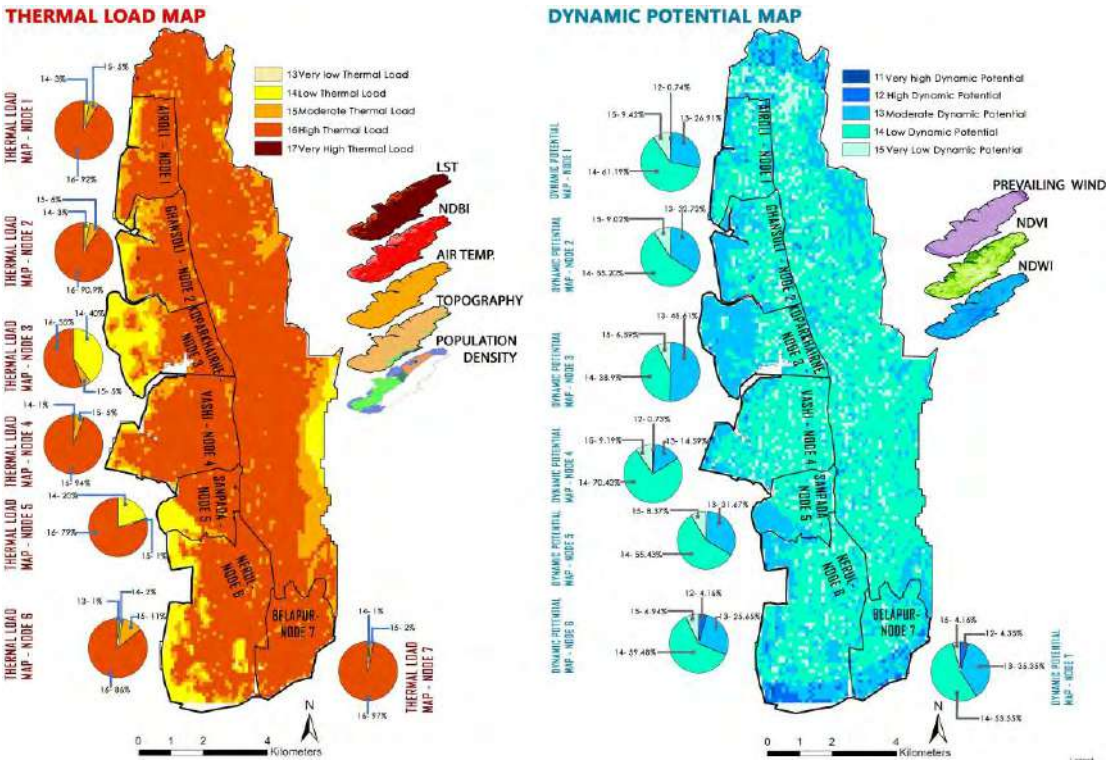

Figure 1 Thermal Load and Dynamic Potential Map for Navi Mumbai, 2018

Source: Map generated by the researcher based on the thermal load and dynamic potential parameters, 2019

2.4. Dynamic Potential Map

The parameters which are in negative correlation with temperature, which can better mitigate the heat load of the city are added together based on the weightages depending on the correlations and regressions to prepare the dynamic potential of the city and results were generated through map and presented in Figure 1, which indicates the rank wise temperature values in the system. The higher ranks indicate low temperature values in the system.

It has been observed that the areas near to the Creek and ponds are comparatively cooler than the inner city. Areas with decreasing cooling effect can be attributed to the lesser extend of Green and Blue infrastructure in those areas. The northern and the southern part experiences much cooler temperature which can be due to creeks on South and North as well prevailing winds which have more velocity, in the study region.

2.5 Urban Climate Analysis Map

The thermal load and dynamic potential values are synergised through the function of raster calculation in GIS to generate the Urban Climate Analysis map (Shown in Figure 3 - left). This results in 9 classes, however, for the purpose of planning information needs, the 9 classes are simplified and collated into 4 classifications as shown is Figure 3 (right). This map acts as

an information and evaluation tool which integrates the climate and planning factors and guides the planners by providing an urban climate-based planning network.

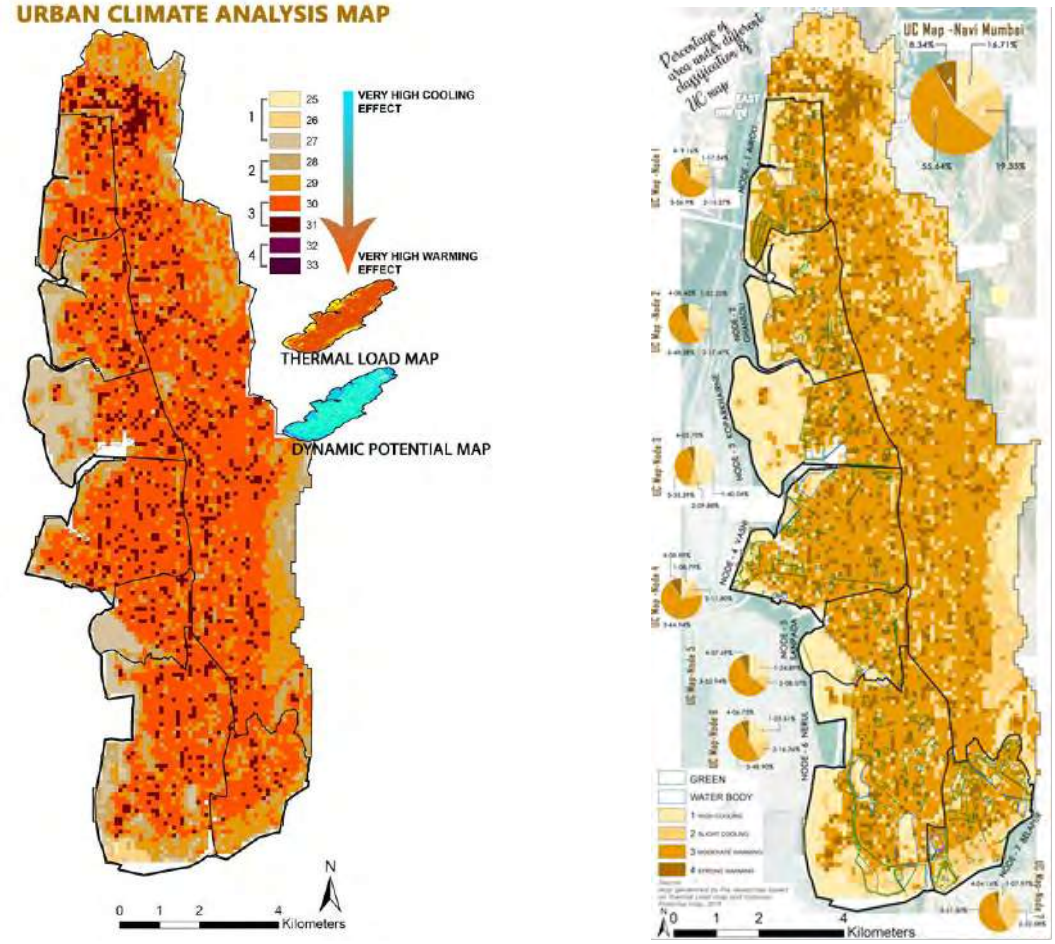

Figure 3 ***(left)*** **Urban Climate Analysis Map and** ***(right)*** **Final Urban Climate Analysis Map for Navi Mumbai, 2018**

Source: Map generated by the researcher based on Thermal Load map and Dynamic Potential map, 2019

It can be seen from the Urban Climate analysis map shown in Figure 3, which in the entire city, there are small patches of dark brown pixels which experiences a higher temperature due to the land use in those areas. At the same time areas near to green and blue infrastructure of the city are comparatively cooler. Thus, through planning decisions, we can incorporate these effective spaces into the core city area which can help in creating a comfortable built environment to sustain. Through the climate analysis map, the bottleneck areas can be identified clearly and the influential parameters pertaining to the same can be understood. This can help in taking planning decisions to make those areas more liveable with respect to the minimizing the effect of higher heat load in the areas. The climate map indicates the status of urban climate environment and the probable issues seen under it. It clarifies the challenges for spatial planning. This map can further give a clarification on how urban climate map is affecting other systems in the city.

3. Planning Tools and Techniques

3.1. Climate Analysis Tool

ArcGIS software was used as a tool to process data acquired from Landsat 8 imagery of USGS portal, as it is the best tool that can turn datasets into useful information. ArcGIS helped in generating computer-based mapping and analysis which could make significant contributions in the areas of geographic planning and environmental science. Specifically, with respect to the green and blue infrastructure and the climatic parameters were integrated with ArcGIS to develop Urban Climate map for the study area.

3.2. Statistical Techniques

Statistical techniques like correlation, regressions, ranking and weighted sum were also used to establish the linkages between various control parameters which decide the dynamic urban climatic environment of the study area.

3.3. Simulation Tool

In order to analyze the climatic environment of the study area, grassroots level administrative boundary has been considered for further detailed investigation i.e, Node; Node-4 was selected based on the fact that it has the least dynamic potential of the study region. A simulation was done to understand the outdoor thermal comforts. To perform the simulation, a 3-D model of the node was drafted with specifications of building height, type of land cover and type of plantation. This was integrated with the climatic parameter experienced in the node which includes temperature, relative humidity and prevailing wind. The simulation model helped in identifying the hot spots in the node which included roads and market area of the node. Thereby, planning interventions were made by improving and adding the Green and Blue infrastructure in the node.

4. Results and Discussion

4.1. Grassroot Level Urban Climate Analysis

The parameters for thermal and dynamic potential of each node were analyzed to understand the Urban Climate experienced in each node. It is clearly evident from Table -2 that out of all the nodes, Node – 3, i.e, Koparkhairne has less percentage of thermal load but due to the more percentage share of dynamic potential in the area, it is able to bring down the temperature of the area as a result, 40 per cent of the area lies under “1” in UC Analysis map which represents a lower temperature region. Node 2,6,7,5 and 1 which are Ghansoli, Nerul, Belapur, Sanpada and Airoli respectively, lies from Lower to moderate to high temperature region because of the distribution of the thermal load and dynamic potential of the area. In these areas the cumulative sum of lower and moderate temperature is almost 50 per cent of the total area. Out of all the nodes, Node- i.e, Vashi experiences a higher thermal load and at the same time the dynamic potential does not have a strong impact to counter the heat ingress due to thermal load.

Table 1 Comparative analysis of thermal load and dynamic potential for all the nodes

S.No	NODES	THERMAL LOAD					DYNAMIC POTENTIAL					UC MAP VALUES

Source: Compiled by the researcher based on node wise analysis of UC Map, 2019

4.2. Observations and Findings

For each node, thermal map, dynamic potential map and their respective urban climate map was generated. It is observed that the nodes experience a strong thermal load in the built – up area, but, at the same time, within the built-up spaces, where the green and blue infrastructure are present, a considerably lower temperature is observed. A very strong cooling factor can be seen in the system which can convert the higher temperature areas to lower or moderate temperature zones thereby, establishing a major share of lower and moderate temperature in the system. Therefore, the areas with stronger dynamic potential are able to influence the thermal load of the system resulting to lower temperature in their respective area. When climate Analysis map is integrated with land use map, the results of climate analysis map gets well synchronized with specific land use allocations of the study area. Further, the cooling intensity of the study area lies under the green and blue spaces designated land uses in the system. Therefore, the node wise study results reflect the real system of the study area.

The map produced by overlaying the boundaries of urban green and blue infrastructure with urban climatic map clearly shows that most of the areas with green and blue infrastructure, experiences a lower temperature (subjected to the characteristic of the Green and Blue infrastructure) thereby, highlighting the potential of green and blue infrastructure to enhance the cooling effect in the system. It is evident that the areas with denser green and blue infrastructure experiences lower temperature compared to other areas.

5. Recommendation and Conclusion

5.1. Planning Intervention and Policy Guidelines

Navi Mumbai is regarded as one of the modern and planned cities of India and hence it has been designed to efficiently manage the urban challenges (CRISIL, 2012). However, various influence of the increased urbanization has altered the climatic condition of the city over the years. It is observed that areas with green and blue infrastructure experience a low thermal stress and high dynamic potential. Therefore, the planning intervention focuses on promoting Green and Blue infrastructure throughout the study area. An urban green and blue infrastructure network is made up of many elements that together facilitate movement through the city landscape. It is estimated that for every 100m^2 of vegetation added to a

park, it can affect 1°C decrease in air temperature. Shashua-Bar and Hoffman (2000) investigated that the green space effect contributes to about 0.5°C cooling of the air temperature comparing to the shading effect. The analysis of the study area typically indicates key points for physical linkages, where an important connection exists or where connection has to be established. Therefore, the researchers have made an attempt to connect the various green and blue infrastructures in the study area to create a flow of benefits obtained from the services rendered from the GBI in the system. This study, thereby, suggests sector wise measures for a climate responsive planning for the city by exploring the optimal planning intervention, which can help to enhance GBI in the system. Based on the findings of this research study, researchers identified four strategic planning interventions as presented in the sequel and recommended to enhance cooling intensity and to promote sustainable built environment of the study region.

(i) PROTECTIVE

- Location of mangroves and ponds in the study area and taking protective measures to sustain the benefits of the resources in the system.
- Prohibition of dumping debris into mangroves and ponds.
- Declare Mangroves area as protected zone.

(ii) DEFENSIVE

- Planting saplings in the areas which has lost the mangrove cover due to encroachment.
- Fencing the new mangrove sapling from high tide.
- Dense Plantation of green cover in the open land separating each nodes.

(iii) OFFENSIVE

- Installing vertical mesh across the cross section of storm water drain to prevent leaves falling into the drains to be disposed off to the creek.
- Collecting the leaves fallen on the surface and making green manure for plants
- Planting trees such as water willow along the drain to increase the green cover in the study area.

(iv) OPPORTUNISTIC

- Planting tree saplings in the vacant land.
- Parking spaces to be covered with a slab where rooftop vegetation can be installed to keep the area cooler at the same time provide shad to the vehicles.
- Rooftop plantation over the railway station.
- Extensive plantation along the sides of the expressway running through the city.
- Skywalks to be developed into a public arena with vegetation and water body for both improving the GBI in the system as well as creating social spots in the city.

(v) RESILIENCE

- Compulsory Rooftop plantation for any new construction.
- Plantation along either side of the highway.
- Rooftop plantation over railway stations, skywalks and parking lots.

(vi) POST PROCESSING

- Research on the climate resilience of the system through simulations with the existing and proposed measures for the improvement of the system.
- Developing the most viable economic measures for resilience in the system.
- Result analysis and display to the public at large.

5.2. Application of Planning Intervention in Node: 4- 'Vashi'

Vashi (Node - 4) was the first node developed by the planning authority of Navi Mumbai, as a result it is one of the most saturated nodes of the study area. Moreover, the dynamic potential of Vashi is less compared to the other nodes of the study area. Therefore, it has been considered for a detailed implication of the planning mechanism. Figure 4 identifies the protective, offensive, defensive and opportunistic area of the node. The existing Green and blue infrastructure have a total area of 1.6 Km^2. The proposed area for green and blue infrastructure development is 1.4 Km^2. Thereby, increasing the existing total green infrastructure to 3 Km^2 which will provide a stronger dynamic potential of the area.

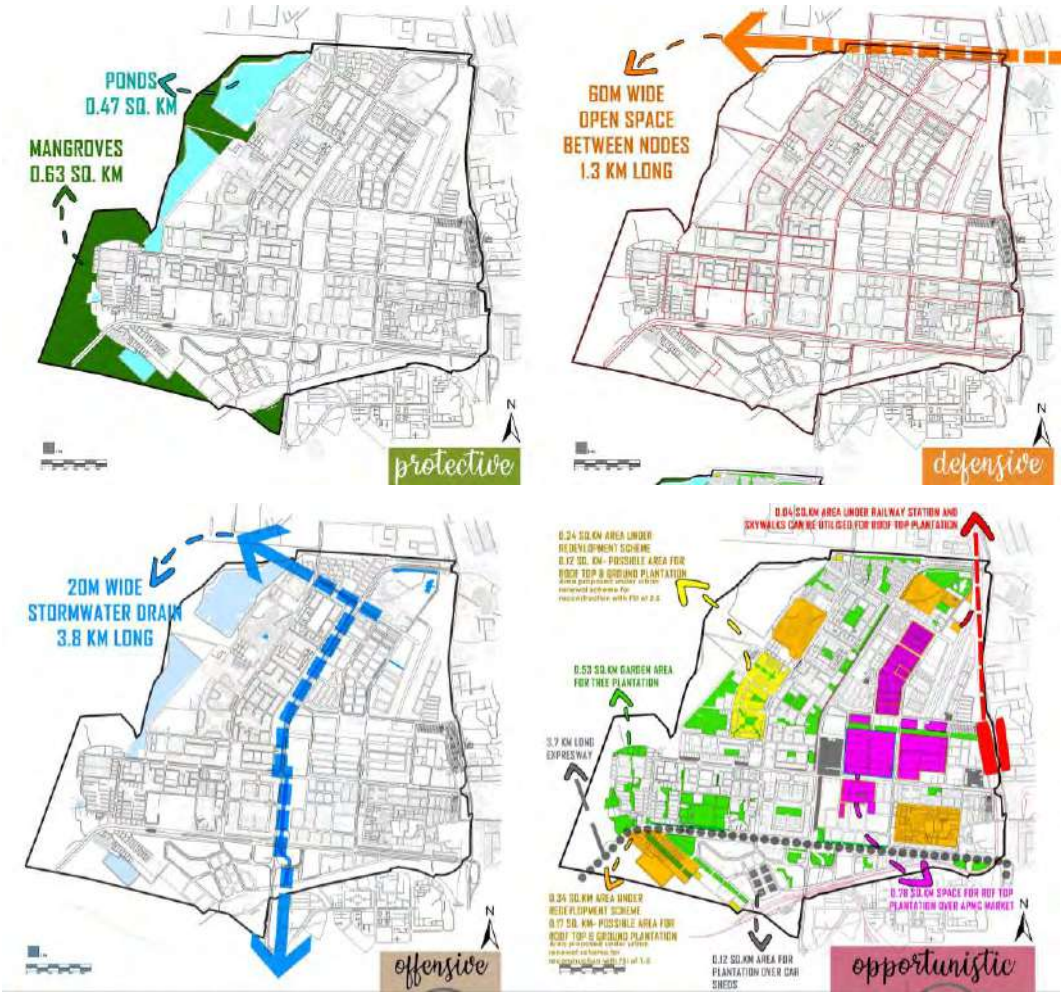

Figure 4 Planning interventions for Node – 4

Source: Generated by the Researcher, 2019

The planning interventions were made by improving and adding the Green and Blue infrastructure in the selected node of the study region. The results with intervention showed a dip in temperature by 2^{o}C for the entire node as shown in Figure 6.

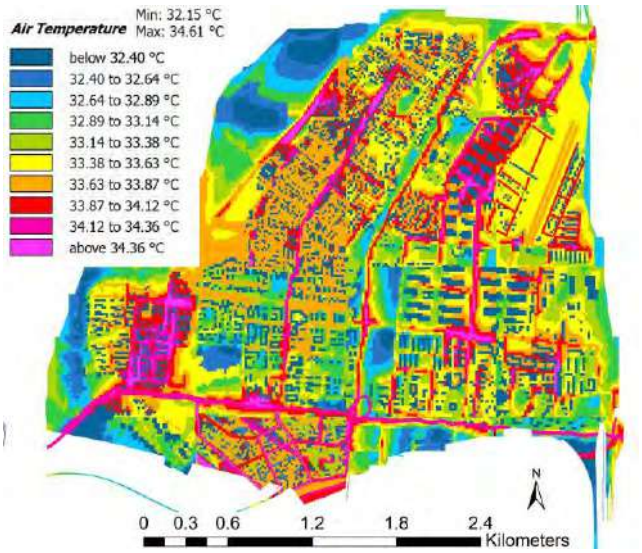

Figure 5 Existing temperature of the node without interventions

Source: Map generated by Researcher based on temperature, relative humidity, prevailing wind, green and blue spaces and building height of the selected node for 9th May 2019 using ENVI-met.

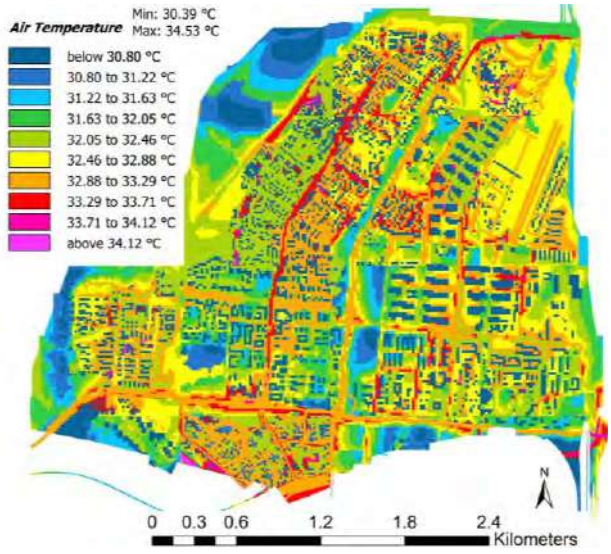

Figure 6 Temperature Difference experienced in the node after interventions

Source: Proposal Map generated by Researcher based on temperature, relative humidity, prevailing wind, green and blue spaces and building height of the selected node for 9th May 2019 (2:00 pm) using ENVI-met.

This research study conclude with the intervention includes 30 M plantation on the nodal boundary, 4 M wide plantation on both the des of the drainage network flowing in the node, 0.78 KM2 rooftop plantations over APMC market. 3 M wide plantation around the periphery of existing gardens, 0.04 KM^2 rooftop plantation across the railway station, 0.02 KM^2

plantation on the sides of the expressway, 0.12 KM^2 rooftop plantation over parking spaces, preserving and protecting the existing mangrove cover and water body and 0.30 KM^2 rooftop plantation over proposed redevelopment area. These planning interventions have facilitated in reducing the temperature of the node by 2^o C in the study region. The results of this research study witnessed that Green and Blue infrastructure plays a vital role in regulating thermal comfort and therefore, it is recommended to have city planners/policy makers to focus on optimal planning interventions, which will pave the way to achieve sustainable living environment in the transforming urban system.

Case Study / Project

Sinking, Growing, Resilient:
a Multidisciplinary Approach to Climate Adaptation in Semarang, Indonesia

Jackson ROLLINGS, Travis BUNT, Rizqa HIDAYANI, Peter LETITRE,
Sander CARPAIJ, Despo THOMA

Abstract

In 2018, the Netherlands Enterprise Agency kicked off Water as Leverage, a program aiming to bring water-based solutions to address climate and urban risk in three Southeast Asian cities: Chennai, Khulna, and Semarang. The '˜ONE Resilient Semarang' team - a group of designers, engineers, economists, ecologists, art activists, and academics - was tasked with developing design-driven, bankable project ideas following an initial phase of research, analysis, stakeholder engagement, and on-the-ground coalition-building with agencies and institutions. In this presentation, members of four partnered organizations on ONE Resilient Team (One Architecture & Urbanism, Kota Kita, Deltares, and Wetlands International) will bring multidisciplinary perspectives to Semarang's current catch-22: it is a city economically dependent on the same extractive coastal industries that exacerbate its subsidence and flood risk, projected for even more drastic urban densification and economic expansion in the coming years. Instead of developing one-off infrastructure proposals for the city, ONE Resilient Team instead chose a more holistic approach centered around a widespread reorientation of water use across the entire city, from coast to upland, from Kendal to Demak - altogether comprised of potentially hundreds of projects.

The embedded goal is to address challenges in a programmatic manner, potentially sparking transformational, bottom-up and top-down change in processes and governance. With the combined disciplines of urban design, community-based planning, water / coastal engineering, and ecological restoration, ONE Resilient Team's conceptual proposal aims to find integrated solutions to the combined water related risks of climate change and socio-economic growth by drawing from expertise across sectors and backgrounds from across the globe. This presentation will seek to address these issues through the prism of four disciplines among many more represented within the team, asking how resilience can operate beyond an individual project as a guiding development principle for climate-vulnerable cities and landscapes.

Research Paper

EXPANDING AN UNDERSTANDING OF URBAN RESILIENCE IN THE REALM OF ADAPTATION PLANNING

Natalie ROSALES, CONACYT-El Colegio Mexiquense; Mexico

Abstract

As cities have become more central to development, resilience, risk assessment and prevention instruments have gained greater importance in urban planning considerations. By using the case study of Mexico City's Climate Action Programme, this piece of work contests the way in which resilience has been embedded in urban adaptation planning. Grounded on a planning evaluation based approach to analyze on which methodologies, tools, and frameworks have been used, and which key actions and strategic lines to building resilient cities are contemplated, this descriptive research incorporates urban-regional metabolism dynamics and environmental data such as carrying capacity, into Mexico city climate change scenarios and vulnerability analysis matrix. By doing so, the article introduces new ideas that can: i) move from risk management to uncertainty oriented planning; ii) understand vulnerability in the context of equitable sustainable development, while highlights the opportunities transformative resilience offers to enable transformations towards sustainable urban futures

Keywords

Transformative resilience, urban planning, urban resilience, sustainability indicators

1. Resilience as a new framework for planning the cities

In the face of such challenges as growing inequalities, natural resources depletion, peak oil, climate variability, extreme weather events and global economic challenges, the arrival of resilience as a concept within the social sciences to inform political rhetoric, as well as a heuristic and operational tool, has positioned it as a new paradigm and a banner (Lampis, 2015).

The concept has crossed disciplinary discussions becoming a thinking approach, which investigates how interacting systems of people and nature can best be managed in the face of disturbances, surprises, and uncertainty (Biggs et al., 2015). It has also been progressively embedded into policy-oriented discussions, mainly focused on climate and global environmental change (Lampis, 2015). In this way, more and more we hear about resilience as an applicable concept to prevention strategies, community empowerment, collaborative initiatives, economic recovery, urban planning strategies, and so on. In fact, the term has been a great catalyst for community management and adaptation planning focused on

identifying specific measures and processes that can address the uncertainties of climate change through action and implementation. Thus we find that at the local level, an increasing movement to build resilient communities has grown over time aiming to "anticipate[s] problems, opportunities, and potentials for surprises; reduce[s] vulnerabilities related to development paths, socioeconomic conditions, and sensitivities to possible threats; respond[s] effectively, fairly, and legitimately in the event of an emergency; and recover[s] rapidly, better, safer, and fairer" (Hearn, 2008).

Following these tendencies the concept has arrived in the urban arena and the efforts to build resilient cities have increased, generating new perspectives and urban planning frameworks to tackle the enormously complex interactions between different (non-scalar) components of socioecological systems, which include governance networks, economic systems, resource flows, social dynamics and the structure of the built environment (Resilience Alliance, 2007). Among these new approaches, stands out the following three: disaster risk reduction (DRR); social vulnerability; and urban political ecology.

1.1. Resilience and climate change adaptation and disaster risk reduction (DRR) approach

Recent discussions on sustainability connect global warming and climate change, and their association with resilience. Becoming a widely debated issue in urban sustainability and risk management literature. The planning resilience approach rooted in risk and uncertainty argues that change will occur, and as unexpected shocks are not able to prediction. Therefore, cities must strengthen their capacity to handle and deal with external threats such as natural disasters (hurricanes, floods, and earthquakes), the depletion of natural resources (oil, water) and shocks (Abhas, et al., 2012).

In this regard, the notions of building resilience refer to the ability of human settlements to withstand and to recover quickly from any plausible hazards. However, also from an economic standpoint, it stresses the importance of recovering from crises, not only by reducing risks and damages from disasters (i.e., loss of lives and assets), but also strengthening the ability to quickly bounce back to a "stable state" (UN HABITAT, 2016).

This vulnerability/resilience paradigm which calls on building resilient and intelligent urban environments, who are able to "anticipate" future shocks, has been driven by international institutions like the World Bank, UN-Habitat, the European Commission, ICLEI, and has mostly replaced a hazards approach in the social sciences (ICLEI, 2012).

As such, there are different initiatives focused on developing city stakeholder's capacity to address the challenges, uncertainty, and unpredictability of all types of change and disturbance. Including natural hazards, such as the Resilient Cities Project from the OECD; the United Nations International Strategy for Disaster Risk Reduction (UNISDR) launched its 2010-11; the Worldwide Disaster Reduction Campaign explicitly including the issue of 'resilient cities'; ICLEI's Resilient Cities initiatives; UN-Habitat City Resilience Profiling Programme; Rockefeller Foundation's 100 Resilient Cities project, just to name a few.

Nevertheless, even when, much of the literature and practices focus on this approach, resulting in disaster reduction and a better understanding of hazard, there is increasing recognition that a more complex part of the equation lies in the way in which societies are organized (Mitchell, 1999).

1.2. Resilience and the critical perspectives approach

The social vulnerability approach

From a critical theoretical framework, there is an essential body of knowledge that investigates and evaluates the social, institutional, and policy roots of urban ecosystem resilience to understand the nonlinear relationships and interacting systems (Campanella, 2006). These studies have focused on how different urban ecosystems can adapt, adjust, renew and transform in response to trauma, national economic and demographic challenges, and global climate change, highlighting an important issue: resilience is the counterpart of vulnerability (Campanella, 2006)

Under this point of view, the social vulnerability approach emphasizes that there are specific social, political and economic processes and structures that lead to vulnerable conditions. So, risk varies not just according to the hazardous agent, as it is distributed unequally among the impacted population and communities. Therefore, advancing resilient actions in anticipation of risk, in reaction to impacts, or recovery from the effects, requires four factors: (1) knowledge of the hazard; (2) accurate perception of the risk; (3) understanding available alternatives; and (4) resources and flexibility. These factors most of the time are out of control of the population as they depend on more significant economic and social forces (Wilbanks, 2008).

In this regard, this social vulnerability approach helps to explain how communities that operate as groups with a sense of collective cohesion and identity, deal with adversity and stress and gain or lose functioning and strength as a result of trauma and disaster (Campanella, 2006).

The political urban ecology approach

Researchers supported by a critical school of thought, remind us that "cities are fundamentally natural, as human and no human residents compose their population, formed from earth material, and supported by ecological processes which are always due to politicization. Whether in the flow of water through the city, the uneven distribution of trees in its landscapes, or the environmental hazards imposed upon its citizens" (Robins, 2012). So, two concepts that have entered urban political ecology in its encounter with resilience approaches are the metaphor of urban metabolism and the notions of environmental justice.

Urban metabolism can quantify not only the dependencies cities have on external resources and how this relation can affect their adaptive capacity. Also, aiding to understand the way in which powerful actors and interests bend and funnel natural materials and forces to increase rents, develop properties, fuel growth, empowering or disempowering communities.

On the other hand, the concept of environmental justice points out that exposure risks are significant and unquestionably associated with historically dis-enfranchised groups (Cutter, 1995). This idea predicated on the well-known fact that disempowered communities (especially racial minority groups and the urban poor) have been located in and around technological and natural hazards (lead smelters, garbage incinerators, or power plants).

These two epistemological assumptions argue that understanding how urbanization operates in metabolizing nature and in the creation and distribution of risks, vulnerabilities, and opportunities among urban dwellers, are imperative for addressing resilience at the

urban scale. So, in order to build resilient communities there is a need for a deeper understanding of public responses to these challenges, and how planning can support synergistic relationships between resilience and environmental (The Bartlett Development Planning Unit, 2016).

Based on these different approaches, the debate about resilience has become central to urban sustainability, so risk assessment and prevention instruments have gained greater importance into urban planning considerations. In particular, the adaptation and disaster risk reduction (DRR) approach has been introduced as a useful framework to tackle the environmental, social and economic risks posed by climate change in cities.

Nevertheless, even when this use of the concept, represents an advance in contemporary planning frameworks, the focus on urban risk management, which has dominated the incorporation of resilience in planning practice, tend to restricts assessment and strategies to anticipate short-term disturbances, such as hazard or disaster recovery; while leaves aside vulnerability, environmental justice, and the capacity of urban systems to adapt, in the wider context of urban sustainable transitions.

In order to illustrate this, the following section will then focus on urban resilience strategies and approaches implemented in Mexico City's planning instruments.

The aim is to chart the contours of a critical assessment, exploring the use of the concept, the shortcomings of the principles adopted and how can we move forward to use this heuristic tool as a part of a comprehensive urban sustainability strategy.

This analysis is grounded on a planning evaluation based approach, and it is divided into three parts: i) a study on which evaluation frameworks, methodologies, tools and key and strategic lines to building cities resilience are contemplated; ii) a quantitative and qualitative analysis that incorporates urban-regional metabolism dynamics and environmental data such as carrying capacity, into the climate change scenarios and vulnerability analysis matrix, in an attempt to forecast future scenarios and define some priorities to increase socio-ecological sustainability and resilience; and iii) a proposal to move from risk management to uncertainty oriented planning.

2. Planning framework for building urban resilience in Mexico City: The Climate Action Programme

Mexico City experienced a fast population growth leading the city spread to vast geographic expansion. This rapid change imposed pressures on urban eco-systems by creating new demands for land and more ecological services; increasing demand for urban infrastructure and services. The tensions due to the rapid growth and undersupply turn into water scarcity, traffic congestion, energy consumption, air pollution, and the appropriation of green areas for development.

At the same time, socio-economic and institutional factors have driven poor people –with a relatively little latitude of choice for house construction- into building houses on steep hillsides, making ecosystems more vulnerable to degradation.

Therefore, the issue of various environmental contingencies, by the hand of the recent intensification of meteorological events due to climate change, has increased cities

vulnerability, giving centrality to issues such as sustainability, and more recently, urban resilience.

In the last years, Mexico City, as an international actor, has positioned itself in the national and global contexts as one of the cities which is driving resilience projects, due to the assumed leadership on the climate change agenda promoted since the COP 16 held in Cancun. So, the debate around resilience concerning climate change has become one of the new narratives permeating the City's different legal planning instruments.

Also, the city has joined the program 100 Resilient Cities (100RC) from the Rockefeller Foundation and has received funding by $ 200 million to boost various programs and resilience strategies since 2015. Additionally, the government has allocated 10% of its budget, representing nearly 17,000 million pesos to boost resilience strategies. This initiative comprises four vulnerabilities areas and stress caused by disasters. i) Financing innovative technology infrastructure; ii) land use; iii) social and community resilience (Quintero, 2016).

Under this context, the main effort to incorporate resilience into planning instruments, identified is the Climate Change Action Programme 2014-2020.

2.1. Mexico City Climate Action Programme and the notions of urban resilience

Mexico City's Climate Action Program (PACCM, in Spanish) for 2014-2020 is a planning tool that integrates, coordinates and promotes actions to reduce the environmental, social and economic risks posed by climate change while simultaneously promoting the welfare of the city's population through strategies contained in the Local Climate Action Strategy (ELAC, in Spanish).

Regarding adaptation, the PACCM aims to increase the city's resiliency as well as the population's adaptation capacities, particularly for the 5.6 million people most vulnerable to extreme weather events, such as flooding. To achieve these goals, the PACCM includes specific actions for each of the strategic priorities that make up the Climate Action Local Strategy shown in Figure 1. These priorities seek to maximize synergies between adaptation and mitigation, in order to increase the cost-effectiveness of implemented actions to make them more attractive to potential funding bodies and other decision-making entities.

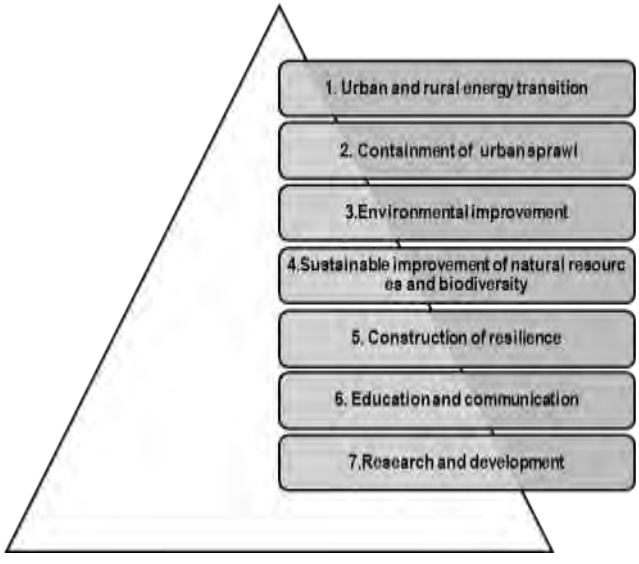

Figure 1. PACCM strategic priorities. Source: Authors elaboration based on Climate change Programme

As can be seen, building resilience to face the adversities of the process of mitigating and adapting to climate change is a particular objective and consequently one of the main components of the Climate Action Programme.

The term resilience is conceptualized as "the ability of citizens to absorb shocks and reorganize while undergoing climate change through decentralization of activities, the diversity of economic sources, decoupling between economic development and emissions CIS, the integration of the city with natural ecosystems, social cohesion and redundancy" (Gobierno de la Ciudad de México, 2014).

Accordingly, with this definition, the programme sets four attributes of an urban system to be resilient (Molina et al., 2013):

- Decentralization. Which refers to spatial dispersion of the critical activities in the city, to allow that in case of a disturbance in an area of the territory, the rest of the city can continue running smoothly.

- Diversity. Economic growth should decouple GHG emissions and integrate environmental concerns. Urban centers should be more efficient and less polluting.

- Flexibility. Ability to face disasters. It may be an administrative type, in infrastructure, economic activity.

- Redundancy. It refers to the duplication of the key and essential city services. The city must continue operating by using alternative networks, before collapsing.

Build upon this theoretical framework (resilience in reference to climate change adaptation), the plan departs from a diagnosis of the current situation of the city, focusing on two main aspects; exposure to multiple risks (extreme rainfall resulting in floods or landslides, droughts, heat waves) and poverty and inequality that contributes to high concentration of vulnerability in marginalized groups. So, vulnerability, as a key concept is a compound consequence of the fragility of the urban systems, the capacity of internal agents - including poverty, social marginalization- and other factors such as exposure to the impacts of climate change.

In this regard, by using indicators of exposure, sensitivity and adaptive capacities, the action programme indicates that the periphery is more vulnerable to climate change. Iztapalapa, Cuajimalpa, Xochimilco and Alvaro Obregon have an outstanding range of medium-high to very high; in contrast to the central areas which have low levels of vulnerability.

Strategies and recommendation for building resilience are placed at the broader context of adaptation to address the specific vulnerabilities to climate change which focuses on five issues:

- Urban and rural energy transition:

Energy efficiency

Renewable energy

- Containment of urban sprawl:

Urban planning instruments

Intra-urban green spaces

Infrastructure mobility and transport

- Environmental enhancement:

Reduction of emissions

Integrated waste management

Integrated management of water resources

- Management of natural resources and biodiversity conservation:

Native species and wildlife

Soil conservation

- Building resilience of the city:

Prevention and mitigation

In this line, the action programme promotes prevention and risk mitigation focusing on creating an environmental and economically active population despite destabilizing events, such as natural disasters caused by extreme behaviour on the elements of weather, environmental degradation, and economic and social crisis. Therefore adaptive mechanisms for building urban resilience are associated with the vulnerability of the population, damage to infrastructure (road, hydraulic, electric) and public health. Also, are associated with the improvement of the administrative, organizational capacity to move from prevention to mitigation of risk.

In this regard, key actions to build resilience refer to designing:

Up-to-date Hazard and Risk Atlas

Prevention Program (hydro-meteorological hazards)

The study, evaluation, and relocation of human settlements situated in risk areas

Early warning system to monitor and forecast hydro-meteorological condition of the metropolitan area

A preventive measure system in case of extreme weather events

Training and dissemination of prevention strategies related to climate change, to strategic sectors

Monitoring and prevention vector-borne integrating information

Prevention diseases program

An Environmental Fund for Climate Change

The strategy also explicitly recognizes the fact that building urban resilience to climate change cannot be achieved through ‘one-time' activity or ‘one-off' projects. Integration of multiple interventions at different scales and across different sectors is a must over time. Also, it emphasizes the role of external actors in catalysing and enabling responses, working with and through internal agents, and influencing where investment in changes to urban management is required.

For instance, it promotes an integrated approach which incorporates three topics: Urban planning, mobility, and environmental enhancement. The programme also remarks that mitigation actions should demonstrate co-benefits in the adaptation actions, and vice versa, seeking a positive impact on environmental and social development.

2.2. Analysis of the adaptation planning framework

Mexico City's adaptation planning framework helps illustrate how resilience undertakes within the aims and practices of contemporary planning instruments; what are the advantages and shortcomings of the principles adopted, and how can we rethink the concept of resilience within this planning frameworks to guide sustainability transitions. Table 1 synthesizes methodologies, tools, and evaluation frameworks.

ISSUE	DESCRIPTION
Urban resilience approach	Building resilience is at the broader context of the adaptation strategy that addresses the specific vulnerabilities to climate change. The planning instrument considers that a city can become more resilient concerning adapting to and ensuring the restoration of basic services, as well as social, institutional and economic activities. Concepts related: The framework focuses on the relationship between vulnerability and climate change. It considers exposure to risk, sensitivity, adaptive capacities, and internal agents. Vulnerability understood as a compound consequence of the fragility of the urban systems, the capacity of internal agents - including poverty, social marginalization, and other factors such as exposure to the impacts of climate change.
Methodologies and evaluation tools	**Methodology** The planning instrument combines investigation, data, and analysis to diagnose vulnerability. Overall the framework provides a robust analytical foundation for understanding vulnerability to climate change which then informs the identification and implementation of mitigation and adaptation actions, seeking synergies and co-benefits. **Methods for analysis consider:** Climate change scenarios Greenhouse compounds inventory emissions, which incorporates black carbon and fluorocarbons. A planning evaluation system which makes the plan (measurable, reportable and verifiable) every action has specific monitoring and impact indicators. It has an online tracking platform which provides information for

	decision-making, in a timely and effective manner. Indicators to measure vulnerability include: exposure to risk, sensitivity, adaptive capacities

Table 1. Analytical table

Based on this, it is possible to determine that this planning instrument combines investigation and data collection providing a robust analytical foundation for understanding vulnerability to climate change. In this manner, can be argue that the action plan in operational terms, is useful for understanding resilience in the broader framework of climate change and urban risk management, as it helps to identify:

- What are the hazards? What are the impacts?
- Who (which agent) or what (sector,) is going to be affected by which aspects of climate change?
- Specific sources of vulnerability and capacities associated with specific groups of agents and systems concerning specific change processes
- What needs to be done to address the impacts of climate change?

Still, as argued before, the focus on this climate adaptation planning and urban risk assessment approach, leaves out important issues that should be taken into consideration to forecast future scenarios and define some priorities to increase socioecological sustainability and resilience. First, an important matter related to resilience is concerning the degree to which cities can tolerate alteration is the level of exhaustion of natural resources. This matter deserves a high priority, as it represents a future shock that can affect environmental vulnerability entering the city in a condition of hysteresis. This concept relates a process of degradation which is not reversible by merely eliminating disturbances and may lead to new states (Westoby et al., 1998).

Cities as complex systems have multiples states, and the path back from a disturbance is often different than the path forward, some impacts may be considered irreversible, and may lead to new states. So, resilience does not always require that the system will return to its previous state or equilibrium but instead can adapt and transform into a new state that will allow it to survive further and future change (Folke, C. et al., 2010).

In this sense, Arefi (2011) argues that cities share these resilience abilities and are the subject of a various range of changes (Arefi, 2011).

Therefore, it is essential to use, as analytical tools, ecological concepts that will present a clear idea of the critical attributes of the urban system: adaptive capacity, self-organization, and transformability (Eraydin, 2013). This includes, natural resources availability, carrying capacity, ecological balance, environmental assessment scenarios, **(Rosales, 2017).** In addition, a resilient strategy should not be based only on mitigating and adapting to climate change, it should incorporate how to carry out incremental adjustments to move the city towards a circular metabolism and sustainable urban futures.

Second, resilience is, a powerful concept as it encompasses a better understanding of the complex interactions between the different components of socioecological systems including resource flows (production, supply and consumption chains; built environment (ecosystem services in urban landscapes); social dynamics (human capital and inequity); and governance networks (institutional structures and organization); their strengths and weakness. Therefore an underlying aspect interwove among these components is the notion of risk and vulnerability, which is not only related to exposure, sensitivity and adaptive capacities of a population but also with the specific social, ecological, political and economic processes that lead into vulnerable conditions (Campanella, 2006).

These multifactorial conditions have a particular interest in assessing resilience because vulnerability can be shifted onto disempowered populations (such as urban peripheries, and rural and peri-urban environments), or gained at the expense of adjacent cities (regional or national) or smaller (district level) systems (Chelleri & Olazabal, 2012).

Understanding the way how cities grow and metabolizes nature through infrastructure, not only reinforces an unequal distribution within regions, urban-rural domains, but also can lead to the empowerment of al-ready powerful and advantaged groups, while disempowers marginalized individuals and groups (Heynen, N., M, Kaika., & Swyngedouw E., 2006) can serve as a starting reflection point to determine opportunities and threats of urban systems to become more resilient and sustainable.

Therefore, indicators that better reflect the complexities of urban flows in relation to resilience, such as the metabolic flows of cities and regions (Rosales, 2018), which are a key component to understand the vulnerability matrix in the wider context of a sustainable development, should be incorporated.

In an attempt to illustrate how these oversights of the climate adaptation planning can be overcome, and properly carry out a resilience assessment, the next section will incorporate urban metabolism and sustainability environmental indicators into the analysis.

2.3. An assessment framework for the use of resilience in urban planning

Understanding urban-regional metabolism dynamics for climate adaptation and mitigation scenarios

In 2012, Mexico City consumed approximately 14 million MWh, which represents 7% of annual national energy consumption. The city's location is in a basin, where there are not intensive processes of electricity generation, oil activities or heavy manufacturing. So, only 20% of electricity is generated within the area, while the rest comes from the National Interconnected System (SENER, 2009). These issues imply that the city needs to design a strategy to be prepared to possible sustainability crises, such as energy shortages, pointing out as well, the imperative to move the city towards alternative (back-up) and diverse energy supply sources.

In the same year, the city produced 31.842 million tons CO2 equivalents emissions which, 80% derives from energy consumption in the form of fossil fuels and electricity, mainly from the transport sector while solid waste is the second factor which contributes to emissions generation (Molina et al., 2013).

Modelling scenarios estimate that in 2020 CO2e will increase to 34.5 million tons, and by 2025 about 37 million tons of CO2e, while the PACCM 2014-2020 will contribute to the

reduction of 8 million tons of CO2e and 2 million tons (Gobierno de la Ciudad de México, 2014).

These facts raise questions that both policymakers and planners need to consider. For example, material flows such as solid waste, which is also a significant contributor to emissions, would imply that building strategies for a resilient city need to set goals for dematerialization (consumption of fewer materials) and how to carry out incremental adjustments to move the city towards a circular metabolism.

In regard to disturbances, the scenarios methodology to project and predict the future risk associated with the climate change impacts, shows that according to the climate evolution patterns for Mexico City in the short (2030) and medium term (2050) possible future shocks could come from: a) The agricultural cycles by changes in the seasonality of temperature and rain; b) The creation of new habitats for the development of pest or disease vectors; c) Changes in biological diversity biomes and; d) Shortage of water resources.

Regarding to natural resources, even if water scarcity has always been a red spot for sustainability in Mexico City, water shortage factor of risk is not considered, in the current model as an environmental vulnerability which could drive changes in the system at multiple scales (for instance, an ecological region). So, if additionally to climate change scenarios we incorporate environmental indicators to understand the urban –regional metabolism dynamics, we can have a broader picture of imbalances in the urban system to forecast possible short and long-term disturbances that will help to adjust in the face uncertainty, designing prevention and adaptation strategies to manage this scenario.

For instance, water stress indicators can reflect the total volume of water extracted concerning the average natural water availability. In the case of Mexico City, water stress in the region is 120% (SEMARNAT, 2010).

Water supply has increasingly come from farther away. So the transfer of water extends about 130 kilometers. In addition to this long distance, Mexico City location in a valley implies that water must be pumped a thousand meters, equivalent to the burning of 3.4 million barrels of fuel per year (Tudela, 1991).

This information, therefore, not only confirms the strong dependency on external sources of water supply but also raises questions about the marked vulnerability to water availability, revealing how this relates to the contribution to green gas emissions; and the levels of environmental impact of the city.

The notions of resilience is related to the capacity to cope with disturbances, alternative stable states of complex systems and a dynamic balance. From this perspective, resource availability of the city to supply urban population demands, and ecological balance are also, two important factors to consider.

Bearing in mind that the predicted Biocapacity of the Earth estimation is 01.8 global hectares per capita (World Watch Institute, 2007), and the following results from the quantification of Mexico City carrying capacity (166, 031 Ha).

LAND USE	Has
Fossil energy absorption *has been related to forest surfaces (172.22 km2) and reforested areas (4 km).*	*17,622*
Built area *Local capacity to support urban infrastructure has been correlated with total built area, which corresponds to urban and industrial land use*	*59,192*
Cultivable area *for food production is related to the agricultural area*	*37,184*
Pastures *are associated with grassland, desert scrub and secondary vegetation.*	*34,527*
Forest	*17,222*
Water *and the category sea (water) is related to water bodies*	*284*
TOTAL	*166,031*

Table 2 Local Source: Authors elaboration based on (INEGI, 2010)

Mexico City to be ecologically sustainable would need about 15,906,631 ha. Ergo, the City has an ecological deficit of 15,740,600 ha because its population surpasses its carrying capacity in 90%, entering in a condition known as ecological overshoot.

These facts reinforce the importance to consider the availability of resources and urban metabolism dynamics, in order to assess its adaptive capacity, self-organization, and transformability. Mostly those related to water bodies to supply the demand, and food self-sufficiency regarding the low production due to the limited agricultural amount of space available. In particular, because climate change can exacerbate impacts affecting agriculture systems and water shortage. So, integrating food security and urban water cycle as analytical elements into urban planning should be established as a critical aspect of any comprehensive urban resilience strategy.

Understanding the vulnerability of urban systems in the context of an equitable and sustainable development.

While it is true that the city has a water shortage, due to the levels of exhaustion of the resource, and the fact that in the Metropolitan Area of Mexico water supply systems have been operating beyond their limits. This situation depends on the specific social-economic condition of the area in such way that unequal access to resources and disparities in the provision of infrastructure affects mostly the population in the southeast areas (Iztapalapa, Tláhuac, and Xochimilco), which have the lowest income levels.

Accordingly, to the Climate Change Action Program, the degree of exposure to the risk in the city varies from low to medium where the vulnerable population localizes on the south (in the delegations Tlalpan, Magdalena Contreras, Álvaro Obregón and Cuajimalpa). Mainly, characterized by irregular human settlements patterns, where the steep slope is very prone to washouts by the presence of water erosion.

Table 3 Degree of exposure to risk of the population in the city. Source: (Gobierno de la Ciudad de México, 2014)

Following the assessment model, when adding the effects of climate change such as 1) Growth in water demand. 2) Increased degradation in catchment areas. 3) Reduced water quality and recharge, among others, it is possible to foresee the way in which some parts of the city will increase their vulnerability.

As the table 2 shows water availability in the different municipalities of the city, already present critical levels of consumption in those settlements with the lowest welfare conditions, while higher income sectors consume over 80% of the water provision available.

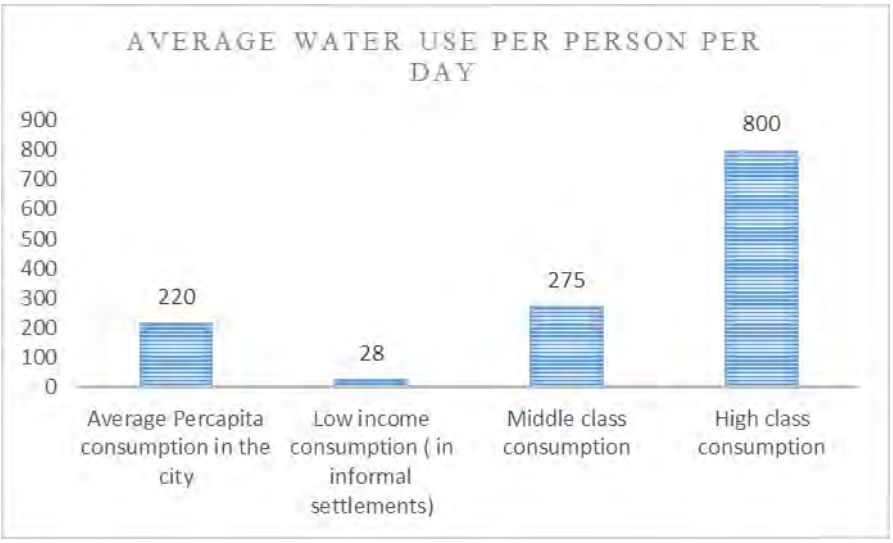

Figure 2. Water consumption inequities. Source: authors elaboration based on (López, 2006)

These contradictions that extend beyond the city limits, due to the way city metabolizes nature, not only reinforce an unequal distribution of metabolic flows within but also generates vulnerability in nearby areas.

For instance, water scarcity impacts ecological systems at a bioregional level. The average production of wastewater in the sub-region in 2012, amounted to 1.66522 million m3. From this, only 78% of channels treatment plants. The water waste re-usage has come up to only 4 %. Then, 22% of the negative externalities of Mexico City are transferred to other regions, displacing environmental risk and vulnerability to rural areas such as the Mezquital Valley (Rosales, 2013).

This better understanding of why people and places are affected differently, and how the growing inequalities in the cities constrain or trigger this conditions of risk and vulnerability in the urban space, and among regions point out critical issues concerning environmental justice at different scales, that should be also incorporated into planning.

Understanding resilience in a wider context. Adaptive capacity, self-organization, and transformability

One of the main aspects that underlies the conceptualization of resilience in the case study presented, is related to the capacity to cope with disturbances and return to a stable state. Nevertheless, as Timon McPhearson argues "…given the often enormous inequities in our cities, we need to be thinking about resilient of what, to what, and perhaps especially, for whom?"… (McPhearson, 2014).

As planner, and inhabitant of Mexico city, I can argue that the city has become a resilient entity, while remains highly vulnerable to factors such as social inequality, uncontrolled growth of urban sprawl, informal settlements, natural resources scarcity, and ecological systems degradation.

The poor and vulnerable are continually being resilient, under the disturbances and changes due to socio environmental dynamics, as that is how they live their lives. In this way, the city has achieved a precarious balance that maintains the urban system "functionality" despite its environmental crisis and its ecological overshoot.

So, one of the questions which raises this case study, is do we really want to maintain this fragile equilibrium and the status quo, or what we need is a new state, and a city resilience transition strategy acting in the interests of the poor and vulnerable and highly degraded environmental systems.

A comprehensive urban redevelopment strategy changing internal and external processes and socio environmental dynamics can provide the means to shift the growth trajectory of the city towards a more equitable, environmentally sound and therefore sustainable direction (Agyeman, 2013). But, how can we move towards this direction?

3. Rethinking adaptation planning

The theory of resilience can support the conceptualization and development of tools, to help understanding the city as a complex socio-ecosystem and manage urban sustainability

transitions, by providing a long-term perspective based on the three key concepts: learning, adaptation, and transformation (Walker & Salt, 2006).

This broader perspective implies going beyond the use of resilience and disaster risk reduction assessment and climate change adaptation.

This latter interpretation based on resilience as a dynamic process involving recover from disturbances, but also to carry-out incremental adjustments (adaptations) and; exploring and expanding the capacity to innovate and transform (Holling, 1973), can then, become the frog leap to move planning adaptation framework towards a more comprehensive and integrated approach to face sustainable transformations.

This process, according to Olsson, requires: (1) preparing for change, (2) navigating the transition, and (3) building the resilience of the new trajectory of development (Olsson et al., 2006).

The question then is, how can this transformative notions of resilience be introduced in existing adaptive planning? This article argues that the shift can be done by a) moving from risk management to uncertainty oriented planning, b) Understanding vulnerability in the context of an equitable, sustainable development; and as a result, c) embedding resilience as a heuristic device in planning models.

3.1. Moving from risk management and climate adaptive planning towards urban resilient transition: uncertainty oriented planning

Moving from vulnerability risk analysis to urban resilience transitions call for understanding urban- regional metabolism dynamics; the degree to which cities can tolerate alteration and perturbances before reorganizing; dealing with uncertainties; conceptualizing what transformations are needed; setting targets and ways of transiting towards sustainability processes and scenarios, and new rationality in planning.

This focus on change and uncertainty, challenge mainstream planning models, based on the two dominating paradigms, rational, comprehensive, and communicative planning, which have dominated the practice. First, because often look at past trends and known problems instead of dealing with uncertainties (Jabareen, 2012). Secondly, because adaptive planning frameworks, which emphasize maintaining the resilience status of the city, do not appear to be contributing sufficiently to the achievement of resilience at the broader context of the sustainable paradigm.

Thus, resilience planning should integrate risk management, adaptive planning in the broader frame of planning for urban sustainability.

As illustrated with Mexico City case study, this integration requires a systemic view for understanding the different processes or components and the way how they interact with each other. For instance, the dependency that cities have on external resources such as food, water, products and energy; and the adaptive capacity of the city to respond to threats related to resource crises or climate/natural disaster events.

These should be complemented by a science policy interaction that can help to design appropriate strategies for a resilience city transition, such as slow exploitation, goals for dematerialization (consumption of fewer materials) and decarbonization (consumption of less carbon).

4. Concluding remarks

Urban resilience transition demands new strategic approaches to planning frameworks, methodologies and evaluation tools. This challenges not only conventional planning models but also states the importance of evaluating the way resilience has been revisited and embedded in contemporary planning. Therefore, it is essential to bring our analytical gaze to the theory and planning practices which attempt to target an urban resilience transition, comprehensively, to promote more suitable and effective proposals towards the construction of sustainable cities.

The analysis of Mexico City Climate Change Programme helps illustrate the incorporation of resilience within the aims and practices of contemporary planning instruments. Also, what the advantages and shortcomings of the conceptual approaches adopted and the proposed strategies are.

In this regard, one of the critical points of the discussion of this article is that evidently, resilience has been, mainly, incorporated in instruments based on DPRS approach resulting on climate adaptation planning.

Even though the above approach is an advance into integrating economic, environmental and social aspects with mitigation and adaptation into planning, there has been a narrow use of the resilience concept.

Urban resilience transitions necessitate going beyond identifying and predicting the impacts of climate change spatially to overcome disaster situations, vulnerability or possible impacts.

Resilience as a heuristic device has the potential to forward sustainable transformations, instead of preserving the status quo of the stable condition on which the city and their inhabitants have found an equilibrium grounded on ecological overshoot, poverty, sprawl, inequality, and threats to human and ecosystem health.

Embedding transformative resilience into planning frameworks offers excellent possibilities to understand the interactions among metabolic flows, the environment, social dynamics and governance networks. As well as the conceptualization of strategies to manage urban sustainability transitions which encompasses: exploring the capacity of urban systems to cope with short-term disturbances and long-term changes; stretch resources to meet the increased demand for shelter, water, secure food security and energy in scenarios of scarcity; adapting to new scenarios; and enable transition of new trajectories of change.

In sum, the value of incorporating resilience into planning should lie on the way this heuristic concept can help us to face transformations towards social, economic and ecological sustainable systems.

Case Study / Project

Relict Ecosystems in Urbanized contexts.

Challenges and opportunities to renature cities, ecological restoration, and biodiversity enhancement through planning for sustainability.

Natalie ROSALES

Abstract

How can planning assist cities to transit from natural resources consumer and waste producers that impact the environment, into natural spaces that enables ecological processes that support life, sustains flora and fauna, enhance biodiversity, and promote sustainable development values? This paper argues this can be done through comprehensive planning strategies that promote a regional and urban environmental development project that enhances renaturing cities from an ecological restoration base. By presenting a case study on a protected area, located in Morelos, Mexico, now embedded into an urbanized context, this explorative research reflects on the challenges and opportunities of relict ecosystems to trigger leverage: renature cities, ecological restoration, biodiversity enhancement, and urban metabolism retrofit. The paper analyzes in a relational manner the challenges ecosystems which formerly ranged over a vast expanse, but are now narrowly confined in urbanized contexts face: informal settlement on core protected areas; environmental pollution, as natural elements such as rivers have become the dump of urban flows; biodiversity loss. The methodology is based on different concepts, methods, and techniques, coming from urban environmental disciplines, which have been conveniently integrated. A body of relational matrices has been developed, to analyze the urban and environmental variables as a whole. This methodology allows us to qualify and to quantify the local and regional environmental impact of cities on protected areas and offers a quick assessment of urban sustainability, which includes metabolic flows.

The vision of environmental services, river restoration, urban biodiversity enhancement, are also considered into the study. As a result of the analysis, the paper envisages the opportunities to renature cities by linking relict ecosystems in a way that urban development strategies can assist recovering the structure and functionality of ecosystems, and through this ecological restoration increase urban biodiversity, environmental conservation, and protection, and give cities esthetic naturalness. By doing so, this piece of work shed light on new ideas that can break down silos between urban and environmental planning and get to a more holistic and sustainable perspective approach to city-making.

Research Paper

SYSTEMS APPROACH: CLIMATE CHANGE, GLACIER MELT AND DEVELOPMENT PLANNING OF THE HIMALAYAN REGION

Sakkeri Ramya, Indian Institute of Technology Roorkee, India
Prof. V. Devadas, Indian Institute of Technology Roorkee, India

Abstract

Experience over the last decade has demonstrated a gradual rise in global temperatures, which coupled with the unpredictable precipitation patterns (rainfall & Snow/ glacier melt are considered as important hydrologic process in the Himalayan basins), are expected to seriously affect the melt characteristics and further increase pressure on available water resources (both quantity and quality). The situation is being exacerbated intensified by the increasing water demands from agriculture, industry and rising population. However, current investigations reveal that there is a lack of a general framework for assessment. The major responsibility of the planning community is to adopt rational planning approach addressing the complexity of the system, yet it is appearing that the models used at various stages are not well developed to keep the same pace. This demands the acknowledgment and a better understanding of the dynamic inter-linkage and interdependence of the complex systems and sub-systems (namely physical, social, economic, ecology, environment, infrastructure, and institutional subsystems) using system dynamics technique.

The aim of this paper is to develop a methodology for assessing the climate change and its impact on a region by demonstrating the inadequacy of sectoral and silo-based planning approaches to address the complex sustainable development challenges whose interdependencies and inter-linkages transcend individual sectors and administrative borders. Further, this paper attempts to present the review of research done on the use of an integrated approach by using system dynamics technique in the context of evolving development plans. It concludes with extending the knowledge to support climate change adaptation and mitigation decisions to achieve sustainable development at the regional scale.

Keywords

System dynamics, Sustainable development, Engineering village, Water resources

1. Introduction

As per Inter Governmental Panel on Climate Change Assessment Report (2007) , more than 1/6th of world population depend on snow-melt or glacier fed rivers and the galciers are expected to continue to melt as the temperature rise. Changes in recent climate and associated impacts on natural and human systems have been reported widely (IPCC, 2014; Azhoni, Jude and Holman, 2018). Himalayan glaciers are sources of freshwater reserves providing headwaters for 10 major river systems in Asia – a lifeline for almost one third of

humanity. Glaciers supply freshwater to 500 million people in Himalaya- Hindu- Kush region and 250 million people in China (IPCC). The system of water resources for sustainable development is a large, complex and nonlinear system and development of social economy can be seriously restricted by potential shortage of water resources (Winz, Brierley and Trowsdale, 2008; Chen and Wei, 2014). The situation is being exacerbated intensified by the increasing water demands for agriculture, industry and rising population. However, current investigations reveal that there is a lack of a general framework for assessment.

The present review paper aims to consolidate the state of the art in climate change, glacier melt and development panning. This study identifies the key knowledge gaps for successful implementation of adaptation strategies. This review paper brings together current literature on climate change, glacier melt and applications of system dynamics with the aim of identifying characteristics that enable decision makers in sustainable development planning of a region. It is divided into five sections. Section 1 has identified the need for consolidating the current knowledge on climate and argues the relevance of this review in the current discourse on climate change adaptation particularly for sustainable development. After the brief introduction to the aim and significance of the review in Section 1, Section 2 brings together the current status of literature. Section 3 identifies the remaining gaps in the empirical literature. Section 4, framework to achieve sustainable development is discussed in detail. Finally, conclusions are drawn with key climate change mitigation and adaptation measures in Section 5.

2. Current state of the literature

The authors performed a systematic analysis of literature on Climate change, glacier melt and development planning (Figure 1), through the following steps: (i) Search for scientific publications on the Engineering Village platform (COMPENDEX and INSPEC) using a set of key words, such as System dynamics; Climate change, and Controlled terms as Water resource; Sustainable development; Planning; (ii) Initial search resulted 2,04,377 records (excluding duplicates) between the years 1884 and 2020, including all document types viz., Journal articles, conference proceedings, dissertations, etc., (iii) Later, to avail the most updated literature on this subject the search was limited to past decade, i.e., between 2009 and 2018, including 1,43,387 records; (iv) further, the authors conducted a search limiting to journal articles only (66,417 records), as they represent a more mature research on this subject with stronger methodological background; (v) To refine the results the search was limited based on controlled vocabulary, such as socio-economic effects, environment factors, climate mitigation, glacier melt; (vi) Content analysis of 614 article abstracts was conducted to validate whether it focused on the role of system dynamics in the sustainable development process, as well as identify the dimension(or dimensions) it is centered on. The authors read full text when in doubt in order to understand its focus; (vii) Exclusion of articles that do not focus on the subject (208 records were excluded) (viii) Categorization of literature (406 records) was done based on focus sector based linkages involved in climate change resilient/sustainable development planning process; (ix) Informetric analysis of literature for 406 records was conducted to observe the trends in literature, identify top journals (Figure 3), determine classification code based on word frequency (Figure 3), and analyse the dispersion of articles in previous years and also with respect to publishers Figure 3. For this purpose, authors employed a software, the VOSviewer, which is often used in

bibliometric, scientometric, and informetric studies; (x) Critical analysis according to defined categories; Currently, the bibliometric, scientometric and informetric analysis are the three main metrics to quantitatively analyze the scientific literature (Qiu, J., R. Zhao, S. Yang, 2017). Santos et al., (2019) explains that bibliometric analysis focuses on the quantitative analysis of the published articles, such as, number of publications per year. On the other hand, scientometric studies quantify the researchers' achievements, such as citation analysis. In contrast to the aforementioned, the purpose of informetric analysis is to obtain additional information, such as word frequency and dispersion of literature.

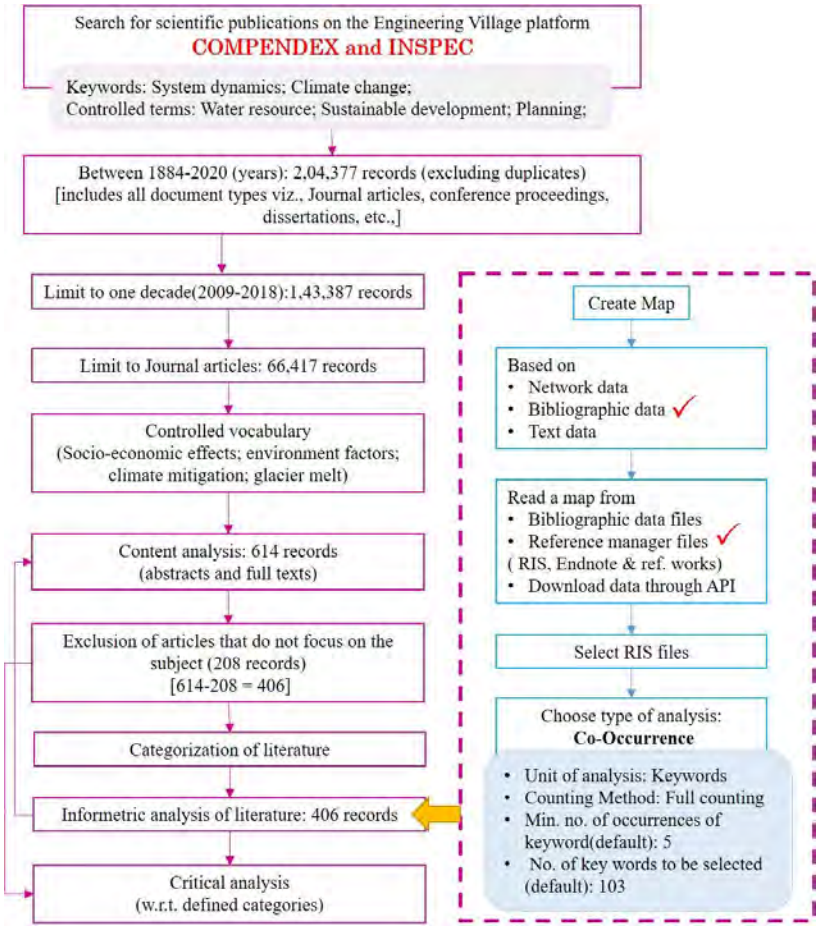

Figure 1: Methodology adopted for a systematic analysis of literature on sustainable development planning and system dynamics

In this study, informetric analysis as carried for the 406 records that are obtained after exclusion of articles that do not focus on subject. The information obtained from informetric analysis was later validated by a content analysis, in which gaps and trends were identified. It is observed that the articles are largely concentrated on the three major pillars of sustainable development, such as environment, economic and social dimensions. However, it is important to note that there is a possibility that an article can fall under more than one category too (Figure 2). Further, it is observed that publications on this subject registered an exponential growth, with 77.5% of the articles being published in the last five years (Figure 2). A total of 1308 authors were identified contributing for 406 published articles. As high as 60 articles are from Journal of cleaner production followed by sustainability with 52 articles, energy policy with 12 articles (Figure 3). Also, Elsevier publications accommodates for 34% of the total articles reviewed and is followed by Emerald, MDPI, Springer, Wiley, etc., (Figure 3).

The articles largely focused keywords (top 5) are socio-economic effects, sustainable development, environment factors, climate mitigation and government policies (Figure 4).Lastly, Figure 5 shows the network analysis and cluster analysis of the top words used by the authors in the Keywords.

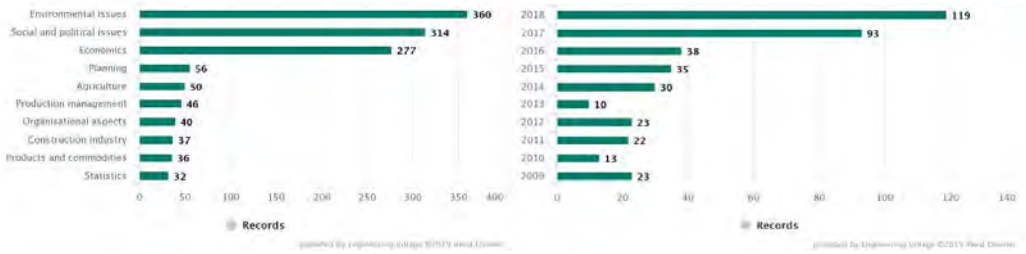

Figure 2:Graph showing articles count based on classification code (left) and year of publication (right)

☑	climate mitigation	127	313
☑	government policies	72	224

Figure 4: No. of Occurrences and total link strength of top 5 keywords identified

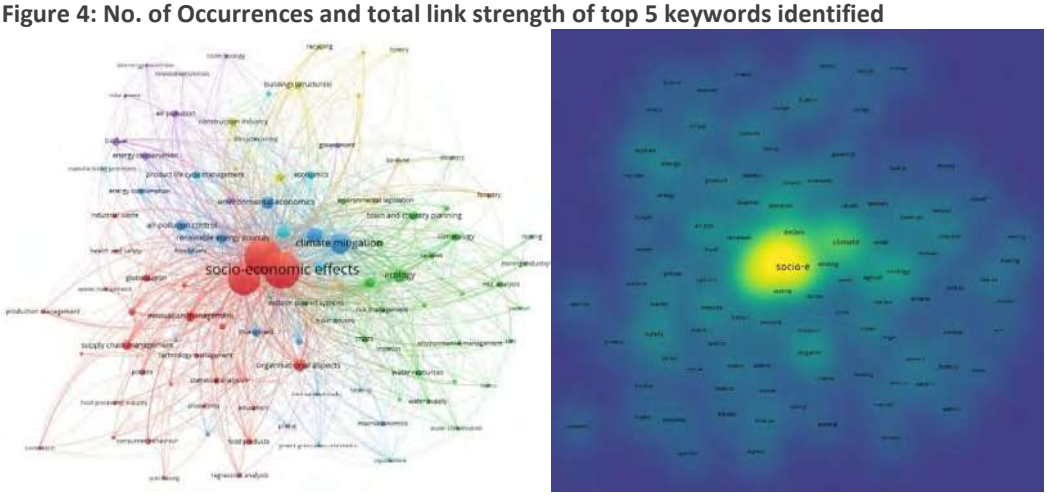

Figure 5:Network analysis (left) and cluster analysis (right) of the top words used by the authors in the Keywords.

3. Remaining gaps in the empirical literature

Climate change has been the focus of much research and analysis for more than a decade now. However, it is observed that the difficulties still exists in understanding the major processes of climate change despite the considerable knowledge of the broad characteristics of the climate. Despite the global implications of the problem, the overwhelming majority of the researchers involved worldwide in studying the problem and its possible solutions are from industrialized countries, and participation of lesser-industrialized countries has been limited (Kandlikar and Sagar, 1999).

According to Miller, Stumm and Stoffel (2012), "Glaciers across the region are generally shrinking but regional and temporal variation exists, and there is little to corroborate statements pertaining to accelerated rates of melt". This research is under taken to draw a defining line under such statements and set the research objectives towards better understanding the processes driving this melt, how climate forces change, and the potential impacts of increased / reduced melt water from glaciers and snow on future water resources under climate change scenarios. This compels climate change researchers not only to study each individual component of the climatic system but also focus on integrated modelling approach to enhance significant advances in understanding the indefinable and complex process of climatic change that enables the future planning initiatives within the region to consider the inter relationships among all the sub systems (seven) that could play a key role in achieving sustainable development.

The comprehensive study of literature reveals that researches have been conducted in the field of sustainable development planning by considering only one or two subsystems, and lack an integrated approach, which considers all seven subsystems of the system together. Some of the key recent studies done by various researchers /organizations are discussed here (Table 1). Also, the authors identified a gap in literature pertaining to the integration of the climate change, Glacier melt, water resource management and sustainable development planning by using system dynamics technique; however, literature on the aforementioned has grown considerably in recent years, which indicates that system dynamics technique is increasingly being used as a reliable method for sustainable development practices.

4. Framework to achieve sustainable development

Framework for development plan formulation by using system dynamics technique has been developed based on rational planning approach (Figure 6). System dynamics is a method of learning complex processes. System dynamics approach considers holistic view to analyze the functional aspect through the spread and backwash effects in all sub-systems of the system. Sterman (2000) states that System Dynamics is fundamentally interdisciplinary and is concerned with the behaviour of complex systems. System dynamics is grounded in the theory of nonlinear dynamics and feedback control developed in mathematics, physics, and engineering. As these tools are used to understand the behaviour of human as well as physical and technical systems, system dynamics draws on cognitive and social psychology, economics, and other social sciences. Also, system dynamics models are built to solve important real world problems.

Table 1: Focus of studies according to type of linkage and identification of the research gap from the literature reviewed

Type of Linkage	Focus of Studies	Sources	Research Gap
Impact of climate change on glaciers	Glacier Melting and Growing Crises	(Singh and Singh, 2013);(Kaltenborn, Nellemann and Vistnes, 2010);(Miller, Immerzeel and Rees, 2012);(Chandrappa, Kulshrestha and Gupta, 2011)	An Integrated Approach considering these linkages

Like many other disciplines, system dynamics has witnessed various changes in its philosophy, strategy, and technique, in the course of its ongoing evolution. In accordance to the problem statement or need of the study, the sub-systems considered in each case differs. The framework developed in this paper is an improvised version from its first application by one of the authors. He has employed System Dynamic technique in different doctoral research theses and masters' theses in supervision of one of the author's at Department of Architecture & Planning, Indian Institute of Technology Roorkee and are presented as follows: Salim (2004) worked on Integrated development plan of Thiruvananthapuram City, Kerala with main focus on population; housing; health, education and energy sub-systems. Similarly, others like Das (2006) prepared Tourism development plan for Bhubaneshwar and Cuttack Region, Orissa by considering tourism and tourism related infrastructure as the catalyst for the development of the region, with focus sub-systems as Population and population density; roads and its networks; railways; hotels and number of beds; land and land-use. Sonar (2006) worked with Information technology as the focus theme for Pune City, Maharashtra by considering sub-systems , such as population and population density; transportation (road lengths); power; commercial area; housing (household units); human resources; information technology industries. Zia (2007) in her work considered the Solid Waste Management (SWM) and required infrastructure for SWM as catalyst for the development of the Kanpur city. The sub-systems considered are: Population and population density; household waste generation, industrial waste generation, commercial and market waste generation, collection, transportation, treatment and disposal; environmental stress, infrastructure requirement in formal sector and manpower requirement in informal sector. Chauhan (2009) used optimal transportation system for the development of the city involving sub-systems, such as Population and population density, household vehicle ownership, residential-parks and playground transportation land-use, vehicular population, modal split and transportation demand. The work of Pipralia (2010) was based on hypothesis that optimal municipal financing management will deliver good services to the city. It was observed from the literature that no work was attempted by employing system dynamics in this line. Sub-systems considered for financial management of Jaipur city are: Population; domestic water supply; waste water; solid waste management, developed urban, residential area, road length and road density; infrastructure network and investment cost; urban finance. Kumari (2015) focused on regional development of Patna Region by increasing the standard of living, involving following sub-systems: Population and population density, sex ratio, literacy rate and IMR (infant mortality rate); area under HYV (high yielding variety) crop, net irrigated area, and rate for fertilizer consumption; electrification of villages, pollution level and road length; use of farm machinery and pesticides; production of cereals, pulses, vegetables, fruits, flowers, milk, egg, meat, fish; GDP from agriculture and allied activities, industrial sector; GDP and per capita income; and sector-wise planned and non-planned expenditure. Energy Management plan for Jaipur city was developed by Kumar (2016) by considering the optimal energy management as catalyst for the development of the system with sub-systems such as, Population, energy generation from sewage waste water, energy generation from municipal solid waste, energy generation from solar photovoltaic system, electricity consumption for domestic buildings, household domestic purpose, commercial purpose, industries, street lights, mixed usages, agriculture purpose, domestic cooking purpose, transportation, total registration of vehicles. Rawal (2016) worked on transportation system of Kanyakumari district by considering sub-systems such as: Population and vehicle growth

model, road network gap index, road network capacity gap index, overall road network level of service, hierarchical road network level of service, GDP and employment, transportation investment, carbon emission gap, fuel consumption gap, transportation area unused or wasted, MSME, tourism growth, District attractiveness index. Land Management plan for Jaipur City was developed by Nigam (2016) using City development index and considered Population, land-use, housing, finance, tax collection, infrastructure (physical and economics), land related institutions, urban environment sub systems. Regional development plan for Lucknow city was developed by Gupta (2017) considering all three pillars of sustainable development concept. The sub-systems involved are Population, health index, education index, housing index, infrastructure index, land-use, crop production, livestock and milk production and horticulture.

The methodology developed in this paper involves stages as follows: Initially the problem is identified through either literature review or theories/concepts or by knowing the current condition/existing scenario of the region through various stakeholders and then a goal is formulated accordingly. Parameters concerning climate change, glacier melt, and sustainable development planning are thereby identified, and the quantitative and qualitative data for the identified parameters is collected by using primary and secondary surveys. Further, data analysis is carried out by applying analytical methods/ techniques that leads to identification of control parameters of the system (region). The identified control parameters are further distributed among seven sub-systems, namely, Physical, social, economic, ecology, environment, infrastructure and institutional. A qualitative/conceptual model is developed, which is represented in the form of causal-loop diagrams with a defined system boundary. Later, qualitative simulation model represented as stock flow diagram is developed by using the following stages: (1) Formulation of base year system dynamic model;(2) Model validation (evaluate and test model); (3) Evolving projected year system dynamic model; (4) Application of the model under different alternative conditions. Results obtained from the analysis are studied in detail, and in case the obtained results are unsatisfactory or contain any error then go to data analysis stage to rectify the error or change the analytical method/technique adopted in accordance to problem statement requirement. Once the results obtained are found satisfactory, then the findings are to be synthesised to evolve plausible solutions and implement the suggested recommendations. Finally, the key indicators/control parameters are tracked and the progress is evaluated in accordance with the problem statement.

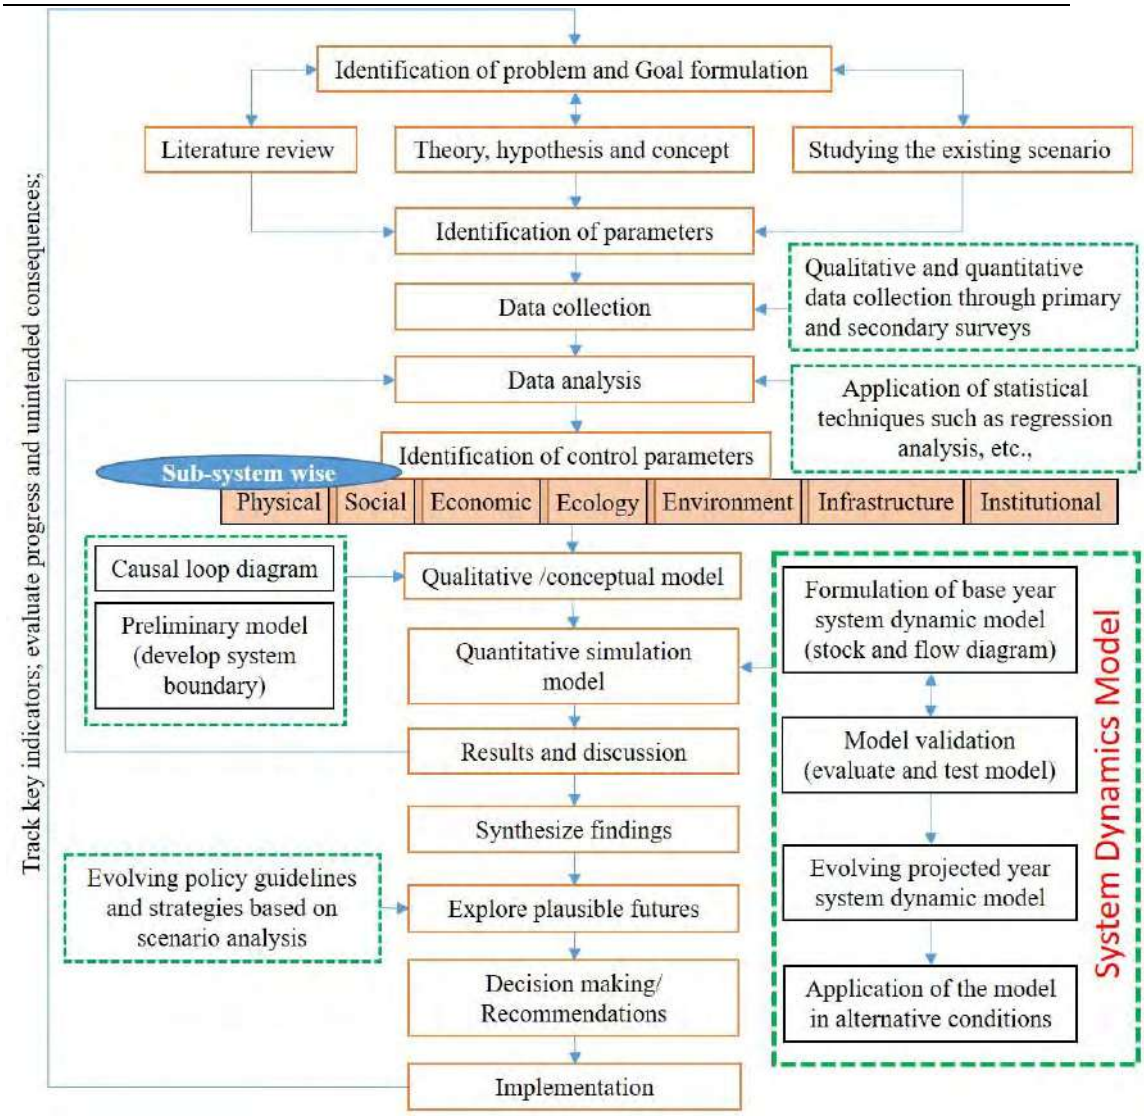

Figure 6: Framework for development plan formulation using system dynamics

5. Conclusion

The present paper studies literature on the role of system dynamics in evolving the sustainable development plan from a perspective of climate change and glacier melt that has not been covered by the existing reviews. Instead of focusing on the application of system dynamics technique in different project phases, the authors' goal was to understand the evolution of literature on this subject and its development according to dimensions of sustainability. The authors were able to successfully answer the research question by conducting an informetric analysis of literature and by classifying it based on the content analysis of 406 journal articles published between 2007 and 2018. The gaps and trends were identified accordingly. It is observed that the articles are largely concentrated on the three major pillars of sustainable development, such as environment, economic and social dimensions. Further, it is observed that publications on this subject registered an exponential growth, with 77.5% of the articles being published in the last five years. A total of 1308 authors were identified contributing for 406 published articles. As high as 60 articles are found from the Journal of cleaner production followed by sustainability with 52 articles,

energy policy with 12 articles. Also, Elsevier publications accommodates for 34% of the total articles reviewed and is followed by Emerald, MDPI, Springer, Wiley, etc., The articles largely focused keywords (top 5) are socio-economic effects, sustainable development, environment factors, climate mitigation and government policies. Lastly, carried out the network analysis and cluster analysis of the top words used by the authors in the Keywords. Despite the comprehensive review performed in this research, the methodology followed by the authors has a few limitations. The Engineering village (COMPENDEX and INSPEC) was the only search engine used in the research. Furthermore, only peer-reviewed journal articles i.e., with a stronger methodological background were reviewed, while books and conference papers were disregarded. At last, the obtained results reflect the keyword selection, meaning that the articles that did not contain any of these keywords were not considered. However, the word selection was carefully addressed so that it included (nearly) all works on this subject. In summary, the main challenge and gap identified by the authors is that there is a lack of an Integrated planning approach considering the linkages between climate change, glacier melt, water resources and development planning. In order to address the aforementioned challenge, a framework for development plan of a region have been suggested in this paper. In conclusion, the climate change adaptation and mitigation decisions/interventions to achieve sustainable development at the regional scale includes, reducing sources of greenhouse gases or enhance the "sinks" that accumulate and store these gases; Stabilize greenhouse gas levels in a timeframe sufficient to allow ecosystems to adapt naturally to climate change; Energy efficiency; greater use of renewable energy; and longer growing seasons or increased yields in some regions to reduce the vulnerability to the harmful effects of climate change.

6. Acknowledgement

This work has used annotated bibliography from Ph.D. research works done by Dr. A. Salim, Dr. D.K. Das, Dr. S. K. Sonar, Dr. H. Zia, Dr. M.K. Chavan, Dr. S. Pipralia, Dr. R. Kumari, Dr. N. Kumar, Dr. T. Rawal, Dr. P. Nigam and Dr. N. Gupta under the supervision of one of the authors (Prof. V. Devadas) at the Department of Architecture and Planning, Indian Institute of Technology Roorkee. Authors thank the Indian Institute of Technology, Roorkee for providing necessary resources, such as Ph.D. theses, lab facilities, engineering village database for doing this study.

Research Paper

DETERMINING URBAN FLOOD VULNERABILITY USING AN INDICATOR BASED APPROACH

Tanaya SARMAH, Indian Institute of Technology Kharagpur; India
Sutapa DAS, (a) Indian Institute of Technology Kharagpur; India and
(b) Indian Institute of Engineering Science and Technology Shibpur; India

Abstract

With increase in urbanisation and climate change, urban flood (UF) is becoming more frequent and intense – surpassing other types of flooding in terms of death and damage to critical infrastructure (CI) buildings. Guwahati, gateway to the eight states of north-east India, is prone to recurring UF – three to four times annually. The lack of an urban drainage network has added to the suffering of the residents. A major portion of the building stock are non-engineered and many new constructions are without UF compliance. Considering that the population and buildings are at risk, this research aims to develop a comprehensive UF vulnerability index (UFVI) as a combination of two indices – human vulnerability index (HVI) and building vulnerability index (BVI). Modified on various concepts of vulnerability assessment for hazards in the developing world, the UFVI has been proposed considering inherent hardships related exclusively to UF. For this purpose, in a prior survey conducted in the 31 municipal wards of the city, relevance of the HVI was checked by choosing residents as survey respondents and the BVI will be conducted based on the concept of rapid visual screening (RVS) of buildings. The HVI stratified the population into five tiers ('very high' to 'very low') and the BVI is expected to stratify the CIs similarly. These two indices will be combined in HAZUS-MH platform to obtain the UFVI ward-wise. This paper puts forward a theoretical explanation of the method that will be incorporated once the BVI is developed and while combining HVI and BVI to develop the UFVI. The composite UFVI that will be obtained will contribute to long-term actions for improving resilience of the existing population and CIs of the city against UF.

Keywords

building vulnerability, critical infrastructure, HAZUS-MH, human vulnerability, urban flood

1. Introduction

Disasters, such as earthquakes, floods, landslides and fires, significantly affect the community and infrastructures. Most of these phenomena are characterised by short action, but their impacts on buildings and other tangible structures, persist for years (Karimzadeh *et al.*, 2014). Some recent disasters in India (e.g. Cyclone Fani 2019, the Kerala floods 2018, the

Uttarakhand flash floods 2013, etc.) or in rest part of the world (e.g. the 2011 Tohuku earthquake in Japan, the 2010 Haiti earthquake, the 2008 Sichuan earthquake in China, etc.), resulted in huge damage to people, buildings and critical infrastructures (CI) (Bach *et al.*, 2013; Upadhyaya, 2018; Senapati, 2019).

Urban floods (UF) are among the most recurring hazards, impacting human lives and causing economic damage throughout the world. (Jha, Bloch and Lamond, 2012) has compiled various case studies from Argentina, Germany, Mozambique, and Indonesia, where UF is an annual issue. And with the onset of climate change, it is apprehended that UF risks will not subside in the future, but its increasing intensity and frequency will threaten many more regions of the world (Jonkman and Dawson, 2012). Casualties and damages are also increasing globally due to (a) haphazard, rapid and unplanned urbanization and (b) the impacts of global change on climate – heavy rains and run-off conditions because there is a direct relationship between urbanization and hydrological characteristics – decreased infiltration, increase in run-off, increase in frequency and flood height (Alaghmand *et al.*, 2010). This scenario implies that urban areas suffer from a comparatively high flood risk due to their high population density and many CIs to cater to this population. Out of the existing body of disaster studies, UF is a comparatively new topic but showing exponential growth in its occurrence in several urban areas of India experiencing rapid development (Sarmah and Das, 2018b).

Different methods to assess or determine hazard, risk and vulnerability to UF have evolved in recent decades (Hartanto *et al.*, 2011; Xia *et al.*, 2011; Gichamo *et al.*, 2012). CIs can be interrupted by a variety of threats. Hence the vulnerability assessment of these buildings and the dependency of the population on these CIs are essential to "build back better" (Bach *et al.*, 2013). In this context, if CIs are affected by flood, it has to be resilient enough to still function or be quickly restored to normalcy (Mcbain, Wilkes and Retter, 2010). Focussing on this, the present study has tried to combine a human vulnerability index (HVI) and a building vulnerability index (BVI) – both developed by the authors in a prior work – to form a composite UF vulnerability index (UFVI) to understand the criticality of UF on the people and buildings in the city of Guwahati – the financial capital of north-east India. Disaster in these north-eastern states has a broader significance because it is graded as seismic zone V of India (Rajendran and Rajendran, 2011) and is situated in the flood prone valley of the indomitable Brahmaputra River. Guwahati, the largest urban area of the region, narrowly connects the seven north-eastern states to the mainland via road, rail and airways. Any critical issues in Guwahati can hamper this connectivity and the lifeline of the entire north-east region will be cut-off (Sarmah and Das, 2018a) thus causing disruption to transport, power and telecommunication and as a result damage to life.

2. Literature Review

This section outlines the direct impacts of UF on the primary receptors – people and buildings (more precisely CI) – and the integration of these two for a holistic UF management scenario.

2.1. Human Vulnerability

UF poses a serious challenge to the lives of people, especially the urban poor of the rapidly growing urban areas in developing countries (Jha, Bloch and Lamond, 2012). These people residing in the informal settlements or slums are frequently at highest risk of UF. (Du *et al.*, 2010) mentioned that more deaths occur during a UF or flash flood event as compared to slower riverine floods. Different authors have noted different death causing reasons in the developing countries such as Bangladesh, Vietnam, etc. In 1990 the United Nations Development Programme (UNDP) along with economist Mahbub-ul-Haq and Nobel Laureate Amartya Sen defined human development in a comprehensive way through the concept of Human Development Index (HDI) (UNDP, 2006), where life expectancy, education and per capita income were used as indicators to rank countries into four tiers ('very high', 'high', 'medium', 'low'). In the same vein, over the years many researchers have developed several context-specific customised indices (Cutter, Mitchell and Scott, 2000; Khan and Salman, 2012; Ghislandi, Sanderson and Scherbov, 2019). As a response to the large and unexpected shock brought by any disaster people's behaviour changes in relation to the magnitude and negative shock and it has been studied how people with different socio-economic backgrounds (the poor), age (the elderly and the youngest members) and gender (the women folk) cope with the losses (Sawada and Shimizutani, 2008; Jha, Bloch and Lamond, 2012). Against this background the authors in a prior study has tried to deal with the losses that communities suffer during and after UF by developing an index depicting human vulnerability.

2.2. Building (Critical Infrastructure) Vulnerability

CIs are often interconnected systems that are so essential to our day-to-day life that any interruption to these services can cause significant disturbance to societies (Bach *et al.*, 2013). Different countries have adopted different definitions of CIs according to their respective requirement. In the United States (US), "CI is defined as systems and assets, whether physical or virtual, so vital to the US that the incapacity or destruction of such systems and assets would have a debilitating impact on security, national economic security, national public health or safety, or any combination of those matters" (Riedman, 2016). Similar definitions have been adopted by Australia, Germany and the European Union. United Kingdom has categorised the CIs according to their uses in UF vulnerability as essential CI, highly vulnerable, more vulnerable, less vulnerable and water compatible development (CPNI, 2016). India till date has no official definition for CIs.

The direct impacts of UF on the buildings affect the basement floors, underground utilities, corrodes metal elements and overall affect the structure that will require repairs and refurbishment (Riedman, 2016). The indirect impacts include the loss of business processes (Jha, Bloch and Lamond, 2012). Hazards can however affect CIs in various ways. In 2005 hurricane Katrina made the drinking water infrastructure in the city of New Orleans inoperable due to power outage in the excessive wind and flood water inundation followed by contamination issues for a prolonged period (Bach *et al.*, 2013). In 2011 river and flash floods in Brazil combined with landslides posed serious risks when the key infrastructures such as electricity, running water and phone lines were affected (Jha, Bloch and Lamond, 2012). India's capital city Delhi suffered from severe water crisis in 2012 where most middle-class households did not have a dependable source of clean water due to extreme heat waves (Bach *et al.*, 2013). Against this background, in an ongoing study by the authors, has

tried to deal with the losses that CIs suffer during and after UF by developing an index depicting building vulnerability.

Current methods of UF vulnerability assessment of buildings are lengthy and detailed processes. It is measured in terms of depth, duration or quality of water, among which the first one is the most common. These are further used for evaluating the cost of damage (Jha, Bloch and Lamond, 2012). (Godfrey *et al.*, 2015) assessed the vulnerability of different building typologies to multi-hazard using depth-damage curves from existing literatures, though very few publications describe the derivation of the depth-damage function in detail. (Kelman, 2002) gave an overview of damages by "slow-rise" flood water based on the depth and duration. (Pistrika, Tsakiris and Nalbantis, 2014) developed a depth-damage curve for an area in Athens, Greece, by using actual flood data and compared the same to the functions of other areas with similar conditions; whereas (Martina *et al.*, 2015) used a synthetic approach to develop a damage model for the buildings of Italy.

Of the many vulnerability assessment methods, Rapid Visual Screening (RVS) is a quick, simple and inexpensive method without performing any structural calculations or instrumentations. Based on sidewalk visual survey a data form is filled up to determine the probable damages caused by a disaster to a structure. Though RVS is mostly used for seismic assessment (IRC-NRC, 1993; JBDPA, 2001; Jain *et al.*, 2010; FEMA, 2015), RVS sheets can be customised based on the context (Lang, 2002) and can be used for other disasters such as cyclone (Dutta and Mukhopadhyay, 2012; Mukhopadhyay and Dutta, 2012). RVS is used to find out if a particular building requires simple precautionary measures during a hazard or it requires detailed investigation. In this manner a homogeneous region can be selected and accordingly ratings can be done to find the recovery measures specific to that area. Moreover, because the synthetic depth-damage curve estimates the potential damage of a building and RVS indicates the level of retrofitting under the disaster, both uses similar principles and hence can be logically combined. (Jha, Bloch and Lamond, 2012) has suggested five restoration steps for buildings which get flooded but remain structurally sound – assess damage, clear and remove standing water and decontaminate, determine appropriate treatment, drying phase and repair phase.

2.3. Linkage between Human and Building Vulnerability

Taking human and infrastructure vulnerability as a whole is an integrated approach to UF management. Most of the losses caused by disasters are due to interaction between the physical environment and the social-demographic features. Determining and considering both the factors enables the identification of points which are highly vulnerable in various aspects, giving a holistic idea of the disaster and the affected area (Yucel and Arun, 2012). Adequate operation and maintenance of the CIs with continuous communication with the people to keep them prepared are two major principles for integrated UF management (Jha, Bloch and Lamond, 2012). Furthermore, the CI itself can become a hazard, as failure of one can have cascading effect on other buildings or even injure people. UF damage to CI is a considerable concern as it affects the ability of the people to respond during the event and recover after it. The UF hazard map of the study area of Guwahati city created by the authors in a prior study, along with the two indices and plotted on map, is a valuable aid to decision-making. The composite index created will also be plotted on map because they are visual tools for communicating the hazard situation (Jha, Bloch and Lamond, 2012).

Approaches such as vulnerability assessment or vulnerability index will help the city to be resilient and reduce the recovery time, allowing business-as-usual to continue.

Human and building vulnerability have been linked by different approaches ranging from global models such as Prompt Assessment of Global Earthquake for Response (PAGER) operated by United States Geological Service (USGS) or local (case-based) models such as HAzards United States – Multi Hazards (HAZUS–MH). HAZUS–MH is applicable for estimating potential losses due to earthquakes, floods and hurricanes, on a regional basis (FEMA, 2015). This hazard analysis tool was developed by the Federal Emergency Management Agency (FEMA), United States in 1997 and over the years has undergone many modifications. It graphically illustrates the identified high-risk locations, in ArcGIS, due to different hazards. Users can then visualize the spatial relationships between population and buildings with the geographic conditions for the specific hazard being modelled.

(Singh, 2005) used HAZUS to estimate building damages (structural and non-structural) and assessed that there is a strong relation between the damage and the number and severity of casualties. An area where buildings are of poor quality and has high concentration of people, there the vulnerability is very high. The author used both the top-down (HAZUS based) and bottom-up (community based) approaches to determine the building and population loss estimation. On the other hand, (Petal, 2004) put forward that although HAZUS categorises buildings and population into four tiers of damage each, it does not give the variation in casualty rates across the building types; but relationship between building damage and casualties can be calculated using seven parameters. In another study on Dehradun city, India, (Gulati, 2006) found that there is a direct relationship between the damage to buildings to the number of people affected. HAZUS, as a tool developed in the United States, its applicability was checked for analysing the buildings and population in the Indian scenario, by (Gulati, 2006), and found that it did not give very realistic results when ward-wise data was considered. But the method gave good results in the city level evaluation. Thus it was inferred that HAZUS method needs modifications so that it gives more accurate results in the Indian context.

3. Methodology

The proposed methodology (Figure 1) aimed to combine the two indices – HVI and BVI – which define the UF hazard profile of Guwahati city and to develop a composite UFVI using HAZUS – MH. After Guwahati became the state capital in 1971, there has been a manifold rise in its population (38.6% decadal growth from 1971) (MHA, 2011). The Guwahati Municipal Corporation (GMC) underwent divisional changes from 34 wards in 1974, 60 wards till 2013 and at present constitutes of 31 wards.

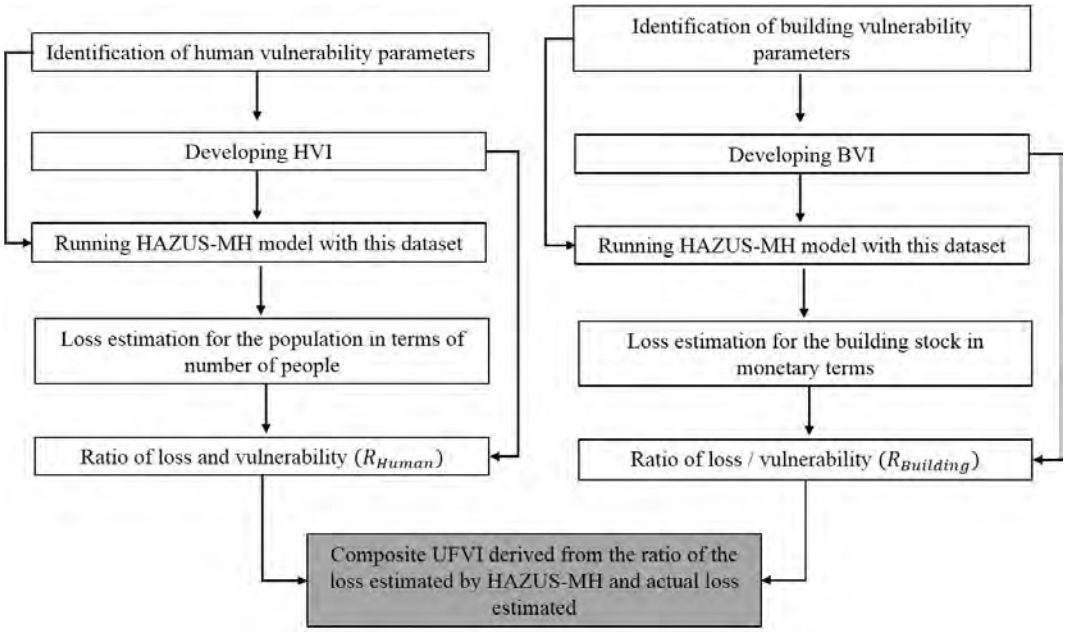

Figure 1: Proposed methodology

In a prior study conducted by the authors, an UF hazard map was developed for the city by taking opinions from experts working on UF. Using analytic hierarchy process or AHP (Saaty, 2008), they compared seven causative factors of Guwahati UF using the conventional 9-point scale (1= equal importance; 9= extreme importance). These factors collated from detailed literature review were – contour and slope; rainfall distribution; soil type; choking of natural drainage; land-use; population density; road network. These seven thematic layers were created using remote sensing data and geo-informatics system to derive the final hazard map of Guwahati. Accordingly, 31 wards were divided into five hazard groups, namely, 'very high' (9 nos.), 'high' (7 nos.), 'medium' (10 nos.), 'low' (3 nos.) and 'very low' (2 nos.). Further, in order to find the vulnerability of the population, ward-wise questionnaire survey was done by taking feedbacks from the residents living with the recurring UF. The questionnaire was developed based on the HDI and other vulnerability indices and modified to suit the current context. It had questions grouped under six key constructs namely, household, education, health, income, dependency on public infrastructure (drinking water, sanitation, waste disposal) and some special conditions during UF. The responses recorded were scored accordingly and HVI was calculated for all the 31 wards. The range between the maximum possible HVI to the minimum possible HVI was equally divided under five HVI groups. The 'very high', 'high' and 'medium' zones had 7 wards in each. And the 'low' and 'very low' zones had 5 wards in each. The result was fairly different from UF hazard map of Guwahati city developed by the authors. It defied the general custom to take flood hazard as flood vulnerability.

In a second study conducted by the authors, the CIs located in the 216 sq. km. of GMC area were surveyed for UF vulnerability assessment using RVS. The sample survey consisted of reinforced cement concrete (RCC) buildings, confined masonry buildings and the typical Assam-type (Ikra houses). This sampling was done from GMC tax records. A combined list of CIs was collated from a list noted by the city local bodies and various literatures. The same was modified to suit the Indian context in the UF scenario (CIs vital for rescue-recovery, essential and others). The authors developed a RVS sheet for assessing the performance of

three types of common building typologies against UF. Each of the parameters contributing to building vulnerability has a 'score modifier' which determines which parameter has a positive or negative influence on the 'base score' or 'overall score' of the building type. Relevant parameters based on their role in defining building vulnerability against UF were collated from literature.

Thereafter, HVI and BVI can be joined in GIS-based HAZUS-MH by running the model with the dataset of the human and building vulnerability parameters. This will give the loss estimation for the population in terms of number of people and for the building stock in monetary terms. The ratio of loss estimated and the vulnerable population will be R_{Human} and the ratio of loss estimated and the vulnerable building stock will be $R_{Building.}$ Using weighted average of both, the composite index (i.e. UVFI) can be calculated. The weights will be calculated using multiple-criteria decision analysis technique.

4. Key Findings and Discussions

After measuring the human vulnerability and the ongoing work of measuring the building vulnerability, it was found by the authors that these two has strongly co-related variables that increase UF vulnerability. Such as education, age, gender, income, past disaster experience, poverty, isolation, lack of social security services, funds for disaster prevention and mitigation, location of buildings, material of buildings, maintenance, unprecedented population growth, CIs providing services, health services, etc. In this study the HVI and BVI will be combined in HAZUS—MH interface to arrive at a common UFVI, because according to (NDMA, 2010; Jha, Bloch and Lamond, 2012) vulnerability maps are based on two major factors – the buildings and CIs at risk and the vulnerability of the users. A total of six constructs in case of HVI and 20 parameters in case of BVI will be considered. The combined UFVI will give a composite index that will represent overall performance of the city during UF. This will categorise the 31 wards of the city into five tiers of UF vulnerability ('very high' to 'very low'). When CIs are situated in UF prone areas and the existing population also cannot be relocated, the composite index will help in enhancing decision-making procedures; for example, investments in the cities can be assigned in the best form. This index after being developed for Guwahati city can be used to determine which wards in the city are most vulnerable to UF.

5. Conclusion

Studies on UF hazard, human vulnerability and building vulnerability has become substantial for CIs since these buildings are used by the entire population. The direct and indirect effects that these CIs face, can severely affect societies and become a threat to the urban areas. The city of Guwahati is submerged in UF waters 3-4 times annually. The present study combines the vulnerability indices of humans and buildings (CIs) to UF in the city of Guwahati, using remote sensing data and geo-informatics. This will identify the city resources (both human and buildings) under threat and thus prioritize the assistance by concentrating efforts in those locations and channelling resources. This is an example of a local scale study which proposes a holistic approach by combining the two approaches (population and CIs). The study is limited only to the CIs of the city and overlooks the possible effects of other

disasters. For instance, Guwahati lies in the flood-prone Brahmaputra valley, which is so mighty and is known as a moving ocean. The entire north-east region is located in the seismic zone V in the earthquake hazard zones of India. Buildings on stilts are good for UF but open storey buildings are dangerous for areas in high seismic zones. Similar method can be adopted for the residential buildings. This is a generic method which can be applied for other disasters such as riverine floods, earthquakes and hurricanes, by considering area specific human and building vulnerability parameters. This study is a novel approach to combine the vulnerability of the human and the building component which defines the structure of any city in a developing country like India.

Case Study Paper

Building Dignity: A participatory concept for climate change-impacts mitigation in informal settlements in North Jakarta

Rolf Schuett, Systemarchi; Poland

Abstract

Jakarta is today the centre of one of the largest and most populated human agglomerations in the world, and the economic and political centre of one of the largest economies. However, Jakarta is also considered a "mega city gone wrong", because of its ongoing challenges. The city faces serious issues in pollution, social inequity, mobility and flooding, which in the next decades are doomed to cause critical consequences to the economic base of millions who depend on the city, not only in the Java region. The continuous growth of population and urban land in Jakarta is also condemned to hit the impacts of climate change first hand. Jakarta is a coastal mega city that already faces the effects of raising water levels, because it is subsiding at a rate of 15cm (avg) per year. This paper analyses the challenges and opportunities of each of these aspects in Jakarta, but it also discusses cultural aspects that may help to stimulate real participation of the population, provided that the legal and political framework applies a background of policies that comprehensive planning can deliver. One of these elements is the Malay concept of "gotong royong"or communal cooperation, which is very popular in rural Java (and has analogies world wide). It has been practiced in the kampungs or rural villages for generations, was eventually integrated, perhaps misused, in political agendas since the post colonial years of young Indonesia in the mid 20th century, yet lacking the expected success it achieves at lower scale. The paper also proposes an example of physical implementation in informal neighbourhoods in Pandemangan, North Jakarta, that the author developed some years ago.

Keywords

Comprehensive planning, participation, informality, climate change impacts

1. Jakarta, "a mega city gone wrong"

1.1. Introduction

The journalist and TV host Teymoor Nabili from Al Jazeera said once about ten years ago "Jakarta is a Mega city gone wrong". And probably this still applies today. Jakarta was at that time a mega city that was trying to deal with severe issues, perhaps the most challenging were waste management (connected to flooding), traffic and insufficient housing. Jakarta also had difficulties to provide adequate drinking water and sanitation services.

Today Jakarta has more than ten million inhabitants, receives each day more than three million commuters who come to work from outside and by 2030 is predicted to become the world's biggest megacity. The challenges grow with the city. Even more, Jakarta is suffering subsidence at alarming rates of up to 25 cm/year (North Jakarta). The main reason behind this phenomenon is the extraction of water from the ground for domestic consumption.

The aim of this paper is to describe the current urban development problems of Jakarta, which in combination with its growing population, its urban sprawl and potential impacts of climate change reflect a situation that can be considered typical for mega cities in developing countries. The paper describes also the background of Jakarta's challenges, which can also be tracked to other regions in the world and can spread as well the same way.

Finally, the author refers to the Malay concept of Gotong Royong or communal cooperation and suggests this as a key to transform the situation of informal settlements in Jakarta in particular, in order to improve the living situation of their neighbours from the inside. A revitalization concept is proposed to this end in the last section of the paper.

2. Analysis

The urban situation of Jakarta will be described in this section under consideration of environmental, economic and socio-cultural aspects. Because the issues are not exclusively local but mostly a world-wide phenomenon, reflections are included to relate them to the global context.

2.1. Environmental challenges of Jakarta

Cities in the world consume 75% of the energy and produce 75% of the world's CO_2 emissions. Just as in any large metropolis, Jakarta faces important pollution issues, which are aggravated because of an ever-increasing motorized vehicle number at a rate of above 9% per year.

Solid waste has been as well mentioned in the media as a major issue. Each Jakartan produces in average 2,9l of garbage per day. A study of 2001 reported that scavengers (who collect recyclable waste) collect up to half of the city's waste. (The Jakarta Post 1, 2009)

One of the consequences of the insufficient solid waste management is that because a considerable amount of waste never reaches treatment plants, it contaminates the storm water collection system, the city water streams and eventually the ocean. Clogged storm water sewers contribute largely to local flooding, a problem which has increased in the last decades. Indonesia is the second largest feeder of plastics into the ocean after China. The activity of scavengers all over the city contributes also to aggravate the problem.

Bridges over rivers are now critical points because of garbage accumulation and the risk of flooding. The macro and micro drainage operate at 50-70% of their capacity due to garbage and silt clogging. The accumulation of garbage on roads affects the automatic railway crossing systems, which is also an eminent risk. (The Jakarta Post 2, 2009; Kurniasari, 2009)

An Article in the April 2019 edition of "Marine Pollution Bulletin" warns about the underestimated financial costs of ocean pollution.

According to the paper, which reports on a metadata analysis of 1100 international datasets, each tone of plastic that reaches the ocean will cause an economic damage of worldwide up to 2,2 billion €/year, translated from a 5% estimated reduction of the potential yield of exploiting marine resources. (Köppe, 2019)

Plastics in the oceans contribute to a heavier pollution with bacteria and algae, which added to the negative effect of bisphenol A (BPA) in fish reproduction, means that this compromises the availability of fish as food resource, which is the diet base of 1,5 billion people on earth. (Beaumont, 2019)

Industrial economies are reacting accordingly. The recently adopted ban 560-35 on single-use plastic items (including plates, cutlery, straws and cotton buds sticks) by the EU Parliament has been a crucial step forward in Europe. The EU Commission assumes that the new regulation will have a cost on the bloc's economy, but eventually will reduce 22 billion € in environmental damages until 2030. (Köppe, 2019)

60 % of Jakarta's waste is domestic household waste, which is collected with no previous separation by the residents. Even more, a study at Atma Jaya Catholic University in Jakarta in 1999 concluded that more than 70% of Jakarta's waste is organic. Both conditions open the possibility to introduce in Jakarta the use of sorting out recyclable waste at home, which can be used as a resource, and to collect organic waste, which can be processed in biodigestors to produce biogas and natural fertilizers. Biogas can be collected as energy resource. Even though its production is controversial, because it is a greenhouse gas, the high amount of organic waste that Jakarta generates justifies this alternative.

Certainly, no matter how well we deal with organic waste, it makes more sense to avoid it to happen than to deal with it afterwards. The "Zero Waste Scotland", for example, is a public initiative that aims to cut carbon emissions by informing and encouraging the society to live more responsively so that Scotland becomes "greener, wealthier and fairer". In 2019 Zero Waste Scotland launched a Food Waste Reduction Action Plan aimed at encouraging citizens to improve the way food is consumed in order to avoid unnecessary food waste. Because that waste rots once it is discarded and it produces the greenhouse gas methane. According to Zero Waste Scotland, food waste is therefore a bigger cause of climate change than plastics. Nevertheless, Jakarta is still far away from introducing policies that effectively would reduce organic waste the way it is being done in Scotland. (NN, bbc.com, 2019)

Bagasse, Paddy (rice husk) and other agricultural sub-products from the region of West Java can be also used as biomass to produce heat and energy with biodigestors, together with organic waste of the city (Benget, 2009). Thinkable would be a network of small units in the neighbourhoods or larger central plants with high technology and efficiency.

There is already a project for generating power with waste in the landfill of Bantar Gebang, a plant could generate 26MW. The waste collection site is the largest in SE Asia and is the main landfill for Jakarta's solid garbage. About 100 000 people live around the place, which is also the base of income of most of them. The first waste-to-energy incinerator started to operate 2019 and generates just under 1 MW. (Purningsih, 2019)

Jakarta has also serious challenges concerning drinking water and sanitation. Only 3% of Jakarta's wastewater is treated. E.coli bacteria are reported to have been found repeatedly in all of the 13 rivers of Jakarta. Because of this risk, private investors build treatment plants

for their housing developments, contributing to the growth of their market value. (Besalicto, 2019)

The drinking water situation in Jakarta affects also about one fourth of the world population. According to a UNO report, 2 billion people have insufficient or no access to safe water. The situation is especially critical in sub-Saharan African countries. (Breda, 2019)

In Fact, in the world four billion people currently have at least once a month no access to drinking water. This figure applies especially to the rural population in countries with insufficient water services in general.

Yet the water situation has improved considerably in most regions. North America and Europe have reached a coverage of 99%, South America 96%, but the sub-Sahara 58% and Oceania 52%. Paradoxically, only 1% of that delivered water is actually drinking water, the rest is used for industry and agriculture.

The problem of basic access to safe water in the world is doomed to get worse. The growing global population and the improving access to water in developing countries imply a growing demand of water, which is in average 1% higher each year since the 1980s.

Stefan Uhlenbrook, water expert at United Nations warns that climate change is another factor that will change water access: dry zones are getting drier and wet zones are getting wetter, which means that the distribution of water sources in the world is not improving.

Unfairly, in many developing countries, in underdeveloped suburbs locals have to pay more for water than the average population in areas with regular service, even though the water quality they get is insufficient.

Uhlenbrook explains that politicians often build less wastewater treatment plants because they don't deliver a visible impact, thus politically these are not as effective as dams or public toilets. Meanwhile in these cities 80% of the wastewater is released back to nature without treatment, which is the origin to even more issues. In sub-Saharan countries like Central African Republic, Chad, South Sudan and Eritrea more than one hundred people out of hundred thousand died in 2017 for consuming contaminated water, actually a totally avoidable situation. In other words, solving the clean drinking water issue is not a knowledge issue but an administrative fail. The situation in Jakarta is even more controversial given the fact that the service is provided by two private companies that operate under concessions of 25 years. (Breda, 2019)

2.2. Economic Issues

Jakarta generates about one fifth of Indonesia's GDP and its GRP per capita is predicted to be the biggest in South Asia by 2030 and a top twenty world wide by 2028. Jakarta's economy is driven by services and manufacturing, including automobile, chemistry and electronics. The city hosts the headquarters of the largest Indonesian corporations dealing with oil, energy, cosmetics, food, trade, insurance and financial services. Its economic growth averaged between five and six percent in the last years, which induces the ground and property prices to rise, and also the general cost of living.

Despite of Jakarta being a magnet for capital and property investment, the unsolved mobility issues, together with the already mentioned subsidence rate, are prompting the government to consider radical measures.

The recently re-elected president Joko Widodo recognized after winning the elections in April 2019 that there is a need to move the capital. Moving Jakarta has been studied for more than sixty years, since Indonesia's independence from The Netherlands. Researchers calculate that a large part of the city may disappear until 2050 under water. Already most of the city's surface is below the sea level. (BBC Mundo, 2019)

Planners are considering three possibilities. The first one is to establish a special government district in Jakarta. The second one is to move the government into new infrastructure to be built in a suburb of Jakarta and the third one is to completely move the government to a new location. Indonesia's territories in the Island of Borneo have been mentioned, more precisely Palangka Raya in Kalimantan, which is on the south of the island.

The environmental impact for Kalimantan would be huge though, since the island's forests are considered not only by the local population as "the lungs of the world".

There is also a political interest to decentralize the administration of the country, and the new location in the centre of the archipelago would serve this purpose, especially because it does not stick to the main island Java.

On the other hand, the traffic issue is also yet to be solved. Among the factors that contribute negatively to the heavily congested roads is the fact that about 70% of the 3,6 Million daily commuters into the city use an own vehicle to travel and only 27% use public transportation, which also does not serve all commuter trips.

Jakarta has probably the worse car traffic in the world. The minister for national development planning has stated that only in Jakarta, traffic jams cost the country 6800 M USD each year. Other sources talk about 7400 M USD (BBC Mundo, 2019). Alternative solutions for mass public transit have been installed amid considerable investments. The most prominent is probably the Bus Rapid Transit BRT TransJakarta, which is considered today as the largest in the world (210 km). In its first years of operation back in 2004, TransJakarta contributed successfully to reduce traffic congestion. However, due to operational and design faults, the system has not had the expected overall impact. Tracks are too often invaded by other vehicles, the assigned Busses consume more fuel than originally estimated, which raises the subsidized costs, and the number of users does not increase due to the unreliability of the system.

Due to Jakarta's dependency on traffic and the growth rate of motorized vehicles in its streets, the role of mobility will become more meaningful in the medium term, to a point that the cost of traffic congestion to the local economy may compromise the viability of many economic sectors. In the eyes of the author, it makes little sense to try solving the traffic issue in Jakarta repeating the same approach. The answer may be much more radical. And the situation has been understood in many large economies worldwide, but transformation processes tend to be more difficult to implement in developing economies (or Newly Industrialized Countries, as in the case of Indonesia).

Cars have transformed our civilization, but they also have pushed cities to sprawl and continue to affect our health and safety. They contribute to 70% of the carbon emissions in the transport sector and pollute the air we breath. 1,25 million people die each year in car accidents and the particulate matter that increases to critical levels with heavy vehicle traffic is considered by the WHO as a group 1 carcinogen. The air pollution with micro particles

$PM_{2,5}$ contributed to 4,1 million deaths from diverse heart and respiratory diseases in 2016. (HEI, 2017)

Prof. Richard Kingston and Ransford A Acheampong from the Spatial Policy Analysis Lab at Manchester University recommend three ways in which cities can achieve less car dependency, so that pedestrians, cyclists and public transport recover public space that once was taken by cars.

They recommend, among other measures, to introduce car-free zones. Examples are Copenhagen, Brussels, Ghent, Madrid, where cars are either not allowed into the city centre or banned if they don't belong to residents. London charges congestion reducing fees. In all cases, socializing campaigns need to be previously organized to gain public understanding and public transport has to be made available to cover the mobility needs. (Kingston et. al. 2019)

Another recommendation relates to public transportation, which has to be reliable, flexible and cost effective. A reflection of its success is the decreasing use of private cars in many European cities, the US and Australia. Millennials are considered today a generation that generally avoids owning a car.

We as planners and urban designers have obviously a main responsibility when it comes to recover the excessive public space that was sacrificed for car transit. But planners need to make sure that solutions are inclusive, housing is affordable and close distances motivate citizens to cycle or walk to their work or the locations they visit on their daily life. The key is to provide again the human scale and human speed that was usual before the automobile revolution and to make sure people understand the benefits, support the changes and adapt their habits.

2.3. Social Issues

The consequences of poverty, high migration, river pollution and subsidence are visible through the existence of numerous slums in Jakarta, most of them located in vulnerable areas. These spaces have been usually occupied by migrants, who set up their homes with their own hands. Tambora is one example. One of the densest slums in the world, where in just under 4,5 square km about 250 000 dwellers live. Even though the government has programmes to relocate slum residents to social housing blocks, most of them refuse to live, because they have no documents, and without identification they are ineligible to take part in the programmes. Besides, they are not willing to leave a place they have lived in their whole life. (Wargadiredja, 2016)

Slums and informal housing areas in vulnerable sites in general lack the basic elements for living with dignity. With no sanitation, scarce open space, critical levels of pollution and despite of living in extreme density, dwellers feel abandoned to their fate. The Jakarta government uses different methods to evict residents and make space for profitable developments. There is no programme that foresees revitalization and inclusiveness, with few exceptions.

Muara Baru is one of the scarcely any examples, where revitalization was chosen instead of bulldozing. But not because it is too valuable to destroy, but because it is located in perhaps the most vulnerable area of North Jakarta, just behind Jakarta Bay, separated from the sea water by a cracking sea wall, which is also sinking.

However, the project goes beyond the recovery of a neighbourhood, the old traditional fishers villages around Muara Baru are the gate to a future so-called Giant Sea Wall, a 40 billion USD new waterfront built on reclaimed land called National Capital Integrated Coastal Development (NCICD), which comprises in total seventeen islets. The project has received important political support, but is socially and environmentally very controversial. Once completed, it would separate the Jakarta Bay from the ocean and convert it into a lagoon. The idea behind it is to pump the water out of the lagoon to lower the water level, so that the rivers from Jakarta can recover their natural flow and flooding in North Jakarta become less likely. Local experts however warn that instead of restoring the natural flow of the rivers, the lagoon could end up becoming a septic pond with polluted water and debris coming from Jakarta. (Sherwell, 2016)

Certainly, Jakarta, especially its coastal area, has reached a point of no return, and something urgently needs to be done to avoid a massive loss of homes and urban fabric with catastrophic outcome. First groups of hundreds of residents in the area have been forced to leave from 2016 on.

In Jakarta poverty and scavenging are obviously two interrelated conditions. However it seems that they are the product of a missing political vision to incorporate alternatives that effectively fight poverty, create opportunities and let as many Indonesians as possible take part in the ongoing economic growth.

Malaysia, Thailand, Philippines and Indonesia have been portrayed by the media in mid 2019 after they rejected containers of recyclable waste from overseas because they were contaminated with diverse other chemical and bio-hazards. Importing recyclable solid waste represents an opportunity to obtain cheap raw materials for manufacturing, but the health and environmental cost is high, and some countries, China ahead of them, have understood that the derived environmental degradation is not worth the effort. Recycling is a booming business in Indonesia, and scavengers don't seem to care about the side effects of their activity, they are happy to have an income. (Whiting, 2019)

Jakarta and other Indonesian cities struggle to tackle the domestic solid and organic waste problems and need to improve its waste management plan to industrial scale. Regrettably, the primitive way solid waste is processed in Indonesia, with the involvement of low income, untrained rural population is neither healthy for the workers nor compatible with the environment. Due to Indonesia's important industry sector, it is certainly feasible to implement a solid waste recycling programme based on the Circular Economy, which allocates for instance household recyclable garbage in the local industry as raw material. Even though it happens today, the applied methods do not comply with minimum international health and safety standards. A change starts with introducing a different approach of packaging material, change of materials for more sustainable alternatives, inducing pre sorting at home, community involvement and public support initiatives.

3. A regeneration proposal for vulnerable settlements in Pandemangang and Sunter Agung districts

Following the analysis of some of the most important challenges in urban Jakarta, the author wants to summarize the findings into a set of ideas as a conceptual regeneration proposal.

The main motivation for the design concept was to look for a way to turn informal neighbourhoods in vulnerable areas into green water absorbers and carbon collectors and combine the process with the *Kampong Gotong Royong* concept. That means, keeping the residents on the site instead of relocating them out of soil they call home perhaps since generations. As well it was a motivation to propose a way to maximize the green areas inside these extremely dense neighbourhoods.

The site that was chosen belongs to the districts of Pandemangang and Sunter Agung, which belong to North Jakarta. The site of the proposal was chosen as a symbolic location, and is not a concrete redevelopment proposal, but an idea of how the author considers that revitalization of Jakarta's slums could work out. Some of these areas have been already considered by private investors for new redevelopment, some of them with luxury character, towers and shopping malls.

The concept incorporates a mix of residential, commercial, services, education, communal infrastructure and green space. All functions are surrounded by a network of paths, corridors and access that maintain a healthy degree of permeability. Most of the site has been covered by at least two layers. The lower one comprises roads and corridors, flooding areas, ground water collection, playgrounds and sports facilities, with the existing water streams below. They also contain the green areas with vegetation and some allotments as urban farming with a biodigester plant. The middle layer, which is essentially a flooding proof elevated layer, contains the residential infrastructure, some services, education, and some communal infrastructure and the network of access bridges. The rest of the built infrastructure, such as services, communal buildings and some commercial buildings are located in areas with lower vulnerability.

The scheme design foresees to respect and conserve representative buildings (key points) in the existing neighbourhood, such as mosques, public buildings and other elements that have some kind of communal value. All other buildings, mostly for housing use, would replace the existing ones, making sure they have a longer life span and provide satisfactory living conditions.

The proposal also incorporates the participation of residents in the design and construction of their houses. Training should be provided to all disciplines involved, from craftsman to carpenter, gardener, etc. This would be a way for beneficiaries to contribute to cover the costs for their homes with their work and also learn new skills that would provide them chances in the labour market.

In the urban scale, a honey comb pattern was chosen to reduce the surface of paved roads and increase the size of blocks without increasing walking distances. Despite of the large areas covered by private ground, an extensive network of walking and cycling paths can be incorporated in the scheme, as well as green corridors and representative sites, where the existing and added key points are located.

On the micro scale, houses are preferably grouped around semi private courtyards, which have the aim to maintain the social dynamics that would arise during construction time, as a way to represent the kampong spirit of G*otong Royong*, communal cooperation, in the big city.

Figure 1 ***The honey comb web is an interpretation of gotong royong in the urban landscape: mutual cooperation to raise the life quality***

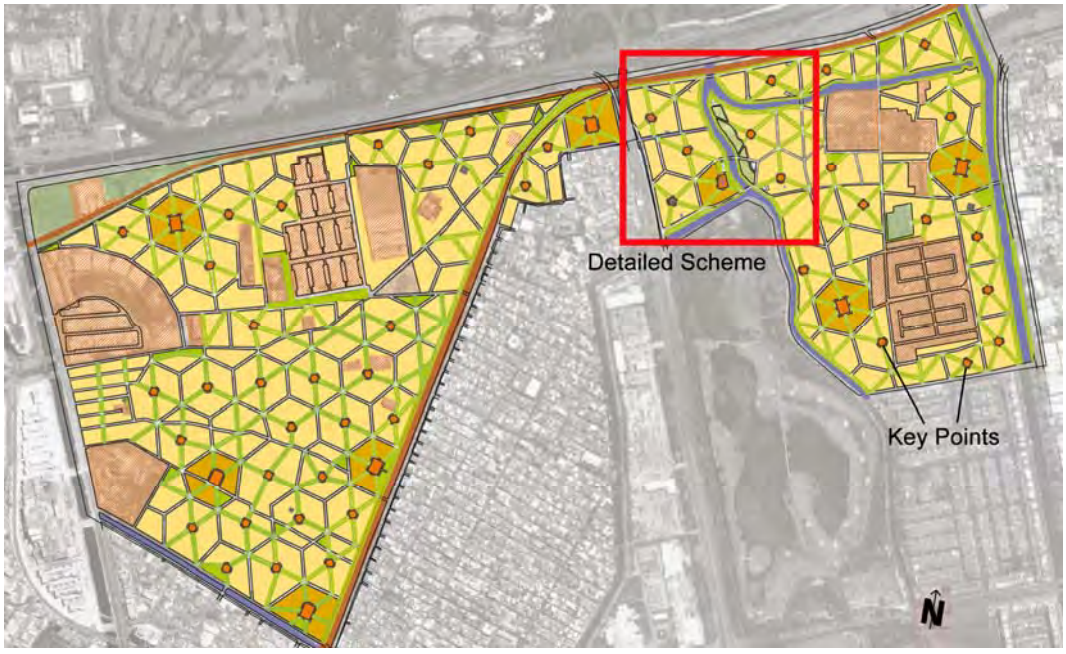

Figure 2 ***The concept applied in the Pandemangan (left) and Sunter Agung (right) districts.***

The traditional communal cooperation can be applied to set up a cooperative-type of neighbours business sector, which includes retail, repairing services, recycling, urban farming, craftwork, child care, elderly care, gardening, etc.

The honey comb pattern also reduces the attractiveness for transit traffic, which is compatible with the neighbourhood character. It is assumed that residents will rather not own a car, but smaller sized mopeds or motorbikes.

The streets that surround the blocks and the green corridors that cut across them should be wide enough to allow the transit of emergency services and also to incorporate vegetation, seating and pedestrian movement.

4. Discussion and Conclusions

Indonesia recovered well from the Asian crisis in the early 2000s, and since 2005 has been experiencing a positive economic growth. However, the gap between rich and poor has also expanded (Diela, 2016).

The author considers that the best way to fight poverty in urban Jakarta is to combine urban revitalization with the improving of the living conditions of the most vulnerable poor population, especially women and children, without moving them out of the city, but instead increasing their chances to benefit from the economic growth.

The simple fact that people increase their earnings and secure their jobs in times of improving economy will also increase the pressure in the market to provide housing opportunities, which pushes planning authorities to increase among other things the built density. And the current trend for sustainable neighbourhoods is to mix uses with living, which reduces distances, increases concentrations of public space and green, and invites residents to share a community-based, often multi cultural townscape.

Inclusive urban revitalisation is not compatible with exclusive high end, west oriented gated developments. Indonesia has a rich, geographically, historically and culturally diverse background that must be incorporated in the way their urban development is guided, for it to maintain a strong and rich local identity.

Communities in many industrial nations have started to realize the monetary and social cost of urban sprawl for the cities and the crises that it causes when it comes to provide new affordable housing. One of the most discussed consequences has been racial and economic segregation due to the separation of exclusive residential zones (and services) from the rest of the city and the drop of conditions for low income families or ethnic minorities. (Badger et. al. 2019)

This shows that planners today finally understand that increasing the built density reduces overall car traffic emissions, prevents urban sprawl, increases the use of public transport and makes cities economically more viable.

The recently broadcasted images of Indonesia receiving (and rejecting) containers of recyclable waste as an import good for their cheap labour to sort and reuse have been shocking. They demonstrate how irrational human consume has turned in developed nations. The worse thing is, the more educated we are, the more we are aware of the impact

of our consumption. But the wealthier we are, the more we potentially contribute to it. Our actions in our micro world play also a role in the global context.

We can influence 72% of greenhouse emissions at home. In fact, 10% of the richest global population cause the most climate pollution and we as qualified planners probably belong to this group or are very close. Certain is that the poor cause very little pollution. The renowned British newspaper The Guardian interviewed several scientists living in the UK and asked them how they contribute to reduce their personal carbon footprint. Their answers were rather predictable. Most have basically given up flying, they own no car or have substantially reduced driving, some eat only vegetarian food and in general they consume much less than the average British population. Concerning consumption, the article mentions C40, a network of the world's largest cities, in which they discuss strategies to reduce climate impact. One of the focuses of research is the impact of consumption. A C40's proposal to address climate change is to introduce a four day working week, which would reduce the speed of the "ever-expanding economies" and thus reduce our capacity to consume and have more time for a balanced life. (Masoliver, 2019)

The 'standard occupancy rate' that the architects among us planners use to measure success of a built investment can be applied to consumer goods. How many times a year does a consumer use their collection of tennis racquets? How often do they use their second, third, fourth winter coat? A 'standard rate occupancy' applied to consumer goods would probably indicate that most things we possess have been just a wasted investment, and an unnecessary impact to environment.

The author of this paper hopes that eventually accurate information about the environmental impact of the goods we buy will become as important as the cost itself, and that this information will be displayed on a price tag in an internationally recognizable, standardized way.

The state of water provision in the world was mentioned earlier. It is recognized as a human right, but we do not necessarily appreciate how valuable it is. Just to put water availability in context: Water is actually an abundant resource in the world. It obviously is. However, almost all of it is salty. Freshwater (which is not automatically drinking water) is less abundant (2,8 % of all the water on earth). Yet drinking water (potable water) is rather rare. Only 0,003% of the total available water in the world is fresh and unpolluted. To understand the rareness of naturally occurring drinking water, in the earth crust (down to 100km depth) gold is only 600 times less abundant, silver is 428 times less abundant, and uranium is only 12 times less abundant than naturally occurring drinking water.

And we cannot forget that the available 'drinking water' is actually not drunk, two thirds of it is used by the manufacturing industry. Every good we consume has an embedded water footprint. According to figures published by FAO, every cup of coffee we drink needed about 140 l of water along its production chain. One kg of beef accounts for 15 415 l of water, one apple costs 70 l, and if we buy it as apple juice, a cup costs 190 l until it reaches the consumer. (Fao.org, 2019)

Nuts are not meat, but they cost also a lot of water: cashews, pistachios, walnuts or hazelnuts need about 15000 l of water per kg to produce. That is, each single pistachio costs 2,6 l of water. The state of California (USA) produces 80% of the almonds that are consumed in the country, and it uses 10% of its rather scarce water resources to grow them. A T-shirt needs 2 720 l, a pair of jeans almost 10 000 l water to manufacture (Guertin, 2017). Even our

electricity may have an imbedded water footprint. Greenpeace has calculated that coal fired power plants need as much water as one billion people consume. That means, even by reducing our electricity consumption, we also save water. (Greenpeace, 2016)

Jakarta is considered by the author as a fascinating case study to analyze the most fundamental challenges of today's planning. Poverty, pollution, traffic, city reinvention, vulnerability… whatever key arises, Jakarta embeds it. In this sense, Jakarta is probably a black box for urban sustainability analysis, a living research book, perhaps a mandatory examination for each future planner or a perfect billboard of examples for each senior planner.

In that sense, it is very fortunate, timely and suitable to congregate this year in Jakarta to discuss urban planning "beyond the metropolis". This experience hopefully will leave a shocking impact in the minds of all participants, one that will inspire the work and shape the influence we as planners exert wherever we work.

Research Paper

CHALLENGES OF SPATIAL PLANNING IN COASTAL REGIONS OF BANGLADESH

A Case for Chalna

Muhammad SHAMSUZZAMAN, City Region Development Programme, LGED; Bangladesh

Abstract

The delta land Bangladesh has a unique coastline where numerous rivers meet the Bay of Bengal, creates a complex net of tidal river estuaries, forming the base for world's largest mangrove forest the Sundarbans. Chalna is small town located at the confluence of Rupsha and Chunkuri rivers, only 9 km north of the Sundarbans, and a well know river port. The Sundarbans, which acts as a buffer between the sea and the human habitats including arable lands. The forest is rich in unique biodiversity and natural resources providing livelihoods of a large number of people living in the towns and villages around it. As the region is near the sea and land morphology is plain and of low altitude it is always vulnerable to natural disasters. Due to global warming and sea level rising the land mass is vulnerable to flooding.
The sign of climate change; erratic behavior of rainfall and draught, intrusion of salinity etc., are changing the usual pattern of agriculture and fishing, affecting the livelihoods of the people here. The eco system of this mangrove forest is also threatened by recent policies of the Government and initiatives of private sectors of establishing high risk industrial establishments like thermal power plant, liquid petroleum gas stations etc., around Chalna and its surrounding region in sprawling manner. The potential of running large number of vessels through the rivers and canals of the Sundarbans might have negative impacts of the flora and fauna living there. Popular protests against these harmful interventions are being observed, international public organizations and concerned learned societies are also recommending not let these damaging developments going on. Although there are some promises from the government to the international agencies, there is no sign of management of such developments. This paper systematically investigates the reasons of this phenomenon, identifies the challenges and concludes that; absence of regional spatial planning in Bangladesh, neglecting the values of environment and public goods, defying the regulations in various ways and not accounting public opinions in the decision making process are the core ones.

Keywords

Challenges of spatial planning, planning in coastal regions, natural and man-made disasters

1. Introduction

1.1. Description of the study area: Chalna and its surrounding coastal region

The study area is Chalna, a small municipality town and its surrounding coastal region which lies in Dacope sub-district of Khulna, a south western district of Bangladesh (figure 1). The study area borders protected forest the Sundarbans and the Bay of Bengal at its south. Chalna is a famous river port located at the confluence of Rupsha and Chunkuri rivers, only 9 km north of the Sundarbans. The Sundarbans are the largest mangrove forest in the world, recognised as a natural World Heritage site by UNESCO. They provide a subsistence living to 3.5 million people and offer protection from cyclones in southwest Bangladesh. The mangroves' extensive root systems help stabilise wet land and coastlines, break up storm waves that exceed four metres in height and result in the areas with good mangrove coverage suffering less from wind and wave surges than those areas with less or no mangroves. (Dudley, N., et al. 2010). The major parts of the town inside the Polder built in the 60s and almost whole part of it is flood free.

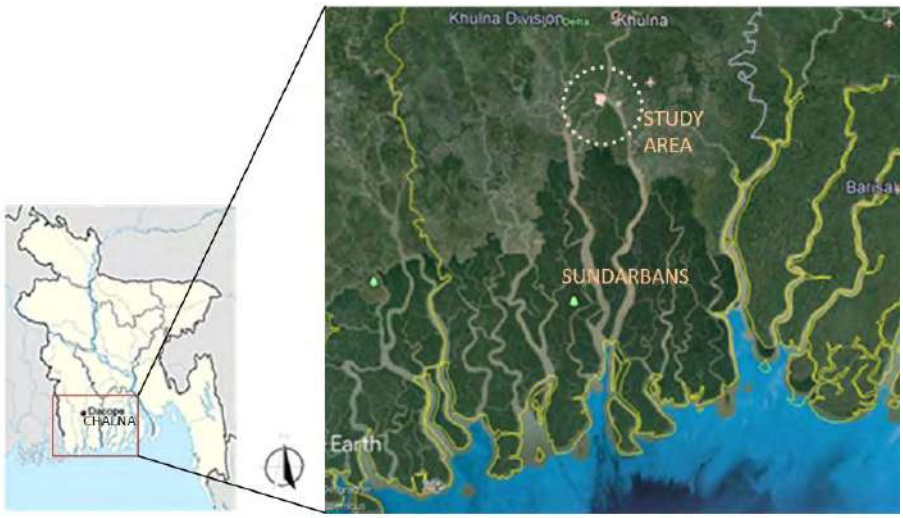

Figure 1 Location of the study area in the context of Bangladesh and the Sundarbans

Unplanned developments those are not compatible with this location are popping up sporadically posing high risk to the ecology and life of the people living here. Following chapters of this paper delineates the research methodology, forms hypotheses, present the evidences for and against the hypotheses and finds out the core hypotheses. Finally conclusions are made based on the comparisons of evidences with the hypotheses which is called Structured Geospatial Analytic Process. An indication of further research is also given at the concluding chapter.

Figure 2 Google view of Chalna town showing Chalnacanal in the middle

2. Methodology of the Study

2.1. The analytical process

Structured Geospatial Analytic Process has been followed as the study/ research methodology. The main steps of this process are Question, Grounding and Team Building, Hypotheses Development, Evidence Development, Fusion and Conclusions. The *question* defines the broad nature of the spatial and temporal patterns the analyst is seeking to ultimately identify. *Grounding is* the raw evidence that reaches the analyst. *Hypotheses* are the tentative representation of conclusions with supporting arguments. *Evidence* refers to snippets extracted from items discovered in the grounding. The *fusion process* is the comparing of the evidence to each hypothetical geospatial and temporal pattern to determine consistency. The *conclusion* is a proposition about which hypothetical pattern(s) is (are) most consistent with the evidence and answers the question. (University Library 2019)

2.2. Research question

News, publications and personal experience about the natural and man-made disasters, environmental changes vulnerabilities, unmanaged developments etc., in the towns and adjacent coastal region gives us the impression that it is highly vulnerable and complex situation and the planning and management of the developments of the area is not functioning properly. The urban areas are managed by municipal laws and there are environmental laws for managing developments in the ecologically sensitive areas. Still spontaneous and harmful human interventions are escalating the vulnerability of natural disasters and climate change impacts. To search for the explanation of this phenomenon the author naturally raised the following research question;

What are the challenges of spatial planning for coastal settlements/towns of Bangladesh which hinders livable, eco-friendly, disaster and climate change resilient development?

2.3. Hypotheses

From intuition and after analyzing the raw evidences News, publications and personal experiences, the following hypotheses are developed by the author;

- Coastal settlements are vulnerable to natural disasters and climate changes
- Human interventions in the coastal area are escalating the vulnerability
- Soft interventions are performing well
- Weak framework for region spatial planning in Bangladesh
- Developments defying urban and environmental regulations in the study area
- Issues of environment and public goods are overlooked indecision making
- Public opinions are overlooked in development decisions

3. Evidences Related to Hypotheses

3.1. Coastal settlements are vulnerable to natural disasters and climate changes

Bangladesh is one the most vulnerable countries of the world exposed to multiple natural hazards, such as cyclones and floods, particularly in its coastal areas. Over the last few years, coastal area of this part of Bangladesh as well as Chalna town has been greatly affected by extreme natural disasters such as cyclones, storm surges, etc. On 25 May 2009, Cyclone 'Aila' hit the coastal areas of Bangladesh. Aila cost an estimated $1.7 billion in damages and losses. Cyclones and associated storm surges and floods have led to almost all the nearly 520,000 natural disaster deaths recorded over the past 40 years in Bangladesh. This country is also one of the most vulnerable countries in the world to the effects of climate change. The country's extreme vulnerability to hydro-meteorological hazards, including storm-induced tidal flooding, is likely to increase due to climate change. (GFDDR n.d.)

The nationwide climate vulnerability index Table of Ministry of Environment and Forest of Bangladesh shows, at Dacope Upazila, the sub-district where Chalna is located, increased number of people will be affected by natural disasters, mangrove forest will be depleted, the health of livestock and poultry will be decreased, groundwater quality will be depleted and land available for agriculture will be decreased due to potential climate change. (Ministry of Environment and Forest 2018)

3.2. Harmful human interventions in the study area

Environmental degradation due to infrastructure development at the natural habitats their ecosystem services have been failed. During 1960s a series of coastal embankments were constructed in Bangladesh to protect low lying lands from tidal inundation and salinity penetration. Although the land within the embankments became highly valuable agricultural land the embankments, however, block the drainage of freshwater from the land within embankment to the other side of the barriers after excess rainfall and /or river flooding. Some sluice gates were constructed to regulate the flows of water when necessary, but most of them became inoperable due to various reasons. If sea-levels rise due to climate change as predicted then higher storm surges could also cause over-topping of saline water behind the embankments. OECD warns that, "climate change could be a double whammy for coastal

flooding, particularly in areas that are currently protected by embankments". (Dudley, N., et al. 2010)

Figure 3 Dried up Chalna canal at inner side of the polder due to non functioning sluice gate

Figure 4 Natural Liquid Gas plant at the south of Chalna

IUCN recommended placing the Sundarbans in Bangladesh on the List of World Heritage in Danger to the World Heritage Committee of UNESCO recently according to a press of IUCN, dated 7th June 2019, due to severe threats from coal-fired power plants and numerous industrial activities in close proximity. The site is part of the world's largest mangrove forest, home to the royal Bengal tiger. However, the recommendation was reverted at the last moment. 'Following a joint IUCN-UNESCO mission in 2016, the World Heritage Committee called for the large Rampal power plant project, to be cancelled and relocated. Despite this, its construction has continued without any assessment of its impact on the Sundarbans' World Heritage values. Two additional coal-fired power plants are being constructed on the Payra River, which flows into the same bay as the Sundarbans. Over 150 industrial projects are also active upstream of the site, and their associated shipping and dredging activities further threaten its hydrological and ecological dynamics. The hydrological systems, which drive this dynamics, are very large in scale and vulnerable to upstream impacts.' (IUCN 2019)

According to the EIA of the said thermal power plant project the aerial distances from the plant to Chalna is only 3.18 km northwest. As such, in case of Chalna, there is a possibility of emission flow toward the town city, when prevailing wind flow from southeast to northwest direction. The boundary of Sundarban reserve forest is 10 km south. The 10 km radius boundary from the Sundarban is only 4 km away from the thermal power plant. (Government of Bangladesh 2013)

So three negative forces; natural disasters, climate change impacts and harmful consequences of human interventions coincides at Chalna and its surrounding areas.

3.3. Soft interventions are performing well in the study area

After experiencing two devastating cyclones of 1970 and 1991, Bangladesh has given significant efforts to reduce its disaster vulnerability. Bangladesh is now considered a global leader in coastal resilience due to its substantial long-term investments in protecting lives. (World Bank 2018)

Bangladesh is often cited globally as a positive example for investment in DRM. The Government of Bangladesh has taken significant steps to strengthen disaster risk management (DRM) efforts. These include:

- Endorsing the DRM Act (2012), which outlines the country's legal framework for disaster management; and
- Mainstreaming DRM into a number of development plans, including the National Sustainable Development Strategy (2010-2021). This strategy recommends increased and cross-cutting investment in DRM.

Global Facility for Disaster Reduction and Recovery, GFDRR has helped enable DRM efforts in Bangladesh since 2007 focused on post-disaster reconstruction, risk reduction, and building urban resilience. GFDRR is providing ongoing technical support and capacity building to the Government of Bangladesh. Activities are supporting several technical areas, including provision of ICT for weather and climate services; assessing user needs for weather, water, and climate analysis; and enhancing technical understanding of instruments, modelling, and use of models for generating weather, water, and climate information. (GFDDR n.d.)

3.4. Weak framework for regional planning in coastal regions in Bangladesh

Urban development regulations and environmental regulations do exist in Bangladesh but there is no practice of regional spatial planning. Due to absence of regional planning framework it is difficult to manage developments beyond the municipal areas. However, Bangladesh Delta Plan 2100 Formulation Project have identified two main challenges for urbanisation and settlement with regard to the Delta plan. One of them is 'providing a holistic long term plan combining (amongst others) water management and sustainable spatial and urban development' under which a regional scale planning strategy have been suggested. (GoB 2019)

3.5. Developments defying urban and environmental regulations in Chalna town and in the study region

Although there are urban development regulations and environmental regulations to manage developments in municipal areas and beyond but many evidences have seen harmful developments in the ecologically sensitive areas, particularly in the coastal regions of Bangladesh. Power plants, natural liquid gas (NLG) plants, shrimp farms, brick fields, various types of industries are sprawling around Chalna and other coastal areas of Bangladesh (Fig. 4 & Fig. 5). Sites of such establishments are chosen for easy sea and river transport facility, existence of vacant land and comparatively lower land prices than upland areas. I many cases these developments are occurring defying the urban development and environmental regulations of the country in various ways.

Figure 5 Industries, shrimp far, thermal power plant around Municipality of Chalna

3.6. Issues of environment and public goods are overlooked in decision making

Coastal areas of Bangladesh are ecologically sensitive and provide ecosystem services, natural resources and employments. A major part of coastal area of Bangladesh is the tidal mangrove forest, the Sundarbans, a natural heritage site recognized by UNESCO bordering south of the study area. Utmost care should be taken for any kind of interventions in this ecologically sensitive area. It is evident that developments incompatible with this environmentally fragile location are increasing gradually putting the nature and the local inhabitants at high risk of environmental catastrophes. The value of natural resources and ecosystem services often undermined by the investors and by the decision makers as well. Frequent news about such interventions and protests against them covers in the media.

An example of reluctance for revoking permissions (granted earlier of declaration of ECA zone) to nearly 150 industrial projects located within the ten kilometre area surrounding the Sundarbans, declared as ECA back in 1999. The permissions never revoked despite there are provision to revoke such permission once the area is declared ECA. Ignorance, administrative

negligence and faulty legislation have put the ecologically sensitive sites in serious degradation. The Environment Impact Assessment of the ongoing Rampal Power Plant project, admits that the 142 tons of sulphur dioxide and 85 tons of nitrogen dioxide that will be emitted daily from the plant will increase the concentration of Sulphur Dioxide (SO2) and Nitrogen Dioxide (NO2) in the air near the Sundarbans. Popular protests, recommendations and writings against the project is continuing. (University 2016)

In a response to the observations of World Heritage Committee on the Sundarbans, the state party, Government of Bangladesh submitted a report on the state of conservation of the property which assures that,

> No environmental clearance or permission has been given to any large-scale industrial projects adjacent to the property.
>
> An overview of current and future development plans until 2041 in the Southwest region of Bangladesh has been undertaken in preparation for the Strategic Environmental Assessment (SEA). A consultancy firm to undertake the SEA was to be shortlisted in January 2019. (UNESCO 2018)

3.7. Public opinions are overlooked in development decision making

Despite tremendous popular protest against the Rampal Power Plant project, the Department of Environment (DoE) of the Government of Bangladesh accepted the project to be feasible. A writ petition filed to stay the project was summarily dismissed by the Supreme Court.

In 2013 a public interest litigation was filed before the High court division praying for a direction upon the respondents to constitute a committee with renowned local and international environment biodiversity and eco-system experts to make impact assessment of the proposed Rampal coal-fired power plant on the environment and ecology, and on the Sundarbans. But the honourable court rejected the petition by saying that -unless things shape up as much as to enable judicial mind to come to a clear conclusion, giving direction for formation of a committee of experts for that matter to suspend a huge development project would be a gratuitous interference by court which is not permissible under law. (Shekh Md Muhibbullah,2017). An article in DW regarding control of politics in Bangladesh mentions that, 'a limited number of people make decisions in Bangladesh'. (DW 2019)

Figure 1 Save Sundarban protesters in Dhaka on July 28, 2016 (Daily Star photo)

(Source: https://www.sourcewatch.org/index.php/Rampal_power_station Accessed 8 July 2019)

4. Fusion: Comparison of Evidences with Hypotheses

4.1. Matrix of evidences and arguments

The hypotheses/ arguments are placed in columns under the argument heading and the evidences are placed in rows under the evidence heading. Each item of evidence is examined at a time to see how consistent that item of evidence is with each of the hypotheses. Evidences are weighted by using notations. Notations C, I, and N/A standing for consistent, inconsistent, or not applicable evidences. The evidence is weighted by using combinations of CC, II, C, and I.

Table 1: Matrix of evidences and arguments

		Arguments						
		Coastal region is vulnerable to natural disasters & Climate change	Harmful human interventions	Soft interventions are working well	Weak regional Spatial Planning	Defying urban & environmental regulations	Issues of environment and public goods are overlooked indecision making	Public opinions are overlooked/ overruled
Evidences	Natural disasters	CCC						
	Climate Change Forecasts	C						
	Polders in 60s		C					
	Power plants&Industrial development in coastal Sundarbans		CC		C	C	C	C
	CDMP/ DRM Act			CC				
	NGO works/ GFDRR program			C				
	Studies on challenges of urban planning				C			
	Delta Plan 2100				I			
	Unplanned developments				C			
	EIA of Rampal		C			C	C	C
	Not revoking industry permissions						C	
	Dismissal of writ petition						C	
	IUCN advices on Rampal				C	C	C	C
	GoB's report to World Heritage Committee on the Sundarbans				I	I	I	
	Public protests					C	CC	C
	DW News on decision making							C

Examination of each of the hypothesis one at a time is done by looking down the column to consider each hypothesis as a whole. Generally, the hypothesis with the fewest "I"s is probably the most likely one. The hypothesis with the most "I"s is probably the least likely one.

The first hypothesis, 'coastal settlements are vulnerable to natural disasters and climate changes' scored 4 "C"ssupported by previous reports of natural disasters and forecast of climate change impacts and it does not scored any "I"s.

The second hypothesis, 'Human interventions in the coastal area are escalating the vulnerability' scored 4 "C"s supported by the evidences of construction of embankments during 60s, recent industrial and power plant developments in the study area. It does not score any "I"s.

The third hypothesis, 'soft interventions are performing well' scored 3 "C"s which is consistent with the evidences that Bangladesh has enacted a Disaster Management Act in 2012 and the Comprehensive Disaster Management Programme has positive results. There are many national and international NGos are working with livelihoods, nature conservation, climate resiliency etc., It has no "I"s.

The fourth hypothesis, 'weak framework for region spatial planning in Bangladesh' got 4 "C"s and 2 "I"s. Uncontrolled industrial and power plant developments in the study region, studies on spatial planning challenges, findings of the Delta Plan 2100, unplanned urban development and recent recommendation of IUCN to placing the Sundarbans in Bangladesh on the List of World Heritage in Danger to the World Heritage Committee of UNESCO support the hypothesis. However, recommendation for preparing coastal regional plans in the Delta plan 2100 and taking an overview of current and future development plans until 2041 in the Southwest region of Bangladesh has been undertaken in preparation for the Strategic Environmental Assessment (SEA) show some initiatives towards regional spatial making.

The fifth hypothesis, 'Developments defying urban and environmental regulations in the study area' scored 4 "C". Issuing permission of large industries in ecologically sensitive areas around the Sundarbans through loopholes of laws and regulations, approval of the Rampal thermal power plant project despite the harmful emissions stated in its EIA report, inclusion of 'water infrastructure' and 'non-renewable energy facilities' and others as affecting factors of the Sundarbans in the provisional agenda to declare it as World Heritage in Danger. (UNESCO, 2019..) , reports of public protests in the media etc., confirms the relevancy of the hypothesis. The hypotheses scored 1 "I"s, due to assuring undertaking Strategic Environmental Assessment (SEA) of the Sundarbans in a report on the state of conservation of the property.

The sixth hypothesis, 'Issues of environment and public goods are overlooked indecision making' scored highest 7 "C" and 1 'I's only. Recent industrial and power plant developments in the coastal area, issuing permission of large industries in ecologically sensitive areas around the Sundarbans, approval of the Rampal thermal power plant project despite the harmful emissions stated in its EIA report, inclusion of 'water infrastructure' and 'non-renewable energy facilities' and others as affecting factors of the Sundarbans in the provisional agenda to declare it as World Heritage in Danger, dismissal of writ petition to form expert committee to review Rampal thermal power plant project, reports of public protests in the media etc., shows the consistency of this hypothesis. The hypothesis scored 1

"I"s, due to assuring to undertaking Strategic Environmental Assessment (SEA) of the Sundarbans in a report on the state of conservation of the property.

The seventh hypothesis, 'Public opinions are overlooked in development decisions' scored highest 5 "C" and no 'I's. People raised their concerns during establishment of the major harmful interventions at the study region, EIA reports and international public agencies made their recommendations but those were properly taken care of. Recently published article in DW Bangla indicates that decisions are taken in Bangladesh by a limited number of people having a chance of disregarding the public opinions.

5. Conclusion

From the systematic comparisons of hypotheses with the evidences the most consistent hypotheses have been identified. The core challenges of spatial planning in the coastal region of Chalna, Bangladesh are; absence of strong regional spatial planning framework in Bangladesh, neglecting the values of environment and public goods, defying the regulations in various ways and not accounting public opinions in the decision making process. So, there is a tremendous scope of working with regional spatial plans in Bangladesh, particularly for its coastal regions.

There are further scopes to adopt the climate resilient and blue-green approaches of designing the infrastructures instead of the conventional ones. There is also scope of exploring the local landscape and building cultures that are generated through generations local adaptive wisdoms.

The public authority need to adopt participatory culture in planning, and collaborating with learned bodies, international authorities, private sectors, NGOs to achieve the goal of planning a coastal town like Chalna in adaptive or resilient way.

Case Study / Project

How to Plan in a Volcano-related Disaster Prone Area?

Lesson Learned from Adaptive Spatial Planning in Dieng Plateau, Central Java

Raka SURYANDARU

Abstract

Located in the Asia Pacific's Ring of Fire as well as has one of the longest shorelines in the world, Indonesia is prone to various kind of disasters. Over the past few years, Indonesia has made headlines around the world due to devastating natural disasters that resulted in environmental damage and thousands of casualties. One of the area that has multiple disaster risks is Dieng Plateau in Central Java. The infamous geopark is prone to at least from landslides, toxic gases, and earthquakes. Based on the data from Local Agency for Disaster Management, the area has a medium risk for landslides, with an average occurence of four to six times each year. It also sits in the I, II, and III levels of earthquake. The deadliest disaster in Dieng Plateau is CO2 toxic gases-with Sinila, Timbang, and Candradimuka Craters are actively emit the toxic gases sometimes. In 2011 and 2013, more than 5.000 residents were evacuated and 20 hectares of agriculture land damaged due to CO2 toxic gases from Timbang and Kalisat craters and landslides.

In 2018, Sileri Crater located in Dieng Volcano area was suddenly erupting phreatic. Batur is one of the sub-districts in Dieng Plateau that is planned to be an urban area currently consists of 3 villages: Batur, Sumberejo, and Pesurenan. Served as the commercial center to support tourism activity in the region, a specific approach needs to be taken to develop the area more carefully. Under the 'Detailed Spatial Plan of Batur Urban Area' project, the consultant introduces adaptive planning for disasters by optimizing land-use in disaster-prone areas. The benefit of this study is expected to be a lesson-learned for stakeholders to promote resilient development. The result obtained from this project is an adaptive spatial planning that is tailored to the region's disaster risk profile and aimed at achieving a higher standard of living.

Research Paper

Spatial planning and design for food security

Building Positive Rural-urban Linkages

Aishwarya Talluri , S.P.A. New Delhi ; India

Abstract

Food is vital for human survival. Food has had a significant impact on our built environment since the beginning of human life. The process of feeding oneself was most people's primary job for the greater part of human history. Urban Migration moved people away from rural and natural landscapes on which they had been dependent for food and other amenities for centuries.[1] Emergence of the cities leads to a new paradigm where the consumers get their food from rural hinterland where the main production of food products happens[2]. In a globalized world with an unprecedented on-going process of urbanization, There is an ever reducing clarity between urban and rural, the paper argues that the category of the urban & rural as a spatial and morphological descriptor has to be reformulated, calling for refreshing, innovating and formulating the way in which urban and rural resource flows happen. India is projected to be more than 50% urban by 2050 (currently 29%). The next phase of economic and social development will be focused on urbanization of its rural areas. This 50 %, which will impact millions of people, will not come from cities, but from the growth of rural towns and small cities. Urbanization is accelerated through Government schemes such as JNNURM (Jawaharlal Nehru National Urban Renewal Mission) , PMAY (Pradhan Mantri Awas Yojana), 100 smart cities challenge, Rurban Mission are formulated with developmental mindset. The current notions of 'development' are increasing travel distances, fuels consumption, food imports, deterioration of biodiversity, pollution, temperatures, cost of living. The enormity of the issue is realized when the cumulative effect of all cities is addressed. Urban biased development becomes an ignorant choice, causing the death of rural and deterioration of ecological assets. Most people live in places that are distant from production fields have been observed as an increasing trend. Physical separation of people from food production has resulted in a degree of indifference about where and how food is produced, making food a de-contextualized market product as said by Halweil, 2002[3] . The resulting Psychological separation of people from the food supply and the impacts this may have on long term sustainability of food systems. Methodology : . Sharing the learning about planning for food security through Field surveys, secondary and tertiary sources. Based on the study following parameters : 1. Regional system of water 2. Landforms 3. Soil type 4. Transportation networks 5. Historical evolution 6. Urban influences A case study of Delhi, India, as a site to study a scenario that can be an alternative development model for the peri-urban regions of the city. To use the understanding of spatial development and planning to formulate guidelines for sustainable development of a region that would foster food security.

Keywords

Food security, spatial planning, urbanisation

1. Introduction

1.1. Najafgahr

Zone L is one of the 6 zones that are demarcated as urban extension and rural area. Najafgahr is designated as a sub regional centre with 6 villages as service and growth centres. Najafgahr is a representative of the trend of transformation in the peri-urban areas of the developing nations. It is often representative of the edge condition of the metro cities that are growing in size, rapidly.

1.2. Current Scenario

By the year 2025, 83 per cent of the expected global population of 8.5 billion will be living in developing countries. Yet the capacity of available resources and technologies to satisfy the demands of this growing population for food and other agricultural commodities remains uncertain[4] . India is projected to be more than 50% urban by 2050 (currently 29%). The next phase of economic and social development will be focused on urbanization of its rural areas. This 50 %, which will impact millions of people, will not come from cities, but from the growth of rural towns and small cities. The current notions of 'development' are increasing travel distances, fuels consumption, food imports, deterioration of biodiversity, pollution, temperatures, cost of living. The enormity of the issue is realized when the cumulative effect of all cities, is addressed.

2. Trends

In the midst of this transformation, it is the urban-rural and rural-urban interaction that is deteriorating. Most people live in places that are distant from production fields, an emerging trend that is a result of our transformation from urban to rural societies. As urbanised specie, Humans have created a distinct division between agriculture and city life.[5]. Contextualisation and positive linkages between urban and rural can be built through a critical dimension of food systems.

Past 40 years, the government of India has emphasized on cereal farming (green revolution) now we are self-sufficient in that area. In many parts of the country, farmers are agitated because of insufficient income out of growing cereals. Speculation of land-use change in urban peripheries forces farmers to sell land for short-term monetary returns, as they lack the skill to adapt farming, to the changing needs of the city and climate. Leading to the disintegration of communities. Parallel to that , many studies have highlighted a shortage of vegetables & fruits. There are large price fluctuations, as they are not supported by the government and their supply is uncertain too. The huge requirement of food in the main consumption centres, like Delhi (25 million people) is transported from long distances (onions from Maharashtra and chillies from Karnataka). It is crucial to reduce transportation cost and energy. A more sustainable farming practice would be to grow vegetables and fruits close to the city and have a high value realization for farmers. This is where farming and industry come together i.e. farming done in an industrial mindset e g: trellising system, poly houses, controlled irrigation etc .Here agriculture is not understood as a primary way of cropping but with a mindset of tertiary and secondary.

When this is projected against real estate development, it will not only provide farmers a better livelihood, it will encourage them to learn and educate. By weaving this into the idea

of Rurban lifestyle at the edge of the city, with cultural characteristics of communities, every part of the city need not be a state-led urban development project, thereby creating a fresh way of dealing with city edges of mega-polis like, Delhi. Through the New urban agenda, agenda 21 , Sendai framework, it is an opportunity to open a new way of developing a fresh mindset and action plan to create an alternate way of developing the urban extension / urban periphery.

3. Significance of Urban Rural linkage:

Urban rural linkages have been defined broadly as the reciprocal flows of people, goods, services, money and environment services with many of these linkages related directly or indirectly to food systems. There are significant changes happening within food systems that impact urban-rural linkages, such as the decline of traditional markets, globalizations of diets and increasing availability of highly processed food. Small holder producers and processers, who often rely on nearby urban areas for market are increasingly competing with food produced from distant sources, often selling for lower prices.

As a result of food system changes, with multiple and interacting economic, environmental and social impacts, urban and rural areas have become less interdependent in a food systems context in many countries. Paradoxically , the severing of local food chains linking rural and urban areas has occurred while urban and rural communities are also becoming more interdependent in other ways , for example in the flow of money labor , culture and social technologies . All these changes are having profound impact on smallholders across the urban rural continuum .the diverging interdependent realities of urban and rural communities need t be addressed if we are to achieve sustainable urbanization, resilient food systems and balanced urban rural development.

By strengthening linkages between people growing and consuming food is an effective way to increase harmony and synergy lessening the gaps between urban and rural communities. The food systems often have an effective policy area through which to strengthen urban rural linkages but the impact of the policy is often diluted during its spatial manifestation.

The 2030 Sustainable Development Agenda invites new narratives, including integration of *peri*-urban and rural sustainable development. climate change , biodiversity loss, land grabbing , water shortage , forced migration as a result of disaster , war and occupation , violation of land , food and other human rights all add to the pressures on food systems , most affecting women ,children and other marginalized members of society . Despite the fact that food and cities are among the seventeen sustainable development goals (SDG2) both with developed targets , indicators and means of implementation , their integration has not been fully articulated . Until interdependence of these two areas is acknowledged as part of the implementation agenda for SDGs balanced urban rural development may not occur or not at all in places where urban expansion is the greatest and this balance is most needed. In order to develop spatial planning framework for strengthening food systems in the immediate peripheries of the city below method was adopted. Earnings about planning for food security through Field surveys, secondary and tertiary sources. Based on the study following parameters: 1. the regional system of water 2. Landforms 3. Soil type 4. Transportation networks 5. Historical evolution 6. Urban influences A case study of Delhi, India, as a site to study a scenario that can be an alternative development model for the

Peri-urban regions of the city. Challenges to integrate urban and rural are specific to local places and there is an urgent need to find constructive ways address the issues . As a solution to strengthening urban-rural connection, FOA (Food and agriculture Organisation) defined a term " city region food systems " in December 2013 " Complex network of actors ,Processes and relationships to do with food production, processing , marketing , and consumption that exist in a given geographical region that includes more or less concentrated urban centre and its surrounding peri-urban and rural hinterland ; a regional landscape across which flows of people , goods and eco system services are managed . " To use the understanding of spatial development and planning to formulate guidelines for sustainable development of a region that would foster food security.[6]

4. Research Parameters

The following parameters provide window to investigate and understand the local region and the origins of it from many perspectives. It is also a framework to explore the potential avenues for transforming the area into city region food system. Through these parameters, a vision to re-imagine an alternate development model for urban extension is imagined, where sustainable urban development is imagined as a consequence of food systems.

4.1. Ecology Historical evolution –heritage characteristics:

Historically, Najafgahr has been cultivated. It falls on the trade route starting from Rajasthan .This trade route is along the foot hills of Aravali range. The presence of Aravali, creates a unique scenario of rich network of natural drains.

4.2. Ecological setting and environmental conditions:

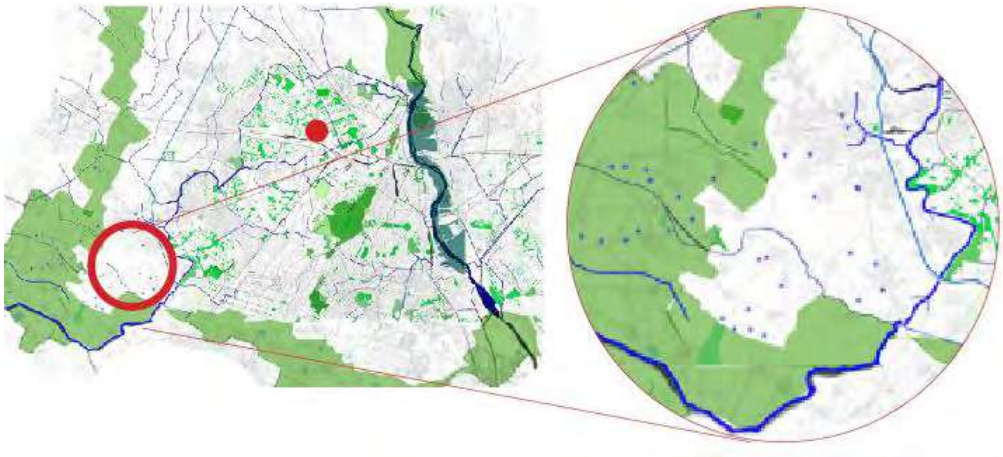

Figure 1 Map: Natural Drains of Delhi , Source : The Yamuna Project

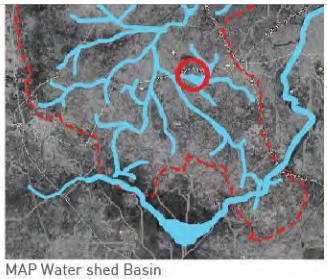

MAP Water shed Basin
Source : GIS

GIS Stream Density map
ource : GIS

Seasonal streams
Source :GIS

Figure 2 Natural Drainage of the village cluster L-3, GIS map Stream density , Seasonal Streams , Source , Author .

The above maps show the network of natural drains from macro scale, meso to micro scale. Analysis of natural terrain, drainage system, seasonal drains, reveals the valley zones. Study of soil and various zones of fertility based on scientific data is mapped. Fertility of soil and natural drain density has a healthy coherence. These valleys are valuable in structuring and guiding demarcation of buildable land. These valleys are zones that must be protected in order to ensure well irrigated region and there for high water table. Super imposition of the two data sets, can reveal structure and function of natural systems that have evolved to fit the natural resources of the given location. Developing an understanding of such kind can inform agro ecology and reveal ways to incorporate into farming systems and food systems. Since the natural water systems is continuous , by strengthening the eco system in these zones can serve as valuable habitat for wildlife , key part of integrated natural systems and a boon to those people who want to observe this aspect of the system Simultaneously , also revealing that areas where built expansion can happen , as shown in Figure 2 . If this system is designed well, along with native species, it will begin to flourish independently. A well-designed interface with this area itself can become a forum for recreation, education and potential economic interaction. [6]

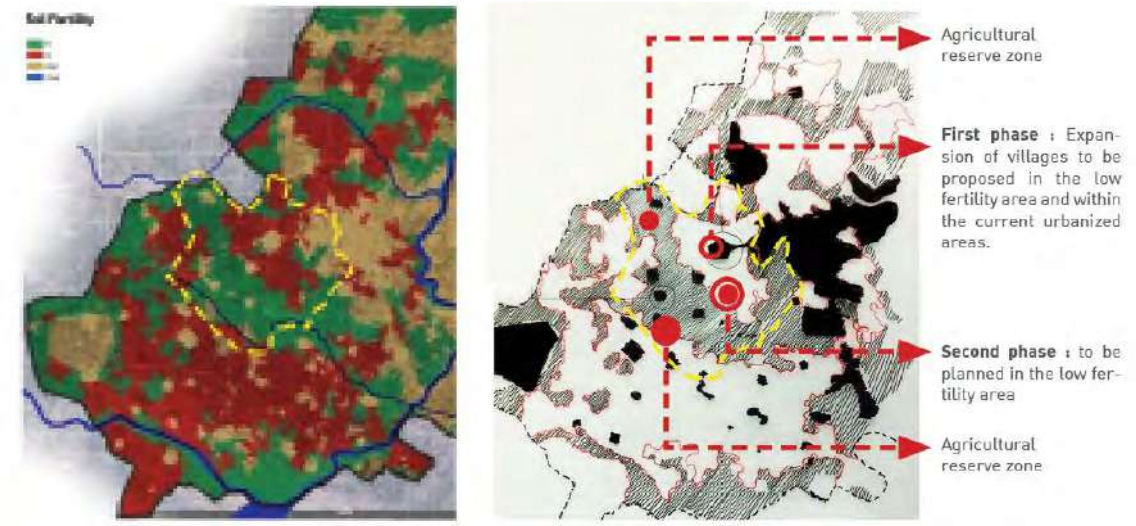

Figure 3 Soil Fertility map, Source: SLUSI , Development zones and protected zones , source : Author

4.3. Social, cultural and demographic attributes:

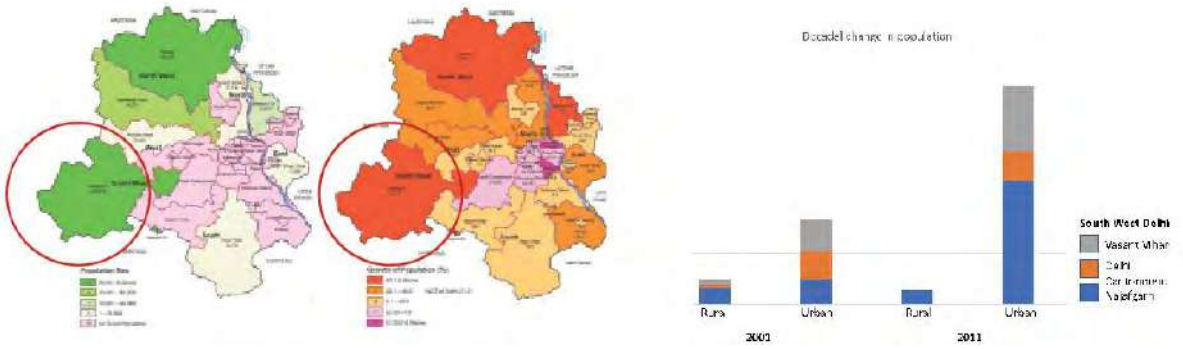

Figure 4 Increase In rural population ,Increase in population , Occupational shift in L-zone , Source : N.C.R.P.B

Decadal growth in population, literacy rate and occupational shift are indicative factors that project that scale of urbanisation.

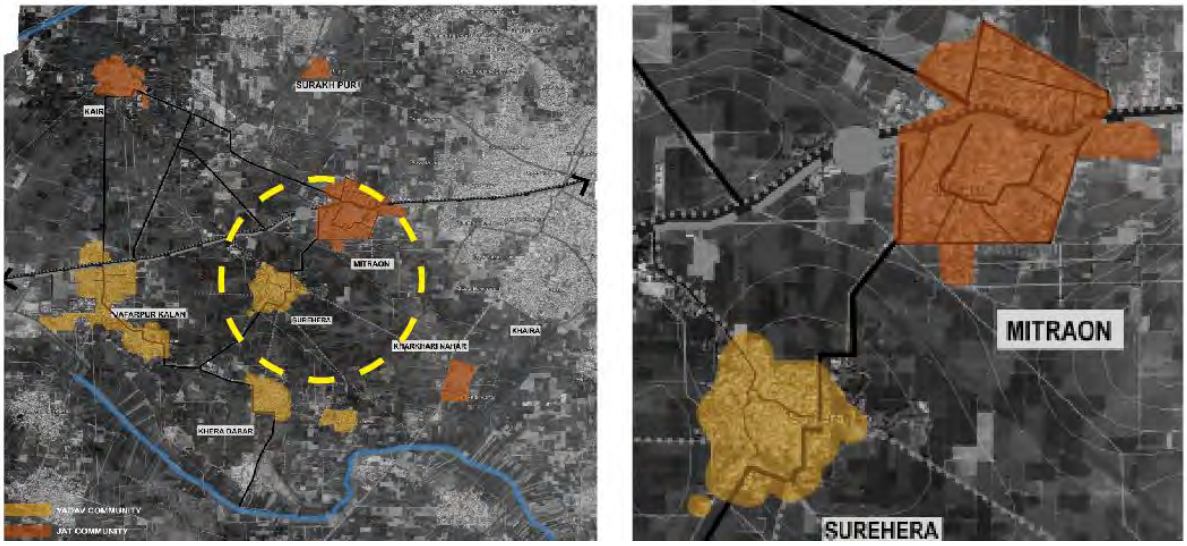

Figure 5 Map : Social Structure in village cluster , Sub cultural groups. Source : Author.

Social structure of clusters: The cluster is divided such that the major census town and the rest of the villages in the cluster are always at a conflict. The Government documents bind this cluster of villages as a unit, but there is a sub cultural divide amongst these. Forming 2 groups. The historical evolution of the 2 communities is fundamentally different and therefore the present day differences are there.

4.4. Morphological districts and their characteristics

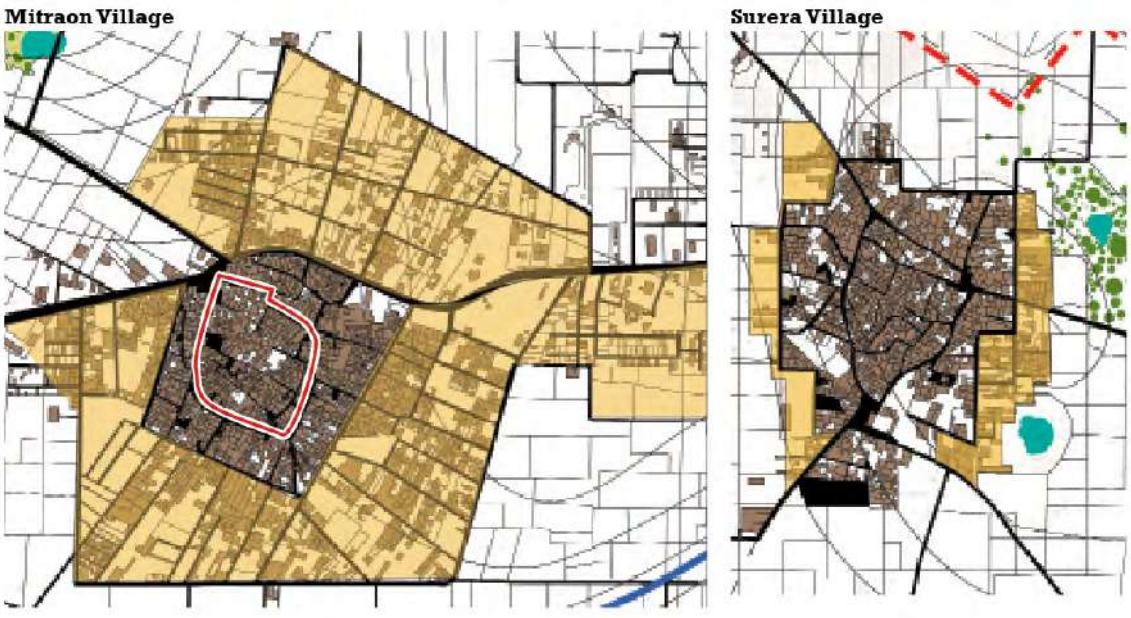

Figure 5 Mitroan village of Jat community, Surera Village of Yadav Community, Highlighting the sprawl .

Morphological character reveals the cultural attributed of the community, their lifestyles, activities and trends of development. The above map indicates the difference in the nature of sprawling according to different communities.

4.5. Physical and social infrastructure – distribution and access:

The hard infrastructure of roads , processing , storage and agricultural services business and the soft infrastructure knowledge , culture and social supports , financial credit and remittance link rural and smaller settlements and intermediate scale cities in different ways than larger cities[2] .

4.6. SPATIAL Recommendations:

Outcomes: To identify systems that reinforce agriculture as green infrastructure in areas those are close to the urban centres, as a defence against an urban-biased expansion of cities.

To strengthen the presence of the local community by providing healthcare, education and social infrastructure and locating facilities by the understanding its cultural fabric.

Facilitate young farmers to develop scientific and technical skills, business and management skills to practice farming with an industrial mindset, thereby creating productive landscape and employment opportunities. To protect and enhance the ecological assets of the place.

Principles to enable this project:

1. Integration of system: Drainage, Movement, Ecological, Agricultural
2. Morphology of interface
3. Function at interface
4. Typology of buildings at the interface

5. Strategy

Strategies are an outcome synthesising information of a broad spectrum into spatial guidelines. The guidelines are crafted with a belief that all policy, programs, social and cultural issues , economic and environmental issues have a spatial translation . Therefore a solution to create the urban rural continuum through the lens of food systems, spatial solution is created.

5.1. 1.1 Regional level strategy:

1. Plantation to be seen in such a way that there blue green infrastructure.
2. To identify and secure water catchment area. And harness it.
3. Using native, indigenous plant species as they are climate adaptive and high yielding.
4. Studying soil to identify least fertile soil -barren land to limit high density construction (if needed) in those boundaries.
5. Moving towards multi crop farming, harvesting greens-vegetables as a part of the increasing higher economic valuation of crop. – Especially in the areas with high real-estate value.
6. Strengthening the role and presence of educational institutes.
7. Implementation of the form guideline in the region in order to strongly secure the predominant identity of this area.

5.2. 1.2 Village cluster level:

1. To strengthen the presence of education institutes at cluster level.
2. Decentralizing the supply chain system according to the strengths and skill of each village.

3. To locate the given infrastructure by the government in such a manner that the inter-connecting bond of the villages strengthens.
4. Creating interface of amongst villages that strengths their relationship with one another.
5. Creating a movement network for efficient movement of produce.
6. Ensuring that the natural drainage is protected by creating bio-swales and dirt tracks at the valley areas.
7. High impacting but less no. of vehicular roads. To avoid dissection of farmlands. Placement of vehicular road is THE MOST crucial part of working in the agricultural landscape. Roads often area the starting point of strip development, with the characteristic widening of this strip, the farm lands tend to become the constantly shrinking backyards.
8. Creating decentralized system of settlements that work as a cluster of villages with each specializing in a service. The FAO studies have shown that when village work in a cluster the profitability can multiply 3 folds. Can be done by creating interdependencies and specializations at the same time.
9. To identify sub-cultural divides and build interface for cohesion.
10. Movement network to have strong hierarchy that will be maintained by the design of the section, such that people are encouraged to walk and cycle and recreate.

5.3. 1.3 Village level

1. In India, MSME accounts for 45% of manufacturing output, fostering growth of MSME sector along with the provision of social infrastructure for hamlets and villages can diversify employment opportunity for the rural population and alleviate the need for migration or give up farming practices.
2. Recreating the rule of commons, something was a fundamental part of village functioning as a unit.
3. Strengthening sense of community
   - By strengthening congregation spaces of the village and making them more accessible.
   - Creating shared facilities.
   - Making space for cultural attributes of the community.
   - Creating new ways of congregation that is inclusive of youth generation.
4. De-congesting core roads to protect the community life at the dense core.

5.4. Local intra village strategy:

1. Protecting, strengthening and creating potential natural drainage spines.
2. Based on soil fertility and capability the village expansion must be located.
3. The interface of the new and the old much be designed to accommodate new scenario and morphological continuum in order to retain the landscape quality.
4. Ensuring no strip development between 2 villages.
5. Careful locational setting of educational institutions based on their capacity and to enhance accessibility.
6. Making this area also be a training foreground and outreach program for the new generation farmers.

5.5. Built Forms

1. Systematizing the new development.
2. Morphological transition with the existing structure.
3. The form must respond to the fact that the soil is loamy.
4. The new structures will be a shared facility (present day commons) therefore modularity is a crucial point in the design.

5. The form must enhance the relationship of the people with farmlands and farming practices.

6. Conclusion

Integrated planning for urban and rural areas around the world is extremely challenging and the rise of structural inequity and polarization is not reducing the level of challenge. And yet, there are new openings and opportunities of developing alternate ways of development. However, the benefits of a balanced urban and rural approach to strengthening urban rural linkages summarized in this paper will only occur with deliberate efforts to integrate urban, peri-urban and rural food system planning in sustainable development planning at all levels. The significance of having an ecosystem of urban and rural is the only way to move towards a sustainable future. The Agenda 21 Document strongly advocates for urban rural continuum and food security, this paper is an attempt to translate the ideas into spatial guidelines, as it is observed, that often the spirit and intentions of the project is lost in translation from text to space .Frameworks for design and planning must be created to factor in new Narratives that are specific to local context so that ecology and biodiversity , therefore sustainability of the region at large is made possible .

Case Study Paper

REIMAGINING PAMBA

Sustainable design strategies for Sabarimala Pilgrimage.

Rahul V, B.arch; India

Abstract

Kerala, an Indian state, known popularly as gods own country, lies one of the ancient temples, Sabarimala. Other than its historical and cultural prominence, this temple is open only for a few days in a year and prohibits the entry of women of 15-55 years of age. The temple is situated along the banks of the river Pamba. The flood plain of this river acts as a transitional area between The Sannidhanam(the temple) and Nilakkal (the parking area) .The Study extends from natural setting of the area to the pilgrim behavioural study . Unplanned development of the Pamba flood plain, without considering the context lead to the study of; Malai Arayans the natural inhabitants of the forest. Their settlement pattern and lifestyle were studied.

Research oriented design strategies were prepared also by considering recent devastating flood in Kerala and the Supreme Court order for women's entry which created lots of riots and chaotic situation within the state. Study includes pre-flood condition, during the flood and after flood scenario of Temple's base camp, situated along the bank of the River Pamba; during seasonal and non-seasonal time. After considering the need of pilgrims and ecological impact, proposal includes design interventions which reduce ecological footprint, waste generation, wildlife threatening and measures to improve tribal life. Design proposal includes study of local materials, documentation of indigenous techniques, construction details and issues of the native tribes. Rather than imposing an alien architecture inside the forest, the study ends up in search of temporary, semi temporary architectural interventions using natural materials and technology. End result of the project includes the whole mapping of Pamba during various stages, the pilgrimage culture and its effect on nature and a whole new design for pilgrim culture which includes women pilgrims; architecturally and non-architecturally

Keywords

Sabarimala, Malai Arayans, Pilgrimage, Flood, Pamba.

1. Introduction

Sabarimala is an ancient temple for Ayyappa (Sasthavu) situated deep inside the western ghats of Pathanamthitta Dist. Kerala, India. Nilakkal, 17 km before Pamba, acts the parking area for pilgrims. Pamba act as the final halting in the journey to Sannidhanam (shrine). Lots of preparations and rituals are happening at Pamba with very less facilities. Sabarimala is one of the area with floating population is greater than existing population of the entire state. Due to this lot of infrastructural facilities are introduced inside the forest, which cause tremendous changes that affected context and environment of the site.

Figure 1. Pamba basin before flood

Source: Google Earth

2. Site Study

2.1. Location

North: Peerumedu taluk

South: Pathanamthitta district

East: Theni, Thirunelveli & Ramnad District of Tamilnadu

West: Kottayam district.

The site area comes under high ranges of Southern Western Ghats with an altitude vary from 100 to 2019 m. The western part of the reserve, where the elevation ranges from 100 to 11OOm, mainly occupies west coast tropical evergreen forests. It is in this biodiversity rich forests where the famous Sastha Temple is situated.

2.2. Climate

. The site experiences a varied range of temperature, humidity and rainfall due to the wide range of altitude. The river side has predominantly salubrious climate. The temperature varies between 19°C and 36°C. During winter months, at high altitudes the temperature is considerably less and frost occurs during the period. The humidity at the foothills varies from 70% to saturation, due to the presence of the river, whereas at higher altitudes it is slightly less. The two monsoons – The south west monsoon during the months of June to august contributes about 60-65% rainfall.

The Northeast monsoon experienced during September to November contributes 20-25 % of the rainfall and 10-15 % of the rainfall is received during January to May as summer rains..

2.3. Malai Arayans

Malai Arayans are the native tribals of travancore forests. The Malai Arayans inhabit mainly the Kottayam, Idukki and Pathanamthitta Districts of Kerala. They are included in the list of Scheduled Tribes officially accepted as such both by the Union and Kerala Governments.

Settlements

The Malai Arayan Village was built generally on high ground mostly by the side of a stream. In defense of possible attacks by wild elephants they built anamadam on trees (tree houses) a bamboo ladder access. They took shelter in them during night and drove off wild elephant by shouting Ayyappa"

The huts were built without windows as a safe guard against the sultry heat of summer. The huts were scattered here and there and they had an easterly orientation. They stored the harvests chiefly paddy and tapioca in the “Anamaadam’’

Materials and Construction

Huts were built of Jungle-wood posts, bamboos, and reeds and thatched with grass. The huts were built without windows as a safe guard against the sultry heat of summer. Some Malai Arayans had huts made of stone or mud, built on foundations about two feet high. Some of the huts had mud walls and rooms with doors and windows fitted on wooden frames. Bamboo mats were used for sitting and sleeping.

3. Pilgrimage

3.1. Rituals

After 41 days of fasting, pilgrims reach Pamba after visiting Erumely either through traditional trekking route or by road. At Pamba, pilgrims take holy bath in the river and visit Pamba Ganapathy temple and continue their trekking to Sannidhanam. Lot of pilgrims stay and take rest at Pamba before taking steep route towards Sannidhanam. They are provided with space for placing 'viri' (bed spread) and take rest. During festival period, (April), the shrine is carried by head from Sannidhanam to Pamba “Arattukadavu” for the holy bath of Ayyappa as part of rituals.

3.2. Activities

SEASON

Continuous flow of pilgrims throughout the day and riversides are filled with them to conduct holy bath. Continuous KSRTC services.Services of TDB, Forest Dept., Ayyappa Seva Sangham, Fire & Rescue, Police force, Health Dept., BSNL, Water Authority, NDMA and many other private service providers. Commercial acitivities like hotels, stationeries, tea stalls, Prasadam counters etc are active during season. Dolly services are available at Pamba at a rate of Rs 4200/-

Figure 2. Mapping during pilgrimage season

OFF SEASON

Major construction and development activities take place. Few KSRTC buses with hault at Pamba. No Communication facilities other than BSNL. Employees of TDB, Police, Forest, KSEB, KWA departments accommodate at Pamba as well as in Sannidhanam. People visit Pamba Ganapathy Temple and conduct rituals like Choroonnu, Bali Darppanam etc.

3.3. Building character

Visually the whole area inside the dense green forest is very shabby. No particular character or look is visible in most of the buildings. In addition, no structures are built by considering fire safety and other precautions. Building materials - Normal concrete construction using concrete blocks and cement. No consideration for environmental impact. Even Sannidhanam also, same construction practice is happening.

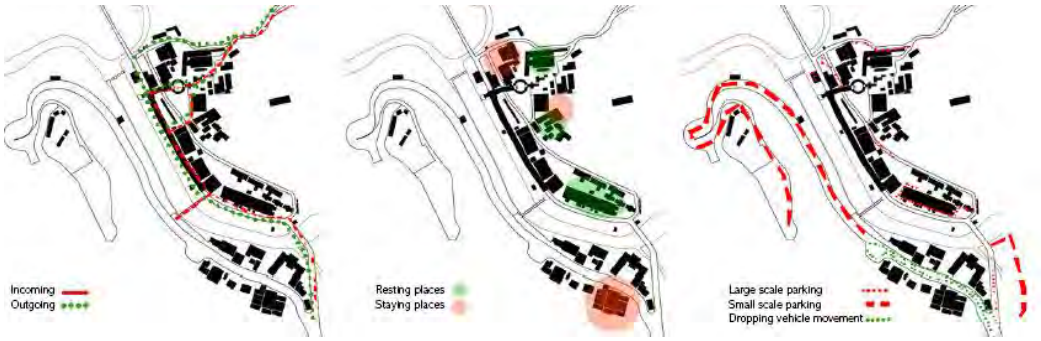

Figure 3. Various parking and vehicular zones

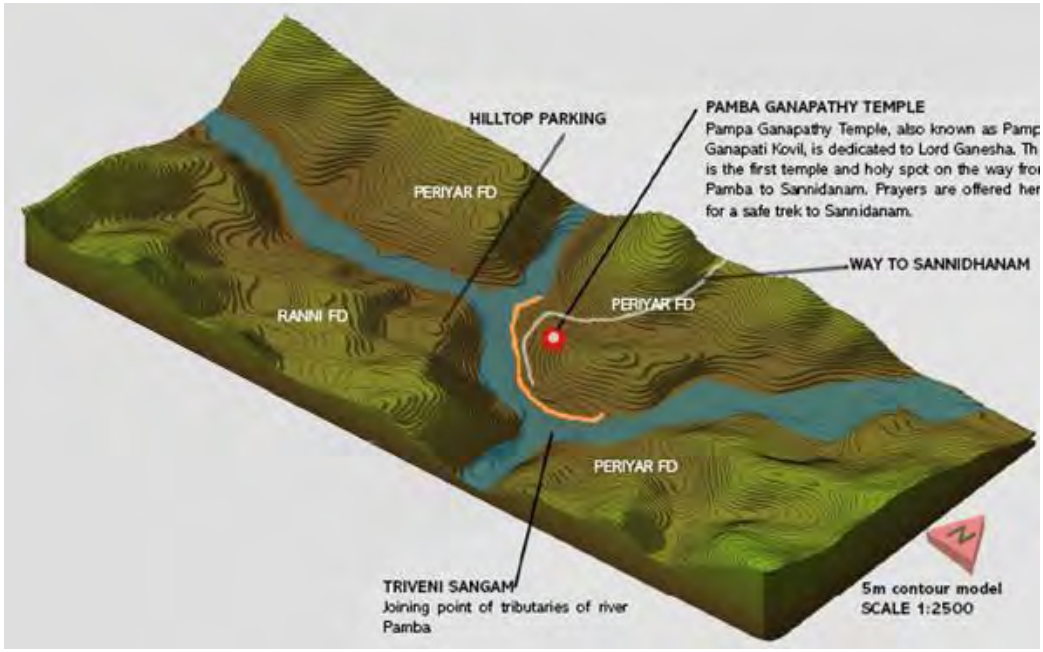

Figure 4. Contour setting of the valley

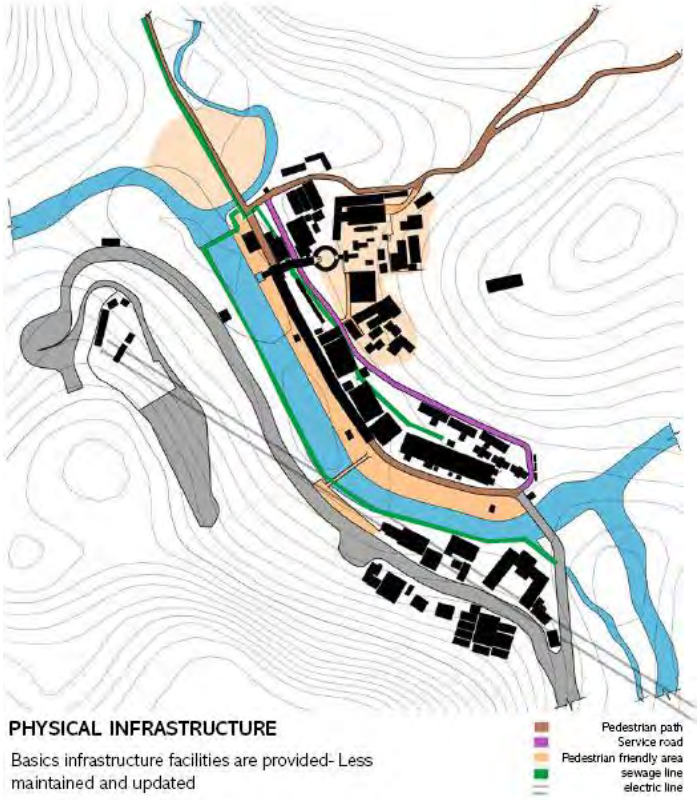

Figure 5. Physical infrastructure

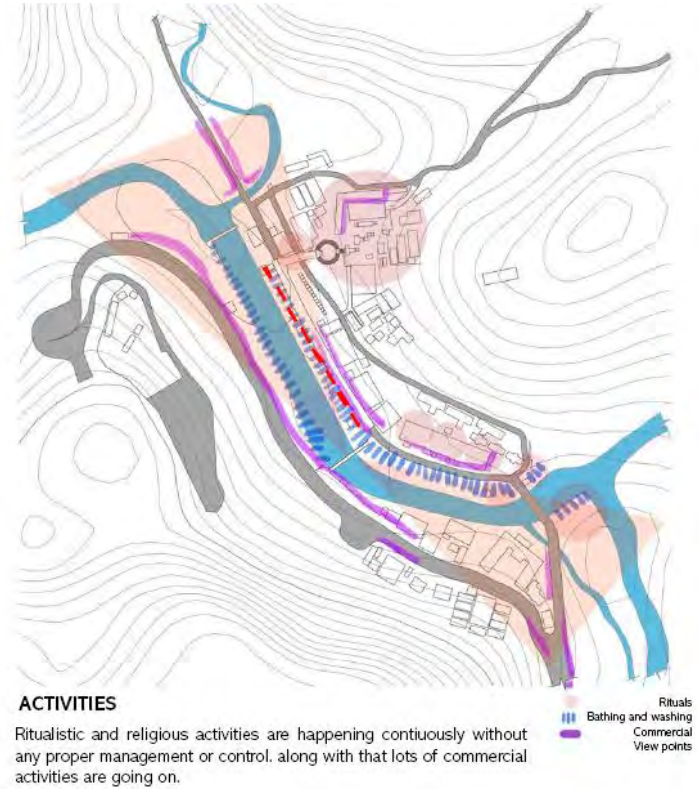

Figure 6. Activities during pilgrimage

3.4. Pilgrim behaviour

Most of the pilgrims are not aware about the proper path and spaces at Pamba. No proper guiding or signage are provided, and it causes scattered movement of pilgrims without any restrictions results uncontrollable crowd.

4. CURRENT EVENTS - FLOOD OF THE CENTURY

Impact of the flood on site was very huge. So many structures are destroyed and river flowing direction is changed. An estimated loss of 100 crore declined the human access to Sabarimala.

Figure 7. Pamba after floods

Source: Malayala Manorama newspaper

4.1. LOSS OF PROPERTIES

The pedestrian bridge, Toilet blocks, Annadana Mandapams, Resting halls, Hotels, Pedestrial paths etc,. get destroyed fully or partially. Most of the temporary structures vanished from the flood plain.

Figure 8. Before and after flood - Hospital

Figure 9. Before and after flood - Bridge

Figure 10. Before and after - Waiting area

Figure 11. Commercial complex

More than the destruction happened, A huge amount of sand get deposited all over the plains. Estimated amount is 2000-3000 load sand. Ground floors of every exisiting structures get filled with sand, about 3m height deposition.

Figure 12. Before and after - Temple bridge

4.2. Master Plan

Even the flood creates a chaotic condition at Pamba and Nilakkal, The masterplan gets more relevant, so that Nilakkal will become the Basecamp for the pilgrims and Pamba will become a transist points with basic facilities. And also masterplan aims at cleaning the Sannidhanam by reducing all the built ups to bring back the natural setting to a more splendid condition

4.3. Findings

Due to increased built up which causes a huge runoff, results in flood with that microclimate. Also the water holding capacity of soil reduced due to the absence of water absorption cycle. Here in Pamba, the whole destroyed structures are construcuted without respecting basic rules and get affected by the flood. Flood plain is always intended to works as a functional wetland which always keeps the water table normal, which reduces the effect of flood.

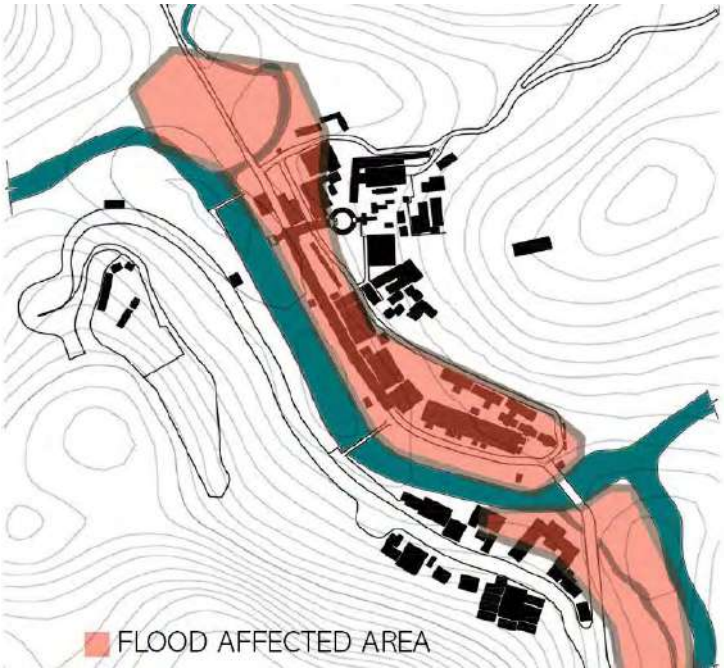

Figure 13. Flood affected area

5. Interventions

5.1. Regional Planning

The whole crowd that directly come to Pamba is controlled at Nilakkal by providing all amenities like parking, rest places, regional hotels, shops etc. All private vehicles are limited at Nilakkal. Then the pilgrims are transported through electric buses up to Pamba. Only mass transportation and emergency vehicles are allowed in this route.

From Pamba, after holy bath and rituals, pilgrims are controlled using queue complexes by prohibiting outside food and water. After visiting Pamba Ganapathy temple, pilgrims directed to Sannidhanam through oneway trek route. Interventions at Pamba will discuss in next chapter.

At sannidhanam, basic amenities are provided and no builtup other than these are allowed. An area with minimum built up area. Nature evokes the spirituality and is emphasized with a subdued architecture.

5.2. Pilgrim facilitation at Pamba

Pilgrims from bus droff off are directed to Ghats through a pedestrian bridge, with passive ventilated porous flooring, which helps to dry the barefoot easily. Bridge directs pilgrims to queue complex, where free medicated food and water is provided in reusable plates and glasses. From here crowd is controlled according to the rush, season and climate. Temporary structures kept inside this complex during off-season so that it can use during seasonal times, whch reduce built up. No built up is provided on Ghats. In case of women entry become common, the symmetry of the complex helps to break the crowd to sides of ghats.

All designs and materials are inspired from the native inhabitants. Implementing a traditional architecture inside forest is not a sincere approach.

5.3. Non-Architectural Interventions

- Whole pilgrimage is redesigned according to current situation, climate and population. Limiting pilgrim count per day using online ticketing.
- Limiting all private holdings at Nilakkal
- Participation of Malai Arayans community for the maintenance and functioning of the system.
- Creating a less carbon footprint from each pilgrim by providing least packed food and bottled water.
- In future all administration and departments will concentrate at Nilakkal. Control rooms and information counters will be provided at Pamba.

Figure 14. Design process

6. Conclusion

The journey to the Sannidhanam to see Swami Ayappan is considered very holy and the pilgrims and devotees follow strict ceremonies to qualify to visit the deity. Even though lessening the burden on the devotees is essential, we have to give something back to the nature, which nurtures us, and not destroy it. The purpose of this thesis has been to design for the needs of the pilgrims who come to visit the deity at Sabarimala after devout austerity, their trek to the deity being part of their religious journey, devoid of unnecessary luxury while retaining the sanctity of the pristine forests which itself was the reason the deity chose it as his abode.. The climate change has led to the Kerala Floods of 2018 washing off large portions of Pamba, which is the place where the pilgrims start their holy journey. The on-going controversy regarding the entry of women to Sabarimala, flooding of the River Pamba, increasing number of pilgrims, the services associated with the huge number of people, encroachment into nature have been addressed.

The design is pilgrim and nature centered accommodating age-old customs, restoring the degraded natural surroundings, actively incorporating passive crowd management techniques through design and planning.

Case Study / Project

360cityscan

Integrated solut ons to face urban challenges

Mattia VANSTEENWEGEN, Etienne DROUET

Abstract

Tractebel has developed the 360 city scan, a holistic methodology to assess cities and guide them according to their needs and priorities. Scans have already been deployed in more than 40 cities worldwide. Based on this scan, we offer integrated approaches to our clients, tailormade solutions leveraging on our urban engineering expertise. The perspectives of the 360cityscan meet the global challenges cities face today: climate change, resource scarcity, technologisation, demographic changes, social transformation and glocalisation. Within cities, the intensity of these challenges is much higher than in rural conditions. All perspectives are somehow related to these challenges; the perspectives give therefore an accurate status of the city against these threats. The perspectives work together as a whole towards a balanced city. The perspectives must be seen as different layers of a city, a balanced city encloses all the different perspectives in a good ratio. When one perspective is underdeveloped, the city does not work properly or excludes citizens. Preferably, each intervention in the city has a positive impact on all the perspectives. We created a tool to measure the level of maturity for the different themes. The inner 2 circles represent the status of the physical system of the theme, the outer 2 circles the 'efficiency' or 'quality'. To illustrate this for 'water': the inner circles indicate the status of the basic infrastructure of water (amount of people with wastewater collection), in the outer circles we measure the level of wastewater treatment by the city. The city is shown in a user-friendly 360 diagram with an individual score for each theme, arranged by perspective. The diagram summarizes in a visual way the maturity of a city and highlights the strength's and challenges. If well designed and managed, cities offer important opportunities for economic development and for expanding access to basic services, including health care and education, for large numbers of people.

Coming from a engineering background of top-level expertise in Energy, Transport, Water, Urban design, the integration of different teams and know-how is essential to deal with the complexity of issues and challenges that cities are facing worldwide and for successful sustainable urban development. Searching for synergy between different disciplines is in this sense key to unlock hidden potentials. When they meet and connect, creative solutions to complex problems are found. Urban processes are also becoming increasingly complex given the fast-changing evolutions in terms of stakeholders, policy governance and political processes. In this perspective a more process oriented and collaborative way of working is needed, with different in between goals of diverse scale and nature instead of blue print masterplanning approach.

This way of working will allow a stronger local embedded and bottom-up approach involving a large set of stakeholders from the beginning to the end. Also Technology is changing the way citizens live, move and work: smart city platforms, BIM, City Information Modelling. Cities are becoming data platforms: as more data are available, urban development projects should be able to collect and exploit them to build new sustainable and liveable cities. For this reason technologies need to be combined with a strong focus on qualitative design in the entire range of elements that compose a city: from infrastructures to public space and buildings. The Integrated Approaches (11) represent innovative transversal domains defined to emphasize the integration of our services and expertise related to cities and territories: Places of mobility - Water Urbanism - Productive landscapes - Recycling territories - Smart networks. All together the Integrated Approaches cover the complexity of issues that cities are facing nowadays through the fundamental paradigm of 'integration'.

Research Paper

Research on the Spatial Effect of Urban Construction on Heat Island Effect in Shanghai Based on Remote Sensing Data

Shuo ZHANG, Shanghai Tongji Urban Planning&Design Institutional Co.,Ltd., China

Abstract

Since the twentieth Century,global urbanization process is constantly accelerating,while the landscape pattern dominated by vegetation was gradually replaced by the landscape pattern dominated by artificial buildings.The change of climate and temperature caused by the expansion of urban construction land and the population aggregation,has aroused widespread concern.Under the background of national new type urbanization,improving the urban environment is the inevitable path to the new type urbanization.

Urban heat island effect is the most prominent feature of human activities impact on temperature,and it has many effects on environment,economy,society,health and so on. Among the existing researches related to urban heat island effect,the influence of urbanization on it has not been paid enough attention.Therefore, the research on the effect of urban construction on the heat island effect is incompletable,and the method is limited to the quantitative analysis as the spatial analysis is insufficient. Based on the existing research,while under the background of urban planning major,taking Shanghai as a typical case, this paper concentrates on the urban heat island effect under the influence of Shanghai urban construction.

First of all,this paper takes the Landsat-7 ETM+ remote sensing image data of Shanghai in 01/08/2000,28/07/2010 and 28/07/2016 as the basic research data.ENVI software is used to retrieve land surface temperature on the thermal infrared band.Then this paper divides the heat island effect level,analyses the spatiotemporal distribution of land surface temperature in different years in Shanghai,and summarizes the evolution characteristics of urban heat island effect, analyzing the spatial impact of urban construction related factors such as urban scale, spatial structure and land use.

Analysis shows that city construction land expansion will aggravate the urban heat island effect.The increment of built construction in the city,the size of the resident population,as well as the population density have significant correlation with urban heat island effect,but the spatial distribution of population density and spatial distribution of heat island effect has no significant correlation.In various types of landuse,residential,industrial and mining,warehousing, commercial services,and transportation land can significantly aggravate the heat island effect, land types like green land, water area and farmland,etc can produce urban cold island effect in some individual area.At the same time,the location, area and shape of the green space and water area have an effect on the distance of reducing the heat island effect.

Keywords

Urban heat island effect, Spatial effect, Urban construction, Remote sensing data

1. Research Background

Shanghai is one of the areas with the fastest urbanization development in China. The expansion of urban construction area and the agglomeration of population to the central area lead to the expansion of the urban heat island effect area year by year. In the 1960s-1970s, the area of the heat island was limited to 100 km^2 in the central area of Shanghai.In the 1980s, it expanded to more than 400 km^2. In the late 1990s, it expanded to suburban areas with an area exceeding 800 km^2. The existence of heat island effect makes the Central District of Shanghai have higher extreme maximum temperature and longer duration of high temperature than the suburbs.

Urban heat island effect is an important environmental problem in a city. Urban planning and construction have an essential impact on it. The results show that urbanization contributes about 20% to 30% of the urban surface temperature warming in the past 50 years. Therefore, the impact of urbanization on urban heat island effect should be paid enough attention. It is necessary to study urban heat island effect from urban planning, urban spatial structure, urban land use and other aspects. This paper will study the impact of urbanization on urban heat island effect from the scale, structure, land use and other aspects, so as to provide new ideas for urban planning and sustainable construction.

2. Research Data Sources

2.1. Remote Sensing Satellite Image Data

The remote sensing satellite data in this paper are Landsat-7 ETM+image data, which are derived from the Geospatial Data Cloud Platform (http://www.gscloud.cn) of the Computer Network Information Center of the Chinese Academy of Sciences. In this paper, the image data of Landsat-7 ETM+in Shanghai from August 1, 2000, July 28, 2010 and July 28, 2016 are selected. The image of 2000 is Landsat-7 SCL-on satellite digital product (1999-2003), and the image of 2010 and 2016 is Landsat-7 SCL-off satellite digital product (after 2003). Detailed information is shown in Table 1.

Table 1 Landsat-7 ETM+Remote Sensing Satellite Data Source Specific Information

Year	Data Identification	Strip Number	Line Number	Data Time	Average Cloud Cover（%）
2000	LE71180382000214SGS00	118	38	2000/08/01	0.34
	LE71180392000214SGS00	118	39		2.44
2010	LE71180382010209EDC00	118	38	2010/07/28	3.13
	LE71180382010209EDC00	118	39		2.46
2016	LE71180382016210EDC01	118	38	2016/07/28	27.19
	LE71180392016210EDC01	118	39		0.19

2.2. Ground Meteorological Observation Data

In this paper, the surface temperature data of 10 meteorological stations (Xujiahui Station, Pudong Station, Minhang Station, Baoshan Station, Jiading Station, Jinshan Station, Songjiang Station, Qingpu Station, Fengxian Station and Chongming Station) in central and suburban areas of Shanghai from 1985 to 2016 are analyzed. The data are from the temperature records of Shanghai Meteorological Bureau and Shanghai Weather Network (http://www.soweather.com).

2.3. Data on Economic and Social Development

The data of economic and social development mainly include the scale and density of Shanghai's permanent population, the total area of built buildings and other indicators. The data come from Shanghai Statistical Yearbook (1984-2016), Shanghai Population Census (the Fifth Census in 2000 and the Sixth Census in 2010), and statistical yearbooks of all districts.

3. Evolution Characteristics of Urban Heat Island Effect in Shanghai based on Remote Sensing Inversion

3.1. Remote Sensing Inversion of Surface Temperature in Shanghai

Landsat-7 ETM + remote sensing satellite image is used to retrieve the surface temperature of Shanghai. Based on the available remote sensing data sources and related data in Shanghai, using ENVI5.2 software platform, using JM&S single channel algorithm and Tan Zhihao single window algorithm to retrieve the surface temperature in Shanghai, the spatial distribution maps of surface thermal environment in different years in the study area were obtained. In order to analyze the spatial distribution pattern of surface temperature in Shanghai more intuitively, the Mean-standard Deviation Method is used to divide the surface heat field. Based on the study of Chen Songlin, the image of surface temperature in Shanghai is divided into six levels, i.e., mu (mean), +0.5std, +1std (standard deviation), with strong heat island area (33.1 C-45.4 C) and sub-strong heat island area, respectively. The spatial distribution maps of the heat island effect in Shanghai are obtained from the heat island area (30.6-33.1 C), the heat island area (28.1-30.6 C), the weak heat island area (25.6-28.1 C), the cool island area (23.2-25.6 C) and the cold island area (0.0-23.2 C).(Figure 1,2,3)

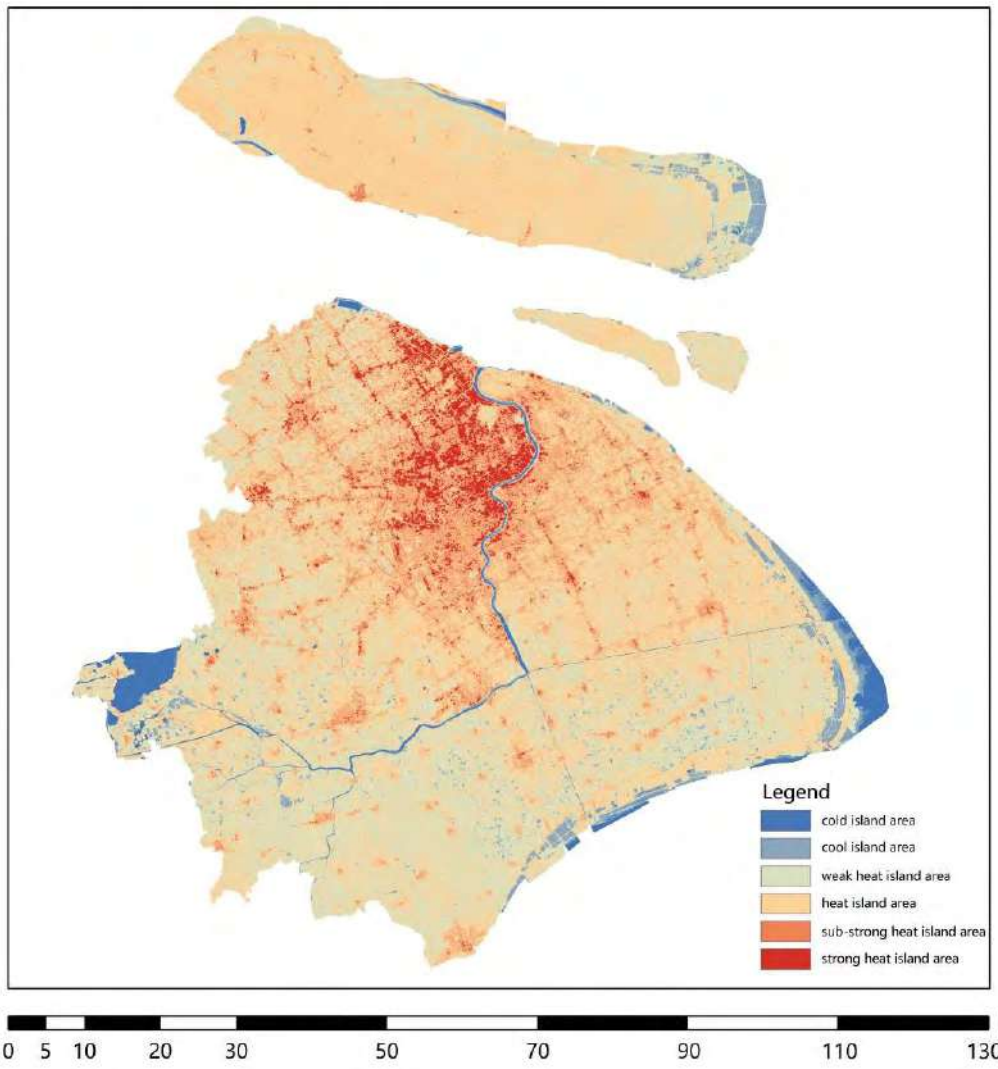

Figure 1 Spatial Distribution Map of Heat Island Effect in Shanghai on August 1, 2000

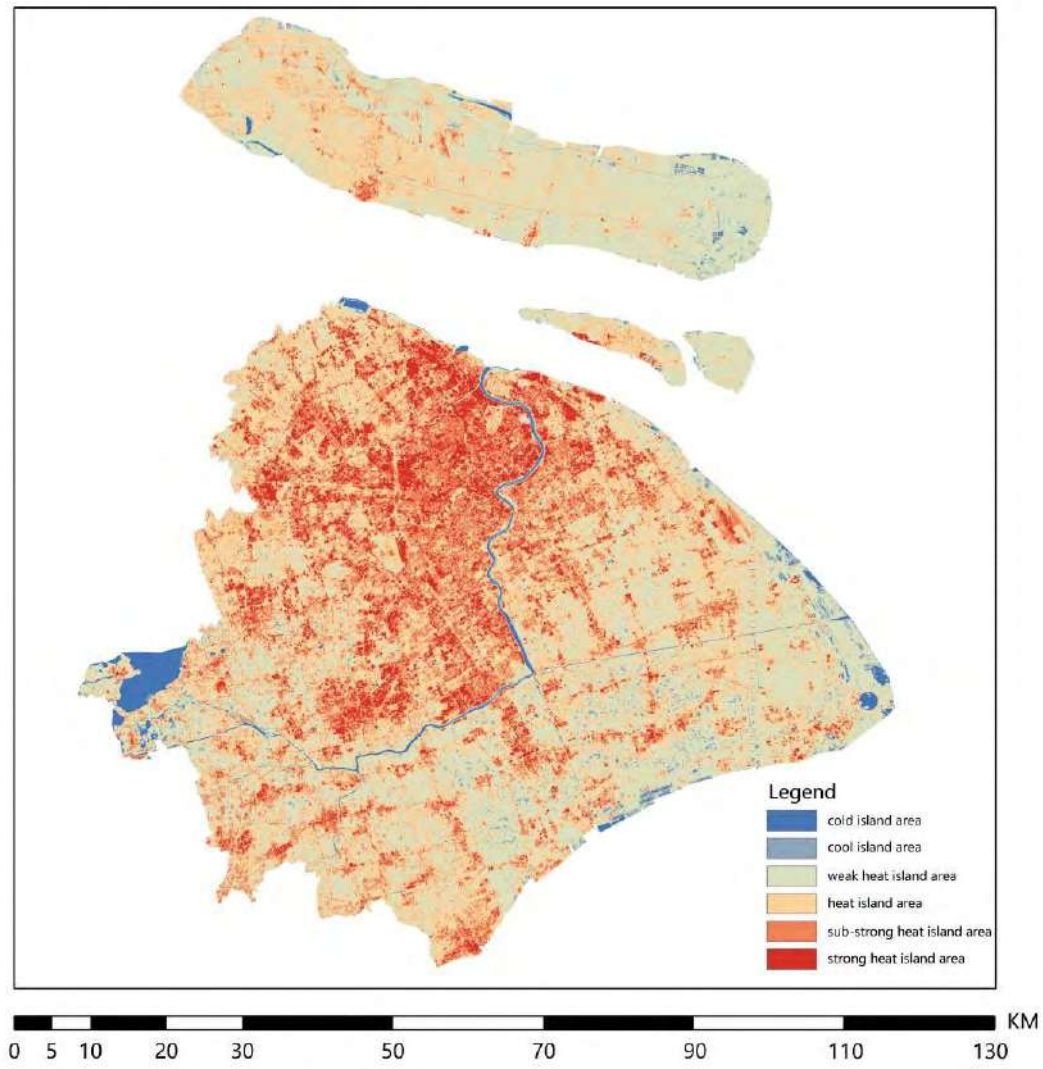

Figure 2 Spatial Distribution Map of Heat Island Effect in Shanghai on July 28, 2010

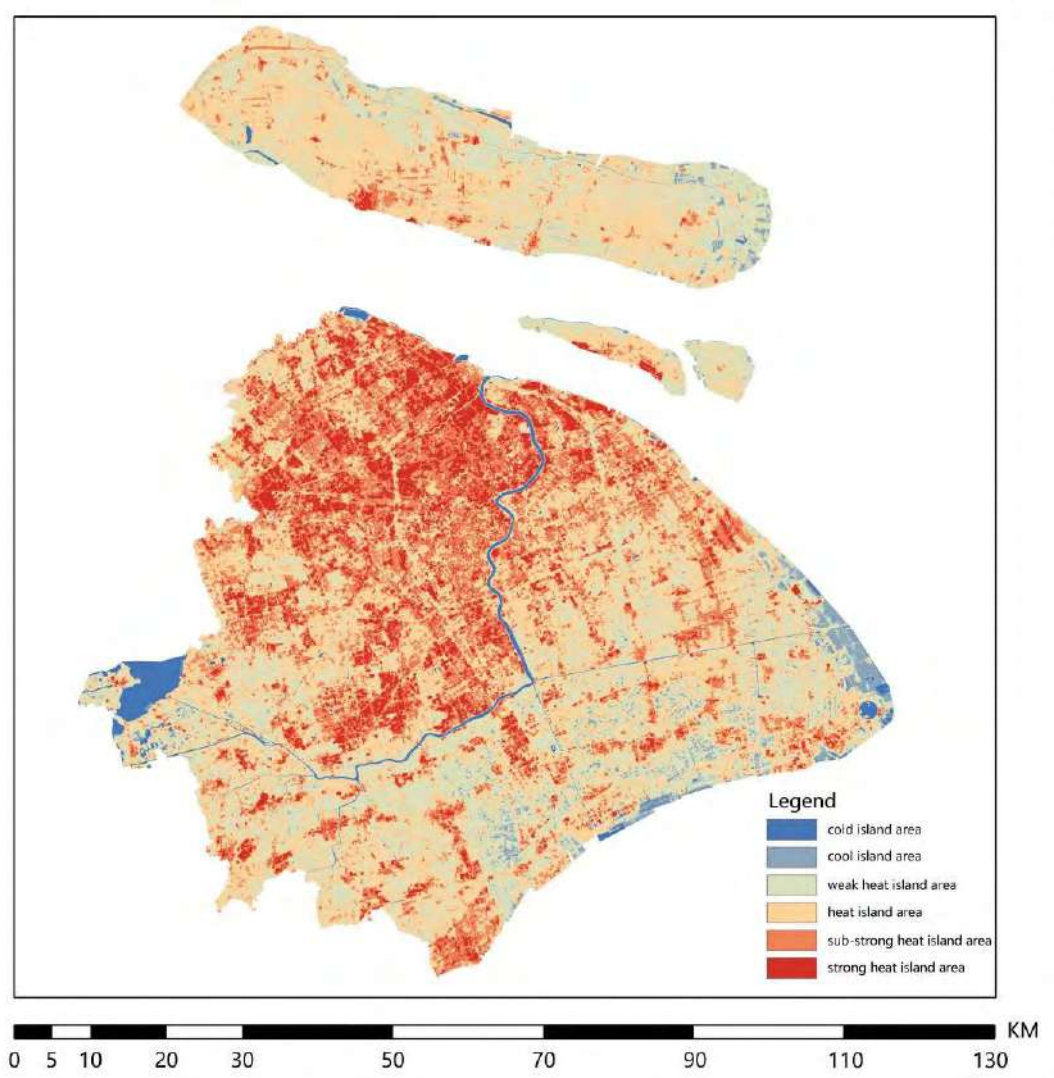

Figure 3 Spatial Distribution Map of Heat Island Effect in Shanghai on July 28, 2016

3.2. Evolution Analysis of the Urban Heat Island(UHI) Effect in Shanghai

3.2.1 Temporal Evolution of UHI

By comparing the spatial distribution maps of the urban heat island effect of Shanghai in 2000, 2010 and 2016, we can see that the urban heat island effect of Shanghai is stable and obvious in three groups of data in different years, months and meteorological conditions, indicating that the urban heat island effect of Shanghai has been formed and has an aggravating trend, and the spatial distribution of urban heat island has a trend of expansion. Statistical analysis of the temporal variation of urban cold and heat island area in Shanghai (Table 2) shows that the urban heat island effect in Shanghai is increasing from 2000 to 2010, in which the area of the strong heat island area increases the most, accounting for about 55% of the total increment of the heat island area; from 2010 to 2016, the urban heat island effect in Shanghai eased, the area of the strong heat island area and the heat island area decreased, but the area of the sub-strong heat island area increased by 165.57%. Overall, from 2000 to 2016, the urban heat island area of Shanghai increased by 281.46 km^2 and showed a steady increase trend.

Table 2 Temporal Change of Urban Cold Island and Heat Island Area in Shanghai

Year	Urban Cold Island		Urban Heat Island		Urban Cold VS. Heat Island
	Area(km^2)	Percentage(%)	Area(km^2)	Percentage(%)	
2000	2117.64	33.40	4222.37	66.60	1：2
2010	1698.71	26.79	4641.28	73.20	3：8
2016	1836.16	28.96	4503.83	71.03	2：5

With the increase of urban heat island area, Qingliang Island area shows a trend of decreasing year by year and accelerating the decline rate, from 278.10 km^2 in 2000 to 153.96 km^2 in 2016. The reason is that in the process of rapid economic development and urban expansion, construction land replaces a large number of natural vegetation and greening. In addition, while the area of strong heat island and sub-strong heat island expands, the area of cool island decreases synchronously, and some of them are polarized by temperature, which transforms into cold island area. The area of cold island area shows a trend of increasing year by year. From 2000 to 2016, it increased by 86.98 km^2 with an average annual growth rate of 14.19%. It is the fastest growth rate of area in all levels of temperature zone. The above changes indicate that the area of extreme temperature zones in Shanghai has grown larger and larger in the past 16 years. Among the six temperature grades, the area of the two extreme grade zones, the strong heat island zone and the cold island zone, has the fastest annual growth rate and an aggravating trend. Relatively speaking, the area of the weak heat Island zone and the cool island zone are gradually declining. However, these two grades are the most livable temperature conditions.

3.2.2 Spatial Evolution of UHI

By analysing the spatial distribution maps of urban heat island effect in Shanghai in 2000, 2010 and 2016, it can be seen that the spatial distribution and structure of urban heat island effect in Shanghai have obvious regularity. Generally speaking, the main cold sources regulating urban heat island effect are large areas of water and green space, such as Huangpu River, Dianshan Lake, Dishui Lake, Gulf National Forest Park, Chongming Dongtan Wetland Park and so on. The main heat sources aggravating the heat island effect are industrial, commercial, station, square and high-density residential areas.

In 2000, the spatial distribution of urban heat island in Shanghai was mainly sub-strong heat island area and heat island area, and the proportion of strong heat island area was relatively small, only in traditional industrial and commercial concentrated areas. Overall, in 2000, the urban cold island area of Shanghai was 217.64 km^2 and the heat island area was 4222.37 km^2, the ratio of which was approximately 1:2. Urban heat islands are concentrated in the central area, while suburban heat islands are few and scattered. The overall spatial structure of heat island is "centralized in the central area and scattered in the suburbs". The inner heat island space in the central area presents a single-center circle-layer distribution. The pattern of scattered heat island in the suburbs basically corresponds to the spatial distribution of new towns and central towns in the suburbs of Shanghai in 2000, including Baoshan Industrial Zone, Jiading New Town, Anting Town, Zhoupu Town and Chuansha Town.

From 2000 to 2010, the urban heat island effect of Shanghai was further aggravated, and the urban heat island showed a trend of expansion. Among them, the area of the strong heat island increased by 230.07 km^2, the area of the sub-strong heat island increased by 141.25 km^2 and the area of the heat island increased by 47.59 km^2. The spatial expansion of the strong heat island area is very significant during 2000-2010. The Shanghai heat island effect

has initially shown the spatial pattern of "main heat island + corridor + secondary heat island". The central area is the "main heat island" of the heat island effect, and a "hot corridor" is formed along the main urban transportation network, which extends to the suburbs and links several "secondary heat islands". In the central area, "main heat island" mainly distributes in the West Bank Industrial Zone of Huangpu River, Nanjing East Road-Nanjing West Road Business District, Xujiahui Business District, etc.; "hot corridor" mainly along Shanghai-Nanjing Expressway and Shanghai-Hangzhou Expressway; "secondary heat island" mainly includes Songjiang, Jiading, Qingpu, Nanqiao and other suburban New cities.

From 2010 to 2016, the area of urban heat island declined considerably, and the urban heat island effect of Shanghai was alleviated. However, the specific analysis shows that part of the heat island region temperature increases, transforms into sub-strong heat island region, and the area of strong heat island region decreases slightly. Overall, since the 12th Five-Year Plan of Shanghai, urban development has focused on ecological environment protection, high-quality healthy urbanization, and the urban heat island effect has been alleviated. Spatially, the mitigation degree of the heat island effect in the central area is more obvious than that in the suburbs. The urban heat island has formed a spatial pattern of "multi-center + two circles + three corridors". The spatial distribution of the urban heat island coincides with the main urban construction areas. By 2016, except for the heat island area formed in 2010, there were local heat island effects in suburban central towns and market towns. To a large extent, the impact of urban construction on the heat island effect is existent and obvious.

4. Spatial Impact of Urban Construction on Heat Island Effect in Shanghai

Under the urban scale, the scale, structure and land use types of urban construction in Shanghai have different effects on the intensity and pattern of urban heat island effect. This paper chooses four indicators, including the scale of built buildings, the scale of permanent population, spatial structure and land use types, to analyze their spatial impact on the heat island effect.

4.1. The Impact of the Scale of Buildings Built on the Heat Island Effect

The increasing scale of urban buildings affects urban wind speed, direction, energy consumption and heat emission. On the one hand, the existence of buildings changes the properties of the underlying surface of the land, improves the roughness of the underlying surface, and reduces the wind speed of the built area. At the same time, the height of buildings varies affects the urban wind direction. On the other hand, city buildings are endowed with different functions. While operating and maintaining different functions, energy consumption and heat emission are aggravated. For example, air conditioning operation of high-rise office buildings in summer releases more heat.

4.2. The Impact of Resident Population Size and Density on the Heat Island Effect

In the process of urbanization, the total resident population size affects the intensity of human activities' impact on the urban environment. The increase of the total population size will increase the energy consumption and heat emission of the city as a whole. The increase

of population density will increase the heat emission per unit area of land. At the same time, the increase of the size and density of the resident population will bring about the demand for regional transportation and residence, energy consumption and energy consumption. Heat emissions will further increase, aggravating the urban heat island effect.

4.3. Impact of Land Use Types on Heat Island Effect

Different types of land have different underlying physical characteristics. The surface albedo is different. The amount of solar radiation absorbed is different, and the land is endowed with different urban functions by man-made, and the way of thermal effect is different, so the surface temperature has different processes. The influence of degree aggravates or slows down the urban heat island effect in varying degrees. Among all kinds of land use types, there are land use which obviously aggravates the heat island effect, such as residential land, industrial and mining storage land, business clothing/public use land, transportation land, etc. There are also land use which significantly slows down the heat island effect and produces local urban cold island, such as cultivated land, woodland, grassland, garden land, water area, etc.

Heat island effect of residential, industrial and mining land

4.3.1 Heat Island Effect of Residential, Industrial and Mining land

By classifying urban heat island in Shanghai on July 28, 2016 according to land use types , the underlying surface characteristics and heat island effects of land use types in urban built-up areas, such as residential land, industrial and mining storage land, commercial/public Service land and transportation land, are explored (Table 4). The analysis shows that the heat island effect and influence degree of different land use types in Shanghai are different, showing different surface temperature grades. Generally speaking, the average surface temperature is: industrial and mining warehouse land > residential and commercial land > transportation land.

4.3.2 Cold Island Effect of Green Space and Water Area

According to the distribution of urban heat island effect in Shanghai on July 28, 2016, the spatial distribution map of urban cold island in Shanghai was extracted (Figure 4). It can be seen that parks, suburban arable land and water in Shanghai constitute urban cold island, which plays an obvious role in weakening urban heat island effect.

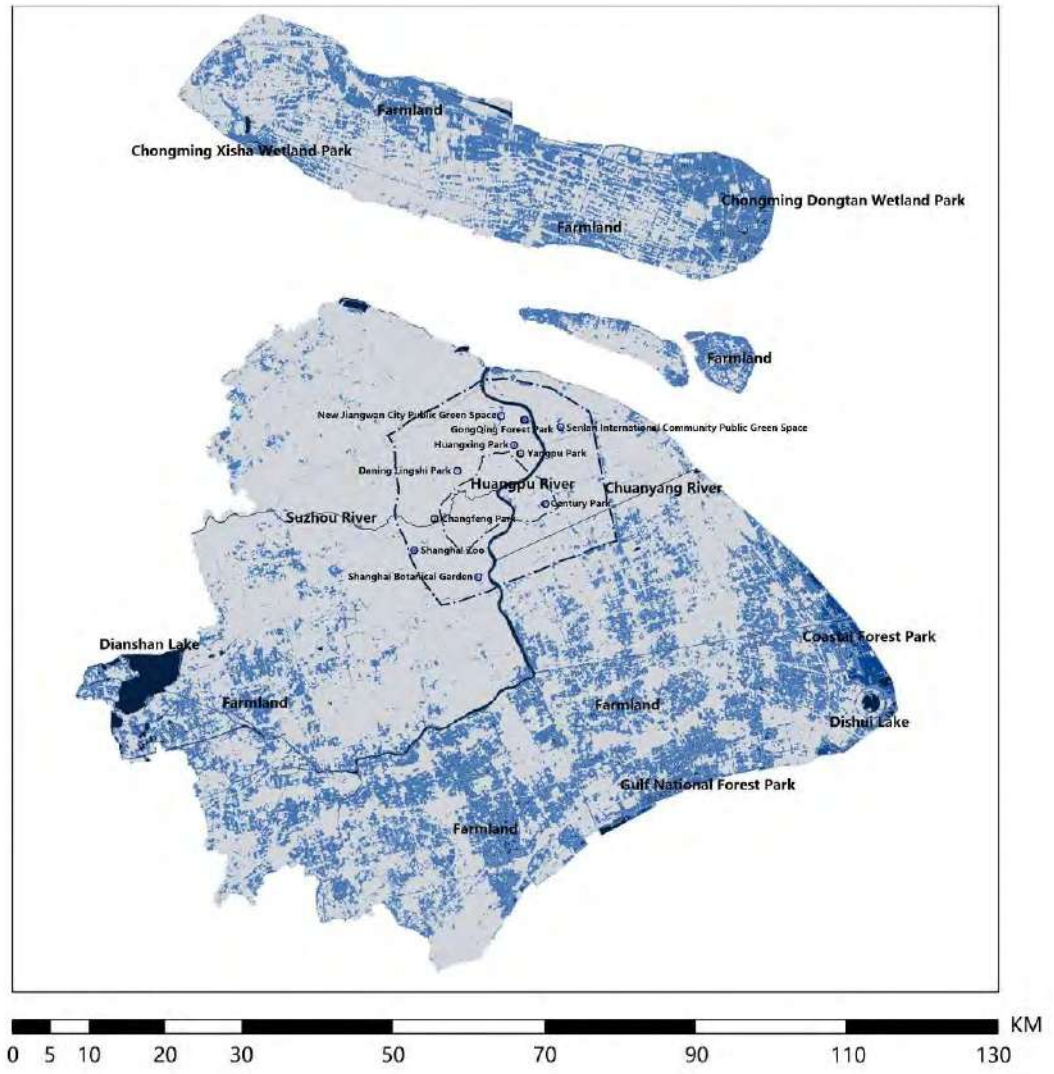

Figure 4 Spatial Distribution Map of Shanghai Urban Cold Island on July 28, 2016

This paper chooses 4 green spaces in Shanghai suburbs and 13 green spaces in the central area as the research objects, carries out "symmetrical" buffer analysis respectively, and counts the information of area, shape and spatial distance to mitigate the heat island effect (Table 3), and studies the spatial impact of green space on urban heat island effect.

Table 3 Statistical Table of Typical Greenbelt Information in Shanghai

Location	Green Space	Area（hm^2）	Block morphology	Average Temperature（℃）	Spatial Distance of Mitigating Heat Island Effect（m）
Suburb	Gulf National Forest Park	23.99	Rectangle	26.32	300-500
	Coastal Forest Park	8.10	Rectangle	25.95	100-300
	Chongming Dongtan Wetland Park	181.00	Rectangle	25.83	1000-1200
	Chongming Xisha Wetland Park	6.75	Rectangle	26.70	100-300
City Center	New Jiangwan City Public Green Space	25.30	Banding	27.10	300-500

	Senlan International Community Public Green Space	29.27	Banding	26.75	500-900
	GongQing Forest Park	29.50	Rectangle	27.52	300-500
	Huangxing Park	62.40	Rectangle	26.51	900-1200
	Yangpu Park	22.36	Rectangle	27.80	100-300
	Daning Lingshi Park	68.00	Irregular	26.42	900-1200
	Changfeng Park	36.60	Irregular	27.13	500-900
	Century Park	140.30	Irregular	26.32	1200-1500
	Shanghai Zoo	74.30	Irregular	26.47	900-1200
	Shanghai Botanical Garden	81.86	Irregular	26.55	900-1200

Green space has a significant cooling effect on the surrounding area, and the cooling effect decreases with the increase of distance. Location, area and shape have an impact on the spatial impact distance of Mitigating Heat Island effect.

A.Location impact of green space: The same area of green space, suburban and central green space for mitigating the heat island effect of the spatial distance is different. And when the green space area is small, the cooling effect of suburban coastal green space is lower than that of central green space of the same area; when the green space area is large, the cooling effect of suburban coastal park green space and central park green space of the same area is basically the same.

B.The influence of green space area: On the premise of the same location and shape, the larger the green space area, the lower the average surface temperature of the green space itself, and the larger the spatial impact scope of mitigating the heat island effect in the surrounding area.

C. The influence of green space shape: On the premise of the same location, the larger the ratio of perimeter to area of green space, the more obvious the mitigation of heat island effect.

Case Study / Project

Resilient Infrastructure Framework

of China Coastal Cities

Shuang ZHENG, Xiaowen HUANG

Abstract

The development of coastal cities is faced with great challenges because of the increasing uncertainties and unpredictable risks. As the coastal portal connecting Dongguan with Pearl River Delta and Guangdong-Hong Kong-Macao Great Bay AreaíÎŒ?í«the Binhai Bay New Area in Dongguan is abundant in various resources and favorable opportunities. Nevertheless, intractable issues such as vulnerable ecosystem and complex stakeholders are also inundated. Combined public infrastructure with resilient city theory is an applicable path which can effectively balance these problems. The idea of resilience is first applied by Holing, an ecologist from Canada, in ecology at 1970s, then scholars from different disciplines take up research of resilience in urban design and planning application. In essence, the concrete definition for urban resilient is ambiguous and contentious, the core of this area is mainly concentrated on controlling degree framework, improving the quality of urban space, optimizing infrastructure and enhancing operating efficiency. Inspite of that, current researches on resilient infrastructures are generally with broad range or lack of operability. It is urgent to establish a targeted and feasible framework to guide resilient planning in coastal cities.

This paper firstly raises the resilient infrastructure strategy in renewal and operation for Binhai Bay New Area which aiming to tackling the ecological issues for instance water pollution, mangrove protection and typhoon. Secondly, by comparing resilient infrastructure planning of Orleans City, Rotterdam Port Area and Binhai Bay New Area, the operation mechanism of resilience infrastructure will be deduced and the operation and management system of resilience infrastructure will also be constructed. Finally, the redundancy and critical value of resilient infrastructure will be discussed, which may provide a comparatively predictable possibility for future planning of coastal cities.

Integrated Metropolitan Governance Framework

for the GCC Future Metropolis

Khaled ABDELLATIF

Abstract

The GCC cities have been witnessing continues changes in its governance systems to cope with the post oil era. Recently the GCC governments have allocated multibillion US dollars to finance major infrastructure and transit projects in most of the major cities. As a result, transit oriented development initiatives and intensive real estate projects around metro stations have taken place without formulating an integrated governance mechanism that would steer the growth of the TODs and eventually shape the GCC metropolises Due to gap between the current GCC urban governance systems and the future of its newly born metropolitan areas, this paper will examine and tackle various patterns, problems and challenges of the current urban governance system, to reach to the optimum scenarios for governing the future GCC metropolis Accordingly, a comparison and a historical analysis of the existing urban governance systems will be covered in this paper supported by political, spatial, economic, demographical analysis to produce an integrated metropolitan governance framework for the GCC future metropolis

The paper suggests several roads maps to govern the metropolitan areas and metropolitanize the major GCC settlements on the short, medium and long terms. In addition, it answers the following questions; how to move from traditional municipal urban governance to metropolitan one? What are the required economic, social and cultural transformation and restructuring programs to support a smooth transition in the governance system? Why is it the right time to develop the metropolitan governance framework for the GCC metropolis? How will the framework guide the smooth transition towards transit metropolitan governance? The outcomes of this paper will provide a road map for the municipal leaders and urban development authorities to formulate a specific governance framework to steer the future metropolis.

Research Paper

Towards a New Paradigm in City Branding and Marketing

The Case of Doha, Qatar

Ali ALRAOUF, Prof. of Architecture and Urbanism
CB, Research & Development Coordinator
Urban Planning Department; Qatar

Abstract

In rentier countries around the Gulf, a paradigm shift is certainly happening. Gulf States resorted to branding strategies which would secure a global recognition for their cities. The paper analyzes the effectiveness of tools used in Doha, the capital city of Qatar to create its own identity within the Gulf States and the rest of the Middle East. The analyzed tools will include City Uniqueness, Quality of Public Spaces, Signature Architecture, Events, Festivals, Cultural Tourism and Facilities. One of the main strategies used in Doha to articulate its brand is enhancing the ability of the city to host global Events, Festivals, and international sports. Competitions and cultural Carnivals. The research illustrates the use of Interesting Architecture, Cultural Facilities, Unique streets, Public parks, City natural and man-made Uniqueness as a City Marketing and Positive Branding Tools. The paper investigates crucial questions including the impact of the digital paradigm on the competitiveness of cities? How to regionally and globally market a city? What are the sustainable and resilient strategies for branding contemporary city? The paper also articulates a model for the case of Doha city banding and marketing which is based on a balanced approach. Such an approach would consider traditional assets including history and heritage. Also, it will include contemporary and innovative assets resulted from the last decade unprecedented investments in the sectors of education, research, culture and knowledge. Hence, the paper suggests a more holistic approach to city branding which would balance between social equity, economic prospertiy and ecological intergrity.

Keywords

Place-branding, Doha's Urbanism, City Marketing and Branding, Post Carbon Urbanity, City as a Destination.

1. The Contemporary Context of Gulf Cities

1.1. The Evolution of Oil-based Urbanism

Once just sleepy desert settlements, the Arab Gulf states of Saudi Arabia, Oman, the United Arab Emirates, Qatar, Bahrain, and Kuwait now exert unprecedented influence on international affairs; the result of their almost unimaginable riches in oil and gas. Miller (2016) provides an account of the achievements of these countries since the 1973 global oil

crisis. In the 1970s, one of the most hot and harsh regions in the world burst on to the international stage. The discovery and subsequent exploitation of oil allowed tribal rulers of the Gulf to dream big (Cooke, 2014). The unprecedented financial revenues substantially helped simple nomads, fishermen and pearl divers to catch up with the rest of the modernized world. Cooke also investigates how the shrewd Arab Gulf rulers who have overcome crisis after crisis meet the external and internal challenges of the onrushing future. In the last decade, the Arab Gulf region has become an East–West hub for travel, tourism, sport, culture, trade, and finance. But can the autocratic regimes maintain stability at home and influence abroad as they deal with the demands of social and democratic reform? Miller (2016) considers an array of factors—Islamism, terrorism, the Arab Spring, volatile oil prices, global power dynamics, and others—to assess the future possibilities. The entire Gulf cities are in the process of diversifying their economic base, with the vision of transitioning to a sustainable post-oil future. They are positioning themselves as places to visit, work and live. Place-branding has emerged as a significant trend across the Gulf cities in the construction of this image and consequently in the production of places. For a long number of years, the concepts of branding and marketing were thought of as notions only related to trade and commercial products. In the last two decades and as a reaction to the globalization paradigm, these concepts became City Branding. Among a rising competition between cities to attract the emerging creative and knowledge class and to capture a share in the global tourism, branding is now a major strategy adopted by many cities around the world to emphasize its unique character and personality. As defined in marketing theories, Branding is not about getting your target market to choose you over the competition, but it is about getting your prospects to see you as the only one that provides a solution to their problem.

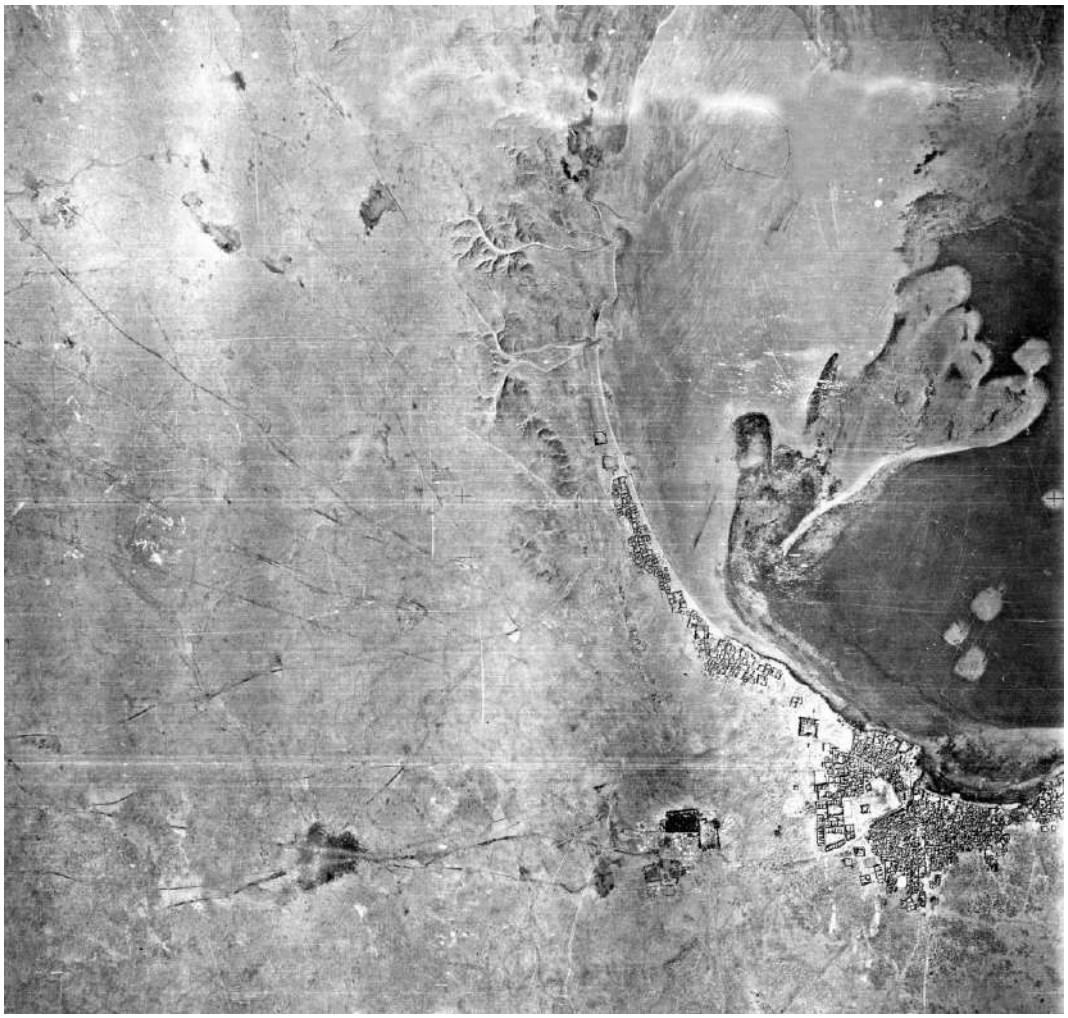

Figure 1 The Origin of Doha as a Traditional Settlement along the GUlf

The strategies used Gulf cities to transform itself into global destinations, were based on three consecutive cycles of development. The first is the move towards dealing with the city image as a replica of global cities like Chicago, Hong Kong and New York' skylines. The second was in building international projects particularly museums to gain the world recognition. The case of Abu Dhabi's cluster of cultural projects on Saadiyat Island including the new Louvre is worth mentioning in this context. The third cycle is related to the notion of hosting global events as Dubai did managing to be selected for hosting the world Expo 2020 or Qatar' success to win the bid for hosting the 2022 FIFA World cup. The three cycles were a result of the unprecedented financial revenuers generated from the oil and gas resources. As these cities compete with each other, aiming to highlight their unique offerings and attempting to clearly distinguish themselves from other cities, they have chosen to rely on place-branding as a tool. The staging of events of international importance (such as Formula One Races in Abu Dhabi, upcoming World Expo 2020 at Dubai and prospective 2022 FIFA World Cup at Qatar), the emphasis awarded to star-architecture and the emergence of strongly themed mega-projects characterize such development. Thus city-positioning and place-branding begin to assume the status of urban development models (Mishra, 2016). All the Gulf cities are in the process of diversifying their economic base, with the vision of

transitioning to a sustainable post-oil future, they are positioning themselves as places to visit, work and live. Place-branding has emerged as a significant trend across the Gulf cities in the construction of this image and consequently in the production of places. With oil resources running out, a focus on the post-oil era is a priority. Assessing the pace of urban development in contemporary Gulf cities revealed number of critical issues (Wippel, 2014). On one hand, the speed of development has social cost, negative relation with the past and the claim for identity loss. On the other hand, such rapid developments contributed to economic diversification, cultural tourism and city branding[i]. The overarching issue is exploring critically the ways in which the Gulf States prepare themselves for the post-oil era, by diversification of their assets, boosting real estate sector, and creating a knowledge economy.

2. The Narrative of Doha, Qatar: An Emerging Urban Brand

2.1. A City as a Vibrant Hub

In the last decade, Qatar has transformed itself into a major hub for numerous economic and cultural activities. Hosting several top-level sporting tournaments, culminating in the successful FIFA World Cup 2022 bid, is contributing in establishing Doha as an emerging urban and development brand within the Gulf and Middle Eastern contexts. Whether to counter regional economic competitors or to further tie Qatar to the economies of the world's leading countries, this brand is designed innovatively to counter a range of security concerns; in short, Qatar is diversifying its dependencies (Roberts 2015; Alraouf, 2016). Furthermore, Qatar has become attractive as a place for foreign knowledge workers and the creative class. This is the class of people who are moving around the world and attracted to the quality of urban environments which maintain their creative and intellectual outputs (Florida, 2002; 2005). Qatar's national vision for the year 2030 consists of basic foundations focused on the necessity of continuous social development in order to achieve a fair and safe society based on upholding human values and social welfare and aims to maintain and improve its economic standards in order to further strengthen its national economy and remain competitive, while continuing to secure and satisfy the needs of its citizens (QNV 2030). Maintaining the current growth of its urban population and fostering quality of life is seen as critical to the future development of the country, as indicated in the national development strategy 2011–2016 (QSDP, 2011). Such vision is supporting the way by which the new generation of knowledge workers decide on where to live as Florida argues (Florida, 2008). Qatar's economy has experienced three transformations.

2.2. Place-branding and Place-making

As place-branding aims at addressing the strategic goal of creating cities which attract residents, tourists, investments and workforces, it attempts to create and promote a specifically designed 'sense of place' (Lang 2011), thus becoming closely integrated with place-making. In addition to the immediate requirement of attracting the global spotlight, it aims at creating a vibrant public realm, considered an important indicator of livable cities. Interest in the public realm has reached high political levels and is evident through documents such as the Public Realm Design Manual (UPC, 2010.). Another point of convergence for both place-making and place-branding is their role in serving the sustainability agenda by addressing the economic, environmental and socials aspects. These

interdependencies of place-making and place-branding present an opportunity for place-making to leverage on branding efforts while also contributing towards it. However, despite the commonalities in these aims, there is an existing gap in the research which explores their relationship, particularly the influence of place-branding on the public realm. Reviewing this gap in research, Bani Hashim, (Forthcoming 2016) discusses the need for planners and designers to understand how place-branding manifests itself in physical and social environments, the 'place' component and the influence of branding on urban form and 'sense of place'. She elaborates that there is a gap in research on studies which examine the effect of place-branding on the place itself. This research aims to contribute towards filling this gap. With reference to the Gulf cities, place-branding has often implied new developments. Backed by a strong political will, the large-scale planning and mega-projects have been unencumbered by issues of renewal or relocation. This accelerated speed of their realization has meant that checks, balances and the possibility of participation and feedback from user are often excluded. These new projects may be looked as experiments requiring further examination. By focusing on how public space is used, the research attempts to establish a connection between built environment professionals and the end users and enrich the availability of studies which examine the relation between place-branding and the place itself.

2.3. Theoretical Thoughts

Several researchers discuss the shared aims in branding and architecture-urbanism as a political tool, a promotional medium and an identity definer (Kavaratzis 2009, Klingmann 2007). Muratovski (2012) explores the role of architecture and integrated design in city-branding, while also discussing notions of territory and iconicity. Place-branding with its manifestation as mega-projects, creation of landmarks and involvement of 'starchitects' affects the consumer experience and has been criticized for failing to craft a unique identity through the standardized 'brandscapes' (Klingmann 2007). Castello (2010) reflects on the complementary nature between place-making and place-marketing with the latter having become a modern instrument and constant complement to the process of creating new urban places. Many urbanists, through their research, have highlighted the importance of the human dimension in urbanism (Jacobs 1961, Gehl 2013) and offered insights into systematically studying environmental behaviour (Zeisel 2006) through international studies in public life (Whyte 1980, Gehl 2013, Mehta, 2007, 2009).

Figure 2 The City's Contemporary Image

3. Suggested Concepts in urban and architectural Branding and marketing

3.1. Branding the city in the Post Globalization Era

Indeed, creating a marketing personality for the city is an important concept that is often difficult to comprehend and interpret. Although it is a new concept, it has become the inevitable application of any city seeking growth and development in the contemporary world. Cities can also generate visual impressions that distinguish them from other cities by focusing on what they own and by planning to add new dimensions to their architectural and urban personality. The most contemporary theoretical theses that established a new era in interpreting the success of the cities, most notably the development thought formulated by the prominent researcher in the field of development studies Richard Florida. He founded a new era in the history of cities and the methods of planning and growth techniques. His intellectual contribution began with his book entitled "The Rise of the Creative Class" published in 2002 in which he addressed a new proposal to understand the fabric of the human society in the post-globalization era. Indeed, the world has surpassed that era and has become the continuation of ideas, markets, investments and the fusion of spatial boundaries. Geography is a dominant feature in which all developed societies, as well as communities seeking a better life.

In his next book, "Who's Your city?", Florida established the importance of place and how our choices of where to live affect our creative contributions. This proposal is closely related to the emergence of the so-called global citizen, or the knowledge workers. Additionally, it calls for a new sector of creative, innovative thinking minds that depend on their contribution to the knowledge sector or rather the areas of knowledge economy as a basis for their professional success. Such phenomena have pushed Florida to warn that the escape of the creative and cultured class of the city leads to its death according to its expression. This new sector of the human community formulates a new conception of the relationship with the geography of the place. It goes beyond the emotional dimensions that make some cling to their first place and make their ability to move limited and restricted by a certain geographical scope may sometimes not exceed several kilometres from his birthplace and origin as it is with large segments of Arab society, this new category of human society is highly dynamic. With its aspirations and hopes in the place of our country and space to unleash its innovative and innovative capabilities in the era of the knowledge and creative economy based on the value Ideas. Hence, the emergence of this category contributed to the development of a new direction in the planning and Constructional thought presented by the literature under the title of the urban competitiveness which stimulated all cities of the world seeking a privileged position on the map of the twenty-first century.

Since the advent of the concept of urban competitiveness, the mechanisms and methods adopted by the cities have emerged, most importantly the city marketing policies to contribute to the consolidation of their presence on a competing world stage. The most radical in the city's marketing policies is to be transformed into a brand or a commercial figure that influences people's consciousness and converts them from their admirers to

advocates and advocates and is responsible for convincing others to create the best intellectual and imaginary impressions of the city. The formulation of a distinctive marketing personality of the city has symbolic value such as international brands, is a process that develops in several stages the first is the awareness of the city and draw attention to it and to believe in it and defend its position and value with enthusiasm we clearly monitor it in the cases of cities such as Paris, London and New York. Therefore, the Imperative questions are; how does the city creates its own brand and distinguished character? How the city market itself? It is no longer surprising that cities are using global marketing experts to formulate a city's branding and marketing strategy. In the following section, suggested strategies that can achieve the city's vision of its distinctive personality, are articulated.

Figure 3 The City's in the Era of Globalization

3.2. Suggested Policies

First: The ability to attract important events and actors with a global impact.

The modern city is no longer a dialogue of its population but extends to the interaction of the world in the era of communication revolution and the unprecedented ability to communicate and an important part of this communication is to move to the stage of polarization of the other through the ability to host artistic events, sports, cultural and economic deepening the idea of communicating with the other The desire to open up to the world emphasizes the global value of the city and reformulates its urbanism and architecture so that it can play this global role.

Figure 4 A Satellite map of the Aspire Zone with all its main components including the sports facilities, the park, the mall, and related community facilities (Source: Courtesy of Urban planning section, Doha).

Second: Employ the architectural and Urban Assets.

The city's valuable architectural and physical heritage is an essential tool to market it if it is activated by preserving it first and then by offering new experiences to interact with the place by re-employing this heritage, as did Arab cities such as Damascus, Medina, Aleppo, Syria, Fez and Marrakech, Morocco. Equally important, what the city will have in its future projects plays a vital role in marketing it. Indeed, the exciting and creative architecture has become one of the most important urban marketing tools of the city. The Guggenheim Museum in the Spanish city of Bilbao, designed by the American architect Frank Geary, was the beginning of the spark of a new methodology that would revive the city and market it through a single building that offers a visual and aesthetic breakthrough in the city's urbanism. Today, the Arab cities have recognized this standard and are competing to attract the stars of the architecture to leave their fingerprints on their architectural map, and their touches are approaching the east after their creativity is limited to the western cities and their flow to the Middle East Square, beginning with Frank Jerry, Jean Nouvel, Tado Ando and Michael. Graves and IBM to Zaha Hadid and they all formulate their creations in Manama, Kuwait, Dubai, Abu Dhabi, Cairo, Damascus and Doha. Any city's architectural and urban heritage has a great value and is an essential tool for its marketing and branding. Heritage when kept well maintained can be activated to provide new experiences of interacting with the place through the introduction of new uses and activities[ii].

Figure 5 The Role of Creative Architectural Interventions in Constructing the City's Brand

Third: Search for the city's natural, cultural, and humanitarian distinctiveness.

The city may be distinguished from mountains surrounded by or rivers that penetrate it or from the presence of high-level cultural elements, especially museums of different types and may be new shopping environments that go beyond traditional ideas or through the ability of the human community in the city to celebrate and the existence of public spaces And the life that the city provides through these spaces, especially in terms of celebrations, festivals and carnivals, whether cultural, artistic, popular or spiritual religious. Even if what distinguishes the city is the style of movement, such as in the Italian city of Venice with its famous Venetian boats or the horse-drawn wagon in the centre of the Austrian city of Vienna or the famous red buses touring the English capital of London. Important is the ability to show this distinction in the scene of crafting the character of the city and its marketing.

Fourth: The formulation of a Brand for the city with historical tributaries and future ambitions.

The goal is to be a conscious monitor of the personality of the city that participates in its planning so that the process of confirming the character of the city and renewing it and installing it in a new form is a continuous dynamic process supported by architectural and constructional projects and patterns of movement and the excellence and distribution of uses Build on the humanitarian and environmental reference to development so that the city becomes a city for all and a model for sustainable development that calls for the rights and aspirations of future generations.

4. The state of Doha: the capital of culture, knowledge, sports and Oasis of Peace

For a city to create its own marketing personality, it must begin with a sincere assessment of its advantages, as well as shortcomings and obstacles, and then try to maximize those features. As Gumathan Gabay argues (2009), the city's marketing is not just a painted slogan, but in the small, subtle details that make the streets Clean, it is in the deep details that make the city's residents ambassadors and proud to belong to it, and then the positive messages move to the actual or digital visitors of the city through the new multimedia. Producing a positive impression is an essential act for cities that want to advertise themselves as chosen destinations for people whether to live, work, entertain or visit. Hence, media outlets are an important area for the city's marketing, and the city has been used in media of all kinds as a sign of the strength of the city and its importance to the European cities ladder in the famous study prepared by Saffron consulting company in 2008 to evaluate 72 European towns. The city's marketing strategy must also be multidimensional and dynamic, responding to cultural, economic and developmental developments. Are we dreaming of travelling to Arab cities; Doha, Cairo, Kuwait, Damascus, Amman, Manama, Tunis, Baghdad, Beirut, and others, is the dream of new generations of the global human community, with unique global values that have a marketing value that makes people scramble to explore or work. Or choose a new home as they all yearn to the fragrant streets, squares and architecture of Paris, London, Vienna, Geneva and New York.

Figure 6 Museums designed by Signature Architects are Enhancing the City Branding, the Case of Museum of Islamic Art, Doha.

Interestingly, in the case of the Qatari capital city of Doha, it has used all the strategies available to market the city locally, regionally and globally, and its class consciously and with time frames that gave the city's reputation and its marketing personality a big and global place but at the same time sustainable and continuous It is not a boom or glow that quickly

switches off. At the level of the polarization of events, Doha was transformed into a world sports capital by hosting the 2006 Asian Games, Tennis championships, horses, golf, volleyball, and world athletics, as well as its contribution to the 2022 World Cup, and the city hosts dozens of international conferences such as Conference of International Chambers of Commerce and consummate political reconciliation. With regard to the use of architectural and urban assets in the historical and contemporary areas, Doha has paid special attention to its architectural and urban heritage and the revival of Souq Waqif, a unique Gulf-wide experience that reflects this trend and has used contemporary architecture to change the line of the city sky and develop its personality As an emerging global polarization hub, Doha has confirmed its own character as a city with a balanced balance between maintaining historical tributaries and developing visions and future ambitions that change the whole city and push it to the world stage. Doha was also concerned with the environment and the importance of preserving it and then enriching the cultural experience of the city through the establishment of various cultural, cognitive and academic projects and interacting with the community of citizens and residents alike, such as the Islamic Museum, the cultural quarter and the educational city, and finally the successful city It is a city that addresses the human being and dialogue with his mind and his emotions and his requirements this latter element, as is evident in Qatar's vision 2030, will make Doha a complete model if all the tissues will be unprecedented and the dream of the Arabs is realized in a city that the whole world dreams of.

Strategies for Positive City Branding: The Case of Doha

Doha as a Sports Capital of the Middle East.

One of the routs to promote tourism in Qatar which will be interrogated in the chapter is turning Doha, the Capital city into a regional and international sports hub. The city was able to host global sports events capital like the 2006 Asian Games, ATP and WTA tennis tournaments, Global Equestrian Tours, golf, volleyball and World Cup in Track and field. In addition to winning the bid for hosting the 2022 FIFA World Cup. The Department of urban planning and urban plan in full coordination with the country's Olympic Committee and the World Cup Organizing Committee to help keep the country cities livable cities attract high-profile sporting events. Urban planning contributes to locate required services especially hotels, playgrounds, markets in addition to the public transport network for high level includes Metro and bus rapid transit buses in addition to pedestrian and bicycle traffic networks.

One of the most prominent projects to prepare Qatar to cement its position as the sports capital of the Middle East is The Aspire Zone: A New Concept for an Urban Community Park where Sports, Retail and Cultural Hub is created. The Aspire Zone, also known as Doha Sports City is a 250-hectare (2.5 km2) sporting complex located in Al Waab district. The project is a complete mega development centered on the concept of branding Qatar as the sports capital of the Gulf. It was established as an international sports destination in 2003. The complex contains several states of the art sports venues, mostly constructed in preparation for the 2006 Asian Games. To complement what was perceived as a newly constructed vibrant urban center in Doha, different facilities and supporting amenities were added gradually. In 2004 Aspire Academy, an educational center for the development of sporting champions was opened. The zone embraces Khalifa International Stadium which

was first built in 1976 and has long been the vibrant center of the country's sporting tradition. As the hosting nation of the World Cup 2022, the Stadium was subjected to a holistic renovation to be compliant with FIFA's stadium requirements. Attached to the stadium is the Qatar Olympic and Sports Museum which will be promoting the positive value of sports. The other sports facilities include Aspire Dome which is credited as the world's largest indoor multi-purpose court and Hamad Aquatic Center. To guarantee the holistic role of the sports zone, the project includes Aspetar, a specialized sports medicine hospital.

Figure 7 Establishing the Needed Facilities to Allow the City to act as the Sports Hub of the Middle East

Branding Qatar via Doha's Emerging Knowledge-based Urbanism

Architecture, urbanism and planning are used, as will be explained in the coming sections, to prepare the country for the post-carbon era and establish a model which transcends the Dubai's dominance as a reference for development in the gulf. Dohaization is consciously perceived as a process to brand Doha in a balanced manner focused on the image and the content (Alraouf, 2016). Such preparation includes creating the environment which would attract knowledge workers and creative people from around the world to settle in Qatar and contribute in its new economical and development paradigm. On a planning level, the new blueprint for the urban development of Qatar titled "Qatar National Development Framework (QNDF)" is the outcome of Qatar's urban planning department and its focus group envisioning Qatar National Master Plan (QNMP). The main pillars of the framework suggest a new form of urbanism for Qatar articulated around planning for sustainable growth, compacted settlements, transit oriented urban development, walkability, mixed use urban centers and positive public realm. Such new planning principles aim at transforming Qatari cities and municipalities into people-friendly places and spaces and create the attractive environment which speaks to knowledge and creative workers considering Doha

and other Qatari cities as their new homes. For instance, enhancing walkability within the West Bay development is considered as a catalyst to transform the city business district from a composition of isolated towers and skyscrapers into a network of activities which would enhance social integration, walkability, public real and urban connectivity.

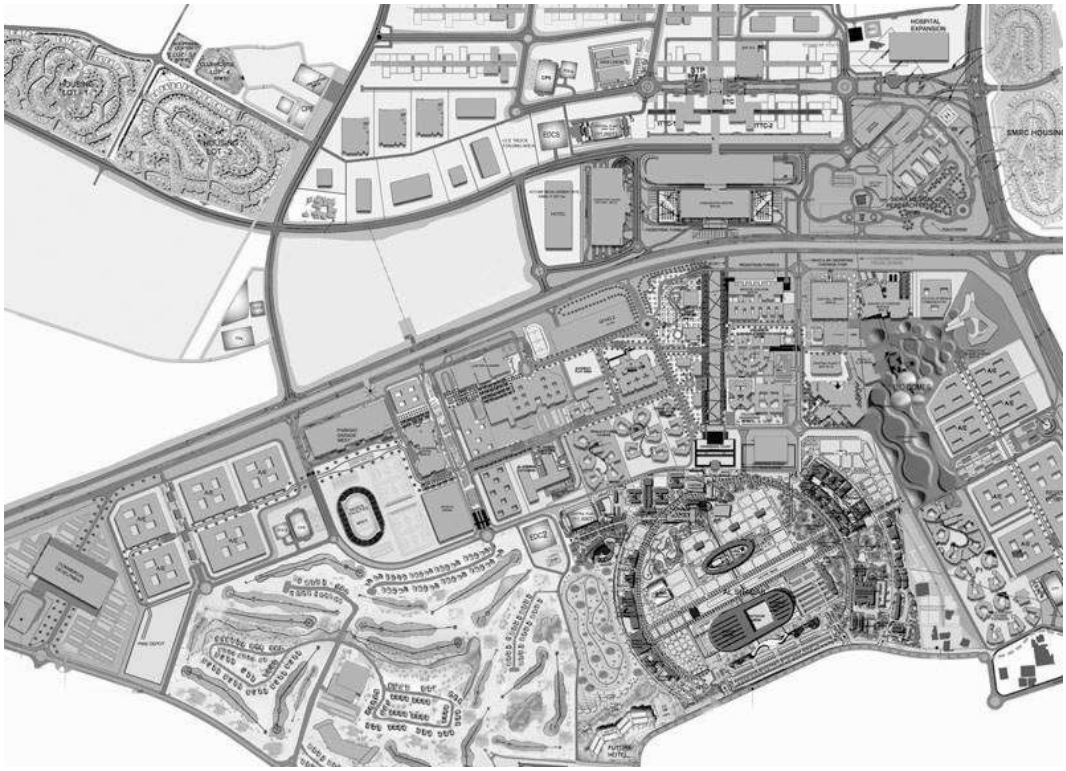

Figure 8 The Master Plan of Education City in the Heart of Doha as a Representation of KBUD

Cultural Tourism in Qatar: From Marginalized to Centralized Economic Pillar

One of the most important features about contemporary tourism is its ability to engage global visitors in memorable and sometimes transformational experiences. The classical interpretation of tourism as an opportunity to merely see local or global landmarks coupled with some sensory interactions with food and entertainments was profoundly transcended by new concepts and approaches. Qatar acknowledges that it is not a country with distinguished natural scenes or unique flora and fauna. Hence, more investment is geared towards cultural tourism using the cultural infrastructure of the country and its capital city; Doha. Hence, the fundamental question while shaping the tourism national strategy was can cultural tourism act as a driving force towards economic diversification. While Qatar critically acknowledges the vitality of considering tourism as one of its main pillars for economic diversification, yet, the State exhibits clearly its unwillingness to compromise religious, cultural, and social values. Such a clear determination resulted in shaping a strategy for tourism development which transcends the typical entertainment-based tourism. So, the challenge was creating a balanced strategy for tourism development in Qatar. Yet, even as Qatar sought to attract visitors, its tourism policy was carefully and strategically crafted to preserve local culture and prevent environmental degradation. Qatar should pursue a high-value, low-impact tourism. The small State should maintain a strict sustainable tourism

policy. Tourism if seen as a significant part of Qatar's economy, all policies and regulations should guarantee and ensure that its natural and cultural resources will be protected and stay attractive to tourists for decades to come. Published in 2014, the Qatar National Tourism Strategy (QNTS) sets out the plan for the development of Qatar's tourism industry over the next few years[1]. In qualitative terms, QNTSS spells out the focus of future tourism development. This will be based on developing a diversified, premium product that attracts families and travelers looking for new cultural experiences.

Qatar as echoed in its vision (QV2030) and tourism development strategy (QTS, 2014), considered the local values and traditions as core components of its identity and character. Therefore, the analysis of the current efforts in Qatar to promote an era of tourism development reveals a number of indicating trends and issues. In the following sections, a discussion is conducted to reveal the alternative approach adopted by Qatar to move beyond the emphasize on entertainment-based tourism which might in some of its components compromise the national values and traditions. Analyzing the Qatar tourism strategy, urban development framework and the State's economic diversification policies substantiates the State's unique approach towards balanced tourism development.

Figure 9 The Heritage Areas as Centers to promote Cultural Tourism

[1] The Establishment of Qatar Tourism Authority: Realizing the fact that tourism is vital in the post-oil economy, Qatar Tourism Authority (QTA) was established in 2011 and changes to National Tourism Council in 2018 after HH the Amir Sheikh Tamim bin Hamad Al Thani issued the Amiri Decision No.74 of 2018.

5. Conclusions and recommendations

This research first provided a background on place-branding, its origins and importance in shaping the public realm of Doha. The new trends in urban planning implemented in Qatar enrich cultural experience in the country, especially the capital city Doha. A number of cultural, academic projects are established to create an interactive knowledge platform with the community of citizens and residents alike. At the same time such projects attract specific quality of tourists, knowledge workers, short and long-term researchers and global travelers. Museum of Islamic Art (MIA), Education City, The Cultural District (Katara) and Qatar National Museums are part of such widely implemented interventions within the fabric of Doha. Such projects have been coordinated and fully integrated with the city to promote cultural tourism in the era of knowledge economy and knowledge-based urban development. The main conclusion of the chapter is that, although tourism development may provide a viable economic solution to some of the major socio-economic problems currently facing the Qatar but as a more holistic approach, knowledge-based urban development should be perceived as the most appropriate answer for the quest to overpass the oil economy era and moving vigorously towards post-oil one. A large part of the motivation behind the KBUD projects in Qatar is clearly the desire to establish the State as both a tourist destination and as an ideal place where knowledge workers might be prepared to relocate. Hence, Qatar's balanced approach to tourism development is becoming a crucial component in its overall strategy to be a balanced representations of knowledge-based urban development State open for a diversity of people composing an interesting tapestry of just, open, and knowledge-based urbanity. The strategic objectives of megaprojects in Qatar are achieved via branding the State as a new destination for cultural events, sports international competitions. It is also achieved via establishing Qatar's new identity as a context for knowledge and creativity attracting knowledge workers from all over the globe. While it is important to note here that Qatar is not only focusing on providing a new milestone in hosting mega sports events but more importantly, using the event as a catalyst for future development and progress. Qatar and as provided in the study, is fully aware of the previous negatives experiences of similar countries that faced substantial failure in transforming hosting the event into an opportunity for development and future legacy. The study shows that the main requirements of Hosting the 2022 FIFA world cup are perceived by the leadership and executive authorities in Qatar as needed for the country not only for the event. Such major strategic difference would make Qatar a winner not only economically but socially, culturally and better prepared for a post-Carbon future.

Case Study / Project

The Role of Local Leadership in Fragmented Urban Development:

the Case of Higher Education Town - Jatinangor, West Jawa, Indonesia

Teri ARGO, Ery Supriyadi RUSTIDJA

Abstract

The Higher Education Town (HET) of Jatinangor is a campus area, a park of cultural technology science, and an urban center for economic activities. As part of Bandung Metropolitan Area, the challenges on social-economic change, deterioration environtment, infrastructure supply, and economic activities has lead to fragmented development that lead No. rooms for urban public space or centralized public services system. Inevitably, HET Jatinangor faces uncontrolled urban space structures, so that it increases urban problems, including densification that borders towards slums features, urban sprawl, scattered housing-apartment buildings and a lack of water supply combined with frequent flooding. These problems affect the regional levels and urban fringe area. The basic question is how local leadership plays a strategic role in urban and economic change. of HET. Using the participative action research method, the study found that the roles of local leadership promotes positively and consistently towards implementation of development plans of HET and towards resources allocation through the urban spatial plans. The study found that local leaders who lead to strong networks among institutions, such as among local government agencies, academics, and local communities, has a grasp of historical understanding of the areas as well as orientation towards providing highly qualified public services drives a performance that warrant respects and understanding among the community members . The study implies that with limited autonomy given to the local level, strong, dynamic and open minded leaderships can fill in the vacuum in urban management of this fragmented governance.

Case Study Paper

Fixing the wrongs against 'rights' in Kalyani (India)

A story of sanitation, two slums, their land tenure, a municipality and the state

Tathabrata BHATTACHARYA, CURE-India; India

Abstract

The paper explores the informal 'means' or approaches adopted by the Kalyani municipality in the state of West Bengal (India) to challenge the unconstitutional limiting of its powers by the state government. It unfolds with a community-based sanitation project; resulting in a dilemma over legitimacy of land tenure in two slums. By understanding the limitations of the municipality, the nature of the sanitation project and the informal 'links' or networks among people, groups and organisations; that were developed to support the programme, witness the degree to which an urban local body can impact the established land administration system in Kalyani and its resultant effect on the understanding of land tenure system in the two slums. It is found that not only did informal means of the municipality help instil faith in the slum communities; it also triggered voluntary slum development initiatives and a strengthened perception of legitimacy of their land tenure. This has further led to implementation of other state-funded projects in the slums, that in the past, required legal land ownership. From a planner's perspective, it imparts a new facet to the land administration of the city and the way land tenure might function in the informal settlements. With sanitation being a human right and a national priority, the study provides an insight into how sometimes informal means are adopted by formal agencies to safeguard formal functions and challenge limiting regulatory environments.

Keywords

Land tenure, Radical Planning, Coproduction

1. Introduction

In response to the weak and ineffective nature of the urban local bodies, the Indian Parliament voted for the 74th Constitutional Amendment Act (CAA) in 1992. It was considered a firm step towards decentralisation (Rai, 1999) and empowerment of the grassroots *viz.* municipality. The Act suggested mandatory and optional reforms to be brought in the municipal governance by the respective states. More importantly, it recommended transferring the responsibilities of land use development and socio-economic planning to the municipalities, adding another dimension to extending democracy at grassroots and urban planning.

In terms of implementation, West Bengal emerged as a frontrunner in democratic decentralisation and among the 'star' states (WBDMA, 2017). Not only did the state execute

the mandatory reforms in record time but achieved greatly in terms of those that were optional under the Act also *(Ibid)*.

However, even after two decades, the urban local bodies continue to remain weak. Despite the Constitutional support, the municipalities could not improve their governance and service delivery (Aijaz, 2007). Although inefficiency and corruption within the municipalities have contributed to the failure (Aijaz, 2007, Sharma, 2011), researches also indicate a greater issue. This issue pertains to the lack of support from the respective states (to the extent of reluctance) and an uneven devolution of power between the state legislature and the city council (Sharma, 2011). Despite the constitutional mandate, the state enjoys an upper hand in municipal matters; partially owing to certain provisions in the 74th CAA that were left *optional* to grant flexibility to the states in designing their individual reforms (74th CAA, 1992) and partly due to 'deep-rooted' socio-cultural perceptions of the citizens (Vidyarthi, 2004).

The paper revolves around this reluctance to share power and legislative 'upper-handedness' of the state. In actions that can only be termed desperate, the Kalyani Municipality adopted 'informal' approaches in leveraging a sanitation project in two informal settlements, to challenge the undue land administration system in the city by the state legislature. This triggered actions and events that developed new understanding of land tenure among the slum-dwellers and impacted the established land administration system in the town.

Ironically set in West Bengal, the author re-examines the methods adopted by a formal agency (the Kalyani Municipality) to claim its formal rights guaranteed by the Constitution and thereby challenge the tenure-based service regulations of the state. To uncover this phenomenon, the paper would try to understand (i) the factors that drove the Municipality to challenge the state; (ii) the approaches adopted by the Municipality and (iii) the consequences of their action.

2. Background

The story owes its roots to the Parliament's rejection to the 64th amendment (Bill[1]) to the Indian Constitution in July 1989. Although it sought to reform and revitalise local governance, the lawmakers opined that the Bill limited the freedom of the state to design local government reforms. Since, functions of local governance was in the State List[2] (CoI, 1949), the decision remained unchallenged.

Giving due cognizance to the objection, the Government of India proposed a new Bill. It was kept 'flexible' in design and provided a greater autonomy to the states. Consequently, two kinds of provisions were introduced in it. Certain reforms were mandatory in nature which every State had to initiate within a year of passing the Bill. These were indicated by the word 'shall' in the new Bill. The second type of reforms were more discretionary, indicated discreetly by the word 'may' in the law (74th CAA, 1992). While the mandatory reforms were

[1] Every law before ratification by the Parliament and the President of India is a proposal or Bill.

[2]Section Seven of Indian Constitution grants greater autonomy over different domains to Union Government (Government of India) and respective States. Items like law and order, public health, agriculture, wealth taxes, land tenure, land reforms, and functions of local government are included in the State List.

aimed at giving financial, compositional and tenure-related autonomy to the local bodies, the discretionary provisions were conceived as a tool for innovative reform of grassroots governance, *optional* for the states *(Ibid)*.

The Bill became the 74th Amendment to the Constitution of India. This conferred a constitutional status to the urban local bodies and entrusted critical functions of city management and service delivery. It was seen by some as a firm step in strengthening democracy in the grassroots (Rai, 1999). It redefined how urban areas were to be managed by linking the lowest levels of democracy to the higher legislative apparatus of the country.

However, some researchers have theorised that the real idea behind the Amendment was to provide greater constitutional protection from irrational decisions of state against the functioning of the municipalities (Misra et al., 1999) and not to substantially change the way the local government was administered (Vidyarthi, 2004). Coincidentally, its Article 243(W) implicitly makes the State Legislature responsible for deciding the extent of powers, jurisdiction and responsibilities that 'might' be enjoyed by the urban local bodies as institutions of self-government (74th CAA, 1992). The State agencies (different departments) and parastatals allegedly retain their power over matters under 12th Schedule[3] by calling for 'specialised' knowledge and expertise in projects; that the municipalities largely lack. In addition, citing 'effective communication between the state politicians and bureaucracy' for expediting implementation of schemes, the departments often side-line the municipalities (Vidyarthi, 2004).

With regards to the municipalities, it has been claimed that the inefficiency of the municipal system, corruption, lack of experience among the staff etc. are impediments to the implementation of the 74th CAA provisions (Aijaz, 2007, Sharma, 2011). However, beyond the conventional criticism of slow government procedures or administrative apathy, Vidyarthi (2004) presents a third kind of perspective that draws from people's perception. He claims that citizens mostly see the municipalities as corrupt, powerless and operating with 'vested interests' and consequently invest their faith in technocratic officials.

3. Theoretical underpinnings

From the discussion above, it can be concluded that owing to some legislative clauses, operational tactics and popular perception, the State often perpetuates a restrictive political environment in its urban areas. It is characterised by complicated and perceptibly unjust exercising of power over critical urban domains. In such a situation, for a municipality, to claim its constitutional powers and address some of its issues requires it to stand in *opposition* to the established state laws and warrants a move towards social transformation through radical planning (Friedmann, 1987).

3.1. Radical Planning

Radical planning has been theorised as deliberate efforts for the transformation of *"social, political and economic structures that create and maintain status-quo"* within one's zone of influence to combat unequal and unjust power relations (Beard, 2003, pg.16). The efforts are a response to long-term, careful critique of the present situation and institutional

[3] Under the Article 243(W), a list of eighteen fields related to city management in the 74th CAA, 1992, that the State has the option to delegate to the urban local bodies.

constraints, informed by *social learning* culminating into practical and operational solutions (Friedmann, 1987). The central characteristic of radical planning has been *opposition* or *conflict (*Beard*, 2003)*. Radical planning is known to exist in many forms (Sandercock and Bridgman, 1999, Harvey, 2000) and is mostly in opposition to the state. However, for the purpose of this paper, it is important to learn about the fact that states (or state machineries) are also capable of engaging in radical planning (Rangan, 1999).

Radical planning is popularly perceived as being *overt* (Beard, 2012, pg.715) and grand in nature, though there are arguments against it (Sandercock and Bridgman, 1999). However, in a political and administrative environment, where open challenges are either admonished, vehemently suppressed or conveniently ignored, radical planning cannot lead to social transformation (Beard, 2002, 2003). It is in such circumstances that Covert Planning makes its contribution *(Ibid)*.

Covert planning is a mode of planning that features non-confrontational efforts; marked by subtlety and undetected ways to impact power relations. These "under the radar" strategies are found to be incremental in nature and produce undercurrents of change without antagonising the authority (Beard, 2012). It is claimed that covert planning comes closest to the tradition of social mobilisation because it involves the strongest desire for emancipation (Beard, 2002).

It should be noted that the theories of radical and covert planning acknowledge the necessity of economic, political and social capital for escaping oppression. However, they do not discuss the means to achieve them (Beard, 2003). Interestingly, Coleman (1988) has established social capital as 'means' in itself; to achieve a certain end. More than a tool, social capital has been seen as *durable networks* (Bourdieu, 2011) that are required for *purposive action* (Lin, 2017). From a collective and community-based perspective, Putnam (1995) suggests that it is the networks, norms and trust that "enable participants to act together more effectively to pursue shared objectives". In marginalised communities, where people suffer from *deprivation of capabilities,* social networks hold great significance. These networks are formed between key people, known as 'agents'. According to Sen (2011), the degree of poverty is directly related to how well an individual can use these 'agents', known colloquially as a 'connections' who works on his behalf and aids in bringing change.

The discussion so far has created a framework that was necessary to critically examine the case of CLHI project in Kalyani. The theory provides a logic through which it is now possible to understand the peculiarity of the actions of the Municipality, the driving force behind them and the results.

4. Context

4.1. Kalyani township

Kalyani is a planned township, 65 km towards north of Kolkata with an area of 29.21 sq.km. It has a population of 1,00,575 people with approximately 24,492 households (Cesus of India, 2011). The population of the town has increased by 15,072 people since 2001. It has most of the services of planned townships but is presently seen as a satellite town for Kolkata. It benefits from its proximity to Kolkata; the largest employment centre of the region, political capital and expanding rapidly into the suburbs. Its proximity to Kolkata with

industries and other institutional facilities, Kalyani proved to be a desirable place for migrants from rural areas and Bangladeshi refugees (between 1947-1971). These, predominantly poor, households settled in large underserved areas that were vacant or conveniently close to job centres and railway stations. Researches have revealed that over the last fifty years, open unused spaces in peripheral wards (predominantly wards 1, 2, 3, 4, 5, 14 and 15) have increasingly come under unplanned and underserved slums (colloquially called *Colonies*) (Choudhury, 2011). However, certain slums can also be found in more central wards (6, 9, 10, 16, 18 and 19). In 2001, there were 16 recognised (enlisted with the Municipality) slums in Kalyani with a population equal to 48% of the total population of the town. The number of such slums grew to 52 by 2012, and were recognised by the Municipality (Tarafder and Islam, 2012) and their location and other features recorded digitally.

4.2. Political Backdrop

At the time of the project, CPI(M)[4] or Left Front ruled the state of West Bengal and the Kalyani Municipality. Being a planned industrial town with reputed educational institutions, Kalyani has always occupied a prominent place in state politics. This had its fair share of disadvantages also. Although the West Bengal government was hailed as a pioneer in the decentralisation of power, it continues to hold the urban area in Kalyani as a Notified Area (a special legal status for areas that are making a transition from rural to urban character). As a result, the state continues to deprive the Municipality of its constitutional functions and appoints an Estate Manager (Kalyani Municipality, 2007, Chaudhuri, 2016) (a senior civil servant-cum-administrator) as a custodian of all land in and around the municipality (barring the defence and railway lands) even after two decades of the latter's formation (circa 1995). This meant that the Kalyani Municipality was reduced to maintaining infrastructure in the town and depend on the state machinery for all land-related matter, including infrastructure development, matters related to development in informal settlements etc. This inability of the Municipality is compounded when certain programmes approach the Municipality directly for infrastructure development in informal settlements. It is because the State prohibits the Municipality from taking any decision regarding land and leaves little ground for it to apply for land acquisition because slums, by definition, are not officially recognised/notified[5] settlements in Kalyani and hence, hold no legal land tenure.

4.3. The CLHI Project

Development in Kalyani is guided by the Draft Development Plan; that was prepared in 2007. However, it does not address the issues of land tenure in the town. In 2006, at the behest of the DFID[6], the Municipality took up the task of making Kalyani an 'open defecation-free' (ODF) town under a flagship programme, KUSP[7]. The total investment by DFID in West Bengal under KUSP was close to USD 5.4 million, aimed at improving infrastructure of cities by encouraging household toilets (Kar, 2006).

Looking at the deplorable sanitation situation in the slums of Kalyani, fifty-two slum settlements were identified by the municipality to be included under KUSP. Since, subsidies to selected poor households to encourage them to build in-house toilets (especially in slum

[4] Communist Party of India (Marxist) ruled West Bengal from 1977 to 2011.
[5] Notification of slums are carried out by the State government; it is the first step in their legal recognition.
[6] Department for International Development, Govt. of United Kingdom
[7] Kolkata Urban Services for Poor (a joint programme of DFID and Government of West Bengal)

areas) had proved ineffective, an alternative method of Community-Led Health Initiative (CLHI) was launched to test the Community-Led Total Sanitation approach (CLTS). CLTS was chosen "…*as an entry point strategy to build community capacity and to strengthen internal social solidarity of slums for initiating collective local action*." *(Ibid).*

Under CLHI, the health-department organised information meetings with the community to understand the existing situations and probable solutions regarding sanitation, along with the experts. "Doable" solutions (economic, durable and scientific) were deliberated upon. In addition, behavioural changes were addressed and local community formed groups to stop open defecation in their surroundings (Lüthi et al., 2010). This lead to a movement where people from all the slums got together to choose natural leaders among them to spearhead CLHI in their locality. Within a year of its inception, all 52 slums were ODF and had built household toilets voluntarily without any kind of government support. The project was exceptionally successful in two slums, Vidyasagar Colony (295 households, 1218 people) in the periphery and Harijan Pally (89 Households, 359 people) near the town-core. While Vidyasagar Colony is a refugee colony that came into existence when Bangladeshi refugees fled war in 1971, Harijan pally was settled by migrants from various parts of India (especially Medinipur in West Bengal, Bihar and Uttar Pradesh). Vidyasagar Colony is located on land earmarked for industrial development and Harijan Pally occupies Kalyani University land. Although no BPL families are registered in the settlement, the residents are considered largely poor.

5. The Study

This section gives the details of how Kalyani Municipality engaged in covert planning. The data and information for this study was collected in the summer of 2015. It involved extensive interviews with people associated with the project. These included the erstwhile municipal Chairman, the municipal officers, state officials, members of the 'expert' team and people from the two slums. Observation and transcripts from community meetings were reviewed, coupled with checking of household survey records.

In the early years of 2000s, the West Bengal government set health on high priority. Consequently, all urban local bodies were given the mandate to take actions to improve health of its citizens by improving the condition health facilities in their respective jurisdictions.

Kalyani Municipality utilized this opportunity to address the longstanding issue of poor sanitation services in slums. From its earlier studies, it had found that almost all slum-dwellers were defecating in the open in absence of individual or community-level sanitation services. With its prior experience in community-level sanitation services elsewhere, getting trapped in maintenance issues, the Municipality targeted development of household-level toilets in all slums. However, providing household toilets in slums were not an easy task. According to Chairman, there were a host of problems:

i. Building sanitation services would require land, the acquisition of which was beyond the purview of the Municipality.

ii. Application for land acquisition for developing sanitation for improving health would not be entertained because none of the slums in Kalyani are notified by the State.

iii. Kalyani being an industrial town had large expanse of vacant lands that were being used for open-defecation. The solution of household toilets might not find takers and reduce into a wasteful expenditure. Prior experiences had suggested that toilets provided by governments had been increasingly used for purposes other than sanitation.

iv. Municipality-aided toilet construction would invite the ire of the State for going against its established management system.

Considering the delimiting condition, the Municipality designed a unique strategy. The Chairman roped in its health department and a team of experts to design a community-level health project. In tandem with the mandate of the state, the project sought to impact the health of the people living in the slums of Kalyani by targeting behavioural change. On surface, the project was directly relevant to the state's larger objective and was given a green-signal by the state without any objection. However, underneath, the project served a two-fold purpose. In lieu of the project, the municipality got the funds required to conduct an exhaustive survey of all the slums within its city-limits. It was informed that this helped in the later stage of the project as a symbol of recognition by the government. In addition, health provided a convenient point of entry into the settlements (that considered every state agent with suspicion) rather than sanitation that involved discussion of risky topics like land tenure.

During implementation, common diseases were constantly linked to open-defecation and absence of sanitation in the area. In doing so, the Municipality set a stage for spatial intervention in the future. However, any sudden building activity could have alerted the state. Therefore, the project was progressed in phases. These phases involved people designing small interventions with deadlines and keeping records of their achievements. An example would be setting-up of children vigil groups that would blow whistles at people defecating in the open. It was gathered, this not only deterred the people to defecate in the open during the day but also gave a sense of unity in the groups.

Numerous meetings and group-discussions were held by the experts and the municipality with the community. Stage shows were organised on necessity of health of vulnerable groups like women, children and old people. Sometimes, the municipality invited state officials to these discussions. It was claimed that such events not only encouraged the community in pursue their goal vigorously but also provided a shade of legitimacy to the process.

Convinced by the efforts of the health department and their own people, the community expressed the intention of building private toilets, close to their houses in both the settlements. It was informed that the Municipality had been able to generate demand for sanitation services in the settlements, as they had truly desired. However, they could not apply for construction funds from the state. Hence, the Municipality pitched the idea of simple designs of toilets that would be developed by the people in consultation with the experts. The Chairman confessed that it was a 'gamble' because in absence of formal land

tenure, investment in toilets was unconceivable. Yet, the Municipality went ahead with the plan because (a) the demand came because of "legitimate" processes of community participation, at a scale that the state had never seen and (b) the Municipality had passed the onus of design and development of sanitation in the slums to the community (voters) and the team of experts (paid by the state), thereby technically not challenging the land laws of the state.

Real sparks of covert planning on the part of the Municipality were visible in the construction phase of the toilets. Interviews revealed that investment in household toilets made people think about the extent of land being held by individual families. This triggered spatial reorganisation of settlements and informal delineation of plots by community-heads in presence of Municipal staffs. According to a Municipal officer, this was not only the first spatial imprint of a health initiative, the event also highlighted the capability of communities to plan for their settlements. The Municipality availed this opportunity and provided small grants for constructing a Club house in the settlements "for holding cultural events". The establishment of a club (funded from state money) renewed the zeal of the people and they started mobilizing private funds for building toilets.

The Municipality cunningly extended water pipelines and rainwater drains to the boundaries of these informal settlements. This was done to respect the state norm of providing urban infrastructure services to only formal land holdings and at the same time, making them accessible to the informal settlements. Simultaneously, the Municipality encouraged the women in the settlements to form savings groups under various central and state government programmes. To fast track their application process, the Municipality set up a special cell. With the additional corpus, available at the discretion of the community women, the Municipality encouraged to use the funds in developing roads, drains etc. in their respective slums. It was told that instead of suspecting anything, the state appreciated the women's role in forming savings groups. This further added to the legitimacy of the project and kept the real intentions of the Municipality hidden.

In case of Harijan Pally slum, the Municipality strategically negotiated with the Kalyani University to obtain a 'No Objection Certificate' for informally developing its land to make it "fit" for human habitation. It is important to note that the Municipality was aware that the NOC held no legal relevance as land vested under a university is controlled by the state education department in West Bengal. However, this created renewed vigour among the people and motivated the community to pursue its spatial development and a deeper faith in the Municipality. For the Municipality, the NOC would create a moral barrier between the State and the slum dwellers, considering that the University owned by the Government of West Bengal.

6. Impact

It is from the impact that the true success of the covert planning method by the Municipality can be assessed. The results of the CLHI project can be divided into two categories- spatial impact and institutional impact.

The CLHI project has contributed to the development of the two slums considerably. Under the reorganisation efforts of the community, the land under the slum was divided

(informally) into parcels of 134 sq.m. (approx.) for every resident family. Provisions of roads and drains were kept in the master plan that was developed. The domestic animals have been provided with a community-level shed that is mutually maintained. A primary school was constructed in an excess piece of land for children of the slum and reportedly, it is partly funded by the Municipality. All these have given Harijan Pally an *appearance* of a planned neighbourhood. In Vidyasagar Pally, the drains and roads have been recently redeveloped from the expenses of the community.

Cultural club buildings in both the settlements have been made permanent and are now used as multipurpose halls for marriage and religious festivities. The success and popularity of community-led activities has resulted in voluntary garbage collection groups that collect garbage from door to door on a regular basis. The vacant spaces, earlier being used as grounds for open defecation, have in case Harijan Pally been planted with trees and in Vidyasagar Colony, lay vacant. Some households have invested in making their living quarters more permanent, citing their participation in a "municipal project" has strengthened their tenure status.

It should be noted that all the above developments happened without a formal legal tenure. The Municipality having involved the state, tactfully into the project has limited the state's opportunities of vehement opposition. Also, in absence of overt and disruptive demands during or after the project by the Municipality or the community, the state administration never felt threatened.

Regarding the Institutional impact, it can be said that the state has also come around its stance of denying service provision in informal settlements. It has been reported that under a state-funded project of building individual toilets (Sobar Souchagar), with permanent materials, twenty-two toilets have been built in Harijan Pally. These toilets are registered in the name of the owner. This can be interpreted as the state's effort to provide some sort of tenure security to the slum dwellers and a commendable success of the Municipality in softening the stance of the State with regards to land administration in Kalyani.

7. Conclusion

From the case presented above, it is quite clear that the municipality was aware of the necessities of the marginalised section of the town and adapted a larger project to respond to a host of issues plaguing their settlements. At the same time, its actions exemplify the capability of grassroots agencies to become agents of change and circumvent policies to usher development. The discussion also highlights the confused state of urban management in India and the necessity of comprehensive policy reform.

Research Paper

BREAKING THROUGH RIGID ADMINISTRATIVE BOUNDARIES

Synergies in 'soft' spaces of cooperation

Karina CARIUS DE BARROS, MSc Spatial Planning

Sindi HAXHIJA, MSc Spatial Planning

Abstract

The concept of 'soft' spaces has been introduced in the pursuit of capturing the reality of cooperation practices, marked by continuous attempts to promote new policy scales, initially through the device of fuzzy boundaries. Within such a challenging context - where interests overlap but administrative units do not - the interaction of actors in these areas often remains weak. The study focuses on exploring cooperation motives and implications arising among stakeholders in these 'soft' spaces of interaction. Through informal and semi-formal processes of negotiation employed by several relevant actors, the two case study regions attempt to overcome the clashes between local, national and supranational political and administrative discourses.

Keywords

Soft spaces, regionalization policies, territorial rescaling, relational networks,

1. Introduction

The necessity to address common interests across borders still face rigid administrative boundaries. Financial power, infrastructure coordination, ecological and environmental concerns are under the regulation of the different actors, with their respective hierarchical structures of government and governance. Shared interests thenceforward, in their application, remain limited within distinct administrative unit.

Following the necessity for spatial planning to focus on 'what works' in terms of implementation and policy delivery, the notion 'soft' spaces of cooperation has been in the spotlight of many academics working on territorial cooperation units. The concept of 'soft' spaces is a recently developed one, therefore, the rationale behind the concept is still to be explored. However, most literature has pointed out to functional needs as usual motivation for the emergence of 'soft' spaces. Allmendinger and Haughton (2009), refer to functional needs as a response to challenges of environmental character. In this case, local communities need to come together to address interests from beyond existing territorial concerns, by bringing in new forms of actor networks in order to challenge the complexity of

social issues and institutions. When restrained within fixed administrative boundaries, it becomes more difficult to reflect the geographies of the problem. Governmental structures, fail to address functional linkages within their politico-administrative territories, therefore, in such scenarios, policy-makers and interested parties need to come up with tailor-made solutions, addressing issues from both sides of the border.

Additionally, as also detected by Allmendinger et al. (2015), these spaces of interaction are motivated by the necessity to create a more efficient arena for stakeholder cooperation. In a context where environmental, social and economic issues are interconnected and pass across rigid administrative borders, sectoral and hierarchic forms of policy-making are no longer efficient. When these new actor networks come together they help to tackle territorial issues by indicating for public authorities the right geographical scale and the focus of policy design, by endorsing in this way, specific strategies or goals. This type of 'soft' space becomes an attempt to re-brand regions and redirect the existent vision of the area (Carius de Barros, 2018).

As a reaction on and reflection of this complex and challenging context, where societies are becoming more fluid, the administrative boundaries should follow. From a societal point of view, this study analyses the mechanisms and processes of governance employed by institutions and communities in these cross-border regions. By looking inside and outside the EU borders, it can contribute to both the European Union Community and the neighbouring countries, by deepening the understanding of cross-border processes inside and outside the border. Following this line of thought, cross-border cooperation programs and projects have been developed as a means of proposing more adequate narratives to the context of hard administrative borders and the communities in these areas.

In addition, this paper explores cross-border cooperation initiatives and their supportive frameworks inside and outside the EU, in order to understand and compare the challenges faced in a 'soft' cooperation context and furthermore, to investigate the role and attitude of the EU as a triggering or hindering mechanism. Within its own administrative boundaries, new processes of territorial rescaling which came as a result of EU Regional Policies can be seen as a driver for 'soft' territorial cooperation. However, these soft and informal spatial approaches go hand in hand with hard and formal regulations which affect spatial development (Haxhija, 2018)

Cross-border cooperation across the outer EU borders is, however, embedded in a highly complex context where different historical path, motivations, policy and institutional frameworks coexist with local and regional attempts of promoting development. While CBC within EU may encompass a narrative of unity and 'soft' territorial cooperation, such activity across the EU outer borders are surrounded by 'hard' spaces as security, exercise of influence and external relations (Carius de Barros, 2018).

The empirical research has been conducted by using two different approaches, border areas inside and outside the EU administrative boundaries. It focuses on the network set-up which involves different governmental and non-governmental bodies from both sides of the border and draws upon alternatives to foster their cooperation despite the different cultural, institutional and organizational arrangements. Through informal and semi-formal processes of negotiation employed by several relevant actors, the regions attempt to overcome the clashes between local, national and supranational political and administrative discourses.

Interviews and on-site analysis are the two main methods which have been used during the data collection process.

2. Concept of soft spaces

Alternative forms of policy delivery, in a highly and increasingly complex context of spatial planning, have been discussed by both academics and practitioners. Increasing recognition is given to the fact that recurrent issues in spatial planning, as environmental and social challenges, are often not limited by the governance units commonly used, such as territorial and political borders (Carius de Barros, 2018). In this context, the idea of soft spaces has been explored as a way to explain ”continuous attempts to promote new policy scales” (Haxhija, 2018, pg 5), which aim to overcome the territorial and governance boundaries typical of planning systems (Allmendiger, Haughton, Knieling & Othengrafen, 2015).

The narrative on soft spaces and its surge relates to the New Labour’s approach to spatial planning in the United Kingdom and the process of devolution it sought to promote (Davoudi & Strange, 2009). Further diving into such notion is provided by Allmendinger & Haughton (2009), who explored the growing demand for alternative approaches to planning in complex, multi-stakeholders scenarios:

> So, whilst planning still needs its clear legal ‘fix’ around set boundaries for formal plans, if it is to reflect the more complex relational world of associational relationships which stretch across a range of geographies, planning also needs to operate through other spaces, and it is these we think of as ‘soft spaces’ (Allmendinger and Haughton, 2009, p.619).

Almendinger et. al. (2015) explains such space as ‘new geographies’ that give the opportunity to gather different actors that, though motivated by various reasons, pursue the solution or improvement of complex issues. These spaces may overlay with fixed administrative boundaries, such as institutional frameworks, but may also entirely deny and challenge those (Othengrafen, Knieling, Haughton & Allmendinger, 2015). Soft spaces are, thus, “flexible governance arrangements that aim at overcoming institutional borders and entrenched practices by inserting new ways of doing things” (Telle, 2017, p.94).

The semi- or in- formality of soft spaces is an essential part of their functioning, which allows for a degree of flexibility, considering its non-statutory governance modes (Metzger and Schmitt, 2012). On the other side, however, the interaction of these soft spaces with well established governmental institutions allow for a certain degree of formality that, consequently legitimates such soft spaces and their networks (Allmendinger et al., 2015; Telle, 2017).

The networks involved in the establishment and functioning of soft spaces may be understood as ‘communities of intent’, i.e. constellations of actors cooperating towards certain goals and motivated by specific challenges (Chilla et al., 2017). While such concept suggests an essential bottom-up nature of communities of intent and, consequently, of soft

spaces, it is important to notice the top-down character of processes present in soft spaces (Haxhija, 2018). In the same line, 'soft' and 'hard' spaces should not be approached as opposite and excluding concepts. As Mezger and Schmitt (2012, p.276) explain, this 'soft' nature should not be understood "as an absolute property of certain spatial entities, and not as eternal but, rather, as a contingent stage in the development trajectories of some spatial entities".

Empirical studies have been developed in the attempt of shedding further light on the functioning of soft spaces, especially under territorial cooperation processes. The Tames Gateway Development Corporation, aiming at brownfield conversion and development is an example. Understood as an 'implementation' type of cooperation, as Chilla et al. (2017) clarifies, it is characterized by a strong participatory aspect that leads actors to take larger ownership of the project.

The ESPON Actarea project, for instance, explores several examples of soft territorial cooperation, concluding these often have a cross-border nature. Such findings relate to Chila et al.'s (2017) findings of what the author defines as 'instrumental' cooperation, where policy frameworks lay the ground for the functioning of such spaces. Instrumental initiatives are often of cross-border nature (Ibid).

In the same context, Telle (2017) suggests an analysis of Euroregions under the concept of soft spaces. The author compares two Euroregions, Šumava and Pomoraví, and present those as soft spaces aiming to manage overarching physical and governance issues. Difficulties to overcome the administrative and political boundaries typical of cross-border contexts are part of the processes for both regions in the pursuit of cooperation across borders.

Finally, it is possible to conclude that soft spaces are involved with the attempts to overcome varying barriers typical of formal, rigid administrative spheres. Stakeholders of different nature, motivated by several reasons, build upon shared interests to reach fruitful cooperation in terms of development. Under the concept of soft spaces, the next section will analyse cross-border cooperation in different contexts, within the EU and across its external borders.

3. The EU approach to soft spaces of cooperation

3.1. CBC within the EU

Due to ever-growing globalisation processes, new forms of territorial cooperation have been introduced in the EU, in order for its cities and regions to become more present transnationally and increase their competitive advantage as global players. The EU Regional Policy has been initiated as a result of – however, not limited to – the necessity to manage dynamics in these new forms of territorial cooperation. Within its framework, new funding opportunities have been developed to support cross-border and interregional cooperation networks. In this new territorial context, it becomes difficult for political action to be fully legitimate by serving only to fixed territorial boundaries and its communities. Therefore, new conditions aiming at taking into consideration the practical and dynamic aspects of

relational spaces, ask for more tailor-made policies and place-based practices. Where the current institutional set-up, fails to explain cooperation going beyond administrative units, 'soft' forms of cooperation make sense to be used in order to explain and analyse these new forms of territorial development (Haxhija, 2018).

While the EU, using the EU Regional Policy as a supporting framework, has been one of the main drivers to trigger the establishment of these new territorial complexes, its political and institutional approach is not parallel to its 'soft' territorial approach. The EU Regional Policy is a clear example of this controversial approach. As stated by Davoudi (2007), the EU Regional Policy contributed to the creation of 'soft' spaces by operating at the NUTS2 level, which in most countries is not part of the statutory system. However, its political and institutional approach does not go hand in hand with its 'soft 'territorial cooperative approach, where strict rules are to be met by local and regional actors in order to receive funding, deflecting in this way the bottom-up planning attitude as an integral part of 'soft' spaces. Suffice to say, that within these new spaces of interaction, governmental actors remain the main entities accountable for the negotiation of agreements and programs (Purkathofer, 2016). Having predefined scales, actors and instruments which influence spatial planning create conflicts and tensions when state-bounded territorial and relational networked governance, are faced.

The same controversial approach of the EU towards 'soft' spaces is spotted in what is known as macro-regional strategies. The EU has been the main driver for the emergence of macro-regions such as the Baltic Sea Region, Danube Region and the likes. These new spaces constitute a new type of planning across Europe were collaborative methods shed light into the importance of widening stakeholder involvement beyond traditional power elites and building new institutional capital by involving social networks (Haxhija, 2018). However, the institutions rules and funding instruments upon which they operate are grounded in old and fixed territorial boundaries. Therefore, these new spaces of network among interested stakeholders, lack decision-making powers for its actors and institutions that emerge as a result of cross-border cooperation.

3.2. CBC along the EU outer borders

Cross-border cooperation along the outer borders of EU, on its turn, has surged and functioned according to a different historical path and different motivations by both EU and partner countries. While CBC within EU encompassed an approach of unity and 'soft' territorial cooperation, its practice across the EU outer borders is surrounded by 'harder' issues as security, exercise of influence and external relations.

CBC, in the context of EU outer borders, played a key role in relations between the Union and its neighbours since the 1990's, through programmes such as TACIS and INTERREG (Wassenberg et al., 2015). TACIS, the Technical Aid to the Commonwealth of Independent States, was a programme established by the EU as a means to support growth of the areas recently independent from Soviet Union and Georgia, focusing on sectors such as energy, food and financials (European Commission, 2018). Such initiative did not focus on cross-border cooperation, but did count with it as one of its dimensions.

Cross-border cooperation gained later a more central role in the INTERREG programmes, who were initially intended to foster a borderless EU, thus focusing on its member states.

However, with the enlargement wave in the 2000's, the programme became more relevant to the outer borders, as a tool to promote cooperation among EU and the candidate states (Liikanen, 2008). INTERREG had, however, its paradoxical role. It became an important tool of connection across EU outer borders enabling, for instance, regional development, infrastructure and environmental projects in the second half of 1990s (Järviö, 2012). However, the essential nature of INTERREG meant it remained an exclusively intra-EU financial tool, therefore its funds could not be applied in neighbour countries (Wesselink & Boschma, 2017). For CBC to be implemented across these borders, a combination of different funding mechanisms was necessary. Such arrangements represented itself a difficulty in the process of developing proper spaces of cooperation across the EU outer borders.

Policy frameworks for cooperation across these borders have developed along time, with the start in 2004 of the European Neighbourhood Policy (ENP). The policy built upon the experience of both TACIS and INTERREG (Khasson, 2013), steering cooperation among EU and its Eastern, North African, Middle Eastern and Caucasus neighbours (EAAS, 2016; Kelley, 2006). Through its instrument (ENPI), the policy set a common framework and funding mechanism for cooperation, which allowed for a maximum 90% of EU contribution.

Such framework, although addressing existing barriers such as funding mechanisms, still comprised of hindering elements in the process of developing spaces of cooperation. As Järviö (2012) clarified, the ENP had a strong external aid dimension that contradicted its own efforts to promote mutual and equal cooperation. Herein, such dimension can be understood as a 'hardness' essence, opposing the proposition of a 'soft' cooperation across borders towards regional development.

The co-existence of both aforementioned aspects also resulted in clashes between EU and neighbours. For instance, the relations between Russia and the EU in the context of the ENP represent an example of the struggles of cross-border cooperation between soft and hard spaces. In 2003, Russia refused to become an EU partner within the ENP framework, as Russia interpreted it as an unbalanced type of arrangement, where the EU had a position of influence over the partner country. A special relationship was created among both actors, around "common spaces" (economic; freedom, security and justice; cooperation in the field of external security; and research, education and culture) (Liikanen, 2008). Russia also introduced 50% contribution of financial allocations becoming the only equal funding partner to the CBC programmes with the EU and, consequently, gaining more influence over those (Järviö, 2011). Disagreements between Russia and EU over regulations and financial agreements have, however, represented a barrier to cross-border cooperation, as evidenced by the delay to the start of the CBC programmes across EU-Russian borders and consequent delay to calls for projects and implementation of the 2007-2013 period (Ibid).

4. Case studies

4.1. The Dutch-German case [1]

The Dutch-German case study (Figure 1) cooperates at a cross-border setting focusing on a common natural linkage and asset such as the Rhine river. It includes the province of Gelderland from the Dutch side and the district of Düsseldorf in Nordrhein-Westfalen.

Both countries work with common supranational European legal and institutional framework when it comes to water and environmental related issues (e.g. Water Framework Directive). Despite this, in reality, cross-border water policy in the area faces noticeable disparities from one side of the border to the other, due to different planning modes, different priorities in their respective territorial agenda and different legal and political conditions. For instance, as mentioned by several interested actors there are different norms and rules when it comes to water quality.

Figure 1 The Dutch-German cross-border region (Haxhija, 2018)

In any case, international (EU) regulations or national involvement in transboundary initiatives (ICPR) are mentioned as tools and policy frameworks used to facilitate cooperation. Therefore, as Haxhija (2018) mentions, international legislation tends to serve as a mechanism to stimulate transboundary governance at a regional level by formally institutionalizing cooperation and putting performance obligations.

[1] The case study draws upon empirical data which have been previously collected and analyzed by Haxhija S. 2018., in ''An institutional and cultural perspective on 'soft' spaces of cooperation: Findings from a transboundary Dutch-German cooperation network.''

As it has been confirmed by both German and Dutch regional bodies during the interviews, cross-border governance in the region is quite complex and not easy to coordinate due to imbalances in policy competencies. When dealing with water management issues the Dutch side has a more concentrated approach with its water boards who are the main responsible bodies at a regional level. Despite the fact that water boards should exist seemingly for all countries as regulated in the WFD, the same cannot be applied to the German side, where water competencies are much more fragmented within different levels. Within such different organizational settings, with the German side sharing competences on water issues among several small organizations, the decision-making process for common issues is prolonged (Haxhija, 2018).

Following this line of thought, there is no direct connection between governmental institutions from both sides. This institutional discrepancy poses a challenge to the cooperation process where both sides of the border have difficulties finding their counterparts to cooperate with.

Other elements challenging the cross-border governance management in the area, are disparities in political commitment across different water governance levels in both sides, where the Dutch side is more agile and willing to push forward the cooperation process. As Haxhija (2018) states ''...the upstream-downstream relationships introduce an element of asymmetry and dependence. The dependence lies mainly on the downstream partners, regional Dutch water authorities, resulting in a more active role in cross-border cooperation on the Dutch side''.

On the other hand, both countries lack the right tools to support cross-border cooperation initiatives. The hierarchical and very formalized institutional structure in the German side seems to be slowing down the cooperation process in the two countries. As stated by interviewees in both countries, the Dutch quick, flexible, heterarchical and informal institutional structure is much more convenient. In any case, the problem that arises here is the fact that there is no common entity with full legitimate power to coordinate the cross-border initiative (Haxhija, 2018). Cooperative networks from both sides of the border try to explore and benefit from additional venues which can foster the process. At a regional level, Euregio Rhine-Waal is the only common entity which supports cross-border cooperation in the area. CBCs established in this area benefit from the history that the Euregio has in cross-border trust building and network. Additionally, in a transboundary context, international arrangements can produce common norms and values by encouraging the integration of the interests of the involved countries (Wiering et al., 2010). However, despite the fact that it works as a catalyst to attract CBC initiatives, it is not equipped with enough decision-making powers and its legal framework cannot prevail over those of each respective country.

All in all, the entire cross-border area communicates due to functional linkages such as ecological, social and economic ones. It can be interpreted as a soft space, which at the moment lacks the right formalized tools to legitimate its decisions. However, its constant progress throughout time shows that there are possibilities to 'harden' the institutions and policy strategies which foster the cooperation initiatives in the area.

4.2. The Finnish-Russian case[2]

The present case study approaches the CBC Karelia programme, across the Finnish-Russian borders, analysing more specifically the cooperation project "Saving our joint treasure: sustainable trout fisheries for the transborder Oulanka river system".

The Karelia CBC programme area include the regions of Oulu, North Karelia and Kainuu in Finland, and the Republic of Karelia in Russia (Figure 2). With three crossing points, the 700 km long border counts with 1.3 million inhabitants in low dense, sparsely populated areas (DG NEAR, 2018). Cooperation in the region is ongoing since the first EU programmes of TACIS and INTERREG, and continues today under the ENPI framework.

Figure 2 The Karelia CBC programme region (Carius de Barros, 2018)

The project herein analysed, "Saving our joint treasure", consisted in the pursuit of a joint management system of brown trout fish stock (Salmo trutta), which inhabit the Oulanka river system across these borders. The species, during its life-cycle, navigates across different parts of the ecosystem within the Finnish Oulanka Natural Park and the Russian Paanajärvi National Park (CBC PROJECTS, 2018a; Metsähallitus, n.d.) (figure 2). In itself, the essence of such project is to address an environmental issue that, as typical of such challenges, is not bound by politico-administrative borders. Therefore, the sustainability of such fish stock depends upon cooperation between actors on both sides of the borders.

[2] The case study draws upon empirical data previously collected and analyzed by Carius de Barros, 2018, in 'The Karelia Cross-border Cooperation Programme: A soft space on the Finnish-Russian hard borders.''

Figure 3 'Saving our joint treasure' project - partners and location (Carius de Barros, 2018)

Taking place between January 2013 and December 2014, activities such as the scientific monitoring of the fish population, studies on socio-economic impact for local fisherman, as well as an awareness campaign on the value of the brown trout stock for the community were elements of the project (CBC PROJECTS, 2018a; EUROPARC Federation, 2018). Participants of the project were Metsähallitus, a Finnish state-owned company managing the country's natural parks; the University of Oulu; the Finnish Game and Fisheries Research Institute (currently Natural Resources Institute of Finland), and the Northern Fisheries Research Institute in Petrozavodsk, Russia (KEEP, 2015a). Other partners were the Paanajärvi National Park; the Municipality of Kuusamo in Finland; and several association bodies representing private owners of water areas along the Oulanka river system in Finland (EUROPARC Federation, 2018).

The motivation of such project is mostly based on an environmental challenge, the sustainability of a joint fish stock management. As Carius de Barros (2018, p.37) finds, the shared resource and shared need to guarantee its survival transforms it into a "transboundary matter which, to be effectively handled, must be negotiated across the distinct formal structures of each country".

Nevertheless, the challenges faced by the project were mostly related to the political and administrative barriers posed by the different spheres across the borders. As the project materials mention as a challenge, activities took place "in a time when high level political relationships between the EU (with Finland as a member) and the Russian Federation were quite challenging" (EUROPARC Federation, 2018). An example is the long delay to the

beginning of the programme start, due to disagreements in high-level between Moscow and the EU over the approval of the ENP CBC framework (Carius de Barros, 2018).

Challenges faced related not only due to the shaking relations between EU, Finland and Russia, but also the different regulatory and administrative demands and cultures (Carius de Barros, 2018). For instance, different standards are applied by Finland and Russia in terms of fishing regulation, which makes it difficult to guarantee the sustainability of such fish stock for all regions involved, which is even more detrimental to the Finnish local economy and biodiversity (Ibid). Furthermore, Visa issues hindering the movement of partners across borders, as well as customs barriers to the transfer of equipment were among the challenges the project faced in order to achieve success (Ibid).

Such challenges were faced by actors in several levels of both project and programme and tackled through mechanisms such as negotiation, knowledge exchange and support that characterize a soft approach to overcome the barriers of the outer EU borders context.

At a higher level, for instance, informal negotiations by interested actors, outside the formal discussion tables were essential to bring about the programme itself. According to Carius de Barros (2018, p.41) findings, the approval of the ENPI CBC programmes required an alternative approach by the Finnish Ministry, “a slight of hand”, which appears to involve an informal diplomatic influence over the process, since the agreement itself did not comply entirely with Russian legislation. At the project level, similar processes took place aiming to overcome the hard borders and its typical barriers, for instance, with exchange of information and support between institutions in the pursuit of visas and permits (Ibid). The centralization of power common in the Russian Federation was also a point of struggle for the Russian and Finnish actors alike, who pursued to maintain a strong partnership to compensate for possible complications coming from higher levels.

A bottom-up approach towards developing a space for cooperation is clear, where local stakeholders count on each other to achieve solutions; programme level actors pursue to influence the Finnish-Russian decision making and negotiation; and where Finnish national level actors pursue to influence supranational levels as an intermediate between EU and Russia (Carius de Barros, 2018).

The project has managed to develop a successful study into the dynamics and challenges in the life-cycle of the trout population as it aimed, as well as strategies of management, generating also the proposal of another project in the fisheries field gathering old and new stakeholders (Carius de Barros, 2018). In this sense, the project can be considered to have developed a consistent soft space where actors are continuously pursuing further development through partnerships and the overcoming of shared challenges.

It is in this context that the Karelia CBC programme can be interpreted as a soft space in construction. Stakeholders, public and private, aim to tackle issues of shared interest. While the cooperation is made possible by the ‘hard’ spaces of policy frameworks, such as the ENP, financial mechanisms, high-level agreements between national and supranational levels, these do also lead to hindering processes. Both programme and project level stakeholders constantly engage in semi and informal negotiation and exchange in order to breach the gap left between administrative spheres and promote development.

5. Conclusions

Both case studies, the Finnish-Russian and Dutch-German borders, reveal a type of soft space motivated by the overcoming of shared environmental challenges.

The Karelia study case shows how the 'hard' spaces promoted by EU frameworks, in this case, the ENP, enable cooperation in the sense it provides a common space, institutional parameters and funding mechanisms that allow for the functioning of formal procedures. Nevertheless, at the same time, such 'hardness' often represent a barrier in itself to the activities of cooperation, resulting in the need for stakeholders to work across such barriers and overcome the very frameworks set in the first place. Soft and hard spaces are thus in constant interconnection, where the latter both reinforces and hinders the former.

The Dutch-German case study is based on flexible and spontaneous networks who come together to solve a joint ecological issue. It is true that within such a flexible cooperation network, actors can easily identify relevant issues and partners to work with, as they are driven by common interests. However, working together in such a 'soft' context of planning their cooperation process is hindered by the lack of common norms, rules, procedures and policy frameworks. At the same time, hierarchical forms of policy-making pose a barrier when cooperating in a cross-border context. This relates back to theories of 'soft' spaces, where hierarchical forms of governing cross border regions are seen as less efficient.

In Karelia the creation of a soft space for cooperation is achieved through informal and semi-formal negotiation mechanisms, support and knowledge exchange among stakeholders.

Carius de Barros (2018) concludes, the Karelia CBC programme "can be understood as the enabler of communication between different levels and interests, as well as a regionalization of decision-making".

Case Study / Project

Fostering Local Leadership for Climate Resilience in Asian Cities

Olga CHEPELIANSKAIA

Abstract

Asia has been rapidly urbanising: half of the region's population now lives in cities and additional 1,2 billion Asians will move to cities by 2050. This unprecedented urbanisation that often takes place at the expense natural ecosystems, which further exacerbates climate risks in Asian cities, making the urban poor most affected. For example, Bangalore and Chennai respectively lost 80% and 90% of their water bodies in the last 4 decades. As a result, Bangalore regularly faces severe floods since 2000 and the massive 2015 flood in Chennai caused an estimated damage of USD 2.2 billion. Both cities are expected to run out of ground water by 2020. In Manila, heavy floods of 2012 were aggravated by the lack of trees and open soil to absorb torrential rainfall water. These example demonstrate that development encroachments over green and blue areas significantly alter cities' natural coping ecosystems and enhances climate risks. Ecosystem based climate resilience has been globally recognised as viable, cost-effective and generating multiple co-benefits for cities. It requires adopting and implementing ecosystem protective and regenerating urban planning and land use regulations. This requirement, in turn, needs transparent and supportive local governance and leadership, which remains a critical challenge in Asia. Root causes of this challenge are numerous: - Limited capacity and expertise in the field of climate change at municipal levels leads to uninformed decision-making; - Short electoral cycles do not incentivize decision-makers to look into long-term interventions. Land use regulations protecting natural ecosystems are seen as less tangible actions compared to engineering solutions such as installing pumping stations in low lying areas or constructing embankments; - Owing to vested interests, personal goals influence approvals of construction proposals that often compromise on a city's green and blue spaces. Relatively weak checks and balances systems reinforce the matter; - Due to weak citizen awareness and engagement, real estate investors and big businesses tend to actively advocate for their interests, which are often not favourable to shared public ecosystems. International programs rarely target these root causes and, consequently, do not achieve meaningful and durable change.

The paper looks at potential solutions to overcome these challenges and foster local leadership for ecosystem based climate resilience. It screens selected case studies that demonstrate how local leadership for ecosystem based climate resilience not only transformed the city but also boosted the career of the leader and led to up-scaling the example. Indeed, recent international steps such as the Agenda 2030, the Paris Agreement or the New Urban Agenda create valuable opportunities for climate sensitive local leaders to fully display their leadership potential and receive adequate recognition. For example, Surabaya Mayor Tri Rismaharini, successfully transformed one of the most neglected Indonesian cities - Surabaya - to a floodless city known for its parks and public initiatives by converting 20% of the territory into green areas.

As a result, she has been re-elected three times and won several international environmental awards. Surabaya is but one of many successful stories of a successful local leadership in an Asia city, which other cities can learn from. Finally, the presentation examines ways of boosting local leadership for ecosystem based climate resilience in Asia and contributions the international development community, national governments, civil society and the media can bring to the matter. Case studies and considerations shared are a combined result of an on-going research and a field international technical assistance work in over 20 Asian cities and 40 Asian countries, conducted in the frame of projects implemented for international institutions such as the ADB, CDIA, UNECE, UNEP, UN ESCAP or UNDP.

Case Study / Project

Role of planning and governance to better manage European metropolitan areas

SPIMA research

Alfredo CORBALAN

Abstract

SPIMA stands for Spatial Dynamics and Strategic Planning in Metropolitan Areas. It is a research project initiated by 10 cities from EUROCITIES Working Group on Metropolitan Areas (Brussels, Oslo, Vienna, Prague, Brno, Lyon, Lille, Torino, Zurich and Terrassa) and financed by the European Union (ESPON programme). The research has been conducted between 2017 and 2018 by 3 European research centres: University of Wageningen (Netherlands), Metropolitan Research Institute (Hungary) and Norwegian Institute for Urban Research (Norway).

Background EUROCITIES is the network representing major European cities. Chaired by Brussels, its Working Group on Metropolitan Areas gathers several cities willing to exchange and advocate on metropolitan issues. In 2013, the Working Group conducted the "MAIA study" to review metropolitan collaboration and governance in 38 European cities. The study pointed out that spatial planning is one of the three main topics of cooperation in metropolitan areas across Europe but that planning and urban governance practices vary by country and have different impacts in different contexts. In 2017, the Working Group initiated the SPIMA study to go a step further and get recommendations on how to improve their metropolitan planning and governance practices.

Key policy question

With the continuous urban sprawl in Europe and the increased linkages between core urban centres and their suburban areas, cities need to cooperate with others authorities to manage together the main spatial dynamics going beyond their administrative borders. But the current planning and governance schemes seem not appropriate to address these complex challenges at the appropriate functional scale. With SPIMA, the ten cities wanted to get an answer to the following policy question: Which spatial planning policy tools and governance approaches can be useful to plan and manage spatial development at metropolitan level, taking into account the institutional and spatial context of each metropolitan area?

Methodology Approach based on the 10 cities case study and methodology composed of:

- data collections, interviews and analysis of the 10 metropolitan areas.

- Individual assessment of each 10 metropolitan areas and comparative analysis

- Individual, national and European recommendations and guidelines.

Main findings 7 common findings in the 10 metropolitan areas studied:

1. No single definition for the delineation of a Metropolitan area. The research proposes an alternative approach: the 'Metropolitan Development Area' (MDA)

2. Three key planning approaches: strategic, statutory and collaborative. Strategic and statutory planning in the 10 metropolitan areas address metropolitan scale 'to a limited extent'

3. Most common spatial dynamics in the 10 metropolitan areas: urban growth, suburbanization in periphery and densification in the centre

4. Institutional frameworks for cooperation: plurality of arrangements from formal to semi-formal or informal. However, the type of legal status is not itself a determining factor for an effective metropolitan planning.

5. Key challenges to manage spatial development in the 10 metropolitan areas: transport and traffic congestion, multilevel cooperation, shared vision on strategic plans and more political involvement

6. Key success factors to implement a metropolitan planning approach: shared governance and mix of tools allowing dynamic interactions between actors and policies.

7. Attempt to build 2 typologies of Metropolitan areas: one based on spatial characteristics (population and density) ; another on Institutional characteristics (status of metropolitan area and number of municipalities)

Guidelines for metropolitan planning approach

To implement a metropolitan planning approach, SPIMA recommends European cities to address 8 action areas:

1. Defining the spatial scale of the Metropolitan Area

2. Involving the relevant actors

3. Identifying the key challenges

4. Establishing governance process and institutional structures

5. Building administrative and knowledge base capacity

6. Assessing spatial dynamics

7. Defining formalization status of Metropolitan area

8. Ensuring success factors, triggers and incentives

Paper

BEYOND THE PLAN

Building In-House Capacity to Plan, Design and Implement Urban and Territorial Transformations, Case of 'Castries Vision 2030'

Frank D'HONDT, Director Territorial Capital Institute, Greece
Haward WELLS – Director National Integrated Planning and Programme Unit, Saint Lucia

Abstract

This paper showcases the importance of 'in-house' planning and 'rapid planning' to reverse 'planning inertia', steward new leadership as well as to boost local planning capacities to address planning challenges in a strategic and actionable way and to overcoming the deficiencies of the traditional static blueprint 'master-planning'.

Keywords

In-house Planning, Capacity-development, Rapid Planning, Community Visioning

1. Introduction

We start on the premise that 'in-house' drafting of urban policy and planning within a short span of time (months, rather than years) is to be preferred over the conventional wholesale outsourcing to private consultancy, especially for small-island states like Saint Lucia, situated in the Southern Caribbean region. It relates to anecdotal evidence that 80% of the knowledge of a city (or any other territory for the matter) is born by its residing communities, with external advisers or consultants only needed to unlock, broaden, deepen and process that community-based knowledge into a visionary and actionable plan. There is not much theory to backup this premise, but we will share what we found and what we find useful as planning practitioners. We are indeed aware of the need for mutual benefit between the theory and praxis of planning, despite the very contextual character of urban and territorial planning. This in-house/rapid planning approach was recently tested in Castries, Saint Lucia's capital city; thanks to all the stakeholders and individuals who voluntarily contributed to a new people-centred Shared Vision for Castries. The visioning exercise was executed within a compressed timeline of only 4 months and a very constraint budget-frame.

The authors of this article were both highly involved in the drafting of the Castries Vision 2030, in their respective roles as external adviser and domestic chair of the planning team. This paper is also their testament form the practitioners' experience with in-house and rapid planning as means to address the pressing challenges related to depopulation of the core-city, informal housing, urban crime, environmental degradation, traffic congestion and last but not least imminent, the eminent threats triggered by climate change. While the content and output of the plan is worth sharing, the emphasis in this contribution will be on the planning process and concerns related to insufficient and ineffective planning capacities necessary to ensure a stepwise implementation of a Shared Vision that will prepare Castries for its Golden Jubilee as the capital of independent Saint Lucia, in 2029.

2. Castries as a typical Caribbean capital city

With 60,000 inhabitants within the city-region, 20,000 in the core-city and only around 4,000 residents left in the original downtown grid-city, Castries is small in numbers, yet by far the largest city on the island – see Figures 1a/b/c.

Figure 1a: Saint Lucia Urban Structure

Figure 1b: Castries planning area

Less than 10km to the north of Castries is the fisherman's town of Gros-Islet, famous for its weekly street-party every Friday. That village, which was highly frequented by Saint Lucian Nobel laureate Derek Walcott, is well-known for its postcard image of Pigeon island. With the passage of time, Gros Islet was gradually developed by the construction of extensive luxury housing and vast tourism estates. An area comprising a large new marina and a shopping mall was eventually built between Gros-Islet and Castries. That area known as Rodney Bay, developed into the most popular tourism settlement within the north of the island, albeit without a clear urban plan. It resulted not only in undermining the economic basis and residential attractiveness of the nearby capital Castries, but also generated a car-dependent traffic volume which hurts the economy, environment and the well-being of the people, especially those within the core-city of Castries where the streets are choked with cars and mini-buses on a daily basis– see Figures 2a/b.

Figure 2a: Mini-buses stationed most of the day in the downtown area, often idling to keep them cool

Figure 2b: Mini-buses encroaching the city-park

These are just some of the reasons why Castries is in fact decaying. Climate change also adds a whole new level of threat, with Castries at risk of devastating floods from both tropical river streams, a rising sea as well as more frequent and severe hurricanes with storm surges up to four (4) meters -see Figure 3.

Figure 3: Flood risks for Castries City-region. Left: river flooding risk; Right: sea flooding risks 1m & 4m (storm surge)[i]

At the more human scale, residents and visitors of Castries complain that the city is no longer attractive to live, study, shop or just stroll around. The wharf that once harboured banana ships is now mainly a container and imported car terminal which in turn generates a lot of traffic and pollution, while the adjacent cruise-ship harbour receives thousands of tourists on a daily basis during the peak cruise season, yet those visitors hardly spend any money off the ship nor in the city, while infrastructural costs and air pollution are disproportionally high in Castries-see Figure 4.

Figure 4: Cargo-port (right) and Cruise-berths[ii]

Yet, Castries remains a dormant beauty blessed by a unique natural harbour and hemmed in by tropical green hills, with ready access to some fine beaches -see Figure 5.

Figure 5a: Castries natural harbour surrounded by hills and beaches[iii]

Despite significant loss of cultural and architectural heritage due to reckless modernization, Castries will always remain the home of Saint Lucia's two Nobel laureates, author Honourable Derek Walcott and economist Sir Arthur Lewis, as well as the home of some typical Caribbean architecture – see Figures 6a/b.

Figure 6a: Restored Derek Walcott house[iv]

Figure 6b: Brazil street in downtown Castries[v]

3. The need for a new vision

The problems are not new, but they have only worsened since the Government of Saint Lucia (GoSL) endorsed the very first National Vision Plan (NVP) for the island, since independence in 1979. The National Vision Plan was an ambitious and costly project which took several years of preparation and was entirely outsourced, albeit with involvement of some domestic architects and planners (there are very few qualified urban planners and designers in St Lucia). The coffee-table book in landscape A3-format, with great photos, graphics and maps, was ready by 2008 and finally approved by the government in 2009 – see Figure 7a/b.

Figure 7a: Cover of National Vision Plan 2008

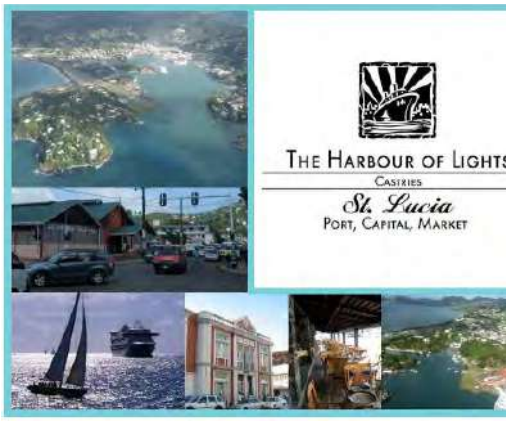

Figure 7b: Branding proposal Castries

The Vision was conceived through the lens of a Miami based consultancy, specialized in tourism and place-marketing. The Plan aimed at boosting Saint Lucia's attractiveness to foreign tourists and tourism related investments whilst maximising the regional share of the growing cruise tourism-market. However, the financial earthquake that devastated Wall Street in 2008, followed by a worldwide financial tsunami, undermined the optimism and appetite to invest in Saint Lucia's Plan and the accompanying bold vision to boost the island's capital city. A lack of political stewardship and professional capacity to readapt the plan and focus public investments towards the same eventually buried the 2008 NVP under a thick layer of dust. Meanwhile the negative trends only got worse and Castries made it onto a chart with Caribbean cruise-ports to avoid; rife of crime and nothing really to see (unless you decide to pay a lot to be driven or sailed to more picturesque places on the island, such as the sulphur springs or majestic Pitons in Soufriere.)

In 2018, 10 years after the conception of the NVP, Prime-minister Alan Chastanet, a well-respected multi-hotel owner and former tourism minister (during the creation of the NVP), decided that it was time to dust off the old vision. Instead of tasking the spatial planning ministry with the review, he endowed the review of the Castries chapter of the NVP to his ministry of Finance, stewarded by the Permanent Secretary of the Department of Finance. - This proved to have been a thoughtful initiative as all ministries have some level of direct dependence or at least a working relationship with the Department of Finance. Stewardship by the - Ministry of Physical Planning would have likely been perceived as 'sectorial' and more detached from the economy and overall national finance/budget cycle. This particular component will be subsequently revisited later on in this paper.

The United Nations Office for Project Services (UNOPS), the UN's building agency which was already operating in Saint Lucia where they assisted with the construction of a segment of a new hospital as well as other critical infrastructures, developed a proposal to help an in-house review of the 2008 plan. The proposal including the designing and setting up a new institutional mechanism to plan and implement the updated plan. However, only the review portion of that proposal was approved, while it was agreed that the implementation mechanism would form part of a follow up stage . Meanwhile UNOPS was also tasked to help with the establishment of a new National Integrated Planning and Programme Unit / NIPP Unit (within the Finance Department), of which co-author Haward Wells was appointed as the director.

4. The planning approach

Principal author Frank D'hondt was contracted as leading planning expert, later complemented by Washington-based urban planner Adriana Navarro Sertich and backed up by the local UNOPS-team led by Christopher Roberts and Fabian Felix. Haward Wells originally worked as an architect at the planning department, it was therefore a logical choice that he was also appointed as chairman of the Castries Planning Team which composed of representatives from relevant ministerial departments. This five (5)member strong core-team was the engine of the planning project and was guided and supported by the Ms Cointha Thomas Permanent Secretary (PS) of the Department of Finance who chaired the Steering Committee (SC) and principal liaison officer to the Prime-minister (PM) on the Visioning exercise – see Figures 8a/b.

Figure 8a: Planning-team meeting in Planning-room

Figure 8b: Discussion with the Prime-minster (standing)

While staffing and resources were being finalized for the abovementioned structures, the lead-expert of the team had already undertaken a preliminary review of the NVP 2008 and drafted a first review note which in summary dismissed the old vision as a document which did not pass- the test of sustainable development as defined by the SDGs, the Climate Accord and the New Urban Agenda. Therefore, with the consent of the Steering Committee, this initial review resulted in a courageous decision to develop a more sustainable and shared vision that would replace, rather than dust off the old 2008 vision for Castries. This illustrates the importance of using the current body of planning knowledge to quickly but critically assess existing policies and plans before simply updating them. It is also important

to stress the fundamental difference between developing a shared vision and a masterplan, which we will further elaborate at the end.

With the project timeline fixed from the inception of the exercise delivery of the final document was scheduled for three months after the start of work. With very limited financial and human resources at hand, an ambitious yet realistic planning approach was required for a success realisation of this exercise. A first critical step was to secure a fixed location (a situation room) where the planning team met and worked, put up maps, created and put up "to-do lists" and invited stakeholders for interactive talks. The space was also the venue for several focus group meetings. It was also at this very same location that two months into the planning works, a critical five-hour long, hands-on meeting, took place between the core team, the Permanent Secretary of the Department of Finance and the Prime Minister of Saint Lucia – see Figure 8b. This proved to have been critical for the ultimate delivery of a final draft-Vision which was eventually endorsed by the country's cabinet of ministers. This indicated the importance of;

i) a dedicated planning room;

ii) an open engagement with the political leadership needed to steward the implementation of the vision.

The second critical step in the planning process was to properly staff and capacitate both the extended Planning Team and the Steering Committee, as the principal authors of the new vision. While the entire operation was initiated and stewarded by the island-government, it was essential to seek and obtain commitment and active involvement by the Mayor's Office. A Mayor is not a very powerful position in Saint Lucia but luckily this Mayor, Mr. Peterson Francis wants to expand the role of the City Council in the redevelopment of the city, thus making him a potentially strong partner for the Prime-Minister as it regards the redevelopment of Castries, and if possible, making him the public face to promote and pursue the Shared Vision.

The third step was to have identified all essential stakeholders and the organization of focus group meetings round clusters of topics that were related to the redevelopment of Castries. In a relatively short space of time, five focus group meetings were held in the 'situation room', followed by a plenary gathering of all focus groups (at an executive level), which was dubbed the first Castries Urban Forum. Thanks to the relentless efforts of the planning team and the addition of new staff to the NIPP unit, the Forum was able to whites the successfully gathering of approximately seventy key stakeholders which included the port authority, Saint Lucia chamber of commerce, vendors association representative, the Saint Lucia National Trust, etc.– see Figure 9.

Figure 9: First Castries Urban Forum

The CUF was co-chaired by the Finance Ministry and the Mayor's Office. The CUF successfully adopted a joint declaration which was prepared by the planning team; – to advocate a people-centred and participatory Shared Vision that is more bottom up than top down. Whilst the time-frame and resources did not all allow for a full-scale participatory planning process with ample access to all residents of Castries and beyond, the CUF at least provided the basis for a multi-stakeholder visioning process. At the CUF, after a briefing, all stakeholders at the gathering engaged in cross-sectoral discussions that elaborated their ideas for a better Castries, based on collective memory-mapping and basic joint-fact finding ;a visioning technique that's well tested all over the world (see e.g. UN-HABITAT, 2012).

Once a draft-report was consolidated, the CUF was reconvened to take stock of the Vision and to have reflected on the -outcome document.

The overall approach to planning was based on the 'Theory of Change' and 'Result Based Management' methodologies. In that sense the Vision is part of a broader strategy to gradually step up the knowledge, instruments, capacities and resources for a participatory strategic planning approach that will result in direct outputs (the Vision report), outcomes (transformational projects implemented) and impacts (a more sustainable land-use and mobility).

As was previously mentioned, an initial expert-review was presented to the Steering Committee, which spurred the final decision to refocus on a new vision rather than having to dust off the old vision. This initial review gradually developed into a more comprehensive review of the NVP, which was in turn informed by the enveloping vision. The final review report was presented as an annex to the new vision, with the request to overwrite the old vision -with the new vision, except for the planning components that were considered as complementary to and compliant with the new vision. Figure 11 is a graphic illustration of what was rejected from the old vision and components that were re-endorsed in that vision.

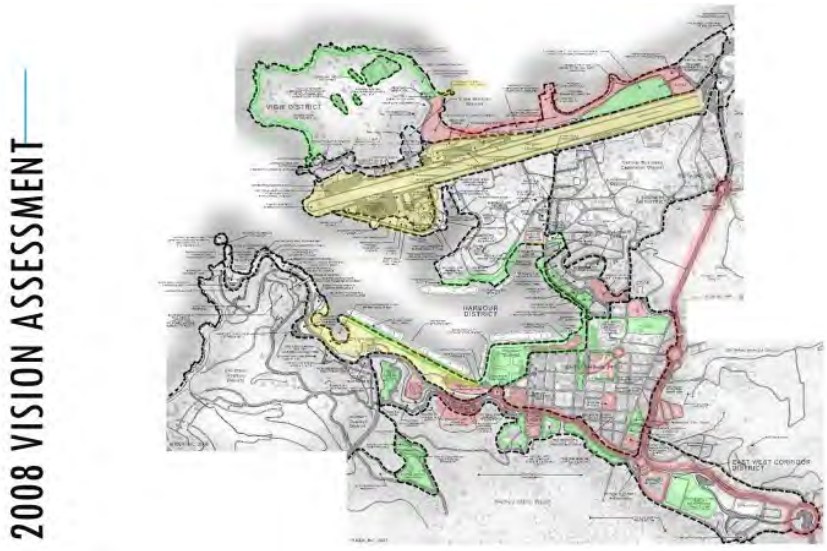

Figure 11: Colour coded review of the Castries spatial outline 2008 (denounced interventions are red-coloured)

From the inception, a draft-content structure of the final report was presented to and approved by the SC as the general guide for the compressed planning works which was to be delivered within that three month period. The initial idea to produce a magazine-styled report did not materialize, however, the final report largely followed the initial content-structure. This assured that the writing-process maintained traction and remained focused. Figure 12 shows the cover of the report which illustrates a more people-centred approach by framing cycling youth around the Derek Walcott square, in downtown Castries.

Lacking the resources for proper imagery, a passionate staff member from the Department of Finance captured drone images of the core-city with his personal equipment, in addition to photos and video's at ground level. Video-recordings were also done of all-important meetings including the presentations of the draft-vision document. This type of material will prove its value in follow up stages of the vision.

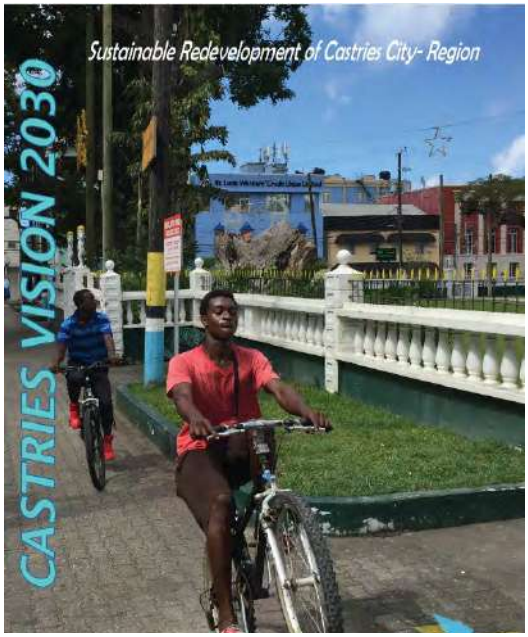

Figure 12: Cover of Castries Vision 2030 report

Finally, a cabinet-note was drafted as per official protocol reflecting the Cabinet of Ministers' wise cabinet-decision to have endorsed the new Castries Vision 2030. The note also included instructions regarding the next steps, as well as some critical conditions beyond the vision plan, such as the need to reform the current planning system, the need for new planning and financial instruments and the need for capacity building as well as institutional innovation.

5. The planning content

The planning report follows a classic sequence of 'past-present-future'. After establishing the planning approach and having introduced the SDGs and NUA as guiding policy frameworks, a chapter was dedicated to the rich history of Castries as a natural harbour, colonized by the French and the British and consequently resulted in a French grid-city surrounded by British military fortresses. This chapter also included the outcomes of the collective memory mapping of all stakeholders involved in the visioning exercise, with a collection of their shared places and the events that constituted their sense of place in Castries and its surroundings. Prominent and mostly elderly people were quoted from their opinions on what should be preserved or restored. There was lots of strong emphasis placed on the lost common and public spaces such as the river, the beaches, the parks and the squares.

The present situation of Castries City-region was captured in a long chapter which attempted to identify some baseline-indicators for what needed to be changed or improved within the new vision document. Given the fact that data were not readily available and that time was limited, planning team members were tasked with the collection of all existing data which was also complemented by the use of relevant expert-analysis. This was essential for evidence-based planning as well as for future monitoring and evaluation purposes. Overall, this chapter on the State of Castries City-region provided convincing arguments necessary for a radical change of gears and the advocacy of 'business as unusual'. At the end of this chapter, a combined SWOT-analysis was presented based on the inputs of the different Focus Groups which was the basis for the definition of three SWOT-strategies which can be interpreted as the following planning or development scenarios;

i) the risky 'offensive strategy'- to bet on tourism as the engine of redevelopment, versus the 'defensive strategy' - to focus all energies on climate resilience;

ii) an in-between 'transformational strategy' -to focus on urban renewal and a more liveable city for its residents

– see Figure 15. These scenarios proved to have been very helpful in the justification of a series of proposed interventions aimed at the implementation of the Shared Vision.

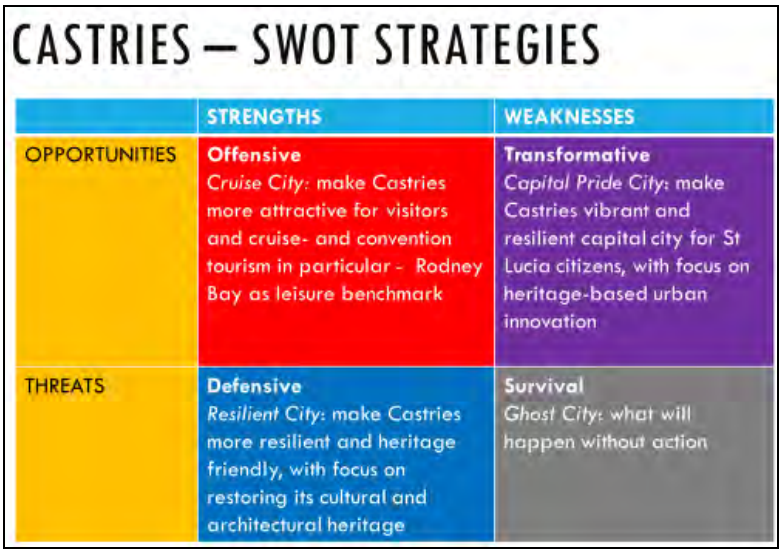

Figure 15: SWOT-Strategies/Vision-Scenario's for Castries 2030

This Shared Vision has been outlined in the next chapter, and it was based on the vision statements t resulting from the Focus Groups and the Castries Urban Forum. An integrated vision statement was derived from ten thematic vision statements. That new statement aligned with the SDGs, the Climate Accord, the NUA and the International Guidelines on Urban and Territorial Planning (IG-UTP) (UN-HABITAT, 2018 & 2018) – see Figures 16a/b.

Figure 16a: Thematic Vision Statements

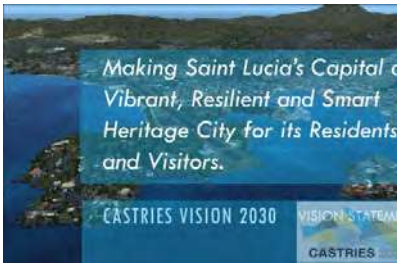

Figure 16b: Integrated Vision Statement

The Shared Vision also included schematic spatial outlines of both the City-region and its Core-city, which was further detailed in the next chapter entitled 'Area-based development'.

Nine strategic focus areas were selected and detailed in terms of development perspectives and desirable spatial interventions – see Figure 17a. This provided a roadmap for a stepwise implementation of the Shared Vision along with ten Transformational Projects, including the necessary regional and international benchmarks for compliance – see Figure 17b.

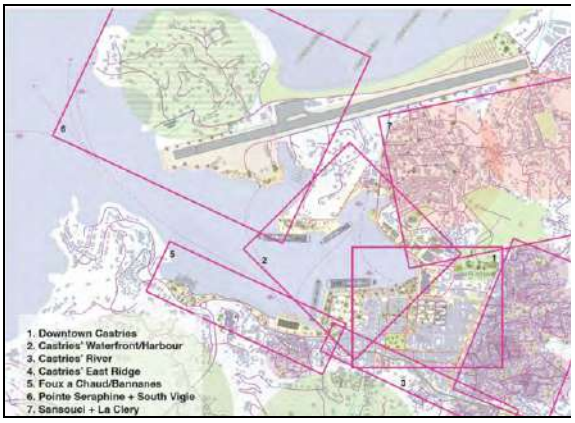

Figure 17a: Area-based development outline and focus-areas

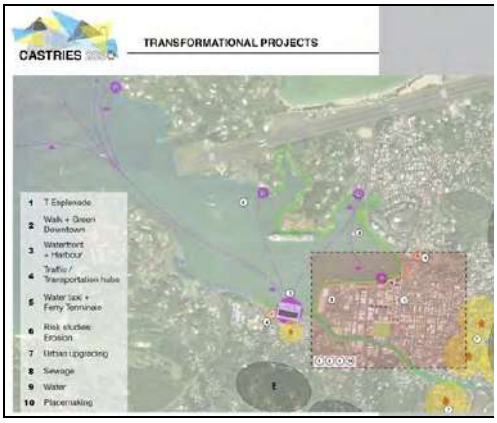

Figure 17b: Overview of Transformational Projects

A final chapter was dedicated to the implementation process of the Shared Vision and it is important to note that this was a glaring omission in the 2008 Vision document. This implementation process includes seven critical parameters necessary for the successful implementation of the vision. Also included was the design, establishment and management

of a specific implementation mechanism such as a Castries Development Agency – see Figure 18.

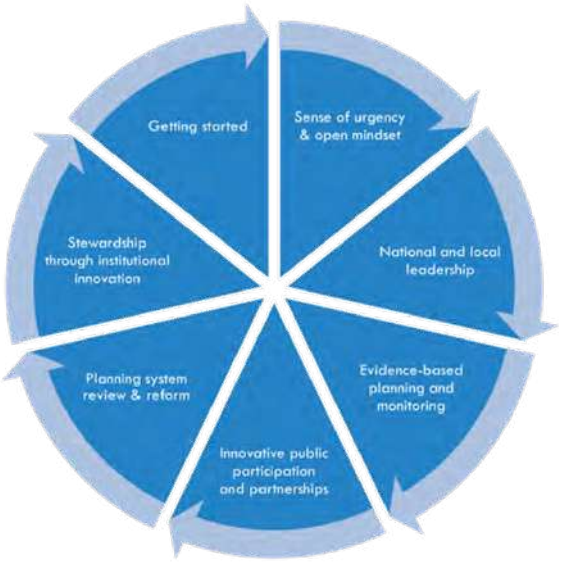

Figure 18: Critical conditions to implement the Castries Vision 2030

6. The executive decision

The draft-report was presented to the entire Cabinet of Ministers by the leading urban expert, backed by other members of the core-team. Whilst the Prime Minister was initially sceptical about the Vision during previous meetings, on this instance, he was instrumental in selling the contents of the vision to other sceptical members of his cabinet. The previously mentioned five-hour long meeting with the island's leader, along with the subsequent reviews to the document after that meeting, greatly aided the way the Cabinet received the final presentation of the vision. The Government of Saint Lucia finally endorsed the Shared Vision as a good basis for further public consultation and as a document that will aid the preparation of a gradual implementation of the Vision, along the line of the proposed transformational projects.

7. The next steps

Immediate next steps include the publication of the Shared Vision and the organization of a larger public consultation drive to rally broader support and to gather more ideas for the actual implementation of the Vision. This consultation process could be best stewarded by the Mayor's Office, however, the Government must also mobilize its efforts island-wide in order to harness additional ideas for the strengthening of the capital city function of Castries.

A crucial next step is to obtain cost-estimates for the Transformational projects and to suggest the financing mechanisms, (both internal and external) for the execution of those projects. Those mechanisms should also incorporate the informal support pledges already received from the World Bank and the Caribbean Development Bank representatives, after having received presentations of the Shared Vision in Castries. Finally, the implementation

mechanism needs to be thoroughly established and made operational at the soonest so as to maintain the positive momentum currently exists around the Castries Vision 2030. As a result of the successful planning approach for Castries, the PS also advocates a similar approach for other cities and territories within Saint Lucia, which will ultimately lead to the gradual revision of the entire 2008 National Vision Plan.

8. Lessons learned

The first lesson learnt was that the planning process design really matters and that it must be well tailored to the local context, the local planning culture and the local planning capacities. A second lesson was that pre-set timeframes and limited budgets for delivering planning products (as was the case for the Castries vision) is not necessarily compromising the quality of those planning products, provided that in-house and local 'agents of change' can be mobilized and empowered.

A third lesson learned was that investing time and trust in political leadership (both at central and local level) can pay dividends when it comes to buying into the planning process. Without the stewardship of both the PM and the Mayor, the planning project would have probably been a more traditional technocratic piece of work. However, the downside to this approach is that a number of planning issues risk being 'over-politicised' as part of the political bargain and can consequently undermine the sustainability factor of the vision. In the case of the Castries Vision, there were indeed a number of 'contentious' issues that to date remain unsolved and may consequently result in the government pursuing developments that are contrary to the Shared Vision.

In this instance a remedy is to at least increase the transparency of decision making, as it also remains a democratic right to make the wrong decisions. Having considered the short-project duration and the low-budget for the execution of a that vision as well as the realisation of a strategic plan for an entire city-region; it is safe to say that such an approach cannot truly be a bottom-up undertaking, nor a an exercise of full participation. . We therefore admit that this was a mistake in the initial process design, however, we must t also acknowledge the unintended change of scope, as the initial exercise comprised only the review of the old vision and not the development of an entirely new vision.

Local planning-process innovations such as the Castries Urban Forum and the open-door planning room guaranteed way more stakeholder consultation relative to the 2008 vision exercise. The final lesson learnt was that all stakeholders involved in this planning project agreed, (whether from Castries or other parts of Saint Lucia) that this in-house/in-sourced multi-stakeholder planning approach worked much better than the outsourced master-planning approach that was applied in the old but binding, 2008 National Vision Plan. The approach even inspired the Finance PS to consider future proposals for the replication of this approach for other areas of the island.

This approach has also inspired the Caribbean Development Bank to extend an invitation to members of the planning team for their participation and presentation of this vision at the next Caribbean Urban Forum, which will be an excellent opportunity to share this invaluable experience with peers within the wider Caribbean region. UNOPS is well placed to link the Castries experience with its similar experience in Willemstad (Curaçao), where the organization supported community and expert-based Visioning workshops that lead to a

roadmap for the localising the New Urban Agenda through an Urban Transformation policy. – see Figure 19. Peer-learning and city to city cooperation are also essential instruments to be incorporated into the planning process design and budget.

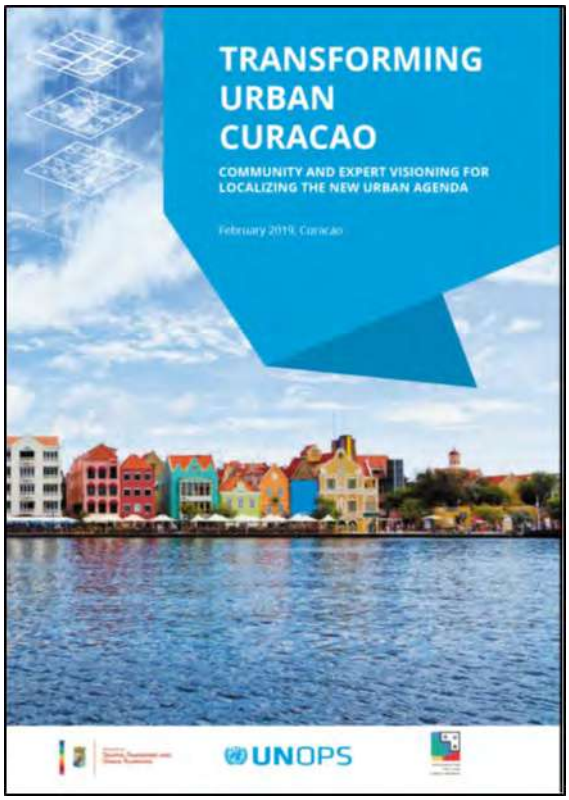

Figure 19: Cover of Curaçao Urban Transformation report co-produced by the Curaçao Ministry of Planning, UNOPS and ISOCARP

This brings us to the larger debate about in-house versus outsourcing of strategic planning projects. As was previously mentioned, there appears to be limited material to support the theory on this issue, at least not in the spatial planning domain. Most of the professional and academic discussion is focused on technically related outsourcing from public to private entities. More on this is elaborated in D'hondt's contribution to ISOCARP Review 15 – 'Beyond the Plan: Building In-House Capacity To Plan, Design And Implement Urban And Territorial Interventions – Learning From Practices From West To East' (ISOCARP, 2019). Outsourcing is generally well understood, while the difference between insourcing and in-house might need some clarification.

In our view, in-house is simply performing a planning activity by contractual staff members of the planning authority or institution, e.g. a national, regional or local planning department, eventually with the help of other departments within the same mother organisation, e.g. the national, regional or local government, or its administration. In-sourcing however, could be considered as a variant of in-house with the help of external experts, whether from private or related public sector. The main difference between out- and in-sourcing is that out-sourced planning tasks are typically executed by a planning consultancy with the bulk of the work done outside of the planning authority, while in-sourcing typically involves planning experts that help to execute the bulk of the work inside the planning authority. Planning actors can apply both in-house/out-house options but a line is drawn between wholesale outsourcing on the one hand and partial outsourcing on the other hand.

In the case of the latter, planning actors execute more than approximately half of the planning work in-house, complemented by in-sourcing and/or out-sourcing – often labelled as the hybrid model. In general, there are two main questions to be answered at the start of a planning activity, namely;

i) whether to opt for the 'in-house', the 'outsource' or the hybrid model?

ii) whether the needs and specific activities for outsource and/or insource should be defined in case of the hybrid option?

Lessons learned from Saint Lucia (and Curaçao) experiences is that these Small-Island States simply do not have the resources to develop all the capacities and skills needed for in-house planning. The resulting dependency on outsourced plans and designs is often more harmful than helpful. Temporary in-sourcing of experts through agencies such as the UN or the World Bank is certainly a smarter way to complement in-house capacities, however, too often the gains are of a temporary nature. Hence, a more sustainable in-house/in-sourcing capacity development pathway could be explored by looking at capacity support mechanisms at the regional level for the Caribbean, or more practically according to the various language preferences of the region (primarily English, French, Spanish, Dutch and/or Papiamentu) – e.g. a Caribbean Urban and Territorial Planning Institute can be established under CARICOM and can comprise different language branches.

9. Conclusion and recommendations

Our cities and territories need good planning and management to thrive while keeping our planet healthy. Planned urbanisation and territorial development provides an avenue for sustainable social and economic development. In 'Leading Change- Delivering the New Urban Agenda through Urban and Territorial Planning', international planning experts strongly advocate to engage in urban and territorial planning processes that are strategic and participatory, with plans that are simple, clear and rapid (SALGA/UN-HABITAT, 2018). However, the high rate of urban growth far outpaces the capacity of many governments and other institutions to plan and manage this growth in a sustainable, effective and efficient manner. In the slipstream of the New Urban Agenda, many scholars have already pointed to the dangerous gap between planning expectations and planning capacities, both in numbers and quality. In her key-note speech at the 52nd ISOCARP world congress in Durban, Vanessa Watson, planning professor at Cape Town University said: "Planning is located as a central implementing tool in the Agenda but is it an approach to planning which can achieve these very high expectations?" (WATSON, 2016). Governments, education providers as well as the planning community will need to step up and scale up efforts to boost the planning capacities needed for basic in-house planning and well stewarded in/outsourcing, not only to advance more sustainable territorial development but as well as to prevent a looming discredit of the planning discipline as not being able to deliver on its promises as expressed by SDG11, the NUA and the IGUTP.

The IGUTP includes a recommendation to: "Design a human resource development strategy to strengthen local capacities, to be supported by other spheres of government, as appropriate; Reinforce institutional and human capacity development at the local level in the areas of planning, design, management and monitoring, through training, exchanges of experience and expertise, knowledge transfers and organisational reviews."

In the handbook to apply the IGUTP (UN-Habitat, 2018), 'planning capacity needs' are considered as essential capacities and skills to meet the planning challenges of a certain territory, while the 'planning capacity aspirations' also look beyond these current needs and towards desirable planning capacities to aspire more ambitious goals on medium and long term. In both cases, capacity development needs to be planned and implemented; this is best referred to as 'Capacity Planning'.

Typically, 'capacity building' often means training. Certainly, this is a major component of Capacity building, however, if decision makers, managers, professionals and technicians are

to operate at full capacity, they need more than just their own capabilities. They need a conductive and supportive institutional and organisational environment. Therefore, capacity building must embrace the following three basic aspects:

i) human resource development;

ii) organisational development; and

iii) institutional development[vi].

Should we look beyond the confines of traditional professional boundaries and state institutions, beyond attempts to micro-manage land-use and the discredited top-down technocratic master plans; then we can discern a new set of skills for planning and managing urban and territorial development which comprises the following: i) Analytical and cognitive skills; ii) Communication, negotiation and inclusion skills; iii) Strategic action skills; iv) Management skills; and v) Monitoring and learning skills[vii].

Equipped with these understandings and tools, a re-thinking of planning capacity support for quality in-house planning is at stake to implement the commitments made through the New Urban Agenda, including: "We will promote the strengthening of the capacity of national, subnational and local governments, including local government associations, as appropriate, to work with women and girls, children and youth, older persons and persons with disabilities, indigenous peoples and local communities, and those in vulnerable situations, as well as with civil society, academia and research institutions in shaping organisational and institutional governance processes, enabling them to participate effectively in decision-making about urban and territorial development."

This will need a parallel two-track approaches which should entail the following:

i) governmental planning capacity development support to local authorities, to central level authorities and agencies in addition to existing governmental capacity providers; and

ii) non-governmental planning capacity development support: legal and planning advice and support for individuals, communities, civil society organisations, business community. This includes planning education and research, as well planning advocacy and awareness (media).

To that this end we advocate territorial platforms (at regional, national and even transnational levels) for capacity planning and development that will provide the institutional support mechanism to address the growing capacity and human capital deficit to implement the Sustainable Development and New Urban Agenda's. These platforms should address both governmental and non-governmental capacity needs and aspirations, as an intermediate agent between national and local governments on one hand, and civil society, the business community and communities on the other hand; while interacting with and seeking occasional support from both the international community and the education and research sectors.

Metropolitan Governance in Southern Europe:

Working Across sSectors and Boundaries

Jose Alvaro Antunes FERREIRA, Joana ALMEIDA, Pedro PINTO

Abstract

Metropolitan areas have long been understood to benefit from the existence of regional governance structures. However, some large urban areas still lack effective coordinating agencies. In the case of Lisbon, Portugal, the legal framework has been steadily refined since 1991 to task the Metropolitan Area with a set of mandates, but has yet to be granted a compatible framework in terms of coordinating power and human/financial resources. Portugal, in comparison to others European countries, suffered a late urbanisation and even more recent metropolization. The accelerated, formal and informal growth of the metropolitan area was achieved through the intervention of a broad but not well-coordinated group of actors with very high costs of effectiveness and efficiency, penalising the quality of metropolitan life. The future, and roles, of metropolitan areas in the country have been entangled in the politically-sensitive debate surrounding regionalisation. Inter-municipal collaboration tends to occur only in contexts of cross-border, mutually beneficial, specific projects and/or where there were incentives for collaboration (such as additional funding).

Our study of comparable southern European metropolitan area governance structures is focused on analysing the scope of their mandates, in terms of sectors and level of planning, management and legislative authority, and highlight a set of 'best practices' for tackling the new political, institutional, and economic contexts. Thus, this paper provides an updated state of the art by critically scrutinising of metropolitan governance models in similar economic, political and cultural contexts. We seek to answer the following questions: What governance models exist in Southern Europe? How do they work? Who is involved? How do public and private entities interact throughout the process? From this analysis, we develop proposals on how to improve metropolitan governance structures.

The methodology is based on the review of literature (legal documents, academic papers) with the objective of identifying the variables to be analysed and the relevant case studies, which is complemented with interviews with experts and stakeholders of each country to refine the information on the inner workings of each metropolitan area governance structure. Four case studies located in Southern Europe were selected considering some governance principles and comparable criteria based on the demographic and economic dimensions as well as metropolitan challenges that they face. We focus especially on answering the question of how/if metropolitan governance structures promote inter-sectoral cooperation and coordination, and how multi-jurisdictional collaboration is conducted. Southern Europe countries have recently furthered metropolitan areas administrative/legislative powers, often accompanied with the creation of elected government bodies, such as a metropolitan mayor or a metropolitan assembly.

Increasing the visibility, transparency, and accountability of regional coordinating authorities therefore appears to be a trend in several southern European countries. These metropolitan areas are now host to a constellation of new actors (private lobbies, interest groups, NGOs) and

emerging societal challenges (aging, climate change, mobility, e-government, economic crisis, immigration, housing, among others) that are often incompatible with fragmentary, sectoral action, requiring instead concerted solution across sectors and involving multiple jurisdictions. Best practices suggest that the creation of truly collaborative networks can, and should be, promoted by the metropolitan areas. These entities should hold a role as mediators between different stakes, and as facilitators of cooperative action, while not foregoing their authority as decision-makers. From our comparative analysis, metropolitan governance structures will become effective only when vested with the appropriate resources (funding, expertise, decentralised authority).

Case Study / Project

Mapping institutions and actors in urban coastal management of Jakarta's Bay

Arif GANDAPURNAMA, Irene SONDANG, Ahmad ZUBAIR, Nala HUTASOIT

Abstract

The coastal is one among the densest area of the cities. Along with rapid development, there are environmental and social pressures. Environmental risk has been an unavoidable part for a long time, and the reduction effort still happened until now. The climate change impact has also contributed greatly to the losses and damages that occur in the coastal area. It is also forecasted that, if global warming continues at its current rate, some areas in Jakarta will be inundated by 2050 (Firman 2010; Measey 2010). Furthermore, many other areas in North and Central Jakarta are likely to be submerged in the future, which will cause major suffering for residents as a result of the physical and socio-economic impacts (Firman 2010).Meanwhile, social cohesion as a result of development and degradation of environmental conditions is also growing day by day. Various types of interests has direct the coastal development to many things depending on stakeholder's interests. Coastal management of Jakarta Bay has a multi-level basis, with different levels of intervention. Engagement between the government, private sector, non-governmental organizations (NGOs), international NGOs, and community-based organizations seeks to fill the gap in coastal management. However, the complexity of its roles and functions has resulted in difficulties in coordination and implementation of programs in Jakarta's Bay. One of the impacts of the absence of a comprehensive understanding of coastal management in Jakarta's Bay is the resistance from any stakeholder and inefficiency of the development program. To see through this context, planning policy and governance of implementation are two of many ways to identify the direction of development along with the stakeholder's interest in urban coastal management. Modified from the United Cities and Local Government analysis in several cities in European and American cities that the dynamic relationships between the government, civil society and the market are bringing about far-reaching changes in traditional ways of governing including implementation the public policies of coastal planning and management. It's not only through coastal society to social service delivery but also through the formation of associative networks, i.e. public-private partnerships which shape policy decisions. Associative networks are contributing to the emergence of a new style of governing based on participation, co-operation and shared responsibility. This research has a comprehensive understanding of governance on Jakarta's bay. Having a mixed method methodology through content analysis and actor mapping tools, this paper describes a network of interactions between state and non-state actors regulating the planning process until implementation in the coastal development of Jakarta. By doing this methodology, we divided into six steps that modified from a concept of actor's interaction to find the linkage among the actors such as 1. Categorize the topics include frame it in an appropriate questions, 2. Identify the actors and grouping with the categorization, 4. List the roles of the actor's internal and external way, 3. Connecting through links between actors, 5. Define influence, motivations among actors, 6. Harvest observations and possible actions of actors. Not only the actors, we also defines the policy from national, province, local until collective agreement that run in practical daily life. Based on the findings, the interrelationships of each actor are complicated so that several policies and plans appear that are not well coordinated. Meanwhile, coastal communities with limited access try to be independent in facing existing problems.

Research Paper

"YENI ISTANBUL": THE EXPANSION OF A GLOBAL CITY

Dimensions of the new mega projects in global cities situated at the periphery of North-American and West-European capitalist economies from a governance and planning process perspective: case study of Istanbul Airport

GEAMBAZU, Ion Mincu University of Architecture and Urban Planning; Romania

Abstract

The spread of neo-liberal political and economic ideology and the proliferation of global capital have created new opportunities and challenges for cities everywhere (Sassen 2012). Within the urban planning discourse, it is generally assumed that globalization leads to the same type of transformations and urban development trends everywhere in the world. However, it cannot create a certain prototype for spatial development or a new spatial order for cities. Rather, it gives a variety of spatial patterns, also called "global urban forms". Recently, these forms have identified themselves spatially within a series of "mega-projects", their intensity being felt in today's global cities, North-American and West-European, but with a domino effect, especially in the cities situated at the periphery of these capitalist economies. Total global megaproject spending is assessed at USD 6-9 trillion annually, or 8 percent of total global GDP, which denotes the biggest investment boom in human history. Never has systematic and valid knowledge about mega projects therefore been more important to inform policy, practice, and public debate in this highly costly area of business and government. It is argued that the conventional way of managing mega projects has reached a "tension point," where tradition is challenged and reform is emerging (Flyvbjerg, 2011). These kind of projects often take place within fragmented and entrepreneurial forms of governance (Harvey 1989; Healey 1997; Gordon 1997a, 1997b; Feldman 1999; Feinstein 2001; Granath 2005; Butler 2007) represented by public-private partnerships, in a societal environment of increased capital mobility and inter-urban competition (Malone 1996). Hence, it is argued, that mega projects have been examples of new governance styles and policy targets, but also object of intensive local planning debates and conflicts based on different actors (authorities, planners, residents, environmental groups, developers, etc.) holding an equal number of views (Hoyle, 2002) which are often difficult to reconcile. Strongly linked to the 2023 Vision of Turkey, the 3rd airport, Istanbul Airport is one of the mega projects that will bring Turkey among top 10 economically powerful countries. Istanbul

Airport distinguishes itself from a myriad of other build-operate-transfer projects by its governance dynamics and planning process. The study employs discourse analysis through which extracts lesson from the decision-making process that will inform planners in Istanbul and beyond.

Keywords

Urban governance, planning process, mega projects, Istanbul, discourse

1. The new mega projects

1.1. Definition and characteristics of the new mega projects

It is known that mega projects have been constructed since ancient time, if we should look at the Maya cities in Mexico or the pyramids in Egypt or the road networks of the Roman Empire, but the first time they were acknowledged as a concept, was in 1970's in order to describe large scale projects by Canadian government and the American contractor Bechtel, who is also the company that constructed The Channel tunnel between England and France, the longest undersea portion of any tunnel in the world. (Merrow et al., 1988)

After WWII, the Fordist state engaged in a series of *"mega projects"* for the restructuration of urban tissue, the efforts to create a modern society with express ways and high rise buildings. Jane Jacobs (1961 pg. 25), ironically named those efforts and the city:

"radiant garden city beautiful". In the "*great mega-project era*" of the 1950s and 1960s (Altshuler and Luberoff, 2003), the projects were monolithic constructions with little attention for citizen participation and environmental issues. Overcoming the social movements of 1960-1970s, the restrictions of the government and the decentralization associated with neoliberalism, these types of developments unwind, but they do not totally disappear (Altshuler si Luberoff 2003). Surpassing these critics on the left, critics on the right argue that these developments were an unnecessary intrusion of the forces of the government and led to unjustified expropriations of private property (Anderson 1964).

Today's infrastructure mega projects play a key role in nothing less than the creation of what many see as a new world order where people, goods, energy, information and money move about with unprecedented ease. Here the politics of distance is the elimination of distance. (Flyvbjerg, B., Bruzelius, N. and Rothengatter, W., 2003) Mega projects are central to the new politics of distance because infrastructure is increasingly being built as mega projects. Thus, the past decade has seen a sharp increase in the magnitude, frequency and geographical spread of major infrastructure projects, supported by a mixture of national and supranational government, private capital and development banks, namely multibillion-dollar infrastructure projects such as airports, high-speed rail, urban rail, tunnels, bridges, ports, motorways, dams, power plants, water projects, oil and gas extraction projects, information and telecommunications technology systems, and so on.

Never in the history of humankind have we built more, or more expensive, infrastructure projects. To put it in numbers, the size of infrastructure projects has grown by "1.5 to 2.5 %

annually in real terms of the past century "(Flyvbjerg, 2014, p.4). "This is the "tension point" where convention meets reform, power balances change, and new things are happening. In short, it is the place to be as a megaproject planner, manager, scholar, student, owner, or interested citizen." (Flyvbjerg 2014, p.22)

But how big is actually this whole mega project industry? McKinsey Global Institutes (2013) evaluated it with a spending need of a total of 57 trillion in between 2013-2030 (McKinsey & Company, 2013). The Economist estimates a total of 20 trillion until 2030[1] and calls infrastructure mega projects "the biggest investment boom in history".(Flyvbjerg, 2014, 2017) Furthermore, these type of projects have proven themselves recession proof, the downturn of 2008 was not even close abating to their relentless drive and with so many resources and side effects tied to them, their study, understanding and management has never been more important. (Flyvbjerg el al., 2003; Flyvbjerg, 2011,2014,2017)

Leher and Laidley (2008) make a distinction between 'old' and 'new' mega projects[2] in the development of urban economies. The current mode of large-scale urban development is different from its predecessor in so far as its focus is flexible and diverse rather than singular and imposing. However, the diversity that the new approach offers, forecloses upon a wide variety of social practices, reproducing rather than resolving urban inequality and disenfranchisement, shifting from collective benefits to a more individualized form of public benefits. (Leher and Laidley, 2008)

The 'new' mega-projects take the form of vast complexes characterized by a mix of uses, a variety of financing techniques, and a combination of public- and private-sector initiators (Lehrer and Laidley, 2008). The construction of new transport infrastructures, or the extension of existing ones, and complex building projects are examples of these new mega-projects (Diaz Orueta and Fainstein, 2008). They involve a transformation of urban space, its built form and its specific land use and changes the social practices in these urban landscapes (Van Marrewijk and Yanow, 2010;Lehrer and Laidley, 2008;Del Cerro Santamarıa, 2013b). Importantly, new mega-projects are often undertaken by state actors operating in collaboration with private interests in the pursuit of gentrification of city-regions within a competitive global system (Lehrer and Laidley, 2008;Del Cerro Santamarıa, 2013a: xxx).

1.2. Performance paradox and impact in megaprojects

The paradox is that when actual versus predicted performance of mega projects are compared, the picture is often dismal. At the same time as many more and much larger infrastructure projects are being proposed and built around the world, the poor performance of the majority of them is striking in terms of economy, environmental issues and public support. Much often the cost overruns are so high that projects who were planned to boost the economy become the main reason for its fall. (Peter W. G. Morris and George H. Hough, 1992; David Collingridge, 1992; Joseph S. Szyliowicz and Andrew R. Goetz, 1995; Mark Bovens and Paul 't Hart, 1996; Hall; Flyvbjerg, 2011).

A study of 130 mega projects constructed, but also under construction, comprising infrastructure mega projects solely of: road ways, rail ways, airports, metro lines, sea ports, rapid transit, bridges, tunnels and hybrid ones that encompass construction of new transportation means together with urban development, is made for this study with the scope of enlarging the findings in the literature review and test their accurateness. The projects are chosen with a conception year from 1950s until today, excluding statistical outliers. In line with the literature review it is clear, also with this study, that although 1950s and 1960s are considered to be the "mega project era", there is powerful increase in their development number after the 1980s until today. (Figure 1,2)

The main differences between the already constructed mega projects and the ones in construction is the growing budgets, not as trend line, but as a quantitative percentage of much costlier mega projects. While the trend considering the costs for the projects already constructed is decreasing, the new wave of mega projects, starting with mostly 2000, is rising, excluding the possible cost overrun until the completion of the project, which could lead to a sizable growth itself. The most expensive project under development is the High Speed 3-Northern Powerhouse Rail (39 billion $ with an unrealistic 8 years estimation time until its finalization) and for the category of the already constructed ones, it is the AVE - Spain's high-speed railway network (44 billion $, within 24 years), the average of both categories being between 20-25 billion $ and more than 50% under 5 billion $.

In contrast with the literature review, there is a decrease considering the period of time taken for the realization of mega projects, this being relatable to the technological advancement or the more efficient management tools employed in the planning process. Also, there is a big difference between the highest values of the constructed and under construction mega projects: The King Shaka International Airport is completed after 40 years, with the cost of 1 billion $ and having a break from 1982 until its revival in 1990 and the Berlin-Brandenburg International Airport is the lengthiest so far for those under development, with already 24 years so far for the planning process and 11 years' delay from the initial finalization date. Breaks within the planning process are due to due to poor construction planning, execution, management, as well as corruption[3] , which lead to a cost overrun of 7 billion $. (Figure 1,2,3,4)

[3] https://en.wikipedia.org/wiki/Berlin_Brandenburg_Airport

Looking upon the graph on types of mega projects, the most expensive constructed mega project is the AVE - Spain's high-speed railway network and lengthiest is the Panama Canal. When we look at both trend lines of these types of projects, we can observe that any delay in a rail mega project becomes costlier than any delay in a canal mega project and taking into account all trend lines, airport mega projects are the costliest in terms of any setback or suspension. (Figure 3)

For the ones under construction, the representative is the costly mega project Stuttgart 21- Germany (hybrid-railway and urban development) with a cost overrun of 2 billion euros and delay of 2 years so far and many problems considering the governance dynamics with opposition and heated debate on costs and benefits and environmental concerns[4] (Figure 4)

In a comparison of costs and the development period on the type of mega project, constructed and under construction: road ways, rail ways, airports, metro lines, sea ports, rapid transit, bridges, tunnels and hybrid ones, the main conclusions are: the disappearance of the canal projects, the presence of sea ports mostly the construction of new touristic ports lately, the abrupt decrease in construction of bridge, road, metro line and airport projects and the increase in rapid transit, tunnel and hybrid projects. (Figure 3,4)

If we look at the most expensive projects under construction from the last three types of project that lately gain popularity, they are: Stuttgart 21- Germany (hybrid-railway and urban development) stated before; WestConnex- Sydney, Australia (tunnel) with a cost overrun of 8.6 billion $, in 2017 the projects third and final stage being abandoned, highly criticized on economic, social and process grounds and being subject of escalating public protests from academics, architects and resident action groups[5]; Grand Paris Express- France (rapid transit) with an unclear target date as 2030. (Figure nr.3,4)

Just as Merrow et al. (1988) stated before, interestingly, developing countries did not do better or worse than developed countries in executing mega-projects, the trend lines are close in terms of performance considering costs overruns and time spent of project development, although in literature review Flyvbjerg (2011,2014) differentiates them in the railway sector. (Firgure nr. 5)

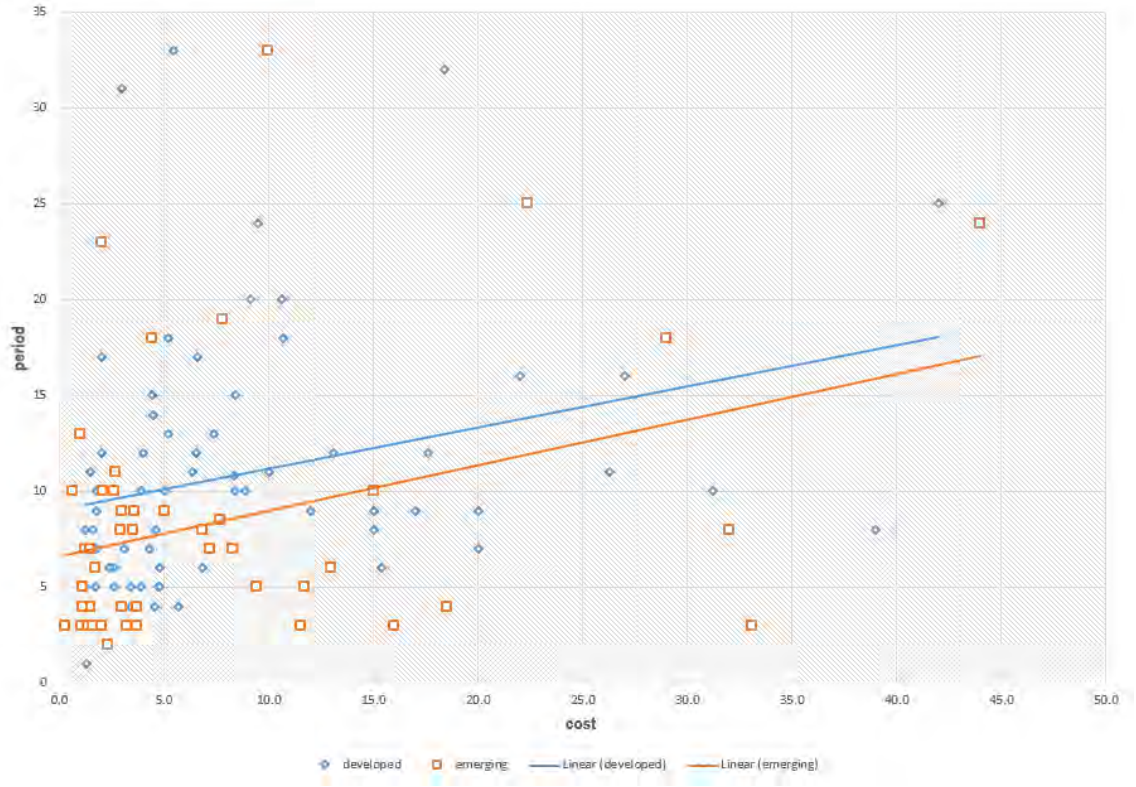

Figure 5: graph on infrastructure mega projects done in developed and emerging countries (1950-2020)- X axis: period, Y axis: cost, legend with types of mega projects

Generally, these developments have been critically examined by many scholars, many of which share the belief that the mega projects are often not addressing the underlying, deep-rooted problems of the cities and furthermore, ignoring the socially and economically unstable landscapes in which they often occur, veritably contributing to the escalation of inequality, polarization and deprivation in the city (Harvey 1989; 2005; Brownill 1990; Gordon 1997b; Hoyle 2000; Saarinen and Kumpulainen 2005; Butler 2007).

Often environmental and social effects of projects have not been taken into account during project development, or they have been severely miscalculated, such problems often destabilize habitats, communities and mega projects themselves, if not dealt with carefully. (Westport, CT: Praeger Publishers, 1998; Paris: OECD, 1993; Roger W. Vickerman, 1994)

Hirschman (1995: vii, xi) calls mega projects "privileged particles of the development process" and points out that often they are *"trait making*", that is, they are designed to ambitiously change the structure of society, as opposed to smaller and more conventional projects that are "*trait taking*," i.e., they fit into pre-existing structures and do not attempt to modify these. The framework of "*exceptionality*" associated with these initiatives favors a more autonomous, if not autocratic, dynamic marked by special plans and projects that relegate statutory norms and procedures to a secondary and subordinated place.

"Exceptionality" is a fundamental feature of the new urban policy, based on the primacy of project-based initiatives over regulatory plans and procedures. These changes involve, as stated before, among other things, the emergence of new policy tools, actors, and institutions, and they have important consequences for urban policy-making in general and for local democracy in particular, considering the increasing inequality in access to decision-making. Therefore, Brenner and Theodore (2004) argue that an important analysis aspect to identify the impact is the role of the state in these kinds of interventions (provision of subsidies, land or special treatment in the tax, etc.) and the level of involvement and its loyalty towards the goals for the public. Mega projects differentiate themselves by the way they combine social and environmental goals with the economical ones, the planning process and impact, reflecting in the same time the level of commitment that the host city has towards the concept of social equity (Fainstein 2009).

1.3. Performance paradox and impact in megaprojects Governance and planning process in mega projects

In literature on mega projects, power, politics and conflicting and opposing interests are generally excluded (Clegg and Kreiner, 2013;Hodgson and Cicmil, 2006). An exception is Flybjerg et al. (2003) who suggest that a main cause of overruns is a lack of realism in initial cost estimates (see revious sub-chapter), motivated by vested interests of partners. Therefore, in his analysis in all continents and despite the differences of geography, political background, social or cultural aspects etc., he identifies a main common characteristic which is misinformation and lack of transparency considering the governance dynamics (Flyvbjerg et al. 2003). Civil society does not have the same say in this arena of public life as it does in others. Mega-projects often come draped in a politics of mistrust, characterized often by a 'democracy deficit'[6] . People fear that the political inequality in access to decision-making processes will lead to an unequal distribution of risks, burdens and benefits from projects. The general public is often skeptical or negative towards projects; the main causes of the mega projects paradox to be inadequate deliberation about risk and lack of accountability in the project decision-making process (Åsa Boholm and Ragnar L¨ ofstedt, 1999; James Bohman 1996)

One of the main issues that is both complex and likely to stir controversy is the question whether mega projects should be publicly or privately led. Understanding the appropriate roles of the two sectors is fundamental to the identification of a process for appraisal and decision making that will ultimately work in the public interest. For major infrastructure projects one could argue an either/or position on public versus private leadership: either such projects should be placed entirely within the public sector – for example in a government department, an agency or a state-owned enterprise – to ensure accountability through the rules of transparency and public control that apply to the public sector; or such projects should be placed entirely in the private sector – for example by means of build-operate-transfer or other concession arrangement – to ensure accountability through competition and market control (Flyvbjerg, Bruzelius and Rothengatter, 2003)

It is argued that two main types of accountability define liberal democracies:

- public-sector accountability through transparency and public control
- private-sector accountability via competition and market control. (Flyvbjerg, Bruzelius and Rothengatter, 2003; Priemus, Flyvbjerg and Wee, 2008 p.138)

According to Clegg and Kreiner (2013) power in mega-projects has to be understood as relational effects, not as sources that can be held by partners. Project design, including contractual arrangements, and project cultures play a role in determining how managers and partners cooperate to achieve project objectives to a greater or lesser extent (Van Marrewijk

[6] term coined by Scandinavians- who like other people around the world have experienced the construction of one megaproject after another during the past decade.

et al., 2008). Therefore, Cicmil and Hodgson (2006b), suggest a more critical approach to understand the planning process of projects by exploring how the relationships between individuals and the project organization are produced and reproduced, how power relations create and sustain social relations.

2. Analyzing planning through discourse

The study of discourse is an important way of understanding how power is mediated in planning, capturing what planners do, how they respond to challenges, how are the planning problems being constructed, how are the solutions prioritized and how are the political pressures handled (Forester, 1989; Healey, 1992b; 1996; 1999; Innes, 1995; 1998) Discourse is a broad exchange of ideas and points of view among various individuals in a particular situation. In urban planning, a discourse might include the set of working papers, plan documents, media coverage, written or spoken statements expressing points of view on issues and proposed ways of addressing them and it has important implications in the policy analysis and planning itself.

Critical theories of Habermas, Derrida, and Foucault often provide the substantive underpinnings of discourse analysis. Many scholars such as Healy (1992b) and Forester (1989) have placed their **planning analysis within the communicative rationality of Habermas[7],** referring to the capacity to engage in argumentation under conditions approximating to an ideal speech situation ('discourse', in Habermas' terminology), with the

aim of achieving consensus (Dews, 1998).

Boyer (1983), on the other hand, employed Foucault's idea of a `genealogical' framework [8]to study how planning evolved over years. In *Dreaming the Rational City*[9], she focuses on the "apparatus of planning: what Focault has defined as the relationships among a set of distinct elements such as professional discourses, governmental institutions, administrative procedures, regulatory laws, legal concepts, architectural forms and plans, scientific statements, and moral proclamations" (p.xi) and on what happened once planning was called upon making cities "new areas for public policy" and " to maintain and preserve sound

[7] "communicative rationality carries with it connotation based ultimately on the central experience of the unconstrained, unifying, consensus-bringing force of argumentative speech, in which different participants overcome their merely subjective views and, owing to the mutuality of rationally motivated conviction, 11 assure themselves of both the unity of the objective world and the intersubjectivity of their lifeworld" (Habermas, 1984, p. 10, cited in Rienstra and Hook, 2006, p.11).

[8] Foucault's genealogical history seeks to deconstruct what was previously regarded as unified (i.e. history as a chronological pattern of events emanating from a mystified but all-determining point of departure), while also attempting to identify an underlying continuity which is the product of "discontinuous systematicities".

[9] *Dreaming the Rational City* is both a history of the city planning profession in the United States and a major polemical statement about the effort to plan and reform the American city. Boyer shows why city planning, which had so much promise at the outset for making cities more liveable, largely failed. She reveals planning's real responsibilities and goals, including the kind of "rational order" that was actually forseen by the planning mentality, and concludes that the planners have continuously served the needs of the dominant capitalist economy.

capital investments already committed to infrastructure and real estate from areas experiencing blight, abandonments and disinvestment" (Boyer, 1983, p.207)

Fairclough (1992; 1995) and Fairclough and Wodak's (1997) critical discourse analysis is derived from Foucault's archaeological and genealogical works as well, exploring the nature of discourse and its relationship with power.In contrast to the Hegelian and Marxist philosophies of history, 'genealogy' is *not* a *holistic* project but a *perspectival* one. Foucauldian genealogy is an history of tracing 'origins' and unearths the *force relations* operating in particular events and historical developments. Foucault describes his genealogy as an "effective history".[10] (Focault,1984, cited in Sembou, 2011, p.2)

Flyvbjerg (1998) who studied extensively mega projects, employs the Foucauldian, Nietzschean, and Kantian notions of power in planning discourse and arrives to the conclusion that rationality is often determined by power and not by ideals of reason or democracy. Varied applications of discourse analysis in the urban policy context are demonstrated, Mienhof and Richardson's (1994) collection of essays explores the discourse on poverty in Britain in the 1990s drawn mainly from the mass media.Other approaches for studying discourses include the use of `rhetoric' (Throgmorton,1993), `framing' (Rein and Schon, 1993), and storytelling (Forester, 1989; Kaplan, 1986;Mandelbaum, 1990; 1991).

The idea of a `discourse coalition' is put forward by Hajer (1993), which he presents as a group of actors who share a social construct.

"A discourse coalition is the ensemble of a set of story lines, the actors that utters these story lines, and the practices that conform to these story lines, all organized around a discourse." (Hajer 1993, p. 47).

To dominate a given political realm, a discourse coalition must fulfill two conditions:

- "it dominates the discursive space (discourse structuration) that is, central actors are persuaded by, or forced to accept, the rhetorical power of a new discourse;
- this is reflected in institutional practices (discourse institutionalisation) that is, the actual policy process is conducted according to the ideas of a given discourse." (Hajer 1993, p. 48).

In the *Discourse Coalitions and the Institutionalization of Practice: The Case of Acid Rain in Great Britain*[11], Hajer writes about how different were the approaches to the environmental politics discourse in the post-World War II period in the context of Keynesian welfare state and the neoliberalist era under Prime Minister Margaret Thatcher in Britain. It had, of

[10] M. Foucault, "Nietzsche, Genealogy, History", in *The Foucault Reader*, ed. P. Rabinow (Harmondsworth: Penguin, 1984), pp. 87-90.

[11] Chapter of the book The Argumentative Turn in Policy Analysis and Planning edited by The Argumentative Turn in Policy Analysis and Planning edited by Frank Fischer and John Forester

course, much more popularity during the first period, considering the values of the state concerned a growth economy based on a social contract between capital and labor in contrast with the Thatcher's aim of reinforcing the industry's competitiveness. (Hajer 1993, p.70)

Linked to these coalitions, Moore Milroy's (1989) deconstructing discourse analysis reveals what was unsaid in planning policy, a certain "tacit" knowledge. Deconstruction is a useful method for studying how planners construct plans that are plausible to the profession and the community and its results can subvert the logic of planning. The strategy of deconstruction is interested in what has been left out, the method uses norms not as guarantors of goodness or plausibility but precisely the opposite, as problematic categories requiring analysis. In Culler's words:

"One frequently finds general agreement, but consensuses adduced to serve as foundations are not given but produced—produced by exclusions of this sort." Milroy 1989, p.316)

In a Habermasian formulation one might ask the question "What are planners recommending here?" in order to see how the proposals are attention-shaping. Specific utterances are interpreted in terms of the model of communicative behavior. In the alternative one instead asks "How is it that these prescriptions are plausible?".

A systematic approach to deconstructing and analyzing arguments in planning has been proposed and refined by various scholars (Dunn, 1993; 1994; Fletcher and Huff, 1990; Gasper and George, 1998). In each of these instances, an argument is deconstructed and mapped by means of some form of diagrammatic representation.

According to Toulmin[12], arguments are composed of some combination of five components:

- Claims (ideas that the arguer would like the audience to believe)
- Grounds (ideas that lend support to the claim and make it more likely that the audience will believe it)
- Warrants (logic of the argument)
- Backing (reasons why the audience should believe the warrant)
- Qualifiers (modify the claim by indicating a degree of reliance on, or scope of generalization of the claim, given the grounds, warrants, and backing available)
- Rebuttals (possible exceptions to the conditions under which a claim holds)

[12] Stephen Toulmin in work The Uses of Argument (1922), indicates three major, necessary parts of an argument, along with three additional, optional parts. The three major parts are the claim, the support, and the warrants.

Although there has been much written about the method and its potential value in planning scholarship and practice, there is less evidence that it has actually been used to produce substantive advances. (Kumar and Pallathucheril, 2004). Kumar and Pallathucheril developed a graphical discourse index that is used in this research, with minor modifications according to the specific empirical case study of this thesis, Istanbul Airport. Claims are arranged along the X-axis in chronological order. For the case study, the chronological order represents the planning process and has milestones identified as critical stages or phases in the project. The Y-axis is used to group claims according to which relevant actor to the planning arena made them. The actors are identified during the decision making process of the project. Taking both X-axis and Y-axis into account, the location of an iconic shape on the index represents a type of claim made by a particular participant at a particular time. Finally, iconic shapes are linked together by lines with arrowheads that indicate how and when original claims and sub claims were supported or rebutted during the discourse. In addition to discerning between the main claims and sub claims, the claims are further classified into their types, such as:

- Designative - claim is used to establish the existence (or nonexistence) of an entity, concept, condition, or action
- Definitive- claim used to define the characteristics that a given action, condition, entity, or concept has or does not have
- Evaluative- claim that assigns value (positive or negative) or judges the relative value of a given action, condition, entity, or concept
- Advocative- claim that calls for a course of action (Fletcher and Huff,1990)

Kumar and Pallthucheril (2004) note that the distinction between an argument and a discourse is highly important as one represents a particular idea or intent to a course of action and the latter is a constellation exchange of ideas among the actors involved. Thus, a dimension of the context, the involvement of actors, institutional and organizational structures is introduced. Considering the particular situation of design review, multiple arguments and counterarguments are made in different points in time during the planning process and decision-making process, by elected officials, professionals and the larger public. Therefore, these arguments are all related to each other in a certain percentage and these relations are represented by the arrows in the model suggested by Kumar and Pallthucheril.

Using this method, the authors have identified many fallacies within the discourse of a particular study case[13], arguments that are persuasive, yet defective. These fallacies appear when the grounds that support the claims are missing or are false or are based on uncertain beliefs. They can be deliberate or accidental, honest or dishonest, considering the distortion in communication (Forester, 1989) and usually result in an inconsistent decisions-making process and adversity in the planning process (Kumar and Pallthucheril, 2002)

3. Istanbul, context of planning

3.1. New urban policy in Istanbul

Turkey, as other developing countries has been experiencing a neo-liberal reconfiguration that is now in its final stage. First the liberalization phase in the 1980s, second the implementation of neo-liberal reforms in the post-1990s period and with the year of 2000, a process of configuring a new market-friendly and regulatory role of the state, by abandoning the institutions of the old state, began (Temizel 2007; Dincer 2011a; Enlil 2011; Erbas and Erbil 2012). Since the 1980s, national policy intended to make Istanbul the focal point of a neo-liberal strategy approach to integrate the Turkish economy with global markets. These economic transformations were visible also in the accelerating transformation of urban space, making Istanbul the showcase of the country's new era of internationalism (Enlil 2011; Uzun 2010). In the pace of decentralization as a solution for more effective forms of governance, in 1994, the authority to make and approve plans concerning estates included in the privatization program, was transferred from local authorities to the High Council of Privatization (OIB). This not only provided exceptional development rights to the owners of these valuable properties located in city centers, but also marginalized the authority of the traditional planning and administration institutions, creating major social, economic and cultural impacts (Dincer 2011a; Erbas and Erbil 2012). By 2000, other leading structural changes as integration of urban fringe to the core, de-industrialization, urban sprawl, renewal of historical areas and re-development of brown field areas have been introduced through a complex agenda of urban regeneration policies into the urban planning practices. The central government created additional laws to enable urban renewal as an exclusive planning tool and therefore making it a debated planning issue in the last decade. (Temizel 2007; Dincer 2011a) Engagement of institutions of central government in decision-making over planning at local scale, transforms the clash of interests in many projects from being the small scale impacts of social, economic or environmental concerns regarding planning to actual questioning of the whole planning system in Istanbul, Turkey. (Dincer 2011 a, 2011b; Enlil 2011; Ergun 2004)

While the purpose of the many projects initiated by the government seems to be in the name of upgrading the built environment and improving the living conditions of the poor or creating new infrastructure for the city, they are made within a top-down approach to planning, reducing to just a transformation of physical space and neglecting the social, economic and environmental dimensions. These aspects along with the unwillingness of government to allow any participation of civil society become the focus of discontent and protest of many engaged in resistance. (Erbas and Erbil 2012; Temizel 2007). Strong opposing governance forms come together: non-governmental organizations, neighborhood associations, Chamber of Architects and Urban Planners and urban social movements are formed with the aim of more justice and inclusionary process in planning. This situation culminated with the events of 28 may 2013 when thousands of people fought against the

"*neo-liberal urban development agenda of the government*" (Taksim Dayanismasi 2013)[14].

3.2. 2023 Vision

In 2011, Turkish president Tayyip Recep Erdogan officially announced the Justice and Development Party's (AKP's) "2023 Vision", aiming to make it one of the world's 10 largest economies by its centenary in 2023.

However, the vision was a much older idea, but on local scale, just for the city of Istnabul. Three months after the 1999 earthquake, without even approving the Earthquake masterplan, "2023 vision" for Istanbul appeared on the agenda. It was actually a strategy called "mega transformation" ("Mega dönüşüm") that was presented before and now with a change of name puts forward "mega transformation projects", "neighborhood transformation projects related to earthquake disaster" and these were pointed to be the main way development path. (Yapici, 2017) It is already in those times that was decided that Istanbul becomes a "corridor city", a goal declared by Topbas, mayor of Istanbul Metropolitan Municipality (Istanbul Büyükşehir Belediyesi-IBB). Mucella Yapici, secretary of Chamber of Architects Istanbul relates that moment with all the transport projects Istanbul did and has in plan to do: 3rd bridge, Marmaray, 3rd airport, Istanbul Canal Project, etc.

The AKP introduced the 2023 Vision in 2011 during the general elections that resulted in Erdogan's third term as prime minister. Critics says that the ambitious goals, which include a 10% yearly average growth rate to reach $2.6 trillion in GDP, are idealistic promises made by a leader seeking electoral success, Jean-Pierre Lehmann, professor of international political economy at Oxford University's Centre for Economics and Foreign Policy Studies says (Kayagil- G20, 2015)

Lehmann also points out that the obsession with growth targets, at the possible expense of society, could prove dangerous and harmful. The AKP's path to growth and social development has been inconsistent, with policymakers looking at these economic targets as an end rather than as a response to the more important question of what type of society the country wants. This is clearly apparent in the already stagnating economy, the high political instability and the tensions caused by unclear and ill-defined strategies in combatting citizen dissatisfaction.

3.3. Istanbul Airport mega project overview

Strongly linked to the 2023 Vision of Turkey, the 3rd airport, now with its name Istanbul Airport is one of the mega projects that will bring Turkey among top 10 economically powerful countries. Istanbul Airport opened its first stage on 29th October 2018, which took place on the 95th anniversary of Turkey's establishment as a republic. For the first time in the history the celebration of the Republic is held in Istanbul rather than Ankara.

[14] Online Source: http://taksimdayanisma.org/?lang=en

When fully completed, Istanbul Airport will be the world's major hub of transport and aviation, as well as having the globes biggest duty-free area. Replacing the Istanbul Ataturk airport, ultramodern architecture and technology have been used with the aim of getting passengers quickly and smoothly to their chosen destination.

The airport is under construction on an area of 76.5 million square meters to the north of Istanbul, 35 km away from the city center and promises to be the world biggest airport biggest airport and largest "Build-Operate-Transfer" project in the history of the Republic of Turkey. (CAPA, 2016; IGA website).With an annual passenger capacity of 200 million (DHMI, 2013), it will respond to the growing needs of the city, which can no longer be fulfilled by the two existing airports - Ataturk, with 37 million annual passengers, and Sabiha Gökçen, with 13 million (Turkish Forum Archive, 2010). Furthermore, this project is planned to be extended by an airport city (CSB, 2014) with a central innovation district, hotels, retail and commercial office space, logistic centers, an expo and convention center, public space, and metro and high-speed rail connections to Istanbul and beyond (CAPA, 2016). On its journey to become "the hub for global aviation", Istanbul Airport will emerge as a strong player in cargo transportation as the trade axis shifts to the Asia-Pacific region. Istanbul Airport will render Turkey an attraction center not only in passenger transport, but also in trade.

Istanbul Airport will distinguish itself from a myriad of other build-operate-transfer projects thanks to the added value it will offer for the Turkish economy. Following the completion of all phases in 2025, the total direct and indirect employment will go as high as 225,000 employees and the household income will rise up to 4.4 billion dollars.

The project in numbers looks like this:

- total investment- €10.2 billion
- 3500 ha (1100 ha services, 165 pedestrian bridges, 8 control towers, parking for 70000 cars, 1 mall, 1 aviation medical center
- 200 million passengers- 90 million phase one (that is finished)
- 300 different destinations
- 12 awards (design architecture, economic and environmental and social sector)
- 3,109 suppliers
- revenue flow into the Treasury in 25 years- €22.2 billion + VAT
- 21,500*- total employment (as of 31 dec 2016)- 225,000 employees in total; indirect Employment- 1.5 million; direct Employment- 100,000
- household income will rise up to 4.4 billion dollars

3.4. Institutional and legal framework- İGA (Istanbul Grand Airport)

IGA was founded on October 7, 2013 to construct and operate Istanbul Airport for 25 years. The İGA journey started on May 3, 2013 when DHMI (General Directorate of State Airports Authority of Turkey) awarded the contract for construction and operation of Istanbul Airport to the Cengiz-MAPA-Limak-Kolin-Kalyon Consortium. Having won the bid for the project, the consortium founded a new company under the name "İGA". Each of the investors has an equal share of 20% in İGA. Cengiz-MAPA-Limak-Kolin-Kalyon Joint Venture operates in different industries nationwide and around the world including construction, energy, tourism, mining, port and airport management. The consortium has undertaken eight airport construction projects so far.

"Already awarded for its design and value-added projects before its opening, the name of Istanbul Airport will be written in golden letters in the history of aviation as "the world's largest airport built from scratch." -message from the Board of Directors of IGA. But beyond this message, it is not surprising to see how the new airport development is presented and marketed as a victory for the whole country, the political sublime together with the technological sublime are known features of megaprojects.

"Bugün aslında biz sadece bir havalimanı değil, bir zafer anıtı inşa ediyoruz." Recep Tayyip Erdoğan (2018) - "Today we are not building just an airport, but rather we won a victory"- a fragment from the speech of Recep Tayyip Erdogan at the opening ceremony of Istanbul Airport. *"Yeni Türkiye'yi İnşa Ediyoruz"*- The statement "We are building the new Turkey"- is also the message present on all billboards and commercials regarding the new airport.

Nordic and partners, architecture office, developed the concept design of the airport and describe the Istanbul New Airport as celebrating the city's long history as the gateway between two worlds. However, they do not accept the affiliation with the decision over the area chosen for the project, the north forest area of the city, also protected area in the 2009 Masterplan or the non-transparent planning process and deaths on the constructions site due to neglect.

3.5. Impact of the Istanbul Airport mega project

Environmental and social impact assessment are two of the key issues in megaproject development. For environmental and social effects of projects, one similarly finds that such effects often have not been taken into account during project development, or they have been severely miscalculated, such problems often destabilize habitats, communities and megaprojects themselves, if not dealt with carefully. (Westport, CT: Praeger Publishers, 1998; Paris: OECD, 1993; Roger W. Vickerman, 1994) Serious issues are identified in the project for the Istanbul Airport. The first EIA report was prepared in 2013, by AK-TEL Engineering Co., on behalf of the Ministry of Transport, Maritime and Communications (MTMC). Although it received a positive decision from the Ministry of Environment and Urbanism (ENVIRON, 2015), the construction was halted by Istanbul's Fourth Administrative Court, due to claims on the project's negative environmental impact. A new EIA report was put into effect in 2014, emphasizing the necessity for a new airport (CSB, 2014).

Deforestation is a serious concern when the scale of the projects is taken into consideration. 80% of the total project area of the third airport consists of forested land (Gürtler, 2016). There are also problems connected to ecosystems. UCTEA warns that Istanbul will be deprived of water as the construction site of the third airport threatens ecologically protected and sensitive areas including water basins (CAPA, 2016). Additionally, the third airport is planned on the migration routes of birds, which is hazardous for the ecosystem. This not only violates the Bern Convention (1979), but also causes possible airplane crashes (Arslangündoğdu, 2014).

Consequently, ENVIRON was commissioned by IGA (Istanbul Grand Airport) for the preparation of the Environmental and Social Impact Assessment (ESIA) in order to support funding applications to international financial institutions. With this report, the present (before project) state of the Project Site has been determined, the significance of the potential environmental and social impacts has been evaluated, and the mitigation measures likely to be taken in order to minimize the defined impacts of the project have been introduced. In line with the Environmental Management and Monitoring Program specified in the Environmental and Social Impact Assessment (ESIA) Report prepared by Ramboll Environ (UK) and the Environmental and Social Action Plan (ESAP) prepared by the Lenders' Technical Advisor (LTA), the Environmental Management Department continues to carry out inspection and audit works with respect to checking of the site compliance with Turkish Environmental Legislation, IFC (International Finance Corporation) Standards, the Equator Principles, and TS EN ISO 14001:2015 EMS requirements, and planning and site application of the necessary actions.

İGA put together the 2016 Sustainability Report in light of the principles of GRI G4 Core. Corporate governance, environmental sustainability, business and social management practices at international standards are collated in a report, with a view to offer a powerful contribution to the development of the sustainability culture in Turkey as well as the sustainable development of the country. As part of the Stakeholder Engagement Plan, more than 100 Meetings Involving 46 Stakeholders were made.

Unfortunately, the number is extremely low for the size of the development and looking closely at the stakeholder list and considering that the Sustainability Committee, established by Sustainability Organization İGA, is chaired by the Company's CEO Yusuf Akçayoğlu, we can easily deduct that it is not a participative and an equitable process. İGA Sustainability Committee is the decision maker in the process of identifying the corporate sustainability priorities for the 2016 Sustainability Reporting process.

Since neoliberal urban policies prioritize urban growth and investments in order to comply with global flows, public interests are frequently overlooked (Baysal, n.d.). In the case of these mega-projects it is possible to identify two types of constraints – (1) the destroying forestlands or farmlands belonging to the state treasury for the same purpose, mentioned before and (2) the urgent expropriation to empty lands for construction. A problem affecting the community is related to property rights.

Consequently, Northern Forests Defense (2015) underlines that megaprojects violate property rights through urgent expropriation. Centralized government and top-down

mechanisms facilitate this process, whilst legal frameworks remain insufficient to secure the rights of citizens.

Therefore, in addition to documentation and the education of the public, the Istanbul Chamber of Architects and environmental NGOs applied to the court for a stay of execution for the mega-projects. Marschall and Aydogan (2015) mention that 75 lawsuits were filed against the various mega projects (including the Northern Marmara Motorway, the Third Bridge and the Third Airport) by the Chamber of Architects from 2007 to 2012. Nevertheless, the construction work was not halted despite the decision of the court in favor of cancellation. Moreover, in some cases the decisions for cancellation by local administrative courts were annulled by higher courts.

3.6. Istanbul Airport mega project discourse index

The discourse index was created by reviewing 300 news related to the development of the Istanbul Airport project, from different sources: iga website, Sabah daily (as being the most widespread newspaper, also available in English), but also opposition newspapers like Radikal or Diken. Moreover, 20 interviews were made with actors involved and against the planning process: urban planners, engineers, economists, lawyers, architects, academics, ngo representatives, chambers representatives, etc. Their expertise was also carefully chosen as strongly related with the subject: urban planning, environmental aspects, political science, sociology, economy, judiciary, etc.

By looking at the graphic, still a work in progress, one can identify easily the fallacies made throughout the discourse, how some arguments have rather a political motivation to it than a technical one. Moreover, one can identify how arguments support themselves, but also how some actors can contradict themselves throughout the discourse. For example, the Ministry of Transport has a good line of presenting the projects as environmental- friendly, but it also presents the EIA (environmental impact assessment plan) as a waste of time. Fallacies in the discourse mean fallacies in decision making.

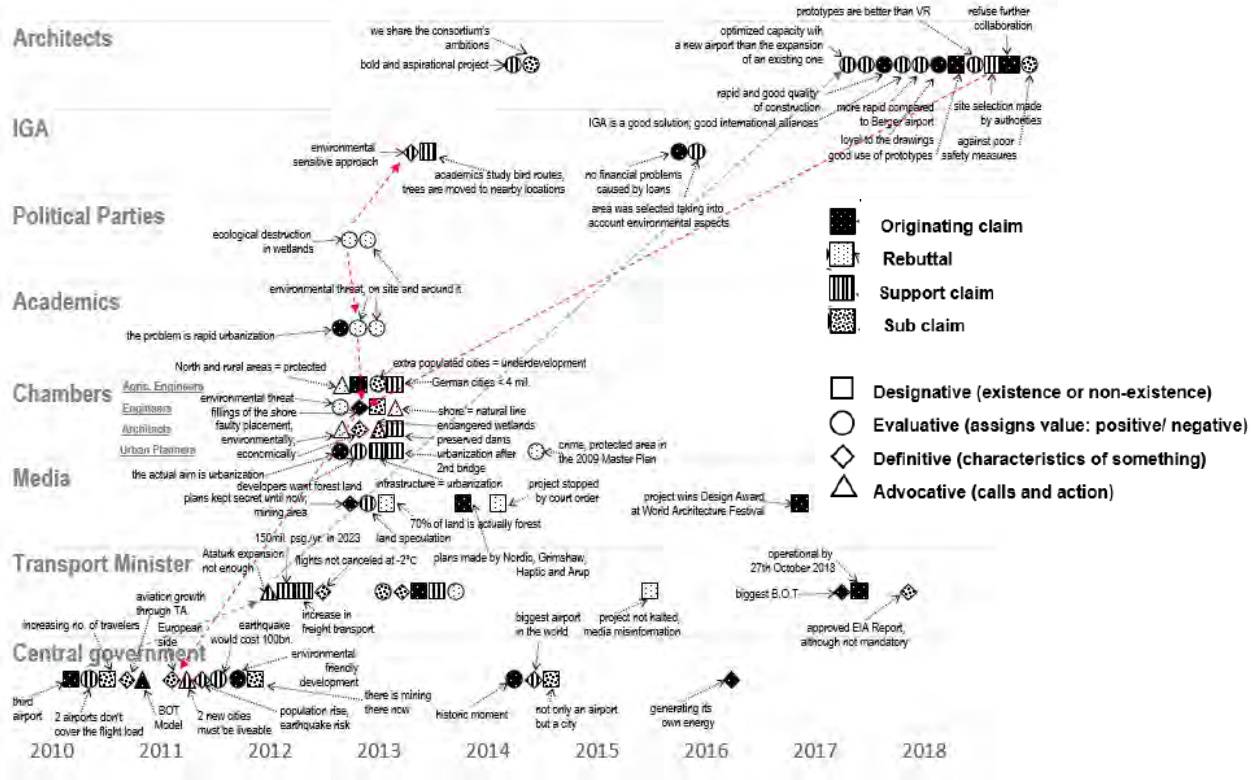

Figure 2 Discourse index of Istanbul Airport

Research Paper

DYNAMICS OF PUBLIC URBAN WATERFRONT REGENERATION IN ISTANBUL

The case of Halic Shipyard Conservation

Serin GEAMBAZU, Ion Mincu University of Architecture and Urban Planning; Romania

Abstract

In the process of globalization, building on the particular spatial scenery of the waterfront, cities tend to refresh their strategies of development to adapt new trends of urban life with huge urban waterfront regeneration projects. These usually focus on a target of maximum marketing and construction of a new image-vision, which aims to represent the city in the global agenda. This aspect is depending on bigger changes in the urban context, the shift in government structures to entrepreneurial forms that involve externalization of state functions (Swyngedouw 2005; p. 1998). The rationale behind the phenomenon of waterfront regeneration and the global embracement of it is now "widely recognized if incompletely understood" (Hoyle 2001 pp. 297), as the relevant literature is based on case studies with focus on the examples of North American and European cities.

The goal is to contribute to the more general, theoretical contention of urban waterfront regeneration in developing countries in understanding their dimensions in terms of governance and planning. The research tackles urban waterfront regeneration in Istanbul, Turkey by studying the most recent initiative of urban waterfront regeneration along Halic /The Golden Horn, the Halic Shipyard Conservation Project.

The theoretical framework that underpins this study is derived from the discourse on new forms of urban governance including private, public and civic actors (Paquet 2001) that influence planning processes and project outcomes. To evaluate the planning process from a comprehensive governance perspective, indicators include: the legal framework, decision-making process, actors and their relations (Nuissl and Heinrichs 2010) and as normative the perspective of an inclusive planning approach (Healey 1997, 2006) helps to evaluate the planning process of the project. As urban waterfront regeneration literature is mostly based upon case study approaches, a critical overview of international examples is conducted. Both primary and secondary data is collected through: literature review, review of laws, review of official documents and land-use plans, an internship, 31 interviews, 91 questionnaires, participatory observation, a workshops, observation and photographs.

The aim is to assess to which extend the top-down governance forms, but also bottom-up grass root empowerment influence the planning process and project outcomes, giving

recommendations for an inclusive planning approach. The second aim is to evaluate the urban waterfront regeneration project studying its impact on the neighboring community. Bedrettin Neighborhood is chosen for analysis and its position in the planning process along with its needs are exposed. The thesis argues the modes in which along with clear targets for the improvement of the quality of life for the neighboring community, the urban waterfront regeneration project, Halic Shipyard Conservation Project, will be able to escape the current deadlocks and collisions between government, investors, resistance and local community and might have a chance to actually set an urgently needed precedent of a new planning culture in Istanbul.

Keywords

urban waterfront regeneration, governance, planning process, Istanbul

1. Introduction

The spread of neo-liberal political and economic ideology and the proliferation of global capital have created new opportunities and challenges for cities everywhere, especially in the so called "global cities". Over the last decades, many cities worldwide have promoted urban waterfront regeneration for a variety of reasons building on the particular scenery of these sites. The success of the first well known urban waterfront regeneration project, Baltimore Inner Harbor regeneration (1960), has served as a prototype for cities around the world with the desire to position themselves in the race to become Global Cities (Harvey 1989) by providing strategically located high-quality investment opportunities to attract global capital, or by constructing attractive spaces to promote tourism and leisure. Nowadays, almost every city at water's edge is engaged in regeneration projects with strong political impetuses and interest from various parties: authorities, developers and neighboring communities (Hoyle 2001). These developments have been critically examined by many scholars, many of which share the belief that urban waterfront regeneration is often not addressing the underlying, deep-rooted problems of the cities and furthermore, ignoring the socially and economically unstable landscapes in which they often occur, veritably contributing to the escalation of inequality, polarization and deprivation in the city (Harvey 1989; 2005; Brownill 1990; Gordon 1997b; Hoyle 2000; Saarinen and Kumpulainen 2005; Butler 2007; Healey 1997; Gordon 1997a, 1997b; Feldman 1999; Fainstein 2001; Granath 2005; Butler 2007).

It is generally assumed that globalization leads to the same type of transformations and urban development trends everywhere in the world. However, it cannot create a certain prototype for spatial development or a new spatial order for cities. Rather, it gives a variety of spatial patterns, also called "global urban forms". This standardization (or 'nothingization', as Ritzer calls it) takes place in many aspects of urban life of global cities everywhere and destroys what is there most alive, the identity and socio-economical constructions of the place. Furthermore, what Relph (1976) and Augé (1995) advice within the popular terminologies of non-places and settings of placelessness is about the construction of spaces which are produced and have their identity extremely embedded in the market dynamics.

Places on where the lack of authenticity with community non-involvement in the construction of the setting has become a normal issue.

The article is studying urban waterfront regeneration as a complex urban intervention, specifically its special governance, resistance and impacts on the neighboring tissue, which could be considered a prism through which broader societal transformation processes and related planning challenges can be understood. The case brought forward is the recent urban waterfront regeneration along Halic/ The Golden Horn, in Istanbul, Turkey.

2. Urban waterfront regeneration in Istanbul: Halic/ The Golden Horn

2.1. Context of planning and institutional framework

Since the 1980s in Turkey´s milieu, national policy intended to make Istanbul the focal point of a neo-liberal strategy approach to integrate the Turkish economy with global markets. This was visible also in the accelerating transformation of urban space, making it the showcase of the country's new era of internationalism (Enlil 2011; Uzun 2010, Çınar, C et al, 2006; İnalÇekiç and Gezici, 2005; Keyder, 2005; Karadag, 2010).

Under this context, during the last thirty-five years, investments have been located within the city in order to change the local landscape pushing it towards the global city image. Therefore, the city has been expanding with multiple mega-projects and naturally, a strong representative symbol of the global, emerged: *waterfront regenerations i*n the valuable "soft" space of inner city usually modifying natural coast profiles.

These territorial changes have been not only modifying natural structures, they have generated such a special urban form by the transformation or even replacement of the original communities and their identities. Behind the consolidation of new waterfronts, local populations are experiencing struggles and contradictory emigrational patterns in the inner city; dynamics that have been usually explained by secondary data, statics and within many articles uniquely pointing on the production of geçekondus. However, it is still not evaluated what happened in those spaces where is a coexistence of new migrants moving to the developments and local populations that are being affected by market dynamics.

In order to understand the planning processes of the regeneration of Halic's waterfront, a reflection is done upon the peculiarities of Istanbul's urban regeneration policies and the institutional framework at city and national level that have facilitated it. Urban regeneration is steered as a tool for development within a special legal framework (Law of Conservation-Law No. 2863) and while the purpose of the projects seem to be in the name of upgrading the built environment and improving the living conditions of the poor, the top-down approach, reduce the projects to just transformation of physical space and neglecting the social, economic and environmental dimensions, which along with the unwillingness of government to allow grassroots participation in the planning process become the focus of discontent and protest.

2.2. Halic/ The Golden Horn: a fragmentized waterfront

Halic, a 7,5 km bay of the Bosphorus strait and the cradle of settlement since the birth of the city, is heavily industrialized and contaminated in the 1970s and since then experiences a long process of transformation along its waterfront.

In line with popular North- Western examples of urban waterfront regeneration at that time, this process is triggered by Mayor Dalan in 1983, who famously stated his mission:

„The water of the Halic will be as blue as my eyes'" (Radikal Newspaper).

The project is sponsored by World Bank and the industrial waterfront is transformed into a huge vacant land which becomes large green park areas (Enlil 2011). Behind the environmental concerns, there was also an economic motivation to bring Istanbul between the competitive global cities with a vision of a "Cultural Valley". The following forced de-industrialization process of the 1980s is impressive and did indeed improve Halic from an environmental perspective, but the clearing process was pursued with a heavy-handed, top-down governmental approach to planning and the legacy of mayor Dalan is contested among academia, civil society, non-governmental organization and experts in planning: The project created an approximately 50m wide strip of vacant land– a great opportunity in terms of offering open green spaces for the city- but destroyed 100 Ottoman-era buildings and an additional 30,000 structures, displaced neighbourhoods within 50-100 m along the shoreline (Köksal 1996, 2005; Yerliyurt 2008; Bezmez 2008) and most importantly brought mass unemployment and poverty in the backstage neighbourhoods populated by former dock and shipyard workers (Köksal 2005; Bezmez 2008; Yeliyurt 2008; Enlil 2011).

The following initiatives to regenerate Halic's waterfront showed no intention of resolving the social and economic burning issues of the neighbouring communities. Within the same top-down planning approach, as in the 80's clearance intervention, urban waterfront regeneration projects are ad-hoc initiative of different bodies of the government depending on ownership and planning rights over the land. Therefore, within privileged legal means facilitated by different governmental bodies and by a national policy on urban regeneration, developments for middle-high income citizens are created:

"With empty convention centres in the middle of poor neighbourhoods, a few art galleries right beside demolished historic buildings, and newly built museums next to squatter housing". (Bezmez 2008 pp. 817).

Although the attempts to transform Halic with the vision of a "Cultural Valley Project" are not different from other urban waterfront regeneration projects around the world, in terms of process, they can't be explained through just one clear framework of public-private partnerships, intense processes of urban entrepreneurialism or gentrification as other classical North-Western examples. As a response to this regime of urban regeneration (Dincer 2011a; Dincer 2011b) urban social movements are formalized in Neighbourhood Associations or non-governmental organization taking an active role in the planning process. (Kerimoglu and Gezici 2010; Dincer- 2011b;Bezmez 2008)

2.3. Decision making process

Social justice has the dimension of a process rather than an outcome and therefore the planning process is of a particular importance to portray “governance of place” (Healey 2003). "The extent to which opportunities for participation are picked up in reality is an important indicator of balancing interests, even though is primarily the privileged, most articulate and directly concerned elements of society that attempt to participate in public decision-making processes ". (Heinrich and Nuissl 2011)

This sub-chapter is an overview on the decision-making process for the urban waterfront regeneration of Halic Shipyards (Tersane-i Amire Arsenal), the latest urban waterfront regeneration development along Halic.: a first attempt in regenerating Halic Shipyards is presented, followed by the current state, two urban waterfront regeneration projects in on-going process of transformation. These urban waterfront regeneration projects are: Halic Shipyard Conservation Project (Haliç Tersanesi Rölöve, Restitüsyon, Restorasyon, Yeni Kullanım ve Peyzaj Projesi) in the area of Halic shipyard and Halic Port Project (Halic Yat Limani Projesi) in the area of Camialti and Taskizak shipyards.

The first attempt to officially create a plan to regenerate the area of Halic, Camialti and Taskizak shipyards is in 2011, when all three shipyards come under the authority of Istanbul Metropolitan Municipality (IMM). The final goal is to create a comprehensive urban regeneration project and reconnect Beyoglu district with its waterfront along the Halic.

Being declared as a Conservation Area, the development is managed by the Department of Historic Environment Protection (DHEP, in Turkish Tarihi Cevre Koruma Mudurlugu is the representative body of Istanbul Metropolitan Municipality in the areas declared for conservation. It is empowered by the Decision No. 313 in 04/06/1999 and has a management role within the project, making sure that the project it is accomplished in line with the requirements of the Law of Conservation), which focuses on the restoration of the historical buildings on the site and change of the current functions in new ones according to the needs of the citizens. DHEP designates through a bid the task of making and designing the plans to Istanbul Metropolitan Planning (IMP- Bimtas S.A., is a semi-private company and also a research centre for Istanbul Metropolitan Municipality. It has long lasting collaborations with academia, neighbourhood associations and wide experience in planning in Istanbul, it is the company that made the last Master plan of Istanbul 2009 and many other important development projects).

In line with the requirements of the Law of Conservation, the Conservation Board No. II is added to the decision-making process. This Board is linked directly and represents the interest of the Ministry of Culture and Tourism, has great power on the project’s outcomes, evaluating the plans and being able to cancel them.

The plans done for a preliminary project (in Turkish "avan proje") start on January 2011 and finish in June 2011, but without any request for participation from the citizens side and no reflection on the surrounding neighbourhoods. The proposed functions for the area are: cultural, recreational, social services and commerce functions and are approved by the Conservation Board No. II in July 2012. The next step in planning process after the preliminary project, according to Main Law of Construction (Law No.3194), is the implementation project (in Turkish: “uygulama projesi”) which did not continue with all

three shipyards. Here a shift in the governance forms of the project changes the planning process along with rising concern on the project's future outcomes: just one of the shipyards went further to the implementation phase under the name of Halic Shipyard Conservation Project, when the area of the other two shipyards is being privatized. Holding the ownership of the land of Camialti and Taskizak shipyards, the Ministry of Transport Maritime Affairs and Communications (MTMAC) decides to withdraw the project from the authority of IMM.

In 2013, a new urban waterfront regeneration project is declared for privatization and classified by the Prime-minister Tayyip Erdoğan as: "*miraculous project*" ("muhteşem proje") which appears with the name: Halic Port Project. The urban waterfront regeneration project is initiated by the MTMAC, under the Law of Privatization, known as Built Operate and Transfer (Yap Islet Devret- Law. No. 3996) and is approved by Higher Council of Privatization (HCP); this also being possible because, according to the Law of Privatization, since 1994, the authority to make and approve plans concerning estates included in the privatization program was transferred from local authorities to the HCP.

The area is given to auction and is announced in the Official Paper (Resmi Gazete, page 28646) on 13 May 2013. The tender is taken on 2 July 2013 by ''Sembol International Investment'',''Ekopark Tourism" and "Fine Otelcilik Girişim Group"(Sembol Uluslararası Yatırım-Ekopark Turizm-Fine Otelcilik Girişim Grubu) for 49 years: 4 years for building and 45 years for usage. The requirements of the project are given beforehand to the investors, being decided by the MTMAC and approved by the HPC. These are: *"two yacht ports, two five stars' hotels, small shops, offices, museums, culture and a congress center".* Taking into account these foreseen outcomes of the project, it can be argued that this development is not designed for the interest of all citizens of Istanbul or the neighbouring community, but rather for tourists and high-middle income class. The promised outcomes of the project are presented in the media through the political discourse as the only information channel for citizens and therefore raised a big wave of criticism from academia and other expert's side, questioning the way decision is being taken.

Therefore, the planning process is lacking transparency and the Privatization Law gives central government power to privatize public land without any consideration of the civil society. Also local municipality has been taken out from the planning process and also the 1/1.000 plans that should be done for the Camialti and Taskizak shipyards are developed by the private investor, this raising questions concerning the conservation of the shipyards.: The only actor from the government side having decision power over the outcomes of this project remains the Conservation Board No.II.

In contrast, the area of Halic shipyard is developed further by IMM within the Halic Shipyard Conservation Project**.** Major actors in the planning process here are: IMM, the initiator of the project, owner of the land and also the provider of the finance in realizing it; the DHEP managing the project, having mainly the responsibility to assure the conservation and restoration of the historical monuments in the area; the Conservation Board No. II, representative of Ministry of Culture and Tourism, having also the main responsibility to assure the conservation and restoration of the monuments; IMP in charge of the plans and design of the project and also IDO (Sehir Hatlari) - a private company of public transport on water, having currently the tender over the area of Halic shipyard**.**

In the interviews with representatives from the planning department of IMP, the team planning Halic Shipyard Conservation Project, it is revealed that the outcomes of the project

will take into consideration the previous suggestions and that the project will respect the 1/1000 Plans of Beyoglu in terms of conservation of the shipyards, along with the recommendations of implementing cultural and recreational activities. Moreover, creation of green spaces is emphasized, the vision being to open the waterfront for the broad public, the citizens of Istanbul. Proposed strategies concerning the development are: *"conservation of the buildings, enhancing the transportation in the area, introduction of recreational and exposition areas, bringing the city to the waterfront, protection of green spaces and ensure the participation of the local people of the area."*

However, the project contains no analysis of impact assessment such as: environmental, economic or social, this showing the physical focus of urban waterfront regeneration in planning, putting in doubt the success and purpose of this project. There is also no information provided for the broader public about the project or the request for any collaboration from the citizen's side. The chance to challenge decision making is possible at the end of the project. As all projects made by municipality, also this one is presented to the community at the end of the planning process, plans are hanged in the Istanbul Metropolitan Municipality building and within 30 days the interested parties have the right to contest the project through court. This leads to questioning the outcomes of the project because of this type of non-transparent planning process that leaves no input from the citizen's perspective.

Therefore, as seen and criticized in other examples of projects along the Halic, the project could also potentially enhance existing socio-economic problems, a matter that will be presented in the following part of the article, by analysing the neighbouring community in rapport to the project.

Looking at the current state of the transformation of the three shipyards, there are two urban waterfront regeneration projects with different governance forms. The area of Camialti and Taskizak shipyards is under the authority of a private investor and it can be argued if the project will benefit the broader public of Istanbul. The area of Halic shipyard remained under the authority of the government, but the planning process is un-transparent and the project is not shared or questioned within the interested public. In an attempt to compare the projects from the perspective of the information available, paradoxically, the Halic Port Project is much more known by the public than the project made by the municipality because of the exposure in the media. However, there is a major gap of good quality information for citizens regarding both projects.

This was reflected in the questioners conducted with the neighbouring community, academia, planners from Istanbul Metropolitan Planning and citizens participating to forums organized by the representatives of the resistance to the regeneration of the shipyards. An urban social movement appeared on 23 August 2013 under the name of Halic Resistance (Halic Dayansimasi). Other opposing parties are: Bedrettin Neighbourhood Association, Chamber of Architects, Chamber of Urban Planners, Assembly of Architects and Engineers, Chamber of Shipbuilding Engineers, Academia and other urban social movements.

2.4. Governance dynamics

With the new more entrepreneurial forms of governance, also new arrangements articulating state - civil society relationship come forward (Swyngedow 2005). In urban waterfront regeneration, urban social movements formalized as community groups or non-governmental organizations, coming often from the neighbouring communities and other interested or affected parties become a source of ideas and influence the pace and pattern of development. They encourage, restrain, warn and provide qualitative overviews. (Krausse 1995; Cau 1996).

These new actors engaged in opposition, observed and identified within the period of this research, are social movements representing partly defined groups of civil society, chambers of experts in field of planning and community organizations: Halic Resistance, Academia, Bedrettin Neighbourhood Association, Chamber of Architects, Chamber of Urban Planners, Chambers of Mechanical Engineers, The Lawyers Association, Union of Chambers of Turkish Engineers and Architects, Neighbourhood Associations and also political parties, such as CHP. However, three main groups of actors in this opposition are chosen to present their interests and roles as they have been most active since the beginning of the planning process: Chamber of Architects, Bedrettin Neighbourhood Associations and the platform where all and others meet, the social movement- Halic Resistance.

Chamber of Architects is the first actor which opposed to the regeneration of the shipyards and gave support to others that came along during the planning process. According to the 6235 Act of Union of Chambers of Turkish Engineers and Architects, the Chamber has the right to sue development projects which are not benefiting the rights of the society. The main reason to be against this regeneration, from their perspective, is that it will create displacement in the neighbouring community, the shipyards will not be conserved and moreover the project will not benefit the needs of the citizens. Although the Chamber of Architects is practicing advocacy planning, it is still a centralized institution that evaluates projects from its expert perspective and has a focus on the concern of conservation of heritage, the monuments existing on the site of the shipyards. The Chamber is also stigmatized as being against all development projects and not seeking solutions, being in conflict with the government, outcome of many law suits against this type of projects. It's the discourse tended to focus towards the cancelation of the projects, but not militating for inclusion, transparency and information, outcome of the mistrust towards " *the neo-liberal agenda of the government and all the mega-projects triggered by it."*

So non-governmental organizations funded in 2005 in order to fight with legal means against urban regeneration project for the community of Bedrettin Neighbourhood, is Bedrettin Neighbourhood Association. As Mr. Cem Tuzun, the representative of Beyoglu Neighbourhood Associations, explains:

"**to** *defend the rights of the citizens against a neoliberal agenda of the government" ; "to keep surviving in our neighbourhoods*". The aim is to fight in court against any regeneration project that could put in danger of displacement the community. "*We want to defend the place where we live, the place where we worked so much for. We took our water from the polluted Halic and we survived Dalan's demolitions. We don't want to go from here and we will fight against this neoliberal agenda*." says Suleyman Songur, representative of Bedrettin Neighbourhood.

Halic Resistance urban social movement is the platform were all interested parties meet and militate against the regeneration of the shipyards. This social movement militates for: *the importance of the shipyards from the conservation point of view* and also its *production potential*. Moreover, it is against the "*clear neo-liberal transformation of the shipyards*". One of the initiators of the movement, Dr. Arh. Gul Koksal calls these urban regeneration projects as: **"***the hegemony of the government***".** As a core, a board was created from representatives of: academia, Chamber of Architects, Chambers of Mechanical Engineers, Bedrettin Neighbourhood Association and former workers at the shipyards. Decisions are taken during meetings or in innovative ways through social media and mail groups. On 19.11.2013 a petition to Conservation Board regarding the clearance of Taskizak and Camialti shipyards was given as a violation of the Law of Conservation. This event builds on the efficiency of the movement in monitoring the development of the shipyards, report any violation of the law and call responsible bodies to action. However, it also depends on the Chamber of Architects for its legal fight, being the institution with the right to sue the urban regeneration projects. In addition to the aforementioned, because of the informal means in which the resistance is reaching the information, false beliefs can be spread to wide public, fact revealed also in the interviews with the participants at the meeting of the movement. Also 45% of the participants come to the meetings not only to support the resistance, but also to inform themselves about the regeneration projects. Therefore, the need of

information is underlined regarding these projects and here is the point where this kind of movements gain popularity for being open to participation and sharing knowledge.

The new actors engaging in resistance have no power in decision making over the projects, but they have influence on the planning process due to their actions. The collaborative networks and their innovative ways of decision taking makes them strong actors that have to be taken into account. These collaborations can challenge or conceivably stop the project. Opposition can be seen as an opportunity in increasing democracy, challenging the projects by creating debate and trying to reach a broader public, being always in contact with the media. Still, their demands in the project cannot be taken as indicator for the needs of the all citizens of Istanbul, rather they can be used as an indicator to the need of change in the planning process towards more transparent and inclusive one and can be used to improve the project.

2.5. Relationships and positions of the actors

Relationships of the actors are "*crucial in understanding the direction of the planning processes*."(Nuissl and Heinrichs 2010). The relationships were established as outcome of the interviews conducted by the researcher and through participatory observation. When mapping the relationships, there are two clusters of actors that do not come together, this situation is reflected on the clash of interests and gap between civil society representatives and the government. One group represents the actors involved directly in the planning process and the other represents the strong opposition. The first ones have hierarchical vertical relationships by territorial responsibility of different governmental bodies and market based relationships by contractual agreements. The other group in opposition to the project is represented by collaborative and horizontal relationships of the non-governmental organizations, social movements and other civil society representatives.

Analysing the actors in opposition and the horizontal network-like relations, overlapping interconnections among them can be observed. The boundaries between these actors are hard to be defined as they cooperate and interconnect with each other rapidly, using innovative means of communication in exchanging of opinions and in deciding common action. When the main actors from opposition, and ones involved in the planning process are considered for their relationship, there is a long lasting conflict between them which resulted from the interviews conducted with representatives of both sides, this making also harder for the two groups to come together. It can be argued that even though the resistance is engaging with the community into a fight against the urban regeneration agenda of the government, undertaking an advocacy planning role, it is also creating a barrier between state and citizens. (Figure 2)

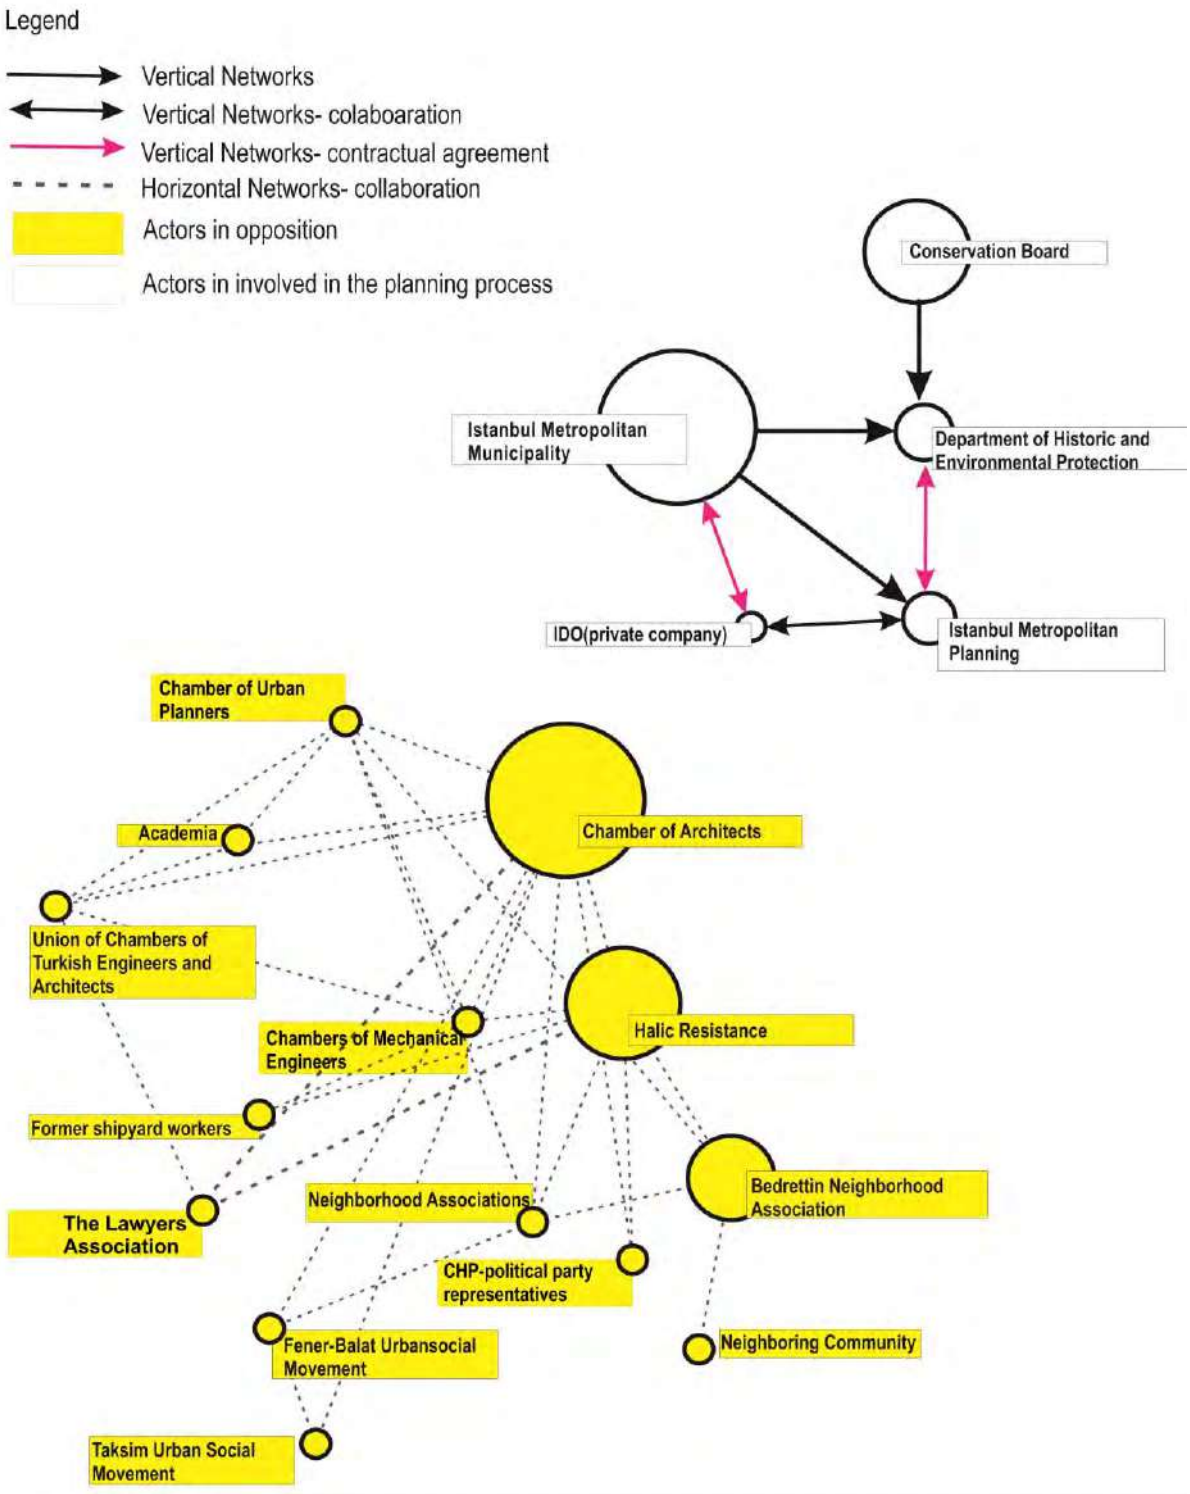

Figure 2 Relations among actors in Halic Shipyard Conservation Project;

Source author (adapted after computer mapping with graphscommons: http://graphcommons.com/graphs/1417)

A stakeholder analysis has been developed as an outcome of the questionnaires and interviews realized with representative of the institutions involved in the planning process, but also with the representatives of the social movements, civil society, neighbouring community, non-governmental organizations, planning experts and academia- mostly all 91 total participants to the interviews and questionnaires in this research. The methodology was taken from the study: Governance and Multi stakeholder Processes by Nancy Vallejo and Pierre Hauselmann (2004)- a product of the Sustainable Commodity Initiative, a joint venture of the United Nations Conference on Trade and Development and IISD. The purpose was to find first the most interested and most powerful actors in the planning process. Than recommendations are given according to the methodology and the results from the questioners are represented in the matrix below. (Figure 3)

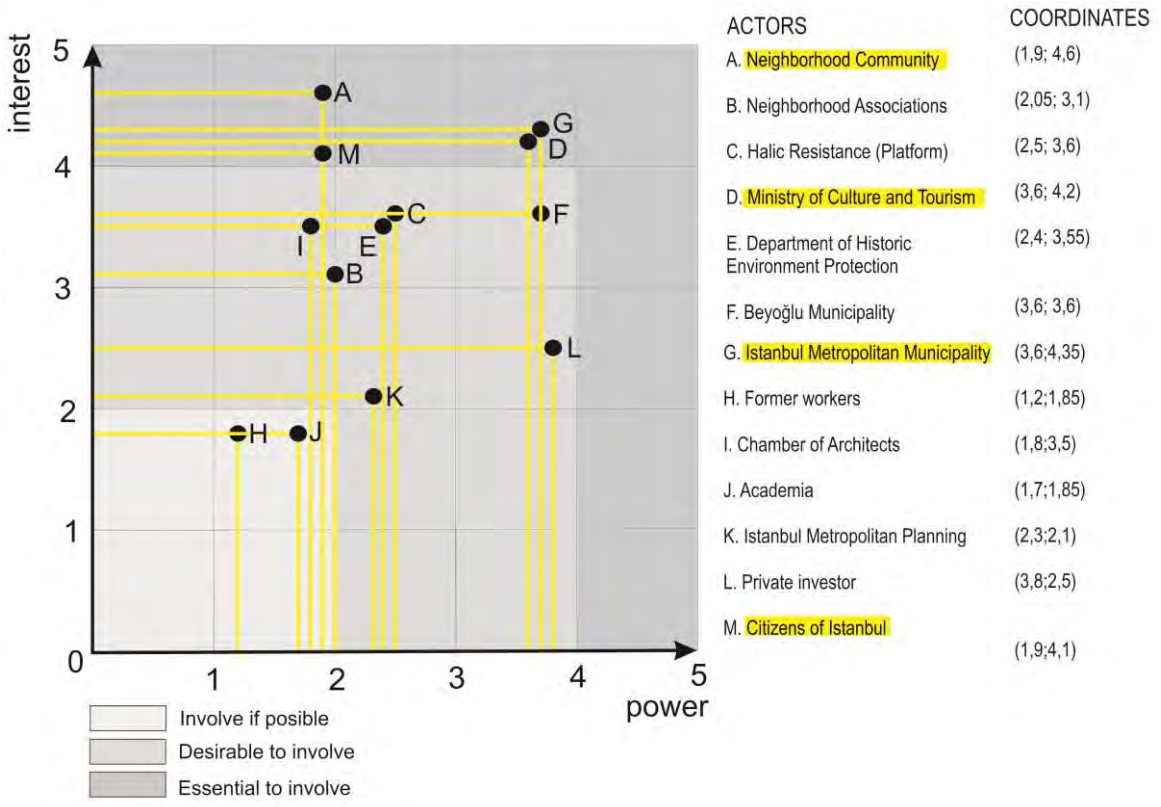

Figure 3 Stakeholder analysis made with the help of civil society

Source author

Methodology:

The last part of the questionnaires conducted had the purpose to identify the interest and power of certain actors involved or opposing the studied project. This exercise provides the researcher with the perception of who should be included in the planning process by placing the actors according to their *power*- ability to influence the project or *interest*- the influence of the project on the actor.

This method was taken from the study: Governance and Multi stakeholder Processes by Nancy Vallejo and Pierre Hauselmann (2004)- a product of the Sustainable Commodity Initiative, a joint venture of the United Nations Conference on Trade and Development and IISD. In the matrix below are recommendations according to the methodology. (Fig. No. 03)

The participants were requested to rate the actors in terms of their power and their interest with marks from "1 to 5". Grading systems from "1 to 5" were chosen, because they are also used in schools in Turkey, making the task of filing of the questioner easier. Power was defined as: actors having the power over decision-making and decision-taking over the project, planning process and outcomes, influence on the project through financial means or having particular knowledge about it. Interest was defined as: actors that are affected by the project outcomes or that have a gain in the project

The actors identified were: Neighbouring community, Neighbourhood Association (Bedrettin Neighbourhood Association), Halic Resistance, Ministry, Department of Historic Environment Protection, Beyoglu Municipality, Private sector, former workers at shipyards, Chamber of Architects, Conservation Board, Istanbul Metropolitan Municipality, Istanbul Metropolitan Planning, Citizens of Istanbul and academia. Also a section for 'other' was left out for the participants to be completed with other actors interested, affected or involved by the project.

The total number of respondents was 81 and they were divided in six representative groups: the government, non-governmental organizations, academia, private sector, urban social movements and the community. A simple mathematical formula was used for calculating the final results, the same share was given to each of the 6 groups.

The answers for every 13 actors were calculated separately, having also two variables -- power and interest:
[0,x; 0,y] in order to place them on a matrix with the axes: x0y.

The formula for every answer was:
[(1+2+3+....+n) / n] *6= x
1,2,3,.....n = the response of one respondent regarding one actor
n= number of the respondents
(1+2+3+....+n) / n = the final grading of a certain group (government, NGOs, academia, private sector, urban social movements and community)
x= the final grade for interest

The same procedure is in the case of power:
[(1+2+3+....+n) / n] *6= y
1,2,3,.....n = the response of one respondent regarding one actor
n= number of the respondents
(1+2+3+....+n) / n = the final grading of a certain group (government, NGOs, academia, private sector, urban social movements and community)
y= the final grade for power

3. Conclusions

3.1. Evaluating the planning process

Halic Shipyard Conservation project is initiated and subsidized by IMM, but the central government has regulatory power over the project outcomes, due to the special national laws designated for urban regeneration. Private sector is added to the decision-making process by IMM, but local government, Beyoglu Municipality, the district in which the project is done, is missing from the planning process. Although the project is made for the public interest, it was found that there is no consideration of giving information or chance for participation to the most interested parties: the neighbouring communities or the citizens of Istanbul. Looking at the decision-making process, the first attempt to officially create a plan for regenerating the area of Halic shipyard was together with Camialti and Taskizak shipyards, but as a result of the deficiencies in legal framework giving total rights to owners of land and central government, the latter ones were privatized.

The lack of information and broadly-based rights of influence are manifested by this opposition that is part of a broader fight against the "neo-liberal agenda of the government". The neighbouring community's need of information and the lack of trust towards projects initiated by the government brings it closer to the actors in resistance. The collaborative networks and their innovative ways of decision taking can challenge and even conceivably hazard the project.

The planning process of this particular urban waterfront regeneration was found therefore as not inclusive, not transparent and not giving opportunity to challenge decision-making in the planning process. Therefore, it can be argued that what could be a good project creating public space and reconnecting the urban tissue of Beyoglu district with its waterfront, will fail to reach its true potential in benefiting the neighbouring community and also the broad public of Istanbul. This due to its exclusive governance, the top down approach to planning and the legal framework given by the national policy on urban regeneration.

At the first glance, urban waterfront regeneration in the context of Istanbul reveals the same features of the popular contested cases of North and Western examples .The privileged governance structures identified in the literature review of urban waterfront regeneration projects aiming economical gain over the conception of a new city image and planning focusing on mostly physical transformation, ignoring the social problems of the neighbouring sites and not taking the opportunity to resolve them can be seen also in the case study.

However, the form in which these outcomes reveal themselves, are different. Much of the literature on urban waterfront regeneration warns about the entrepreneurial governance forms, the private-public partnerships and the active role of private sector in the development of the projects, which lead to displacement of the communities, gentrification and other negative impacts. In the context of Istanbul, the leading factors are an entrepreneurial government and also a national policy on urban regeneration designated by the central government. In contrast with other urban waterfront regeneration projects around the world, which reveal citizens struggle with displacement, job opportunities, social housing opportunities and public space at waterfront as reasons for opposition, the case study presents also other encompassing motivations. The strong and constantly growing opposition is also part of a leading strategy of the citizens of Istanbul to get back the rights to the city. This is owed to long term accumulation of tensions facing the current urban

planning practices in Istanbul, Turkey. The resistance, therefore, is not outcome of the particular regeneration of Halic shipyard or the privatization of the other two shipyards, Camialti and Taskizak shipyards (part of Halic Shipyards- Tersane-i Amire Arsenal), but rather of a bigger picture of urban regeneration projects done in Istanbul.

Hence, there is a waterfront regeneration project made for public interest, but the rights of the future users of the space, of the neighbouring community and mostly of the citizens of Istanbul are in this way lost behind a neo-liberal agenda of the central and local government, un-transparent planning processes and the fight of the strong opposition parties gaining ground of governance landscape.

3.2 Recommendations

In term of urban waterfront regeneration there is a clear need for success not only by those at the top. Levine suggests equity in planning and democratized redevelopment agenda process that target residents in greatest need and policies that better link this regeneration to neighbourhood's economic needs. (Levine 1987b) Unfortunately there is no necessary linkage between economic growth and social equity.

One may argue that only through a change towards a more inclusive planning approach, along with clear targets for the improvement of the quality of life for the neighbouring community, the studied urban waterfront regeneration projects will be able to escape the current deadlocks and collisions between government, investors, resistance and local community and might have a chance to actually set an urgently needed precedent of a new planning culture in Istanbul.

The top down-governance forms have to combine with the bottom-up governance forms in order to achieve a physically and socially successful development. The citizens of Istanbul must be informed and included in the decision-making process in the planning process. The Municipality of Beyoglu has to be incorporated into the planning process, defining the link with the citizens from the district in which the project is done.

Taking into account the importance of the area by its location and accessibility, but also its cultural and historical value at local, national and international level there is a need in having a broader voice of influence and expertise into decision-making from various planning experts and academia. The management bodies in urban waterfront regeneration were found of great importance, scholars designating them as the reason for success of these interventions. The narrow approach to urban regeneration focusing on physical transformation given by the national policy, verified by Conservation Boar No.II and managed by the DHEP has to be enlarged and has to take into consideration more factors through impact assessment studies of social and environmental aspects.

Lastly, the project has to include the neighbouring community in the planning process and its needs considered. By including the community in the planning process, the project can also resolve old social and economic problems left heritage since the forced deindustrialization of the area, thus, creating more heterogeneous environments in the city. The project can help to improve the quality of life for the neighbouring community with creation of: public green spaces, culture and education facilities, health facilities and also playgrounds for children.

Also job creation is proposed, but this only by keeping production going at the shipyard. It has been proved in other waterfront regeneration projects around the world that the jobs from cultural, tourism and other retail activities were absorbed by middle income population. All these points can be achieved only by involving directly the community in the planning process and in the implementation phase. It was found that the neighbouring community is open to communication, and is willing to give input that will enrich the projects outcomes and therefore it can be engaged into participatory planning methods in the further planning process.

Considering the bigger picture of urban regeneration; will the citizenship struggle of Istanbulities will overcome and change the current approach to planning of an entrepreneurial government and the market forces is a question that we should pursue. However, what we are facing in the case of Istanbul can be resolved just by democratic mechanisms within the planning process, by understanding the territory as political and social construction. We have to focus on change and how to make it happen because as one of the respondents explained, we want to "keep *surviving in our neighbourhoods*".

Under current conditions, urban waterfront regeneration in the context of Istanbul presents a different picture from a number of similar interventions of this type studied in the existing literature. In order to come with a comprehensive theoretical framework that explains present-day urban waterfront regeneration and how these kinds of mega-projects shape urban spaces, it necessitates the analysis of different localities in distinct geographical settings.

Visual Communication and the Mediatized City

From Billboards to Offices of Urban Planning in Cairo

Mennatullah HENDAWY

Abstract

Visual communication in urban planning and design disciplines is the main form of creating as well as exchanging their ideas and interpretations about the urban environment, not only among planners/architects, but also between them and the general public. Many urban scholars in Egypt also addressed the role of visualizations and graphics in planning as well as its communication (i.e. Selim (2015) and Abotera & Ashoub (2017)). Today, by simply walking in the streets of Cairo or opening one of the national TV channels, one get captured by hundreds of real estate ads that share certain characteristics that can be summarized in two points; promoting moving out of Cairo and buying a new apartment or villa in a new city or a nearby compound, and the use of almost the same visual symbols (i.e. 3d models of the apartments overlooking a big green area, swimming pools, shopping centers....etc,) that resembles how the future city looks like. The above introduction exposes the significant role visualizations play in planning and designating cities, however, to what extent these dominant narratives and visuals impact/construct the professional planning practice, is still under-researched. This is interrogated in this paper through adapting an assemblage ontology and using Actor- Network-Theory (ANT) starting from the street urban-visual experience and going backward to one of the micro publics that creates it (planners and planning offices). This paper adapts a reverse/ backward process trying to unravel the layers behind the construction of street billboard. Using ANT, urban visualizations and media are perceived as both the method for research and the method for understanding planning practice and planners' role accordingly. This study shows a first scratch in the communicative network of urban projects in Cairo written from the perspective of assemblages and human-non-human actants - using ANT, telling the story of how media co-construct the urban in Egypt. In general, different actants are formed between human and non-human actors (media) in relation to different communicative situations. The planning knowledge that is communicated to the general public in Cairo's streets showed to be mostly consisting of 3d rendered urban images with English or French slogans promising a greener and bluer future. Meanwhile, the contact between planners and the general public doesn't go beyond these images. Planners are constantly met with the images they produce in the streets (which is emancipated by their education and the omnipresence of similar images all over the streets). This makes planners themselves get caught in reproducing what they produce (market).

The study does not show how planners influence the public by their 3d images, but rather how planners are embedded and enrolled and impacted by what they produce. So in a way, planners visualize plans and after that these images recreates planners. In the end, media as an important tool in communicating planning and the city to the general public, urban planners become one of the influenced micro public who does not only create it also but also get affected by it. In a mediatized city like Cairo, planning is media

Case Study / Project

Urban planning agencies

A key support for metropolitan governance

Eric HUYBRECHTS

Abstract

Metropolis and Megapolis are facing huge challenges due to their extreme complexity and their responsibility to drive the economic and social development of countries. Today, more than 50% of urban dwellers are living in metropolitan areas of more than 500,000 inhabitants. The metropolis is the main artifact of the present century. Managing the metropolis is one of the main challenge of today, balancing between citizen representation, efficiency of public service delivery, regulation of land and real estate markets and quality of life. Metropolitan areas are the engine of growth, then high energy consumers. Their responsibility regarding GHS and climate change is huge. The frequent changes in the governance systems to manage territories and public services make difficult to conduct strong and clear policies for development. The necessary intertwin between territories, technical sectors and different levels of administration create high complexity in the management. The power of decision is shared between a lot of actors. Managing metropolitan areas requires collective intelligence support by strong technical bodies to feed the public debates with relevant data, analysis and forecasts.

Metropolitan planning agencies are disseminate on large metropolis due to the necessity to prepare policies and strategies on the metropolitan complexity. They are interdisciplinary teams covering social, spatial, economic and environmental fields. Among the main metropolitan planning agencies there are very different status. For example, we consider Seoul Institute which emerge from the academic field, the Paris regional planning agency that is a semi public body dedicated to Paris region and its numerous territoires, Regional Planning Association of New-York which is supported by sponsor-members or Beijing Planning and Design Institute which is a body inside the Municipality. They play an important role as metropolitan observatories. They play an essential role to prepare policies and strategies in different fields as urban planning, climate, energy, housing, land and real estate, mobility, environment, economic development. The new global network of Metropolitan and territorial planning agencies provide support to strengthen these bodies and help metropolitan areas to create their planning agencies.

Case Study / Project

Developing the regulations for rapid urban growth

The new Centre Plans and TOD of the Doha metropolis, Qatar

Slawomir LEDWON, Fatma AL-BADER, Noora AL-SUWAIDI

Abstract

In less than a few decades Qatar äóñ a country in the middle of the Arabian Peninsula äóñ has grown from a fishing and pearl hunting nation into the most affluent economy with the highest GDP per capita in the world. The population increased from just over a hundred thousand in the 70s to around 2.5 million currently. These major changes had to be reflected in the spatial growth of the country, mainly the metropolitan area of joint Doha and Al Rayyan municipalities.

Such rapid changes needed a parallel evolution of planning regulations and approaches to spatial development, that did not exist before. Planners had to introduce to the country and implement a whole new system to meet the needs of developers, but also to be able to control its development and make sure it follows a coherent vision. Very basic regulations were substituted by complex strategies.

The project of Qatar National Master Plan has developed Qatar National Development Framework 2032 (QNDF), which was approved as a national policy. It introduced many contemporary concepts into the planning and strategies of the country. Together with Qatar National Vision 2030 (QNV2030) and its National Development Strategy it was a foundation for any new initiatives.

Initially the new regulations that were developed were temporary and called Interim Zoning Regulations. Their objective was to provide basic development requirements for the rocketing demand. The simplistic approach was easy to implement, but did not reflect the nation's aspirations to develop a contemporary, efficient and competitive metropolis.

QNDF has put forward a concept of developing centres within the metropolitan area. These were to be aided by the new public transport system, based mainly on new metro lines, which were expected due to winning the FIFA 2022 World Cup hosting rights.

In order to achieve these goals, the QNDF has identified a hierarchical network of centres to allow future growth äóñ from town and city centres to metropolitan and capital city centres. For the whole country a Municipality Spatial Development Plan (MSDP) has been developed. While for the central neighbourhoods, including the new public areas of the stations, there were no special regulations. And the traditional approach to planning did not allow for mixing uses within one lot. Therefore there was a need to develop more complex centre plans and focus on transit oriented development (TOD) around the new metro stations, which are currently under construction by Qatar Rail. TOD sites were also addressed in a new masterplanning process with the developer. Currently a more advanced regulations for the Capital City Centres are prepared, including form based regulation to shape the existing and future form.

The presentation explains the evolution of planning in Qatar, and the rationale behind the latest approved centre plans. It gives examples of and the experience and comments on which were successful and why. Also reflects critically on items that will need to be revised. It discusses the applicability of such approach in both developed and developing settings.

The presented case study can be useful as a reference point on city growth and regulatory measures to steer these changes in rapidly changing environment. It can also show how to shift from land use based simple zoning into more complex regulations also relating to form. Concepts of mixed use development and private sector involvement are also discussed.

Research Paper

Infrastructure Imbalance, Financial Investment and AIIB's Role: Non-state Actor in Regional Governance

Xiangyi MENG, M.S. in Urban Planning, School of Architecture, Tsinghua University; China
Taofang YU, Associate Professor, School of Architecture, Tsinghua University; China

Abstract

The Asian Infrastructure Investment Bank (AIIB), a new multilateral development bank, is an emerging force to solve the problem of infrastructure imbalance in developing countries in Asia. Only a few existing researches focuses on infrastructure investment and spatial governance. Based on the economic geographical framework of density, distance and division, this paper attempts to analyze three traditional governance modes in the context of infrastructure imbalance in developing countries in Asia: low-density sprawl, long distance and limited accessibility to central markets, and spatial division. Infrastructure has obvious positive externalities and will widen the differential rent gaps through land value increment, which will bring higher economic density and agglomeration economies. After analyzing the AIIB's 38 approved investment projects, this paper takes Colombo urban regeneration project in Sri Lanka, Gujarat rural roads project in India and Mandalika tourism infrastructure project in Indonesia as examples, to explore the AIIB's non-state role in spatial governance.

Keywords

Asian Infrastructure Investment Bank (AIIB); Infrastructure-led Development; Density, Distance and Division (3Ds); Under-developed Areas; Differential Rent.

1. Introduction: Infrastructure Imbalance in Asian Developing Countries

According to relevant theories of public economics, infrastructure is a category of "quasi-public goods" with rivalry and non-excludability. Rivalry of infrastructure will generate positive externalities of land value increment and more private capital. However, its non-excludability makes it difficult for the public sector to avoid the "Tragedy of the Commons" caused by free riders. Features of quasi-public goods result in insufficient incentives for private investors as the private benefit is far less than the overall social benefit from the infrastructure construction (World Bank, 1994; Mankiw, 2012). Meanwhile, infrastructure is characterized by large investment amount, long return period, huge "sunk cost" and high initial risk. Only when a completed network forms can infrastructure fully perform its functions (McCann and Shefer, 2004; Ehlers, 2014). These economic attributes make public

investment a major source of infrastructure financing, for which private capital is not easy to access (World Bank, 1994; Asian Development Bank, 2017).

Developing countries in Asia are suffering from severe infrastructure imbalance and infrastructure investment gap. The rapid economic development and urbanization have given rise to much more demands for urban and regional infrastructure (Straub and Terada-Hagiwara, 2010). Public capital alone cannot meet the increasing needs. However, the private sector and international capital markets are far from being tapped (Ehlers, 2014).

The Asian Development Bank (ADB) estimated that Asia and Pacific Region would need an investment of $22.551 trillion from 2016 to 2030. In 2015, the infrastructure investments in 25 developing member countries were $881 billion, but there was still a financing gap of $459 billion. The public sector overwhelmingly dominates the existing infrastructure investment. It accounts for 92%, much more than any other financing sources, including Multilateral Development Banks (MDBs), an emerging force in infrastructure investment, which only accounts for 2.5% (ADB, 2017). The research conducted by McKinsey Global Institute indicated major needs of approximately $20.1 trillion in developing countries in Asia from 2016 to 2030 (McKinsey Global Institute, 2016). Meanwhile, another report released by the World Economic Forum evaluated infrastructure capacity worldwide in terms of transportation, electric power and water supply (Figure 1). The report indicated that the infrastructure gap and imbalance was so evident in developing countries in Asia that an effective solution was of great urgency. (Schwab, 2018).

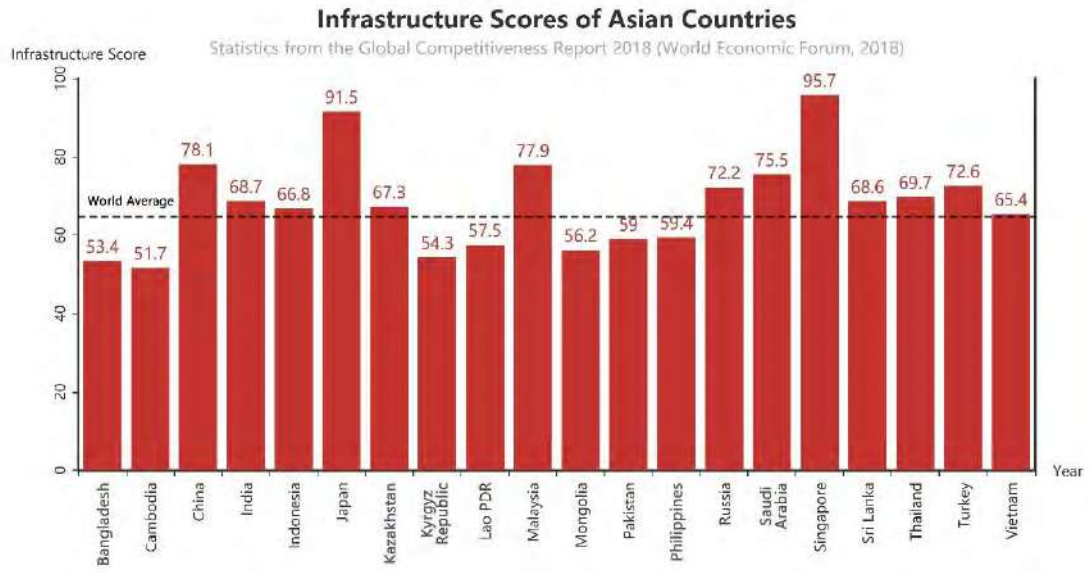

Figure 1 Infrastructure scores of Asian developing countries

Source: Authors' compilation from the Global Competitiveness Report 2018 (Schwab, 2018).

Under such circumstances, the Asian Infrastructure Investment Bank (AIIB), established in January 2016, gradually becomes an emerging force in infrastructure investment. Initiated by China, it aims at bridging the long-existing and huge infrastructure financing gap in developing Asia by further investments, and promoting sustainable economic development. (AIIB, 2015). Unlike the World Bank, the Asian Development Bank and other existing multilateral financial institutions with diversified business domains in multiple countries, the AIIB mainly focuses on Asian developing economies and the investment in sustainable

infrastructure projects, playing a potential critical role in addressing Asian issues. In recent years, researches on the AIIB mainly analyze its development process (Etzioni, 2016) and institutional administration structures (Chin, 2016; Callaghan and Hubbard, 2016), and some are conducted from international political perspective (Hameiri and Jones, 2018; Wilson, 2019). However, there is few researches on the AIIB's infrastructure investment projects and spatial governance. This paper, from the spatial perspective, attempts to provide a theoretical framework to describe the participation of multilateral financial institutions in regional spatial governance.

How to solve the problems of infrastructure imbalance and financing gap in developing countries in Asia? As an emerging force in infrastructure investment, how does the AIIB participate in regional governance as a non-state actor? To answer these questions, the paper, based on the World Bank's framework of "Density, Distance and Division", analyzes the AIIB's approved projects, the traditional governance phenomena in the context of infrastructure imbalance, and the revolution brought by the external capital.

The paper is divided into four parts:

(1) Background: economic attributes of infrastructure and infrastructure imbalance in Asian developing countries;

(2) Research materials: basic information and spatial distribution of the AIIB's 38 approved projects;

(3) Theoretical framework: the economic geographical framework of density, distance and division; traditional spatial governance shaped by the long-standing infrastructure imbalance in developing countries in Asia; and positive externalities of infrastructure through differential rent;

(4) Case studies: three projects located in Sri Lanka, India and Indonesia, and AIIB's spatial governance effects through infrastructure investment.

2. Research Materials: AIIB's Approved Projects

Selected research materials were mainly the published documents on AIIB's official website (https://www.aiib.org), including 112 documents of 38 approved infrastructure investment projects. The research materials cover basic financing information, environmental and social planning frameworks, and the latest implementation progress. Additionally, the research materials also contained the AIIB's establishing agreements, documents concerning banks' management framework, investment policy, business strategies and other basic regulations, relevant news reports and documents of the proposed projects. The basic institutional information, annual reports and project documents of the World bank and Asian Development Bank published on their official websites were also used as extra information during the research. The documents of the AIIB's 38 approved projects were classified according to 10 attributes. They are the project location, types of infrastructure, total project investment amount, investment entities and their investment ratio, co-financing with other multilateral banks, the status of guarantee, attributes of borrowers and implementation agencies, maturity period, project risk levels, and the time of approval and implementation periods.

As for location, the AIIB's 38 approved projects are carried out in 15 developing Asian countries, which embodies AIIB's innovative feature of regional, developing countries dominance. Among them, 9 are in India, 5 in Indonesia and 4 in Bangladesh. The 3 countries have the largest number of approved projects. The remaining 12 countries have one or two respectively. Except for that, two fund projects involving financial intermediaries are not country-specific but serve developing regions in Asia as a whole[1]. The AIIB's focus on developing Asia is also reflected in its membership. It reserves 76.6% total subscriptions of contributions for regional member states (AIIB, 2019a), which is higher than that of the Asian development bank (63.4%), a regional multilateral development bank (ADB, 2019).

The AIIB focuses on infrastructure-related financing projects. The 38 approved projects cover Energy (34.2%), Telecommunications (2.6%), Transport (23.7%), Urban (5.3%), Water (13.2%), Finance (13.2%), and multi-sector (5.3%)[2]. The projects mainly focus on trans-regional energy and transport infrastructure, at the meantime, they have more specific and diversified subsectors (Figure 2).

Risk and return is the core concern of private multilateral financial institutions. Relevant attributes include guarantee status, and the attributes of borrowers and implementation agencies. Such factors have an obvious influence on the risk and profit outlook of the AIIB. The guaranteed projects can be further divided into projects with sovereign-backed financing (SBF) and projects with non-sovereign-backed financing (NSBF). SBF means that loans have sovereign guarantee, and others are identified as NSBF (AIIB, 2017a). According to the attributes of borrowers and implementation agencies, projects are further classified into public-sector-led projects and private-sector-led projects in this paper. The public-sector-led projects refers to those whose borrowers and implementation agencies are governmental institutions, state-owned or state-controlled enterprises, and social institutions and organizations established by governments for special purposes. The private-sector-led projects refers to those whose borrowers and implementation agencies include private entities, such as the institution established by a joint-stock company which is jointly owned by diversified stakeholders for special purposes. As an emerging multilateral development bank, the AIIB has 29 projects guaranteed by sovereign credit, 27 of which were led by the public sector of recipient countries. And among the other 9 projects with NSBF, 2 are led by the recipient countries' public sector.[3] Sovereign guarantee and the leading role of the public sector will help financial institutions reduce investment risks at the early stage of their establishment, accumulate project investment experience step by step, and pursue long-term returns.

Based on the basic information of these projects, this paper analyzes the traditional governance phenomena in the context of infrastructure imbalance in Asian developing countries and, by studying the following 3 projects, analyzes the modes of the AIIB's participation in spatial governance.

3. Theoretical Framework based on Density, Distance and Division

3.1. Literature Review

Review of Literature on 3Ds

Density, Distance and Division (the 3Ds), three elements of economic geography, were regarded as the core of regional economic development in the world development report published by the World Bank in 2009. According to the report, the density of economic, capital and technical elements per unit land can be used for evaluation of local economic outcomes efficiency (World Bank, 2009). Studies have fully proved that high-density agglomeration economies promote continuous economic development and urban economic output efficiency (Wheaton and Shishido, 1981; Ciccone and Hall, 1993; Gallup, Sachs and Mellinger, 1999). The distance from a region to the core market, or the accessibility to the core market, can be used for the evaluation of the region's potential for obtaining spillover effects and integrating into market exchanging system (World Bank, 2009). It is generally acknowledged that the longer the distance from the region to the core market is, the less the spillover effects of capital the region will obtain, and the longer distance is an unfavourable factor for production efficiency, employment opportunities and wages in the region and for agglomeration economies (Rosethal and Strange, 2001; Roberts and Goh, 2011). Division refers to the geographic and social impermeability and barriers because of borders, languages and regulation systems among regions. It can be used to evaluate the regional economic integration. In Asian developing countries, factors for spatial division exist widely. These factors can be divided into institutional factors and social-cultural factors. The former includes national borders, regional administrative boundaries and regulation systems, while the latter refers to languages, cultural customs, religions, races, etc. (World Bank, 2009; Wang *et al*, 2018).

It is generally acknowledged that higher density of economies, shorter distance to the central market and less division will develop agglomeration economies and improve the overall economic efficiency (World Bank, 2009). A few researches have analyzed under-

developed regions and especially Asian developing economies based on the framework of 3Ds. They have proved that the relation between 3Ds and economic development also applies to developing countries and under-developed regions (Guo and He, 2012; Wang *et al.*, 2018). However, only few studies analyze the traditional governance phenomena, and especially land use features, using the framework of 3Ds.

Review of Literature on Infrastructure and Governance

Infrastructure supply is closely related to regional governance. Infrastructure imbalance is a major reason for regional under-development, while diversified external sources of infrastructure investment can improve the governance structure (Mengistu and Adams, 2007; Ogun, 2010; Sorensen, 2018). In Asian, African and Latin American developing countries, inefficient governance of the public sector and limited capacity of public investment have severely influenced the supply of basic infrastructure, which increasingly attracts global attention. Emerging forces such as non-governmental organizations (NGOs), the private sector and international donors are increasingly participating in the developing economies' improvement of infrastructure and governance. Social infrastructure aid such as governance structure improvement is gradually replacing physical infrastructure aid (Nunan and Satterthwaite, 2001). Compared with the internal forces in developing countries, "non-state" governance can bring institutionally and spatially changes to the recipient countries from the outside in a more profound and direct manner (Mengistu and Adams, 2007). For instance, the World Bank, the Asian Development Bank and other existing multilateral financial institutions have assisted the recipient countries through infrastructure investment projects, as well as assisted their social governance through technical assistance, anti-corruption mechanisms and capacity building (Bafoil and Lin, 2010).

Although there are substantial researches on infrastructure, regional governance and diversified external forces, only few researches analyze traditional governance phenomena in the context of infrastructure imbalance and the role of infrastructure in spatial governance. This paper mainly focuses on the two aspects.

3.2 Analyzation of Traditional Governance Phenomena in Asian Developing Countries based on 3Ds

As mentioned before, the infrastructure imbalance and financial investment gap have long plagued developing countries in Asia. The long-term infrastructure imbalance results in limited endowment of density, distance and division, causing problems of low-density sprawl, long distance and limited accessibility to the central market, and severe spatial division. In this paper, we classify the traditional governance phenomena into three categories: (1) the low-density sprawl existing in urban areas and towns; (2) long distance and limited accessibility to the core market in under-developed areas; (3) the spatial division and collage in the most under-developed urban and rural areas, or unpopulated zones (Table 1).

First, the low-density sprawl exists in urban areas and towns in Asian developing countries. It still functions under contemporary governance discourse systems, with public and private sectors jointly providing management, public services and goods. However, the low saving ratio and low investment ratio of cities' public finance lead to low returns rate of land output. The long-existing inefficient development has led to an undifferentiated network in terms of spatial connection, without spatial centers and nodes. Social diversified capital is of low

liquidity and lack of encouragement for converging, so the effect of agglomeration economies is not obvious. As for the land use, low-density, high-homogenized urban sprawl is the core feature in such regions.

Second, under-developed areas have long distance and limited accessibility to central markets. Studies have fully proved that long-distance and cross-regional infrastructure, such as transportation and communications can effectively shorten the spatial distance, reduce transportation costs and promote liquidity of business capital. On the contrary, remote location and limited accessibility brought by the lack of regional infrastructure will hinder the regions' participation in the regional trading network and decrease spillover effects of central market (Limão and Venables, 2001). Other infrastructure, such as electricity and fossil energy, can also improve the economic density of the region. In under-developed regions in Asia, infrastructure imbalance isolates a large number of remote areas which are far from central markets, and the connections between these regions are often vulnerable and uneasy to establish. Due to the lack of capital elements, land use in remote areas also indicates the primitive features of low economic density.

Third, spatial division and collage are common in the most under-developed urban and rural areas, or unpopulated zones in developing countries in Asia. Diversified institutional and social division factors, such as local tribes, clans, special interest groups, warlord separatists and administrative boundaries, have contributed to an autonomy based on localism. The fragmented regions hinder trans-regional and large-scale infrastructure investment, planning and construction, making it difficult to form a unified capital market within the region. Clans and tribes, which are commonly seen in rural areas of developing countries in Asia, maintain the governance of villages and tribes by blood ties. When facing these aforementioned existing circumstances, planning and construction of regional infrastructure often encounter difficulties such as civilization conflicts, land acquisition problems and resettlement reimbursement. These remaining forces make the regional infrastructure far from reaching the living standards of contemporary people. Special interest groups, such as gangs in urban slums and opposition regimes across Asia, generate a "self-organizing" governance which means being independent from the public governance. Such groups are only responsible for the economic and social affairs within their groups, such as collecting taxes, providing protection services, or providing basic public services like sanitation and electricity. There are strong centripetal forces and cohesion inside these groups, but insufficient spatial connections between groups, which embodies the spatial division and collage. Land is usually fragmented and combined with inefficiency.

Table 1 Analyzation of traditional governance in Asian developing countries based on 3Ds

Traditional Governance	Scope	Governance	Spatial connection	Land use features
Low-density sprawl	Under-developed urban areas and towns	Inefficient contemporary governance: low investment rate and low rate of returns	Undifferentiated network: lack of spatial centers or nodes	Undifferentiated land use and low-density sprawl

Long distance and limited accessibility to the core markets	Remote districts with limited accessibility	Isolated autonomy	Vulnerable and uneasily-established connection	Low density and fragmentation
Spatial division and collage	Most under-developed urban/rural areas, or unpopulated zones	Autonomy by local tribes, clans, special interest groups or within administrative boundaries	Centripetal division and localism	Fragmentation, inefficiency and collage

3.3 Differential Rent under Infrastructure-led Development

According to the theories of economic geography, a higher economic density will bring about increasing return and agglomeration economies, which is the foundation for regional divergence and locational selection (Krugman, 1991). The positive externalities of infrastructure play a significant role in increasing economic density, and sound infrastructure is the foundation for agglomeration economies (McCann and Shefer, 2004). As for the under-developed districts, remote location, limited accessibility to urban agglomeration economies and spatial division are often the main causes of poverty (Partridge and Rickman, 2008). Meanwhile, infrastructure, especially roads and highways, will effectively shorten the distance, improve the connectivity among human settlements and the flow of capital, business and labors among regions (Limão and Venables, 2001). However, agglomeration economies are closely related to the process of widening the gaps in differential rent. Only few researches focus on the relationship between 3Ds, infrastructure and differential rent.

Differential rent, including Differential Rent Ⅰ and Differential Rent Ⅱ, refers to differences in land production efficiency because of differences in land capability and location. Differential Rent Ⅰ refers to land output efficiency differences caused by the differences in soil fertility and location, while the latter refers to land output efficiency differences caused by the differences in investment, technology and new equipment (Marx, 1909). After the construction of infrastructure, although natural features of the land don't change, the improvement on location will attract emerging elements like capital, public amenities, modern technology and high-quality labor force, as well as raise both Differential Rent Ⅰ & Ⅱ. In the infrastructure-led urban and rural development, the positive externalities of infrastructure play a significant role in improving economic density, which will lead to spatial spillover and land value increment (McCann and Shefer, 2004). During this process, differences will increase and gaps in differential rent will be widened, which will attract capital with stronger land rent affordability to the central zone of mega-cities, and thus form agglomeration economies.

In developed countries, the function zones in urban and rural areas are clear and development is driven by agglomeration economies (Gottmann, 1957), Unlike them, the typical urban and rural land use in developing countries in Asia is summarized as the

"Desakota" model. Due to high population density, huge demand for production and business activities within limited space, and the international context of integrating into the world market and undertaking industrial transfer from developed economies, economic activities in developing countries in Asia have the characteristics of highly mixed and undifferentiated sprawl from urban center to rural in terms of land use (Ginsburg, Koppel, and McGee, 1991). Infrastructure imbalance in under-developed regions in Asia results in low capital density, long distance to central markets and fragmented area division. The long-standing problem of infrastructure imbalance has such consequences: (1) The lack of infrastructure narrows the gap between actual rent and the absolute rent, which will lead to less encouragement to generate surplus value and widen the gaps in differential rent. (2) It is the natural feature of capital to chase economies of scale so that an undifferentiated land will not be favorable enough to attract gathered capital. Only little capital with weak rent affordability will locate in these areas. (3) Differences in functions and landscapes between city centers and suburban areas, or built-up areas and rural areas are not obvious. And an urban-rural low-density sprawl pattern has formed. (4) In the long term, it is easy for this governance mode to get caught in a "closed vicious circle", that is, lack of investment – imbalance and shortage in infrastructure – undifferentiated differential rent – unattractiveness to capital - lack of investment again.

Infrastructure-led development is relatively more sustainable and can form agglomeration economies. First, infrastructure will become the driving force of improvement in geographical location and land rent value increment. Then, capital with stronger land rent affordability will inflow, which will upgrade the industry, capital density and economic vitality, which is the initial effects of aggregation economies. Third, the capital-intensive districts will expand to surrounding areas, which will optimize overall functional zone division and spatial structure of the city.

4. Case Study: AIIB's role in Regional Governance

Generally, regional governance involving bilateral or multilateral external forces has two modes. The first mode is mainly for the public sector, and often financially backed by sovereign credit. Because of its low risk, such loans generally have a long maturity period and are suitable for large-scale, long-distance infrastructure investment in developing countries. In such projects, the AIIB will not directly participate in the distribution of profits, but only receive a certain proportion of loan interests as the investment revenue after the maturity period. The second mode is mainly for the private sector, often with a non-sovereign back. Because of the limited economic and credit capacity of guarantees, financial institutions tend to pursuit short-term profit. In the second mode, financial institutions usually adopt "direct" governance methods such as participating in land development as shareholders, holding shares of the projects and obtaining operating dividends.

At present, the AIIB's 38 approved projects are mainly sovereign-backed financing. The AIIB's indirect spatial and institutional governance, that is, not participating in regional governance as a political, administrative or implementation entity, reflects the AIIB's role of an "non-state" actor. Based on the aforementioned 3Ds framework, this paper analyzes the AIIB's role in regional spatial governance, with cases of Colombo urban regeneration project (increment of economic density), Gujarat rural roads project (improvement in accessibility)

and Mandalika tourism infrastructure projects (spatial integration). All the three projects are sovereign-backed, with standalone financing (without other multilateral development banks as co-financers) and without the AIIB's direct participation in the distribution of profits. Among them, the urban regeneration project is analyzed as the main case, because in this case, economic density and agglomeration economies have the most direct and profound influence on space.

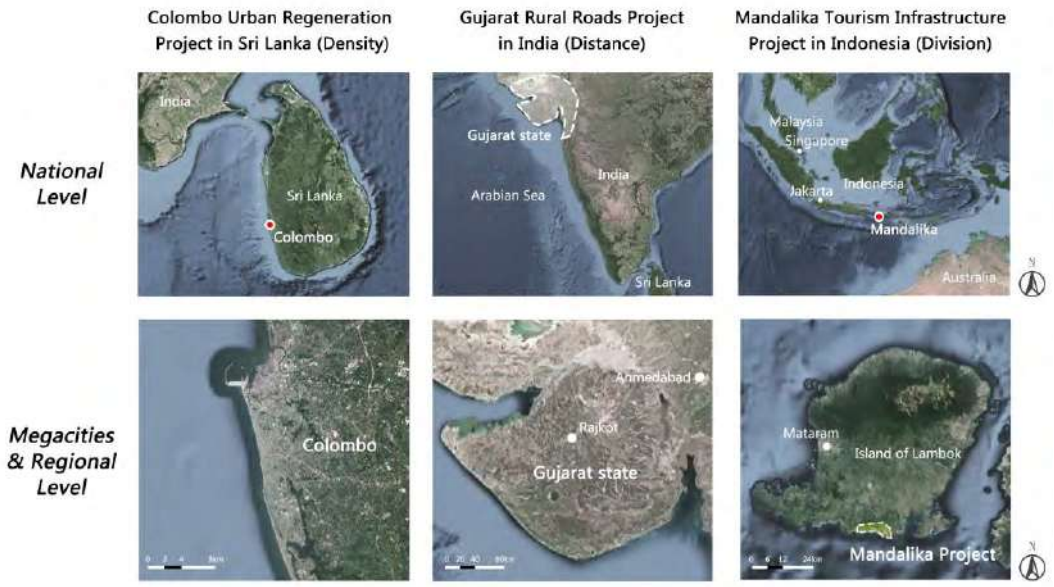

Figure 3 Locations of selected projects

Source: Base maps are from the Google Earth. The projects' locations are from the AIIB's investment documents (AIIB, 2017b; AIIB, 2018; AIIB, 2019b).

4.1. Density: Colombo Urban Regeneration Project in Sri Lanka

Colombo urban regeneration project is a typical example of dealing with low-density sprawl within urban built-up areas through widen of differential rent by infrastructure investment. Colombo is the largest mega-city with the highest economic and population density in Sri Lanka. However, like the most cities in under-developed regions in Asia, the land use of Colombo is characterized with obvious low-density sprawl. In 1960s, the Government of Sri Lanka built one-or-two-stories buildings with low density to handle the housing problems of low-income people (AIIB,2019b). Most of them have suffered long from the severe deficiency in electricity, drainage system, road access, etc. According to a survey of Urban Development Authority, there are still 68,812 households, over 50% of Colombo's population, living in 1499 such underserved communities in Colombo (Urban Development Authority, 2018a). In terms of land use, commercial land is now concentrated in the north-south narrow regions near the west coast. Low-story communities have taken up vast tracts of urban land, resulting in the low-efficient, low-density land use. Limited unused land hinder the expansion of urban commercial district, which seriously affects the accumulation of capital and the promotion of economic density. Additionally, the newly built-up areas have to turn to the suburbs which are farther from the city center (Urban Development Authority, 2018b; AIIB, 2019b). In consequence, the phenomenon of cities and towns encroaching into peripheral villages and woodlands became increasingly severe.

In the background of low-density sprawl, AIIB supports the Government of Sri Lanka through standalone infrastructure investment to carry out urban regeneration, aiming at regenerating the underserved low-income communities by demolition, and land redevelopment in Colombo, Sri Lanka, to provide affordable housings for the bottom class and improve land economic density, utilization efficiency and potential profits by infrastructure construction and commerce redevelopment. According to the financing documents, this AIIB-led project has two major tasks. One is to build 4074 affordable multi-story apartment units, which will be carried out in 6 blocks with 17.4 acres of land in total, to meet the residential needs of low-income groups. The other one is to redevelop the 92 acres of vacated land in 10 blocks (Figure 4). 6 acres of land will be used for basic infrastructure and the rest 86 acres of land for commercial redevelopment. Small pieces of land will be directly auctioned to developers. Medium-sized land will be auctioned after being sub-divided and equipped with infrastructure by implementation agency. Public-Private-Partnership (PPP) will be applied to large-sized land, replacing implementation agencies with elected private partners for land redevelopment (AIIB, 2019b).

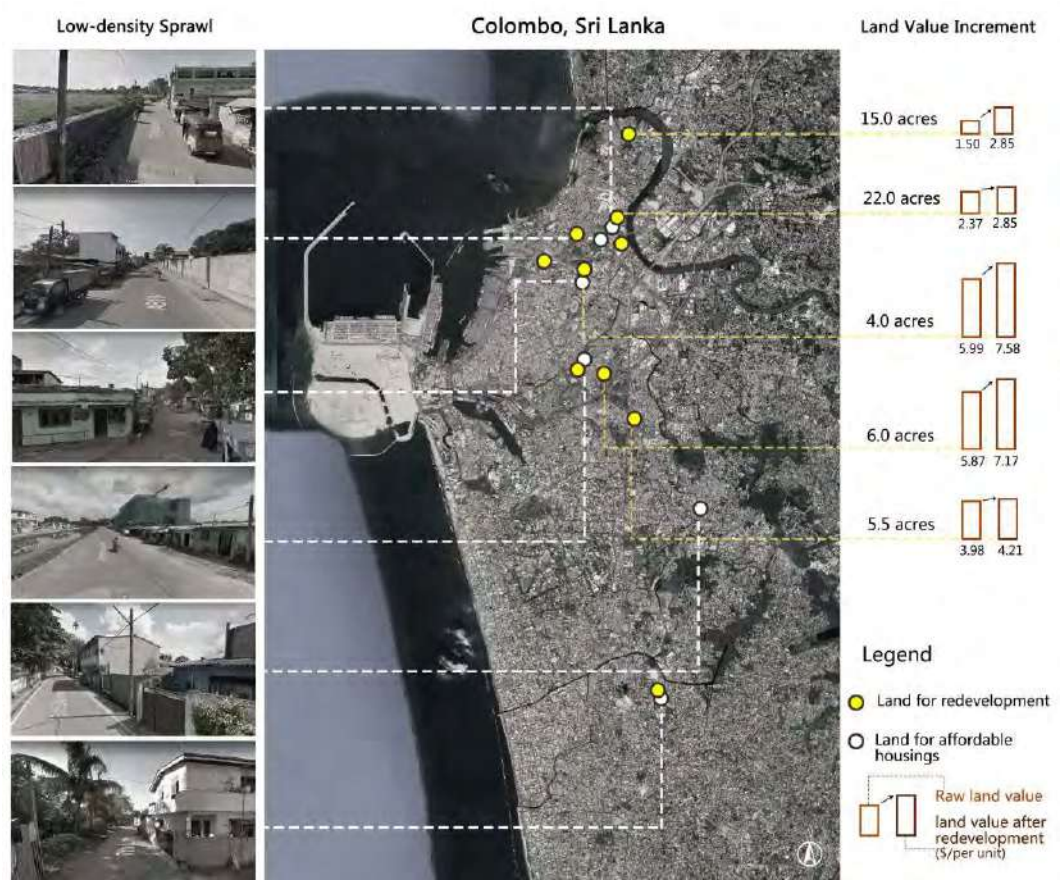

Figure 4 Locations of land for affordable housings and redevelopment in Colombo

Source: Base map and street view pictures are from the Google Map and statistics are from the AIIB's financing document of the project (AIIB, 2019b).

Urban regeneration and land transaction involves multiple stakeholders with diversified demands. Firstly, the public sector represented by states and state-owned institutions, as land owners and implementation agencies of the regeneration, will enjoy the long-term economic benefits brought by land value increment. It is estimated that per unit land price

will increase 6%-166% after land redevelopment (AIIB,2019b; see graphs of land value increment in Figure 4). The infrastructure investment will increase the differential rent of regenerated land, and attract more private capital investment as a financial leverage. After that economic and capital density will increase and agglomeration economies will be formed. Meanwhile, the homogenized urban network will develop new economic centers and nodes during the land redevelopment, and the urban spatial structure will be optimized (Figure 5). Current spatial pattern of high concentration of commercial capital in coastal areas will be gradually replaced by the multiple-center pattern in megacities. Spillover effects of new commercial centers will also promote the upgrading of surrounding areas, and hinder the expansion of built-up areas to rural areas. Additionally, highly-intensive commercial redevelopment will provide funds for future regeneration.

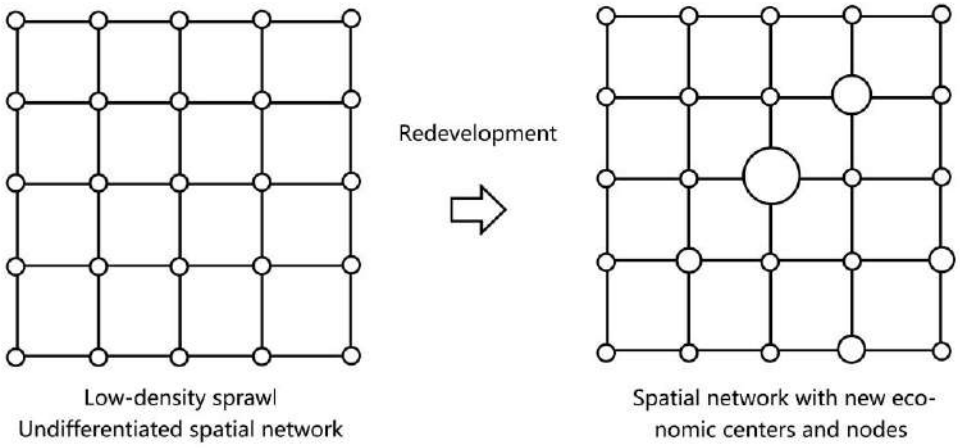

Figure 5 The AIIB's role: from low-density sprawl, and the undifferentiated urban network to the network with new economic centers and nodes

For low-income residents, housing conditions from original "underserved communities" to current affordable housings with adequate infrastructure have substantially improved their living conditions. However, it may also bring about gentrification, with the increase of living costs and "crowding-out" effect for low-income groups. The involuntary relocation may also result in negative, irreversible social impact on individual social networks and cultural memories of low-income residents.

As private partners, developers and contractors will replace governmental agencies to carry out land subdivision, planning and infrastructure construction. The revenue will be distributed between public and private sectors based on the share of contributions (AIIB, 2019b). Maximum profit, which is the core concern of private enterprises, will encourage developers to make a balance between benefits and risks, and fully realize the land's profit potential during commercial redevelopment.

Finally, as the financial provider from outside, the AIIB's financial investment will assist the under-developed regions to jump out of the vicious circle of "low investment, low profit and low efficiency", and move towards an infrastructure-led development path. Meanwhile, the AIIB is subtly pushing the recipients to form a modern governance mode, through mature multilateral project management. The origin intention is to avoid and mitigate risk of investment that widely exists in Asian developing economies, such as inefficient implementation and damage to environmental and social sustainability. The Colombo urban

regeneration project is run by a specially-established department with modern management structure. Monitoring of implementation by the AIIB will run through the process of planning, financial supply, procurement and construction. The AIIB will provide necessary technical assistance. In each project, the AIIB evaluates the transparency of governmental agencies, environmental and social sustainability, and potential revenue. The Colombo project is rated as "Highly Risky", especially in the aspects of governmental credit, and land acquisition and resettlement (AIIB, 2019b). It will urge the local public sector to pay attention to the anti-corruption, and improve the environmental and social inclusion by respecting the interests of low-income groups. By these aforementioned mechanisms, the local governance will get gradually improved.

In conclusion, the AIIB's role in spatial governance is to promote multiple stakeholders to take part in urban regeneration, promote value increment of specific land, gather capital elements, and gradually change the traditional development mode of low-density sprawl. As shown in Figure 6, the graph reflects the traditional mode of low-density sprawl before land redevelopment in Colombo: the central business district of Colombo has strong land rent affordability, while areas outside the central business district are characterized with undifferentiated low-density sprawl. The differential rent is very close to the absolute rent. As shown in the Figure 7, after the infrastructure construction and land redevelopment, the land rent curve moves upward and the differential rent increases. The increased differential rent will be shared as profit among the public sector, local residences, developers and the AIIB. The public sector will get profit from land premium. Local residences will enjoy the improved housing conditions. Developers will get economic returns under interests' incentives. The AIIB will acquire a certain rate of interests after the maturity period, although it will not directly participate in the project implementation and distribution of profits, which indicates AIIB's non-state role in regional governance. Additionally, governance structure in under-developed areas will get improved gradually with the introduction of the AIIB's "outside-in" multilateral governance and the guidance of modern management mechanism.

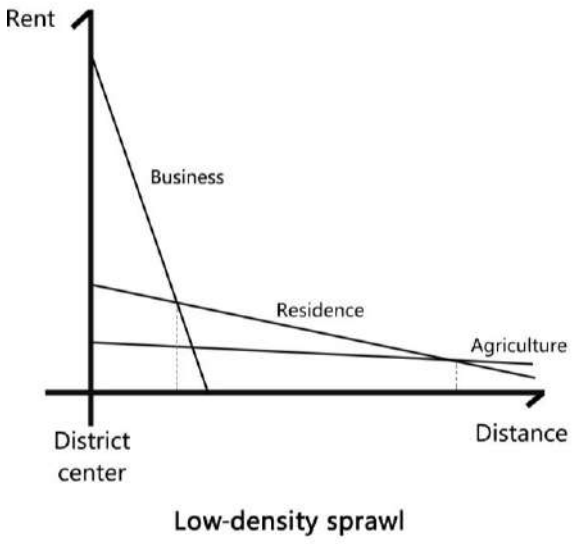

Figure 6 Low-density sprawl before land redevelopment in Colombo

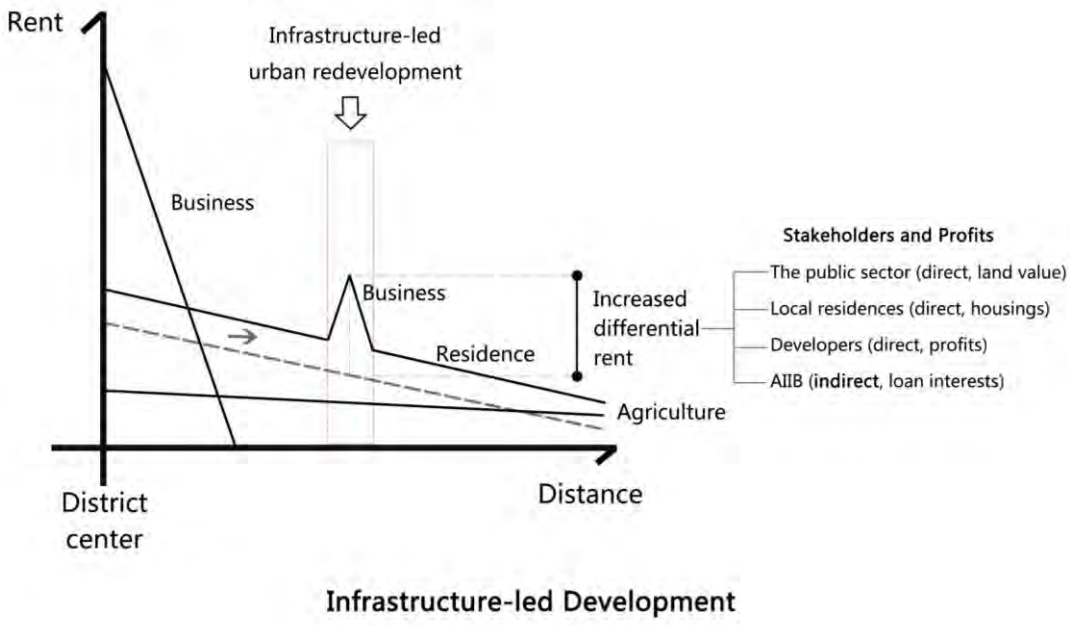

Figure 7 A new infrastructure-led development mode after land redevelopment

4.2. Distance: Gujarat Rural Roads Project in India

It is necessary to construct cross-regional infrastructure because of the demands for regional social-economic connections such as transportation and telecommunications, as well as the uneven distribution of fossil energy, electricity and other resources. In the AIIB's 38 approved projects, regional infrastructure projects aiming at shortening the spatial distances among districts, including construction of inter-city highways, urban rail transits, power transmission, natural gas pipelines, and upgradation of rural roads, account for approximately 45%, which shows that the AIIB mainly focuses on shortening spatial distances, improving the free flow of population, capital and commodities, and promoting the even distribution of energy and resources.

The Gujarat rural roads project is sovereign guaranteed by government of India and invested by the AIIB alone. Gujarat, located on the western coast of India, is a relatively developed region of the country, but 57% of its population still live in rural areas (Government of Gujarat, 2017). The project has two tasks. One is the reconstruction of 5045 km unhardened and non-planned roads, and the upgrading of 2518 km hardened roads that have not been maintained for years. And the other one is to upgrade and maintain those planned roads regularly in the following years (AIIB, 2017b). It is estimated that the project will change 8 million rural people's travelling conditions and way of life (AIIB, 2017b).

India has preliminarily established a road system consisting of "national highway", "state highway", "district road", "village road" and "non-planned road" (AIIB, 2017b). However, there are still many remote villages that are far from main roads and lack road branches, and first and second connectivity rural roads which are linked to the national, provincial and district road networks. There are still long distances from villages to central markets, villages and better service facilities. The remote villages are isolated and autonomous. Land is mainly used for agricultural production and housing (AIIB, 2017b). The gap between differential rent and absolute rent is not obvious. The production activities and the way of life in such villages

are in a primitive, self-sufficient and inefficient manner. Moreover, spatial divisions caused by languages, customs and races are quite common. There are still large proportions of scheduled castes (6.74%) and scheduled tribes (14.74%), and some primitive tribal groups still suffer from pre-agricultural living conditions. These tribes mainly use dialects, with a literacy level of less than 50%. In terms of social customs, they have inherited the worship of deities, arranged marriage within communities, and unique customs and festivals (Government of Gujarat, 2017). Localism forces represented by tribes and clans have the feature of introversion because of the lack of transportation infrastructure and the connection to modern societies.

Distance to central markets is the core element that influences rural economic development. Because of the AIIB's investment in transportation, the spatial distance between rural settlements and central markets will be shortened. Influences on spatial governance brought by the investment can be shown in the following three aspects. First, a closer economic connection with higher-grade service points will take shape. Remote villages will be interconnected with higher-level settlements and regional central markets, and will be influenced by the spillover effects of their economic and capital elements, which will increase rural economic density. Agricultural products and agri-processed products will require less transportation time and economic costs, and have the opportunities to be sold with more profits. The service scope of schools, hospitals and other serving institutions located at higher-grade service points will be expanded, which can improve the medical services, and diversify commodity markets in remote rural areas. Second, the formation of linear corridors will be accelerated and in nearby areas, the land price and economic density will increase. Meanwhile, as the population increases, villages will expand alongside roads. Third, the transportation infrastructure will connect the isolated villages and tribes to modern societies and realize spatial de-division.

4.3. Division: Mandalika Tourism Infrastructure Project in Indonesia

Mandalika tourism infrastructure project in Indonesia is a typical infrastructure-led case in the most under-developed rural areas or unpopulated zones. Mandalika, located in Island of Lambok, is one of the Indonesian most economically backward provinces. The project is mainly located in a less-developed rural area with severe poverty. There are 77 villages scattered in the region, with nearly 10000 agricultural households and more than 30000 rural people. Among them, approximately half of the households are struggling in the "lowest to five welfare categories" living conditions. And the population below the poverty line in the region accounts for about 16%. (AIIB, 2018; ITDC, 2018) Indigenous people in Mandalika are mainly Sasak. Current land use has primitive and pre-industrial features, with vast unoccupied dry land, farm land and forest land. Meanwhile, transport infrastructure in the region is insufficient. 72% roads are unpaved earthen roads, which severely influences the economic connections between villages and external markets, resulting in universal spatial division (ITDC, 2018).

The project aims at providing the most basic infrastructure including roads, water supply, drainage systems and electricity, which are now in an extreme shortage. Public investment in infrastructure will lead to the upgrading of regional environment, attracting private investment in tourism industry such as hotel and retail business. After the improvement of tourist facilities, the region will attract an increasing number of tourists, their average stay and consumption, which will increase public and individual income with a unprecedented

speed. Moreover, the project will bring about more than 30000 direct jobs in hotel business and 60000 indirect jobs in relative industries, which will effectively improve the household living standards (AIIB, 2018).

The AIIB introduces Special Economic Zones (SEZ) like Mandalika to realize its spatial governance in under-developed rural areas and unpopulated areas. By doing so, transportation and telecommunication infrastructure are getting significantly improved, which can effectively reduce spatial division. Governance in these under-developed regions has a distinctive pre-industrial feature. Due to the localism forces like clans and tribes and limited accessibility, settlements are quite scattered and inward, showing the land-use pattern of spatial isolation and division (Figure 8).

Due to the lack of endogenous economic driving forces such as technologies, capital and high quality labors, and the limited public financial capacity, the region has been trapped into a "closed-loop" development with low investment rate, low savings rate and low rate of return. The only way to break this "closed-loop" is to establish "Special Economic Zones" with the help of top-down external forces, which will help form a "central zone" with high agglomeration of capital and economic activities. The central zone's spillover effects will further promote the development of its surrounding areas.

During this process, economic density of per unit land will increase, and the former phenomenon of spatial division and collage will be gradually replaced by the centralization brought by "Special Economic Zones". Governance achievements and the return in the public sector will be realized. Driven by the infrastructure investment, the private companies engaged in business and accommodation will join the tourism market and make profits. The indigenous people will have more job opportunities in tourist industry, and thus will get higher family income, and will gradually get rid of poverty through self-employment or being employed in the private sector. In conclusion, in Asian under-developed rural areas of the pre-industrial level or unpopulated zones, the AIIB's infrastructure investment will promote the development of regional economic centers and reduce the spatial division caused by ethnic, tribal and cultural customs.

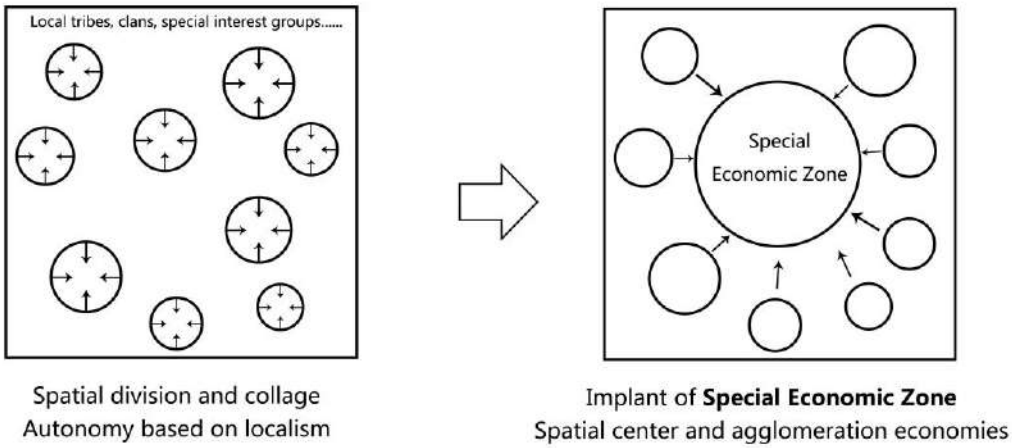

Figure 8 The AIIB's role: from spatial division to agglomeration economics by the SEZ

5. Conclusion

The paper mainly focuses on the framework of density, distance and division of economic geography, traditional governance modes in the context of infrastructure imbalance in developing countries in Asia, and spatial governance brought about by the AIIB's financial investment. The developing countries in Asia have suffered from severe infrastructure imbalance and a severe shortage of investment. This problem has gradually drawn attention from the academia and society. The traditional public-sector-lead mode is not sustainable. The Asian Infrastructure Investment Bank is gradually becoming the emerging force participating in infrastructure investment in developing countries in Asia.

The framework of density, distance and division is appropriate for analyzing the traditional governance modes in developing countries in Asia. Based on the AIIB's 38 infrastructure investment projects, this paper attempts to analyze traditional governance modes and the AIIB's role in non-state governance under this framework. With current infrastructure imbalance, urban and rural development in developing countries in Asia is characterized by low-density sprawl, long distance and limited accessibility to central markets, and spatial division. The AIIB's participation in regional governance is realized through spatial and institutional governance. As for its spatial governance, the AIIB's infrastructure investment will increase land economic density, shorten distance to central markets and achieve spatial de-division. As for its institutional governance, the AIIB will introduce financing supply policies under the supervision of multilateral stakeholders, modern management and behavior constraint mechanism from the outside, which will assist developing countries jump out of the "closed-loop" and gradually optimize their state governance.

In the Colombo urban regeneration project, the differential rent gaps among regions are widened because of land redevelopment, which will lead to an increase in capital density and form agglomeration economies. In the Gujarat rural roads project, distance from remote villages to central markets are evidently shortened, which will decrease the transportation costs and increase the agricultural output. Meanwhile, spatial division because of tribes and remoteness will get mitigated. Indonesia Mandalika tourism infrastructure projects will mitigate the phenomenon of spatial division caused by races, poverty and cultural customs through building a centralized "Special Economic Zone" in the under-developed area.

As aforementioned, the AIIB's role in regional governance could be reflected in spatial and institutional aspects. However, in most approved sovereign-backed projects till now, the AIIB will not directly participate in the distribution of profits. It will only receive a certain proportion of loan interests after the maturity period as an external financial institution. The AIIB's indirect role, that is, not working as a political, administrative or implementation entity which directly participates in spatial governance, institutional governance and distribution of profits, reflects the bank's role as a "non-state" actor in regional governance.

However, there are still several unanswered questions. For example, can such outside governance mode reflect international political and economic games? Can projects in Asian developing countries and the introduction of such governance system reflect the value judgement and ideology of external member states? Does the integration of remote villages into modern governance system potentially threaten the authenticity of cultures? They involve the value judgement and choices of different stakeholders. It takes time to fully

answer these questions. We need to continuously focus on and further study the projects' implementation and the AIIB's future development.

6. Acknowledgements

We would like to express our sincere gratitude to Assistant Professor Amit Chatterjee from Department of Urban and Regional Planning, School of Planning and Architecture, Bhopal, India. Professor Amit Chatterjee provided precious suggestions for the paper's preliminary version, through ISOCARP's "Mentor and Mentee" program. Thanks for his academic advice and encouragement during the mentoring process.

Case Study / Project

Democratic Urbanism

A Method for City-Building

Joel MILLS, Erin SIMMONS

Abstract

In recent years, the field has witnessed a discernable trend toward the retrenchment of autocratic approaches to city-building and more passive approaches to public participation in major planning and design work about the future of the city. Too often today, expensive public processes are failing to result in popularly supported policies and plans. A growing chorus of notable city-building professionals have expressed frustration with the public backlash to their work, decrying the spread of NIMBYism and denigrating the citizenry they are reliant upon for support. Ironically, this trend runs parallel to an ever-increasing public appetite for meaningful involvement in decision-making processes. Many localities are struggling with limited capacity around facilitated public processes, leading to a marked increase in conflict, controversy and distrust as high stakes public conversations are often poorly designed or mismanaged. The resulting decline in the quality of public processes and civil discourse is adversely impacting our collective abilities to make key decisions to meet our core challenges, ranging from urban systems to housing to climate change. Preparing urban professionals for the 21st century requires an education in democratic techniques. Well-designed public processes that involve citizens in city-building pay huge dividends.

The lessons of the past half-century are clear: When urban democracy expands, cities flourish. Democratic Urbanism represents more than a planning or design exercise. It is a method of city-building that integrates democratic ideals into the urban design process and applies broader shared governance models to the implementation of community aspirations, creating places of deep meaning that are broadly 'owned' in the civic mindset. It is a process that carries forward in the implementation of a collective vision, through actions small and large from all sectors of society. Ideally, it involves the intentional alignment of individual and group interests and actions in pursuit of a collective vision for the future city. It is dependent upon a healthy civic infrastructure. This interactive session will include a number of case studies, short films and exercises from the American Institute of Architects' half century of work in its design assistance program. These cases demonstrate the value of democratic approaches to city-building, highlighting communities that have applied democratic urbanism to achieve remarkable transformations across a variety of contexts.

Some of these stories are young, representing nascent efforts, while others show impacts lasting over decades. Collectively, they form a hopeful narrative that demonstrates our civic capacity to overcome the stark challenges of the 21st century and reinvent our communities. They also illustrate the advantages of a democratic method for city-building that is broader than conventional practice, one based in a collaborative approach to governance that offers guidance to local leaders across the world working on the front lines of change today.

Research Paper

MAKING TOD IMPLEMENTABLE IN INDIAN CITIES

From Theory to Practice

Jyoti Vijayan Nair, NIUA; India

Abstract

India's staggering economic growth in the past decade and the unpredecented rate of ubanisation call for solutions that go beyond the paradigm of traditional planning. Transit Oriented Development (TOD) is widely acknowledged as the solution to sprawl, longer commute distances and carbon emissions– problems that are typical of rapidly urbanising economies. However, TOD has largely been a buzzword in Indian policy documents for over a decade, as the country still awaits its first fully implemented TOD project. This paper studies three key TOD proposals in the megacities of Delhi, Mumbai and Ahmedabad and aims to examine their approaches for want of an effective framework to evaluate the feasibility of TODs across the country.

Keywords

TOD, Redevelopment, Implementation, Policy

1. Background

1.1. TOD in India

Much like their European counterparts, traditional Indian cities are characterised by compact, high-density inner cores, which continue to thrive as major activity hubs even today in many cities like Delhi, Ahmedabad, Hyderabad, Madurai, etc. With the advent of the motor vehicle, city planning evolved to pave way for carriageways and planned development, the way we understand it today. Although western town planning principles made their way to create some of the first planned cities in India like Chandigarh, Bhubaneshwar, Gandhinagar, the impact of centuries of colonisation and exploitation did not wear away easily. Consequently, a crippled economy post-independence was unable to cope up with the pace of urbanisation, and issues relating to rural and refugee migration. Seven decades after independence, India is now home to 5 megacities with a population over 10 million (Nations, 2018), and is slated to overtake China as the most populous country in the world by 2027 (United Nations, 2019). As a result of the State's inability to meet housing demands, Indian cities now face a dire space crunch as informal settlements occupy a major chunk of prime city land. Yet, building norms have not evolved to adapt with the challenges of an exploding population, as most cities continue to follow outdated planning regulations that were imported from car-driven western economies in the 60s. Land-based zoning, minimum setback norms, parking minimums and other such regulations exacerbate issues relating to sprawl and longer commute distances. Latest available government data (MoSPI, 2015) shows that Delhi has the highest number of registered private motor vehicles in the country, followed by Bengaluru, Chennai, Ahmedabad and

Mumbai (see Figure 1). Besides increasing dependence on cars, these vehicles occupy a major chunk of city space in the form of on-street and off-street parking, which can otherwise house the urban poor. A study reveals that 'the annual demand for additional parking spaces for cars can be equivalent to as much as 471 football fields in Delhi, 100 in Chennai, 58 in Chandigarh, and 179 in Gurgaon' (Rowchowdhury et al., 2018). Clearly, land utilisation has to be managed in a more efficient and democratic way, if Indian cities aspire to meet future housing demand.

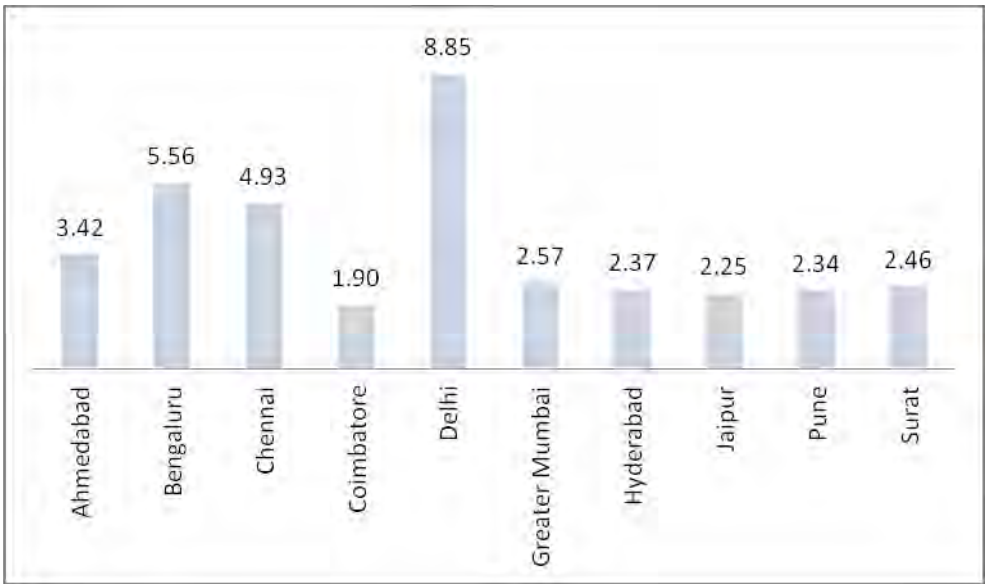

Figure 1. Top 10 Cities with maximum number (in millions) of Registered Motor Vehicles
(Source : Ministry of Statistics and Programme Implementation, 2015)

The need for reducing sprawl and vertical mixing is increasingly being acknowledged in the Indian urban policy context. Learning from their Eastern neighbours like Tokyo, Singapore and Hong Kong, Indian cities are realising the potential of Transit Oriented Development (TOD) as the way forward for rapidly urbanising developing economies. TOD encourages high density, mixed-use living environments that bring live, work and leisure closer to transit, thereby eliminating the need for personal vehicles and thus promoting active travel. Urban practitioners believe that the design principles of TOD coupled with democratic land assembly mechanisms and innovations in project finance could give our cities the much needed makeover and promote sustainable mobility.

1.2. Emerging Policy Climate

The policy climate in the past decade has been in favour of encouraging TOD, as central and state governments are exploring various models to make TODs implementable. The country's first draft TOD Policy for the city of Delhi was released in 2012 (DDA, 2012), as an addendum to the Master Plan Delhi-2021. It was notified with many revisions in 2015 (DDA, 2015), and is being further refined in 2019, as it awaits final notification. The Ministry of Urban Development (MoUD) also released the National TOD Policy (MoUD, 2017) as a guideline for all states to formulate their respective state-specific TOD policies. The states of Jharkhand and Madhya Pradesh now have a policy framework in place, while cities like Ahmedabad, Kochi, and Bangalore have attempted to incorporate TOD in their Master Plans. However, barring the advanced stage of resolution of Delhi's TOD policy with clearly defined institutional setups and plot assemblies for brownfield redevelopment, TOD policies for

most cities just about preach universal principles of urban design as 'special norms' for TOD Influence Zones[1]. Replicating urban design guidelines in the name of state policies without contextualisation or devising of appropriate institutional structures does not help enable TOD as implementable projects.

Numerous TODs are being proposed countrywide, however it's realisation on ground is largely hit-and miss. Delhi's first TOD- the East Delhi Hub at Karkardooma Metro Station was a major proposal by the Unified Traffic and Transportation Infrastructure (Planning and Engineering) Centre (UTTIPEC), that did not fructify amidst much hue and cry, and disagreements between government agencies (Sabikhi, 2016). The website of the Directorate of Urban Land Transport (DULT), Bangalore mentions many proposals including the TOD pilot project for Navnagar, Hubli. However, none of these exist on ground. From a TOD Zone parking management perspective, the World Resources Institute (WRI) studied Ghatpkopar Suburban Rail station area in Mumbai to make recommendations to the Mumbai Development Plan (Rangwala et al., 2014), while a station area accessibility proposal for Indiranagar Metro Station in Bangalore was made as early as 2011 (EMBARQ, 2011). Unfortunately, these too stand as unimplemented academic exercises.

The only promising example of TOD implementation on ground is that of Ahmedabad's proposed Central Business District, wherein the Ahmedabad Urban Development Authority (AUDA) delineated TOD corridors in the last Master Plan and used Gujarat State's progressive land reconstitution mechanism- the Town Planning (TP) Scheme to develop land for brownfield redevelopment. Despite the technical delays in plan preparation (TNN, 2017), if implemented, the CBD will be the first successful example of brownfield TOD in the country.

1.3. Gaps in Implementation

Multiple reasons are attributed to the colossal failure of TOD in India. Firstly, **TOD is largely misunderstood as a tool to increase Floor Area Ratio (FAR) only**, while the aspects of integrated mobility, more public spaces, accessible greens, active street frontages, and minimal parking are sidelined. Ahmedabad's norms relating to Urban Design (setback, building heights, active frontages), permissibility of uses and parking in the TOD notified zone, are the same as across rest of the city (AUDA, 2015). This defeats the purpose of creating a special compact and walkable TOD Zone.

Secondly **normative Masterplans lack the dynamism that can adapt to demand, and often tend to dissociate themselves with on-ground realities** relating to land ownership and size of plots. Delhi's TOD policy (DDA, 2015) attempted to address this issue by devising bottom-up plot assembly mechanisms and appropriate institutional setups. However, putting this enabling framework in place itself took 7-8 years.

Lastly, the biggest issue with TOD policies is that the **norms are uniformly applicable across all TOD station areas, irrespective of context**. A blanket policy across transit stations having significantly different urban conditions is unlikely to fructify without a context-specific action plan. Recognising this gap, Delhi's upcoming revised TOD policy pushes for a phased implementation of TOD on selected nodes instead of the city as a whole (Chitlangia, 2019).

[1] typically delineated as either nodes/circles of 500m radius around metro stations or corridors of 500m on both sides of Bus Rapid Transit Systems

This welcome move is not only an opportunity to identify nodes with high potential but also determine a distinct vision for each node, that will aid in the city's image-making process. TOD policies for other cities are yet to reach this level of streamlining.

1.4. Aim

This paper aims to explore a mechanism for cities to assess feasibility of TOD at a given station *before* a detailed proposal is drafted. It advocates a process of station area selection using a broad set of indicators that can help classify stations into categories of high, medium and low potential for TOD and therefore assist policy-makers in decision making. The methodology will not only provide a framework to predict the success or failure of a potential project, but will also assist in building a case for TOD at a given station.

One of the key conclusions that the paper aims to arrive at is a set of observations on the scope of TOD in densely populated core-city regions versus the sparsely developed peri-urban regions. Broad thumb rules for the development of these may help public and private players understand potential areas for investment and hence work out the economics for such projects.

2. Literature Review

2.1. TOD Zone Delineation

In the case of cities like Tokyo, Hong Kong and Singapore, that are globally acknowledged best practices in TOD, development follows transit and therefore station areas naturally tend to be transit-oriented. Tokyo's strategy of allowing private rail companies to readjust land in greenfields and creating new towns around expanded railway lines, coupled with redevelopment of large parcels of city land around stations, are well-regarded lessons in land assembly and brownfield redevelopment (Suzuki et al., 2013). Hong Kong on the other hand, followed the successful Rail+ Property model (see Fig 2.) wherein the government grants MTR-the privately run railway company, property development rights for station areas at 'before development' market rates. MTR in turn prepares the master plan and co-develops the station area with the developers, while sharing the profit with them on an after-development' market rate (Cervero and Murakami, 2008).

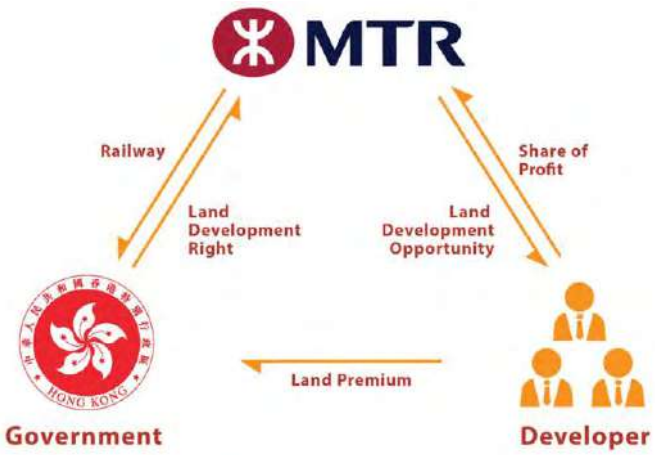

Figure 2. Hong Kong's Rail + Property Development Model *(Source : MTR)*

In the case of Singapore, since 90% of land is owned by the government through acquisition under the Land Acquisition Act of 1967, subsidised public housing by Housing Development Board (HBD) has always been planned around transit stations as shown in Fig 3. As a result, 82% of Singaporeans have access to affordable housing around high capacity transit (Bin and Naidu, 2014).

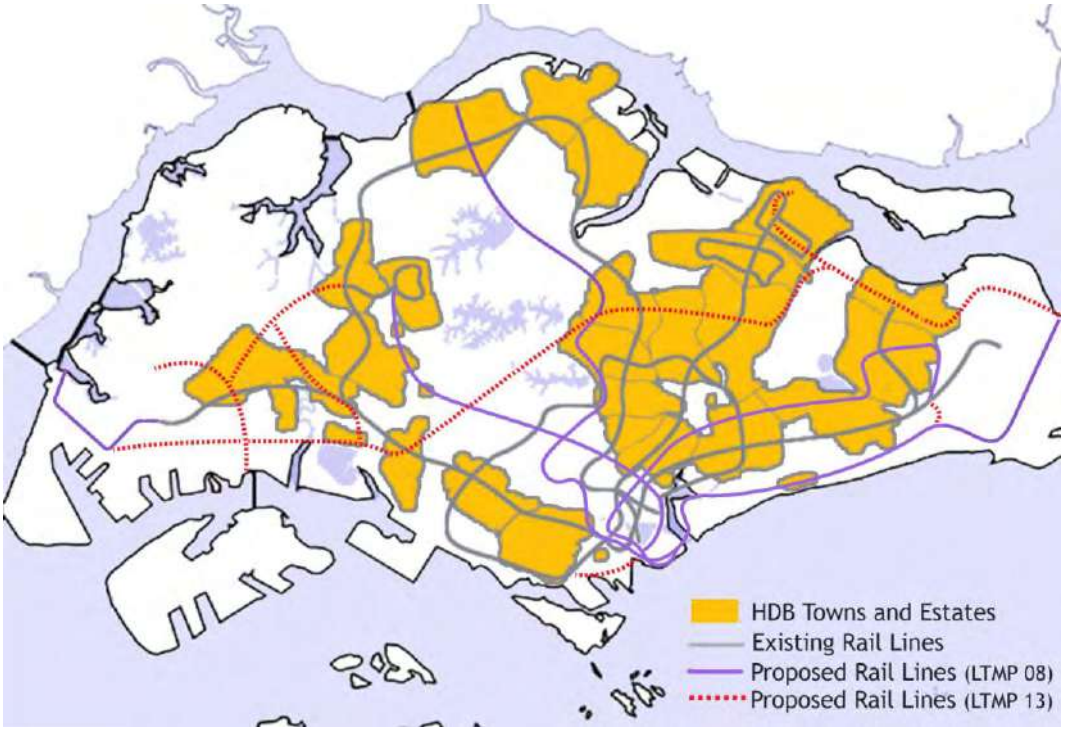

Figure 3. Singapore's Railway Lines vs Public Housing Pockets *(Source : Housing Development Board)*

In most Indian cities except Mumbai and Kolkata, mass transit has only been a recent development[2] unlike in the case of Tokyo, Hong Kong, and Singapore. Therefore TOD in India is mostly imagined as a brownfield redevelopment process, as transit follows development in areas that generate maximum revenue to easily finance the system. The major critique of this however, is a total lack of station area planning, poor accessibility and a lack of integration between different modes of transfer from stations, primarily because land around stations is owned by mutiple entities (Agarwal et al., 2019). As a result, transit is essentially an afterthought instead of being the primary planning strategy. Since its very first Master Plan for 1981, to the last for 2021, Delhi's Master Plan almost never addresses land use and transport integration as a core strategy, even as the Delhi Metro Rail Corporation (DMRC) made its first line operational in 2002.

Acknowledging this issue, the TOD policies therefore, act as an addendum to the process of planning, wherein a certain catchment zone around transit stations/ corridors are delineated and notified as areas of special development, with norms that are different from the rest of

[2] Although Mumbai's Suburban railways and Kolkata's trams have existed since 1853 and 1873 respectively, Mass Rapid Transit as we know it today has existed only since early 2000s. Delhi Metro became operational in 2003, Ahmedabad's Bus Rapid Transit System- Janmarg, began operations in 2009 while Bengaluru's Metro became operational in 2011, followed by Mumbai in 2014, Jaipur and Chennai in 2015, and so on.

the city. In Ahmedabad, this zone is a 400m wide corridor on either sides of the Bus Rapid Transit (BRT) System. In the case of Delhi, the delineation is at a node of 500m radius around Mass Rapid Transit (MRT) Systems or Metro. For National Capital Region (NCR)'s regional rail that connects 5 neighbouring cities to Delhi, TOD Zone is imagined as a node of 1km around stations. The difference in the principles of these delineations depend on the perceived impact of the type of transit system on its surrounding areas. Although the corridor/ nodes are notional boundaries, the actual TOD Zone is determined by local land uses and road layouts (see Fig 4.)

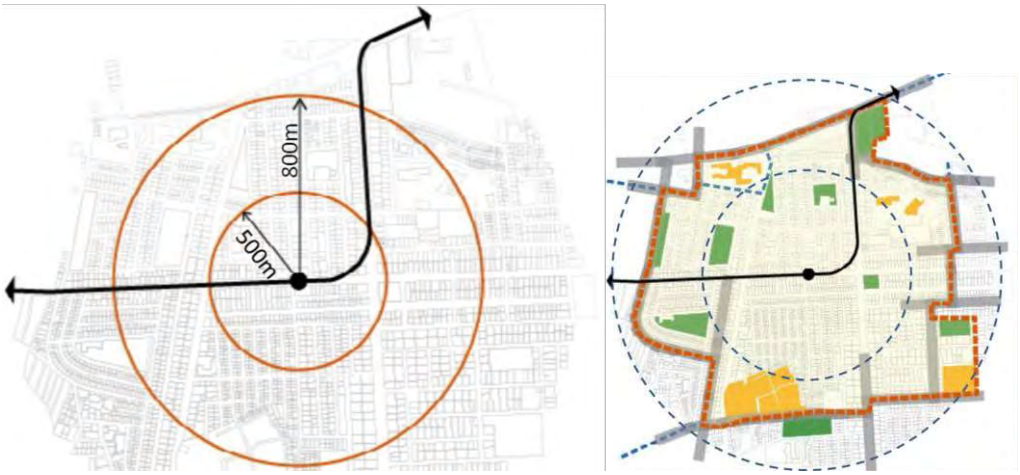

Figure 4. TOD is planned around 500-800m notional circle, the exact boundaries of which are determined by existing road layout and land uses *(Source : National Institute of Urban Affairs)*

Once the zones are delineated, appropriate institutional setups and plot assembly mechanisms need to be put in place to facilitate large scale redevelopments based on the design principles of TOD mandated through special development control norms as outlined in the TOD policy.

2.2. Design Principles of TOD

There are various available definitions and principles of TOD through various national and international policies, literature and standards. According to the Institute for Transportation and Development Policy (ITDP), *"Transit-Oriented Development stands for the rights of all to access the city: to walk and cycle safely, to easily and affordably reach the most distant destination through rapid and frequent transit, and to live a good life, free of dependence on cars. It stands for access to opportunity, education, services, and all the resources available via no- or low-cost mobility options."* (ITDP, 2017). Through mixed-use developments, compact and high density living environments, it emphasises on eliminating the need to make trips and saving commute time and money. Cervero and Kockelman in 1997 identified three "Ds"- *Density, Diversity,* and *Design* as essential components of transit-oriented development (Cervero and Kockelman, 1997), to which Cevero later added *Distance to Transit* and *Destination Accessibility*. The MoUD's National TOD Policy (MoUD, 2017) goes a step further and outlines 'Guiding Principles' that are primarily from a design perspective *(Complete Streets, Multimodal Integration, Last Mile Connectivity, NMT network, Traffic Calming, Mixed Lane Uses, Optimised Densities, Street-Oriented Buildings, Managed Parking, Informal Sector Integration,* and *Housing Diversity)*, and 'Supporting Principles' that are from an implementation perspective (*engage Private Sector, Land Value Capture, Right Size*

Infrastructure, Technology Integration, High Quality Transfer System, Barrier-free Environment and *Preserved Open Spaces*).

ITDP's TOD Standard outlines the following eight core principles of urban design, each supported by specific performance objectives and easily measurable indicators, or metrics. The tool can be used to evaluate projects for their 'TOD-ness' (Joshi et al., 2017) and propose recommendations for their improvement, albeit strictly from a design perspective.

1. ***Walk :*** Through adequate and shaded sidewalks, pedestrian crossings and active frontages.
2. ***Cycle :*** Through a well connected cycling network and access to safe cycle parking.
3. ***Connect :*** Through smaller block sizes, a tight grid of vehicular and pedestrian network.
4. ***Transit :*** Through easy accessibility to Transit stations.
5. ***Mix :*** Through an adequate mix of commercial, residential and recreational uses with a component of affordable housing.
6. ***Densify :*** Through higher FAR and planned density (persons per hectare).
7. ***Compact :*** Through adequate adjacencies and various transit options.
8. ***Shift :*** Through on-street and off-street parking management.

However, there is a growing concern about TOD being misunderstood as merely 'Transit-Adjacent Development (TAD)' than actually being Transit-Oriented (Joshi et al., 2017). The proposals by Indian Railway Station Development Corporation (IRSDC) to develop railway land near select stations as high density commercial and residential hubs, is although being hailed as an example of successful TOD implementation (Das, 2019), the extent of its adherence to TOD principles is something that remains to be evaluated. Besides, most cities still rely on archaic building norms that are contradictory to the very principles of TOD. For example regulations like mandatory provision of front setbacks, parking minimums for each plot, no norms for an integrated street network, active frontages and prohibition of boundary walls, etc. defeat the purpose of creating compact and walkable TOD neighbourhoods that promote Jane Jacob's idea of 'Eyes on the Street' .

2.3. Land Assembly Mechanisms

Unlike in the case of Singapore, majority of land in India is privately owned. Therefore, redevelopment for TOD purpose is conventionally done by public acquisition of land. The National Land Acquisition Act (Right to Fair Compensation and Transparency in Land Acquisition, Rehabilitation and Resettlement (RFCTLARR), 2013), which enables compulsory acquisition of land, is the primary tool to acquire land in India for public purposes[3] (Mathews et al., 2018). However, the costs involved in acquisition are high and the means to finance such projects are still being explored through fiscal and non-fiscal measures. Secondly, delays in procuring land through RFCTLARR has also led state-based agencies to frame alternate land assembly mechanisms (Nair, 2016) like Land Readjustment, Land Pooling, PPP, market price negotiations, land lease policies, etc.

These alternative frameworks are deemed more progressive and bottom-up in their approach, as they provide the land owners with incentives like higher FAR and relaxation on

[3] The Act is a revision to the traditional National Land Acquisition Act of 1894, which was repealed due to issues relating to unfair compensation to land owners and 'severe imbalance of power between the state and the land losers' (Wahi, 2018).

certain norms to make redevelopment a financially viable and profitable option. This categorically means land owners have a choice to form a consortium and amalgamate plots if they want, without mandating land surrender as the only option, as in the case of land acquisition. The government's involvement is limited to infrastructure provision for the new development, in return for a certain percentage of land for public uses such as affordable housing and public green spaces (as in the case of land readjustment). This ensures that even smaller plot are compensated in some way or the other, say through a smaller dwelling unit but with a much higher market value. Needless to say, this is a gradual process and requires a lot of consensus building between land/ property owners.

One of the earliest methods in land readjustment or reconstitution in India was the Town Planning Scheme (TPS) which was introduced through the landmark Gujarat Town Planning and Urban Development Act, 1976 (Ballaney, 2008). The TPS mechanism has been used extensively for the provision of serviced land for development, especially in the peri-urban areas of Ahmedabad. While this mechanism has largely been successful in the peripheries, its success in the urban cores is often contested due to apprehensions regarding carrying capacity of existing infrastructure to support high densities (Dutta, 2015). The entire delineated TOD zone around Ahmedbad's BRT System, as well as the proposed CBD of Ahmedabad rely on the TPS Scheme.

Delhi's TOD Policy (DDA, 2015) uses a similar bottom-up approach wherein individual plot owners within the TOD zone can voluntarily amalgamate plots, partner with developers to form the 'Developer Entity' and redevelop into large scale TOD projects that follow special TOD norms as outlined in the policy. A small percentage of the land is returned to the Development Authority for provision of public greens, as is 50% of the mandatory affordable housing units developed as per the norms. Although the urban design regulations align with the TOD principles, it may take more than just a few years for the idea of redevelopment to percolate into Delhi's real estate market. A way to expedite the process could be through implementing TOD in government-owned lands, as pilot demonstration projects (as was intended through the East Delhi Hub Proposal at Karkardooma Station in Delhi). However, a high quality TOD requires high capital investment and is not possible without the intervention of the private sector. Cities must explore similar strategies to select pilot station areas and devise appropriate financing and institutional setups for land assemblies, in order to put TOD on the fast track.

3. Methodology

3.1. Conceptual Framework

Clearly, the concept of TOD in India is past its nascent stage. It’s design principles and benefits are clearly acknowledged, as is evident from various projects and government policies. Often projects are conceptualised and undergo various design iterations for months/ years, without fructifying on ground due to practical reasons like land ownership and assembly frameworks, project financing, and sometimes, even unforeseen negative impacts on existing urban context. The objective of this paper is :

- to identify criteria or parameters that impede TOD implementation on ground, and

- to develop a framework that can help assess the feasibility of a TOD project at various stages of its inception, i.e. *Pre-Planning, During Planning* and *Post-Planning*.

This will be done through a case study of the following three TOD proposals from different contexts, that have made news in the urban development fraternity.

1. Proposed Central Business District (CBD), Ahmedabad; *(Status : Under Implementation)*
2. Railway Station Development, Habibganj-Bhopal; *(Status : Approved by Implementing Authority)*
3. Karkardooma Metro Station Development, Delhi; *(Status : Not Approved by Implementing Authority)*

For the first two phases (Pre-Planning and During Planning), the paper uses **methods** like **Spatial and Quantitative Analysis** of the three projects using *Master Plans of the proposal, context study on satellite imagery, and a review of development numbers/ area statements from the proposals*. The last phase (Post-Planning) involves a **review of available literature** on *state-specific TOD Policies, Development Model, and Institutional Setup* (See Fig. 5).

3.2. Scoring

The projects are scored on the basis of these criteria- the underlying principle being that each phase carries equal weightage (5 points each). The criteria under each phase carry equal points – 1.66 each in the 'Pre-Planning' Phase, 1 each in the 'During Planning' Phase, and 2.5 each in the 'Post-Planning' Phase. Finally, the project that scores between 1-33% is deemed Low Probability TOD, 33-66% is Medium Probability TOD and 66-100% is High Probability TOD.

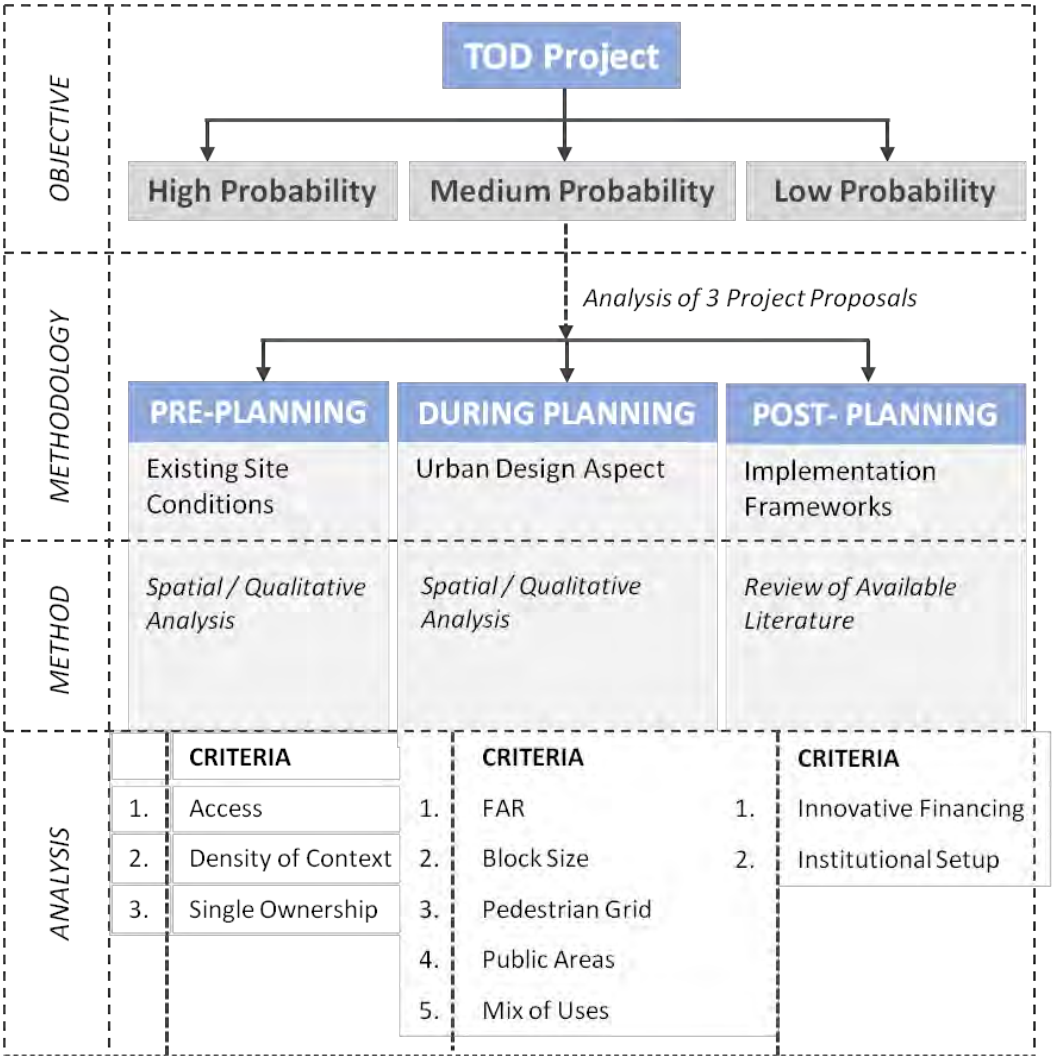

Figure 5 Conceptual Framework

The scoring however, is limited to establishing only a qualitative framework for a quick and initial TOD Project Feasibility Assessment. It does not analyse details such as *Parking Numbers*, detailed *Distribution of Proposed Uses, Affordable Housing Units*, etc. due to data unavailability. The scoring will have to be read in conjunction with policy climate, nuances in land ownership and the political will to implement TODs. Besides, for the 'During Planning' phase, there are already well-established comprehensive set of National (MoUD National TOD Policy) and International indicators (ITDP TOD Standard 3.0) as discussed earlier, which require a bigger and more detailed study, and is beyond the scope of this paper.

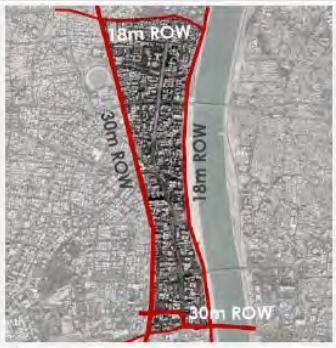
3.3. Analysis of TOD Proposals

The three projects have been analysed on the basis of the conceptual framework in tabular form, as mentioned in Fig. 6.

AHMEDABAD	BHOPAL	DELHI
Central Business District	*Habibganj Railway Station*	*Karkardooma Metro Station*
		
Area : 125 Ha **Type of Transit :** BRT System	**Area :** 29.6 Ha **Type of Transit :** National Railways	**Area :** 28.8 Ha **Type of Transit :** Metro Station

PRE-PLANNING

ACCESS

Access from all 4 sides : 30m road from two sides, and 18m road from other two sides.	Access from 2 sides : both 30m road on opposite sides.	Access from 1 Side exists : 28m road and proposed 30m road access from the opposite side

SURROUNDING DENSITY

		
Legend : Medium Density High Density Very High Density Low Density	Legend : Low Density Very Low Density Very High Density Undeveloped Land	Legend : High Density Very High Density Medium Density
Mostly surrounded by medium density	Mostly surrounded by low to very low density	Mostly surrounded by high to very high density

Multiple - PRIVATE ENTITY	Single - PUBLIC ENTITY	Single - PUBLIC ENTITY
DURING PLANNING		
EXISTING AND PROPOSED FAR		
Existing : 1.8 Proposed : 5.4 3X	Existing : 1-1.5 Proposed : 3 2-3X	Existing : 1 Proposed : 2 2X

	Mix of Uses	✓	1
Post-Planning *(5- Points)*	Innovative Financing	✗	0
	Institutional Setup	✗	0
			6.66 = **44%**

Figure 7 Scoring of Projects

3.5. Observations

- Based on the scoring, **Ahmedabad CBD** qualifies as a **High Probability TOD** and fares very well in all phases, with an overall score of 82%. Although, multiple ownership of land is seen as a limitation here, Ahmedabad's bottom-up land assembly mechanism, i.e. the TP Scheme, outweighs the project delays caused by land pooling and plot reconstitution by AUDA. However, being a CBD proposal, the project cannot be seen as a complete TOD project due to the predominance of commercial over residential and recreational uses.
- **Habibganj Station, Bhopal** also qualifies as a **High Probability TOD**, with a score of 70%, primarily due to its location in a low density area and the PPP Model of Development devised in its financing. However, the design needs serious considerations for it to become TOD-friendly. Ideas of walkability and public spaces are yet to be reflected in the masterplan.
- **Kakardooma Metro Station Delhi,** on the other hand, despite faring extremely well in the design phase, gets classified as **Medium Probability TOD** (51%), primarily due to its location in a busy and congested part of the city and the lack of financing and institutional mechanisms to ensure its implementation. Its exceptional design principles not only focus on high density development and public spaces but also advocate an appropriate mix of uses with housing for the Economically Weaker Section (EWS) category. However, this project has the potential to fare as a very high potential TOD project if Delhi TOD Policy's institutional setup (released a few years after the Karkardooma proposal came out in public domain) can be applied and Private Developers can be incentivised to develop this piece of public land.

4. Conclusions

The paper demonstrates equal significance of all three phases in the planning and execution of TODs. Karkardooma in Delhi is a classic example of how **design alone may not be enough** to implement TOD on ground. Theoretical design aspects of TOD aside, context and finance become the most important factors for decision-makers, who also have a responsibility towards existing populations and may not want to tamper with their day-to-day activities. This also indicates the inadequacy of highly complex TOD Design Scoring exercises to evaluate TOD projects.

Therefore, **TOD may be more easily implementable in** areas with low population, i.e. the **peri-urban regions** (as in the case of Habibganj), compared to dense urban cores. However, this has to be complemented with adequate design. In contexts like Ahmedabad CBD and Karkardooma, special care has to be taken to not disrupt everyday life and therefore may be a slower process, yielding dividends gradually over a span of decades. This time factor will have to be foreseen before dense urban regions are picked for TOD, unlike in the case of Habibganj wherein the land is leased for a small period of 45 years to the developer.

Since India is still struggling with various land assembly mechanisms in both greenfield and brownfield areas, projects like Karkardooma and Habibganj are low-hanging fruits because of **public land ownership,** and therefore must be on government's priority list. Projects like CBD, although follow the right approach in land assembly, still require plenty of public

consultations and workshops with plot owners, apart from various other time and resource-intensive events to garner consensus and attract investment from developers. For Indian cities to reap instant benefits from TOD, strategic selection of potential and the most suitable station areas is the key.

Case Study / Project

Planning and Management Experiences of Global Metropolitan Area

- A Lesson of New York Metropolitan Area, Tokyo Metropolitan Area, Paris Metropolitan Area, and London Metropolitan Area

Huihui NAN

Abstract

This study uncovers the drivers of four major metropolitan areas' success from government management and planning perspective. New York metropolitan area, London metropolitan area, Tokyo metropolitan area, and Paris metropolitan area are internationally recognized as the four major metropolitan areas around the world. They have a large population, a vast territory, a high degree of economic and factor aggregation, and strong international exchange capabilities, bringing together the greatest wealth and most advanced productivity in the world today, playing an increasingly important role in the urban economy and global economic competition. What drives these metropolitan areas to become the engine of the world economy? Can their success be replicated by other regions and countries?

After reviewing the development process of the four metropolitan areas, some factors, including urban functions, regional division of labor, transportation, social equality and environment protection, necessary for the success of urban development were discovered. First, evacuate certain functions of the city, such as education and industry, to surrounding cities or new towns, alleviate the pressure on the city center, avoid excessive urban spread, and help maintain the competitiveness of the metropolitan area. Second, a good regional division of labor is the key to gaining competitive advantage in the metropolitan area. Each city within the metropolitan area should scientifically locate the industrial division of different grades of cities according to its own foundation and characteristics. On the basis of division of labor and cooperation and complementary advantages, we will give full play to the advantages of overall agglomeration and achieve industrial upgrading of core cities. In the end, a äóìsymbiosisäó of the metropolitan area with division of labor, complementary functions and coordinated development will be formed. Third, the transportation network constitutes the skeleton of the metropolitan area. While meeting the needs of commuting, the transportation network strengthens the internal and external links of the metropolitan area, and guides the rational distribution and orderly transfer of industries and populations within the metropolitan area, providing a powerful guarantee for an efficient and orderly industrial division of labor between cities. Fourth, the equalization of public service facilities can promote the rational use of resources within the metropolitan area, and can also promote exchanges and integration of people, and avoid imbalances in supply and demand within the region. Fifth, in dealing with the overall ecological environment quality of the region, it is necessary to break down political barriers, achieve integration of ecological environment protection inside the metropolitan, and achieve regional win-win.

Research Paper

TOWARDS EFFECTIVE PLANNING OF TRANS-BORDER CITY REGIONS

three Australian case studies

Daniel O'HARE

Associate Professor Urban Planning, Bond University, Australia

Abstract

Polycentric city regions are expanding worldwide, often spanning national borders. Using literature review and document research, comparative case studies of regional planning of Australia's emerging internal trans-border city regions are presented. The paper examines fifty years of trans-border planning efforts at three urbanizing borders of the Australian state of New South Wales, demonstrating different levels of commitment and success, partly depending on the proximity (or remoteness) of each trans-border city region to the capital cities in each state or territory. Evidence is provided that effective trans-border planning of city regions depends on overcoming differing levels of commitment to trans-border planning by the state jurisdictions involved.

Keywords

Trans-border, cross-border, city-region, regional planning

1. City regions

1.1. The rise of city regions

With the rise of "global city regions" since the late twentieth century (Simmonds and Hack 2000; Scott et al. 2014), there has been increasing acknowledgment that new models are replacing the twentieth century urban conception of a metropolis. The phenomenon of the polycentric city region has superseded the old idea of suburbs radiating out around a single city centre or 'CBD' (Garreau 1991; Calthorpe and Fulton 2013). Suburbs are becoming urbanized within these new city regions and 'placeless' suburbs are beginning to be transformed through the creation of denser, mixed use suburban centres connected by efficient public transport (Al-Kodmany 2016; Beske and Dixon 2018).

These polycentric city regions are increasingly spreading across state and national borders. Such trans-border city regions have been noted around the world, including in Europe, Asia and the Americas/ North America. Well known examples include:

- the expansion of Shenzen (and other Pearl River Delta cities) and neighbouring separately-administered Hong Kong;
- Aachen-Maastricht-Liege (Germany, Netherlands and France);
- San Diego (US) – Tijuana (Mexico); and

- the 'BonNYWash' crescent embracing Boston, New York and Washington across several north-eastern states in the USA.

In addition to trans-border city regions such as these, there are increasing examples of cross-border collaboration in economic development corridors such as the Dublin-Belfast corridor (linking Ireland and Northern Ireland), the Oresund corridor between Copenhagen (Denmark) and Malmo (Sweden) and the link across the Causeway between Singapore and Johor, Malaysia. Such corridors typically involve a focus on improving transport connections and partnerships to improve the combined international competitiveness and economic well-being of formerly discrete cities and towns.

This paper examines the uneven progress of policy for regional planning of Australia's emerging internal trans-border city regions since the 1970s. Three contrasting case studies are presented, focusing on regional plans in three trans-border city regions. As an exploratory research paper, the case study methods used are a combination of literature review, document research and policy analysis of city-regional plans. Comparisons are made with selected international trans-border city regions.

The Australian case studies illustrate that development of effective trans-border city regions, even within one country, depends on overcoming differing levels of commitment to trans-border planning by the state or territory jurisdictions involved. This commitment may also be shaped by the different balance between resources (eg infrastructure, jobs) and population within a city region that spans across state or national borders. Proximity to a major city, particularly a state capital city, seems to be another factor influencing state government commitment.

2. Three Australian case studies of trans-border city region planning

2.1. The rise and fall and rise of trans-border city region planning 1967-2019

This paper presents the only three case studies of trans-border city region planning that have occurred in Australia to date. As an island continent, Australia has no international trans-border city regions, so the three case studies occur across internal borders of states and territories. All three are at the borders of the most populous state, New South Wales (NSW), with the neighbouring states of Victoria and Queensland, and with the Australian Capital Territory (ACT) around the national capital, Canberra. The differences in approach are at first surprising, however these differences reflect different priorities during different decades, as well as different forms of urbanisation across borders in the three cases.

Despite internal state and territory borders being the sites of expanding trans-border city regions, there has been limited recognition of the need for – or progress towards – more integrated planning of these city regions in Australia (O'Hare 2011). The most impressive progress has been led jointly by the ACT and NSW governments, where the trans-border planning and significance of the national capital, Canberra, has been recognised and increased since the 1990s through effective translation of new spatial planning concepts – the Sydney-Canberra Corridor and the 'Capital Region' – into cross-border plans and strategies with overt support by the two governments and surrounding local governments.

The support of the ACT Planning Authority for a cross-border approach has been motivated by the relatively tight physical boundaries of the Territory within which Canberra is located. Canberra's population of just over 400,000 is contained within a constrained spatial Territory of 2,358 square kilometres, but the city services a large trans-border region by providing jobs, health, education, cultural institutions, higher order retailing and other services. Suburban development now transcends the Capital Territory border into the surrounding rural shires within NSW, and many Canberra workers commute from surrounding large and small towns and rural areas that offer affordable housing within attractive settings.

NSW has arguably been an Australian leader in trans-border city region planning as three of its four state/territory borders are sites of expanding city regions:

- Canberra and the ACT is surrounded by and socioeconomically and physically intertwined with the surrounding region across the Territory border.
- One of the fastest-growing regions in Australia, South-East Queensland (SEQ) is beginning to merge with the expanding NSW Far North Coast region, just over 100 kilometres from Brisbane, the capital city of the adjoining state of Queensland.
- The twin regional border cities of Albury (NSW) and Wodonga (Victoria) have experienced fluctuating levels of collaborative planning efforts since the early 1970s.

While the ACT and NSW have led Australian efforts towards collaborative trans-border planning of city regions, the other two states, Victoria and Queensland have been less consistent in progress towards that aim.

The order in which the three Australian trans-border planning case studies are presented in this paper requires a brief explanation. Albury-Wodonga is presented first to provide a long term perspective – fifty years – on trans-border planning in Australia. It is a case that initially involved the most creative governance arrangements and promised the most, but has not been consistently followed through due to political and other issues. The case study concludes by exploring an encouraging contemporary resurgence in interest that appears to have been led from the local government level over recent years and supported by initiatives from both states and the federal government more recently.

Following the Albury-Wodonga case, the paper explores the development and transformation of Canberra's trans-border regional planning over the past thirty years. The final case study section of the paper investigates uneven moves towards regional planning linking SEQ and Far North Coast NSW as a trans-border city region. The final case study is the most populous and rapidly growing of the three.

2.2. Albury Wodonga: the first trans-border planning experiment, 1960s to the present

"*What began as an ambitious dream* [in 1967] *became a more modest experiment, which was changed into a regional development exercise as it was dismantled slowly* [between 1989 and 2007]" (Pennay 2005:xi).

Albury-Wodonga is a trans-border city region approximately 300 kilometres from Melbourne and 550 kilometres from Sydney. Two towns established here on each side of a major river crossing on the inland route between the two state capitals in the nineteenth century. This crossing point also intersected with the furthest reach of the riverboat traffic that operated along the Murray River during that century. Both were originally agricultural service towns

for the adjoining rich agricultural regions in the Murray valley. Albury's growth and importance were enhanced as the interchange point for passengers on the interstate rail service between Sydney and Melbourne from 1881 until the standard guage rail service was established in 1962. The two towns grew into cities in the twentieth century as significant marketing centres and manufacturing places for rural products such as wool and after World War 2, other manufacturing. Their roles also expanded as major regional centres for State Government departments, major regional hospitals, education and other services.

Integrated trans-border planning for development of Albury-Wodonga was motivated by 1960s concerns by the two state governments to decentralise development and population from Sydney and Melbourne, where long term population drift to the cities was bringing major challenges of population growth, housing shortages, affordability, traffic congestion and pollution which were coming to be seen as unmanageable. The decentralisation push was also aimed at providing Australians in non-metropolitan areas with a more equitable share of national resources and economic and social opportunities. In 1967, the Victorian Government suggested, to both the NSW Government and the Australian Commonwealth (Federal) Government, that Wodonga (in Victoria) and Albury (NSW) be planned and developed "as one complex" for "accelerated development" (Pennay 2005).

In 1972, a new Federal Labor government announced a National Growth Centres program to drive decentralisation of the state capital cities. Of the several regional centres designated as growth centres, Albury-Wodonga was the only trans-border one. The Albury-Wodonga Development Corporation was formed through a 1973 agreement and supported by legislation passed by the federal government and two state governments, formalising a cross-border region spanning two states and seven local councils (Pennay 2005). The Development Corporation was given responsibility for strategic planning of the trans-border city region and was made the planning authority for major urban expansion projects. Its principal function was "to acquire, hold, manage and provide land in those areas designated for development" (NSW State Records, n.d., no page). The national Growth Centres strategy was abruptly abandoned with the dramatic removal of the Whitlam federal government in 1975. The Albury-Wodonga Development Corporation's powers were curtailed and its planning powers removed, but it was not formally wound up until 2007. It continued to develop and sell the remaining land for urban development, and its legacies include urban and regional infrastructure and a regional framework and mechanism for parklands development. Following the dilution and eventual demise of the Development Corporation, collaboration in cross-border collaboration devolved to the two city councils via issues-based organisations and an informal Alliance of Councils and Shires of the Upper Murray (Brown and Bruerton, 2009).

The Albury-Wodonga Development Corporation planned for a trans-border city of 300,000 people by 2000 (Pennay 2005), a population six times that of the area in 1973 (Harris and Dixon 1978). The current combined population of the two cities has only reached about 100,000, while growth of both Sydney and Melbourne has been dramatic over the same period, in a continued trend of centralisation of population, political and economic power in Australia's primary coastal capital cities.

Current efforts towards trans-border planning seem to be more driven by the local governments of Albury and Wodonga, with less involvement of the surrounding rural shires

that were part of the 1970s Growth Centre initiative, and with less immediate connection with the two state governments.

The *Two Cities One Community: Strategic Plan 2017-2021* was adopted jointly by the Mayors of Albury and Wodonga in 2017 with the message: "Our community does not necessarily see a border. They cross a river to share facilities, venues, infrastructure and services. They expect community leaders to adopt a regional perspective and advocate to state and federal governments on issues that impact their day to day lives" (Albury City and Wodonga City 2017: 3). However this plan is a twin cities plan rather than a city region plan, as it does not include surrounding rural shires that interact with these cities, and which were part of the Albury-Wodonga Growth Centre initiative of the early 1970s.

State Government Regional Plans addressing Albury-Wodonga as a trans-border city region

A desktop review of documents and websites suggests that the commitment of the two state governments to coordinated planning of Albury-Wodonga as a trans-border city region is mixed. This paper seeks evidence in the regional planning of the two states for identified regions along the Murray River state border, as well as evidence in the policies and actions of the Cross-Border Commissioners who have been appointed in each of these two states. The Murray River, which divides the twin cities of Albury and Wodonga and the planning jurisdictions of the two states, also divides the northern Victorian region of Hume from the southern NSW region of Riverina Murray.

The three states addressed by this paper (NSW, Victoria and Queensland) all use regional plans to provide their broad frameworks for land use and development, the role of key regional centres, infrastructure provision, economic well-being and environmental management. The approaches vary in each state, with Queensland's regional plans having been restricted to "State Interests" since 2014. The ACT, in contrast to the states, is effectively a city-state. Its planning addresses not only the urban area of Canberra and land within its borders, but also interactions with the region of NSW that surrounds Canberra.

The Riverina Murray Regional Plan is "centred on creating more jobs, strengthening the region's cities, towns and villages, sustainably managing its agricultural, extractive and natural resources and protecting the nationally significant Murray River" (Department of Planning and Environment website https://www.planning.nsw.gov.au/Plans-for-Your-Area/Regional-Plans/Riverina-Murray). Although the regional plan is jurisdictionally restricted to the NSW side of the river border, cross-border issues are prominent and the plan notes that Albury-Wodonga is one of three "regional cities" in the region and that it is the largest of seven cross-border communities. Aboriginal communities from both sides of the river are acknowledged in the Minister's foreword.

Albury and Wodonga are described in the plan as functioning as "a single economic centre, with employment, investment and services accessed across both locations", with Albury alone servicing "an extensive catchment of approximately 200,000 people [and providing] higher-order services, including for business, office and retail uses, and arts, culture, recreation and entertainment, which support the needs of smaller settlements across the region and in cross-border communities" (NSW Government 2017a: 57).

The Riverina Murray Regional Plan prominently demonstrates NSW government awareness that the region is closer to the interstate capital of Melbourne than to its own state capital

of Sydney: it boldly – in very large print – "acknowledge[s] the important role of this region's centres and their relationship to, and export potential with, Melbourne and Victoria…." (NSW Government 2017a: 9).

The vision and goals of the Riverina Murray Regional Plan are supported by 29 "directions" and accompanying actions. Goal 4, Strong, connected and healthy communities is supported by Direction 23, "Create a connected and competitive environment for cross-border communities", which in turn is supported by Action 24.1 "Work with the Victorian Government and cross-border councils to examine: barriers to and enablers of economic, housing and jobs growth; service delivery models; and infrastructure delivery, including transport infrastructure" (NSW Government 2017a: 51).

In contrast, the Hume Regional Growth Plan, from the Victorian side, is much less overt in its recognition of the trans-border city region, focusing more attention on Wodonga as a regional city in its own right, despite acknowledging "the influence of the combined urban area of Albury-Wodonga (recognised as one of Australia's 18 major cities) in the Upper Hume sub-region" (State Government of Victoria 2014: iv). The area covered by Victoria's Hume Regional Growth Plan includes four of the seven cross-border communities included in the NSW Riverina Murray Regional Plan: "Of these settlements, Albury provides a significant economic gateway to New South Wales and creates opportunities for Wodonga to leverage off this broader economic conurbation" (State of Victoria 2014: 58). Potential benefits from a new inland freight rail line (now under construction) and possible future high-speed rail between Sydney-Canberra-Melbourne are identified as providing opportunities for Albury-Wodonga, although this Regional Growth Plan has a tendency to highlight only Wodonga and other settlements within the state of Victoria.

In considering regional transport links, the Hume Regional Growth Plan notes that people from southern NSW travel to Melbourne for healthcare and that Albury-Wodonga benefits from "a reciprocal agreement that provides a single public health service, available to residents of either state. Hospital facilities in … Albury-Wodonga … provide higher order services to the wider region, including southern New South Wales" (State of Victoria 2014: 64).

Notwithstanding acknowledgment of cross-border settlements including Albury-Wodonga, the Hume Regional Growth Plan seems to step back from the innovative approach of the 1960s that led to Australia's boldest experiment in city region planning through cooperation between the federal government, two state governments and seven local governments in the 1970s growth centre project. The current plan does map Albury and Wodonga as comprising a cross-border settlement, and the plan identifies future urban expansion areas south-east of Wodonga that were first identified for development in the 1970s growth centre plan, but no link is made to that earlier thinking.

The Hume Regional Growth Plan identifies the southern sub-region, within commuting distance of Melbourne, as an area that expects more significant growth than the Albury-Wodonga city region. This supports the argument by Harris and Dixon (1978) that Albury-Wodonga was too far from a major city to achieve the population and economic growth envisaged in the 1970s.

Cross-Border Commissioners and joint state agreements

To deal with the many inconsistencies and inefficiencies faced by residents and businesses located in cities and regions on state borders, both NSW and Victoria have appointed Cross-Border Commissioners in recent years. In 2012, the NSW Government established the Office of the NSW Cross-Border Commissioner in order to identify and resolve cross-border issues. The current NSW Cross-Border Commissioner is based in Wagga Wagga, in proximity to NSW borders with both Victoria and ACT. The NSW Cross-Border Commissioner is attached to the Department of Premier and Cabinet, and thus has access to key decision makers in government. In 2018, after pressure from Murray River communities, the Victorian Government also appointed a Cross-Border Commissioner, and the first Commissioner is based in Wodonga and operates under the auspices of the Minister for Regional Development. The Cross-Border Commissioners both have a wide remit to address incompatibilities between legislation and regulations across borders, and urban and regional planning is just one of those many issues. The NSW Cross-Border Commissioner has assisted in the development of agreements between that state and both the ACT (in 2016) and Queensland (in 2017) as discussed in the other case studies below, but there is not yet a similar agreement with Victoria. Given the success of the NSW Cross-Border Commissioner in dealings with the other states, it is anticipated that the existence of Cross-Border Commissioners in both NSW and Victoria will lead to a strengthening of cross-border initiatives in future planning for Albury-Wodonga as an expanding trans-border city region.

Return of the Federal Government to city region planning: a Regional Deal for Albury-Wodonga

Following its withdrawal from the Growth Centre projects in 1975, the Australian Government has generally been prepared to leave urban issues to the two lower levels of government until 2015, when it reintroduced a Cities portfolio. This reflects wider recognition that cities and city regions are critical to the e conomic and social well-being of Australia. One of the new initiatives of the federal government is to fund City Deals, a partnership scheme based on the UK model, whereby the three levels of government and the community work in partnership to align planning, investment and governance to deliver "a shared vision for productive and liveable cities" (Australian Government, nd, https://www.infrastructure.gov.au/cities/city-deals/index.aspx).

The federal government also offers similar place-based Regional Deals, and Albury-Wodonga was announced as a pilot cross-border regional deal recipient in March 2019 (Australian Government 2019). Under the ten-year AUD$3.2 million deal, the federal government, two state governments and two city councils will engage with business, industry and the community to develop and implement a strategy for population growth and economic development to ensure that Albury-Wodonga "remains a nationally-significant, liveable and prosperous region" (ibid.). If implemented well, this regional deal promises to be a major means of achieving better outcomes for Albury-Wodonga by treating the trans-border city region as one.

2.3. Integrating Australia's Capital City and its trans-border region, 1995 to 2019

Australia's capital city Canberra, founded in 1911, has been comprehensively planned since 1959 by the ACT Planning Authority and its predecessor the National Capital Development Commission. The city's strong history of planning initially occurred solely within the spatial constraints of the 2348 square kilometres of the Australian Capital Territory (ACT). By the 1990s there was increasing recognition that Canberra played a valuable role as the major city for the surrounding region of NSW, and Canberra's planners became increasingly involved in NSW planning of the surrounding trans-border region.

An early example of this trans-border approach to city region planning was the adoption of NSW's first Sydney-Canberra Corridor Strategy in 1995 (McKenzie 1997). The emphasis of that strategy was as much on connections with Sydney as with Canberra, as well as the corridor itself which consisted of a string of towns and smaller cities set in a scenic and productive landscape along the 200 kilometre highway and rail corridor linking the two major cities. The ACT planners followed this in 1998 with the production of the ACT and Sub-Region Plan. NSW updated its corridor study in 2007 to become the Sydney-Canberra Corridor Regional Strategy 2007-31. The strategy recognised and sought to plan for the effects of the growth of both Sydney and Canberra on the region between the two capital cities. Although the Corridor Strategy's focus was mainly on the region between Sydney's outskirts and the ACT border, it gave prominent recognition to the fact that Canberra and the immediately adjacent smaller NSW city of Queanbeyan effectively operate as a single metropolitan area.

The Corridor Strategy refers to the 2006 signing of two Memorandums of Understanding (MOUs) entitled the ACT–NSW Cross-Border Region Settlement Agreement and the ACT–NSW Cross-Border Water Supply Agreement. At the same time, both governments signed the ACT-NSW Regional Management Framework Agreement (RMFA) (ACT and NSW Governments 2006). These MOUs were signed by the ACT Chief Administrator and the NSW Premier and have laid the way not only for updated MOUs since then, but more importantly for an expansion of the cooperation between the two jurisdictions in the planning of Canberra as a city region that extends beyond the ACT borders.

The ongoing commitment of both governments to Canberra-region cooperation since the 1990s can be attributed to decades of voluntary cooperation through diverse formal and informal collaborations including the Regional Leaders' Forum (RLF); the Capital Region Development Board (CRDB); and sub-regional planning strategy working groups. The cooperative approach formalised through the Corridor Strategy and MOUs (renewed in 2011 and 2016) has enabled current regional planning to be increasingly collaborative across the border, including at the levels of the surrounding local governments.

An important regional governance mechanism, established in 2015, is the Canberra Region Joint Organisation (CRJO), which "provides a forum for councils, State agencies and other stakeholders to work together at a regional level to identify shared priorities [and deliver] better outcomes for communities" (CRJO website, 2019). The three core functions of CRJO are: (1) regional strategic planning and priority setting; (2) intergovernmental collaboration; and (3) regional leadership and advocacy (ibid.) The 10 NSW local governments in the region

surrounding the ACT are CRJO members and the ACT Government is an associate member of the organisation.

The region surrounding the ACT border is now addressed by the South East and Tablelands Regional Plan 2036 (NSW Government 2017b). "The combined population of the local government areas within an hour's commute of the ACT, and the Territory's population itself, will increase to more than 660,000 by 2033 – a larger population than the Gold Coast today." (ibid., p4). Of the planning instruments reviewed in this paper, this regional plan is the most overt in its recognition of the significance of the cross-border relationship. The vision of the plan is for "a *borderless region* in Australia's most geographically diverse natural environment with the nation's capital at its heart" (ibid., p8, emphasis added). The regional plan is framed within this strong conception of the region as "a connected and borderless Canberra region." There are no inter-regional rivalries here, just a community-supported conviction that the prosperity of the region is dependent on Canberra and vice-versa. Canberra's airport, its jobs market, high order services, cultural institutions and lifestyle qualities are seen as assets for the region. Conversely, the region is recognised for providing additional housing opportunities (both affordable and prestige), recreational opportunities (ranging from bushwalking and camping to snow skiing and beach surfing), fine produce and scenic landscapes.

The NSW regional plan refers to its evolution from consultation with the ACT Planning Authority and the local governments of the region. In particular, it acknowledges the complementary approach taken by the ACT Planning Strategy 2012, which "acknowledges that Canberra's success depends on its relationship to surrounding areas. It acknowledges the importance of regional collaboration on biodiversity, transport and economic development" (NSW Government 2017b: 13). Those sentiments are reinforced in the 2018 "refresh" of the ACT Planning Strategy (Direction 1.4, p46), which is perhaps otherwise more focused on Canberra itself within the ACT border (ACT Government 2018). The ACT Plan reciprocates by emphasising that the NSW South East and Tablelands Regional Plan 2036 contains several joint initiatives and actions in parallel with the matching ACT plan and policies (p48). Mutual calls for collaboration are acknowledged, most notably by Canberra Region Joint Organisation (CRJO), as is the ACT-NSW Memorandum of Understanding for Regional Collaboration, as well as collaboration arrangements with a key adjoining council (p49).

The South East and Tablelands Regional Plan 2036 has provisions to protect the flight path for Canberra Airport, which is seen as vital to the economy of the surrounding region (Action 1.1, p15). Direction 19, "strengthen cross-border connectivity", addresses the importance of achieving legal and contractual reforms to allow seamless cross-border public transport services for towns and housing developments within commuting distance of Canberra (p44).

As Canberra's ACT Planning Strategy 2012 and 2018 seek to transform low density Canberra into a more compact urban form, the NSW South East and Tablelands Regional Plan acknowledges and attempts to limit the corresponding increase in development of low density development across the border (Direction 25, p53). This is an attempt to guard against the experience of Vancouver, Washington in the US, where significant car-dependent low density development has provided an unofficial alternative to the compact settlement pattern pursued across its border with Portland, Oregon (Bae 2000, in O'Hare 2011). Under Direction 26, proposals are advanced for cross-border infrastructure and monitoring systems

for land, housing and water requirements. In the final section of the Plan, key planning priorities are identified for those NSW local government areas that adjoin the ACT border.

CRJO and the ACT Government are currently lobbying the federal government to back a "Canberra Region Deal" to boost the city and its region by a coordinated investment in infrastructure and enhanced 'borderlessness' in delivery of higher order services such as tertiary education and health care (CRJO and ACT Government 2019).

2.4. SEQ and North Coast NSW: uneven approaches to cross-border planning 2005-2019

The third Australian case study city region that spans state borders is South East Queensland (SEQ) and north coast NSW (NCNSW). SEQ is a large and fast-growing city region which encompasses the Queensland capital, Brisbane and several smaller cities with a total region population of 3.5 million, projected to be home to 5.3 million by 2041 (Queensland Government 2017). SEQ's urban interface with the state border, with a combined population of approximately 700,000, consists of the City of Gold Coast (Queensland) and the contiguous urban area of Tweed Shire in NSW (ABS 2019). Gold Coast-Tweed is Australia's sixth largest city and one of its most rapidly growing city regions. Gold Coast Airport, straddling the border, serves as international gateway to both regions.

Cross-border planning in this large trans-border city region is significantly under-developed, particularly from the Queensland side. Regional plans have been in place in these two adjoining regions since 2005 and 2006 respectively (Queensland Government 2005; NSW Government 2006). From and including that time, there has been a steady building of attention to trans-border issues from the NSW side and a fluctuating level of interest from Queensland. There has not been a true bilateral commitment to the promise offered by the statement that "the NSW and Queensland governments have formed a partnership to share information and promote consistent sustainable planning strategies" (NSW Government, 2006: 44).

The SEQ Council of Mayors, a powerful regional local government advocacy organisation, was established in 2005 to represent the interests of the fast growing SEQ regions. It recognises that SEQ has grown into a city region that is "no longer just a series of disparate geographic areas but a region that, in practical terms, functions as a single metropolitan area" (Council of Mayors website, accessed 21 July 2019). Given that the SEQ region extends to – and, de facto, across – the state border, it is astounding that neither of the two councils abutting the urbanised section of the border – Gold Coast City (in Queensland) and Tweed Shire (in NSW) – are currently members of this influential and highly effective group of ten SEQ councils. Consequently in the otherwise sophisticated current proposal for a SEQ City Deal partnership between the federal, Queensland and local governments for transforming SEQ into a high-performing polycentric city region, there is only one mention of the state border, and that is as the southern boundary of the region (SEQ Council of Mayors and Queensland Government 2019: 8) rather than a transition line in the contiguous settlement pattern. It is therefore not surprising that the document does not advance the case for improved cross-border coordination in planning and development.

Despite their non-participation in the Council of Mayors, the border local governments of Tweed Shire and Gold Coast City have a strong relationship. An agreement exists between the two border councils, providing for bi-monthly consultations between their strategic regional planning teams "to coordinate planning, infrastructure and response to traffic

issues (Brown and Bruerton, 2009, p.57). In practice, this level of cross-border council communication and collaboration happens less frequently, but is invoked to deal with major issues including planning updates (senior planners, pers.comm.).

The current state-level regional plans for the two adjoining regions are *ShapingSEQ: South East Queensland Regional Plan 2017*, and the NSW *North Coast Regional Plan 2036*. Both were released in 2017, soon after the two states renewed their partnership MOU – similar to that noted for the ACT and NSW, above – aimed at information sharing, resolution of cross-border anomalies, and promotion of consistent sustainable planning strategies. The two regional plans show starkly contrasting levels of commitment to the updated *Queensland and New South Wales Statement of Principles and Priorities for Cross-border Collaboration 2016-2019* identifies four key focus areas for cross-border collaboration: i) regional economic development, ii) aligning services and sharing information, iii) local transport, iv) issues of national significance (Queensland and NSW Governments, 2017). As with the ACT-NSW MOU, the document is accompanied by an annual Worklist detailing planning projects. The worklist is reviewed through an Annual Report.

ShapingSEQ's ambitious 50-year Vision and specific 25-year goals for plan delivery do not carry the collaborative cross-border aspirations of the MOU very far forward. The border is largely ignored, other than in acknowledgment of opportunities for North Coast NSW to benefit from SEQ's significant population growth and employment market and the tourism potential of the World Heritage landscapes that span the border. It recognises that upgrading infrastructure will connect the regions and support access to employment and recreation, while also enhancing the flow of goods, services and skills (Queensland Government, 2017). Commitment to the MOU is not prominent in *ShapingSEQ.* While not completely ignored in mapping within *ShapingSEQ*, the border and interactions beyond it receive little attention. The border is termed the Southern Gateway (Queensland Government 2017: 142). This gateway comprises an emerging "Regional Economic Cluster" (REC) hosting priority sectors that offer cross-border services including an international and domestic airport, major regional hospitals health, manufacturing (focused on aviation industries) and tourism infrastructure.

In contrast, *North Coast Regional Plan 2036* brings cross-border planning much more to the fore, including in its Vision statement: "Northern communities have established important links and are integrated with a burgeoning [SEQ.] …. Southern and coastal communities are building relationships and leveraging opportunities from the Pacific Highway upgrade" (NSW Government, 2017). The NSW Department of Planning and Environment stresses the importance of collaboration with the Queensland Government by strengthening communities of interest and cross-regional relationships (NSW Government, 2017). The contrasting regional planning visions reveal the different significance the two states place on cross-border collaboration: NSW acknowledges its importance, Queensland downplays it. *North Coast Regional Plan 2036* dedicates an entire strategy to cross-regional collaboration, The fifth of 25 "Directions" of the Plan is to strengthen cross-regional relationships, with cross-border connections prominent in the rationale and actions under this direction (NSW Government 2017: 25-26). Cross-border relationships are prominent in the text and maps conveying the *North Coast Regional Plan 2036,* and almost absent in *ShapingSEQ.*

The NSW Cross-Border Commissioner has noted key issues affecting many community and business sectors: summer time zones, trade registrations/licences, fees and costs, education,

transport, health, community services, policing and legal differences, emergency management, agriculture, environment, and tourism. (NSW Government, 2012). Those trans-border concerns that could be addressed in city region planning are taken up in the Plan, and the Cross-Border Commissioner is declared a key agent in achieving the Plan's cross-border outcomes: "The NSW Cross-Border Commissioner, the Queensland Government and councils will work together to better integrate cross-border servicing and land use planning to remove any barriers to economic, housing and jobs growth" (NSW Government 2017: 12).

The hard work ahead of the NSW Cross-Border Commissioner is demonstrated most starkly by the lack of cross-border commitment from the Queensland side that is evident in the current City Deal proposal, as discussed earlier in this section.

3. Conclusions

This paper has reviewed three Australian case studies of the planning of city regions that transcend internal state or territory borders. Despite such efforts commencing up to 50 years ago, the three case studies do not combine to tell a story of a uniformly successful model of trans-border city region planning at these three borders of the state of NSW.

The limited success of Albury-Wodonga in attracting sustained growth in population, employment and facilities may be because these twin border cities are so far from the nation's capital cities which attract the greatest population and investment: Melbourne is 300 kilometres away (Harris and Dixon 1978). It is yet to be seen whether cross-border collaboration will be renewed by the "Regional Deal" securing the involvement of three levels of government including both states with their respective Cross-Border Commissioners.

The Canberra region has the advantage of being centred on itself as a capital city of critical population mass and national political and cultural importance. In addition, it is part of a connected corridor of urban centres extending 200 kilometres from the outer suburbs of the NSW capital, Sydney. The ACT and NSW Governments, together with surrounding local governments, provide the most exemplary approaches to collaboration in trans-border planning. The critical success factors demonstrated here over the past 25+ years arguably include:

- willing cooperation between the state and territory governments and their planners;
- clear conceptualisation and political and public uptake of narratives of a Sydney-Canberra Corridor and a Capital Region;
- The signing of a MOU between the ACT Chief Administrator and the NSW Premier in 2006 and its continued support and implementation by the two governments;
- the desire of surrounding rural shires to benefit economically, socially and culturally from their proximity to the national capital;
- a consistent record of actively addressing cross-border issues in plans made by the ACT government, NSW government and local governments over a sustained period;
- the involvement of the NSW Cross-Border Commissioner where necessary to broker expansion of Canberra across the territory border into NSW.

Lessons from ACT-NSW border need to be drawn on to address cross-border regional planning as the third case study city region, Queensland's SEQ, continues to grow across the border into the North Coast of NSW. This trans-border city region is the most populous and fastest growing of the three case studies, manifesting the continued growth of the 200 kilometre coastal city extending from Brisbane, the Queensland state capital which is only 100 kilometres from this border. Plans by the NSW Government, eg the 2006 Far North Coast Regional Strategy and its successor the 2016 North Coast Regional Growth Plan, have addressed the border and key cross-border centres for some years now, while the most recent SEQ Regional Plan, Shaping SEQ 2017, pays scant attention to cross-border planning issues, and these issues are not prominent in the plans of the two local councils that address development of the contiguous urban development that crosses the border. The unevenness of the response is surprising, given that a MOU and cooperation agreement have existed between the State Premiers of Queensland and NSW since 2006. On the other hand, it is not so surprising that NSW is further advanced in trans-border planning as it has fifty years of experience dealing with these issues on three of its four land borders, while Queensland only faces these issues at one of its borders, and this occurs at the periphery of the state's main city region, SEQ, which is centred around the state capital of Brisbane.

Further research will include key informant interviews with senior planners and community leaders in the three trans-border regions studied here, as well as international comparisons with city regions that transcend international borders.

Research Paper

Informal planning: a tool towards adaptive urban governance

Theodora PAPAMICHAIL, ETH Zurich, Institute of Spatial and Landscape Development; Switzerland

Ana PERIĆ, ETH Zurich, Institute for Spatial and Landscape Development; Switzerland; University of Belgrade, Faculty of Architecture; Serbia

Abstract

Formal planning instruments and procedures have often been unpopular and ineffective for solving complex spatial issues, such as urban sprawl or transport congestion. As a result, such conflicts turn into complex planning tasks that usually exceed the provisioned time and funding, especially when faced with adversarial interests of actors from different organisations, sectors or social groups. Hence, informal planning, as a non-binding supplement to official planning instruments, is often considered highly effective. In its broadest sense, informal planning includes the principles of collaborative dialogue, diverse networks, trustful relationships and tailor-made processes among interested parties. Consequently, informal planning processes foster sound decision-making delivering a spectrum of problem-oriented solutions and increasing public consensus, while enacting experimentation, learning, change, and the creation of shared meanings among stakeholders. However, informal planning cannot be taken for granted – it is strongly interwoven with the planning culture influenced by the historical and political background, and the current socio-economic conditions.

This paper revolves around several pillars. After an introductory section, a brief historical overview firstly identifies the place of informal planning in various planning models that have appeared since the 1960s. More specifically, informal planning is analysed against the theoretical concept of collaborative rationality. Finally, the paper focuses on a specific informal planning procedure called the 'test planning method', being analysed against the previously elaborated theoretical background. As this instrument links both formal and informal planning, its comparison and interrelation with the theoretical background of collaborative rationality contributes to elucidating the following attributes of adaptive (collaborative) urban governance: 1) flexible and agile institutional arrangements supportive to various kinds of urban planning mechanisms (not only official tools), 2) proactive and imaginative planners ready to accept solutions created outside the technical domain of instrumental rationality, and 3) inclusion of numerous stakeholders to exchange various information and different types of knowledge, i.e. expert and experiential knowledge. Observed through the example of the test planning method, the article finally highlights the successful aspects of informal planning, however, pointing also to its shortcomings, which could be expected in the societies with a lack of key democratic elements.

Keywords

Informal planning, adaptive urban governance, collaborative rationality, test planning method.

1. Introduction: challenges of formal planning

In recent years, global socio-economic transformations have strongly challenged the spatial planning practice. An indicative example refers to the countries of Eastern and Southern Europe, which in particular have experienced a prolonged economic crisis with tremendous impact on numerous facilities, services, and infrastructures. Increasing demand for housing, the provision of low-interest mortgages, and the significant, but not sustainable investments in major urban projects manifest the crisis unevenly across space (Papaioannou and Nikolakopoulou, 2016). In late 2009, international financial markets collapsed stranding millions of new owners with speculative debt few could sustain. The results were catastrophic, especially for southern economies, generating a prolonged recession. Massive state-financed rescue and recapitalisation of the financial system staved off complete collapse. Concerning, for instance, infrastructure management, national (and regional/local) governments have borrowed to fund infrastructure that encouraged such inefficient development – i.e. building roads for unsustainable sprawling development rather than trains for compact sustainable development (Zifou, 2015).

Taking into consideration the discussed socio-economic challenges, current spatial problems in such environments flow from the complexity of decision-making among hierarchical levels of political and economic competition among private firms (developers, lenders, investors, land owners), households (owners, renters), political organizations (political parties, advocacy groups, non-profits) and public officials (elected, administrators, professionals) (Papamichail and Perić, 2018). All these agents make plans, but the ensuing decisions are neither transparent nor coordinated. Legal and regulatory arrangements of spatial planning context usually fail to bring at the same table all the actors who are respectively responsible in decision-making, or provide effective feedback and controlling mechanisms against fast-track investments or uncontrolled privatization of public land and infrastructure. This results in, not only in exclusive benefits, but it also reflects to uneven spatial development across Europe, strengthening the dipole of the North-South. Despite the cohesion policies and tools of EU, countries with partially developed culture in collaboration have a different rhythm of adoption of such cohesion instruments than countries with an integral approach in spatial planning. Therefore, the question comes which informal supplements are appropriate to boost joint responsibility and support weak formal planning systems.

Briefly put, informal planning activities sacrifice authority for joint responsibility. Instead of focusing on actions of control, informal planning focuses on those whose actions shape the future consequences of spatial development (e.g., the flooding, the traffic, etc.), as well as those who will bear most of these consequences (Papamichail and Perić, 2018). Current formal planning structures usually limit people in these respective social positions and locations apart. On the contrary, informal action brings some of these people together and creates alliances in order collaborate towards making plans and setting directions of spatial development. Formal planning processes are usually trapped between political elections and the competition of economic investment. The informal approach invites politicians and investors to join in temporary collaboration beyond the restriction of formal roles. The collaboration is democratic and focused on deliberation among these participants. The

payoff is not increased power, but purposeful criticism on reciprocal learning processes to conceive and compare problems and solutions for a place that combines causal assessment and political judgment (Briassoulis, 1997; Scholl, 2017; Papamichail and Perić, 2018).

The paper starts with focusing on the notion of informal planning and its supplementary role to the formal system, as well as its cognitive and practical contributions. This is followed by a brief overview of the main planning models in order to determine which of these contain the elements immanent to informal planning. The principles of collaborative rationality are particularly highlighted as they serve as a sound conceptual background for the informal planning practice. To be more specific, the next section describes the test planning method as a link between formal and informal planning and how it put those principles in practice. The concluding sections outline the main principles of informal planning and how they support adaptive urban governance, while they interpret the effectiveness of the informal approach arguing that informality works best for complex problems that formal systems fail to face.

2. Informal planning

2.1 The notion of informal planning

Informal processes are also referred to in the literature as: "nonstandard, underground, illegal, hidden, shadow, unobserved, submerged, irregular, invisible, unofficial, parallel, silent, alternative, paraplanning, opaque planning, shadow state" (Briassoulis 1997). Some of these terms indicate that, in the beginning, informality was connected to poverty and marginality. The informal sector was firstly introduced into international literature by the report of the International Labour Office Employment Mission in 1972, Kenya (Lubell 1991; Briassoulis 1997). The physical implications of informal activities have been analysed extensively and prove how informal systems provide everyday practices, illustrating cases such as squatter settlements in developing countries (Briassoulis 1997).

In a broader context nowadays, the term informal mainly relates to the non-institutionalised planning activities carried out either as a preliminary phase that supplements the formal planning process (Scholl, Staub and Vinzens 2013; Hoch, Scholl 2018) or as collaboration completely overlapping with formal planning (Briassoulis 1997). Therefore, it is of utmost importance to arrive at a better explanation of the concept of informal planning through its relation to formal planning. Briassoulis (1997) defines the three main criteria on the basis of the causes of informal planning: 1) degree of state regulation, 2) demand for planning, and 3) cost of planning. When mutually combined, these shows that informal planning appears whenever there is low state regulation but high demand for planning (e.g. in transitional societies driven by market demands). In cases where, on the one hand, there is weak state planning and low planning costs but also where state regulation is fully enforced but costs of planning are high (e.g. great infrastructural projects demanding additional resources to the available public ones), informal planning comes to the fore. Similar to the latter, high demand accompanied by high costs of planning provides room for informal planning activities (Papamichail, 2019).

It is hard to argue over a precise definition since 'informality' meets a broader spectrum of criteria, as mentioned before, and according to Schönwadt (2008) there is no planning "per se"; he notes that: "Planning is always carried out by people who possess specific biological and psychological idiosyncrasies, who nearly always interact with organizations or cooperative projects, who live and work in their own social and cultural milieu, and who have certain aptitudes, skills, and shortcomings, which is to say restrictions", while, based on the view of Tewdwr-Jones and Allmendinger (2002, 214f), he goes on to argue that "there is not one dominant paradigm in planning today..." dismissing the idea that the collaborative/communicative approach is the only approach to planning alive today. Hence, taking into consideration the shift in planning models explained previously, the degree of state regulation places the emphasis on the role of planners as public officials and their relationship to the activities of other stakeholders. More precisely, defining, on the one hand, the position of planners in the decision-making arena and, on the other, their link to non-public sector actors (civic society, individuals, interest groups) elucidates the roots of informal planning in a number of models, which appeared as a reaction to the rational planning.

Briefly, informal planning concerns non-institutionalised processes that supplement the formal institutional practice, increasing joint responsibility between actors. Informal planning through temporary and provisional processes deals with spatial conflicts that formal planning processes fail to fulfil. This does not mean that informal planning processes overlap or disregard formal planning frameworks, but that they supplement them in order to enable actors to communicate, cooperate and coordinate planning tasks between different institutional levels and sectors (Hoch and Scholl 2018), thus dealing with complexity and uncertainty in practice.

2.2 The evolution of informal planning

The rise of informality and the causal complexity of structural problems is related to the shift between first and second generation planning models. Instrumental rationality in planning emerged through the movement of Positivism in the 19th century, which aimed at applying the achievements of science and technology — however crude — to policy-making (Faludi, 1973). Therefore, on the basis of the following steps towards planning tasks, the rational model has been claimed as being too positivistic, ahistorical, and most of all, apolitical: (a) Analysis of the situation, (b) setting of goals, (c) formulation of possible courses of action to achieve those goals, and (d) a comparison of the consequences of each course of action (Meyerson and Banfield, 1964; Muller, 1993; Schönwandt, 2008). This planning model has also been characterised by its top-down approach, supporting the implementation of policies ignoring the public interest and social differences.

By the early 1970s, many analysts had begun to question not only the efficacy of the rational model in planning, but the possibility of the rational planning model in total, turning from technical to collaborative rationality and accepting uncertainty in planning (Hoch 1994). This

critical perspective for the first-generation model was introduced by various scholars such as Lindblom, Forester, Rittel, Heally, Innes, etc. Later it was Rittel who contrasted the "first generation" model in planning with that of the "second generation". In particular, Rittel and Weber (1973) highlighted the importance of societal problems and dilemmas in planning in a different perspective from that of planning as an applied science:

"A great many barriers keep us from perfecting such a planning/governing system: theory is inadequate for decent forecasting; our intelligence is insufficient to our tasks; plurality of objectives held by pluralities of politics makes it impossible to pursue unitary aims; and so on. […]

The kinds of problems that planners deal with - societal problems - are inherently different from the problems that scientists and perhaps some classes of engineers deal with. Planning problems are inherently wicked." (p.160)

The theoretical approach of the so-called "wicked" problems brought various changes in planning theory. The questioning towards the rational model of planning resulted in six planning models that followed: the advocacy model, the (neo) Marxist model, the model of equity planning, the radical model, the liberalistic model of planning, and the collaborative/communicative model (also referred as the model of social learning and communicative action). Figure 1 illustrates the main representatives and objectives of each planning model. The theory of 'communicative action' of Habermas has been criticised as to the basic conditions framing this conversational context as "ideal speech", which in turn set some constraints for planning in practice since there is no space free of power (Flyvbjerg, 1998, Schönwandt, 2008). Based on the Habermas' (1984) theory of communicative action, the work by collaborative planning scholars provides an empirically tested assessment of collaborative rationality: cooperation among numerous stakeholders, obtaining valid information, and exchange of information and different types of knowledge – expert and experiential (Booher and Innes, 2002; Forester, 1989, 1999; Healey, 1992, 1995; Innes, 1995; Sandercock, 1998).

RATIONAL MODEL OF PLANNING	ADVOCACY MODEL OF PLANNING	NEO-MARXIST MODEL OF PLANNING	THE EQUITY MODEL OF PLANNING	RADICAL MODEL OF PLANNING	LIBERALISTIC MODEL OF PLANNING	COLLABORATIVE/ COMMUNICATIVE MODEL OF PLANNING
Before 1960s	*Mid 1960s*	*End of 1960s-mid 1970s*	*1960s*	*1980s*	*1980s*	*1970s-1980s*
Meyerson *Banfield* *Faludi*	*Davidoff* *Reiner*	*Lefebvre* *Castells*	*Krumholz* *Mier*	*Grabow* *Heskin*	*Sorensen* *Day*	*Habermas* *Forester* *Friedmann* *Healey* *Innes* *Hillier*

Positivistic, ahistorical, apolitical model of planning. "Top-down" approach supporting the implementation of policies ignoring the public interest and social differences.	The "Public" is not taken for granted in contrast with the politically "top-down" approach of rational planning.	Planning becomes an instrument of: -Rationalisation and legitimatization - Negotiation and mediation between the differing demands of various groups. -Regulator or valve for the pressure and protest of the governed classes.	The city administration is an arena in which a political agenda is debated, and planners act in favor of the interests of the disadvantaged *within* this arena.	Planners become the free-lancers, acting outside the system and identify themselves with the unprivileged social groups, usually living and working with them in the deprived areas.	The market as the main regulator of spatially relevant activities, therefore the market-oriented instruments can be seen as a means of informal planning conducted by the private sector actors.	The power of knowledge and learning was favored. Planners involve the "public" (stakeholders and inhabitants) by incorporating their knowledge and abilities diminishing the power of official authorities and providing equity between responsible 'players'.

Figure 1 - Seven models of planning (Source: T. Papamichail 2019, based on Schönwandt 2008).

Briefly put, the preliminary outlines of informal planning can be found in four planning models: advocacy, radical, liberal, and collaborative planning. In the advocacy planning model, the planners step out of the main planning boards, councils and committees in order to objectively represent the disadvantaged social groups and their interest. The public interest is not taken for granted; on the contrary, it must be defined through assessing the needs of the weaker parties (Davidoff & Reiner 1962). The radical model follows this line of thought; however, it goes a step further. Planners become the freelancers, acting outside the system and identifying themselves with the underprivileged social groups, usually living and working with them in the deprived areas (Heskin 1980). The liberal planning model emphasises the role of the market as the main regulator of spatially relevant activities; therefore, the market-oriented instruments can be seen as a means of informal planning conducted by the private sector actors (Sorensen 1983). Finally, the collaborative planning[1], ideologically based on the power of knowledge (be this expert and/or experiential) and good argument, diminishes the official authorities and makes all the stakeholders relevant and equal players in the game. A collaborative approach combining professional knowledge about spatial causes and consequences with the diverse interests and ideas of various stakeholders can be understood as informal planning, particularly within the emerging and transitional democracies.

[1] Many different terms revolving around the same idea of unhampered collaboration have appeared in recent decades: 'communicative-argumentative turn in planning' (Forester, 1989), 'planning through discussion and cooperation' (Healey, 1992), 'communicative planning' (Sager, 1994), 'pragmatic approach' (Hoch 1994), 'inclusive discourse' (Healey, 1995), 'communicative action and interactive practice' (Innes 1995), 'planning through consensus building' (Innes, 1996), 'collaborative planning' (Healey 1997), 'discursive practice' (Sandercock, 1998), 'deliberative planning' (Forester, 1999), etc. (Perić and Soltaniehha, 2015).

2.3. Collaborative rationality

Innes and Booher (2010) further argue for the relevance of informal planning based on collaborative rationality in the context of complex spatial problems. They elaborate five principles to use to judge if and when to collaborate.

- Diversity and interdependence. Interdependence among diverse actors motivates participation and spreads risk and reward as each contributes to joint conceptions of problem and solution. Learning about mutual gains and risks encourages commitment to joint action now within an encompassing framework as future commitments remain provisional – open to changing circumstances and shifting participants.
- Collaborative dialogue, trust and knowledge. Collaborative dialogue among participants in small groups requires that each listen and learn from each other. Focusing on interests and intentions fosters trust as it informs judgments about causality and possibility. Future consequences replace attachment to rules and positions.
- Networks. Networks among the stakeholders include a wide variety of possible interrelationships. This may include interdisciplinary cooperation, i.e. cooperation among various sectors within administrative structure, but also intersectoral cooperation, which includes mutual activities across public, private and civil sectors.
- Monitoring and feedback. Accountability and responsibility animates the entire plan from the outset. Evaluation accompanies every phase because the plan provides an ongoing guide for relationships and not a blueprint.
- Small, diverse working groups. Convening small temporary groups of people with a stake in a pressing complex spatial problem makes it possible to build relationships tied to resolving the problem. People are more willing to trust others and reconsider old habits in the context of relationships tied to shared purpose yet provisional and sensitive to impacts for others.

Based on the Habermas' (1984) theory of communicative action, the work by collaborative planning scholars provides an empirically tested assessment of collaborative rationality: cooperation among numerous stakeholders, obtaining valid information, and exchange of information and different types of knowledge – expert and experiential (Booher & Innes, 2002; Forester, 1989, 1999; Healey, 1992, 1995; Innes, 1995; Sandercock, 1998). Hence, how the principles of collaborative rationality relate with the deliverables of informal planning? The informal system taps the insight of diverse social experience to improve practical judgments about complex problems. Planning in such settings embraces the conventions of deliberative democracy linking small group discourse with scientifically informed causal and interpretive analysis of problems and solutions (Papamichail and Perić, 2018).

3. Test planning method: between formal and informal planning

Numerous informal – or, as often called, 'collaborative' - planning processes have been developed; however, the one described below, the Test Planning Process, is based on the Action-Oriented Planning approach (Scholl, 1995) and it links formal and informal responsibility. More specifically, the Test Planning Process (TPP) is the informal planning method for creating concrete and feasible proposals and solving challenging tasks in spatial planning. It stimulates a critical discourse about implementing the solutions for complex and long-term spatial problems (Scholl et al., 2013, Scholl 2017). Instead of traditional/formal spatial planning methods, the TPP implies a collaborative process among numerous stakeholders with different interests, which combines top-down with bottom-up approaches. More than a common competition, the TPP gathers competitive ideas from various planning teams coordinated by an interdisciplinary steering committee. The resulting contributions are introduced, discussed and, after close evaluation, presented to an executive committee for further elaboration and implementation (Scholl et al., 2015; Papamichail, 2015).

According to Scholl et al. (2013), there are seven key theoretical principles underpinning test planning as a method:

- Concurrence of ideas. The core of test planning is the competition between various ideas. As a result, the most efficient solution is given to the contractor within the framework of the given conditions.
- Rhythm. Ideas and solutions mature due to repeated discussions and continuous testing throughout regularly scheduled meetings.
- No 'winner'. Unlike a traditional competition, there are no unique winning proposals. Since complex tasks often do not have ideal solutions, this method examines the different ideas of the teams and selects those that are most appropriate.
- Ad hoc organization. Test planning is an independent process and even the contributions of local and regional officials are considered according to the TPP rules. As a result, alternative, impartial solutions can emerge.
- Communication. Test planning cases are usually about areas whose future has a strong public interest. To gain public support for the results and attract various actors, communication and marketing of the various steps and solutions is important from the beginning.
- Finding problems and solutions. Apart from the final solutions, a redefinition or identification of new problems in addition to the given ones often takes place. This turns test planning into a dynamic process.
- 'Protected' process. Ideas and solutions are first discussed and tested in closed meetings between the teams and the steering committee before any public announcements in order to develop strong argumentation for the solution, and which paves the way for fruitful dialogue with various actors and the public to follow.

A typical organisation and structure of the Test Planning Process is indicated in Figures 2 and 3.

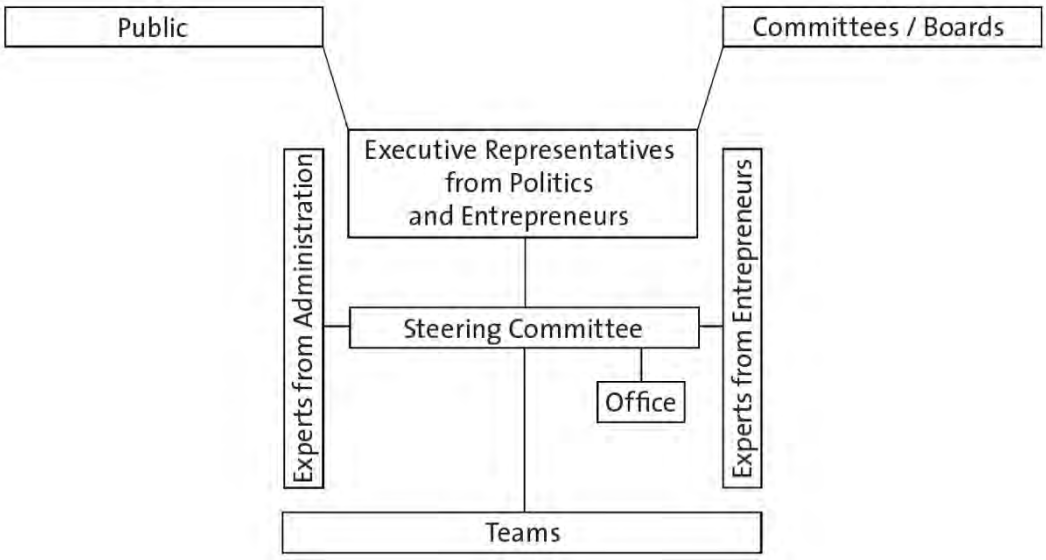

Figure 2 - Typical structure of a test planning process (Source: ARL 2011 in Scholl 2017).

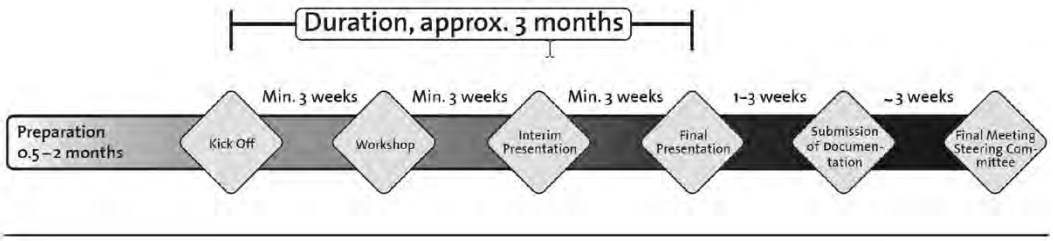

Figure 3 - Typical organisation of a test planning process (Source: ARL 2011 in Scholl 2017).

As to the structure of the process (Fig. 2), the role of each group is, in brief, as follows (Scholl 1995, 2017):

Executive Representatives from politics and entrepreneurs: The Executive Committee consist of two to five representatives (all with voting rights) of the commissioning political authorities and organizations. It distributes the formal mission for conducting a test planning process, is regularly informed about the working progress of the Steering Committee, and approves the definitive recommendations resulting from the test planning process. The Executive Committee also selects the coordinating chairman from within its members.

Steering Committee: The Steering Committee comprises usually seven to twelve persons (all with voting rights), who are experts from the commissioning body as well as independent experts. Additional experts, without voting rights, can be also invited. The Steering Committee leads the test planning process content-wise, is in direct discussion with the

planning teams, and formulates the recommendations from the team proposals to submit them later to the Executive Committee, while it selects the coordinating chairman from its members, usually based on the suggestion of the Executive Committee.

Planning Teams: A minimum of three, maximum four, interdisciplinary teams work on problem-solving proposals to address the problems presented in the task description (Task Mission), which is the same for all teams. The selection of the teams should provide a diversity of qualified teams from the region, and elsewhere, national or international. A pre-qualification phase can support the selection.

Steering Committee's Office and the Preparation Group: The Steering Committee has an office assigned to it, responsible for writing up the protocols, performing other tasks, and organising the meetings, as well as the preliminary assessments and synopses of the team proposals for the final meeting. In addition to the Office, during the preparation phase of a test planning process, a Preparation Group is required. This group is responsible for the compilation and preparation of the basic information on the test planning task description, the preliminary assessment of the projects and the operative leadership of the process.

The Test Planning Process is rooted in the case of the Vienna Model (1975), Vienna's need of flood protection for the Danube River, while it has been implemented in several other cases such as Frankfurt's regeneration of the urban area along the Main River waterfront (Stadtraum Main), the Swiss cases of Solothurn's revitalization of one of the largest brownfields, the transformation of the abandoned military airport at Dübendor, the case of Brig Railway Station, or the brownfield regeneration of Bovisa Gasometri in Milan (Scholl 2017). In those cases, besides the previously described steps and role models, two more elements contributed significantly in the impact if informal planning; the formulation of the conciliums, e.g. in the case of Vienna and Frankfurt, or the formulation of platform associations, e.g. in the cases of the Limmat Valley and Brig. The role of the concilium concentrated on preparing the ground for a common discussion before, during and after the implementation of an informal planning process. Likewise, the composition of platform associations, consisted of representatives of the stakeholders, was a result of informal planning and it supported the following formal planning processes, creating common ground for exchange knowledge and information among the actors and the public.

How well do the elements of the TPP incorporate the principles of collaborative rationality? Figure 4 offers a graphic image detailing important overlaps.

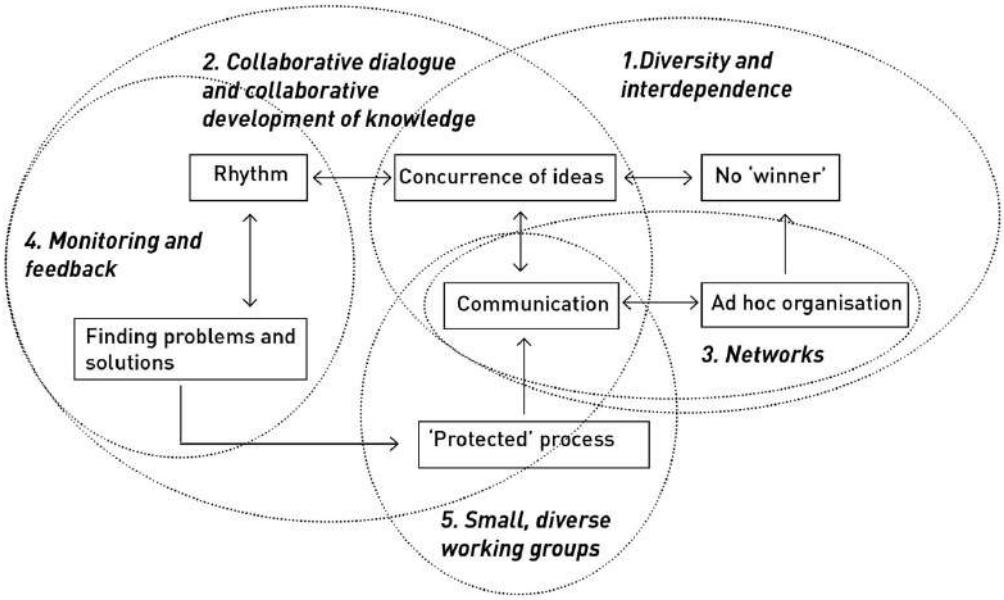

Figure 4 - The interrelation between five principles of collaborative rationality and seven principles of the test planning process (Source: Papamichail and Perić 2018).

4. Towards adaptive urban governance through informal planning?

Based on the interrelation of informal planning and collaborative rationality, the five principles are following (Papamichail, 2019):

- *Inclusive, flexible & transparent processes towards joint responsibility.* They increasing security for the process based on trust building, eliminating misconceptions, and managerial relations or 'behind the scenes' actions. Furthermore, it includes all responsible actors and overcomes administrative and institutional borders as well as adapts to tasks of different spatial (national, regional, local) and power (national, regional, local) scales and projects (brownfield regeneration, transport development etc.), creating new spaces for action.
- *Non-linear, but simultaneous processes based on the three-cycle design.* They provide knowledge as to how to act simultaneously at the right moment, dealing with various aspects of sustainable development, accelerating decision-making saving time and funding resources. Such processes stimulate a spectrum of problem-oriented solutions that are not often visible or commonly accepted in the beginning, and offer both purposeful criticism and the time to come up with robust ideas and solutions.
- *Focus on public consensus building*. Based on collaborative dialogue, informal planning not only produces agreements and plans, but it also enacts experimentation, learning, change, and building shared meaning among all affected parties. This counterbalances hierarchical and political mandates, as well as administrative procedures, which preclude the kind of conversation needed to avoid

the pitfalls of adversarial positions and posturing. Moreover, it weakens ideological and personal commitments that usually blind officials and clients to problem complexity and adaptive solutions.

- *Potential and problem-oriented scenarios and solutions.* Informal planning complements with problem or potential-oriented planning scenarios and solutions based on concurrence of ideas. Unlike the usual concept of a competition, the concept of the concurrence of ideas delivers multi-functional concepts based on diverse aspects and ideas. As a result, this provides holistic plans based on commonly accepted frameworks and conditions.
- Actor networks based on role differentiation. offer diversity and interdependency between the participants based on an ad hoc and clarified structure. This structure includes a commission (representatives of executive authorities), a guiding group (which binds representatives from both public authorities and private sector) and working groups (planning teams). Not less than three different working groups ensure plurality of ideas and solutions, testing even those that have been disregarded.

Hence, the principles of informal planning contribute the following, concerning the promotion of adaptive urban governance in environments of crisis: 1) flexible and agile institutional arrangements supportive to various kinds of urban planning mechanisms (not only official tools), 2) proactive and imaginative planners ready to accept solutions created outside the technical domain of instrumental rationality, and 3) inclusion of numerous stakeholders to exchange various information and different types of knowledge, i.e. expert and experiential knowledge, 4) problem-oriented scenarios and solutions of spatial and urban development, based on the concurrence of ideas.

5. Conclusion

Informal planning shows how it can supplement formal planning structures and serve as a tool for adaptive urban governance. Even though, in several cases, informal planning is not accepted fully by different planning cultures, it presents a potential and long-term impact. Namely, informal planning processes:

- Point out a step-wise development concerning complex tasks in spatial planning based on concrete arguments, which emerge through clarification processes.
- Provide shared experience to inform simultaneously formal national institutions or transnational institutions, i.e. EU institutions, policies and instruments, providing information channels among international, national, regional and local level of spatial planning.
- Include numerous stakeholders and smooth the paradoxical role of planners, who act between formal and informal responsibility.
- Provide a spectrum of action, especially in countries challenging socioeconomic environments, and it might happen opening the door for further research.

Reinforcing strategic decision-making and a step-wise development are the tools for paving the way towards a new planning culture. Nevertheless, changing planning culture is a long-term process, which may or may not be successful. This does not depend only on planners and their readiness to understand, accept new skills and adapt these to the local settings, but it depends more on the general socioeconomic conditions, which provide a secure and stable context for innovative planning to happen. For instance, the adoption and interpretation of informal planning in countries with immature society in collaborative planning processes, e.g. in Greece, or no background in deliberative democracy, e.g. China, Iran, can still provide challenges regarding the misinterpretation of the role of informal planning towards favouring again fast-track investments and focusing on the benefits for a few. For creating a mature background, the systemic support is needed as a backbone, i.e. though education – only in this case planning finds a fruitful ground for interpreting and implementing informal procedures. This opens further questions for future research steps concerning the transfer of tacit knowledge in countries with partially developed culture in collaboration and deliberative democracy.

Case Study / Project

Organizing Urban Governance in Vietnam:
an Investigation on Housing Development in Ho Chi Minh City

Thai Son PHAM

Abstract

This paper aims to identify and discuss urban governance related issues in Vietnam through an in-depth investigation on housing development in Ho Chi Minh City (HCMC). In the literature review on urban governance regarding housing policy, the paper highlights five dimensions of urban governance that Richard Stren (2007) proposed: capacity, finance, diversity, security and authority. After that, the paper examines major challenges in capacity and authority dimensions of urban governance in HCMC based on extensive working experience with the city's technical departments and empirical analysis on various secondary documents on housing development,. The findings show that HCMC has a huge responsibility of providing housing for its growing population but receives inadequate decentralization from central government, causing a lack of financial resources, an institutional fragmentation and a weak coordination framework with poor community engagement. The paper concludes that current configuration of urban governance in HCMC is not sufficient to address housing as cross-cutting and multi-faceted issue and proposes integrated approaches towards a good governance system with broader implications that go beyond the single case of Ho Chi Minh City.

Research Paper

Decentralisation and devolution in growing megacities

Case of Bangalore, India

Ananya RAMESH, India
Nirupama M VIDYARTHI, India

Abstract

Through the 73rd and 74th Amendment Act of 1992, India sought to empower urban and rural local bodies. On the contrary, parallel modes of governance have undermined them. In the case of megacity Bangalore, two such modes i.e Electronic City and Smart City are studied to unpack the status of decentralisation. Key person interviews serve as primary data. Following the enquiry of decentralisation and devolution, elements of disconnectedness emerge. Disconnectedness can be seen between parts-affecting the whole, embodied as intents as well as outcomes through tools of planning, administrative, legal, political and economic choices. This leads us to enquire how we can retain decision-making power within the democratic realm and strengthen the role of local bodies in megacities. Unpacking the dynamics of decentralized governance is critical across megacities globally, as cities continue to seek autonomy not just in functioning but identity and influence, in the network of global flows.

Key words

Democratic decentralization, Electronic City, Smart City, Disconnect

Introduction

The United Nations (UN) define megacities as those with a population mark of over 10 million, where Bangalore features in the top five megacities in India with a population of 10.5million (United Nations, 2018). The Census of India, 2011 refers to Bangalore as an Urban Agglomeration under the million plus category, governed by a Municipal Corporation. In India, megacities are categorised based on their contribution to the Gross Domestic Product (GDP) and their role as central to the 'economic future' of the country (McKinsey Global Institute, 2010). Cities in this framework are viewed as concentrations of investment, labour and infrastructural provisions. This makes them vital tools in the 'growth' narrative calling on governments to 'remove barriers in product, land and labour markets' (McKinsey Global Institute, 2001).

Megacities as a process

Harvey deconstructs these 'utopian' (Harvey, 1996) ideas of growth in cities and argues that they are not entities, but processes of 'accumulation of capital across time and space' (Harvey, 1996) especially the big agglomerations which act as the primary centres of 'capitalist creative destruction' (Brenner, 2013, p. 108). In cities like Bangalore this is especially marked in the processes of creating a 'world class city' (Ong, 2011) more pronounced since the mid-1990s (Goldman, 2011a). Michael Goldman discerns the flow of capital and its effect on the transformation of Bangalore from a quiet pensioners town to a

'third world Megacity' (Goldman, 2011a) catalysed by the growth of the IT industry. This makes Bangalore a frontier of "speculative urbanism" (Goldman, 2011b) with the transnational agencies aiming it to connect to a global network of flows while undermining the local bodies. Urban as a 'process of transformation unfolding in diverse sites, territories and landscapes' as proposed by Brenner helps visualise the case of Bangalore with urbanisation bleeding into the "non-urban" and helps ascertain the capture (Brenner, 2013) and its facilitation, at the expense of the local government. When regional competitiveness (Kennedy, 2017) is at odds with local political competence, capital finds non-capitalist spaces and strata ((Luxemburg, 1951) as cited in (Idiculla, 2015, p. 5)) to engage with; to ease the process. Yet for the very same reason, states invite capital in the very same flagship cities, willing to give up some level of control. This can be viewed as a reason for regional imbalances and certain cities growing into megacities and city regions.

In megacities and urban agglomerations, the local governments most often are limited by administrative jurisdictions that do not match the extents of urbanisation (Baud and Wit, 2008, p. 8). Viewing megacities as processes, urges us to look beyond the logics of administrative and jurisdictional boundaries, observing the dynamic nature of part to whole relationships. Spatial, regulatory and financial provisions within these processes define parts, as a dynamic identity and its relationship with the megacity; owing to the multiple processes within megacities.

Decentralisation in India: the institutional framework

The 73rd and 74th Constitutional Amendment Act (CAA) introduced in 1992 can be viewed as a milestone in the attempt to decentralize and strengthen rural and urban local governments as the third tier within the federal structure. The 11th and 12th Schedules added through these CAAs give a detailed list of functions to be carried out at this level of government. The 73rd CAA has better implementation since it actively regulates decentralisation in rural areas through clear demarcation between state and panchayat raj; devolving financial and administrative power proportionately to function autonomously (Baud and Wit, 2008, p. 24). The 65th CAA 1990, a precursor to the 74th CAA failed to be implemented since it sought an unprecedented move within the federal structure, empowering the urban local bodies i.e. municipalities as the third tier of government. Opposed on the grounds of 'bypassing' the state government which are the building blocks of the nation i.e. 'India as a Union of states', the 74th AA toned down this proposition, offering state governments discretionary powers (Baud and Wit, 2008, p. 54). In Karnataka, Karnataka Municipalities Act and Karnataka Panchayat Raj Act provide the framework and institutional structures.

In the case of Bangalore creation of parallel modes of governance through parastatals and taskforces, citing technical expertise as the reason laterally shifts the decision-making power away from the ULBs which has been discussed widely discussed by scholars under the Collaborative for Advancement of Studies on Urbanism through Multi-Media (CASUMM). These studies also establish the undermined power of municipalities due to lack of devolution of power to the Ward Committees, capture of fiscal control and decision-making through creation of financial intermediaries and pre-conditioned loans from international financial institutions. It is in this context, Leo-Saldanha from Environment Support Group rightly points out that "we are ritually decentralised, but effectively centralised".

Studying the complexity of "market-based practices" in Bangalore, Benjamin (Benjamin, 2010)articulates that the impact of neoliberal forces when "policy and programmes favour the big interests over these everyday-practices" poses a threat to the essence of democratic processes and decentralisation. The current approach to democratic decentralisation coupled with regional competition (Kennedy, 2017) and corresponding policy incentives by the state government, are "removing the remaining obstacles to the global presence of capitalism" (Schuurman, 1997) which is discussed through the two cases.

More than two and a half decades after the CAAs, democratically elected urban local bodies remain disempowered. New forms of governance such as Special Economic Zones, Infrastructure Corridors, Industrial Townships, Smart City etc. can be seen as countering this intent, through creation of "enclaves of exception" (Idiculla, 2015, p. 20). We hypothesise that "exception" ((Schmitt, 1985; Agamben, 2005) as cited in (Idiculla, 2015)) as a key intent in these new forms of governance, is leading to various degrees and forms of 'disconnect'. Not only has this shifted decision-making outside the democratic realm and altered the dynamics of local governments, but the disconnects are posing challenges to dynamics within a megacity's parts as well as the regional dynamics. Viewing these disconnects as outcomes, this paper aims to unpack two instances (i.e. Electronics City Industrial Township Authority (ELCITA) and Smart Cities program) of such exception initiated through programmatic and financial exception respectively; implemented through alternate modes of governance .The authors unpack the resultant disconnects as outcomes of processes that contest, claim and retain decision making within the democratic realm and the dynamics of impairment and systematic shift in power away from local bodies aimed at serving other interests.

Case 1: Smart City

Megacity fueled by visions of a World Class city

According to Harvey long-term investments in built environment, infrastructure of communication, production to name a few, facilitate the 'circulation of capital' across time. (Harvey, 2000). Apart from utilizing land to accelerate peri-urban transformations, there is a rising interest in 'Urban Renewal' programs seeking to uplift the core city areas. It is through a combination of 'underestimated costs and overestimated revenues' that projects get approved and bring in funds (Flyvbjerg, 2005, p. 1) They project visions and rendered images of the the city on completion of the project. One of the recent proponent of this 'Urban Fantasy' (Watson, 2014, p. 215) in India has been the Smart City Mission. Often referred to as the 'pet project' of the Prime Minister, it is highly centralised in its conception of development, favouring a certain model of 'futuristic' development, often overlooking the actual needs of the cities or areas where the mission is implemented.

Basic Infrastructure vs 'World-Class Infrastructure'

Carrying forth the JNNURM model, the Smart City Mission seeks to bring in large amount of investment into cities. But just as JNNURM the Smart Cities Mission seeks to restructure the functioning of municipalities. This is usually at the cost of provision of basic services (Baindur and Kamath, 2009). In the mission mode, the State and ULB seek to create and demonstrate 'convergence' with larger national goals and other schemes. The cities conceptualise

projects to fit the requirements of the Central Scheme, the predominant incentive being access to the grants. In this process the convergent goals overlook the city's requirements.

Brigade Road, one of the 7km of roads in the core city of Bangalore selected for the 'Smart SURE' roads which will feature IoT (Internet of Things) based interventions. 'These roads will have 50 smart card-enabled public bicycle sharing points, 30 e-rickshaw stands, 35 e-toilets, water ATMs, 420 sensor-based smart dustbins and 50 designated vending kiosks -all of which will be connected to 1,250 smart telecom towers that will double as street light poles. Not to mention, these roads will also have wi-fi connectivity.' (Ministry of Urban Development, 2016). The disconnect between such proposals and the reality of the various parts of the city faces inadequate water supply, sewerage management and lack of basic services especially for the urban poor is evident.

A large part of the Pan City Proposal for Bangalore focuses on 'Smart' technocratic interventions such as e-governance, B-TRIPS etc. (Ministry of Urban Development, 2016). The call for an overhaul in governance with an intensive use of technology causes a disconnect in the system and induces a demand for 'expertise' which is to be fulfilled by a number of Private players offering allied products and services (Ong, 2011).

Focus on Area Based Development

Though ABD is intended to streamline the goals into smaller spatial entities to be tackled as a project, the Bangalore Smart City proposal is far from execution with very less transparency on the progress of the Mission. Officials claim that the DPRs (Detailed Project Reports) are being prepared at this stage.

The mission talks of concepts like 'Retrofitting' and 'Redevelopment' of existing areas; 'Redevelopment envisages an area of more than 50 acres, identified by Urban Local Bodies (ULBs) in consultation with citizen',this raises questions of equity and inclusiveness as various identities manifest spatially in cities. A look at the Smart City proposals of Bangalore shows trends that ABDs concentrate too much on spatial interventions alone, which view retrofitting and redevelopment as an exercise in aesthetics; modernisation, place-making, material changes etc. It is however a manifestation of 'splintered urbanisms' (Graham and Marvin, 2001) with resources being directed to select areas in the city. 2,090 crores are the current estimates for the projects under Bangalore Smart City with Rs 1,666 crores with over 80% just for the ABD projects (Ministry of Urban Development, 2016). The larger budget for the ABD projects will run the risk of creating 'islands of excellence' (Idiculla, 2015) creating a spatial disconnect between the selected areas in the core and other parts of the city.

Since a large portion of the financing of these projects relies on investments from the private sector and Public Private Partnerships, they depend on the market mechanisms for their completion. These Market forces will play out differently in different cities depending on various factors; highlighting existing patterns of boosterism and inter-region competition. The actual spatial forms that these economic forces would take in a city like Bangalore is to be seen. How they are linked with existing economic nodes would decide their feasibility and working.

Governance in an SPV model

The Smart City Mission aims to tap into the 'spirit of competitive and cooperative federalism' (Ministry of Urban Development, 2015) creating competition in the process of selecting the cities and in the delivery of the pre-defined projects. This would depend on the ambition,

ability to repay and the 'comfort' provided to the lenders. Apart from the influencing reforms and policies, certain financial tools like Special Purpose Vehicles are employed to create a financial island disconnected from the liabilities of the constituent partners. Special Purpose Vehicles have become increasingly popular in delivering and operating projects often compromising on transparency. They allow for securitization of assets, distribution of risks, and the goal-oriented approach seeks to instil confidence and minimise risks for the investors.

The Smart City SPV is to implement, plan, appraise, approve and release funds, manage, operate, monitor and evaluate the various projects. This is overseen by the State level 'High Powered Steering Committee'. An 'Apex Committee' at the central level would monitor the entire mission. This in a sense created parallel structure of entities disconnected from the democratic realm, with State and ULBs asked to delegate their powers to the respective mission counterparts.

A large aspect of creating an SPV allows operational autonomy and acts as a means to bypass the local elected representatives and the democratic accountability. Fiscal decentralisation not the same as decentralisation as per the 74th CAA; 'withdrawal' of the Central and to an extent the State governments in the financing of the projects does not lead to autonomy for the ULBs functioning. The decision making in the case of the SCM is largely concentrated with parastatal intermediaries like KUIDFC, the 'High Powered Steering Committee' at the State Level, the monitoring and evaluation of the projects also rests with the SPV and not with the ULB.

There is no mention of the role of the Ward Committees or the elected corporator in the SCM document especially when it mentions the city level governance with the Smart City Advisory Forum. According to the document the forum will include the District Collector, MP, MLA, Mayor, CEO of SPV, local youths, technical experts, and at least one member from the area (Ministry of Urban Development, 2015). This further distances and takes away from the existing role and powers of the local representatives. The Ward Committees have started functioning now and it's largely the civil society pressure that has strengthened its position in the City. Though there are several shortcomings in its current functioning, State and Central policies are actively undermining its position and powers as laid out in the 12th Schedule.

Cities are not products but multiple processes that require constant dialogue with its citizens. The Mission document calls for the delegation of the powers and responsibilities that rests with the State/ ULB to the SPV. This erodes the current threads of accountability and limits the interaction of the citizens to a grievance interface. Its parallel mode of working creates disconnects in the larger system undermining the already disempowered local units of governance.

Case 2: Electronics City Industrial Township Authority (ELCITA)

With economic liberalisation in the 90s, Bangalore opened its markets to foreign investment and launched the Karnataka Information Technology (IT) Policy in 1997. Electronic city (e-City) which was set up as a hub for electronics industries in the 70s, underwent a paradigm shift from electronics to IT with the setting up of Software Technology Parks of India (STPI), (an autonomous society under the Ministry of Communication and Information Technology,

Government of India) in 1991 (ELCITA, 2017). Today e-City is known as the 'Silicon Valley of India', employs over 1.5million people and is spread across 903 acres. Entry of IT into the Indian market can be seen as the moving of capital, seeking new avenues and territories as discussed by (Harvey, 2003) outside of saturated capitalist economies, to gain from reinvestment. Spatially, this phenomenon is concentrated in the peripheries of cities not only because of land availability but the presence of non-capitalist strata ((Luxemburg, 1951) as cited in (Idiculla, 2015, p. 5)).

Creating the enclave of exception

At inception, in the 70s, the Government of Karnataka (GoK) along with Karnataka State Electronics Development Corporation Limited (KEONICS) developed e-City as a single land use estate reserved for electronics industries, imagining it as the future of the state. This defined the island of exception spatially and based on land use. After the entry of IT industry, the island was also defined institutionally in 1992 with creation of Electronics City Industries Association (ELCIA) and handed over maintenance in 1997; to cater to 'special needs' of industries within e-City (ELCIA, 2014; ELCITA, 2017). In 2012, BBMP passed a resolution (The Hindu, 2012) to include e-City under its jurisdiction viewing it as a revenue source in terms of tax, magnet to attract investment into the city, attract educated migrants and in turn boost the state economy. But ELCIA opposed this in order to avoid paying higher taxes to BBMP which is an Urban Local Body (ULB) versus the lower tax they were paying to the panchayats which are rural local bodies. Given these considerations by the GoK, ELCIA lobbied for the Industrial Township status (ELCIA, 2014) to secure the state of exception and operate autonomously, which was granted in 2013. e-City was managed by parastatals Karnataka Industrial Area Development Board (KIADB) and Karnataka State Small Industries Development Corporation Limited (KSSIDC) and KEONICS (ELCITA, 2017), violating the 73rd and 74th Constitutional Amendment Act (CAA) and with the Industrial township status, the village panchayats are facing a loss of revenue in addition to loss of power (since taxes are now collected by ELCITA and not the village panchayats), failing the intent of the 73rd and 74th CAA.

Governing council of ELCITA has elected and State Government nominated members (ELCITA, 2017). The system of nomination in every council allows the State to retain control and limit autonomy. The chairperson selected from the five elected members doesn't have any executive powers, while these powers are vested in the Chief Executive Officer (CEO) who is appointed by ELCITA, sometimes under political pressures from the state government (Aworti, 2003), challenging the exercise of autonomy. This reflects the nature of ELCITA as a local body which is not headed by a democratically elected representative but by an autonomous Authority which is under state control to an extent.

Enclave of exception; relationship between the megacity and its parts

"…Bangalore city has 45% leakage whereas 5% leakage with ELCITA distribution...everyday meter reading is noted and problems are resolved immediately… unlike BBMP, property tax collection is 95% this year and was 97% last year and we have a paperless office and all the work is online for transparent functioning…". During the interview, the CEO of ELCITA talks about the efficiency in governance and quality of service delivery within the e-City jurisdiction with a sense of accomplishment. It is the ring-fenced spending of revenues within the e-City jurisdiction that offers ELCITA the opportunity to provide, monitor and maintain services better. This has led to a stark contrast in quality of infrastructure and

service delivery which can be observed during surveys. This resultant disconnect is a function of the status of "exception", bureaucratic reach as well as the delimited technical expertise and financial power. Another outcome is compromised service delivery to other parts of the city owing to disproportionate distribution of resources and regional disparities (Tantri, 2014, p. 13). Examples in this case include limited fleet of air-conditioned buses on other routes in Bangalore as there is an oversupply on the e-City route, congestion enroute since elevated expressway to e-City is tolled etc.

Status of decentralisation in the case of ELCITA

The altered modes of governance lay out the spatial, legal and economic models for the development of enclaves. Institutional design, municipal autonomy, control over land and revenues of ELCITA within the e-City jurisdiction, has dictated the terms of development and undermined the local governments as discussed in this section.

Provisions to bypass the local body and reroute decision-making

Policy provisions to enable the state of "Exception": To attract IT companies to Bangalore and e-City, the GoK presented several subsidies and simplified the process. With the first Karnataka IT Policy released in 1997 (Government of Karnataka, 2011) it offered several tax subsidies (on computer hardware and peripherals, 50% subsidy on stamp duty and registration charges), exemptions (work contract tax, entry tax for five years, sales tax for ten years, electricity tax for captive power generation without limit, sales tax on fuel without limit) and land cost subsidy based on employment generated. Even with the electricity tariff slabs, software companies are considered industrial and not commercial thereby offering a subsidy on this front as well.

The Karnataka IT policy recommends the creation of a single window agency to administer the concessions and incentives which will be headed by the Principle Secretary Department of Commerce and Industries, retaining power at the state government level. The Industrial Policy has proposed raising bonds to raise funds for IT infrastructure and education. But the revenues from these bonds will be under the control of CM's task force, with no representation from the respective local bodies. The State Policy for Special Economic Zones (SEZ) (Government of Karnataka, 2009) recommends the declaration of SEZs as Industrial Townships under the 2002 Amendment to the Karnataka Municipalities Act. Even the choice of locating these large estates on the periphery of the city can be explained as "untrammelled accumulation" of capital to engage with non-capitalist space and strata to gain influence and initiate transformation ((Luxemburg, 1951) as cited in (Idiculla, 2015, p. 5)). GoK has plans of setting up several SEZs, industrial centers and the IT corridor in the future (Government of Karnataka, 2011) and these will occupy large footprints within the city limits or within village jurisdictions. In this context, the current policy provisions retract power from the local bodies on accounts of revenue streams, decision making as well as infrastructural capacity. In these systematic ways, by carving out enclaves from within the jurisdiction of the local bodies, granting clearances at the state government level and allowing a bigger stake for private actors, leaves the third tier of government as ceremonial, failing the intent of the 74th constitutional Amendment.

Planning exemptions and spatial implications: Creation of e-City as a single use land parcel and IT and Industrial Policy provisions were the first steps towards building-up the state of exception easing the regulatory requirements and process for industries. In case of IT and

industrial developments, the ULB is disempowered through certain planning exemptions as discussed below. Any IT development with less than 5kVA power consumption has no locational restriction, and the Karnataka Industrial Policy (Government of Karnataka, 2016) has recommended an amendment to the Karnataka Municipalities Act to give powers to KIADB and KSSIDC to approve building construction plan of industrial units notified as industrial areas/estates/townships. Not only does this violate the master plan provisions prepared by Bangalore Development Authority (BDA) (which is already illegal since BDA is a parastatal) but also takes away the ULB's role of building plan sanction and reroutes it through state level agencies such as KIADB and KSSIDC.

Growth of e-city involved physical expansion and acquisition of a larger land parcel. The state, in favour of a "business-friendly rather than market-friendly" approach ((Rodrik *et al.*, 2004; Kohli, 2006a, 2006b) as cited in (Idiculla, 2015)) acted as an agent to acquire land, and handed it over to private developers, aiding the corporate-led economic growth as well as the ensuing gentrification (Smith, 2002; Sampat, 2010) as cited in (Idiculla, 2015)).

All these provisions, have supported and strengthened the state of exception, providing the IT houses in the ELCITA jurisdiction more than the elbow room they were lobbying for through ELCIA.

Ambiguity, contradictions and violations

Ambiguity in provisions of the Amendment Act and implementation: Another instance that raises questions regarding the process, is monolithic industrial land use in e-City that afforded it the industrial township status. While the zonal regulations permit residential use and the Chapter XVI-A 364 (B) of the Karnataka Municipalities Act (Government of Karnataka, 1964, p. 869)on Industrial Township recommends a resident member in the council of the Industrial Township Authority, ELCITA was sanctioned since it did not involve any residential areas. It is for the same reason, Whitefield, another IT hub in Bangalore has not been granted this status as it is a mixed-use development.

Conversing with the CEO of ELCITA, we gathered that in the manner of consolidation of territory and granting the industrial township status to e-City, residential land use was consciously excluded while demarcating jurisdiction, resulting in a monolithic single-use fabric. This has led to a ripple effect on the housing real estate outside of its boundary which can be seen as "traces of planning" (Bhan, 2012) beyond the jurisdiction. Though these are pockets of reterritorialized power, their impacts are much beyond its jurisdictions, across sectors of infrastructure, real estate, economy etc.

Access to the township is thoroughfare but controlled. What this means is for those that are permitted it is free access, while hawkers and street vendors are restricted. This approach to decentralisation creates sterile spaces that are heavily controlled, and every enterprise measured and regulated resulting in a private enclave accessible only to its members. Unlike a public authority that provide services to all legal citizens, such enclaves operate on customer basis, including only those who pay for services (Baud and Wit, 2008, p. 19). Not only is this approach exclusive, but contradictory to public nature of the authority, constituted through the Karnataka Municipalities Act.

Violating the 73rd and 74th Constitutional Amendment Act (CAA): While the 12th schedule added under the 74th CAA mentions provision of public amenities as a function of the local body, the civic amenities sites are under the control of the development authority which is a

parastatal. In the case of ELCITA, after KIADB acquired the land and before handing over to ELCIA, the civic amenities sites were sold out. This not only deprived e-City the opportunity to develop public amenities but is illegal for the state controlled KIADB which acquired the land, to dispose it off without consulting the panchayat or municipality under whose jurisdiction the land parcel was located.

Planning carried out by BDA, a parastatal is against the 74th Amendment as the 12th Schedule mentions urban planning and planning of land use as the responsibility of the ULB. Land and development being controlled by a parastatal is also a key reason for no progress in implementing the Metropolitan Planning Committee (MPC) also recommended by the CAA.

Contradictions within constitutional provisions: Article 243Q of the Indian Constitution which mandates the constitution of a municipality in every state, makes the exception for areas notified to be an Industrial Township. The contradiction between Article 243Q and the 74th Constitutional Amendment Act (CAA), exempts areas declared as Industrial Townships from creating a municipal body. Utilising this contradiction within the constitution, in 2003, GoK introduced an Amendment to Karnataka Municipalities Act 1964 (Chapter XVI-A, 364(A) to 364(Q)) which includes the provisions to carve out Industrial Townships as autonomous municipal jurisdictions, governed by an Industrial Township Authority. Under the same provision, e-City jurisdiction was declared as an Industrial Township in 2013 and Electronics City Industrial Township Authority (ELCITA) was created.

Disconnects as outcomes

Disconnects as contradictions against the local setting: Large portion of ELCITA's revenue is property tax, Central Industrial Security Force (CISF) Security fee and water charges. This can be compared to the largest expenses on estate maintenance, municipal functions and security services (ELCITA, 2017). This one-to-one reconciliation of income and expenditure which is ring-fenced within the e-City jurisdiction affords high quality infrastructure and service delivery. Unlike a municipality or panchayat which collects tax under different slabs and redistributes it across the jurisdiction. This limits the financial ability to improve quality of infrastructure and service delivery. ELCITA on the other hand, with its niche industry members is able to shift to digital systems, improving tax collection etc. In addition to the resulting contrast in service delivery and infrastructure quality due to the ring-fenced spending, ELCITA's approach to administration accentuates this contrast, causing a physical disconnect as well as a systemic one. ELCITA promotes "transparency" in its functioning through its "paperless office" and "digital" platform (ELCITA, 2017). Considering majority of its adjacent areas are under rural jurisdiction, for these authorities to interact, this technocratic approach makes it inaccessible and exclusive. The state of exception and notion of an island is strengthened through exclusivity in process, deepening the disconnect.

Functional disconnect: ELCITA through its constitutional provision and legal mandate, is immune to local governance and has no obligation to the civil society. The functions of the Industrial Township Authority of "social development" and "safeguarding interest of weaker sections and improvement of slums" (ELCITA, 2017) do not come into the picture since the e-City jurisdiction is only industrial land use. In order to fulfil its municipal responsibility, it operates under "Corporate Social Responsibility (CSR)" initiatives through ELCIA but not through its own funds. CSR activities include initiatives in healthcare, education, capacity building, sewage treatment etc. in the neighbouring villages (ELCIA, 2014, 2015). These are project-based initiatives as good-will gestures of corporates and not in the true spirit of a

public body. This redefines the accountability an ULB holds towards its citizens since there are no individuals involved but institutions as corporate bodies to negotiate with. Increasing urban character within the majority rural surroundings, shift from agriculture to informal economy (such as drivers, housekeeping staff etc.), change in land use, are some of the changes that can be seen during surveys, as an outcome of such an approach. This has led to disconnects within the adjacent areas, where physical changes are not in complete sync with the demographics and governance, rural by jurisdiction while competing on urban terms.

During the same process, consolidation of territory and devolution of power to build competence through mechanisms such as industrial townships, infrastructure corridors, SEZs, smart city programs etc. "… underscores the importance of political leadership, of the state and other organized actors, both local and supra-local" (Kennedy, 2007). In the ELCITA case, since the autonomous municipal jurisdiction was carved out of two villages, the village panchayats lost control over these areas as well as revenue. In this manner, the power held by the panchayats prior to reconfiguration of jurisdiction was then re-routed through an additional Industrial Township Authority whose purview and interests are bound by the limits of the township. As a result, the neighbouring areas within the megacity are subject to spatial and functional disconnects. Can megacities afford these disconnects and imbalances as a cost to the current approach of decentralisation, given their primacy and growing needs?

(Keil, 1998) suggests viewing the globalised state as altered socio-spatial scales rather than as being replaced by market forces and the local state with perforations, negotiating alternatives to the hegemonic globalisation. In the case of e-City, ELCITA, the local authority is itself a product of hegemonic globalisation, the capitalist forces of the IT industry. Within enclaves such as ELCITA, how can we then perceive the local state as a space empowered for resistance and negotiation?

Discussion

Post economic reforms, role of the state is seen as transformed from a provider to a facilitator and enabler, with increased participation of private actors in service provision (Batley, 1996). (Swyngedouw, 2005) refers to the new modes of governance where administration and implementation is increasingcoply handed over to private economic actors as well as parts of the civil society, as "Governance-beyond-the-State". Though this arrangement is intended to empower grassroots and democracy, on the contrary, it has created new institutions, empowering new actors while disempowering others. The two cases of ELCITA and Smart City can be viewed through this lens, where these new institutions have been given municipal and financial powers respectively, disempowering the local government and altering the dynamic of the megacity Bangalore and its parts.

(Idiculla, 2015) argues that the state cannot be seen as withdrawn from its role as a provider, rather be viewed as in an "alliance" with influential private players. The terms of this alliance between the state and the private players are crucial to understand the impact on decentralised governance and extent to which the ULB is undermined or empowered. Looking at this flow of private capital as "neoliberalism as exception" (Ong, 2006), shows how the economic liberalisation has been more business friendly than market friendly ((Rodrik *et al.*, 2004; Kohli, 2006a, 2006b) cited in (Idiculla, 2015)), illustrating the nature of

this alliance and changing dynamic of the local governments. The state and its agencies have worked towards creating a business-conducive climate, through spatial, legal and infrastructure provisions; to attract capital in the form of IT companies, industries, infrastructure projects, state and central programs etc. These shifts and instances demonstrate how the state itself, has structurally and systematically, dismantled and limited the power of local governments.

The current approach to decentralisation shows devolution of responsibilities and liabilities while the power and funds are still held by the State. This demonstrates forms of "delegation" (Baud and Wit, 2008, p. 9) to parastatals such as the Bangalore Development Authority, semi-autonomous agencies such as ELCITA and SPVs such as the Smart City Mission, which are instances of "Governance-beyond-the-State" (Swyngedouw, 2005). Tasks and funds are power (Eaton, 2001) and to unpack why the current approach of decentralisation has not really devolved power, the "movers and blockers" (Baud and Wit, 2008, p. 10) of the process are critical to the conversation about decentralisation. In the competitive dynamic (Kennedy, 2017) state governments seem to be willingly or unwillingly handing-over reigns to private players and capital; through different policy, financial and legal provisions. The state government through these provisions and new governance models is enabling "enclaves of exception", thereby taking on the role of "movers" of the process. On the other hand, these enclaves of empowered private actors, utilise this state of exception and adopt exclusive approaches, leading to disconnects and eventually limiting and in some instances blocking the process of democratic decentralisation.

In the current governance model of Bangalore, engaging with the question raised by (Schuurman, 1997) where decentralisation could be viewed either as a progressive political stance for people's benefit or a mechanism to ease the presence of capitalism; perforations for resistance (Keil, 1998, p. 617) in the local state (urban and rural local bodies in this case) are important. This will allow people to negotiate and resist the forms and boundaries of these enclaves so that democratic process precedes/guides private interests and flow of capital. As a result, we can view the "local state as linked to the nature of uneven social development" ((Duncan and Goodwin, 1987) as cited in (Keil, 1998)) working towards the benefit of people.

Conclusion

On the institutional front, Ward Committees must be empowered to act the basic units of city planning and administration; with the power to handle local politics. Instituting Metropolitan Planning Committee (MPC) as the clearance authority will help position these enclaves as part of the megacity system to develop a comprehensive vision and plan for the megacity and its parts. Parastatals who are currently involved even developing and delivering service, must limit their activity to developing infrastructure by putting to use their technical expertise and further engage in regular monitoring, evaluation and betterment and advising the local governments. This would not only result in compliance with the provisions of the 12th Schedule under the 74th Constitutional Amendment Act (CAA) but afford ULBs the opportunity to coordinate the city systems considering the growing and changing needs of a megacity.

The 73rd and 74th CAA proposed institutional frameworks such as Ward Committees (WC), Gram Sabhas (GS), District Planning Committee (DPC) and Metropolitan Planning Committee (MPC) along with setting up of Finance Commissions, to ensure integrated-contextual planning and accounting for financial requirements of the municipalities and panchayats. These provisions primarily seek to empower democratically elected local institutions who represent the people and the current approach has resulted in several disconnects. To fulfil the intent of democratic decentralisation and address the disconnects, instituting democratic process for people's engagement, is equally crucial. This requires "enabling conditions" where participation becomes "a means to hold the state accountable through new forms of governance that involve a more direct state-civil society relation" (Cornwall and Gaventa, 2001). While the disconnects as discussed earlier, are detrimental to this process, participation is pivotal in bringing power back into the democratic realm. This will facilitate shifting people's agency from being "users and choosers of services to makers and shapers of policy" (Cornwall and Gaventa, 2001). People can then enter the realm of "public service decision making" through active involvement but this also brings to the fore tension between "disputed identities of consumer, citizen"((Barnes, 1999) as cited in (Cornwall and Gaventa, 2001)). (Barnes, 1999) highlights the possibility of participation itself reinforcing exclusion and co-option by the powerful. In this scenario, it becomes important to discuss the "infrastructure of participation" as articulated by (Shah, 2013) to be able to leverage participation as integral to democratic process. Referring to participation as an opaque word which can be misunderstood as the same and every context, he urges us to understand the forms and mechanisms people have used to mobilise and negotiate power constellations. This also includes recognising and acknowledging the ownership, passages and regulators of access by ways of which participation is legitimised. Therefore, "infrastructure of participation" in addition to empowering local institutions is important to negotiate the shift from "consumers" to active "user involvement" (Barnes, 1999) and bring decision-making back into the public realm thereby paving the way for democratic decentralised governance.

Case Study Paper

Preparation of the National Urban Policy Framework

Practical point of view

SIMKUTE, Z; Lithuania

Abstract

In the end of 2018, The Ministry of Environment of the Republic of Lithuania released a third draft or Lithuanian Urban Policy Framework (LUPF). The document is still reviewed by the National government and relevant stakeholders. Official approval is pending. Efforts to prepare such a document started in 2008 but were unsuccessful. Latest draft of LUPF was based heavily on the International guidelines of urban and territorial planning (IG-UPT), New Urban Agenda, Agenda for Sustainable development 2030 and reacted to the IPCC report published in the end of October 2018. The Goal of LUPF was to create the value basis and precondition for inter-institutional, cross-sectoral cooperation between different administrative levels and stakeholders in order to achieve sustainable urban development. The LUPF was not supposed to be a vision, nor it was supposed to become a toolbox of development guidelines. The document was a basis to restart a planning culture in a country that historically has a difficult relationship with it. It was intended to be a document defining relationships between stakeholders who directly or indirectly impact development decisions no matter how powerful they are or what sector they present. Prepared proposal is not a final document and is intended to be a live framework that must be updated and reviewed in a circular way. This paper will review the preparation process, structure and the content of the document. Paper will conclude with a list of questions that still need to be answered and advice to countries and cities who are planning to prepare such a document in the future.

Keywords

National urban policy framework, planning culture, urban governance

1. Towards an urban policy framework - two failed attempts and one pending

The proposals for the Lithuanian Urban Policy Framework have been prepared in 2018 after recognizing the need to holistically look at the development of urbanized and urbanizing areas, considering the value of culture, existing and planned infrastructure, harmony between nature and heritage.

There were two big efforts before to prepare such an urban policy (in 2009 and 2016) which were both unsuccessful. First attempt might have failed due to an introvert preparation process, while second attempt focused too much on specific territorial planning problems failing to see the bigger picture of Lithuania in the global context of development challenges.

Thus, a decision was made in 2018 to step back and take a deeper look at what is really needed to be successful on the third attempt.

1.1. First attempt

The issue of the National Urban Policy Framework (or Urban Agenda) for the Republic of Lithuania was first raised in 2007, during the first Lithuanian Urban Forum. The Resolution of the Forum states "The current situation of urban development in Lithuania raises legitimate concerns for the professional and civil society. It is necessary to formulate a new type of urban policy oriented towards sustainable development and quality of life, which respects private property and at the same time gives directions and guidelines for urban development in Lithuania."

In 2009, a draft of Lithuanian urban policy framework was prepared. It was reviewed by the National Government but not approved. The formal reason for which was that the document did not meet the legal requirements for the structure and language in which such a document should be prepared. Looking retrospectively, it might have had something to do with the fact that although the policy draft was contracted from a group of respected planning specialists, it was prepared in isolation without involvement of either governmental institutions, professional networks, academia or civil society.

1.2. Second attempt

In 2016, after the annual Lithuanian Urban Forum, a resolution was drafted which initiated the preparation of Lithuanian Urban Charter. The resolution states "Following the global and European trends, the knowledge of ten-year urban Forums could become a base of the Lithuanian Urban Charter – Lithuanian Urban Development Guidelines by 2030, which would set the main goals of urban development, housing, strategy and would include urban terms adopted by the EU."

In the end of 2016, the Ministry of Environment of the Republic of Lithuania initiated the creation of the Lithuanian Urban Charter preparation group. This group was made of representatives from the ministry, academia, professional community and young planners' network. At the beginning of the year, different stakeholder groups were invited to the meetings of the working group to discuss the issues of urban development in Lithuania. Based on the reflections collected in these meetings, Ministry prepared an outline for the Lithuanian Urban Charter which was presented during the 11th Urban forum in the autumn of 2017.

The outline for the Charter provided an overview of the problems of urbanized territories and gave preliminary suggestions how urban development should move forward/how these problems could be solved. The biggest challenge of this outline was that the problems defined in the meetings were very specific to specific stakeholder groups. These required solutions that are as specific as the problems themselves. **Charter become a checklist of problems with specific solutions rather than becoming a document of guiding value-based principles and tool for cooperation** which was named as one of the major problems stopping urban areas to develop in a sustainable way. On the other hand, unlike the first

attempt, the process to prepare the Urban Charter was open to different stakeholder groups and their opinions and suggestions shaped the document.

1.3. Third attempt

In summer of 2018 the Ministry of Environment commissioned the preparation of "Proposals for the Lithuanian Urban Policy" (LUP). The firm chosen for the job was our young urbanism-architecture office that was involved in the working group of the Urban Charter. Thus, began the process which is the key topic of this Case Study paper.

2. Context of Lithuania

2.1. Status quo

Figure 1 Location of Lithuania (LT) in Europe

To understand better Lithuanian Urban Policy Framework and why it is the way it is, it is important to understand several key facts about the country its culture and mentality of Lithuanians.

Lithuania is a small, post-socialist country with a population of less than 3 million people in in Eastern Europe (Figure 1). Since country restored its independence from Soviet Union in 1990, it has been developing fast. On May 1st, 2004 Lithuania became part of the European Union. As a new member, country got access to EU structural funds that were used to improve, transport, communications and social infrastructure, upgrade public spaces, increase productivity of agriculture and industries and other. European investments

contributed heavily in the growth of the economy and improvement of quality of life. Being a member of EU also resulted in an opportunity for people to move freely for work, education or leisure to other EU countries. Between 2004 and 2017, more than 600 000 people emigrated from Lithuania, around 100 000 only between 2004 and 2005 (European migration network, 2019). According to the department of statistics, 67% of people in Lithuania live in urban areas. Average population density in the country: 4,.08 persons/square kilometre. Due to internal and external migration, most concentrate in big cities while regions end up shrinking. While most of the population lives in apartment blocks, most development is happening in suburban belts around cities.

Country is mid-way to prepare the National General Plan. Current state analysis of the plan concluded seven major problem areas for the country that are related to human resources, economic activity, unsustainable urban development patterns, environmental pollution and conflicts of interest in costal, boarder and natural areas.

2.2. Post-socialist baggage

After the Second World War, while western countries developed their planning culture, explored best ways to meet society's needs, Lithuania was part of the communist bloc. Here, progress was slow, and times were unpleasant. 50 years of occupation left its mark in the history, in the shape of cities, in behaviour and culture of society.

The five-year plans guided development in the Soviet Union. They defined what was to be produced and therefore what conditions are needed for this production and therefore how cities look like and function. Every aspect of life of people was planned: what people do, how they move, where they live, how they live, what they work, where they learn, how they spend their leisure. Planning and architecture were perfect tools to realize political agendas, implement the five-year plans and control societies.

In 1990 Lithuania restored its independence. There was a lot of anger and natural rejection of the old system and many attributes associated to it. Statues of Stalin and other soviet heroes fell, were destroyed or were taken to landfills, many nationalized industrial sites were abandoned. People of an independent Republic could finally choose where and how to live.

Although zoning plans remained as the main tool to control urban development, territorial planning efforts gave little or no direction. “Lithuanian cities underwent big transformations which frequently took place without any clear strategy or masterplans” (Bardauskiene, D, 2007).

Contemporary post-socialist has been going through a complex transitional period from Socialist Ideology to a free market-oriented economy. Orientations to private funds and a more global neo-liberal approach to planning is common to the whole of Europe, but the process is gradual, (Newman & Thorneley 1996) while Eastern cities are going through a ‘Shock therapy” (Smith 2007) period. The collapse of Communist state meant that all policies and attitudes had to be changed or revised in a matter of years. The new law of territorial planning on an independent Republic was adopted in 1995. General tendency for cities was to plan for growth, for private car, for private house, for shopping malls. Throughout

independence period, sprawl, big scale commercial developments, reduced quality of public space and automobilization become dominating patterns of a contemporary Lithuanian city.

Socialist period made a huge damage for planning culture in Lithuania and probably other countries of the former Soviet bloc. After being oppressed for 50 years society nobody, especially national government should restrict people achieving their personal ambitions. Planning with common good in mind was "the thing of the past". Every person got an opportunity fight for their own rights, their own land, their own wellbeing, private land is untouchable.

This change in mentality is crucial to consider when talking about why the proposal for the LUPF focuses on recreating planning culture rather than on the vision for development and sustainable development guidelines and why this proposal as well might be rejected.

3. Process of preparing the proposal for the National Urban Policy Framework

A contemporary country with growing economy, beautiful nature and cultural heritage but low capacities of cooperation between sectors and institutions, imitation of procedures for stakeholder involvement but an enormous potential of a well educated innovative society took a step for the third time to prepare a document that was no longer development guidelines but a "relationship contract" for sustainable urban development.

Proposal for the Lithuanian Urban Policy Framework **aims to create a flexible framework and a prerequisite for inter-institutional, cross-sectoral cooperation between different levels of administration with a view to the sustainable development of urban areas.**

Document emphasizes on the role of territorial planning for sustainable urban development. Territorial planning is seen as a tool to create conditions for democracy, equity, prosperity, adaptation to climate, economic and social changes.

Proposal for LUPF is NOT: a development vision, a set of development guidelines, rules for territorial planning or a planning document of some sort as it is defined in Lithuanian legal system.

The preparation process was divided into two parts: Analysis of international and local documents and relevant cases and definition of the guiding themes, the structure and content of the document

Final document is composed of three interconnecting sections: Directions (1), roles and responsibilities (2) and implementation and monitoring measures (3). LUPF defines four themed directions (1) that local and national governments and relevant stakeholders should follow to ensure Sustainable development of Lithuanian urban areas.

Four directions: Mitigation of climate change impacts and resilience to climate change; Synergy and strengthening of urban links; Liveability and social equity and sustainable spatial development. Roles and responsibilities (2) for National and local governments and relevant stakeholders were prepared reusing and localizing most of the recommendations from the IG-UTP. This section defines roles of each interest group in the implementation of the value driven directions for sustainable urban development. Last part – implementation and

monitoring (3) – is a part where suggestions are given to how to start the implementation of guidelines and responsibility division. This part consists of four sections: Monitoring and evaluation of sustainable development; Participatory decision-making process; Partnerships and Capacity Building.

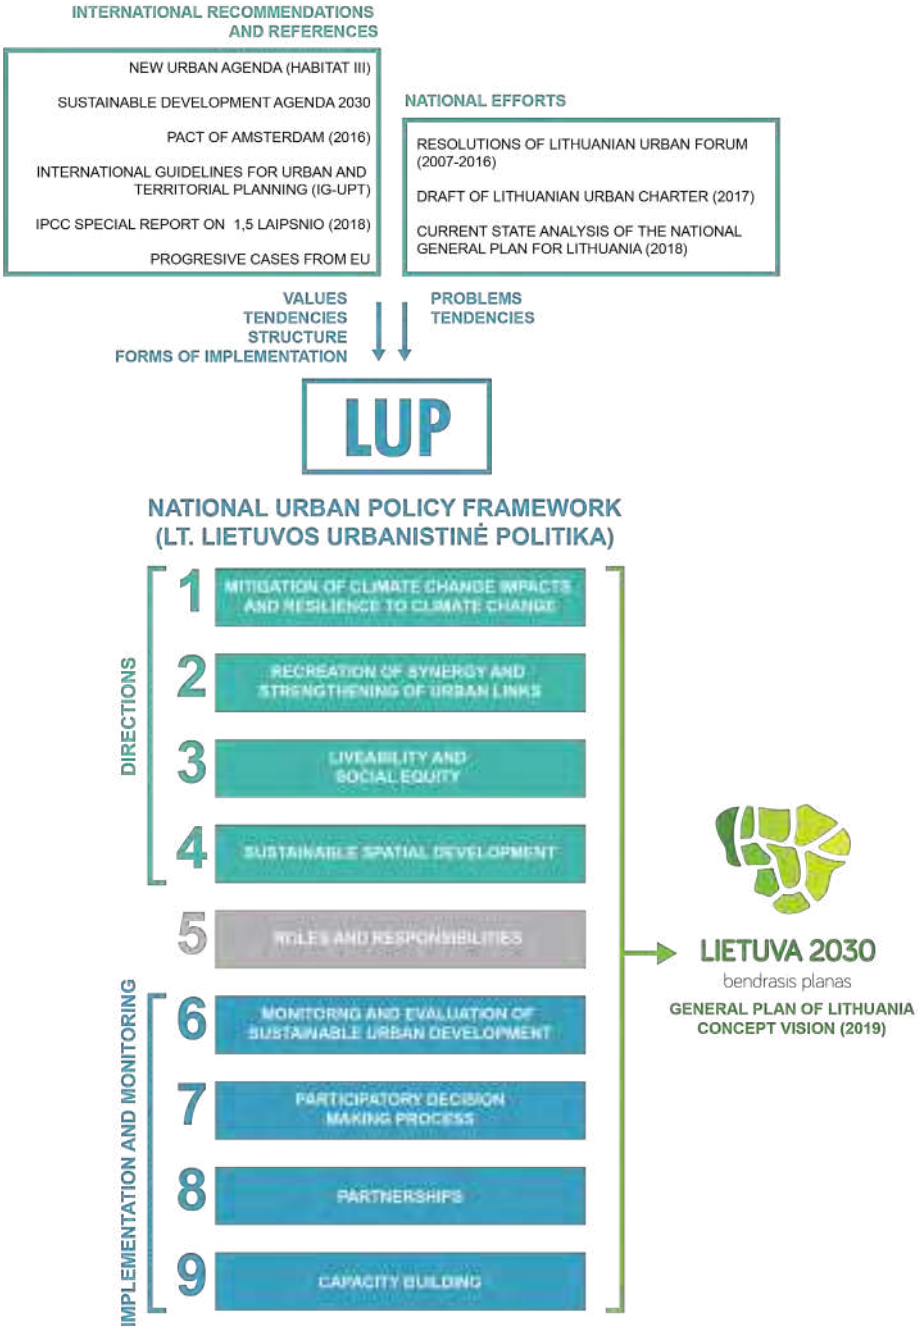

Figure 2 LUPF methodology

3.1. Preparation process

The process started with an in-depth review of international recommendations, Lithuanian strategies and policies connected to the object of the LUPF and previous attempts to prepare urban policy framework and finally bring everything into a coherent, easy to understand value-based document.

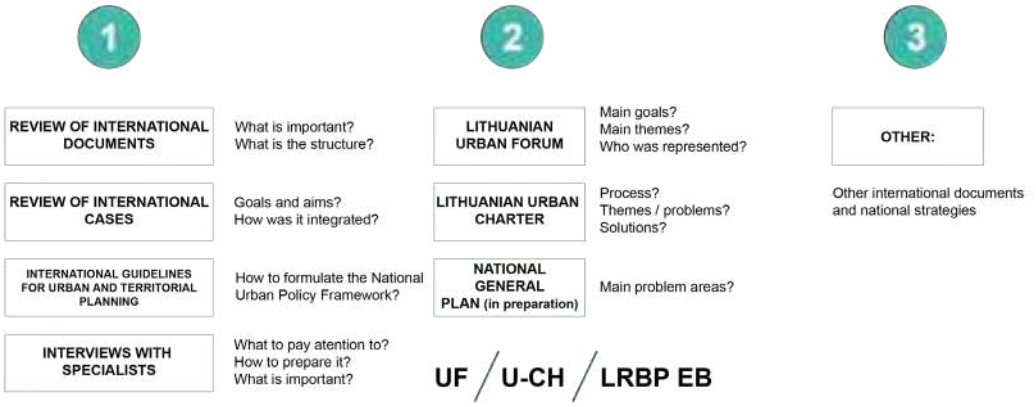

Figure 3 LUPF analysis methodology

3.1.1. Analysis of international recommendations and references

First step of the analysis was to analyse international documents related to sustainable urban development that included: Sustainable development agenda 2030, New Urban Agenda, Pact of Amsterdam, European Urban Charter, Leipzig Charter. These documents provided a better understanding of possible structure of the document, how to formulate ideas and what themes are important to consider.

International Guidelines on Urban and Territorial Planning (UN Habitat, 2015), *International Guidelines on Urban and Territorial Planning (IG-UTP) Handbook* (UN Habitat, 2018) and *National Urban Policy: A Guiding Framework* (United Nations Human Settlements Programme, 2015) were key documents, from where a lot of concepts and ideas were reused and localized to Lithuanian context. These are truly most useful sources that have bulletproof structures and logic that cover complex concepts.

Three cases chosen for reference analysis were: Agenda Stad (2017), Project Ireland 2040 (2016) and Sustainable development agenda of Estonia (2015). Agenda Stad is concept adapted in the Netherlands in 2017 that aims to encourage economic growth, living quality and innovations by encouraging collaboration between cities to solve urban challenges. Agenda Stad proposes to create partnerships between cities and regions called “City deals”. These partnerships are based on development themes such as new economy, adaptation to climate change, attraction of talents and circular cities. This document inspired to include possible partnership themes in the proposals for LUPF as one of implementation measures. The National Planning Framework and its National Strategic Outcomes and priorities of the National Development plan “Project Ireland 2040” gave an overview of how country that as Lithuania faces problems of shrinking urban regions, define their priorities and development goals. This document inspired to look deeper into possible relationships between urban and rural areas in Lithuania. Sustainable development agenda of Estonia was a case from a neighbouring country with similar history as Lithuania. This document inspired to look further into how country views local challenges of emigration, preservation of local culture and global challenges of adaptation to climate change.

3.1.2. Analysis of Local documents

Second step was to form informative conclusions from the previous efforts to prepare the national urban policy and understand better evolution of problematics that was used in Lithuanian urban forums between the years 2007 and 2017.

Analysis showed that same topics concern planners in Lithuania for more than ten years and yet there is no solution for these problems (poor inter-institutional collaboration, poor cross-sectorial problem solving, uncontrolled, fragmented urban development etc.). This showed that yet another attempt to define problems that were discussed among planners for 10 years in the form of a draft for Lithuanian Urban charter, was not a solution. As explained previously, the second attempt to prepare the national urban policy was concentrating on collecting ideas from relevant stakeholders and the document ended up as a checklist specific of problems with specific solutions, solving which will not tackle systematic problems with urban planning and urban development. These observations helped build a stronger argument that development guidelines or sustainable development toolbox is not a for a country that needs a reboot of a planning culture in general.

3.2. Directions

The selection of direction was a back and forth process. First suggestions for directions focused on the triad of sustainable development: social, economic and environmental aspects. It was later decided that as sustainable development is not a divisive concept and any topic should consider all three aspects of the triad at the same time, therefore it is not a good idea to separate directions into these three topics. Directions in the proposal for LUPF are understood as aspects to be considered while making national or local spatial development decision. At the same time any decision should inherently be aiming for sustainability (social, environmental and economic at the same time).

Proposal offers four directions:

3.2.1. Mitigation of climate change impacts and resilience to climate change

Direction suggest guiding sustainable development in a way that would help mitigate climate change impacts and increase resilience to climate change effects. It calls for ambitious actions to implement decarbonization measures in all sectors, reduce consumption, get ready for extreme events in order to ensure provision of essential services in case of an natural disaster.

3.2.2. Recreation of synergy and strengthening of urban links

Direction suggest looking at urban and rural areas as urban regions: territories that are associated with urban centre by energy provision, goods distribution networks, people commuting to work, water and waste management. It is emphasised on the necessity to create synergies between urban and rural areas, to collaborate and complement each other, share resources. It is encouraged to use territorial planning as a tool for creating conditions for territorial cohesion, reducing ecological footprint, encouraging circular economy.

3.2.3. Liveability and social equity

Strong communities are essential for liveability of urban areas therefore direction suggests creating conditions for community development, economic opportunities for small and social business, creation of possibility to consume culture and preserve tangible and intangible cultural heritage.

3.2.4. Sustainable spatial development

Direction emphasises on spatial aspects of urban development and is divided in four sub-sections: Accessibility to housing, sustainable mobility, engineering services and public spaces. Emphasis is placed on creation of compact environments, effective use of resources, accessibility to water and sanitation, monitoring of housing provision, encouragement of public-private initiatives to upgrade public spaces.

3.3. Roles and responsibilities

The implementation of Lithuanian urban policy framework will require inter-institutional, cross-sectoral co-operation and an inclusive decision-making process. LUPF encourages to look at urban development beyond the administrative boundaries, to look at urbanized and urbanizing territories holistically in order to achieve systematic changes.

IG-UTP (2015) is an irreplaceable source of definitions of different roles and responsibilities for five main groups that directly or indirectly effect urban development: National institutions, Local administration, Professionals and professional organizations, Civil society and NGOs. A fifth group (academic society) was added to the list.

Essential aspect about this section that each group gets a definition of their role and responsibility in urban development and within these rules and responsibilities they relate to other groups. For example, Local administration should encourage access to decision making for the civil society, while civil society should actively participate in the planning process. In this way, a network of interlinked participatory process is created.

3.4. Monitoring and implementation

Last section of the LUPF is composed of four sections: Monitoring and evaluation of sustainable urban development; Participatory decision-making process; Partnerships and Capacity building.

3.4.1. Monitoring and evaluation of sustainable urban development

Throughout the preparation process of the LUPF it became evident that there is a gap in knowledge of how cities are developing. It was impossible to say if cities were developing in a compact way or not as there was no data to support it, no measurable definition with indicators. One could only make conclusions from observation and they would be correct. This section calls for definitions of what sustainable development is and measurable indicators to monitor it.

It is suggested to start with a perception questionnaire to understand better how cities perceive their own plans, what concepts are unfamiliar to them or where most misunderstanding lies.

3.4.2. Participatory decision-making process

Proposals for LUPF highlights the importance of inclusion for urban development. Successful implementation of the LUPF requires openness and the involvement of stakeholders and communities. Inclusion methods require continuous development and maintenance of a community. Section brings attention to the fact that it is common that civil society lack skills to give informed opinions about technical documents therefore it is essential to create conditions of involvement in a language and media different people could understand and respond to. Moreover, it outlines rules for participatory process: consistency, feedback, respect for time and knowledge, understandable media, establishment of common ground and transparency which are essential for a dialogue.

3.4.3. Partnerships

LUPF suggests establishing voluntary engagement partnerships between state, municipal institutions, business representatives' professional associations, NGOs and academic community. Partnerships could be a great way to start sharing experience between cities. It is suggested to create cross-sectoral partnership themes which would bring a more diverse stakeholder group to the table.

3.4.4. Capacity building

Last section of the LUPF emphasises on the need to raise competence of all actors involved in the urban development process. It is focused on administrative and organizational skills, learning about innovative planning methods and systematic thinking. All of which is essential for a constructive dialogue between different institutions and representatives of different specialist fields.

3.5. LUPF as a system

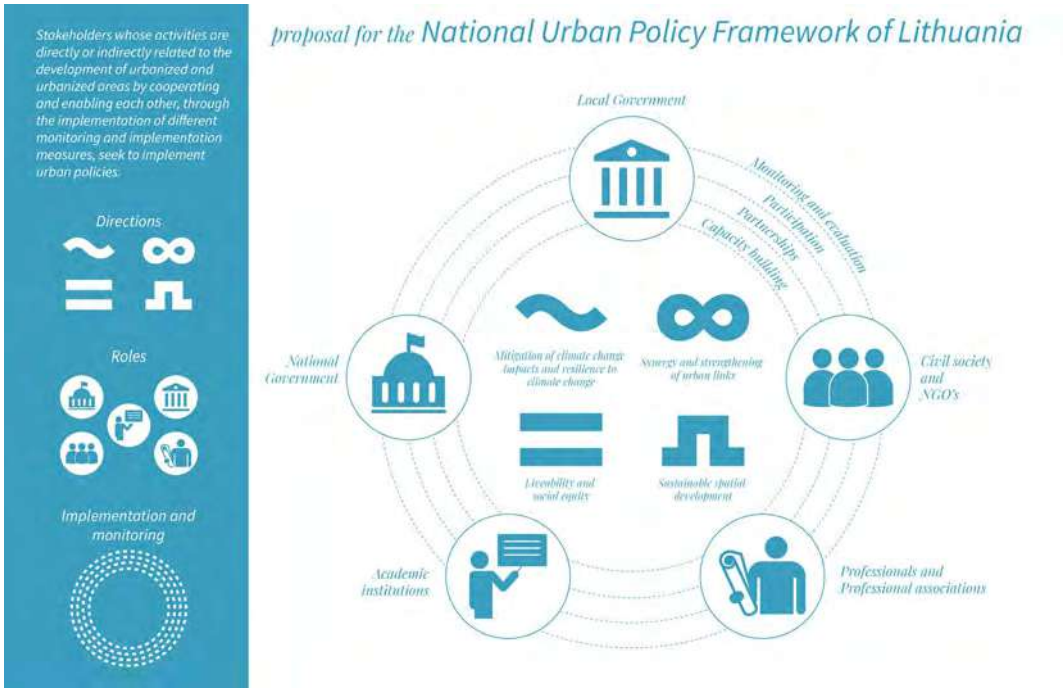

Figure 4 Structure of the Lithuanian Urban Policy Framework

Directions, roles and implementation and monitoring measures are a part of a LUPF system. One part cannot work without the other. The logic of the structure is that LUPF directions for sustainable development can only be achieved if all stakeholder groups work together in implementing, monitoring, sharing knowledge through partnerships, and building their capabilities.

4. Conclusions

The case of Lithuanian Urban Policy Framework is an example of an attempt to organize a system of collaboration, create a base for the National tradition of planning. Although there is a great amount of knowledge and valuable experiences to learn from, localizing logical, sustainable, time proven directions is not an easy task. It makes it even more complex if the culture is resistant to accept necessity to plan in a collaborative way. There is a need for a flexible process, a multi-disciplinary language that is necessary not only to adapt knowledge and good experiences but also to create a new one.

4.1. Reuse and adapt

Although there is a tremendous amount of immensely valuable recommendations prepared by international planning society that could just be translated and used, in countries like Lithuania, that does not have a strong planning culture, direct implementation would mean making a leap in knowledge of how urban areas should develop and there is resistance to making this leap. Therefore, it is an interest of us to share our experience and discuss with fellow planners on how to deal with these issues and integrate international knowledge locally.

4.2. Establish a base before defining development guidelines

Original ambition of the Ministry was to prepare guidelines for urban development. Document was intended to become a toolbox of general truths about urban development concentrating spatial aspects of the city: compact city development, sustainable mobility, quality of public spaces. Soon into the process it become evident that such guidelines are necessary, and they should be further elaborated based of the overall development vision for Lithuanian cities which was to be outlined in the new comprehensive plan for the territory of Lithuania. Preparing development guidelines before the National development vision would be counterproductive as process for generating a vision and further development guidelines requires a very different process that what was planned for this document. What was clearly missing before starting to work on a vision, was a urban policy framework - a value base that defines general directions and relationships between different groups involved in urban development.

4.3. Connect policy with something of national importance

Proposal for LUPF got more weight because it was connected to the preparation of the new General Plan of Lithuania. Original intention was to include different aspects of the policy to the development of the vision for Lithuania 2030. In this way, valuable aspects from the policy become part of a legal document that will guide development for upcoming 11years.

Un-planning the Metropolis

Urban Transformative Capacity as a Transdisciplinary Heuristic and Disruptive Sustainability Strategy

Marc WOLFRAM

Abstract

Transforming urban areas and processes represents a core challenge and necessity for shifting current development pathways at all scales towards sustainability (UN, 2016; Acuto et al., 2018; CitiesIPCC, 2018). While empirical insights into the transformation dynamics of sectoral and/or geographically delimited socio-technical and social-ecological systems have multiplied over the past decade, very little is known so far about the particular dynamics of urban transformations i.e. deep and radical shifts in the interdependent cross-scale configurations of multiple complex systems including e.g. water- energy- and food provision as well as transport, housing, production and consumption. Approaches to conceive of and practically shape such highly complex and uncertain processes are therefore dearly needed (Elmqvist et al., 2018; Frantzeskaki et al., 2016; Webb et al., 2017; Wolfram et al., 2017).

This presentation takes up this question of what can help or hinder cross-scale systemic urban change by discussing the concept of urban transformative capacity (Wolfram et al., 2019) - a relational form of power resulting from particular forms of agency and interactions in a given institutional and spatial-material setting. Drawing on recent empirical and conceptual contributions, it reflects specifically on the utility of this lens to enhance critical knowledge co-production processes and help the shaping of new coalitions and strategies for addressing urban transformations in practice. Urban transformative capacity thus opens up novel perspectives for deep systemic change within and beyond the metropolis through dismantling path-dependencies and supporting emergence i.e. un-planning: It provides both a heuristic tailored to guide the transdisciplinary exploration of barriers and drivers in multi-system reconfigurations, and a framework for deriving actions that enable desirable transformations while preventing undesirable ones or lock-in.

Four entry points are highlighted as key to trigger the development of urban transformative capacity in practice:

1) Adopt novel transdisciplinary self-assessment techniques for transformative capacity,
2)Foster inclusion and empower deviant agency and its diversity;
3) Close the intermediation gap and partner with local academia working on sustainability,
4) Challenge and reinvent formal and informal urban planning institutions and practices.
