of Jinxi is to provide food and economic contributions. Advantages and Past: Setting the tone of Jiangnan Water Township and Fish and Rice Township for Jinxi. After the founding of New China and the reform and opening-up, the economic development of the eastern coastal areas has been rapid. Jinxi is close to Shanghai, and has the advantage of location and policy of getting a month ahead of others. Under the background of the rapid development trend of the "Southern Jiangsu Model" and "Kunshan Model", Jinxi has achieved good development results.

Figure 3: Schematic Map of Beijing-Hangzhou Grand Canal

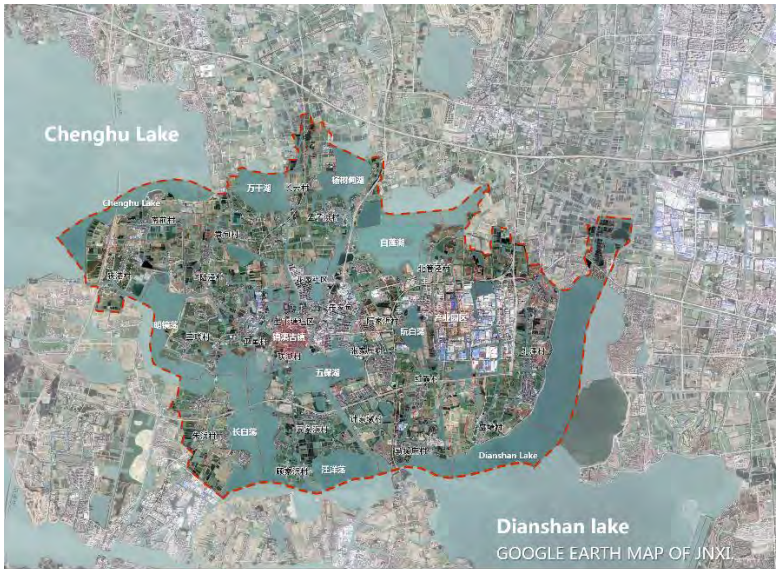

Figure 4: Research Scope of Jinxi Town

2.2. Trend analysis

Jinxi is in The Core Hinterland of Yangtze River Delta Metropolitan Circle——Shanghai Metropolitan Circle , according to Shanghai Master Urban Planning (2017-2035) ,jinxi belongs“New Economic Zone of Ecological Civilization”. In the Upper Planning of Kunshan City, The Nature of jinxi is to be the famous historical and cultural towns in China, the towns

of folk museums, and the famous tourist towns in the south of the Yangtze River with abundant lake resources. Kunshan has established the urban nature of "livable and industrial big cities with high quality development, famous international intelligent manufacturing cities, important strategic fulcrum linking Shanghai and Jiangsu, green ecological city with Jiangnan characteristics". The general plan also proposes to further dock with Shanghai and integrate into Suzhou, and strive to build Kunshan into a pilot demonstration area for the Yangtze River Delta to implement new development concepts, achieve higher quality development and a higher quality of life.

National level: preserving grain production function - 100,000 mu of good farmland in Kunshan and 1000 hectares of good farmland in Jinxi. Consensus at the regional level: At present, the premise of rural development, regional ecological maintenance is an indispensable function.

Ultimate goal: The experience of developed countries can eliminate the gap between urban and rural areas and achieve the goal of "integration of urban and rural life with differences, no gaps, mobility and barriers". So, Is it most likely that the integration of urban and rural life will be the first to achieve "difference, no gap, mobility, barrier-free"?

2.3. Contemporary Mission

Rural rejuvenation adheres to the guiding ideology of socialism with Chinese characteristics in Xi Jinping's new era, deeply implements the spirit of the Nineteenth National Congress of the Party and the Party congresses of provinces and municipalities, adheres to the combination of macro-policy orientation and local actual conditions, bases itself on "new background, new opportunities and new requirements", and avoids "urbanization, disorder and homogenization". Constructing the Rural Revitalization space to develop as a breakthrough, realizing the "three transformations" in planning orientation, and promoting the whole rural revitalization of Jinxi Town.

Thought change one: More importantly, high-quality development should be made from the perspective of developing the new ecological economy to find breakthroughs.

Second, we should explore the characteristics of the countryside. The countryside is no longer just a dependency of the city.For example, tapping rural leisure and recreation functions, preserving the regional characteristics and cultural heritage of Jiangnan Waterfront, improving rural living environment, improving agricultural quality, improving people's lives, and ultimately achieving the same level between urban and rural areas.

Figure 1: Current situation and trend & Main features and challenges

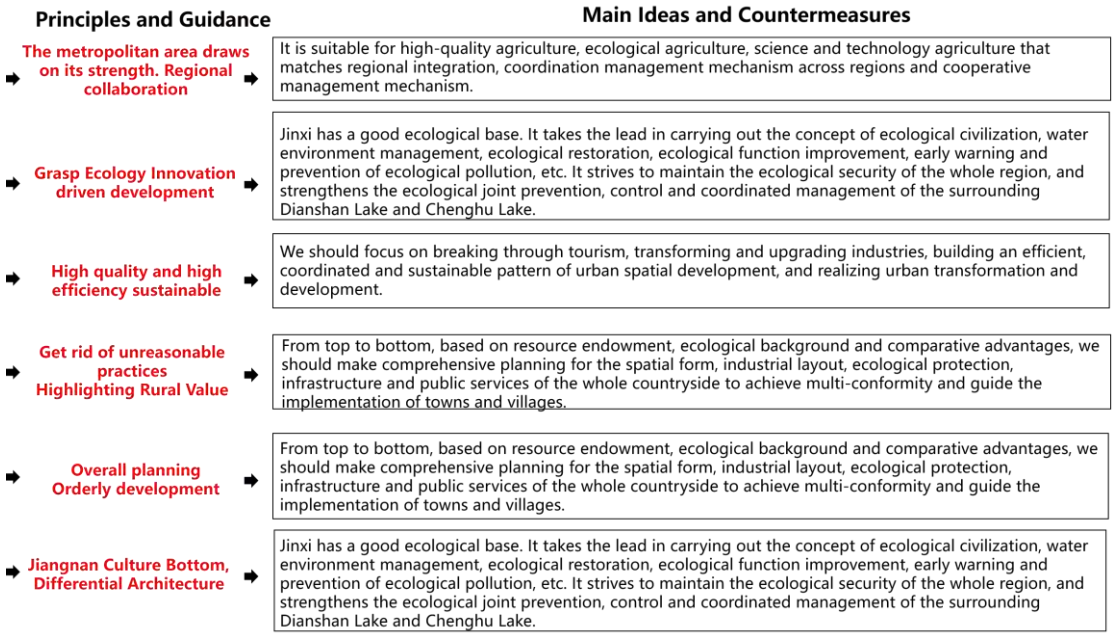

Figure 1: Principles and Guidance & Main Ideas and Countermeasures

3. Survey: the current situation of rural development in Jinxi Town

3.1. Functional positioning

lack of coordination between urban areas and rural areas at the macro level, failure to highlight their own characteristics at the village level, weak implementability, and weak links at the town level.In the latest Kunshan Master Plan, The Nature of jinxi is to be the famous historical and cultural towns in China, the towns of folk museums, and the famous tourist towns in the south of the Yangtze River with abundant lake resources.

At present, the planning of Jinxi can be summarized into four main areas.： Living Area、Eco-industrial Park Area、 Lake-side Area and Rural area.

The positioning of the area around Dianshan Lake considers the cooperation relationship with its surroundings carefully. However, from the current positioning of the living area of ancient towns, the collaborative area around Dianshan Lake, the eco-industrial area and the surrounding rural planning, it is found that there is no close cooperation between them, and it is difficult to cohesive and develop, thus forming a competitive development trend. In addition, the importance of Jinxi as an important ecological conservation area around the lake has not been reflected, and the characteristics of the water towns in the south of the Yangtze River are not obvious.

Functional positioning

The lakeside tourist resort mainly consists of recreation and ecological sightseeing.

Development orientation

Planning and utilizing rivers, lakes, wetlands and green spaces in the plot to create eco-tourism sightseeing areas.

Source: Controlled Detailed Planning of Lake-side Resort in Jinxi Town, Kunshan City

Functional zoning map of lakeside resort

Land use planning map of lakeside resort

Functional partition

Four districts:

1.Dianshan Lake Resort: Depending on the beautiful natural scenery along the coast of Dianshan Lake, it mainly serves the accommodation, catering and leisure of the tourist population.

2. Chessboard Waterfront Recreation Area: Build lake-side eco-agricultural sightseeing, resort hotels, wetland parks and water experience centers.

3.Wangyangdang Ecological Conservation Area : Popular science education in conservation.

4. Changbaidang Ancient Kiln Art Area: Combining the ancient kilns near Zhujiadian, Zhubang and other villages, as well as the southern part of the town, the ancient kiln art zone is developed to form a kiln-themed tourist area.

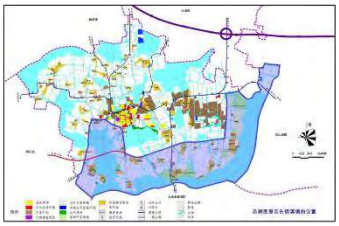

Figure 5: Detailed Control Planning of Jinxi Town Living Area in Kunshan

Functional positioning

It is a small town comprehensive area with the characteristics of giving priority to the comprehensive service function of cities and towns and taking into account the leisure tourism of water towns as a whole.

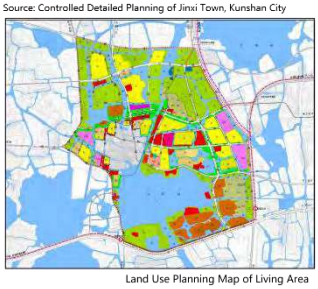
Development orientation

Promote people-oriented and smart growth model to form small towns with tourism characteristics under the background of new urbanization.

Functional partition

Generally speaking, the river system and main traffic arteries are divided into five functional areas. Four urban living areas and one tourist and leisure area.

Source: Controlled Detailed Planning of Jinxi Town, Kunshan City



Land Use Planning Map of Living Area

Location Map of Living Area in Jinxi

Figure 6: Detailed Control Planning of Lake-side Resort in Jinxi Town,

3.2. Population problems:

the income gap between urban and rural areas causes regional population factors to flow, which leads to the restructuring of rural social structure in Jinxi Town; self-built houses have high cost, high idle rate and low utilization rate.

The total population base of the town area is small, ranking behind Kunshan, and the population growth rate is slow. In 2017, the total registered population of the town was 446,000. The total population ranks seventh in 11 towns and districts of Kunshan City. Jinxi local aging phenomenon is prominent, in 2017, the proportion of the elderly over 60 years old is as high as 31%. Kunshan is one of the 10 cities with the highest proportion of migrants in China, and ranks fourth. Jinxi Town has a smaller migrant population than the immigrant population, and belongs to the population-importing region. Local young people in Jinxi go to the surrounding big cities to develop, while young people who come to work here come to Jiangsu Province or Anhui Province and Henan Province from farther regions. In 2017, the temporary population of Jinxi Town was 254,000, which reached half of the total household registration population. The proportion of young and middle-aged people from other places was high, reaching 95%.

The total population base of the town area is small, ranking behind Kunshan, and the population growth rate is slow. In 2017, the total registered population of the town was 446,000. The total population ranks seventh in 11 towns and districts of Kunshan City. Jinxi local aging phenomenon is prominent, in 2017, the proportion of the elderly over 60 years old is as high as 31%. Kunshan is one of the 10 cities with the highest proportion of migrants in China, and ranks fourth. Jinxi Town has a smaller migrant population than the immigrant population, and belongs to the population-importing region. Local young people in Jinxi go to the surrounding big cities to develop, while young people who come to work here come to Jiangsu Province or Anhui Province and Henan Province from farther regions. In 2017, the temporary population of Jinxi Town was 254,000, which reached half of the total household registration population. The proportion of young and middle-aged people from other places was high, reaching 95%.

Therefore, improving the disposable income of Jinxi's rural areas, introducing, cultivating and perfecting the rural talent echelon, achieving the continuous increase of rural residents'income, ensuring and improving the living safety and quality of the people living and working here are also the problems to be solved in this rural revitalization.

rank	city	administrative level	province	The proportion of immigrants to permanent population
1	Dongguan	Prefecture-level cities	Guangdong	75.68%
2	Liuyang	County-level city	Hunan	72.06%
3	Shenzhen	Planned separate cities	Guangdong	67.71%
4	**Kunshan**	**County-level city**	**Jiangsu**	**50.21%**
5	Zhongshan	Prefecture-level cities	Guangdong	50.08%
6	Foshan	Prefecture-level cities	Guangdong	46.38%
7	Jinjiang	County-level city	Fujian	45.87%
8	Xiamen	Planned separate cities	Fujian	43.74%
9	**Shanghai**	**Municipality**	**Shanghai**	**40.08%**
10	Yiwu	County-level city	Zhejiang	38.39%

Table 1：Ten cities with the highest proportion of migrants in China

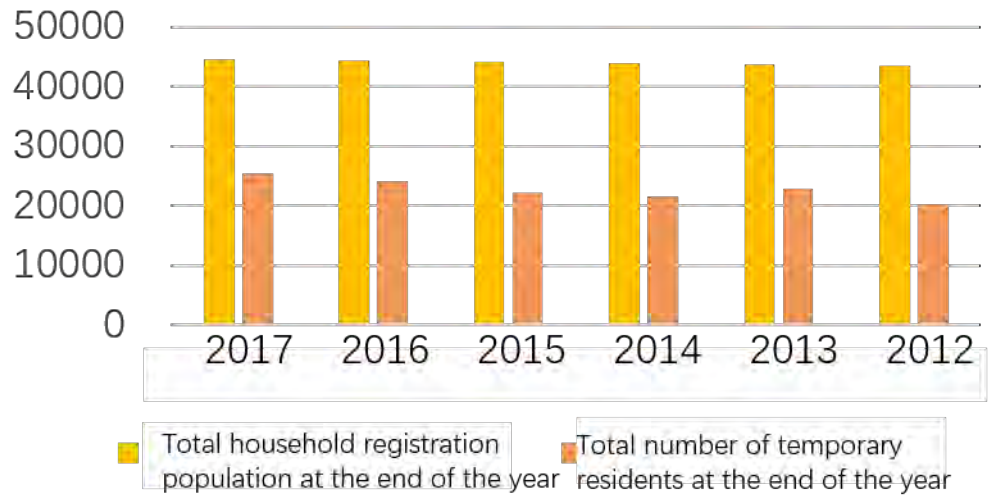


Table 2：Household Registration Population and Temporary Resident Population in Jinxi Town, 2012-2017

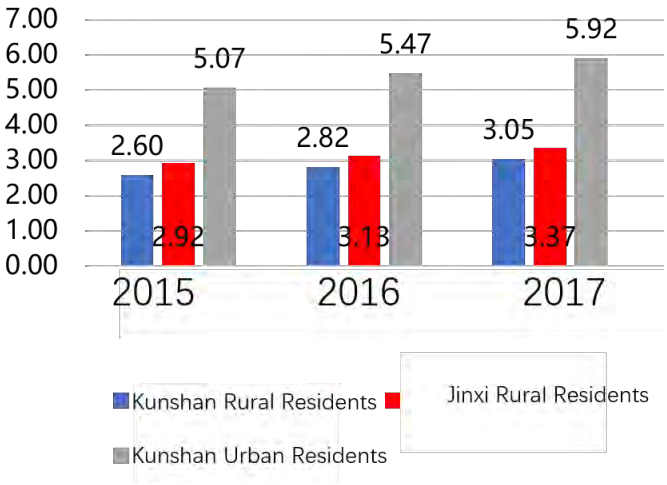

Table 3: Per capita disposable income of Kunshan urban and rural residents and Jinxi rural areas from 2015 to 2017(ten thousand)

3.3. Industrial problems:

agricultural growth is weak, the transformation of village industry is imperative, the service industry of tertiary industry is showing a growth trend, and has the potential and trend of creating "ecological new economy"

Kunshan City has long been in the forefront of the county economy in China. The land transfer of Kunshan City has basically been completed, and is operated by village land joint-stock cooperatives and various professional cooperatives. Kunshan Development Zone and High-tech Zone are the leading industrial parks in which the industrial manufacturing industry is developed; the modern service industry represented by Huaqiao Jingkai District is developing rapidly; and the tourism industry of ancient towns represented by Zhouzhuang is deeply rooted and flourishing.

Jinxi's total economic output is not high, but its agricultural performance is outstanding. According to the level of modern agricultural equipment, the total power of agricultural machinery and the number of large and medium-sized tractors in Jinxi Town are in the front rank among the districts and towns, and the proportion of primary industry is the highest. Compared with 11 towns and districts in Kunshan City, Jinxi Town ranks third, seventh and ninth in total grain output, total output value of agriculture, forestry, animal husbandry and fishery, and total GDP in 2017, respectively. Kunshan City vigorously promotes the development of green transformation of agriculture. Jinxi Town has also taken measures such as reducing fertilizer and pesticide, green ecological three-dimensional agriculture and so on to improve the quality of agricultural development. Farmers are not satisfied with the dividend distribution of cooperatives. The main reason is the efficiency of land management and the fairness of distribution. It is suggested that the quality of agricultural products be improved and local brands be promoted.

Jinxi's total economic output is not high, but its agricultural performance is outstanding. According to the level of modern agricultural equipment, the total power of agricultural machinery and the number of large and medium-sized tractors in Jinxi Town are in the front rank among the districts and towns, and the proportion of primary industry is the highest.

Compared with 11 towns and districts in Kunshan City, Jinxi Town ranks third, seventh and ninth in total grain output, total output value of agriculture, forestry, animal husbandry and fishery, and total GDP in 2017, respectively. Kunshan City vigorously promotes the development of green transformation of agriculture. Jinxi Town has also taken measures such as reducing fertilizer and pesticide, green ecological three-dimensional agriculture and so on to improve the quality of agricultural development. Farmers are not satisfied with the dividend distribution of cooperatives. The main reason is the efficiency of land management and the fairness of distribution. It is suggested that the quality of agricultural products be improved and local brands be promoted.

In summary, the development of primary production agriculture is limited by the area of cultivated land (water surface). Agricultural economy will show weak growth depending on traditional operations, and new agricultural growth paths need to be explored. It is imperative for the industrial transformation of the second industry to take place in the village, and the service industry of the third industry is showing an increasing trend. Generally speaking, Jinxi does have the potential and trend to build a "new ecological economy".

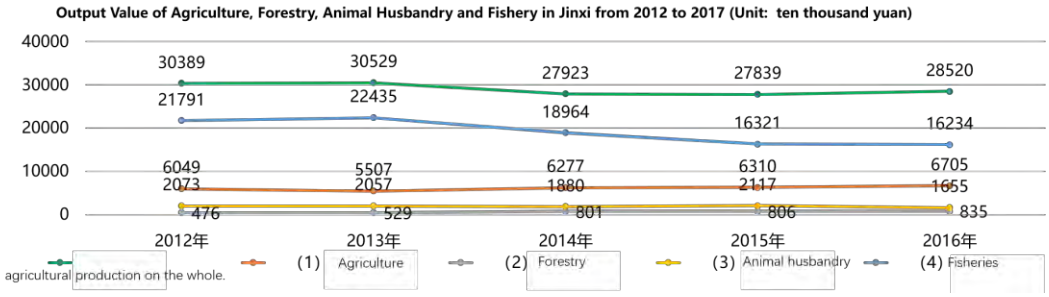

Table 4: Output Value of Agriculture, Forestry, Animal Husbandry and Fishery in Jinxi from 2012 to 2017

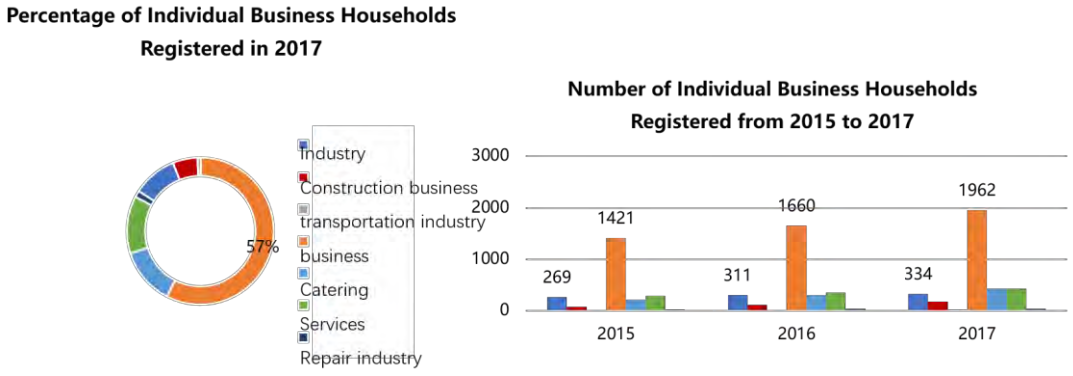

Table 5: Percentage of Individual Business Households Registered in 2017

Table 6: Number of Individual Business Households Registered from 2015 to 2017

3.4. Spatial problems

too dispersed space, resulting in the lack of organic links between the districts; land use indicators reduction, affecting the re-allocation of small public facilities, production facilities, and the problem of idle space resources.

The current spatial structure lacks support for future diversified industries, and because the space is too dispersed, the linkage between villages and communities is not strong, and the utilization rate of public facilities is not high. It is necessary to strengthen the linkage between villages and communities and promote the rational use of space resources.

In order to achieve the overall target of grain production security in Kunshan City, the cultivated land area of Jinxi increased year by year. From 2012 to 2016, the average annual growth rate of cultivated land area in Jinxi Town was +4.22%, and the production space increased. However, the lack of new land indicators led to the shortage of production facilities, such as grain dryers. In the future, the reduction of industrial land in villages will lead to severe transformation of enterprises in villages. According to the questionnaire survey, villagers hope that villages/communities need to increase public activity venues: parking lot, rice milling center, public activity space, garbage collection points, vegetable cultivation space, etc. Because of the lack of new land indicators in villages, it is impossible to allocate them.

Part of the idle space resources mainly come from the plot land after the closure of the village enterprises, which is temporarily idle due to the need for high-cost land restoration investment to return cultivated land, and the idle workshop of some large industrial districts. The other part is the outsourced project land, which is idle due to the enterprise's own business reasons.

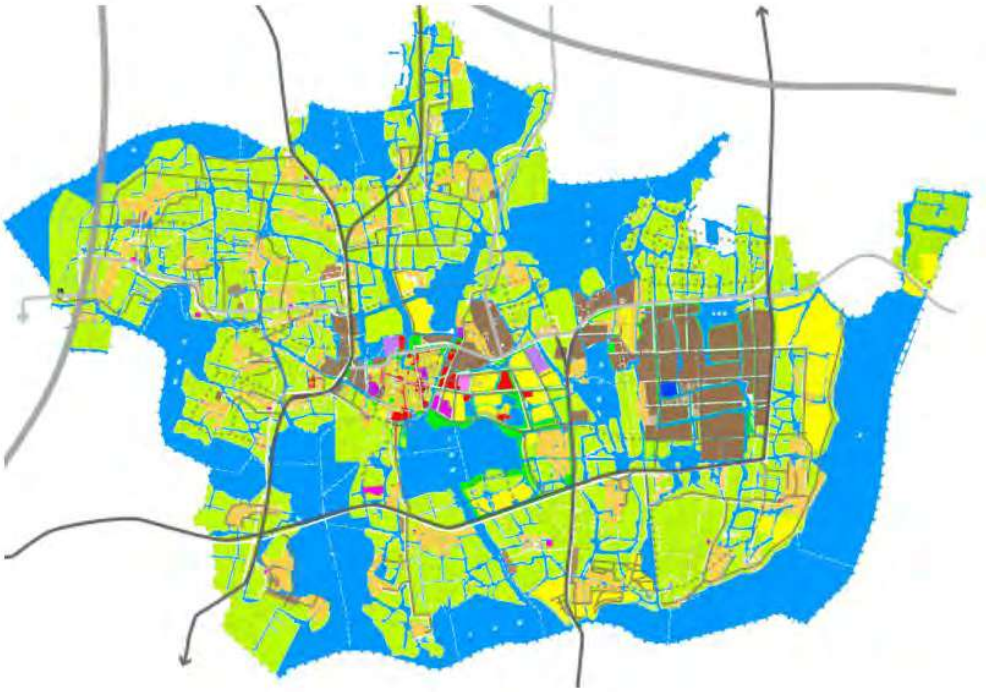

Figure 7: Current Situation of Jinxi Town in 2018

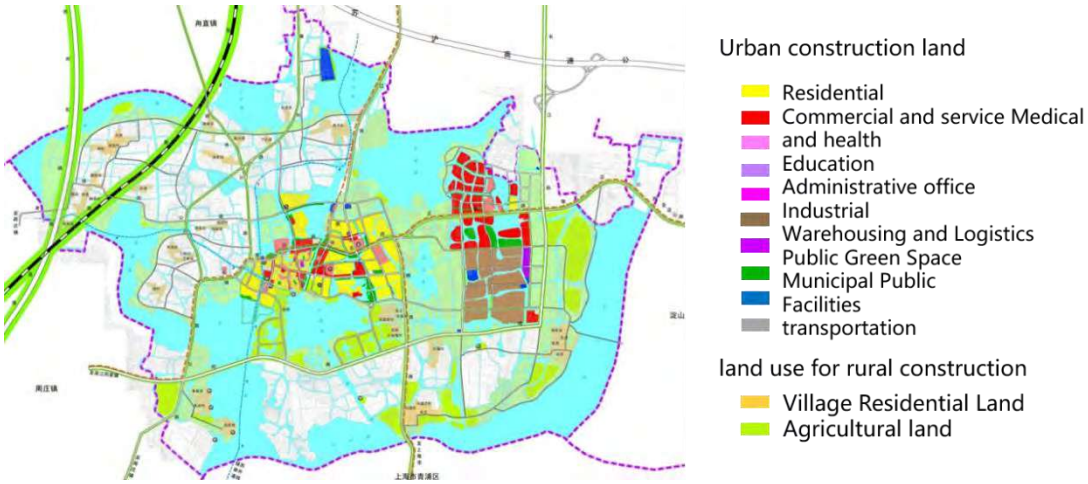

Figure 8: Planned Land Use of Jinxi Town in 2030

4. Strategy: Development Strategy of Rural Revitalization

4.1. Development Orientation Strategy

4.1.1. Development Orientation

New Jiangnan Water Village as Beautiful as Poetry and Painting

4.1.2. Development Goals

1) Shanghai Metropolitan Cooperative Development Zone New Jiangnan Water Town Model

2) The Benchmark of Agricultural and Rural Modernization in Suzhou

3) Model of Urban-Rural Integration Development in Kunshan City

4.1.3. Staging objectives

1) New Form of Business: A Model of Urban Modern Agriculture Development

- We will promote structural reform of the agricultural supply side. Around promoting the upgrading of the industrial system, production system and management system of agriculture, the modernization level of agriculture will be further promoted.
- Promote the integration of agriculture, commerce, culture and tourism, promote the development of modern services such as tourism, exhibition and cultural creation, and promote the integration of Rural three industries.

2) New Life: A Model of Urban-Rural Integration Development

- We will further promote the development strategy of urban-rural integration, promote the free flow and balanced allocation of urban and rural factors, and build a new urban-rural relationship with mutual interaction and complementary symbiosis.
- To meet the needs of accelerating the transformation of the age structure, employment characteristics, lifestyle and quality of life of new rural people, and to build a new way of production and life in rural areas.
- It meets the requirement of two-way interaction between urban and rural areas. Improve the level of infrastructure and supporting services, attract urban capital and residents through high-level livable environment construction, and promote urban-rural integration.

3) New Jiangnan: A Model of Spatial Form of Water Township in New Jiangnan

- Rehabilitation of local ecology, inheritance of local culture, protection of local form, with the concept of global landscaping, scenic spots, accessibility and participation, shape Damei agricultural water form.
- Strengthen the comprehensive improvement of rural human settlements environment, build a new beautiful countryside (block), repair soil, control water quality, and build a beautiful local environment.
- Combine the functional format with the shape shaping to ensure the strategy of shaping the differentiated style of production, life and ecology.

4.2. Population structure optimization strategy

4.2.1. Promoting population mobility and optimizing population system

To cope with the needs of citizenization, innovation and entrepreneurship, equalization of basic public services in urban and rural areas, the trend of aging, and population mobility, we should reduce the cost of withdrawal from rural areas by replacing urban housing with rural property and land replacement, and reduce the cost of urbanization through household registration reform. We should innovate the mechanism for the introduction and cultivation

of rural talents, and comprehensively cultivate new types of professional peasants, professionals and scientific and technological talents. The basic services of employment, social security, housing, education and medical care should be guaranteed, and a complete policy system should be formed to ensure equal treatment for transfer residents and local residents.

4.2.2. Guarantee public service facilities and create a rural public activities circle

To cope with the needs of citizenization, innovation and entrepreneurship, equalization of basic public services in urban and rural areas, the trend of aging, and population mobility, we should reduce the cost of withdrawal from rural areas by replacing urban housing with rural property and land replacement, and reduce the cost of urbanization through household registration reform. We should innovate the mechanism for the introduction and cultivation of rural talents, and comprehensively cultivate new types of professional peasants, professionals and scientific and technological talents. The basic services of employment, social security, housing, education and medical care should be guaranteed, and a complete policy system should be formed to ensure equal treatment for transfer residents and local residents.

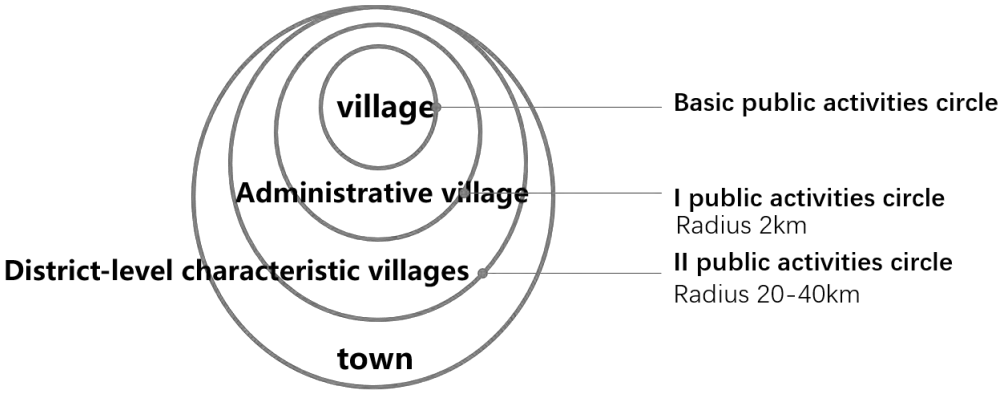

Figure 9: public activities circle in Rural Community

4.3. Industrial Development Strategy

To excavate the cultural value, leisure value, ecological value and economic value of the countryside, take building "one town and one product" of Jinxi Town as a breakthrough point, take the lead in realizing agricultural modernization town and sharing pastoral water villages around Dianshan Lake area as the goal, and realize the sustainable development of the new ecological economy.

4.3.1. Deep integration and upgrading of industrial system

To consolidate the agricultural foundation and further promote the integration of primary, secondary and tertiary industries. With modern agricultural parks, new rural pastoral complexes and characteristic rural areas as the main carriers, we should guide and support industrial and commercial capital and social forces to participate in Rural Revitalization and the integration and development of rural primary, secondary and tertiary industries.

4.3.2. Ecological wisdom and optimization of production system

Rooting in the ecological concept, using modern technological means to comprehensively improve the production level.

1) Agricultural development model green: improve the quality of cultivated land, high-standard farmland construction; reduce inputs to achieve zero growth of fertilizers and pesticides; recycle waste, improve the utilization of straw and other resources; industrial ecological coupling, the development of ecological recycling agriculture.

2) Intelligent agricultural production and operation: agricultural technology and equipment, mechanized intelligent equipment; the development of agricultural Internet, rural e-commerce and so on; information-based circulation supervision, implementation of quality and safety traceability system, etc.

3) Agricultural management service informationization: agricultural socialization service, the establishment of information system to serve agricultural production; villagers in the palm of Jinxi, to build a government service system of mobile micro-messaging.

4.3.3. Cooperation and Sharing to Activate Business System

1) Give full play to the leading role of the new business entities, and realize the organic connection between small farmers and the development of modern agriculture. Innovation and development of rural cooperative economic organizations. Supporting the well-conditioned community joint-stock cooperatives to explore the establishment of modern enterprise management system in the mode of joint-venture development.

2) Optimizing the quality of collective economic development. Appropriate development and construction of agricultural and trade markets, urban complexes, science and technology entrepreneurship parks and other business projects to increase collective income. For the development of residential and pension projects using idle farm houses, support rural collective economic organizations to activate the utilization of idle farm houses and homesteads, develop resi dential and pension projects by means of leasing, pooling and equity.

4.3.4. Supporting and perfecting the industrial chain of Agricultural Engineering in an all-round way

1) Give full play to the leading role of the new business entities, and realize the organic connection between small farmers and the development of modern agriculture. Innovation and development of rural cooperative economic organizations. Supporting the well-conditioned community joint-stock cooperatives to explore the establishment of modern enterprise management system in the mode of joint-venture development.

2) Optimizing the quality of collective economic development. Appropriate development and construction of agricultural and trade markets, urban complexes, science and technology entrepreneurship parks and other business projects to increase collective income. For the development of residential and pension projects using idle farm houses, support rural collective economic organizations to activate the utilization of idle farm houses and homesteads, develop residential and pension projects by means of leasing, pooling and equity.

3) ndustrial Platform Construction Project. At present, there are about 1500 rice processing enterprises in Jiangsu Province, with an annual output of 25 million tons, accounting for 9.3% of the country. However, there are many small and bulk processing factories with low equipment level. There are only a handful of large-scale precision processing enterprises such as grain and oil in northern Jiangsu, rice cultivation in Sukeng, Jiangnan Spring in Changzhou and Baoying Baobao grain and rice industry. The

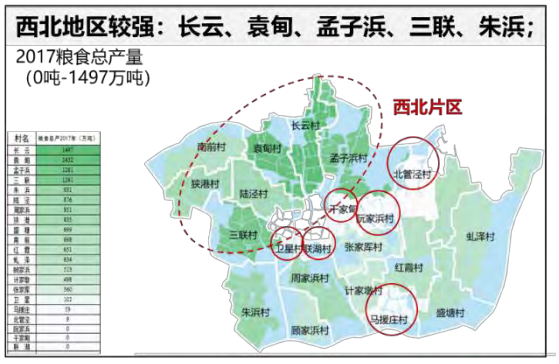
idle rural collective construction land can be replaced, and the grain processing base in Jinxi Town can be established to be responsible for production and grain processing, the entity marketing platform for exhibition, and the township founding base for publicity and promotion, so as to form a perfect industrial engineering chain.

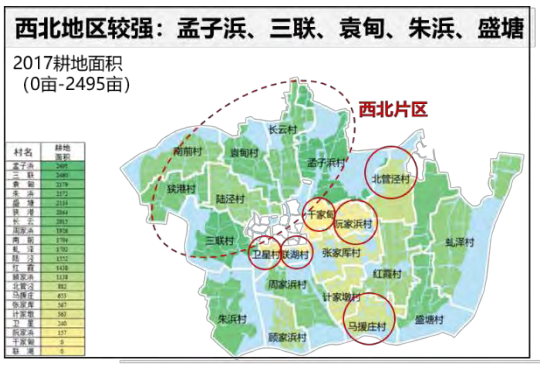
4.4. Space Development Strategy

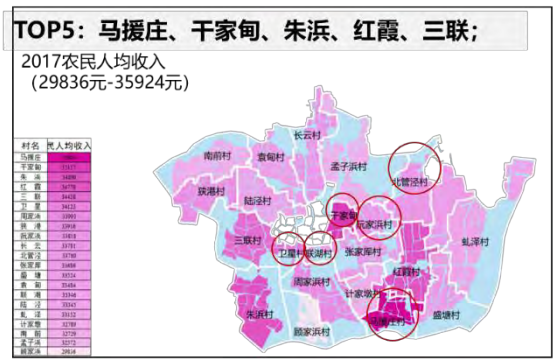
Based on the principle of layout optimization and sharing of public service facilities, we should guide spatial renewal, maintain the leading role of agricultural production function, improve the service quality of the three industries, reduce the consumption of land and open space, improve the utilization efficiency of existing land and open space, and reconstruct villages in various ways with "industrial transformation" as the core. Material space environment, activating the vitality of traditional culture. Improving the rural human settlement environment and forming a sustainable development pattern of urban and rural ecological environment integration and complementarity, economic, social and ecological coordination.

4.4.1. Spatial Assessment and Classification of Rural Areas

From the analysis of gross national product, population statistics, industrial statistics, agricultural land area, gross grain production and per capita income of farmers, the relationship between industrial functions and spatial distribution is obtained. For example, the overall cultivated land area and yield in the northwest region are relatively high (7 villages); other villages (9 villages) with agricultural production function as the main function, and villages (6 villages) with non-agricultural production function as the main function; the overall economic strength of villages is proportional to the population (3 villages).Only a small number of villages have weak secondary industry (5 villages) and the tertiary industry around the lake region has more development potential (3 villages).







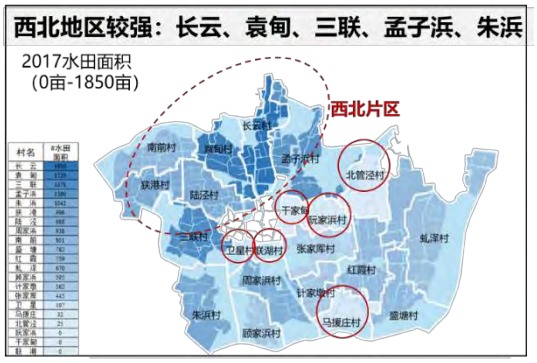


Figure 10: Sketch map of spatial assessment: Agricultural land area (arable land area, paddy field intensive); gross grain production; spatial assessment of per capita income of farmers

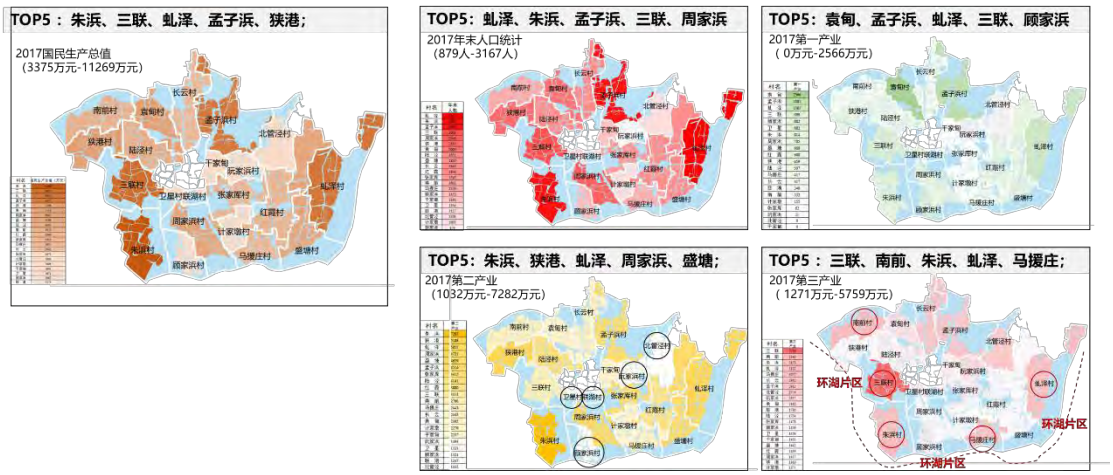

Figure 11: Sketch map of spatial assessment: GNP; demographic statistics; output value of first, second and third production

4.4.2. Strengthen the implementation of space use control

On the basis of the delimitation of "three districts and three lines", we should strictly protect the lake wetland, coordinate the protection of Dianshan Lake and Chenghu Lake, and control and manage the internal lake. Strictly abide by the permanent basic farmland red line, basic farmland management and control standards.

4.4.3. Optimizing Rural Development Space

1) Reconstructing the planning structure of rural revitalization: one center, one corridor, two axes and four districts.

- One Heart: Jinxi Ancient Town Comprehensive Service Center
- One Corridor: Huanjinxi Vigorous Corridor
- Two axes: along the Jin-Shang road Development Axis and Bailian Lake Ecological Development Axis
- Four Areas: Modern Agricultural Production Zone, Ancient Town Comprehensive Service Zone, High-tech Industrial Zone, Lake Rim Leisure Resort.

Figure 12: Structural sketch of Rural Revitalization Planning in Jinxi Town

2) Create efficient and intensive rural production space. Build Jinxi model of linkage among agricultural production area, rural community, Jinxi town area and Rural Creative Zone. Rural Creative Zone: Develop into an ideal life village cluster with multiple meanings; develop scientific and technological agriculture in agricultural production areas; build 22 rural communities around comprehensive service centers in villages; and form a more complete supporting area with the focus of Jinxi town.

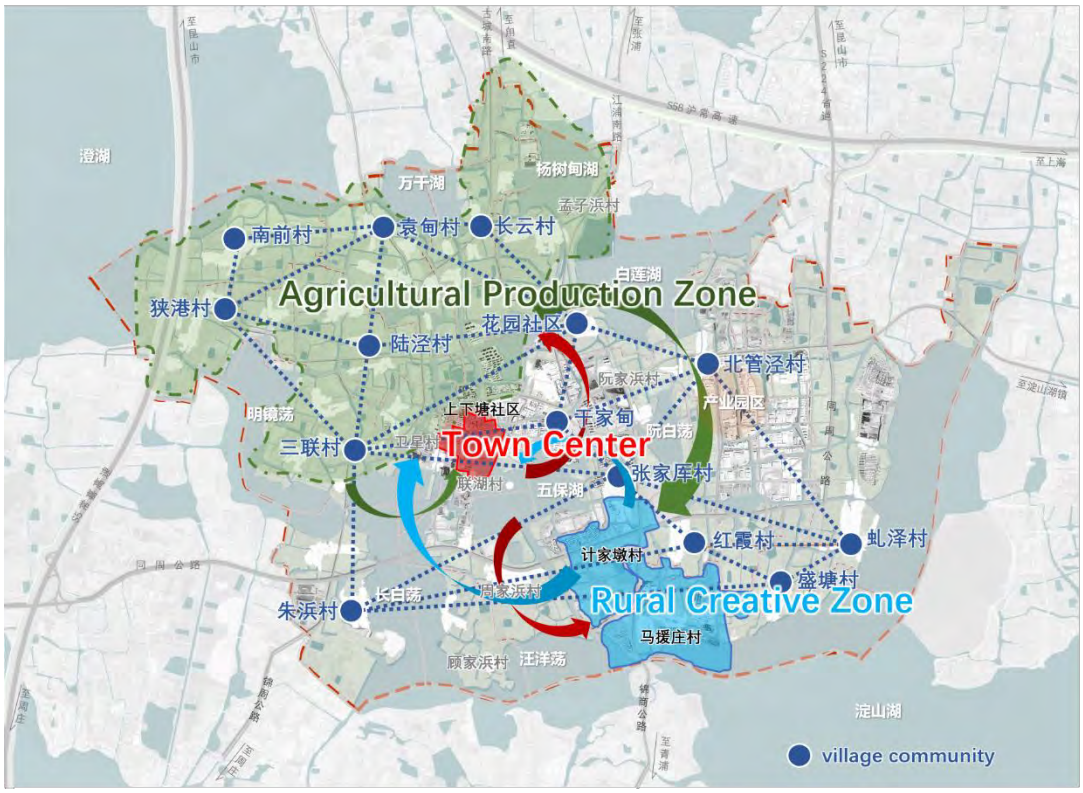

Figure 13: Four-zone linkage diagram

3) Build a suitable living space in the countryside. According to the characteristics of each village, there are high-quality fields, farmland and water scenic spots, green exhibition and marketing areas, community living areas, ancient village tourist areas, ancient kiln art areas, lakeside resorts, etc.

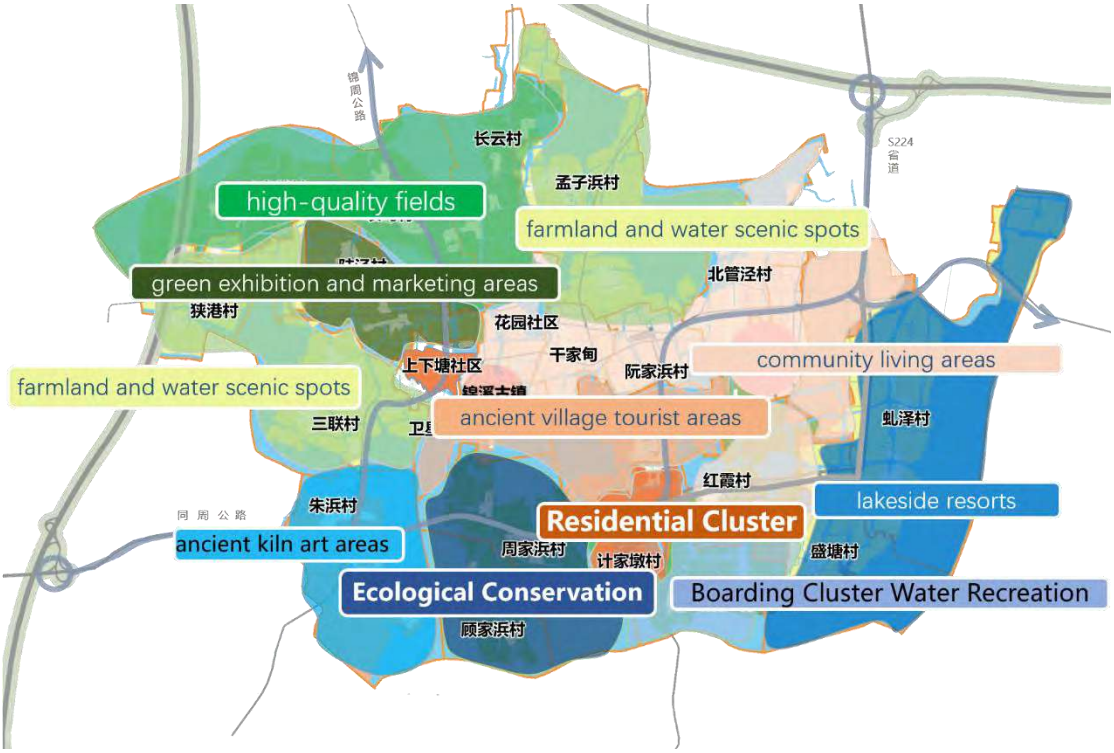

Figure 14: Distribution of Village Characteristics

4) Create a blue-green interwoven Shuimei Jinxi. Improve environmental quality. Water environment: "Five lakes, three ripples, six pools and five patches" regionalized regulation, proposed integrated watershed protection mechanism, control of agricultural non-point sources, enhance runoff control, establish a rainwater runoff management system consisting of roads, water system vegetation buffer zones and rainwater gardens. Ensuring biodiversity of farmland ecosystem, improving and restoring farmland soil, and strictly controlling chemical fertilizer, agricultural waste and agricultural water discharge.

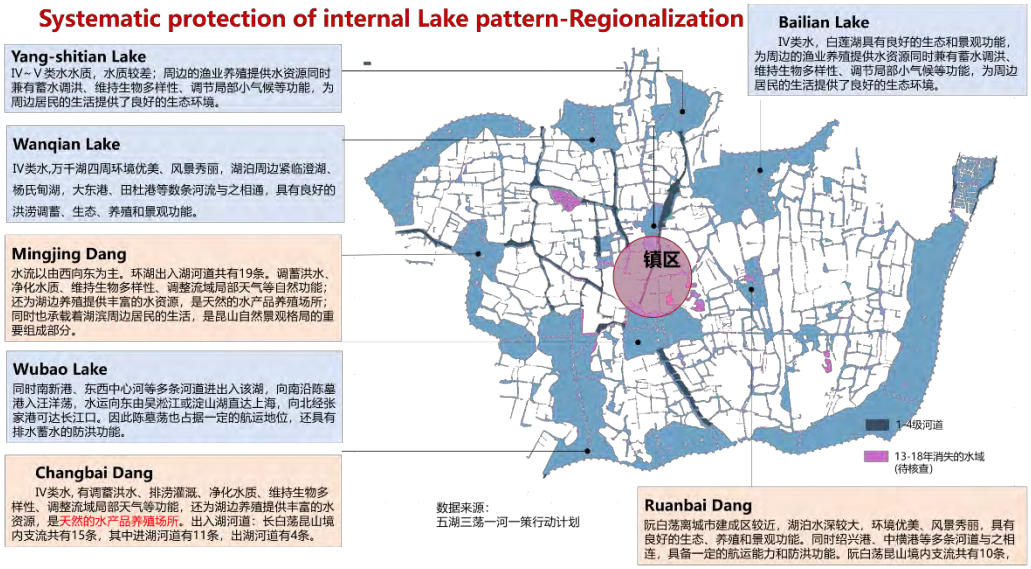

Figure 15: Schematic Map of Regional Renovation of "Five Lakes and Three Dangs"

5. Case Study: Villages Revitalized in Rural Areas

5.1. Case Study of Agricultural Upgrading Village: Changyun Village

5.1.1. Target positioning

High-efficiency and High-quality Agricultural Benchmarking

5.1.2. Staging objectives

1) Leading Party Construction Policy Innovation
2) Technology Agriculture & Application Practice
3) Stereoscopic Agriculture
4) Re-upgrading Changyun Model

5.1.3. Main paths

Continue to give full play to the advantages of Changyun's state-level cooperatives, continue to upgrade policies, agriculture and operation

1) Scientific and Technological Agricultural Experimental Field
2) Upgrading Crab Culture in Paddy Field
3) Renewal of duck farming in paddy fields

5.1.4. Strategies

Strategies for Agricultural Industry Upgrading: Leading the Application of Agricultural Technology; Developing Three-dimensional Agricultural Economy with Ecological Circulation ; Creating Urban Leisure Agriculture.

Changyun Model Upgrading Strategy: Upgrading the Model of "One Town One Product"; Constructing Cooperative Development Mechanism; Shaping the Brand Characteristics of Changyun.

5.2. Case Study of Industrial Integration Village: Xiagang Village

5.2.1. Target positioning

Eco-oriented Agricultural Park

5.2.2. Staging objectives

1) Ecologically Beautiful Leisure Fishing Village
2) North Portal of jinxi
3) important Eco-node of Chenghu Lake
4) Best natural outdoor classroom

5.2.3. Main paths

1) Restoring Ecology

Combining the construction of Chenghu ecological conservation area, Ecological Corridor around the lake and small industries that have been cleared away, we should further expand ecological effects, strengthen ecological conservation and control, and build demonstration

sites for ecological civilization construction. At the same time, we should attract tourism with ecology, introduce green tourism products, and attract tourists to increase vitality.

2) Expanding Industry

On the basis of the current agriculture, we should supplement the service industry and tourism industry, re-integrate the resources with the idea of "agriculture + tourism", dig the tourism resources in depth, and promote the transformation of regional industries and expand employment opportunities.

5.2.4. Strategies

Core development issues: through an ecological chain, a cultural chain, protecting the ecological background, coordinating spatial elements, transforming traditional agriculture, innovating urban and rural co-ordination

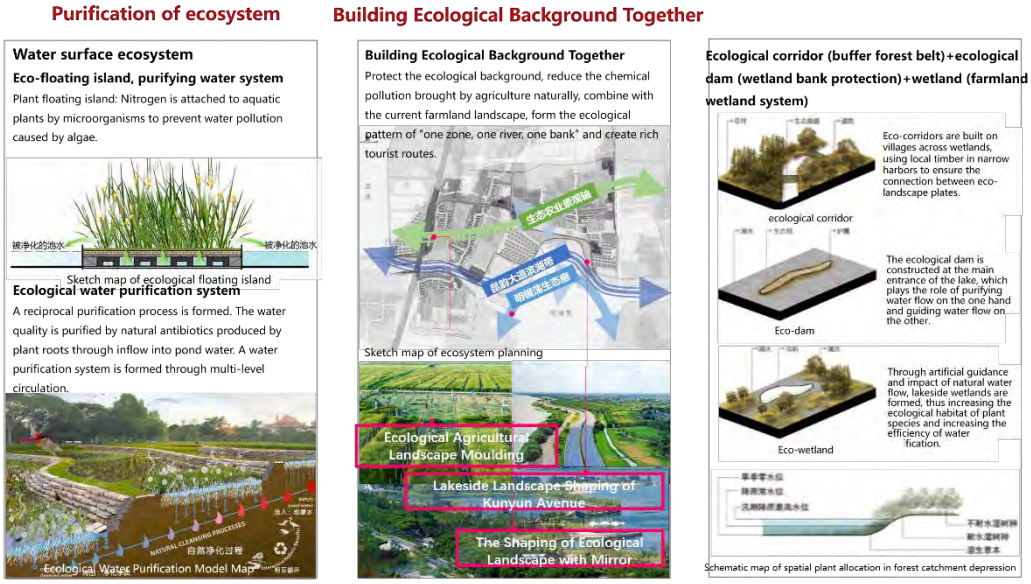

Figure 16: Strategy schematic

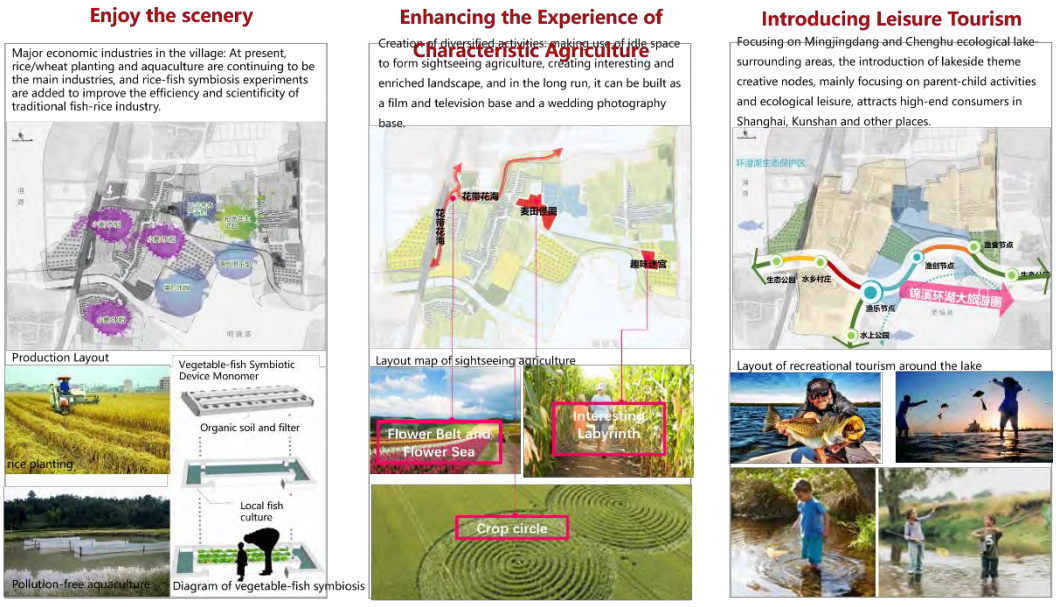

Figure 17: Strategy schematic

5.3. Case Study of Village of Village Community Type: Zhangnan Village

5.3.1. Target positioning

Demonstration Village of Renovation of Human Settlement Environment in Water Township of Jiangnan

5.3.2. Staging objectives

1) The most livable pastoral community
2) rural tourism Leisure destinations
3) Shanghai Suburbs Living in Water Township
4) The Experience of Slow Life

5.3.3. Main paths

1) Village upgrading and environmental optimization
2) Business Form Introduction and Crowd Attraction

- Link up with Jijiadun to build an international Fanxin Jiangnan on the west side of Dianshan Lake.
- By virtue of the location advantage close to the international metropolis, we can gather the strength and wisdom of different groups, and provide "golden tricks"“
- Attracting and retaining international villagers, returning visitors, elderly people, tourists and local villagers

5.3.4. Strategies

1) Leisure tourism Countermeasures

- Improvement of water environment
- Space Node Optimization-Sharing
- Restoration of ecosystems

2) Countermeasure of Village Promotion

- Traffic network of dredging Road
- Supporting High-end Service Facilities
- Optimizing Public Activity Space

3) Measures to Improve Human Settlement Environment

- Improvement of water environment
- Space Node Optimization-Sharing
- Restoration of ecosystems

5.3.5. Master plan

Figure 18: Zoning format layout of ZhangNan Village

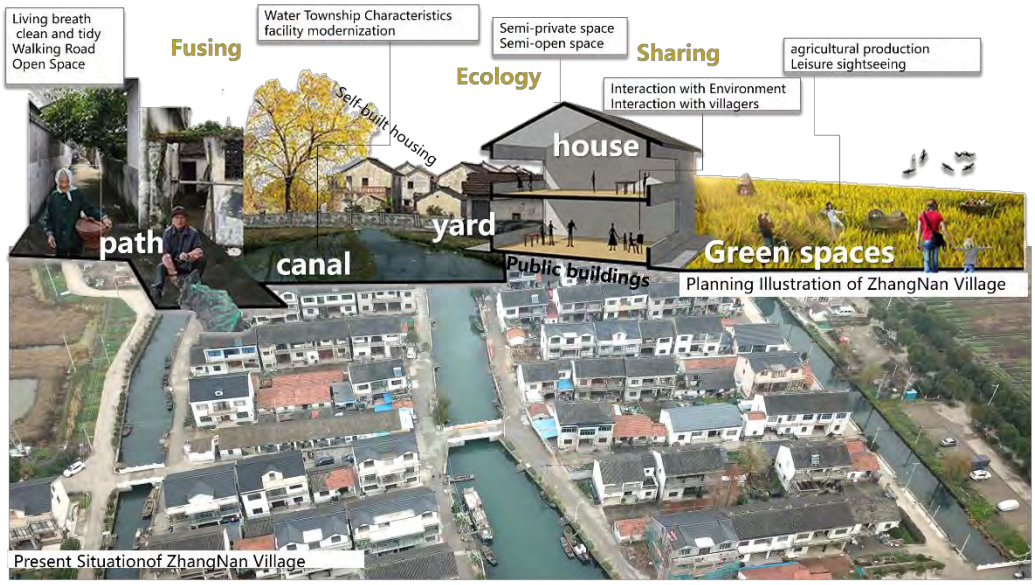

Figure 19: Design Concept- New Jiangnan Water Township

5.4. Case Study of Industrial Returning Village: Zhubang Village

5.4.1. Target positioning

1) Jinxi Town Industrial Transformation Demonstration Village

2) Agricultural Creation, Cultural Creation and scientific Creation Fusion Creative Culture Park

5.4.2. Staging objectives

1) Industrial Sites Thematic tourist destination
2) Art and Culture Exhibition Settlement
3) History and Culture Exhibition Museum Group
4) Highlands of Kunshan's innovation

5.4.3. Main paths

Plant renovation, facility matching and environmental renovation

Combining Zhudianyao ancient kiln art culture and Jinxi township enterprise culture, introducing R&D companies and universities, leading the transformation and operation of local enterprises, taking into account the comprehensive format, focusing on the transformation of scientific research results, and setting an example of Jinxi industrial transformation.

5.4.4. Strategies

1) Regional Linkage Countermeasure

- Space-Culture Linkage Axis
- Lakeside Scenic Belt and Great Tourist Circle Around the Lake
- Integration of Four States and Three Creations
- Space renovation of workshop

2) Strategies for Cultural Inheritance

- Comprehensive Culture and Activating Space
- Integrating Innovation and Exploiting Potential
- Organic Renewal and Vitality Promotion

3) Strategies for Space Upgrading

- Forming Industrial Heritage Cluster
- Constructing landmarks of landmark Tourism
- Completing the Historical Mission of the New Era

Figure 20: Current Situation and Problems Analysis

Figure 21: Master plan

6. Conclusions

At present, the proposal of the national strategy of Rural Revitalization is of great significance to realize the integration of urban and rural areas and the modernization of agriculture and rural areas in China. As the villages in the core circle of Shanghai Metropolitan Circle, we should take "industrial prosperity, ecological livability, rural culture, effective governance and rich life" as the general requirement, seize the opportunities for development within the circle of Shanghai Metropolitan Circle, take "ecology, sharing, integration and high quality" as the core concept, adhere to the agricultural standard, and adhere to urban and rural areas. Overall planning, from the "positioning, population, industry, space" four aspects of an all-round strategic deployment, to promote institutional innovation of the physical mechanism. Meanwhile, the strategy of Rural Revitalization should respect history and local customs, adhere to the idea of urban-rural co-ordination according to different types of villages, put forward planning strategies according to local conditions, so as to make rural revitalization into an acceptable, concreted and operable strategy system, and help Jinxi become a blue-green interweave in the future, glowing brilliant and vigorous——New Jiangnan Water Township.

Construction and Empirical Study of Evaluation Index System of Rural Revitalization in China's Metropolitan Areas from the Perspective of Social Ecosystem

-- Taking Villages and Towns Around Shanghai as Examples

Dianhong ZHAO, Shanghai Tongji City Planning and Design Research Institute Co., Ltd..; China

Abstract

Since the reform and opening up, the development of township enterprises is the core of southern jiangsu in Shanghai metropolitan area, which has experienced rapid urbanization and industrialization, and the urbanization rate has reached 75. The high level of 9%. While great achievements have been made in urban and rural development, rural revitalization still faces many challenges, such as environmental pollution, local population loss, migrant population agglomeration, social structure reconstruction and other issues in rural settlements. Realizing sustainable development of rural settlements has become an urgent goal of rural revitalization in southern Jiangsu. Based on understanding of the metropolitan areas around the country revitalization of the Chinese built from rural agricultural modernization and new Jiangnan water to the three dimensions of urban and rural integration development 4 levels of hierarchy model of rural revitalization of the top as the goal layer index, followed by rule layer contains a prosperous industry, ecological livable, local custom civilization, effective governance, well-off five first-level indicators, again for child criterion layer contains rural industrial structure, agricultural science and technology level, rural marketization, livable natural environment, artificial environment livable, social environment livable, culture education 24 secondary indexes such as the construction of public cultural development, Finally for solution layer contains characteristic industrial output value accounted for the proportion of total output, non-agricultural production value accounted for the proportion of total output, proportion of total labor force non-agricultural industry practitioners, comprehensive agricultural mechanization level, per million population the number of agricultural science and technology personnel, agricultural science and technology innovation achievements conversion, forage-livestock system of agricultural products and farmers credit loans into 116 tertiary indicators. At the same time, an empirical study was conducted on the revitalization of 20 villages in Jinxi town around Shanghai, China, to test the feasibility and application value of the evaluation index system, and also to suggest the direction of policy intervention.

Key words

rural revitalization, Social ecosystems, Evaluation index, South Jiangsu

1. Revitalization background

1.1. The overall requirements of the National Rural Revitalization Strategy

Rural revitalization calls for giving priority to development in agriculture and rural areas. We need to establish and improve systems, mechanisms and policies for integrated urban and rural development, and accelerate the modernization of agriculture and rural areas.

1.2. Mission deployment of the rural revitalization strategy in Jiangsu Province

Based on the five aspects of rural revitalization, the general plan of rural revitalization strategy of Jiangsu province (2018-2022) puts forward the main indicators of rural revitalization strategy implementation plan based on the actual situation of Jiangsu province.

Table1：Jiangsu province rural revitalization strategy implementation planning major indicators

	serial number	Main indicators	unit	attribute
Prosperous industry	1	Comprehensive grain production capacity	Ten thousand tons	binding
	2	Contribution rate of agricultural science and technology progress	%	prospective
	3	Agricultural labor productivity	RMB ten thousand/person	prospective
	4	The ratio of processing output value and total agricultural output value of agricultural products	——	prospective
	5	Leisure agriculture and rural tourism receptions	Thousands of people	prospective
Ecological livable	6	Village green coverage	%	prospective
	7	The proportion of villages that deal with household waste	%	binding
	8	The proportion of villages that treat domestic sewage	%	prospective
	9	Comprehensive utilization rate of livestock and poultry pollution	%	prospective
	10	Rural sanitation toilet penetration rate	%	prospective
Local custom civilization	11	Village comprehensive cultural service center coverage	%	prospective
	12	The proportion of civilized villages and towns at or above the county level	%	prospective
	13	The proportion of full-time teachers in rural compulsory education schools with a bachelor's degree or above	%	prospective
	14	The proportion of cultural and entertainment expenditure of rural residents	%	prospective
Effective governance	15	Rural planning and management coverage	%	prospective
	16	The proportion of villages with integrated service stations	%	prospective
	17	The villagers committee shall autonomously meet the standard rate according to law	%	prospective
	18	The proportion of villages where the secretary of the village party organization concurrently holds the post of director of the village committee	%	prospective

	19	Rural harmonious community construction compliance rate	%	prospective
	20	The proportion of villages with strong collective economy	%	prospective
Life rich	21	The engel coefficient of rural residents	%	prospective
	22	Per capita disposable income of rural residents	Ten thousand yuan	prospective
	23	Income ratio of urban and rural residents	——	prospective
	24	Regional water supply household rate	%	binding
	25	Administrative village dual - lane four - level road coverage	%	binding
	26	Standardization of basic public services in rural communities	%	binding

1.3. Action initiatives for rural revitalization in Suzhou

The people's government of Suzhou municipal party committee of the communist party of China (Suzhou about implement the strategy of rejuvenating the country to speed up the opinions on promoting the development of the urban and rural integration, to encourage deeply involved in the country revitalization of the industrial and commercial capital, innovative rural talents cultivating mechanism, the village-level collective economy development, promote the construction of county-rural beautiful four aspects as the realization of Suzhou rural revitalization of the main measures.

1.4. Kunshan City Implements Rural Revitalization Strategy

The implementation plan of Kunshan city's three-year promotion project to implement the strategy of rural revitalization is a top priority. The specific performance is "four hundred thousand mu" agricultural industry pattern, the improvement of modern agricultural park, the construction of agricultural product quality and safety system, the utilization of idle farm houses and homestead, community cooperative joint development and other related measures.

2. Interpretation of the Jinxi

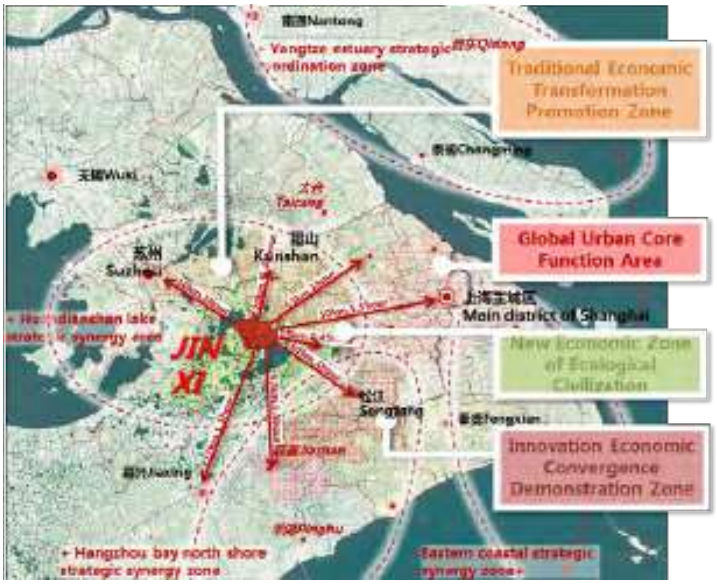
2.1. Jinxi Cognition

2.1.1. Location Features: Around the Lake, Shanghai, Shanghai and Su 1h

Jinxi town is located in the south of Kunshan city, Jiangsu province, bordering Dianshan lake in the east and yicheng lake in the west, bordering jinze town, qingpu district, Shanghai city in the south, and adjacent to luzhi town, wuzhong district, Suzhou city and zhangpu town, Kunshan city in the north. Jinxi town covers a total area of 90.69 square kilometers. Jinxi town has jurisdiction over 3 communities and 20 administrative villages. There are 65,997 permanent residents in Jinxi, including 43,283 registered residents.

Jinxi is located in a superior location, which is located in Jinxi town, an ancient water town in the south of the Yangtze river between the international metropolis Shanghai and the famous historical and cultural city Suzhou. It belongs to Kunshan city, Jiangsu province. It is 50 kilometers away from Shanghai downtown in the east, 30 kilometers away from Suzhou downtown in the west, and 20 kilometers away from Kunshan downtown.

Figure 1: Jinxi location analysis chart



2.1.2. Traffic characteristics: high-speed surround, five vertical and four horizontal

Jinxi town is adjacent to huchang expressway (S58) in the north and changjia expressway in the west. Intercity railway (planning) and track S3 (planning) : from wujiang along tongzhougong road to tongli, zhouzhuang, Jinxi and Dianshan lake, east to Shanghai.

In the town area, the north-south jinzhou gong road and jinshang highway lead to zhouzhuang, while the east-west puqing road, zhengwei east road and the same zhou road lead to zhouzhuang and Suzhou. Kunzhou line (the planned five-level channel) of the main waterway in the town runs through the town, connecting the sushen inner harbor line of the third-level channel in the north and the sushen outer harbor line of the third-level channel in the south.

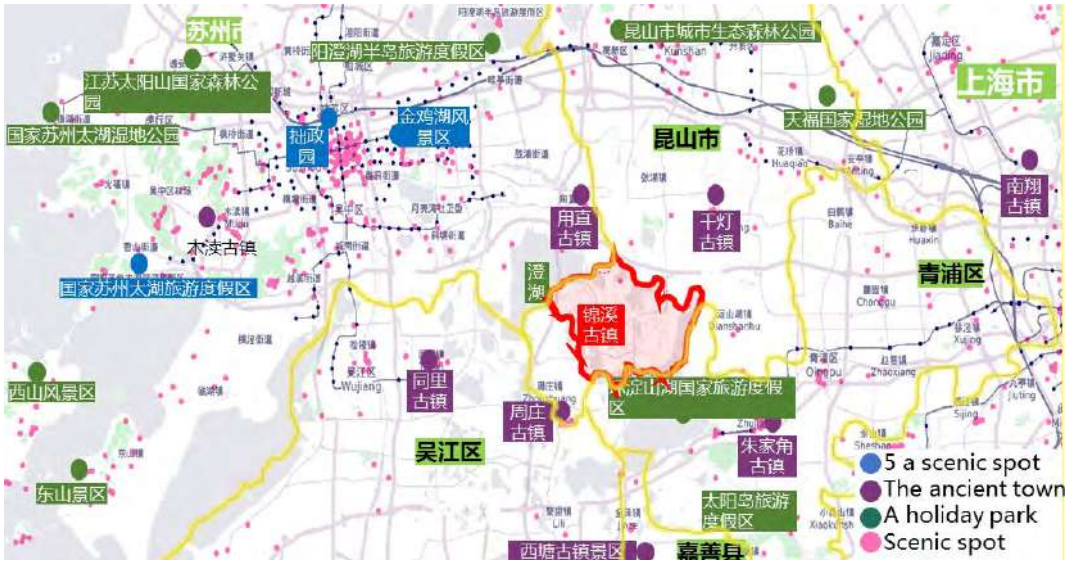
Figure 2: Traffic Analysis Diagram of Jinxi Neighborhood

2.1.3. Cultural Characteristics: Ancient Kiln Town, Art Town

(1) long historical context and rich historical relics. Jinxi has a long history of more than 2500 years. The water network and stone Bridges are interwoven all over the town. The buildings are built along the river and by the water, forming a pleasant environmental landscape of "small Bridges and flowing water", with typical characteristics of Jiangnan water town. There are one provincial cultural protection unit in Jinxi -- zhudian ancient kiln site group, 13 municipal cultural relics protection units such as Chen concubine watermound, Jinxi ancient inland river waterway, tongshendao courtyard and wenchang pavilion, and 4 municipal control and protection units such as wine workshop. In addition, there are a number of historical and cultural value of conservation buildings.

(2) there are many intangible cultural heritage projects. Jinxi town has the largest number of intangible cultural heritage projects in Kunshan, including Jinxi xuanjuan and Jinxi brics. Jinxi has long been known as the hometown of Chinese folk museums. Jinxi has 11 folk museums, such as zhang provincial art museum, China ancient brick museum, maroat mud zen workshop, China Jinxi xuanjuan art museum, China yixing purple sand museum, Jinxi outstanding figures museum and modern folk pot ware museum.

Figure 3: tourist resources distribution around Jinxi



2.2. Development status

2.2.1. Economy: Rural Watchman of China's Most Developed County Economy - Jinxi Agricultural Color

Kunshan: the vanguard of China's county economy. The industrial manufacturing industry in Kunshan is developed with Kunshan development zone and high-tech zone as the leading industrial parks. The modern service industry represented by the huaqiao economic development zone has developed rapidly. Zhouzhuang as a representative of the ancient town tourism and deep.

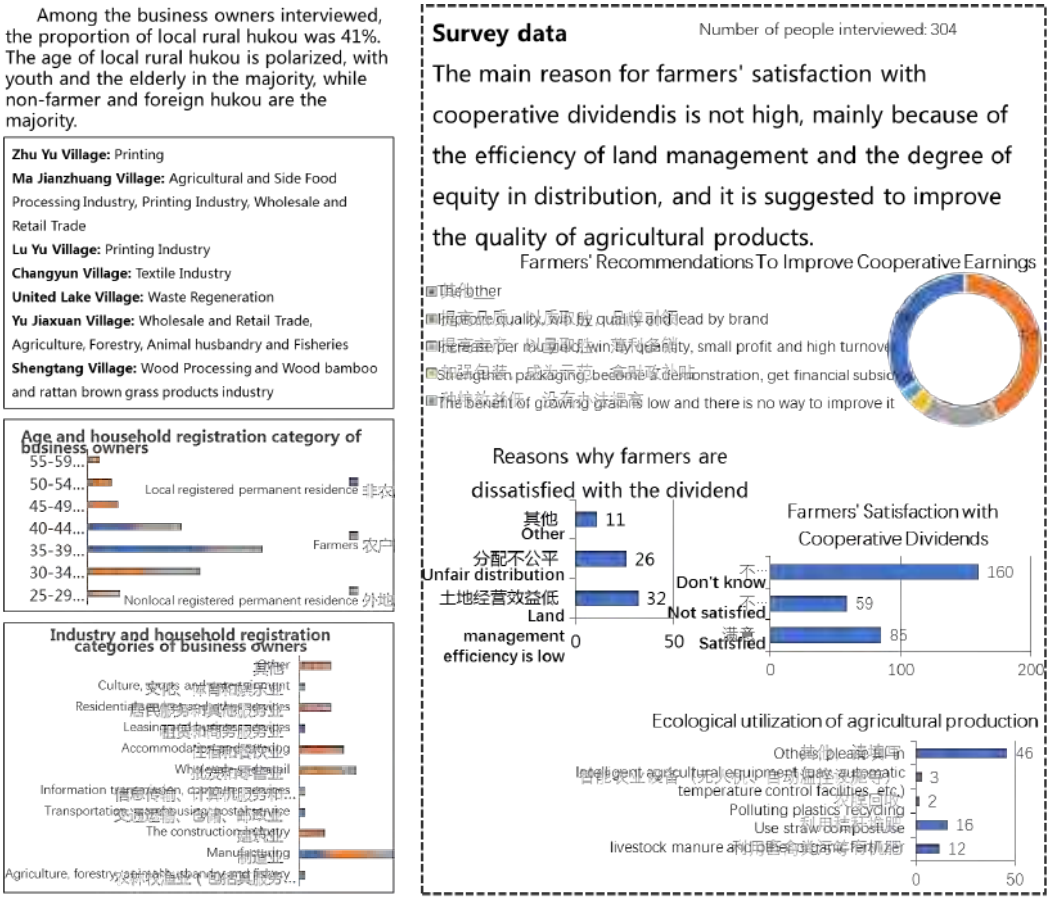
Jinxi agricultural nature. In 2017, the GDP of Jinxi town was 7.511 billion yuan, higher than that of zhouzhuang town. The per capita GDP of registered population is 168,500 yuan; The primary industry accounted for 2.86%, the highest proportion. In 2017, the number of rural households in Jinxi town was 11,822, accounting for 76.46% of the total, ranking third and second respectively in Kunshan. The rural population is 36,904, accounting for 82.77% of the

town, ranking 5th and 3rd respectively in Kunshan. In the case of near-regional urbanization in Kunshan and even Suzhou, Jinxi rarely retains a quiet countryside.

(1) Jinxi agriculture, forestry, animal husbandry and fishery is relatively balanced, but its comparative advantage is not prominent enough. In 2017, the total output value of Jinxi agriculture, forestry, animal husbandry and fishery reached 271 million yuan, ranking the 7th, and there was a significant gap between Jinxi and baicheng (strong fishery), a big agricultural town, and zhangpu (strong rice). Jinxi ranks third in total grain output, third in rice area and sixth in per mu yield.

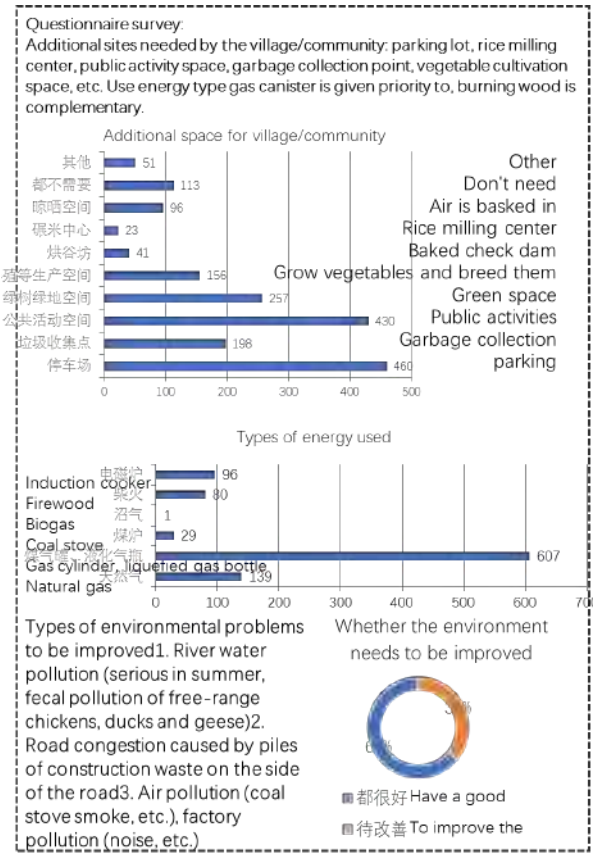
(2) the growth of all industries in agriculture is sluggish, and new growth points need to be explored to break bottlenecks. Modern agricultural equipment level, Jinxi town agricultural machinery total power and the number of large and medium-sized tractors in the district in the forefront. The operation level of moderate scale agriculture is relatively close to each district and town in theory. The transfer of land in the whole city is basically completed, and it is operated by village land joint-stock cooperatives and various professional cooperatives. Kunshan city vigorously promotes the green transformation of agriculture, and Jinxi town also takes measures to reduce chemical fertilizers and pesticides to improve the quality of agricultural development.

Figure 4: jinxi economic survey chart



2.2.2. Space: Jinxi, which relies on traditional development paths, needs to seek new development paths under the goal of land reduction and value-added

Figure 5: jinxi Space survey chart

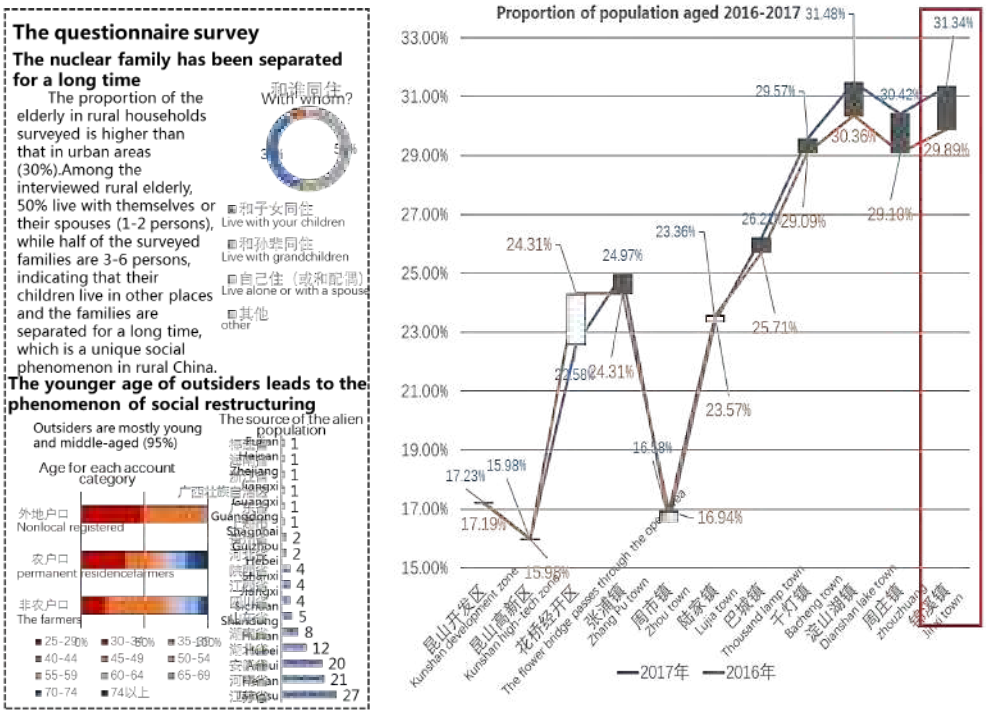


The cultivated land area of Jinxi town increases year by year: from 2012 to 2016, the average annual growth rate of cultivated land area of Jinxi town is +4.22%, which is negative only in 2017. Jinxi water environment ranks first with zhouzhuang in Kunshan city: the water quality of rural river in Jinxi town reaches the standard rate up to 98%, and the water quality of river in market towns reaches the standard rate up to 96%. Limited by the cultivated land (water surface) area, the path of agricultural economic appreciation is difficult: the cultivated land area and the breeding water surface area have a certain correlation, and there is a game between the policy guidance of "returning the pond to the field" and the farmer "changing the field to dig the pond"; The area of rice was basically stable, while the area of rape and vegetables decreased sharply. Jinxi local agricultural products brand less. Under the target of reduction planning, it is imperative to "move" village industrial land: Kunshan master plan proposes that the construction land scale will be reduced from 433 square kilometers to 406 square kilometers at the end of the planning period, so as to achieve the "reduction" of construction land and energy consumption emissions and the "increment" of spatial benefits.

2.2.3. Population: Regional Population Factor Flow, Triggering The Reconstruction of Rural Social Structure

The aging phenomenon in Jinxi is prominent: in 2017, the proportion of the elderly over 60 years old in Jinxi town was as high as 31%, second only to Dianshan lake town, but the growth rate was the fastest in the past two years, and the proportion of the elderly over 60 years old in each district of Kunshan town was more than 15%. At present, Jinxi town is Kunshan city aging phenomenon prominent district town. About half of the registered population live in Jinxi, ranking last in Kunshan: in 2017, there were 25,400 temporary residents in the town. It ranks 10th among 11 towns and districts in Kunshan, with about 170 people settling down in Jinxi every year. "Structural adjustment of rural community and liquidity society" : because a two-way flow of Jinxi town population and the villagers' social and economic attributes of the differentiation and broken reconstruction, based on the relative weakening of family, based on all kinds of industry cooperation to strengthen the industry margin, new geopolitical bond formation, therefore, and translated into a half open half an acquaintance social relations.

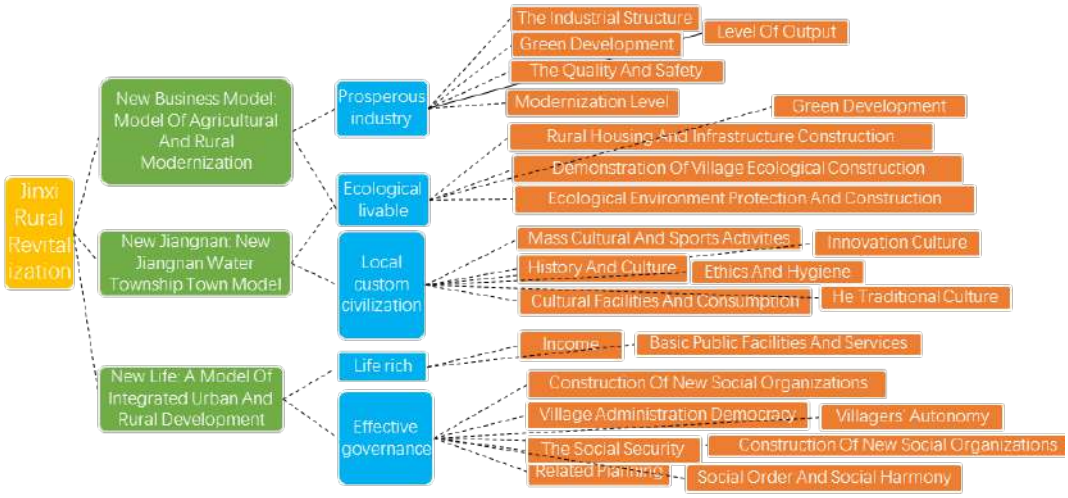
Figure 6: jinxi Population survey chart



3. Construction of evaluation index system of rural revitalization in Jinxi

The plan integrates five secondary indicators, 24 tertiary indicators and 116 tertiary indicators of Jinxi rural revitalization from the perspectives of agricultural and rural modernization, new Jiangnan water township and integrated development of urban and rural areas.

Figure 7: structure chart of rural revitalization evaluation index system



3.1. Industry Prosperity： Benchmark for Agricultural and Rural Modernizatin

3.1.1. further consolidate agricultural scale, intensification and mechanization, and improve agricultural production efficiency; We will accelerate efforts to make agriculture smarter, greener and better branded to improve the quality of agricultural development. We will make agriculture more integrated, organized and Shared, and give small farmers a greater sense of achievement

According to the requirements of relevant national policies, the follow-up work of land right confirmation shall be promoted to consolidate the results of land circulation and proper scale operation of agriculture since the eleventh five-year plan. We will further strengthen development of high-standard farmland, fish ponds and vegetable plots, and promptly update some obsolete equipment and facilities. We will build a service center of "whole-process mechanization + comprehensive farming", and accelerate the integration of the links of efficient planting and protection of rice and wheat, drying of producing areas, straw treatment and mechanization of farming and harvesting, so as to form a whole-process mechanization solution of grain, oil and crop production with characteristics of water villages.

We will make full use of modern information technology, build demonstration bases for smart agriculture (fishery), and promote the application of information technologies such as the Internet of things, intelligent control, and satellite positioning in agricultural machinery equipment and operations, so as to realize precise cultivation of field crops, smart fish pond breeding, and intelligent production of fruits, vegetables, flowers and plants. The work requirements of "one control, two reduction and three basic measures" should be implemented in the whole town, that is, the total amount of agricultural water and the pollution of agricultural water environment should be controlled, the use of chemical fertilizers and pesticides should be reduced, and the waste of livestock and poultry, agricultural film and crop straw should be basically recycled, comprehensively recycled and harmless. Promote the construction of public brand, enterprise brand and "three products and one standard" products in Jinxi town in different levels, with emphasis on rice, duck and aquatic products.

On the basis of agricultural production, we will promote the processing and marketing of agricultural products (e-commerce), develop leisure agriculture, extend the industrial chain and increase added value. On the basis of existing village cooperatives, Jinxi agricultural cooperative association is established to realize re-organization, coordinate agricultural resources and jointly develop market. We will improve the mechanism for linking the interests of village-level cooperatives, strengthen the governance of cooperatives, ensure fair and reasonable distribution of surplus, and increase the dividend income of rural households.

3.1.2. Jinxi industry prosperity indicator system

Figure 8: Jinxi industry prosperity indicator system

Level Indicators	The Secondary Indicators	Unit	Attribute
The Industrial	Output Value of Agriculture, Forestry,	One Hundred Million	Prospective

Structure	Animal Husbandry And Fishery	Yuan	
	Among Them: Fishery Proportion	%	Prospective

3.2. Ecological livable: A Model of The Famous Town of Xinjiang South Water Township

3.2.1. Deline the three zones and three lines, strictly observe the ecological bottom line, and construct a symbiotic, blue-green interwoven tour system

The demarcation of "three districts and three lines" is the core content of land space planning, which plays a guiding and limiting role in rural revitalization planning in space, especially the demarcation of permanent basic farmland red line and agricultural space,

which should be strictly followed in the follow-up rural functional unit planning and village planning.

First-level control area of ecological protection red line: Wubao lake, northern waters of Changbaidang and Dianshan lake; Secondary control areas of ecological protection red line: Chenghu lake, wanhua lake, Yangshitian lake, Bailian lake, Mingjingdang, Wangyangdang and the southern waters of Changbaidang.

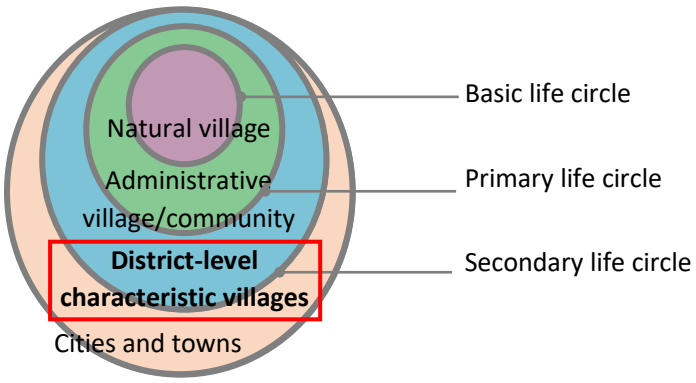
	Scale farm (village) control rate	%	

3.3. Life Rich: Increase the supply of rural public services and improve the level of supporting facilities

3.3.1. guarantee public service facilities and create rural community living circle

The planning forms the public service circle based on the activity path of people, takes the travel convenience as the principle, generates the public service facility space system of the district-level characteristic village based on the radiation range, population scale, constructable land scale, existing service facilities and other factors, and repeatedly checks the selection of the central village through overlapping or lack of service circle .

Figure 11: Model diagram of Jinxi public service system



3.3.2. Jinxi Life Rich Indicator System

Figure 12: Jinxi Life Rich Indicator System

Level indicators	The secondary indicators	Unit	Attribute
income	The engel coefficient of rural residents	%	prospective
	Per capita disposable income of rural residents	ten thousand yuan	prospective
	Income ratio of urban and rural residents	%	prospective
Basic public facilities and services	Regional water supply household rate	%	binding

	Bus stops are 5 minutes' walk away	%	prospective

3.4. Local Custom Civilization: A Model of The Famous Town of Xinjiang South Water Township

3.4.1. Inherit and flourish rural culture, develop and activate innovative culture

Rural culture is the root of urban culture. We will carry forward and flourish rural culture and protect and develop traditional village resources. The revitalization of Jinxi village should sort out and inherit the rural characteristic culture; Protect and activate the use of traditional villages, pay attention to the protection and use of rural natural landscape, ecological environment, history and culture; With "industrial transformation" as the core and rural cultural landscape as the starting point, the village material space environment should be reconstructed in various ways, traditional culture should be inherited and enriched, and innovative culture should be developed and activated.

Figure 11: Jinxi regional cultural integration map

3.4.2. Jinxi Local Custom Civilization Indicator System

Figure 12: Jinxi Local Custom Civilization Indicator System

Level indicators	The secondary indicators	Unit	Attribute
Cultural facilities and consumption	Coverage rate of village comprehensive cultural service center (service function compliance rate)	%	prospective
	The proportion of civilized villages above the county level	%	prospective
	The proportion of rural residents' expenditure on education, culture and entertainment	%	prospective
Mass cultural and sports activities	The number of fairs or festivals held	number of times	prospective
	Cultural auditorium	number of times	prospective
	Moral class	number of times	prospective
Innovation culture	Entrepreneurship + new type of professional farmers accounted for the proportion of permanent residents	%	prospective
	Innovation environment renovation rate	%	prospective
History and culture	Establishment of agricultural civilization memory museum	%	prospective
	Canton	%	prospective
The traditional culture	Number of traditional folk customs projects	%	prospective
	Will follow villager	%	prospective
	Manual of civilized customs	%	prospective
	Cultural activities in the countryside	%	prospective

	Cultural skills school (wenxin lecture hall)	%	prospective
	"One about four meetings"	%	prospective
Ethics and hygiene	The proportion of civilized villages at or above the county level	%	prospective

3.5. Effective governance： Model of integrated urban and rural development

3.5.1. Jinxi model integrating agricultural production area, rural community, Jinxi town and rural innovation park

Jinxi ancient town "small bridge and flowing water family" features Jiangnan water town, improving the quality of folk museums with a collection of people, supporting urban communities in the evening; With Jijiadun village and ma Yuanzhuang village as the focus, it has developed into an ideal life village cluster with multiple meanings. South front village, Xiagang village, Lujing village, Yuandian village for the development of scientific and technological agriculture; Build 22 rural communities around the village comprehensive service center.

3.5.2. Jinxi Effective governance Indicator System

Figure 13: Jinxi Effective governance Indicator System

Level Indicators	The Secondary Indicators	Unit	Attribute
Related planning	Village planning and management coverage	%	prospective
	The proportion of villages with integrated service stations	%	prospective
Construction of new social organizations	The villagers committee shall autonomously meet the standard rate according to law	%	prospective
	The proportion of villages where the secretary of the village party is also the director of the village committee	%	prospective
	Rural harmonious community construction compliance rate	%	prospective
	The proportion of villages with strong collective economy	%	prospective
Village administration democracy	Township party committees and governments are in power according to law	%	prospective

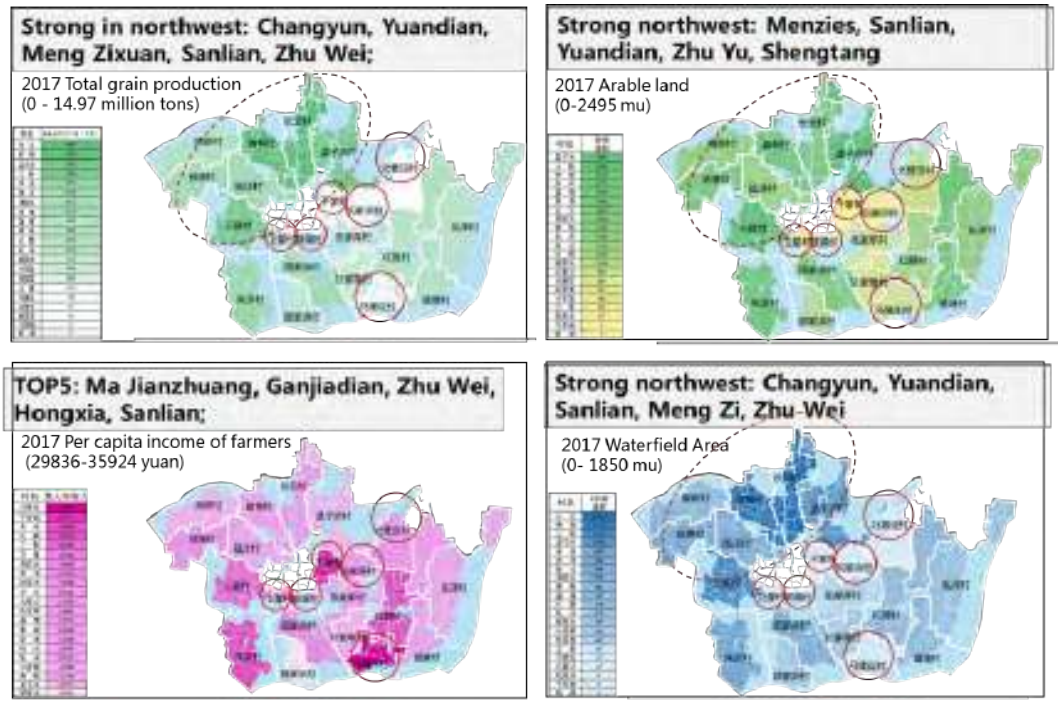
4. An empirical study on the rural revitalization of 20 villages

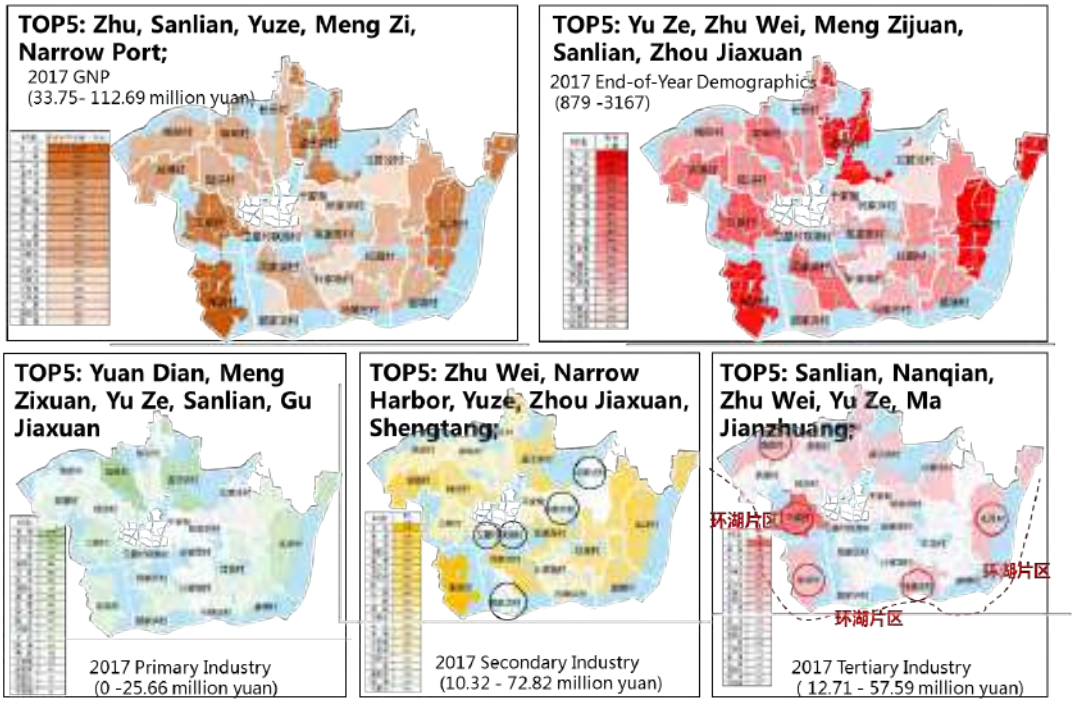
4.1. Co-ordinating urban and rural development space

4.1.1. Quantitative assessment:

Through the research on the cultivated land, paddy field, population and other relevant data of Jinxi town in 2017, it is concluded that the 7 villages in the northwest of Jinxi, such as Mengzibin, Changyun and Yuandian, have prominent agricultural production functions due to the reasons of cultivated land and paddy field area. The proportion of residents' construction land in Ganjiadian, satellite village, Beiguanjing and other villages adjacent to the township and industrial park increased significantly, showing a weak agricultural production function.



The overall economic strength of Zhubang, Sanlian and Qiuze villages with relatively developed secondary industries is in direct proportion to their population. The tertiary industry in the area around the lake is generally developed.



4.1.2. Improving the urban and rural planning structure

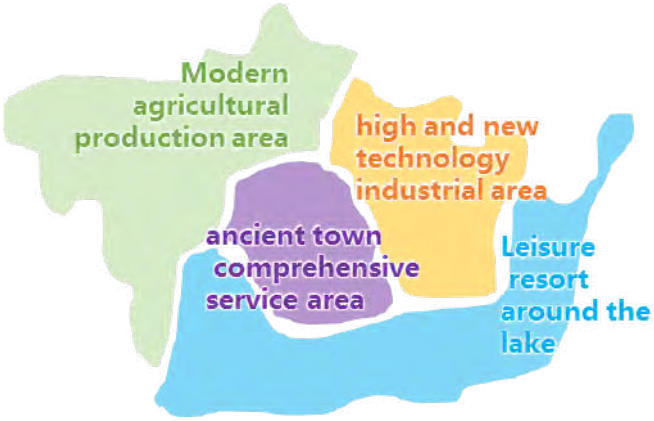
The planning has formed four functional zones, including modern agricultural production area, ancient town comprehensive area, high and new technology industrial area and surrounding lake leisure and resort area, to effectively guide the development of each area and village.

The modern agricultural production plate in the north with ecological agriculture as the main body. With high-quality ecological agriculture background, to ensure food production safety, apply for "Jinxi rice" and "Jinxi barb fish" green brand, brush Jinxi "rural rice fragrance" name card, with Jinxi water charm rice fragrance town, provincial agricultural characteristics in the national "double innovation and innovation" exposition, demonstration of modern urban agriculture development.

Ancient town tourism as the main body of the central town comprehensive plate. With rich tourism and cultural resources, Jinxi is the base for developing watertown cultural tourism resort and developing cultural tourism industry.

High-tech industry sector in the east with science and innovation industry as the main body. To improve the level of intelligent manufacturing and build a high-level r&d center is an important path for Jinxi enterprise transformation and upgrading. Through the elimination of backward production capacity, in the industrial structure optimization and upgrading to obtain greater initiative; We will actively promote the three-year project of accelerating innovation and transformation to promote high-quality economic development, and promote high-quality economic development through innovation and transformation.

Lakeside holiday as the main body of the southern lake leisure holiday plate. Relying on the beautiful natural scenery along Dianshan lake, carry out ecological agriculture sightseeing around the lake, popular science education, ancient kiln art exhibition, leisure vacation, wetland tour and water experience activities.



4.2. Classification to promote rural development

4.2.1. Villages in agricultural production

Changyun, path and Sanlian village, with rice as the main agricultural products, will focus on developing green three-dimensional agriculture (shrimp farming in rice field, crab farming in rice field, duck farming in rice field and other demonstration fields of three-dimensional farming), rape flower sightseeing, agricultural experience and agricultural science and education. The path relies on the advantages of convenient transportation and industrial land stock, and makes use of the opportunity of industrial district reconstruction to build the promotion platform of real agricultural trade exhibition and exhibition. Relying on Mingjingdang and Changbai dang, Sanlian has built leisure agriculture, lake-dang sightseeing

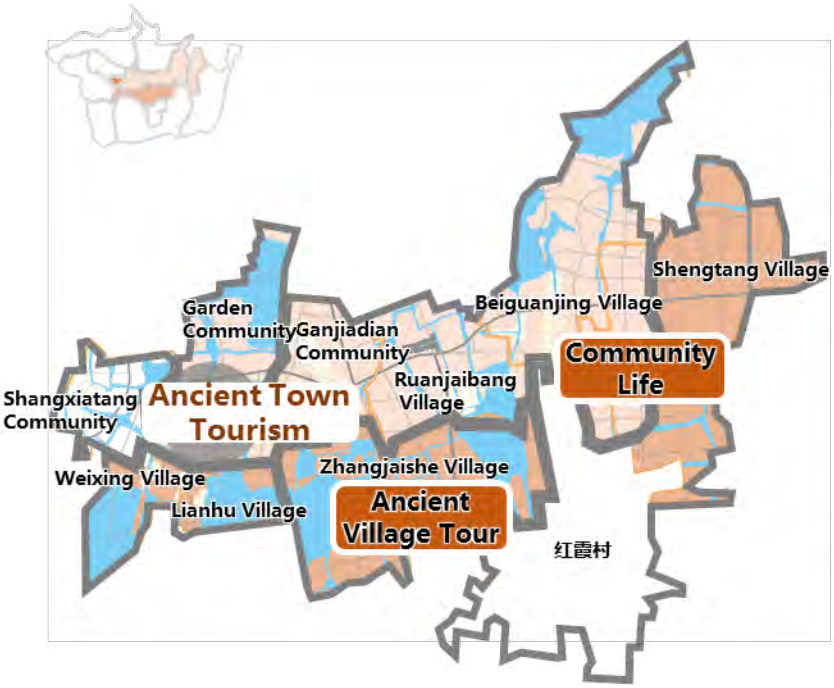
and tourism vacation, focusing on the construction of lakeside health inn, four seasons orchard, four seasons flower sea, flower nursery base, slow post and other tourism projects.

The four villages of yuandian, menzibang, nanqian and xiagang mainly produce rice and ecological aquatic products. Yuandian village relies on wanqian lake to develop efficient fishery and ecological agriculture. Relying on bailian lake and yangshi tian lake, mengzibang develops water leisure tourism, urban leisure fishery and water sightseeing market. Xiagang village and nanqian village, relying on chenghu, focus on the cultivation of efficient fishery and breeding, the development of lake fishing and recreational fishing, especially the construction of ecological vegetable base and sightseeing corridor around the lake.

4.2.2. Community Living Villages and high-tech industrial zone

In the future, shangxia pond community and garden community can develop homestay, catering and other tourism activities in combination with ancient town tourism. Satellite village can be combined with ancient town tourism, moderate war farmhouse, slow post; Lianhu village will increase the richness of ancient town tourism with water recreation and other activities.

Ganjiadian, ruanjiabang, beiguanjing and other villages should reasonably resolve the impact of "landlord economy" on the rural landscape and safety, share service facilities for high-tech industrial parks, and develop homestay and catering appropriately. Zhangjiaku village focuses on developing tourism projects such as ancient village tour, declaration and other intangible cultural heritage display.



4.2.3. Resort villages along the lake

Qiuze village and shengtang village build the dam view scenic area relying on the coast of dianshan lake. This area relies on the beautiful natural scenery along the coast of dianshan lake, mainly providing accommodation, catering and leisure services for the tourist population. Jijiadun village, hongxia village and ma yuanzhuang village rely on the chessboard water surface reconstruction to build the ecological agriculture sightseeing around the lake, the resort hotel, the wetland park and the water experience center. This region mainly provides catering, leisure, entertainment, accommodation and other services for tourism. Gu jia bang village and zhou jia bang village mainly rely on the existing ecological resources of wang Yang dang to carry out conservation science education; Zhubang village mainly focuses on tourism accommodation and sightseeing vacation, and the ancient kiln in the south of the town, develops the ancient kiln art area, and forms a sightseeing and tourism area with kiln as the theme.

Research Paper

URBANIZATION MECHANISM STUDY UNDER THE DYNAMIC OF STATE CAPITAL

A Case Study about Northeast China with the Construction of the Chinese Eastern Railway in the Early of 20th Century

Abstract

Since the industrial revolution of the 18th century, the modern economic system gradually matured and rapidly expanded in the world, especially the state capital investment relying on the railway, which drastically changed the urbanization process and city agglomeration pattern around the world. At the end of the 19th century, due to the important strategic value of the Far East, Russia raised state capital, built the Siberian Railway directly to Vladivostok, especially the C.E.R. across Northeast China, induced capital competition among China, Japan and Russia around the port and railway construction right and management right, formed the SMR system centered on Dalian, the C.E.R. system centered on Vladivostok, and the Chinese railway system centered on Huludao, laid the city structure of the "hub-railway network-hinterland" model centered on the port city in Northeast China, which promoted the development of commercial cities, hub cities and industrial and mining cities. Under the special tariff system, China, Japan and Russia relied on port-railway capital competition, forming the city development dynamic mechanism oriented by the export-oriented economy, that has the important theory value for how to effectively use the state capital advantage to promote the development of the macro-regional city system in the context of economic globalization.

State Capital, Urbanization Mechanism, the Chinese Eastern Railway, Hub-Network-Hinterland Structure, Northeast China

Foreword

After the industrial revolution of the 18th century, the modern economic system gradually matured and rapidly expanded worldwide. In the 19th century, in the context of the Russian Far East Policy and the Japanese Mainland Policy, the Far East, Especially Northeast China, gradually became the focus of international competition due to its special geographical location and abundant natural resources. Under the joint participation of China, Japan, Russia and other countries, with the national military strength as the backing, the state capital penetration as the means, and the harbor and railway construction as the carrier, a fierce competition of rights and interests had been launched, which promoted the rapid modernization and urbanization of Northeast China, which gradually became the region with relatively developed social economy in the Asian, and even in the world in the early 20th century, that has important value and significance in the history of modern human social development and urban development. Based on this, the paper, taking the expansion of the Russian and Japan colonialism in the Far East in the early 20th century as the background, and taking the port and railway construction under the support of state capital as clue, with literature research methods and field investigation methods, systematically sorts out the urbanization process of modern Northeast China, explores the dynamic mechanism of national capital on regional urbanization, to enrich the history study of urban development in the modern Far East.

1. Natural and Historical Background of Modern Northeast China

In the early Qing Dynasty, according to the Sino-Russian Treaty of Nibuchu, the Northeast China, east to the Sea of Japan, southeast to the Tumen River, northeast to Okhotsk Sea and the Sakhalin Island, north to Waixinganling mountain, northeast to the Gelbiqi River, is extremely large. (Ping Bu etc., 1987) After the Second Opium War, China and Russia signed the Aihui Treaty and Beijing Treaty in 1958 and 1860, Russia occupied the vast land which north of Heilongjiang River and east of the Wusuli River. (Ping Bu etc., 1987) Northeast China of this paper, including today's Liaoning, Jilin, Heilongjiang provinces, and Chifeng, Tongliao, Xingan league in eastern Inner Mongolia and northeastern parts of Hebei Province. At the end of Qing Dynasty, where was the jurisdiction of the Shengjing general, Jilin general, Heilongjiang general, in addition, included the Inner Mongolia's Zhelimmu League, Zhaowuda league and Zhuosuotu league. During the Republic of China, where was Fengtian, Jilin, Heilongjiang Province and northeastern part of Rehe Province.

1.1. Natural Geographical Environment of Modern Northeast China

The development of modern cities in Northeast China is restricted and supported by natural geographical environment. In the Northeast China, the west part is the Daxinganling Mountains, the north is the Xiaoxinganling Mountains, and the east part is the Long White Mountains, which are the watersheds of the Liaohe, Sungari, and Inner Mongolia Plateau rivers, the Heilongjiang main stream, the Suifen River, the Tumen River and the Yalu River, (Fig.1)"the mountains are not very high, all have a large forest, one of the rich sources of Manchuria and Mongolia."(Fujioka, 1929) The central part of the three major mountains is the Songliao Plain, with the Changchun-Tongyu Line, the southern part is the Liaohe Plain, the northern part is the Songnen Plain, accounting for about one-third of the Northeast

China, also accounting for one-third of Chinese plain, “this vast wildness, producing a large amount of food, makes Northeast eligible to China’s barn.”(Chengjing Wang, 1947) “The vast plains are not only suitable for agriculture, but also buried unmeasurable minerals.” (Fujioka, 1929) In modern times, the reserves of coal had been explored were 15 billion tons, the iron ore reserves were not less than 2.7 billion tons, and the distribution of coal and iron resources is very concentrated, laying the natural foundation for the development of modern industry.

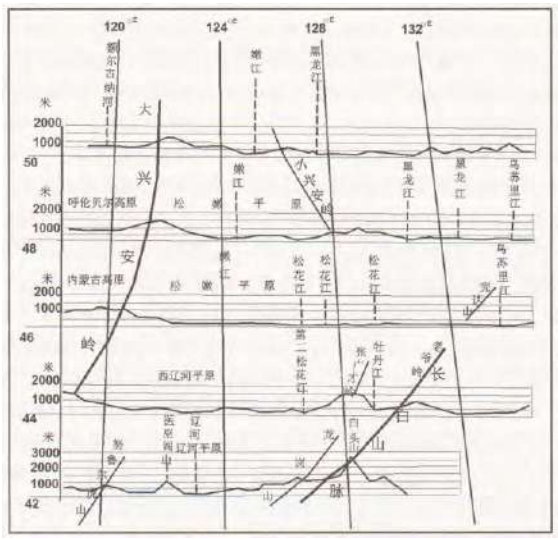

Figure 1 Schematic Diagram of the Natural Geographical Environment in Northeast China (Zhen Li, 1993)

1.2. Urban Development in the Early and Middle Qing Dynasty

Northeast China, as the birthplace of the Qing Dynasty, began to build willow walls in the early Shunzhi period, to prohibit the inside residents from crossing the wall for harvesting, farming, hunting and grazing. The willow walls started from the south of Phoenix city, turn to northeast to Xinbin, then turn to northwest to Kaiyuan, and then turn to the southwest to Shanhaiguan connecting the Great wall. (Fig.2) During the Kangxi period, the new willow walls were built from Kaiyuan to the Jilin. The interior of the walls was the jurisdiction of Shengjing general, one side of the walls was the Mongolian pasture, the other side is the royal paddock, the people of Han, Man and Mongolia were not allowed to cross the wall at will. The willow walls were roughly build along the boundaries of natural climate, vegetation, soil, etc. which were also the tangible economic zone, political system and cultural and traditional boundaries.

1.2.1. City Development Status in the Southern Liaoning Region

The middle and lower reaches of the Liao River in the southern Region of the Northeast China are located in warm temperate zones, with superior agricultural resources. In the first year of Shunzhi, a large number of Manchus moved to China proper, led to the land ridiculous. In the 10th year of Shunzhi (1653), due to financial difficulties, Liaodong Reclamation Recruitment Order was issued, Liaoyang Fu was set up to lead Liaoyang Xian and Haicheng Xian, and manage the local Han nationality. In the 7th year of Kangxi (1668), the recruitment was stopped and the ban was imposed, but it did not prevent the Han people from moving to the Northeast China. In the 10th of Xianfeng (1860), when Yingkou

was opened, Shengjing General governed Fengtain, Jinzhou 2 Fu; Liaoyang, Fuzhou, Yizhou, Ningyuan 4 Zhou; Xingjing, Xiuyan, Phoenix, Cahngtu, Xinmin and Jinzhou 6 Ting; Chengde Haicheng, Gaiping, Tieling, Kaiyuan, Jinxian, Guangning 7 Xian. All of these Fu, Ting, Zhou, Xian, the Han area were mainly distributed on the banks of the Liao River and the coastal Plain, where were the main agricultural area in the Northeast China.

Figure 2 Schematic Diagram of the Distribution of the Willow Wall (Qijun Zhang, 1966)

1.2.2. City Development Status in the Eastern Jilin Region

The eastern region of the Northeast China included the Long White mountain area, the vast plains of the middle and lower reaches of the Sungari River and the Heilongjiang River, where as the home of the Manchu ancestors, regarded as the holy land of Qing Dynasty, full of paddocks and forests. Expect the Manchus, the residents were mainly Daurs, Ewenkis, Oroqen and Hezhe, who lived in tribal forms, mainly fishing and hunting, the social economy was very underdevelopment. Since the early of Qing Dynasty, the southern margin of Jilin and Heilongjiang had agricultural development, relying on prisoners, traders, illegally entered Han people, and the people who stole gold mines.(Tingyi Guo, 1987) During the Sino-Russian Yaksa War, in order to resist the invasion of Russia, built the Post-road and a large number of sailors and craftsmen were introduced. With the increase of immigrants, in the 4th year of Yongzheng (1726), the Qing government set up Yongji Zhou, and set up Changning Xian in Bodune and Taining Xian in Ningguta, this was the first administrative setting in Jilin since the founding of Qing Dynasty. In the 13th year of Qianlong (1748), set up Jilinn Ting. In the 5th year of Jiaqing (1800), set up Chuangchun Ting. In the 15th year of Jiaqing (1810), set up Bodune Ting. In addition, the eastern region of Northeast China was rich in ginseng, suede, antler, medicinal materials and other valuable specialty products, there were active commodity transactions with China proper. Before the 6th year of Yongzheng (1728), Ningguta was the center of specialty trades such as the fur of the

northeastern ethnic groups, every spring, the ethnic groups in the lower reaches of Heilonngiang River came one by one, paying tributes such as suede, and selling all kinds of skins in exchange for production and daily necessities. In the 7th year of Yongzheng (1729), the Qing government decided that the tributes of the ethnic groups in the lower reaches of the Heilongjiang River and the Wusuli River were managed by the Sanxing, and then Sanxing replaced Ningguta and became the largest fur trade center. The valuable products in the eastern region were sold to China proper, and exchanged for the items needed for production and life, the business travels along the Post-road flourished and promoted the cities development. (Zhaokui Xu, 1959)

1.2.3. City Development Status in the Western Heilongjiang Region

The northern part of northeast China included most of the Songliao Plain, the Daxinganling Inter-span, and Keerqin sand land in the upper reaches of the West Liao River, where had long been the cradle of the northern nomads. In the vast middle and upper reaches of the Heilongjiang River, in order to defend against the invasion of Russia, the Qing government set up Heilongjiang General in the 22nd year of Kangxi, originally stationed in Heilongjiang City (Now Aihui), in the 29th year of Kangxi move to Mergen (Now Nenjiang). In the 38th year of Kangxi (1699), as the land of Murgen could not accommodate the more people, Heilongjiang General moved to Qiqihar, in 10th year of Xianfeng (1860), who commanded Heilongjiang, Mergen, Qiqihar 3 deputy generals, Hulunbeier deputy head general manager, Butehasuolun and Dahu 2 Zongguan. In this region, except for the Heilongjiang, Mergen, Qiqihar and the Post-way station, as well as the Hulan River basin and Jieya River Basin and the farmland of the prisoner, there were a few agricultural tribes, the vast region were nomadic areas and safari areas. Inner Mongolia was adjacent to Heilongjiang Province, mainly Zhelimu League, Zhaowuda League and Zhuosuotu League. The residents were mainly Mongolian, and nomadism was the main economic mode. In the early of Qing Dynasty, in order to obtain the necessary living and production materials, the Mongolians organized the merchants went to Guihua and sold the livestock and livestock products. Later，the merchants gradually went deep into the Mongolian grassland society, “loading groceries with big wheel carriage, travelling around Mongolia.” Most of the merchants also traded in the places where the population was concentrated such as the palaces, temples, and the Post-way stations, and some also used the larger temples to hold temple trade. The increase of merchants and the prosperity of trade had promoted the rapid development of commercial cities in Mongolia. Especially from Shengjing, the Bahu Road, going north, passing the Fakumen, Zhengjiatun to Qiqihar, where mostly was grassland, the traffic conveniently, had become the important trade path. The Mongolians on the Hulunbeier Grassland often traveled thousands of miles to Qiqihar for trading, afterwards, due to difficulties in travel, they selected the land on the bank of Yimin River, where was fertile, traffic conveniently, constructed several earthen houses, to attract Shanxi merchants, and gradually developed into the Mongolian trade centre, now Hailar.

2. Modern City Development Based on State Capital Competition

The Northeast China is bordered by Japan in the south and Russia in the north. They were all ambitious countries in modern times. Japan was trying to realize the Mainland Policy since the Meiji Restoration. Russia intended to realized Peter the Great’s Eastern Estuary Plan. So

Northeast China became the battlefield for Japan and Russia hegemony in the Far East. Japan and Russia had invaded the Northeast China with Military means and then carried out large-scale capital invasions to ensure the realization of their military and political goals. Modern Japan and Russia's economic aggression was based on the intake of port and railway construction rights, focusing on railway operation and resource development, controlling trade circulation, and conducting colonial investment, especially the competition for the construction and operation rights of the port and railway, rapidly promoted the modern urbanization of the Northeast China.

2.1. Russia's Far East Policy and Capital Expansion

2.1.1. The Far East Policy of Modern Russia

In history, Russia was a continental empire, during the period of Peter the Great, who made the development strategy to find the seaport on east and west sides. In the 10th year of Xianfeng (1860), according to Sino-Russian Beijing Treaty, Russia invaded the vast area east of the Ussuri River and built Vladivostok into the military port for the Russian Far East Fleet. Since the 1980s, due to the continuous setbacks in the expansion of Europe and Central Asia, Russia actively operated the Far East. The main objectives of the Far East Policy: First, invaded Korea and Northeast and Northwest China, and took where as the basis for further encroachment on China; Second, with UK, USA and Japan to compete for hegemony in the pacific, dominating the Far East.

2.1.2. The Chinese Eastern Railway Company and the Construction of the C.E.R. and Dalian

After Russia invaded Haishenwai, renamed to Vladivostok, meaning "controlling the East." The west and southwest of Vladivostok is close to China and Korea, east facing Japan across the sea, and the south is adjacent to Peter the Great Bay, which has the important strategic position, but it has a freezing period of up to five months, this largely limits the actions of Russian warships. Furthermore, Russia planned to build the Siberian Railway, if it could pass Northeast China directly to Vladivostok and had an excellent non-freezing port, that would be ideal for Russia to implement the Far East Policy. After the Sino-Japanese War, Russia had made meritorious efforts to "force Japan to return the Liaodong Peninsula", in the 22nd year of Guangxu (1896), signed the "Sino-Russian Secret Treaty" with China, and obtained the right to construct the C.E.R. in Northeast China. (Ping Bu etc., 1987) In the same year, China and Russia signed the "Contract of Cooperation of the C.E.R. Company", "Chinese will invest 5 million Kuping silver, establish the partnership with the Russo-Chinese Bank, the profits and losses will be recognized as shares." "the Russo-Chinese Bank is responsible for the construction and management of the railway, and form the C.E.R. Company." (Ping Bu etc., 1987) In the 24th year of Guangxu (1898), Germany occupied Jiaozhou Bay, Russia took the opportunity to dispatch the fleet occupy Lushun. In the same year, China and Russia signed the "Lushun and Dalian Land Rent Treaty", the first paragraph stated: "in order to preserve the Russian Navy's sufficient land use on the northern coast of China, China leases Lushunkou, Dalian Bay and Nearby waters to Russia." The eighth paragraph stated: "from the date of signing, China allow build a branch Railway form a station of trunk railway to Dalian Bay." (Ping Bu etc., 1987) Since then, Russia realized the dream of seeking an excellent non-freezing port in the Far East and the right to build the southern branch. In August 1899, the Tsar issued the decree on the construction of Dalian Freeport, and took it as the basis for operating the Northeast China. In the 27th year of Guangxu (1901), the C.E.R.

trunk line from Manzhouli to Suifeihe and then to Vladivostok was completed and opened to traffic. In the 29th year of Guangxi (1903), the southern branch from Harbin to Dalian and Lushun was completed and opened to traffic, and the situation of the Northeast China was greatly changed. (Fig.3) At this time, Russia was in the heyday of the Northeast China, who connected the C.E.R. to Europe via the Siberian Railway and attracted the world's goods to Dalian to import and export.

Figure 3 Northeast China Railway Network in 1907 (Author Self-painting)

2.1.3. Russia Controlling the Northern Region based on Port and Railway Facilities

After the Russo-Japanese war, Russia lost all the rights in the southern region, in order to ensure the rights and interests in the northern region, who shifted the focus from Dalian to Vladivostok, and used the C.E.R.to control the northern region of Northeast China. From the perspective of specific economic behavior, the C.E.R. took Harbin as the midpoint and was divided into three parts: the west line (Harbin to Manzhouli), the south line (Harbin to Changchun), and the east line (Harbin to Suifenhe). The west line across Lubin, Hulun, Buxi, Longjiang, Anda, Zhaozhou, Hulan seven Xian, shipping goods account for two-thirds of the Heilonngjiang province. (the C.E.R. Economic Investigation Bureau, 1927) The east line, crossing the eastern mountains, was dominated by forestry output. The south line, the area is densely populated, the goods transported were mainly produced along the line. In addition, the land in the lower reaches of the Sungari River was gradually developed in the late Qing Dynasty. The C.E.R. and Sungari River shipping had established the intermodal transport. The grain produced along the Sungari River were transported by inland water to Harbin and the transported to Vladivostok via the C.E.R. (Lengjiu Yun, 1935) In order to strengthen the central position of Vladivostok and to confront the Japanese-controlled Dalian, The C.E.R. Administration had established the double freight rate standard for the south line. In order to obtain goods from Changchun to Harbin and east to Vladivostok, the freight fare of the south line was extremely low. At the same time, in order to prevent the goods in the southern part from entering the northern part via the South Manchuria Railway (SMR), which freight fare of the south line was extremely high. In 1917, the Russian October

Revolution, Vladivostok was occupied by the Allies, the port facilities were greatly damaged, and the Ussuri Railway and the C.E.R. were almost completely out of service. In 1921, the domestic situation of the Soviet Union resumed stability, the Ussuri Railway and the C.E.R. returned to besiness, and Vladivostok's trade also gradually recovered. In 1931, the Jilin-Huining Railway was opened to traffic, all the cargo was transported southward. In 1935, the Soviet Union had to sell the C.E.R. to Japan.

2.2. Japan's Mainland Policy and Capital Expansion

2.2.1. the Mainland Policy of Modern Japan

In 1868, Japan's Meiji Restoration, under the guiding principle of "expand the territory and establish the national prestige in the world," formulated the Mainland Policy, that is, using force to invade the neighboring continent. In 1985, the Sino-Japanese War broke out, Japan invaded the Liaodong Peninsula, and was interfered as conflict with the Russian Far East Policy. In 1905, after the Russo-Japanese War, Japan inherited all the rights of Russia in the southern region of Northeast China. In 1927, Japan clearly stated the aggression policy: "want to conquer the China Proper, must first conquer the Manchuria and Mongolia." After the Manchurian incident in 1931, Japan fully encroached on the Northeast China, in the course of its aggression and expansion, "Japan want to invade Manchuria and Mongolia, whether the politic, economy or military, all need rely on railway, therefore, the railway actually ranks first in Manchuria and Mongolia issue." (Qi Zhu, 1930)

2.2.2. South Manchuria Railway Company and the Construction of "Three Ports and Three Lines"

In 1905, after the signing of the Portsmouth Treaty between Japan and Russia, Japan decided to follow the British East India Company, backed by the strength of the state, and carried out railway management in the form of private company. (Chijun Hu, 2011) On June 7, 1906, the Japanese government established the South Manchuria Railway Company (SMR Co. Ltd), and passed the "SMR Co. Ltd Regulations" on August 14. According to the regulations, SMR Co. Ltd would operate the railways and affiliated businesses in northern region of Northeast China, the company's capital was 200 million yen, among which, the government invested 100 million yen (50% of the shares). Although Japan recognized that SMR was the joint property of China and Japan, but its vice presidents and directors were all appointed and removed by the Japanese government, the business policies were also decided by the Japanese government, and half of the company capital was state capital, all of these determined that it was entirely a national policy institution. As the first president of SMR Co. Ltd, Goto Shinpei said; "originally established SMR Co. Ltd and recommended me as the president, probably not to regard the SMR Co. Ltd as a profitable cause, its essence was the vanguard of the implementation of the imperial colonial policy or the empire development." (Fuquan Zhang, 1989)

In 1910, in order to compete with Russia, after occupied Korea, Japan established "Three ports and Three Lines" program for the most convenient contact with Japan. First, the south port and south line, namely Dalian port, SMR and Andong port, Angdong-Fengtian railway. After 1906, Japan took Dalian port and SMR as the basis for capital expansion, in order to control the cargo transportation of south of Changchun and compete with the C.E.R., a special freight policy of 'Dalian Centralism' was adopted. During the Russo-Japanese War, Japan built the light railway from Andong to Fengtian and forcibly rented it after the war. In

1911, the Yalu River Railway Bridge was completed, by 1913, the three-line transport of "Japan, Manchuria and Korea" was realized, the goods could be transferred from the Japan Tieshanyang railway to Busab, then to Xinyizhou railway of Korea, and then connected Andong-Fengtian railway, directly to Fengtian of Northeast China. Second, the west port and west line. In 1913, the Yuan Shikai government and Japan signed "the Summary of Railway Loan Appointment Scheme," Japan proposed the "Manchuria and Mongolia Five-Railways" plan, which included the Taonan-Chengde Railway. (Ping Bu, 1987) In 1918, the Duan Qirui government and Japan signed the "Manchuria and Mongolia Four-Railways Loan Preparation contract," Japan proposed the construction of Taonan-Rehe, and the branch to someone port. (Yuou Lan, 1932) After the establishment of the Manchukuo, the Huludao Port was expanded, and the Jinzhou-Chengde railway was built, so far, the western region of Northeast China had a complete railway network and the nearest port. Third, the east port and east line. East port took Korea Qingjin port as main port, and took Luojin port and Xiongji Port as auxiliary ports. East line planned to use the Cahngchun-Huining railway as the main line, with the Changchun-Dalai railway, Yanji-Hailin railway, Jilin-Wuchang railway as the nutrition line. (Tongwen Wang, 1933) Japan's construction of the Jilin-Huining railway had experienced a long history, in 1923, they built the Tianbaoshan-Tumen light railway in the name of mining. (Yuou Lan, 1932) By 1933, the Dunhua-Tumen railway was completed, in 1935, luojin port was put into use, the mileage from the Japan via the Jilin-huining railway to center of Northeast China was greatly shortened.

2.2.3. Japan Controlling the Southern Region Based on Port and Railway Facilities

On the basis of monopoly on ports and railway, Japan actively promoted the export of bean goods to the world, and replaced national products with Japanese goods. In 1913, SMR Co. Ltd carried out mixed storage and transportation of soybeans, soybean cakes, soybean oil and wheat, to strengthen the control of the transportation and marketing of agricultural products in Northeast China. With the cooperation of large Japanese commercial companies and many small and medium-sized commercial enterprises, SMR Co. Ltd had monopolized and controlled the commodity circulation network from ports, railways and hinterland villages.

At the beginning of the establishment of SMR Co. Ltd, the investment was mainly focused on railways, ports and other infrastructures, after the First World War, began to strengthen investment in the industry and mining use the profits of transportation. Before 1931, Japan's industrial investment in Northeast China mainly carried out by SMR Co. Ltd, accounted for 60%. (C. F. Remer, 1953) SMR Co. Ltd invested 37.96 million yen in Anshan Iron Plant in the two years of 1918 1919, accounting for 80% of the total profit. SMR Co. Ltd adopted the comprehensive operation principle, in addition to railway, port and mine, also including machinery, electricity, gas, coke and iron. At the same time, SMR Co. Ltd also invested Japan's private industry, especially the defense industry and emerging industries, for example, which directly participated in the South Manchuria Sugar Company, Manchuria and Mongolia Wool Company, Manchuria and Mongolia Fiber Company, they were known as Fengtian three major companies. By 1931, SMR Co. Ltd had actually formed a huge trust, including large and small enterprises, almost monopolized all the heavy industry in Northeast China.

2.3. China's Un-Treaty Port Policy and Capital Competition

2.3.1. Un-Treaty Port Policy in the late Qing Dynasty

Since the Sino-Japanese War, Japan and Russia had successively invaded Northeast China. In the 26th year of Guangxu (1900), the Boxer Movement broke out, Russia occupied the entire Northeast China. The important minister of the late Qing Dynasty, Zhang Zhidong, governor of Hunan and Hubei province, proposed the Qing Government: "if the Northeast China open to the world and trade with all the countries, all the interests of industry, commerce and mine will be enjoyed by all countries, we collect the tax, that is what Westerners called the opening for trade, also is the mutual containment strategy I proposed." (Modern History Data Editing Group, 1980) The Qing Government adopted Zhang Zhidong's proposal, rewarded the interests of the railway, mining, industry and commerce, and actively contacted the UK, USA, Japan to restrict Russia, at the same time, these countries had also prompted the process of opening up the Northeast China. In 1903, China and USA signed the "Continuation of the Treaty on Trade and Transportation," China opened two Un-Treaty Ports, Fengtian and Andong. After the Russo-Japanese War, in order to coordinate the contradiction among Japan, Russia and other countries in Northeast China, Zhang Zhidong once again proposed the response of "opening up everywhere". The Qing Government quickly established the principle of opening up Northeast China. In December of the same year, China and Japan signed the "Convention Treaty of the Northeast China" and "attachment". The first paragraph of the "attachment" stated: "Chinese government promised, after the retreat of Japanese and Russian Troops, that will open the following Un-Treaty ports: Phoenix City, Liaoyang, Xinmintun, Tieling, Tongjiangzi, Fakumen of Fengtian province; Changchun, jilin, Harbin, Ningguta, Hunchun, Sanxing of Jilin province; Qiqihar, Hailar, Aihui, Manzhouli of Heilongjiang province." (Ping Bu, 1987) Since then, the competition between the various countries including Japan and Russia in Northeast China had gradually turned into capital invasion from military invasion. In 1909, China and Japan signed the "China-Korea Tumen River Border Treaty," and open Longjingcun, Juzijie, Toudaogou and Baicaogou. (Ping Bu, 1987) In 1914 and 1916, Jinxian, Huludao, Taonan, Liaoyuan, Kaiyuan, Xian of Fengtian province and Chifeng of Rehe opened as Un-Treaty ports, the international trade network had been formed throughout the Fengtian province and Jilin province and parts of Heilongjiang province and Rehe province.

2.3.2. Construction of Huludao Port and the East, West and South Three Trunk Lines

After the Russo-Japanese War, in the situation of the southern region and northern region being controlled by Japan and Russia Respectively, the Qing government clearly recognized the importance of port, railway construction and management rights, hoped to use the "open door" proposal put forward by UAS to counter Japan and Russia. In terms of competition in capital, the Harriman Railway Acquisition Plan, Xinmin-Fakumen Railway Plan, Jinzhou-Aihui Railway Plan, and the Knox Railway Neutralization had been proposed, due to the change of international relations, the resolute opposition of Japan and the compromise of the Qing Government, these plans all soon died or halfway. (Chijun Hu, 2011) In the late Qing Dynasty and the early Republic of China, in order to resist the economic monopoly of Japan and Russia, China planned and implemented the Huludao port and the East, West and South three trunk Line construction plan. First, Huludao port construction plan. Huludao, about 12 kilometers form Lianshan station of Beijing-Fengtian railway, is a rare non-freezing port in the Bohai Bay. In 1908, when Xu Shichang was the governor of the Northeast China, he believed that a good seaport and a complete railway network were the key to maintaining the rights of the nation, therefore, the British engineer xiusi was hired to survey the Bohai Bay and chose Huludao as the port. Construction began in August 1910, and

stopped due to the Revolution of 1911. In 1920, Zhang Zuolin and the Beijing government negotiated that the central government and the local government each invest 5 million yuan to build the port, later as the civil war, stopped again. In January 1930, the Northeast China Transportation Committee decided to continue construction and contracted with the Dutch construction company, which was scheduled to be completed in five and a half years and built into a large port with an annual throughput of 5 million tons. Second, the east, west, south three trunk lines plan. In May 1924, in order to counter the SMR and the C.E.R., the Northeast Fengxi Regime established the Northeast Transportation Committee, which planned to build 35 railways up to 10,000 kilometers in 15 years, to form the Chinese independent railway network, including: the east trunk line, from Huludao via Jinzhou, Shenyang, Hailong, Jilin, Wuchang, Yilan to Tongjiang in the lower reaches of Hilonngjiang River; the west trunk line, from Huludao via Jinzhou, Dahushan, Tongliao, Taonan, Angangxi, Qiqihar, Nengjiang to Heihe; the south trunk line, from Huludao, via Chaoyang, Chifeng to Duolun of Inner Mongolia. In 1921-1931, the northeast Fengxi government, using national capital and technology, completed 10 railways including Dahushan-Tongliao railway, Fengtian-hailong railway, Jilin-hailong railway, Hulan-Hailong railway, Qiqihar-Keshan railway, Taonan-Suolun railway etc., the total length up to 1,521.7 kilometers, accounting for 25% of mileage of Northeast China. (Naikun Yang, Yanxiong Cao, 2005) (Fig.4)

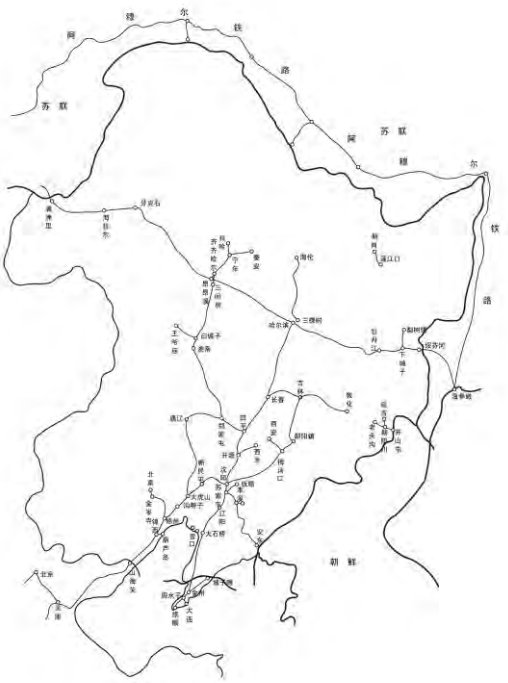

Figure 4 Northeast China Railway Network in 1931 (Author Self-painting)

2.3.3. China's Economic Confrontation Rely on Port and Railway

At the end Qing Dynasty and the beginning of the Republic of China, the Northeast China local government built Chinese own railway, breaking the situation that foreign capital monopolized the railway network, forming the SMR network under the jurisdiction of Japan, The C.E.R. network jointly managed by China and Russia, and China own self-built railway network, China had supervision and management right over two railway networks. In December 1929, in order to recover the railway controlled by the Japan, the Fengxi authority

formulated the cargo transport plan of the west four lines (Beijing-Fengtian railway, Siping-Taonan railway, Taonan-Angangxi railway and Qiqihar-Keshan railway). In January 1931, the east four lines (Beijing-Fengtian railway, Fengtian-hailong railway, Jilin-Hailong railway and Jilin-Dunhua railway) cargo transport plan was formulated, in this way, carried out fierce competition about freight rate and cargo with SMR. China railways used the silver standard to calculate the price, at that time, the price of silver was low, so the freight rate of China railway was lower than that of SMR, which based on gold standard. In addition, Fengxi authority also encircled the SMR through various administrative means, for example, set tax gate around the SMR subsidiary, all goods were taxed, as a result, the operation of the SMR became bleak, other industries, such as coal and iron, also been severely affected. For example, in 1930, the total revenue of passenger and cargo transportation of SMR was 91.307 million yen, decreasing 30.796 million yen from the previous year, SMR Co. Ltd had to adopt austerity policy and cut staff. (Shixuan Jin, 1932) In the four years before the Manchurian incident, is “the golden age of Beijing-fengtian railway, the annual profit reached more than 50 million yuan.” (Yusi Wang, 1932) As the monopoly of Dalian port and the SMR was challenged, Japan finally launched the Manchurian Incident and resorted to force to implement the Manchuria and Mongolia policy.

3. Urbanization Mechanism and Dynamic of Modern Northeast China

In early and middle Qing Dynasty, the society in Northeast China was in the stage of natural development, city is still in its infancy, the political and military functions were the fundamental driving force for the cities. During this period, in the southern region of Northeast China, some towns gradually developed into political centers due to historical foundations and immigrants, such as Fengtian, Liaoyang, Haicheng, Jinxian, Guangning and Kaiyuan etc. In order to consolidate the frontiers, the Qing government carried out military immigration and agricultural cultivation, and established military towns, which were the basis of the cities formation in northern region of Northeast China, such as Ningguta, Jilin, Bodune, Aihui, Qiqihar, Mergen and Hulunbeier, etc. In modern times, with the invasion of foreign political, military and economic forces, opening port for trade, constructing port and railway infrastructure, stopping ban, a large number of immigrants, and reclaiming the land were the driving forces of the city development in Northeast China.

3.1. Urbanization Mechanism of Modern Northeast China

3.1.1. the Intensive Birth of Modern Commercial Cities

In the early and middle Qing Dynasty, the cities in Northeast were distributed along the Post-roads, rivers and frontiers, and urban functions were dominated by politics and military. In the 8th year of Xianfeng (1858), according to the Sino-British Tianjin Treaty, Yingkou became the international trade port in the Northeast China. Under the circumstance that the western countries’s commodities dumping in and Northeast China products exporting to the world, the economic functions of Yingkou was increasing day by day, which meant that the modern cities were completely different from the traditional era in terms of the driving force. In the 24th of Guangxu (1898), Russia rented Dalian and announced open to world as free port. Later, in order to prevent Russia and Japan from occupying the Northeast China, the Qing government adopted the policy of “All-round open, countries contain”, opened up

about 30 Treaty ports and Un-Treaty ports. (Fig.5) Except for a few cities such as Phoenxi, Ningguta, Sanxing, and Aihui, which still maintained their original scale and even decline due to geographical location and improper site selection, under the promotion of the external economy, most of the cities had accelerated the development, and expanded the scale. The city form has been spatially displaced due to the planning of commercial districts, forming a new core that was strongly contrasted with the old city. The city functions were mainly from traditional politic and military to economy and politic.

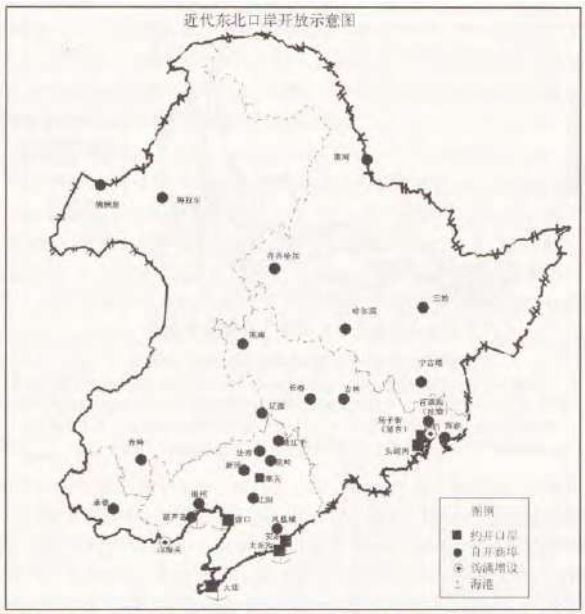

Figure 5 Schematic Diagram of Modern Northeast Opening Port (Yufu Jin, 1944)

3.1.2. the Rapid Rise of Hub Cities along the Railway

At the beginning of the construction of the C.E.R., according to the sixth paragraph of “the Contract of Cooperation of the C.E.R. Company”, “where the company builds, manages and protects the railway, and the land need to mine sand, stones, lime, etc. near the railway, if it is official land, it will be given by government, regardless of the price; if it is peoples land, it will be paid by the company at the current price, once in a lump sum or in a yearly basis.” (Ping Bu, 1987) So that Russia can form the specific railway subsidiary through various means as free occupation, purchase, and long-term lease. In fact, regardless of the C.E.R. or the SMR, their railway land was expanding through various legal or illegal means, far beyond the area required for railway construction and operation, included the land used for the city, for farm, for forest and for mine. The railway subsidiary was similar with the concession and leasehold established by western countries in China, which had had an important impact on the rise, transformation and economic development of modern city of Northeast China. (Weirong Cheng, 2008) The Russian railway subsidiary area had reached more than 1,300 square kilometers. On the eve of the Russo-Japanese War, the C.E.R. trunk line and the southern branch line had formed a series of railway hub cities, such as Suifenhe, Yimianpo, Hedaohezi, Ashihe, Manzhouli, Hailaer, Boketu, Angangxi, Anda, Yaomen, Sanchahe, Gongzhuling, Dashiqiao etc. (Xiaofan Qu, 2001) The SMR subsidiary area increased to 482.8 square kilometers in 1931, and there were 30 cities covering more than 1 square kilometer. Since 1907, the SMR Co. Ltd successively formulated and implemented the city plan for the key railway subsidiary of the SMR, such as Wafangdian, Gaiping, Xiongyuecheng, Dashiqiao,

Haichheng, Yingkou, Anshan, Liaoyang, Benxihu, Fushun, Andong, Fengtian, Tieling, Kaiyuan, Sipingjie, Gongzhuling, Chuangchun, etc. (Xiaosong Wu, 1999)

In addition, the railways built by the foreign capital, Sino-foreign capital and national capital in the eastern region and southwestern region in the early 20th century also had a significant impact on the development of modern Northeast China cities. The foreign capital and Sino-foreign capital railways mainly included the Andong-Fengtian railway, Jilin-Changchun Railway, Jilin-Dunhua railway, Siping-Zhengjiatun railway, Zhengjiatun-Taonan railway and Tannan-angangxi railway. The national capital railways were mainly the east and west lines, as well as short line such as Hulan-Hailun railway in Heilongjiang province. The east line included the Fengtian-Hailong railway and Jilin-Hailong railway; the west line from Dahushan to the west via Zhangwu to Tongliao, at Tongliao connected the Sino-Japanese Capital Zhengjiatun-Taonan railway and Taonan-Angangxi railway, and then north to Qiqihar-Keshan Railway. The Hulan-Hailun railway, from Harbin Majiakou through Hula, Suihua to Hailun. The railway drove the rapid growth of passenger and cargo transportation, promoted economic development and population growth, and made some stations develop into modern cities.

3.1.3. the Rapid Form of Modern Industrial Cities

In the early and middle Qing Dynasty, the industries in Northeast China were mainly traditional handicrafts and small coal industries. By the end Qing Dynasty, along with the large capital investment of Japan and Russia, the modern industrial and mining industry in Northeast China developed rapidly. Modern industrial enterprises used machinery to carry out large-scale social production, absorbed a large amount of labors, and promoted the development of population and cities. Fushun, Anshan, Benxi in the southern region and Zhalainuoer and Hegang in northern region were the typical representatives. Anshan is a typical city formed by Japanese capital for mining industry in the southern region of Northeast China. In August 1909, Anshan Discovered iron ore. In 1917, the Anshan Iron Institute was established by the SMR Co. Ltd, there were huge smelting furnaces, hot blast stoves, power station, and mechanical fields. In modern East Asia, it gradually became the second largest iron center after Japan's gossip, and it was known as the "Iron Capital". (Zhenfu Li, 1926) By the eve of Manchurian incident in 1931, the population had reached more than 20,000, and the prototype of Anshan city had formed. Zhalainuoer, in the eastern of Manchouli, discovered coal in 1901. According to the fourth paragraph of the Sino-Russian "Renewal Contract of the C.E.R. Company", "allow to mine the coal needed for railway, where the railway passing by." In the 28th of Guangxu (1902), started to construct the well. In 1905, the annual output reached 460,000 tons. Zhalainuoer was the center of the mining area, and the important station on the west line, it had rapidly developed into a coal mine city in modern times. Hegang was located on the left bank of the lower reaches of the Sungari River. Coal fields were discovered in 1914. In 1918, Chinses merchants raised funds to build mines. "the coal produced by Hegang is good, 140 Kilometers away from Harbin and only 17.5 Kilometers away from Sungari River." (China Second Historical Archives, 2001) In 1926, the railway reached the Lianjiang port on Sungari River, the traffic conditions were greatly improved, the number of workers and residents was increasing, and the business developed. In 1929, Hegang Coal Mine Company planned 5 streets as a commercial site. Under the interaction of the expansion of coal mines and commercial development, Hegang has become an emerging mining city.

3.2. Urbanization Dynamic of Modern Northeast China

3.2.1. the Special Tariff Exemptions and Concessions Policy

After the opening up of Treaty ports and Un-Treaty ports, the Northeast China formulated a series of tariff exemption and concession policies under the further requirements of Russia and Japan based on the extremely low tariffs of other ports in China, that promoted the rapid development of the society and the city in Northeast China. First, the land tariff system. In 1862, the Sino-Russian Land Trade Regulations stipulated that the border trade between the two countries would not be taxed within 50 kilometers. In 1907, China and Russia signed the "North Manchuria Taxation Regulations," stipulated that all goods transported by railway to the station within 50 kilometers of the junction will not be taxed, the tariffs payable in other regions shall be implemented on the principle of less than one-third. In the northern region of Northeast China, 17 cities including Harbin, Manzhouli, Hailar and Qiqihar had been implemented. (Ping Bu, 1987) Second, Exemption of the second tariff. The so-called exemption of the second tariff referred to goods that had already paid customs duties in a port in China proper, when they re-entered the other ports, that would not pay again. Under the recommendation of the Chief Tax Officer Hurd, in 1907, the Qing government promulgated the "Northeast China Ports cancel the second tariff License method", stipulated that all foreign goods in Tianjing, Niuzhuang, Andong, Dalian, etc. have already completed importing formal taxes, and that Chinese goods have already completed re-imported half-taxes, if they are transported to port of Northeast China, no matter how they are carried, all license should be issued and no tariffs would be re-applied. (The SMR Economic Survey Association, 1987) In the subsequent Sino-foreign trade, all the ports in Northeast China were implemented according to this method. Under the above-mentioned tariff exemption and concession policies, the Lushun and Dalian area in the southern region, the C.E.R. subsidiary and Sino-Russian border area, Andong and China-Korea border area, and the Un-Treaty port all had developed rapidly.

3.2.2. Capital Competition among China, Japan and Russia

Capital is the blood of social and economic development. After the open of modern Northeast China, fierce capital competition had been launched around port, railway construction and foreign international trade, forming the Chinese Yingkou Silver Financial System, the Japanese Gold Yen Financial System and the Russian Ruble Financial System, the competition of capital had rapidly promoted the social and economic development of the Northeast China.

First，Yingkou Furnace Silver financial system. In the 11th of Xianfeng (1861), Yingkou opened up and the business flourished, various domestic and foreign silver currencies poured in and there was an urgent need to establish a suitable monetary system. In the same year, the first silver furnace appeared in Yingkou. In the 3rd year of Tongzhi (1864), Yingkou's standard currency Yingbao was produced, and other currencies were exchanged into Yingbao for trading. In the early years of Guangxu, the Yingkou Furnace Silver was issued, a check credit currency. In the 9th year of Guangxu (1883), Yingkou Furnace Silver financial system was mature, that is, merchants accessing Yingbao to the silver furnace, all need be registered and can be transferred to other silver furnace accounts, the account is settled on the first day of the third, sixth, ninth, and twelfth month of the calendar, and interest is paid for the deposit at the expiration date.

Second, the Russian ruble financial system. After the Sino-Japanese War, in order to repay the compensation for Japan, in the 21st year of Guangxu (1895), China and Russia signed the "Four Percent Loan Contract" and form the Russo-Chinese Bank. The bank regulations promulgated by Russia stipulate that the bank is not only responsible for the general banking business of Russia in China, but also responsible for collecting various taxes in China, operating enterprises related to local and national treasury; casting the currency permitted by the Chinese government, returning the interest of the Chinese government's public debt; laying railways and wires in China. Any draft contract signed between the bank and the Chinese government needs to be submitted to the Russian Minister of Finance for approval in advance, in fact, it is the agent of the Russian Ministry of Finance in China. (Ping Bu, 1987) In the 22nd year of Guangxu (1896), China and Russia signed the "Contract of Cooperation of the C.E.R. Company", stipulated "Russo-Chinese Bank will be responsible for constructing the railway. And then Russia took the C.E.R. as basis to issue the ruble. (Bank of China General Administration, 1987) At the beginning of the establishment of the Russo-Chinese Bank, the registered capital was 6 million rubles, after several times direct government investments, in the 3rd year of Xuantong (1911), the circulation reached 100 million rubles in Northeast China. (Shutong Hou, 1931) Since the ruble entered the Northeast China to 1917, the Russo-Chinese Bank had the greatest influence in the financial industry, and has become the hub and medium of capital flow among Europe, the province of China proper and northern region of Northeast China.

Third, the Japanese gold yen financial system. After Russo-Japanese War, the SMR Co. Ltd took over the railways and various undertakings in the southern region of Northeast China, in order to cooperate with the expansion of the Japanese forces represented by the SMR Co. Ltd, Japanese financial institutions entered Dalian on a large scale, and gradually expanded along the SMR with Dalian as the base. After the Sino-Japanese War, the trade between Japan and Northeast China became increasingly prosperous. In the 26th year of Guangxu (1900), Yokohama Specie Bank first set up branch in Yingkou to operate trade exchanges between Japan and Northeast China. In the 20th year of Guangxu (1902), a silver check of "pay once see" was issued. After the Russo-Japanese War, in 1906, the Japanese government granted it the right to issue silver vouchers, and stipulated that the silver vouchers were the legal currency of the Japanese in Northeast China, and were forcibly circulated in Dalian and the SMR subsidiary. With the expansion of business, Yokohama Specie Bank had successively established branches in Lushun, Liaoyang, Tieling, Anton, Changchun, Harbin etc. business scope had expanded greatly. Then the Japanese government granted it the responsibility of acting as the national treasury, therefore, at that time, Yokohama Specie Bank was actually the central bank of Japan in Northeast China. In the 2nd year of Xuantong (1910) the Japanese government granted it concurrently operated long-term real estate loans on the grounds that there no similar financial institutions. In 1917, Terauchi Masatake cabinet reorganized Japan's finances in Northeast China, Yokohama Specie Bank was responsible for issuing silver vouchers, specializing in trade exchanges. Korea Bank was in the position of the central bank, acting as treasury, issuing gold vouchers, which is the central institution of commercial finance. The Toyo Colonial Society operated real estate investment and handled long-term industrial loans. Three banks had a division of labor and cooperation, each with a focus on field, under the unified guidance of the Japanese government, they work together to expand.

3.2.3. Export-Oriented Port-Railway Network-Hinterland City Structure

In the early and middle Qing Dynasty, most of the cities in Northeast China were distributed along the waterway traffic line or the land Post-road traffic line, and mainly military and political towns, although there were also close economic activities at that time, mainly followed the main political and military route, from Beijing via Shanhaiguan, Jinzhou, Shengjing to Jilin, and then from Jilin to Qiqihar, Sanxing and Ninggua respectively, was an inward-oriented defensive cities structure centered on Beijing. With Treaty port and Un-Treaty port opening and the construction of the C.E.R., Northeast China, as the water-land transport region of the Siberian Railway in the Far East, had undergone the qualitative transformation of the internal mechanism of the cities system development. Especially since the construction of the C.E.R., the railway transportation line centered on the coastal, riverside or borderside Treaty port or Un-Treaty port had been gradually extended, the medium cities and small cities along the railway were generated and rapidly developed due to the transit and distribution of the goods. First, Dalian-SMR city system. After the Russo-Japanese War, Dalian, as a port gateway city, stringed up town nodes of different levels along the railway, and formed the outward-oriented “hub-network” city structure. According to the SMR Co. Ltd investigation, the cargo of Dalian port in the 1920s swallowed the area around the SMR between Dalian and Chuangchun, as well as the surrounding areas of the branch railways such as Sipingjie-Taonan railway, Taonan-Aangangxi railway, Jilin-Chuangchun railway, Jilin-Dunhua railway, etc. (The Investigation Division of the SMR Ministry of Civil Affairs, 1923) Especially the Shenyang and Chuangchun along the railway, they were not only the core of the region, but also the important nodes affecting the secondary cities such as Siping, Jilin, Tongliao, Taonan etc. Second, Vladivostok-the C.E.R. city system. Harbin, Manzhouli and Suifenhe in the northern region of the Northeast China were the port cities, their radiation space is the hinterland of the south line, west line and east line of the C.E.R. with Harbin as the center. At the same time, the C.E.R. and the Zhuhe and Yilan etc. along the lower reaches of the Sungari river had frequent cargo transportation. (The C.E.R. Economic Investigation Bureau, 1927) In addition, the port city of the eastern region, southeastern region and southwestern region of Northeast China was also connected to the hinterland by railway, formed the “port-network” city system. For example, during this period, Andong became the hub city in the southeastern region, and was closely connected with the cities along the Yalu River, meanwhile, the hinterland cities of the Andong-Fengtian railway also developed rapidly, such as Huanren, Tonghua and Linjiang etc. (The Industrial and Commercial Division of the SMR, 1927)

Conclusion

In the early and middle period of Qing Dynasty, Northeast China, as the birthplace of Qing government, implemented the ban policy for a long time, the city development mainly relied on the Post-road system construction centered on Beijing-Shengjing-Jilin, the driving force for city development was mainly political and military. At the end of the 19th century, with Europe as the center, international capital actively expanded in the world, Russia formulated the Far East policy and built the Siberian railway to the Far East, Japan formulated the mainland policy and expanded to Korea and China, Northeast China gradually became the focus of the international geopolitics. Japan and Russia have resorted to force to invade Northeast China, after the construction of the C.E.R., that gradually evolved into the economic invasion based on state capital investment and competition for port and railway

construction rights and management rights. In order to maintain the political rights in Northeast China, the Chinese government implemented the "Open Door" policy, successively opened up about 30 Treaty Ports and Un-Treaty Ports, and raised national capital to build China's own port and railway network. In the fierce competition among China, Japan, Russia and other countries, Formed the SMR system centered on Dalian, the C.E.R. system centered on Vladivostok, the Chinese railway system centered on Huludao, also laid the city structure of the "hub-railway network-hinterland" model centered on the imported cities of the Northeast China, which promoted the development of commercial cities, hub cities and industrial and mining cities. Under the special tariff system, China, Japan and Russia relied on port-railway capital competition, forming the city development mechanism oriented by the export-oriented economy, that has the important theory value for the development of contemporary macro-regional urban systems in the context of economic globalization.

Case Study / Project

Training Session on Child-responsive Urban Planning

Jens AERTS

Abstract

Analysis of the main urban contexts shows that urbanization does not necessarily induce sustainable urban environments for children. Children and their families, especially the most disadvantaged, are confronted with spatial inequity in multiple ways: the high cost of living and access to urban services; the unequal geo-spatial distribution to urban services; the poor characteristics of the built environment; and the inequitable spatial distribution of land and urban space.

An unsustainable built environment constraints children's access to urban services in a physical way, due to unequal distribution, ineffective planning and lack of quality in design and construction. It leads to urban-specific environmental health problems that health support systems cannot address alone and shifts the focus from communicable to non-communicable diseases. The built environment also reveals itself as a protection issue when children and their caretakers cannot evaluate risks, be prepared or be safe. Finally, the built environment also influences to what extend children's participation is possible, in terms of public space where children can congregate and other infrastructure that allows physical, social and digital connectivity. On the positive side, the built environment offers realms of opportunity where cities commit to the respect of children's rights and planning for equity. Despite the strong correlation between the vulnerability of the most disadvantaged children and the built environment, child right and development specialists have not been familiar with the language of those who can address these issues.

Therefore, UNICEF wants to lead on developing the needed advocacy and technical support, by calling cities to commit to Child Rights and Urban Planning Principles and by offering guidance to urban planning stakeholders on how to prioritize children and thereby ensure cities thrive as homes for healthy, safe, green and prosperous communities. Amongst these stakeholders, build environment specialists working in cities, governments, community-based organisations and the private sector are key. Therefore, UNICEF and ISOCARP want to collaborate on joint advocacy and capacity development amongst its urban planning members and partners. Based on the recently published Handbook on child-responsive urban planning, UNICEF proposes to organise a half day training session to previously enrolled participants.

The training has the following format, under further development:
- Introduction Child Rights and Urban Planning Principles
- Presentation case studies (Indonesia/Asia and global)
- Workshop with break out session, facilitated with a checklist
- Presentation capacity development package of three types of tools for child-responsive urban planning: spatial planning tools (area-based), children's participation stakeholder engagement (process-oriented) and geo-spatial data management for child-centred decision making (evidence based).

The aimed outcome of the training session is to provide the participant urban planners with the knowledge and the technical tools on the why, what and how to put children central in their daily practice. Participants should feel inspired and comforted after the workshop to lead on this topic in their professional environment, by training further their staff, by proposing innovative approaches to their clients and partners, by elaborating guidance and policies in a city or national level.

A synthesis of the handbook on child-responsive urban planning can be provided for publication as a paper in the congress Publication. In dialogue with ISOCARP, this training can also be the start of a certification mechanism for child-responsive urban planners.

Research Paper

A DREAM OF OPEN DEFECATION FREE INDIA?

Decolonize and innovate urban sanitation to reach those left behind

Mahak AGRAWAL, Urban Planner; India

Abstract

India, a country now known as one of the world's fastest-growing economy, continues to be inhabited by 40 per cent of the global population of open defecators. Nearly 536 million people in India defecate in the open every day. To rectify this multifaceted issue, Government of India launched the Clean India Mission, famously known as the Swachh Bharat Abhiyaan, in 2014. Sanitation became a national political priority for the first time in India. The Mission renewed a hope to address a myriad of issues associated with open defecation. But this hope has only been fulfilled partially in the past five years.

The paper highlights the issue of open defecation with a case of the National Capital Territory of Delhi (NCTD), finding answers to one question: what is the role of an urban planner in liberating Indian cities, especially Delhi, from sanitation deprivation and open defecation. National Capital Territory (NCT) of Delhi is identified as the case area for the project for two prime reasons: one, the extent of sanitation deprivation in the city; and second, the administrative capital of India often forms a precedent for the rest of the nation.

The paper is structured into three broad sections: first, the extent of sanitation deprivation in urban India and analysis of policies- planning and non-planning, formulated in response to the issue, is highlighted. Second, the extent of the issue is investigated for the case of Delhi in context of policy frameworks; third, urban narratives of sanitation deprivation captured across select six clusters of jhuggi jhompri[1] in the National Capital Territory are highlighted to exhibit differences in access and use of sanitation facilities, in context of the pan-India Clean India Mission. The paper concludes at a note of hope- envisioning a city and a country where no one is deprived of their basic human right to improved sanitation, or has to defecate in the open, and also details out implementable strategies and policies for Delhi and urban India.

Water and Sanitation, Urban planning, Urban narratives, Open defecation, Justice

1 Introduction

India's Prime Minister Narendra Modi in his speech marking the birth anniversary of Mahatma Gandhi on October 2, 2014 launched the Swachh Bharat Abhiyaan (also known as Clean India Mission). The Mission was launched as a national movement, bringing urban sanitation to the stature of a political priority pan-India, envisaging a clean India, free of open defecation by October 2, 2019, a date marking 150th birth anniversary of the father of the nation- Mahatma Gandhi, who believed 'Cleanliness is next to Godliness'. The Mission brought with it, a herculean task of cent per cent eradication of open defecation across the

[1] settlements of urban poor identified by the Delhi Urban Shelter Improvement Board (DUSIB), Government of National Capital Territory of Delhi (GNCTD) as "an encroachment on public or private lands. They are therefore seen as illegal" (DUSIB, 2014)

country in a span of five years, overlooking the fact that open defecation is an ageless reality culminating from over hundred years of inequities- roots of which may be traced to ancient history and societal laws of India, as well as colonial legacy of British India.

Several studies, including the documented works of Burra et al (2003), Prashad (2001), Chaplin (1999, 2011), Mushtaq (2009), Doron and Raja (2015), deliberate on the issue and history of urban sanitation and open defecation in India, whilst a few investigate deprivation in urban India, and just a few explore sanitation deprivation for the National Capital Territory of Delhi. While Mushtaq and Prashad trace the evolution of urban sanitation practices in colonial India, Chaplin argues that sanitation in India is primarily guided by colonial legacy of unfair and inequitable distribution of sanitation facilities, and perpetuated by restrictive policies of Government of India post-independence. Deviating from colonial politics of sanitation, Burra et al (2003) focus on the inadequacies of public toilets in Mumbai, highlighting failure of public toilets in India to provide good quality sanitation services for a variety of reasons, cardinal being the incapability of service providers to account for regular supply of water to use, and maintenance of these facilities.

Therefore, the paper does not reiterate research, project findings that have been documented already. It builds on the existing literature and focuses on city planning policies, whilst simultaneously examining multifaceted relationship of sanitation deprivation and open defecation with urban development and planning, public health, economy, environment, education, safety and security.

The project investigates the scope of interventions and role of an urban planner in liberating Indian cities from sanitation deprivation and open defecation, particularly the national capital. In search of answers to this central question, the paper is structured into three sections: first, highlights the extent of sanitation deprivation in urban India and the findings from analysis of policies- planning and non-planning, formulated in response to the issue. It argues that inequitable distribution of sanitation facilities to the urban poor, favouring the middle classes and elite groups of the Indian society by the British, is systematically perpetuated by the establishment of urban planning and development institutions.

In the second section, the extent of sanitation deprivation and open defecation is investigated for NCT of Delhi in context of policy frameworks. It begins with a critical review of the three master plans of Delhi to date, and also underscores the issue of multiplicity of agencies and departments working on the subject of sanitation in the city, and therefore, a lack of coordination amongst these is identified as one of the biggest roadblocks to the vision of ‘open defecation free (ODF)’ Delhi.

In the third section, urban narratives of sanitation deprivation captured across select six jhuggi jhompri clusters in NCT of Delhi, exhibit the implications of the restrictive view of urban sanitation policies. The paper concludes on a note of hope, envisioning a city and a country where no one is deprived of their basic human right to improved sanitation, whilst elaborating implementable strategies and policies for Delhi and urban India.

2 Sanitation Deprivation in urban India

Nearly 200 years of direct rule by the British Government, over the people of India profoundly affected all aspects of life, culture and society, including city sanitation. While modern city planning emerged in India in the early 20th century, the period from late 18th

century to early 20th century was characterized by the British led Sanitary Revolution- a critical period in the evolution of urban planning and sanitation in India. Cities were physically segregated into distinct areas for European and indigenous population. Modern sewerage network was laid for areas inhabited by the Europeans and middle class, elite indigenous cohort, whilst several slums and squatters were cleared and relocated to city periphery- all in the name of sanitary revolution aimed at improving aesthetics and public health of the cities.

Roots of urban sanitation in India can be traced to the late 1800s, whereby to improve the sanitary conditions of urban centres, British India adopted its home-grown model of urban planning- implemented in 'home' cities including London, where planning emerged post-industrialization with a need to address problems of public health and unsanitary living conditions. While in India, sanitation became a matter of concern post mutiny of 1857 (Chaplin, 2011, 1999). It is thus imperative to investigate urban sanitation and planning thereof in India at three time frames- one, the pre-colonial period, wherein sanitation and much of the household norms were guided by the laws of Manu; second, the British India period which laid the foundation of city planning and urban sanitation of modern India; third, the post-independence period which continues to perpetuate the British India legacy of city planning and inequitable distribution of sanitation services.

2.1. Urban Sanitation in pre-colonial India

Much before the Britons came to India, the country and its people functioned upon the ideologies of Manu, a Hindu saint who wrote the Manu Shastra. Considered as a bible of the time by Hindu sect of the country, the Shastra conceived toilets and people associated with toilets, that is the manual scavengers, as 'dirty' (Hopkins & Burnell, 2009). Earliest form of social segregation, on the principles of sanitation, was not uncommon. People of higher caste were privileged to either have toilets or defecate in open, but not responsible to dispose it. The undignified burden of picking up the night soil was thus endowed upon the lower caste or Dalits. Hence, the societal practice of untouchability was born. Cities and villages had separate areas which could be inhabited by these untouchables. Often, they were located in the periphery of habitation area. In other words, the social-sanitation divide had a physical manifestation.

It is interesting to note, that India also boasts of having one of the earliest sanitation systems intertwined with town planning- as excavated from the Indus valley civilization in 2600 BC.

2.2. Urban Sanitation in British India

With the increasing power of British India and social unrest amongst the natives, several revolts and demonstrations were organized by the public. The mutiny of 1857 was one with the largest impact- on colonists as well as natives. Cities emerged as focal points of this nationwide mutiny. Once the wave of rebel subsided, what was left was destruction and depravity, sanitation deprivation being one of the leading outcomes.

To improve the state of sanitation deprivation in towns and cities, the British India set up a Royal Commission to look into the sanitary state of affairs of India, particularly for the areas inhabited by the Army (Mushtaq. 2009). The Commission soon published a statement called as the White Paper of the Royal Commission, which called for an immediate and necessary revolution in the state- the Sanitary Revolution.

This Revolution was based on three principles. The first principle accentuated the social sanitation divide initiated by Manu Shastra, and propagated by the physical segregation of towns by British India. Towns and cities were divided into separate areas for indigenous and European population. The latter settled in well planned residential areas of model towns, cantonments and civil lines (Mushtaq, 2009), while the indigenous were left to rot in their own waste. The second principle builds upon the first, augmenting the British India belief that natives are dirty. Even if you provide them with facilities, they will continue to remain dirty. Thus, the principle deprived natives from enjoying the benefits associated with a modern sewerage network while extending the same for areas inhabited by the Europeans and upcoming housing areas for the middle class and elite. The third principle conceived slums and squatters as hotspots for diseases and everything insanitary. Slums were cleared from the city's core and relocated to the periphery, similar to the principles of Manu Shastra.

Multitude of public health problems however, continued to persist. Sanitation deprivation and open defecation was a huge issue that the British was unable to handle from the recommendations of the Commission. It was realized that until the problem is solved at local level, a city's public health will situation continue to derogate. To address deplorable conditions and public health in India, urban planning was thus born.

British India believed that use of land and planning principles across a city would alleviate sanitation and public health status of cities. Following this, municipalities were established in select urban centres of the time, including Madras, Bombay, and Delhi, to provide civic basic urban infrastructure and amenities at the local level. Improvement trusts were established to re-organize and plan chaotic habitations. Numerous development authorities came up as a beacon of hope for the British India. These authorities were discharged with the functions of preparing a development plan that would guide the use of land for various purposes, including the storage, treatment, and disposal of human waste. System of calculation-based land budgeting was borne, which emphasized and continues to focus on extension of modern sewerage network and establishment of ancillary infrastructure for collection, storage, transportation, treatment, and final disposal of human waste into a water body.

Summing up, sanitation deprivation in colonial India was accentuated by planning and administrative policies, which were instrumental in propagating for unequal treatment of native and European population, and areas inhabited by them- through inequitable distribution of sanitation infrastructure. Sewerage networks were laid down for the middle class and elite (Chaplin, 1999, 2011) while urban poor drowned in their own waste or were relocated to fringes, in the name of sanitizing the city.

2.3. Urban Sanitation in post-independent India

Seven decades post-independence, yet the sanitary state of urban India has not changed much. Planning policies continue to emphasize on extension of sewerage network through its calculation-based augmentation plan, ignoring the fact that urbanization in Indian cities differs from that of the West. In India, around 60 to 70 per cent of urbanization is unplanned. Extension of planned sewerage network in such areas is a complex task. To fill this gap in urban sanitation chain, sectoral policies step in. These sectoral policies, formulated by technical wings of central ministries, do not solve the problem either. Often guided by political agendas of ruling parties, the policies restrict their focus on provision of basic 'minimum' facilities to the poor.

Post-Independence several sectoral policies and planning guidelines have been formulated and implemented for tackling the issue of sanitation deprivation and open defecation either with a head-on approach or sinuously. Examination of these policy frameworks leads to two key findings: first, the scope of sanitation expanded to include not just mere provision of facilities but also talks of gender-inclusivity and environmental sustainability on paper; second, the urban sanitation system continues to perpetuate colonial legacy of restrictive policy and planning, focussing on provision of toilets and augmentation of sewerage network, without linking the two.

For instance, in 1956, the Slum Areas (Improvement and Clearance) Act was notified with a need to clear cities of increasing number of slums whilst improving the sanitary state of cities (Government of India, 1956). Propagating the colonial principles, the Act perceived slums as 'public nuisance'. But amidst implementation of the Act, the Central government realized that cities were still knee deep in their own waste, and the problem of open defecation and sanitation deprivation could not be solved by mere relocation of slums. Thus, a new approach was formulated- focus shifted from clearance and relocation to provision of basic minimum infrastructure on-site to urban poor, as per the provisions of Environmental Improvement of Urban Slums (EIUS) scheme of 1974. Around same time, liberation movements were being organized by social workers to abolish the practice of manual scavenging and restore the dignity of manual scavengers (Government of India, 1993). Consequently, the Integrated Low-Cost Sanitation Scheme was enacted in 1980, and revised in 2008. Envisaging abolishment of the inhumane practice of scavenging, the scheme provided for conversion of dry latrines into low cost twin-pit latrine (Government of India, 2008).

Soon after, another scheme known as Urban Basic Services Program was implemented in 1985. The program focused on imparting education to urban poor, to enable and encourage them to use facilities provided under the Environmental Improvement Scheme. However, like several other sectoral policies implemented post-independence till the economic reforms of 1990s, sanitation continued to be a small component of a larger scheme on affordable housing or poverty alleviation. Also, India being a country that continues to reside in its villages, major portion of central and state funds for sanitation sector were diverted to rural India. To sum it up, urban sanitation was enervated via these policy frameworks.

Post 1991, however, the scenario transformed. With liberalized economy, increased flow of international aid for large infrastructure projects and growth of public-private partnerships, large urban renewal projects were initiated. In 2006, the Central government's flagship programme- Jawaharlal Nehru National Urban Renewal Mission (JNUURM), was launched. The programme made huge outlays particularly for urban infrastructure projects, including urban sanitation. Basic Services to Urban Poor (BSUP) programme was launched as a sub-mission of the JNNURM, with an aim to improve the quality of life and infrastructure for urban poor. However, even till this point, urban sanitation remained a component of a larger programme.

With the economic reforms of 1990s, another significant change to sanitation happened. Public health and sanitation, an item of the State List of the Constitution of India, became a responsibility of urban local bodies with the devolution of powers in 74th Constitutional Amendment Act. Yet, delivery of the human right remains a critical issue.

It was only in 2008, with the notification of National Urban Sanitation Policy, that an exclusive and comprehensive policy was penned for urban sanitation at the Centre. Novelty of this policy is that it identified open defecation as a challenge to urban development- a fact and reality of urban India no other document had earlier given due diligence to. The policy envisaged '100 per cent free from open defecation' as the goal (Government of India, 2008).

The biggest boost to urban sanitation and open defecation came to India six years later, whereby urban sanitation became a subject of multidisciplinary discussions and debates, and a political priority under the Swachh Bharat Abhiyaan or the Clean India Mission. Launched by Prime Minister Narendra Modi, as a national drive for making India clean and free of open defecation, the urban component of the Mission continues to follow the path of its predecessors while emphasising on the provision of toilets. Moreover, the scope of Mission's urban component is inclusive of statutory towns (less than 40 per cent of total urban centres of India) only. Despite this limited area of interest of the Mission, one noteworthy provision of the Mission is its inclusivity of distressed population, which is inclusive of not only the urban poor, but also manual scavengers, rag-pickers, construction labours, migrants, homeless and other vulnerable sections of urban society.

Yet, the Mission has become a lost opportunity (PTI, 2016). It continues to perpetuate the age-old mantra of constructing more and more toilets. For example, in his visit to Australia in 2014, Prime Minister Modi preached Indian diaspora to participate in the Mission by constructing one toilet in the village of their origin (Doron & Raja, 2015). With the approaching deadline of 2019 and no significant changes in the usability of toilets or the status of open defecation, the Centre directed state governments to levy fines ranging from Rs 200 to Rs 5,000 for littering, urinating or defecating in public spaces, an amount that could account anything from a day's wage to monthly wage of a person (HT Correspondent, 2016). What could not be achieved through provision of toilets is now being attempted by way of levies.

Up until now, the paper elaborated on the tunnel vision of sectoral policies of urban sanitation. But when it comes to planning policies and guidelines, the situation is not much different, just the focus differs. For example, the norms of Central Public Health and Environmental Engineering Organization (CPHEEO), suggest one public toilet at every one kilometre of road length in urban areas and equal number of toilets for men and women. But the norms are rarely adhered to.

Finding a toilet is difficult in a city, while finding a toilet for women is rarer. The latest Urban and Regional Development Plans Formulation and Implementation Guidelines, 2014 borrow the standards from CPHEEO manual and recommend public toilets' provision in all vending zones and markets; in areas of high volume of people (like railway stations, bus terminals, public open spaces, et cetera). Taking a step further, the guidelines specify the design of toilets shall have adequate water closets for women, children and differently abled (Government of India, 2014). In simple words, the planning norms are evolving around toilets, but becoming more inclusive in approach and design.

These manuals and guidelines act as bible for planners working in city and state level planning and development authorities, whilst the practitioners continue to follow colonial legacy of controlling the use of land through master plans. In these statutory plan documents, a planner forecasts population, water demand, and thereby estimated wastewater generation. Comparing the estimate with existing treatment capacity, a planner

prepares a land budget for augmentation of wastewater treatment capacity, and earmarks land for infrastructure expansion.

Summing up, planning policies focus on augmentation of sewerage treatment capacity while the sectoral policies focus on increasing number of toilets- both missing the critical components of usability, adequacy, and accessibility. The sanitation chain therefore, remains broken, with severe implications for socio-economically distressed.

Sanitation deprivation in urban India can also be identified as a form of colonialism, where interests of a few are attended to, at the expense of the majority. Introduced by Britons, urban planning and policy frameworks to address the issue of open defecation and sanitation deprivation still reek inequity and injustice.

2.4. Sanitation deprivation as a challenge to urban India

Perpetual dependence on restrictive policies of urban sanitation, both planning and sectoral, has aggravated sanitation deprivation to an extent that India ranks 1st across globe in terms of population of open defecators (World Bank, 2017). The report accounted for over 40 per cent of world's total open defecators as residents of India. This equates to more than 536 million persons across rural and urban India that can be found defecating in open spaces, along railway lines, roads, drains and other such public spaces, scarring their life and soil.

Sanitation deprivation rots the nation with severe long-term impacts as well, accounting for annual loss of 2.4 trillion or 6.4 per cent of national Gross Domestic Product (DASRA, 2014), equivalent to 60 per cent of environmental health burden of the country. The economic and environmental burden of sanitation deprivation is also related to inefficient treatment of wastewater in cities. The Central Pollution Control Board (CPCB) report of 2010 points out this inefficiency in class I and class II cities whereby 70 per cent and 92 per cent of untreated sewage, respectively, contaminate surface and groundwater resources on a daily basis (Central Pollution Control Board, 2010).

But the implications of sanitation deprivation are not limited to public health, environment and economy alone. It also affects education and safety, particularly of women- one in every four girls drop out of school because of lack of sanitation facilities in school (DASRA, 2012). In search of open spaces that are closed off to surroundings, women often travel long distances from home, making them vulnerable to sexual harassments. For example, in a 2012 study of Delhi slums, 70 per cent girls and women were found to be victims of verbal harassment on a daily basis, with 50 per cent of them falling prey to grave physical and sexual assaults (DASRA, 2012). For India therefore, sanitation deprivation is a pan-India issue with long term impacts on multiple dimensions of development, particularly the health of public, economy of nation, environmental quality, education status of girl child and safety and security of females.

Being associated with multitude impacts on multiple dimensions, sanitation deprivation is a perpetual challenge for urban development of urban India. The 597 million persons defecating in open account for 53 per cent of country's total population (Census of India, 2011), but only 4 per cent of it resides in urban India. Despite the small percentage, the issue of sanitation deprivation and open defecation is a challenge to urban development for three main reasons: first, 81 per cent of India's urban households have access to latrine facilities but only 33 per cent of them are connected to modern sewerage network; second, 19 per cent of urban households do not have a latrine facility within premises – a figure which can

be broken down into 6 per cent using shared toilets and 13 per cent defecating in open (Census of India, 2011); third, and the most important reason for the accentuation of sanitation deprivation in Independent India relates to rural-to-urban migration (Table 1). Every decade, urban areas are expanding in number and population, but so are the slums within them, primarily due to increasing migration and limited access to affordable housing. Simultaneously, percentage of households having access to latrine is improving by each decade but in absolute figures the number of households that do not have latrine facilities is still significantly large.

Census year	Number of towns	Households (in millions)		Annual migration to urban areas (in millions)	% of households availing latrine	
		Urban	Slum		Access to latrine (within and outside premise)	No latrine
1981	3949	29.3	5.6 **(19%)**	5.8	57.4	42.6
1991	4615	40.7	9.3 **(23%)**	6.6	63.8	36.2
2001	5161	53.6	10.2 **(19%)**	10.2	73.7	26.3
2011	7935	78.8	13.9 **(18%)**	15	81.4	18.6

Table 1: Access to Latrine facilities in urban India, 1981-2011
Data Source: Census of India (1981, 1991, 2001, 2011)

Limited capacity of civic authorities and urban local bodies to keep up with the demand for adequate sanitation, several organizations are coming up across states and cities to help address issues and challenges associated with sanitation deprivation particularly for urban poor. Mahila Milan is one such organization which works with and for pavement dwelling women in Mumbai. The organisation gave up waiting on government's promise to provide toilets and pooled resources from the community to construct community toilets in 1990s. In 2013, the 'Right to Pee campaign' was launched in the city (Patel, 2013) by sanitation deprived women with the demand to make existing male-biased public toilets sensitive and inclusive of the women as well (HT correspondent, 2016).

The same organization, in collaboration with the NGO- Society for the Promotion of Area Resource Centres (SPARC) and the National Slum Dwellers Federation forged a partnership called the Alliance in 1987, to address poverty and related challenges in the city, including the challenge of open defecation. Three major strategies adopted by the Alliance whilst working with local communities include- self-surveys and enumeration, housing exhibitions, and toilet festivals. The Alliance works at grassroots level to gather information on communities and design appropriate toilets for slum dwellers. These toilets differ from state provided infrastructure as they are sensitive to local demand and are better quality toilets (Sriram, 2016). Through works of the Alliance in tackling issues of open defecation it is clear that to resolve issues on ground, local knowledge and urban narratives are imperative and capable of guiding public policies and programs (Kumar, 2016).

3 Sanitation Deprivation in NCT of Delhi

Urban sanitation systems for the NCT of Delhi, and its planning, development, operation and maintenance involve multiple agencies at all scales of governance- Centre, state, city, district and local; for it is a union territory and the national capital. At the Centre, Delhi Development Authority outlines the vision and provisions within the statutory plan documents, also known as a Master Plan. Since 1957, the Authority has formulated three Master Plans for Delhi- the Master Plan of Delhi, 1962- 1982, succeeded by the Plan for

1982-2001, which is superseded by the current Plan of 2001-21. With each plan the scope of sanitation has expanded but the emphasis remains on augmentation of treatment capacity through population-based wastewater calculations, land budgeting, and extension of modern sewerage network (DDA, 1982, 1990, 2007).

At city level, the urban sanitation systems' administration is led by two main agencies- first, the Delhi Jal Board (DJB), and second, the Delhi Urban Shelter Improvement Board (DUSIB). The former agency is the sole provider of water for the city and is also discharged with the responsibility of laying down sewerage network and augmenting its capacity periodically. However, it is not mandated to provide the human right to all. It thus, conveniently limits its service delivery to planned developments with minor interventions for unplanned developments of slums and unauthorized colonies. Delhi Urban Shelter Improvement Board however, focuses on the provision of community toilets in identified unplanned settlements within the city, identified as jhuggi jhompri cluster[2] (JJ cluster).

At the local level, the city's urban sanitation system is governed by the five urban local bodies – North, South and East Delhi Municipal Corporation, the New Delhi Municipal Council and Cantonment Board. Each of these local bodies manage sanitary state within its jurisdiction area- by daily sweeping of streets, solid waste management, and constructing urinals in public spaces- often ignoring the needs of women in design, planning or management.

The urban sanitation is a complex responsibility of multiple agencies at three levels of administration for the National Capital Territory of Delhi. For reasons of restrictive policy emphasis and incoherence in coordination and functioning of these systems, the extent of sanitation deprivation and consequently open defecation is perpetually on the rise.

3.1. Extent of sanitation deprivation in NCT of Delhi

The National Capital Territory of Delhi, inaugurated in 1931 by the British has witnessed tremendous growth of population, spatial extent, as well as demands for basic amenities, including adequate sanitation. Even though the city's growth rate is declining, population of the capital in 2011 was enumerated at 16.75 million- an increase of 2.94 million from 2001 census. With this exponential growth, supply in response to the rising demands for adequate sanitation, by competent authorities has not been able to cope up. As a result, only 89.5 per cent of city's households have access to latrine facility within their premise, of which around 45 per cent are connected by sewerage, while remainder 10.5 per cent of households either have shared public toilets outside their premise or defecate in open. Presently, over one lakh households defecate in the open (Census of India, 2011) in Delhi.

Data however, often hides more than it tells- what this Census data on latrine facilities fails to reveal are the ground realities or the true extent of depravity and open defecation across the city. If we compare the district wise percentage of households having no access to latrine facilities in 2001 (Figure 1A) and 2011 (Figure 1B), it is clear that the situation has improved significantly for Delhi, particularly the peripheral districts of North West, West, South West, and South Delhi. But examining percentage of households defecating in the open (Figure 1C), it is evident that the peripheral districts alone account for over 87 per cent of households defecating in open in the city (Census of India, 2001, 2011).

[2] "an encroachment on public or private lands. They are therefore seen as illegal" (DUSIB, 2014)

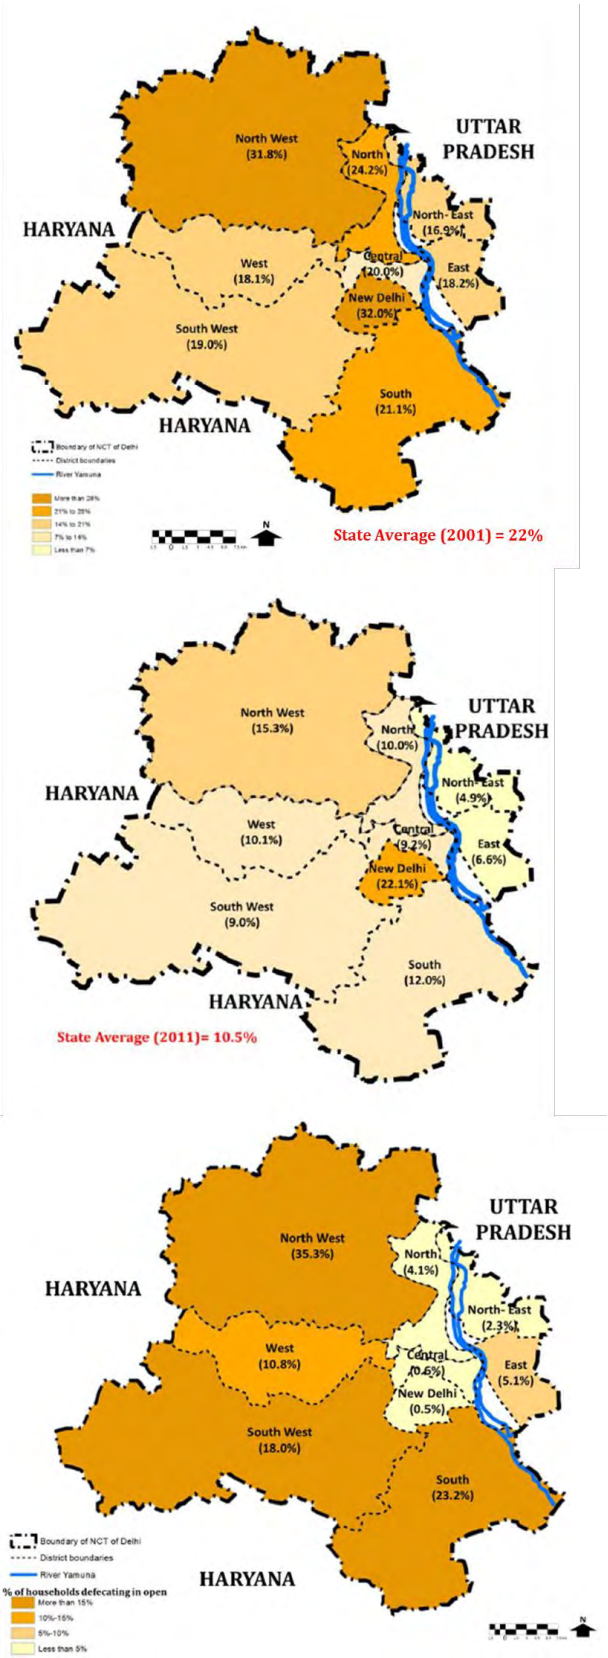

Figure 1: District wise distribution of percentage of households (from top to bottom) A. having no access to latrine facility within premise, 2001; B. having no access to latrine facility within premise, 2011; C. defecating in the open, 2011
Extracted from: ORGI 2001, 2011

This anomaly has a two-fold explanation- one finds its basis in planning practice, and second in sectoral strategies, administration and management. The second explanation refers to the 2003-05 partnership between the Sulabh International[i] and the Municipal Corporation of Delhi; formed for construction of community toilet complexes in slums of the city. Majority of these toilet complexes were constructed in the peripheral districts or New Delhi district, as land availability was higher in these districts than in densely populated districts of central Delhi or east Delhi. But, for users, these complexes did not solve their true purpose- of eradicating open defecation or urination. Open defecation was still a mundane routine for many.

Some of the key reasons for the failure of this partnership were: one, many clusters converted the complexes either to storage units; second, women could not avail it for its male biased design; third, preferred to defecate in open lands which offered much cleaner environment to relieve than these ill-maintained toilet complexes.

The period between last two census enumerations (2001-11) therefore, witnessed a numeric improvement in access to latrine facility, yet people preferred to defecate in open.

The second explanation for this data anomaly emerges from restrictive view of planning profession, in practice. Planners prepare land budgets for augmenting sewage treatment capacity for each revision of master plan, wherein capacity calculations are made by

forecasting population for horizon year, estimating water demand, and equating 80 per cent of this demand as total wastewater generation (DDA, 1982, 1990, 2010). But, these calculations for determining the use of land for urban sanitation ignores one simple fact- not all households with access to water supply (Figure 2A) are connected by piped sewers (Figure 2B). As a result, land and capital are being allocated for augmenting sewage treatment capacities which would never be utilized to the designed capacity.

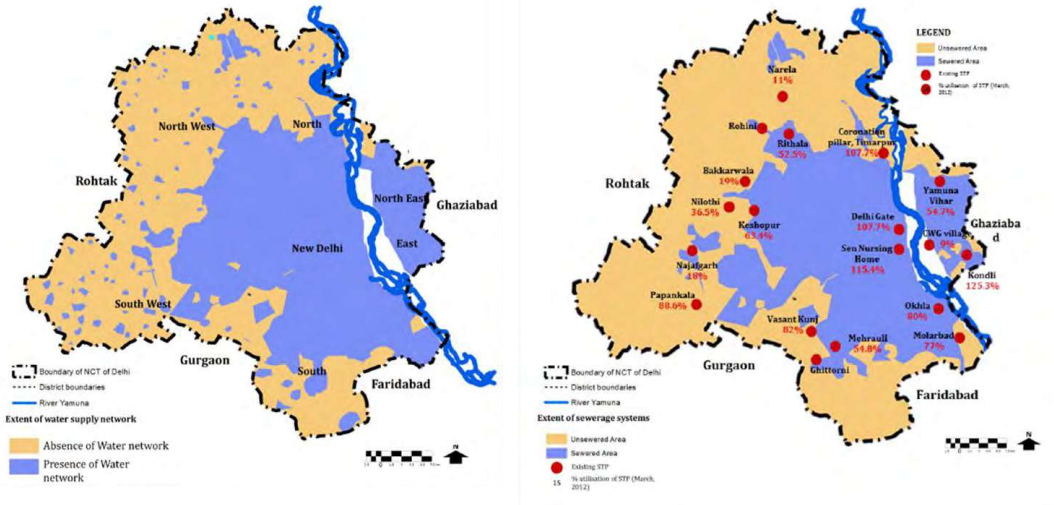

Figure 2 (from left to right): B. Extent of sewerage network in NCT of Delhi and
Extracted from: ORGI 2001, 2011

The cumulative effect of this misguided focus is that over one lakh households are defecating in open every day in the capital with 48 per cent of them being urban poor. Benefits of policies and programs at various levels of administration have been unable to trickle down- as envisaged, the basic human right to adequate sanitation for those at the lower rung of socio-economic ladder.

In the next section of the paper, a few of the hotspots of depravity- six jhuggi jhopri clusters, have been studied in detail and documented for their official and unofficial stories.

4 Narratives of Sanitation Deprivation in NCT of Delhi

With 48 per cent of households defecating in open being those of urban poor, sanitation deprivation and open defecation continues to be intermixed with poverty. Several initiatives have been undertaken by welfare state to provide basic minimum facilities of sanitation and water supply to these deprived pockets, but envisaged benefits are yet to trickle down. The section captures ground realities of six jhuggi jhompri clusters of Delhi. Official and unofficial stories are discussed in brief to highlight sanitation deprivation as an indicator of poverty which manifests spatially.

The six clusters have not been selected at random and do not come with any bias to the author or the project. A technical methodology supports selection of the clusters. Wards 68, 63 and 154 were first identified as the wards with highest, lowest and average slum households, respectively (Figure 3). After selection of wards, information system of the Delhi Urban Shelter Improvement Board was referred to identify specific jhuggi jhompri clusters in each of these three wards, which would have highest, lowest and average slum households. That is, stratification was done at two level- first, city level to identify a ward; and second,

ward level to identify specific cluster. Eventually, only one cluster could be identified in ward 63, three in ward 68 and two in ward 154.

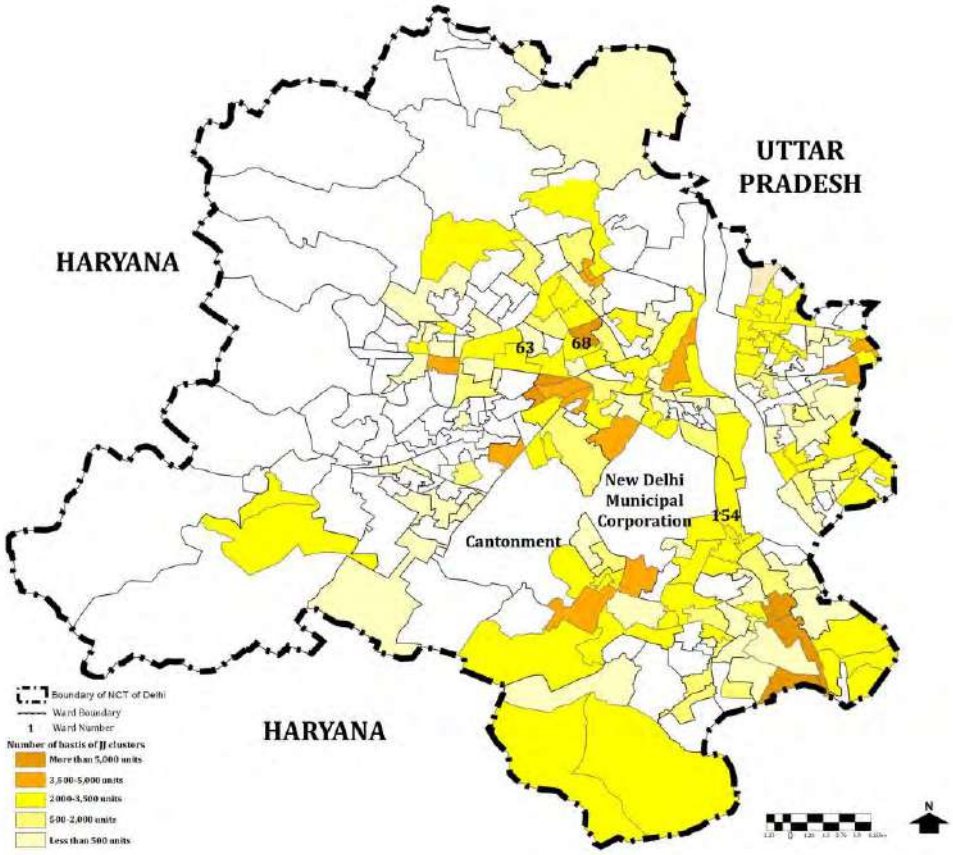

Figure 3: Ward wise distribution of JJ clusters across NCT of Delhi, 2018
Extracted from DUSIB data (2019)

4.1. JJ Cluster, near Kohat Enclave, Pitampura

Jhuggi jhompri cluster in Ward-63 near Kohat Enclave, Pitampura, is a 40-year-old settlement of 50 households squatting on 668 square meters of DDA-owned land which was originally planned as a green space for the elite of Kohat enclave. An island of informal housing, surrounded by luxurious bungalows (Figure 4A) and flats, it is inhabited by migrants from villages in and around Bandhikui town of Rajasthan state in northwest India, which came to the city in search of employment and soon became daily wage construction workers for the upcoming Rohini and Pitampura neighbourhoods in the 1970-80s. Less than 500 meters from the nearest metro station and outer ring road, the cluster enjoys benefits of public mode of transport for travelling beyond the neighbourhood, as construction work in the area has reached a plateau.

One look at the settlement and anyone would presume that it is one of those clean and sanitary clusters which has been blessed by its local political representative (councillor) with

all the basic amenities any human requires for a healthy living except affordable housing (Figure 4B). But a walk through the cluster and conversations with its dwellers reveals a different picture.

Figure 4 (from left to right): A. JJ cluster- an island of deprived surrounded by the elite; B. informal housing units on either sides of drain
Picture credits: Author

The cluster is devoid of any form of latrine facility, or drainage but has one stand post to supply water an hour or two every day. Accepting perpetual denial by civic authorities, the community has adapted itself, constructing a drain which bisects the cluster into two halves (Figure 4B). But for relieving themselves, there is not much the community has been able to do, despite political attempts in the past to construct pucca toilet for the cluster. The Pradhan/community leader of the community recounts promises of a ward councillor prior to 2009 to construct toilet which were quashed by the elite, and instead surface of cluster was covered with concrete and a stand post was erected to silence the demand for human right. A year or two later, the Public Works Department started with construction of a small toilet, but the effort was stalled and ultimately demolished by the kothiwalas[3]. As a result, people go behind their houses to defecate (Figure 5).

[3] A term given for people who live in bungalows (or 'kothi' in Hindi language)

Figure 5: Site for open defecation within the JJ cluster
Picture credits: Author

Dismantling common misconception amongst non-deprived, urban narrative of the cluster revealed that it is not true the community is unaware of the implications of open defecation. They do. They are well aware of the issue it brings to them during monsoons, particularly on their health and productivity. Yet, they have no option, but to pee and defecate in their backyard. In an interview with the executive engineer of the DUSIB for the north-west zone, the unofficial story of past efforts to provide toilet to the community was reiterated. He also highlighted the conflict between the rich and poor as the main reason for uncertainty of proposals by the authority, with the recent one being a bio-digester toilet.

Sanitation being a human right is denied to the community by power and influence of the rich. The latter fails to comprehend that open defecation may be a lived experience for the poor, but its implications are not confined to the cluster. Efforts are being made by respective public agencies, but uncertainty of their implementation hovers.

4.2. Madrasi Camp, Jal Vihar

Madrasi Camp is a jhuggi jhompri cluster located in Ward-154, on a piece of land owned by the Indian railways, for over 30 years now. Surrounded by Barapullah drain in the north and railway line in the east, the community of 411 households uses the two open spaces- drain and railway line, for defecation (Figure 6).

Figure 6: Women travelling back to the cluster, having traversed railway line to find an open yet hidden from the surroundings, a site to relieve
Picture credits: Author

The cluster derives its name from the Madras regional language spoken by its community which has migrated from different parts of Tamil Nadu to settle in the area in 1982, as per the Railways' records. With close-knit work-home relationships with the surrounding

neighbourhood, the cluster continues to expand, despite eviction notices issued in 2007 and 2010. Falling under the jurisdiction of South Delhi Municipal Corporation, it is provided hand pumps as well as open drainage channels on either side of the approach road to the settlement. But it is deprived of a toilet facility.

The camp being situated on central land requires DUSIB, an agency of state government, to negotiate and sign a memorandum of agreement with the Indian Railways before constructing any facility. The Centre however, continues to negate such efforts, in the name of discouraging further growth of the cluster. The unofficial story elaborated by Magesh, the community leader highlights similar efforts by the Municipal Corporation of Delhi in early 2000s, whereby a tender was passed for construction of community toilet and given to a private contractor, but the construction never took place. As a result, the entire community relieves itself in the open, either along railway tracks or along the drain. When it gets crowded during peak hours, men travel down to the drain to defecate while women and children relieve in closer proximities of home.

The dangers of defecating along the two available open spaces is well known amongst the community. Magesh and his wife mourn the loss of few children of the community on the tracks while several have lost a limb. The community unanimously demands for a safe and adequate site for relieving themselves. But it seems the demand will persist as a dream for the community amidst land conflicts.

4.3. JJ Cluster near DPS Mathura road

Another cluster located within ward-154, is a squatter of 212 households' on DDA owned land. This Muslim dominated settlement is built along the famous Sunder Nursery, and its inhabitants earning livelihood from scrap dealing.

Dialogue with the community reveals that the local name of the cluster is Amir Khusro Basti and it fell under the constituency of the former Vice President of India. They praise the dignitary for providing them with clean and separate toilets and bathing units for men and women, much before the Swachh Bharat Abhiyaan came into being. The installation work in 2013-14 provides the community with well-maintained and adequate number of toilets, as per the DUSIB norm of 1 water closet for every 10 households- which is an effort initiated by political influence and implemented by South Delhi Municipal Corporation in partnership with a private contractor.

This cluster and recent initiatives to provide quality infrastructure sets an example for others to follow. It demonstrates that political impetus and power when associated with a cause, be it as dirty as that of shit, it does get responded to.

4.4. JJ Cluster, Prem Bari Bridge along railway line, Wazirpur Industrial Area

Jhuggi Jhopri at Prem Bari Bridge is one of the largest clusters of Delhi. Located linearly along the railway line near Prem Bari Bridge, the cluster comprises of 3,799 households, and lies next to the proposed master plan green across the railway line, and Wazirpur Industrial area on the other side. Majority of community is working as wage labour in various industries within the area, while a few works as domestic workers, drivers, sanitation workers in the surrounding residential neighbourhood.

In 1990s the cluster was issued an eviction notice under the large-scale clearance drive of slums on public land, particularly the Indian Railways' land. The cluster became a focal point

for hunger strike by the then President of India, Mr. VP Singh, following which evictions were deferred and the slum was notified. With legal notification, it got included in the list of slums that were provided community toilet complexes, despite conflicts between land owning agency and providing agency.

At present, the 3,799 households are provided with one community toilet complex consisting of 30 water closets for both men and women, which equates to one water closet for every 126 households (~567 persons). Moreover, the facility is located at a tail end of the linear cluster and is ill-maintained. The doors to toilets are unstable, many do not have any door. As a result, 18 out of 20 persons using the facility are still defecating in the open- at least once a day, either along the railway track or in the proposed master plan green. For many, relieving within the facility is no different than defecating in open (Figure 7).

Figure 7: (Open) defecation in closed premise
Picture credits: Author

Due to its location at a tail end of the cluster, accessibility for women is a serious issue. One out of every five women does not feel safe to travel over 700 meters from their home to the facility. For select users, facility's design ensures a biased access to males and discouraged use for children and females. In a recent initiative by the DUSIB, a double storied toilet complex has been proposed near the existing facility, but the proposal is yet to receive a nod from the Indian Railways. Though the proposed facility promises reduced stress on existing facility, but issues of open defecation and biased access will continue for its location near already existing facility.

4.5. JJ Cluster on DDA Park, Chander Shekhar Azad Colony, Wazirpur Industrial Area

JJ cluster on DDA Park- Chander Shekhar Azad colony is situated amidst warehousing units of Wazirpur industrial area (Figure 8). This 35-year-old settlement of 775 households is situated on 0.8 hectares of DDA-owned land, but is devoid of a sanitation facility.

The cluster has come up on a proposed park locked on all sides by warehouses, leaving no space for construction of a toilet complex that could fulfill need of the community. But 300 meters away from the settlement, an ill-maintained (Figure 8) and overused community toilet complex was constructed as part of MCD-Sulabh collaboration in 2003-05.

Figure 8: Ill maintained facilities with sewage deposited outside the facility
Picture credits: Author

The complex consists of 30 closets for both men and women, which equates to 1 water closet for 26 households. During daytime, community uses the facility, while at night they prefer safety over hygiene and relieve themselves in proximity to home.

4.6. JJ Cluster at B-46, Wazirpur Industrial Area

The cluster at B-46 Wazirpur Industrial Area is a small pocket of 21 households squatting on 443 square meters of DDA-owned land. The community hails from a small village of Rajasthan, and is engaged as either sanitary workers or daily wage workers within the industrial area. The basti located amidst warehousing and storage units is devoid of space to construct a permanent structure and does not have access to any complex within 500 meters distance. Therefore, it has been provided with a mobile toilet unit consisting of 7 water closets for both men and women (Figure 9).

Figure 9: Ill maintained facility with sewage deposited flowing the facility in a space which is not distinct from recreational space for the children of the cluster
Picture credits: Author

The facility is not maintained and whatever waste is generated it is directly dumped into the open drain channel flowing behind the unit. This open space where toilet unit is located and drains flow carrying human waste, coincides with play area for children (Figure 9). The slum is practically living, working and playing in waste.

5 Conclusion and a way forward

The paper concludes with identification of the root cause of sanitation deprivation, which finds basis in the limited scope of urban sanitation policies. These policies- planning and sectoral, perpetuate sanitation deprivation which has a physical manifestation, and unjust

implications on urban poor. For the national capital too, open defecation is a mundane routine for the poor. The extent varies, but the deprivation is common.

It is also evident that Indian planners takes an elitist and modernist view of sanitation, excluding any discussion on open defecation in master plans – the primary policy instrument for tackling city sanitation. Addressing multitude of challenges that emerge or are linked to sanitation deprivation and open defecation in India, the task at hand is uphill, and a radical change in the current approach is thus required for realising the dream of open defecation free cities.

First and foremost, a **new framework** of examination, developing solutions and interventions, and monitoring, needs adoption. This framework is composed of eight parameters of adequacy, accessibility, affordability, finance, coverage, efficiency, quality of service and environmental sustainability (indicated in Figure 10). This framework of parameters has been based on the established fact that: one, sanitation deprivation is more than just provision of toilets; or calculation-based augmentation of sewerage; and third, data often hides more than it tells. Thus, to capture the real extent of sanitation deprivation, the framework comprises of 8 parameters based on service level benchmarks conceptualized by the Ministry of Urban Development and the Performance Measurement Framework for Urban Water and Sanitation (CEPT University, 2010) as well as the shortcomings identified from examination of policies for the project.

Parameter	Sub-Parameter	Indicator/ Benchmark	Explanation
ADEQUACY	Coverage of toilets	100%	• Sanitation is associated with universal service obligation (USO). It is a human right which needs to be provided to all socio-economic groups of society
	Water supply to facility	30-45 lpcd	• Adequate amount of water is needed for flushing out night soil, to ensure its use
	Adequacy of sewage treatment capacity	100%	• Treatment capacity available shall match with the amount of wastewater generated
ACCESSIBILITY	Location of facility	Walking distance to suit all users	• In case toilets are not available within premises, they shall be located within suitable walking distance from household. Locating toilets in secluded and distant sites, increases people's preference to defecate in nearby open area
	Bias in access	• Gender sensitive • Differently abled sensitive • Child friendly	• All members of community, irrespective of their gender, age or disability shall be able to access the provided facility
	Legality	• Notified slums • Non-notified slums	• Being associated with USO, (il)legality cannot be a criterion for depriving people of their right. DUSIB is mandated to submit an undertaking, in which it is to be highlighted that the structure will exist only till the date of existence of JJ cluster
AFFORDABILITY	Percentage of income spent on sanitation facility	• Free, else not imposing financial burden on household	• Being a human rights, one should not be charged to be able to access it • If facilities cannot be free of cost, then household expenditure to avail the facility should not impose an economic burden
FINANCE	Cost of Construction	100% borne by public agency	• The amount of money spent on construction and maintenance of city level sanitation infrastructure is to be borne by concerned public agency as provision of sanitation infrastructure is their mandate • The amount of money spent on construction and maintenance of toilets and wastewater collection network will be borne by state government
	Cost of Maintenance		
COVERAGE	Coverage of sewerage network services	100%	Denotes the extent to which the underground sewage (or sewerage collection) network has reached out to individual properties across the service area
EFFICIENCY	Efficiency of sewage collection	100%	Amount of wastewater collected shall be equal to amount of generation
	Efficiency of sewage treatment	100%	Amount of wastewater collected shall be equal to amount of wastewater treated
	Efficiency in redressal of complaints from users	100%	Percentage of sewage-related complaints redressed within 24 hours of receipt of complaints in the given time period
QUALITY OF SERVICE	Maintenance of existing facility	Periodical Repairs and maintenance	Once a facility is provided, it requires timely repairs and maintenance works to ensure continuing usage of facility
ENVIRONMENTAL SUSTAINABILITY	Extent of reuse and recycling of sewage water	20%	The percentage of wastewater received at the treatment plant that is recycled or reused after appropriate treatment for various purposes

Applicability of sub-parameters
- At city level
- At community level
- At city and community level

Figure 10: Framework for assessment of sanitation deprivation
Developed by Author (2016)

Within this framework the parameter of adequacy looks beyond the provision of toilets, and includes adequacy in terms of water supply to flush out the waste and adequacy of treatment capacity, to dispose-off the waste safely. Second, accessibility of sanitation facilities examines not only the physical accessibility but also social and legal accessibility. Affordability and financial parameters insinuate sanitation as a human right to be provided

to all by the state. The parameter of coverage looks into the spatial extent of sewerage network while efficiency is assessed in terms of collection of sewage, its treatment and disposal as well as efficiency of redressal system towards user complaints. To ensure that the structure provided by public, private or a partnership of the two is actually put to use, maintaining the quality of service is crucial. This maintenance has to be conducted at periodic intervals with accountability to its users. Lastly, environmental sustainability examines extent and emphasis on reuse and recycling of sewage water.

Testing the framework for the identified clusters, it is evident that one theme that binds all these episodes- sanitation deprivation is a routine for Delhi's poor, with variable extent. Four of the six clusters have access to some form of sanitation facilities, but still inadequate numbers and inadequate supply of water to flush out the waste renders the infrastructure useless after a period of time. Moreover, open defecation is a common practice even amongst those who are using the facilities, either due to inadequate number of closets or ill-maintained units. Also, the access to these facilities is biased. Due to space constraint or conflicts between land owning agency and Delhi Urban Shelter Improvement Board, facilities get located at such sites that not all segments of communities are able to access it. Mostly, women travel in groups to use them. Also, affordability, along with quality of service and efficiency of collection and treatment, is often not addressed in these clusters.

Sanitation deprivation is a public health concern as well as violation of human right that has long term implications on productivity of nation. In light of political impetus being given to sanitation deprivation and open defecation under the Swachh Bharat Mission, the way forward requires **realignment of existing urban sanitation policies**, **revision of planning norms** to make them more inclusive and responsive to issues of spatial inequities, supported by strong **implementation and regulatory mechanisms**.

As planners we need to rework our modus operandi and deviate from mere augmentation of sewerage network. Despite implementation of the three master plans, issues of inequitable spatial distribution of sanitation infrastructure, biased access and inadequate maintenance, still plague the general public. As a step forward, we need to **identify open defecation as a challenge to urban development** in our statutory plans and highlight the extent of depravity. Third, we need to **discard the blueprint approach** emphasizing on modern sewerage. That is, planning like the administration needs to get decentralized. Low cost area-based solutions need to be adopted for sanitation deprived pockets of the city. These efforts can either be taken by the authority itself or in collaboration with land owning agencies or NGOs or other such parties motivated by societal good.

Lastly, as planners we need to **re-look at our calculation-based augmentation plans** and work towards a judicious use of land. The current calculations need to be modified. Instead of augmenting the treatment capacity based on existing demand supply gap, a planner needs to look into the fraction of households having access to water supply and those having access to piped sewers. After all, only the wastewater collected through sewers will be treated, so why waste money and land on creation and maintenance of infrastructure that would never be utilized to its built capacity. Ultimately, planning is practiced for the people. The idea is to account for official as well as unofficial stories through urban narratives and cater to one and all.

In the end, to eradicate open defecation from a society whose foundation is still influenced by Manu Smriti, and decades of social, physical segregation and accompanied psychological

differentiation brought upon with the Sanitary Revolution in mid-19th century, sanitary foundations need to be dug deep and a radical change in the current approach is required- ensuring no one and no place is left behind, through more equitable and environmentally sustainable interventions and innovations.

Research Paper

Place-making in Indonesian Kampung: A Case Study of Bustaman, Semarang

Creating Urban Spaces that Enhance Local Empowerment

Poeti Nazura Gulfira AKBAR, Erasmus University Rotterdam; The Netherlands
Jurian EDELENBOS, Erasmus University Rotterdam; The Netherlands

Abstract

For almost a decade, there has been a grassroots movement in the country that adopts place-making in kampungs (Indonesian urban informal settlements) through cultural and contemporary art festivals. The common issues that have been faced by almost every kampung are to maintain their existence in the city where they tend to be excluded, marginalized, and demolished. Place-making has been held with the hopes of improving the aesthetic appeal of the kampungs, creating new opportunities for the residents to develop creative output relevant to their neighborhood and communities' specialties, and strengthening the local identity to protect kampungs from the demolishment threat (Kustiawan et al. 2015; Lieshout 2014; Prasetyo and Iverson 2013). Although many pieces of research from a different part of the world have shown that "temporal" place-making through cultural and art festivals provides many social benefits to the individual and their communities, it seems to be unclear from the global South context. Consequently, uncertainties exist whether place-making brings positive impacts on social aspects of residents in the context of developing countries, particularly those who live in problematic areas such as urban informal settlement dwellers. It is indeed an area that has been little explored in the place-making literature (Lew 2017). Therefore, this study will contribute to understanding the implications of place-making towards the public life of informal settlers, particularly in Indonesia. The main purpose of this study was to examine the impacts of place-making on the local capacity in Indonesian kampung. The research was carried out using a sequential mixed-methods in Bustaman, Semarang. Results from multiple regression analysis showed that place-making through regular "everyday life" and temporal "festivals" have significantly influenced local empowerment. While the qualitative findings further explained that place-making can promote local empowerment by encouraging youth's participation, increasing the organizational and mobilizational capacity of the local community, providing knowledge exchange, and broadening local community's perspectives about their place and community. This study also demonstrated that different types of place-making bring a different kind of impact towards particular socio-economic groups. Therefore, to achieve a better quality of place-making, the enhancement of relational resources between different age group is necessary. Finally, these findings raise important questions and suggestions for incorporating place-making into neighborhood planning efforts.

Keywords

Place-making, kampung, urban informal settlements, empowerment, mixed-methods

1. Introduction

The rationale for developed countries to introduce various arrangements of place-making from a neighborhood to a city level is multifold. It was said by previous researchers who investigated place-making in developed countries that place-making can promote local empowerment by increasing capacity of local community (Douglas 2016; Goldstein 2016; Main and Sandoval 2014), providing knowledge exchange between stakeholders (Rios and Watkins 2015; Dukanovic and Zivkovic 2015), broadening local community's perspectives about their city and communities (Houghton et al. 2015). Several authors observed that place-making also helps fostering social connection in communities, which is found explicitly in the form of strengthening network between different social groups (Ho and Douglas 2008; Peng 2013; Rota and Salone 2014), break down cultural barriers (Sandoval and Maldonado 2012), and create new friendship between local communities (Piribeck and Pottenger 2014). In addition, place-making can contribute to the improvement of quality of life, such as building positive image to place (Andres 2013; Chan 2011b; Knight 2010; Lombard 2014), increasing safety (Lazarevic 2006; Teernstra and Pinkster 2016a), liveability (Cilliers et al. 2015; Semenza 2003), and well-being (Foo, Martin, et al. 2015) while other researchers found that place-making is an essential factor to reinforce the identity of both place and its inhabitants. For instance, enhancement of individual and communal confidence towards their cultural identity (Rota and Salone 2014), higher sensitivity to place histories (Ho and Douglass 2008; Lazarevic et al. 2015), and cultural regeneration (Andres 2012; Chan 2011).

Similar to other cities in the developed world, the use of place-making as a tool to redevelop and reimage areas, particularly that are perceived as problematic, has become increasingly popular in Indonesia. For almost a decade, there has been a grassroots movement in the country that adopts place-making for kampungs. The terms 'kampung' is equivalent to an urban village, which refers to an informal settlement area that exists in a city and mostly associated with the slum. Kampung is the smallest administrative unit in the urban area that can be classified as a neighborhood unit. The common issues that have been faced by almost every kampung are to maintain their existence in the city where they tend to be excluded, marginalized, and demolished. Therefore, place-making through art and creative festivals has been held with the hopes of improving the aesthetic appeal of the kampungs, creating new opportunities for the residents to develop creative output relevant to their neighborhood and communities' existing assets, and strengthening the local identity to protect kampungs from the demolishment threat (Kustiawan et al. 2015; Lieshout 2014; Prasetyo and Iverson 2013).

It is still unclear, however, whether temporal place-making through art and cultural festivals have made any real contribution to these aspects. While there is a growing concern about the use of art and cultural festivals in Indonesian kampung, many of them paid much more attention to explain the festivals using perspective of cultural tourism (e.g. Podlaszewska 2017; Puspitosari 2015; Silver et al. 2017; Susetyo 2015), physical and spatial outcomes (e.g. Hutama 2016; Nasution 2015; Roychansyah 2014; Safira 2012; Surya, 2008), and stakeholder interrelations (e.g. Ekomadyo et al. 2013; Rahmany and Djajadiningrat 2014). The investigations of art and cultural festivals in kampung within the place-making context using residents perspective is indeed understudied. Meanwhile, regardless of a wide arrange of research from a different part of the world have shown that place-making provides many social benefits to the individual and their communities, the benefits of place-making have been less evident within the global South context. Most of the researches on place-making conceptualizations and applications have been done in the western cultures and developed countries, mainly from North America, Europe, and Australia. An example is given from a current literature study about methodologies for quantifying the value of place-

making in which Cohen et al. (2018) explicitly stated that the study was limited to the developed countries. Given that socioeconomic, physical, and institutional contexts in those groups are distinctly different from the former ones, their outcomes might also differ. This argument is supported by Lew (2017, p.461): "The world-making context (cultural dynamics, political economy, and social values) of Asia, Africa, and South America, especially at the regional and local scales, can be quite different from those of the West, resulting in different community challenges, needs, and solutions".

Consequently, uncertainties exist whether place-making brings positive impacts on social aspects of residents in the context of developing countries, particularly those who live in problematic areas such as urban informal settlement dwellers. Therefore, an investigation on social outcomes of place-making towards residents in Indonesian kampung will contribute to understanding the implications of place-making. The main purpose of the study is to understand the effects of place-making through regular and temporal practices on local empowerment of residents in Indonesia urban informal settlements. The following research question is addressed to guide the study: *To what extent place-making influences social aspect of kampung residents?*

With three sub questions:

a. *How is the relationship between regular and temporal place-making towards local empowerment?*
b. *How do the relationships come about in the two kampung cases?*
c. *To what extent the socio-economic aspect of kampung residents influence the relationship between place-making and local empowerment?*

2. Literature Review

This section will present literature review on place-making as a social process, classification of regular and temporal place-making, and its impact on local empowerment.

2.1. Place-making as a Social Process

A large and growing body of literature has investigated the concept of 'place-making', and yet, the notion and definition of place-making within discourses reviewed appear nebulous and contested. It ranges from a stable definition of place, as is the case of a 'locale' or physical settings of social activity, to one that encompasses the dynamic human and non-human agents influencing site character (insert references). To frame this study on a clear definition, the latter perspective on place-making is taken into consideration.

The concept views that urban places are embedded in the built environment and come into being through 'reiterative social practices' (Cresswell 2004). Many earlier authors has described place-making as an on-going process of enhancing the quality of places through creation and transformation, which are in these cases, refer to build environment and physical area in various scales from public places, urban open space, neighbourhood, town, city, to region (Benson and Jackson 2013; Brunnberg and Frigo 2012; Buser et al. 2013; Douglas 2016; Elwood, Lawson, and Nowak 2015; Lombard 2014; Quayle and Driessen Van Der Lieck 1997). Franz et al. (2008, 316) defined place-making as "collective appropriation of the own environment by the residents that has the potential to create new 'places' of identification for the local residents". Therefore, remaking a public place is a social activity of involved people (Arefi 2014; Lombard 2014). Many claims that the right to make space is not designated to expert and professionals, but also a right to residents and other stakeholders (Lepofsky and Fraser 2003). Friedmann (2010, 159) for example claims that "making places is everyone's job." Individuals make spaces, and these are socially negotiated, constantly

changing and contingent (Pierce et al. 2010). Lepofsky and Fraser (2003, 132-133) argue with their concept of 'flexible citizenship' that place-making is not only for professionals and neighborhood residents, but must be open for 'external' stakeholder groups that have a decision-making role even though they are not residents of the particular target neighborhood. In this case, place-making is viewed as a social process in which local activities construct place (Pierce et al. 2010; Silberberg 2013). While some authors called this approach as 'place-making as a process', it has also been known as 'bottom-up place-making' (Arefi 2014; Bendt et al. 2013), 'organic place-making' (Lew, 2017; Sofield et al. 2017), and 'community-led place-making' (Pierce et al. 2016; Silberberg, Lorah, et al. 2013). These authors, although using different terms, confirmed the capability to attain positive results from place-making that does not rely on targeted and advanced skills, but mainly on the full effectiveness of influential mutual relationship of places and their communities in generating those desirable results. To summarise, place-making is defined as an activity of integrating various actors, functions, means, and dimensions in order to transform urban places.

2.2. Classification of Regular and Temporal Place-making

In this study, regular place-making refers to some characteristics of place-making that is the collective 'mundane' activities of ordinary residents in their neighborhoods. In the literature where the characteristic was found, some scholars, either partly or wholly, drew upon 'everyday life' to explain place-making (Douglas 2016; Elwood et al. 2015; Friedmann 2010; Lombard 2014). Everyday life was defined as a process where places are claimed and shaped through everyday social practices. This concept of everyday life was acknowledged as the essence of 'lived space' by Lefebvre (1991, p. 362), identified as a representational space inhabited or used by people imposing their "private worlds upon the public realm." Drawing from his idea, more recent scholars of place-making have put forth the ideas of the 'lived place-making' which is defined as "those bottom-up processes by which people appropriate space for daily living through small, individual gestures, and social relationships that attach meaning to space" (Balassiano and Maldonado 2014, p. 647). While Lew (2017, p. 49) called it as 'place making', or "how a culture group imprints its values, perceptions, memories, and traditions on a landscape and gives meaning to geographic space." Together, these scholars emphasis on the ability of ordinary citizens or users to become involved in the formation of space.

In the literature, place-making is also characterized as 'temporary' to refer its uses of urban space (Andres 2012; Marshall and Bishop 2015; Silberberg et al. 2013). Besides 'temporary,' this characteristic of place-making is applied in different terms by other scholars. While Till and McArdle (2015) chose 'interim space' to consider short-term projects such as a pop up event in Dublin's park by an artistic collective, 'temporality' was adopted by Rota and Salone (2014) and Kern (2015) to categorize several formally organized activities by local neighborhood-level organizations, such as annual music festivals. These terms, albeit called differently, are principally the same in explaining the 'temporary' characteristic of place-making as place activations through occasional events at the neighborhood or block level. A number of authors also used 'temporary' to describe a specific approach of place-making which called 'tactical' (Douglas 2016; Lew 2017; Lydon et al. 2012; Wyckoff et al. 2015). This approach is described as "a bottom-up approach led by community groups looking to test, change, improve aspects of their locale and often using temporary, low-technology interventions" (Cohen et al. 2018, p. 13).

Some early authors also include the distinguishing characteristic between the place-making daily by residents and the place-making that is enabled by people or organizations who are not necessarily the residents but have the power to control a place. For instance, in their study about place-making in rural communities, Balassiano and Maldonado (2014) used

the dichotomy of 'lived' and 'facilitated' place-making to differentiate between everyday life activities by residents and place-making intervention by government. Another example was from Kern (2015) who differentiate the everyday life and temporality based on the time occurrence and involved actors. While everyday life place-making refers to daily activity by ordinary residents such as talking, smoking, playing cards, or drinking coffee while sitting in the corner of a parking lot in neighborhood; weekly farmers markets and music performances, occasional flea markets, one-off events, and annual summer festivals were grouped under 'temporal events'. By this, the temporal place-making, refers to place activations through occasional events, both small and large scale, in public spaces. His intention to divide the two was because he found that the latter one, which was more formally organized by local neighborhood-level organizations, had influenced the 'everyday life' of a particular group of residents.

Table 1. Regular and Temporal Place-making Characteristics

Characteristics	Regular	Temporal
Frequency	Daily, weekly, monthly, occasionally	Annual, biannual
Scale	Individual, group, community, block, neighborhood level	Neighborhood or block level
Facilitation	Mundane, everyday life	Facilitated
Involved actors	Local residents, including neighborhood organizations	Individual or local organizations other than residents
Nature of Activity	Promoting well-being, establishing infrastructure, caring for public spaces, promoting social cohesion, and empowering women	Promoting art and culture, social cohesion, recreational activities, and supporting young people

2.3. Place-making as a Tool to Enhance Local Empowerment

Local empowerment is defined as a process of change in which individuals or groups of local community, who initially has little or no control, have gained more power and capacity to intervene in particular things that affect their lives. This capacity can be in forms of solving problems, motivating and persuading other residents to involve, participate and work collectively for making and remaking their places. The indicators of local empowerment were mainly based on a study by Stewart (2010) about measuring community empowerment for place-making in forestry and Peng (2013) who used the same indicators to measure the effect of institutional capacity in place-making practices towards local sustainability.

As mentioned in the previous chapter, one of the basis of empowerment is local knowledge. Regarding this, De Carteret (2008) found that place-making through everyday life activities support residents in gaining informal knowledge as a result of their involvement in the activities and also from ordinary conversations they have with their neighbors. He also found that the character and purpose of the activity itself were the two main factors from the everyday activities that can be a bridge to facilitate an exchange of information and opportunity to learn by one another. The relationship between everyday life activities and empowerment were also investigated by Balassiano and Maldonado (2014). They argued that empowerment could be reached when people perceive themselves to have a high level of control towards their spaces. By this, they further stated that the degree to which people perceive they have 'control over spaces' can be determined by their contributions to the maintenance or improvement of these space and their participation in community activities or events.

Several studies discussed the value of place-making as a process, mainly the temporary, event-based, and tactical initiatives by grassroots and community-driven, that

brings positive benefits to community empowerment and engagement through deliberative discussion and collaboration (Cilliers et al. 2015; Silberberg et al. 2013). This argument was supported by Flanagan and Mitchell (2016), stating that the social networks formed through project participation also facilitated knowledge-sharing and peer-to-peer learning. One specific example by Dukanovic and Zivkovic (2015) underlined the importance of two temporal and experimental projects in central riverfront of Belgrade as vehicles for community participation. They found that the project not only brought positive changes in the physical aspect of the place but also offered a learning experience to the participants through active involvement during the project, from preparation to implementation. In this case, the participants were also given the opportunity to become tutors and project managers of the next event. As a result of the arrangement of temporal activities, the participants were able to gain knowledge and skills in interdisciplinary and collaborative work. This study concluded that enthusiasm for improvement of city spaces through temporal place-making was rooted in a synergy of the citizen, expert, and public sector.

3. Methodology

3.1. Area of Study

Data collection was done in an urban kampung in Indonesia, Bustaman, which is a high-density urban settlement located in Purwodinatan sub-district, Semarang City. It consisted 0.6 ha with a population density equal to 590 people per ha. The kampung consists of 2 RT, namely RT 04 and RT 05, where approximately 400 inhabitants live. Despite its limitation as city's slum area, it has high productivity level based on its goat-trading and culinary activity. It is popular with its Gulai Kambing or goat curry making, which has been a local tradition since the Dutch colonial period. Most residents rely on goat trading with various jobs, from butchers, goat merchant to catering that specializes in the goat curry. Besides the goat, Bustaman is well-known with its historical value. This kampung got its name from Kyai Bustam, a religious leader and a communicator between the Dutch government and the locals in the 18th century. He was also the great-grandfather of the most internationally known Indonesian painter, Raden Saleh Bustaman. The rich history and tradition makes this kampung become an important part of the history of Semarang, especially with the fact that the kampung was built at the time of Semarang formation.

3.2. Place-making Practices in Two Kampung Cases

Temporal place-making in Bustaman was started by Hysteria, a local organization who has involved in Bustaman since 2013. The organisation was officially formed in 2011 and focused on youth empowerment, art, and urban issues. Since then, Hysteria has coordinated with various grassroots communities, artists, and students in Semarang and surround. Their activities included discussions, exhibitions, workshops, festivals, and other type of community facilitation based activities. As a commitment to their main aim to contribute in solving city's issues, along with other communities including Rujak Centre for Urban Studies, Hysteria formed Peka Kota which means, literally translated, "sensitive city". The core program of the platform was to raise kampung issues at the city scale, including how to use everyday life knowledge of the dwellers to be considered by the government for making city's master plan. By then, they started the program in several Semarang kampungs, which one of the first was Bustaman.

3.3. Sampling, Data Collection, and Analysis

To answer the study research questions, mixed methods approach is used, specifically based on the sequential explanatory mixed method. This study begins with a quantitative strand

and then conduct a second qualitative strand to explain the results obtained from the quantitative data and analysis. It is also important to mention that the two approaches were connected when selecting the interview participants and developing the interview protocol based on the results from the questionnaire results from the first phase. In the last stage of the research, the results of the quantitative and qualitative phases were integrated during the discussion of the outcomes of the entire study.

Quantitative Phase

Since the type and number of place-making practices were implemented differently in a particular block (RT) of the kampung, there is a high possibility that the perception of residents would be different in each block, and therefore, the population of kampung does not comprise a homogenous group. Regarding this, a proportionate stratified random sampling was chosen since it involved a process of dividing the population into homogenous subgroups, which in this study, the participants were divided per RTs before doing the sampling. After the number of households in each block (RT) was selected, the next stage of the sampling process involved identifying the eligible households and household members to be surveyed. To randomly select households, the researcher acquired documents by the local RT leaders which contained a list of addresses in every RT in Bustaman. The document was then enumerated and organized in sequence. By using a computational method from www.randomizer.org, some random numbers were generated and used as a sample. It is also important to note that the survey respondent is limited only to residents who ever participated in at least one of the regular activities in the kampung and/or the art festival. That is to say, the survey respondents were either active, inactive, and former participants of regular and temporal place-making activity in Kampung Bustaman. Residents who never participate or attend regular and/or temporal place-making in kampung are not included in the sampling and were substituted instead. Regarding the sample size based on Yamane's formula, the 67 respondents were residing in Bustaman.

Qualitative Phase

To further understand and elaborate survey results, 15 in-depth interviews with purposefully selected residents of the selected kampungs were conducted using semi-structured interviews. The face-to-face interviews were done between August – September 2017 and were digitally recorded. For this phase, the interviewees were selected from those who responded and completed the survey in the quantitative phase. The participants, who consisted of residents with different level of participation in a different type of place-making practices, were asked to participate in having an interview on the given study subject. All semi-structured interview were transcribed, coded and analysed using the software of Atlas.ti. After all the important statements and words had been coded, the codes were grouped by similarity, and a theme was identified and documented based on each grouping.

4. Results

In this study, quantitative data and results provided a general picture of the research problem through unpacking the various constructs that link to two types of place-making and investigate them separately, measure the relationship between influential factors and social outcomes of place-making, and gather socioeconomic data of local residents. While the qualitative data and its analysis refined and explained those statistical results by exploring the participants' views in more depth and further explaining why certain relationships tested in the first phase were significant and why some were not significant.

Table below displays the results from the MLR analysis and indicating that among respondents from involved households that both of regular and temporal place-making had

positive relationships with local empowerment. They significantly influenced the empowerment, which were found significantly at F (5, 221) = 25.172, p = .000, with an R^2 of .363 (See Table 4.6). The score of partial correlation coefficient (β) implied that the temporal place-making (β = .530) affected empowerment more than regular place-making (β = .261). Meanwhile, the predictive equation suggesting that the respondents' empowerment increased by 0.363 and 0.179 for each point of the arrangement and participation in temporal place-making and regular place-making consecutively.

Table 2. Results of Multiple Regression Analysis

Independent variables	B	β	t-value	P	Tol.	VIF
Constant	*3.820*		*23.428*	*.000***		
Age	-.080	-.162	-2.922	.004**	.938	1.066
Temporal Place-making	.363	.530	6.712	.000***	.463	2.161
Regular Place-making	.179	.261	4.570	.000***	.882	1.134
Regression equation: Empowerment = 3.820 + .363 (Temporal Place-making) + .179 (Regular Place-making)						
R^2 = .363 F (5, 221) = 25.172 (P=.000) ***						

Taking into consideration the complex nature of Indonesian kampungs, particularly on the process of making and using public space, statistical relationships as outlined above seemed to not adequately capture this complexity, and thus, the following paragraphs go further to look at how these relationships between two types of place-making and local empowerment are shaped.

4.1 Impacts of Temporal Place-making on Local Empowerment

According to the quantitative findings, temporal place-making positively and significantly influenced local empowerment of residents in the kampung. In response to this, there were two positive views on temporal place-making recurred throughout the qualitative analysis, namely youth capacity and opportunities to transfer knowledge.

Many respondents commented that youth organizations in Bustaman have been more active ever since temporal place-making took place in the kampung. One respondent who is a leader of Ikatan Remaja Bustaman (IRB), or Bustaman Youth Organization, explained that the organization had been deactivated for eight years long until finally Hysteria came and persuaded the youth to revive IRB. Since then, not only IRB has been active, but also youth have played an active and vital role in Bustaman. Furthermore, the majority of participants demonstrated that temporal place-making provided participation opportunities in mainly three aspects: concept development, public relations, and operation. Most of the interviewees confirmed this positive impact of temporal place-making by saying that throughout the concept development and framing stage, it offers a knowledge exchange process between the residents and Hysteria. While the residents gained a clearer understanding of their kampung's issues, the local organization also obtained new knowledge about the kampung and the community. Some other interviewees made more point that now they can make things that they could not before participating. In the current event, some youth claimed that they made a booklet, flyer, some DIY decoration equipment, sponsorship proposals and invitations, all mainly by themselves. A few other youths also explained that the concept of the current event was developed mainly by the residents, while the local organizations only helped them for advisory. Lastly, the evaluation that was held by the local organization and residents after the festival was also a way of empowering. In this case, through sharing feedback and lessons learned from the festival, the residents learn how to make the better ones in the following year. All those interviewees stated that

the dominant role of youth in temporal place-making only happened currently. While in the previous events, Hysteria was the one who executes most of the festival preparation to the end of its implementation. From all the statement above, it indicates that there is an increased capacity among residents, particularly youth, to volunteer and participate in their communities.

The other opportunity to transfer knowledge is offered through open discussions with experts, academia, and city officials which were held as part of the festival and targeted for broader groups of residents. For instance, during the first festival in Bustaman, a former rector of the local university and a representative of local art institution were invited to talk about the importance of the kampung in historical context. In return, residents were offered chances to share their stories, opinions, and aspirations during the discussions. The other evident came from the Forum of 12 Art Activists Semarang Kampung which was started in 2017. On this meeting, there were twelve representatives from different kampungs including Bustaman, where the representative of each kampung explained their kampung's condition, both issues and potentials. Sometimes they also invited experts such as architect and urban planner. This kind of discussion can be an excellent opportunity for knowledge exchange between expert and locals. For the residents, not only it can lead to gaining more understanding towards their kampung's issues, but also benefitting knowledge of self-professed experts in a broader context such as demolishment issue in cities. As one interviewee of women neighbourhood organization put it, *"This discussion reminded me that Bustaman is just like other urban kampungs, like those demolished kampungs in Jakarta… if we do not have a strong foundation, we will get demolished too."* Another interviewee also stated that this kind of discussion was needed because it did not only make the residents more aware of their kampungs but also an excellent start to building strong communal identity and organizational foundation in the kampung. *"I hope this discussion will be continuous, and we can support each other and be the strong basis for the kampung which is not less powerful than private sectors"*.

Despite the formal preparation meetings, the core concept development process, which called as 'framing,' was started long way before and done through informal discussions. During the framing process, Hysteria helped the residents to elaborate their needs and unidentified issues in the kampung into coherent themes. For instance, there were some negative comments about the motorcycle parking spaces which scattered around in almost every narrow streets in the kampung; the unhealthy multi-functioned spaces that was used as slaughterhouse and gathering; and the most populous alley in the kampung, *Gedong Sepuloh*, which has about then houses with a combined population of 140 inhabitants. For people who obtain higher education or work in community services might easily see that the recurrent problems in the comments mentioned above from the residents were related to public spaces. However, that was not the case for kampung dwellers who have limited educational background and career field. In the beginning, before Hysteria gives them guidance and coherent framework, most of the residents were clueless in developing a comprehensive understanding of the issue they faced. As a member of Hysteria explained, *"Residents are aware of their problem because they have been facing it for a long time, but they don't know how to refine it*."

According to the quantitative findings, it was found that age is one of the controlled variables that has significantly and negatively influenced local empowerment of residents in the kampung. The interview findings, could only partly supported this relationship. Based on the analysis, temporal place-making was found to have a more positive impact on young people and young adult than any other age groups. One of the possible reasons is related to task divisions during temporal place-making, in which a more significant part of the tasks is given to youth. Many interviewees from both kampungs confirmed the dominant role of

youth, while there is minimum participation amongst kids, housewives, and elderly. Most of the youth, with some help of a male adult group, is mainly in charge of all the preparation stages including internal funding resource. For housewives group, however, was only responsible for catering services. Several respondents explained that these tasks divisions were not randomly appointed. Indeed, it was done through the willingness of each group to participate during the place-making. For instance, one respondent argued that she must take care of her little daughter because no one would watch the kid if she joined too. Commenting on this issue, another respondent said:

> *"The problem is that my husband doesn't work here, he works outside of the city, so I also need to work to support my family. But my son is active in the youth organization, so he almost always updates some news to me."*

This view was supported by youth participants explaining that it was a practical way of thinking for participant who already has a family to not participate in temporal place-making, given that the nature of the activity itself is energy and time consumption and not to mention dominated with contemporary art.

4.2 Impacts of Regular Place-making on Local Empowerment

Similar to the poor neighborhoods where their dwellers are struggling to make ends meet, making and remaking their place through spatial and physical interventions is essential for kampung residents. The corollary of this is that there are always improvements that can be made, especially on the basis of the necessity that refers to the residents' needs upon the presence of those spaces in their kampung. In Bustaman, regular place-making through physical activity is clearly seen through the development of various facilities and infrastructure, particularly in recent years. For instance, constructing adequate public sanitation, paving streets that during the rainy season creates big puddle everywhere, and creating community spaces that are more comfortable for regular meetings and daily gatherings.

Empowerment is also evident by the record that within eleven years (2006 – 2017), residents were able to mobilize themselves in handling ten important physical improvements around public spaces in the kampung with limited environmental and economic resources. Not to mention, from 2009 until 2017, the improvement was arranged every year by the community who was in charge of initiation to maintenance. It is not surprising therefore that the development process has cultivated the practice of mutual self-help based on cooperation through sharing responsibilities. This is not suggesting that place-making is always unequivocal or even peaceful. Indeed, conflict occurred several times during the process, mainly because of different opinions among residents, from discussion on design and planning, task divisions during construction, to the management of contribution. Nonetheless, the diversity of opinions in deciding the community needs reflects the empowerment and collaboration process. In this matter, decision-making is made as to the interplay amongst residents in determining their future, while collaboration can be seen through the fact that the community has been able to embrace diverse perspectives without compelling conflicts into various collective actions.

As the development of public space cannot be carried out by the community itself, mainly in the financial sense, some alliances and partnerships with external agencies also took place to ensure the permanence and quality of the public spaces. In this way, not only residents extend and strengthen their external networks through collaboration that

occurred during the development process, but it also provides opportunities to transfer knowledge among the stakeholders. Among the various subjects taught by non-profit organization and government, a good example as a result of the high learning process can be seen related to financial management assistance. Until the year when the fieldwork was conducted, residents have independently managed the sanitation contribution so they can pay all the maintenance costs, and some public spaces were even financed partly through the contribution.

Another form of empowerment is palpable during the process of daily social activities. In this case, Bustaman shows its potential to be a self-supporting kampung since all the process along with necessary skill and materials for the goat trading are available in this kampung every day. In addition to empowerment, the fact that residents have done the business until today means that they help in preserving Bustaman's identity as kampung of goat where it holds cultural heritage in the form of all essential knowledge for running the business. Interestingly, another identity has emerged through everyday life, which includes two other activities, in this case, are culinary business and *guyub* tradition. The diverse movement and nature of those activities, that run every day for almost 24-hours, have enlivened the kampung while also given a distinctive character and meaning to it. Altogether, they created a place identity for those who dwell in. At the same time, the presences of those daily enterprises also contribute in sustaining the self-help practices within the community, in the sense that the local's struggle to support their livelihood does not stop them to help each other. For that reason, these activities undoubtedly cannot be overlooked if one talks about the self-help practice of Bustaman residents.

Taken all these practices of regular place-making in Bustaman, their wider impacts can be seen through how they simultaneously bring positive impacts on the quality of life in kampung through the creation of socially favorable public spaces. Several qualities such as accessibility, security, and liveability were attributed. In this case, regular place-making has not only able to improve the local environment which resulting in better health and safer environment, but also bring social benefits that were perceived to improve the well-being of the kampung residents such as the vibrant environment.

5. Conclusions and Implications

This paper underscores the relationship between regular and temporal place-making on local empowerment. Overall, the qualitative analysis revealed two positive impacts of regular place-making, which are the improvement of organizational and collective capacity. The importance of temporal place-making was seen through the opportunities to transfer knowledge with external stakeholders and general improvement among residents, particularly youth, to actively participate in the kampung festivals and to revive the youth organization in both kampungs. Interestingly, the analysis showed that while temporal place-making had a more positive impact on young people and young adult than any other age groups, most participants who involved in regular place-making are the older generation.

However, regarding the impacts mentioned above, the overall results demonstrated that the organizational capacity and the opportunities to transfer expert knowledge are mainly obtained by a few of active groups of residents who play fundamental roles in running and organizing place-making practices in the kampung. These active groups were known as cadres of social organizations in the kampung, members of youth organization, and individual activists without any assigned responsibility. The analysis of

interviews with key informants also demonstrated that place-making process creates an opportunity for these core group of residents to empower and develop themselves.

This study also revealed some challenges that could affect the impact of place-making on the empowerment, mainly the lack of financial and human resources in the kampungs. The relatively low socioeconomic conditions of kampungs not only hinders many residents from participating in place-making but also create dependency on external stakeholders. Another barrier to the implementation of place-making in kampung is to generate interest in their kampung improvement programs amongst other residents, in order to implement and sustain regular and temporal place-making. More considerable efforts are needed to ensure a higher level of enthusiasm and participation in place-making.

Research Paper

The Implementation of Children Friendly City in DKI Jakarta through Assesesment of Children Friendly Integrated Public Space

Dhea Andriani, Urban and Regional Planing, Faculty of Engineering; Pakuan University
Indarti Komala Dewi, Urban and Regional Planing, Faculty of Engineering; Pakuan University
Janthy T Hidayat, Urban and Regional Planing, Faculty of Engineering; Pakuan University

Abstract

The government of DKI Jakarta province is attempting to build public space to change the city face by means of constructing Children Friendly Public Space (thereafter called RPTRA) as the attempt of supporting Jakarta to be Child-Friendly City. In realizing a Child-Friendly City in DKI Jakarta it is supported by several governor regulations governing RPTRA standardization, RPTRA Management Guidelines, and the DKI Jakarta government also makes Jakarta grand design towards a Child-Friendly City. According to the Governor Regulation Number 196 of 2015, Child Friendly Integrated Public Space is an open place or space that combines community activities and activities by implementing 10 (ten) family empowerment and welfare programs to integrate with child-friendly city program. This RPTRA is part of a child-worthy infrastructure to achieve the fulfillment of one of the 24 child-worthy city indicators set by the Republic of Indonesia Minister of Women Empowerment and Child Protection Regulation Number 12 of 2011 concerning District/City eligible for children Indicators. The government of DKI Jakarta province built 6 (six) RPTRA in Kemayoran, Central Jakarta with each RPTRA having different characteristics. RPTRA Mutiara Sumur Batu has the highest score of 1.66 and RPTRA Harapan Mulya, which is 1.62. The purpose of this research was to assess the suitability and characteristics of RPTRA in Kemayoran District. This research method used GAP analysis, observation, and questionnaire. The results of this research showed that the RPTRA in Kemayoran Subdistrict is still not optimal because only 2 RPTRA have good values, while the other (4 RPTRA) still have constraints in developing RPTRA as fulfilling children's infrastructure.

Keywords

Child-Friendly City, Infrastructur Child Friendly, Public Space

1. Introduction

Infrastructure is a matter that is closely related to the conditions of development in the city today, while there are still many infrastructure conditions in the city that have not shown child worthiness. There are many types of talking about infrastructure, ranging from decent homes, transportation, educational facilities, drainage channels, green open space, sports fields, to children's playrooms. Of these, the problem of availability of Green Open Space is a problem that is currently not resolved.

The development of the Central Business District in DKI Jakarta, especially Central Jakarta from the construction of office buildings, companies, to dense housing on the outskirts of the city, continues to use existing urban spaces. This causes a change in the surrounding environment, especially urban public spaces, and contributes to changing the pattern of community activities in it, so that many settlements are densely populated and the population is quite high in age but lacks public space for children to play.

The importance of fulfilling child-friendly public spaces in realizing Child-Friendly Cities in Kemayoran District, Central Jakarta City can be seen from the large number of children, which is 397,896 people. Reaches 35% of the population in Central Jakarta City *(BPS Jakarta Pusat 2018)*. So the government needs to make various efforts to improve the quality of children and fulfill facilities and infrastructure facilities that are pro-children in the planning and implementation of government development documents. Child worthy infrastructure is one indicator that must be met by the government in an effort to realize a child-friendly city.

The Government's efforts in realizing the achievement of the Child Friendly City concept are also supported in the Republic of Indonesia Minister of Women Empowerment and Child Protection Regulation Number 12 of 2011 concerning Eligible District / City Indicators. Where in the regulation to develop a Child Friendly City in each district / city, it must refer to 24 indicators of the fulfillment of rights and protection of children which are broadly reflected in the 5 clusters of children's rights, namely (1) Cluster of Civil and Freedom Rights; (2) Family Environment Cluster and Alternative Care; (3) Basic Health and Welfare Clusters; (4) Educational Clusters, Use of Leisure Time and Cultural Activities; and (5) Special protection cluster.

Public open space is a shared space, where the community carries out its functional and ritual activities in a community bond, both daily life and in periodic celebrations that have been determined as something open, where the community conducts personal and group activities. Whereas the Child Friendly Integrated Public Space is an open place and / or space that integrates activities and activities of citizens by implementing 10 (ten) main programs of family empowerment and welfare to integrate with the Child Friendly City program.

Child Friendly Integrated Public Space is also a manifestation of the commitment of the DKI Jakarta Provincial Government to ensure the fulfillment of children's rights so that children can live, grow, develop and participate optimally in accordance with human dignity and receive protection from violence and discrimination. RPTRA can also be described as one of the child-friendly infrastructure in the form of a park designed with a modern concept that is child-friendly, equipped with various supporting infrastructure facilities such as Gazebo / pavilion for children's learning venues, sports facilities, children's forum secretariat, Community Reading Park, internet / wifi network, toilets, etc.

Thus it is expected that Child Friendly Integrated Public Spaces can become the center of public interaction as well as a medium of learning and development of children's interests and talents. With the availability of Child Friendly Integrated Public Space, it is expected to be able to fulfill a playground that is friendly to children and can help in realizing a Child Friendly City, which is a city that is humane, comfortable and friendly to the community, especially children.

2. Research Methods

The study was carried out in 6 Child Friendly Integrated Public Space spread across Kemayoran District, namely RPTRA Harapan Mulya, Krida, Serdang Baru, Bandar Kemayoran, Mutiara Sumur Batu, and Kampung Budaya. The method used in this study is GAP analysis, questionnaire, and qualitative descriptive method. This analysis / Gander Analysis Pathway (GAP) analysis is to find out the gap or conformity between the realization of existing conditions of Child Friendly Integrated Public Space with a model (standards, policies etc.). This can be linked to policies in the RPTRA standardization policy. The calculation formula for the average value of realization of Child Friendly Integrated Public Space is as follows:

$$\bar{x} = \frac{x_1 + x_2 + x_3 + \ldots + x_n}{n}$$

Information :

$\bar{x}$ = average value of realization

x = Criteria measured

n = Total RPTRA criteria for overall observation

Whereas to find the calculation of conformity value (G) the following formula is used:

$$G = R - K$$

Information :

G = Average value of conformity

R = Average score for realization

K = Value of average policy score

Qualitative methods are research procedures that produce descriptive data in the form of written or oral words from people and behaviors observed (Moleong 2007). As for selecting respondents, the questionnaire was submitted to the RPTRA visitors. Indicator criteria can be seen in the following table.

Table 1 Indicator

No.	Variable	Indicator
1.	Accessibility	• Entrance • Sidewalks • Crossing Place

No.	Variable	Indicator
2.	Facilities	• Multipurpose room • Library room • Lactation room and KB space • Management room • Family Welfare Development Room • Toilet • Sports fields (futsal / basketball / badminton) static sports facilities • Children's playground • Running / jogging track • Path of reflection • An amphitheater • Garden • Parking lot • Park bench
3.	Activity	• Communicate • Exercise • Service activities • RPTRA environment • Place of community association
4.	Convenience	• Vegetation • Distribution of Garden Lights • Distribution of Trash Can • Security officer

3. Results and Conclusions

3.1. Result

Based on the results of the research, the ideal value for each RPTRA is 2. Where the value of 2 is the result of distributing questionnaires to the community and comparison with the results of expert interviews. Then according to the results of the assessment of accessibility aspects and facilities having higher values because RPTRA is provided to the community, so accessibility is one of the needs that can facilitate the community in reaching RPTRA from its place and facilities are facilities that can support community needs in carrying out their activities or activities while in RPTRA. The results of the conformity assessment on the RPTRA in Kemayoran Subdistrict show that there are only 2 RPTRAs which have good values, while the other 4 RPTRAs still have some obstacles in the development of RPTRA as fulfillment of children's infrastructure. Mutiara Sumur Batu RPTRA achieved the highest rating with a value of 1.66 and RPTRA Krida and Bandar Kemayoran had the lowest rating of 1.42. For more details, can be seen in the following table.

Table 2. Suitability of Child Friendly Integrated Public Spaces in Kemayoran District, Central Jakarta

No.	RPTRA	Standar RPTRA		Facility Availability	GAP
		Variable	Indicator		
1.	Harapan Mulya Kel. Harapan Mulya 3.446 m^2	Accessibility Facilities Activity Convenience	-Entrance -Sidewalks -Crossing place -Multipurpose room -Library room -Lactation room and KB space -Management room -Family Welfare Development room -Toilet -Sports fields -Children's playground -Running/jogging track -Path of reflection -An amphitheater -Garden -Parkiring lot -Park bench -Communicate -Exercise -Service activities -RPTRA environment -Place of community association -Vegetation -Distribution of Garden Lights -Distribution of Trash	-Multipurpose room - Library room - Lactation room and KB space - Toilet - Sports fields - jogging track - Path of Reflection - Children's playground - An amphitheater - Garden - Park bench	1,62
2.	Krida Kel. Serdang 639 m^2			- Multipurpose room - Library room - Lactation room and KB space - Toilet - Sports fields - Path of Reflection - An amphitheater - Park bench	1,42
3.	Serdang Baru Kel. Serdang 1.202 m^2			- Multipurpose room - Library room - Lactation room and KB space - Toilet - Sports fields - Children's playground - Path of Reflection	1,47

No.	RPTRA	Standar RPTRA		Facility Availability	GAP
		Variable	Indicator		
			can -Security officer	- An amphitheater	
4.	Bandar Kemayoran Kel. Kebon Kosong 586 m^2			- Multipurpose room - Library room - Lactation room and KB space - Toilet - Sports fields - Children's Playground - Path of Reflection - An amphitheater - Garden	1,42
5.	Mutiara Sumur Batu Kel. Sumur Batu 1.202 m^2			- Multipurpose room - Library room - Lactation room and KB space - Toilet - Sports fields - Children's Playground - Path of Reflection - An amphitheater - Garden - Parkiring lot - Park bench	1,66
6.	Kampung Budaya Kel. Utan Panjang 515 m^2			- Multipurpose room - Library room - Lactation room - Toilet - Sports fields - Children's Playground - Path of Reflection	1,44

No.	RPTRA	Standar RPTRA		Facility Availability	GAP
		Variable	Indicator		
				- An amphiteater - Garden	

The characteristics of RPTRA indicate that each RPTRA has its advantages and disadvantages depending on the location and availability of facilities and services provided. The more complete the available facilities and the many RPTRA activities the higher the visitors. RPTRA Harapan Mulya is an RPTRA with the highest activity value because it has the most extensive land and has a lot of service activities compared to other RPTRAs while RPTRA Krida has the lowest value because of limited facilities and limited service activities available.

Case Study / Project

Hunger in revered spaces

Exploring the impact of planning on the university campus food system in South Africa

Rouve BINGLE

Abstract

This exploratory study examines how campus planning and its spaces affect the food security of students. The study is conducted on the campus of the University of the Free State in South Africa and uses a mixed methods approach which includes an online survey, qualitative interviews and a site inspections. The data is used to determine the state of the campus food system as well as gauge respondents opinions on the subject of food access, availability and management. Traditionally a university campus is considered an axiom of sophistication and enlightenment. These principles also translate to the physical layout and appearance of the campus and services. For many societies universities have become a symbols of reverence and privilege and as such they are absolved from certain criticisms that might be found elsewhere in the built environment. A disconnect can occur between the needs of students and the campus offerings. Although the traditional blueprint has been extremely successful it should be adapted to adres the changing needs of new generation students in the South Africa.

The University of the Free State (UFS) is such an example of changing needs and is located in one of the poorer regions of South Africa. As a result, the institution registers many students who come from vulnerable and marginalised communities. Poverty and food insecurity are directly linked and as a result, many students experience degrees of hunger while attempting to complete their studies. It is also assumed that this problem is not unique to the UFS and more widespread throughout the country. The problem is set to grow due to the increase in the cost of living which includes transport, accommodation, tuition fees and food. The circumstances first generation students find themselves is complex. For many a degree is seen as a means for the entire families to uplift themselves. This puts tremendous pressure and stress on students who are often just able to pay registration fees. The true cost of living is not always taken into consideration and students are forced to survive on a meagre daily budget. Many are unsure how they will find funds to continue from the one semester to the next one. Hunger becomes a reality and many experience it to certain degrees. Also, cheap, fast and unhealthy food at the student canteen is the only choice due to time, convenience and financial constraints. It should be realised that campus planning can help solve this problem.

Planning should take into consideration all possible options for strengthening and accessing the local food system and introduce spatial alternatives and services not conventional to a campuses. Food planning as a sub-category of urban planning is especially relevant for citizens of the Global South and universities, as micro communities, can provide valuable lessons for planners as these institutions often function as incubators for new ideas.

Research Paper

OUTLINES FOR ACCESSIBLE ROUTES ON SIDEWALKS:

a new challenge for small Brazilian cities

Fernando Domingues CAETANO, Autonomous Social Service PARANACIDADE and Pontifical Catholic University of Parana; Brazil

Jeronimo Paulo da Cunha Pimentel de MEIRA, Autonomous Social Service PARANACIDADE; Brazil

Suzi Cristini RODRIGUES, Autonomous Social Service PARANACIDADE; Brazil

Abstract

Sidewalks in Brazilian cities still have physical conditions that hamper pedestrians to move, especially those citizens with mobility impairments. Despite improvements on legal provisions, aiming to build more accessible cities, its fulfillment is still far from what is desired. The purpose of this paper is to present a method (virtual audit) to support local administrations, in particular of small cities, to define accessible routes on sidewalks where their precariousness tends to be more significant. In order to illustrate the method application, it is shown a exploratory study in the Central Business District of Quitandinha municipality, located in Curitiba Metropolitan Area. The method allows a comprehensive knowledge of site problematic and it is expected to stimulate: i) local administrations to evaluate their sidewalks situation in order to include their suitability in their investment agendas; and ii) regional and federal administrations to develop public policies towards urban environment qualification.

Key words

Sidewalk, Accessibility, Mobility Impairment, Small City, Brazil

1 Introduction

Sidewalks of Brazilian cities have inadequate physical conditions that hamper or even prevent pedestrians from moving, especially those with mobility impairments. The 2010 Brazil Population Census indicated that 69.0% of urban households benefited from paved sidewalks in their surroundings, lower than the percentage of paved streets (81.7%). The worse situation was observed concerning curb ramps, available to only 4.7% of total urban households.

Brazilian legislation has advanced on setting up planning mechanisms aiming to build more accessible cities. In 2015, the federal law to protect the rights of people with mobility impairments modified the Statute of the City (urban planning federal law), inserting the request of accessible route plan to those municipalities that are required to enact Comprehensive Plans - CPs.

Therefore, the accessible route plan is mandatory for cities: i) with more than 20,000 inhabitants; ii) members of metropolitan areas or urban conglomerations; iii) where the municipal government will intend to use the instrument established in paragraph 4º of art. 182 of Federal Constitution; iv) members of particular tourist interest areas; v) inserted in the area of influence of developments or activities with significant environmental impact in the regional or national domain; vi) included in the national cadaster of municipalities located in areas susceptible to natural disasters.

The Statute of the City now establishes that the accessible route plan has to follow the CP and that sidewalks must be executed to assure accessibility to pedestrians' attractors, either public or private, such as public offices, health care, educational, social assistance, sports or cultural facilities, post offices, commercial banks or bus stops. Although improvements on legal provisions concerning accessibility, its fulfillment is still far from what is desired.

Among the states of the Brazilian federation, Parana has the highest number of municipalities with CPs approved by city councils: 383 out of 399 (IBGE 2015). Even though most part of Parana municipalities have CPs, they do not have accessible route plan. In fact, most cities of the State of Parana are too small, and their municipal population are less than 20 thousand inhabitants. Besides that, local governments lack experience or technical capacity which restrict the elaboration or implementation of public policies towards urban development.

Within such an ongoing scenario, since 1989 the State of Parana Constitution established that cities with less than 20 thousand inhabitants (306) would receive technical assistance from a state urban development agency to define general rules relating to urban land use. Currently, the state agency with this mission is the Autonomous Social Service PARANACIDADE, linked to the State Department of Urban Development and Public Works - SEDU under a management contract.

Most recently in 2018, the State Public Prosecution has settled that local governments are responsible for sidewalk works and maintenance which conflicts with a common understanding that it is adjacent properties owners' responsibility: sidewalks, as part of public space, are public property. Those municipalities required to have CPs ought to provide their adaptation following accessibility standards; otherwise it can result in local authority's liability (MINISTÉRIO PÚBLICO DO PARANÁ 2018).

Therefore, the purpose of this paper is to present a technical method, developed by PARANACIDADE staff, to support, most of Parana municipalities, in accessible routes' definition in downtown sidewalks. The whole method consists of two stages. The first one, explored in this paper, employs a virtual street audit, using secondary information available from official sources and Google Street View - GSV. The second stage involves field visits to survey and analyze the data that complement the site diagnosis, accomplished in the first stage, to develop an accessible route project.

Initially, it is described the 5 steps that take place during the first stage: i) delineation of the Central Business District - CBD; ii) location of both public or existing private facilities as pedestrian attractors within CBD area; iii) development of a pedestrian network draft that assures access to attractors; iv) remote survey of sidewalks physical conditions; and, v) preliminary physical works proposal to guarantee universal accessibility, with estimate costs.

Previously, however, a brief quantitative evaluation of sidewalks situation in Parana municipalities is presented, considering available data.

2 Sidewalks in Parana Municipalities: A General Quantitative Overview

Parana, located in the Southern region of Brazil, is the sixth most populated state. It entered 2016 with an estimated population of 11.2 million inhabitants (IPARDES 2018). The state has a high degree of urbanization, since its cities offer greater job opportunities and better essential infrastructure services, putting pressure on local administrations to increase supply. Between 1990 and 2000, the annual urban population growth rate has reached 2.3% due to rural-urban migration. This urbanization process has increased the proportion of people in urban areas - from 73.4% to the current 85.3%. In addition to institutional weakness and insufficient financial resources availability, designed to attend the needs of the expanding urban population, urban infrastructure and primary services deficits became significant.

Aiming to support urban planning and management, in 2010, the institution in charge of the statistics in Brazil (IBGE) produced information about the occurrence (or not) of 10 distinctive urban characteristics of household surroundings. The selected urban characteristics are: i) street name sign; ii) street lightning; iii) street pavement; iv) street tree; v) storm drain; vi) waste accumulation; vii) open sewer; viii) curb and gutter; ix) sidewalk; and x) curb ramp (IBGE 2010a).

Table 1 shows that, in 2010, the percentage of Parana urban households with sidewalks in their surroundings was 58.6%, lower than the national level (69.0%). Besides that, only 9.7% of households in Parana had, in their surroundings, curb ramps. Although its level compared to that of Brazilian municipalities (4.7%) was higher, it was still deficient.

Table 1: Percentage of households with two urban characteristics in the State of Parana

RANGE	POPULATION (n. of inhabitants)	MUNICIPATILITIES	URBAN CHARACTERISTIC	
			Sidewalks (%)	Curb ramps (%)
1	Less than 5,000	98	56	11.1
2	5,001 - 10,000	105	48	8.3
3	10,001 - 20,000	109	48	8.1
4	20,001 - 50,000	55	51	9
5	50,001 - 100,000	14	57	8.5
6	More than 100,000	18	64	11
	PARANA	**399**	**59**	**9.7**
	BRAZIL	**5,570**	**69**	**4.7**

Source: IBGE 2010a.

Municipalities with a population between 5,001 and 20,000 inhabitants presented the lowest proportion of urban households with sidewalks in their surroundings: no more than 48%. Moreover, only those municipalities with a population above 100,000 inhabitants, and therefore, with the largest numbers of urban households, had the most significant percentage of households with sidewalks (64%), exceeding state average (59%), but still lower than national mean level (69%).

The data collected by IBGE concerning sidewalks were only related to quantitative aspects restricted only to the existence (or not) of the sidewalk, that is, "…paved path, designed for pedestrians, usually in a higher level than travel lanes" (IBGE 2010a), and the results in Parana are bad. If qualitative aspects were also considered, probably the state situation would be even more dramatic, especially because of restrictions imposed on people with mobility impairments.

Table 1 also shows that the percentage of Parana's urban households with curb ramps in their surroundings was higher than Brazilian average level, although both were very low (9.7% and 4.7%, respectively). In Parana, the municipalities with a population less than 5,000 inhabitants and more than 100,000 inhabitants presented the highest percentage (11.1% and 10.6%, respectively).

Although the data here considered were as of 2010, it can be assumed that current deficits of sidewalks and curb ramps are still very significant in Parana. Therefore, public policies, that ought to contribute to their considerable decrease, are becoming not only necessary but urgent.

3 A Method to define Accessible Routes on Sidewalks

In Brazil, it is remarkable the lack of urban planning concerning sidewalks in order to guarantee the existence of accessible routes as defined in the Brazilian technical standard NBR9050. It can still be said that, even nowadays in Brazil, among sidewalk's functions, adequate pedestrian's movement is one of the less considered. It is common the presence of obstacles on clear paths, such as inadequate vehicles access to properties, street lighting poles, street furniture and trees.

Theoretical references highlight walkability in urban design debate, aiming to make our cities more walkable (Lo 2009; Speck 2012; Forsyth 2015). To implement accessible routes in Brazil, sidewalk design has to consider NBR9050 width standards for each of the three sidewalk zones: street furniture zone, clear path and frontage zone.

The street furniture zone is defined as the sidewalk section between the curb and the clear path, where street furniture and sidewalk amenities should be implemented, such as lighting, benches, traffic signs and green infrastructure elements. The minimum width recommended to accommodate all these elements is 0.70m. Nevertheless, this specification is not, in practice, taken into account, and besides that, those elements use to be located in the clear path.

A clear path, where accessible routes should be implemented, is the pedestrian through zone that ensures a safe and adequate place to walk. It must be free of any obstacle, with gentle cross slope (less than 3%), minimum width of 1.20m and free from a 2.10m height.

According to NBR9050, the minimum clear path width of 1.20m is required to comfortably absorb a flow of 25 pedestrians per minute, in both directions. The clear path width must be increased due to sidewalk impedance factors, such as i) shop windows or façade stores at the building line (+0.45m); ii) urban furniture (+0.25m); and iii) building entrance at the building line (+0.25m). It can be said that, in Brazil, compliance with these normative provisions is not the rule, but the exception.

The frontage zone defines the section of the sidewalk that functions as an extension of the building. According to NBR9050, the existence of this space is only possible on sidewalks width larger than 2.00m, allowing room for vehicle access to properties, without interference in clear path specifications. As in the case of the street furniture zone, it is common in Brazilian sidewalks, due to their small widths, that the function of the clear path is affected by the coexistence of the function designed to the frontage zone.

Besides the minimum standards specified to accessible sidewalks, it is essential to point out additional relevant aspects that can contribute to improve walkability, such as continuity of pedestrian routes; accessibility of facilities to people with different impairments; connections to street network and transit services; safety of crossings; visual interest; and perceived security (Lo 2009).

The virtual street audit to define accessible routes was selected considering the inadequate urban planning capacity of local government staffs, particularly in small municipalities, where it may be even nonexistent. Virtual street audits, using secondary data, including GSV, were considered viable to understand the diversity of built environment aspects (Kelly et al. 2013; Lee and Talen 2014; Hara et al. 2015; Hara and Froehlich 2015; Saha 2019).

Most of the aspects related to the physical conditions of a preliminary proposal are shown in Table 2. The secondary information sources used in this method were: i) urban digital cartography; ii) urban digital orthophotos; and iii) GSV.

Table 2: Aspects considered to evaluate walkability conditions

ASPECT	ZONE	ATRIBUTTE	VIRTUAL AUDIT	INFORMATION SOURCE
Topography	Clear Path	• Longitudinal Slope	Yes	1
		• Transverse Slope	No	--
Size	Clear Path	• Width	Yes	1 / 2/ 3
		• Length (block)	Yes	1 / 2 /3
Obstacle	Clear Path	• Street Tree	Yes	3
		• Urban Furniture (traffic light, light pole, public telephone, fountain, trash can, awning, bench)	Yes	3
		• Pavement (material, irregularity)	Yes	3
		• Light Pole	Yes	3
		• Vehicle Access Ramp	Yes	3
Equipment	Travel Lane / Street Furniture	• Crosswalk	Yes	2 / 3
		• Curb Ramp	Yes	2 / 3
		• Traffic Light	Yes	3
		• Elevated Crosswalk	Yes	2 / 3
Thermal Comfort	Street Furniture	• Street Tree and Shading	Yes	1 / 2 / 3
Convenience	Street Furniture	• Bench	Yes	2 / 3
Safety	Street Furniture	• Street Lighting	No	--

As a case study, it is presented a preliminary proposal of a sidewalk accessible route within CBD of Quitandinha, located in Curitiba Metropolitan Area, to illustrate the application of the suggested method.

4 Definition of an Accessible Route in the Central Business District of Quitandinha: a Case Study

The municipality of Quitandinha, with around 5,000 urban inhabitants, belongs to the third-class interval of Table 1, with the worst percentages of sidewalks and curb ramps supply in the surroundings of households.

Around 24% of Quitandinha municipality inhabitants declared themselves as disabled people (IPARDES 2018). This large contingent of people, added with those with reduced mobility, makes the lack of accessibility a priority issue in urban local agenda.

The first step of the proposed method consists in CBD delineation. According to Sepck (2016), starting to improve the CBD physical conditions can help to improve all other parts of the city. If the CBD doesn't look good, the same also happens with the rest of the city. In Parana, only 10% of its municipalities have neighborhoods officially defined, mostly the large ones (IBGE 2010b).

PARANACIDADE, based on Quintandinha Comprehensive Plan (historical evolution of urban land use and zoning law) and on urban cadaster, has conducted a study that outlined 10 neighborhoods, including CBD. The latter's limits took as reference the spatial concentration of, public or private, service and commercial activities, comprising an area of 55.35 hectares (9.5% of urban growth boundary), and a set of 17 streets with a total extension of 5,638.80m (12.4% of the urban street network).

Figure 1: Location of CBD area within Quitandinha Urban Growth Boundary
Source: SEDU/PARANACIDADE INTERATIVO 2019.

In the second step, 121 pedestrians' attractors were identified within CBD: 99 from private sector and 22 consist of public agencies (Figure 02). Public facilities are grouped in 2 blocks, whereas commercial activities are more equally distributed among the main street (Eleuterio Fernandes de Andrade Avenue) and two other streets (Expedicionario Street and Padre Francisco Street).

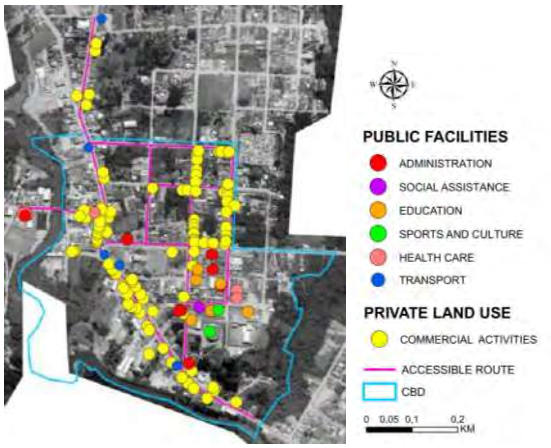

Figure 2: CBD Quitandinha Accessible Route Final Proposal

The first accessible route proposal was defined considering the connection of all the 121 pedestrians' attractors identified within CBD (third step). Nevertheless, the high longitudinal slope of the initial section (2 block frontages) of Estalisnau Socek Street and of the total extension of Abilio Alves Street compel to their exclusion. In both cases, the longitudinal slope was higher than the allowable standard for wheelchair users, as specified in NBR9050. So, the total length of accessible route first proposal was 7,828.54m (comprising 11 out of 17 Quitandinha CBD streets and 50 out of 67 central block frontages), which allowed the connection of 97% of all identified pedestrians' attractors (Table 3).

Table 3: Extension and number of block frontages of the CBD accessible route proposal

STREET	BLOCK FRONTAGE					
	CBD		CBD ACCESIBLE ROUTE			
			FIRST PROPOSAL		FINAL PROPOSAL	
	LENGTH (m)	Nº	LENGTH (m)	Nº	LENGTH (m)	Nº

TOTAL	**9,407.44**	**67**	**7,828.54**	**50**	**7,992.28**	**52**

*Accessible route extended to other points of interest located outside the CBD limits.

Additionally, to make connections with other two near relevant public facilities, outside CBD, (bus station and public health unit), it was necessary to expand the first proposal of an accessible route, including 4 block frontages of Acelino Ribas Pinto Street 2 of Marciano de

Carvalho Street, achieving the total length of 7,992.28m (comprising 10 streets and 52 block frontages). Figure 2 illustrates the street set of the accessible route final proposal.

In the fourth step, physical conditions of the accessible route sidewalks have to be virtually audited. However, fully audit was only possible in the CBD main street (Eleuterio Fernandes de Andrade Avenue) where information from GSV was available. Nevertheless, the analysis concerning the other streets was taken forward restricted to those aspects that could be evaluated considering the two other secondary information sources.

Sidewalks widths analysis pointed out the need to their enlargement: Jose de Sa Ribas Street, where City Hall is located, has the largest sidewalk width (1.90m); three other streets have sidewalk widths near the minimum required by NBR9050 in relation to clear path (1.20m); and the rest (6) has their sidewalks' width with less than 1.00m. To ensure full accessibility, total sidewalks widths should be increased - considering commercial land use - which directly implies travel's lanes width narrowing.

Only 4 out of the 52 central block frontages has length less than 100m; half of them, between 100m and 120m; and the rest, over 150m, reaching the largest block frontage length of 765m. The latter group corresponds to 60% of the accessible route total extension (7,922.28m), which possibly requires the implementation of midblock curb cuts, together with crosswalks, to assist people with mobility impairments.

Along Eleuterio Fernandes de Andrade Avenue, different types of obstacles in the clear path were recognized, such as i) 6 trees out of 11; ii) 10 urban furniture elements out of 19 – 5 vertical signs, 3 awning's support, 1 bus shelter and 1 public trash; iii) improper materials for sidewalks pavement (73%), added to the irregularity of those deemed appropriate (27%), compromising accessibility in almost all sidewalks of the route; iv) 6 light poles out of 38 (the improper location makes them an obstacle to pedestrian flows); and, v) 21 vehicle access ramps out of 35 (affecting the clear path transversal slope).

The existing crosswalks (20) are only 25% of the overall estimated need (82), and, in 3 streets (out of 10) they do not even exist. The survey results revealed a worse situation for curb ramps: there are only 6% of the total number required (150). In addition, there is only one elevated crosswalk along Eleuterio Fernandes de Andrade Avenue. This kind of element should also be available in other accessible route streets, as is the case for Expeditionary Street where several public facilities and educational establishments are concentrated.

Regarding the thermal comfort aspect, the existence of shading elements along the accessible route was evaluated. Of the 48 trees identified, only half of them provide shade over sidewalks. Based on the estimated need of 191 trees, the deficit is approximately 87%. Even in the Expeditionary Street, which has the greater contingent of afforestation (12), thermal comfort is far from desired (22), since distances between existing trees oblige pedestrians to walk extensive stretches under sun exposure.

Virtual audit, using GSV, allowed to identify 7 commercial awnings, of which 4 are continuous and contribute for 40 meters of shading along Eleuterio Fernandes de Andrade Avenue. The 3 other remainder awnings provide 15 additional meters of shade, although not continuously. No other convenience elements, such as benches that could provide rest along the footpath, were identified in the furniture zone.

Once the accessible route within Quitandinha CBD was audited, the fifth and last step consisted in quantifying the required physical interventions as well as in estimating their costs, so that the municipality can anticipate the required financial resources for their works.

Pavement materials that provide uniform and regular surfaces, such as asphalt and concrete were favored. Although it does not meet this criterion, it was also considered the paver block, due to its recent and wide dissemination in Parana cities' sidewalks.

Due to scarce information, the present analysis was grounded on the sidewalks' adaptation requirements of Eleuterio Fernandes de Andrade Avenue central segments, to which GSV was available. So, the estimated total costs for the other streets were based on its average costs.

Initially, lot-by-lot land use, urban furniture in sidewalks, and zones' widths were audited to identify width sidewalk readjustment requirements (Figure 3). As a result, sidewalks widths needed to be increased, as follows, to: i) 2.60m in central blocks where commercial activities concentrate; ii) 2.40m in residential areas where frontage zones are needed; and iii) 2.15m where urban furniture is available.

Figure 3: Sidewalk impedance factors – Eleuterio Fernandes de Andrade Ave.

Figure 4 illustrates the shifts on sidewalks widths. It should be noted that the required narrowing of travel lane width does not compromise the street service capacity.

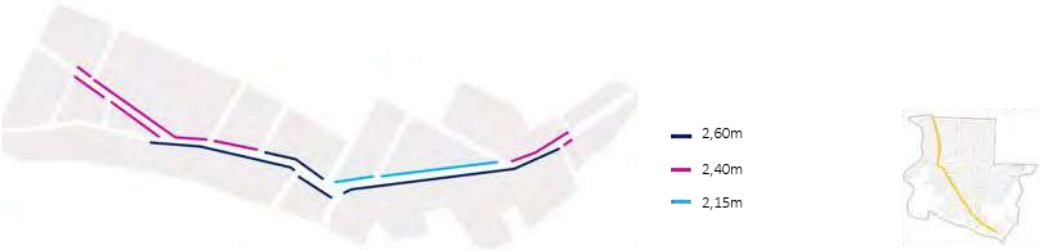

Figure 4: Sidewalks widths proposal - Eleuterio Fernandes de Andrade Ave.

Moreover, it was identified the needs to replace sidewalks pavement and execute additional physical interventions, such as tactile paving, car ramps in access zones, curb ramps at intersections, public lighting poles, and pedestrian crosswalks. Since in CBD pedestrian flows are most intense, no infiltration strips were proposed on the accessible route.

The estimate project cost for each of the 3 sidewalk pavement alternatives is presented in Table 4. The scope of the intervention area is 4,586.45m^2 (corresponding to 70% of total area), due to pavement material inadequacy or poor conditions of maintenance.

Table 4: Total and average costs estimates of sidewalks in Eleuterio Fernandes de Andrade Ave. according to pavement alternative

SIDEWALK PAVEMENT ALTERNATIVE	TOTAL COST (R$ 1.00)	AVERAGE COST (R$ 1.00)
Asphalt	399,525.93	87.11
Concrete (in-situ)	452,092.59	98.57
Paver block (precast)	531,870.30	115.97

The total project cost of supplying and adapting urban elements that guarantee universal accessibility and adequate comfort conditions for Eleuterio Fernandes de Andrade Ave. was estimated in R$ 388,682.25 corresponding to the average cost of R$ 84.75. The item that most impacted final budget was light poles installment (85%).

Based on estimate average costs and on accessible route final proposal total area (19,927.97 m^2), the budgets for the 3 sidewalks pavement alternatives were appraised as follows: R$ 2,515,868.64 for asphalt; R$ 2,683,639.47, for concrete (in situ); and R$ 2,938,334.51, for paver block.

These amounts accounted from 36 to 42% of the potential indebtedness capacity of Quitandinha municipality to borrow money to finance investments in 2019 (16% of its net current revenue) or from 52 to 61% of the average value of its investment expenditure for the two-year period 2017-2018 (Tesouro Nacional 2019).

5 Conclusions

The requirement, in the federal sphere, for cities already obliged to elaborate CP, to plan accessible routes, demands, in the state and municipal spheres, a wide building capacity effort concerning the content and methods related to this plan. Even though this legal requirement has already been in existence since 2015, there is no city in the State of Parana with an accessible route plan.

To develop an accessible route plan for Quitandinha, a small city obliged to elaborate an accessible route plan, proved to be a challenge from its very beginning due to scarce and limited available data concerning physical aspects of its streets. Nevertheless, the efforts made so far are much smaller than those required to redesign and rebuild a lot of Brazilian urban streets, such as Eleuterio Fernandes de Andrade Ave. of Quitandinha, aiming to guarantee sidewalks universal accessibility.

Virtual audit contributed, despite limits of GSV coverages, to get a preliminary broad site comprehension by compiling several types of spatializable data (pedestrian attractors, topography, street features, obstacles, equipment, thermal comfort, convenience and safety physical elements) from different information sources of public access. Besides that, this method enables to propose a set of physical interventions and gives support to estimate its investment costs.

It is expected that this feasible method encourages: i) local administrations to audit sidewalks situation to include in their investment agendas aiming urban walkability improvement; and, ii) regional or national governments to define public policies towards urban environment qualification.

Research Paper

The Importance of Participation and Inclusion in African Urbanization

A focused look at Transport and Housing Projects

Constant CAP, Naipolitans; Kenya

Abstract

According to the World Bank (2015) Africa's urbanization rate has surpassed other parts of the world. It is believed that by 2030, over 50% of Africans will reside in Urban Centres. Kenya is among the African counties that has experienced a tremendous increase in her urban population. This is most visible in the capital, the primate city of Nairobi. The growth has led to increased pressure on basic needs like housing, transport, water, education and security. Coupled with unequal economic development and social benefits, the result has been the tremendous expansion of informal sectors across fields.

To respond to some of this pressure, the central government has vowed initiate large projects in housing, transport, water and others (Republic of Kenya, 2018). Newly enacted legislation also provides for the establishment of multi-sectoral urban boards to oversee the delivery of some services. Among the major projects coming up include Affordable Housing schemes and Mass Rapid Transport investments such as Bus Rapid Transit and expanded commuter rail systems.

However, experience from the past both in Nairobi and other Cities has taught us the importance of inclusion, empathy and participation in such projects. Recent times have shown that public projects tend to ignore these and other key elements leading to massive failure of investment.

The paper investigates case studies from similar projects in other parts of Africa, Bus Rapid Transit Projects in Lagos, Dar es Salaam and South African Cities; past Slum Upgrading and Housing Projects in Nairobi and other parts of the continent. The research methods also involve data collection on inclusion and participation from those who are affected directly by these proposed projects as well as the impacts that previous projects have had.

The results from the study show that without proper communication and participation there are several misunderstandings on liveable spaces in cities. These include misinterpretations of the challenge's citizens face, on the intentions of proposed solutions as well as the socio-economic decision-making process of citizens. The implication of this leaves an unhealthy competition between existing informal 'structures' in various sectors against the new government driven proposals. The results are that those meant to benefit end up not being the primary beneficiaries.

In conclusion, the role of putting people primarily as the centre objective of planning remains critical and key. For African planners, diverting from this will increase the existing inequalities and lead to further social divisions.

Africa, Participation, Informal, Transport,

1. Introduction

Urban areas have grown and developed at an astronomically high rate over the last century. The United Nations estimates that at present 55% of the world's population lives in urban centres. This is expected to get to 64% by 2050.

Though Africa has the lowest level of urbanization, Sub-Saharan Africa's urbanization rate is the highest in the world (Mckinsey, 2016). Africa experienced an increase in her urban population growth rate from 3.52 (2005) to 3.61 (2005-2010) to 3.70 (2010-2015). This currently lies at 3.58 (2015-2020). The growth rate of African Cities and towns is currently unmatched with Asia's at 2.80 (2005) to 2.43 (2005-2010) to 2.61 (2010-2015) and 2.56 (2015-2020). Europe, which is highly urbanized has experienced a growth rate of 0.33 (2005) to 0.46 (2005-2010) to 0.35 (2010-2015) and is currently at 0.35 (2015-2020). United Nations Population data 2019).

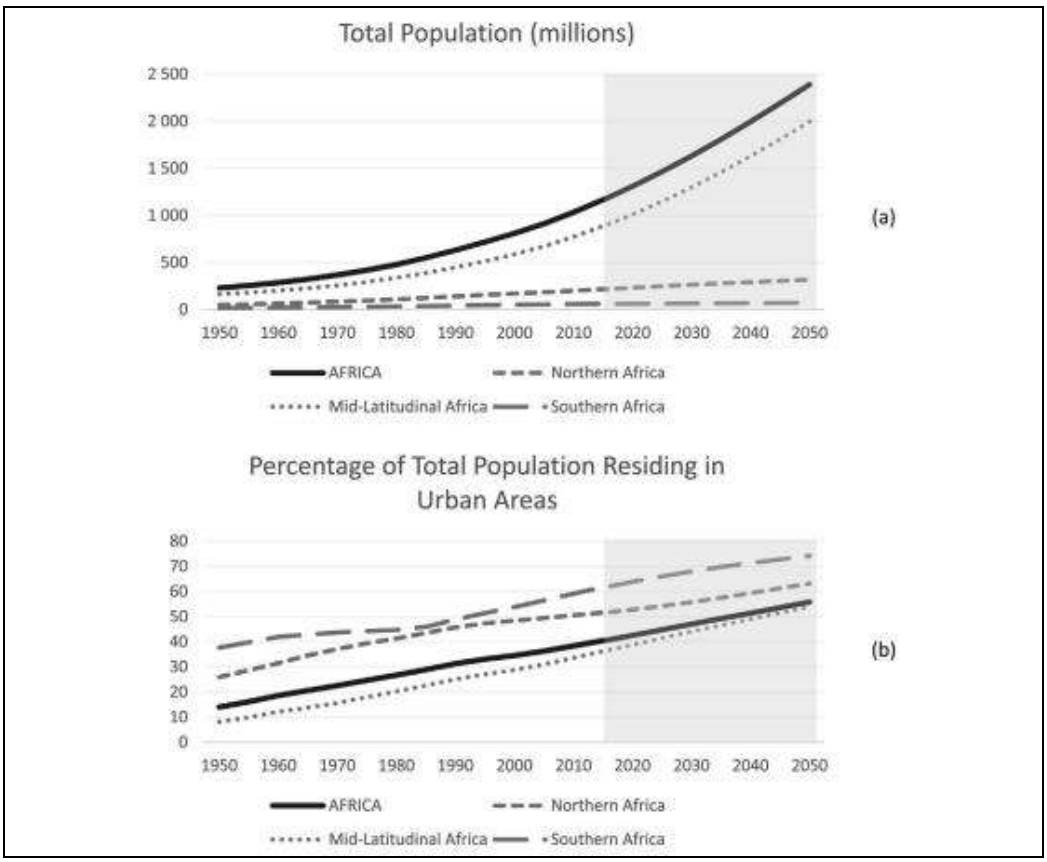

Figure 1: African population trends 1950-2050, Source: Guneralp

Rapid urbanization is seemed to be increasing the continent's productivity. Africa's urban population growth, however, has brought unique challenges and observers are questioning whether urban infrastructure, especially housing and transportation, can meet the needs of the ever-growing population (Anderson and Galatsidas, 2014). These challenges are coupled with high levels of unemployment, the growth of informality and various environmental risks and hazards. Traffic congestion, shortage of affordable housing, poor service delivery like

solid waste management and water supply environmental degradation through pollution are also evident.

The popular approach taken towards solving many of these challenges has been through engaging in bi-lateral agreements and more recently private-public partnerships. These are directed towards the development of mega-projects in affected fields. The transportation sector has seen a lot of focus on the development of highways and link roads. In housing, slum upgrading and multi storey affordable housing projects have been attempted. Bus Rapid Transit is currently being championed as a means of tackling transportation and congestion challenges. Multi-storey markets are being driven as possible solutions to the informal trading problems.

Inclusion, empathy and participation are important factors to be considered in urban development projects. Public participation is an action or a series of actions a person takes to involve themselves in affairs of government or community (Uraia, 2016). The role of participation has increased though legislation in the Kenya Constitution 2010. Kenyan policymakers have put strong emphasis on transparency, participation and accountability in the new Constitution and legal framework (World Bank ,2013). Global experience, however, shows that it takes time for systems to be put in place and for legal requirements to be fully functional. Many times, participation is only applied as a formality to 'rubber-stamp' pre-determined projects. Views of citizens are rarely looked at substantially and projects are determined in board rooms, seminars and studios. The results have been catastrophic, with very little understanding of the social infrastructure and ecosystem of citizens lives.

2. Public Participation in Urban Planning and Development

2.1. The Ladder of Public Participation

Participation can take different approaches as per the ladder of participation developed by Sherry Arnstein in 1969. The lowest levels those of 'Manipulation' and 'Therapy' which fall under the sub context of 'Non-Participation.' The highest levels are those of 'Citizen Control, Delegation and Partnership' which fall under the sub contexts of 'Citizen Control.' The middle sub context is that of tokenism which covers placation, consultation and informing.

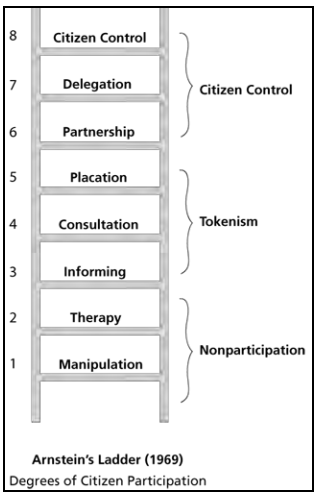

Figure 2: Arnstein's Ladder of Citizen Participation

The importance and necessity Citizen Control levels of participation other than the more dominant non-participation and tokenism methods cannot be undervalued. This importance has been visible in the successes and failures of many development projects in cities. Repetition of the same brings about similar if not worse results.

Some key necessities for good public participation include timely access to information; Reasonable access to the process of formulating and implementing policies, laws, and regulations; Protection and promotion of the interest and rights of minorities; Providing multiple opportunities for public participation; Legal standing of those interested or affected and Reasonable balance in the roles and obligations of county governance and non-state actors (Uraia, 2016).

2.2. Legal Framework for Participation

Under the 2010 Constitution, Kenya opted towards decentralization of powers, changing the relationship between government and citizens. The 2010 Constitution and new legal framework place a strong emphasis on strengthening public participation. (World Bank 2015).

Under Article 1(1-4), The Constitution states that, all sovereign power belongs to the people of Kenya. It adds that that the people may exercise their sovereign power either directly or through their democratically elected representatives both at national and county level. Article 33 points out that public participation should respect the freedom of expression of all participants while Article 35 guarantees citizens the right to access information.

Participation is important in governance and development because it enables 1. Increased trust between public officials and the community. 2. Citizens have a sense of belonging and trust in their community leaders. 3. There are diverse views from a greater citizenry, 4. Citizens are better informed on various developmental projects and government initiatives. 5. Community concerns are more focused and prioritized for public officials to address comprehensively. 6. Citizens' diverse and unique skills are revealed to government officials and to the community. 7. It contributes in setting the priorities of the community and better decision making. 8. The citizens is more aware of community concerns and can effectively judge government responses on issues affecting the community. 9. Public officials get a better understanding of community needs and are able respond effectively (Uraia, 2016)

2.3. Participation in Urban Development

Beazley (1994) states that for public participation in urban planning to be effective it ought to be equitable and efficient. Public participation is a critical aspect of the success of public infrastructure megaprojects (PIMs), in which ineffectiveness is a constant problem (Wu, 2019). Urban Mega projects have significant impacts on cities, on the way we practice planning and the way we involve the community in decision making processes (Beazley, 1994). Community members are constantly asking themselves how much influence they can have on the nature and shape of such projects.

Public participation is also important for the proper achievement and execution of the Sustainable Development Goals. Sustainable Development Goal Number 11 that SDG11 talks of inclusive, safe, resilient, just and democratic cities (UN Habitat, 2016). The New Urban Agenda, which was signed by several in 2016 represents a shared vision for a better and more sustainable future (UNHabitat, 2016). It describes how when well-planned and well-managed, urbanization can be a powerful tool for sustainable development. It covers key

thematic areas which include: Social Cohesion and Equity (Liveable Cities), Spatial Development, Urban Ecology and Environment, Urban Economy, Urban Frameworks, Urban Housing and Basic Services. This is not possible to achieve without proper participation, which according to Maceratini (2018), gives the greatest opportunity is to create trust between government and communities.

In urban development and planning projects there are several key factors that should be handled when attempting good and effective public participation. Maceratini identifies five as key and these include: 1. Every step in the decision-making process is taken involving the community, 2. Having a multi-dimensional perspective, listening to all voices 3. Involving all people, no matter what the rank or position in society (Engagement) 4. Space for dialogue between stakeholders 3. Social inclusion

Likewise, there are five challenges that emerge when one wants to have good public participation. These are: 1. Identifying key stakeholders, 2. Involving them throughout the process and keeping their trust 3. Making stakeholders communicate and sharing what they know 4. Understanding territory and enduring that the project transforms projects into opportunities and 5. Ensuring that the result is adopted by everyone.

3. Metropolitan Transportation Projects

3.1. Bus Rapid Transit in Lagos, Nigeria

The Lagos Bus Rapid Transit (BRT) was launched in 2008. It is a 22 Km segregated lane with 3 terminals and 26 stops. The private sector provides rolling-stock, recruits and trains crew and manages operations. The route was selected based on Gateway corridor High traffic demand Less Resettlement Action Plan. This BRT system is the first of its kind in sub-Saharan Africa and is the only example of a comprehensive and integrated approach to improving public transport. (Mobereola, 2009)

Mobereola (2009) states that there was an intentional attempt to involve stakeholders from the start and this was done through Study tours with union executives, a Series of high-level meetings with Union members, the involvement of senior politicians and the inauguration of BRT implementation committee. BRT officials were constantly engaged the public and promoted the new system. Negative comments primarily revolved around the need for more routes and buses.

The BRT development process included the formation of a Cooperative comprising Union members on the BRT corridor. A steering committee comprising Lagos Metropolitan Transport Authority (LAMATA) and the funding bank which provide professional advice on the management of the cooperative and BRT operations was also established.

In order to protect union members interests, a transparent cash slow process was designed. An interesting development was the Bi -lateral operation where Danfoes (Mini and Midi buses) and Molues (big yellow buses) operate on the service lane while BRT buses operate on the BRT lane.

This new form of the BRT scheme aimed at delivering a transport system that would meet the needs of local users, while improving citizens' quality of life, economic efficiency, and safety. Its success stems not solely from its infrastructure but from a holistic approach that has included reorganizing the bus industry, financing new buses, creating a new institutional

structure and regulatory framework to support it. It also involved training the personnel needed to drive, maintain, enforce, and manage it (Mobereola, 2009). An evaluation in 2009 pointed that over 200,000 commuters used the bus system daily. Passengers enjoyed a reduction of 30 percent in average fares and a saving of 40 percent in journey time. Public transport waiting time was also reduced by 35 percent (brtdata, 2019). The project is deemed to have met and exceeded its development objectives, proof that there is no substitute for a well-conceived project managed by a competent implementing agency (Gorgam et al, 2017).

3.2. Reya Vaya Bus Rapid Transit, Johannesburg, South Africa

Johannesburg has a Bus Rapid Transport system called Reya Vaya. Studies indicate that it has lower passenger demand, poorer financial performance and higher subsidy requirements than initially hoped (Venter, 2016). In 2016, it catered for only 1100 daily boarding's per kilometre as compared to the minimum of 8000 in other cities.

The South African government recently admitted that it had been a mammoth flop. Commuters have shunning the system in favour of taxis and ordinary buses. One major setback has been its low area coverage which makes informal taxis more favourable (Mabena, 2017). This has forced the government to highly subsidize the service as the fare revenue is not enough to sustain it (Venter G, Hays C, 2017).

Findings from a study done with a local community revealed that little community participation was conducted prior to the implementation of the transportation project. The interviewed participants stated that they were not involved in the determination of the routes that Rea Vaya would take (Venter, 2016). This left many wondering who the development is for: the government's or the community's? The project was also rushed in order to be ready in time for the FIFA World Cup in 2010.

The lack of or poor participation is seen as one of the reasons why those implementing the project failed to realize what Venter (2016) pointed out from his research: that distinct market segments had different needs e.g. Choice passengers have a very limited willingness to pay for the travel time savings procured with dedicated trunk lanes, but place much higher value on good access, higher frequencies, and, above all, the overall service quality.

3.3. Dar es Salaam Bus Rapid Transit (DART)

For more than fifty years, residents of Dar-es-Salaam city faced public transport problems which were seen through traffic congestion and several fatal vehicle accidents. A Bus Rapid Transport system was proposed as a possible solution to these challenges.

A study done in Dar es Salaam prior to the development of the BRT system stated that though many were of the perception that it would be helpful in reducing travel time, it was perceived to benefit specific groups of people, particularly professional workers or a 'higher class' (Joseph, 2018). Based on the physical location of the DART line, the number of transfers for individuals commuting from peri-urban area to the CBD changed from one (direct route) to two transfers. However, since the BRT system started its operation in 2016, it has been found to be an effective solution for urban transport problems in the city. The benefits of the system have been recognized though improved mobility and satisfaction with public transport (Chengula and Kombe, 2017).

Matteo R (2015), discredited "win-win" narratives by showing what some Tanzanian actors stood to lose from the implementation of the Dar es Salaam Rapid Transit scheme. He points out that there was slow implementation of the transport system due to the tepid commitment to the project by the Tanzanian government. This was due to domestic politics, and the government's attempt to respond to the priorities of the World Bank without alienating local actors. Some of these actors wield considerable electoral power.

The urban poor and vulnerable also face access constraints. It has also been noted several the stations are not aligned with stops, stands, and stations of other modes. Consequently, most passengers spent up to 20 minutes to walk to the DBRT stations/terminals (Chengula and Kombe, 2017). There are also concerns about fares, which are 55% more than *daladala's (informal transport minibuses).* This is despite an initial pledge from DART officials that they would be comparable (Matteo, 2019). These high fares have forced many of the poor to use informal transport systems which run parallel to the BRT but in normal traffic. The higher fares given benefit to those who can afford to travel without any worry of traffic congestion. For the service to be more inclusive, some form of government subsidy will be necessary (The Citizen, 2016).

From a technical perspective, Chengula and Kombe, (2017) state that for the DBRT system to be viable life cycle cost and sustainable project there should be connections between DBRT truck roads and arterial roads and coverage of remote areas. In this regard, informal public transport is still key to taking people to work, school, shopping and social matters. Time efficiency, flexibility, mode availability, and access to high- and low-density unplanned areas are some of its key features that BRT system is unable to fully replicate. (Joseph L, et al, 2018).

4. Metropolitan Housing Development Projects

Housing remains a visible symptom of the vast poverty affecting the poor in Africa's cities. The development of informal settlements in sub Saharan Africa has been one of the highlights of its urbanization process over the last 50 years. Governments are also unable to keep up with and provide social housing for the urban poor. A more recent trend has been to 'formalize the informal' through slum upgrading projects. These have been done in several cities with varying levels of success. Affordability, however, remains a challenge in the formal housing market for low income households. *In Situ* upgrades through community participation have become more common recently and are being considered as global best practice (Williams, 2006).

4.1. Lagos Metropolitan Development and Governance Project (LMDGP)

Lagos is one of the largest cities on the continent and experiences a massive housing shortage. 60-80 percent of urban Nigerians are estimated to live in slums and informal/squatter settlements. The World Bank financed the Lagos Metropolitan Development and Governance Project (LMDGP) as an attempt to improve living conditions of slum dwellers by enhancing their access to infrastructure and services. The project started with a demolition with only a 24-hour notice (without written notification). This completely undermined essence of consultation and participation. In what could be an attempt to cover face by some, extensive consultation was conducted throughout the preparation and implementation of the Relocation Action Plan (RAP) for the 2,296 displaced households in

Badia East. This included at least nine consultative meetings. The RAP uploaded on the website of the Lagos State Government, advertised through three national newspapers, and four hard copies were made available for 21 days in the Apapa-Iganmu Local Council Development Area (LCDA) (World Bank, 2015). The bank stated that the full extent of the risks associated with involuntary resettlement as a result of the LMDGP's slum upgrading and other activities was not have been fully apparent at the beginning of the project, especially considering the complex political economic dynamics. A report on the project added that the promoting if comprehensive and integrated urban planning approaches was necessary (World Bank, 2015).

World Bank policies require the engagement of communities in any project that might involve displacement. In Badia East, these requirements were ignored (Pereras, 2016). Sinani, (2014), in his article *'The World Bank Just Made Lagos Poorest Poorer'* states that Badia communities are demanding justice. He points out that 'The least the World Bank can do is implement its own policies.'

4.2. Kenya Slum Upgrading Project (KENSUP), Nairobi

The Kenya Slum Upgrading Project was established by the Government of Kenya and UNHabitat to construct and resettle residents of Kibera's Soweto East Village in more decent and sustainable housing. Approximately 6299 residents who lived in 976 structures were affected. The residents were moved to reside at a 'decanting' site as the new high-rise structures were constructed. According to (Komollo, 2017), very little participation was done, and stakeholders did not have access to maps and drawings of the proposed project. On the ground, most dwellers also claimed that they were not consulted (Good Fortune, 2009).

There was also little information on the financing structure for the residents. This was worrying as many predicted that they would be requested to pay more that the rents that they had been paying at the slums.

Eventually, when the time to relocate came there were several hitches as some houses had already been allocated to outsiders. Some tenants who were awarded houses ended up losing them due to inability to pay up. Others rented the houses out and moved back to the informal settlement. They cited various reasons for doing this. Amongst them was the inability to support themselves in the new neighbourhood and inability to access infrastructural services because of distance and high rent rates (Mureithi 2016).

To date the decanting site remains occupied while the houses are fully occupied. But about half of those who officially received houses in the new apartments in Soweto East no longer reside there. These units have either been given away, sold or rented out (Higgins, 2013).

The project was deemed to be an extension of earlier top-down interventions in the settlement. This was the typical case where state actors shift the boundaries of the formal and the informal and at the same time acting inside and outside these shifting boundaries (Flink, 2016). The discontent caused among the dwellers led to more problems. Adegun (2018) suggests that this is an indication on how Kenya's government is ignoring social and economic factors when relocating people from slums.

4.3. Zwelisha Slum Upgrading Project, Durban

In South Africa, the proliferation of informal settlements has deepened poverty and unemployment levels, prevented empowerment and increasing inequality. (Mbutu, 2014)

Patel, (2013) points out Zwelisha, an upgraded settlement north of Durban, South Africa, as an example of a successful slum upgrade. He uses data from an ethnographic study to show that successful outcomes are intrinsically tied to the way the upgrade process is implemented. He explains the importance of the continued and consolidated power and influence of the local community development committee (CDC) following upgrade. The residents agree that the upgrading was a success citing the improved quality of life they now have.

The CDC led the residents through the entire process of applying for the housing subsidy, depending on whether they were eligible (Mureithi, 2016). However, there ought to be caution of how the state's approach to community participation in slum upgrades may consolidate and legitimise informal power relations that may not be necessarily benevolent (Patel 2013).

In this case, formal changes in the settlement that led to improved security of tenure and improved quality of life (defined by residents lived realities) depended upon informal continuities.

5. Results, Insights and Findings from this Study

Lind (2011) states that Urban planning with public participation has not always been deemed necessary. As recent as 50 years ago, planners were considered 'demigods' who had transformed cities to be beautiful, healthier, cleaner, and more stable places. Planners had come to be trusted by the people. However, recent experience has led to Gorham et al, (2017) to point out that urban transport projects can only be successful if they are cooperative, involving all stakeholders. Flick (2016) defines stakeholders as the individuals, groups, or organisation, who may affect, or be affected, by a decision, activity, or outcome of a project. He explained that it is important for every stakeholder to be considered and considered in order to provide successful projects. This requires a solid communications plan and proper stakeholder analysis. General stakeholder management process consists of stakeholder identification and gathering relevant information, analyse stakeholders and their potential impact, and at last, developing adequate management strategies. (Flick, 2016).

Although studies have focused on public participation, a method that can measure and improve its effectiveness is lacking. (Wu, 2019). Up to date, the urban development process of Nairobi is still dominated by public interventions permeated by non-participatory technocratic instruments of urban space production (Omenya and Huchzermeyer 2006; Oyugi and Owiti 2007). There is new hope however to improve urban governance through citizen participation in planning given the recently enacted urban policies. (Mwaniki et al, 2015). A Study done in Nairobi Central Ward by University of Nairobi revealed that there was a very weak relationship between public awareness and participation in urban planning projects but there was no relationship between degree of accessibility and public participation in urban planning projects. It was also established that there exists a weak

positive correlation between a person's financial situation (income, expenditure and savings) and their participation in urban planning projects.

The success and failures of the projects above depict the importance of some of the key necessities of good public participation as listed earlier. A simple analysis can showcase how the success can be measured against the parameters given.

Principle	**Lagos BRT**	**Reya Vaya**	**Dar BRT**	**Lagos Slum Upgrade**	**Durban Slum Upgrade**	***KENSUP***
Access to information	Good	Poor	Average	Poor	Good	Poor
Access to policy formulation process;	Good	Poor	Good	Poor	Good	Poor
Protection minority rights	Good	Poor	Average	Very Poor	Good	Very Poor
Opportunities for public participation;	Good	Poor	Good	Poor	Good	Poor
Legal standing of those interested or affected;	Good	Good	Good	Poor	Good	Poor
Balance in the roles of various actors	Good	Good	Good	Poor	Good	Poor

Figure 3: Estimated Levels of success of participation per project Source: Study

From the information collected and looking at the table above can give a general overview of what levels of public participation were experienced at the different projects. The levels of participation are also an indication on how empathetic those behind the projects were as well as how well the projects were communicated to stakeholders.

Lagos BRT	Reya Vaya	Dar BRT	Lagos Slum Upgrade	Durban Slum Upgrade	*KENSUP*
Citizen Control	Tokenism	Tokenism	Non-Participation	Citizen Control	*Non-Participation*

Figure 4: Participation Levels taken at each project Source: Study

It is quite noticeable that there is a relation between the success levels of urban development projects and the levels of participation. Rucker (2011), stated that If the people who live around a proposed development oppose a development, chances are those people know something that is important to the health of their neighbourhood and the larger community. He views them as the source of its collective intelligence. At lower levels of participation, at times seen as 'conventional' participation or 'rubber-stamping' as is known in Kenya, it makes the mistake of privileging a few. Different project will affect different actors where their specific interests will vary depending on project type but also throughout the project's execution. (Flick, 2016). Participatory planning cannot be a paper commitment that is confined to policy documents, theoretical debates and municipal business plans.

There is therefore a need to identify ways to make this concept a reality, particularly in addressing developmental needs (Mbutu,2014).

Klopp et al (2019), point out that a key problem is that the focus on BRT as a "project" to displace and modernize the existing transport system. Additionally, in areas of transport governance in Africa there are low levels of transparency, information sharing and public participation in decision-making. Consultants are also well known to invite the public for participation meetings with little intention of making any changes to their proposed projects.

Planning professionals' failure to engage with communities in an integrated and inclusionary manner has made things even worse when it comes to community empowerment initiatives (Mbutu, 2014).Even though locals can share their socio-economic and cultural perspectives to make projects successful, professionals continue to assume their own perspective of the different fields to be correct. Residents have a level of detail and a critical perspective that can make the difference between whether a proposed project supports the health of the community or creates a new burden (Rucker,2011).

6. Conclusion

The necessity to put people at the centre of all planning and development activities cannot be ignored. This starts with proper identification of stakeholders and understanding how project will impact and influence their lives. Their participation in the planning process can help prevent 'white elephant' projects and ensure that social justice takes place accordingly. A lot of wastage in both time, money and other resources can be avoided when and extra effort is put into this.

Citizens are also more aware of their right to be consulted and the failures of 'top-bottom' projects have raised many concerns. Unfortunately, we still see many public agencies and private consultants approaching participation merely to approve projects without looking the potential long-term challenges that this brings.

These are lessons for the Kenyan government as they approach the Affordable Housing projects under the Big 4 Agenda as well as Nairobi Regeneration Strategy. This will enable them to ensure that further socio-economic divisions are not created from projects that aim at serving the urban poor.

Understanding the real reasons why people oppose a project requires the willingness to do so, the humility to listen, and the internal fortitude and self-assurance to admit that possibly, we don't know everything that there is to know. That is the real mark of wisdom. (Rucker, 2011)

IMPROVING THE QUALITY OF PUBLIC SPACE

IN BOGOR CITY THROUGH CSR FUNDING SCHEME

Adriadi DIMASTANTO, Rachmatika Fitri INSANI TANJUNG, Tri SAPTIWI

Abstract

Bogor is a city located 40 km to the south of Jakarta, which is a satellite city in the Greater Jakarta Metropolitan Area and has unique characteristics among other cities in the Metropolitan. The city has a characteristic as a garden city, which in its history, was called by the Dutch colonial as a "buitenzorg" or a "pleasant city". The Dutch colonial government as well as Britain in the era of their governance designed this city as a city of rest. One of them is indicated by the existence of the Bogor Botanical Gardens and the vast presidential palace in the heart of the city. Unfortunately, today Bogor continues to experience degradation in terms of the quality of space. Congestion, chaos, slums, and a myriad of other problems that are commonly faced by cities over 1 million inhabitants. In the last 5 years, Bogor has improved. One of the most important things that had been done by the local government was the improving quality of public spaces such as city parks, plazas, pedestrian ways, etc, and the attempt to restore the character of the city as a garden city. Over time, the city government began to face several obstacles, especially funding. Inadequate fiscal capacity of the local government makes the mission of improving the quality of urban public space stagnant. In one year, on average the government budget was only 2.5 trillion, and on average only 10 billion per year was allocated to build city parks, where the amount of this budget was seen as very minimal. Facing this obstacle, the city government innovated by inviting the private sector to contribute to the provision of city parks, one of which was through the CSR scheme. This was something that was not normal in Indonesia, and it was seen as one of the innovations in building city parks. This paper aims to explain one of the city park development projects in Bogor using the CSR fund scheme, which took place in April 2016-February 2017. The preparatory activities took place in April-August 2016, while the construction took place in September 2016-February 2017. The Project was the construction of outdoor children playground in the city center by utilizing CSR funds from one of the convenience store companies, which were channeled through children's foundations, and later appointed a third party to design and build the park. Activities were carried out with a "design and build" scheme, where the third parties (consultants and contractors) carried out the design and the construction as well. The development process was carried out through various stages such as discussions with local residents, with the mayor and his staffs, and discussions with funders as well, with the city government as a facilitator. It can be learned from this project that financing innovations through CSR scheme can be arranged to improve the quality of urban space towards a more livable city. This model can be one of the best practices and should be replicated in various cities in Indonesia.

Case Study / Project

Developing a Spatial Transformation Scoring Tool

to Monitor South African Catalytic Housing Projects

Raeesa GHOOR, Keneilwe PHOLO, Karishma BUSGEETH

Abstract

Spatial transformation is an important concept in the South African housing sector and has a specific meaning in the South African context (HDA, 2017a). Spatial transformation in South Africa is not only about restructuring or change but additionally deals with redressing the spatial legacies of apartheid (ibid). The Spatial Transformation Scoring Tool (STST), developed by the Monitoring and Evaluation, Knowledge Management and Research Planning unit in the Housing Development Agency is currently being used to assess housing projects classified as catalytic projects. Catalytic projects are intended to be high impact, sustainable and integrated mega human settlement projects (HDA, 2017b). The STST was initially developed through a study the HDA published in 2017 analysing one of government's housing programmes, the integrated residential development programme (IRDP), in four case studies (HDA, 2017a). The STST has since evolved to encompass approximately 160 indicators within ten pillars. The spatial transformation indicators aim to monitor change in the urban environment via the ten pillars of land value-add, integration, socio-economic development, functional and equitable residential property markets, public safety, return on investment, urban management, quality, a human settlements transformation scorecard and transversal alignment (HDA, 2017a). It is a tool that is constantly evolving and adapting with the unit's interaction with project managers, town planners and other professionals in the sector. The monitoring of catalytic projects with the STST have highlighted several challenges as well as opportunities both for catalytic housing projects and the STST. The STST is proving to be an effective planning tool.

This paper intends to explore the challenges, opportunities and lessons learnt of the STST in monitoring housing projects in South Africa. References: HDA. (2017a). Case Study Paper

Planning Transit Oriented Development (TOD) in an African City Facing Rapid and Informal Urban Growth

The Case of the Urban Mobility Plan of Conakry, Guinea

Sebastien Goethals, Citilinks; Belgium
Alioune Thiam, AfriAccess; Senegal

Abstract

Originally planned at the extremity of a peninsula, the capital of Guinea has faced a continuous demographic and spatial growth during the last decades, marked by insufficient actions in terms of planning regulations.

Surrounded by the Atlantic Ocean and vast areas of mangroves, Conakry forms a linear and narrow agglomeration of 40 kilometres long spreading on its peninsula. Its current population of 2.5 million inhabitants is projected to reach more than 5 million people by 2040, while its spatial growth has already reached its natural limits. Many of the informal settlements that characterize the urban structure of Conakry suffer from poor accessibility and from one of the lowest urban densities of street networks observed in Africa. Started in 2017, the Urban Mobility Plan of Conakry (EU funded program to national transport sector), has targeted the strategic and operational planning of a multimodal public transport network combined with a healthier and decentralized urban development model.

Marked by a constrained spatial growth and a unique but underused railway infrastructure originally built for mining transport, Conakry brings a rare opportunity of transit-oriented development application in a context of informal urbanization, associating BRT and railway, pedestrian accessibility and road safety with polycentric redevelopment.

The lack of urban governance and planning culture in Conakry makes many synergies between transport and land use invisible to the eyes of local decision-makers. Responding to the lack of urban development strategy and land use control, the Urban Mobility Plan of the Guinean capital came along with multiple short-term actions and decision-making tools with the aim of starting to implement the plan's orientations through smaller actions and initiatives integrated into larger strategies for the city. The article illustrates the methodology of the Urban Mobility Plan as an operational decision-making tool for Conakry and a strategic investment plan to associate economically viable infrastructure with people-oriented public spaces and accessibility for all.

Transit-oriented development; Conakry; Polycentrism; Mass transit; African cities; Multimodal

1. Urban form, (im)mobility and impoverishment

1.1. Conakry, a spatially constrained urban growth for a booming urban population

Since the independence of Guinea, Conakry's urban population has been growing at an annual rate of 6%, with a population reaching 2.5 million in 2017, and its urban area has quintupled in size. The geography of the Guinean capital is marked by specific natural conditions: a narrow peninsula surrounded by the Atlantic Ocean at its extremity and by mangroves and wetlands, that are also the cradle of the halieutic resources of the country.

Urbanization of Conakry hasn't been coupled with economic growth or with coordinated urban policies able to address appropriate response to the demographic growth. Happening along a corridor of three to five kilometres wide, urban sprawl was led in only one direction, in the axis of the peninsula, eventually to be stopped by the Mount Kakoulima.

Figure 1 Drone view of the KM36 intersection, Dubreka

New settlements grew informally mostly along the three main roads connecting Kaloum, the historic centre and port of Conakry, with the rest of the country. Conakry (and its historic centre at the extremity) is not only a capital city but also a major port and logistic hub in Guinea and West Africa, benefiting from two specific railway lines built in the early 20th century to link Mamou, Kankan and the mining activities in Fria. These two railway lines naturally run along the urbanizing peninsula, bringing a critical potential infrastructure for public transport and accessibility to urban settlements. However, such railway has been mainly used for freight trains, at the exception of the recently operated Conakry Express, a passenger train running twice a day between Kaloum and Kagbelen, 34 kilometres away.

1.2. Constrained mobility, inefficient transport system and dramatic lack of accessibility

The importance of Conakry as a logistic hub with its Port and as a main market place in West Africa (market of Madina) attracted most of the efforts and attention in terms of planning and investment to freight traffic and logistic issues. While only three main radial trunks (Fidel Castro urban highway, Le Prince Road and Corniche Nord) are linking the city centre with the rest of the agglomeration, Conakry suffers from one of the lowest densities of urban roads among Africa cities. Primary roads are assuming multiple functions and roles, absorbing linear and informal market places, freight traffic coming from the Port and most of the motorized traffic and pedestrian flows, with almost no pedestrian space to walk on. This situation is amplified by the dramatic lack of secondary roads and paved streets giving accessibility to neighbourhoods, which diverts most of inter-neighbourhood traffic and flows to the primary roads.

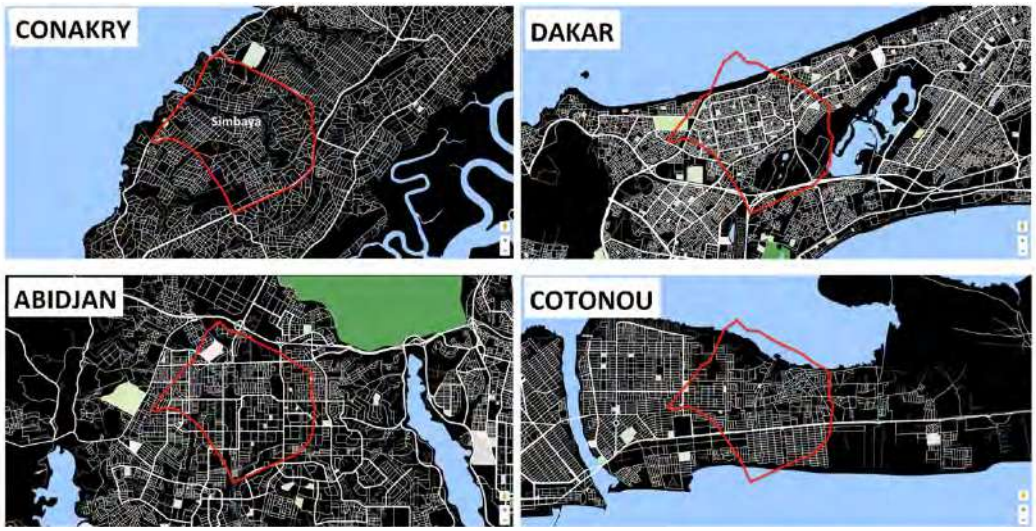

Figure 2 Compared densities of road and street networks in four West African cities

With a city centre located at the extremity of the peninsula and no decentralization policy, commuting trips have constantly increased over the years and have been concentrated on the very few main roads that were never designed for a city and for its people. Public transport, mostly consisting on minibuses called magbanas, shared taxis and taxi-motorcycles offer relatively low-cost services but with poor conditions of transport. Daily commuters face extreme conditions of road unsafety and congestion, most of them spending around 20% of their monthly income to reach their destination.

This lack of accessibility in human conditions leads to the increasing impoverishment of the urban populations and represent one of the main obstacles to a healthy urban development, as accessibility to opportunities for everyone is completely lacking. The urban form of Conakry reinforces this trend, as the fare of the journeys is based on the distance to destination. The more Conakry grows, the more its poverty increases.

2. Planning mobility for Conakry: Where to start?

2.1. The "transit master plan for Conakry", a traditional planning tool facing institutional and urban complexity

In 2017, the transit master plan of Conakry ("Plan de Déplacements Urbains" in French) was initiated and funded by the European Union and its support program to transport infrastructure, at the attention of the Ministries of Transport and of Public Works. In Guinea, urban mobility and transportation are organized and supervised by the national government. The governorate of Conakry still has little capacity to respond to the scale of urban growth's challenges faced by the city. However, the government initiated his Inter-ministerial Committee for Territorial Planning, reuniting 12 ministries. In this context, the transit master plan is at risk to be a technical study without effect. The institutional legitimacy of the plan became therefore an essential factor of success, an issue that led the team to create the Urban Mobility Working Group during the study, including all the stakeholders concerned by transportation in Conakry, and dedicated to become the working group that will implement the future urban transport authority.

In order to respond to urgent mobility issues and to anticipate the future demand and challenges, the plan has been conceived as a holistic mobility plan, targeting priorities according to feasibility with timeframes (2020 to 2040) and to scales and levels of interventions (metropolitan area, district, neighbourhood, street).

One major challenge was to elaborate actions with synergies and mutual benefits between pedestrians, mass transit and other public transport services, transporters syndicates, freight traffic and logistics stakeholders (rail & road). One of the approaches to face this complex patchwork of street/road users and transport stakeholders was to create a decision-making tool that everyone could understand. The mobility plan was therefore translated into an investment plan divided in 5-years periods, including traffic and safety measures at all scales and accompanied by design guidelines. The metropolitan scale of the vision of Conakry for 2040 has been illustrated by a physical model of 5 meters long expressing and synthetizing all the proposed actions for each mobility mode and at each spatial level.

Figure 3 Urban Mobility Plan of Conakry: Five-Year Investment Plan, period 2

2.2. Identifying the major obstacles to mobility and liveability

Eight major obstacles to a sustainable and healthy mobility of populations have been identified in Conakry. These obstacles are to be observed in the perspectives of the

demographic growth of Conakry, constrained geographically by almost no possible spatial growth. While the population of the agglomeration, including Coyah and Dubreka, will exceed 2.8 million in 2020 with an average density of 16,000 inhabitants/sq.km, these numbers are projected to be doubled by 2040. Such population growth also means a young urban population, with more than the half of it under 20 years old. The question of urban densification is more critical in Conakry than in other African cities because of its geographical specificities. Coyah, Dubreka and Kouria might absorb partly this demographic growth, but the major environmental risk is in the gradual urbanisation of the wetlands and mangroves, home to a rich but fragile ecosystem, and also an essential economic (halieutic) resource for the local population.

In this context, the most important obstacles to mobility and to viable city have been addressed:

- Conakry has only one economic and administrative urban centre (Kaloum), and its main market (Madina) is also located at the extremity of the peninsula;
- The density of roads and paved streets is dramatically low and leads all the traffic flows to the main trunk roads;
- Road safety issues are growing proportionally with the rapid urban population growth;
- Informal public transport is inefficient and becomes a source of congestion and unsafety itself;
- Existing road networks cannot allow the implementation of an appropriate public transport system with financial viability;
- The railway infrastructure running through the city is underused for both passengers traffic and freight traffic;
- Urban population density is constantly increasing in settlements that were never conceived to absorb such demographic pressure;
- The urban agglomeration is growing in only one direction, further away from the city centre, increasing the lack of accessibility and the cost of transportation for (sub)urban population.

2.3. Nine key measures to unlock Conakry's urban populations

The complex relation between the lack of planning, hyper-concentration of key economic functions, road safety issues, lack of accessibility to opportunities and impoverishment of local populations required to think beyond transportation and mobility and to anticipate appropriate land use policies. Nine key measures were identified as starting points to develop short to long-term strategies in each sector with a holistic approach:

- **Implement immediate actions** considering current physical conditions and institutional capacity, such as **low-cost interventions** on street rehabilitation in Kaloum, road safety measures, pedestrian space protection and parking management;
- Develop a **multimodal mass transit network** (heavy rail transit + bus rapid transit) using and improving existing infrastructure, adapted to a linear agglomeration of 45 kilometres long;
- **Hierarchise the street networks** of Conakry and address **design guidelines** for each type of axis, including road safety measures, pedestrian accessibility, speed limitations and parking management;
- Create or reconnect **networks of streets and secondary roads**, using existing and unpaved paths;
- Elaborate **holistic traffic plans** for each neighbourhood;
- Elaborate a multi-scale **Pedestrian Master Plan**, introducing the concepts of pedestrian corridors and multifunctional public spaces;
- Shift the majority of **road freight traffic to the railway**, and develop accordingly the **dry port** of Kagbelen, to be combined with the construction of a major market area and urban logistic hub along the railway;
- Plan a **polycentric city relying on TOD**, by decentralizing economic, administrative and logistic functions in 3 metropolitan subcentres and 9 mixed-used hubs and districts;
- Create a **metropolitan transport authority** that will be able to lead a mass transit network project and integrate land use and urban transport policies to achieve transit-oriented development (TOD).

3. The urban form challenge and the TOD approach of accessibility for all

3.1. A multimodal mass transit system using the existing infrastructure

To decentralise Kaloum and Madina's functions and achieve a polycentric city with more spatial equality in accessibility along 45 kilometres of urban settlements, three major metropolitan subcentres were proposed. Koloma would absorb government and ministries offices and administrations, as planned earlier by the national government. Sonfonia would become an urban free trade zone. Kagbelen would see its dry port developed further with enhanced railway infrastructure and logistic facilities, associated to a new primary market district able to gradually deconcentrate the activities in Madina. Every new subcentre operation is associated to affordable housing programs.

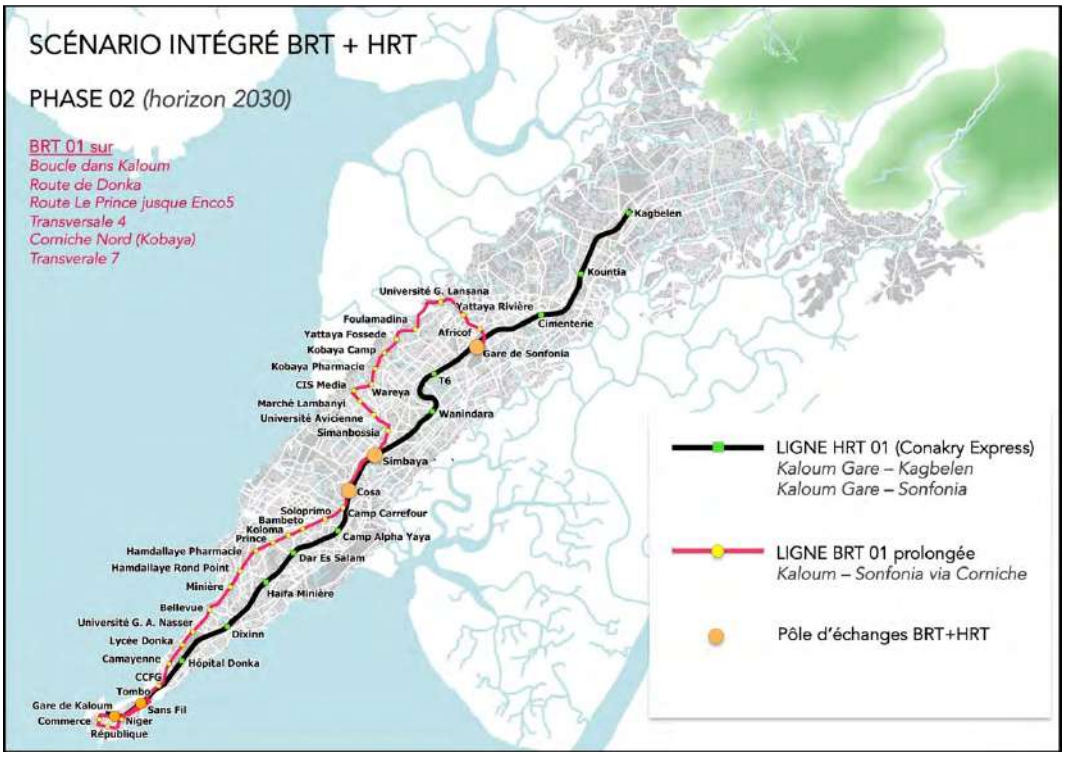

Figure 4 Projected Mass Transit Network (BRT+HRT), Horizon 2030

To make such urban decentralization feasible along one corridor, a multimodal mass transit network has been planned, combining Heavy Rail Transit (HRT) and Bus Rapid Transit (BRT) lines. The mass transit system has been planned and designed to serve most of densely populated areas, markets and potential new developments along the railway infrastructure.

By 2030, the enhanced Conakry Express service (Heavy Rail Transit) is planned to operate with 30 round trips a day between Kaloum and Kagbelen and serve 15 stations along the 34 kilometres of the CBK line. Its fleet of 15 trains (with a capacity of 2400 passengers/train) is planned to ride on a rehabilitated and reinforced infrastructure with two to three railway tracks, combining local and express services with no fare zones in order to respond to the linear urban form and its accessibility issues.

Since the mass transit system responds to a demand oriented to longer distance urban trips, the existing minibuses and shared taxis shift to shorter distance trips with lower fares, and find their spatial and economic synergy with the BRT and the HRT.

The first phases of implementation of the Bus Rapid Transit (BRT) network connect the boulevards of central Kaloum with the district of Ratoma along the Route de Donka, the Route Le Prince and the Corniche Nord along the Northern seafront to reach then the future multimodal hub of Sonfonya railway station. With its 35 kilometres of central bus lanes and 33 closed BRT stations protected from the traffic, the network is planned to operate 450 trips a day with a capacity of 205 passengers per bus and a fleet of 96 biarticulated buses.

Together, the total capacity of the multimodal mass transit system covers 235,000 trips per day and per direction, which represent an annual gain of 1 million ton of CO2 emissions for the mobility in Conakry by 2030. During peak hours, the system will be able to carry 21,500 passengers per hour and per direction.

Within mechanized daily trips, the modal share of public transport is projected to reach 41%, to be compared with the 17% observed by the surveys in 2018.

In 2030, more than 800,000 people will live in a 10 minutes walking distance from the 15 train stations and 33 BRT stations.

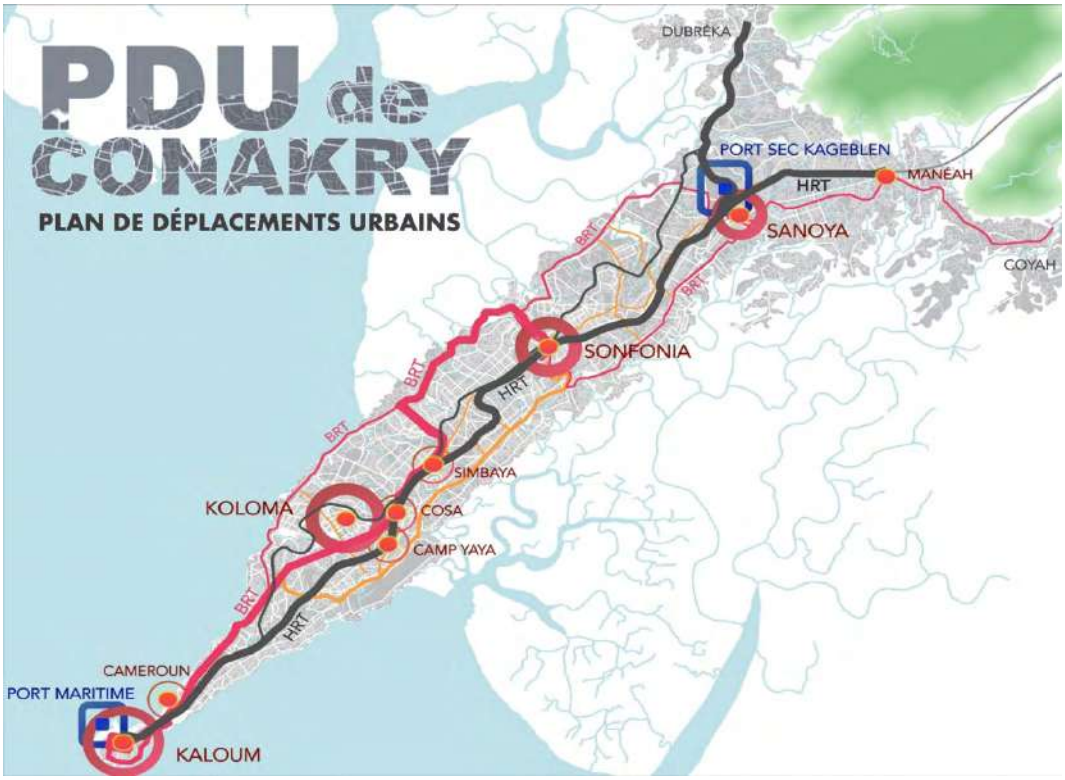

Figure 5 Conakry Polycentric Development Plan

3.2. How a mass transit system can improve urban liveability and road safety?

A synergy of 2 different mass transit services has been elaborated to solve various issues of accessibility within the neighbourhoods and slums. The advantage of the railway system (HRT) is that its infrastructure covers dense areas that are isolated from the primary roads. When the HRT network will have been extended to the second existing infrastructure of Conakry (Fria line), it will unlock a dozen of urban and suburban settlements that have suffered from isolation. Nine hundred hectares of lands have also been identified around train stations to develop affordable housing programs, markets, logistic hubs and key metropolitan functions.

Investing in railway infrastructure reinforcement with 2 to 3 railway tracks along the CBK line also means many benefits for the freight traffic since the capacity of the network will be able to absorb both passengers and freight trains. This configuration allows a better financial feasibility and sustainability of the system, as long as the institutional framework's evolution allows such infrastructure to be shared by different operators.

The financial feasibility of the reinforcement of the railway has to be viewed in a wider way if we consider this infrastructure as the future spine of the city. The plan identified it as a major asset that could include 6 meters wide pedestrian and cyclable corridors running along the 57 kilometres of urban railway lines (CBK and Fria lines).

Figure 6 Design guidelines : projected section of the Boulevard Diallo, Kaloum

Developing a BRT network brings a different attention to urban liveability improvement. In the case of Conakry, most of BRT lines have been planned on existing primary roads, currently suffering from congestion and unsafety. The integration of a BRT trunk on a primary road brings the opportunity to create a new urban boulevard associating public spaces, road safety, BRT stations and tree coverage together in the neighbourhoods that have suffered the most of social unrest and traffic accidents, such as Bambeto along the Route Le Prince. In 2018, five important road viaducts projects crossing major road intersections have been planned and funded to increase the capacity of the Route Le Prince to absorb motorized traffic demand.

One of the priorities of the Mobility Plan was to find an agreement on the immediate reconsideration of these planned works and the integration of BRT stations on each flyover.

3.3. Articulate mass transit, urban logistics and TOD

Along the study of the transit master plan of Conakry, it became evident that the logistic activities of Conakry and its Port as well as his market of Madina - one of the largest markets of West Africa - were at the heart of Conakry's transport infrastructure and mobility. Markets in Conakry are the main centres of economic vitality and traditionally spread along major roads, 'where the demand can be met'. This concentrated economic vitality is also source of traffic congestion and road safety issues, as roads have to absorb a vast diversity of pedestrian and motorized traffic flows.

The orientation of the Mobility Plan is to implement logistic hubs for consumer goods along the railway infrastructure, so new markets can be gradually located in safer areas away from the main roads and closer to the new distribution centres. Shifting urban logistics from road to rail represents a major potential transformation for road safety conditions for everyone, but it's also a tool of decentralization of the economic activities in the case of Conakry.

Figure 7 Physical model of Conakry 2040 (1/10,000)

One of the main conditions of the modal shift from road (trucks from the Port to destination such as markets) to rail (freight trains) is to develop the dry port of Kagbelen 35 kilometers away as an important logistic hub, not only for Conakry but also for Guinea. If most of the freight is transferred from the maritime port to the dry port by rail, it pushes away the trucks away from the city. The only way to make it work in terms of urban logistics is to associate the dry port development with a new commercial hub and market area which will benefit from the logistic hub of Kagbelen and its train station. Since Conakry is a "market city" (ville-marché), the combination of a national logistic platform, a commercial district, a major train station, multimodal hub and a new market could lever the polycentric potential of the city and move gradually the centre of gravity of the agglomeration in the centre of the peninsula.

Figure 8 Urban logistics and markets relocation

The strategic plan of Kagbelen area, included in the Mobility Plan, proposes a railway connection to Dubreka, connecting with the Fria railway line to be rehabilitated into a standard gauge track. The outer districts of Dubreka and Coyah wouldn't be suburban anymore but the surroundings of a major and accessible metropolitan subcentre. Sonfonia would benefit itself from its high level of connectivity with Kagbelen and emerge as another subcentre for Conakry.

Planning a polycentric Conakry relying on mass transit and TOD is currently a complex challenge because economic drivers to achieve such result are currently weak. It requires to develop creative synergies between the main economic urban sectors (commerce, logistics), shared infrastructure with financial viability and multimodal use (railway and pedestrian corridors) and TOD with local characteristics and specific needs (markets, affordable housing projects, mixed-used development). In the case of Conakry, the elaboration of the Mobility Plan illustrates how much logistics has conditioned and constrained the development of the Guinea capital and how it can be rather used to lever the financialization of a healthier urban mobility and transport infrastructure with associated benefits for pedestrians, bicycles and accessible neighbourhoods for all.

If investment strategies in economically viable transport infrastructure integrate better the social realities and local economic characteristics of African cities, an appropriate urbanism could start to emerge and open the gates to singular forms of polycentrism relying on micro urban economy, rather than on imported models of commercial urban development.

Case Study Paper

HEALTH DISTRICTS

Creating healthy cities

David GREEN, Perkins&Will; USA

Abstract

This paper addresses trends in research related to health in urban environments. It is focused on how regulations control development and the resulting public health outcomes. Regulations significantly impact public health and as such there should be legal and scientific mechanisms to monitor the efficacy of adopted regulations.

Cities are critical to the efficient operation of society. Beyond just issues of quality of life, they are large consumers of natural resources. There is a growing concern that the form of cities may have a profound effect on public health: chronic diseases related to obesity, heart disease, and asthma, among many others. But in general, governments are making decisions about their development in the absence of critical data and analysis that provides direction for these actions. There is a clear need to establish research that provides a scientific basis for rationalizing city planning and urban design. This is an opportunity to use the protocols driving research to inform the methodology of urban and city design.

An internationally supported system of testing and evaluation protocols, both for proposed regulations and adopted regulations, is still absent from planning and urban design processes. Jurisdictions continue to rely on theory and precedents alone when adopting new regulations. Because of the significant impact that the built environment has on the health, safety and well-being of the general population, it seems logical that the profession would adopt scientific research protocols.

In addition, this paper will examine several specific cases across the globe, regulated and designed by a diverse group of professionals, that articulate the issues outlined above and provide methodologies to frame a scientific method for planning and urban design at a consistent, international level.

Keywords

public health, development regulations, health, safety, welfare, zoning,

1. Introduction

1.1. Analytical Rigor

We have, for the past eighty years, used a quasi-scientific set of criteria to direct and regulate the design and construction of our cities and districts towns and suburbs. From the very beginning, pseudo-scientific measures formed the foundation of the professional planning movement. In this process, however, the rigors of basic research and scientific methods have been remarkably absent in reflection on the efficacy of planning's impact on the built environment. Abstract planning principles are translated into operational

regulations without a basic protocol for testing, evaluating, and modifying assumptions based on the results of evidence. The reticence of the profession to test and evaluate is further complicated by the fact that planning is ultimately implemented through a series of legal documents – regulations. Once adopted, regulations are notoriously difficult to change, both due to the precedential nature of the legal system itself and the seemingly inherent credibility bestowed upon regulation by virtue of its own adoption.

At its core, the planning profession is charged with creating rules and guidelines for the development of urban and suburban places through constitutional police powers: to provide for the health, safety and welfare of the general public. Ultimately, effectiveness of planning means, such as zoning, can and should be measured. For example, Justice George Sutherland states that plans and their regulations must "expand or contract to meet the new and different conditions which are constantly coming within the field of their operation" in the seminal Supreme Court case, Village of Euclid, Ohio v. Ambler Realty Co. (Village of Euclid, Ohio v. Ambler Realty CO, 1926). He went on to say that, "in a changing world it is impossible that it should be otherwise." What Sutherland knew as a fact, and the planning profession seems unwilling to address, is that planning is only as good as its ability to positively affect the health, safety and welfare of the people in places it impacts. And, if our impacts are not positive, we are obligated by the law to improve our regulations.

The creation of an internationally supported system of testing and evaluation protocols, both for proposed regulations and adopted regulations, is still absent from planning and urban design processes. Jurisdictions continue to rely on theory and precedents alone when adopting new regulations. Because of the significant impact that the built environment has on the health, safety and well-being of the general population, it seems logical that the profession would adopt scientific research protocols. To avoid doing this would be analogous to the pharmaceutical industry, in the absence of the Food and Drug Administration, releasing new drugs to the public without trials and then turning a blind eye to potentially negative outcomes.

2. Regulations

2.1. The Birth of Regulations

The impetus for regulating the built environment came from conditions that we can hardly imagine today. In the second half of the nineteenth century, people were living in conditions that were extremely unhealthy. For example, extreme population density grew in the Tenth Ward of lower Manhattan without infrastructural support – population densities were as high as 1000+ people per acre, or roughly 50 times the density of Manhattan today. (Allen, 2010) Most of this population lived in tenement houses with little natural light, open pit latrines, and no air circulation. With the publication of books such as Jacob Riis's "How the Other Half Lives,' the public began demanding reform through regulation and local jurisdictions responded. (Riis, 1970) One of the most important steps forward was New York State's adoption of the 1901 Tenement House Act. Figure 1 illustrates the impact of regulations as demonstrated by the evolution of houses themselves. The Tenement House Act served to open living quarters to light and air, and set the conditions for healthier living environments.

While the 1901 Tenement House Act is representative of the changes that were affecting individual building form and execution, it was with the adoption of the 1916 Building Zone Resolution of the City of New York that the role of regulations addressed what is commonly understood as zoning. The catalyst for this action was the completion of the Equitable Building in the financial district of the city. The building was reputed to cast a seven-acre shadow across the district at certain times of the day and year, with significant detrimental effect upon those other buildings in the affected area, and upon the general health and welfare of residents and office workers in the district. As a response, the city of New York adopted the Building Zone Resolution. The resolution provided for a number of requirements, including the zoning of the city into areas for residential, commercial and unrestricted uses, the requirements of yards for light and air, and restrictions on the height and form of buildings to ensure natural light and air for the district in general, not solely for the individuals occupying the buildings. The regulation had a significant impact on the quality of the city as demonstrated in Figure 2, the height and setback requirements for buildings permitted under the new resolution. Further, the regulations were easily tested and evaluated to determine the efficacy of their providing more light and air into the city streets and parks. (Building Zone Resolution, 1916)

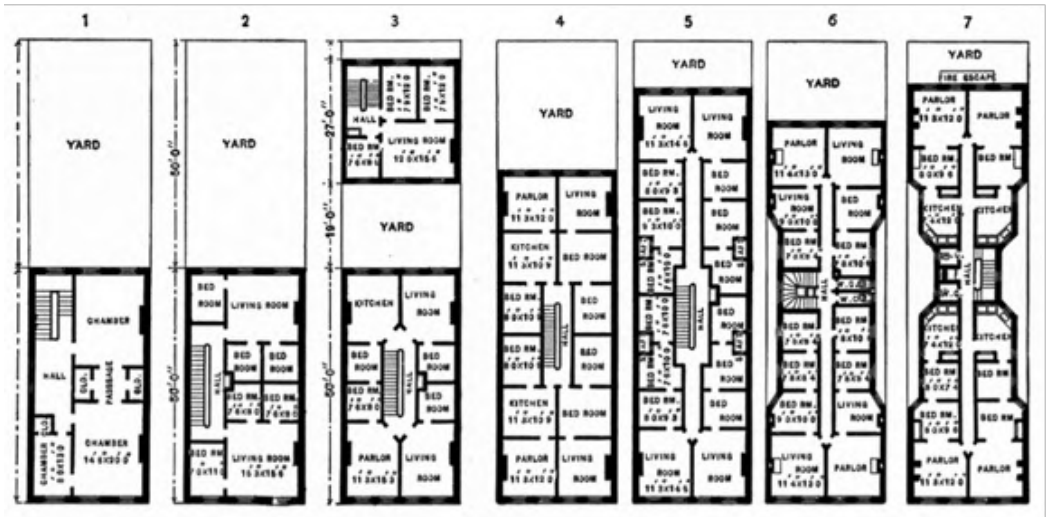

Figure 1 Tenement Transformation

Figure 1 above shows the evolution of the Knickerbocker tenement house type leading up to the 1901 Act and subsequent to the Act. The transformation from 5 to 6 demonstrates the direct, positive effect the Act had on the living conditions of the residents; in this case, the diagram illustrates shafts for natural light and air included on sidewalls between the buildings, which were lined up in rows.

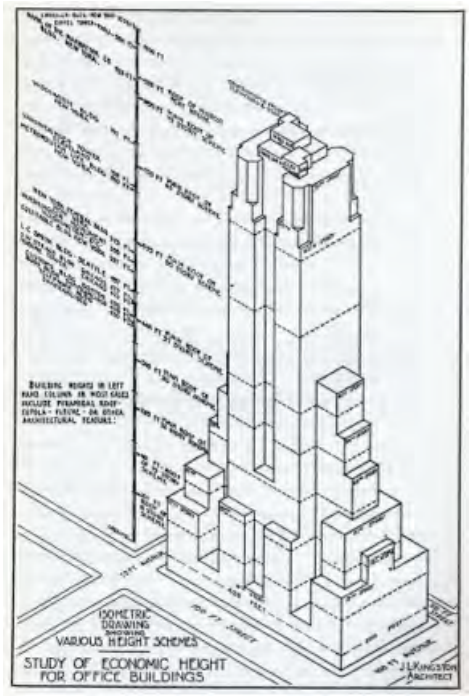

Figure 2 Diagram, 1916 Building Zone Resolution

Figure 2 above demonstrates the logic and application of new building design from the 1916 Building Zone Resolution. It specifically describes the setback requirements for new buildings to ensure light and air reaches the streets below. (Building Zone Resolution, 1916)

This original ordinance was updated and modified thousands of times over the course of 45 years until the 1961 Zoning Resolution superseded it. The adoption of this ordinance signaled the acceptance of a radically transformed understanding of the way regulations operated. Instead of relying on simple, straightforward guidelines that were easily tested, the newly adopted regulations were much more reliant on formula-driven criteria for development. This transformation created a scenario in which it was almost impossible to project the physical outcome resulting from the regulations because each project was easily manipulated based on local and site-specific conditions. This is demonstrated in Figure 3, a seemingly simple calculation to determine building massing and spacing that opened the process to infinite possible results, most of which led to unintended consequences such as degradation of the surrounding public space in terms of light and ventilation at the street level. In addition, there was almost no incremental testing of the proposal to ensure that it would garner the desired results and that those results would meet the constitutional guarantees of health, safety and welfare. While the specifics of the 1961 Resolution were not copied verbatim into other ordinances across the country, the logic of regulating the development of cities and towns and suburbs was predicated on this Resolution almost universally. The following section demonstrates two very specific regulations that were adopted, generally, throughout the country without testing and evaluation, and the impact they have had and continue to have on the built environment. (1961 Zoning Resolution, 1961)

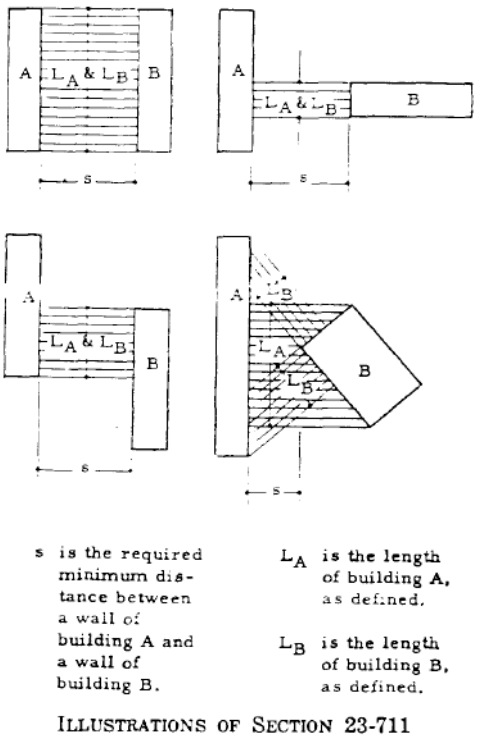

Figure 3 Diagram, 1961 Zoning Resolution

Figure above illustrates the fundamental change with the adoption of the 1961 Zoning Resolution. It describes the calculations for meeting building spacing requirements. (1961 Zoning Resolution, 1961)

The 1961 Zoning Resolution had profound impacts on the way we plan and construct cities. At the time, none of the assumptions upon which the new Resolution was based were tested; not prior to the adoption of the new code, nor after its adoption.

The impact this and other regulations had on the built environment and ultimately on public health can be demonstrated through numerous examples, two of which are outlined below.

2.2. Regulating Local Streets

In the seminal United States zoning case, Euclid v. Ambler, the core issue before the court was the question of protection of single-family neighborhoods. The case was brought to the court in a time, the 1920's, when questions of appropriate uses in these neighborhoods were critical. It was not uncommon to find toxic uses, such as rendering plants, slaughterhouses and tanneries, interspersed with people's dwellings. At the time of the case, there was a clear need to separate these extremely unhealthy operations from the districts where families lived. (Village of Euclid, Ohio v. Ambler Realty CO, 1926) Over the course of subsequent decades, however, the protection of single-family neighborhoods expanded greatly. This is demonstrated in a number of regulations adopted, especially through the 1950s, that include minimum lot sizes for single-family homes, and extreme restrictions on corner groceries, neighborhood restaurants and other uses that had historically been a part of the rich mixture of a healthy neighborhood. While there are many examples of regulations that were adopted that have, and continue to have, negative impacts on the

health, safety and welfare of the general public, there are some that stand out especially as clearly demonstrating the need for scientific study to determine the true impact they have. Further, they demonstrate the legal implication of the enactment of such regulations.

A specific example of this can be found in the subdivision ordinance adopted by the City of Atlanta in 1957. It included, as did many other ordinances adopted throughout the country at the time, a seemingly simple, clear and intelligent requirement that cut-through traffic (traffic moving through a particular geographic area with no intention of stopping in that area) should be minimized, or if possible, eliminated from single-family developments. The statement, "Local streets shall be so laid out that their use by through traffic will be discouraged," was a prominent element of the Atlanta Ordinance. (Part 15 Subdivision Regulations, 1957) The requirement has led to a very particular development pattern as demonstrated in Figure 4. Individual suburbs are designed and developed in such a way that there is absolutely no connectivity between the subject development and other contiguous or proximate developments (residential or commercial). This seemingly benign requirement has had enormous impact on the lives of the inhabitants of the communities developed under this ordinance.

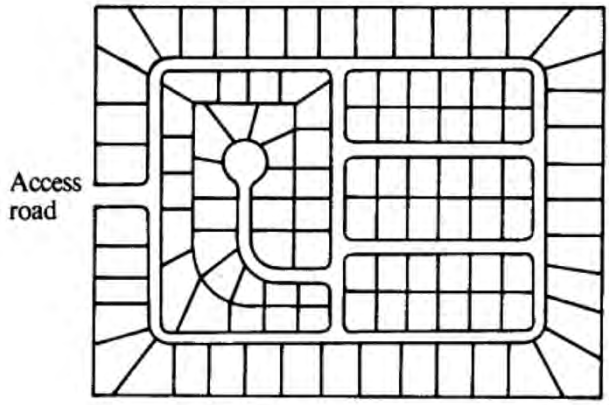

Figure 4 Diagram, Typical Street Pattern

When this ordinance was originally adopted, it was not tested or evaluated, and so no determination could be made about its ability to actually provide a healthy and safe environment for its occupants. Today there is mounting evidence that instead of being a healthy and safe development strategy, it is actually causing unhealthy and unsafe results for the inhabitants of the areas developed under the regulation. (Ewing, R., et al, 2003) Certainly further investigation is warranted to expand and verify the initial research, but this expanded research is extremely slow in coming. As with all regulations and laws, changing these ordinances is extraordinarily difficult.

It is here, in the evaluation of regulations, that the practice of following a scientifically dictated protocol for research would prove beneficial. If basic research provided the data and subsequent interpretation to correlate a regulation with specific health or safety issues, including obesity, asthma, heart disease, pedestrian and vehicular deaths and injuries, elevated crime rates, or even long-term house values (an issue of welfare), the professionals charged with creating and adopting such regulations would have much greater certainty that

they were creating healthier, safer and more economically vibrant developments, and they would be fulfilling their professional obligation to ensure the constitutional guarantees upon which Justice Sutherland based the ruling that made the regulations constitutional in the first place. Further, from a legal standpoint, it would be much easier to modify existing regulations if there was compelling scientific research to back up the proposed modifications.

2.3. Regulating Block Size

Current research indicates that walking provides health benefits; that areas of cities with more pedestrians (people walking) are safer; (Ozbil, A., et al, 2015) and that areas of cities with more pedestrian traffic, particularly commercial, are more economically robust. (Boarnet, M. G., et. al, 2008) (Litman, T. A., 2017) As with most current information regarding cities, towns and suburbs, and the efficiency of their operation, more research is needed to understand correlations between walking and urban planning. But taking the premise that more people walking in cities promotes the health, safety and welfare of the general population, current regulations can be evaluated based on their efficiency in producing developments that are conducive to pedestrian activity.

Throughout the United States, the single most difficult element to incorporate into new development, redevelopment, and other forms of modifications to a jurisdiction's physical layout is the creation of new streets. This difficulty stems from several issues: maintenance costs borne by the jurisdiction, a pre-conceived notion that more streets are less environmentally beneficial, and, as demonstrated in Section 2.0, a general belief that more streets lead to more traffic. Each of these issues demands additional research, but it is extremely difficult to replicate the highly connected street systems of cities and towns constructed in the pre-regulatory era. In this specific case we are focusing on expanding pedestrian activity, and the effect the street system and the regulations that drive street locations have on the efficacy of providing pedestrian activity.

Figure 5 Block Dimensions New York, Crosstown and Uptown

As a basis for researching the correlation between street layout and pedestrian activity, the first step is to identify areas that seem to promote pedestrian activity and those that seem to suppress it. An example of the former is New York, arguably one of the most pedestrian cities in the world. In New York, specifically Manhattan, the streets are highly connected,

with resulting block sizes of 200 feet in the north-south direction, and block sizes generally between 500 and 800 feet in the east-west direction. In this system, there appears to be a correlation between the size of the block face and the level of comfort in walking similar distances. As demonstrated in Figure 5, a walk in the north south direction of 10 blocks is perceptually different from a walk in the east-west direction of the same distance. This begins to identify the possibility that the physical distribution of streets has a direct effect on the comfort of the pedestrian, and further on the efficacy of the system to produce the desired result, more pedestrian activity. It is generally perceived to be easier to walk the half-mile uptown than the same half-mile crosstown. A similar observation was made by Jane Jacobs in her book *The Death and Life of Great American Cities*, in which she advocated for the use of short blocks to increase the number of potential route choices for pedestrians and to avoid monotonous streets. (Jacobs, 1961)

The research on block dimensions and its correlation to a supportive system for pedestrian activity is not the end, however. It is merely an analytical method for providing cities with the tools to create more energy-efficient and healthier overall systems. The increased number of people who walk due to myriad factors will have a direct impact, we assume, on the reduced use of fossil fuels for automobiles. It should also create a more efficient overall system for distribution of utilities and a more resilient infrastructure layout, which minimizes rebuilding when single buildings are reconstructed or newly constructed. In addition, increased walking should correlate, again, we assume, to decreased numbers of health problems such as early onset diabetes, heart disease and asthma. However, the basic research to prove or disprove this is currently almost nonexistent. Cities are, in aggregate, among the largest users of energy, and home to the greatest number of people, yet the national planning community and the funded research within which it is engaged, is minimal. There is a clear need for an increase in research in these areas.

The physical layout and efficiency of the pedestrian system in this case is tied directly to the original regulation that dictated where and how streets would be laid out as Manhattan developed. In this case, it was the Commissioners' Plan of 1811, a survey and plan that identified the location of streets as the city grew. The power of the regulation in this case was in the certainty of the outcome, and, in retrospect, the value of the plan for producing (or allowing) significant pedestrian activity. (Bridges, 1811)

Throughout the twentieth century, however, the methodology for the laying out of streets changed radically. As indicated in Example 1, connected streets were discouraged or prohibited. (Part 15 Subdivision Regulations, 1957) (Ozbil et al, 2011) (Peponis et al, 2008) (Peponis et al, 1997) (Peponis et al, 1998) (Christova et al, 2012) Further, streets were no longer identified in a specific plan, which might guarantee short block faces and highly connected system, but instead were placed project-by-project based on capacities of individual projects and the demands those projects would place on the vehicular efficiency of the system. The resulting pattern of development is indicated in Figure 6. It clearly shows the physical implications of the regulations, including limited intervening public streets, expanded parking requirements, and significant building setbacks, among other requirements that led to the disappearance of the connected system of pre-regulatory cities. The outcome of these regulations is development patterns that deter inhabitants from walking. There appears to be a direct correlation between the sizes of blocks (or the frequency of streets) and the level of pedestrian activity. This is further indication of the need for a rigorous research platform for the investigation of these issues.

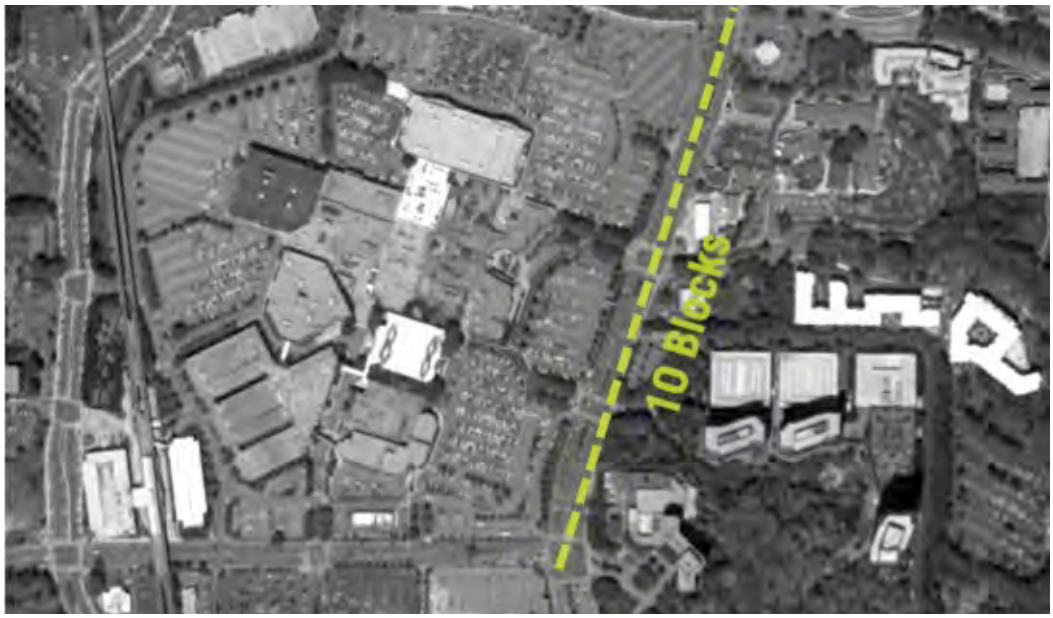

Figure 6 Block Dimensions Suburban Atlanta, Perimeter Center

2.4. Correlation Between Regulations and Development Patterns

The first trajectory is exemplified through a simple analysis of the relationship between regulations in place and block sizes. Assuming the hypothesis offered in the previous section that "walking provides health benefits" is accurate, then what was the correlation between regulations in place and the resulting block sizes, and by extension frequency of streets? Figure 7 below indicates the results of a cursory investigation into the relationship between the existence of subdivision regulations and the size of blocks. In this statistically limited sampling, the data suggests that there is potentially a significant correlation between the mere presence of a regulation and the efficacy of creating small, consistent block sizes.

The conclusion derived from this limited investigation is that there is an inverse correlation between the degree to which regulations are implemented and the efficiency of creating consistency; the stated goal of the regulation. If this is verified through further research, it implies that the regulations adopted to provide for health, safety and welfare are resulting in development patterns that are inconsistent with the goals of the regulations.

Looking more closely at a sub-set of projects, we can start to see how recent design and planning work compares to these more broad findings. A look at over 50 projects completed around the world within the last 10 years demonstrates that, despite the best intentions of the designers, the average block size for these modern district and campus plans is even larger the post-1928 block size, at 7.71 acres. When only research district projects are taken into account, the average block size is similar, at 7.59 acres (Table 1). This could be the result of the traditional "buildings in a park" typology, only recently falling out of favor for a more urban format, or it could be influenced by something else entirely. Without a rigorous analysis process it is very difficult to understand the causes and effects of design decisions.

This early work supports the proposal that there should be regional, and even national, systems in place to track these issues. The computing power and much of the data already exists, but the planning profession is slow in making moves to identify critical data that

would form the foundation for a more rigorous and directed national research agenda. (Allen, 2010)

Observation 2: the standard deviation of average block size in the following selected cities has increased from .79 to 6.14 from pre-1928 subdivision to post -1928 subdivision.

	Pre 1928 Block Size				Post 1928 Block Size		
		avg. acres	max acres			avg acres	max acres
1	Atlanta, GA	3.70	8.26	1	Atlanta, GA	22.87	44.49
2	Boston, MA	3.09	4.13	2	Boston, MA	9.45	14.46
3	Baltimore, Md	3.29	5.78	3	Baltimore, Md	14.93	22.72
4	Charleston, S.C.	4.12	6.07	4	Charleston, S.C.	16.89	25.25
5	Chicago, Illinois	3.51	4.96	5	Chicago, Illinois	14.74	19.10
6	Los Angeles, CA	4.41	7.89	6	Los Angeles, CA	8.01	16.08
7	New York, N.Y. (Manhattan)	2.60	3.67	7	New York, N.Y. (Manhattan)	7.72	13.31

2.5. Tracking and Projecting Data

Once we begin to understand the interaction of regulations and development historically, the next step is applying this knowledge to current and future projects and places. To do this involves first developing a method of recording baseline data for such projects. Perkins+Will have recently undertaken such a program for all of their urban design-scale projects. The program, called PlanMetrics, lays out 9 key metrics captured for each project greater than 5 acres. The associated data (figure 8) is then collected, compared, contrasted, and subjected to further inquiry.

The database grows as more projects are completed. In this way, Perkins+Will have begun a system of testing whether or not their own projects meet their stated intent, both defined by the clients, planners, and designers involved, but also by the regulatory context in which they are created. Data collected and referenced in Table 1 includes project area, right of way area, total public blocks, and number of intersections, for example, along with other vital statistics. With more advanced analysis, information such percentage of park area or intersection density, can be recorded and compared. An example of this level of analysis on both a single project, as well as cross multiple projects, can be seen in figures 9 and 10.

D	E	F	G	H	I	J	K	L
7546.22	5575.18	1971.03	2092.53	1795.51	1101.17	241.61	1813	1277
4051.10	3755.87	305.22	76.95	229.17	712.70	34.61	87	70
3343.48	2810.57	732.91	0.00	345.92	331.84	40.57	146	120

Figure 8 Sample Project Datasets from PlanMetrics

The database grows as more projects are completed. In this way, Perkins+Will have begun a system of testing whether or not their own projects meet their stated intent, both defined by the clients, planners, and designers involved, but also by the regulatory context in which they are created. Data collected and referenced in Table 1 includes project area, right of way area, total public blocks, and number of intersections, for example, along with other vital statistics. With more advanced analysis, information such percentage of park area or intersection density, can be recorded and compared. An example of this level of analysis on both a single project, as well as cross multiple projects, can be seen in figures 9 and 10.

This method is not limited to Perkins+Will projects – any district, neighborhood, city, or region around the world can be analyzed using the same method of metric collection, thereby establishing a comparable set of baseline information for projects that are anecdotally deemed “successful” or “unsuccessful.”

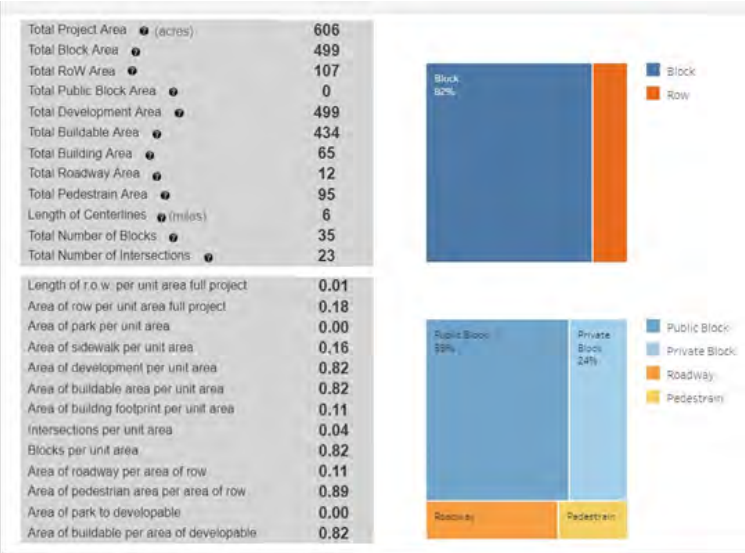

Figure 9 Sample Project Analysis from PlanMetrics

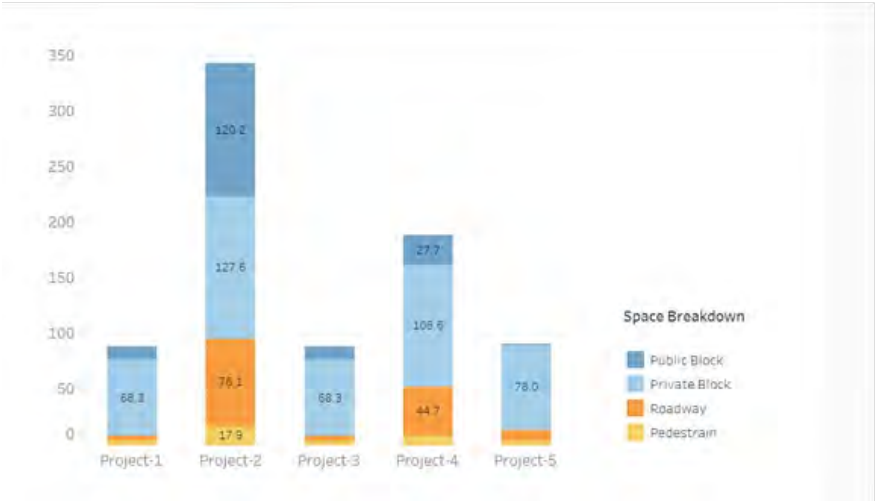

Figure 10 Project Analysis from PlanMetrics

One particular project type that lends itself to this analysis method is the research environment. Often owned (or at least operated) by a single entity, these projects are complex districts with multiple building types, public (or publicly accessible) streets and open spaces, and often their own set of governing regulations. Increasingly, research environments are districts integrated seamlessly into the larger city and thus have many of the same opportunities and challenges as the neighborhoods outlined in previous sections. Beyond the practical advantages, these places of research should be laboratories for understanding the impacts of the design standards and regulations that create them.

An example of this approach of collecting baseline data and projecting project performance is the infrastructure plan for Innovation Square in Gainesville, Florida (figure 11). The research and innovation district is located at the heart of downtown Gainesville, and is

owned and operated by the University of Florida. This complex interaction of municipal and institutional interests led to challenges in project coordination, but also interesting opportunities for learning from the project. A key concern for the stakeholder group was understanding the potential for energy efficiency onsite, as well as coordinating a complex system of utilities and public realm features. First, the team developed a coordinated strategy for they physical layout of utility infrastructure based on project goals as well as site constraints. An analysis of baseline and efficient utility use in comparable buildings was then performed to create a framework of understanding for project performance (figures 12-13). While not directly related to testing of regulations per se, this example serves as a powerful precedent of a methodology to test potential impacts of design and policy decisions before final construction has taken place.

3. Case Study One

3.1. Innovation Square

One particular project type that lends itself to this analysis method is the research environment. Often owned (or at least operated) by a single entity, these projects are complex districts with multiple building types, public (or publicly accessible) streets and open spaces, and often their own set of governing regulations. Increasingly, research environments are districts integrated seamlessly into the larger city and thus have many of the same opportunities and challenges as the neighborhoods outlined in previous sections. Beyond the practical advantages, these places of research should be laboratories for understanding the impacts of the design standards and regulations that create them.

An example of this approach of collecting baseline data and projecting project performance is the infrastructure plan for Innovation Square in Gainesville, Florida (figure 11). The research and innovation district is located at the heart of downtown Gainesville, and is owned and operated by the University of Florida. This complex interaction of municipal and institutional interests led to challenges in project coordination, but also interesting opportunities for learning from the project. A key concern for the stakeholder group was understanding the potential for energy efficiency onsite, as well as coordinating a complex system of utilities and public realm features. First, the team developed a coordinated strategy for they physical layout of utility infrastructure based on project goals as well as site constraints. An analysis of baseline and efficient utility use in comparable buildings was then performed to create a framework of understanding for project performance (figures 12-13). While not directly related to testing of regulations per se, this example serves as a powerful precedent of a methodology to test potential impacts of design and policy decisions before final construction has taken place.

From this, the project team created a system for projecting energy use based on various options, in this case both block-by-block, and by different phasing scenarios. The resulting dashboard compares these potential build-out scenarios to conventional and energy-efficient baselines, as well as the various options to each other. (Figures 14-16)

By projecting and analyzing this information in context (Figures 11-13) the project team was able to make better decisions about the balance of building types and the importance of an energy efficient scenario based on actual data, rather than intuition or standard practice.

In this situation, the scenarios tested were independent from regulation, and were limited to shifts in the balance of building typologies. However, the process of defining success, testing scenarios, and ultimately adapting design and policy based on observed outcomes in this smaller controlled environment demonstrates one potential method for developing similar tools to evaluate these and other metrics as a more comprehensive research protocol evolves.

The proactive approach to understanding utility capacity led to a unique investment model specific to this site, based on the evidence provided by rigorous analysis of the various options and the resulting detailed understanding of the preferred design scenario. Scaled up, this type of approach has the potential to influence our understanding and thus design of many aspects of research environments that we currently take for granted, as well as district and neighborhood planning and design more broadly.

4. Conclusion

4.1. Future Research Plan

Moving forward it will be key to incorporate lessons learned from the methods outlined above into a comprehensive research strategy. The approach of such a strategy should be three-fold: first, no progress can be made until there is a consistent and reliable way to gather and record data about existing and planned places. A well-defined but simple data set should be the base for informed decision-making. Second, for both society and the profession, there needs to be further study into what constitutes “success” in the various aspects of the built environment. This can include health, safety, comfort, energy consumption, and any number of other metrics which have value for the lives of people in cities and towns. Data without a contextual metric is essentially meaningless. Finally, to fully capture the power of the data, tools and systems for projecting impacts of planned designs and regulatory changes, as well as tracking progress in real time after they are realized, are crucial to verifying hypotheses about “success.” In this way a system of trial and adjustment can be created to ensure that regulations are indeed having the impact they are intended. To this end, regularizing a key set of questions about the performance of place in relation to the regulations that shaped that place is imperative in creating better laws and guidelines. While there may not yet be a mechanism for a national or international research program, individual jurisdictions and the designers and planners who work with them can begin to ask these questions and build the database that will eventually inform a larger conversation, as well as adopt and further develop tools such as those presented in Section 3. The more data that is collected and shared, the easier it will be to make the case for more universal participation in research activities, as well as changes to law and regulations that shape our physical environment.

4.2. Concluding Remarks

This paper examined the current and future trends in research as it pertains to city planning and urban design. It is intended to demonstrate the need to reconsider the methodology used in planning cities, towns, districts, and suburbs. There is a significant lack of scientific

rigor in the research protocols, and further a lack of research in general, in these arenas. The paper poses questions and identifies potential fundamental problems with the current system, and further identifies the need for support for these efforts.

Regulations drive the pattern of development almost to the exclusion of all other influences. They are legally binding and not easily susceptible to change. However, the method through which current and future regulations, and the environment in which they are created, can change is through the implementation of stringent protocols for basic research. The built environment affects our health, safety and welfare, and the rigor with which we investigate the effects on the public should be commensurate with those efforts.

Many of the questions that need to be addressed such as the relationship between urban form, pedestrian movement, and public health cannot be adequately addressed because we do not have a database of sufficient size and depth on the variables of urban configuration to adequately research the issues. Is there a relationship between energy consumption, public health, and the configuration of urban infrastructure? The same questions remain unanswered for energy consumption, and especially re-use of existing infrastructure in light of land use changes over time. What configurations offer the greatest accommodation of change? The aim of this paper is to propose that these efforts are in the national interest of the citizenry, and that as we regulate for the development of cities, we should create a research base to align the regulations that dictate our actions with scientific evidence.

Research Paper

Exploring automobile dependency of housing estate residents and *kampung* dwellers in suburban Bandung, Indonesia

Fenita INDRASARI, Research Institute for Housing and Human Settlements, Ministry of Public Works; Indonesia

Abstract

Housing and transportation has become a pair of factors when it comes to decision of buying a house for the middle-income. This particular group of society is unique as they are aspired to luxury yet with limited affordability, particularly in the developing countries such as Indonesia. In many cases, housing estates are built in the form similar to gated community. Built in the suburban when usually the new housing estates are located quite in far distance to facilities, the residents are forced to own private vehicle(s) to conduct their daily activities. This situation shows the tendency of automobile dependence (Newman & Kenworthy, 1996; 1999). It has also been reflected in the vehicle ownership statistics figures and the notorious traffic congestion of Indonesian cities.

The middle-income housing and their gated community has not only impacted their own travel pattern but also the residents living in kampung adjacent to their housing estate. Kampung dwellers have also reflected the middle-income characteristics with their lifestyle and automobile dependence. It has become eminent in suburban Bandung where pockets of kampung are found to be hidden amidst the housing estates whilst cars are parked on the roadsides. This is problematic in terms of affordability where they cannot really afford to own a car or motorbike as well as to rent a parking space since they usually live in small houses at kampung.

To understand the above phenomenon, this paper tries to explore the extent of automobile dependency of the residents living at housing estate and its adjacent kampung at three locations. Data collected from questionnaires and group interviews are descriptively analysed. Results have shown that most residents travel in far distance to reach their job location but do not travel in far distance to conduct their shopping, studying, and exercise activities though some of them own a motorbike. The latter is due to the presence of mobile green grocers, warung, traditional markets, good quality schools, sport facilities and open spaces within walking distance to their houses.

However, these nearby facilities are regularly visited mostly because the residents can travel within shorter distance through access points made available for public use. These access points help to create a network of alleys and streets connecting kampung and these facilities through the housing estates. When these access points are restricted or non-existed, the travel pattern would differ as has been uttered by the kampung dwellers. In one of the cases, the following disconnections between the kampung alleys and streets of housing estates have made the kampung dwellers altered either the location or the transportation mode of their activities.

There are lessons to be learned from these travel patterns. Housing estate development shall always have access to the kampung that have existed and vice versa. Such spatial connections may contribute to a change of travel behaviour

from automobile dependence to active travel. However, it should be kept in mind that these results may not be generally applicable to other places with different socio-economic and spatial characters. Further work in the field may be benefited from more cases and larger population sample.

Keywords

Gated, housing estate, kampung, travel

1. Introduction

Housing and transportation has become a pair of factors when it comes to decision of buying a house for the middle-income. This particular group of society is unique as they are aspired to luxury yet with limited affordability, particularly in the developing countries such as Indonesia. In many cases, housing estates are built in the form similar to gated community. Built in the suburban when usually the new housing estates are located quite in far distance to facilities, the residents are forced to own private vehicle(s) to conduct their daily activities. This situation shows the tendency of automobile dependence (Newman & Kenworthy, 1996; 1999). It has also been reflected in the vehicle ownership statistics figures and the notorious traffic congestion of Indonesian cities. According to BPS (2018), the number of motorbike ownership in Indonesia has escalated from a little less than 20 million in 2002 to more than 105 million in 2016 and 113 million in 2017. According to the Tomtom traffic index, Jakarta has gained the seventh place in 2018 from the fourth place in 2017 for its notorious traffic congestion. Meanwhile based on the 2017 Inrix global traffic scorecard, Bandung is within the 'big 60' by having its roads congested for more than 45 hours a week.

While Jakarta's congestion rate have decreased according to the index, presumably due to constant improvement of its public transportation network, a similar positive trend cannot be seen in other Indonesian cities. Furthermore these traffic indexes reflect the city but do not reflect what happens at the neighbourhood level. This paper argues that, at the neighbourhood level, the middle-income housing and their gated community has not only impacted their own travel pattern but also the residents living in *kampung* adjacent to their housing estate. *Kampung* dwellers have also reflected the middle-income characteristics with their lifestyle and automobile dependence. It has become eminent in suburban Bandung where pockets of *kampung* are found to be hidden amidst the housing estates whilst cars are parked on the roadsides. This is problematic in terms of affordability where they cannot really afford to own a car or motorbike as well as to rent a parking space since they usually live in small houses at *kampung*.

2. Literature review

The impact of residential development to travel has received extensive attention in the past two decades particularly since it has mostly taken shape as gated communities with perimeter walls, gates and cul-de-sacs. Duany, Zyberk & Speck (2000), for example, have argued that cul-de-sac which originally conceived as youth's great playground has in fact made kids dependent on some adult to drive them around and lose their independent mobility. It was possible since the residential area with cul-de-sac layout increase distance

between uses that are already been segregated. Perimeter walls and gates or cluster is basically producing the effect similar to cul-de-sac's in which traffic accumulates at one point and access points are made limited or singular hence forcing everyone to overcome a lengthy distance to reach uses. They include private roads, which limit public access (Charmes, 2010; Grant & Curran, 2007).

To cope with the further distance resulted by the disconnected street layout between the ones within the housing estates and the existing road network, people who resides in the adjacent settlement may also need to own private vehicles particularly if their access to a direct route is cut-off. As a result, automobile dependency would be higher if travel options are restricted as evidenced in Indonesia as well as other Asian developing cities (Barter, 2000; Bowen, 2006; Handy, 2002; Rosa, 2007).

In terms of walking, a particular radius catchment area that is within reach of reasonable walking distance is the parameter. The distance, usually a quarter mile or 800 meters, derived from the 10-20 minutes walking with medium speed (Hess et al., 1999; Southworth, 2005). This walking distance has been considered as universal parameter which aligns with the walking speed range of pedestrian behaviour from various culture (Mateo-Babiano & Ieda, 2007). If distance between uses lies beyond the walking distance, it is more likely that people are driving their private vehicles and vice versa.

The effects of gated communities to travel, however, do not apply universally but are instead differentially distributed and dependent on lifestyle, household structure, and different capacities to overcome distance (Maher, 1994; Nicholls, Phelan, & Maller, 2015). Whilst distance is the main factor, its association to time and cost follow at the second place. Other factors that influence one's travel decision are socio-economic and physical condition. For example, one's income may affect their travel options, whilst options are available, not all options are considered as viable due to their limited affordability. Connectivity to transit has also been sought to add travel option for increasing the possibility of less car use (Cervero & Kockelman, 1997; Ewing & Cervero, 2010; Hoehner et al., 2005; Khattak & Rodriguez, 2005; Schwanen & Mokhtarian, 2005; Rodriguez et al., 2006).

3. Methods

To understand the automobile dependency phenomenon as resulted by private roads and housing estate development, this paper tries to explore the extent of private motorised vehicle use by the residents living at housing estate as well as the *kampung* dwellers living at the adjacent area. There are three study cases, as seen in figure 1, in which all of them are located in suburban Bandung and built in the early 1990s. The first study case is KM, a housing estate surrounded by perimeter walls which has three guarded gates for entry and three pedestrian access points open during the day. NH, the second case, has perimeter walls with only one guarded gate for entry. NH has two pedestrian access points which used to be open all day from Monday to Friday but then closed at all time since the middle of 2018. The third case, PC, is an open housing estate which does not have perimeter walls and guarded gates. Vehicles can enter PC from three ways while pedestrians can enter from anywhere possible since there is no perimeter wall surrounding the housing estate.

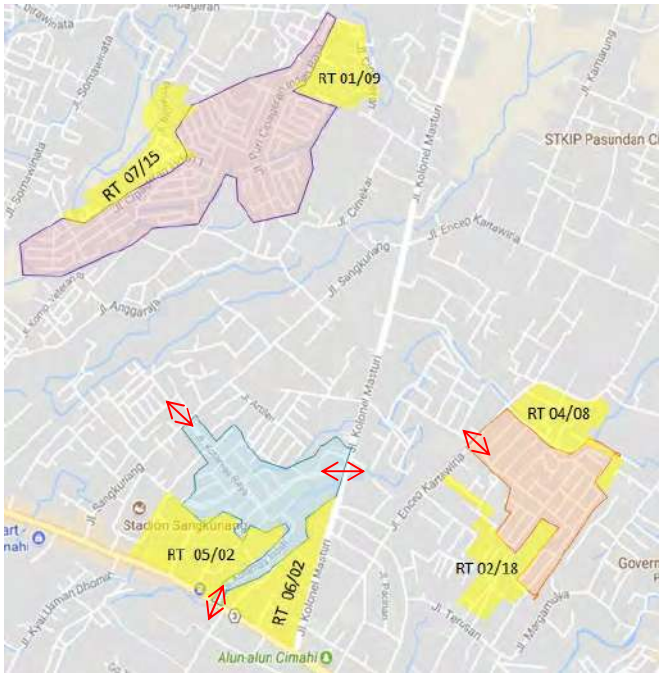

Figure 1 Location of study cases
(Bottom left-right: KM, NH; top: PC)

Data for this study comprised of mode of transportation, route and location of the activities to work, groceries shopping, study, and exercise. These data were collected using two different tools: questionnaires given to random housing estate residents and group interviews of the *kampung* dwellers. For the group interviews, participants are housewives who came to the session because of the neighbour leaders request. Prior to the group interview sessions, the author and team has come to visit the neighbour leader permission and cooperation. In discussing the analysis results, data from each group of participants are presented in separate in order to show the different pattern of mobility which may have been caused by the street network and access points as well as their associated socio-economic status. A total of 136 people have provided the data described in this study. Other than the charts and pattern shown in maps, interview quotes from the *kampung* dwellers are provided to enrich the data as an explanation to the pattern.

4. Results and Discussions

In exploring the extent of private motorised vehicle use, result of data analysis is provided into five sub-sections according to each type of activity and ended with an overall discussion.

4.1. Work

From the total amount of participants, as provided in figure 2, thirty per cent either work at home or no longer work since their retirement. Meanwhile, majority of people drive their private motorised vehicles to work which located at a various distance from 5 km to 30 km. Only a small percentage of participants who live in the *kampung* walk or ride angkot (one of the public transportation mode in Bandung) to work. None of the estate residents walk or

ride angkot to work (see the bars coded with KM-r, NH-r and PC-r). Further explanations on the mode choice and routes taken are provided in the quotes and map in figure 3.

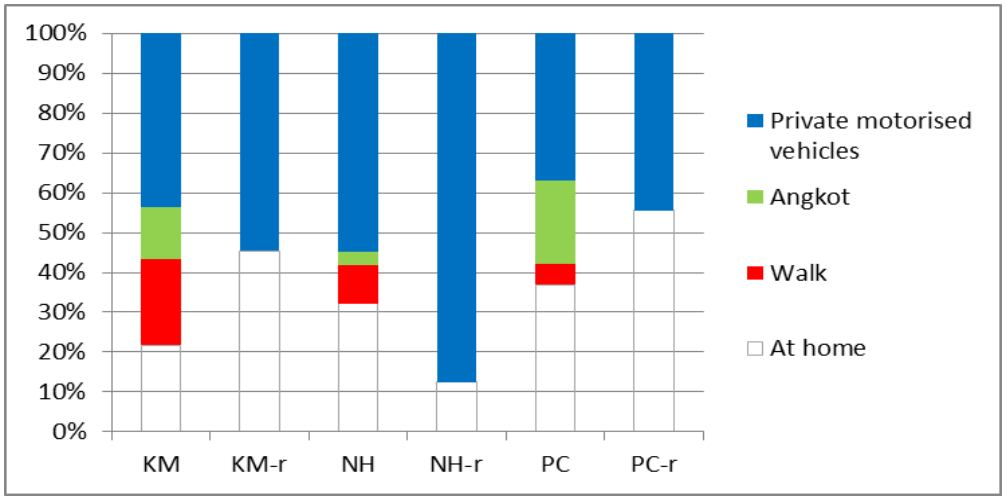

Figure 2 Mode of transportation to work

One participant who lives in the *kampung* adjacent to KM housing estate said that when her husband rides a motorbike from work, he mostly go through the *kampung* alley and rarely through the housing estate. The reason for not going through the housing estate is because of the guarded gate in which he has to ask the security guards every time he whishes to pass by as provided in the following quote:

> "At night [he] goes through the north alley … My husband usually comes home at 11 at night … though the security guards also live in this *kampung* it would still be a bother to ask [them] only to open the gate in the middle of the night" (RKM)

To ride an angkot, the *kampung* dwellers who live adjacent to KM housing estate have to walk for 300 meters through the private roads within the estate, carry on through the other *kampung* alleys, before finally reach the public roads in which several angkot routes are served. Meanwhile the *kampung* dwellers who live adjacent to PC housing estate only need to walk for 50 meters to halt Cidahu route angkot.

Walking is only done by several participants whose workplace located within walking distance from their home, including who works as household servant at the housing estate as well as those who has a warung (stall) at home. It should be noted though that walking distance radius, as has been drawn as red circle in the map, is not the same as the real network distance that one has to go through. This is evidenced in one participant's experience who sells fresh fish and seafood at Pasar Atas, a traditional market located within 250 meters radius. Drawn as red line in the map, the usual route she takes to work is 350 meters long through the pedestrian access provided by the housing estate which leads to other *kampung* alleys. Should this access is shut, she would have to walk for 1200 meters and take three times longer (drawn as yellow line). She is fully aware of this condition as seen in the quote below:

> "I work by selling fish at Pasar Atas every morning until 2 PM from 5 AM. Sometimes I ride motorbikes but I mostly walk; me and my husband. Walking

[route] is much nearer when the KM [housing estate pedestrian gate] is open. If it's closed, [I have to] walk further and take [more] time all the way to go out at the petrol station" (ISKM)

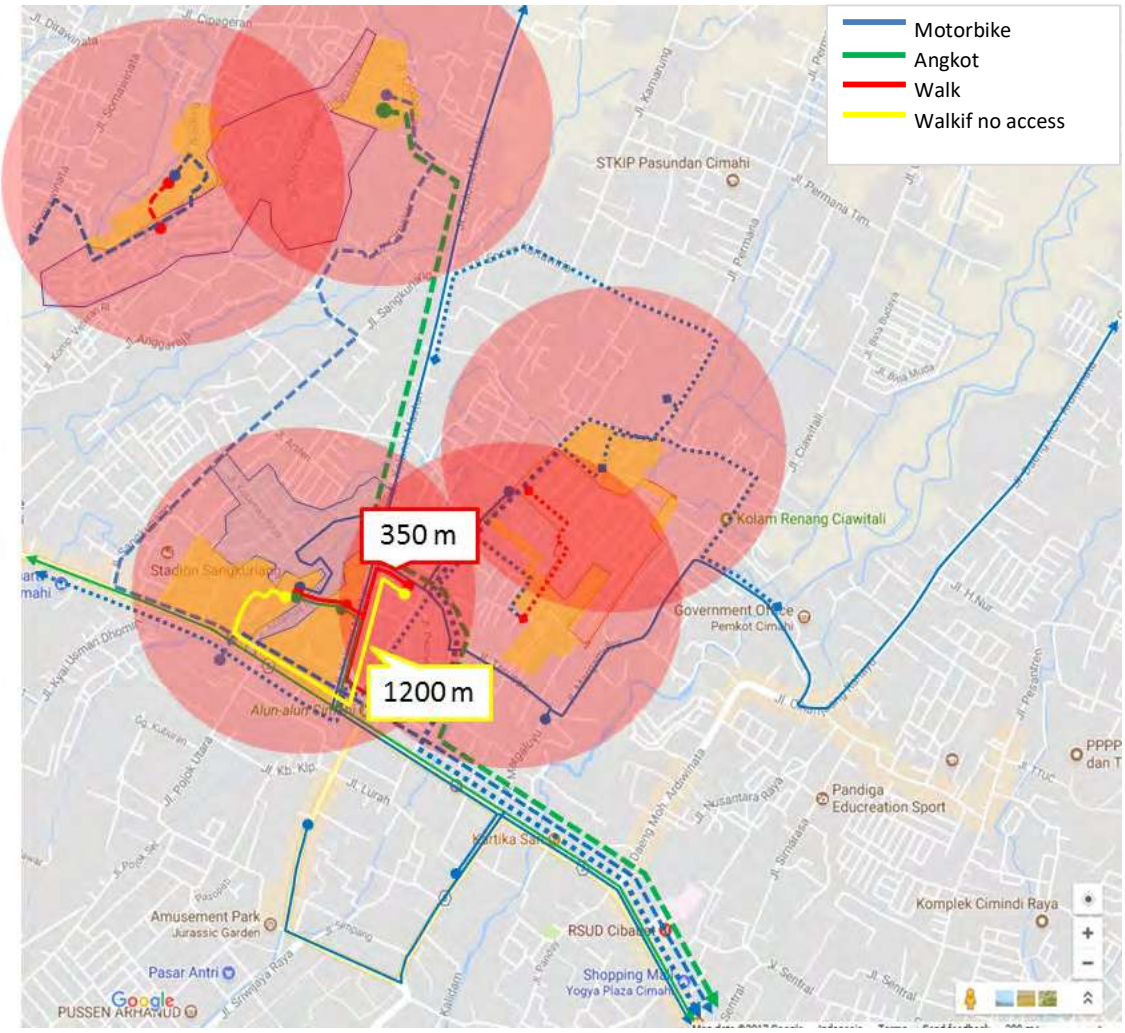

Figure 3 Route and mode of transport to work

On another case, there is a participant who used to work as a household helper at NH housing estate. She desbribed that the shut down of pedestrian access has become a factor in making a decision to resign from work. Not only her, the school children have also been affected by the access being shut. Though the *kampung* dwellers have complained, the access is still shut due to security reason. The quote below describes such conditions:

"When I used to work, I can still go through that door [pedestrian gate]. We cannot go through now. It becomes far since we have to go all the way to the front. That is why I stopped [working]. I pity the school children [since] they have to walk further. I had once being asked to be a representative of this*kampung* dwellers to deliver our complaints to NH [housing estate residents]. They [NH

residents] responded 'Go ahead [open the pedestrian gate] if you are willing to be responsible if there is any burglary here'" (INNH)

4.2. Shopping

For groceries shopping activities, the top graph in figure 4 shows that the majority of participants walk. However, there is a notable difference where the *kampung* dwellers mostly walk or ride *angkot* to buy groceries while the housing estate residents are divided between walk and riding their vehicles.

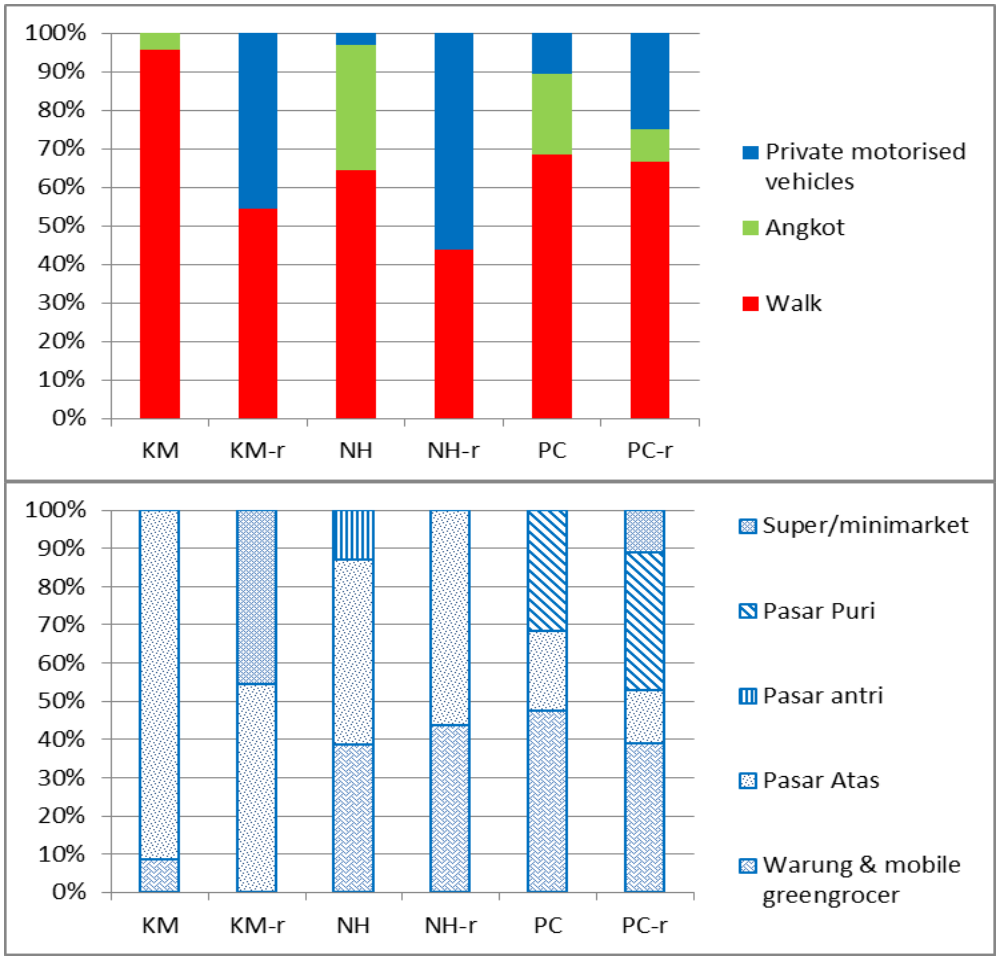

Figure 4 Mode of transportation and destination for shopping activities
(Top-bottom: Mode of transportation, shopping destination)

The bottom graph in the same figure explains that the destination for groceries shopping makes the difference of such different mode of transportation. The *kampung* dwellers all go to either *warung*/mobile greengrocer or the traditional market which very easily accessible. On the other hand, estate residents who go to the traditional market are divided: KM estate residents walk to Pasar Atas located 300 meters away, NH estate residents ride their private vehicles to Pasar Atas located 600 meters away, and PC estate residents can walk to Pasar Puri, ride angkot to Pasar Atas (2 km away), or ride their private vehicles to Pasar Antri (5 km away). The locations of these traditional markets are provided in figure 5. Looking at the shopping destination of estate residents, only a small part of residents go to supermarket:

nearly 50per cent of KM residents and 10 per cent of PC residents. The supermarket which the participants go to differ based on the distance to their houses starting from the nearby minimarket to the big supermarket within less than 5 km away. PC estate residents go to the west while KM and NH go to the east. While these residents shop once a week to once a month, the rest who shop at *warung*, mobile greengrocer and traditional market buy groceries in every two days or a few times a week.

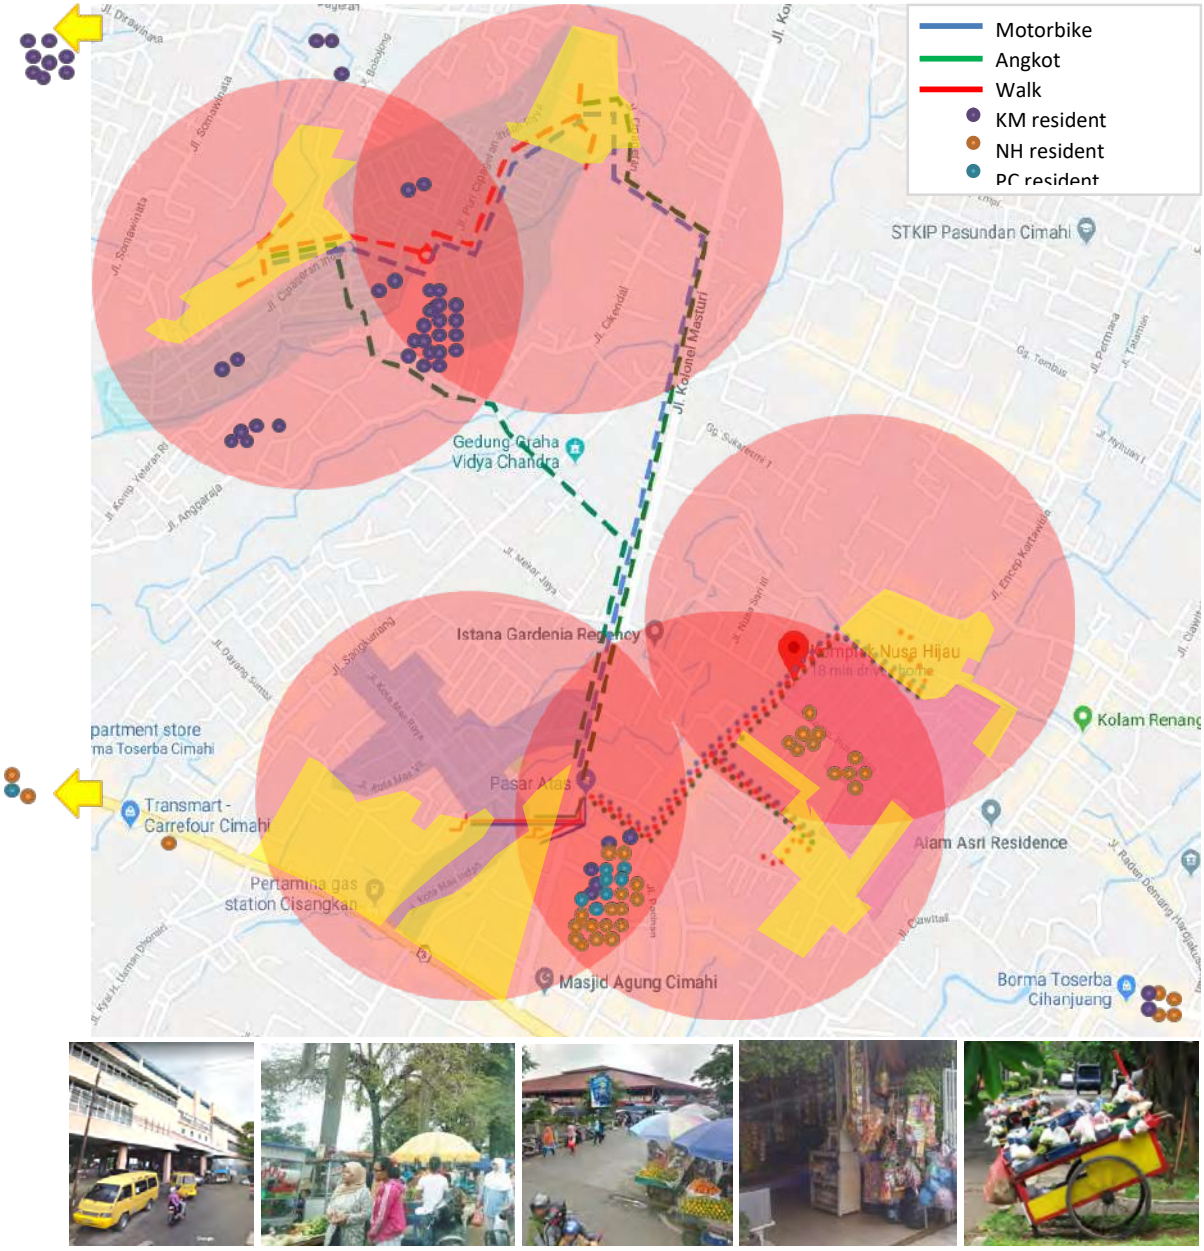

Figure 5 Route and mode of transport to shop
(Bottom left-right: Pasar Atas, Pasar Puri, Pasar Antri, typical warung, mobile greengrocer)

The patterns of groceries shopping to *warung*, mobile greengrocer and traditional market are provided in the following quotes. The reason is mostly due to the locations which incur no travel cost.

> Pasar Atas, sometimes [I shop there] everyday on foot. The price must be about the same, [I shop there] because it is near (NKM)

> Sometimes [I shop] at Pasar atas, sometimes to the mobile greengrocer. Just walk through here [to go to the market], the alleys, very near…at least 6 times a month. I buy rice [at the market] since the mobile greengrocer does not sell rice (DKM)

> I buy vegetables daily at the mobile greengrocer…or *warung*, the nearest one. I shop every day but only a little, only the necessities, spend about 2000 [rupiah]. Let the mobile greengrocer come so I do not need to spend travel cost to go the market. It is budget efficiency, honestly (TRNH)

To go to Pasar Atas which located 600 meters away from their houses, NH *kampung* dwellers sometimes ride *angkot* and sometimes walk depends on traffic as well as their mood as the quotes below describe:

> Sometimes I ride *angkot* but sometimes in the morning there is traffic congestion so I walk. It is very congested. I go there [Pasar Atas] every day (NNNH)

> If I go to Pasar Atas I ride *angkot*. If I felt like walking then I like to walk through the NH housing estate, it is nice to stroll. Most of the time [I shop at] *warung* though (INH)

4.3. School

From the total amount of participants, provided in figure 6, nearly half have no school-aged children; either their children are still very young or have become adults. The modes of transportation of these school-aged children are divided almost equally between those who walk, ride *angkot*, and ride private vehicles (drive themselves or drop by their parents). Looking at where they reside, no contrasting difference can be found between the estate residents and *kampung* dwellers, for example KM *kampung* dwellers and NH estate residents do not ride angkot to school. The school location that both *kampung* dwellers' and estate residents' children attend to are within reasonable distance in which 5 km at the furthest.

The patterns on the use of mode of transportation to school are highly varied. It differs due to high variety of factors, such as the age of the children, the angkot route, the parents' schedule, as well as friends who accompany the children. These factors are uttered by the participants in the following quotes:

> My eldest child studies at SMP Pasundan 1 di Ciawitali near the city government office. The youngest at SD Mandiri 3 Cipageran at Sawahlega. They go to school with their father. The youngest goes home on foot while the eldest rides *angkot*. The route started from KM housing estate, to Citeureup, to Police Office. The youngest walk around 10 minutes usually with friends (AKM)

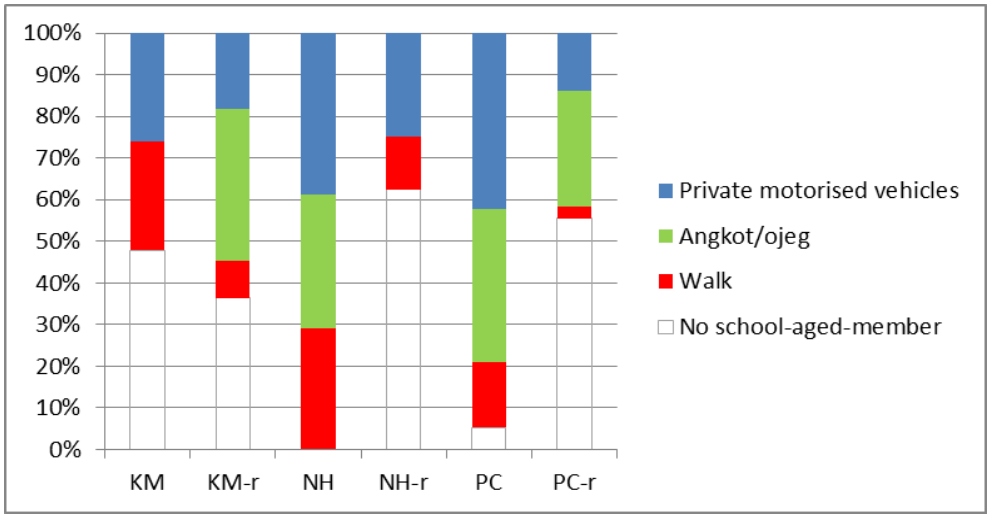

Figure 6 Mode of transportation to school

The shut down of pedestrian access in NH housing estate have affected one of the *kampung* dwellers. She said that her child has to overcome further distance from previously only 600 meters to become 900 meters. However, they are dealing with it as quoted below:

> My eldest studies at SDN Mandiri 5 Cimahi. Walk [to school] not too far through Sudarman alley. Previously [before the pedestrian gate was shut] was nearer. We though about moving to a new school, but he is now at the 4th grade so only two years left [until graduation] (ASNH)

Different to the two other locations, participants at PC housing estate and *kampung* dwellers who ride *angkot*, *ojeg* or private vehicles are much more than those who walk. The routes shown in figure 7 show that the schools are located outside the walking distance. The following quotes describe:

> The eldest child now studies at UNISBA and rides motorbike there. He used to study at SMA 3 Cimahi, SMP 3 Cimahi, and SD Cimahi 1. He rides motorbikes since the final year of junior high school (SMP). Before that, his father drops him off the motorbike (ISPC)

> **My eldest studies at SMK 3, Cipageran and the youngest at SDN Mandiri 1 at the 5th grade. The eldest usually rides Grab, the youngest rides angkot (LIPC)**

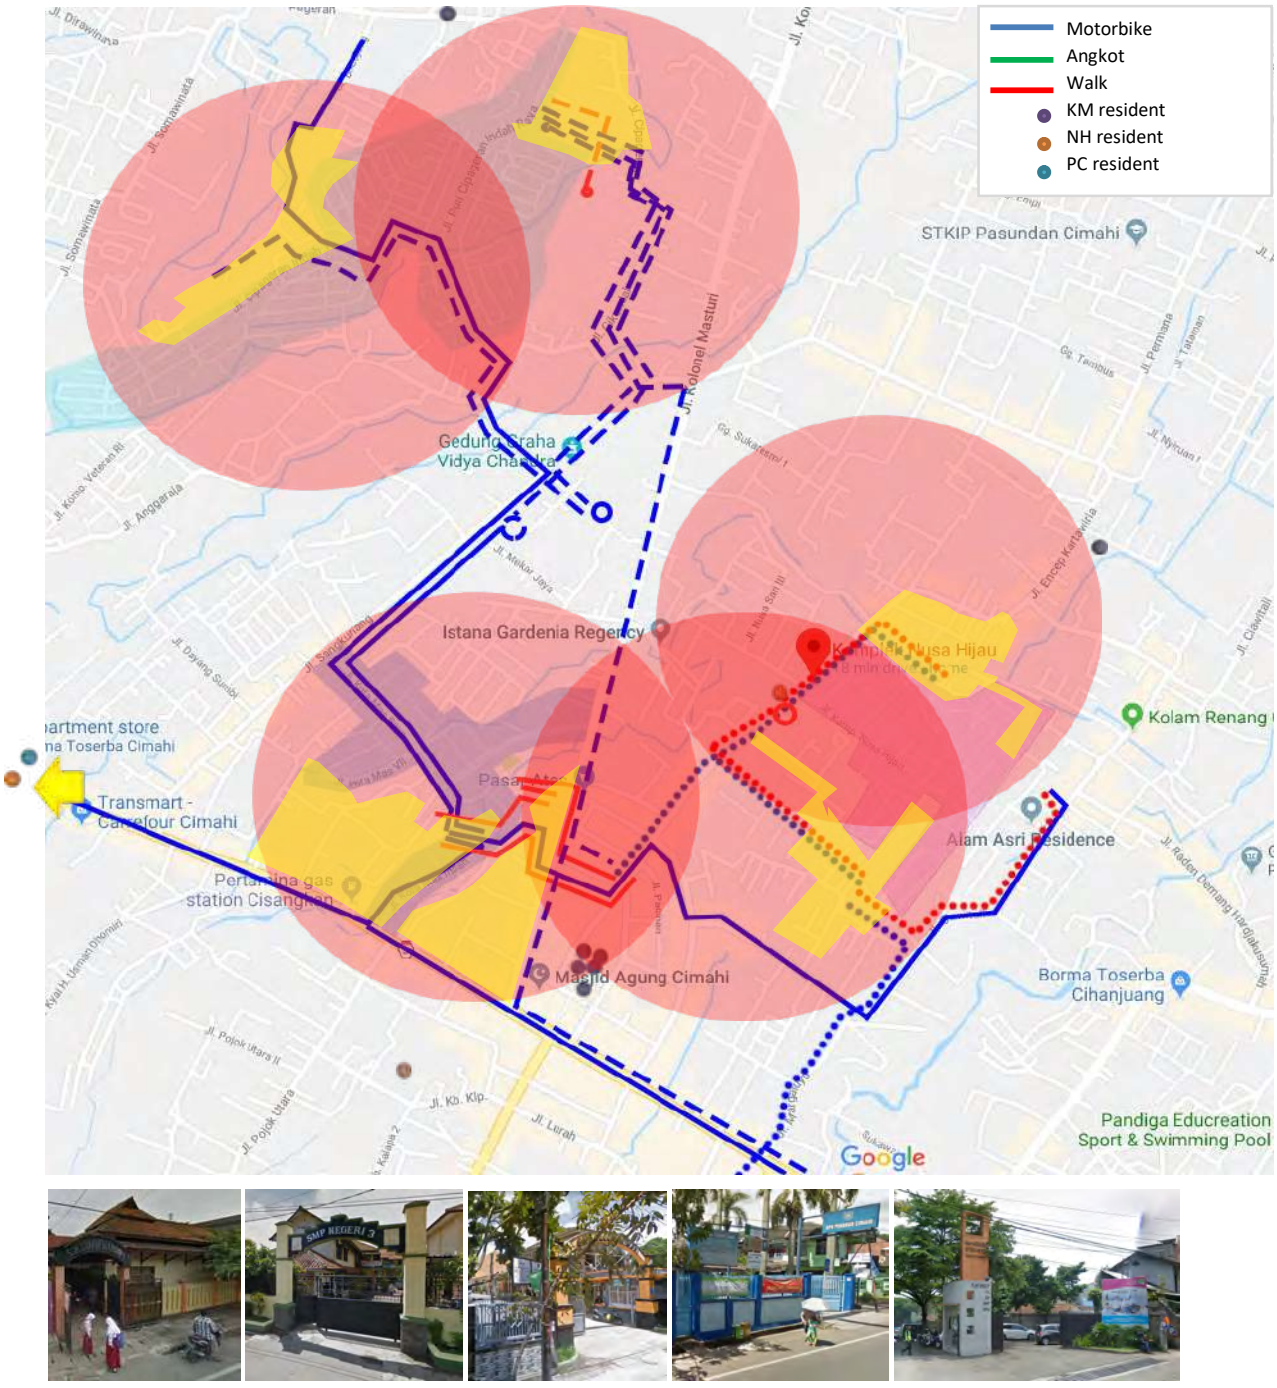

Figure 7 Route and mode of transportation to school
(Bottom left-right: public primary schools [SDN, SMP, SMK], private schools)

4.4. Exercise

For exercise activities, the top graph in figure 8 shows that around 30per cent of participants exercise at home or do not exercise. Meanwhile, 50 per cent walk as a form of exercise as well as to reach the destination to do an exercise. Only a small percentage of participants ride private vehicles or *angkot* since they travel between 3 to 5 km. Looking at where they reside, no contrasting difference on travel mode can be found between the estate residents and *kampung* dwellers.

The bottom graph in the same figure shows the destination of exercise at each case. In KM, the estate residents exercise by walking around the area. While most *kampung* dwellers exercise at Sangkuriang stadium located just on the other side of KM housing estate, some of them exercise at Brigif (5 km away) and Kenfer swimming pool (3 km away), and only a few exercise at KM housing estate. Similar to estate residents in KM, most estate residents in NH and PC exercise by walking around the area and the rest exercise at Brigif. The *kampung* dwellers in NH and PC exercise at various locations: Most NH *kampung* dwellers exercise at several locations within 1 km radius and a small portion exercise at Brigif and the NH housing estate; Most PC *kampung* dwellers exercise at the neighbourhood field, 10 per cent exercise at PC housing estate, 5 per cent at Kenfer swimming pool (3 km away), and the last 5 per cent at a nearby sport stadium.

The variety of exercise locations of the *kampung* dwellers are caused by several factors such as shopping, availability of instructor, and accompany. These factors are mentioned in the following quotes:

> [I exercise at] Sangkuriang or Brigif stadium. I exercise at Sangkuriang stadium because it is closer [than Brigif] and it has a market (*pasar tumpah*) as well. I go there through KM. If I go to Brigif I like to ride motorbike, much more to see there. Exercise while shopping (DKM)
>
> [Sometimes I do gymnastics (senam)] at RSGM (dental hospital) every Tuesday and Sunday. Usually I go to Permana…by riding *angkot* twice a week. An instructor is provided there (RNNH)
>
> We like to do gymnastics (*senam*) in the rear of Ramayana [near the old townhall] every Sunday morning. I walk there with fellows [who live] here (*ibu-ibu disini*). We never ride *angkot* since the route would be further (*jauh muter-muter*). It is better to walk, not far through shortcuts (LNH)
>
> At the old townhall we do Zumba every Sunday. At KM we exercise at 6 AM, then we continue at the old townhall at 8 AM. We walk [because] it is near (SKM).

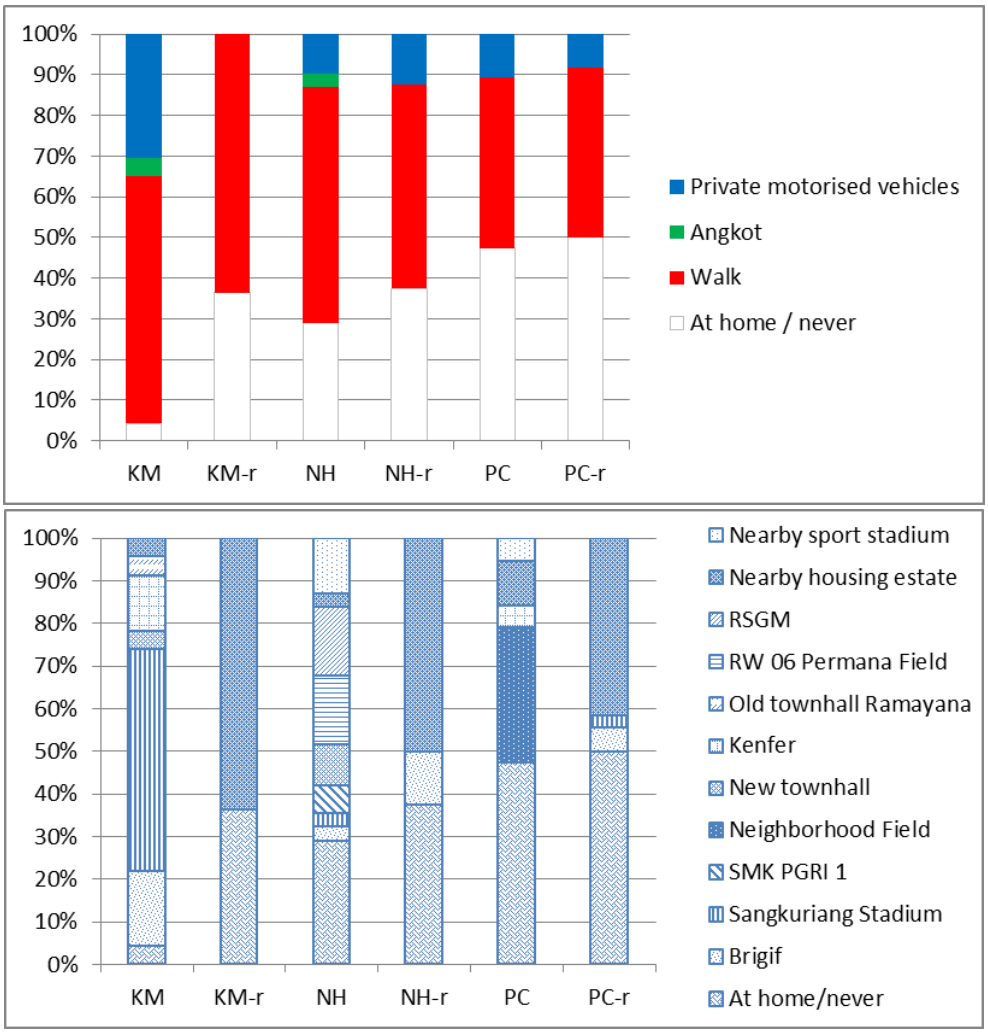

Figure 8 Mode of transportation and destination for exercise activities
(Top-bottom: Mode of transportation, exercise destination)

For the NH *kampung* dwellers, some of them used to exercise at a park in NH housing estate. However, they no longer do so since the shut down of pedestrian gate as quoted below:

> I also used to like to do gymnastics (*senam*) there [at a park in NH]. After that [the shut down of pedestrian gate] I walk [as an exercise] to Ciuyah all the way to Kamarung since I have a friend who used to be a neighbour live there. I almost never exercise [at NH] anymore. I had once exercised there by riding a motorbike but then never again (SRNH).

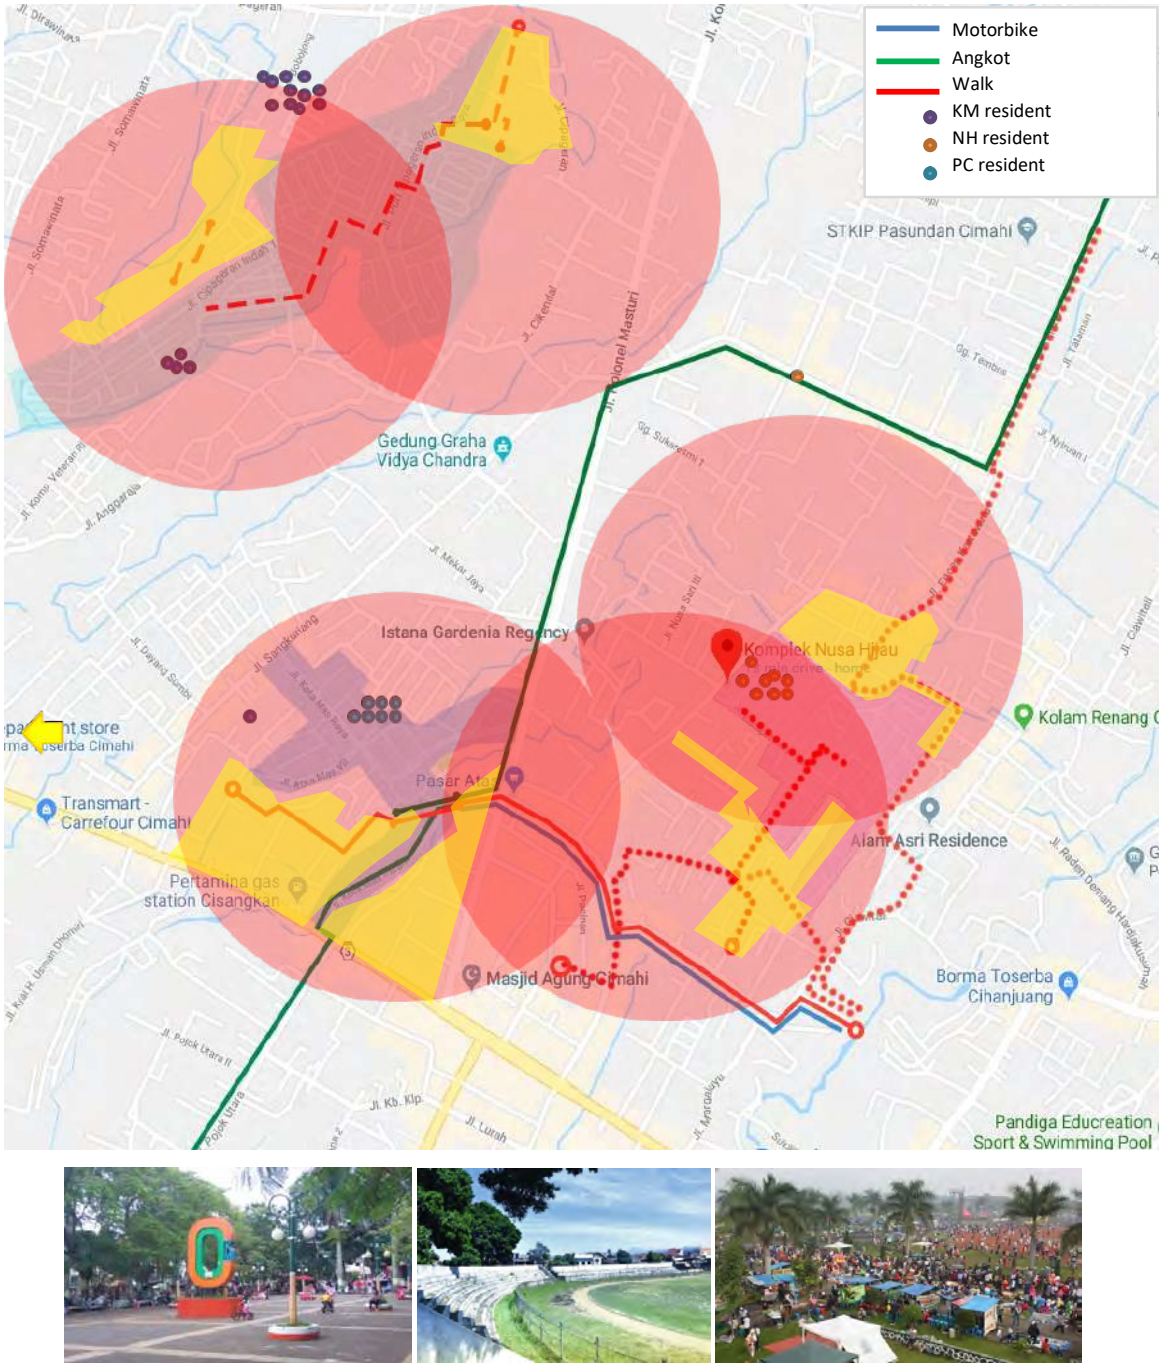

Figure 9 Route and mode of transportation to school

4.5. Discussions

To understand the phenomenon of how the middle-income housing and their gated community has impacted travel pattern, this paper tries to explore the extent of automobile dependency of the residents living at housing estate and the dwellers living at adjacent *kampung*. The journey to four kinds of activities can be grouped into the following patterns.

Majority of participants drive their private motorised vehicles to work which located at a various distance from 5 km to 30 km. Only a small percentage of participants who live in the *kampung* walk or ride *angkot* as the public transportation to work. None of the estate residents walk or ride *angkot* to work. For groceries shopping activities, the majority of participants walk. However, there is a notable difference where the *kampung* dwellers mostly walk or ride *angkot* to buy groceries while the housing estate residents are divided between walk and riding their vehicles. The children, both living at the housing estate and *kampung*, go to school by walking, riding *angkot*, and riding private vehicles (drive themselves or drop by their parents). For exercise, no contrasting difference on travel mode can be found between the estate residents and *kampung* dwellers. Fifty per cent walk as a form of exercise as well as to reach the destination to do an exercise. Only a small percentage of participants ride private vehicles or *angkot* since they travel between 3 and 5 km to do the exercise.

Most residents travel in far distance to reach their job location but do not travel in far distance to conduct their shopping, studying, and exercise activities though some of them own a motorbike. The latter is due to the presence of mobile green grocers, *warung*, traditional markets, good quality schools, sport facilities and open spaces within walking distance to their houses. However, these facilities are visited mostly because there are pedestrian access points through the housing estates made available for public use.

When these access points are restricted or non-existed, the travel pattern would differ as has been uttered by the *kampung* dwellers. A number of participants have mentioned that travelling to work, grocery shopping, school, and exercise has been made easier owing to the pedestrian access points. In one of the cases, the following disconnections between the *kampung* alleys and streets of housing estates have made the *kampung* dwellers altered either the location or the transportation mode of their exercise activities. The weaving of a network comprised of *kampung* alleys and private roads of housing estate has proven to be beneficial for the *kampung* dwellers. In several examples, such as in shopping and exercise activities, it has also changed them from riding a motorbike to walking. It has showcased the impact on creating a healthier and more affordable travel behaviour.

Owing to this pedestrian access, *kampung* alleys become connected to the streets within the housing estates and create shortcuts for pedestrian to walk through. Such network is a privilege for the pedestrian, since they cannot be accessed by cars and in some parts difficult to be accessed by motorbikes due to the narrow alleys.

5. Conclusions

There are lessons to be learned from these travel patterns. Housing estate development shall always provide access to the *kampung* that have existed and *vice versa*. Such spatial connections will promote a change of travel behaviour from automobile dependence to active travel. However, it should be kept in mind that these results may not be generally applicable to other places with different socio-economic and spatial characters. Acknowledging the large amount of gated communities in Indonesia, further work in the field may be benefited from more cases and larger population sample.

Case Study Paper

Urban morphology and behaviour mapping in Abu Dhabi's public spaces.

Informality as an interaction of cultural context and urban form.

Abstract

Abu Dhabi's galloping growth is shepherded by a stringent set of standards and guidelines for both the public space and the built environment. Its urban form that follows the main characteristics of most new Arab cities (automobile dependency, modernist grid and monotonous suburban sprawl) has already started gaining the attention of scholarly research. However, that research body still misses a critical analysis of the dynamic interaction between the qualitative quotidian practices and the produced urban form. Such an analysis could shed light on the relationship between socio-ethnic groups and urban space programming and appropriation.

This paper presents findings from an ongoing research program for the search of a link between the design and use of public spaces, and the surrounding urban morphologies within the diverse sociocultural context of Abu Dhabi. Fourteen public spaces of the city (both formal and informal ones) were examined in terms of their typology, functions and social profile, as well as for the correlation with their urban context and the public transportation networks. In situ methodological approaches such as behavioural mapping, impromptu discussions and photography were applied in order to shed light on the intricate particularities and qualitative properties of public spaces. The mapping of the public spaces was conducted under the prospect of comparability, either between themselves or with future studies in similar cities in the Middle East and beyond.

The research program – albeit not completed yet – amplifies the importance of informality as an indicator of urban health and as a reminder of insufficient urban planning programming and urban design practices. It also underlines the importance of preserving or even pursuing informality as a catalyst of social cohesion, cultural flexibility and inclusivity. Furthermore, certain urban morphologies, related more to a higher and a more organic degree of pedestrian connectivity seem to optimally contribute to a more diverse and successful public space.

Future phases of the program could also reveal relations on the metropolitan scale with regard to mobility, public transportation needs, strategic approaches and the need to control urban sprawl and densities. This case study of Abu Dhabi could then become of valuable guidance on rewriting public space design manuals and on exporting urban doctrines.

Keywords

Abu Dhabi, informal, urban morphology, public space, culture

1. Researching Abu Dhabi

1.1. Introduction to context

While often dwarfed next to Dubai in terms of scholarly attention, Abu Dhabi is emerging as a paradigm of a new Arab city in the Gulf region. Its transformation from a seasonal fishing post to a contemporary global hub – as fuelled by the oil boom – has been achieved under a consistent and pragmatic political will (Kyriazis, 2017). Its five decades of history, although shallow compared to most cities, were enough for the city to grow to the extent that construction moratoriums were issued twice in order to allow the city life to catch up (Elsheshtawy, 2008). Automobile dependency still dominates and shapes the urban form (Montagne, 2016) resulting an expensive sprawl against both urban fronts: the desert, with a post-modernist suburban lifestyle and significant horizontal segregation; and the waterfront, through constant reclamation on a sensitive marine ecosystem and the production of exclusive expatriate-based resort-like developments (Kyriazis, 2018). Catalyst to that is the effort of the city to keep up with the latest trends on global urban design and real estate developments while pushing for high targets in tourism that led to emphasis on security and public space privatization (Samarrai, 2018). The urban and architectural scales are controlled by a meticulous set of manuals, partially aligned with the local cultural and climatic conditions. Especially with regard to the public space, it is the analytical manuals, privatization and an almost Orwellian level of security that generate a sense of over-management (Kyriazis, 2019).

1.2. The research project

In a city that was created in a tabula rasa for the sake of modernization (Al Fahim, 2014) and where the built environment is renewed to the degree of risking to eradicate even those shallow layers of modernist history (Menoret, 2013 and Elsheshtawy, 2008), its citizens – expatriate in majority – are a permanent testament of its temporality. A labor/sponsor based residency system underlines this property. However, they provide a pulse to the city as well as a seemingly uninterrupted collective memory that ensures the continuity of its existence (Elsheshtawy, 2019). The public space is their field of action. The street, the square, the alley; a space of interaction without which urban life would not exist (Lefebvre, 2003).

It is this space and its interaction with its users and the urban form that is under research. A city-wide behavioural analysis that would highlight social parameters and could associate them with the urban morphology. In this light, the research team combines forces from two institutions and three disciplines: Architecture, Sociology and Human Geography. Documenting the behavioural profile of public spaces and superimposing it to the urban form and mobility patterns would answer questions related to the genesis and impact of informality, to the consequences of zoning practices and to the interconnectivity of the public realm (Kyriazis, 2019).

Quotidian urbanism has been studied thoroughly in many cities for the last decades, following the influence of Jane Jacobs, William Whyte, Kevin Lynch, Jan Gehl and others. Middle Eastern cities were also examined, as their pre-modern, organic urbanity highlights the importance of randomness and spontaneity (Elsheshtawy, 2011; Robabecciah, 2018; Alawadi, 2019). However, this meticulous study of Abu Dhabi is critical, as the role of informality is tested – and eventually becomes essential – against a condition of over-management and overregulation. Aspects of Abu Dhabi's daily patterns have already been studied (Alawady, 2019; Elsheshtawy, 2019), but this project includes the entire metropolitan area, aspiring to juxtapose the intricate urban morphologies with the public space users and their diverse sociocultural backgrounds.

1.3. Methodology

Achieving comparability and representativeness within that mega-scale was a key target for the research project. Comparability regarded the formal/informal dualism, different neighbourhoods of the city as well as with other cities in the region. This hypothesis raised the issue of splitting the city to major parts with distinct urban/social characteristics.

The analysis of urban and statistical data would precede the social/behavioural one. However, since access to any statistical and demographic information was limited, the observational part should involve an upgraded empirical analysis, supported by impromptu discussions with public space users (instead of a formal questionnaire). Simultaneously, the role of photographic documentation became even more critical for both parts. Public space photography was a sensitive issue concerning privacy and socio-cultural particularities and special techniques were applied (Kyriazis, 2019).

Observations covered morning-afternoon-evening time slots for both weekdays and weekends, thus adjusting to quotidian religious practices and labour patterns. Furthermore, due to the extreme climatic conditions of Abu Dhabi, most daytime observations were conducted during winter. They include description of actions, brief profiles of public space users (nationality, occupation, commuting means and origin etc.) and mapping of their pathways and actions within that space. This mapping would get superimposed to the urban analysis for a spatial visualization of the observational grid. Furthermore, those profiles will be used to reveal mobility patterns at the metropolitan scale.

2. Analysis - Observations

2.1. Selection of studied public spaces

A first effort to pinpoint all existing public spaces in Abu Dhabi highlighted the volatility of the informal ones as well as the necessity of acquiring information of any elusive yet remarkable activities around the city (figure 1).

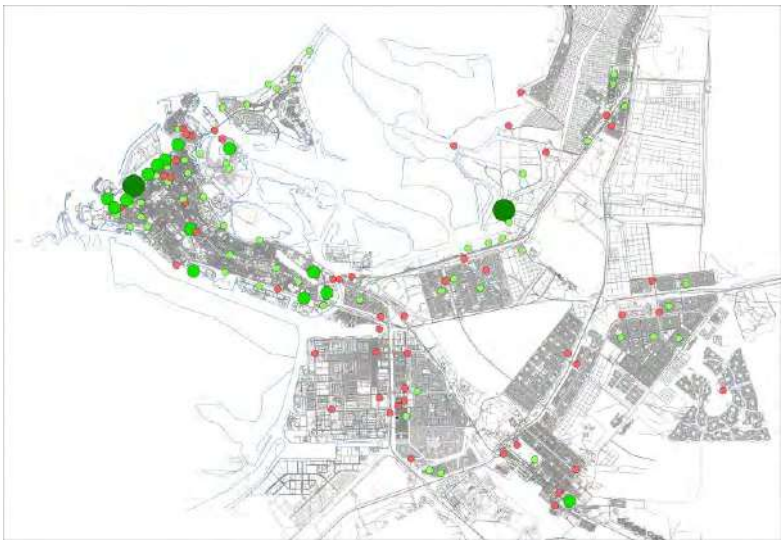

Figure 1: Map of public spaces in Abu Dhabi. Formal spaces are in green (sized after their importance/impact) and informal spaces are in red.

For addressing issues related to observations' time management and comparability without compromising its scientific principles, the city was divided in seven zones with distinct morphological characteristics and ethnic distribution (in numerical order): the downtown superblocks, the mid-island low-rise villas, the institutional Maqta channel, Khalifa City, the industrial suburbs, the desert sprawl suburbia and the waterfront expatriate free zones (figure 2).

Two public spaces were chosen from each zone; a formal and an informal one. This way, observations from all fourteen spaces in various timings and days would secure a representative enough reading with comparable results. Special attention was given to issues that could affect the objectivity of the observations, such as the intricate climate of the region and major religious events (i.e. the holy month of Ramadan).

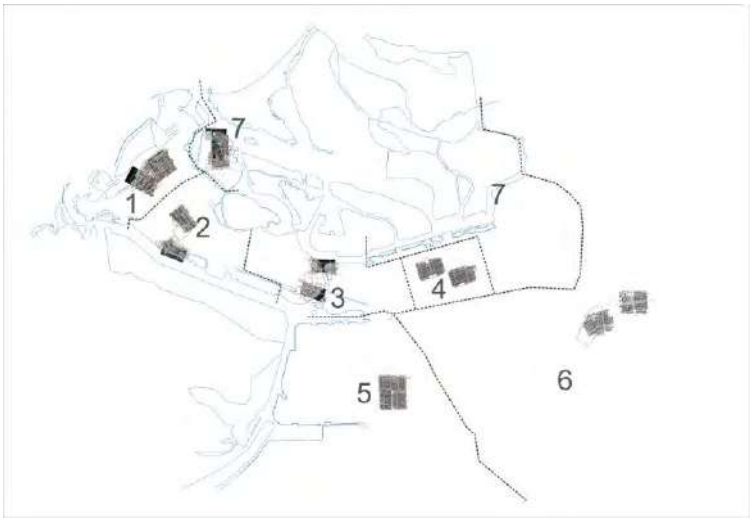

Figure 2: Map of the selected public spaces to be studied.

2.2. Urban Analysis

A layered urban analysis was necessary both for comprehending the morphological distinctions that the aforementioned grouping induced and for becoming the basis upon which the behavioural mapping will take place. All fourteen chosen spaces are depicted in thematic layers of urban morphology, namely Built-up space, building heights, land uses (ground floor and overall), pedestrian space and road network (figure 3).

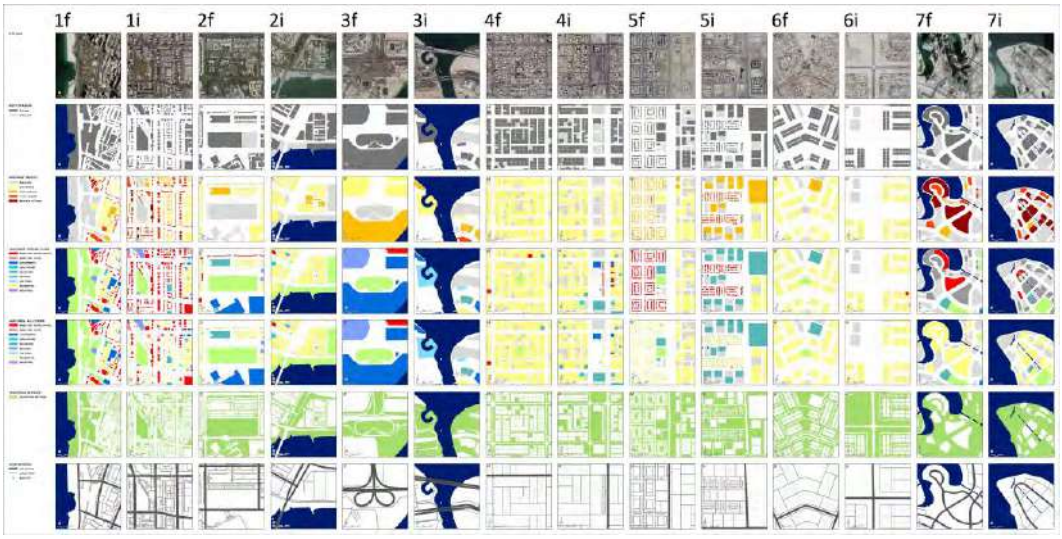

Figure 3: Urban thematic maps of the fourteen assigned spaces (as numbered in Figure 2 with "f" and "I" standing for Formal and Informal). All mapped areas are 1x1km in dimensions.

The theme maps alone reveal patterns of relations between the studied spaces and their urban surroundings. Density, heights and plots' shapes consist a first level of reading related to walkability, accessibility and porosity.

3. Observation findings

3.1. Behaviour mapping

While only few observation slots remained at the time this paper was authored and most of the digital mapping process is still under way, several significant findings have already emerged. These findings are a fruition of activity observations, qualitative information from the public space users and from the mapping itself.

The research team sought for both formal and informal activities – regardless of the formal/informal status of the site itself. This distinction was elusive (especially in formal spaces) but clear once occurred. However, activities on informal public spaces also display timing and usage patterns, thus highlighting the absence of formal public spaces or the absence of specific uses/activities within them, in major parts of the city.

However, this project focuses not only on the public spaces themselves, but also on their relation with the surrounding urban morphology. The mapping of pathways and activities (figure 4) focuses more on the latter.

Figure 4: Mapping of pathways and activities of public space users (source: authors).

3.2. Formal Public Spaces

The formal public spaces chosen in this project can be divided into three categories, in terms of design sequence: The ones that were created and designed at an ad-hoc basis, like the famous Corniche downtown park (as part of the waterfront regeneration). The parks with plots allocated by Master Plans that got developed later in an isolated fashion (like the parks of areas 4f, 5f and 6f shown on figure 4). Lastly, the parks that were created in residual urban spaces i.e. within highway junctions (like the park on area 3f).

Observations showed that in most of these public spaces, informal actions were less than few and they were usually hinging on alternative use of sport courts (due to overpopulation in other, popular sports), small-scale and time-limited occupation of playground equipment (by sleeping Municipality workers or smoking youth) and arbitrary car parking at unpaved edges of the areas. Security personnel assigned by the Municipality however rapidly quench most of these cases. Other surprises like trash collectors searching on bins and users of quad-bikes inside grass-landscaped areas were rare.

Regardless of the size and importance of the public spaces, it seems that their success depends on the presence of flexible areas within them; areas devoid of a program, areas open to experimentation, adaptation and customization. In the studied cases, this is manifested by open areas of greenery that can easily adapt to cultural particularities and habits (i.e. family pic-nicks) but also absorb extra demand in popular segments of the park (i.e. football courts etc.). Furthermore, such spaces are also capable of accommodating local-scale attractions introduced by individuals that rent their needed space from the Municipality. Thus, some revenue comes back to the local authorities (or to park managers) and at the same time, initially unforeseen uses enrich activity options.

3.3. Informal Public Spaces

The informal spaces chosen are either underdeveloped (or not developed at all) public spaces or undeveloped private plots. While many informal spots of Abu Dhabi have established some kind of permanence – albeit a delusive one – many others disappear or appear at surprisingly frequent rates, underlining a condition of temporality. Practically speaking, figure 1 would need constant updating.

Informal spaces usually serve in absence of formal alternatives in a neighbourhood. Therefore, they highlight the deficiencies of the preceding master plans in supplying public spaces in general or specific facilities that could address demand from local residents. This also indicates a gap on the usually top-down urban planning processes and their inability to reflect on the social dynamics of the city. Abu Dhabi – as well as many of the Arab cities of the Gulf – is highly ethnically diverse with the indigenous population occupying only 19% of the total (SCAD, 2018), the majority being from the Indian subcontinent (India, Bangladesh and Pakistan). In this light, it is not surprising to witness so many spontaneous cricket games (especially in sectors 3, 4, 5 and 6). Other sports performed are volleyball (mostly by Indians in the 5i spot), badminton (on pedestrian sidewalks of the 1i area) and football.

In most of these cases, informal gatherings function as community condensers. The Indian volleyball gatherings on area 4f resonated as friends' meetings after working hours, to end up in running neighbourhood championships. Similar settings appear in cases like the Bangladesh square (Elsheshtawy, 2019). Such post-work ethnic gatherings also display a sense of resistance to the daily routine, to labour anxieties and transience.

However, the expatriate communities are not the only ones that express their quotidian anxieties this way. The local youth (including other Arabs) also try to unwind themselves and socialize in manners related to automobiles and engine sports in general, a phenomenon frequently met in the region (Menoret, 2013). The Bateen beach (sector 2i) is a hot spot for impromptu jet ski races during the sunset. To this direction, the informal cases of the areas 4i and 6i are indicative of the consolidation of the private car as a personality extension as well as of the profound impact of the monopoly of this means on shaping the city's urban morphology. The car is used to shortcut big-sized, dirt/sand-covered city blocks and to stop at canteen stations for drive-through dinner orders. Canteen stations are an upcoming trend in Abu Dhabi: apart from following major events in the city (about sports, concerts and the like), they also make self-organized groups, occupying informal public spaces next to highway entrances to the residential suburbs. This trend is so vibrant that the Municipality have been trying to settle the canteen groups in temporarily formalized areas.

3.4. Illegality Vs Informality

The use of unfenced vacant private plots and the performance of several actions in formal public spaces have often been the subject of criticism from local authorities. After raising issues of security and socio-cultural particularities, informal behaviour is sometimes demonized or even penalized (Gulf News, 2018). However, wide scholarly research has shown that security issues truly arise in the absence of street life and informal urbanism (Jacobs, 1961). In addition, such measures tend to strengthen the sense of segregation and temporality and actually function as a catalyst for informality and a reply to oppression (Menoret, 2013).

Interestingly, there is also the issue of a proper definition of informality and illegality by both local authorities and designers. This became apparent on many of the formal spaces through the popular action of barbequing. While barbequing is a favorite task for many park visitors (mostly with an Arabic background), the official parks' signage was clearly prohibiting it. Some of the parks were later equipped with special built-in barbeque stations but the signage remained. Fishing is another popular but occasionally controlled activity. Conversations with Pakistani and Indian fishermen found in the 7i site implied a matter of public space clarity and quality in terms of preserving a high-end image of a public space and matching it with the "values" of its urban surroundings.

3.5. Informality and Space Privatization

The need to issue special permits for photography in the sectors 2f and 7f reminded the research team of other impactful space-generating forces of the city: the very real estate players, developers and private stakeholders. Public space privatization under the theoretical approaches of neoliberalism and the motivation of surplus value generation (Lefebvre, 2003) by definition oppose the notions of openness and inclusivity (Harvey, 2013). They deny any element of surprise and improvisation as they advocate for a fully monitored "surgery room" urbanism with predefined experience provisions. However, observations showed that public space privatization eradicates (but does not completely annihilate) informal activity, as even in the most diversely designed spaces users' unpredictability and the need for customization are inherent properties with universal value.

Further support to this approach comes from an incident prior to the observations' launch. The initial choice for the 7i sector was a countrywide known kite surf beach in Yas Island. Situated on the opposite side of the Yas global entertainment hub (that includes venues like the Yas Marina F1 race track, the Ferrari World and the Warner Bros World amongst other luxurious destinations), this beach was an informal haven for kite surfers and the like. It offered ideal wind alignments, easy access from a nearby highway and zero development; a setting naturally expressing the sense of freedom associated with these sports. However, in ignorance to the dynamics and potential of that attraction, permits were granted for private water sports facilities that fenced the area. Consequently, kite surfers stopped using that beach, all informal activities ceased to exist and the city lost a unique attraction.

3.6. Behaviour and the urban morphology

Most of the aforementioned cases and behaviours were the products of in situ observations. However – as aspired from the early stages of this project – their juxtaposition to the urban context (figure 4) should provide valuable insight on the dynamic interface and their intertwining properties that form or provoke each other.

Density does not seem to be associated with any kind of activity (formal or informal) apart from increasing the total amount of flows and the rate of unpredictability. However, its morphological manifestation makes a difference. The use of podiums on high-rise buildings on Reem Island (areas 7f and 7i), fully occupied with car parking spaces for the towers' dwellers, strips the street level of any life and produces elevated areas of exclusivity. Thus, pedestrian flows and activities of any kind in adjacent spaces are limited and channelled, with fewer opportunities for spontaneous socializing. In full contrast, on-street retail maximizes the randomness of pedestrian flow (areas 1i, 4i, 5i). Similar to that dualism, formal parks with single entry point like the Umm Al Emarat park (2f) are isolated from the urban fabric and have more predictable flows.

Moving to lower densities, the key sociocultural notion that shaped the urban morphology is privacy. The public-private dualism becomes more absolute and distinct than ever in the form of the plot walls that surround the "floating" or setback villas. The sikkak (pedestrian alleys) in between are the only reminder of an obsolete morphology and typology of Arabic residential architecture, the courtyard house. The transition was rapid and tailor-fitted the urge for display of an upgraded social status (Kyriazis, 2018). Public spaces 4f, 6f, 4i, 6i and even 2f are surrounded by such housing plots and pedestrian flows to/from them is streamlined through the sikkak in between.

However, low density, extreme zoning and sprawl pay their own price. Large plot sizes and oversized street corridors increase distances and discourage walking. Even in the ideal temperatures of the Abu Dhabi winter, the majority of people drive small to middle distances to reach a park. Furthermore, rigid zoning practices left suburbia devoid of local retail shops. This was a documented (by discussions with users) shortage that if restored, it could attract more people from greater distances.

3.7. Urban mobility

While the research phase of mobility in the metropolitan scale is still in process, several key points have emerged, using the interviews and part of the urban analysis.

Most (but not all) of the selected public spaces are serviced by means of public transportation (bus in particular). However, really few of the users select the bus to visit them. Cars consist the majority of means used, with walking, bicycle and motorcycle following.

With regard to distances travelled on purpose for a park visit, it became clear that formal spaces' users may travel bigger distances – even across the city. Apart from the cases of 1f (Corniche) and 2f (Umm Al Emarat park) that are country-wide known public spaces and may attract large numbers of people from afar, smaller parks also attract people from afar due to the existence of specialized facilities (i.e. football courts etc.). Opposed to them, most trips to/from the informal spaces come from their related neighbourhoods. Exceptions to this observation are activities related to community bonding, like the volleyball matches of area 5i.

4. Conclusion

What started as a humble attempt of this research team to document and map some of the already familiar public spaces of Abu Dhabi, ended up as a revelation. Under the seemingly permanent flashy wrapping of curtain wall urbanism and exclusive (in every sense) architecture, there lies a layer in flux. People, citizens and visitors that live, work, move, socialize and get entertained. They acknowledge transience as a constant and they resist on a daily basis. It is that quotidian struggle that is showcased.

The urban form contributes as an inherent piece of the condition. It highly affects urban mobility, quantities and qualities of public space and behavior within. The public spaces are the recipients of this quotidian anxiety. Therefore, proper planning, programming, designing and maintaining of these open spaces is key to the ability of a city to absorb all those vibrations and clashes.

Informal urbanism and informal behavior are major components of this relation. They are urban and social health indicators, as adaptation, improvisation and surprise are elements that produce and ensure openness, democracy and inclusivity. They imply smart and active citizens, in an era that "smart" only addresses corporate interests (Koolhaas, 2014). Informality is not theofied but becomes essential in disclosing weaknesses, shortages and environments of exclusion and conflict that otherwise would remain elusive.

The behavior mapping of Abu Dhabi's public spaces, apart from the value of documentation itself, is a project that may argue in favor of updating the existing city manuals and guidelines with filling in a gap between urban governance and a textbook yet sterile urban morphology: the social layer, the people, both owners and users. A pathway towards actual social sustainability. This may include an argument for a shift towards program flexibility. Neighborhood and public space design could invest in introducing participatory processes. The city should develop reflexes that would enable it to harness the values of informality. Furthermore, this project could set a paradigm for research on behavioral mapping and social mobility in all Arab cities in the region and beyond, with similar sociocultural and climatic conditions.

Case Study / Project

Health and the city:

creating built form and planning for the physically active

Slawomir LEDWON

Abstract

One of the most common cases of deaths in developed countries are non communicable diseases - such as obesity, heart related problems and diabetes. Many of these are easily preventable and can be managed by each individual. Paradoxically the evolution of our civilisation, technology and growth of cities has lead to many diseases of affluence, which pose a great threat to the society.

Contemporary planning practices have introduced the concepts of walkability and connectivity to make pedestrian movement easier, reduce traffic and manage resources. They have discussed the shift from individual motorised transport to cycling in terms of sustainability and efficiency. But what is missing in this discussion is which features of the built form encourage people to exercise and be more active in cities, thus more healthy. Even in the simplest activities like walking, jogging or running can make a huge impact of the well being of citizens. But they also need an encouraging environment.

There is a growing awareness among citizens regarding healthy lifestyle. That includes not only proper nutrition and balanced diet, general health but also physical fitness. Instead of watching television, which quite recently seemed as a popular and attractive leisure activity, people prefer to spend time exercising, training and taking care of their bodies. It doesn't matter if their goals are how they look, feel or fit they are. Each of those have one thing in common äóñ better health and longer life expectancy.

This case study discusses the principles of good design for healthy cities. How cities can be more suitable for physical activities of its citizens? Which built form features are most appropriate for that? How to design the environment which would aid healthy lifestyle? Strategies for encouraging active lifestyle in cities are also discussed. It also presents the initiative of ActiCity (acticity.org) to promote good urban design and planning for aiding active and healthy lifestyle. The project currently focuses on running in cities.

Applicability of the study's findings are universal, as they explain a set of guidelines and refer to case studies of best practices that can be implemented in other cities. It pitches the ideas for further development, research and implementation of the proposals. It discusses measuring the performance and use of space, such as the runnability index.

Case Study / Project

Empirical study on the evaluation of publicness of public space

- taking Chinese megacity as the case

Juan LI, Anrong DANG

Abstract

China has been exploring the way of applying the market economy in Chinese context. The market force will play a more dominant role in resource allocation in the next phase and the dependence of urban development on private investment will be reinforced continuously. The issue of privatization of public space in Chinese cities, especially in megacities, starts drawing the attention of academic fields in urban studies. However, researches addressing the impact of privatization on Chinese urban public space are rare.

This research aims at providing a lens for elaborating the following questions which include: 1. how public the public space is in Chinese megacities, 2. what factors impact the publicness of urban public space, 3. whether there exists a great difference in the publicness of publicly owned public space versus that of privately owned public space. Based on an extensive literature review, this research theoretically deduces that the main factors impacting publicness are multidimensional and interactive which include accessibility, management, and inclusiveness. By an in-depth analysis of the three dimensions, an elaborate measurement model including six sub-dimensions and 20 indicators has then been proposed within Chinese context in light of existing models. This research has applied the measurement model to both publicly and privately owned public space in a Chinese megacity -Beijing- to conduct a comparative analysis of the two types of public space. Taking Beijing as the case, empirical study finds that the overall scores of publicness of both sorts of public space indicate no great difference. Nevertheless, scores of the three dimensions impacting publicness show inconsistent results with the overall scores. Privately owned public space get a higher score on the accessibility dimension than its publicly owned counterparts, but a much lower score on inclusiveness dimension. The management dimension demonstrates the biggest difference between the two sorts of public space that publicly owned public space shows more care about the maintenance of space while privately owned public space put more efforts on the control of space.

To sum up, the privatization of public space shows a partially negative impact on the publicness of public space from the perspective of multidimensional analysis. This research also makes significant progress on the evaluation of inclusiveness dimension which has posted a great difficulty in the measurement of users' density and diversity within a specific public space. Taking advantage of emerging new data, this research could take a direct look at the users of public space and give a precise picture of how diverse the users are and how different publicly and privately owned public space are in the inclusiveness dimension. Besides, the measurement model developed in this research is flexible and open-ended, and it can be adjusted and applied according to different cultural context. In this way, we hope to provide a useful tool for urban planners, designers, policymakers and governments who bear the goal of an inclusive city in mind.

Research Paper

CHILDREN-FRIENDLY DESIGN OF URBAN PUBLIC SPACE

based on the study of shanghai,china

Author SHUAI LI, Tongji University; China

Abstract

At present, more than 50% of children live in big cities.But with the increasing number of motor vehicles and shrinking public spaces , children have less and less opportunities for outdoor activities, resulting in obesity and sub-health problems. Therefore, it is very important to build children-friendly public spaces in metropolis. This study takes the Shanghai,china as an example.Firstly,through questionnaires,it is found that ensuring the safe movement of children and inspiring their spontaneous activities are key points to build children-friendly public spaces.Meanwhile, The public spaces near the home are the most used environment by children. Therefore, open spaces in metropolis areas need to be planned carefully for children near their homes.Then it is way much better to make sure children's places of daily life, such as homes, schools, green spaces, sports venues and so on, can be connected in a safe path. Secondly, for building the safe path for children ,the safety of each spot along the path is analyzed by SP method, which is a mathematical algorithm , in order to find the risk factors and to avoid them in the future. Then we establish the action plan of "line space + point space" to build the children-friendly urban public space system. Line space refers to meeting the basic safety space needs of children through the improvement of the routes to school, including reducing the impact of motor vehicles, safe road facilities, and enhancing road lighting system. "Point space" refers to the promotion of children's outdoor activities through the arrangement of multi-level outdoor children's playgrounds and green spaces, including safe green parks, security platforms and so on. Finally, it is hoped that the "Safety Line Space + Interesting Point Space" plan will establish a safe and inspiring path for children to travel,linking home, school, green space and sports venues,which they use mostly in their daily life. Then we can ensure the safe movement of children and inspire children's spontaneous games in big cities for a children-friendly goal.

Keywords

Child-friendly design, Children's independent mobility(CIM), Safe path space,Stated preference(SP) method

1. Theoretical research

1.1. Child-friendly city

The concept of Child Friendly City (CFC) was put forward at the Second UN Conference on Human Settlement Environment in 1996. The meaning of CFC is: a city governance system that can hear the voice of children and realize their needs, priorities and rights (Shen , 2015). The goal is to reach the four basic rights of children : the right to subsistence, the right to development, the right to protection and the right to participation. In the same year, in order to

make the world aware of the importance of big cities for children's growth and the urgency of response measures, UNESCO launched the "Growing up in the City" (GUIC) plan, and proposed that children can walk safely on the streets alone, meet and play with other children, live in an environment free of pollution and green space, and upgrade the original neighbourhood.

Thus, the Netherlands, Austria and other places carry out a large number of systematic practices, and become a global model. The research on the relationship between children and urban space in China starts around 1990. Some scholars use Beijing, Shanghai and other big cities as objects to find that the playspace in business complex gradually become an important space for city children (Li,1999), or set up safety facilities in high-rise residential areas and point out specific guidance (Shen,2015). Until recent years, Changsha, Shenzhen and other cities have put forward the slogan of creating child-friendly cities.

1.2. Spatial influence factor of children's independent mobility(CIM)

"Children can walk safely on the street alone" is the four construction principles of building a child-friendly city in GUIC plan.Over the past decades, the degree of freedom of children under 18 years of age to engage in public space activities without adult companionship has declined dramatically (Hillman et al., 1990; Kingham & Usher, 2007). It causes that increased use of cars to pick up children; increased obesity among children; reduced use of public spaces such as parks and streets; and increased fear of strangers among children (Malone, 2007). At the same time, Kingston (2007) pointed out that if five-year-olds could not play independently, they would not be able to actively interact with their peers and would be more dependent on their mothers, which to some extent led to the aggravation of obesity, autism, violence and anti-social problems of urban children. Therefore, many scholars are focusing on the influence factor, especially on building environment of public space .

Table 1 Spatial influence factor of CIM according to references

auther	country	sample	Spatial Influencing Factors
Leobach and Gilliland (2014)	Canada	143, girls=94, boys=49	Residential location type,distance from home to school,people density,land use mix,proportion of people,commercial land use,intersection density,road density
Villanueva(2012)	Australia	1132, girls=499, boys=478	Distance from home to school
kytta(2004)	Finland	223, girls=80, boys=147	Recreational facilities
Islam(2014)	Bangladesh	109, girls=42, boys=67	Proportion of residential,commercial land use,intersection density,dead end street,vehicular street width
Broberg and Sarjala(2015)	Finland	202, girls=108, boys=94	Distance from home to school,people density,recreation density,road density,proportion of main roads
Carver(2014)	UK	977, girls=499, boys=478	Land use mix,road density,proportion of main roads

Broberg(2013)	Finland	901	Distance from home to school,residential density
Fyhri and Hjorthol(2009)	Norway	1282, girls=705, boys=577	Distance from home to school
Christian(2015)	Austrilia	181, girls=100, boys=181	Distance from home to school,recreational facilities
lin chang(2009)	Taipei	168	Distance from home to school,intersection density,vehicular street width,residential location type
Monsur（2011）	Bangladesh	60, girls=16, boys=44	Distance from home to school、recreational facilities、dead-end street、vehicular street width

We can see that distance from home to school (8 times in the table), density of recreational facilities (5), density of intersections (4), density of people flow (4), land use (2), width of traffic roads (2), proportion of commercial land (2), proportion of main roads (2), population composition (1), proportion of commercial land (1) all affect children's independence. Significant indicators of travel are established.

1.3. Stated Preference Method

Stated Preference Method is a spatial research method based on user preference, that is, "people's subjective preference for multiple alternatives under hypothetical conditions" (Fang , 2015). The SP method obtains people's spatial environment preferences in complex situations through scenario preference questionnaire, and can anticipate factors that do not exist, so it can be easily transplanted to the planning and design of spatial environment. It is widely used in traffic analysis and environmental assessment abroad (Louviere, 2000). However, domestic research is relatively late. Fang (2015) uses SP method to study the recreational preferences of Shanghai residents'country parks, and puts forward specific research paths of SP method. Zhu(2016) is conducive to SP method to study the evaluation and optimization of urban road bicycle travel environment in Shanghai. The research path of SP method is as follows: firstly, through pre-investigation, obtain spatial elements and levels; through orthogonal design, extract preference options, form questionnaires; data collection, establish discrete selection model and other major steps.

STRP1：Pre-survey: Determining Elements and Levels STEP2：Orthogonal Design to Extract Selection

STEP3：Data Collection and Establishment of Discrete Selection Model

STEP4：Analytical Model, Practical Application

Figure 1 4 steps of SP method

2. Research Design

2.1. Subject: City children (Grade 4-6)

The object of this study is children in urban environment. According to the research of children's developmental psychology, children aged 6-12 use outdoor space most actively. Children aged 10-12 have mature acceptance of concepts and self-reaction ability. The research on children's independent and safe walking path space is mainly aimed at children

aged 10-12.According to the situation of China.,the age corresponds to children are grades 4 to 6 in primary school. Therefore, two primary school students of 4-6 th grade are selected as the main research objects (Fig. 2). The surrounding built environment is rich, close to the city's commercial center, with typical urban road organization, high traffic density, many shops and other city conditions.

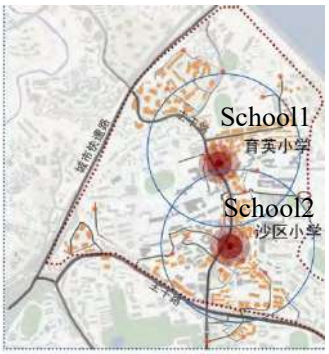

Figure 2 Research area

2.2. Pre-survey design

As for the pre-survey, the questionnaire needs to determine and evaluate the relevant elements and levels of children's safe path space to school. Firstly, the parents and students in the survey area were pre-surveyed by combining 10 significant indicators affecting children's safely individual movement with 15 indicators collected from existing studies. Each respondent selected the most influential factors to them. Finally, 10 factors related to the creating of safe path are identified, and the uncontrollable elements of children's psychological planning are eliminated. Each factor contains 2-4 levels. The definition and level of these elements are shown in Table 2. Level 1 is the most safe category for parents and students, while the effect of other levels decreases at one time. These elements are divided into three categories: path space elements, path traffic elements and path social elements. Spatial factors include distance from home to school, recreation place, danger place, proportion of commercial land use; path traffic factors include vehicle flow, number of crossing the street, cross street help ; path social factors include density of people,people composition,density of Help-seeking facilities.

Table2 Influence factors and levels by pre-survey

kinds	Influence factors	level1	level2	level3	level4
path space elements	distance(m)	<500	500-1000	>1000	
	Recreation place	none	Community Garden	park	shop
	Danger place	none	Underground passage	Construction site	
	Proportion of commercial land use	high	middle	low	
path traffic elements	Vehicle flow(number of car/an hour)	<1000	1000-2000	>2000	
	number of crossing the street	0	1-2times	3-5times	>5times
	Cross street help	Street Guider	Traffic lights	Zebra crossing	none
path social	Density of people （number of	>60	2-60	<2	

element s	people/minute)				
	People composition	Familiar people	Unfamiliar people		
	Density of Help-seeking Facilities	high	middle	low	

2.3. Data collection

Based on SP method, the questionnaires let the children and their parents choose the best one among the two virtual children's paths, and use SPSS to orthogonalize them, resulting in 128 paths with representative, homogeneous and independent elements, 64 selection scenarios, which were randomly distributed to the subjects in five sets of questionnaires. The axonometric mapping of children's school path elements is placed on both sides of the text description comparison table, and the related influencing factors on the path are visually represented by the graphic (Figure 4), so that the respondents can make quick choices without looking at the table. The online questionnaire is combined with the field survey. 158 valid questionnaires for parents were collected.

Choise10. Which path do you think is more safer?		
Path 1	Influence factors	Path 2
500-1000	distance(m)	500-1000
none	Recreation place	shop
Underground passage	Danger place	Construction site
<1000	Proportion of commercial land use	>2000
1-2 times	Vehicle flow(number of car/an hour)	0
Traffic lights	number of crossing the street	Traffic lights
Street Guider	Cross street help	none
2-60	Density of people (number of people/minute)	>60
Familiar people	People composition	Familiar people
high	Density of Help-seeking Facilities	high

Figure 3 question example in the questionnaire

3. Spatial Preference Model of Children's Safety Routes

3.1. Model Construction

The SP method obtains the relative importance of each factor through parents and children 'view on children's safe path selection, which is in line with the theoretical basis of discrete choice model - stochastic utility theory. According to this theory, the effect of safe environment on parents is the judgment basis when individuals make choices, that is, when respondents answer questionnaires, they will choose the most effective safe environment for them to go to and from school. The expression of the discrete selection model used in this paper is as follows:

$$V_i=\alpha_1 dis+\alpha 2 rp1i+\alpha_3 rp2i+\alpha_4 rp3i+\alpha_5 dp1i+\alpha_6 dp2i+\alpha_7 pl1i+\alpha_8 pl2i+\alpha_9 vf+\alpha_{10} nc1i+\alpha_{11} nc2i+\alpha_{12} nc3i+\alpha_{13} cs1i+\alpha_{14} cs2i+\alpha_{15} cs3i+\alpha_{16} dop+\alpha_{17} pc1i+\alpha_{18} dohcf1i+\alpha_{19} dohcf2i$$

In the formula, I is the choice of the path, I is the plan of choosing different children's paths to and from school. Vi is the visible utility of choosing a certain path. α 1-19 is the element to be fitted by the model. The other variables are the important impact indicators listed in Table 2.

3.2. Model Results

Using Nlogit5 software to fit the model, the results are as follows: Table 3, which shows the mean value of variable parameters, and also the parameters used in subsequent evaluation applications. The overall goodness of fit of the model is Rho Square = 0.3598, which is a good result in similar studies. Except for the medium density of help-seeking facilities (significance 0.84) and the construction site (significance 0.798) in the hidden danger space elements, the parameters of all variables have reached a high statistical significance, and accord with the common sense. According to this analysis, most of the construction sites in the city have obvious protection and isolation measures, and urban children have a strong sense of prevention, so the effectiveness of this experiment is not significant. At the same time, parents think that medium-density rescue facilities such as alarm booths and patrol posts are not enough for children's safety. They should increase the layout density, so the indicators are not significant.

Note: Some variables have no specific measurement index, so they are in the form of virtual variables. In each variable, the lowest level of utility is set at 0, compared with other levels.

The model constructed in this paper is the utility model of children's safe routes to school. The idea is to find out some factors affecting children's safety and to avoid them. The optimal level of the elements is set to 0, and the reference values are mostly negative, which shows that the selected elements have a negative impact on the safety of the path (Fig. 5).

From the results, we can see that among the three factors, the path space factor, the path traffic factor and the path social factor have a significant impact on children's school safety. Among them, the path space factor and the path traffic factor are the main factors affecting parents'judgment.

In terms of road space elements,recreation place in urban path elements become the most worrying factor for parents,especially the community garden and park. Through interviews and analysis, it is known that children in cities have less space for outdoor activities, and the special outdoor space for children is also scarce. While playing in general space, children are more likely to encounter collisions, falls, scratches and other injuries when playing. At the same time, Parents are more worried that the lower proportion of commercial space will be dangerous to children because of the vitality of streets and the reduction of crowds. Finally, we found that the farther away from school, the lower the utility, but the impact is not significant. Because in the current urban environment, high-quality teaching resources are not fully distributed equally, parents let students enter a far schoo for better educational resources, andparents do not think that distance factors will bring more harm.

In terms of road traffic elements, motor vehicle traffic is not as worrying to parents as it is in the traditional sense. Parents are worried about whether their children can get help in the process of crossing the road and the number of times they cross the road. Because in the urban environment, the impact of motor vehicles is inevitable, the number is not terrible..But the number of roads has a significant impact, and the more the number of times, the greater the degree of concern of parents. Meanwhile zebra crossing is not safe in the eyes of parents. Only street lights and street guide without assistant crossing can improve the safety of the path.

In terms of path social factors, the density of human flow has a positive impact on safety utility, and the greater the density of human flow, the higher the safety utility. However, the composition of the population has no significant impact on the utility. It may be that in the urban mobility environment, it is difficult for parents and children to find a large number of familiar people. Meanwhile, the medium and low density of help-seeking facilities have a negative impact on the safety utility. Parents believe that only high density security posts, patrol mobile platforms and so on can guarantee children's safety.

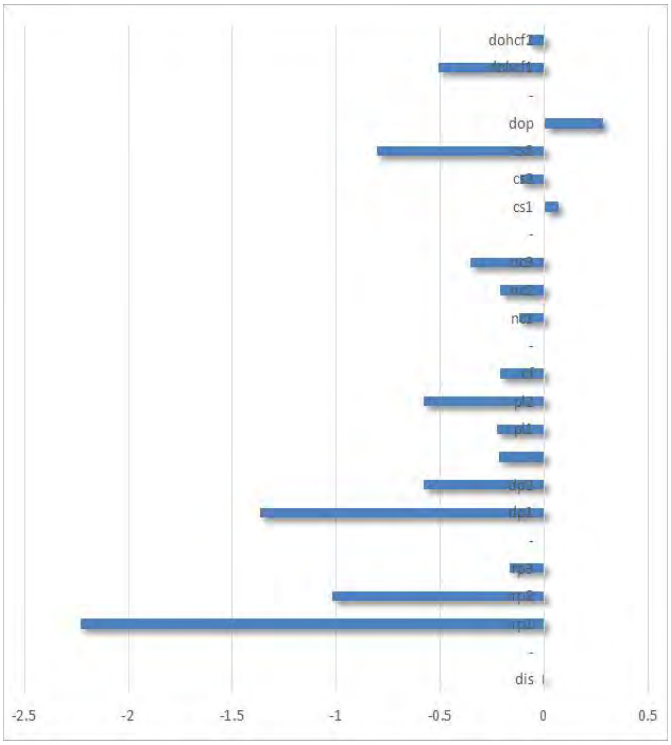

Figure 4 Model results

4. Conclusion

Based on the above model, we can find the preference for the spatial factors of children's safe path of public space in high-density urban environment. It is found that the factors of path space, path traffic and path society have significant effects on children's safety. Among them, the path space factor and the path traffic factor are the most important factors.And recreation place、 dangerous place、 crossing the street without any help are the top3 influential factors.Therefore, we can modify and adjust the most effective indicators one by one.

Firstly, for path space element.Recreation place on the way are the first objects to be adjusted, which have the greatest impact on children's safety , especially the open public space most commonly used by children such as community parks and street corner parks.. At the same time, Attention need to be paid on dangerous space such as underground passage. They also need to maintain a certain proportion of commercial space of children's way to and from school, so as to form vitality and gather people, so as to provide more weight for children. Social public protection.

Secondly, for path traffic element.We need to improve the traffic assistance for children when crossing the street. The high traffic volume in the city can not be changed. What parents really worry about is whether the children have assistant facilities such as street guide, traffic lights, zebra crossing and so on in the process of crossing the street. In the case of crossing the street, the safety effectiveness shows positive value. At the same time, the relevant signs such as student's path guide board can also play a positive role. Effect.

Thidly,for path social element. We can increase the density of students'help-seeking facilities and increase patrol posts and mobile security platforms during the period of students' going to and from school. At the same time, urban space should pay attention to the attraction of the density of human flow and create a good public space atmosphere, which will also bring positive effects on children's safety.

Finally we establish the action plan of "line space + point space" to build the children-friendly urban public space system. Line space refers to meeting the basic safety space needs of children through the improvement of the routes to school, including reducing the impact of motor vehicles, helping children to across the street, setting crossing points near schools during school hours,increasing the density of students'help-seeking facilities. "Point space"

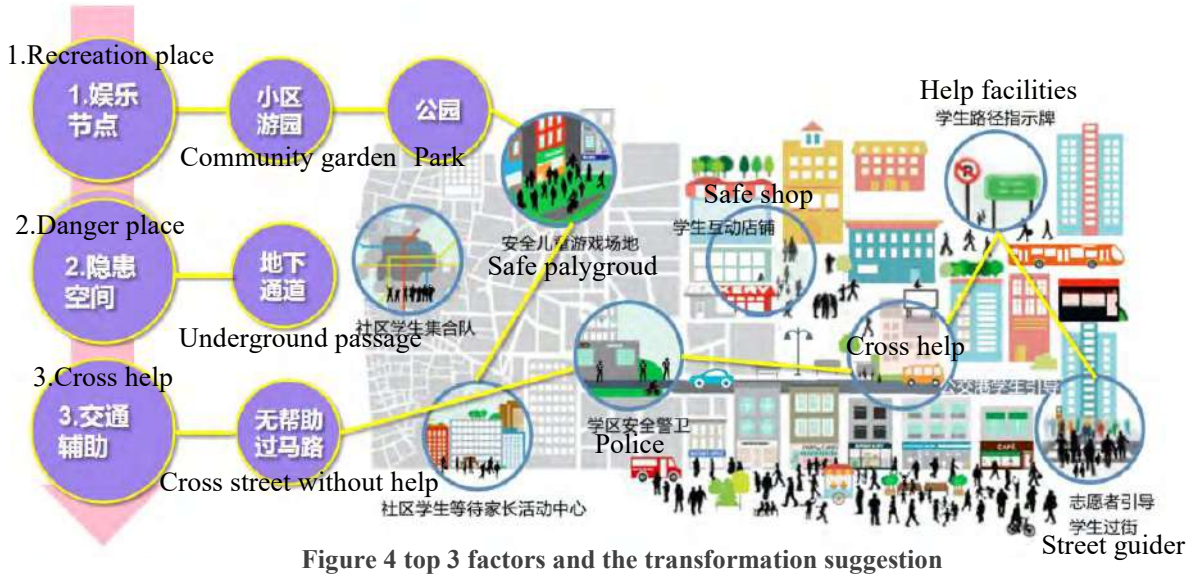

Figure 4 top 3 factors and the transformation suggestion

refers to the promotion of children's outdoor activities through the arrangement of multi-level outdoor children's playgrounds and green spaces, including safe green parks, security platforms and so on. Hope this through this study, we can provide a reference evaluation index for children's safe travel space environment in high density urban environment, and also provide the steps and key points for regional transformation.

Neighborhood Environment and the Elderly's Subject Well-being

Xuhui LIU, Phd candidate, Department of urban planning, Tongji University; China

Yifan YU, Professor, Department of urban planning, Tongji University; China

Xin SUI, Department of urban planning, Tongji University; China

Abstract

Background:

In the context of an aging society, the physical and mental health and quality of life of the elderly have received more and more attention. Among them, in the field of mental health of the elderly, subject well-being is an important concern.

Many studies have shown that the environment has a certain impact on people's mental health. In the field of landscape, public health and architecture, most of the studies focus on the natural environment, including the number and proportion of green space, the distance to green space, the characteristics of green space, as well as the building density, building form, road network density and layout in the built environment. However, in China, the specific environment elements that are more comprehensive and more closely linked with urban planning and management need to be studied.

Objectives:

Relevant research shows that more than 80% of the activities of the elderly are completed within 1 km of the neighborhood. This study takes neighborhood environment as the main research area and research object. The objectives include: 1, to find the status of the elderly's subject well-being in Shanghai; 2, to find the impact of the neighborhood environmental factors on the subject well-being of the elderly; and therefore, 3, to put forward some suggestions for neighborhood planning to promote the subject well-being of the elderly.

Methods:

Based on the data of the Fourth Survey on the Living Conditions of the Elderly in Urban and Rural Areas of China, 3431 urban residential samples in Shanghai were selected and analyzed in this study. The subject well-being comes from the question, "General speaking, do you feel happy?" Options include five levels, ranging from very happy to very unhappy. According to the existing literature and the specific requirements of Shanghai urban planning compilation and management, the environmental factors are summarized as 20 indicators in four aspects: natural environment, housing conditions, urban form and facility environment. According to the sample address, the environmental factors indicators are calculated in GIS. The data are analyzed by the method of path analysis in Mplus7.4.

Results:

70.9% of the respondents felt very happy or happy, while only 2.2% of the respondents said they were unhappy or very unhappy. Non-agricultural household registration, higher education, better self-rated economic status of the elderly, the better of the subject well-being of the elderly. Under the control of the basic characteristics and socio-economic attributes of the elderly, the per capita green space area, housing construction area, road network density and location conditions have a significant impact on the well-being of the elderly.

Conclusion:

Under the control of socio-economic variables, community environment can significantly affect the subjective well-being of the elderly. In the planning of community life circle, improving the level of green space per capita in the community, improving the housing conditions of the elderly, and building a high-density road network system are effective measures to promote the subject well-being of the elderly.

Key words:

The elderly, Subject well-being, Neighborhood environment.

1. Background

1.1. Ageing is a major challenge for the current society

In the world, the population is growing rapidly and the trend of aging is spreading rapidly. According to the World Population Outlook issued by the United Nations in 2017, the total population of the world is about 7.6 billion by 2017, of which 910 million people are over 60 years old. With the low fertility, the global aging problem is becoming more and more serious. The report issued by the World Health Organization points out that the impact of population ageing is usually more important than population growth (WHO, 2008). Compared with developed countries, the social and economic development speed of developing countries often fails to catch up with the development speed of population aging (WHO, 2003). Aging has become an important issue facing all countries in the world.

China has entered the stage of rapid aging development. By the end of 2016, the total population of China was 1.374 billion, of which 16.1% were over 60 years old and 10.5% were over 65 years old (National Statistical Bureau of the People's Republic of China, 2015). Shanghai has entered an aging society since 1979. According to statistics, as of 2017, the registered population of Shanghai is 483.6 million people aged 60 and above, accounting for 33.2% of the total population, and 317.67 million people aged 65 and above, accounting for 21.8% of the total population (Shanghai Aging Science Research Center, 2018). The state and local governments have promulgated relevant policies for the cause of ageing, which provide guidance for the development of the cause of ageing. Paying attention to the elderly, promoting healthy aging and active aging are important issues in urban development.

1.2. Better well-being of old age is an important goal of the cause of aging

According to WHO's definition of health, psychological well-being is an important part of the health of the elderly. Under the guidance of healthy aging and active aging, the mental health of

the elderly is an important goal of our work.

Since Wanner Wilson wrote The Relevant factors of self-reported well-being in 1967, psychological research on well-being has gone through more than 40 years. Well-being is the central issue of philosophy, ethics, economics and sociology. Well-being index is the focus of the government. If GDP (gross domestic product) and GNP (gross national product) are the criteria to measure the wealth of the country and the people, then the Gross National Happiness Index (GNH) is the criterion to measure the happiness of the people, and the wealth of the country is for the happiness of the people and for "creating our happy life" (the conclusion of the report of the 16th National Congress of China, 2002). CCTV put forward slogans such as "Starting towards Happiness" as the expression of "Happiness Fever" at the media level.

2. Literature review

2.1. Subject well-being

The explanation of well-being in the 1997 edition of Wechsler's English Dictionary is: a good or satisfactory living condition; a state of health, happiness and prosperity.

The study of happiness can be traced back to ancient Greek philosophy. Traditionally, the concept and theory of happiness can be classified into two basic types: hedonic and eudemonia. The hedonic view of "happiness theory" originated from Aristippus's philosophy. The Eudaimonic view of happiness comes from the perspective of Aristotelian school. Aristotle puts forward the view that happiness is the self-realization of human beings, therefore, his theory of happiness is also called perfectionism (Zhang Lu, Zuo Bin, 2007).

Based on different philosophical traditions, there are two orientations in the study of modern well-being: Subjective well-being (SWB) and Psychological well-being (PWB). Subjective well-being develops from the theory of happiness. It pays attention to emotions and life satisfaction. It believes that human happiness is expressed by human emotions. Happiness means satisfaction with life, with more positive emotions and fewer negative emotions (Diener E, Eunkook S, Richard L. et al., 1999); and psychological well-being is expressed by reality. The present theory evolves to focus on personal growth, self-acceptance, autonomy, life goals and so on (Zhang Lu, Zuo Bin, 2007).

Diener, an American scholar, put forward in 1984 that subjective well-being refers to the overall assessment of the quality of life of an evaluator according to his own criteria. His research on subjective well-being has a great impact on Chinese scholars (Li Zhi, Xie Chaohui, 2006). Diener (1984) believes that the basic characteristics of subjective well-being are subjectivity, relative stability and integrity.

The well-being of the elderly is not only an important criterion for judging the quality of life of the elderly, but also one of the necessary conditions affecting their physical and mental health. (He Quan, Zhang Shi, Wang Ping, 2015).

A large number of studies have shown that subjective well-being is an important comprehensive psychological index to measure the mental health level and personal quality of life of the elderly (Zhang Wei, Hu Zhongming, Li Hongjuan, 2014).

2.2. Influencing factors of subject well-being

Initial research on objective influencing factors was mainly carried out along the dimensions of demographic projects. Wilson pointed out in his Relevant Factors of Self-proclaimed Happiness that happy people are young, healthy, well-educated, well-paid, religious, married, and intelligent and so on. These projects are considered to be the determinants of happiness. With the deepening of research, many studies have pointed out that objective factors have little explanatory power on well-being. Demographic items (such as gender, income, intelligence level, etc.) can only explain less than 20% of the changes in well-being, while external environment can only explain 15% of the changes in well-being (Jin Huihong, Chen Yu, 2012).

It has been found that age is an important factor affecting people's well-being. Many studies have confirmed that happiness decreases with age (Baird, Lucas, & Donnellan, 2010; Godoy-Izquierdo et al., 2013; Mroczek & Spiro, 2005). However, some studies have found that the relationship between happiness and age is a U-shaped curve (Lobos et al., 2016). At the same time, from the perspective of gender, there is no significant difference in the overall SWB between men and women. However, gender differences still exist in different dimensions of SWB (Wang Fang, Chen Fuguo, 2006).

A literature review found that happiness is not associated with age, but that it is important to have good social relations as well as be self-confident and extroverted (Ferraz, et al., 2007). Although happiness is a subjective experience, it is related to psychological and socio-cultural traits (Ferraz, et al., 2007), social support, and social engagement in activities outside the family (Seligman, 2003). Social capital and social participation are also important factors (Cooper et al., 2011). Good interpersonal relationships can lead to an increase in positive emotions, and individuals can achieve high happiness (Wang Fang, Chen Fuguo, 2005). Social support and social participation in extra familial activities (Seligman, 2003). Health is also a influencing factor of subject well-being. Nan, et al. (2014) found that the relationship between happiness and mental health was greater than that between physical health. A study found that illness does not directly lead to a decline in happiness, but what matters is the degree to which illness interferes with everyday functions (Angner et al., 2013).

2.3. The Impact of Environment on Mental Health and Subject Well-being

Environment refers to the total of natural and artificially modified natural factors affecting human survival and development, including atmosphere, water, ocean, land, mineral deposits, forests, grasslands, wildlife, natural relics, human relics, nature reserves, scenic spots, cities and villages (the Environmental Protection Act of the People's Republic of China, 2015). Natural Environment (NE) is the sum of all kinds of natural factors surrounding people and the material basis for human survival. Built environment refers to all kinds of buildings and places that can be reconstructed by man-made construction, especially those that can be changed by policy and human behavior, including the location and design of residential, commercial, office, school and other buildings, as well as the location and design of pedestrian, bicycle, greenway and road (Handy S L, et al., 2002). Built environment is a combination of a series of elements related to land use, transportation system and urban design. As one of the important factors to promote public physical activity and health, built environment is an important entry point for urban planning to actively intervene in health (Lu Feidong, Tan Shaohua, 2015).

Neighborhood is the main place where people live and the basic unit of a city. Neighborhood

include hardware elements such as space environment, facility configuration, and software elements such as social humanities. As the basic unit and space carrier of people's living and social interaction, neighborhood is closely related to people's health and well-being (Croucher et al., 2007; Hu Yuting, 2017).

More and more studies have confirmed that the built environment has a significant correlation with people's mental health. Although there are various methods and different conclusions in these studies under different backgrounds, it has become a fact that the environment has an impact on human behavior and other factors, or in a way of direct exposure, affects human mental health.

In conclusion, the environmental factors affecting mental health mainly include the following aspects: green space, housing, density, road network, etc.

2.3.1. Green space

A number of research cases showed that the increase in the number of green spaces is conducive to improving people's mental health level and promoting people's health perception. Canadian research shows that increasing tree planting in a city block can improve people's health awareness in a way that is equivalent to an increase in personal income (Omid Kardan et al., 2015). The total number and area of public green space are significantly correlated with better mental health and support dose-response relationship. Providing adequate public green space within local neighborhoods and walking distance is important for positive mental health (Wood, L., 2017).

The proportion of green space is the proportion of the area of green space/green space in a certain range, and green coverage is also used to characterize it. The percentages of green space within 3 km radius interact significantly with the number of health complaints and perception of general health caused by stressful life events (Agnes E. van den Berg et al., 2010); the areas occupying more than 8% of the park area are positively correlated with SRH (Parra, D.C., etc., 2010); and those living in neighborhoods with higher percentages of green space are positively correlated with self-reported health (Parra, D.C., 2010). People reported a lower risk of sleep deprivation (Thomas Astell-Burt et al., 2013); people living in urban areas with more green spaces (a high proportion of green spaces) were happier, showing significantly lower mental pain and higher happiness (Mathew P. White, Ian Alcock et al., 2013). Characterized by the percentage of green space in the 1km buffer zone, the residents in the greenest area had lower risk of psychological distress and less sedentary time than those in the least green area. Interaction between sports activities and green space was observed (Thomas Astell-Burt et al., 2013). Vegetation coverage is positively correlated with the lower prevalence of depression, anxiety and stress. There is a quantifiable relationship between mental health and the natural characteristics of the neighbourhood that people actually experience (Daniel T. C. Cox et al., 2017).

2.3.2. Density and Road Network

The density of built environment includes population density and construction density (such as volume ratio, housing density, etc.).

The construction density of the built area within 300 meters of the residential area has a significant correlation with mental health. In the study of Sarah Foster et al. (2010), residential

density is the ratio of residential area to the number of residential buildings in the service area, and it is one of the constituent indicators of community morphological index. The community morphological index was significantly correlated with the decrease of crime fear.

Street network accessibility is characterized by street sports potential (overtaking volume of street sections) and street connectivity (the number of sections connected to a certain section, i.e. the density of street intersections). Research shows that the reduction of psychological distress is associated with higher accessibility of local street networks ("mobile potential") (Chinmoy Sarkar et al., 2013). Using street connectivity in a 0.5-mile buffer zone as a measure of design, poor street connectivity has a negative impact on life satisfaction [Xinyu (Jason) Cao, 2016].

The number of intersections is also an important indicator of street network. Street connectivity is calculated by the ratio of three-way intersection to total service area. The comprehensive community morphology index is significantly related to the reduction of crime fear. A more walkable community is also a place where residents feel safe (Sarah Foster, 2010). The number of total intersections within the radius of 300 meters around the residential area was significantly correlated with the happiness dimension (Elizabeth J Burton et al., 2011).

2.3.3. Service facilities

Australian studies found that, independently of other factors, the higher the degree of land use mixing, the higher the risk of depression (Dick Saarloos, 2011). Retail service availability was associated with a 40% increase in the risk of depression, regardless of other factors, including other land use. Although local retail stores help walking, this may increase the risk of depression in older men (Dick Saarloos, 2011). The use of cultural facilities is positively correlated with the physical and mental health and subjective well-being of the elderly (Liu, Y., et al., 2017).

2.3.4. Location

Residential location is characterized by seven categories: major town centers, major town districts, major town margins, large town centers, large town margins, small towns and villages. Research shows that residential location in urban and rural areas is one of the measures of the constructive environment with the greatest number of significant correlations with health (Elizabeth J Burton, et al., 2011). Mental health is determined by neighbourhood level. Residents living in neighborhoods farther away from the city center tend to have better mental health (Hongwei Dong, Bo Qin, 2017).

Therefore, we can see that environmental factors can be divided into two categories. One is the environmental factors of physical space itself, such as location, green space level and density, road network and other characteristics. On the other hand, it is the environmental factors of service facilities, which represent the public service level of the environment, and service facilities are often based on the physical space environment.

Mathew P. White, et al. (2017) pointed out that although people are increasingly interested in the relationship between natural environment and subjective well-being (SWB), previous studies have various limitations in methodology and theory. Under the background of Shanghai's high-density human settlements and Oriental culture-oriented environment, it is worth discussing the relationship between built environment and mental health, especially with people's subject well-being which has been paid more and more attention. The environmental

construction towards good subject well-being will be a necessary Supplement for the research in the above-mentioned fields.

3. Objectives

Based on the survey data and combined with the existing characteristics of Shanghai's urban planning compilation and management, this paper mainly answers the following questions:
1. The general well-being and distribution characteristics of the elderly in Shanghai at present;
2. Under the control of other variables, does the built-up environment of community affect the well-being of the elderly? What is the impact?
3. What aspects should we pay attention to in the construction of a well-being-oriented community environment?

4. Methods

4.1. Data sources

Based on the data of the fourth survey on the living conditions of the elderly in urban and rural areas of China (the fourth survey), 3431 urban residential samples in Shanghai were analyzed. The data are sorted in spss22 and analyzed in Mplus7.4 by the method of path analysis.

4.1.1. Neighborhood Environment

According to the existing literature and the specific requirements of Shanghai urban planning compilation and management, the environmental factors are summarized as 11 indicators in five aspects: green space, housing conditions, urban form (including building area volume ratio and road network density) facility environment, and location. According to the sample address, the environmental factors indicators are calculated using the GIS platform.

4.1.2. Subject well-being

Subject well-being comes from the question in the fourth survey, "In general, do you feel happy?" Options include five levels, ranging from very happy to five very unhappy.

4.1.3. Control variables

(1) Gender
This index data comes from the "the fourth survey" questionnaire. In the "A - basic information" part of the questionnaire, there are questions about “A1- the gender of the elderly interviewed ", "1" is male and "0" is female.
(2) Age
This index data comes from the "the fourth survey" questionnaire. In the "A - basic information" part of the questionnaire, there is a question “A2 -the age of the interviewed old people". The age of the elderly is divided into six age groups: 1: 60-64 years old, 2: 65-69 years old, 3: 70-74 years old, 4: 75-79 years old, 5: 80-84 years old and above.

(3) Household Registration

This index data comes from the "the fourth survey" questionnaire. In the "A - Basic Information" section of the questionnaire, there is a question " A3 -What type of household registration do you belong to?" There are three options: "1 agriculture, 2 non-agriculture and 3 unified household registration".

(4) Education

This index data comes from the "the fourth survey" questionnaire. In the "A - basic information" part of the questionnaire, there are six options: "A5 -your educational level", including "1 have not attended school (including literacy classes), 2 primary schools (including private schools), 3 junior middle schools, 4 senior high schools/secondary vocational schools, 5 colleges, 6 undergraduates and above". The higher the value, the higher the educational level of the elderly.

(5) Marital status

This index data comes from the "the fourth survey" questionnaire. In the "A - basic information" section of the questionnaire, there are questions "A8- your current marital status", "1 have a spouse, 2 widow 3 Divorce, 4 never married." The data are arranged as nominal variables, 1 as having a spouse and 0 as having no spouse now.

(6) Economic situation

This index data comes from the "the fourth survey" questionnaire. In the "E- Economic Situation" section of the questionnaire, there is a question, "Which of the following do you think your economic situation belongs to?" There are five choices: "1 very abundant, 2 relatively abundant, 3 basically enough, 4 more difficult, 5 very difficult", The lower the value, the better the self-assessment economic status of the elderly.

4.2. 3.4. Analytical methods

(1) GIS (Geographic Information System)

The GIS platform is helpful to calculate the spatial relationship of data and to express it intuitively. It is the basic work platform of this study.

(2) SPSS 22

Data are collated and basic descriptive analysis is carried out.

(3) Mplus 7.4

Path analysis is carried out.

5. Results

5.1. Descriptive analysis

Table 1 Happiness of the elderly interviewed

		count	percentage（%）	Effective percentage（%）	Cumulative percentage（%）
effective	Very happy	712	20.8	20.8	20.8
	Comparatively happy	1719	50.1	50.1	70.9

	Generally happy	921	26.8	26.9	97.8
	Comparatively unhappy	60	1.7	1.7	99.5
	Very unhappy	17	.5	.5	100.0
	total	3429	99.9	100.0	
missing		2	.1		
total		3431	100.0		

The proportion of the elderly who choose "relatively happy", "general" and "very happy" is the highest. More than half of the elderly feel "relatively happy", and only 2.2% feel "relatively unhappy" and "very unhappy".

5.1.1. Population differences

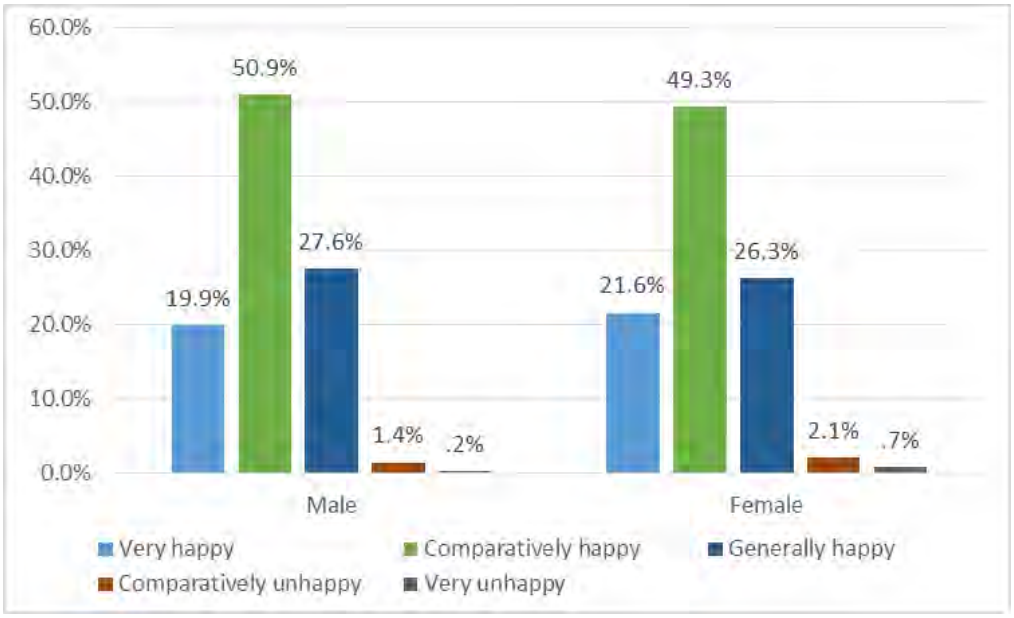

Figure 1 Differences in happiness among the elderly interviewed by different genders

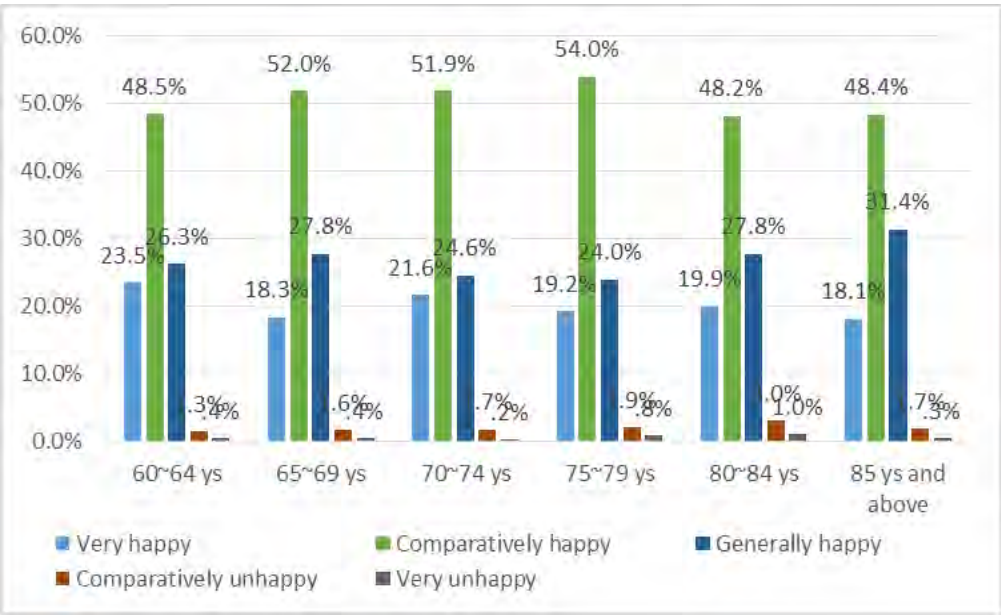

Figure 2 Differences in happiness among the elderly interviewed at different ages

There is no significant difference in happiness between men and women. There was no significant difference in happiness among the elderly of all ages.

5.1.2. Regional differences

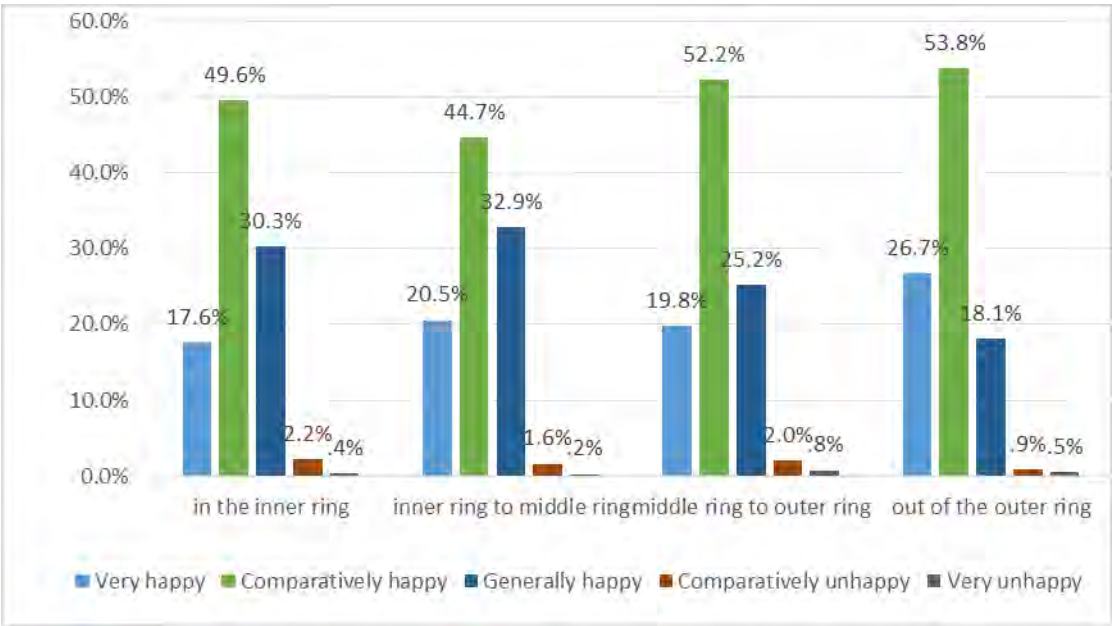

Figure 3 Regional differences in happiness among the elderly interviewed

There were significant differences in happiness among the elderly in different regions (Sig < 0.001). The proportion of "very happy" and "relatively happy" old people outside the central city is higher than that in the central city; the proportion of "general" and "relatively unhappy" old people is lower than that in the central city; the proportion of "very unhappy" old people is 0.2%-0.8%, and there is no significant difference in different regions.

5.2. The impact of community environmental factors on the well-being of the elderly

5.2.1. Impact of green space, housing and urban form

Table 2 Model 1

The Influencing Elements of Happiness	Estimate	S.E.	Est./S.E.	P-Value
Gender	-0.025	0.016	-1.535	0.125
Age	0.023	0.018	1.302	0.193
Household register	**-0.091**	**0.017**	**-5.331**	***
Marital status	-0.03	0.018	-1.683	0.092
Education	**0.148**	**0.018**	**8.25**	***
Self-reported economic status	**-0.314**	**0.018**	**-17.811**	***
Proportion of green space area	0.01	0.018	0.562	0.574
Per capita green space area	**0.055**	**0.017**	**3.248**	**0.001****
Housing area	**0.099**	**0.018**	**5.454**	***
Housing type	0.03	0.016	1.894	0.058
Volume ratio	0.013	0.017	0.753	0.451
Road network density	0.018	0.02	0.906	0.365
Location(Distance to downtown)	**0.076**	**0.024**	**3.181**	**0.001****

Among personal characteristics, household registration, educational level and self-assessment of economic status have significant effects on the well-being of the elderly. Non-agricultural household registration, older people with higher education level, and older people with better self-assessment of economic status, have higher happiness.

From the point of view of material space environment factors, the per capita green space area, housing construction area and distance to the city center have a significant impact on the well-being of the elderly. The more green space per capita and housing construction area per capita, the higher the happiness of the elderly. From the location of the elderly, the farther away from the city center, the happier the elderly are.

5.2.2. Impact of public facilities

Table 3 Model 2

The Influencing Elements of Happiness	Estimate	S.E.	Est./S.E.	P-Value
Gender	-0.024	0.017	-1.472	0.141
Age	0.028	0.018	1.613	0.107
Household register	**-0.089**	**0.017**	**-5.237**	***
Marital status	-0.028	0.018	-1.539	0.124
Education	**0.148**	**0.018**	**8.238**	***
Self-reported economic status	**-0.311**	**0.018**	**-17.672**	***
Proportion of green space area	0.014	0.018	0.776	0.438

Per capita green space area	0.034	0.018	1.86	0.063
Housing area	**0.104**	**0.019**	**5.586**	***
Housing type	0.027	0.016	1.619	0.106
Volume ratio	0.011	0.017	0.625	0.532
Road network density	**0.058**	**0.027**	**2.131**	**0.033***
Location(Distance to downtown)	**0.088**	**0.025**	**3.529**	***
Number of public service facilities	-0.025	0.029	-0.865	0.387
Medical distance	0.003	0.017	0.152	0.879
Number of transport facilities	-0.043	0.026	-1.655	0.098
Distance of traffic facilities	0.018	0.018	1.049	0.294

After adding the facility environment variables, we found that besides the significant impact of personal characteristics in model 1 on the well-being of the elderly, the per capita green space area, housing construction area and distance to the city center are still the significant factors affecting the well-being, but the per capita green space area is no longer significant, and the density of road network has also become a significant environmental factors. As far as the environmental factors of facilities are concerned, there is no significant correlation between the number of public service facilities, medical distance, the number of transportation facilities and the distance to transportation facilities and the well-being of the elderly.

6. Discussion

6.1. Personal characteristics and the subject well-being of the elderly

Previous studies have consistently confirmed that individual socioeconomic attributes have a significant impact on mental health (Claire Dujardin et al., 2014; Becky P. Y., Loo et al., 2017; Hongwei Dong, Bo Qin, 2017), and that in the process of environmental impact on mental health, there are differences among different populations in the process of environmental impact.

The household registration system has an important impact on the distribution of people's resources and living opportunities, and has become the most important parameter to depict the inequality of China's social structure (Zheng Bingdao, Wu Xiaogang, 2013). Studies have confirmed that household registration has an important impact on people's political, economic and professional status (Lu Yilong, 2008). Using the survey data from 2010 to 2013, Li Wenjie and Luo Yuhui (2016) found that the social stratum structure of the agricultural household registration population has obvious physical labor characteristics. Agricultural household registration holders are far less likely to enter the management class or even the non-manual labor class than Non-peasant household registration holders. Due to the difference of social resources obtained by household registration, the physical health and mental health of the elderly with different household registration will be affected. In this study, household registration has a significant impact on the subject well-being of the elderly. The elderly with agricultural household registration have a worse sense of happiness than those with non-agricultural household registration.

Similarly, the educational level has a certain impact on the occupational and economic status of the elderly and the corresponding social resources. Studies have also confirmed that education has an important impact on health (Hu Guangyu, Duojun, 2010). In this study, educational level has a significant positive impact on the well-being of the elderly. The higher the educational level, the better the subject well-being of the elderly.

Previous studies have found that income level, education level, social stratum and social network all have an impact on the health of the elderly at a significant level of 1% (Liu Changping, Wang Lianjie, 2017). Economic status has a significant impact on the mental health of the elderly (Yang Benfu et al., 1999; Ning Ziheng et al., 2001; Tangdan, 2010; Hu Guangyu, et al., 2010; Zhang Xia, Yang Yifan, 2017). Like previous studies, economic status has a significant positive impact on the well-being of the elderly. The better the economic situation is, the happier the elderly will be. Economic status is one of the most important factors affecting the health and well-being of the elderly.

6.2. Green space and the subject well-being of the elderly

Green space is an important environmental factor in existing research. The quantity of green space is a very important and common environmental measure index. However, in the existing studies, few studies have linked the number of green space with the number of population, considering the per capita green space occupancy level under different population densities. From this perspective, green space is measured and the impact of the environment on human health is analyzed.

In the process of analysis, in terms of the number of green space, considering only the green space density represented by the proportion of green space area, there is no significant correlation between the number of green space represented by the proportion of green space area in community life circle and the physical health and mental health of the elderly.

Further in-depth analysis of the current situation of green space distribution in Shanghai shows that the proportion of green space in the studied neighborhoods has a slight downward trend from the city center to the periphery. Although the spatial distribution of green space is relatively balanced in the city center and the periphery, considering the distribution of population, from the perspective of per capita index, the distribution of green space in the city obviously still has great differences. According to the population density of each research neighborhood and the calculation of the per capita green space area, the research community from the city center to the periphery shows a significant trend of gradual increase, that is, from the city center to the periphery, the per capita green space area enjoyed by the per capita is increasing. From the per capita index, the per capita green space level in the suburbs is significantly higher than that in the central city. From the perspective of the whole city, the per capita green space level of each community is more than 100 times different, and only from the per capita green space level of each community in the central city, the per capita green space value is 10 times different.

In this study, the proportion of green space has no significant impact on the health of the elderly. While combined with the analysis of per capita green space index, we find that per capita green space area is significantly related to the subject well-being of the elderly. Compared with the spatial distribution, per capita green space area is a more effective indicator to promote the mental health of the elderly.

Therefore, for green space, it is not enough to consider the balance of spatial distribution. More

importantly, it is to match the population distribution in order to better integrate with the actual needs of people. Only by combining with human needs and serving as the basis of spatial layout, can we better and more effectively play its internal functions and achieve the original purpose and goal of planning.

6.3. Housing Conditions and the subject well-being of the elderly

Existing studies have shown that good quality of housing and neighborhood environment and safe social environment are the main reasons for the improvement of subjective and physical health of the elderly (Liu, Y., 2017). Living in Low-Rise housing, better living conditions and healthy physical and social environment have a significant impact on positive mental health (Ghuncha Firdaus, 2017).

Path analysis shows that housing area has a significant positive impact on the subject well-being of the elderly when controlling the basic socio-economic attributes of the elderly and considering the impact of all built-up environmental factors such as community location. Housing construction area reflects the quality of housing conditions for the elderly. Meanwhile, the larger building area is related to the larger number of people living together (Sig. = 0.010), which is conducive to reducing the loneliness of the elderly and improving their mental health.

Relevant analysis shows that there is no significant correlation between the housing conditions of the elderly and their self-reported economic status. Therefore, it can be said that housing conditions are independent of economic status and have a significant positive impact on the subject well-being of the elderly themselves.

6.4. Road network density and the subject well-being of the elderly

Studies have confirmed that high road network density has a positive impact on mental health [Chinmoy Sarkar et al., 2013; Xinyu (Jason) Cao, 2016]. High-density road network design is often associated with more diverse functional layouts and promotes walking opportunities for the elderly to their destinations, thereby enhancing their social participation and physical activity. Considering the facility environment data at the same time, the analysis of this study shows that the consistency with the above study, road network density has a significant role in promoting the subject well-being of the elderly.

6.5. Location and the subject well-being of the elderly

Location has a significant impact on the elderly's subject well-being. This is consistent with the above descriptive, that is, the elderly in the periphery of the central city are significantly better than those in the central city in terms of subject well-being.

Location reflects the difference of population distribution. At the same time, location also determines the characteristics of various elements of built environment. At the same time, location also reflects different social and economic conditions.

6.6. Facility Environment and the subject well-being of the elderly

There are small number of researches that take public facilities directly as an independent variable to analyze the relationship between environment and health. However, the number of public facilities is often related to the diversity of land use and road network density. The higher the diversity of land use within the community, the more public facilities. Land use diversity has been shown to have a significant impact on mental health. For example, although the overall

impact of land use combination is not significant, it also has a positive and negative impact on life satisfaction (Xinyu (Jason) Cao, 2016). The higher the degree of land use mixing, the higher the risk of depression (Dick Saarloos, 2011). Previous study (Zhu Weijue, 2010) has also showed that medical distance has a significant positive impact on the health of the elderly. The nearer the medical distance, the better the physical health performance of the elderly.

In this study, land use mixing degree was not directly measured, but in terms of the number of public facilities, medical distance, transport facilities and transport facilities distance, these facility environmental variables were not significantly related to the well-being of the elderly.

7. Conclusion

Based on the sample of elderly people in Shanghai, this study explored the relationship between neighborhood built environment and elderly's subject well-being. The path analysis in the structural equation model shows that the household registration, educational level and self-assessment of economic status of the elderly can significantly affect the well-being of the elderly. Under the condition of controlling the basic social and economic attributes of the elderly, some neighborhood environmental factors have significant effects on the happiness of the elderly, including per capita green space area, housing building area and distance to the city center. When the environmental variables of facilities are added, the influence of green space is not significant, and the density of road network has a significant positive impact on the well-being of the elderly.

This study of the elderly in Shanghai is consistent with the existing research conclusions, which confirms the positive effect of green space on mental health, as well as the significant impact of road network density, housing conditions and location (distance to the city center). From the perspective of community construction, improving the per capita green area index, increasing the density of road network and improving housing conditions will be conducive to enhancing people's happiness.

Research Paper

STRATEGIES ON HEALTHY URBAN PLANNING & CONSTRUCTION FOR CHALLENGES OFRAPID URBANIZATION IN CHINA

Chengcheng LIU, Tianjin;China

Abstract

In the past 40 years, China has experienced the largest and fastest urbanization development in the world. The infrastructure, urban environment and medical services of cities have been improved significantly. The health impacts are manifested in the decrease of the incidence of infectious diseases and the significant increase of the life span of residents. However, the development of urbanization in China has also created many problems, including the increasing pollution of urban environment such as air, water and soil, the disorderly spread of urban construction land, the fragmentation of natural ecological environment, dense population, traffic congestion and so on. With the process of urbanization and motorization, the lifestyle of urban population has changed, and the disease spectrum and the sequence of death causes have changed. Chronic non-communicable diseases have replaced acute infectious diseases and become the primary threat to urban public health. According to the data published by the famous medical journal The LANCET on China's health care, the economic losses caused by five major non-communicable diseases (ischemic heart disease, cerebrovascular disease, diabetes mellitus, breast cancer and chronic obstructive pulmonary disease) will reach US$23 trillion between 2012 and 2030, more than twice the total GDP of China in 2015 (US$11.7 trillion).

Therefore, China proposes to implement the strategy of "Healthy China" and develop the policy of "integrating health into ten thousand strategies". Integrate health into the whole process of urban and rural planning, construction and governance to form a healthy, equitable and accessible production and living environment. China is building healthy cities through the above four strategies.

The main strategies from national system design to local planning are as follows.

First of all, the top-level design of the country. There are two main points: one point, the formulation of the Healthy China 2030 Plan determines the first batch of 38 pilot healthy cities and practices the strategy of healthy city planning; the other point, formulate and implement the national health city policy and issue the National Healthy City. The evaluation index system evaluates the development of

local work from five aspects: environment, society, service, crowd and culture, finds out the weak links in the work in time, and constantly improves the quality of healthy city construction.

Secondly, the reform of territorial spatial planning. In order to adapt to the rapid development of urbanization, China urban plan promote the reform of spatial planning system, change the layout of spatial planning into the fine management of space, and promote the sustainable development of cities. To delimit the boundary line of urban development and the red line of urban ecological protection and limit the disorderly spread of urban development as the requirements of space control. The bottom line of urban environmental quality and resource utilization are studied as capacity control and environmental access requirements. The grid management of urban built environment and natural environment is carried out, and the hierarchical and classified management unit is determined.

Thirdly, the practice of special planning for local health and medical distribution facilities. In order to embody the equity of health services, including health equity, equity of health services utilization and equity of health resources distribution. For the elderly population, vulnerable groups and patients with chronic diseases, the layout of community health care facilities and intelligent medical treatment are combined to facilitate the "last kilometer" service of health care.

Finally, urban repair and ecological restoration design are carried out. From the perspective of people-oriented, on the basis of studying the comfortable construction of urban physical environment, human behavior and the characteristics of human needs, to tackle "urban diseases" and make up for "urban shortboard".

China is building healthy cities through the above four strategies. Committed to the realization of a constantly developing natural and social environment, and can continue to expand social resources, so that people can enjoy life and give full play to their potential to support each other in the city.

Keywords

the strategy of "Healthy China", national system design, territorial spatial planning, integrating health, intelligent medical treatment, urban repair and ecological restoration design

China's rapid urbanization has brought great challenges to the urban environment. Therefore, China proposes to implement the strategy of "Healthy China" and integrate the concept of health into national strategies such as top-level policy design, territorial space planning reform, smart city big data, urban repair and ecological restoration design.

In the past 40 years, China has experienced the largest and fastest urbanization development in the world. The infrastructure, urban environment and medical services of cities have been improved significantly. The health impacts are manifested in the decrease of the incidence of infectious diseases and the significant increase of the life span of residents. However, the development of urbanization in China has also created many problems, including the increasing pollution of urban environment such as air, water and soil, the disorderly spread of urban construction land, the fragmentation of natural ecological environment, dense population, traffic congestion and so on. With the process of urbanization and motorization, the lifestyle of urban population has changed, and the disease spectrum and the sequence of death causes have changed. Chronic non-communicable diseases have replaced acute infectious diseases and become the primary threat to urban public health.

According to a study on The burden of disease in China published by The prestigious medical journal The LANCET, from 1990 to 2017, The mortality rate of chronic non-communicable diseases has increased significantly in The past three decades, and The top five causes of premature death are stroke, ischemic heart disease, lung cancer, chronic obstructive pulmonary disease (COPD) and liver cancer. This has been accompanied by continued declines in maternal and child mortality. High blood pressure, smoking, salty diets and outdoor air pollution are the top four risk factors for death and loss of life in 2017.The shift in China is largely the result of economic growth and improved education, and is closely linked to the development and effective implementation of China's national action plan for communicable diseases. The study found that people in China's eastern cities, coastal areas and wealthy provinces are generally healthier than those in rural and poor areas in the west. And a set of medical and health data research data show that during 2012 to 2030 in China, five major noncommunicable diseases (ischemic heart disease, cerebrovascular disease, diabetes, breast cancer and chronic obstructive pulmonary disease) caused economic losses will amount to $23 trillion, is China's GDP in 2015, more than two times ($11.7 trillion). China is also facing a severe aging population. As the average population ages, age-related diseases, such as musculoskeletal diseases, impose increasingly severe economic and medical burdens on individuals, families and the government. In addition, a growing number of working-age people spend most of their time in office environments, leading to an increase in the incidence of lower back and neck pain, suggesting that policies are needed to prevent this occupational hazard, and that improvements in tobacco consumption, high-salt diets, air pollution and other problems remain slow.

Figure 1 The leading causes of death in China (1990-2017)

Take cardiovascular and cerebrovascular diseases as an example to study the impact of urban environment on human health. There are many reasons for the difference of cardiovascular mortality, but the reasons are external and internal, which are mainly attributed to the environment and lifestyle. The incidence of cardiovascular and cerebrovascular diseases increases year by year, which is not only related to the improvement of diagnosis level, but also closely related to the aggravation of air pollution and the acceleration of lifestyle pace in recent years. According to data from the Chinese center for disease control and prevention, the number of deaths from various diseases attributed to outdoor air pollution was analyzed. The results showed that the threat of major cardiovascular and cerebrovascular diseases caused by haze was higher than that of lung cancer. The data showed that the amount of coal burned and the concentration of fine particles (PM2.5) in the air were positively correlated with the death from coronary heart disease and cerebrovascular disease, among which the amount of coal burned and PM2.5 concentration in northeast and north China were higher than those in other regions. Dust and harmful gases in the air (such as carbon monoxide and sulfur dioxide) not only increase the burden of the respiratory system, but also seriously affect the function of the cardiovascular system, destroy the function of the cardiovascular endothelial system, and promote the occurrence of atherosclerosis and myocardial infarction.

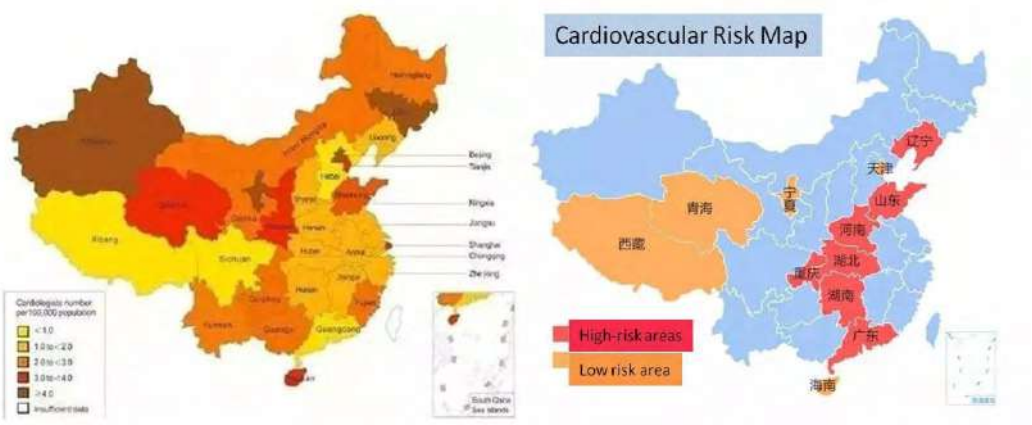

Figure 2 Cardiovascular risk map

Therefore, China proposes to implement the strategy of "Healthy China" and develop the policy of "integrating health into ten thousand strategies". Integrate health into the whole process of urban and rural planning, construction and governance to form a healthy, equitable and accessible production and living environment. The main strategies from national system design to local planning are as follows.

1. First of all, the top-level design of the country

There are two main points: one point, the formulation of the Healthy China 2030 Plan determines the first batch of 38 pilot healthy cities and practices the strategy of healthy city planning; the other point, formulate and implement the national health city policy and issue the National Healthy City. The evaluation index system evaluates the development of local work from five aspects: environment, society, service, crowd and culture, finds out the weak links in the work in time, and constantly improves the quality of healthy city construction.

1.1 Main strategy on "Healthy China 2030" Program Outline

In order to build a healthy China and improve people's health, China has launched a healthy China strategy: the outline of the "healthy China 2030" plan. Industrialization, urbanization, population aging, disease, ecological environment and lifestyle changes, etc., to maintain and promote health brings a series of new challenges, health service supply insufficient overall and the contradiction between the growing demand is still outstanding, health development and coordination of economic and social development needs to be enhanced, needs to solve the relationship between health as a whole from the national strategic level important and long-term problems. National health is the fundamental goal of building a healthy China. Based on the two focus points of the whole population and the whole life cycle, provide fair and accessible, systematic and continuous health services, and achieve a higher level of universal health. The main strategic content of urban planning includes four parts: popularization of healthy life, optimization of health services, construction of healthy environment and development of health industry. Including optimization of health services, improve the health care, construction of health environment, development of health industry related to urban planning and construction sector specific strategies are: to improve the physical quality, strengthening the universal public health services in-depth development, strengthen the key crowd health services, health movement, strengthen the environmental problems affecting health management, perfecting the system, development of health service of new forms of public safety.

Main strategic contents	Major planning strategies
Promoting healthy living	◎Improve the physical fitness of the whole people: improve the public health service system
Optimizing health services	◎Strengthening public health services that cover all the people: promoting equal access to basic public services and health; ◎Provide high-quality and efficient medical services: improve the medical and health service system, such as the layout and planning of urban medical and health facilities. We will strengthen health services for key population groups, such as promoting healthy ; aging and planning the layout of old-age care facilities. Such as maintaining the health of the disabled, such as barrier-free urban planning
Building a healthy environment	◎Further carry out health campaign: strengthen the comprehensive improvement of urban and rural environmental health, build healthy cities and healthy villages and towns; ◎We will intensify efforts to deal with environmental problems affecting health: we will carry out prevention and control of air, water and soil pollution, implement a plan to discharge all industrial pollution sources to standards, and establish and improve systems for monitoring, investigating and assessing environmental and health risks; ◎Improve the public safety system: promote road traffic safety, improve emergency response capacity
Develop health industry	◎New types of health services: Internet health services, TCM health tourism, health culture and medical tourism, health culture and sports medical rehabilitation, and health service clusters

Figure 3 Main strategic contents of Healthy China 2030

1.2 National healthy city evaluation index system

The national healthy city evaluation index system includes 5 first-level indicators, 20 second-level indicators and 42 third-level indicators, which can objectively reflect the overall progress of the construction of healthy cities in various regions. Taking into account China's vast territory, large population and uneven development of the national conditions, is a healthy city construction should follow the basic requirements. When building healthy cities, local governments should, on the one hand, work in accordance with these indicators, and on the other hand, solve and improve prominent local health problems and their influencing factors based on the characteristics of each city, so as to carry out the construction of healthy cities as a whole.

2. Secondly, the reform of territorial spatial planning

After 40 years of exploration, great achievements have been made in China's urbanization development. At the same time, this stage is also a stage of "crossing the river by feeling the stones", and we need to constantly summarize experience and gain and loss. Therefore, in order to adapt to the changes brought by the rapid development of urbanization, China has promoted the reform of the spatial planning system, from spatial planning layout to spatial refinement governance, and promoted the sustainable development of cities. China has the following sectoral planning sequences: economic and social planning sequences, urban and rural construction planning sequences, land and resources planning sequences, regional development planning sequences, ecological and environmental protection planning sequences and so on. Among them, there are 23 ecological and resource and environment constraint plans, and 68 development and construction plans. In order to better unify these plans, avoid waste and protect the ecological environment, the state studies to define the boundary line of urban development, the red line of urban ecological protection, and limit the disorderly spread of urban development as space control requirements based on the "evaluation of resource and environment carrying capacity" and "evaluation of the suitability of land space development". Study the bottom line of urban environmental quality and the upper limit of resource utilization, as capacity control and environmental access requirements. Grid management of urban built environment and natural environment, and determine the classification of management units.

2.1 "Double Evaluation"

The "double evaluation" is "resource and environment carrying capacity evaluation" and "land space development suitability evaluation". Land space planning is an important basis and means for macro-control of rational development, utilization and governance of land, and an effective way to regulate the relationship between development and resources and environment. As the basis of national spatial planning, "double evaluation" needs to meet the inherent requirements of "necessity", "utility" and "usability" put forward by national spatial planning, and fully support the compilation of national spatial planning. "Double evaluation" is the essence of the regional resources and environment characteristics of cognitive tools and methods, finally exports should strengthen the conclusion of the analysis, respectively to form "bearing pressure - carrying capacity - bearing potential" and "problem

and to partition pattern - risk identification -" development potential analysis conclusions of three levels, increase support to space planning.

2.2 Designation of "Three Zones & Three Lines"

"Three districts and three lines" : according to three types of urban space, agricultural space and ecological space, three control lines, namely urban development boundary, permanent basic farmland protection red line and ecological protection red line, are drawn respectively."Three zones" (three types of Spaces) refer to the urban space: the land space whose main function is the production and living of urban residents, including the urban construction space, the industrial and mining construction space and the development and construction space of some township governments; Agricultural space: the land space that takes agricultural production and rural residents' life as the main function and bears the functions of agricultural production and rural life, mainly including permanent basic farmland, general farmland and other agricultural production land and rural living land like villages. Ecological space: the land space with natural properties that provides ecological services or products as the main function, including forests, grasslands, wetlands, rivers, lakes, beaches, wasteland, desert, etc. The "third line" (three control lines) refers to the red line of ecological protection: it is an area with special important ecological functions within the scope of ecological space that must be strictly protected by force, and it is the bottom line and lifeline of safeguarding and maintaining national ecological security. Red line for protection of permanent basic farmland: refers to the space boundary of farmland that may not be occupied or developed and needs permanent protection according to the demand of population and social and economic development for agricultural products in a certain period of time. Urban development boundary: within a certain period of time, the regional spatial boundary that can be used for urban development and concentrated construction, including the existing urban built-up area, the optimized development area and the areas that must be planned and controlled due to the needs of urban construction and development.

3. Thirdly, the practice of special planning for local health and medical distribution facilities

Data can change lives, everyone believes. Buy goods on the Internet, use mobile phone SMS to quickly pick up goods; How far is the bus to wait, open the location prediction distance; Through the wireless hospital system, you can register for free...As part of smart cities, these once utopian visions are becoming reality. In April 2018, China successively promulgated the "about promoting the development of" health "Internet + opinions on the further" Internet + medical health "for the convenience of benefit the people activities notice and other documents, from the policy level vigorously promote the construction of" Internet + medical health ", promote the growth of the health care market, for the people provides the omni-directional, the whole cycle to reflect health service fairness of health services including health services, health services and utilization of fairness and equity of health resources distribution. For the elderly, vulnerable groups and patients with chronic diseases, we will

combine the layout of community health and medical facilities with the smart medical treatment with big data to facilitate the "last kilometer" of health and medical services.

Medical care is about every family, and nothing can stop people from yearning for intelligent medical care. In 2019, with the beginning of the first year of 5G, smart medicine gradually turns many "impossible" into "possible", and its coverage of universal benefits becomes broader, deeper and more possible. The layout of local health and medical facilities will be combined with smart medicine, including AI follow-up system for patients, Internet hospital, remote specialized medical service, "smart hospital", "cloud mastery" of medical data, 120 emergency command system, etc.

4. Finally, urban repair and ecological restoration design are carried out

From the perspective of people-oriented, on the basis of studying the comfortable construction of urban physical environment, human behavior and the characteristics of human needs, to tackle "urban diseases" and make up for "urban shortboard".

4.1 Urban Repair

Urban repair is to avoid demolition and construction as much as possible and promote organic renewal. We should not only protect the original texture, but also allow the construction to happen. Urban repair is a new thing in theory and practice, and its positive significance is mainly reflected in the following aspects: first, it is conducive to the gradual urban renewal and transformation; Second, it is conducive to sustainable urban development; Third, it is conducive to the protection and continuation of famous cities and ancient towns; Fourth, is advantageous to the environment renovation and the city image beautification. In a word, urban repair is a new concept of urban design and a renewal method of urban construction put forward during the period of urban development from extensional expansion to concentric development. City repair, is around the "let the people in the city life more convenient, more comfortable, more beautiful" goal, USES the good method for urban planning and design concept, system, progressive, targeted way, constantly improve the quality of urban public services, improve the condition of municipal infrastructure, the excavation and protect the city history and culture and the social network, make the space of city function system and its carrying a place of repair, make up and improve the comprehensive system, make cities more livable, more dynamic. The measures for improving the physical environment should adjust measures to local conditions, can include demolition of illegal construction, control and guide the urban space morphology and skyline, the color of city and architecture, city night view lighting, urban greening landscape, outdoor billboards and so on many measures, gradually make urban and landscape environment harmony, improve the inner quality of urban physical environment, show the features of city in the form of whole space.

4.2 Ecological Restoration

"Ecological restoration" refers to the restoration of the original ecological functions of the ecosystem, such as soil and water conservation, microclimate regulation, biodiversity

maintenance, and development and utilization, with the help of appropriate artificial measures, by making use of nature's self-healing ability. Ecological restoration is not to restore the ecosystem to its original state, but to restore and improve the function of the ecosystem through restoration. Ecological restoration, is "to create good living environment as the central goal", aims to make damage to the structure and function of urban ecosystem restoration to the front of the interference of the natural condition, on the one hand, the city development to minimize the interference of ecosystem, on the other hand, through a series of means to restore the self adjusting functions of urban ecological system, make its gradually have the ability to overcome and eliminate outside interference, especially when changes in the external conditions still have to build a new balanced ability, promoting the ecological system in the process of dynamic constantly adjust and balance. Due to the high self-regulation capacity of the ecosystem and a large number of feedback mechanisms, the complexity and long-term nature of ecological restoration are obvious. In the face of the destruction of the ecological environment, we should first stop on the urban ecological system in mountains, rivers, coast, destruction of wetlands, vegetation, soil, adjustment of urban land use pattern, start from the local ecological elements to repair, in a planned way step by step to promote the ecological elements of the occupied "reclamation", gradually recovery, reconstruction and improve urban ecosystem self-regulation function.

China is building healthy cities through the above four strategies. Committed to the realization of a constantly developing natural and social environment, and can continue to expand social resources, so that people can enjoy life and give full play to their potential to support each other in the city.

Case Study / Project

Building Indian Neighbourhoods to Thrive in:

Guidelines for Planning, Design & Policy for Infants, Toddlers plus Their Caregivers in India

Rushda MAJEED, Patrin WATANATADA

Abstract

Planning and designing a city to better meet the needs of babies, toddlers and the people who care for them is one of the best investments a city can make. Growing evidence from neuroscience, public health, education and economics makes it clear: experience shapes the developing brain. One of the best ways to ensure good experiences is to support the people who care for babies and toddlers, beginning in pregnancy. City planners have a big role to play. Clean air and water. Walkable neighbourhoods that cater for the basics a young family needs. Multi-generational public spaces close to home that allow small children to explore safely. Safe routes and reliable transport that make it easy for caregivers traveling with small children to get to healthcare, childcare and healthy food. Such urban amenities help lay a crucial foundation in the early years of life for good health and learning into adulthood. And they make cities better for people of all ages. Yet babies, toddlers and the people who care for them can be invisible to city leaders and planners as a group with specific needs. That's why the Bernard van Leer Foundation's Urban95 initiative supports cities worldwide to ask and answer a bold but simple question: if you could experience a city from 95cm - the height of a 3-year-old - what would you change? This workshop will take participants through India's Infant, Toddler & Caregiver planning, policy and design guidelines, developed for and at the request of India's Smart Cities Mission by a team convened by the Bernard van Leer Foundation's Urban95 initiative and BDP. It will be hosted by the Bernard van Leer Foundation.

Case Study / Project

Realising the potentials of a design-dividend

towards a lovable urban future

Gregor MEWS

Abstract

Australia is one of the most urbanised countries in the world. At the same time, it is one of the highest per capita emitters of global greenhouse gas emissions. Despite of its material wealth, evidence in relation to the state of children health indicate that growing up in cities is of deep concern to ensure long term prosperity on societal level. The present generation are the least fit and the fattest they have ever been. Spatial fragmentation, social marginalisation, mental health issues and serious cardio-metabolic disorders have been on the rise in adolescence and early adulthood. As it stands, future generations will be off for worse. The problem that Australia finds itself in is created in part by our own actions. Currently we are still operating either in institutional regulatory silos, within technological harsh market competition, ecological unsustainable development patterns, and under enormous fiscal constraints within academia and organisations operating in the civil/societal fields. In absence of a national urban policy and political resistance on cohesive climate change policy, the argument for change within an individualistic society require a reframing. For example, a design-dividend provides benefits to positive financial uplift for development interests resulting from human-centred urban design to ensure liveable and healthy urban future for all. Good design generates a range of public benefits. Capitalisation of a design-dividend starts by addressing the needs of children and young people in the design process. The contribution will introduce some of Urban Synergies Group global key initiatives and collaborative thought leadership with the University of Canberra, Health Research Institute in the nexus of improving health outcomes for children and young people in urban systems.

Critical reflection on the applied systems approach in relation to safe independent childhood mobility (walking and cycling), encounters with nature in public spaces and designing connected play spaces for all will open up space for an engaging discourse on the need for a paradigm shift in the way we continue to shape healthy communities. About Urban Synergies Group Urban Synergies Group to date have been working in the global arena, particularly in contributing to the New Urban Agenda and advocacy of the Sustainable Development Goals (SDG) 3- Good Health and Wellbeing, 11- Sustainable cities and Communities, SDG- 13 Climate action and SDG 17- Partnerships for the goals. We believe that now is the time for to engage in international goals and to realise the potential of a paradigm shift from urban liveability to urban lovability that leaves no one behind.

Case Study / Project

Livable and just public space

- Conceptual approach to urban walkability on the case of Ljubljana, Slovenia

Matej NIKSIC

Abstract

The research addresses the issue of urban livability through the (un)supportiveness of the built environments for walking. It claims that urban environments must be pedestrian-friendly if the community's quality of life is to be achieved. It goes further and relates urban walkability to the urban justice issues. It gives a comprehensive review of the literature on walkability and the different aspects of urban justice embedded within it in terms of social, environmental, health, transportation and economic conditions.

This review sets the scene for a case study of Ljubljana, the capital and biggest city of Slovenia, which has gone through a major socio-economic transformation from socialist to capitalist system in the last three decades. The case study shows how urban walkability was tackled by two distinctive urban planning approaches: the socialist in the 1945-1990 period and the contemporary neoliberal which started in 1991 and is ongoing. It discusses how the two different conceptual approaches to urban walkability affect the urban livability and urban justice on concrete examples in the city. It reveals how the walkability assets of the city have been (dis)encouraged in accordance with the respective socio-economic system and how this affected people's right to use the city, and how it changed the livability of the neighbourhoods. It gives special attention to the contemporary measures as they reflect the realities of a city traversing from a socialist to a capitalist model while more or less successfully retaining the ideals of a just city via investments into the walkable public spaces. This focus brings some lessons learnt for other similar contexts around the globe where the welfare state is decreasing and the accumulation of the capital is becoming the paramount ideology.

The research aims to point out the power and responsibility of urban planning as a discipline in providing the urban walkability conditions within the just city agendas. It points out the need for the planners in the transitional socio-economic contexts to develop new skills and competences to assure social and spatial cohesion as a precondition for the truly livable places.

Case Study / Project

IAP's Indonesia Most Livable City Index (MLCI):

A Perception-Based Survey to Measure City Livability Index

Dayinta PINASTHIKA, Puteri Rizqi AMELIA, Elkana Catur HARDIANSAH

Abstract

In today's urbanizing world, where almost half of the world's population lives in cities, livable city is a necessity. City livability depends on how cities can provide safety and security for the peoples, fulfill their basic needs, provide easy access to public services and infrastructure, have a good quality of the environment, better economic, social and cultural conditions, assure citizen's participation, and others. Some parties measured city livability quantitatively using various criteria, such as OECD Better Life Index, Mercer Quality of Living Survey, Monocle Magazine's Most Livable City Index, The EIU Global Livability Survey, and Forbes Livable City Index, which then resulted in the list of most and worst livable cities in the world. These surveys have been globally trusted as a reliable, valid, and recognized index and have become global references. However, none of those surveys put citizen perception as the basis of measurement. They were based on secondary data, statistics, and were reviewed from the perspective of the researcher. None of the surveys had measured city livability based on citizen's perceptions. While perceptions are quite significant since it describes the real conditions perceived by the peoples.

The "Indonesia Most Livable City Index (MLCI)" developed by the Indonesian Association of Planners (IAP) surveys city livability based on citizen's perceptions. This survey had been carried out since 2009 and was last held in early 2017. The indexing measurement was carried out based on 28 assessment criteria developed by the research team. MLCI 2017 surveys 26 cities throughout Indonesia by involving the IAP Regional Office voluntarily as surveyors. The survey resulted that the average livability index of Indonesian Cities was 62 of 100, which indicates that there were still many citizens who feel uncomfortable living in their cities. The survey had also resulted in groups of cities including the top tier cities, average tier cities, and bottom tier cities. Surveys that are held regularly have also been able to show an increase and decrease in the livability index of the city from period to period. In addition, from the survey results, it was found that what aspects were satisfying and unsatisfying according to citizens in each city surveyed. It can be learned that perception can be used to measure the city livability index and is worth considering as one of the legitimate methods of measuring the livability of a city. It can then be used as inputs for government and other stakeholders in terms of providing the citizen's needs.

Research Paper

Analysing the perceptions of the elderly on space vitality and related environmental factors based on residential community

Hang SUI, Dalian University of Technology; China
Dongfeng YANG, Dalian University of Technology; China

Abstract

Environmental perception of the residential community has a non-negligible impact on a healthy lifestyle for the elderly. The perceived level- and actual satisfaction- of the elderly offered by the "space vitality" of the residential community is closely related to the physical and mental health for the elderly which also largely determines their quality of life. From the perspective of urban planning, it is a crucial measure to identify and effectively regulate the critical environmental impact factors of the residential community that affect the perception and experience of the elderly, to promote the construction of the age-friendly community. This paper took Dalian, China as the research range, and took the elderly as the object of research in relation to the perception of space vitality within the residential community and its associated environment-related factors. Correlation analysis was used to identify the potential environmental factors related to the perception of space vitality by the elderly. It found that the general level of the elderly's perception of space vitality has a positive correlation with many elements of the built environment e.g., the perception of the diversity, or the landscape of leisure places, which are both related to overall spatial quality. However, it does not show a significant correlation with the social environment. Therefore, useful suggestions are made on how to improve the elderly's perception of space vitality within the residential community, particularly in prior planning and design practice. The optimization of the spatial quality of the built environment should be the core point of concern. By optimizing the arrangement of the relevant elements of the site, the elderly's level of perception and satisfaction with the space vitality of the residential community should improve; furthermore, the physical and mental health of the elderly will be promoted in line with their quality of life.

Keywords

Healthy aging, Residential environment, Space vitality, Age-friendly community

1. Introduction

For the elderly, the perceived level- and actual satisfaction- offered by the "space vitality" of the residential environment has a non-negligible impact on subjective well-being and a

healthy lifestyle. In psychology, the concept of well-being is based on a combination of factors to do with personal quality of life and mental health (Wang et al., 2013). Subjective well-being often stems from an individual's subjective feelings about their daily life and their physical surroundings (Zhang, 2014). Research has shown that cultivating positive environmental perceptions is crucial for the promotion of healthy aging among the elderly. The person who actively participates in physical activities could be more likely to experience the well-being from the feelings of physical and psychological than those who access medical services passively (WHO, 2012). Moreover, a positive environmental perception not only contributes to mobilizing active participation in physical activities but also improving levels of physical health. It could offer significant mental health benefits generally, thus creating an interplay between participants and the environment. (Smith et al., 2002). Therefore, special attention on public spaces of residential community is necessary. It serves as the leading site for the daily activities of the elderly, and as a facilitator of social activities for communication and exchange among neighbours. The space vitality from the residential community often reflects the material and spiritual needs of the elderly.

Research by Chinese scholars on space vitality and its related factors mainly focuses on two aspects – the characteristics of urban space morphology and intensity of use for certain activities. Jiang developed a quantitative system for evaluating street vitality based on the vitality composition index including things like functional diversity and traffic accessibility. This system integrated the vitality characteristic factors such as the number of activists and their stopping time for the space area. (Jiang, 2013). Additionally, Long and Zhou discussed the impact of the population density on street vitality. Through a quantitative analysis of six indexes, including location, transportation accessibility, and mixed functions, Long and Zhou proposed the vitality factors from the different street types have the differentiated features. Its content has deepened the quantitative exploration of street vitality (Long et al., 2016). With increasing insights into urban space vitality in a cognitive context in recent years, attention has shifted to individual perception. Based on reviewing relevant international research, Ye highlighted the influence of street accessibility and the fitting degree of morphological elements on the role of urban vitality (Ye et al., 2017). He also conducted an empirical test of residents' activities, drawing connections between the strength of selected events and levels of space vitality (Ye et al., 2016). Similarly, Huang and Xu measured space vitality by looking at the intensity of quality street activities (Huang et al., 2017). In summary, the focus of existing research on urban space vitality has gradually shifted from focusing on the functional and social dimensions to the cognitive — the relevant research with individual behaviour and perception, attracting increased attention.

While the existing research has achieved fruitful results, deficiencies exist in the following aspects: The first is related to sample limitations. Previous research mainly aimed at ordinary urban residents, and despite the serious implications of an aging population, there has been a lack of discussion of the elderly as a specific research subject. The second deficiency is the fact that the definition of “space vitality” has failed to accurately interpret the essential characteristics of the concept of “vitality.” Can indicators such as the number of people, their stopping time, and population density adequately reflect space activity? Can “functional diversity” effectively express space vitality? The answer is no. Thirdly, although existing research has dealt with the idea of “perception,” it has not regarded individual behaviour as an area for focus. The essence of the current study still lies in measuring the

relevant elements of the built environment from the perspective of objective observation, making it impossible to examine the subjective experiences of individuals intuitively.

This paper takes the city of Dalian as its research range. Setting the individual perception, perceptions of space vitality for the elderly residents in their respective residential community was measured through the use of questionnaires. Utilizing methods of statistical analysis and considering the relevant elements of the built and social environment, this paper aimed to explore the complicated relationship between environmental factors and space vitality. The primary finding has been that the perceptions of space vitality among the elderly have a positive correlation with many elements of the built environment. However, a significant association with the social environment has not been shown to exist.

2. Concepts, Methods and Data

2.1. Concepts

The space vitality of the residential community is essentially the embodiment of the diversity of daily activity opportunities in the public space within and outside these communities. To a certain extent, space vitality depends on the environmental quality of the residential community and its surrounding area. Jane Jacobs brilliantly pointed out that the interweaving process between human activities and living places has created the concept of space vitality (Jacobs, 1961). Kevin Lynch further proposed that vitality, as an essential indicator of urban morphology, can provide a pleasant living environment for the continuation of living organisms. Therefore, "space vitality" is generally recognized as a measure of the quality of a space related to daily activities, and as the primary criterion for measuring the quality of urban morphology. Its external representation is closely related to the daily activities that people can pursue in a specific space (Tong, 2014), and its intrinsic motivation mainly stems from the combined effects of built environment characteristics and the underlying social environment factors (Ye et al., 2016). In existing studies of street vitality, the diversity of functions or activities inside and outside of the street interface often regarded as the main source of street vitality (Jacobs, 1961). Similarly, the diversity of functions and activities inside and outside of the residential community can be considered to be a representation of its space vitality. Diversity, as a concept closely related to space vitality, can be regarded as the scope of activity opportunities in a specific space. It reflected in people's daily lives, specifically in whether public spaces inside and outside of the residential community can provide residents with sufficient enriching activities.

The approach to developing residential community should consider both the built and social environment. When talking about the environment of the residential community, it is traditionally understood that we are referring to the “built environment.” Space vitality has not been regarded as “an isomorphism by spatial characteristics and social activities behind it.” (Ye, 2014) until the concept “duality” of urban space vitality has been put forward in recent years (Lees, 2010; Marcus, 2010). It is believed that the generation of urban space vitality originates from the joint action of the relevant factors of the residential environment, namely, the built and social environments. In this sense, the two factors above should be considered comprehensively in the analysis of the relationship between the residential community and space vitality.

2.2. Methods

➢ ***Data measurement***

Subjective evaluation methods are used to obtain the variables for space vitality and environmental factors. Firstly, the elderly's perception of space vitality divided into three categories: physical-training activity, leisure activity, and shopping activity. Combined with relevant literature and field investigation, it determined that 18 physical activity indicators are selected for measurement and become into the overall indicators and classification indicators on elderly perception for the activity opportunities (Figure 1). Among, the household activity excluded because it almost unconstrained by the objective condition. Secondly, this research the perception of environmental factors divided into two levels as the built environment and social environment, in order to identify the relationship between space vitality perception and residential environmental factors further. Thereinto, the built environmental perception includes places diversity, places accessibility, pedestrian facilities, and landscape environment, and the social environment perception include neighborhood livability, neighborhood security, and neighborhood-trip safety.

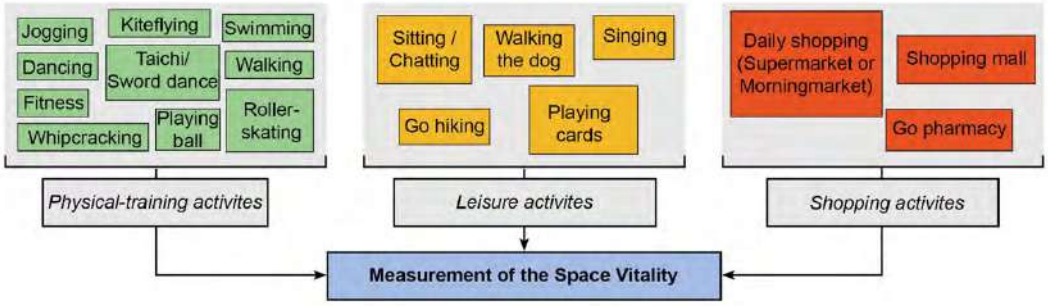

Figure 1 Physical Activities Classification (Source: drawn by the author, 2019)

➢ ***Data analysis***

This paper used the SPSS software is used to analyse the correlation between the environmental factors and activity opportunities by aggregated indicators and classification indicators, for exploring the relationship between various related factors and space vitality of the environment. Combining the value of Sig and the correlation coefficient of Kendall, the results of correlation analysis divided into four levels (strongest significant and high correlated, stronger significant and high correlated, strongest significant and medium correlated (no present in the result), stronger significant and medium correlated) with statistical significance. At the same time, through the on-site observation, big data, Google Earth, GIS, and other tools, the distribution characteristics of the variables mentioned above are visualized at the spatial level.

2.3. Data base

This paper took the main urban area of Dalian as the research range, the questionnaire interview conducted among the elderly residents. A total of 365 interview questionnaires were taken, and one invalid survey (exceeding the scope of the study) was excluded. Finally, the questionnaire information of 364 respondents was constructed to become the primary sample database of the study. The sample extraction during the interview comprehensively considered the equilibrium distribution of the proportions of the number of people, age, gender (Figure 2) and other factors in the spatial range, and is quite representative. The

results (Figure 3) show that the perceived level of activity opportunities of the elderly at the intermediate level (70%) in general. At the same time, the number of people at low level accounts for a certain proportion (26%) of the total sample size, while the ratio of high level is relatively very few (4%). Therefore, for identified effectively for the environmental impact factors of the spatial vitality, this paper divided the perception of environmental factors by the elderly into two parts: built environment perception and social environment perception (Figure 4).

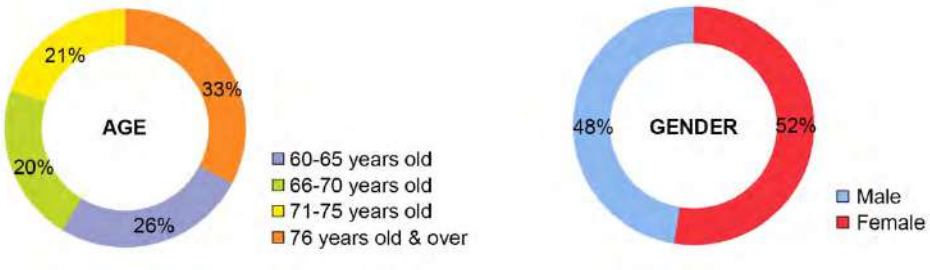

Figure 2 Age and Gender Proportion of Respondents (Source: drawn by the author, 2019)

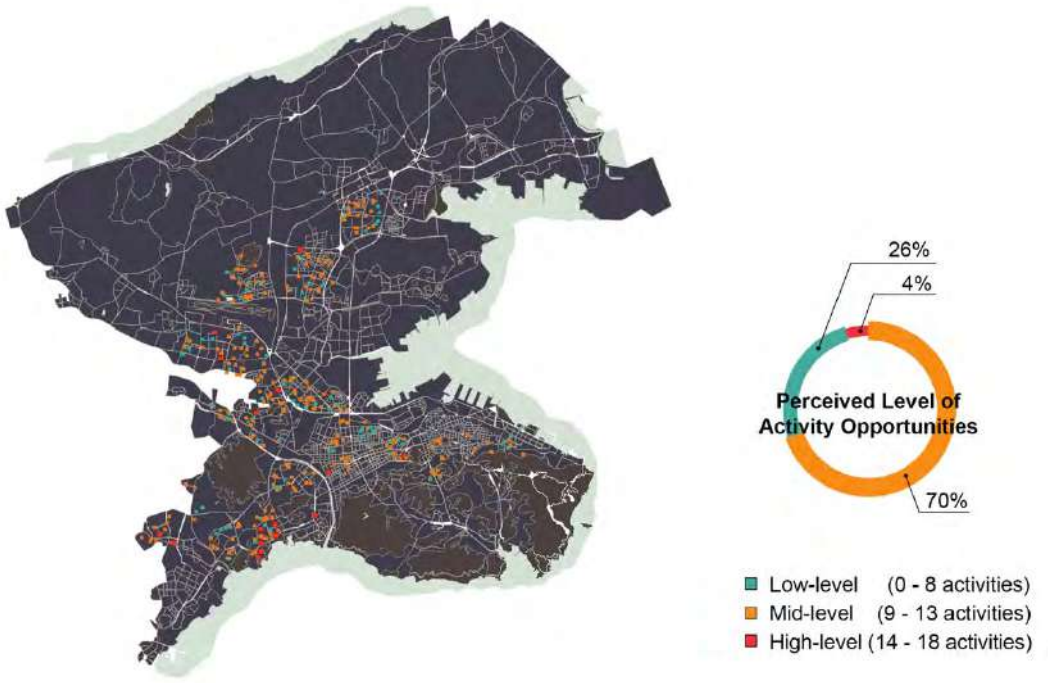

Figure 3 Distribution and Proportion of Activity Opportunity Perceived Level (Source: drawn by the author, 2019)

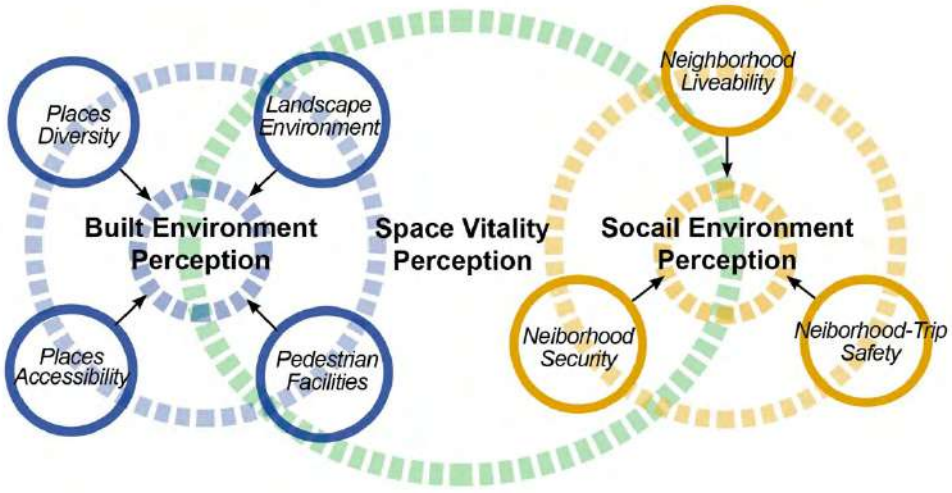

Figure 4 Classification of the Relevant Environment Factors (Source: drawn by the author, 2019)

3. Results

Given the complicated relationship between spatial vitality perception and related environmental factors, it divided the research process into two stages: firstly, the paper explored the statistical correlation between the space vitality perception on the overall level and environmental factors. Secondly, it separately observed the statistical correlation between activity opportunities on three dimensions of space vitality (physical-training activities, leisure activities, and shopping activities) and environmental factors (built environment and social environment). Among them, the places diversity, places accessibility, pedestrian facilities and landscape environment in related environmental factors regarded as the essential elements of built environment perception. The liveability, security and trip-safety of neighbourhoods are considered to be the essential elements of social environment perception. Through correlation analysis, it obtained the following main findings.

3.1. Space vitality and related environmental factors

There is a certain degree of the positive correlation between the built environment perception and overall-level of space vitality perception. Specifically, the Diversity of leisure places, landscape situation of leisure places, the landscape satisfaction of leisure places shown strongest significant and high correlated with the overall-level indicators of activity opportunities. There is a stronger significant and medium correlation between the accessibility of leisure places and the overall-level indicators of activity opportunities. However, there is no significant correlation between the perception elements of the social environment and space vitality.

From the results of correlation analysis (Table 1), three of the ten indicators for built environmental perception passed the double-tailed test with confidence of 0.01, and one passed the double-tailed test with confidence of 0.05. Combined with Kendall correlation coefficient R, according to its correlation significance and correlation degree, the order is diversity of leisure places (p=0.000, r=0.160), landscape situation of leisure places (p=0.003, r=0.126), landscape satisfaction of leisure places (p=0.004, r=0.120), and accessibility of leisure places (p=0.019, r=0.099). The above show that there is a relatively strong correlation

between the perception of the built environment and space vitality. The higher the satisfaction of the elderly to the built environment, the more activity opportunities they perceive, and the stronger the space vitality of the residential areas. The correlation analysis results mean that although there is an association among the indicators between the factors of social environment perception and space vitality, it is not statistically significant.

Statistical Significance (S.S.): ● : Stongest (p<0.01); ○ : Stronger (0.01≤p<0.05); – : General (p≥0.05)

** In this study, the range of R determined according to the actual sample size and statistical analysis results.*

This result shows the built environment factors are essential to the space vitality. High-level space vitality perception often with the high-intensity built environment perception. It also shows that although social environment perception can promote the perceived level of space vitality, it is not the leading factor. The phenomena may be due to the improvement of life quality, which changes the activity needs of the elderly. The requirements of individuals are gradually evolving from distance-oriented to function-oriented and quality-oriented. Therefore, in a certain of the range (depending on the health status of the elderly), the diversity of the choice of place functions and the superiority of landscape quality have a strong attraction to elderly, so that they break through the “proximity principle” shackles.

Another phenomenon that the correlation between the diversity of leisure places and the activity opportunities is higher compared with other indicators, which coincides with the view of Jane Jacobs. She said that the diversity and identity of urban spaces could enhance the cohesion of communities and the attraction of individual behaviour activities, thus stimulating the vitality of the area.

Table 2 Correlation Analysis between the Activity Opportunities Perception and Related Environment Factors (Source: drawn by the author)

			Activity Opportunities Perception (Classification Level)

** In this study, the range of R determined according to the actual sample size and statistical analysis results.*

3.2. Physical-training activity opportunities and related environmental factors

There is a positive correlation between the perception of built environment factors and the perception of the physical-training activity opportunities. Specifically, there is the strongest significant and high correlated relationship between the diversity of leisure places and physical-training activity opportunities. The accessibility of leisure places, landscape situation of leisure places, the landscape satisfaction of leisure places was stronger significant and medium correlated with the physical-training activity opportunities. The neighbourhood-trip satisfaction, as a factor of the social environment, also shows a stronger significant and medium correlation with this kind of activity opportunities.

From the results of correlation analysis (Table 2), one of the ten indicators for built environmental perception passed the double-tailed test with confidence of 0.01, and three passed the double-tailed test with confidence of 0.05. Combined with Kendall correlation coefficient R, according to its correlation significance and correlation degree, the order is diversity of leisure places (p=0.000, r=0.155), accessibility of leisure places (p=0.022, r=0.100), landscape situation of leisure places (p=0.024, r=0.097), and landscape satisfaction of leisure places (p=0.032, r=0. 920). Specifically, the positive correlation between the diversity of leisure places and physical-training activity opportunities shown that the variety of leisure places could provide participants with more choices for physical-training activities. The places diversity could improve the perceived level effectively of physical-training activity opportunities for the elderly. The correlation analysis results also show that the higher the landscape quality of leisure places and the stronger the satisfaction of the elderly on the inner needs provided, the more obvious the perception of the physical-training activity opportunities in the areas. In terms of the result, the neighbourhood-trip situation is the only social environment factor which passed the double-tail test with a confidence level of 0.05. It means that the built environment perception is more likely to have an impact on the perceived level of physical-training activity opportunities of the elderly than the social environment perception.

In conclusion, there is a positive correlation between the diversity of leisure places and the perception of physical-training activity opportunities. And then, the relationship between the accessibility of leisure places and the perception of physical-training of opportunities is slightly higher than the impact of landscape situation of leisure places and the landscape satisfaction of leisure places to the later. The reason could be that compared with other types of activities, the physical-training has more definite purpose and location. The elderly could a more easily perceive the area which has a higher degree of functional support and the more selectivity of the route. Furthermore, because walking, jogging, and other types of physical activities mostly occur in the residential area and the surrounding sidewalks, so the traffic conditions and parking of vehicles have an impact on them. It could explain why the satisfaction of neighbourhood-trip affects the perception of such opportunities.

3.3. Leisure activity opportunities and related environmental factors

There is almost no statistical correlation between the perception of leisure physical activity opportunities and the perception of the built environment and social environment. Only the diversity of leisure places shown stronger significant and medium correlated with the perception of leisure activity opportunities.

As shown in Table 2, only one index (p=0.022, r=0.102) of leisure place diversity in built environment related factors passed the confidence level test of 0.05, and the results of Kendall correlation coefficient R shown a low correlation between them. Besides, other related environmental factors did not pass the significance test of the correlation. The study finds that the association between the diversity of leisure places and perception of leisure activity opportunities is significantly lower than that between the diversity of leisure places and the opportunity perception of physical-training activities and shopping activities.

In summary, there is almost no statistical correlation between built environment perception, social environment perception, and leisure activity indicators. The reason is easy to explain that the most obvious difference among physical-training, shopping and leisure activities is that the occurrence of physical-training and shopping activities is more dependent on the

built environment, and many activities could be carried out without accompany. Compared with the first two items which care about the built environment, leisure activities pay more attention to the activity companion (e.g., family members, friends, pets).

3.4. Shopping activity opportunities and related environmental factors

There is a positive correlation between the perception of the built environmental factors and the perception of shopping activity opportunities. Among them, the landscape satisfaction of leisure places, landscape satisfaction of the communities, the pedestrian facilities satisfaction, the landscape situation of leisure places all shown the strongest significant and high correlated with the perception of shopping activity opportunities. And the diversity of leisure places and communities were the stronger significant and medium correlated with the perception of shopping activity opportunities. But with the analysis result, there is no statistically significant correlation on perception between social environment factors and the indicators of shopping activity opportunities of the elderly.

Table 2 shows that five of the ten indicators of the built environment have passed the significance test of the correlation, four of them passed the confidence level test of 0.01 and one passed the confidence level test of 0.05. Combined with Kendall correlation coefficient R, according to its correlation significance and correlation degree, the order is landscape satisfaction of leisure places (p=0.004, r=0.134), landscape satisfaction of communities (p=0.005, r=0.133), the satisfaction of pedestrian facilities (p=0.005, r=0.133), landscape situation of leisure places (p=0.008, r=0.126), and the diversity of leisure places (p=0.018, r=0.111). Among them, the correlation coefficient between landscape satisfaction of leisure places and the perception of shopping activity opportunities is the highest. The landscape satisfaction of leisure places is the most critical factor to the latter meant that the perception of shopping activity opportunities could be improved when the identity of the landscape quality strengthens.

In conclusion, the positive correlation between the landscape satisfaction of leisure environment and the perception of shopping opportunities is the most obvious, and other indicators followed by it. The above results could attribute to the fact that shopping activities of the elderly often accompanied by physical-training and leisure activities — most elderly accustomed to daily-shopping as a way of physical exercise. On the way back to home from shopping places, they commonly used to have a rest at the roadside, the square around the residential area, and the courtyard and achieves the purpose of participating in more than one activity at the same time. The landscape satisfaction of leisure places and the satisfaction of pedestrian facilities on the way also have a major impact on the perception of such activity opportunities. It should be the reason for the spatial quality indicators (landscape environment, pedestrian facilities, etc.) are positively correlated with the perception of shopping activity opportunities.

4. Conclusion and Revelation

Nowadays, awareness of healthy aging is the deepening of people. The importance of spatial vitality perception at the community level in the process of improving the quality of life and health level of elderly residents has gradually become prominent. Based on the analysis of the complicated relationship between environmental factors and spatial vitality perception, this paper draws the following three conclusions. Firstly, the overall level of elderly space

vitality perception positively correlated with many factors of the built environment (such as diversity of leisure places, landscape situation of leisure places, and landscape satisfaction of leisure places). But the correlation between the former and social environment was not significant. Secondly, the perception of the elderly on physical-training activity opportunities is closely related to the diversity of leisure places. The perception of the senior citizens on shopping activity opportunities is highly correlated with landscape satisfaction of leisure places and the residential community, the satisfaction of pedestrian facilities and landscape situation of leisure places. Thirdly, there is no statistical correlation between the perception of leisure activities opportunities and the built environment and social environment. In brief, there is a close relationship between the quality-related factors of the built environment and the perceived level of space vitality.

In order to improve the perceived level of space vitality, this paper puts forward suggestions from the following two aspects. On the one hand, the key point is to optimize the spatial quality of the built environment on the community level. Ensure the richness of the space in residential areas for outside activities. So as to enhance the type selectivity for activities of the elderly. At the same time, taking the "people-oriented" concept of ecological liveability to organize and optimize the landscape facilities to enhance the sensory experience of the elderly on neighbourhood activities (especially for the physical activities, shopping activities). On the other hand, the timely repair and maintenance of pedestrian facilities should be ensured, and the roaming interest and suitability of road space need to enhance. For example, the planner can base on maintaining the integrity and tidiness of road pavement, the feasibility of walking in streets to improve by optimizing the green vision rate of streets and other ways to promote the interest of walking activities. With planning strategies, the willingness to participate in outdoor activities should be mobilized to meet the health needs of the elderly.

Research Paper

SECONDARY CITIES AND FORCED MIGRATION

Accommodating refugees and asylum seeker in Indonesia

Akino TAHIR, Resilience Development Initiative; Indonesia
Risye DWIYANI, Bandung Disaster Study Group; Indonesia
Saut SAGALA, Bandung Institute of Technology; Indonesia
Nino VIARTASIWI, Resilience Development Initiative; Indonesia

Abstract

Forced migration trend around the world is increasing. UNHCR estimated that more than 65 million people are forcibly displaced in 2015, representing about 26% of all international migrants. In relation to forced migration, secondary cities are also impacted, with many of such cities attract forcibly displaced migrants who view them as more accessible and 'friendly' compared to primary cities. Many secondary cities support the needs of migrants as a first point of entry, shelter, asylum and informal employment. In Indonesia, UNHCR recorded almost 14,000 person-of-concerns in 2015. They are present in about 13 cities, with at least four is considered secondary cities. Although small, the number of forced migrants in Indonesia is expected to increase slowly along with the increasing trend of forced migration around the world. The study explores the capacity of secondary cities in Indonesia in accommodating the influx of refugees and asylum seeker, with Makassar as a case study, using a simplified City Resilience Framework developed by Arup International Development (2015) as a framework. By understanding the system and how it affects displaced people, it is expected that the focus for future improvement that contributes to the city resilience can be identified.

Keywords

Urban refugees, secondary cities, city resilience, Indonesia

1. Global Forced Migration and the Role of Cities

The influx of refugees into countries and cities is an emerging global issue. Doubled over the past two decades. In 2018, there are more than 70.8 million of possibly displaced people worldwide[1], making 1 in every 108 people worldwide forcibly displaced (UNHCR, 2019). Asia and the Pacific alone hosts some 4.2 million refugees mostly from Afghanistan and Myanmar, 2.7 million IDPs and 1.6 million stateless persons. Of this number, two thirds live in urban and suburban areas.

Traditionally, humanitarian actors provide essential services directly to affected population. Working through direct engagement, humanitarian actors often establish parallel structures to deliver their services. However, there is a growing recognition that such approach is no longer appropriate as it can disrupt or undermine existing channels, affect the roles and

responsibilities of local actors, and create tensions with local host communities (IRC, 2017). This needs a change in paradigm, in how humanitarian and development actors work together to support cities to extend their services to the displaced communities.

In 2015 and 2016, countries adopted the 2030 Agenda for Sustainable Development (SDG) and the New Urban Agenda. More than 40 targets across 15 of the 17 SDGs, including SDG 11 on making cities inclusive, safe, resilient and sustainable, have direct implications to migration. The New Urban Agenda adopts an inclusive urbanization model that considers population movements and promotes and protects the rights of all people, while building on their capacity and responds to humanitarian and development concerns. Meanwhile, in the Global Compact for Migration (GCM) and the Global Compact for Refugees (GCR) adopted by countries in 2018, UN General Assembly acknowledges the role that cities play in migration and refugee management.[2] This includes, for example, a recognition to the need of supporting local authorities, finding new mechanism for local engagement, and identifying new ways of working between humanitarian and development actors.

Cities are responding to these global agreements. Mayors and leaders from around the world gathered at the the 5th Mayoral Forum on Human Mobility, Migration and Development in Marrakech in 2018 to endorse GCM and GCR. Included in the statement is a reaffirmation that "*while acknowledging that immigration is a state prerogative, cities are at the forefront of managing the impact of migration. As first responders, cities constantly innovate and develop pragmatic solutions that can have a positive impact at the national and international levels, and therefore, a structured dialogue with local governments on migration issues at national and international levels is fundamental"* (Marrakech Mayors Declaration, 2018). The endorsement put an emphasis on enabling the economic, social and cultural inclusion of refugees, as well as a non-discriminatory access to services and livelihoods. In many countries, this role is taken on by secondary cities (Cities Alliance, 2017).

Secondary cities will account for the largest share of urban growth in developing Asia in the future (Storey, 2014). Already now, these cities are where 20% of the world's population live (UCLG, 2016). The term is mostly used to describe the second tier in the hierarchy of cities.[3] Countries have different ways in approaching their development, but greater levels of decentralisation, devolution, and autonomy will drive a more competitive, dynamic, and self-sufficient growth (Roberts, 2014). While state policy is important as an enabler, facilitator and competitor, secondary cities are on the frontlines of new urban agendas that drive innovations and new policy initiatives, and this requires a reorientation of research and policy attention (Storey, 2014). However, most are not well-prepared with outdated infrastructure, limited financial capability and institutional capacity posing major challenges. In dealing with the impact of global forced migration, they require support to access technical and financial instruments/assistance from global partners (Cities Alliance, 2018).

With all the aforementioned background, this study intends to understand how cities are responding to the global trend of forced migration. The goal is to explore the capacity of secondary cities in accommodating the influx of refugees[4], with Makassar in Indonesia as a case study. By understanding the urban system and how it affects displaced people, the study is expected to identify the focus for future improvement that contributes to city resilience. This rest of this paper is followed up with the explanation of methodology used, the case of urban refugees in Makassar and how the city provides an example of accommodating urban refugees.

2. Methodology

This study relies on mix-method approaches. We adopted the city resilience framework developed by ARUP (2015) as it is one of the most comprehensive available frameworks. Makassar was selected because it is a typical secondary city that functions as a major economy and transportation hub in eastern part of Indonesia. The city hosts almost 10% of total refugee population in Indonesia, making it the third biggest refugee-hosting city in Indonesia after Jakarta and Medan.

2.1. City Resilience Framework

Resilience in this study is used as a concept to understand how different part of the urban systems responds to the impact of forced displacement. Here, resilience refers to "*the ability of the urban system to anticipate, absorb and adapt to shocks and stresses and to respond in ways that preserve, restore or improve its essential functions, structures and identity, while also maintaining the capacity for adaptation and transformation*" (Kirbyshire, et al., 2017)). Urban resilience is a system thinking approach where city is seen as a system or a collection of components that are connected to one another, which may include Built environment, Supply chain and logistics, Basic infrastructure, Mobility, Municipal public services, Social inclusion and protection, Economy, and Ecology (UN Habitat, n.d.).

While several resilience frameworks exist, none explicitly designed for mass displacement, except for a modification of a City Resilience Framework (CRF) originally developed by Arup International Development (2015). CRF outlines 52 indicators under four dimensions of urban resilience: leadership & strategy, health & well-being, infrastructure & ecosystems, and economy & society (*Table 1*). This study is following Kirbyshire, et al. (2017)'s modification of the CRF that clusters the urban system most affected by a rapid influx of displaced people into: Adequate shelter, health care and protection; Basic service provision; Economic development and employment; and Social and political inclusion and community cohesion. As CRF comes with a ready-to-use rapid assessment tool and guideline, we took this advantage by not developing a new assessment tool but instead, making several adjustments that suit and reflect mass displacement context. The final product was used to see how the city fares in each indicator, by giving scores ranging from 1 (very low) to 5 (very high) based on the available data. The result is used to identify the strengths that the city has from resilience point of view and to examine the gaps in welcoming refugees to the city.

2.2. Data Collection

The study relies largely on qualitative analyses based on desk review, targeted informant interviews and field observations. Desk review and interviews were conducted to understand the implementation of global and national refugee management framework and the role of cities in managing refugees, especially in Makassar. Interviews were conducted to the Mayor of Makassar, Politics and National Unity office (*Bakesbangpol*), Social Affairs Office (*Dinas Sosial/Dinsos*), Education Office (*Dinas Pendidikan/Disdik*), and Health Office (*Dinas Kesehatan/Dinkes*), Local Planning Office (*Bappeda*), Housing Affairs Office, Women and Child Protection Office (*DP3A*), Immigration's Detention House Office (*Rudenim*), IOM Makassar, UNHCR Makassar, Subdistrict Offices, and local NGOs. Observation was conducted at several refugee community houses. At the same time, interviews were conducted to several refugees with different gender, country of origin and duration of stay. The open-ended interviews explore their experience of migration, refugee management and

Health and Wellbeing	Economy and Society
Goal 1. Minimal human vulnerability 1.1 Safe and accessible housing 1.2 Adequate energy supply 1.3 Inclusive access to safe drinking water 1.4 Effective sanitation 1.5 Sufficient food supply	**Goal 7. Reduced exposure and fragility** 7.1 Comprehensive hazard and exposure mapping 7.2 Appropriate codes, standards and enforcement 7.3 Effectively managed protective ecosystems 7.4 Robust protective infrastructure
Goal 2. Diverse livelihood and employment 2.1 Inclusive labour policies 2.2 Relevant skills and training 2.3 Dynamic local business development and innovation 2.4 Supportive financing mechanisms 2.5 Diverse protection of livelihoods following a shock	**Goal 8. Effective provision of critical services** 8.1 Effective stewardship of ecosystems 8.2 Flexible infrastructure 8.3 Retained redundant capacity 8.4 Diligent maintenance and continuity 8.5 Adequate continuity for critical assets and services
Goal 3. Effective safeguards to human life and health 3.1 Robust public health systems 3.2 Adequate access to quality healthcare 3.3 Well-resourced emergency medical facilities 3.4 Effective emergency response services	**Goal 9. Reliable mobility and communications** 9.1 Diverse and affordable transport networks 9.2 Effective transport operation and maintenance 9.3 Reliable communication technology 9.4 Secure technology networks
Economy and Society	**Leadership and strategy**
Goal 4. Collective identity and community support 4.1 Local community support 4.2 Cohesive communities 4.3 Strong identity and culture 4.4 Actively engaged citizens	**Goal 10. Effective leadership and management** 10.1 Appropriate government decision-making 10.2 Effective coordination with other government bodies 10.3 Proactive multi-stakeholder collaboration 10.4 Comprehensive hazard monitoring and risk assessment 10.5 Comprehensive emergency management
Goal 5. Comprehensive security and rule of law 5.1 Effective systems to deter crime 5.2 Proactive corruption prevention 5.3 Competent policing 5.4 Accessible criminal and civil justice	**Goal 11. Empowered stakeholders** 11.1 Adequate education for all 11.2 Widespread community awareness and preparedness 11.3 Effective mechanisms for communities to engage with the city government
Goal 6. Sustainable economy 6.1 Well-managed public finances 6.2 Comprehensive business continuity planning 6.3 Diverse economic base 6.4 Attractive business environment 6.5 Strong integration with regional and global economies	**Goal 12. Integrated development planning** 12.1 Comprehensive city monitoring and data management 12.2 Consultative planning process 12.3 Appropriate land use and zoning 12.4 Robust planning approval process

Table 1. Dimension, Goals, and Indicators of City Resilience Framework

arrangement (e.g. protection, living arrangement, etc), access and use of public and social facilities, economic and social participation, and experience of spaces in Makassar. Special care was given to interviews with minors to ensure consent are given by guardians.

2.3. Limitation of Study

Several limitations were identified during the study. *First*, although the City Resilience Framework by ARUP has been used in many cities around the world as a practical tool to assess city resilience (see for example works by 100 Resilient Cities pioneered by the

Rockefeller Foundation), its use to assess resilience in the context of mass displacement is limited. Kirbyshire, et al. (2017)'s attempt to 'translate' the tool for mass displacement context is limited to conceptual modification and this research is perhaps one of the first attempts to use the modified tool in practice, especially in the Asia and the Pacific region. As such, we acknowledge that the process of experimenting with the tool is still ongoing and there will be more discussions necessary before it can be used more appropriately to assess how cities can be better prepared in the future to deal with mass displacement. Moreover, due to limitation in resources, the assessment in the research was done by researchers, not through collaborative effort of relevant stakeholders as the tool was intended to.

Second, while there has been several papers, reports, and discussions available on urban refugees internationally, such literatures on Indonesia, and Makassar in specific, is very limited. It resulted in heavy reliance to interviews and observation results, and thus, affecting the quality of data triangulation. We acknowledge researcher bias during the study design, data collection, analysis and report writing. Moreover, confirmation bias may happen as the researchers form a hypothesis or belief and uses respondents' information to confirm that belief. To reduce such bias, researchers went through an iterative process of discussion and reflection throughout the research process. *Third*, while the government, international organisations and other relevant stakeholders in Makassar are open to discussion, several key information was not accessible at the time of the research. This includes for example demographic profile of the refugees, guideline for selection of community house or other guidelines related to refugee management by international organisations in-charge. Such information was obtained through interviews and triangulated only by iteration of the same information by different stakeholders and/or local news records.

3. Refugees in Makassar

Indonesia has been hosting refugees from overseas since 1975 with the arrival of Vietnam and Cambodia refugees. While it is a non-signatory of the 1951 Refugee Convention or the 1967 Refugee Protocol, the Government of Indonesia (GOI) cooperates with United Nations High Commissioner for Refugees (UNHCR) and various organizations to serve and find solutions for international refugees transiting in Indonesia. In 2016, GOI set its first legal framework on refugee protection, a Presidential Decree on Handling of Refugees from Overseas (Perpres No.125/2016). The regulation acknowledges the "refugee" status and stipulates the protection of refugees while they temporarily stay in Indonesia. The policy to separate refugee cases with human trafficking cases and to honour the principle of non-refoulment is regarded as a good approach in refugee management (Ansori, et al., 2017). The regulation also sets that the budget for handling refugee issues is from state budget through relevant ministries and other unbinding sources. The following section describes the current situation of refugees in Makassar and how the city elements responded to the situation, based on field interviews in April and June 2019.

3.1. General overview

Makassar is the capital city of South Sulawesi province with a population of 1,653,386 in 2015 and annual growth rate of 4.11% (Makassar Local Planning Agency, 2015). The city has been a hub since Gowa Kingdom opened its ports for international traders back in the 16-17th century and the port developed to be the main trading gate to eastern part of the

country (Marihandono, 2008). According to the Spatial Plan 2015-2034, the city envisions to be “A liveable world city for all”. Makassar was awarded the second most innovative city in Indonesia in 2018 by the Ministry of Home Affairs. Meanwhile, the governor of South Sulawesi was received an award in 2016 from the Minister of Law and Human Rights for superior efforts of the Makassar immigration authorities in “supervising foreigners”.

Since 2015, the city government has an annual MOU with International Organisation for Migration (IOM); the first city in Indonesia to do so. The legal framework allows IOM to work with relevant city offices, such as *Bakesbangpol, Dinsos, Disdik,* and *Dinkes*, for provision of services and protection to refugees in the city. The government opens the access to existing services for refugees, especially education and health care. The government also allow linkage to existing system for other public services and infrastructure such as energy, clean water, wastewater and waste management, transportation, public spaces, and others. However, with the absence of the operational guidelines of the Perpres No.125/2016 at the local level, the city is unable to allocate special budget for refugee management, and as such limits the government ability to be more actively involve. Currently, the budget is not separated from budget for pro-poor policy and programs (*Bappeda* Interview, 18 June 2019).

As of June 2019, there are 1,813 refugees living in Makassar (IOM Interview, 21 June 2019). Majority received allowance and assistance from IOM, which include provision of community housing and facilities, support to access health services, basic education for children, and skills building programmes for youth and adults. A small number of refugees (37 people in June 2019) do not receive IOM assistance because they arrived in Makassar after 15 March 2018, which as per IOM internal policy, are not eligible for assistance. They are living independently, with limited support from local organisations or individuals. Meanwhile, UNHCR provides protection-related support while processing their refugee application.

3.2. Shelter and basic services

There are 26 community houses or shelters in Makassar where refugees live. They were formerly functioned as rented rooms for college students or workers, spreading in 8 out of 15 districts in Makassar. Buildings are mostly two storeys or higher, located within settlements of local communities or small-scale business areas. Each shelter houses refugees from different country of origins. Based on observation, there are two types of community house according to the demography of the building occupants, i.e. female-only and mixed family-and-single male. All shelters are equipped with electricity, water and sanitation systems. Occupants received limited quota for electricity and paid for their excess bill, while other utility fees are paid by IOM through shelter management. Quality of the shelters vary, but all are accessible to local market, health care facilities, schools and. Some shelters are shown decreasing standard of quality services, such as deteriorated water and sanitation quality, bad air circulation, lack of common spaces and open spaces.

The room is usually designed for two people (or more if children), with beds, AC, cupboard and a bathroom. Family with children can have more than one room depending on the number of the children. Some shelters also provide TV in common areas, although some own TV in their room. Most shelters have kitchen for communal use. In the shelter with no communal kitchen, families cook inside their rooms. Washing machine is available in the common area, but some occupants buy their own machine and do laundry inside their room. It is common for refugees to have smartphones to communicate with their families or friends. Some shelter provides internet connection for free, some refugees pool resources to

provide it on their own, while some others use mobile connection. Refugees are not allowed to have a driving license and affordable public transportation in Makassar is lacking. Bicycles and walking are the common mode of transportation, although some reported a sense of insecurity due to accident or crime. Only male refugees use bicycles, female refugees walk or take public transportation. Pedestrian ways are only available in the city centre, so those living in areas with high volume of traffic are prone to accidents.

3.3. Healthcare and Education

On healthcare service, refugees under IOM protection receive service at the same standard of healthcare service as majority Indonesian, delivered by local community health centre (Puskesmas). Puskesmas also provides vaccines, pregnancy check-up, and regular educational session on health-related topics. Puskesmas will refer refugees with serious medical cases to appointed hospitals depending on the type and complexity of the case after obtaining IOM approval. Healthcare for refugees has not yet linked with public healthcare system under JKN (National Health Insurance) program because it is unclear who will pay for the monthly membership fee and which insurance plan's category the refugees will fall into. However, IOM Makassar created a program parallel to JKN membership scheme, where refugees are provided with basic health services at the same rate as JKN rate with IOM covering the fee. Inpatient treatment is covered under the basic coverage but can be upgraded at the patient's request and own funding. A medical team in IOM is assigned to oversee the overall healthcare activities.

In education sector, Makassar government and IOM now agreed to provide early childhood education and basic education for refugee children, allowing them to go to public school for free subject to available slots in the schools. Several refugees attend private high school with scholarship from the school. Currently there are 17 primary and secondary schools accepting refugees, although there is no accessible data on the number of refugee children attending school. Some students reported dropping out due to bullying, language barrier, or high transportation cost. Responding to the situation, some refugees organized informal classes for children in shelters, including a non-formal school in one shelter. IOM also engage Indonesian volunteers to teach informal classes at some shelters, both for children and adults. Meanwhile, UNHCR accommodates refugees through *Kejar Paket*, an existing non-formal public education system that follows the national curriculum. There is still no solution to the challenge of providing higher education, except through informal vocational trainings provided by *Disdik* and local NGOs who collaborate with UNHCR and IOM. While organized quite regularly, refugees reported that it is not sufficient.

3.4. Economy and employment

Pertaining to Indonesian regulation, working is strictly forbidden for refugees. All refugees under IOM care received monthly allowance of around $100 USD per adult and $40 USD per child. They use it for daily basic needs, such as food, drinking water, personal hygiene, transportation and communication fees. Some received support from family members abroad, some engaged in informal economic activities, some others utilize technological advance to engage in e-commerce activities. Those not under IOM care are relying on their family members who are already under IOM care, individual donations, or support from local NGOs. Meanwhile, the city government acknowledge that the allowance is below the local salary standard (UMR) and deemed insufficient. In an interview with the Mayor, he stated that Indonesia needs to explore an innovative policy to allow refugees to work as working is

a form of self-actualization and can contribute local economy and social development. However, the Mayor limited the possibility to certain professions such as blue-collar jobs (Mayor Interview, 29 June 2019).

3.5. Leisure and social life

Based on observation, refugees spent majority of their time at shelters, in their rooms. This is especially true for the elderly, children who are not at school or any other educational activities, and women with family. Interactions among occupants vary depending on the shelter design and homogeneity of country of origin in the shelter. We observed more interaction among occupants in shelters with common spaces and kitchen.

Field observation showed that compared to those living in business or mixed-use area, refugees living in shelters located in residential areas have more chance to interact with locals and generally have better impression of the host communities. Women have more motivation to interact with local housewives or sellers in the market, while children who go to public school made friends with Indonesians. Young, male refugees venture outside of the shelters more often than female refugees, for example to play football with their local friends, go to gym or other sports facilities, parks, malls or local markets. Female refugees usually go out to the local markets or shopping malls, rarely beyond that. Going out for outing, even to nearby beaches, is very rare and some reported negative experience with crime or accident.

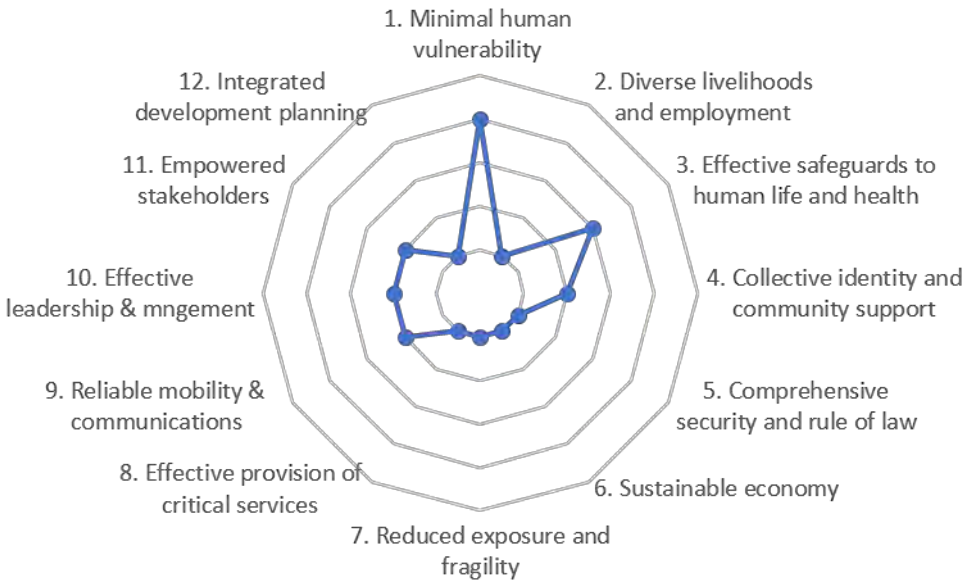
Refugees are bound to *Rudenim's* regulation on movement. They can leave the shelter from 5 or 6 am and should be back before 10 pm. Staying overnight requires permit that can only be obtained at the *Rudenim* office in Gowa Regency, about 45 minutes from Makassar city centre by car. Refugees must report once a month to *Rudenim*, which can be done through the shelter management or *Rudenim* staffs placed in several shelters. Political and social association are not allowed. Hence, refugees who staged protest at IOM or UNHCR offices to demand for faster resettlement processes or other demands are at risk of being detained in the Detention Center (IDC) managed by *Rudenim* in Gowa Regency. Moreover, refugees can be detained in the IDC if deemed as causing public disturbance, which can be interpreted in the broadest sense. The length of detention is at the discretionary of the *Rudenim* Head.

4. Discussion

This section provides the results of an assessment on Makassar city resilience in facing refugee issue as a new type of stress to its urban system (Figure 1). In general, the assessment showed that in managing the influx of mass displacement in Makassar, *minimizing human vulnerability* has the highest score among resilience goals. Meanwhile, the lowest score is the goals related to livelihood and employment, security and rule of law, economy, exposure and fragility, critical services, and integrated development planning. The following part provides explanation on these resilience goals within the clusters of urban system most affected by mass displacement as described in Section 2.1.

4.1. Adequate shelter, health care and protection

The highest scores for minimizing human vulnerability and safeguards to human life and health (Indicator 1.1, 1.5, 3.1-3.3, 5.1) showed that fulfilling basic needs is the first priority for the relevant stakeholders, including the city government, and our research showed that



Source: Analysis

Figure 1. Scoring of Makassar City Resilience in Refugee Management based on CRF Indicators

this priority has been met well. It is important to note that this is possible because the government received a high degree of support from IOM that enable the majority of refugees staying in Makassar to afford food, shelter and health care. Linking health care for refugees to existing public system also enables affordable services that will otherwise boost the healthcare cost for the refugees if they were to access private services. Problems are evident for those who are not under IOM care. If the number increases, the city government must find ways to support them.

Related to protection, there are three relevant city resilience indicators: effective systems to deter crime, competent policing, accessible criminal and civil justice (Indicator 5.1-5.3, and 5.4). The scores are lower as security and rule of law in Makassar is somehow understood as a responsibility of *Rudenim. Rudenim* is a part of the national government system, hence city government has no influence over their decision even though related city elements (police, *Bakesbangpol*) are involved. Missbach, et al. (2018) noted that treatment of refugees and asylum seekers in Makassar remains imbued with security and surveillance motives. In the absence of a clear and transparent mechanism to other city stakeholders, the approach to security and rule of law is prone to subjectivity of *Rudenim* officials. This increases the vulnerability of refugees who got caught up in the system. It is to note that one aspect of protection, that is protection to women and children rights is linked to the city's mechanism. The Integrated Service Centre for Women and Child Protection (P2TP2A) will handle cases of, for example, domestic violence, harassment, child abuse before *Rudenim* intervenes.[5]

4.2. Basic service provision

This cluster includes indicators on basic infrastructure and services, such as water supply, electricity, drainage and sanitation, other utilities, environment, transportation, communication, building codes, green ecosystem, and public finance. The scores are higher for indicators related to physical infrastructure and services (Indicator 1.2-1.4, 7.2-7.3, 8.2,

9.1-9.3), because they are basically provided by IOM who must conform to a certain internal standards and city regulation. Moreover, the infrastructure and services are connected to the city-wide system, with either IOM pays the fees directly to the utility providers or the refugees themselves pay for the cost of transportation and communication which are still affordable. The score is lower for public finance indicator (6.1) as the city do not have financial mechanism to provide budget for infrastructure and services for refugees. This is not a problem for now with IOM supporting the city government but may be a problem in the future should the number of refugees outside IOM care increases.

4.3. Economic development and employment

All relevant resilience indicators in this cluster (Indicator 2.1-2.4, 6.3-6.5) have the lowest scores because of the Indonesian policy that prohibits refugees to work. Higher scores were given to indicators related to informal economy considering the reality that some refugees are engaged in informal activities among themselves or with local community. This shows that Makassar has, to some degree, rather adaptable economy albeit informal and people can find alternative to engage in livelihood activities. The Mayor's personal view on possibility of work for refugees also showed a positive intention that can encourage economic integration in the future should the national policy direction changes.

4.4. Social and political inclusion and community cohesion

There are several topics covered under this cluster. Education indicator (11.1) has the highest score because refugees have the same access to basic education as Indonesians, albeit various limitation in practice. Our analysis showed that all stakeholders put education as one of the highest priority services to be made available, and this priority has been met well. Makassar became of the first cities to open its public schools to refugee children. Moreover, international and local organizations also worked to fill the gap through informal or non-formal education, including vocational skills building to those who cannot enter public education system. Indicators related to governance (10.1-3) scores higher considering the overall response of the local government in welcoming refugees in Makassar. The first key decision of the then-mayor to establish a working MOU with IOM and to take collaborative approach, both with internal and external stakeholders, are the main driver behind all the advances behind the city's refugee management approach.

On the other hand, indicators related to community support and social participation (Indicator 4.1-4.4, 11.3) score lower for several reasons. The ability of refugees to build community cohesiveness and social support among them is heavily influenced by shelter design and distribution of occupants in the shelters, as people are more likely to feel supported by others who come from similar background. Although refugees have access to public spaces, sports facilities, and other open spaces in the city and they regularly interact with host communities, their movement is relatively restricted and closely monitored by the authorities. This resulted in limited expression of identity, either individually or in group, and thus limited overall social participation. In this sense, while the city has 'control' over physical spaces in which refugees can utilize for social purposes such as leisure or interaction with others, it barely has influence over the social spaces in which the refugees can actively engage, express opinion and participate in the larger society.

There are several other indicators that are given the lowest score because they were hardly mentioned by any of the stakeholders during the interviews nor showed up in any documents discussing refugees in Makassar. They include indicators related to disaster management preparedness, response and contingency plan (2.5, 3.4, 6.2, 7.1, 7.4, 8.3-5, 9.4, 10.4, 10.5, 11.2) and integrated development planning (8.1, 12.1-4). This indicates that the topics are not considered relevant nor important for the stakeholders when discussing refugees. The current development planning process and output in Makassar has not seen refugees as potentially posing additional stress to the existing urban system.

5. Conclusion

In this study, we have shown how the framework of city resilience can be used to to measure the relevance of urban resilience framework with urban refugee case in Makassar.

The study found that in managing the influx of refugees, Makassar has several strengths that the city can leverage on: 1) the early decision to link public service provision to refugees with existing system in the city; 2) the decision to work with IOM and secure its support on shelter and assistance to refugees; and 3) collaborative approach, good internal coordination, and welcoming culture of the city leaders. These points hold the key to good refugee management in the city, which indicates the ability of the city to adapt and respond to stress. The study also identified gaps that the city can focus on to improve their urban resilience in the context of mass displacement: transparent and accountable mechanism in enforcing security and rule of law, exploring alternatives to livelihood activities for refugees within the boundary of national regulation, financing mechanism for refugee management outside of IOM support, encouraging the creation of social space where refugees can express themselves more freely and participate more in the society, and include refugee management discussion in the city development planning process and outcome. Addressing these gaps, however small, will reduce the vulnerabilities of refugees when transiting in Makassar and help the city to be more resilient in the future.

Furthermore, the exercise that we conducted on Makassar can be extended in other refugee-hosting cities with similar situation. This is especially considering that all around the world, cities are at the forefront of the global response to the increasing impact of forced migration. Thus, developing a methodology that integrates urban resilience framework that is adaptable to urban refugee phenomena will be essential.

[1] This includes refugees, asylum seekers, and Internally Displaced Persons (IDPs).

[2] While GCR recognizes the important role that cities play, it does not detail how it should work at the local level. For an analysis of key components in GCR that are relevant to cities, see Brandt & Henderson (2017)

[3] Roberts (2014) noted that there are three broad spatial categories of secondary cities: Sub-national cities that are centres of local government, industry, agriculture, tourism and mining; City clusters associated with expanded, satellite and new town cities surrounding large urban metropolitan areas; and Economic trade corridors that are growth centres planned or developing along major transport corridors. The characterization can also be based on its function and integration in a system of cities.

[4] Going forward, the term "refugee" in this research refers to refugees, asylum seekers and stateless persons, and excluding IDPs, illegal migrants, or other people of concern

[5] In Indonesia, Makassar is regarded as an advanced city in programming in child protection system although agencies working at the primary level (prevention) and secondary level (early detection) are still lacking (Save the Children, 2018)

Research Paper

Sustainable Urban Development: Building Healthy Cities in Indonesia

Linda DARMAJANTI, Urban Development Studies, Universitas Indonesia; Indonesia

Daniel Mambo TAMPI, Architecture Engineering, National Institute of Science and Technology; Indonesia

Irene Sondang FITRINITIA, Urban Development Studies, Universitas Indonesia; Indonesia

Abstract

The urban process or commonly called urbanization is a phenomenon that is occurring in several regions in Indonesia. In 2045, the projection results show 61.7% of Indonesia's population will live in urban areas. In the process, cities in Indonesia are facing several challenges related to Urban Infrastructure, decent and affordable housing, clean environment, local economic, slum, and urban poor (Social welfare). These indicators can have a positive impact on increasing the city index with healthy city categories, but also can have a negative impact with the increasing gap between the poor and the rich. The purposes of this study are to find out which cities in Indonesia fall into the category of healthy cities and to find out what factors and actors play a role in building healthy cities in Indonesia. The analytical method in this study is log frame analysis. The result is building healthy cities is closely related to the availability of aspects of life in urban areas: health services, environmental, and socioeconomic aspects. There are 3 cities in Indonesia: Palembang, Solo and Denpasar City. Building a healthy city is also an effort in improving health status, health facilities, cleanliness, garbage services, food availability, clean water, security, safety, park facilities, public transportation, art and culture facilities, housing, urban economics, religious facilities, and urban planning quality. Healthy cities in Indonesia will be achieved if efforts to improve not only physical health but also mental, social, economic and spiritual health are achieved. Finally, building a healthy city in Indonesia is an effort to contribute to sustainable urban development.

Keywords

Urbanization, Healthy City, Urban Development, Sustainable

1. Introduction

1.1. Subheading 1.1

Healthy cities are cities that continue to create and improve the quality of the physical and social environment and expand community resources that enable people to support one another. To carry out all functions of life and develop the maximum potential of society (Glouberman, 2014). To realize a healthy city, an approach that is in accordance with the urgency of the city's problems is needed. In the urban context, urbanization is an issue that cannot be released and will continue, especially in cities in developing countries. This phenomenon is related to increasing population and the extent of the city's physical

development. Rapid growth and development requires the city to prepare and organize various facilities that can support activities in urban areas.

Based on the projection results in Indonesia, in 2045, 67.1% of the population will live in urban areas (Ministry of National Development Planning, 2019). In the process, urbanization produces many impacts on the aspects of infrastructure, socio-economic and environment. The impact also adds to the long list of problems with the issue of the low quality of human life in urban areas. This is motivated by the unpreparedness of cities to provide basic needs of the community as a result of the process of urbanization. The basic needs includes in the form of inadequate housing prices, low quality of clean air and water, security, employment and other supporting facilities. The easiest thing to see regard the health issue in city is the pollution issue have been occurred in Jakarta for these past two weeks (Jakarta Post, July, 2019). Achieving a good quality air in Jakarta has been very challenging since the transportation mode in Jakarta less integrated. Even there is a "newcomer" MRT, but the effect still does not give a big effect to air status in Jakarta. Since the real time indexed and Greenpeace had announced that Jakarta being heavy polluted according the World Health Organization (WHO) standards which known as PM2.5. It was above the WHO's safe limit of 10 micrograms per cubic meter (µg/m3). This particle is very harmful if come into human respiratory system and the human body. Vehicle engines, industry, wood and coal burning becomes source that exacerbated the atmosphere. Therefore, city dwellers face a clear and present enemy called air pollution.

Another thing is the existence of contagious tropical disease while mosquito become vector of the dengue fever. Since the urbanization dense the area with the built up area, it eliminate the mosquitos habitant and could trigger the distribution of dengue fever. More than 2,000 people in Indonesia's capital Jakarta have been diagnosed with dengue fever in January this year, with one person confirmed killed by the mosquito-borne disease (Strait Times, March 2019)

Currently these challenges are faced by cities in Indonesia. If these things are not immediately corrected and their quality is improved, the consequence is that there is a gap /inequality development between the poor and the rich. This will also hamper efforts in realizing sustainable urban development. The following is a projection of the Indonesian population in metropolitan cities.

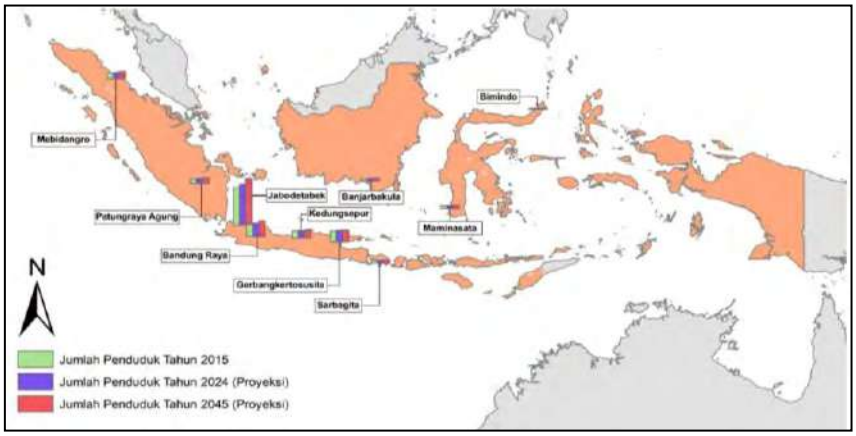

Figure 1. The Projection of The Indonesian Population in Metropolitan Cities (Source: Ministry of National Development Planning, 2019)

Figure 1. Indicates that there is an increase in the number of residents in 2 periods of 20 years between 2015-2024 and 2024-2045. The Jabodetabek area is an urban area that is superior in terms of population, followed by Bandung Raya, and Gerbangkertasusila. The metropolitan cities above need to pay attention to the challenges of urbanization by building a healthy city concept. In addition, it should be noted that aspects must be improved by looking at the city index based on aspects of security, safety, health, health facilities, cleanliness, solid waste, the city's economy, food sufficiency, quality of city parks, clean water services (IAP, 2017). These aspects are a support in building a healthy city.

The WHO measurement, until the Ministry of Health Index and Livability City Index. The concept of a healthy city involves two important aspects, namely place and people in addition to improving the quality of the physical environment, healthy cities also play a role to improve the quality of human life, ensure the welfare of the urban community, and access for all. The purpose of writing this article is to find important factors and actors in building healthy cities and any city that is ready to implement a healthy city. The concept of a healthy city is also part of efforts to realize sustainable city development.

2. Materials and Method

2.1. Materials

The Healthy cities concept focuses on the process, not just the outcome. It is obvious from the definition that a Healthy City requires a continuous development process that has no end point. lt is not necessarily one that has achieved a particular health status. It is conscious of health as an urban issue and is striving to improve it. Any city can be a Healthy City if it is committed to health and has a structure and process to work for its improvement (Department of Health, Hongkong, 2007)

The Healthy Cities approach emphasizes the way that the city environment (conceived very broadly) influences the health of residents. This approach explicitly acknowledges the diversity and interconnectedness of the many elements of urban living. It is a holistic approach that assumes that everything within a community is connected, and cities therefore need to get many sectors involved in developing public health policies. (Glouberman, 2014). In their approach to healthy cities, “health” includes not only physical health, but also mental, social, economic, political, and spiritual health. They list the following 11 features of a healthy city: 1) A clean, safe, high-quality physical environment (including housing quality). 2) An ecosystem that is stable now and sustainable in the long term. 3) A strong, mutually supportive, and non-exploitative community. 4) A high degree of public participation in and control over the decisions affecting one's life, health, and well-being. 5) The meeting of basic needs (food, water, shelter, income, safety, and work) for all the city's residents. 6) Access to a wide variety of experiences and resources with the possibility of multiple contacts, interaction, and communication. 7) A diverse, vital, and innovative city economy. 8) Encouragement of connectedness with the past, with the cultural and biological heritage, and with other groups and individuals. 9) A city form that is compatible with and enhances the above parameters and behaviours. 10) An optimum level of appropriate public health and sick care services accessible to all. 11) High health status (both high positive health status and low disease status). This list serves as a guideline for cities participating in the Healthy Cities movement, sponsored by the World Health Organization. Hancock and Duhl in Gloubermen (2014) also emphasized the importance of the involvement of local governments in health promotion.

In addition to the factors in building healthy cities in Indonesia, the previous factors are also related to Several Missions in Sustainable City Management in Indonesia, namely Mission 2 Livable and Inclusive, Mission 3 Advanced Cities, Green City Missions in order to Manage of metropolitan cities in Indonesia. Mission 2 Providing basic service access for every resident to basic services (a.l. settlement, transportation, drinking water, sanitation). Healthy city planning should be viewed as healthy urban planning and readily connect the two into a more holistic approach to improve the health and lives of communities. (Portney, 2017). Using planning to achieve healthier cities occurs at the intersection of two disciplines. Although having a history of collaboration, and having common roots, the two disciplines have built-up working practices that make joint working difficult (Arthurson, Lawless & Hammet in Grant, 2019). A simple caricature of the two disciplines would be:

- Public health: Population level interventions focused on people.
- Planning: Population level interventions focused on place.

Of course, in reality public health can be concerned with place and environment, but in other instances having just a narrow focus on the individual. An approach for using the physical planning and design of cities was specifically developed within the World Health Organization (WHO) European Network of Healthy Cities. This initiative began in 1988, and is still continuing today, with phase VII launched in 2018. Each phase lasts about five years, with cities across the WHO European region eligible to apply phase by phase (Grant, 2019).

Sustainable urban development seeks to create cities and towns that improve the long-term health of the planet's human and ecological systems. It assigns human and ecological systems equal importance, and implies that the health of both is interdependent. (Wheeler, 1996)

2.2. Method

The method of data collection in this article is a literature study of healthy city concepts, using livable city index IAP 2017 and the management mission of sustainable cities in Indonesia. The analysis in this article is to use the log-frame analysis method. To answer the first goal, namely modifying data based on city index that is feasible for 2017 IAP, selecting several indicators related to the concept of a healthy city then selecting 3 cities with the highest number of indexes. To answer the second goal in this study is to analyze what needs to be improved in developing healthy cities based on the concept of healthy cities in developing countries that are integrated with factors in the city index that is feasible for 2017 IAP, and analyze who the actors / stakeholders play a role in cities that are close to the criteria for healthy cities, namely Palembang, Solo and Denpasar City. At the end of the analysis, triangulation of data will be displayed to explain the purpose, theory, methodology, analysis, result and source of data.

3. Result and Discussion

3.1. Cities with Healthy City Index

The following is a healthy city index indicator table taken from the 2017 Livable city index IAP book, there are 16 indicators chosen in terms of building healthy city concepts namely security, safety, health, health facilities, cleanliness, garbage services, urban economics, food, housing, park facilities, clean water, transportation, art and cultural facilities, public participation, religious services and urban planning quality. The following is a healthy city index table in Indonesia.

Table 1.Indonesia Health City Index

No	Cities	Point	Average Point	Explanation
1. Security				
1	Banjarmasin	73	58	A security sense of city residents from crime
2	Pekalongan	69		
3	Denpasar	68		
2. Safety				
1	Palembang	63	55	A sense of security from disaster, and the quick response of disaster early warning
2	Solo	62		
3	Semarang	62		
4	Yogyakarta	61		
3. Health				
1	Solo	66	58	Living environment free from the threat of disease outbreaks
2	Semarang	65		
3	Depok	63		
4. Health Facilities				
1	Bandung	77	71	An easement of obtaining health services and quality of health services
2	Semarang	76		
3	Solo	75		
4	Balikpapan	75		
5. Cleanliness				
1	Palembang	70	58	The level of cleanliness of the air, the level of cleanliness of the river and the level of cleanliness of the city road
2	Samarinda	69		
3	Palangkaraya	63		
4	Banjarmasin	63		
6. Garbage Service				
1	Balikpapan	77	63	Quality of solid waste services in the city
2	Palangkaraya	69		
3	Semarang	69		
4	Makassar	69		
5	Bandung	68		
7. Urban Economics				
1	Palembang	66	57	An easement of getting a job, easy to develop business, and afforfability of living costs
2	Pekalongan	63		
3	Yogyakarta	62		
8. Food				
1	Denpasar	81		An easement of obtaining basic needs and the quality of
2	Bandar Lampung	81		

3	Mataram	80	76	nutrition of food consumed
4	Pontianak	79		
5	Balikpapan	79		
6	Palangkaraya	79		
9.	**Housing**			
1	Manado	66	58	An easement of owning a house and the physical quality of a residential house
2	Palembang	65		
3	Pontianak	64		
10.	**Park Facilities**			
1	Denpasar	77	65	How easily city residents access and use city parks, assess the quality of city parks, and how easily disabled people access and use city parks
2	Malang	75		
3	Bandung	74		
11.	**Clean Water**			
1	Malang	81	75	Access to clean water services
2	Surabaya	81		
3	Tangerang Selatan	80		
4	Manado	79		
12.	**Transportation**			
1	Bandung	65	56	City traffic conditions, traffic accident rates, road quality, availability of public transportation, quality of public transport services, and ease of reaching the destination
2	Palembang	63		
3	Palangkaraya	61		
13.	**Art and Culture Quality**			
1	Denpasar	68	60	Using arts & cultural facilities, then on the quality of the facility itself, and how much frequency the city residents enjoy the arts and culture festival in their city
2	Solo	62		
3	Palangkaraya	61		
4	Surabaya	61		
5	Malang	61		
6	Yogyakarta	61		
14.	**Public Participation**			
1	Banjarmasin	55	38	Citizen involvement in city development
2	Pekalongan	46		
3	Makassar	45		
4	Solo	45		
15.	**Religious Services**			
1	Banda Aceh	83		The level of quality of religious

2	Manado	82	56	services in the city
3	Pontianak	82		
4	Banjarmasin	81		
16.	**Urban Planning Quality**			
1	Makassar	76	76	General quality of the city
2	Palembang	74		
3	Bandung	71		

Source: Modified from IAP Livable City Index, 2017

Based on the 16 Indicators above, there are 3 cities with the top indices which can be categorized as cities that are ready to go to a healthy city. These cities are Palembang, Solo and Denpasar. The city of Palembang is superior to 7 indicators, namely Safety, Cleanliness, Solid Waste Service, City Economy, Housing, Transportation, and Quality of City Planning. The City of Solo excels at 5 Indicators, namely Safety, Health and City Health Facilities, Arts and Culture Facilities, and Public Participation, Denpasar City excels at 4 Indicators namely Security, Food, Garden Facilities, and Arts and Culture Facilities. The following is a list of the top 3 cities that have been processed based on 16 livable city index indicators for IAP 2017.

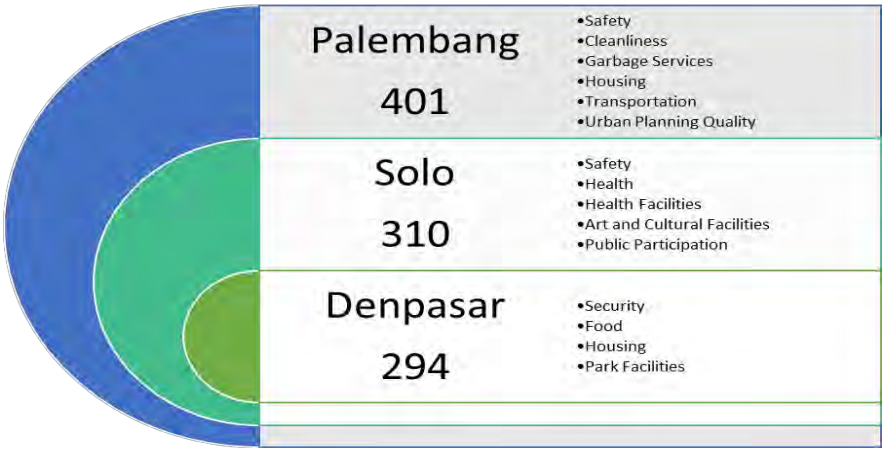

Figure 2. Top 3 Toward Healthy Cities in Indonesia (Source: Private Process, 2019)

Figure 2. describes the 3 cities in the top list of several healthy city concept criteria. Although it is still far from the concept of a healthy city, this is a good step to continue to improve the quality of the places and activities of people who live in the city. There is no maximum quality limit in building a healthy city. Building a healthy city is a process that must be sustainable because it will be related to the issue and dynamic. To continue the ongoing process, it is necessary for actors who play an important role in realizing a healthy city in Indonesia. The strategy in building healthy cities in Indonesia will be outlined in the log-frame analysis table which contains how to achieve nobel aim, goal and purpose.

3.2. Factor and Actor of Building Healthy City in Indonesia

The following is a log-frame analysis framework table that explains the description of nobel aim, goal and purpose in building healthy cities in Indonesia

Table 2. Log-frame Analysis Building Healthy Cities in Indonesia

No	Noble Aim			
	Building Healthy Cities in Indonesia			
	Goal	**Factor**		**Important Assumptions**
1	Increasing Place and Environment Quality	Health facilities, Cleanliness, Garbage Services, Housing, Park Facilities, Transportation, Art & Cultural Quality and Urban Planning Quality		By increasing the index on these factors it is assumed that it can improve the quality of the place and the city environment
2	People	Health, Security, Safety, Urban Economics, Food, Clean Water, Park Facilities, Transportation, Art and Cultural Quality, Religious Services, Public Participation		Increasing the index on these factors is assumed to increase people quality
	Purpose	**Measurement**	**Actor**	**Important Assumptions**
1	Health facilities	The ease of getting Health Services	City Health Agency	Assumed to reach goal 1
2	Cleanliness, Garbage Services, Park Facilities	The level of cleanliness of the air, the level of cleanliness of the river, and the level of cleanliness of the city road	City Sanitation and Landscaping Office and Environmental Agency	Assumed to reach goal 1
3	Housing	The ease of owning a house and the physical quality of a residential house	Public Housing Agency and Settlement Area	Assumed to reach goal 1

4	Transportation	City traffic conditions, traffic accident rates, road quality, availability of public transport.	Department of Transportation	Assumed to reach goal 1
5	Art & Cultural Quality	Use arts & cultural facilities, then towards the quality of the facility itself	Culture and Tourism Agency	Assumed to reach goal 1
6	Urban Planning Quality	General city quality in the city	Cipta Karya, Spatial Planning and Land Agency	Assumed to reach goal 1
7	Health	The living environment is free from the threat of disease outbreaks	Health and Environmental Agency	Assumed to reach goal 2
8	Security	The security of the city residents from crime or crime	Regional Police	Assumed to reach goal 2
9	Safety	A sense of security from disasters, and the speed of disaster early warning	Regional Disaster Management Agency, Meteorology and Geophysics Agency	Assumed to reach goal 2
10	Urban Economics	Ease of getting a job, ease of business development, and affordability of living costs	People's Economic Agency	Assumed to reach goal 2
11	Food	The ease of getting basic food and the nutritional quality of food consumed	Agriculture and Health Agency	Assumed to reach goal 2
12	Clean Water	Access to clean water services	Environment and Public Works Agency	Assumed to reach goal 2
13	Park Facilities	How easily disabled people access and use city parks	Agency of Sanitation and City Parks and Social Service	Assumed to reach goal 2

14	Transportation	The quality of public transport services, and the ease of reaching the destination	Department of Transportation	Assumed to reach goal 2
15	Art & Cultural Quality	How much frequency do city residents enjoy art and culture festivals in the city	Cultural and tourism agency	Assumed to reach goal 2
16	Religious Services	The level of quality of religious services in the city	Religious Service	Assumed to reach goal 2
17	Public Participation	Citizen involvement in city development	All Services and All Elements of the Citizen	Assumed to reach goal 2

Source: Personal and Modified from IAP Livable City Index 2017

Table 2. Describes the description of log-frame analysis on how to build healthy cities in Indonesia. The nobel aim of the log-frame analysis is to build healthy cities in Indonesia. To achieve the nobel aim, there are two goals, namely place and people. To achieve the goal place, The index is needed on 8 factors, assuming to increase the index of those factors, the quality of the place and the environment of the city will improved. To achieve the goal of people, The index is needed on 11 factors, assuming that increasing the index on those factors is assumed to increase people quality.

Each goal has actors who play a role in building a healthy city for the first goal, the actors who play a role are the City Health Agency, City Sanitation and Parks Service as well as the Environment Service, Public Housing and Settlement Services, Transportation and Transportation Agency, Cultural and Tourism, Cipta Karya, Spatial Planning and Land Agency. Then, the actors who play a role in the two people 's Goal, namely the Health Service and the Environmental Service, Regional Police, Regional Disaster Management Agency, Meteorology and Geophysics Agency, People's Economy Service, Agriculture Service and Health Service, Environmental Service and Public Works Service, Sanitation Service and City Parks as well as the Social Service, Transportation and Transportation Agency, Culture and Tourism Agency, Religious Services and all Services and All Elements of the City Community.

Finally Building a healthy city is also in line with the sustainable city development mission carried out by the ministry of planning and national development in Mission 2 Livable and Inclusive, Mission 3 Advanced Cities, Green Cities in Management of metropolitan cities in Indonesia. Sustainable city development will continue to run in accordance with the concept of sustainable city development that has been conveyed earlier that Sustainable urban development is like that to improve the long-term health of the planet's human and ecological systems. It assigns human and ecological systems equal importance, and implies that the health of both is interdependent. The following is a table of triangulation in writing this article

Table 3. Triangulation

No	Tujuan	Theory	Methodology & Analysis	Result	Source of Data
1	Cities with High Index (Healthy Cities Criteria)	Hancock and Duhl, Glouberman	Choosing 3 Cities by calculating index on each factor, Descriptive Analysis	• Palembang 401 points • Solo 310 points • Denpasar 294 points	IAP Livable City Index 2017, Personal Statement, Personal Modification
2	Factor and Actor	United Nation, WHO, Ministry of National Development Planning, Grant, Portney	The factors are divided into 2 goals, the actors based on their responsibility to deal with and using Log-frame analysis	Factors: Place, Environment and People Actor, Government and Citizen	IAP Livable City Index 2017, Personal Statement, Personal Modification

Source: Personal Modified, 2019

Table 3. Shows triangulation of data on the objectives achieved, namely top 3 with high index, factor and actor. This discussion uses the theory of Hancock and Duhl, United Nation, WHO, Ministry of National Development Planning, Grant and Portney. The analytical method used is Choosing 3 Cities by calculating the index on each factor, Descriptive Analysis. The factors are divided into 2 goals, the actors based on their responsibility to deal with and use Log-frame analysis. The results of the first goal obtained were that there were 3 cities with the highest index in relation to the concepts of healthy cities namely Palembang, Solo and Denpasar. The second result is factors that are divided into two goals, namely place and people. The source of data comes from IAP Livable City Index 2017, Personal Statement and Personal Modification.

4. Conclusion

To deal with various urban challenges in Indonesia, various innovations and quality improvements are needed, especially in building healthy cities. Based on the analysis, it was concluded that building healthy cities in Indonesia requires 16 factors, namely safety, health, health facilities, cleanliness, garbage services, urban economics, food, housing, park facilities, clean water, transportation, art and cultural facilities, public participation, religious services and urban planning quality. The importance of the role of actors is also needed. Such actors are like the relevant government agencies and the community as beneficiaries as well as those responsible for maintaining the quality of the factors. Furthermore, based on the results of the analysis, there are 3 cities with the highest indexed that can be categorized as cities that are ready to go to healthy cities, namely Palembang, Solo and Denpasar City.

Each of these cities still needs to increase the index on factors that have not reached the average index.

To develop the concept of a healthy city, it is not only focused on human (individuals) but also concerns people who live in cities or public health. Healthy city is not only physical health but also mental, social, economic and spiritual health are achieved. In addition to people, the concept of a healthy city also focuses on place, namely improving the ecological system and quality of the city. Finally, building a healthy city in Indonesia is a continuous and interdependent process through cross actors and cross factors to realizing Sustainable Urban Development.

Research Paper

The Pedestrians' Stories: Towards Walkable Cities in Indonesia

Sustainability in Transportation

Natalia TANAN, Ministry of Public Works and Housing; Indonesia

Laksmi Tungga Dewi Jaya WISNU WARDANI, Reka Urban-Perubahan Iklim; Indonesia

Abstract

The paper discusses the process of providing walkable pedestrian facilities in cities in Indonesia which is considered lacking due to the limited number and poor quality. In the past few years, the government has been improving and developing the walkable pedestrian through policy and regulation, as well as physical development. This action is also linked to the green city program, in particular, sustainable transportation. However, the physical development and implementation of policy and green city program are not as smooth as expected due to the limitation of urban space, human resources, and finance. The study focuses on identifying problems and introduces arrangements that could improve the quality of pedestrian facilities. It applies interviews, questionnaires, and design competition to gather input from the public. Two cities in Indonesia are selected as the case studies, namely, Bogor and Banjarmasin. In each city, the study selects a location to elaborate for the design competition. The study analyses the walkability condition in each zone using nine parameters that emphasise on pedestrian conflict with other modes, availability of pedestrian path, availability of crossing, the safety of crossing, the behaviour of the motorcyclist, amenities, disable facility, buffer, and security. The finding points general problems such as poor amenities and lack of disabling facility, as well as the problem of motorcyclist behaviour. Besides problems, the study also identifies local potentials that could support the improvement of walkable pedestrian facilities. Those findings are important to improve the pedestrian facilities and develop an understanding of local condition since each city has different characteristics. The study applies those findings as an input to develop policy on the pedestrian facility of the green city for the Ministry of Public Works and Housing. The policy links to the green city program that addresses eight attributes, namely the green planning and design, open green space, green community, green waste, green energy, green transportation, green building, and green water. Further, the policy also emphasises five components of walkability, accessibility and connectivity, attractiveness, comfort and equality, safety, and security. Combination of green city attributes and walkability components are used for the planning-design and development of walkable pedestrian facilities in the urban area in Indonesia.

Keywords

Walkability, Pedestrian Facilities, Green Transportation, Green City

1. Introduction

In Indonesia, the walkability concept is being used to improve the quality of pedestrian facilities in urban areas. The implementation of this concept is expected could improve the accessibility and connectivity, upgrade the attraction or beauty, increase comfort and equality, safety and security. In short, the walkability concept should encourage walking activities that beneficial to the sustainable development of transportation in the green city to provide life balance in ecological, economic, and social aspects.

In Indonesia, the national government introduced the concept of green cities to improve environmental quality. Under the ministry of Public Works and Housing, the green city program, which called *Program Pengembangan Kota Hijau (P2KH)* was launched in 2011 that involves collaboration between cross-sectors. One of the points that address in the P2KH program is green transportation that links to the non-motorized vehicle and walking activity. This paper discusses walking experiences in a few cities in Indonesia and the national government efforts to implement the walkability concept that involves local governments and public engagements.

2. Methodology

This study focuses on analyzing the walkability index in two cities in Indonesia. The study combines the concept of walkability and green city. Therefore, it applies a mixed-method that combine qualitative and quantitative methods. The qualitative method is focused on the interviews and design competition, while the quantitative method is based on the walkability index. It is expected that finding from this study could help to identify potential and problems in walking, as well as deliver design criteria that could support walking and green transportation.

2.1. The Walkability Index

The walkability index focuses on identifying and assessing the quality of walking (Arup, 2016; Qingnan, Claudia, Sarmiento, & Obelheiro, 2013; Jeff, 2012; Leather, Fabian, Gota, & Mejia, 2011; Krambek & Shah, 2006). This study applies two methods to assess the walkability index, the first is the Global Walkability Index and the second is the walkability approach from ADB. The Global Walkability index is an approach that uses to evaluate the quality and performance of walking using three components, (1) safety and security, (2) convenience and attractiveness, and (3) policy support (Krambek & Shah, 2006). On the other hand, the walkability approach from ADB also applies the concept from GWI with some adjustments on Asia context (Tanan & Darmoyono, 2017). The study considered that the ADB approach could help to identify the priority areas that need for improvement (e.g. areas with high pedestrian traffic but with low walkability assessments) (ibid).

Table 1 Comparison of GWI and ABD Walkability Approach

Comparison Factors		GWI	ADB
Component	Comfort	√	√
	Safety	√	√
	Security	√	-
	Attractiveness	√	-
Assessment method	Qualitative	√	√
	Quantitative	√	√
Implementation	Cities in Developed Country	√	√
	Cities in Developing country	√	√

2.2. The Green City

The green city concept was implemented in some countries in the world to create a friendly living environment (The Economist Intelligence Unit, 2012; Matthew, 2006; Shandu et al., 2014). In Asia, the ADB introduced the green city index that has eight indicators, namely energy and CO2, transport, land use and buildings, waste, water, air quality, sanitation, and environmental governance (The Economist Intelligence Unit, 2012). This index was adapted to the Green City policy in Indonesia and used to assess the green city index in some cities. This study also uses the green city index to analyze the correlation between mobility and land use planning system in Indonesia, in particular, to support non-motorized transportation and encourage walking activity.

3. Walking Experiences in Indonesia

In urban areas in Indonesia, walking activities are still not an option. However, Indonesia is considered as the lowest rank in walking activities with an average of 3,513 steps per day (Althoff et al., 2017 in BBC, 2017). Compare to other cities or countries such as Hong Kong with the average citizen walks 6,880 steps per day and Ukraine with an average of 6,107 steps per day (ibid). The study of pedestrian facilities in urban areas in Indonesia aims to find out the walkability index in pedestrian facilities as well as identify why walking is less favourable in this country.

In Indonesia, the concept of green transportation was introduced in 2011 under the government program of Green City policy in order to support the Law no 26/2007 on Spatial Planning. The Green City policy focuses on bringing balance between ecological, economic, and social factors (Ministry of Public Works and Housing, 2011; Darmoyono & Tanan, 2015). The program was called Green City Development Program (*Program Pengembangan Kota Hijau* or P2KH), the Ministry of Public House and Housing is responsible for managing this program. This program has four attributes, namely (1) water resources and energy, (2) waste management, (3) integrated transport systems, and (4) healthy environment between nature and built environment using the principles of sustainable development (Ministry of Public House and Housing, 2011). The green transportation concept is linked to the attribute ecological. The concept encourages walking activity as a significant activity to reduce the use of the motor vehicle. It is expected that the provision of pedestrian facilities could improve the physical condition, as well as economic and social activities in the urban area.

Table 2 Green City Attributes P2KH in Indonesia

Attribute	Description
Green planning and design	Planning for city and region that focuses on the capacity to manage resources efficiently and create balance between nature and built environment.
Green open space	Green open space that provides safety, comfort and aesthetic quality for urban and regional area.
Green community	Communities that concern with environmental issues and socio-cultural.
Green waste	Government, private sector, and community manage and prevent waste problem.
Green energy	Renewal energy that balance development activity in city or region.
Green transportation	Transportation system that could reduce negative impact on the environment.
Green building	Building design and construction that environmentally friendly.
Green water	Water management: water absorption management and reduce peak of runoff for natural resources.

3.1. City of Bogor

The city of Bogor close to DKI Jakarta and it is known as a destination for tourism (Botanical Garden, the Palace of Bogor, etc.) and education (Bogor Agricultural Institute or IPB). As a one of the cities that has significant history, Bogor has a historical street, the corridor of Sudirman street. The Sudirman street is know as the heritage axis that connected the Palace of Bogor. This street is a secondary arterial street that has two ways and four lanes, which each of them has a width approximately four meters. This street also has a wide sidewalk with width around 2.5 meters to 3.5 meters. Although the sidewalk quite wide, nevertheless, it has limited trees shade, limited facilities for disabilities, and used as parking are for motor vehicle at some parts. Those conditions challenge this corridor as a heritage axis. Improvement is needed to upgrade the quality of pedestrian facilities as well as strengthen the historical character.

Figure 1 Corridor of Sudirman Street, Bogor City (adapted from the Municipality of Bogor, 2014)

3.2. City of Banjarmasin

Banjarmasin is the capital city of the South Kalimantan Province. The city accommodates various activities such as trade, government administration, education, social services, and so on. The Martapura river through this city and used as a route for water transportation, while the waterfront is a public open space for the local people. This waterfront area is flanked by two major streets, the Jendral Sudirman street and Pierre Tendean street. Along these streets are commercial areas, offices, residential, and education facilities. Because of its scenic view, this area becomes one of the tourist destinations in Banjarmasin. Both locals and tourists enjoy the landscape of the waterfront as well as for sports and culinary destinations. Aware of the potential, the city government improves the open space along the waterfront area. Even though the improvement is being carried out, efforts are still needed to escalate the quality of pedestrian facilities. The provision of disabled facilities, growth shade trees, upgrade the signage system, develop vehicle parking area, and others.

Figure 2 Corridor of Martapura Promenade, Banjarmasin City

4. Achieving Walkable City in Indonesia

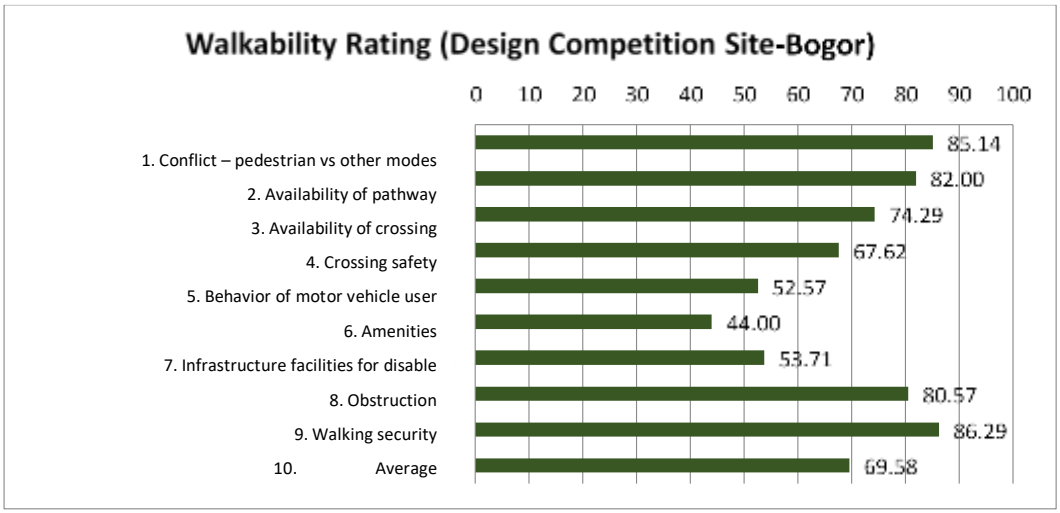
Achieving a walkable city is a challenge for most cities in Indonesia. However, to support the green city concept, in particular, the green transportation concept, those cities have to accommodate this demand and improve the quality of pedestrian facilities. Therefore, to identify the quality of pedestrian facilities, the Ministry of Public Works and Housing conducted a survey and later followed by a design competition to gain innovative idea from the public. Then, this input will be used to planning and design pedestrian facilities in a guideline for Indonesian cities.

4.1. Walkability Survey in Bogor

The walkability survey in Bogor is conducted along the corridor of Sudirman street. It applies two methods, (1) inventory of pedestrian facility and (2) interview to the pedestrian. The survey of inventory pedestrian facilities uses the Global Walkability Index to identify some factors related to the current condition of the pedestrian facilities at the site. While, the pedestrian interview is about getting information on pedestrian perceptions and preferences, as well as characteristics of pedestrian and the trip. Input from the survey helps to identify the condition of pedestrian facilities based on the types of activities and trip purposes.

Apparently, the pedestrian inventory survey is a site-specific that focuses on the segments on the right and left along the corridor of Sudirman street. The survey identifies problems and potentials of the pedestrian facilities along the corridor. It also points the type of pathways and the intersection, green open space (parks), location with limited interaction with to the motorized vehicle. The results of the assessment of this corridor are as follows (see figure 3):

Based on the survey result, the sidewalk has three different characteristics, (1) sidewalk close to the Palace of Bogor has the best quality due to the wide dimension, the low conflict between pedestrian and other modes of transportation and equipped with a barrier. The second (2) is the corridor with green shade trees that provide shade and create a comfortable walking environment. The third (3) is the commercial segment, which has the lowest score of the walkability index. Most of the sidewalk space was used as parking areas for motor vehicles, which limited the access for the pedestrian. Another problem that identifies from the survey is the speed of the motor vehicle, which could danger the pedestrian crossing the street.



This zone has 3 clusters, (1) the segment next to the Bogor Palace (the best condition); (2) the green open space area that is clean, calm and comfortable to walk; and (3) a commercial area where most of the space on the sidewalks is for motor vehicle parking area.

From the survey, the commercial area has limited amenities and narrow sidewalks at some segments. The corridor also has limited number of pedestrian-crossing and no pedestrian bridge to support mobility. A few parts of the sidewalk are under construction, which close the pedestrian accessibility.

Figure 3 Walkability Rating at the Design Competition Site, Bogor City

The walkability rating at corridor of Sudirman Street is as follows:

Table 3 Rating of walkability at corridor of Sudirman Street

Parameter	Walkability Rating
Conflict – pedestrian and other mode of transportations.	85.14
Availability of pathway	82.00
Availability of crossing	74.29
Crossing safety	67.62
Behavior of motor vehicle user	52.57
Amenities	44.00
Infrastructure facilities for disable	53.71
Obstruction	80.57
Walking security	86.29
Total Average	69.58
Results	Average

The interview survey focuses to gain information about perception and preference on pedestrian facilities and characteristics. the study uses two formulas to determine number of samples, (1) Population unpredictable/known – population is the city inhabitant and (2) population unpredictable/known to achieve accuracy of 95%. Bogor City has population approximately 1,013,019 people (BPS City of Bogor, 2014). The calculation is as follows:

$$n = \frac{1{,}013{,}019}{1+(1{,}013{,}019 \times 5\%^2)} \quad (1)$$

Result, n = 399.84 ≈ 400 sample

$$n \geq \frac{1}{5\%^2} \quad (2)$$

Result, $n \geq$ 400 sampel

The calculation shows that the study needs at least 400 samples to gain 95% accuracy, while the survey manages to collect data from 480 respondents, which is more than the minimum requirements.

The survey reveals that in general, most of the respondents are agree that facilities for pedestrian are available and accessible (with some notes). Nevertheless, they point out the condition of sidewalk that not friendly to the special need people, in particular people with disability, elderly, children, and pregnant woman (see Figure 4). The survey also requests the participants to make a list of priorities three times to see what is considered necessary to pedestrians (see Figure 5). In the first round, the respondents demand to improve the infrastructure for disabilities (16.5%). The second round shows that the participants demand a pedestrian-crossing to cross the street (19.8%). The third round, the respondents' concern with the motorists' behavior that less interest in pedestrian safety (15.8%). These findings help the study to identify the problems and potentials of this corridor and seek a creative solution.

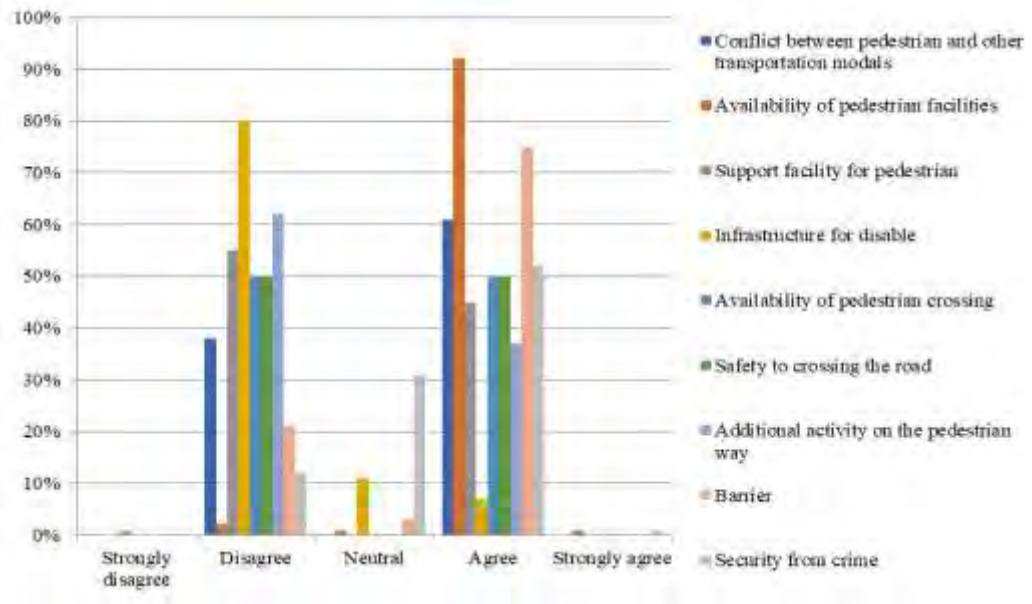


Figure 4 Ranking of the Pedestrian Facilities Condition at the Competition Site, Bogor

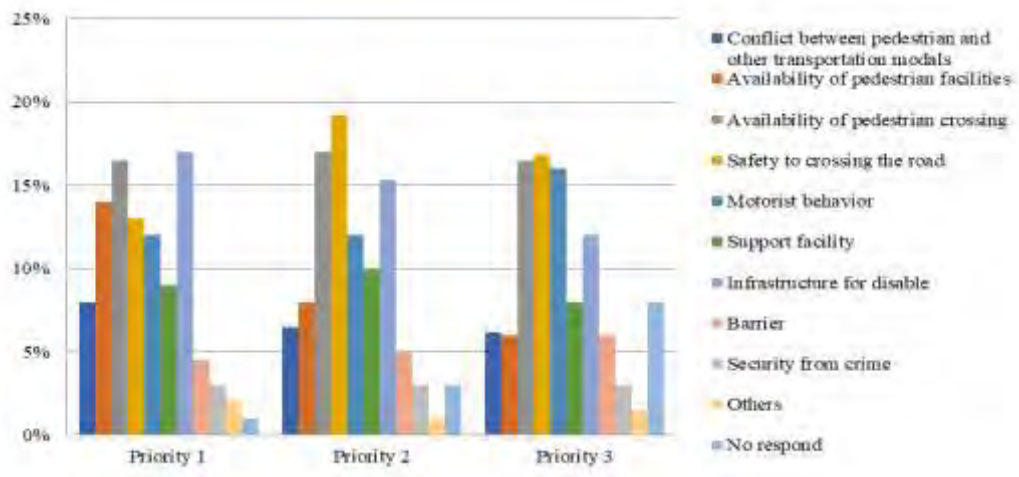

Figure 5 Respondents' Priority for the Facility Improvement, Bogor

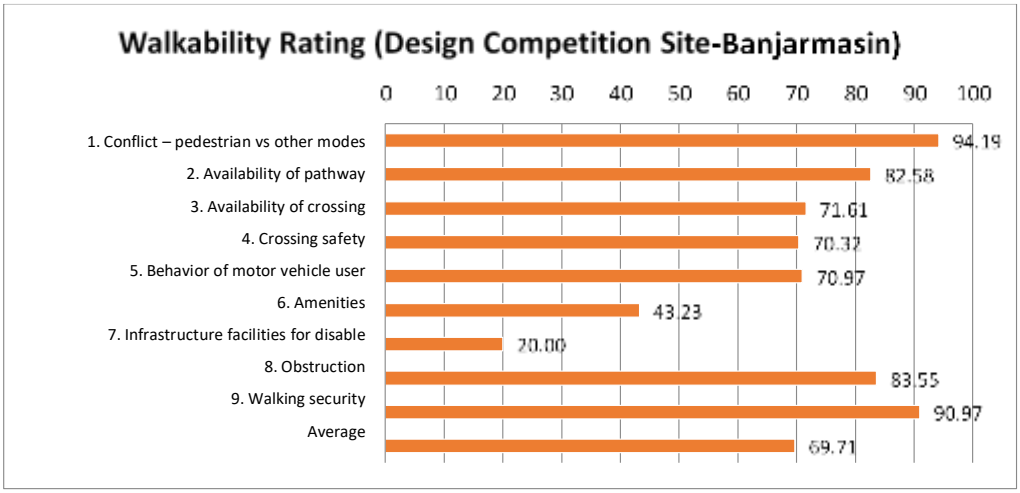
4.2. Walkability Survey in Banjarmasin

In Banjarmasin, the walkability study also conducts through the inventory of pedestrian facilities and interview with the pedestrians. The study applies the Global Walkability Index to collect data and analyze the condition of pedestrian facilities along the Martapura promenade. In order to get information and understand pedestrians' perception and preference, characteristic of the walkers and journeys, this study conducts interviews. In general, the walkability survey provides information about the condition of pedestrian facilities in Martapura promenade based on types of activities and trip purposes.

The pedestrian inventory survey along the Martapura promenade focuses on two corridors of Sudirman street and Pierre Tendean Street between segments Merdeka bridge and Old Market bridge (Jembatan Pasar Lama). The survey identifies potentials and problems as follows:



The pedestrian facilities along the Martapura promenade has a good quality; however, there are few infrastructures that need to be improved such as steering tiles for disable, signage system, ramps, and others. The pedestrian facilities have attractive design due to the requirement as a tourist destination. In general, the available facilities are lighting, shade trees, safety fences, police posts, and others.

Figure 6 Walkability Rating at the Design Competition Site, Banjarmasin

Sudirman street is one of the major streets in Banjarmasin city that has many of government offices. As a major street the vehicle speed on this street is quite high. Nevertheless, during peak hours this street deals with traffic congestion. Almost similar, the Pierre Tendean street is in an area that dominated by residential, educational, and mixed functions. Despite the vehicle speed is moderate, during peak hours the street also deals with congestion problems. In order to provide pedestrian safety, improvement on pedestrian facilities is needed. Based on the survey, the pedestrian facilities along at this segment have characteristics: (1) main access to the Martapura river and water transportation, (2) each street has a different tone; Sudirman street (domination of government offices) and Pierre Tendean Street (housing area, education facility, and mixed-use area), (3) limited green corridor – shade trees, (4) high speed vehicle on Sudirman street, (5) limited parking space at Sudirman street and Pierre Tendean street, and (6) traffic congestion during peak hours on both streets. In order to provide safety to pedestrian, improvement on pedestrian facilities is needed.

The walkability rating at corridor of Sudirman Street is as follows:

Table 4 Rating of walkability at the Design Competition Site

Parameter	Walkability Rating
Conflict – pedestrian and other mode of transportations.	94.19
Availability of pathway	82.58
Availability of crossing	71.61
Crossing safety	70.32
Behavior of motor vehicle user	70.97
Amenities	43.23
Infrastructure facilities for disable	20.00
Obstruction	83.55
Walking security	90.97
Total Average	69.71
Results	Average

From the interviews, the study gathers information about perception and preference on pedestrian facilities and characteristics. The Banjarmasin case also wants to achieve accuracy of 95%, therefore it applies two formulas which are, (1) Population unpredictable/known – population is the city inhabitant and (2) population unpredictable/known - assuming Banjarmasin is a destination city for tourism; therefore, some of the pedestrians could be tourists from other cities. Banjarmasin City has population approximately 666,223 people (BPS City of Banjarmasin, 2015). The calculation is as follows:

$$n = \frac{666223}{1 + (666223 \times 5\%^2)} \quad (1)$$

Result, n = 399,759 ≈ 400 sampel

$$n \geq \frac{1}{5\%^2} \quad (2)$$

Result, $n \geq$ 400 sampel

From the calculation of formula 1 and 2, the study needs at least 400 samples in order to get 95% accuracy. The survey only collected data from 300 respondents, nevertheless, if the calculation is reversed, the error level of 6.4% is still acceptable.

The interviews results show that most of the respondents consider that the conflict with the motor vehicle is minimum, as well as pedestrian facilities, are provided along the promenade (see Figure 7). However, many of them argue that the facility for disable, security, and pedestrian-crossing facility are limited and need to be improved (see Figure 8). Therefore, the study asks the pedestrians (respondents) to make a list of priorities regarding improvement on pedestrian facilities. The list has nine-parameters of priorities that related to the pedestrian facilities improvement and respondents must make the list of priority three times. Accordingly, these lists will help the study to understand the respondents' preferences and their rank of priorities development. Still, some of the respondents have difficulties in setting priorities. Because of this condition, the study only selects the top three

over the nine-parameters. The three stages of respondents' preferences are: (1) reduce the speed of motor vehicle for pedestrian safety (motorists' behaviour) (15.3%), (2) provision of pedestrian-crossing facilities (currently this segment does not have any pedestrian bridge) (16.7%); (3) improve the amenities (12.7%). The ranking of the three stages priority can be seen in the following Figure 8.

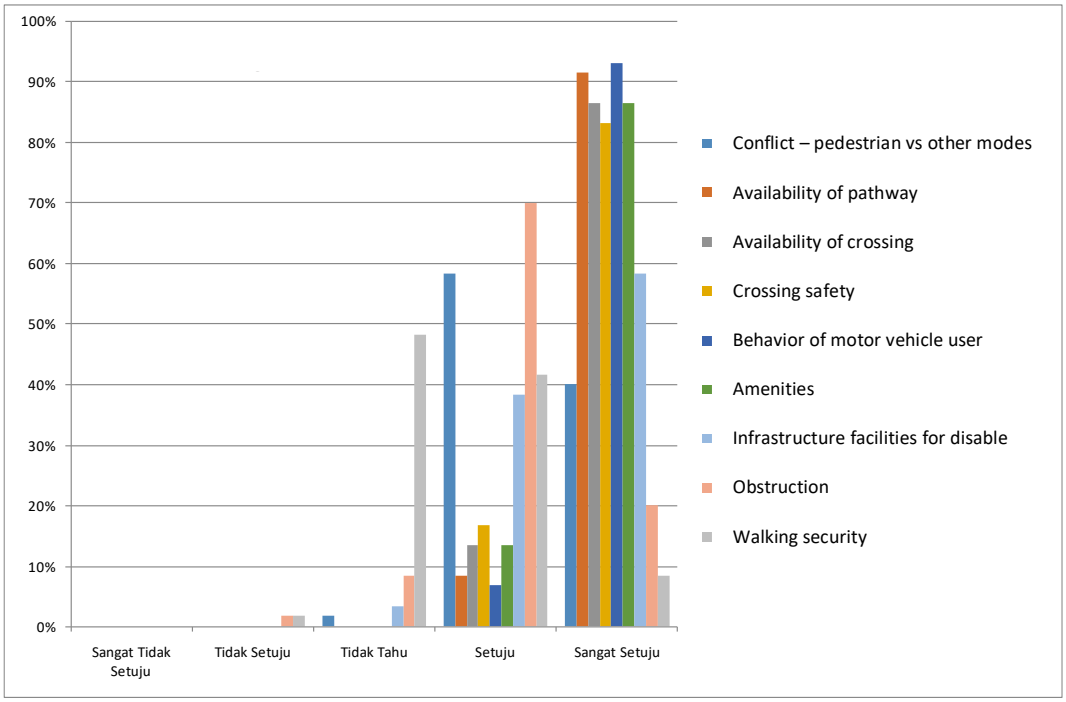


Figure 7 Ranking of the Pedestrian Facilities Condition at the Competition Site, Banjarmasin

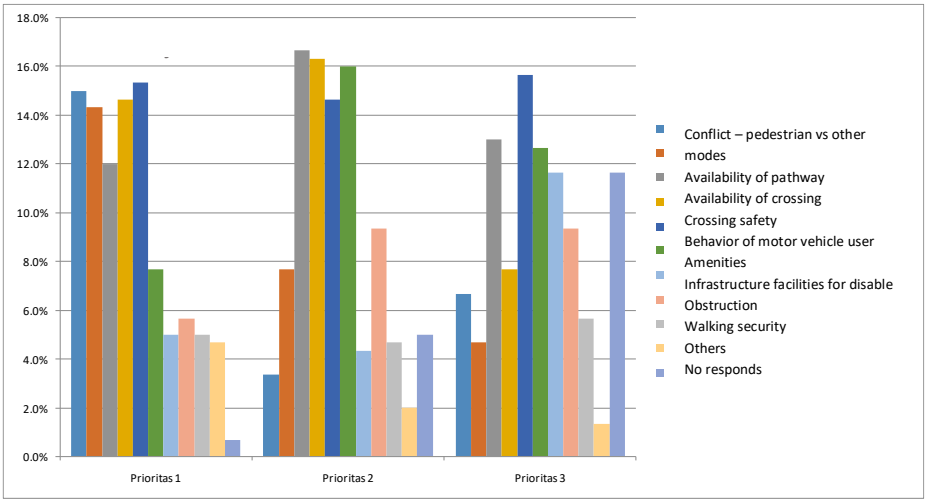

Figure 8 Respondents' Priority for the Facility Improvement, Banjarmasin

5. The Design Competition

The Ministry of Public House and Housing would like to gather more ideas from the public; therefore, they initiate a design competition in those cities, Bogor and Banjarmasin. The design competition was held in 2015 and aims to gets smart, innovative and realistic ideas for improving the quality of pedestrian facilities based on green city concept in Bogor and Banjarmasin. The competition introduced three design criteria based on the green city concept, namely: (1) green transportation, (2) green building, and (3) green open space. Besides that, participants have to meet the requirements in each city. In Banjarmasin, the participants have to design a pedestrian path along the riverbank. At present, the pedestrian lines at the edge of the water are cut off by the bridge. The continuous pedestrian path at that time was not yet possible because the bridge height was too low. In the future, Banjarmasin city government has a plan to increase the height of the bridge so that it is possible to make continuous access under the bridge. The design of pedestrian paths under the bridge must prioritize aspects of safety and security for the user, mainly because this river is the circulation path of freight and passenger ships. Besides, participants must also consider the use of space under the bridge at night. User safety and security are essential aspects of design. While in Bogor, the participants have to manage limited space of pedestrian because of trade and service activities that forced the pedestrian walking on the street at specific locations. With this condition, Sudirman street corridor has not been able to provide an image as a heritage axis that has historical value. The design competition is expected to improve the quality of pedestrian facilities along the Sudirman street corridor that encourage walking activities. The design competition got positive responds and received twenty-two design proposals.

5.1. Bogor City

The “Dialogue between Spaces” was the second winner of the design competition. It has the meaning of collaboration between nature, economic, and cultural factors as a representation of a public space in the city of Bogor. According to the team of jury, this concept had original idea and focused on utilize the local characteristic. Using the tag-line of Dialogue between Space, the designers would like to introduce the 3K zone label-attributes: Contemplating Space-Contemporary Space-Colonial Space-and the nodes connecting and set the axis of Sudirman Street. Other interesting points from the design are:

1. Integrated the walkability principle (improve pedestrian facilities, provide comfort and equality, and safety).
2. Build a sky walk to connect areas such as residential, commercial, office and recreation, and landmarks.
3. Improve green open space through develop buffers, multipurpose pathways, natural furniture, and connected green canopy.
4. Encourage integration of eco-friendly transportation with the Pedestrian path.
5. Innovative design of pedestrian facilities and amenities (book shelter, story frame, Skywalk, swing chair, pedestrian path with Batik motif, etc.).

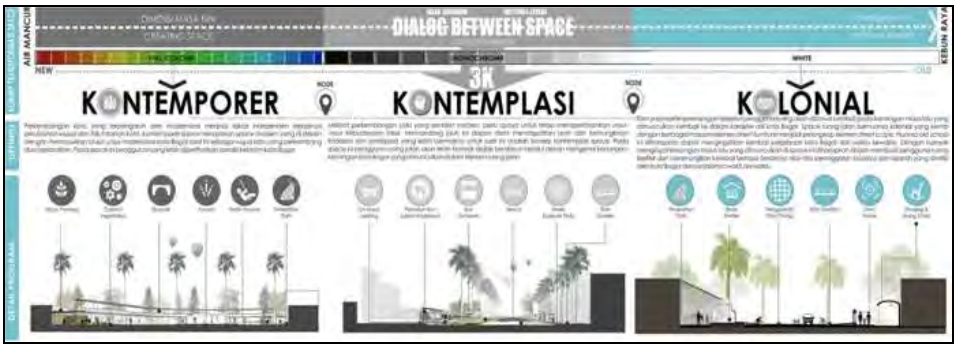

Figure 9 The 3K Zones of the Sidewalk at the Sudirman Street, Bogor

5.2. Banjarmasin City

The "Great City Walk: Banjarmasin – Martapura Green Movement" was the winner of the design competition. The designer translated the local dialect of Baugal (Banjar dialect), which means 'moving'. Moving defined the urban citizens activities, able to walk, run, and move freely. This made the idea of this design original and rooted locally. Besides that, the designer also able to combine the components of the city of Banjarmasin that are integrated with the elements of the Martapura River. The designer creatively associates with the network system approach, based on strengthening the urban infrastructure network system as well as the river infrastructure network system. The designer succeeded in describing future infrastructure ideas, including:

1. River traffic with waterways and interchanges.
2. Integrated the street network system with the river terminals.
3. Drainage system integrated with river revitalization.
4. Demonstrating energy traffic intersection and stop APU stops.
5. Develop social infrastructure in pedestrian and community infrastructure designs.
6. Ecological integration in complementary infrastructure and street equipment.

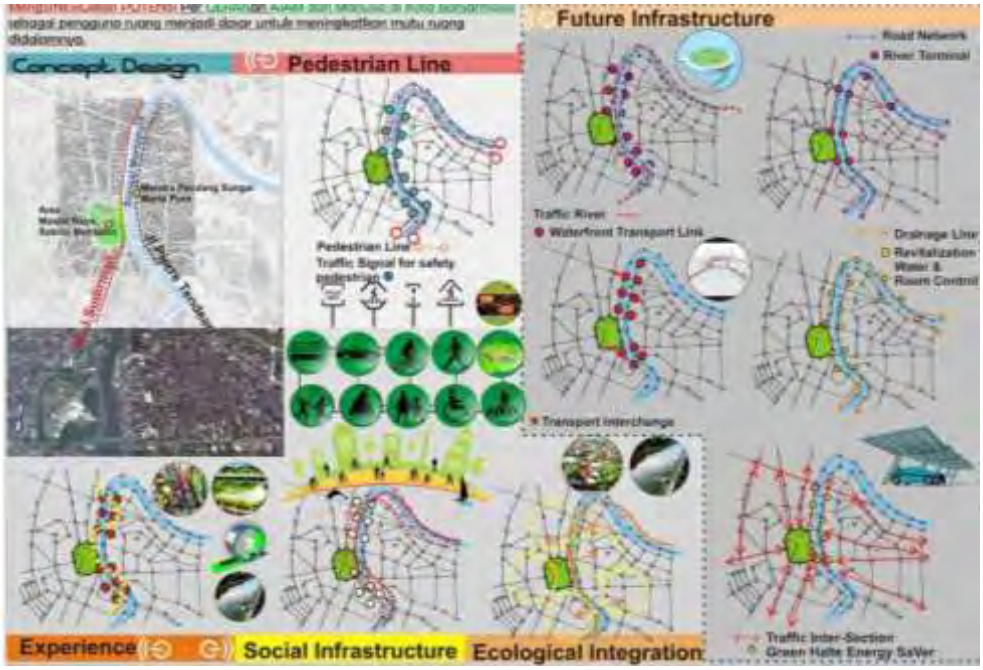

Figure 10 The Concept of Great City Walk: Banjarmasin – Martapura Green Movement

6. Conclusions

The study concludes some findings:

1. In general, the local governments have provided pedestrian facilities; however, some facilities still need to build and improve to encourage walking activity.
2. Study on the walkability index helps to identify potentials and problems regarding the walking activity.
3. Further study regarding the walkability index needs to be carried out after the improvement of pedestrian facilities to identify the potential increase of walking activity.
4. The design competition brings some innovative ideas to improve the quality of pedestrian facilities. Nevertheless, a few of the ideas must be adjusted to the real condition.
5. The public participation through the survey interviews and design competition is useful to gather information and understanding regarding the idea of pedestrian facilities from the public.

7. Acknowledgments

The authors would like to thank the design team "Great City Walks: Banjarmasin – Martapura Green Movement": Jimmi Roy Tampubolon and design team "Dialogue between Spaces": Ardhyasa Fabrian Gusma ST, Eka Pradhistya Prasidhanta, and Anisa Yulia Rakhmanita.

Case Study / Project

Importance of air quality management

for public health and development progress in Jakarta, Indonesia

Lynn TANG, Vivian PUN, Ririn RADIAWATI

Abstract

Air pollution levels in metropolitan Jakarta, capital city region of Indonesia, are high and rising, posing a serious public health threat to 32 million residents. it was estimated that over 5.5 million people in DKI Jakarta (58% of the population) suffered from various air pollution-related illnesses (e.g., asthmatic bronchiale, coronary artery diseases) in 2016, and the associated direct medical cost could go as high as IDR 51.2 trillions (or USD 3.9 billions). Experts also reported that the total economic cost of health problems associated with air pollution in Jakarta would increase to 2.5% of Jakarta's expected GDP in 2015 (or 4.3 trillion rupiah or USD403 million) as opposed to 1% in 1998, if no action to control air pollution is taken. In 2017, the annual average concentration for particulate matter with aerodynamic diameter of less than 2.5 micron (PM2.5) was 41 ug/m3; daily concentrations rarely meet the World Health Organization's health-based air quality standard of 25 ug/m3. The current official air pollution monitoring conducted in Jakarta is inadequate: PM2.5 is not monitored nor have there been recent assessments of particle composition to inform source apportionment.

These limitations and a lack of reliable emissions inventories and regional air pollution data are barriers to planning and implementing greater control of air pollution in DKI Jakarta. In 2018, the Governor's office announced äóìGrand Design: Air Pollution for a Healthy Livable Cityäó to carry out a multi-stakeholder assessment and planning process to produce recommendations for air quality improvement in Jakarta.

This talk highlights approaches to combining strategic use of innovations in air pollution monitoring, emissions estimation and source apportionment modeling to inform near-term control measures for priority sources at a local and regional level in Jakarta. Topics to be addressed will include: multi-stakeholder collaborative approach for complex issues like air pollution, the importance of strategic communications and public awareness of air pollution health effects, emerging results from source apportionment work underway to identify leading PM2.5 sources in the metropolitan area, the policy implications of emerging local data on air pollution and stunting, and the challenges of addressing both local pollution sources within direct control of DKI Jakarta and transported pollution from sources such as episodic haze from peatland fires.

Research Paper

BETTER PLACES FOR A LIVABLE – AND LIVELY – CITY

A method of Post-Occupancy Evaluation of public spaces

Gabriela de Souza TENORIO, University of Brasilia, Brazil

Abstract

Public spaces that attract and retain diverse people are crucial to foster urbanity and tolerance, and build stronger and livelier communities, especially in big cities. The simple coexistence of similarities and differences in public spaces can, to say the least, validate our own essence and offer us a possibility of growth. Sharing the same space with other people – even without interacting with them – favors social learning. Theory suggests that thought, feeling and behavior can be altered by observation. The search for public spaces that make urbanity viable is desirable in any society (especially in more unequal societies, as one can find in developing countries). However, inspired by ideas built on the critique of great urban agglomerations after the Industrial Revolution, cities around the world have undergone transformations that did exactly the opposite. As a series of lifeless places began to emerge, several researchers tried to figure out why this was happening. These researchers found that just wanting to create a lively place was not enough. It was necessary to scrutinize the behavior of people in public spaces in order to understand the relationship between their configuration and use. The knowledge they have built has been largely responsible for the increasing concern with public spaces and their relation to public life since the 1960s. Cities around the world are realizing that empty places could be full of people, and that not only a place full of people is something positive, but an empty place is not. They are learning to see underused public spaces as social, cultural, environmental, and financial waste. However, even with so much information available, it is still possible to find, in any contemporary city, public spaces that fail to support public life. Frequently, little or nothing is done to make them safer or more attractive, diverse and pleasant. It is even more worrying to realize that such places continue to be created. This is the focus of this paper. It brings together available knowledge and experiences in the area of public space design. It also complements, structures and translates such experiences and knowledge into a Public Space Post-Occupancy Evaluation Method, which stresses the importance of observing people and their activities. As a result, one can better understand, observe, assess and, thus, manipulate the main attributes of a public space that may influence its capacity to attract and retain diverse people on a daily basis. The method is offered as a tool to support those who deal with public spaces at different levels – from academic studies to municipal management. It has been used in Brasilia, Brazil, for the past 7 years, with positive results in governmental decision-making processes. A case study is briefly presented to illustrate its use.

Keywords

Public spaces, public life, urbanity, Post-Occupancy Evaluation, method

1. Introduction

As a concept, livability – just like quality of life – can be controversial in terms of its meaning from the point of view of individuals. According to Ruth & Franklin (2013), urban life expectations may vary according to several factors, such as the stage of life people are in, or their preference for using individual transportation. However, in the context of city planning it is important to acknowledge that our attempt to distribute urban onuses and bonuses in a fair manner among the entire population – without undue privileges – leads us toward considering the collective good, focusing on points in common, rather than individual or group preferences and desires.

As urban components, public spaces are capable of favoring collectivity. When addressing the concept of livability, Jacobs & Appleyard (1988), Young & Hermanson (2012) and Herrman & Lewis (2017), among others, often consider public spaces as streets or parks (and less so in the form of squares). There is a clear concern with securing a good mix and distribution of housing and other activities, so as to create walkable areas and favor public and non-motorized transport, and thus avoid road traffic and pollution. In addition, from the perspective of preventive medicine and promotion of physical well-being, parks and walking/recreation areas are an important tool against health conditions caused or aggravated by urban life, such as obesity, heart and respiratory problems, etc. The terms "community" and "neighborhood" are widely used in the context of public spaces. Coexistence and social interaction, on the other hand, are not as common, since they can also take place in enclosed spaces, such as gyms or community centers.

However, it is important to point out that public spaces are not only leisure and exercise areas, nor links between different urban activities: they connect human beings, as they offer us an opportunity to see other people (co-science) and share the same space with them (co-presence). They are not only a means for us to meet individual needs, but rather a tool that enables us to perceive ourselves as part of a whole. Public spaces welcome and reveal differences, while allowing us to choose between isolation and interaction. It is in them that individuals find collective life, and are able to exercise their urbanity.

The dictionary definition of urbanity points us towards important social values: “Courteousness and refinement of manner" (Lexico, 2019). According to Holanda (2002), it represents one of "democracy's dearest universal values.” It is present in the exercise of tolerance, in the negotiation of interests, in empathy, collaboration, and participation in temporal life. As a concept, urbanity includes the idea of face-to-face interactions, which can only take place among individuals who share the same space. Yet, for this to happen, such spaces must be able to attract and retain individuals.

The search for urbanity – and for public spaces that make it viable – is established as something desirable in any society. However, inspired by ideas built on criticism of how post-Industrial Revolution cities led to great human agglomerations, many cities around the world underwent transformations that gave rise to a number of lifeless areas – despite their early claims that such places were meant to be used by people. Several scholars, then, began to try to understand why this was happening, and found that the mere intention to create a living space was not enough. It was necessary to conduct an unbiased observation of people's behavior in such places so as to understand the relationship between their

configuration and use. The knowledge built by them was largely responsible for the increased concern with public spaces that favor urbanity observed since the 1960s.

However, even with so much information available, it is still possible to find lifeless public spaces in cities. In many of them, little or nothing is done to make them more attractive, safe, adequate, diverse, or pleasant to the population. The worst of all is that such places are still being created! It is in this context that a method has been developed to help change this reality. It helps us to understand, learn how to observe, evaluate and, consequently, manipulate the main attributes of a public space that may impact on a place's ability to favor co-presence, so that our cities may be not only livable, but also lively.

2. The method

The method was first presented by Tenorio (2012) in her doctoral dissertation. Since then, it has been improved, building on reflections arising from its application in practical activities developed at the Faculty of Architecture and Urbanism of the University of Brasília (Tenorio, 2014); collaborative actions performed with the Government of the Federal District to improve the central areas of Brasilia (Tenorio & Kronenberger, 2017); and MA theses that focused on the topic of public spaces (Menezes & Reis, 2015; Cardoso, 2019).

The work is based on the Space Syntax Theory, as it highlights the inextricable relationship between the form of human settlements and the society that produces, uses and reproduces them. According to this theory, "Spatial order is one of the most striking means by which we recognize the existence of cultural differences between one social formation and another, that is, differences in the ways in which members of those societies live out and reproduce their social existence." (Hillier & Hanson, 2003)

Form attributes harmonize with social expectations that are based on peoples' cultural patterns, from which Holanda (2011) draws two major socio-spatial paradigms: formality and urbanity. While the first considers cities according to spatial patterns that contemplate segregation, border control, high hierarchy, and separate functions, the other favors integration, elimination of borders, proximity, low hierarchy, and diversity of uses. The paradigm of urbanity has been the foundation for our knowledge about public spaces.

With these expectations in mind, the method brought together available knowledge and experiences on the design of public spaces, and translated, complemented and structured them. It built on research developed by the following authors: Jane Jacobs (1961); Jan Gehl (2006, 2010); Jan Gehl & Lars Gemzo (1996); Christopher Alexander et al., (1977); William Whyte (1980); Bill Hillier & Julienne Hanson (1984); Allan Jacobs & Donald Appleyard (1987); Frederico de Holanda (2011); Project for Public Spaces (2005) and (2008); and Congress for the New Urbanism (1993). The parameters found in the evaluation part of the method come from this literature review.

The method includes 5 steps: 1) knowledge of the place; 2) public life survey; 3) public life evaluation; 4) public space evaluation; and 5) recommendations.

2.1. Knowledge of the place

The method starts with selecting and visiting the place to learn about it, or to see it with different eyes (if you already know it). Researchers should try to access it in different ways, on different days and times, to walk, explore, experience and register it. These field trips will

also allow researchers to produce or update a detailed plan of the place and its borders, as well as define survey spots for the next stage. In addition, it is essential to know the area of the city where it is located, to study it in its urban context with the support of texts, maps, drawings, aerial photos, statistical data, legislation, etc.

2.2. Public life survey

This step presupposes systematic field trips to perform pedestrian flow counts and a survey of stationary activities. The greatest benefit of going to the field is the fact that researchers can remain on site for enough time to absorb the dynamics of how the place is used. We are interested in finding out who is doing what, where and with whom. The procedures suggested by Gehl & Svarre (2013) and by Project for Public Spaces (2005) are applied at this stage. Pedestrian flow counting spots are selected, from where passers-by are counted, usually in 10-minute slots. The results are subsequently multiplied by 6 to obtain an hourly average. For stationary activities, which will later be transformed into behavioral maps, records are taken every two hours at a fixed spot. Informal interviews, photographs, questionnaires, and other techniques (such as image research) may and should be incorporated into this step. The collected data are then processed and presented as charts.

2.3. Public life evaluation

This step is based on checklists linked to subjects and activities. All these items are used to create a spreadsheet to be filled after the field trips.

For subject evaluation, a key requirement is for the place to have people – diverse people, all the time, and every day (i.e., excluding previously scheduled events, parties, demonstrations, etc.). Thus, the evaluation items are:

1. **People**. Although this may seem obvious, it reminds us of how important it is to focus on people, not on the place. A place may be considered beautiful, but if it is always empty, it is considered inefficient as a support for public life, and would therefore not do well under this criterion.

2. **Diverse people**. The place should allow for the co-presence of diverse people, in terms of gender, generation, race, ethnicity, etc. This diversity should reflect the society where the place is inserted, and include local residents. The existence of diverse people should contemplate individuals as well as couples and groups. Researchers should observe whether they can identify any prevailing groups, and whether such groups might inhibit the presence of other groups or individuals. An important point highlighted in the literature is the strong presence of women. In public spaces, women are more vulnerable and more subject to unwanted approaches, and therefore they tend to be more selective about where to linger. A gender-imbalanced location is considered problematic.

3. **People, all the time.** The selected place should have people most of the time and throughout the week, and their presence should be evenly distributed. If the place is crowded only during lunchtime on weekdays, it probably has some issues. This assessment should consider aspects related to the place and its people, such as climate and culture, which might influence the daily life and the use of public spaces.

   There are some public spaces that do not attract people every day. However, when they do, they receive a number of people that hardly any other place in the city might contain. They are usually very large, and are meant for symbolic rather than temporal

use. Such symbolic places are important, though they carry the burden of being empty most of the time.

Regarding **activities**, public spaces should have:

4. **People passing by.** Passing by is a very common activity in any public space. The expected number of people will depend on the characteristics of each place. Some public spaces are central, close to activities that attract the public, and therefore one might expect to find a large number of passers-by. On the other hand, some spaces are more local, and the daily flow of people is less significant.
5. **People lingering.** Whether they were passing by and decided to stop, or they meant to go to that public space to stay there, the presence of people lingering at one place is evidence that such place offers reasons for that choice. There is no set parameter to establish an optimal lingering time: it can be influenced by various factors, including climate, for example. But in fact, the more people linger at one place, the more successful it can be considered as a public space.
6. **People meeting, either voluntarily or by chance.** Public spaces should enable random encounters involving people that know each other and also complete strangers, as this is the very basis of urbanity. However, they should also provide a place for people to arrange meetings with friends, acquaintances or strangers, with a clear indication that they chose to do that.
7. **People keeping and watching the place, either formally or informally**. Public spaces require people to maintain them, either formally or informally. The same can be said of those responsible for their surveillance. Informal surveillance – Jane Jacobs's "eyes on the street" – is always welcome.
8. **People performing various activities.** The more diverse and simultaneous activities are identified, the better the place will perform as a support for public life. Such activities may: (a) take place within a public space, through the support of its constituent elements (people playing on a sports court, children climbing trees, young people talking in the shade); (b) take place near its borders, whether they stay there (in shops or cafés) or move towards the public space (someone buying an ice cream near the border and eating it on a bench in a square); and (c) be motivated by the presence of people in the place (people distributing fliers, street vendors, street musicians). If, in addition to their daily use, the spaces still host, sporadically or frequently, scheduled activities, this means that they are managed well and are valued by the community. These activities may be passive or active.

2.4. Public space evaluation

After getting a picture of public life in your space, it will be possible to determine whether it favors it, and to what extent. It will also be possible to tell if such life is consistent with the place's characteristics and its role in the city. For this assessment, one should bear in mind that there may always be more people in the place, that they can always be more diverse, and that they can always perform more activities, for longer, in a better way.

If a place is successful in public life, it is important to understand why, so as to use it as part of your repertoire, or as an example of good practice (it is also interesting to find out if there is anything else that can be done to make it even better). If it is not successful, it is important

to understand the reasons for its poor performance. Thus, the evaluation of public life does not dispense with the evaluation of how that specific public space is configured.

Several authors focus their studies only on the physical characteristics of the **place** (flooring, furniture, shading) and fail to observe the elements that define it, that is, its **interface** (surrounding buildings and their public/private relationship, their doors and windows, the activities they offer), as well as the wider **context** of the area (location in the city, zoning, accessibility, population density). Often the main reasons for a place's limited use are not linked to its local attributes, but rather to its location away from the main flows of people, or their belonging to a monofunctional zone.

For this step, we use two spreadsheets with the same characteristics of the previous ones to deal with public space configuration elements: global attributes, or **urban context;** and local attributes, i.e., **interface** and **place**.

Regarding global attributes – **urban context –** one must analyze the configuration of the area in the city where the place is. In general, in order to favor the presence of people:

9. **Areas should be compact.** Their open space/total area ratio should not be very high. They cannot have idle and residual areas, and their buildings should occupy the ground efficiently, thus increasing the use of infrastructure and favoring the implementation of public transportation.
10. **Areas should be integrated.** The presence of the following elements should be minimal: cul-de-sacs, places with few access points, and very large blocks. With more connections, route alternatives are expanded, which not only promotes a better distribution of activities and people through the urban fabric, but also favors the implementation of public transportation systems and decreases travel times.
11. **Areas should provide a mix of diverse uses.** Except for very specific situations involving health and safety issues or risks, they should offer a variety of activities. They should be well distributed, be complementary, and function beyond business hours.
12. **Areas should offer different types of housing – well distributed and with a certain degree of density**. Housing should be one of their main uses. The areas should envisage different types of housing so as to accommodate diverse people. This avoids the development of zones with very homogeneous population, which would result in low diversity levels in public spaces. The density may vary within the area, which also favors diversity, but cannot be very low.
13. **Areas should favor the mobility of pedestrians, cyclists and public transportation, rather than cars.** Using private cars on a daily basis should be a less enticing option than other means of transportation. Parking spaces should be limited, and should not be free. These areas should be able to offer an integrated public transport system and a cycling system. Walking, cycling and using public transportation should be easy and enjoyable experiences.

Regarding local attributes (**interface and place**):

14. **Places should act as passages to other places**. They should be favorably located in relation to their area in the city, and preferably be connected to other places. This would favor the constant flow of passers-by.
15. **Places should have clear boundaries, and their size should be consistent with their characteristics**. Interfaces should be clear, as well as the distinction between public and private. The size of the place should be proportionate to its role in the urban context.

16. **Buildings should be of different types and present different characteristics** so as to accommodate diverse people and activities.

18. **The boundaries of the place should have many doors and windows opening towards it.** There should be no blind spots (out of sight for doors or windows). The boundaries should have "eyes on the street" (Jacobs, 2007), which provides informal vigilance and, consequently, a sense of security.

19. **Places should be at ground level** (Whyte, 1980), in line with the natural relief. This allows greater accessibility to the whole area and favors the visualization of its activities from surrounding private spaces.

20. **Places should be accessible by public and non-motorized transport, and should offer pedestrians good access and circulation options**. The connections between places and their boundaries should prioritize pedestrians, be frequent, open, safe and at ground level, and avoid underground passages or elevated walkways. These places should present no obstacles to pedestrian circulation, and should be accessible.

21. **Interfaces between places and their surrounding areas should support diverse activities.** It is essential to have a mix of housing and activities that run day and night, such as establishments that sell food – bars, restaurants, outdoor cafes, etc.

22. **Public spaces should contain places and elements that enable diverse activities, so that they can be seen as a destination.** They should be passive and active, available on weekdays and weekends, and appeal to a variety of people. Places should adequately support the activities identified in the public life survey.

23. **Places should be pleasant and comfortable in terms of temperature, light, sound and air quality** (including odors). They should be well lit at night.

24. **Building and maintenance costs should be compatible with governmental reality**.

25. **Places should have their own identity, and act as an element that favors the orientation of people in the surrounding area and within the place itself.**

26. **Places should have elements that symbolize their history, population and characteristics and, ideally, they should be a symbol of their surrounding area, including elements that make them memorable.**

27. **Places should avoid causing negative affects and should provide a sense of security, so that pedestrians can feel that they control the place, and that someone is watching over them**. In addition, they should make everyone feel that they also belong there, that they are entitled to be there, and to do something positive for them.

28. **Places and their components should be beautiful and well cared for.**

2.5. Recommendations

After assessing the elements of public space configuration, one should try to understand their relationship with the public life observed there, so as to identify correspondences and discrepancies, and eventually conclude whether or not there is a need for intervention. A summary of the tables will point out any negative and positive aspects.

If a public space is assessed as good, one should consider how to make it even better. If not, it will be necessary to study the variables that performed poorly, and consider how to reverse this. The interventions that will be recommended as a result of the study can be listed from the simplest, cheapest and/or shorter term (which can even be applied on an experimental basis) to the most complex, expensive and/or longer term.

In general, not all variables can be manipulated. In some cases, it is not desirable that they should be, since this would mean disregarding what such public space represents. Having clarity on the place's role in the city is therefore the first step towards filtering the variables that should be manipulated, the degree of manipulation to which they can be subjected, or what agents may be involved in their transformation process.

This is consistent with the guidance we find in PPS (2005) on the need to develop a collectively built vision for the public space under scrutiny. That is why one cannot interfere in a public space without considering the people that have a direct link with it: who they are, what they think and how they act.

3. Method application

A brief case study seeks to exemplify the post-occupation evaluation of public spaces in Brasilia's Bus Station Platform, located in the heart of the city. It is a UNESCO World Heritage Site of modernist DNA and a design based on the paradigm of formality. In other words, it has negative characteristics for public daily life. Below the platform we will find Brasilia's urban bus terminal and its central subway station (figure 1).

Figure 1. City Center, Brasilia, Brazil. In the foreground, the Bus Station Platform, with clear spaces for private cars, and its two squares, one on the left and the other on the right. In the background, we can see the Esplanade of Ministries. Photo by Joana França.

In order to gain knowledge on the place, we analyzed the documents that originated the city layout, data on urban and metropolitan contexts, and cultural heritage legislation. We also carried out an image survey, which relied on mental maps made by interviewees. The public life survey was done on a Tuesday and a Saturday. The flow count took into account the access points to the area, as well as internal flows originating from the bus station. There is a significant presence of street vendors. The data collected in steps 1 and 2 are shown in figure 2.

Figure 2 Step 1 (Knowledge of the Place), and Step 2 (Public Life Survey)

The public life evaluation identified an intense flow of passers-by, together with a very low number of people lingering in the squares, with strong male presence (uneven population). The diversity of activities performed by the subjects were considered poor: the place is just a passageway. The public space evaluation shows that it scores high in terms of location, symbolism, identity and beauty. Its results were poor for the vast majority of global attributes (rigid separation of functions, absence of housing, mobility favoring individual transportation); and particularly poor for local attributes, such as comfort and the offer of support equipment for different activities (figure 3).

Figure 3 Step 3 (Public Life Evaluation), and Step 4 (Public Space Evaluation). The tables summarize the assessment. The results range from red (very bad), orange (bad), yellow (reasonable), light green (good) and dark green (very good). This image represents just the conclusive summary; each of the assessed categories must be justified according to the data collected, supported by the literature and illustrated with images or graphs.

Our recommended vision for the Bus Station Platform is that it should fulfill its role as the most privileged point in the city, revealing elements that are meaningful for the population and which, therefore, should be appreciated at leisure. It should assume its role as a key element in the city center, favoring the connection to other neighboring sectors. It should be the core of urban life and a comfortable, safe, diverse place, widely used on several days and times, favoring pedestrians and public transportation users.

Based on this assessment, with no prejudice to the attributes of a World Heritage Site, we recommend minor interventions that do not interfere in the macro structure of the landscape, but that make a great difference for pedestrians: adjusting the road traffic system; reducing the area meant for cars; offering priority, safety and comfort to passers-by; providing shading on routes and squares; enhancing the place with street furniture; organizing the presence and activity of street vendors; and revisiting original ideas from the time when Brasilia was created, such as back-lit advertising panels.

4. Final considerations

Our method seeks to show that we can learn more about the places we are studying. Interventions need to be informed, context-appropriate and effective if they want to fulfill their purpose of attracting more people to public spaces, and keeping them there. It highlights features that can eventually be developed, according to their need or feasibility, within the field of knowledge of each of the items present in it. It favors breadth rather than depth – two potential research strands.

So far, its application has shown that it can be useful for its intended purpose, including corrections, adaptations and extensions. Evidence of potential benefits and problems in existing places helps us to create new public spaces that do not reproduce unfavorable realities for social appropriation, and that can be useful to the community in the construction of a living and livable city.

Research Paper

Study on Community Planning Strategy of Demolition and Resettlement Amid Urbanization

——Taking the constructive detailed planning of Longhai South District of Shandong Province as an example

Fujun XIA, Shanghai Tongji Urban Planning & Design Institute, China

Abstract

Along with the rapid growth of urbanization, a large number of villages in China are converted into demolition and resettlement communities due to government land replacement or village relocation and so on. However, most of the demolition and resettlement communities are different from ordinary commercial housing communities in terms of spatial characteristics, governance models, and social relationships, and currently some plans have many problems such as neglecting the livelihood of the residents and the public participation in the form, so the research on the relevant planning strategies is significantly important. In light of the problems existing in the existing demolition and resettlement community planning, combined with the construction detailed planning practice case of Longhai South District, a four-point planning strategy is proposed through the combination of theoretical research and actual cases: First, strengthening public participation can assist planning and design, the electronic questionnaire combined with the on-site discussion are recommended to public participation in the demolition and resettlement community. At the same time, public participation can guide the planning and design to make it more rational and pertinent, and to some extent, to revise the planning and design conditions. Second, innovative organization management system is beneficial to the promotion of the conversion process of farmers to the citizenship. Third, planning should not only consider the space but ignore the future livelihood of the residents, and it is of great importance to increase the employment opportunities and income sources of the residents. Fourth, the fairness and homogeneity of the demolition and resettlement community planning is particularly important, much attention should be paid to the continuation of the traditional context.

Keywords

demolition and resettlement community, constructive detailed planning, planning strategy, urbanization

1. Introduction

With the rapid advancement of China's urbanization process, the number of villages has also decreased drastically. The statistics show that China's administrative villages decreased from 629,100 to 580,900 in the 10 years from 2005 to 2015.1 Each year, a large number of villages are converted into demolition and resettlement communities due to government land replacement and relocation of villages, and most of them are resettled. However, most of the demolition and resettlement communities are different from ordinary commercial housing communities in terms of spatial characteristics, governance models, and social relationships. Therefore, the planning strategy needs to be matched in the relevant planning and design.

Wu Ying and Wang Lan (2018) analyzed the spatial characteristics and residents' evaluation of 31 communities (village committee is changed to community committee) in Dezhou City of Shandong Province, Nantong City of Jiangsu Province, and Chongqing City, and found that there are production difficulties and some inappropriate public facilities allocation problems in the villages, it is proposed that the residents in the villages should consider the employment of the residents in the site selection. We should further strengthen the public space allocation in the public space, and carefully consider the design of the room type with a flexible manner according to the needs of the residents. Li Qin (2013) pointed out that public participation in the planning and construction of European and American settlements pointed out that public participation should improve legislative and institutional guarantees, increase residents' awareness of participation, increase public participation, establish mass organizations, and set up a sound public participation system. Sheng Dong (2016) analyzed the problems and causes in the process of demolition and resettlement community in urban and rural areas, and proposed countermeasures to strengthen the management of demolition and resettlement community from the aspects of pre-planning, institutional setting, system innovation, service improvement and propaganda guidance. Chen Ming (2018) pointed out that in order to eliminate the defects of governance mode and the problem of governance difficulties in the demolition and resettlement communities, it is necessary to establish a unified urban and rural social governance system, rationally select the governance model according to local conditions, and adopt the community shareholding cooperation system as a starting point to promote the collective economic management reform.

2. Status quo of demolition and resettlement community planning

2.1. Community planning methods for demolition and resettlement are basically the same as that of ordinary commercial houses

There is no market-based bidding mechanism in the resettlement and resettlement communities to regulate the distribution, so the requirement for fairness and uniformity is very high. However, the planning method of many demolition and resettlement areas is still the same as that of ordinary commercial houses in that “grand green land” and “king building”(buildings in high quality and with high price) are designed in order to pursue space

quality and economic benefits. Social conflicts are easy to be created due to disputes during the housing phase.

2.2. Focus simply on space while ignore the employment and livelihood of farmers

The community service object of demolition and resettlement is of great difference from the general residential area. The villagers moving into the resettlement community means they will leave the cultivated land on which they depend for their survival and lose their main source of livelihood. At present, however, the domestic rural demolition and resettlement community often focuses on the promotion of living space and the improvement of the living environment, and lacks consideration of the livelihood of the rehousing residents, resulting in the population urbanization work being formalized so that resettlement residents can not integrate into urban life smoothly, and their quality of life has declined, making the process of urbanization of rural population lag behind.

2.3. Public participation is formalized

The demolition and resettlement housing is the residence provided by the government for the resettlement residents so the government and development units play a decisive role in the land use and spatial layout and the degree of public participation is weak. Besides, most public participation is mainly based on ex post participation and passive participation, which means public participation stays in superficial publicity and symbolically listening to opinions, and the actual users of the settlements are difficult to play a role in planning decisions.

2.4. The lack of heritage in traditional culture

The demolition and resettlement community has its determined main body of residence, mainly farmers who once lived in the countryside. They used to gather and communicate in public spaces in front of the courtyard, in the lanes, under the trees, next to the wells. However, in the community planning for demolition and resettlement, it often lacks the inheritance of traditional cultural context and lacks the traditional public space for community interaction, which seriously weakens the sense of belonging and belonging of community residents.

2.5. The corresponding organizational management mechanism is not perfect

Since the conversion of farmers to the public is extremely complicated and the corresponding management mechanism is not perfect, some problems have arisen. First of all, the management subject is chaotic, the village committee and the neighborhood committee exist at the same time, and the daily management might be in a mess. Secondly, the management power is not clear, and the intersection of multi-agent management power leads to the vacuum of some transaction management.

3. Demolition and resettlement community planning strategy

3.1. Strengthening public participation in assisted planning and design

3.1.1. Strengthening public participation is extremely important for community planning for demolition and resettlement

Ordinary commercial housing is difficult to be publicly involved in the planning stage in that the main body of the housing is not clear. However, the construction of the demolition and resettlement community is mostly government-led and the residents are often clearly resettled at the planning stage. Therefore, public participation in the planning stage is feasible. Strengthening public participation can directly influence the planning plan at different design stages, and at the same time improve the rationality and pertinence of the program and enhance the sense of belonging of residents.

1) Community construction is more reasonable

Conventional community planning gives the government design indicators and requirements. And then the planners make plans and apply for approval. However, the in-depth and extensive public participation enables planners to understand the tangible benefits and needs of the government and residents more comprehensively and deeply. With comprehensive consideration of the demands of the government and residents, decision-making bias caused by unilateral voice can be avoided, thus making community construction more rational.

2) Planning solutions are more targeted

Extensive and in-depth public participation can truly understand the living habits and living needs of the actual residents, thus making the planning scheme more local and targeted.

3) Enhance residents' sense of belonging

Public participation provides residents with an opportunity to express their needs and participate in planning and design, so that they can participate in planning and decision-making. The community can better meet the residents' residential and emotional needs and enhance residents' sense of identity and belonging.

3.1.2. Public participation recommendation method

Most of the residents in the demolition and resettlement community are farmers, and the main body of the residents is the elderly and children. In addition, many young children are working outside the home. Therefore, the traditional paper questionnaire is difficult to cover all the people. In contrast, the e-questionnaire is not limited by the geographical factors of the survey population, and has the advantages of rapid feedback, convenient sending and receiving, and convenient statistics. At the same time, with the deepening of planning and design, different problems will arise in different stages needed to be understood. It also has the advantage of multiple rounds of distribution, which can guide planning and design in all aspects of different stages. However, the electronic questionnaire has certain limitations in some issues that require subjective expression, and needs to be supplemented by on-site discussions.

3.2. Innovative organization management system

As for the residents living in the resettlement community, they not only face an identity transformation from farmers into citizens, an change of living environment, but also the change of lifestyle habits, economic income and housing demand. The original rural management system has been unable to meet the requirements, so the organization management system is an important part of the process of demolition and resettlement community construction. How to break through the original system and mechanism and explore the new system of resettlement community management is of great significance for promoting urban and rural planning and maintaining the rights and interests of residents.

3.2.1. Identify the main body of management responsibility and standardize the management system

The demolition and resettlement community often has the problem of overlapping management organizations. It not only retains the village committee, but also resets the neighborhood committee. There are problems such as overlapping management powers and responsibilities, and there are two sets of management methods in some affairs. Some of the affairs management is left unattended, resulting in the timely and effective protection of residents' needs. The author proposes that the demolition and resettlement community can attempt to merge the village committees, establish a community neighborhood committee with unified powers and responsibilities, take the community neighborhood committee as the main body of management, and carry out vertical management of the resettlement community. At the same time, they can guide the residents to set up the owners committee who can directly participate in the community management, forming a management system in which community residents' committees and resettlement residents work together.

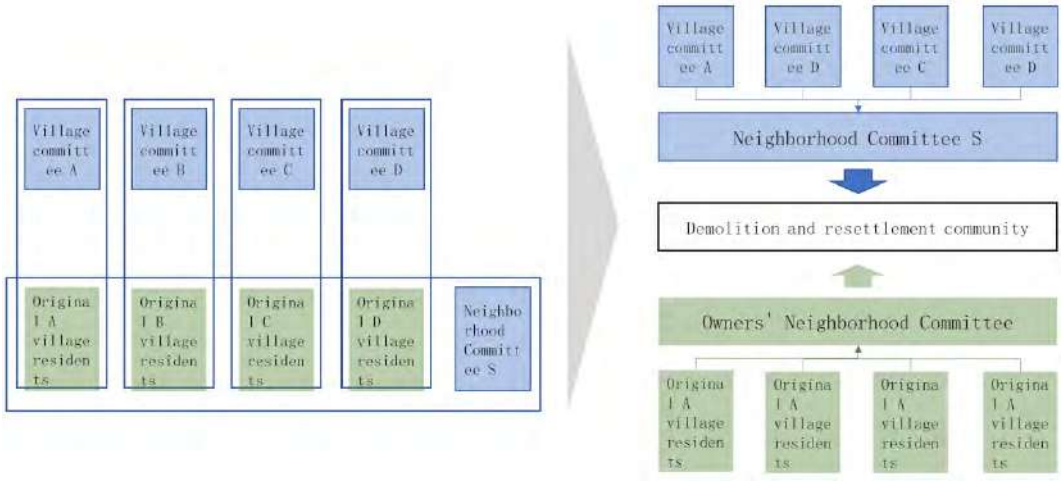

Figure 1. Transformation of the community management system for demolition and resettlement

Image source: painting by the author

3.2.2. Innovative collective economic organization model

The rural collective economic assets are an important material basis for ensuring the livelihood of the villagers. Since the demolition and resettlement community residents have lost the land cultivated in the past, how to protect the villagers' lives through the collective

economy is particularly important. However, in the past, collective assets were generally directly managed by the government and its market economy could not be effectively played. The author proposes that the modern enterprise system can be integrated into the administrative management system through the reform of the collective economic system, the separation of government and enterprise, and the use of the form of community shareholding cooperation, through inventory checking, quantification of stocks, and clarification of property rights. On the one hand, collective assets are managed through professional managers. On the other hand, the one-person-one-vote system of shareholders is implemented based on the participation of shares, fairly maintaining villagers' voting rights. In the distribution system, the income of the residents is increased by dividends.

3.3. Increase employment opportunities and income sources for residents

To solve the livelihood problems of the residents in the resettlement community, it is necessary to carry out the employment and income distribution. On the one hand, increase the employment opportunities of the community residents, increase the income of the labor, and on the other hand, enrich the income sources of the community residents and protect the interests of the residents.

3.3.1. Increase employment opportunities for community residents

The driving force of villagers moving into the demolition and resettlement community mainly comes from the support of policies, which is a passive urbanization behavior. Although the living environment of the resettlement community residents is improved, they lose the necessary source of life, mainly due to the levy of cultivated land, low literacy, lack of work skills, etc, which makes it impossible for residents to afford the cost of living and community management funds, which in turn has led to a decline in the quality of life. In order to solve this dilemma employment opportunities for the villagers in the planning and construction of the demolition and resettlement community must be considered. First of all, the strategy of function mixing is adopted in the space to ensure that the living area meets the demand, and the commercial space such as catering and retail, or the industrial space such as hand workshops are laid out. Secondly, the community coordinating department, enterprise resources, and the organization of specialized personnel to carry out targeted skills training for the relocated villagers according to the needs of the post. Finally, the community cooperates with enterprises to create employment opportunities. On the one hand, the community provides employment opportunities in service centers such as service centers and sanitation, and on the other hand, it signs a targeted employment agreement with enterprises to increase employment.

3.3.2. Enriching the income of community residents

The author proposes that the plan should change the form of one-time compensation for the demolition and resettlement community in the past, and construct a distribution system that combines labor distribution, capital allocation and welfare security. Among them, the distribution according to work mainly relies on the protection of residents' employment and the distribution according to the number of residents' labor. The allocation of capital is mainly based on the shareholding system of the community, and dividends are based on the number of shares of the residents. The welfare guarantee is to provide basic living for the poor. Through the combination of the three methods, the residents in the resettlement community will be steadily increased, the rural people will make a smooth transition to the

community, and while pursuing the efficiency of the market economy, the fairness will be taken into consideration to ensure the living of the residents in the community.

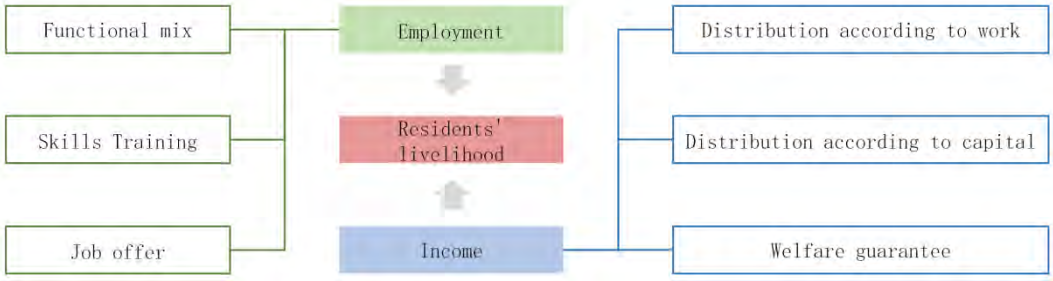

Figure 2. Ways to solve the livelihood problems of the residents in the resettlement community

Image source: painting by the author

3.4. More targeted spatial planning

The same as the planning of ordinary residential areas, the demolition and resettlement community should consider the combination of building groups, transportation methods and organization, public service facilities, municipal facilities and other relevant planning principles. However, at the same time, due to a series of reasons such as the demolition and resettlement community housing can not be sold by the market bidding mechanism, the change of the residential identity from the villagers to the citizens, spatial planning needs to pay attention to three aspects: fairness and homogeneity, continuity of traditional cultural context and flexibility of the program.

3.4.1. Fairness and homogeneity are particularly important

Most of the demolition and resettlement communities are government-led, so there is no corresponding market bidding mechanism in the housing phase. If there are large differences between the units, many neighborhood disputes and social contradictions will often be attracted. Therefore, the fairness and equity of the demolition and resettlement community planning Goodness is especially important. It is necessary to avoid the design techniques of “King building” and central green space, and the fairness of the units should be as fair as possible, so that the green landscape, road traffic facilities and public service facilities enjoyed by each type of house are relatively good.

3.4.2. Continue the original cultural context

The residents of the demolition and resettlement community were originally farmers. In the planning of demolition and resettlement community, the original cultural context should be continued, and the customary community public space formed by the villagers should be inherited and expanded. Much attention should be paid to the setting of the space where the original residents once gathered and exchanged, and attempt to restore all the vitality of the original residence, as well as the inheritance of the original habits and customs, and enhance the sense of identity and belonging of the residents.

3.4.3. Flexible program

It is impossible for each type of plan to be absolutely good, because the floor, space and landscape environment, roads and transportation facilities, public service facilities and other elements are different for different types of houses. The planning program needs to be

flexible in these aspects. Besides, through the combination of different elements, each household (and other elements it belongs to) should be basically average.

4. Empirical study on constructive detailed planning of Longhai South District

Longhai south District is located in the west of the township of Longgu Town, Juye County, Heze City, Shandong Province. It is a resettlement community for the relocation of villages in the coal-pressing area, which mainly undertakes the relocation of two villages in East Bihai and North Bihai, as well as villagers in Liuhai Village and other three villages that have not yet been resettled. In addition, the planned site is relatively flat and the slope is small, so several villages will form a water surface in the next 2-3 years due to coal mining subsidence of the New Dragon Group. The villagers will have no land to farm, but the New Dragon Group will subsidize 1,500 yuan for each mu a year.

60㎡	18	16		34
totle	798	734	300	1832

Source of data: organized by the author according to planning requirements

4.1. Public participation in assisted planning and design

At the beginning of the design, villagers in East Bihai and North Bihai villages temporarily rented houses in the towns and villages because of the occupation of the village land. At the same time, many village children worked in the field. Many factors have led to the questionnaire not being distributed in paper form. Finally, the public participation was carried out by means of a combination of electronic questionnaires and on-site discussions.

4.1.1. Public participation and planning process

According to the planning and design conditions and on-the-spot investigations given by the government, combined with the design intention, the first electronic questionnaire was distributed, mainly to survey the age, living place, living habits, and the needs of the elderly for elevators and so on. A total of 734 copies were filled out. Among that, 718 copies are valid questionnaires.

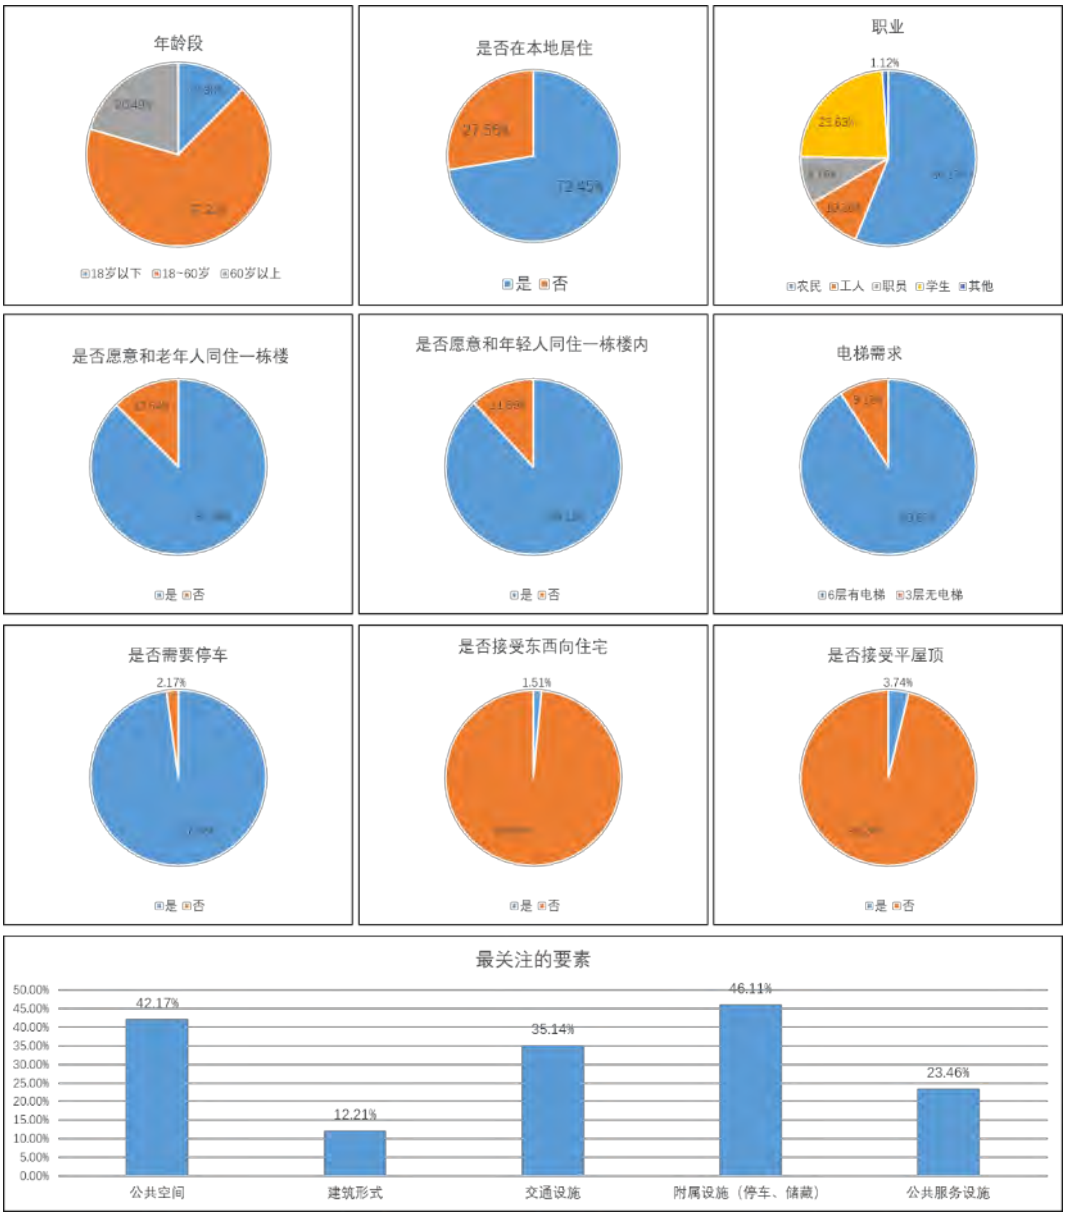

Figure 6. First questionnaire chart

Image source: painting by the author

In order to pursue the richness and change of space, the plan attempts to combine the north-south and the east-west housing, but the results of the questionnaire show that 98.49% of the residents do not accept east-west housing. Thus, it is determined from the beginning of design that all the units are north-south. The way to avoid the iteration of the planning scheme.

During the investigation, it is found that the elderly houses in the surrounding demolition and resettlement areas are all three-story elevator-free houses, and they are independently set in the corners of the community, which is not conducive to community integration and the physical and mental health of the elderly. The plan intents to mix old people's houses in other units. However, this idea faces the question of whether young people and old people

are willing to live in the same building or does the elderly accept the problem of changing from a 3rd floor elevator-free house to a 6th floor elevator house? The questionnaire results show that 87.46% of the elderly and 88.11% of young people don't mind mixing, and 90.87% of the elderly accept 6-story elevators.

Due to cost considerations, the government asked the residential roof to be a flat roof. However, the results of the questionnaire showed that 96.26% of the residents did not accept the flat roof. Combined with the existing situation that the surrounding resettlement areas were all sloping roofs, they persuaded the government to change the design conditions and change the slope roof to flat roof.

Through the first questionnaire survey, the following three points are determined to guide the planning and design: First of all, the house must be arranged in a north-south direction. Second, the roof form is a sloping roof. Third, the elderly houses can be mixed with other units.

After determining the mix of old people's houses and other types of houses, there must be an elevator on the mixed-use 6-story house. However, setting up the elevator will increase the corresponding cost and post-maintenance costs. Whether all residents want the house with elevator on 6-story of the house is uncertain. At the same time, the 110-square-meter unit in the planning and design conditions must be equipped with a 1:1 ratio of the ground floor garage, but whether the residents really need garage parking or a lower floor space is worth exploring. Combined with the deepening of the program and the advancement of the planning stage, a second electronic questionnaire was issued, focusing on whether the elevator is installed on 6-story building and whether the demand for the underground garage is necessary.

Figure 7. Research and on-site discussion

Image source: the photo was took by the author

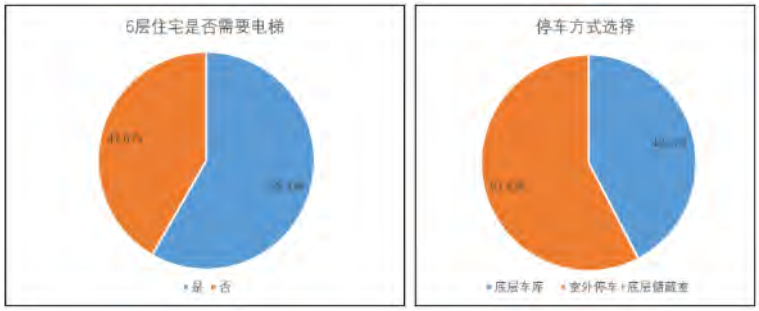

Figure 8. Statistics of the second questionnaire

Image source: painting by the author

According to the results of the questionnaire, about 58.33% of the residents chose the 6-story residential buildings with elevators. Therefore, the planning and design of 6-story residential buildings should include two types, one the elevator and the other without elevator. 42.37% of the residents chose the ground floor garage, and 57.63% of the residents chose the combination of the outdoor parking space and the bottom storage room, which verify the previous conjecture. At the same time, the planning plan did not need to design too many garages on the ground floor, resulting in the disadvantages of excessive depth.

4.1.2. Public participation in the guidance and revision of the planning plan

Some ideas for the beginning of the design can be clarified by means of public participation. According to the statistics of the actual residents' wishes, the planning and design techniques can be guided and limited, so as to avoid the repetition of the plan and a plan that is more in line with actual needs can be made. At the same time, different issues of industry at different stages can be clarified through public participation.

The planning and design conditions for the demolition and resettlement areas are mostly provided by the government, and the actual resident residents are less involved. However, through public participation, the government can fully understand the needs of the residents. What is more, it will also make up for the planning and design adjustments to a certain extent, and correcting the planning and design conditions will help the program to become more reasonable.

4.2. Organization management

At the beginning of the planning, a management system consisting of neighborhood committees, owners' committees and property companies has been established. The community of Longhai south District merged the village committees of Bihai and Liuhai involved in the demolition and resettlement, and established the community committee of Longhai south District, which is mainly responsible for daily life needs such as administrative management, social welfare, culture and education, publicity and education, and mediation of residents' disputes. At the same time, the community residents are guided to set up owners' committees, exercise the right of self-government, safeguard the common interests of the owners, and effectively supervise the residents' management power.

Starting from the two aspects of space and system, the plan solves the livelihood problems of community residents. First of all, construct commercial buildings in the community, so

that the internal functions of the community can be mixed to provide space security for the residents. Secondly, 30% of the commercial building area is taken as collective property, and the remaining 70% is allocated to households according to the proportion. The 100 square meter residential area is allocated for a commercial area of 2 square meters. Finally, the community set up a company, the residents convert the commercial building area into stock shares, entrust the company to operate in a unified manner, and the operating income is divided into internal dividends according to the stock.

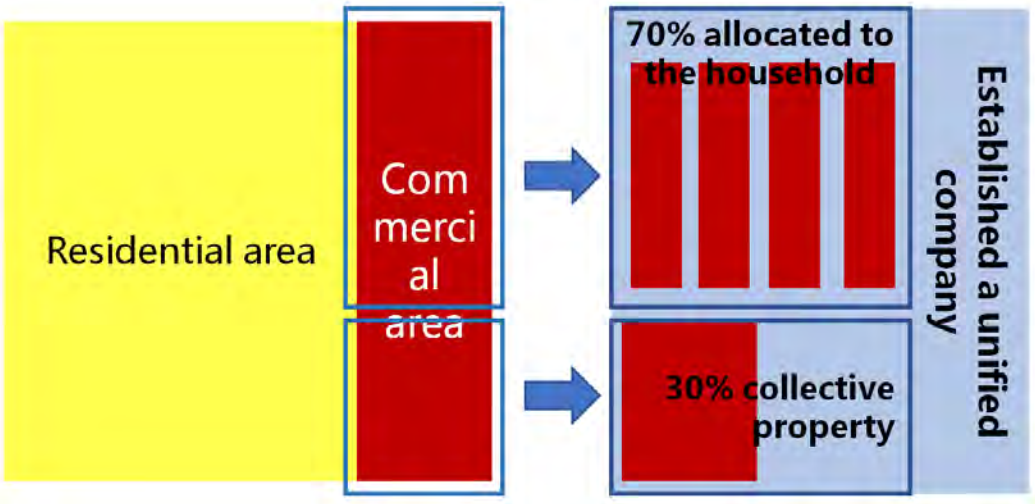

Figure 9. Community distribution and management model of community in Longhai south District

Image source: painting by the author

4.3. Spatial planning

After many rounds of communication and revision with the government and villagers, the plan for "one core, one axis, one belt, three districts" was finally formed. The planning method of the courtyard concept and the setting of the market axis make the plan achieve fairness and homogeneity as much as possible, and continue the traditional cultural context. At the same time, through the planning techniques such as wind simulation and noise simulation, let each A household has achieved the best quality of living under the existing conditions.

Figure 10. Planning master plan

Image source: painting by the author

Figure 11. Aerial view

Image source: painting by the author

4.3.1. Courtyard group

Taking "harmony" as the concept and the three images of "water" as the context, the plan connects three theme areas in series to form the theme of 11 groups of courtyards.

Figure 12. Schematic diagram of the courtyard group

Image source: painting by the author

There is no concentrated green space in the whole demolition and resettlement area, and each group has the same elements, which ensures the relative goodness of each group. A central square is set up in the center of the group, with construction activities and old trees and children's activity bunkers on both sides. Under the shade of ancient trees, there is a new place of communication for each courtyard group. People can chat and drink tea under the tree. The bunker is set around the ancient trees to facilitate the elderly to look after the children in the process of communication.

Figure 13. Aerial view of the group

Image source: painting by the author

4.3.2. Market axis

The survey finds that there is a market opening only one day a week in the south side of Longhai south District, which is very popular. However, since there is no corresponding space bearing, it causes traffic congestion and environmental mess. It is planned to set up a north-south non-mixed road in the middle of the resettlement area, reduce the speed by designing landscape pieces, and introduce the original southern market into the community, which not only continues the original living habits of the surrounding residents, but also increases the popularity of the resettlement area. At the same time, it also solved the urban problems caused by the previous market.

Figure 14. Market comparison chart

Image source: painting by the author

4.3.3. Flexibility plan

According to the statistics of the questionnaire, the demand for elevators varies from residents to residents. According to the development trend of elevator configuration and the relatively high proportion of elderly people in Longhai south District, the demand for elevators will become higher and higher in the future. In order to meet the interests of different groups of people and consider the future development, it is planned to reserve the location of the elevator shaft for all 6-story houses, but residents can choose elevators according to their needs.

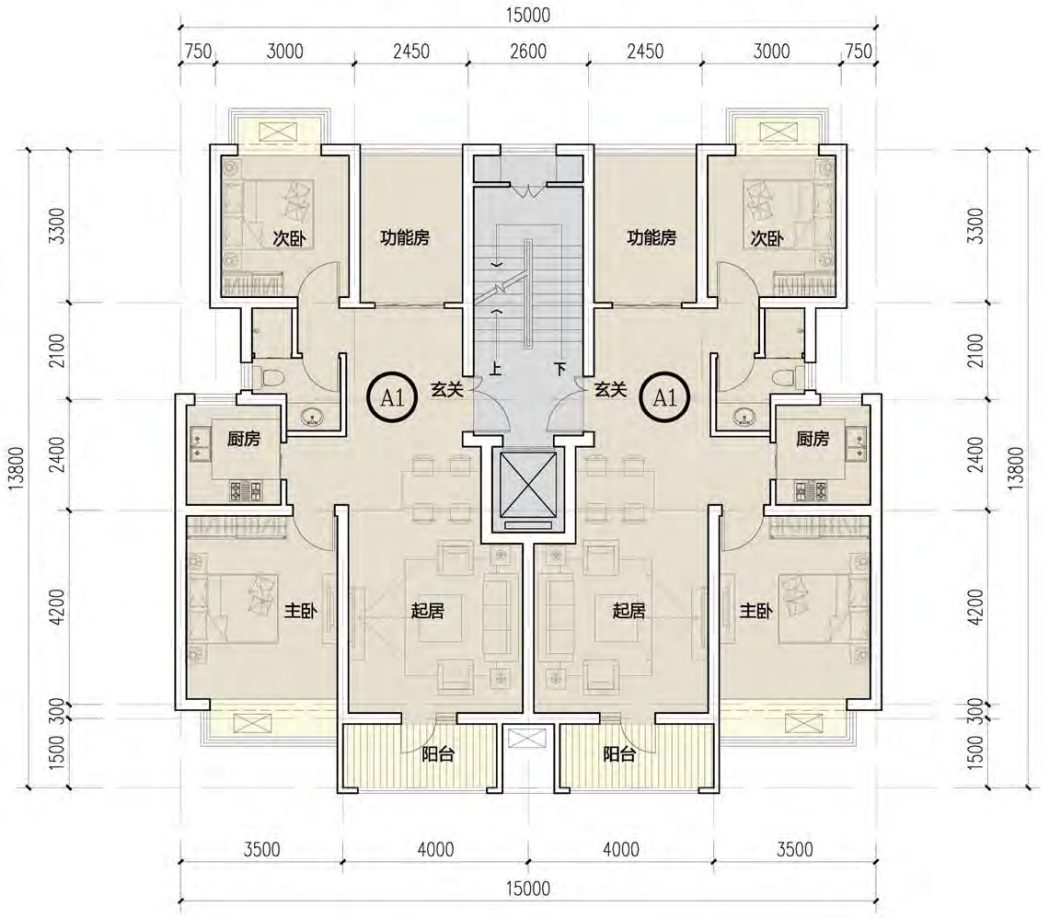

Figure 15. Plane floor plan for 90+90 units

Image source: painting by the author

It is planned to set up a parking garage and a plurality of storage rooms on the ground floor, and each storage room has a separate door. It is considered that different storerooms are allocated according to the different floors and garage sizes of different houses, and the uniform requirements are achieved through the flexible configuration of other elements.

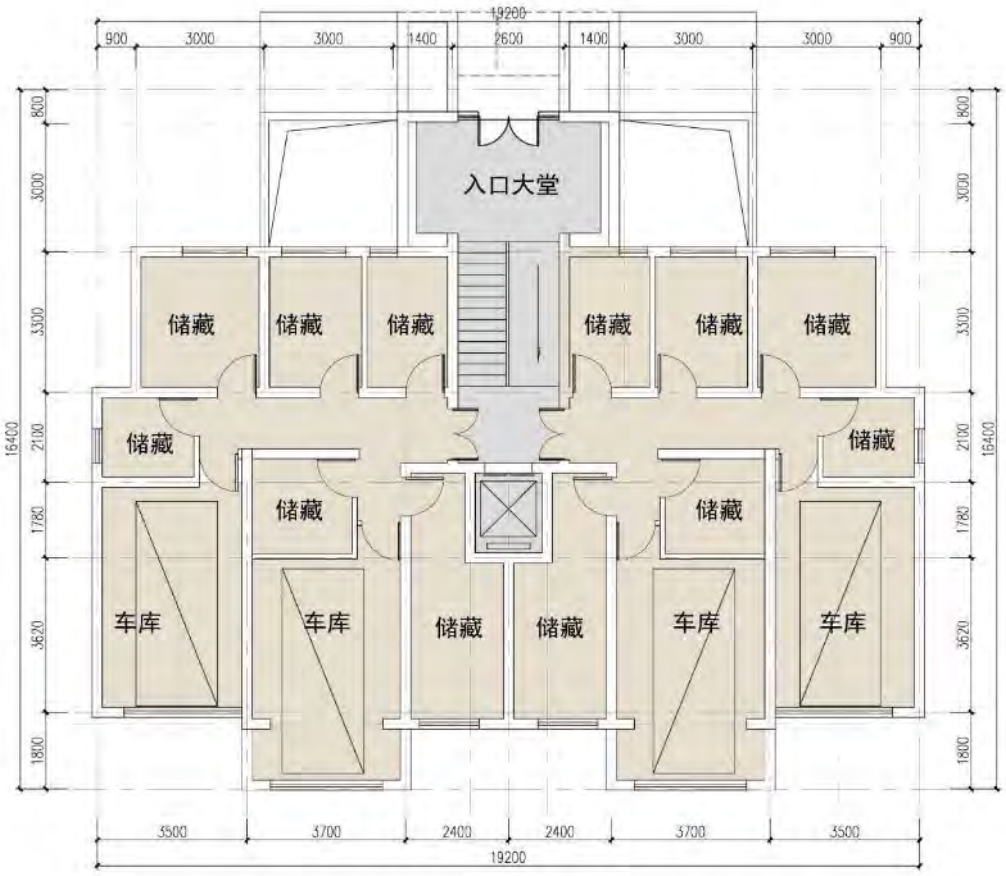

Figure 16. The ground plan of the 110+110 unit

Image source: painting by the author

4.3.4. Application of planning techniques

There is a railway 40 meters south of the planned land, which has some noise interference to the community. Through wind simulation, noise simulation, sunshine analysis and other technical means, the wind speed in each courtyard group can be controlled at its smallest state in winter and largest in summer, and the interior of the community is least affected by railway noise. By doing so, the living quality reaches optimal under the existing conditions.

5. Conclusion

The urbanization has undergone a rapid growth across the country. A large number of villages in China are converted into demolition and resettlement communities due to government land replacement and relocation of villages each year. For the time being, the demolition and resettlement communities have many problems such as it has the same planning means as ordinary commercial housing communities, it simply pays attention to space while neglecting residents' livelihoods, or the public participation is in the form and so on. Hence, the research on planning strategies for demolition and resettlement communities is of great importance.

In light of the problems in the existing demolition and resettlement community planning, combined with the construction detailed planning practice case of Longhai South District, a four-point planning strategy is proposed through the combination of theoretical research and actual cases: First of all, strengthening public participation can assist planning and design, the electronic questionnaire combined with the on-site discussion are recommended to public participation in the demolition and resettlement community. At

the same time, public participation can guide the planning and design to make it more rational and pertinent, and to some extent, to revise the planning and design conditions. Second, innovative organization management system is beneficial to the promotion of the conversion process of farmers to the citizenship. Third, planning should not only consider the space but ignore the future livelihood of the residents, and it is of great importance to increase the employment opportunities and income sources of the residents. Fourth, the fairness and homogeneity of the demolition and resettlement community planning is particularly important, much attention should be paid to the continuation of the traditional context.

Research Paper

Users' Perceptions of Walkability Attributes in Residential Areas: Reliability and Validity

Yang Ye, Harbin Institute of Technology; China

Abstract

In recent years, urban environmental quality and urban vitality have attracted more scholars' attention than ever as Chinese cities experienced a rapid development stage. To test the influence of urban built environment on walkability in residential areas, this study developed a questionnaire to perceive the users' perception of walkability around their neighbourhood in residential areas, which was based on the Neighbourhood Environment Walkability Scale for Mainland China (NEWS-MC). The original Neighbourhood Environment Walkability Scale (NEWS) are developed for use in USA to measure residents' perceptions of the environment attributes, and has been applied in many countries, such as US, Australia, Korea and Hong Kong, and be modify to be Neighbourhood Environment Walkability Scale for Mainland China (NEWS-MC) and been applied in Chinese cities. NEWS-MC has been found have moderate to high rest-retest reliabilities and good criterion The evidence illustrated high-walkable neighbourhoods be found with higher density, land-use mix, street connectivity, more safety and have more aesthetics elements. In this study, we modified NEWS-MC to reflect the characteristics of cold region Chinese built environment and people's behaviour mode. To perceive the final version of Neighbourhood Environment Walkability Scale for cold region Chinese cities (NEWS-CRC), We made a pilot study which include 50 samples, then interview 800 residents from 6 selected residential districts in Harbin (the capital city with highest latitude in China) which were different in walkability attributes and economic status. The final version of the NEWS-CRC included 8 subscales and 3 single items (76 items in total). Test-retest reliability showed moderate to high except 4 items . In total, the NEWS-CRC could illustrate residents' perceptions of walkability attributes in cold region Chinese cities and could be use in other Chinese urban attributes studies related to walking.

Keywords

Keyword 1, keyword 2, keyword 3 (3-5)

1. Introduction

The high speed of cities sprawl and urban regeneration worldwide make public space and acclivities in public space gain increasingly attention than ever. Meanwhile, there is growing interest on research about relationship between built environment attributes and residents' physical activity. Studies focus on walking suggest than higher residential density, higher

level of land use mix- both diversity and accessibility, more aesthetic elements are attributes could hence more walking, and associated with neighbourhoods more walkable .

'Walkability' is referred to and generally defined as "...the extent to which walking is readily available as a safe, connected, accessible and pleasant mode of transportation". In the last decade, there were increasing evidence of the influence of neighborhoods built environment characteristics on walkability. Smith and Clifton illustrated that an built environment friendly to pedestrians usually includes characteristics such as high density, convenience to walk to facilities, system coherence, high street connectivity, safety from traffic and crime, comfortable and attractiveness . Researcher in urban planning and transportation also identified key environment attributes on creating walkable neighborhood. Cervero and Duncan found density, trip distance, land use diversity, existing of sidewalk and bike lane could affect people's choice of walk or bike . The studies by De bourdeaudhuij demonstrated the effects of space proportion, size of block and traffic congestion on user's choice of travel mode .

To make more research on influence of urban environment's walkability on physical activities and psychological health or residents, valid measures of walkability are needed. The Neighborhood Environment Walkability Scale(NEWS) and its abbreviated version(NEWS-A) are developed for use in USA to measure residents' perceptions of the environment attributes . They value built environment characteristics that are believed to affect residents' walking choice. Both NEWS and NEWS-A have been found have moderate to high rest-retest reliabilities, and good criterion The evidence illustrated high-walkable neighborhoods be found with higher density , land-use mix, street connectivity, more safety and have more aesthetics elements . Although NEWS and NEWS-A have been applied in many countries, such as US, Australia, Korea and Hong Kong, the validity and reliability of the NEWS or NEWS –A have not been examined in mainland China.

2. Method

2.1. Measures

Neighborhood Environment Walkability Scale(NEWS) is a instrument used to obtain residents' perception of built environment attributes related to walking and bicycling around where they live. The original NEWS includes 98 items and is rarely used, the abbreviated version of it, NEWS-A , which has similar structure to the full version but has fewer items in subscales, is commonly used and have been applied in many countries (Brazil, Australia, Poland, Korea, Mexico, and Hong Kong). So in this study we also used NEWS-A as the source to develop the NEWS version which appropriate for Mainland China(NEWS-MC). NEWS-A has 8 multi-item subscales, a) residential density; b) land-use mix-diversity; c) Land-use mix-access; d) street connectivity; e) infrastructure and safety for walking; f) aesthetics; g)traffic hazards and h) Crime safety, and 5 single-item subscales, including Lack of parking, lack of cul-de-sacs, hilliness, physical barriers and social interaction while walking. All items except the ones in residential density and land-use mix-diversity subscales are rated on a 4-point Likert scale(1- strongly disagree, 2-disagree, 3-agree, 4-strongly agree). Items in residential density subscale are rated on 5-point Likeert scale, by asking about the frequency of perceive certain type of residences, and weighted ratings are summed to make a residential

density perceptions score. Land-use mix-diversity is assessed by time walking from home to various types of destinations, with responses ranging from distance for 1-5mins walking(coded as 5) to distance for more than 30mins walking(coded as 1).

2.2. Participants and procedures

2.2.1 Development and adaptation The original NEWS and NEWS-A were developed in US, to develop a version of NEWS which could adapt Chinese cities' build environment attributes and reflects residents' need, 15 experts from multi-research fields, urban planning and urban design(7members), public health(3 members), environment-behaviour studies(2 members), physical activity(2 members) and Rehabilitation & Healthcare(1 member) were interviewed with a goal to draft a NEWS-MC. All members of the committee reviewed NEWS-A, we also provided them NEWS-Youth , NEWS for senior citizen and NEWS Hong Kong as reference. Committee members gave their opinions on whether each item should be kept, modified or deleted, or any item should be add after careful thinking about items relevant to mainland Chinese urban environment characteristics and residents' behaviour mode. In total, 57 items in NEWS-A were kept, 9 of them were modified , 17 new items were added and 1 item was deleted considering their relevant to the study setting. (Table 1).

Items in residential density subscale were modified to fit the medium to high residential density characteristic in mainland Chinese cities. 'detached single-family residences' and 'townhouses or row hoses of 1-3 stories' were merged into a single item as these kind of residential buildings are very rarely in mainland china; apartments of 4-6, 7-12 and more than 13 stories were modified to apartment of 4-7, 8-18, 19-26 stories and apartments of 27 stories or more was added to this subscale, as 7, 18, 26, 27 and above stories residential buildings are the extreme height for multi-stories, mid-high rise, high rise and super high rise residential buildings through the Chinese building codes. 5 items in land –use mix-diversity were also modified to fit Chinese urban environment(see Table 1). 17 items were added to the questionnaire to provide a better match mainland Chinese urban built environment features and culture background- medium to high population density and building density, high percentage of walking or using public transportation in daily travel, high risk of air pollution and safety issues related by traffic and crime. Item 'video store' was deleted because it is very rarely in mainland Chinese cities now, maybe caused by the development of internet everyone watch or buy movie or video online(see Table 1).

2.2.2 Test-retest reliability Potential participants were chosen from the four Harbin residential neighborhoods mention above, the economic status were obtained from national 2015 Census data. Walkability was measured by residential density, intersection density, destination density(service, commercial and facilities), road density(length of street could walk per km2) and type of street block(square grid, radial shape or have many cul-de-sacs). These data were achieved from baidu map(http://map.baidu.com/).

Four residential neighborhoods, with 125 potential participants were chosen randomly from each neighborhood. The survey were done in March 2017, We went to each neighborhood in both weekday and weekend, morning, noon and evening. When picking the participants, firstly we found the people showed up in that area and asked whether they lived in this neighborhood, if the answer was yes, we further asked whether they would be willing to be reassessed 10 days later after the first survey, and they were told if they finished both survey, they will get 10RMB as reward. After confirm lived in that residential neighborhood and agreed to attend both survey, one became our participant. The process was the

interviewer and the participants added each other as 'friend' on wechat (a social App with high popularity in smart phone holders of all ages, add as friends mean two can message each other, and could also pay and receive money, receive and send documents to each other) , then sent them the NEWS-MC questionnaire forms, the participants could contacted the interviewer by wechat if they had any questions about the questionnaire. After they sent the first-time forms back, they could get 3RMB. 10 days later we sent them the forms again, and gave who sent forms back 7RMB, the ones who did not sent form back were reminded twice on wechat. The interval between the two surveys ranged from 10-16 days(average 12.4 days) . The recruitment rate of the first survey was 85%, 92, 93, 85 80and participants responded the second survey, so the total recruitment rate is 70%.

Table 1. Adaptations of the NEWS-A for Mainland Chinese

Item
Addition items
Distance to community doctor service
Distance to Chinese drink or noodle shop
Distance to Chinese non-fast food restaurant
Distance to Bakery/dessert/cake shop
Distance to community centre
Distance to copy /scan passport photo-taken shop
Distance to place could pay all kinds of fees(gas, water, cable TV and internet)
Distance to pets' food or clothes shop
Shopping areas are easily accessible via public transport.
The streets are so crowded that it is difficult to walk.
Need to walk over a pedestrian bridge or through a wide road to access the nearest services
There are 'hawkers' and shops on the streets and sidewalks blocking the way
There are many cars parking on the sidewalks blocking the way
There are indoor, air-conditioned places (shopping malls) where people can walk
The streets of my neighborhood are often slippery in winter
The level of air pollution in my neighborhood is often high
It is unsafe to walk in my neighborhood because of objects dropping from high-rise buildings
There are many homeless people, drunk people in my neighborhood
Modifications items
Two items detached single-family residences and townhouses or row hoses of 1-3 stories merged into a single item
apartments of 4-6 stories change to apartment of 4-7 stories.
apartments of 7-12 stories change to apartment of 8-18 stories.
apartments of more than 13 stories changed to 'apartments of 18-26' stories. Additional item referring to commonness of apartment buildings with more than 26 stories added .
Destination 'fruit/vegetable market' renamed 'fresh food market' .
Destinations 'fast-food restaurant' renamed 'Chained Western or Chinese fast-food restaurant' .
Destination 'non-fast food restaurant' changed to 'Western/international non-fast food restaurant' .
Destination 'recreation centre' changed to 'recreation centre or outdoor recreation space' .
Destination 'clothing store' changed to 'clothing & shoe store' .
'Walkers and bikers on the streets can be easily seen by people in their homes' changed to 'walkers and bikers on the streets can be easily seen by other people' .

3. Results

Four hundreds and twenty-five participants attended the first survey, with 227 men and 198 women, mean age 45.2. 48% participants had a collage degree or above. Among all participants, 32% of them own 1 car or more, and 45% reported they use public transportation 'very often'. Three hundreds and fifty participants completed both surveys (193 men and 157 woman), response rate was 82%. The sample size per neighborhood was: 90 and 93 in high-walkable neighborhoods, 82 and 85 in low-walkable neighborhoods.

Through previously built satisfaction systems, we took ICC value below 0.50 as poor, 0.50 to 0.75 as moderate, and above 0.75 as reliability. Test-retest reliability for all subscales and single items of the NEWS-MC are shown in Table 2. All subscals and single-items except one-hilly roads-showed moderate to good level of reliability(>0.75), 6 subscales or single items show high level of reliability (>0.90), and all $p<0.05$.

Table 2 illustrates the results of mean scores on neighborhood walkability subscales between residents from high-walkable and low-walkable neighborhood. Residents from high-walkable neighborhoods provided ratings indicative of higher residential density($t(412)= 6.85$, $p<0.001$), land-use mix-diversity($t(420)= -10.97$, $p<0.001$); Land-use mix-access ($t(420)=4.15$, $p<0.001$); street connectivity($t(415)= 2.93$, $p<0.001$), infrastructure and safety for walking($t(397)= 5.32$, $p=0.006$), traffic hazards($t(399)=2.07$, $p=0.021$), parking difficulties($t(408)= 6.81$, $p=0.004$), physical barriers($t(388)= 8.74$, $p<0.001$) and social interaction while walking($t(386)= -4.85$, $p<0.001$). Mean while, residents from low-walkable provided higher ratings of aesthetics($t(418)= -6.28$, $p=0.008$) of their neighborhoods. Residents' perception of crime safety($t(385)= 8.76$, $p<0.315$), not have many cul-de-sacs($t(408)= 5.79$, $p<0.438$), and hilliness($t(408)= 5.79$, $p<0.570$) did not show difference between low and high walkable neighborhoods.

4. Discussion

The result of this study indicated the link between walkability and residents' perception of built environment attributes. By using NEWS-MC, a form designed to obtain residents' perception of walkability attributes in medium to high density mainland Chinese cities, as instrument, this study examined the test -retest the reliability and validity of the subscales and single items of NEWS-MC. Moderate to high level of reliability was founded from the result of test-retest reliability of NEWS-MC. The intra-class correlation range from 0.65 to 0.98, which showed a higher reliability than the result in United States(0.58-0.80), Australia(0,62-0,88) and comparable to those observed in Hong Kong(0.57-0.99). The difference may because in US and Australia the researcher used self-administered survey, in this study although we sent the NEWS-MC form to participates but they could communicate with the interviewer by wechat so it kind of like a interviewer administered survey which was used in Hong Kong studyi. Besides, the time interval of first and second survey was 10-16 days, which is shorter than the previous studies (14-21 days).

The result of this study supports the applicability of the NEWS-MC to medium to high-density cities in mainland China and most Asian cities, such as Harbin. The data showed significant difference in residents' perception on built environment characteristics between high-walkable and low-walkable urban areas. Residential density, land-use mix-diversity, Land-use mix-access, street connectivity, infrastructure and safety for walking, traffic hazards, parking difficulties, physical barriers and social interaction while walking illustrated residents could perceive higher level of attributes in these subscales from high-walkable neighborhoods. The walkability of the neighborhoods was objectively measured by residential density, land-use mix, and pedestrian sidewalk connectivity, and the residents' self-reported result reflected the difference of perceiving these attributes. It is observed that the different direction of ratings on aesthetics, low-walkable neighborhoods were rated higher in most of the items in this subscale, which is the same in Australia and Hong Kong, may be attributed to residents' preference open view and street streets and more green bushes or grass which the low-walkable neighborhoods had more to other aesthetic elements, such as street furniture and sculpture, which the high-walkable neighborhoods had more. The insignificant on crime, hilliness and cul-de-sacs subscales were likely because Harbin is a flat city without many hill and the public order is very good here, and the road network in Harbin is basically grid or radiate, the cul-de-sacs is very rare even in residential area, so residents can not perceive the relationship between items in these subscales or single items and walking.

The mean values comparison between NEWS-MC to NEWS Untied States, Australia and Hong Kong indicated that, as hypothesis, residential density was rated much higher than US and Australia but lower than Hong kong. This can be attributed to the fact that the overall mainland Chinese cities are medium to high density, the urban residential density is higher than US and Australia, but lower than Hong Kong. Land-mix diversity was rated higher in both high-walkable and low-walkable neighborhoods than all the other three studies. It should be notice that the previous studies all used the long version NEWS and we used NEW-A the measure instrument, precluded a direct comparison of the findings.

The limitations of this study include:1) The participants are the ones who will to attend the survey, not matched on individual respondent demographic. 2) we only do research in for residential neighborhoods, the small number of areas and small sample number of participants may have limited the reliability and variability of some items. 3) We may omitted some environment attributes that related to walkability of medium to high density mainland Chinese cities.

In conclusion, the result of this study support reliability and construct validity of the NEWS-MC, so we could take the NEWS-MC as a instrument for further study of cross-national or international research on the relationship between built environment characteristics and residents' walking choice.

Research Paper

Outdoor public space activities characteristics of children and their inter-generational parents and design strategies from the health perspective: A case study in Harbin, China

Qing YUAN, Ran GUO, School of Architecture, Harbin Institute of Technology; Key Laboratory of Cold Region Urban and Rural Human Settlement Environment Science and Technology, Ministry of Industry and Information Technology; China

Abstract

With the rapid urbanization of China and the establishment of the new family structure of "four-two-one" (four grandparents-two parents-one child), taking care of children by the their grandparents has become pretty common in the current Chinese urban families. Currently, 41.43% of the elders in China raise and take care of their grandchildren. Such proportion demonstrates an increasing trend annually. In the meantime, it has been shown from the statistics that the major the groups exercising in the public area during the working days are the children and their inter-generational parents (as 'the Group' in the following). Due to the preschooler's special feature of requiring accompany in amusements, the preschoolers and their inter-generational parents have been the second major users of outdoor public space (OPS) in the cities of China following the older groups. As the major place where the daily life and leisure activities of the Group happen, the environment quality of the urban public and OPS has direct impact on the physical and mental health of the Group. To design and build an appropriate OPS, it is necessary to have a deeper understanding regarding the psychology and behavior demands of the children and their inter-generational parents. This paper aims to have a discussion about this issue. This study is carried out by taking the questionnaire as the major method, which is combined with field research with interview. The questionnaire consists of two parts, network questionnaire and on-site questionnaire. 515 copies of effective questionnaire are received. There is a survey questionnaire designed in the study based on the social-ecological models for the Group by taking three factors into consideration, which are individuals, families and society, material environment and ecological environment. Based on the survey result, information of the Group, such as the overall distribution, health status, activity characteristics, space use restrictions, and preference of the OPS was collected. The result of this specific study shows that: (i) The Group is mainly distributed in four spaces, park green lands, squares, community activity place and spontaneous activity space. There are great differences of the functions of different OPS. (ii) The proportion of the grandparents taking care of their grandchildren usually live in the local city and have a good economic condition. At the same time, the result of emotion self-assessment of the grandparents who are engaged in taking care of children properly is more satisfying. (iii) In terms of the status of the

use of OPS, the activity type of the Group is much concentrated. The activity frequency of the group is related to the walking distance while the duration of the activity is related to the fatigue state of grandparents. (iv) The security of space is the major factor restraining the development of activities. The lack of social communication is the main factor causing the low participation of activities. Besides, the bad condition of microclimate environment will also decline outside activity participation degree greatly. This paper makes a deep investigation and research on the urban OPS, mainly focusing on the connection between OPS, space comfort, facilities arrangement, the social attribute of the Group and healthy activities. Research limitations: The activity feature of the Group in the urban OPS can be influenced by other factors, such as the urban integral economy level, traffic condition, population and social economy science. More detailed problems still require further study.

Keywords

outdoor public space design, public health, children and their inter-generational parents, activity characteristics, design strategies

1. Introduction

As the major place for bearing residents' outdoor activities, forming positive social life and interpersonal communication (Chen Z and Ye M, 2009), outdoor public space (OPS) has been extensively researched in terms of effectively promoting the physical activity (Deborah C, et al., 2006), relieving psychological stress (Tan SH and Li J, 2009) and improving quality of life (Karmanov D and Hamel R, 2008). There is also abundant evidence to support that participating in outdoor activities appropriately is beneficial for physical and mental health of the elderly and children (Listed N, 2009). Meanwhile, the outdoor environment has been increasingly proved as the key spatial factor affecting population health by scholars (Wang L, et al., 2016).

In the urban areas of China, the contradiction between getting on at work and fulfilling family commitments makes the young and middle-aged people have too much pressure to take care of their own children (Yang JH and Li LL, 2016). It's very common that the elders take care of the grandchildren. With a large number of one child moving into the marriage age, the "four-two-one" family structure has gradually become the main forms of the Chinese family structure currently (Hui LB, 2010). The rising age of first birth, the adjustment of birth policies including the two-child policy (Liang HY, 2013) and the increasing number of a single-parent family (Sun JJ and Zhang HK, 2013) has all led to more preschoolers receive care from their inter-generational parents. It has been shown from the statistics that currently, 41.43% of the old in China provide support and take care of their grandchildren (Sun JJ, 2013), and the proportion shows an increasing trend annually (Burn K, et al., 2015; Meng XJ, et al., 2004). In addition, taking care of grandchildren is also the main reason for the migration of the elders in China. More than half of the migrant elders in Beijing came for this reason and became "Lao Piao Zu" (elderly migration group) (Meng XJ, et al., 2004). Despite enjoying the joys of family, elders are also forced to accept physical and mental stress due to some factors including care tasks, changes in family roles, and being far away from hometown (Listed N, 2009; Liang HY, 2013; Zhou J, et al., 2016). Therefore, in recent

years, the social phenomenon of inter-generational care (taking care of children by their grandparents) has attracted more and more attention from scholars of all circles.

Inter-generational care is a kind of inter-generational support behavior, which not only requires time (Sun JJ, 2013), physical labor and material wealth of the elderly, but also affects the physical and mental health as well as life quality of elderly and grandchildren to a large extent (Sun JJ and Zhang HK, 2013). Statistics show that due to the special feature of preschools of needing accompany in their amusements, the preschoolers and their inter-generational parents (as 'the Group' in the following) have been the second major users of urban outdoor public space (OPS) in the cities of China following the older groups (Zhang Y, 2007). Bringolf, et al. (2017) have conducted a study exploring the conditions of the outdoor environment elements. The perception of the companions on the outdoor public space will not only affect the OPS activity quality of preschoolers directly, but also change the physical and mental health status of the inter-generational parents. As the main place for the daily life and leisure activities of the Group, the quality of OPS will have direct impact over the physical and mental health of the Group.

Although the phenomenon of inter-generational care is very common and relevant policies also attach the focus on this care behavior from the elders in China (GOSC. PRC, 2011). However, the current research on the Group mainly concentrated on sociology, pedagogy, medicine and other fields. There are few studies related to the health activities and space use from the health perspective. At the same time, due to the lack of understanding about inter-generational support and conflict (Zhang Q, 2014) in the health activities for preschoolers and their inter-generational parents, the differences in subjective spatial preferences, activity characteristic, psychological and behavioral needs, and other aspects between the Group and the other elderly and children are still not clear. Combined with the space construction and the Group needs, this paper selects representative OPS for investigation and research, and puts forward optimization design strategies to meet the demands of inter-generational relations.

2. Methods

Based on the theory of social-ecological model, a questionnaire is designed in this research regarding the outdoor activities of the Group from three aspects including personal, family and social subjective factors, material factors and ecological and environmental factors (Kang LP, et al., 2015). Afterwards, information is collected about the activity characteristics, health status and spatial preference of preschoolers and their inter-generational parents under the influence of inter-generational relations.

The survey is mainly based on questionnaire surveys, combined with field surveys and interviews. The questionnaires are composed of online and on-site questionnaires, which are distributed at the same time. The online questionnaires are produced by SO-JUMP (a professional questionnaire platform, https://www.wjx.cn/) and distributed through the WeChat social software. The on-site questionnaires are distributed in several residential communities, kindergartens and urban OPS with intensive activities of the Group, which all have different location conditions and the consumption levels in Harbin, Hei Longjiang Province (Figure 1). On the premise of sufficient respondents, the survey is conducted from

April to June (2018/04/03~2018/06/15), when the weather condition of Harbin is relatively suitable, in order to ensure the interference of weather condition on the subjective needs of the Group could be excluded. The survey subjects are preschoolers' inter-generational parents who are responsible for taking care of preschoolers' daily life as well as preschool children. When the preschoolers are unable to complete the questionnaire due to their limited cognitive levels, relevant information is provided by their inter-generational parents instead. At the same time, during the on-site questionnaire survey, respondents with strong participation consciousness are selected for in-depth interviews to collect the overall and general characteristics of the target population widely, avoid the influence of individual cognitive differences and ensure the random data samples. A total of 515 effective questionnaires are received, including 196 online questionnaires and 319 on-site questionnaires.

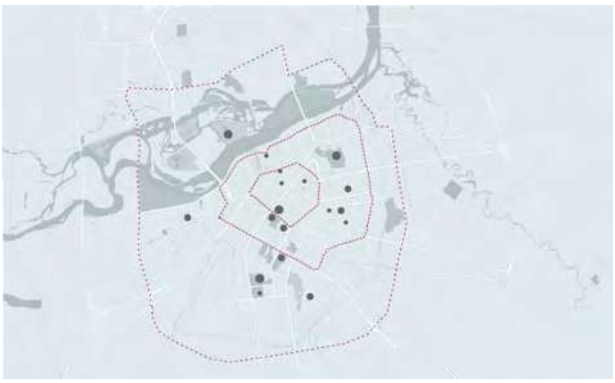

Figure 1 Distribution areas of questionnaires in Harbin

3. Results based on field surveys and interviews

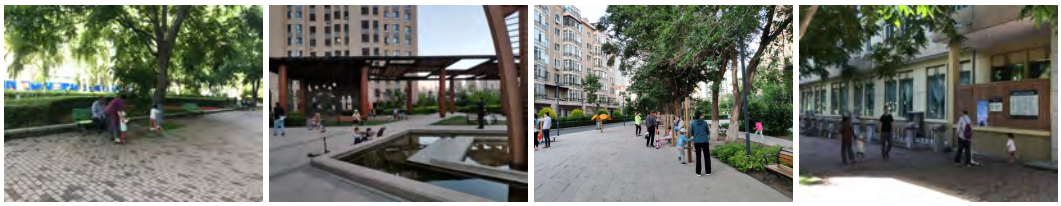
The daily activity demands and consciousness of leisure and entertainment of the Group are increasingly enhanced and meanwhile are also getting diversified. The urban outdoor public space can be divided into four types, namely green space, square space, residential outdoor space and spontaneous activity space, according to the spatial functions and forms as well as the activity rules of the Group (Figure 2(a)~(d)). All types of OPS have slightly different functions and activity carrying rates.

Green space. It is mainly for leisure and entertainment function, with diverse space types, population composition, and preferable plant coverage. For the Group, green space provides relatively large activity and play areas, rich services and entertainment facilities, including comprehensive parks, special parks (such as botanical gardens), etc.

Square space. It is relatively wide with plenty of public space available for the Group. However, mainly based on great number of pavement, it has single landscape type, microclimate environment and limited public services facilities, which is not very participating and suitable for recreational activities for the Group.

Residential outdoor space. It is the most convenient and frequently-used outdoor public space type for daily use of the Group. Spaces such as greening, rest, leisure and fitness are mostly constructed and designed. However, the available space types and quantities remain quite limited. Users are relatively fixed, most of whom are residents in the community.

Spontaneous activity space. Based on the willingness and preferences of the Group, it also satisfies the space needs of spontaneous activities, which are usually variable and accidental, including street space, surrounding space of public service facilities (such as the outer space of commercial buildings), surrounding space of landscape structures, etc.



(a) (b) (c) (d)

Figure 2 The four types of urban OPS

4. Results based on questionnaires

4.1. The characteristics of the Group in OPS

4.1.1 The proportion of inter-generational parents who are healthy, live in the local city and have middle range of income is high.

Taking care of grandchildren is a kind of inter-generational supportive behavior that has certain requirements for health conditions, financial capability and time cost of the inter-generational parents. Among the surveyed the Group, the age range of inter-generational parents interviewed is from 49 to 75 years old. Meanwhile, the proportion between 60 and 64 years is the highest, which is about 38.0%. There is no significant gender difference in the proportion of male and female inter-generational parents. The proportion and intensity of children taken care of local inter-generational parents are higher than those are outsiders. In addition, the proportion of inter-grandparents who have middle range of income and self-assessment as "basically free from financial stress" is the highest, which further indicates that those inter-generational parents with better conditions and abilities will take more care of their grandchildren.

Table 1 Information of inter-generational parents in OPS

Gender	Male	264	51.30%
	Female	251	48.70%
Age	49~54	21	4.10%
	55~59	102	19.80%
	60~64	198	38.30%
	65~70	116	22.60%
	70~75	78	15.20%
Identity	Local	323	62.70%
	Outsider	192	37.30%
Self-assessment of finance	Wealthy	111	21.50%
	Basically free from financial stress	228	44.30%
	Financial stress	176	34.20%
Self-assessment of health	Healthy	248	48.20%
	Ill health	267	51.80%

4.1.2 The emotional self-assessment results of the inter-generational parents who participate in the care activities moderately are better.

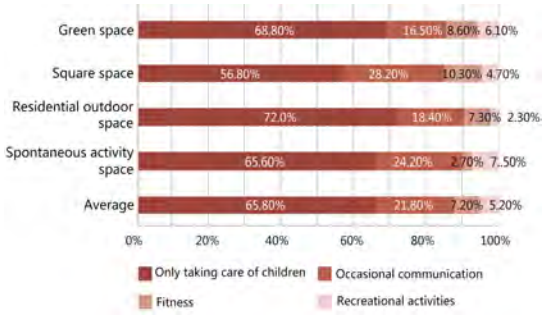
The behavior and activity characteristics of preschoolers make the inter-generational parents always keep busy. Among the surveyed, the proportion of inter-generational parents involved in daily caring for grandchildren is as high as 76%. Besides, in this group, the proportion of grandparents who take care of grandchildren all day long is about 40%. The proportion of fatigue feeling and negative emotions generated of grandparents with prolonged care is significantly higher than that of whom being involved in caring for part of the day. In addition, as a form of social participation, nearly 80% of inter-generational parents consider that they can maintain a relatively good mental state by caring for their grandchildren to participate in outdoor activities, especially in fighting against negative emotions such as loneliness and depression. However, when grandchildren have abnormal emotions or accidents, the inter-generational parents will show more obvious anxiety and stress. In general, there is an inverse "U" shaped relationship between the duration of taking care for preschool grandchildren and the emotional self- assessment results of inter-generational parents group. Those results are similar to a previous study about the relationship between the care of grandchildren and the attitudes toward aging among Chinese older People (Sun JJ, 2015).

4.2. The characteristics of activities and OPS utilization of the Group

4.2.1 Activity types are concentrated

Among the surveyed samples, the major types of daily activities of 3 years' children in the outdoor space mainly include playing with children's recreation facilities and doing simple sports. The phenomenon of watching children of other age groups to do the activities is quite obvious. On the basis of the same preferences mentioned, children around the age of 4 hold avid interest over sand, mud, stone, water and other natural elements. However, the behaviour of watching others' activities is reduced. Children aged from 5 to 6 years old prefer sports and role-play games, and their interest in electronic devices is gradually increasing. This is basically consistent with Joe L's conclusions about the behavioral characteristics of children's games (Joe L Frost, 2015).

The main activity types of the inter-generational parents in OPS, the proportion of physical activities and daily social activities, are main based on "only taking care of and accompanying their grandchildren" and "occasional communication with others while taking care of their grandchildren", the proportions of which are significantly different from fitness and recreational activities (Figure 3). With the increase of grandchildren age, the proportion of fitness and leisure activities (playing cards and chess, etc.) of inter-generational parents also increases. However, there are limited changes. Meanwhile, the activity types are still focused on their grandchildren, which are relatively concentrated (Figure 4).



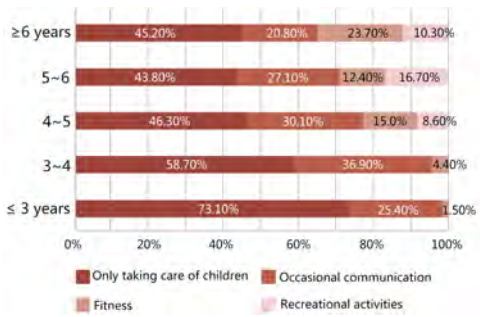


Figure 3 Inter-generational Parents' Activities in Varied OPSs

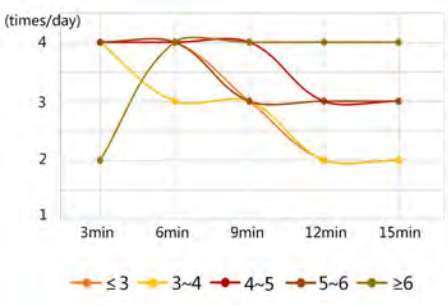
Figure 4 Activities of Inter-generational Parents with Preschoolers of different Age in OPSs

4.2.2 Activity frequency of Group is correlated with walking distance

Walking distance refers to the average walking length of the daily one-way trip to the activity site. The activity site within the acceptable walking distance range can better stimulate the subjective initiative of participating in activities. It is generally accepted among the Group that walking distance had decisive impact over the daily travel of the Group, which is the most important factor affecting activity frequency. For the walking distance within the acceptable range of the Group, activity frequency has a significantly negative correlation with the walking distance, and they prefer an environment with convenient walking condition (Figure 5). Among them, the activity frequency in outdoor activity sites is high when it can be reached within 9min walking distance. In addition, although the residential outdoor space is limited in the degree of visual richness and content of recreation, it has become the most frequently-used activity site for the Group due to it is easy access to (Figure6).



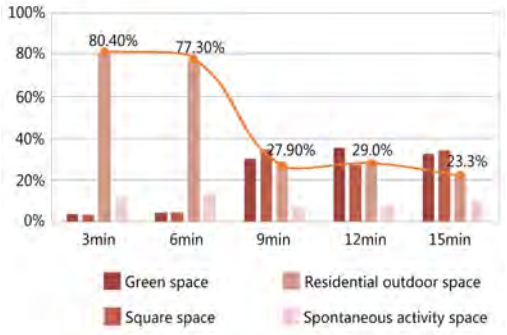


Figure 5 Relationship Between Walking time and Frequency of Activity Among Preschoolers of Different Age Groups

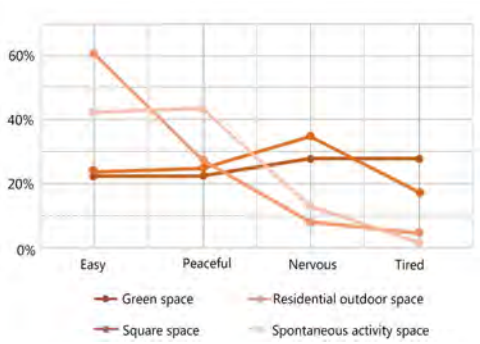
Figure 6 Choice of OPS based on Walking Time

4.2.3 Activity duration of the Group is associated with fatigue state of inter-generational parents

Generally, the single continuous activity duration of the Group is 0.5 to 3 hours, and the majority go out for 2 to 4 times a day. Due to the preschoolers' special feature of needing accompany in their recreation, which makes inter-generational parents have little chance to rest while taking care of their grandchildren. Furthermore, the number and layout of the rest

facilities in the activity sites are unreasonable, which can lead to different degrees of physical and mental fatigue for the inter-generational parents (Figure 7). Although there are individual differences in age, personality, physical quality and other aspects, only 26.88% of the inter-generation parents consider that such care work is easy (Figure 8). Most of the inter-generation parents express that they will stop outdoor activities in advance when they feel tired. The activity duration shows a significant downward trend with the increasing fatigue of inter-generational parents.



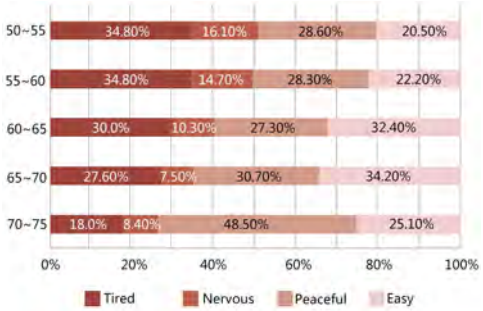


Figure 7 Emotional Cognizance of Inter-generational Parents in Different Spaces

Figure 8 Emotional Cognition of Inter-generational Parents of Different Age Groups

4.2.4 Safety is the primary factor restricting the activities

Through the interviews, it is found that due to the potential safety risks in the composition of open public space population composition, vehicle traffic acting, site facilities and other aspects, inter-generational parents are usually very cautious when they take care of grandchildren. Besides, they mainly focus on children and even keep their grandchildren within their sights all the time. According to the survey data, in the process of caring for grandchildren, only 5.04% of children have suffered from accidental injuries in the activities for more than 3 times, such as road traffic crashes, falls, bruises. There are 66.81% of children have never suffered from any accidental injuries, which demonstrates the importance that inter-generational parents attach to grandchildren safety (figure 7). By making the statistics and ranking the environmental factors of restricting outdoor activities, the safety is the primary factor that affects choosing play areas of the Group.

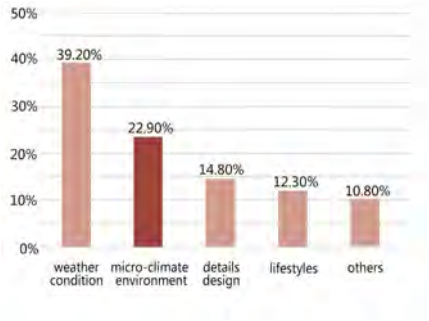
4.2.5 Lack of social interaction is the main reason for restricting inter-generational parents involved in activities

Among the surveyed group, the time for interests and hobby of 80.42% inter-generational parents is largely occupied due to that they need to take care of their grandchildren. Besides, 64.68% of the inter-generational parents express that except family members, the main partners are other grandparents, who get to know when they accompanied their grandchildren. They chat during this caring process of their grandchildren and further discuss the time and contents of joint activities. At the same time, they also express that they have to always follow the children. Coupled with noisy site, less life intersection, accent and other restrictions, there is no in-depth interpersonal communication and chat. Grandchildren become their common and only topic of their conversation. From the perspective of demands, inter-generational parents have the highest demand for the social interaction of

the OPS, in order to deepen their communication and broaden the original social network (figure 8).

4.2.6 Participation in outdoor activities drops sharply during the cold seasons

The Group has a relatively weak constitution and has poorer tolerance to cold weather. The survey results show that nearly 80% the Group once reduced winter activity frequency due to low temperature and cold wind. However, with the increase of health awareness of inter-generational parents, the proportion of the Group who still adheres to the outdoor activities in cold seasons is more than 70%. Through making the statistics and ranking the environmental factors restricting winter outdoor activities of the Group, there are three activities lacking of suitable activity sites, poor accessibility and delay maintenance of public space respectively. Among them, on activity sites, poor micro-climate adaptation is the primary factor for the decline in the activity participation and usage rate of space during the cold seasons (Figure 9). Comfort mainly affects the sensory needs of people. Figure 10 shows the comfort needs of micro-climate environment of respondents in different OPS, involving temperature, wind, sunshine, sound and air quality. Among them, the comfort needs of the Group present obvious seasonal differences. It has been found that the comfort needs for sunshine, wind speed and the air quality are comparatively higher in early spring, late autumn and winter.



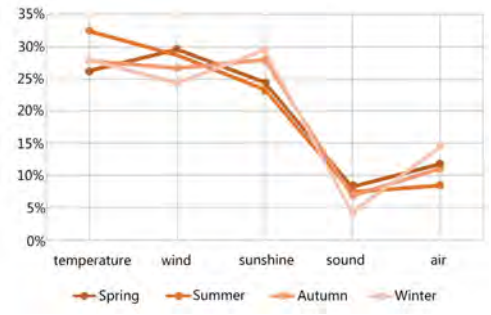


Figure 9 Reasons for Decrease in the Group Activities during Cold Seasons

Figure10 Microclimate Requirements in Different Seasons

4.3. The OPS satisfaction of the Group

4.3.1 Space satisfaction is mainly related to the activity experience of preschoolers

The interviews revealed that although the needs of inter-generational parents for OPS were different, the overall comments of OPS mainly depended on the emotional satisfaction level of grandparents. The satisfaction of OPS has a significantly positive correlation with the emotional level of grandchildren during the activity, and the comfort of children is the most important factor for the satisfaction. In addition, according to the comments of inter-generational parents, the degree of accessibility, plant richness, service facility perfection and facility maintenance are the key objective factors impacting satisfaction (figure 10). Meanwhile, there are demographic and sociological differences for the satisfaction. Age, economic levels and habitation are significantly correlated with the satisfaction, which are three subjective factors.

4.3.2 Trip satisfaction is affected by walking distance

Walking is a transporting mode of energy and time consumption. Walking distance is negatively correlated with activity satisfaction. Through making the statistics and ranking the factors affecting trip satisfaction, the top three are walking distance, less vehicles, walking path with great landscape.

The average daily walking distance of the Group is 0.46km (average time 6.9min). The satisfaction proportion of the Group with the walking less than 5min is more than 70% while the rest of the respondents think that walking within 10min is a suitable distance. Inter-generational parents express that the distance within 10min to 15min is the upper limit that their grandchildren could bear, while the proportion of the Group who walk more than 30min is less than 3%. Considering the age structure of the Group and taking 1.2m/s as the basic walking speed (children's walking speed is about 1.2 ~ 1.4m/s (Zhou T and Chen X, 2015)) while the comfortable walking distance is about 400m, and the acceptable walking distance is about 1km.

5. Conclusion

5.1. Space of the inter-generational sharing

The planning and design strategies of OPS usually lacks the consideration of inter-generational sharing. Reasonable space design can improve the using rate and also promote communication. In addition to taking care of their grandchildren, the activities that both grandparents and grandchildren participate in include running, strolling, resting and using fitness apparatus. According to the subjective evaluation data, 67.2% of the inter-generational parents express that the above activities can be participated jointly. The design of size, scale and of details in activity space lacks consideration of both children and adults, which affects the activity frequency. Secondly, as the public space is less functionally compatible, the number of spaces that can satisfy the needs of two groups are small. Meanwhile, such type of activity site is single, all of which extremely limited the activities and reduce interactions. In addition, most of the space elements are monotonous, which is unable to have long-term visual attraction for children to satisfy their immense curiosity and imagination to extending their play duration effectively.

5.2. Space comfort needs

For winter cities with long cold periods, the impact of micro-climate conditions on public outdoor space is mainly reflected in the wind environment and solar environment (Liu YQ, 2006). The lack of considering the cold climate features in design part of OPS of severe cold regions results in harsh microclimate environment. Factors like large building shadow areas and cold wind can have serious impact over the outdoor activities in cold seasons (Jiang CY and Leng H, 2017), especially for elderly inter-generational parents and young children. Regarding air quality and noise, in recent years many studies on health leisure activities have pointed out the air quality will affect the health of cardiovascular and respiratory systems directly. Bad acoustic environment will cause both physical and mental harm to people including audition, vision, even affecting people's nervous system and having irritable and fractious emotion (Dong JY, 2013). The interviews and observations revealed that the different locations result in large differences in the comfort needs of the Group. The demand for air quality and acoustic environment mainly comes from the activity sites along the roads.

The poor air quality caused by vehicle exhausts, the noise pollution caused by traffic and fitness activities (such as square dance) all have adverse influence on the Group, such as shortening time, decreasing frequency and intensity, reducing interaction activity and affecting the emotional of the Group.

5.3. Facility allocation

Bringolf, et al. (2010) deemed that the objective conditions of he outdoor environment will affect the outdoor activity quality of preschoolers and their companions directly. The level of OPS service facilities is another important factor restricting the activities of the Group.

In order to explore the influence of the OPS design elements on the health activities of the Group, an analysis of 5 aspects was carried out, the results of which have demonstrated that "activity facilities" > "service facilities" > "sanitary facilities" > "landscape" > "space scale". In terms of "activity facilities", the proportion of the Group's needs for children's playgrounds and sports facilities is higher than that of the middle-aged and elderly people. Respondents have expressed that children's activity facilities are relatively simple, which cannot attract children's attention for a long time and satisfy their curiosity and desire to explore and therefore increase the fatigue feeling of inter-generational parents to some extent. In terms of "service facilities", there is an obvious demand for the number and arrangement of rest facilities as well as rain-shelter facilities. Meanwhile, the service and the service facilities layout are not designed in combination with spatial functions and user needs reasonably. In terms of "sanitary facilities", demands for toilets and dustbins are much higher than that for other items. The details, management and maintenance of sanitary facilities are unsatisfactory, which limits the travel distance and range of activities. As for "landscape", the Group has the highest demand for the planting compared with the pavement areas and landscape structures. It is generally considered that the activity experiences are poor in hot seasons and the greening construction still needs to be strengthened.

6. Discussion

6.1. Establish urban open public space system

The urban OPS system meeting the health needs should connect the Group and the public space more closely, improve health functioning of public space fully and effectively, and enhance overall health level of the Group. Given the differences of the space levels, such as urban, block, and community, the planning processes and designs of OPS by the frequency and preference of using type should be different. The activity space within the walking distance limit and the space of random activity should be emphasized, which makes OPS arrangement consistent with the needs of the Group activities and plays different health roles. In addition, the Group is sensitive to the overcrowded or empty open space in the activities, providing a public space of appropriate scale, which not only ensures the activity needs and gathers popular, but also avoids the space waste and poor microclimate condition caused by large scale.

6.2. Promoting the inter-generational sharing of OPS

Urban OPS should develop inter-generational sharing design gradually to make the Group feel more convenient in the activities. Firstly, they need to determine the source of use objects and their activity types, and create a functional composite space composed of

sub-spaces with different functions. During the design and reconstruction processes, they need to pay attention to functional compatibility of the OPS based on the needs of preschoolers' activities and also taken into account the needs of inter-generational parents' communication and fitness. Sharing space can provide children with more sites and possibilities for activities, thereby increasing social interaction opportunities among the inter-generational parents, deepening understanding gradually each other and broadening the social network. Besides, the spaces and facilities are designed based on the Group scale, meet the requirements and standards of children and adults in pavements, facilities, and pedestrian path organization, which can offer support for mutual participation in activities. In addition, in terms of landscape, create attractive and interesting landscape can have great impact on improving visual comfort and the spirits, thus promoting the outdoor activities of the Group effectively.

6.3. Optimizing public space comfort

In order to eliminate the utilization restrictions of affecting the Group's sensory needs, attention should be paid to the comfort needs design of the OPS. As the decline of inter-generational parents' physical functions and resistance, sunshine and wind have a great impact on them. For northern cities with long cold seasons, areas with high wind speed in winter and no wind in summer can be assumed to be green areas while areas with windy summers and low wind speeds in winter are arranged as activity areas of the Group (Leng H, et al., 2007). The activity facilities and sites are placed in areas with shadows in summer and sunshine in winter. Deciduous tress can be planted around the activity areas to maximize sunshine hours during the winter. In terms of plant species, cold-tolerant evergreen trees, such as Chinese pines, camphor pines and other native species, can be planted around the public space to create an evergreen effect, and resist cold winds inside the open space during cold seasons effectively (Leng H and Yuan Q, 2014). In terms of air quality and noise improvement, increasing the plant community and green plants density in the activity sites along the roads can balance off the adverse effects of driving noise and exhaust on children and the elderly.

6.4. Improve facilities of open public space

Urban space should improve facilities gradually to be used in the Group activities easily. OPS should give priority to the physical state of inter-generational parents so that they can take care of their grandchildren closely. Based on that, the location, quantity and direction of the rest facilities, shelves and shading facilities should be designed. In the meantime, diversified rest options should also be provided, such as the installment of stood-leaned against rest facilities. During the selection of pavement materials, attention should be paid to the protective characteristics of the materials, especially the non-slip and moisture resistance of the paving materials. The suitable paving materials can be selected according to the characteristics of various activities, such as soft materials suitable for children's activity sites. Wood and plastic should be used as the major materials for seats and other rest facilities, avoid the use of hard, sharp materials such as metals and stones. Bright colors are used to decorate the ground pavements, signs, sculptures, fitness facilities and children's recreational facilities, which not only can be convenient for inter-generational parents to be hard to identify due to poor eye sights, but also can reinforce the boundary range of children's game space through using bright color. In addition, the space design should consider barrier-free facilities and the height differences between spaces to avoid the

obstacles for pram to go through and the other potential danger of falling, fracture and so on.

An in-depth research is conducted on urban outdoor public space, focusing on the correlation between factors such as the public space system, spatial comfort, facility condition, and social attribute of inter-generational group and health activities. Urban outdoor public space should be designed and reconstructed according to characteristics of the Group, which is of great significance for improving life quality of the Group, promoting public health and bringing long-term health benefits. In addition, the activity of the Group may also be affected by other factors, such as the overall economic level of the city, traffic system, population and social-economic characteristics, etc. More specific and targeted problems need to be further studied.

Research Paper

Association between Neighborhood Built Environment and Body Mass Index among Chinese Adults: Hierarchical Linear Model

Mengqi Zhong, Tongji University; China
Yuanyi Shen, Tongji University; China
Yifan Yu, Tongji University; China

Abstract

Obesity is becoming a global health problem. With the living standards of residents have improved rapidly in China, the problem of obesity becomes a serious threat to people's health. Although obesity effected by many factors, the role of the built environment in relation to obesity among population should be taken into consideration. This paper examines the association of built environment and body mass index with the hierarchical linear model, based on the data from 2016 China Labor-force Dynamics Survey (CLDS), which involves 29 provinces in China and investigates 401 villages or communities as well as 14226 families. In this paper, the village or community is used as the basic analysis unit, and the body mass index of the residents is used as the dependent variable, and neighborhood built environment (e.g. density of exercise facilities, square or park and distance to them) is as independent variables, socioeconomic status (e.g. age, gender, education, marital status, income and employment status) and health and exercise characteristics (e.g. self-rated health, average weekly exercise time and frequency) are as control variables. Participants are adults aged 15-65 years (n = 21086; 63.30% rural vs urban). With the independent variables from both individual and residential levels, hierarchical linear model is applied respectively to examine how body mass index is affected. Additionally, samples are classified by age group, urban/rural neighborhood and we figure out which factor mainly effected different groups. We explore that BMI is higher in high- vs. low-facility density neighborhoods but not significantly differ by neighborhood income. Overweight/obesity (BMI >= 25) is lower in high-developed districts. Physical fitness is higher in high-income neighborhoods but unrelates income. We conclude that living in walkable neighborhoods is associated with more physical activity and lower overweight/obesity but not with other benefits. Adults in higher-income neighborhoods have lower BMI and higher mental condition. These findings have important implications for urban planning and the corresponding improvement strategy is proposed.

Keywords

body mass index, health facilities, built environment, hierarchical linear model

1. Introduction

1.1. Background

Obesity rates have been rising globally in recent decades. According to the World Health Organization, more than one in ten people in the world are now classified as obese (WHO,2013). Nowadays, obesity is considered as one of the most important medical and public health issues of our time (Ells L & Cavill N, 2009). Obesity can be measured in various ways. Body mass index (BMI) is the most commonly used measure of assessing obesity in adults. (A Must and SE Anderson, 2006). BMI is used not only for assessing weight at the individual level, but also at population level assessment for its measurement method is very convenient and practical. Based on individual height and weight, BMI is calculated as weight in kilograms divided by the square of height in meters.

$$\mathrm{BMI} = \frac{weight(kg)}{height(m)^2}$$

1.2. The danger of obesity

Many studies have investigated how BMI contributes to the morbidity and mortality of various related diseases. BMI as a measure of unhealthy weight and related diseases in the population, different studies using statistical methods to analyze it may help to determine the correlation between obesity, health characteristics and influencing factors. Epidemiological studies have shown that people with very high BMI have a high risk, such as severe (⩾35kg/m 2) or morbid (⩾40kg / m 2) obesity (CM Kitahara, 2014), and underweight will increase its morbidity and mortality. Both overweight and obesity are associated with the incidence of multiple comorbidities including type II diabetes, cancer and cardiovascular diseases, which can pose a threat to people's health and place a heavy burden on the health care system. Maintaining a healthy weight is important in the prevention of the large disease burden in the future. (Daphne P Guh et al., 2009).

1.3. Influencing factors of BMI

BMI is affected by many factors. In 1989, Sobal and Stunkard (1989) first studied the relationship between socioeconomic status (SES) and obesity. The understanding and pursuit of attributes that are valued in developed societies, such as healthy and lean bodies, people in higher socioeconomic groups tend to have a healthier diet. Meanwhile, education may also mean expectations of individual achievement, whether in general or health, weight and appearance. Studies have shown that it is reasonable for high-educated women to favor the pursuit of thin attributes. (McLaren L, Kuh D, 2004). Women in low- medium human development index countries have the most common positive correlation between SES and body size.

In the context of urban planning, some scholars pay attention to the relationship between built environment and BMI. Access to physical activity facilities is the most common measure of the built environment. Urban construction environments, including parks and other green spaces, and recreational projects that provide structured settings for sports, may also create opportunities for physical activity that affect the increase of obesity (Jennifer Wolch et Al., 2011). Hoehner et al. (2013) found that the characteristics of the built environment around the home and workplace may affect the BMI, and the increase in recreational facilities

(exercise facilities and parks) can decrease the individual's BMI, which may increase the exercise opportunities of residents due to the increased facilities. Giles-Corti B, Macintyre S, Clarkson J, et al (2003) calculated the distance between the study participants' homes to the nearest recreational facility, showing a positive correlation between the distance from the nearest facility and the increased risk of overweight. Gordon-Larsen P, Nelson MC, Page P, et al (2006) found that there is a positive correlation between the number of recreational facilities and the likelihood of being overweight. Mobley LR, Root ED, Finkelstein EA, et al (2006) found a significant negative correlation with BMI using density measurements (the number of fitness facilities per 1,000 inhabitants, in the postal code).

2. Methodology and data

2.1. Methodology

In the social sciences, we have variables that describe individuals. The group consisting of individuals also has a series of variable descriptions. In this case, the data structure has a stratification phenomenon. Ordinary linear models are difficult to measure data on two levels, so a hierarchical linear model is chosen.

Hierarchical linear modeling allows the data to be structured in at least 2 levels. In this model, the first level is the repeated measure (time or condition) nested within the second level, which is the person-level data (Raudenbush SW, Bryk AS, 2007). The first level captures the within-subject variation, whereas the second level describes the between-subjects variability(Van Der Leeden R.,1998).

In practical application, the regression equation is built with the first-level variables, and then the intercept and slope in the equation are used as the dependent variables, while the variables in the second-level data are used as the independent variables. Then two new equations are established. Through this process, the influence of different level variables on the dependent variable can be explored.

2.2. Data

The data used in this paper is from the China Labor-Force Dynamic Survey conducted by the Center for Social Survey (CSS), Sun Yat-sen University in 2016. The survey uses a multi-stage, multi-level probability sampling method, which is proportional to the size of the workforce. The survey conducted a biennial tracking of urban and rural villages in China, and established a comprehensive database of labor force surveys, including three levels of tracking and cross-sectional data of individual labor, family and community. Its content covers migration, education, work, health, social participation and other information. At present, the CLDS has included the 2011 Guangdong Provincial Trial Survey, the 2012 National Baseline Survey, the 2014 Tracking Survey, and the 2016 Tracking Survey. The 2016 CLDS survey was conducted in 29 provinces, municipalities and autonomous regions across the country (excluding Hong Kong, Macao, Taiwan, Tibet, and Hainan). A total of 401 village community questionnaires, 14226 family questionnaires, and 21086 individual questionnaires for 15-64 labor force populations were completed. After deleting the samples with missing data values, a total of 12,648 samples from 374 village neighborhood committees were obtained for analysis.

2.3. Measures

Individual-level independent variables

In the individual-level, the study includes variables such as individual socioeconomic attributes, self-reported health, and exercise status. We transform the descriptive variables into dummy variables for analysis.

Table 1 Individual-level independent variables

Variable	Definition
UNITTYPE	1:community; 0:village
GENDER	1:female; 0:male
AGE	in years
MARRIAGE	1:married;0:otherwise
EDUCATION	1:elementary school and below
	2:middle school
	3:university and above
INCOME	total income in 2016
EMPLOYME	1:employed; 0:otherwise
HEALTH	1:very bad
	2:bad
	3:moderate
	4:good
	5:very good
WHETHER EXERCISE	1:yes; 0:no
EXERCISE TIME	1:0min
	2:1-150min
	3:150-500min
	4:500-1000min
	5:over 1000min

Neighborhood-level independent variables

In the neighborhood-level, we mainly use the density of exercise facilities and parks/squares in the neighborhood unit as well as the frequency of use of these facilities as independent variables. This paper argues that the density of recreational facilities and the atmosphere of physical activity can affect the physical activity of the residents and futher affect their BMI.

Table 2 Neighborhood-level independent variables

Variable	Definition
Exercise facilities density	=quantity / area
Park/square density	=quantity / area
Frequency of use of exercise facilities density	1-5: frequency from less to more
Frequency of use of park/square	1-5: frequency from less to more

Outcome variables

We use BMI as the dependent variable, and the BMI is calculated by height and weight. The obtained BMI is divided into 5 levels according to WHO standards. The current WHO BMI cut-off points of <16.0 kg/m2 (severe underweight), 16·0–18·49 kg/m2 (underweight), 18·5–24·9 kg/m2 (normal range), ⩾25 (overweight), 25–29·9 kg/m2 (preoboese), ⩾30 kg/m2 (obesity). (WHO Expert Consultation, 2004).

Table 3 Outcome variables

BMI	Definition	nutritional status
1	<16.0	severe underweight
2	16.0-18.49	underweight
3	18.5-24.9	normal range
4	25.0-29.9	Preoboese
5	⩾30.0	obesity

3. Data analysis

3.1. Model

We build models based on the above conditions. The model is as follows:

Level-1 Model

Y = B0 + B1*(UTYPE201) + B2*(GENDER) + B3*(AGE) + B4*(MARRIAG) + B5*(EDUCATION) + B6*(INCOME) + B7*(EMPLOYME) + B8*(HEALTH) + B9*(WHETHER EXERCISE) + B10*(EXERCISE TIME) + R

Level-2 Model

B0 = G00 + U0

B1 = G10

B2 = G20

B3 = G30

B4 = G40

B5 = G50

B6 = G60

B7 = G70

B8 = G80

B9 = G90 + G91*(EXERCISE FACILITIES DENSITY) + G92*(PARK/SQUARE DENSITY) + G93*(FREQUENCY OF USE OF EXERCISE FACILITIES) + G94*(FREQUENCY OF USE OF PARK/SQUARE)

B10 = G100 + G101*(EXERCISE FACILITIES DENSITY) + G102*(PARK/SQUARE DENSITY) + G103*(FREQUENCY OF USE OF EXERCISE FACILITIES) + G104*(FREQUENCY OF USE OF PARK/SQUARE)

3.2. Analytic strategy

First, we establish a stochastic regression model of the first level of variables. Based on the significance test results of the first-level variable regression analysis, we determine whether the difference of the first level of variables on the second level is significant. If the difference is significant, we will select the variables on the second level to establish a regression model for further analysis. This paper uses HLM 6.08 software to run the hierarchical linear model.

4. Result

Descriptive statistics are provided in Table 4. Of all the samples, 33.6% are urban residents and 66.4% are rural residents. 83.8% of them are women and 16.2% of them are men. 86.9% samples are married while 13.1% samples are otherwise. 0.5% of people are severe underweight, 6.4% of people are underweight, 67.6% of people are normal range, 22.3% of people are preoboese, and 3.1% of people are obesity.

Table 4 Descriptive statistics for dependent and independent variables

VARIABLE NAME	N	MEAN	SD	MINIMUM	MAXIMUM
Individual-level					
UTYPE	12648	0.34	0.47	0	1
GENDER	12648	0.84	0.37	0	1
AGE	12648	45.63	12.83	16	96
MARRIAGE	12648	0.87	0.34	0	1
CENUSACC	12648	1.41	0.83	1	5
EDUCATION	12648	3.64	2.35	1	11
INCOME	12648	33658.48	61158.56	100	305000
EMPLOYMENT	12648	4.25	1.16	1	10

HEALTH	12648	3.66	0.96	1	5
WHETHERE	12648	0.29	0.45	0	1
EXERCISE TIME	12648	1.5	225.46	0	5130
BMI	12648	4.2	0.87	1	5
Neighborhood-level					
EXERCISE FACILITIES DENSITY	374	9.54	91.17	0	1666.67
PARK/SQUARE DENSITY	374	5.77	86.29	0	1666.67
FREQUENCY OF USE OF EXERCISE FACILITIES	374	2.54	1.98	0	5
FREQUENCY OF USE OF PARK/SQUARE	374	1.79	2.17	0	5

We use a hierarchical linear model to analyze the impact of the built environment on BMI, which is done in several steps. Step one, we run the empty model and get the variance within the group is 0.35851 while the variance between groups is 0.02972. ICC(1)=0.076552>0.059, ICC(2)=0.703>0.7. So, this data is suitable for HLM analysis. Step two, we put the level-1 variable into the model and get the model1. Step three, we put the level-1 and level-2 variables together into the model to get the model2. Results are provided in Table 5.

Table 5 Multi-level analysis of community environments on labors' BMI

	Model 1			**Model 2**		
	Coefficient	error	P-value	Coefficient	error	P-value
Fixed effects

First, the results of model1 are obtained. Unit type, gender, marriage, education, employment and per week exercise time are significant at the level of P<0.05. Unit type, gender, marriage, and per week exercise time is positively related to the result of BMI while education, employment is inversely related to the result of BMI. Further explanation is that urban units, women, married, and long-term exercisers tend to increase the level of BMI while the increase in education and work can lower the BMI level.

Next, we added the independent variables at the neighborhood level to establish the level-2 regression model to explain the differences between regions. When the regression coefficient of the level-2 variable is the same as the coefficient symbol of the level-1 variable, it indicates that the effect of the level-2 variable on the level-1 predictor is enhanced, and the direction of action is consistent with the direction of the level-1 coefficient. Conversely, the regression coefficient of the level-2 variable is opposite to the level-1 sign, indicating that the level2 variable has a weakening effect on the correlation of level-1.

This paper argues that the number of facilities and the atmosphere in the neighborhood can influence whether people exercise and their exercise time. We get the result of model2. In terms of whether people exercise, park/square facilities and frequency of use of exercise facilities have a strengthening effect on the level1 variable, and the algorithm density and frequency of use of park/square have a weakening effect on the level1 variable. Among them, the exercise facilities density is significant at the level of $P < 0.05$, and the park/square facility density and frequency of use of park/square is significant at the level of $P < 0.1$. The addition of the level-2 variable increases the impact and significance of level-1 on the BMI.

As for per week exercise time, the park/square density and frequency of use of exercise facilities have a weakening effect on the leve-l1 variable, and the exercise facilities density and frequency of use of park/square have a strengthening effect on the level-1 variable. Among them, the performance density was significant at the level of $P < 0.05$.

5. Discussion

Our findings are consistent with previous literature findings that indicate that individual-level and community-level factors have an impact on residents' BMI. The study found that at the individual level, the socio-economic attributes of residents have an impact on BMI. At the community level, the community's exercise facilities, parks, squares, and the frequency with which residents use such facilities also have an impact on the individual's BMI. Our sample-level design refers to the previous literature and shows the advantages of both individual and community levels, but the impact of community-level variables on individual-level variables still requires more research to prove.

Despite this, the study has its own limitations. Our samples come from all over China. The geographical diversity of China is quite different. The living habits and cultural traditions of residents are also quite different. Some key variables affecting BMI may not be measured.

Meanwhile, the limitations of research on the environmental impact of our health outcomes involve the complexity of measures and linkages. This is an inherent feature of the multifactorial nature of the environment, where all aspects of the community can have both positive and negative effects on health. The community environment in which residents choose to live may have been influenced by the socioeconomic attributes of themselves. Prosperous communities may be close to both parks and fast food restaurants that have a negative impact on BMI, and these complex connections are difficult to measure directly. Future research should address many of these limitations.

The Spatio-temporal Disparities in Healthy Food Accessibility: A Case Study of Shanghai, China

Mengqi Zhong, Tongji University; China

Yifan Yu, Tongji University; China

Abstract

The supply of healthy food is distributed unequally in city. The accessibility of healthy foods is affected by both locations and traffic conditions. This paper examines spatio-temporal disparities in healthy food accessibility in Shanghai communities. Firstly, we choose all communities in Shanghai and use python as a crawling tool to collect healthy food store POI (e.g. agricultural markets, vegetable markets, fruit markets, aquatic seafood markets, supermarkets and comprehensive markets) from Gaode Map and get 23,436 points to calculate the amount and density of healthy food store in various communities. Secondly, after comparing Baidu Map and Gaode Map, leading platforms of Web GIS services in China, we choose Baidu Map to collect data to study the spatio-temporal difference in accessibility by using network analysis and developing a crawling tool to collect different travel time (e.g. walking and public transportation) for each community to the closest healthy food store at each time of day (0:00-24:00). Thirdly, we set up a variable to see at what time are people in the communities able to reach their nearest healthy food store in 15 minutes and the ratio of the above-mentioned time to the whole day is calculated so that we can evaluate the temporal disparities of healthy food accessibility. Additionally, we use global and local spatial autocorrelation to analyze the spatial patterns of the temporal disparities of healthy food accessibility, based on the Moran's index and the local indicator spatial association (LISA) index. Finally, on the basis of the research above, the food desert map is drawn. The results of this analysis identify the communities in Shanghai with the greatest need for improved access to healthy food stores and the variance of accessibility affected by the traffic in different times will be taken into account. Ultimately, this study explores a more complete and realistic condition of healthy food accessibility in Shanghai and the corresponding improvement strategy is proposed.

Keywords

healthy food accessibility, spatio-temporal disparities, food deserts, spatial autocorrelation

1. Introduction

1.1. Background

Obesity rates have risen sharply in recent decades, and according to the World Health Organization, more than one in ten people in the world are now classified as obese (WHO,2013). The rise in obesity rates is blamed on increased consumption of sweet and energy-dense foods (WHO,2002). A series of studies have shown that diet can affect health and unhealthy dietary intake is associated with a higher incidence of multiple adverse health outcomes (World Cancer Research Fund/American Institute for Cancer Research, 2007), including many major causes of death such as heart disease and various types of cancer (Jamie Pearce et al.,2009). High density of fast-food restaurants and corner stores that offer prepared foods is always related to unhealthy dietary intake, while easier access to healthy food stores, like fruits and vegetables stores, should improve the residents' diet nutrition and subsequently enhance their well-being and health(key,2011; Kent and Thompson, 2014, Story et al., 2008, Taylor, 2015).It's important to choose healthy food for health promotion, while there are many factors that influence people's choices. Factors affecting dietary intake have been well-explained at the socio-economic level including educational level, employment status, income and cultural differences (Dowler, 2001). As research progresses, scholars are paying more and more attention to the supply of healthy foods in the community. People tend to make food choices based on the food access in their immediate neighborhood (Furey et al., 2001),which suggests that factors in the built environment play a key role in people's diets (Morland et al., 2002b; Rose and Richards, 2004) .

However, the number and types of healthy food stores are not evenly distributed in the city, which may lead to disparities in accessibility of residents to healthy food stores. Studies have proved that low-income areas have a lower density of healthy food stores and higher food prices compared to higher income areas (Hendrickson et al., 2006).

The uneven distribution of healthy food stores in city may result in the lack of healthy food accessibility for some community and the formation of food deserts can be observed. Food desert are commonly defined as areas with restricted access to healthy and affordable foods as well as a variety of other nutritious options (USDA ERS, 2013), which is more likely to be observed neighborhoods where disadvantaged groups concentrate (Black et al., 2014). In order to reduce the food desert and promote better access to healthy food for the people of the city, the neighborhood food environment should be emphasized.

1.2. methodologies of accessibility measurement

Accessibility measures how easy it is from the origin to the specified destination (Widener & Shannon, 2014). Previous literature often uses GIS to calculate the accessibility of healthy foods based on the location of residential areas. Some early studies measure the accessibility of residents to healthy foods by the service radius of food stores based on the Euclidean distance, but it ignores the impact of the actual environment on accessibility of healthy foods. Recent literatures often use a road network-based approach and begin to study the situation of people's actual healthy food accessibility in the city. However, they don't consider the differences associated with the use of different travel methods. Some scholars have found that private vehicles play a key role in improving access to health foods in western countries (Wang et al., 2014). The situation is different in China that residents

often get health foods by walking or public transits. We should consider the impact of residents' transportation patterns in the actual food acquisition process. Meanwhile, food access is not only geographically restricted, but also subject to time constraints (Chen and Clark, 2013). Travel time is affected by traffic conditions, and we should calculate the travel time and the time spent on waiting (Farber, Morang, and Widener, 2014). Differences in time costs can also affect accessibility of healthy foods.

2. Methodology and data

2.1. Research scale and method

The 2018 edition of "Urban Residential Area Planning and Design Standards" stipulates that a 10-minute living circle should be equipped with a vegetable farm. Therefore, this paper takes the community level corresponding to the living circle as the research scale, and studies the community of Shanghai as a research object, with a total of 5432 communities.

Our method is comprised of 3 stages: travel time estimation, accessibility metrification, and spatial autocorrelation. In the first stage, we calculate travel time (e.g. bus and walking) from each community in Shanghai to its nearest health food store. In the second stage, these travel times are converted into measurements of accessibility and temporal variability. In the third stage, we calculate the community's average travel time and analyze the global and local spatial autocorrelation in Shanghai.

2.2. Data

The research data is divided into three parts: community, health food store and travel time. First, the data and location at the community level are from the sixth census in Shanghai. Second, the health food store mainly obtains its geographical location. The study is based on the map of Gaode. Platform, crawling Shanghai POI data in 2018, and screening various stores that provide healthy food, including vegetable shops, fruit shops, seafood seafood markets, supermarkets and farmer's markets, etc., screening a total of 18,526 data; third, travel time is mainly Based on the Gaode map platform, climb the real-time bus route planning time and collect the changes in travel time from each community to the health food store.

3. Community-level healthy food reachable time

3.1. Status of Shanghai Health Food Store

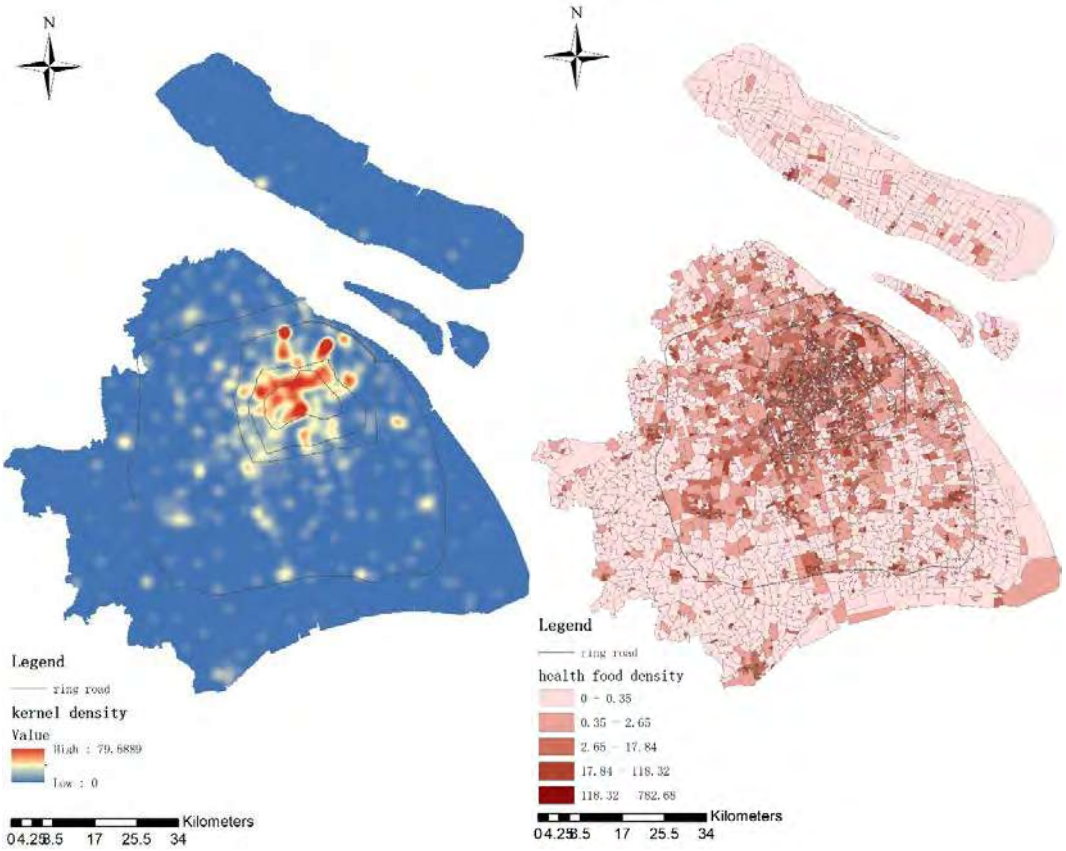

Figure 1 the kernel density of healthy food store

Figure 2 the density of healthy food store

There are a total of 18,526 health food stores in Shanghai. The concentration level of healthy food store in Puxi is significantly higher than that in Pudong. There are four loop lines in Shanghai and the density of healthy food store is highest in inner ring road. The northern part of the middle ring road to the inner ring road is relatively high concentration, and this area has radioactive extension to the outer ring area. There are fewer healthy food stores outside the outer ring line, which are distributed in spots. In the community level, there are no healthy food stores in 1879 communities, one healthy food store in 806 communities, and two health food stores in 589 communities. The Jixiang community in Hongkou District has the highest density of healthy food stores-782.0 per square kilometers.

3.2. Measurement of travel time

The Gaode Map (https://www.amap.com/) is China's leading electronic navigation platform. It uses the door-to-door method (Salonen & Toivonen, 2013) to find the shortest travel route in the road network and based on real-time traffic information (including traffic volume, speed, sidewalk, one-way and restricted turns), It can provide a more realistic travel time calculation. The Gaode Map is employed to calculate the travel time of the community to the health food store.

The specific way is as follows: first, we use ArcGIS to calculate the geometric center of all communities in Shanghai. Based on the Shanghai road for network analysis, we use these community geometric centers as the origin, all healthy food stores in the city as the

destination and calculate the travel time of a community to all health food stores. Later, we select the nearest travel time for a community and pair the community with the nearest healthy food store. Second, we develop a crawling tool to harvest the daily travel time from each community to each healthy food store during 6:00–22:00 every 20 minutes on the 14th June 2019. The crawling tool is written by Python from the web pages of Gaode Maps. The travel time collected includes the time of walking to bus station, travel time, and waiting time. The data of 5380 communities in Shanghai is collected, however, 52 communities cannot be located in network analysis, so the data is missing. Considering people's shopping habits, bus and health store business hours, the data collection period is determined. During the data collection process, when the community is close to the nearest healthy food store, the public transportation time will be converted into walking time, which is more in line with the real situation to measure the actual shopping behavior of the residents.

3.3. Average travel time and changes in the community

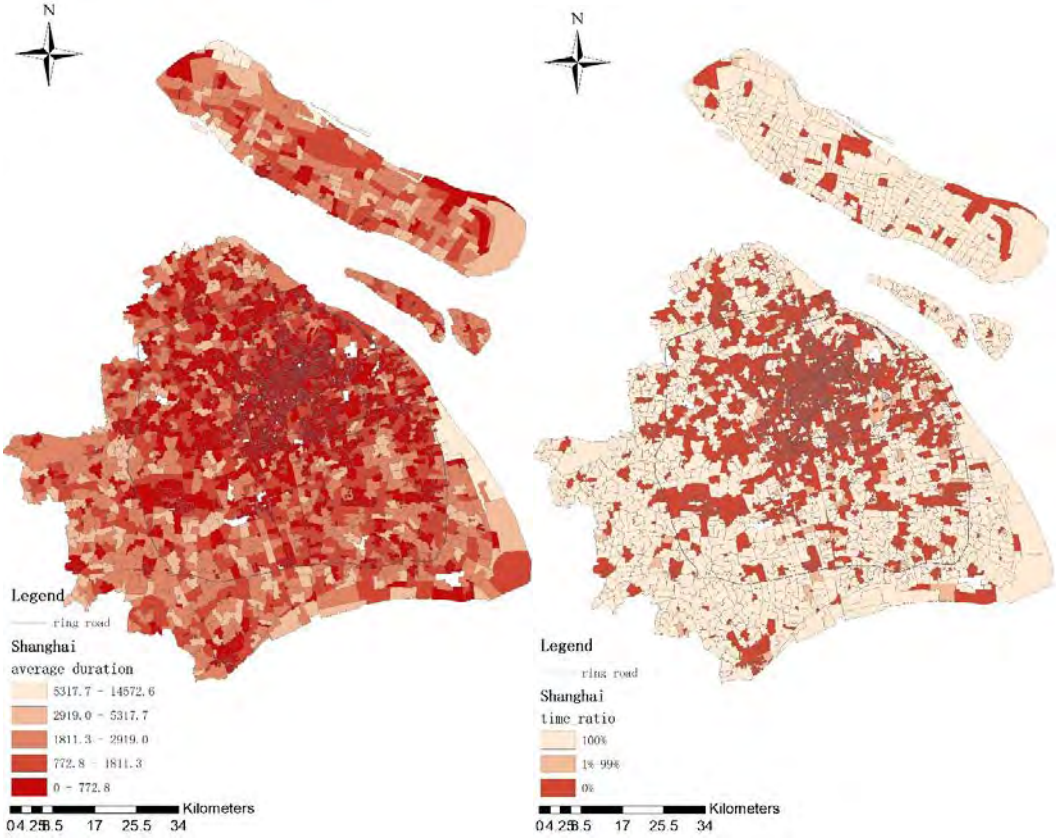

Figure 3 average travel time for healthy food in the community

Figure 4 the percentage of time that the community gets healthy food within 15 minutes

We calculate the travel time collected throughout the day to measure the accessibility of communities to healthy foods. The shorter average travel time is, the higher the accessibility of the community is. The results show that the average travel time of residents within middle ring road is shorter, and the accessibility to healthy foods is higher.

The accessibility of the south and east part of the area between the outer ring road and the middle ring road is good, and the accessibility of some communities in the north is slightly

poor. From the suburban ring road to the outer ring road area, the travel time of the community has gradually increased, and the accessibility has gradually weakened. However, there are still some plaque-like communities with good accessibility of healthy food. The community outside the suburban ring road has a longer average travel time, and the accessibility of healthy food in these communities is poor, especially in the eastern coastal areas of Pudong District and the northern part of Chongming County.

Based on the 2018 edition of Urban Residential Area Planning and Design Standards, the concept of a fifteen-minute living circle plan is proved. We measure whether community residents can reach the nearest healthy food store within 15-minute travel and calculate the percentage of time that residents can reach the nearest health food store within 15 minutes during the day in order to measure the accessibility from a time perspective. The average city community in Shanghai has a healthy food travel time of 738.0 seconds, which basically meets the requirements of the 15-minute living circle for the vegetable market planning. Specifically, there are 3,885 communities in the city that can reach healthy food stores in 15 minutes, and the proportion of time that 114 communities reach healthy food stores within 15 minutes is between 0-1. However, 1381 communities can't reach the health food store in 15 minutes all day, which affected by both long-distance and poor traffic conditions in this part of the region.

3.4. Community case

The travel time from the community to the healthy food store changes with the variation of traffic volume. We take the following six communities as examples to draw a travel time change chart for one day. It can be found that the travel time of the Gaoxiong Road community is short travel time and doesn’t change. However, the travel time of other communities have some change during the day. Some communities have shown an increase in peak travel time in the morning and evening, which is consistent with the traffic pressure.

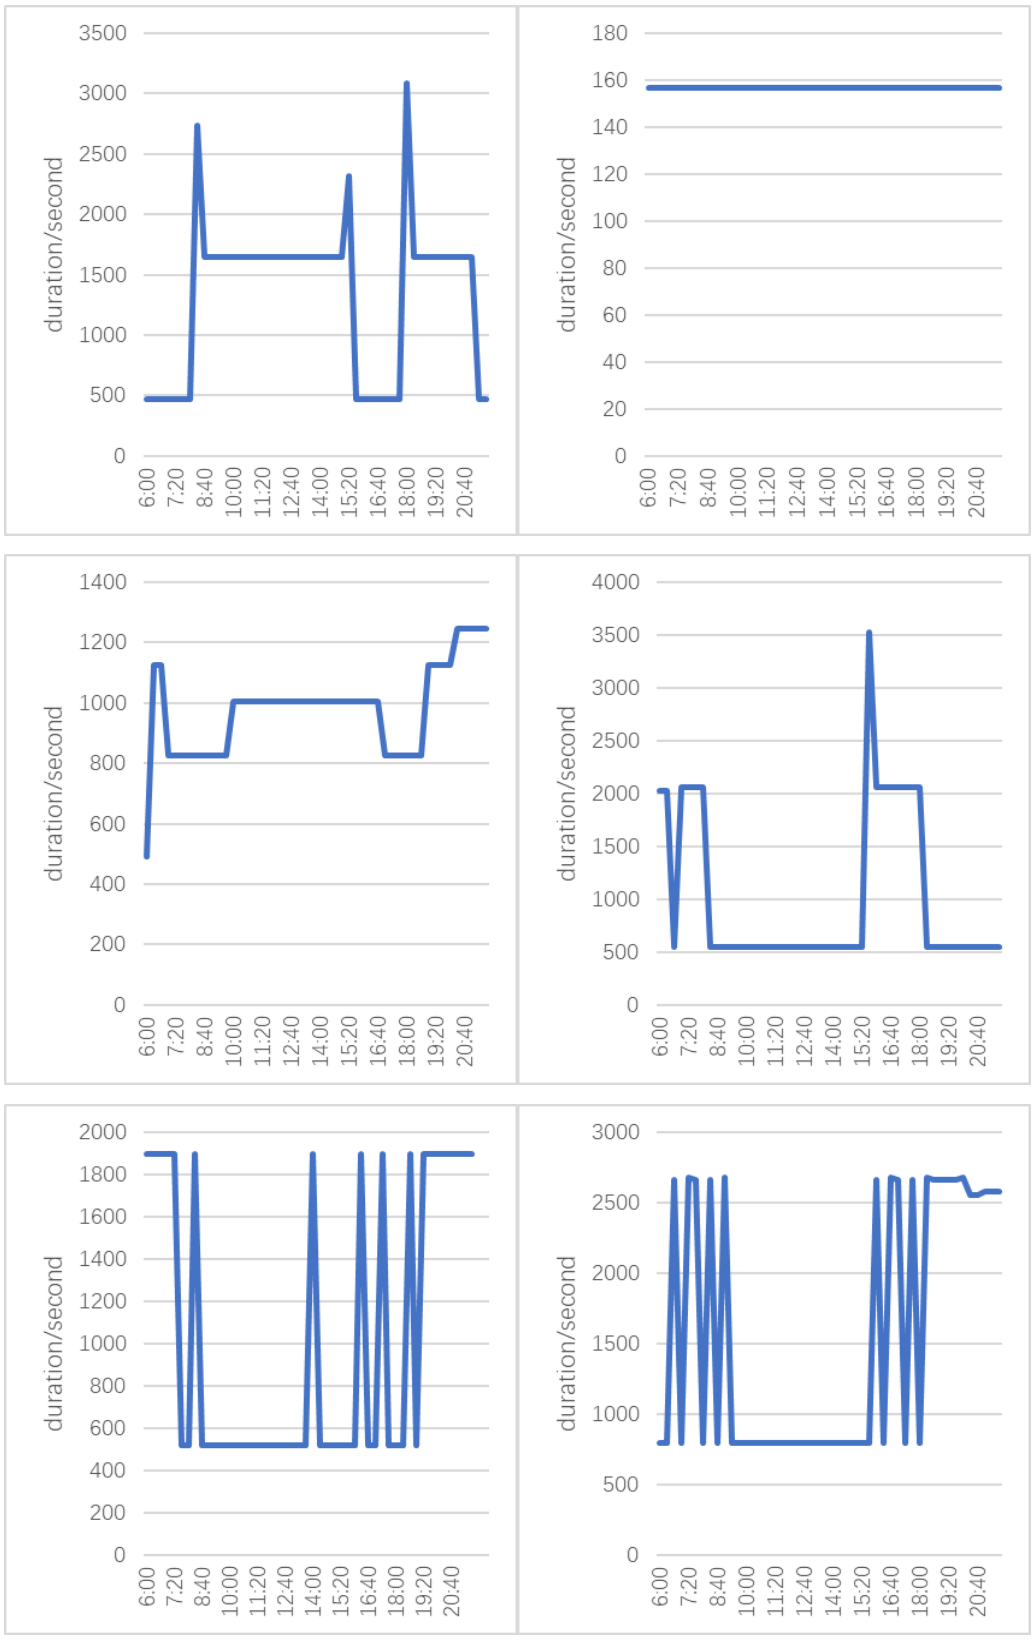

Figure 5 Travel time 1) Dongsenhanbi community, 2)Gaoxiong Road community, 3)Huakang community, 4) Xinmeigonghe community, 5) Shiwan community, 6)Gonghe villiage.

As for the travel time during the day, the Gaoxiong Road community in Huangpu District is the shortest, and the proportion of time is 100% that healthy food store can be reached within 15 minutes of the day. The Dongshenhanbi community in Yangpu District and the Xinmei Gonghe Community in Jing'an District are both close to its nearest healthy food store, however, travel time is greatly affected by traffic conditions, and the proportion of time is also affected that healthy food store can be reached within 15 minutes of the day.

Table 1 Case community travel time

community	district	Average travel time	Proportion of time that healthy food store can be reached within 15 minutes of the day
Dongsenhanbi community	Yangpu District	1319.4	66.7%
Gaoxiong Road community	Huangpu District	156.8	100%
Huakang community	Xuhui District	979.2	66.7%
Xinmeigonghe community	Jing'an District	1020.5	29.2%
Shiwan community	Pudong District	1035	37.5%
Gonghe villiage	Minhang District	1563.3	41.7%

4. Spatial autocorrelation

4.1. Method

Spatial autocorrelation is a measure of the correlation of the same variable in different spatial locations. Since the spatial autocorrelation is attributed to the geographical location, the closer the spatial location is, the more similar it is (Lin Jinyao, Li Xia, 2014). Using the spatial weight matrix, the similarity of the position is measured. Based on the average travel time of healthy foods in the community, the spatial autocorrelation of healthy food accessibility in Shanghai community is studied. We use the GEODA software to construct the spatial weight matrix of the data through the Queen method. Spatial autocorrelation is further divided into global spatial autocorrelation and local spatial autocorrelation and we combine the two method to study.

1) Global spatial autocorrelation

The global spatial autocorrelation can measure the overall distribution of the elements and determine whether this phenomenon exists in the space with agglomeration characteristics. The Moran's I reflects the similarity of the spatial unit properties of spatially adjacent regions.

The Moran's I is used as the global autocorrelation statistic, and the value range is [-1, 1]. At a given level of significance, when the Moran's I is significantly positive, there is a significant positive correlation between the observations, and high (low) observations tend to cluster with high (low) observations, presenting a pattern of high agglomeration and low agglomeration. When the Moran's I is significantly negative, there is a significant negative correlation between the observations, and high observations tend to be clustered with low observations, presenting a spatially dispersed pattern (Xie Zhengfeng, Wang Qian, 2009). The Moran's I is as follows:

$$I = \frac{n\sum_{i=1}^{n}\sum_{j=1}^{n} w_{ij}(x_i - \bar{x})(x_j - \bar{x})}{\sum_{i=1}^{n}\sum_{j=1}^{n} w_{ij}\sum_{i=1}^{n}(x_i - \bar{x})^2} = \frac{\sum_{i=1}^{n}\sum_{j\neq i}^{n} w_{ij}(x_i - \bar{x})(x_j - \bar{x})}{S^2\sum_{i=1}^{n}\sum_{j\neq i}^{n} w_{ij}}$$

among them:

$$S^2 = \frac{1}{n}\sum_{i}(x_i - \bar{x})^2 \qquad \bar{x} = \frac{1}{n}\sum_{i=1}^{n} x_i$$

It is verified by standardization statistic Z whether there are spatial autocorrelation relations in n regions.

$$Z = \frac{I - E(I)}{\sqrt{VAR(I)}}$$

2) Local spatial autocorrelation

Local spatial autocorrelation is a local indicator that measures the spatial connection of each unit. It is an indicator that describes the degree of spatial aggregation between regional units with significant similar values around the unit. Local metrics for spatial associations of all units are proportional to global spatial metrics. The Moran's I is as follows:

$$I_i = \frac{(x_i - \bar{x})}{S^2}\sum_{j} w_{ij}(x_j - \bar{x}) = \frac{nz_i\sum_{j} w_{ij}z_j}{z^T z} = z_i'\sum_{j} w_{ij}z_j'$$

The local Moran's I is verified by the normalized statistic Z:

$$Z(I_i) = \frac{I_i - E(I_i)}{\sqrt{VAR(I_i)}}$$

4.2. Spatial autocorrelation results

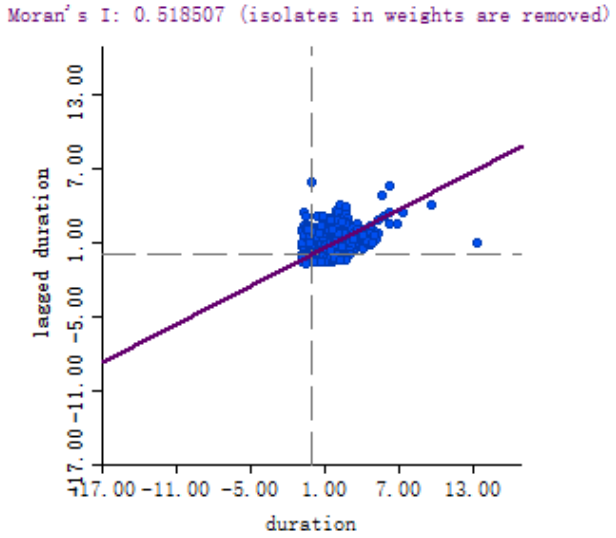

Figure 6 Moran's I of the average travel time of the community.

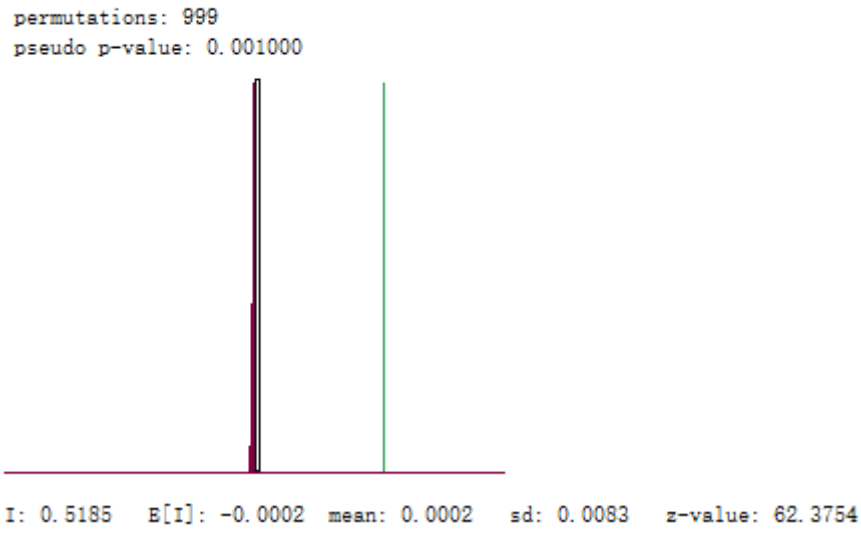

Figure 7 Random test of community average travel time

The Moran's I of the average travel time of the Shanghai community is 0.518507, and the global indicator is 999 tests p=0.001, which is significant in the case of 99.9%. The Z value is 62.3754, which is positive and significant, indicating that the average travel time of healthy foods in Shanghai community is not completely random in space, but shows spatial agglomeration and positive spatial autocorrelation with similar observations. (high or low values) tend to spatially aggregate. That is to say, in Shanghai, the areas where the community has a higher (or lower) average travel time for healthy foods tend to be adjacent to the communities with higher (or lower) average travel time.

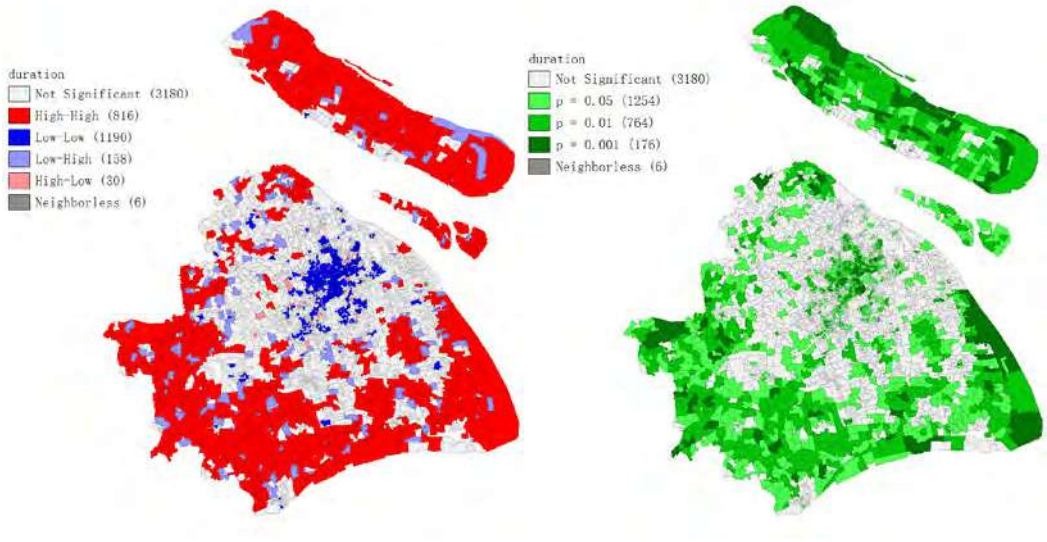

Figure 8 community average travel time local spatial autocorrelation and significance level

Most of the urban core areas within the Shanghai middle ring road are low-low areas. The average travel time of the communities themselves and surrounding communities is low. The spatial difference in this area is small, and there is strong spatial positive correlation. There are a few high-low areas around the core area. The average travel time of the community is higher but the surrounding level is lower and the spatial difference is larger. In fact, this may be due to the overall dispersal and local concentration of health food stores in the suburbs. Most of the areas outside the suburban ring road are high-high areas. The average travel time of the community and surrounding communities are high and the spatial difference is small. There is a strong spatial positive correlation. The level of significance is generally significant in the central and far-suburban areas of the city, and is not significant in the periphery of the city center.

The analysis found that the population density in the central area as well as the accessibility of healthy foods in the community were both high, and the population density in the peripheral areas as well as the accessibility of the community health foods were both low. There was a high correlation that the concentration of the population promotes the increase in the density of health food stores, and the facilities are closely related to the service population under market regulation. The distribution center of the health food store in Shanghai is still very prominent, showing a high center and a low level at the periphery. The centrality of the spatial distribution of health food stores in Shanghai is very prominent, showing a high center and a low level at the periphery, which is also related to the development history of Shanghai. The old city center of Shanghai, like Huangpu District and Jing'an District, has a long development period and has a long history of residents. All kinds of facilities are well-equipped and relatively livable, forming a strong centrality. With the development of Shanghai's urban construction, the central city has been expanding, making population and land development continue to spread to the periphery, and the transportation network is expanding outward. Under the regulation of the market economy, healthy food stores are also opening up with the accumulation of population. The expanding

scope of population agglomeration has led to the formation of a transitional zone with low accessibility, low or non-aggregation areas between urban center and peripheral areas.

In general, the accessibility of community-level healthy foods in Shanghai has a layer structure. The central area has strong accessibility, while the accessibility of the peripheral areas is weak. Meanwhile, both areas have autocorrelation, and also show a certain center-peripheral structure.

5. Conclusions and Discussion

5.1. Conclusions

Healthy eating intake can improve people's health. If cities can better provide healthy food to residents , it can better promote healthy city development. This paper uses multi-source data to analyze the accessibility of healthy foods in Shanghai community residents. Firstly, based on the healthy food store POI, we use the ArcGIS software to analyze the basic situation of the city's healthy food stores, and find that there are a large number of healthy food stores in the core area of the city within the outer ring road. Meanwhile, the density of health food stores in the Puxi area is significantly higher than that in the Pudong area, and the healthy food stores outside the outer ring road are pointy agglomeration. Further, we collect the whole city travel time to the nearest health food store based on the Gaode map platform and get that the average time for the Shanghai community to get healthy food travel time is 738.0 seconds, which meets the requirements for the farm in the 15-minute living circle plan. The overall situation is good, but there are large differences between the regions. The communities within the outer ring road have higher accessibility to health food stores, and the accessibility of peripheral communities is lower. During the day, some of the communities are far away. Travel time is affected by traffic conditions, which causes certain differences in time costs.

Using the community average travel time of healthy foods for spatial autocorrelation analysis, it is found that average travel time is concentrated in the central and suburban areas, and the surrounding areas of the central area are scattered. The average travel time of healthy foods in the downtown area of Shanghai is low, that is, the accessibility of healthy foods is high. The accessibility of healthy foods in and around them is high, and the spatial difference is small. There is strong positive correlation. The accessibility of healthy foods in Shanghai suburbs is low for themselves and the surrounding areas and spatial differences are small. There is strong spatial correlation.

Meanwhile, the degree of accessibility between urban centers and peripheral areas is low. A transitional zone between the city center and the surrounding area that has a low degree of accessibility, high or low, or non-aggregation. This area is close to the central area and is the key area for future urban development and construction. The current conditions are obviously insufficient. It is urgent to take measures to improve the accessibility of healthy food in this area. In the long-term, efforts will be made to improve the accessibility of urban suburban communities, and gradually transform communities with insufficient accessibility into areas with better accessibility.

5.2. Discussion

This paper mainly uses the POI data of healthy food stores. The POI data volume is large and it is easy to reflect the distribution of facilities. However, the POI data can only be expressed in the form of "points" and cannot reflect the service scope, grade, scale and other information of the facilities. It is difficult to conduct a more in-depth analysis. POI data has strong advantages in reflecting the spatial distribution and density of facilities, and can analyze the distribution structure or characteristics of the facilities. However, the in-depth study and discussion of facility accessibility should be further combined with urban population, transportation, land use and other aspects to analyze comprehensively.

This article discusses residents' access to healthy foods and only selects the accessibility of the nearest healthy food stores. It does not take into account other factors that affect residents' choice of healthy food stores, such as: price, healthy food type, consumption habits, etc. Future research should be combined with questionnaires, interviews and other research methods. From a human perspective, let us fully measure the availability of healthy foods.

Case Study / Project

Cultural sensitive approach in water management

for a volcanic river basin of Yogyakarta Metropolitan Area

Vicky ARIYANTI

Abstract

Although there is substantial literature on the implementation of integrated water resources management and multilevel governance of water, less attention is given on how and why cultural values contribute to the integration level of its implementation. Thus, this paper examines cultural ecological knowledge impacts on current water management practices in Opak sub-basin, Yogyakarta Special Region, Indonesia, which is threatened by the volcanic activities of Mt. Merapi in its upstream. Therefore, it uses the research question of " How and why does the cultural ecological knowledge impacting the water resources management in a volcanic river basin?" We used a qualitative approach to the case study of Opak Sub-basin to investigate a comprehensive understanding, with 57 in-depth interviews, three focus groups, and three months of observation (July-August 2016 and January 2018). The analysis was done using Atlas.ti software for axial coding on several concepts used in this paper, such as cultural ecological knowledge, integrated water resources management, disaster risk reduction, and volcanic river basin management. The codings were arranged using multilevel governance theory, which for this case study proposes three phases of volcanic river basin management: Normal (pre-eruption), Disaster (onset eruption), and Normal+ (Post-eruption) within existing governance levels: national, regional, and municipal. The analysis answer the how part of the question by detecting the main activities of actors within the context of water governance, the relationships between actors, and existing boundary spanning operations within the current interaction attempts in multilevel governance. It reveals that cultural boundary-spanning actors (water whisperers) are the answer to the why part of the question. These actors are more active during disaster volcanic river basin management (VRBM) phase. With them, the cultural ecological knowledge was brought into the interaction attempts. This condition contributed to the highest level of integration. Therefore, we argue that the integration level of water resources management is higher when more cultural ecological knowledge is used in the interaction attempts. The paper proposes that an understanding of the cultural ecological knowledge enables a better implementation of integrated water resources management for this volcanic river basin.

Case Study Paper

Inheritance and Development of Traditional Minority Culture in Southwest China:

A Case Study of Miao, Dong and Dai Nationalities

Lin CHEN, PhD candidate of College of Architecture and Urban Planning, Tongji University; China

Abstract

Guizhou Province and Yunnan Province are located in the southwestern part of China, with a large number of ethnic minority areas, of which Miao, Dong and Yi nationalities are important ethnic groups in terms of quantity and distribution. This part of China retains a large number of landscapes and traditional buildings, including terraces, Miao Village, Dong Village and Drum Towers, which are important components of the traditional culture of the Miao and Dong nationalities. Meanwhile, in Zunyi City of Guizhou Province, traditional folk religious culture is still preserved, and the text, language, songs, and utensils have been effectively passed down. Moreover, in Xishuangbanna of Yunnan Province, the traditional wooden structure which is inhabited by the Yi nationalities is still provided with typical national characteristics. And all aspects of clothing, food, housing and transportation are of great cultural characteristics. The entire village has a large number of intangible cultural heritage. This paper introduces the inheritance and development of traditional cultural changes in Guizhou, Yunnan Province in southwest China from the perspective of anthropology. The minority learners mentioned in this paper retain the essence of culture, but also attract more people to understand traditional culture and inherit and develop traditional culture. Otherwise, government, media and residents, including encouraging tourism, increasing cultural and tourism projects, publicizing intangible cultural heritage to attract people to understand and disseminate traditional culture, and making Chinese traditional culture develop in the new era. Chinese traditional culture has a long history and it has been passed down from ancient times to the present. The ethnic minorities in the southwestern region have retained their independent and complete national culture because of their geographical location and traffic. Therefore, they are highly recognizable. In short, Chinese traditional culture has great national characteristics and is the essence of Chinese culture. It is also an important part of world culture.

Keywords

Anthropology, Southwestern China, Traditional cultural, Inheritance,Development

1. Introduce

Guizhou Province is located in the hinterland of southwestern China. Meanwhile it's a world-renowned mountain tourism destination and a mountain tourism province. It's also a national ecological civilization pilot zone, and an inland open economy experiment area. Guizhou Province is a multi-ethnic province[i]. Yunnan Province is located in the southwestern border of China, and the east is connected to Guizhou Province. Yunnan is the province with the largest ethnic group in China. In addition to the Han nationality, there are 25 ethnic minorities with a population of over 6,000. Among them, 15 ethnic groups are unique to Yunnan. Otherwise, Yunnan ethnic minorities are staggered, showing large mixed living and small settlements[ii].

2. Traditional Cultural Types of Minorities in Southwest China

2.1. Architectural culture

The traditional architecture of ethnic minorities has a long history. Due to the influence of the natural environment and the characteristics of the nation, its rich architectural culture also has very distinctive characteristics, which fully reflects the living habits, thinking concepts and religious beliefs of ethnic minorities. It also makes the traditional architectural culture of ethnic minorities an important part of national culture. Among them, the Pile Dwelling is a typical representative of the Miao nationality architecture, the Drum Tower and the Wind and Rain Bridge are typical representatives of the Dong nationality architecture, and the Dailou is a typical characteristic building of the Dai nationality. Most of the these structures are selected from the nearest material, and the shape and the characteristic are harmonious with the natural environment, which have the cultural connotation of their own nation.

Figure 2 Guizhou Dong people's wind and rain bridge(Photo by Chen Lin)

Figure 3 Guizhou Dong people's Drum Tower(Photo by Chen Lin)

Figure 4 Yunnan Dai people's traditional Dailou(Photo by Chen Lin)

2.1.1 Practical concept according to local conditions

Since ancient times, the residents living in Guizhou Province have mostly lived in agriculture, while Guizhou Province is located in the mountain plateau. There are very few plains. In order to preserve the farmland to the greatest extent, the residents use mountainous and sloping land that is not suitable for use as cultivated land. On top of it, a traditional structure, the Pile Dwelling ,with Guizhou national characteristics is built. This type of construction not only destroys the natural environment in a large amount, but also makes full use of the non-cultivated landforms, minimizing the deforestation and waste of cultivated land. The rear half of the Pile Dwelling is placed against the rock above the ground, and the front half is supported by wooden columns. Because the second and third floors of the structure and the eaves are beyond the perimeter of the structure, a suspended sling posture is formed, which is called the " Pile Dwelling "[iii]. From the longitudinal section, the shape forms a unique landscape. When observing these hanging structures, it is natural, especially in the Miao Village, which is surrounded by mountains and rivers. The slinged structures is like a eagle flying high in the Miao Village with a sense of nature[iv].

Figure 5 Guizhou Miao pelple's Pile Dwelling（Photo by Chen Lin）

2.1.2 Building materials sustainability concept

In Guizhou and Yunnan Province, the building materials used in traditional structures in ethnic areas are mostly adapted to local conditions and locally. Soil, stone, trees, bamboo, straw, etc. can be used as materials for building houses [iv]. For example, the Miao people's Pile Dwelling , the Dong people's the Drum Towers and the wind and rain bridges use wood, stone and mud as the main building materials in the nearby forests. The Dai Lou in Yunnan Province use wood and bamboo. These materials are obtained from the surrounding environment and are often more adapted to the local climate, geography and other conditions. The people living here use the resources given by nature, and they also know how to give back to nature. Plants are often planted near their homes, which not only increases the comfort of living, but also maintains the local soil and water, reflecting their respect for nature and endless belief. For example, the Buyi people are used to planting bamboo and other plants around the village, which is named "Zhailin" by Buyi people [iii].

Figure 7 Yunnan Xishuangbanna traditional thatched cottage（Photo by Chen Lin）

Figure 8 Yunnan Xishuangbanna Dailou uses wood and bamboo raft as building materials （Photo by Chen Lin）

2.1.3 Diversified functional culture

The drum tower and the wind and rain bridge, which are public structures in the villages of southwestern Guizhou Province, play different functions in their respective national cultures.

The drum tower is mainly made of wood, with many eaves and columns, which are mainly used for placing cowhide drums, while the drum tower and drums form important public buildings and cultural things of the Dong people. In addition, the wind and rain bridge breaks through the single function of the bridge, and integrates the styles of bridge, pavilion, gallery and leaning. There is a roof on the bridge, which can be used for people to rest on the benches on the side of it (Fig. 9). Meanwhile, there are Dong people's folk paintings ,flower and bird landscape paintings on both sides of the bridge (Fig. 10), making the wind and rain bridge more artistic and ethnic. The whole bridge pavilion is connected by wood, which is integrated into one. It not only has the basic functions of the bridge, but also has functions for pedestrians to rest, watch the scenery, avoid the wind and rain. During the festival, the wind and rain bridge also gathers the Dong men and women to hold entertainment and religious activities on it [iii]. As a residential structures, the Pile Dwelling is generally divided into three layers. The lower tier store debris, stack firewood, and store production tools such as plows and hoes for easy access. The middle tier lives to make people live off the ground, avoiding the attack of insects and beasts, and protecting people from the influence of moisture; the upper layer of grain storage can not only avoid food moisture, but also can be used at any time [iv].

Figure 9 Guizhou Diping Twon wind and rain bridge(Photo by Chen Lin)

Figure 10 Paintings on the wind and rain bridge(Photo by Chen Lin)

2.2. Religious culture

Religious belief is a series of spiritual worship concepts, behavioral patterns and ritual systems produced by people in their production, life or entertainment, which are hopeful, praying for happiness and maintaining psychological security. The content is very rich. In the Daozhen Miao and the Gelao Autonomous County of Zunyi City, Guizhou Province, people have the religious beliefs of the the Gelao people. Ancestor worship, heaven and earth worship, sun and moon star worship, wind and rain and lightning worship, mountain water and fire worship and animal and plant worship are the basic contents of the original religion of the Gelao and the Miao people in Guizhou Province. The original inhabitants of the Gelao people considered themselves to be descendants of the bamboo king, who was their ancestor. Up to now, the legends of the bamboo king and the custom of revering bamboo have been widely spread among the Gelao people in various places. For example, in the Meijiazhai country, Daozhen Gelao and Miao Autonomous County, when the first boy was born, parents should bury their placenta and some egg shells in the bamboo forest to pray for the protection of the bamboo king. During the Spring Festival, every household must go to bamboo forest to offer bamboo king money. There are quite a few places where bamboo wares are used to worship the ancestors or to harvest. Moreover, the Gelao people in Guizhou Province are full of worship for the sun, the moon and the stars. They regard the sun as a spiritual thing, and they are called "the sun bodhisattva" and are enshrined in the temple. The Gelao people believe that the representatives of Thor and justice should enjoy the incense of human sacrifice. Many places have built a Thor temple, dedicating to the Thor Buddha. The Gelao people in Guizhou Province also believe that the earth and rock are

closely related to human life. People believe that life comes from the land, and the land can bring peace to the people. The mountains, rivers and the gods of the land give sacrifices. Therefore, build a temple for setting the mountains and rivers, the land of the gods, to give sacrifices. Some strange shapes of landstone and stalactites are also regarded as spiritual objects. Stone buddhas, stone pigs, and stone goddess in the Gelao area can be seen everywhere. People devoutly put on red cloth and scented candles. Animal and plant beliefs and worship are worshipped by animals and plants or fantasy animals. The Guizhou Gelao people think that they may bring their own gospel or threat, so they are awe-inspiring and sacrificed[v].

During the field investigation in Daozhen Miao Autonomous County, Zunyi City, Guizhou Province, the author found that the Gelao people still retain relevant words and symbols (Fig. 11) and the molds for making these characters and symbols (Fig. 12). The transcripts record some eulogy and songs about religious ceremonies. Some residents also retain the crafts of making religious utensils and personally make some utensils used in religious ceremonies (Figure 14-15). On special religious anniversaries, local residents will still carry out some religious activities to sacrifice their ancestors and worship the gods. This tradition has been passed down to the present day.

Figure 15 Gelao people wear masks(Photo by Chen Lin)

2.3. Intangible Cultural Heritage

There are a large number of intangible cultural heritages in Guizhou and Yunnan Province. According to the statistics of relevant departments, more than 30 projects in the Yunnan-Guizhou ethnic minority area have been included in the list of national intangible cultural heritage, including folk oral literature, folk festivals, folk music and folk dances, as well as

folk crafts[vi]. In Xishuangbanna, Yunnan Province, people's clothing, food, shelter and transportation all have national characteristics, reflecting people's hard work and wisdom. The Dai people nationality Zhang Ha, the Dai people ethnic brocade skills, the Dai people drum production skills, the Dai people traditional umbrella craft, the Dai people bamboo building construction skills, Xishuangbanna minority tea customs, etc. are listed as intangible cultural heritage.

3. The way of inheriting and developing traditional culture in Southwest China

Under the background of globalization, traditional culture has been greatly impacted in the contemporary era. But as the essence of culture that has been handed down for thousands of years, it should be scientifically passed down and developed in the contemporary era. On the one hand, these valuable cultural wealth can be passed down from generation to generation, on the other hand, traditional culture can be developed into a culture that meets the spiritual needs of the contemporary people in the new era. With the joint efforts of the state, society and residents, the traditional culture of Southwest China has been effectively passed down and developed through the following three methods.

3.1. Development tourism

The development of tourism has a positive effect on the return of local culture, traditional culture, the highlight of national identity and the expansion of the traditional living space of ethnic traditions[vii].Nowadays, people like to see different landscapes and experience different human relationships through tourism. They can also interact with human landscapes in the process of tourism. People from different regions and cultures can exchange cultural information in this process and directly experience the cultural enjoyment that traditional culture brings to people. In Guizhou Province, many villages in the form of tourism invite visitors to participate in their lives, experience the authentic Dong people's life. So the visitors can understand the traditional customs of the traditional culture of the Dong people and carry out deep cultural tourism. The author was fortunate to participate in the local Dong people's wedding during the field investigation in Diping Township, Liping City, Guizhou Province. The local marriage still retained the traditional customs, and the groom needed to marry the bride before dawn. The bride's dowry also retained the traditional customs of several categories of essential items, and the traditional way of carrying accompanied to her husband's family. The day before the wedding, the villagers gathered together to prepare food for the next day wedding banquet. On the wedding day, with the method of open-air banquet to welcome all the guests, visitors can also join in with sincere blessings and feel the local culture. This kind of cultural experience of direct participation often reminds people of the time, and can appreciate the charm brought by traditional culture. It is more conducive to the inheritance and development of traditional culture. Tourism has become an effective way for people to understand and inherit traditional culture. The direct economic benefits brought by tourism can improve the living standards of local residents and promote local economic development. Under the premise of meeting basic living needs, people have more time and energy to participate in the traditional culture construction, so that the local traditional culture can be better developed.

Figure 19 Villagers in Dongzhai prepare food for the wedding(Photo by Chen Lin)

Figure 20 Villagers in Dongzhai prepare food for the wedding(Photo by Chen Lin)

Figure 21 Tourists take a group photo with the bride and groom(Photo by Chen Lin)

3.2. Cultural communication

Because the southwestern region is located in the middle of the mountain, the traffic conditions are not very convenient. So in the long period of time, it was in a relatively closed state. But it is precisely because of this environment that the local traditional culture is more preserved. In such an era of information, on the one hand, we guarantee the traditional culture is not affected by the impact of the cultural globalization, more keep its characteristics. On the other hand, it spreads the traditional culture of Southwest China and makes more people to understand traditional culture. Inheriting and developing traditional culture is the responsibility given to us by the times. Nowadays, in many villages, digital intangible cultural heritage databases and museums have been built digitally, such as the “Miao Nationality Costume Database” of the Guizhou Provincial Museum, the “Taijiang Miao Nationality Embroidery Museum” in Taijiang County, and the "Suojia Miao Nationality Ecological Museum" jointly built by the Kingdom of Norway and Liuzhi District of Liupanshui City[viii]. The museum enters the village to establish a real ecological or “live” museum, recording and inheriting local traditional culture with modern means of communication. As an important window for propagating national culture, carrying forward the national spirit and inheriting national civilization, the museum plays a pivotal role in the protection of the national cultural heritage. Moreover, as a working mode or a means, the object of protection should be a fresh cultural whole. It requires itself not only to protect the static culture, but also to protect the dynamic culture; It is necessary not only to protect the status quo of culture, but also to accept the facts of cultural change and development, thus maintaining the dynamic development of culture in the historical process. In fact, what

intangible cultural heritage really needs is the display and inheritance of living state, as well as the self-survival ability to make it live state and inheritance[ix].

While traditional culture brings us spiritual pleasure, it is also indispensable that people play the role of the media. The essence of traditional culture often takes time to consolidate. It needs to be taught orally and passed down from generation to generation. The inheritance of such culture is usually handed down by teachers and apprentices of folk organizations or family inheritance, which requires people to participate in either way. Therefore, we must pay attention to the cultivation of the "inheritors". The government encourages the younger generation to systematically study traditional culture and skills. When necessary, professional colleges and universities can cultivate professional talents in the form of joint construction to ensure the inheritors' talent reserves.

3.3. Increase the number of cultural tourism projects

The cultural tourism project is a clear market positioning form, which mainly combines local characteristics to form a cultural brand effect and form a new cultural industry. It promotes the development of tourism and other related industries, and ultimately promote cultural and artistic exchanges between ethnic groups. In 2005, Guizhou Province held the “Colorful Guizhou” series of competitions and introduced the relevant content of intangible cultural heritage through the competition project. Explore continuously, sort out and restore the intangible cultural heritage of ethnic minorities through the development of ethnic tourism, and reproduce the minority traditions. Thus, revitalize and carry forward the intangible cultural heritage of ethnic minorities. People can understand the history and culture of ethnic minorities in entertainment. "Colorful Guizhou" has become the representative of ethnic minority tourism industry in Guizhou Province, and it has become a model for the protection and development of intangible cultural heritage of ethnic minorities in China [vi] . Open a folk museum, publish a series of books and brochures to publicize traditional folk customs, and make people understand the folk culture in traditional culture through the reproduction of original scenes, traditional national costumes and artifacts.

The cultural tourism project generally pays more attention to people's participation. Through some specific activities, people are involved, such as inviting people to participate in the production process of ethnic dishes, visiting the production process of Miao people silver jewelry, and opening up some self-service farmhouses to let people experience the country life themselves. Such a collision of different national cultures not only promotes the spread of traditional culture, but also brings new vitality to its development. In addition, Miao Village ,Dong Village and Dai Village not only have deep traditional culture to attract people, but also have beautiful natural landscapes such as terraces, mountains, streams, and ancient trees. It is the best choice for tourists to commemorate and also become a base for various artists to create art and collect art styles. Artists create artistic creations here, and integrate natural landscapes and human landscapes into their works. These works are the most authentic records. With the spread of the works, traditional culture is also deeply rooted in the hearts of the people.

Figure 23 Tourist photo of hundreds years of Bodhi tree in Xishuangbanna, Yunnan Province(Photo by Chen Lin)

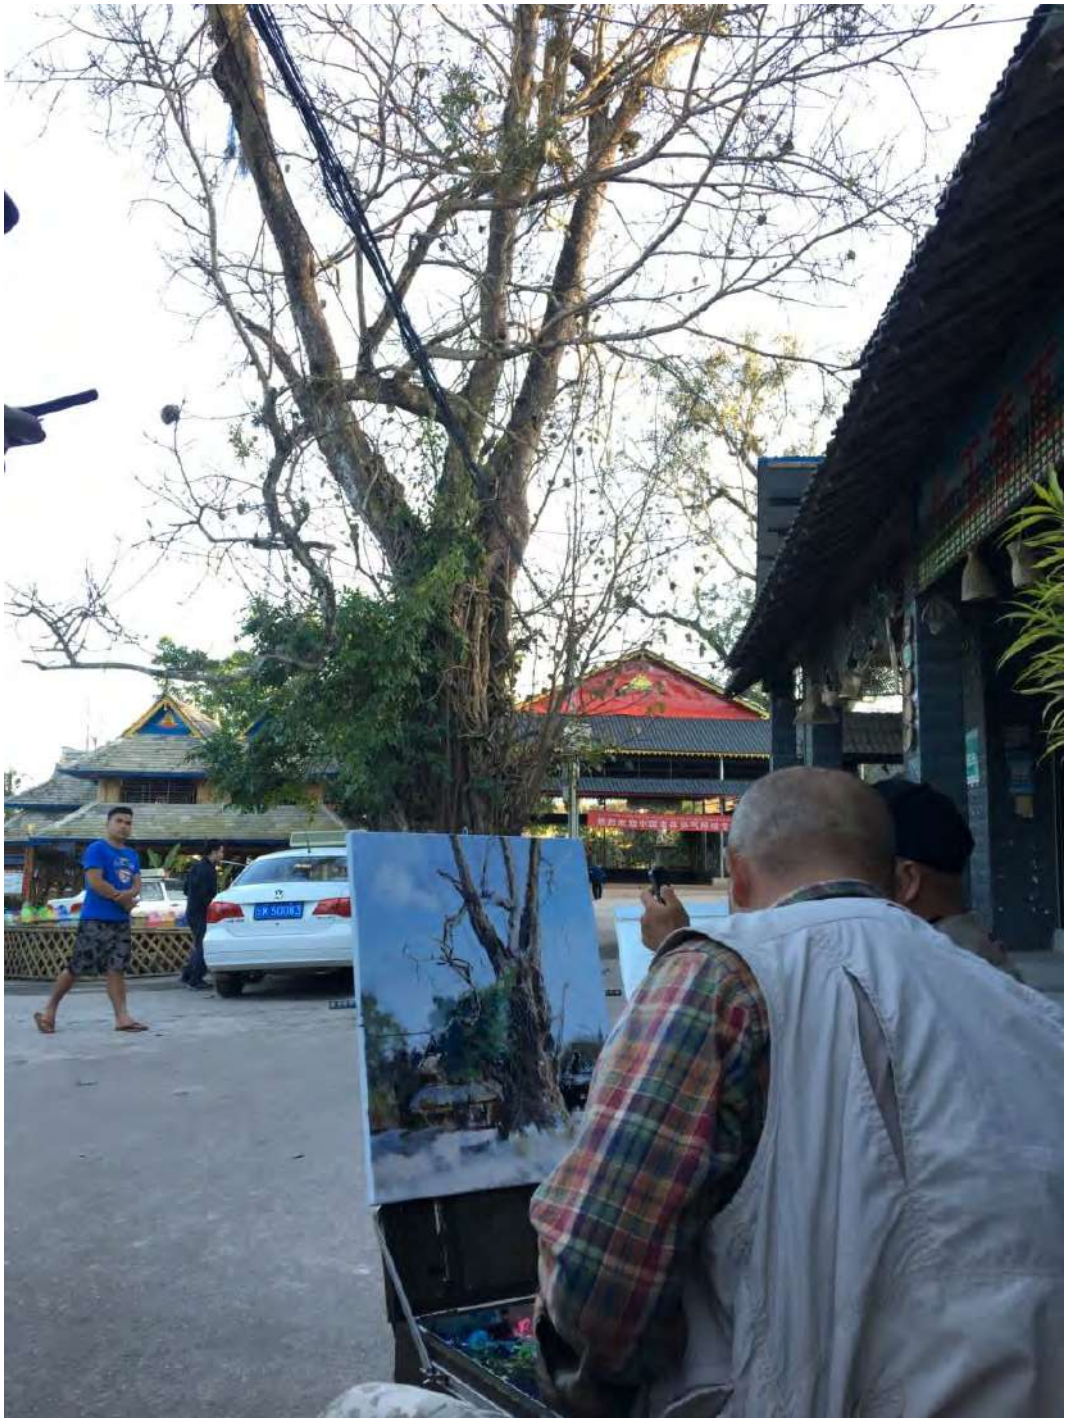

Figure 24 The painter is making paintings in Xishuangbanna, Yunnan Province (Photo by Chen Lin)

4. Summary

The Yunnan and Guizhou provinces are the ones with the largest concentration of ethnic minorities in China. And the traditional culture of ethnic minorities represented by the Miao, Dong and Dai ethnic groups is very distinctive. There are a large number of intangible cultural heritages in all aspects of clothing, food, housing and transportation. The intangible cultural heritages pass down from generation to generation through teacher-apprentice teaching or family inheritance mode. Meanwhile, The the drum towers, wind and rain bridges of the Dong nationality, the Pile Dwelling of the Miao nationality, and the Dai Lou of the Dai nationality are representative of the traditional architectural culture and have been developed in the inheritance of the past. The Miao, Dong and Dai residents living in the village still retain the traditional customs of marriage and funeral. In the context of the contemporary era, combined with the development of tourism, cultural and tourism projects will be vigorously developed with the joint efforts of the state, society and residents, so as to attract people from different ethnic groups to experience local culture here.

Research Paper

Revitalizing historic urban quarters by Cityscape-control plan

The case of Xi'an, China

Xiaoxiao DENG, SHANGHAI TONGJI URBAN PLANNING &DESIGN INSTITUTE CO., LTD; China
Dihao ZHANG, SHANGHAI TONGJI URBAN PLANNING &DESIGN INSTITUTE CO., LTD; China
Shuang YAN, Administrative Committee of Qujiang New District, Xi'an; China

Abstract

In globalization ear, a large number of cities around the world are losing their features with the impact of powerful alien culture. Furthermore, China has been experiencing rapid urbanization. Full speed construction calls for the standardization instead of the uniqueness, which have brought threat to characteristics of cities. Homogeneous images of cities can be seen everywhere.

Local cityscape, as the identity of the indigenous culture, is becoming increasingly scarce resource and competitive power for city in the field of global competition. Cities in China, who have realized the importance of history and culture in recent years, started to preserve and improve local cityscape by the tools of urban planning and design.

Taking the historic urban quarters around the Daming Palace National Heritage Park as an example, the Cityscape Control Plan is researched as a method to preserve and optimize the cityscape in the historic area during the process of urban regeneration.

The project is located in Xi'an, a megacity with more than 9.6 million population. Daming Palace used to be the imperial palace of the country in Tang Dynasty (AD634-896). Quarters around it has become a decayed area with squatter settlements nowadays. The municipality tries to bring in new opportunities for the area with a Cityscape Control Plan, which offers a possible solution to combine global and modern function with local and historic cityscape.

Learning from the theories of city image, urban morphology and typology, the concept of cityscape and Cityscape Control Plan are defined theoretically.

Secondly, an integral cityscape structure for the area is constructed and several spatial guidelines are created in terms of morphology，street interfaces, building heights, architectural styles, architectural colours, etc. All the guidelines are integrated and detailed to specific form codes for each blocks, which can be used as an administrative tool to restrict all the related construction activities.

With these efforts, the historic features and innovative features are combined to identify a unique cityscape in this area, bring in a "glocal" (global-local) solution for the revitalizing of the historic mega city as Xi'an.

Keywords

Cityscape Control Plan, local culture, urban regeneration, historic urban quarters

1. Background

In the age of globalization, cities are located in the opening network of global capital, information, science and technology, which triggers the assimilation of cultural value. The mainstream culture in advanced countries has become the dominant culture all around the world, leading to continuous interweaving and conflicts with the indigenous cultures. During this process, as the material carrier of culture, cities are unavoidably impacted by alien cultures, and the original difference of cityscape expressed due to regions, nations and history gradually disappears, which has become a worldwide problem.

On the other hand, China is in the process of rapid urbanization. Full speed construction calls for the standardization instead of the uniqueness. As a result the traditions and features of cities give place to standard and simple modern architectural style, the pleasant urban space shaped by history is eroded, the cityscape all around the world is increasingly homogeneous day by day.

Facing the similar cityscape here and there, people start to introspect how to rebuild the sense of identity of their hometown by preserving culture and features of cities. The fierce competition of cities in globalization also let the administrators realize the importance of unique cityscape, which can add up the vitality, attract talents and bring investment and chances for their cities.

Therefore, Cityscape control plan as a tool to combine global and modern function with local and historic cityscape has been paid more attention. Each city that is situated in the global network is seeking for a possible solution, which is “how to become modern and to return to sources; how to revive an old, dormant civilization, and take part in universal civilization.” (Paul Ricoeur, 1965)

2. Concept definition

2.1. Historic urban quarters

The preservation of the historic city has experienced a long process. The protecting objects start from individual landmarks, monuments and sites (International Charter for the Conservation and Restoration of Monuments and Sites, 1964) to historic areas (Recommendation concerning the Safeguarding and Contemporary Role of Historic Areas, 1976), and then to historic towns and urban areas (Charter for the conservation of Historic Towns and Urban Areas, 1987). To sum up, the definition of historic urban quarters is increasingly enlarged and deepened, which includes not only physical environment but also social cultural structure, and consists not only buildings but also the continuous ensemble of the surrounding environment.

2.2. Cityscape

Cityscape is not an academic word in the field of urban plan. It originates from a literary concept, expressing the physical form of cities and the potential cultural connotations. Therefore, cityscape includes two parts: the visible part consists of the natural environment and the artificial environment of cities; the invisible part includes the social-cultural features that affects urban developing process, for instance, religion, history, ethic and law, etc. After it is applied into the planning field, the meaning of cityscape is enriched in a further way. It is

influenced by the trends of society, economy and culture, and made up of the several contents, including the construction of physical environment, the display of cityscape, the creation of urban culture and the extraction of urban spirit.

2.3. Cityscape control plan

As a new planning category, Cityscape control plan hasn't shaped a mature and systemic standard (Duan, Dezheng; Wang, Liyuan; Wang, Jin; 2013). In China, cityscape control plan is generally regarded as an assistant research tool for master plan, or as a special type of plan independently. In terms of content, it not only includes the overall cityscape of whole city on the macro level but also specific cityscape for each block on the micro level. In the practice of planning, the cityscape control plan on the macro level emphasizes more on blueprinting and qualitative description, which is hard to be used in implementation and management (Dai Shenzhi, Liu Tingting, 2013). On the other hand, the micro level's cityscape control plan has not formed mature planning method and the content of it is always confused with urban design. In this background, the paper attempts to explore an experimental planning method for the cityscape control plan based on the practice of the historic urban quarters around the Daming Palace National Heritage Park.

3. Case research

3.1. Introduction

The project is located in Xi'an, a megacity with more than 9.6 million population. Daming Palace used to be the imperial palace of the country in Tang Dynasty (AD634-896). The palace covers an area of about 3.2 square kilometres, whose size is 4.5 times of the Forbidden City in Beijing. The spatial structure of the palace is grand, and the architectures are exquisite. It is referred to as "the peak work of Chinese palace architectures." As Tang Dynasty declined, Daming Palace became a heap of ruins in a fire (896 AD). After the changes of several dynasties, Daming Palace quarter had been covered with farmland for a long time, until it became squatter settlements for displaced person in World War II. The narrow alleys, the crowded houses, the dirty sanitation and the high crime rate made up of the first impression that the decayed area. Since 1970s, the area started a regeneration project. Later on, the construction of the National Heritage Park (2010) and the reconstruction project of the railway station north square (2015) brought new vitality and tourists to the area.

The renewal of the urban quarters around the Daming Palace National Heritage Park is continuing. There are still about 0.75 square kilometres land to be updated, the old function (the place used to gathered large urban markets of building materials) cannot satisfy the diverse needs of residents and tourists, the declined landscape of the block is incompatible with the long-standing and elegant heritage park, and the messy streets and the squatter buildings cannot bring the sense of belonging for the neighbourhoods.

Figure 1 Land renewal proposal of the historic urban quarters around the Daming Palace National Heritage Park

3.2. Research framework

There are two main tasks concerning the cityscape control plan of Daming Palace area: Firstly, how to revive a historical area without architectural remains (there are only rammed earth ground foundation sites in Daming Palace National Heritage Park), and awaken sense of identity of communities. This area plays a significant role for the city and even the country, it stands for the cultural peak of Han civilization, and it is also an important tourist destination of the city, attracting a large number of domestic and foreign tourists every year. The municipality and planning experts are trying to seek for the cityscape that can represent the characteristics of this area, not only coordinating with the historical context, but also adapting to the diverse modern functions in the future.

Secondly, there remain a variety of old city quarters formed in different periods; for instance, the remains of Palace, the squatter settlements, the building material markets and the industrial zone. Although not every history period is enjoyable, as a unique memory of the city, they should all be respected, and we hope to keep all these remains and integrate them into the city life in a positive way in the future.

The regeneration system consists of two parts, that is function updating and cityscape improvement. Several specific guidelines and strategies are raised step by step, resulting to the planning documents that can be effectively implemented in macro to micro level.

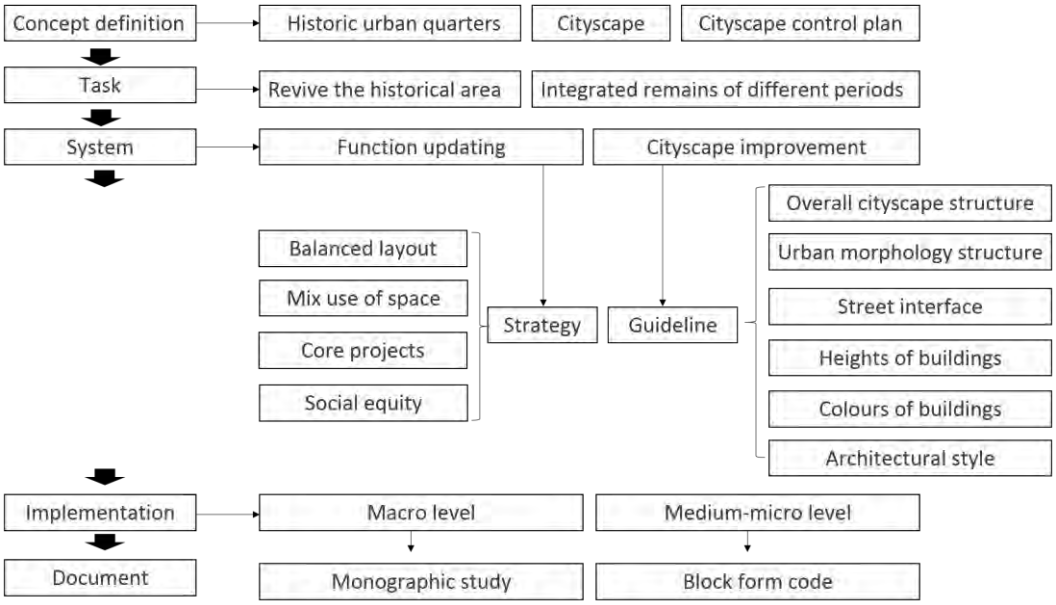

Figure 2 Research framework

3.3. Function updating

At the present stage, the dominant function of the historic urban quarters around the Daming Palace are building materials market and the residence. There are also a few cultural leisure and tourism service activities. According to the master plan, this area will become a comprehensive area where business, tourism and culture are combined together. According to the research, though the total squares of culture and commerce spaces in the area can meet the needs of tourists and commercial people, there are still four problems. First of all, the location of each domain determined by the master plan is too concentrated, which goes against the balanced development and continuous public space; secondly, the degree of mixed land-use is low, which has negative effect on the urban vitality; thirdly, there are insufficient flagship projects to driver the development of surrounding neighbourhood; last but not the least, how to avoid the gentrification influence brought by function replacement during the regeneration process.

Four corresponding strategies are proposed. Firstly, the balanced layout, it refers to disperse the centralized commercial, cultural and office space moderately, forming a pattern of concentrate partial and disperse generally. The second strategy is the mix-use of space, which means to mix the function of the blocks and buildings in three-dimension, creating more dynamic possibilities. The third strategy is to take transformation of industrial zone, northern art block, and the upgrading project of building materials market as three dominant projects, to combine commerce, culture, hotel, catering, leisure, entertainment together. In addition, rich activities such as design show, artistic performance, forum, history lectures, and signing sessions are planned, aiming to form a dynamic and comprehensive centre for the region and promote tourism and business as well. The fourth strategy is to make sure of sufficient living space, to build a variety of new apartments for different groups, including SOHO apartments for young graduates, social apartments for middle-income people, and serviced apartment for tourists etc., meanwhile, equal and friendly public space for the neighbours are constructed, such as museums, cultural palaces, squares, streets etc.

According to research, it will provide about 2500 residences and 20000 job positions for the society during the regeneration process.

3.4. Cityscape improvement

There are many factors that affect cityscape, and the decisive factor lies in the physical form of the city. Referring to the theory of morphology, M. R. G. Conzen (1960) divides urban form into three basic objects, they are town plan, building fabric and land utilization. Saverio Muratori refers city as urban organism, it includes city, block, architecture and detail. In The Image of City, Kevin Lynch (1960) classified physical forms of city into five elements: paths, edges, districts, nodes and landmarks. Based on the theoretical study, we can see that as a comprehensive system, cityscape includes the relationship from the whole to the part. Accordingly a framework for cityscape system from macro to micro level is constructed. In macro level, the structure of overall landscape, morphology of blocks, street interface, and architectural style are guided. In the micro level, the layout of the open spaces, the interface of street and the facades of buildings of certain block are regulated in detail, consisting the specific form codes for each blocks that can be applied to implementation and management of the plan.

3.5. Guideline for the overall cityscape structure

The overall structure of cityscape refers to the comprehensive of elements of cityscape in the form of point, line and surface (Fang Haojie, Zhou Yubin, 2012). The structure of the historic urban quarters around the Daming Palace National Heritage Park is mainly affected by the interaction relationship between the nodes of the heritage park, the metro station, the train station and the surrounding blocks. It is composed of 80% general blocks, 20% node blocks and three main street interfaces. The general blocks are regulated with strict guideline, in order to construct a coordinate and consecutive morphology. The node blocks adopt the way of flexible guidance, which emphasizes innovation and vitality, aiming to create attractive landmark space.

Figure 3 Overall cityscape structure

3.6. Guideline for the urban morphology structure

Morphology is the basic element of cityscape, which determines the texture and spatial form of the quarters. As the historic urban quarters around the Daming Palace have a long history, and the difference historical period left different urban formation. The quarters are regarded as sediment accumulated level by level; the building type and fabric unit of each stage are overlaid. Each block was matched with corresponding morphological module according to its original spatial fabric and updated function. There are five morphological modules in this area: traditional block with small courtyard, cultural block with building groups, shopping mall transformed from big volume market buildings, modern business building and residential apartment.

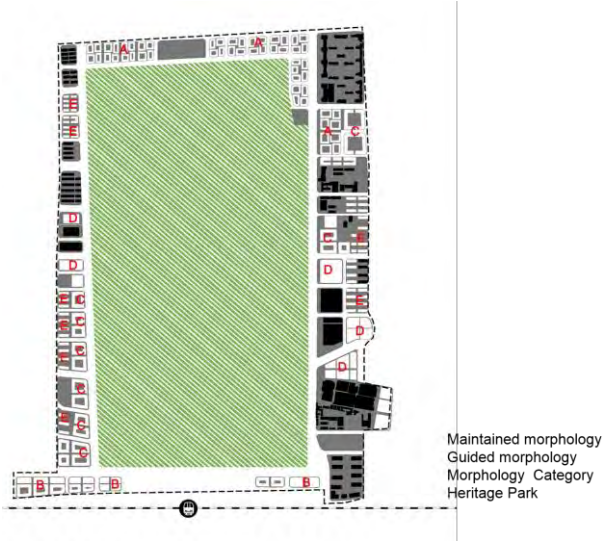

Figure 4 Urban morphology structure

Table 1 Urban morphology Modules

	A	B	C	D	E
Category	Traditional block	Cultural block	Office & Business	Commercial complex	Residence
Space	Block with yard	Building groups	Block with yard	Mall	Apartments
Height	1-3 stories ≤15 meters	3-5 stories ≤24 meters	4-9 stories ≤36 meters	4-9 stories ≤36 meters	12 stories ≤36 meters
Dimension	40-100m 40-100m 6-15m	60-120m 15-25m 60-120m	80-150m 80-150m 15-25m	80-150m 80-150m	80-150m 80-150m

3.7. Guideline for the street interface

The land utilization rate around Daming Palace National Heritage Park is relatively low, some part of the land is blank and the layout of the buildings is scattered. As a result, the interfaces of streets are relatively fragmental. Street as linear open space has a rich tradition in western countries and the façade of street is always supposed to be highly continuous as the displaying stages of city life and the security monitoring of the public activities. In

Oliveria's (2013) view, higher uniformity of architectures will bring higher urbanity, which means a form to promote urban activities. He put forwards a concept "alignment of buildings" as an assessing parameter of urban form. Harvey (2014) explains "Street wall continuity" as one of twelve streetscape skeleton, which means proportion of edge intersecting buildings on the more /less continuous side of the street.

On the other hand, the traditional Chinese wooden architectures and the unique concept of "set of etiquette" pay more attention to the architectural complex than the interface of the blocks and streets, making the façades of the street wall sporadic (Zhou Yu,).

In order to meet the requirements of the continuous wall facade in modern streets and respect the tradition of Chinese architectures at the same time, the continuous street façade only focus on the bottom part of the building below 15 meters, which is decided by the perspective of the pedestrians. This part of building corresponds to the form of rammed earth stylobate of the traditional Chinese buildings, and they will form a continuous street façade by controlling "Build-to-Line Rate", that refers to the percentage of the continuous building façades in the whole street length.

The upside parts of more than 15 meters, corresponding to the main woody bodies of the traditional Chinese buildings, encourages flexible composition of buildings; and the unique streetscape comes into being consequently.

Table 2 Build-to-Line Rate

Build-to-Line Rate (R) =continuous building façades length (B) /whole street length (L) *100%

Road	Build-to-Line Rate
TAIHUA Road	90%
XUANWU Road	80%
JIANQIANG Road	80%
ZIQIANG Road	80%
TAIYUAN Road	75%
PIJIU Road	75%
YINHEFANG Road	75%
HANYUAN Road	75%

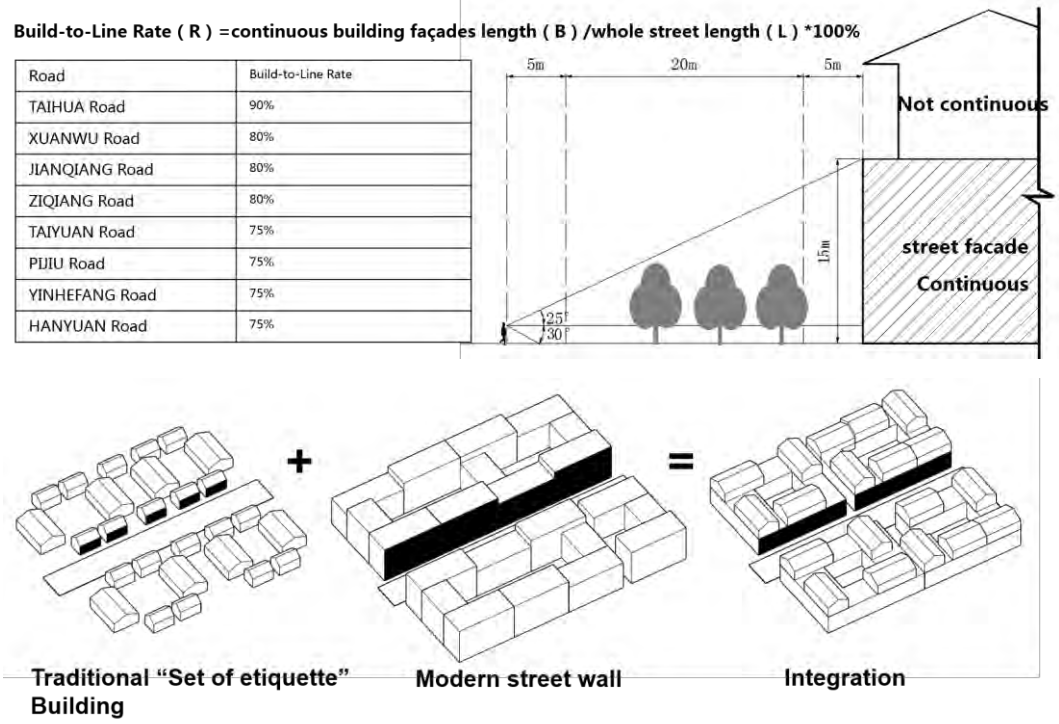

Figure 5 Combination of street wall and traditional "Set of etiquette" Building.

3.8. Guideline for the height of building

The height of building is the key factor that influences the transformation from the plane layout to three-dimensional space of city. The studying area is a part of the heritage protection control district of Daming Palace, so the cultural heritage protection department

authorize strict height control guideline for the surrounding buildings. Based on this, a further research of building height was made with hierarchical control method and viewshed control method. The hierarchical control method divides the height of buildings into the first level, the second level and the third level according to their distances to the heritage park, referring to the height of heritage in the National Heritage Park and the function, the land value of the surrounding blocks. The viewshed control method selects the important sight corridors in the surrounding area and limit the maximum height of the buildings with the principle that all the buildings in viewshed should not block the important sight line. The two methods are overlaid to control the maximum height for all the buildings in the area.

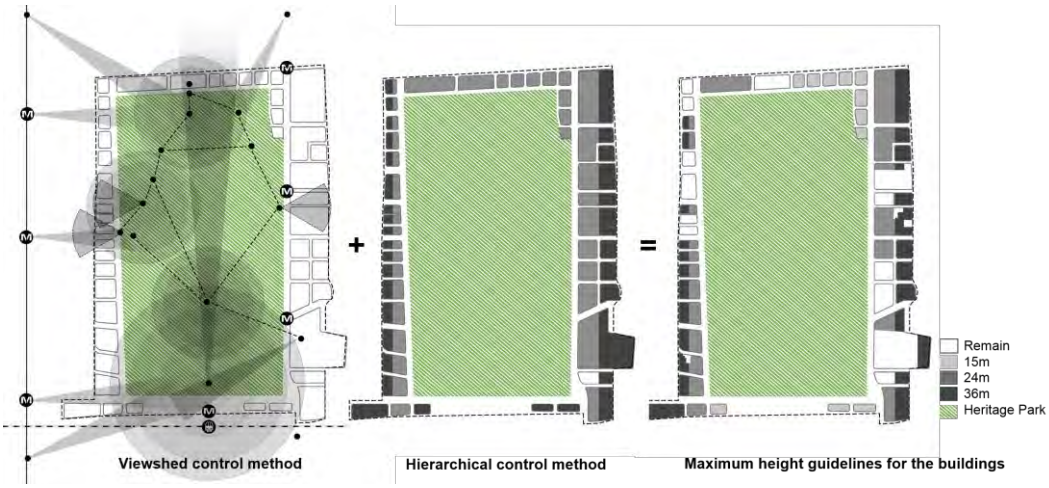

Figure 6 Maximum height guidelines for the buildings

3.9. Guideline for the colour of building

Researches in terms of urban colour planning have long-term practice all around the world. Miechael Lancaster (1996) raised the concept of colorscape firstly, referring it as the important carrier of historic, cultural and aesthetic information of city. Turin's Colour Database, Paris's Colour Gene and Tokyo's Tokyo Urban Colour Planning all played an important role for the harmonious urban building environment. The main controlled object of building colour in the area is divided into basic colour, sub colour and embellishment colour. During the research, 500 sampling colour points were measured and the sampling data are converted into the Munsell colour system by software. Then the harmonious range of colours was analysed and digitize by three values of hue (H), value (V) and chroma (C). The basic colour range of the buildings in this area is concentrated in 5 ranges: non-chroma, low-chroma and low-value, low-chroma and high-value, mid-chroma and high-value, mid-chroma and low-value. A detailed colour atlas was made correspondingly as the standard of data control.

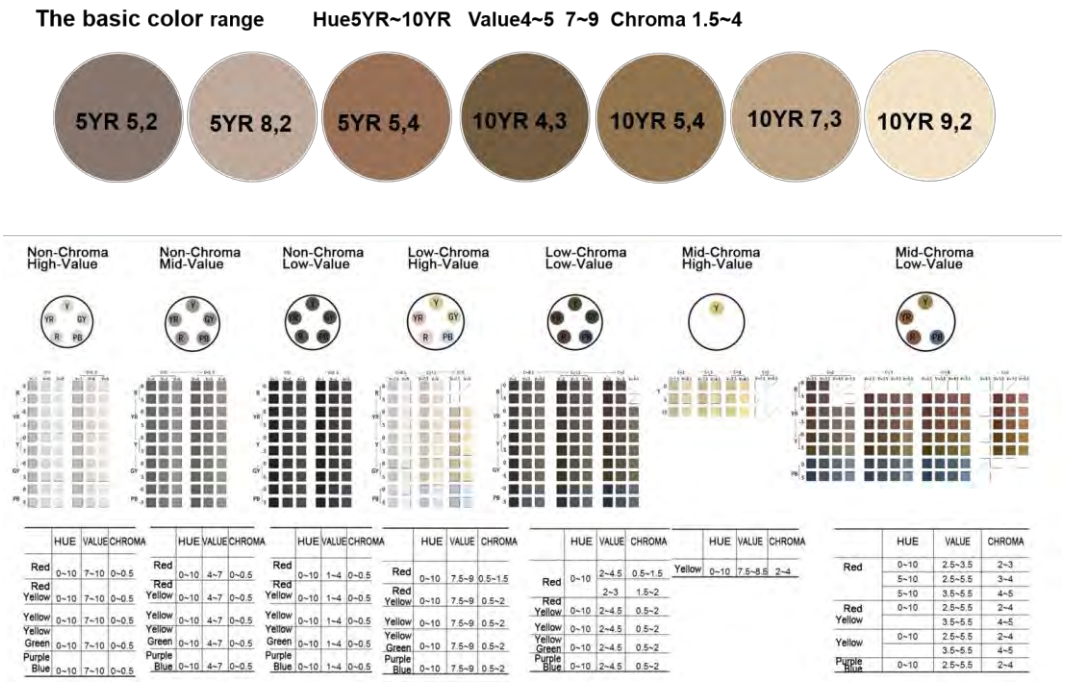

Figure 7 Basic colour ranges of the buildings

Since there is no architectural heritage in Daming Palace National Heritage Park, the research about the colour of traditional buildings in the area is based on historical document and fresco of Tang Dynasty. It can be seen that the architectures in Tang Dynasty is relatively bright-coloured (high chroma and high value), red and green are used massively, which is not harmonious with the forms of modern architectures. In order to inherit the elements of the traditional style in Tang Dynasty, meanwhile, meet the aesthetic and functional needs of modern architecture, the typical colours of architectures in Tang Dynasty were picked as the sub and embellishment colours and used in the design of architecture details, such as entrance space, roof, column, doors and windows, etc.

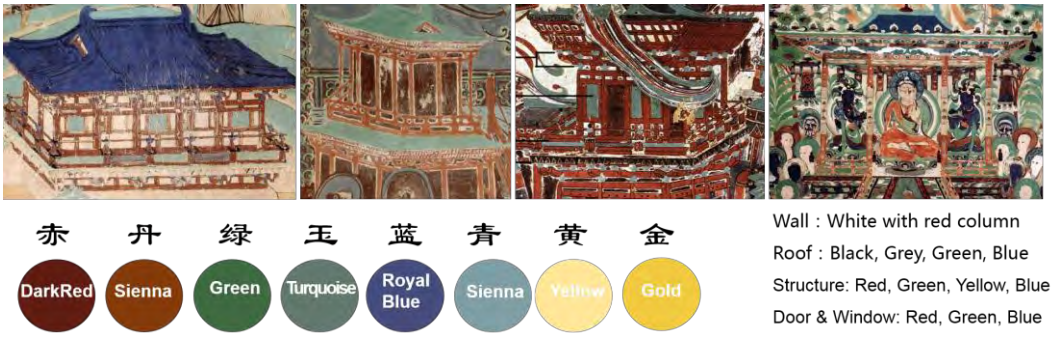

Figure 8 Sub and embellishment colours of the buildings

3.10. Guideline for the architectural style

Architectures are the leading elements of urban space, which determine the first impression of cityscape, and the appropriate architectural style could be the most obvious demonstration for the indigenous history and culture. Caniggia and Maffei (2001) emphasized that the architectural and urban texture types, which represented cultural and spiritual connotations of historical cities should be consecutive on time and space. A difficult problem was raised in research: what kind of architectural style should be encouraged and

commanded in the future in this area with profound history and culture but lacking in antique building remains. As wooden buildings are difficult to survive in war and historical changes in thousands of years, there is no architecture heritage in the whole historical area, and other contemporary architectural relics such as industrial factory buildings, construction materials markets and squatter settlements showed very fragmented architectural style. It is impossible to rebuild the area as it used to be in the history, as the reconstructed antique buildings are veracious and unworthily when they cannot match with the modern lives. While according to the questionnaires and interviews, it is difficult for modern architectures to satisfy the sense of belonging and identity of local residents. What's more, totally modern style of architecture is not benefit to the development of tourism, as tourists prefer to see a cityscape that can reflect the historical and cultural characteristics of Tang Dynasty around Daming Palace.

Therefore, the architectural style of this area was identified as contemporary -Tang style, which is to deconstruct the characteristic elements of architectures in Tang Dynasty as "style genes", and combine them with the practicability of modern architecture. Above all, the dominating feature of Architecture in Tang Dynasty was summarized, including the symmetrical spatial form, the three-section architectural façade (roof, wall and rammed earth stylobate), and the enormous and gentle roof form. Then the characteristic detail elements of Tang Dynasty building were extracted as the "gene bank" of architectural, which were strongly suggested into further architectural design in regional regeneration.

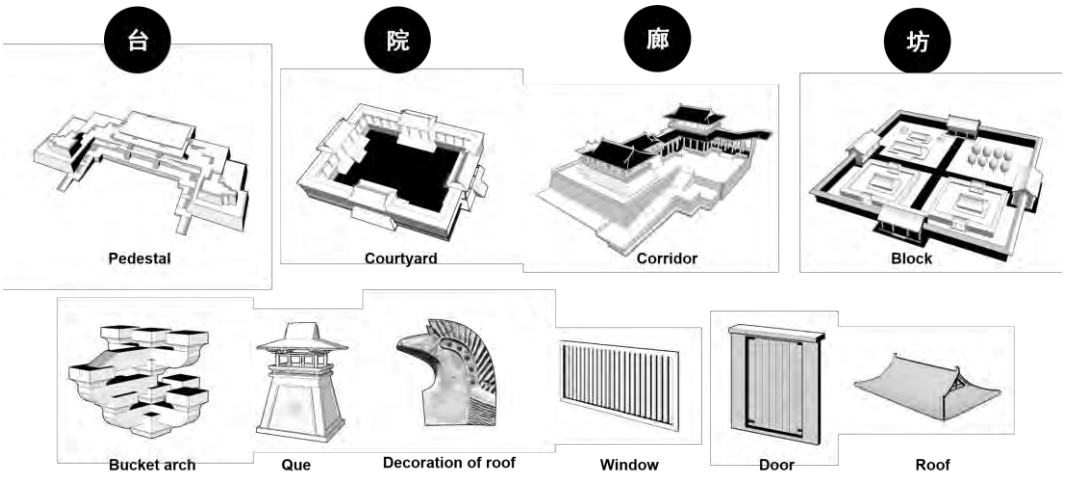

Figure 9 "Gene bank"of architectures in Tang Dynasty

Concerning how to combine these architectural genes of Tang Dynasty with modern architectures, a great deal of designing experiences in China and Japan are studied. In general, there are 4 types of contemporary -Tang style architectures: the Antique type, the Reform type, the Integration type and the Iconic type. The Antique type refers to imitate the traditional Tang-style wooden buildings entirety, all the volumes, materials and facades are built as the same way as the antique buildings. The Reform type means to inherit the basic shapes and overalls outline of the traditional architectures, keep the "three-section architectural facade " with the stylobate, the wall and the roof, while use the modern materials and structure. Instead of complete traditional facade, the Integration type is integrated of modern facade and the traditional facade innovatively, and the strict compositions and geometry ratio of traditional building are break and transformed into more freedom style. The Iconic type is the method of decorative art; it is based on modern

style and decorated with Tang-style architecture details, such as the doors, windows and columns etc. The first form are generally used in architecture groups of tourist attractions or museums, the other three forms are more suitable to the comprehensive modern functions, so they are recommended as the architecture styles in the regeneration procedure of the historic quarters around Daming Palace.

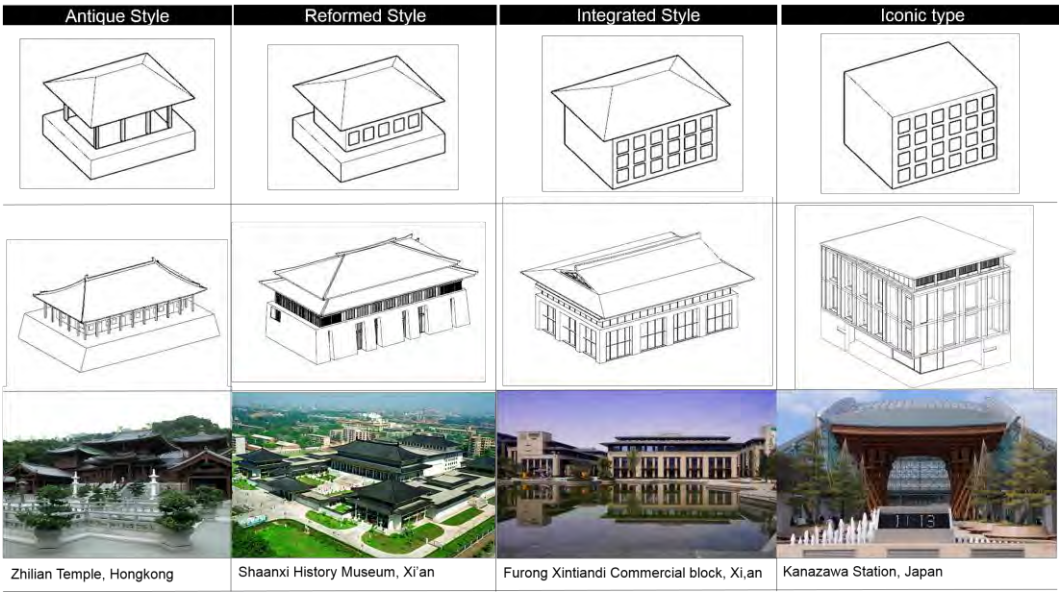

Figure 10 4 types of contemporary -Tang style architectures

3.11. Plan implementation

The practice of cityscape control plan includes two levels, the macro level and the medium-micro level. On the macro level, the plan works as the monographic study of master plan or a subject Plan independently. It decides the cityscape orientation of the city, forming the important cityscape systems, such as spatial structure, morphology, building style, etc., all the systems were regulated with specific guide documents, which would inherit into the relevant detailed plan of the area as important reference.

The medium-micro level transfers all the macro-level systems guideline to detailed, quantitative controlling index, and create legal block form codes for all the quarters without dead angles. In the form codes, the boundary and capacity of block, the location and node of open space, the morphology and style of architecture were controlled and regulated in detail. The form codes will be used to restrain the construction activities in the regeneration process after it is approved. When the land is transfer from municipality to developers, the guideline of cityscape can be attached as a subsidiary documents, and in this way the cityscape of the historic quarters were guided and preserved generally.

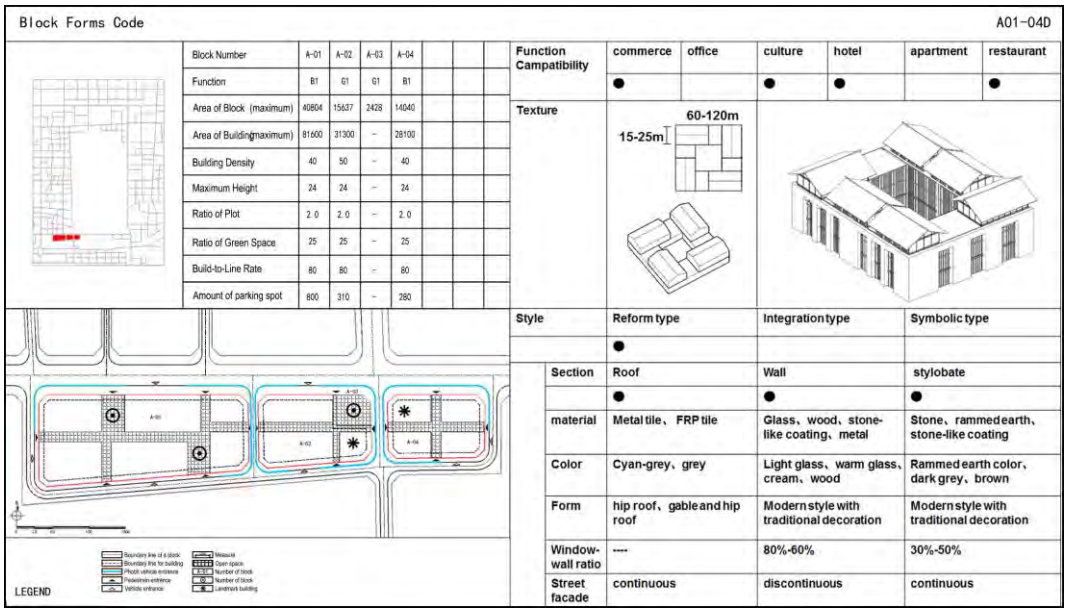

Figure 11 Block form code

In every stage of plan implementation, a coordinate a system of the relative groups are organized, including administrative officers, experts, estate developers, and public representatives, who participated through discussion and communication. The planning contents are altered in time with all the feedbacks and suggestions to make sure of the practicality of the plan.

4. Conclusion

The distinction and uniqueness of a city are the products of complex spatial evolution and the social process, representing the features of specific regional culture. In globalization ear, faced with the invasion of powerful alien culture and the spread of urbanization, the global cities are losing their traditional characteristics. The diversity of urban cultures and cityscape were increasingly declining. Historic mega city as Xi'an calls for a more farsighted GLOCAL solution, which can not only suits to the globalized demand of modern global cities, but also protect the traditional local culture.

During the regeneration process of the historic urban quarters around the Daming Palace National Heritage Park, cityscape plan is used as a tool to integrate mixing urban function and physical environment with indigenous characteristics. Inheritance and innovation are combined to revitalize a region with "glocal" (global-local) cityscape, and motivate sense of belonging for neighbourhood and attraction for the tourists.

Of course, the cityscape control plan of historic urban quarters around Daming Palace is just an experimental project towards specific historic urban quarters under the certain context, and the plan is in process. The study of revitalizing global mega city by Cityscape-control plan needs more research practice.

Research Paper

Healthy City versus Resilient Planning Paradigm

Case Study of New City Centre in Lodz, Poland

Małgorzata Bronisława HANZL, Lodz University of Technology; Poland
Lia Maria BEZERRA, Warsaw University of Technology; Poland

Abstract

In the current article, we are looking at some of the challenges of planning for healthy and resilient cities with a focus on the features of the physical structure. In order to examine the physical structures, we use qualitative assessment based on the comparative framework and the typo-morphological approach. We look for criteria of assessment based on the already existing indexes of health measurement. The above attempt is illustrated by the case study of the city of Lodz, Poland. We are looking at the best solutions which would enable healthy lifestyles and climate-resilient development. Our discussion refers to optimal models of mixed-use development and streetscapes of a central part of Lodz, namely focused around so-called New City Centre of Lodz, indicating possible alternative paths of its redevelopment. The methodological approach is supported by background research into the fields of resilience and healthy lifestyles.

Keywords

healthy city, lifestyle, urban form, streetscape, resilient planning

1. Introduction

This paper looks at some of the challenges of planning for healthy and resilient cities with a focus on the features of the physical structure. We examine desired densities and open spaces proportions, green areas, as well as the role and extent of transportation networks. In order to examine the physical structures, we use qualitative assessment based on the comparative framework and the typo-morphological approach. The above quest for the balance is illustrated by the case study of the city of Lodz, Poland. Initially, the model of development which has been prepared for the whole area within administrative borders of the town, with the special focus on the central areas is based on the typological classification. It includes the detailed analyses of a variety of the 19th-century neighbourhoods, with the special attention on their morphological development. The actual picture is further joined by the presence of open spaces related to transportation land uses, as numerous open parking lots. Taking into account the property structure, the elimination of some of these parking lots may be partially done through temporary use policies and recently introduced rehabilitation regulations. We analyse the potentials behind the presence of these large open spaces and define

future path options for their reuse in this paper. We are looking at the best solutions which would enable healthy lifestyles and climate resilient development. The Lodz municipality has addressed the problem of preparing the analyses and proposing strategies to redevelop some of the areas as green spaces, which we include in the paper. Based on the analysis of the case study, we attempt at the research of relationships between the fields of urban studies: resilience, planning for healthy urban environments and quality of life. Our discussion refers to optimal models of mixed-use development of a central part of Lodz, namely focused around so called New City Centre of Lodz, indicating possible alternative paths of its redevelopment. The methodological approach is supported by background research into the fields of resilience and healthy lifestyles. The relationships between the culture of usage of space and the urban forms have already been discussed extensively in similar research (for instance Thomson, Newman 2018, Fisher-Kowalsky et al. 2019). In conclusion, we summarise the discussion by providing the assessment and reasoning of the development methods.

2. Healthy cities versus climate change

2.1. Relationships between the domain of climate change planning and healthy city paradigm

Cities are major foci of production and consumption and its inhabitants rely on resources and services that are secured from areas outside of the city perimeter. Cities are not independent, but rather depend on their local, regional and global systems to function. Cities form complex systems, where climate change impacts not only the blue, green and grey infrastructure but also basic surrounding resources that guarantee the life in cites, from water and food supply to waste disposal, energy production and transportation, which draws severe consequences to the well-being and health of also those that live in the city.

Due to its individual characteristics, potential climate change impacts will be different, but can be generalised into mainly flooding, water scarcity, and heat island effect, which generates primary and secondary impacts, each having their own influence on the city system and the health of its inhabitants. Urban dwellers live in a higher concentration inside urban perimeters, which exposes them to contagious diseases that are prone by crowding, as epidemiological outbreaks by viruses, bacteria but likewise of rodent and vector-borne diseases. The current urban lifestyle also exposes dwellers to diseases related to noise, water and air pollution and other unfolding complications associated to vulnerability, causing violence and inequality.

Climate change impacts the health of urban dwellers in many ways and is often distributed unequally among more vulnerable segments of society (UN-Habitat 2014). Poorer urban inhabitants often suffer due to their informal or risk-prone dwelling condition and overall sensitivity, limitations on reactions to climate change impacts. Within poorer communities, women and girls are impacted more severely due to their traditional roles in the community. When analysing age and gender solely, the elderly and the young suffer with the direct and indirect impacts associated with climate change, as they're less able to sustain injuries or illness, but also women suffer differently than men. A World Health Organisation (WHO 2014) study found more supporting evidence that despite climate change-related disasters impact the health of both men and women, on average, natural disasters

kill more women than men, which is proportional to the harshness of the disaster and effect women the most in countries where they have lower social, economic and political status.

Studies (Elmqvist et al. 2013, Hardin and Jensen 2007, Bowler et al 2010) have confirmed that green and blue infrastructure can reduce some of climate change's health impacts within cities through focused design. The placement of vegetation and water can help in alleviating extreme temperatures locally. The studies show that heat can be absorbed by water areas while greenery reflects solar radiation and aids in diminishing temperatures locally by shading and evapotranspiration. Urban greenery has the additional quality of being able to reduce air pollutants primarily nitrogen and Sulphur oxides (Hartig et al 2014). The combination of blue and green infrastructure can contribute with reducing flood-related health risks, by stabilising the soil and reducing the risk of landslides, while the design of water areas can also provide planned areas to hold off excessive rainfall or water surges complementing future-proof drainage systems. Vegetation and urban green areas as parks and gardens can contribute to alleviating noise pollution while providing areas for relaxation, de-stressing, physical activity and community encounters.

The potential impacts that climate change can have on urban dwellers' health could be partially reduced by city planning. In what it relates to the physical characteristics of an urban area, mitigation strategies that include careful green area design, vegetation protection, diminishing urban heat islands, improving the air pollution management, future-proofing water management can have a positive impact on the amelioration of urban dwellers health undergoing climate changes.

2.2. Urban Health Indicators

The measurement of urban dwellers' health is linked to various characteristics and circumstances, physical settings, living and working conditions, environment, quality of services, community organisation, among many more. The interest in population health is not recent but has increased with the growing worries that come with future proofing our settlements. Measuring and correlating such vast themes is far from a simple task, however, once established it aids the understanding of the current status of urban health and is capable of strengthening governance within the area (Doyle 1999), and aiding decision makers and planners to make better choices for the future. The mapping of urban health and its application can link planning inputs, health outcomes and economical benefits, becoming in itself a resource in the community (Green et al 2009).

One of the most prominent measurements that take into consideration health within a given urban geographical boundary is WHO's Urban Health Index (UHI). The UHI provides insights on various health indicators that enable the temporal and geographical comparison (WHO 2014b). The index separates its themes under five main umbrellas – health, environment, geography, economics and social demographics – where each are then subdivided firstly into relevant domains, and secondly indicators, which are catered to the data available in the analysed area. The UHI itself has the flexibility to adapt to the specificity of the local context, while keeping a solid measurement capable of being compared throughout different localities.

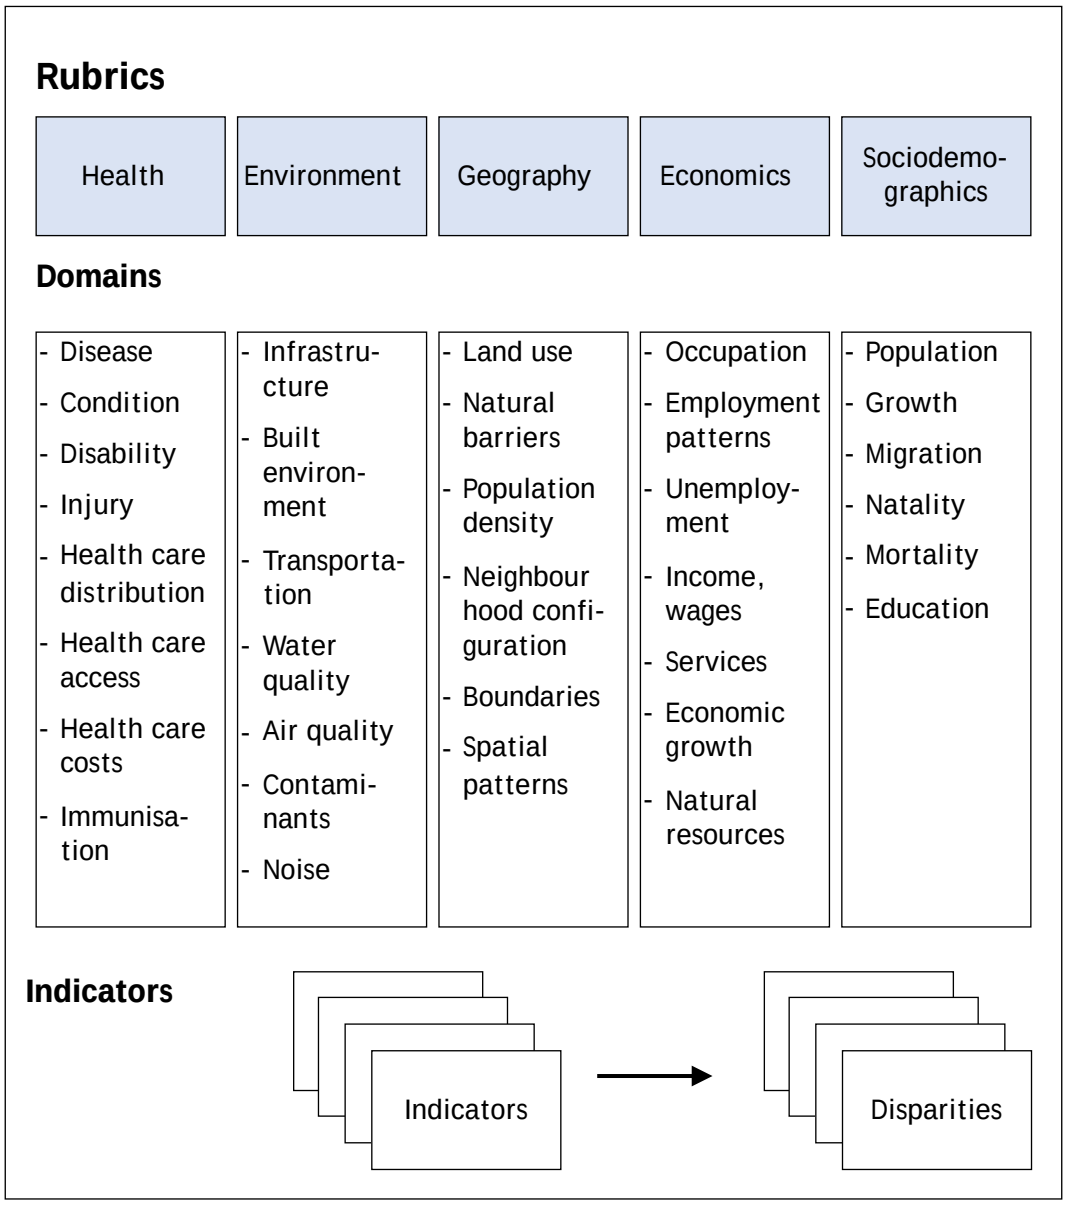

Figure 1 Framework for Classifying Measures of Urban Health, redrawn after: WHO (2014b, Figure 2)

The five main umbrellas over which UHI is based upon has been similarly used in its predecessor Health Cities Indicators (HCI) in 2012: health, health services, environmental indicators, social economic indicators. The HCI is designed in 2012 is a review of a set of indicators selected in 1998, which is a succession of improvements on the analytical framework (WHO 1998, Webster et al 1996 in Webster 2012). These can be grouped in 3 main groups: health, environment and social economics.

Table 1 presents two sets of health assessment factors based on two recognised elaborations (Webster and Sanderson 2012; WHO 2018). The list of indicators by Webster and Sanderson (2012) is of more normative character. The UHI (WHO 2018) offers a choice of collections of measures which might be applied based on the data availability.

Table 1. Two frameworks for assessment of urban health

Index	**Healthy City Indicators**	**Urban Health Indicator**
Abbreviation	HCI	UHI
Year	2012	2018
Author	Webster P. and Sanderson, D.	WHO
Application	Europe	Urban Areas
Themes/indicators		
Group 1 HEALTH	Health	Health
	mortality	disease
	main causes of death	condition
	low birth weight	disability
	Health Services	injury
	city health education programs	health care distribution
	immunization rates	health care access
	inhabitants per primary health practitioner	health care costs
	inhabitants per nurse	immunization
	percentage of population covered by health insurance	
	availability of services in foreign languages	
	health debates in city council	
Group 2 ENVIRONMENT	Environmental indicators	Environment
	air pollution	infrastructure
	water quality	built environment
	sewage collection	transportation
	household waste treatment	water quality
	green space	air quality
	derelict industrial sites	contaminants
	sports and leisure facilities	noise
	pedestrianization	Geography
	cycle routes	land use
	public transportation access	natural barriers
	public transportation range	population density
	living space	neighborhood configuration
		boundaries
		spatial patterns
Group 3 SOCIALECONOMICS	Socioeconomic indicators	Economics
	percentage of population in inadequate housing	occupation
	homelessness	employment patterns
	unemployment	unemployment
	poverty	income, wages
	availability of child care	services
	age of mothers at time of birth	economic growth
	abortion rate	natural resources
	employment of disabled people	Sociodemographics
		population
		growth
		migration
		natality
		mortality
		education

3. Methodology of assessment

3.1. Qualitative assessment

In the current paper, we would refer to a set of factors which might help evaluate the urban environment on a neighbourhood scale. We propose a simplified framework which might contribute to the assessment of the specific urban design solutions. The evaluation refers to physical urban structures and their relationships with specific lifestyles. The framework covers some normative components of sustainable urban design, including mobility and transportation, greenery and natural environment, promotion of social capital through public spaces and social participation, preservation and reuse of old structure, mixed-use development, compact development and appropriate densities. These postulates repeat in documents since Agenda 21 (UN 1992); they contribute a commonly recognised assessment framework for sustainable urban design. In our proposal, we looked for similar normative axioms in urban health framework and examined their interrelations. Then we combined the principles as a single assessment matrix and applied to the chosen study.

3.2.Typo-morphological approach

Further, we apply the typo-morphological approach to the analyses of open and unused spaces. These spaces are, for the most part, responsible for the perception of the urban settings. In this category, there are both spaces which serve the recreation and public life - public squares and parks, and these which are subordinated to the transportation needs - first of all, streets. The urban landscapes might be classified (Newman and Thompson 2018, Marshall 2005) into groups related to the primary development of various modes of transportation: pedestrian, based on public transportation, cycling or based on individual, car transportation. The modes of transportation contribute an explicit relationship with various types of lifestyles; the widespread presence of individual car-based transportation proves the dominance of unhealthy sedentary lifestyles, whereas the presence of comfortable pavements and cycle paths offers the opportunity for more active lifestyles.

3.3.Analyses of planned conditions

Further, we applied the typo-morphological approach to the analyses of planned, built structures. The reading of densities, the contribution of mixed-use development, the Green Area Ratio let us explore the future conditions of urban environment. Specifically useful proved the GAR, which is expressed through the parameter of *'biologically active area'* defined by the Polish building code (RMI 2002) as:

- *'area with soil surface arranged in a way which assures natural vegetation,*
- *50% of the surface of terraces and decks, if they are arranged as permanent lawns or flowerbeds with such surface - their size cannot be smaller than 10m2,*
- *surface waters'.*

This parameter strongly affects both local safety and stability of functioning of urban environments thanks to the management of the water retention and, at the same time, it is responsible for the urban heat island (UHI). In the current situation of climate change, the UHI, and desertification together with flash floods are next to strong winds, the three principal challenges for central Poland.

4. Case study - New City Centre of Lodz

4.1. Background information

The New City Centre of Lodz project extends next to the redeveloped railway station Łódź Fabryczna (Hanzl 2011). It contains several heritage post-industrial edifices and 19th-century tenement residential structures which used to accommodate social housing. The redevelopment plans cover circa 90 ha which spreads between streets Sienkiewicza, Narutowicza, Kopcińskiego, Tuwima. The railway station has been hidden underground to provide fast railway connection between Warsaw and Wrocław. The undertaking involves stakeholders at various levels who orchestrate their efforts to rehabilitate a large central area located in the direct proximity of the town's main street Piotrkowska. The project, which started in 2007, when the City Council approved the project and in 2008 when a culture institution EC1 was established (Wycichowska 2008), assumed more specific forms along with the approval of two local plans of urban development by the City Council in Lodz: III/40/14 and III/41/14. Parallel to the construction of the new Fabryczna railway station which replaced former terminus, the several new streets were built.

4.2. Qualitative assessment

The health aspects of the urban environment tend to be assessed against a framework which refers to the more holistic scale - such a research has been also performed for Lodz, without however selecting a specific neighbourhood ((Kaleta, Makowiec-Dabrowska, Jegier 2004). In case of a single location, more normative features apply. In order to be able to evaluate the current case study, we have chosen some of the elements which refer to the local environment and characterise with more normative aspects. Table 2 contains a full list of the assessment criteria, along with the case study assessment performed for a given list of features.

In order to propose a framework of assessment of urban health (UH), we have picked up the factors referring to the environment from the lists of Healthy City Indicators (Webster & Sanderson 2012) and Urban Health Indicators (WHO 2018). We then completed the framework adding the most commonly listed features of Sustainable Development (SD), as discussed above. It is clear that the project of the New City Centre of Lodz still needs many adjustments in order to satisfy the criteria, both for urban health and sustainable development. The provision of open green spaces, leisure facilities, recreation and organised public space is for now very low. Instead, there are many open spaces of large roads adjusted for the needs of car transportation. Whereas there are pavements and some cycling infrastructure is also present, they are mostly in the open air, and the users of them have to deal with strong winds and high insolation in summer. Streets' greenery is still to be planted, however not everywhere the space for it has been satisfied. The parks approved in the local plans of urban development have not been organised so far, and their spaces have been taken by automobile infrastructure. The positive aspects refer to the development of mass transportation - tramways and buses - connected with the station which after the construction of the underground connection between the two main railway stations in Lodz: Fabryczna and Kaliska, has got a chance to become a primary hub of public transport in the city.

Table 2 Qualitative assessment based on the proposed framework which refers to the categories of sustainable development (SD) and urban health (UH).

	Activities/ Goals	SD	UH	Case study Assessement
UH	Air pollution - low levels	X	X	-
	Green space availability	X	X	-
	Sport and leisure facilities	X	X	-
	Pedestrianisation	X	X	+/-
	Public transportation access	X	X	+
	Living, social space	X	X	-
	Low levels of noise	X	X	-
	Balanced population density	X	X	+/-
	Protection against UHI and draughts	X	X	-
SD	Compact development/ appropriate densities	X	-	+/-
	Preservation of old structures and their reuse	X	X	+
	Sustainable transportation/ mobility	X	X	-
	Promotion of social contacts through better social spaces	X	X	+/-
	Promotion of citizens' participation	X	X	+/-
	Protection of natural environment	X	X	-
	Mixed-use development	X	-	+/-

4.3.Typo-morphology of the streetscapes and planned development

The streets' system in the area went through a major transformation. Several new streets have been built, other altered significantly. Some streets designed in the plans still wait their turn. Summarising the process of transformations we might notice the typological shift from more equal distribution of 19th-century multi-use street layouts to more specialised segregation including streets adjusted to performed specific roles. In this group the major share (12% of the site) is taken by the automobile roads. This category would be the most prone to changes in future along with the shift to more pedestrian/public transport oriented city. They require planting of trees and adjustments to enable constructions along. Another emerging category are pedestrian streets, which offer a valuable residential environment, they are however scarce (2% of the site). Besides other types include: tram way integrating streets, traditional streets and interior streets. Figure 2 shows profiles of the largest group of automobile streets in the area.

Figure 2 Car oriented streets, total area: 111 147m2, 12% of the area of the area covered with the local plans of urban development under consideration.

The analysis of the planned development has focused on the Green Area Ratio parameter (Figure 3) and enabled counting of the runoff from the site. The analysis proves that there is still a lot to be done to satisfy the needs for proper organisation of water management in order to reduce the negative impacts of both flash floods and urban heat island; both of these phenomena have a major impact on urban health conditions.

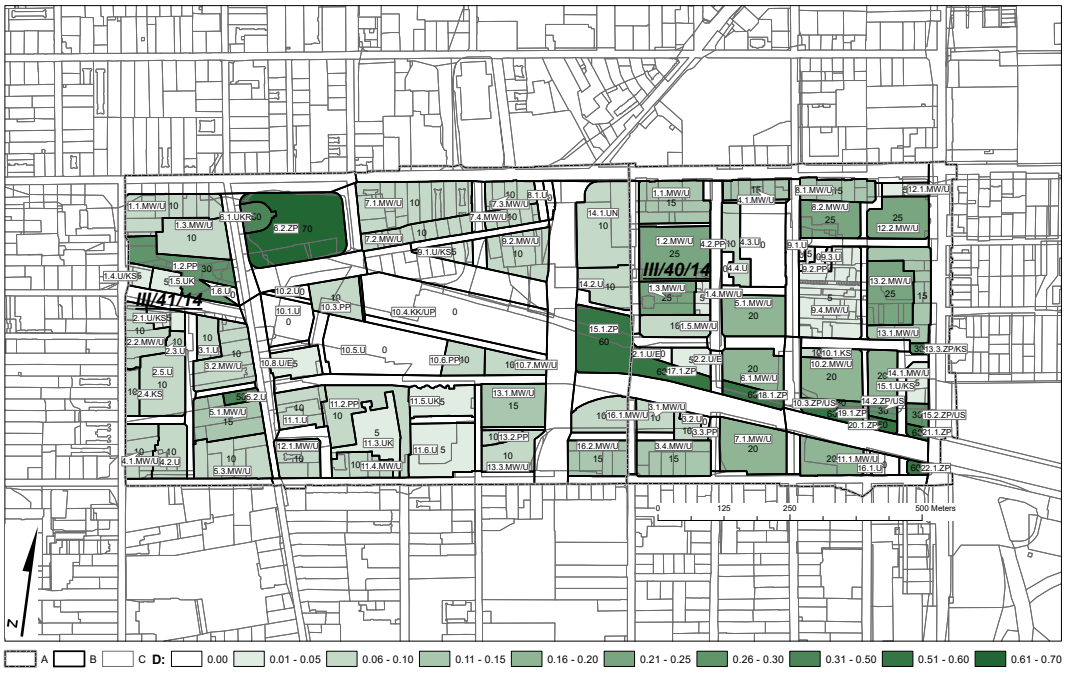

Figure 3 Green Area Ratio values for the local plans of urban development (III/40/14 and III/41/14).

5. Conclusions

In the current paper, we propose a method of evaluation of urban design interventions based on the normative frameworks of sustainable development and urban health assessment. The latter used the already predefined methods with a particular focus on the relationship between lifestyles and forms of the urban environment, notably streetscapes. We compared the three frameworks: of sustainable development, urban resilience and urban health looking for overlaps and mutual relationships. In the next step, we applied the method to the case study of a large-scale urban redevelopment project of New City Centre in Lodz. The project occurs to fail to fulfil many of the criteria of the proposed research frameworks.

The typo morphological analysis shows the transformation of the street network from the traditional, 19th century one into the hierarchical layout with pedestrian streets and car subordinated roads. The latter category dominates, which makes explicit the dominance of a car as a principal mode of transportation. This is associated with the predominance of sedentary lifestyles and creates threats for citizens' health. Still, some new streets which integrate tramways have been constructed, which improved the integration of public transportation system.

The preliminary analysis of the transformations of the area so far proves the need for more green infrastructure; the current levels of GAR remain very low. The focus on the development of GI is needed to improve the water management and to diminish the impacts of urban heat island (UHI). The assessment criteria enable benchmarking of the project strategies so far and look to adjust the strategy in future.

The study confirms the role of urban voids: open public spaces (including streets and parks) which influence the quality of urban life. Methods to assess their relationships with urban health have been developed. This current study proved that an attempt at the methodology for analyses and assessment may become a useful tool for urban design. The current experience gave us the initial thoughts on the conditions which have to be fulfilled to apply the method to a project. Further steps include the application of a similar methodology to other case studies, including larger scale ones.

Research Paper

The essence of Urban form and its Relationship with Urban Aesthetics: A case from Rajshahi City, Bangladesh

Ferdous Farhana HUQ, Rajshahi University of Engineering & Technology; Bangladesh
Imzamam Ul Khan Shuvo, Rajshahi University of Engineering & Technology; Bangladesh
Nidalia Islam, Bangladesh University of Engineering and Technology; Bangladesh

Abstract

The identity of a city is visibly recognized by observing its urban form. The development plans of the cities of Bangladesh address land use planning and ignore the aptness of urban form. As a result, the cities of Bangladesh are growing haphazardly and turning into an urban jungle rather than aesthetically pleasing habitable urban space. This study explores the intrinsic nature of the urban form of the major cities of Bangladesh as well as compares the urban form of major cities of Bangladesh with selected cities from around the world. This study conducts Physical Observation on building frontage, elevation, plinth level, footpath, doors and window pattern by employing transect method to acknowledge the character of the urban forms of the selected study area of Rajshahi city of Bangladesh. The findings of the study answer why the urban forms of the cities of Bangladesh look similar irrespective of cultural and geographical context. The findings shed lights on the weaknesses of current building codes regarding the compatibility of the design of the building elements as well as the relationship between building and street which leads to the degrade the urban aesthetics. Based on the findings some strategic and design solutions are provided with a view to improving the look of the city form.

Keywords

Urban form, Urban Aesthetics, Building façade, Building Elevation

1. Introduction

Urban morphology, urban form, and urban fabric are three terms that are highly interlinked with each other. According to Moudon (1997) urban morphology analyses the transformation of a city from its birth to its present state by identifying and dissecting its components. When it comes to the talk of the city's components, the first term comes is the 'physical form' of a city. Several researchers in their study have confirmed that a city can be read and studied by analyzing its physical form (Moudon 1997; Lynch. K 1959; Levy.A, 1999; Lu.S et.al, 2019). Whereas Dempsey.N et al. (N.D) have clearly mentioned that a city's physical characteristic hence physical form is officially termed as 'Urban form'. On the other hand according to Levy. A (1999), 'urban form' signifies the form of 'urban fabric'. Many recent works have disclosed different dimensions of urban fabric (Thompson & Newman 2018, Muller, 2004, Newman and Kenworthy 1999, Newman and Kenworthy 2016). Based on their work the urban fabric can be summarized as a large fabric of urban form that

portrays the essence of physical characteristics of a city. Therefore, the Urban form is the smallest unit of studying urban fabric as well as urban morphology. Dempsey et.al (n.d) in their study have mentioned density, buildings, layout, , and transport infrastructure as the major five elements of urban form, other researchers have generally address four fundamental elements of urban form which are buildings, open space, plots and streets (Moudon.V.A 1997 , Levy.A 1999). Kevin Lynch (1960) in this book discussed the effects of paths, edges, districts, nodes and landmarks on developing the image of the city. Urban aesthetics highly depends on the successful design of physical characteristics or urban form. Qualities of urban form are determined by the qualities of its fundamental elements and quality of urban form influences the human perception and visual complexity (Boeing, 2018). urban aesthetics is highly co-related with 'good visual complexity'. Good visual complexity depends on variety in buildings types, design details, street furniture, signage, human activity, light and shadow, textural details of street trees and urban open spaces. If the design becomes too predictable and controlled, the visual complexity becomes lost. Very few, similar, predictable, or too disordered to be comprehensible urban design produces poor visual complexity. Therefore the elements of urban forms have to be designed by maintaining a balance between order and disorder with unity and variety (Clifton et al. 2008, Elsheshtawy 1997; Gunawardena et al. 2015; Ewing and Clemente 2013; Boeing 2018).

This study focuses on understanding the tangible built environment of Rajshahi city from the perspectives of Urban aesthetics and finds out the influence of the modification of built forms on urban aesthetics.

2. Study Area

Figure 1 Map of the Research Area

Source 1 Author's preparations from Rajshahi Detailed Area Plan (2004-2024)

The study has been conducted at Malopara area located at the heart of Rajshahi which is one of the fast developing cities of Bangladesh. Three roads from Malopara named (1) MoniChootr, (2) Malopara road and (3) Malopara to Mohila college roads are studied for this research. These three roads have some unique buildings dated since 19th to the 20th century

which makes this area different from other areas in terms of urban form as well as urban aesthetics (Field Survey, 2018). formsFor the study, three roads of Malopara has been chosen. On these three roads, many types of uses are found. The lengths of the three roads are 0.14 km, 0.09 km, and 0.41 km respectively. The total length of the study area is 0.64 kilometer.

3. Method of the Study

The method of the research is inspired from the method suggested by Lamas (1993) to understand the city by studying its elements i.e. ground, parcel, buildings, block, façade, vegetation, streets , squares, courtyards, monument, street furniture and larger structures (Lamas 1993 in Monteiro, n.d; Barbosa et.al, n.d). This research chooses Buildings, façade, ground, and street to study as these elements are the most relevant aspects to examine in the study area. To examine, the selected elements of urban forms direct observation method is used. A checklist was prepared to collect the basic information of the buildings. Transect method was applied where selected streets were divided into transects to classify the typical elements of each section (Watson, Plattus, & Shibley, 2004). Three roads were mapped and characterized on the transect map. The panoramic survey was conducted where the photographic panorama of the study area was created to produce a detailed picture of the site (Anderson, 1978). The color, texture, materials, door and window pattern of the buildings were observed and noted as a part of studying the façade of the buildings. Building elevation survey was conducted to identify the elevation of the streetside buildings of the study area as building elevation is considered to be a significant component that explains urban form. Along with buildings elevation, Building's plinth elevation and footpath elevation were drawn by following a similar method. The data collected from the direct observation and field survey were visualized by using AutoCAD and 3d Sketch up the software to develop the findings of the research.

4. Findings and Discussions

4.1. Visual Complexity

The significant finding from three transects of three roads presents the dominance of are mixed-use building, blocked footpath, incoherent shop banner, haphazard electric wire, unmatched window pattern, different plinth level, irrelevant building shape, variety in building height and frontage, unmatched color and materials, few unique character door, window, veranda pattern, unique old buildings, broken dustbin and haphazard electrical wire. Visual complexity depends on the unity in the variety of the mentioned elements (Clifton, 2008, Boeing, 2018). The visual complexity of these roads is found to be high due to the lack of order developed by the construction of the modern building by not considering the design and pattern of neighboring buildings. The new-fashioned typical buildings are destroying the unique and traditional character developed by the old buildings in the study area. Mixed-use buildings in the study area have shops at the ground floor which follow various types of the pattern of their shapes, size, front material, nameplate color and nameplate size which degrade the aesthetics of the area. In a residential area, buildings are different in size, plinth level, height, color, texture, nameplates, door, and windows which

denigrate the balance and harmony of the overall streetscape of the research area.

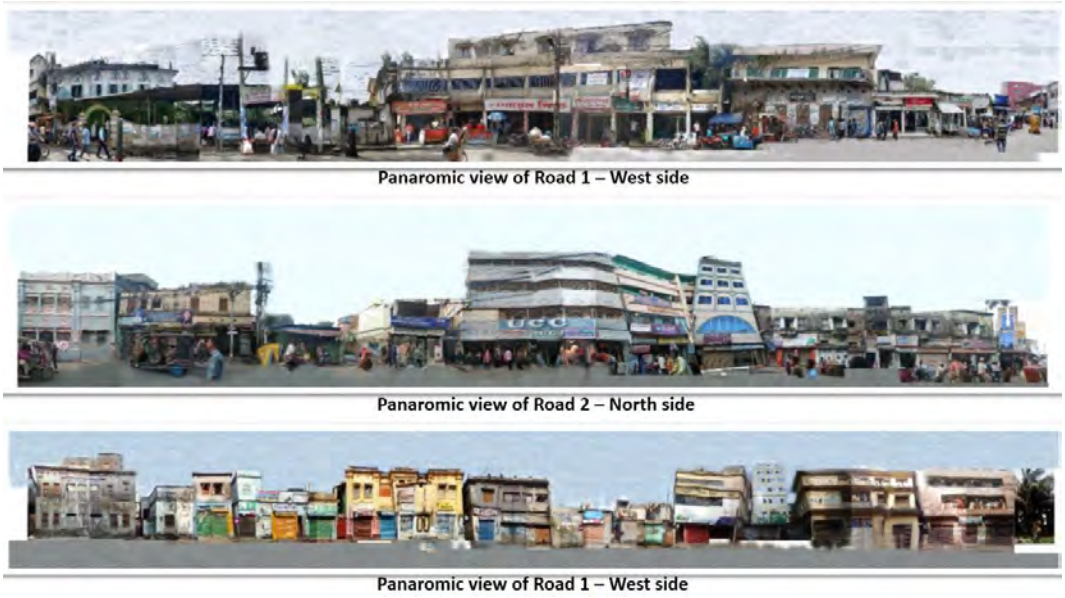

Figure 2 Panoramic Analysis of Research area

Source 2 Field Survey, 2018

4.2. Façade Scenario

The study area has many old, traditional style historic buildings which form a unique character in the area. But this character is being ruined due to the unconscious development trend. Findings from panoramic analysis approve the findings generated from transect analysis. The panoramic analysis focused on observing the color, texture, materials, plinth level, door, window, and veranda pattern. The panorama of First Street shows the ununiformity on the veranda and shop banner in terms of color and width. Panorama of the second street shows different plinth level of buildings which disturbs the image of the urban form by damaging the edge. The harmony of the building frontage is ruined due to not maintaining the unity in terms of color, texture and window pattern in buildings. According to the third panorama, shops uses different colored gates. Frontage material of the building is different and many buildings are identified using tiles in frontage which violates the unity in urban form hence destroys the urban aesthetics. Some building is found that has no plaster or broken plaster in the facade. Many buildings use different types of veranda and window pattern which has no harmony with the neighboring buildings (Figure 2).

Building Elevation Analysis of the streets suggests that most of the buildings of the study areas are one to three-story buildings. Few 4 to 5 storied buildings have been observed in the study area which is new buildings. Placement of high rise new modern buildings alongside single to double story old traditional buildings without maintaining the color, material and design harmony disturbs the look of the urban form at some points of the street.

Table 1: Gate and door pattern analysis of the study area

Road 1_ Moni Chottor	Road 2 _ Malopara	Road 3_Malopara to Mohila college
		No of Pattern: 7 Material and phase of style: (1) Steel+concrete, old (2) only Steel (3) Only concrete old, (4) Glass (Modern), (5) Only Wood, old (6) Glass +Steel and (7) Tin, Shutter style	No of Pattern: 6 Material and phase of style: (1) Steel, Local name is ketchi gate, Old, (2) Tin, Shutter style, (3) Glass (Modern) (4) Steel+concrete, old, (5) Steel+concrete, old, (6) Only Wood, old	No of Pattern: 13 Material and phase of style: (1) Only Wood,old (2) Only concrete old, (3) Steel+concrete, old, (4) Steel, Modern (5) Steel (Modern) (6) Tin +Steel (Modern) (7) Steel, Modern, (8) Steel, grill style, modern, (9) local name is ketchi gate, Old, (10) Only Steel (Modern) (11) Steel+concrete (Modern), (12) Tin, Shutter style, (13) Glass +steel (modern).
Remarks: Old types of gates are made with concrete and steel with more sophisticated design quality than the modern gates which are mostly made with steel.		

Source: Prepared by Author

Table 2: Window pattern analysis of the study area

Road 1_ Moni Chottor	Road 2 _ Malopara	Road 3_Malopara to Mohila college
		No of Pattern: 9 Material and phase of style: (1) Sliding glass, modern (2) Wood+steel, old (3) Glass +Steel modern (4) Sliding Glass , Modern (5) Wood+ Steel, old (6) Glass +Steel, old (7) wood+ steel , old, (8) Only wood , old; (9) Wood+ concrete, old	No of Pattern: 7 Material and phase of style: (1) Wood+steel, old; (2) Only wood, old (3) Only Wood; (4) Wood+ Steel, old (5) Only Wood, old ; (6) Wood + Concrete, old; (7) Glass+steel	No of Pattern: 9 Material and phase of style: (1) Only Wood, old (2) Wood +glass, old; (3) Only wood, old, (4) Wood+Steel, old (5) Steel+wood (Modern) (6) wood +Steel+concrete, old; (7) Steel+glass, old, (8) Wood+glass (9) Sliding glass window, modern

Remarks: In most of the buildings windows are made with a combination of wood, steel, and glass following traditional window pattern. New buildings are using sliding window made with steel and glass. Window pattern of this study area is found to be unique and modern buildings should be guided to use windows inspired by the design and materials from the old buildings of the study area.

Source: Prepared by Author

4.3. Footpath and Plinth Level Analysis

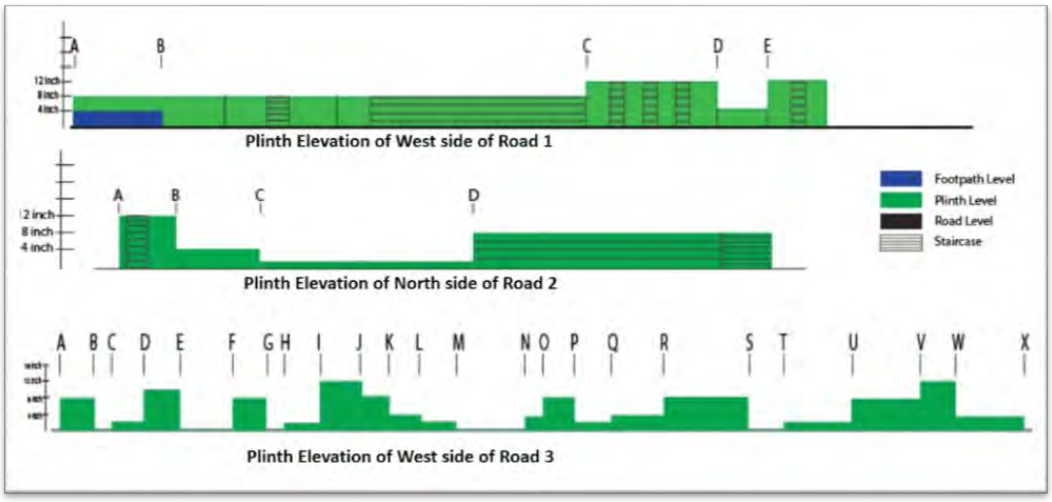

Figure 3 Plinth Level Analysis

Source 3 Field Survey, 2018

Footpath exists only from A to B of road 1 with an elevation of 4 inches from road level. Plinth level elevation is 8 inch from A to C, 12 inches from C to D, 4 inches from D to E and again become 12 inches from E to rest of the road. On the second road, a great variation of plinth level from 2 inches to 12 inches has been noticed. An extreme variation of plinth level elevation is observed at road 3 where elevation varies from 0 inches to 12 inches. There exist no footpath exists in road 2 and road 3. People use stairs to reach plinth level from road level in road 1 and 2. Such variation of plinth level not only destroys unity and harmony in the design of façade but also damages the aesthetics of urban streetscape (Figure 3).

5. Conclusions:

Research findings show the existing trend of streetscape development in Rajshahi city completely ignores the harmony, unity, and complexity of urban form. It is evident that the unique antique streetscape of Rajshahi city is under threat due to the ad-hoc development. To preserve the elegance and grace of this beautiful city we need to introduce some design guidelines for front façade at streetscape level. The guidelines should be able to give user full freedom to use a variety of materials and spatial planning freedom as well as regulate the new development to preserve the unique character of a street. To maintain the basic characteristic of streetscape- plinth height, building elevation, color, materials, scale, and proportion should be introduced to establish the order of urban form. Heritage corridor or streetscape preservation is very common worldwide. In the developed world, design architects, conservation architects, and planners work in a team to prepare a guideline for

areas with unique characteristic and heritage building to prevent random development. This research strongly suggests introducing policy guideline based on the context of the particular area to preserve the beauty and classical aesthetic order of Rajshahi city. Rajshahi City Corporation needs to work on its disordered visual complexity incorporating Architects, Urban planners to establish the harmony of the streetscape.

Research Paper

Improving the identity of historic city by considering hydraulic infrastructure (the case study: Qazvin city)

Nasim IRANMANESH, Islamic Azad university west Tehran branch,
department of Architecture; Iran

Abstract

Recently the importance of maintaining of historic identity of the cities is an obvious matter in restoration of a city. Each city depends on its cultural perception and its wealth, tries to reserve and repair its cultural heritage.

This matter has been done in many cities in the world and many historic urban fabrics have been restored and rehabilitated to be visited by many tourists to enjoy their atmosphere and physical and spiritual features.

Iran is a country with limited water resources but in spite of this fact there are many ancient civilizations and old cities with valuable urban fabrics in them which have intellectual irrigation.

The water of most cities of Iran mostly harvested from underground water by a technic which is called Qanat which irrigate city and farms. Water supplement in urban fabric and locating the hydraulic structure in cities had an important effect in forming the city which this impact shouldn't be ignored in repairing or rehabilitation of urban fabric.

In the other word hydraulic infrastructure of historic cities of Iran in hot and dry region is an important factor which shouldn't forget during planning for rehabilitation. The route of water either underground route or surface water and also hydraulic structures which have been located in the path of water should be preserved.

The case study is Qazvin city which its historic hydraulic infrastructure and hydraulic structures had an important effect in forming the city.

Keywords

hydraulic infrastructure, urban restoration, cultural heritage, Qanat

Introduction

Iran is an ancient country with an old civilization. Most parts of this country have hot and dry climate with a limited source of water. But Iranians have overcome with this problem by harvesting underground water and irrigate their settlement by this water. In Iran water harvested mostly by an intellectual technique which is called Qanat. Qanat brings water of alluvial fans from far distances to settlements. The water supplement in these city followed from the underground or surfaced net of water. The historical water supplement of Qazvin city had an important and direct effect on morphology of city. In the other word the morphology of city was formed according the water resources of this city and placing the hydraulic structures obeyed the path of water in cities as well. This paper discusses about the effect of water supplement on physical form of the historic area of city and deduces that how any rehabilitation planning can't be success without considering the its historic supplement of water in Qazvin city.

1. A brief explanation about Qazvin city and its water resources

The case study of this research is Qazvin city a historical city in Iran with a rich traditional urban planning and architecture which have been shaped during different eras.

1.1. Qazvin city and his historic water supplement

Iran has been located in hot and dry region and limitation of water is always a big problem of this country. In spite of this serious problem Iran is an old country with an ancient civilization which can be survived by harvesting underground water by an intellectual technique which is called "Qanat" or "Kariz".

Actually in most parts of Iran there is a "Karizian civilization "which has been appeared and survived by this technique of harvesting water.

Qazvin city is an Iranian city which has been located nearly in north of Iran. This city is an ancient city with a rich history but with few sources of water. This city was the capital of Iran four hundred years ago and after that it was an important city in commercial activities so during these eras Qazvin needed more water and harvested this water by Qanats.

Water resources of Qazvin included two main seasonal rivers and some wells which earned underground water, after growing the city and its population water was earned by Qanat which some of them are still alive and have water.

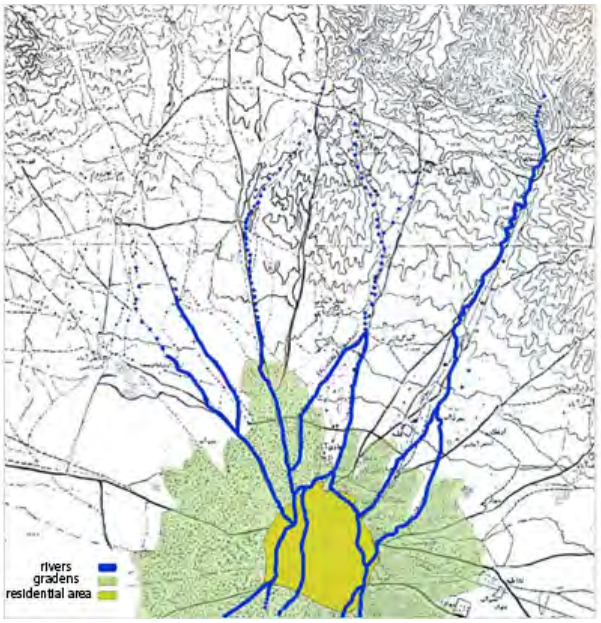

Figure 1 -Old location of Qazvin city (ancient garden whole around the city and seasonal rivers)

The system of Qanat included a horizontal corridor which brings water of alluvial fans toward the settlements. The structure of Qanat consists of a mother well which digs in an aquifer and transfers the water of this well by a horizontal corridor to the destination. To build this horizontal corridor a series of wells is needed to help digging the corridor and be able to maintain the Qanat (figure 1).

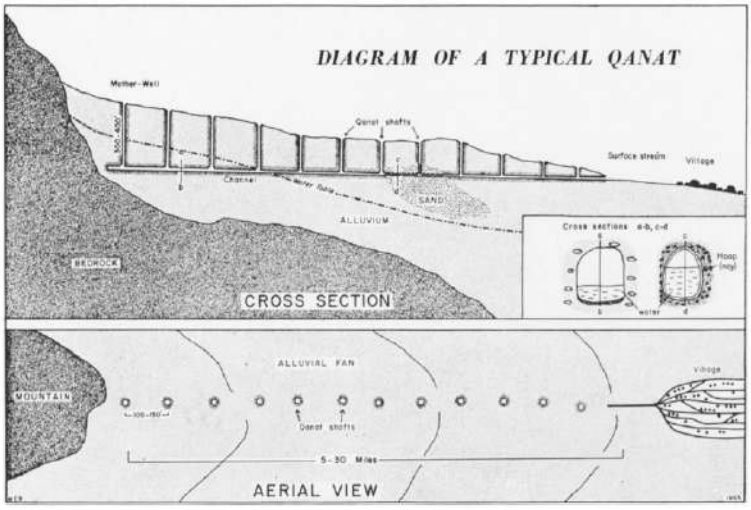

Figure 2: the section and plan of Qanat (source: English)

2. Traditional hydraulic structures in Iran

Water was used in cities for various purposes such as drinking, washing and irrigation. There were several hydraulic structures to meet each function, Iranians built bathes, water reservoirs, ice houses and other buildings that each of them was used for saving water or washing. Hydraulic structures of Iran were built very intellectually and these structures were mostly similar in most parts of Iran (dry and semi dry region of Iran). Here is the brief explanation of hydraulic structures of Qazvin city.

2.1. Historical hydraulic structures in Qazvin city

Traditional hydraulic structures in Iran were mostly included different structures such as: Traditional bath, water mill, ice house, wash house, water reservoir and "Payab" or "Akhoreh"

The brief explanation of each structure is:

a- ***Traditional bath***: Iranian society has a great consideration for individual cleaning and bath because of the religious belief. Qazvin city had numerous bathes because of this reason as well.

b- ***Water mill***: as it was mentioned Qazvin has two main seasonal rivers which 27 watermills were located on them to provide flour for the citizens.

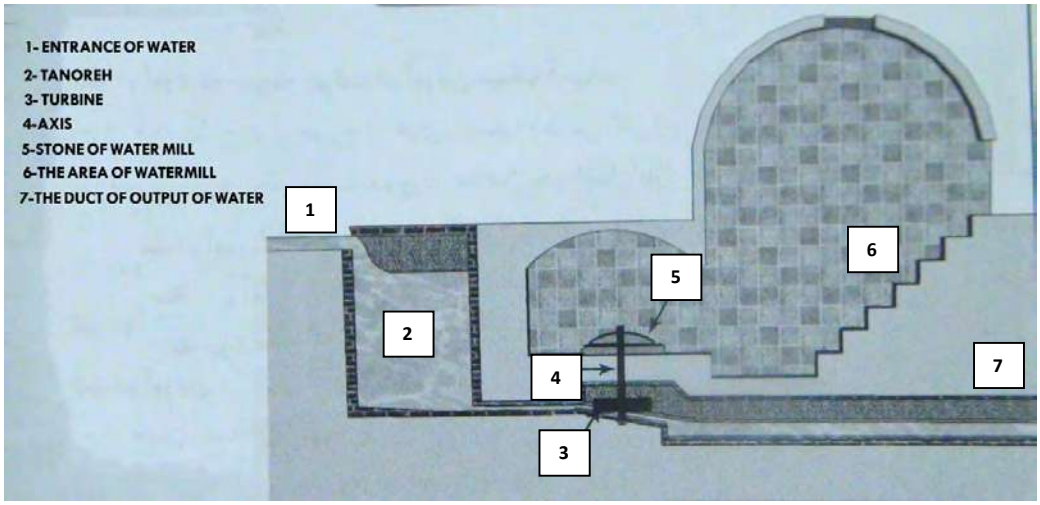

Figure 3. section of a watermill in route of Qanat (source:Semsar Yazdy)

c- ***Natural ice house***: in past time ice was produce by a special technique, it means that water was frozen in shallow pools in winter and the provided ice was stored in huge structures which nearly were similar with water reservoirs and during summer this ice was taken from these reservoirs and was consumed.

d- ***Wash house***: citizens needed water to wash their cloth and dishes and there were two wash houses in Qazvin for women to wash cloth or dishes.

e- ***Water reservoir***: water in Qazvin was very limited and fresh water should be saved in public or private water reservoir. Public water reservoir were huge buildings which its tank was dug in the earth and covered by a doom or vault.

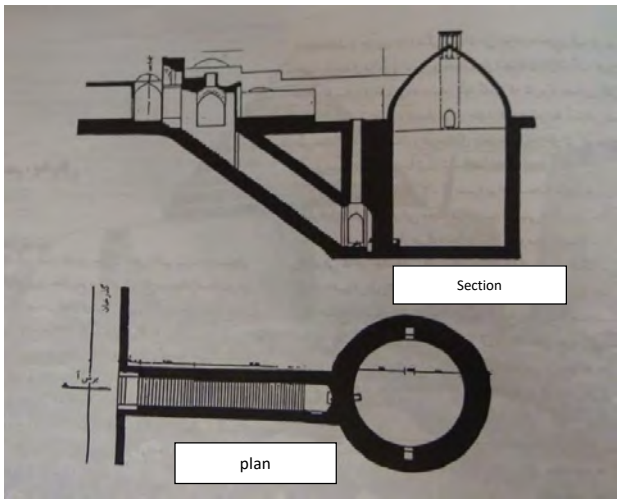

Figure 4: section of a water reservoir in Kashan city (source: Ghobadian)

f- ***Payab or Akhroh***: this structure is an access way to reach the underground water of Qanat. Actually it is a stepped way that reach to the water of Qanat which flowed underground. In Qazvin city people called it “Akhoreh”.
All the mentioned structures were irrigated by the water of Qanat and location of them were determined by the path of water of Qanat.

This structures were located directly on the path of Water which flowed on the ground or underground. In some case water were lead to these structures by a stream or by pipes and a person who was called “Mirab” was responsible to be supervisor on diving water between hydraulic structures and houses and other buildings.

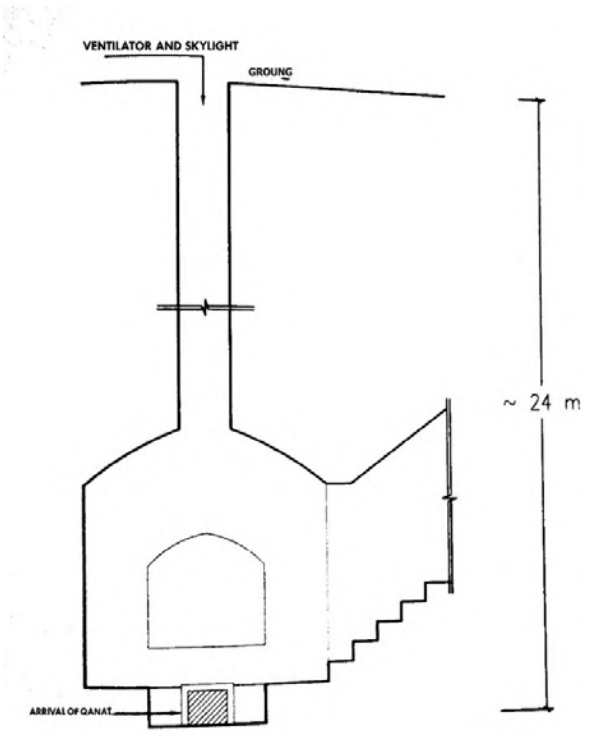

Fig 5. Section of a Payab (source:semsar Yazdy)

2.2. The effect of traditional water supplement in historical fabric of Qazvin

It is obvious that the traditional water supplement in historic area of Qazvin had an important effect in its morphology.

Qazvin is surrounded by flourish gardens which has more than one thousand years. This gardens are irrigated once or twice in a year by two seasonal rivers Dizaj and Aranzak.

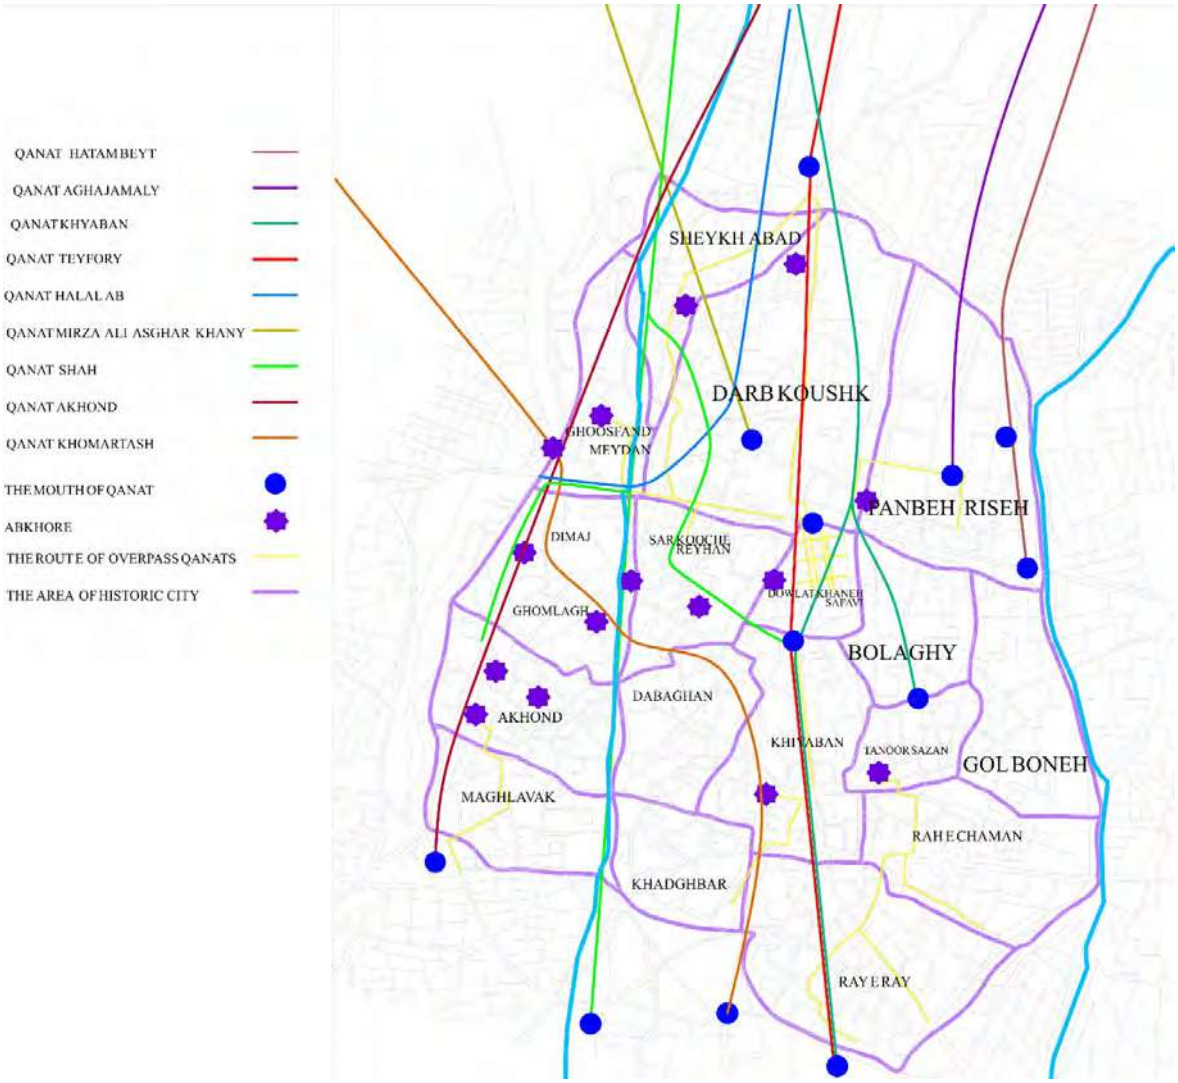
City of Qazvin was irrigated by eight Qanats which mother well of all of them are in the north of city.

The path of underground water and surface water mostly determined the net of roads and lanes in cities. Water flows in lanes because it was mostly belonged to all citizens and a person who is responsible for dividing water (in Persian "Mirab") distribute water between citizens according their ownership of water.

Location of hydraulic structures were determined according the path of water as well. Water reservoir, bath, ice house, wash house,"Akhoreh" and so on were located according the path of water of Qanats or rivers.

For example, the location of great mosque was determined in a way that an "Akhoreh" can been built for people to be able to wash and to be ready to do religious porpuses.

So the priority in locating the great mosque was the accessibility of prayers to the water of Qanat. This role was for the other hydraulic structure as well. Their locations were according the path of Qanats.



Map 1: The route of water in districts of Qazvin city

3. Conclusion

Water is the main factor in forming a settlement in hot and dry region of Iran. Iranian harvested this valued element from underground aquifer and build their

cities and villages. Water infrastructure in such cities has the main role in morphology of city again.

Water flowed mostly in common lanes in cities and hydraulic structures and other buildings were placed according the path of water. This fact has an important effect in morphology of cities. Actually it should be said that initially the road network had been formed and after that its land use and then lots and its dimensions were determined during the forming of cities and villages.

So if we want to have any restoration activities or rehabilitation or any similar activities in reviving identity of historical cities of Iran we should consider water infrastructure of them first or at least simultaneously. In the other word in historic cities water infrastructure can't be ignored in rehabilitation activities and if we aim to revive the real identity of these cities water infrastructure and its features is a main element in that cities.

But unfortunately this fact mostly neglected by architect and urban planners during restoration activities in historical cities of Iran.

But this aspect (traditional water supplement) is an important part of the identity of an Iranian historical city in hot and dry region. Carful and technical restoration of water infrastructure and hydraulic structures of a historic city causes a more real historic city with its real features and can attract tourists which are interested to an Iranian city with its amazing characteristics.

Research Paper

Study on Urban Morphology Optimization Based on the Construction of Urban Memory Structure

Take Dazhi Street in Harbin as an example

Haixuan Zhu, School of Architecture, Harbin Institute of Technology,Key Laboratory of Cold Region Urban and Rural Human Settlement Environment Science and Technology, Ministry of Industry and Information Technology; China

Abstract

In the late 1970s, China began the process of rapid urbanization. With the continuous expansion of urban scale and the rapid increase of urban population, the trend of urban homogeneity is deepening. Some problems, such as the lack of urban characteristics and the destruction of urban memory, are becoming more and more prominent. For this reason, urban construction also lacks the cultural deposits. Therefore, in order to make up for the lack of urban characteristics in rapid urbanization, the establishment of urban memory structure and the strategy of urban morphology optimization have become the current issues that should be concerned and discussed. Based on this, this paper takes Dazhi Street in Harbin as the research object, combs the historical evolution and development context of Dazhi Street by reading relevant historical documents and collating and comparing several versions of urban planning drawings in Harbin. The combination of questionnaire survey and field research is used to study the architecture, street interface, public space and overall spatial form of Dazhi Street in Harbin. Therefore, through the study of Dazhi Street, firstly, we construct a relatively complete urban memory structure. Based on the urban memory structure and the current development situation, we put forward five aspects of urban morphology optimization strategy: the continuation and display of historical context characteristics, the unity and symbiosis of architectural style along the street, the coordination and improvement of urban street functions, the optimization and promotion of urban Street landscape, and the improvement and integration of urban street facilities to further highlight Harbin's urban characteristics. It also provides some reference for other cities with rich historical heritage and prominent cultural characteristics to construct urban memory structure and further enhance their locality and uniqueness.

Keywords

Keyword 1, keyword 2, keyword 3 (3-5)

1. The Significance of Constructing Urban Memory Structure

1.1. Highlighting Urban Characteristics and Promoting Urban Sustainable Development

The development of a city reveals its long history and profound connotation, and urban memory is a continuation of this development process, which is the continuation of the continuity and uniqueness of urban development through collective memory. It is precisely because of the existence of urban memory that the evolution of urban material structure and social culture is influenced by this continuous memory, which makes the physical form of the city have continuity and shows unique features and images different from other cities. Nowadays, many cities in China are lack of urban characteristics, which is due to the destruction of the historical context of the city, leading to the interruption of urban memory. Through the construction of urban memory structure, we can clarify the context of urban development and find the consistent important elements in urban memory, which is of great significance for the continuation of urban history, highlighting the characteristics of the city, improving the status quo of urban convergence and promoting the sustainable development of the city.

1.2. Strengthen people's sense of identity and belonging to the city

Memory transforms the city from instantaneous to eternal, from limited to infinite. In urban history, the activity of memory has never stopped. Everyone, everything is in memory, but also in the process of being remembered (and re-remembered). It can be said that cities exist by memory[1]. Morever,"cities are places for people's collective memory[2]".This collective memory is based on the common histories to produce the emotions and common will. The most important element that makes people identify with themselves and others as a collective is the common history. These common histories condense into precious memory space, and also leave people a unique city memory, reposing people's feelings and sense of belonging to the city. Establishing urban memory structure can make people's memories have roots to follow and traceable, and connect them with the current life, so that the historical and cultural connotations and humanistic values of the city can be widely transmitted and deepened, and people's sense of identity and belonging to the city can be enhanced.

1.3. Shaping the Spirit and Culture of the City

Cities are an organic whole of the interaction between human beings and the environment. In the process of the formation of urban material form, the most important thing that can not be ignored is the impact of human beings on cities. Cities are constructed by people's subjective initiative. For cities, memory is a key factor in the formation and development of cities. It reflects the relationship and interaction between people's subjective consciousness and external physical environment. The city memory constitutes the spirit and soul of the city. With the development of the city, the city memory is constantly concrete and deepened in the process of its development. Culture includes both material and conscious factors. It is a unique way of thinking, attitude towards life and accumulated civilization in the course of history developed by the social community. It is also a bridge between individuals and collectives, and between future generations and previous generations. Through culture, people of different nationalities and times transmit, continue and develop their ideas about

life. Culture is closely related to the city. It is the product of the collective construction and identity of the city and is directly related to the spirit of the city people. Globalization and modernization make cities develop at a high speed and standardize, which leads to cultural convergence. This situation not only causes the similarity of the external image of cities, but also relates to the convergence of people's life style, behavior and psychology in cities. Therefore, the construction of urban memory structure has far-reaching historical and practical significance to embody the city's personality and vitality, inherit cultural traditions, enhance the charm of the city, and promote the development of the city.

2. Establishing Urban Memory Structure

2.1. Elements of Urban Memory Structure

The reason why urban memory has become a collective memory is that although each individual memory is not the same, they all take the city they live in as a reference, thus producing urban memory. All the material elements in the city, such as urban spatial pattern, geographical landscape, buildings and structures, as well as some non-material historical events and cultural traditions, are the carriers of preserving and transmitting urban memory, which can arouse people's memories related to it. Different memory individuals in different times realize communication and dialogue in the time-space staggering through urban memory carriers. In addition, the elements of urban memory also contain the content of vertical time. From its emergence to its continuous development, cities have gone through different times and stages of development, during which all intangible memory elements are retained in the physical form of cities in various explicit or implicit ways. "With durable buildings and institutionalized structures, as well as more durable symbolic forms of literature and art, cities connect the past, the present and the future." Thus, urban memory is a complex dynamic system, which involves not only the material and non-material elements of the city, but also the subjective consciousness and emotion of people. Therefore, urban memory is a process that incorporates the vertical elements of time and is gradually constructed in the social system through the collective creation and identification of cities.

2.2. Urban Memory and Urban Morphology

In a broad sense, urban form includes not only the material form composed of physical externalization factors such as geographical region, natural environment and material structure, but also the intangible and immaterial form categories related to human behavior psychology and urban society, such as politics, economy and culture. The overall image and characteristics of a city are determined by both. The evolution and development of urban material form reflects the function of city as the material carrier of history and preserving city memory. The urban spatial pattern and buildings record the social life and events in different historical stages of the city, which solidifies and precipitates the urban history in the form of materialization. Compared with the urban memory of language and writing, the urban material space form is more directly influenced by political, economic and social reality, so it can more vividly reflect the changes of the times and the occurrence of important historical events. Although in different periods of urban development, the material space form of the city will be adjusted or changed on the basis of the original city because of the need of urban construction at that time, in order to show the political and

economic characteristics of the city at that time, in this process of continuous evolution, there are always some parts that can be preserved, so that the city can be preserved. The material form of the city still maintains its connection and continuity in the process of change. Therefore, urban physical form is also one of the most effective ways to arouse urban memory. The material traces of the city and the information contained in the material form constitute the familiar life background of the citizens, which enables them to maintain a sense of security and belonging psychologically. By analyzing the material form of the city, people can not only read the history of the city clearly, sort out the clues of the city memory, so as to construct the structure of the city memory.

2.3. Classification of Memory Elements in Urban Morphology

Memory elements in urban form include not only visible material elements, but also invisible non-material elements such as major events in the city, daily life stories of the city, which together constitute the ideological and cultural traditions contained in all memory carriers of the city. At the same time, as a perceptual experience of the environment, urban memory should also be based on the cognitive basis of the urban spatial form. In this paper, the elements of urban memory in urban form are divided into the following categories.

(1) Natural elements: refers to the overall natural environment, which is the basis of memory generation and function;

(2) Artificial elements: all buildings and structures that provide shelter for human beings and their functions and activities;

(3) Humanistic elements: tangible and intangible elements such as human culture created by urban people that are worth remembering and inheriting;

3. Analysis of Memory Elements in Dazhi Street

3.1. Artificial Elements

3.1.1 Spatial pattern

（1） The influence of western planning thoughts

Dazhi Street is located in the new city (today's Nangang District), which was planned by the Russians at the end of the 19th century. The planning reflects the traditional European urban planning ideas and has obvious Baroque city characteristics. The history of Baroque city began in Rome in the 17th century. It has the characteristics of openness and dynamic, and pays attention to the overall visual effect of urban space. In Baroque city, single building becomes a part of the system, space gains new importance and becomes the real part of the whole city. Baroque city also emphasizes the role of urban focus, which constitutes the city's landscape system. Therefore, as the focus of the city, the architecture must have obvious spatial characteristics. Therefore, the dome of the church, the Obelisk and other important monumental buildings with spatial significance are arranged in the focus of the urban system. The elements in the city interact and submit to a dominant focus, and radiate many broad straight streets from the focus plaza, connecting these focus points[3]. The urban planning of modern Paris, Washington and Petersburg were all carried out under the influence of Baroque thought. As one of the most representative Baroque cities, Paris had a far-reaching

impact on the planning and construction of many cities in the world. Both Napoleon I and Napoleon III devoted themselves to the improvement of Paris by Baroque technique and implemented their respective Paris plans. During Napoleon III, Osman's Paris reconstruction plan focused on the construction of a number of boulevards, including Rivoli Avenue, Sebastopol Avenue and Saint-Michel Avenue, which are the arteries connecting east and west and north and south through the center of Paris，constitute the basic frame of the city. After the reconstruction of Paris, the major cities in many European countries took Paris as a model for urban planning in the second half of the 19th century.

（2）Spatial pattern characteristics of Dazhi Street

The new city chose the highest position in Harbin, which laid the foundation for Harbin to become the geographic environment, administrative management and social and cultural center. In the planning and layout of the new urban area, the greatest feature is to use Baroque techniques, strengthen the form of composition, and use the spatial form of urban planning to express the colonial ruler's will and political ideas [4].The overall layout of the new city takes the form of grid, radial road network and circular square. The planning combines the topography with the direction of railway lines, and the overall spatial pattern develops East-West along the terrain and railway. At the same time, the highest terrain is chosen as the main street of the new city, named Dazhi Street, for key planning and construction [5]. Dazhi Street is the main axis of the East-West development of the new city, with a design width of 43M. It is called " The backbone of Harbin ". It is vertically intersected with the Chezhan Street of the North-South Axis (today's Hongjun Street). These two axes constitute the main space skeleton of the new city. At the intersection of Dazhi Street and Chezhan Street is St. Nicholas Central Cathedral. Five radiation roads are formed from the church square, which becomes the center of the new city and echoes with the Harbin Railway Station on the Chezhan street.In addition, with the square as the demarcation point, the new city is divided into East and West parts. The western part is the administrative office area and the railway staff residential area. With the office building of the Middle East Railway Administration as the core, a large number of buildings related to the Middle East Railway System are arranged, such as Railway clubs, men's and women's business schools, railway technical schools, residences of senior railway staff and residences of railway workers; the eastern part is a commercial district and a national Consulate area, with national consulates, shopping malls, cinemas, post offices, churches and squares on both sides of the street.

The spatial pattern of Dazhi Street reflects the distinct planning idea, people's social life and urban development, and the historical and cultural significance of Harbin. In the development of more than one hundred years, the spatial pattern of Dazhi Street has been constantly self-renewed, which is more closely related to the people living in it and more deeply integrated with the development of the city.

3.1.2 Historical Architecture

The historical buildings formed and preserved in the course of historical development are witnesses of the history of urban development, and also the essence of urban architectural culture. These historic buildings show ingenious design and flexible construction wisdom in adapting to local environment and satisfying functional requirements. At the same time, they also reflect the living habits, local customs and religious beliefs of the time in

architectural style and architectural type, and play an important role in the continuation and development of architectural culture. It also provides an important basis for the construction of urban memory structure.

The unique historical process makes Harbin show the characteristics of blending Eastern and Western cultures.As early as the 1920s, Harbin has been known as "Oriental Moscow" and "Oriental Little Paris", and a large part of this city image comes from the unique buildings in the city. The formation of urban architectural style in Harbin is closely related to its natural environment, geographical location, technical conditions and social and historical conditions. Firstly, in terms of natural environment conditions, Harbin is located in a cold area, and buildings need good thermal insulation, so Russian style buildings which are basically similar to the natural environment can be well integrated and adapted. Secondly, because Harbin is located in the Middle East Railway Transportation Hub, it can provide convenient conditions for the transportation of building materials [1]. At the beginning of the 20th century, Harbin initially formed a whole new system of western architectural types, which laid the tone of urban architectural style with Russian style, New Art Movement, eclecticism and other styles as the main style. The buildings in Dazhi Street are mainly of these styles, which can be divided into administrative office buildings, residential buildings, religious buildings, cultural and educational entertainment buildings and residential buildings according to the types of use.

(1) Administrative office architecture

The administrative office buildings in Dazhi Street are mainly divided into three categories: the Middle East Railway System Office Building, the consulates of various countries, and the office buildings of urban administrative agencies at all levels. The Middle East Railway Administration Building, built in 1902, is the largest and most important administrative office building in early Harbin. It is the seat of the Leadership Center of the Middle East Railway and the political center of early Harbin.

Command of Amur Military Region outside Russia	1904	Russian Architectural Style
Middle East Railway Authority Office	1910	Eclectic architectural style
Soviet Consulate General	1924	Russian Architectural Style
American Consulate	1907	Renaissance Architectural Style

(2) Residential building

Private residence occupies a very important position in the development history of Harbin architecture. At the corner of the intersection of Yaojing Street and Garden Street, the most luxurious villa was built, which was the official residence of Holwart, who became Director of the Middle East Railway Administration in 1903.But he did not choose to live here, so the building was temporarily used in the Middle East Railway Club and its library during 1907-1910; after 1911, it was used as the Russian Consulate-General, which had been the office building of the Soviet Consulate-General in Harbin from the mid-1920s to the end of the Patriotic War. At that time, many luxury villas in Harbin were converted into public welfare places or office places after the owners left. For example, the Afanasiev Villa, located at the corner of Dazhi Street and Yaojing Street, became the largest railway Library in the Far East. Most of the residences of railway staff are located in residential areas not far from the office building of the Railway Bureau and the Railway Club building. They are distributed in Garden Street, Hegou Street, Jiaotong Street, Haiguan Street, Central Street (now Shenyang Street), Beijing Street, Jianzao Street (now Haicheng Street), Gongsi Street, and a part of them are located in Dazhi Street [6]. The soil in Harbin was fertile enough to be fired in large quantities

into bricks and used as building materials. At that time, Russian architects used a large number of these building materials, so most of the residences of workers in Harbin Middle East Railway were built of bricks. On the one hand, the cost of materials was low. On the other hand, the cold climate in winter in Harbin required higher thermal insulation performance of buildings. Building thick brick exterior walls can play a strong role in resisting cold. In addition, the building uses herringbone wooden roof structure to form a single-storey double-slope roof, and the clear water is painted with a uniform beige color, which makes the overall style of the residential community harmonious and unified.

Middle East Railway Senior Staff Residence	Early 20th century	Eclecticism architectural style
Middle East Railway Russian Workers'Housing Complex	Late Qing Dynasty and Early Republic of China	Russian Architectural Style

（3）Religious architecture

Harbin city is very characteristic of those religious buildings belonging to different denominations, churches have become an important symbol of Harbin[7]. Foreigners and Chinese people in Harbin, religious beliefs including Orthodox Church, Catholicism, Christianity, Judaism, Islam, Buddhism and so on, formed the coexistence of various religious buildings in Harbin. In terms of quantity and scale, the Orthodox Church is the most prominent. In 1899, St. Nicholas Cathedral laid its foundation in the new city and was completed in December 1900. It has existed for more than 60 years since then. St. Nicholas Cathedral is located at the intersection of Dazhi Street and Chezhan Street (today's Hongjun Street), the commanding heights of the city, in the heart of the new city. The plane of the building is symmetrical along the axis with the Greek cross layout in the North-South direction.The building is Russian style, the facade is made of log overlay, the wooden roof at the entrance has three "onion roof" decorations, the main part of the roof is unequal hexagonal, the top also has "onion roof" decoration [8]. In 1908, the Sabbath Church of the

Virgin Mary was built in Harbin's new cemetery (in today's Nangang Cultural Park) and has been preserved to this day. There are also several non-external churches in Harbin, among which the small church of business school is perhaps the most distinctive one of the similar churches. Since the October Revolution of 1917, a large number of exiled Russian emigrants have entered Harbin, which has set off an upsurge in church construction. As a result, since the 1920s, a large number of new churches have appeared in Harbin, mostly brick structures. he Notre Dame Church was moved to East Dazhi Street in 1930. It is built in Byzantine style with brick and wood structure. With the construction of Harbin city, a cemetery appeared in the suburbs of the city, later known as the old cemetery.In June 1941, not far from St. Nicholas Cathedral in Dazhi Street, a monument to the victims of the war against the Communist International was established, which is a typical architectural style of Russian churches in the 17th century.In addition, due to the national upsurge in Harbin, a number of traditional Chinese religious buildings have been built, including the Confucian Temple, the Jile Temple, the Puyu Middle School and so on.

Harbin Confucian Temple is not only the last well-regulated Confucian Temple built in the whole country, but also one of the antique buildings influenced by western architecture in the early Republic of China. It is characterized by the use of western architectural technology and materials to reflect the connotation of traditional Chinese architecture. The gold pillars of the main hall (Dacheng Hall) are converted into reinforced concrete, and the top stones of the gold pillars are made of terrazzo.

Confucious'Temple	1926	Chinese Traditional Architectural Style

(4) Cultural,Educational Entertainment Architecture

Harbin's modern cultural, educational and entertainment architecture started earlier. School buildings appeared one after another in the early 20th century. The Middle East Railway Administration built Harbin Railway Technical School and Business School in Dazhi Street around 1906. After the completion of the Middle East Railway, the Middle East Railway Administration began to pay attention to the training of professional cadres for "correct use of railways". For this reason, the railway system has opened several schools in Harbin, the most important of which is the Business School. The teaching building of Harbin Business School (male school and female school) is composed of two parts which are identical and symmetrical. The school is in the best position in the new city, juxtaposed with the Middle East Railway Administration Building, opposite the two buildings is the Middle East Railway Club Building [6].Established in 1906, the campus of Sino-Russian Industrial Technical College includes teaching buildings, dormitory buildings, office buildings, practice factories and residences, all of which are in the style of Art Nouveau architecture.Later, after several expansion, it was the predecessor of Harbin University of Technology and Harbin Institute of Architectural Engineering. The Puyu Middle School (now Harbin Third Middle School), which was built and put into use in December 1927, was designed by Russian architects, but the whole building belongs to pure Chinese classical style. Puyu Middle School is the first large-scale Chinese-style building built in Harbin. It is the first successful attempt to integrate Chinese traditional architectural style with European architectural style. It also has the first innovation of key technologies, such as using concrete pilasters instead of log pilasters, but it still maintains a purely Chinese classical style in appearance[6].

In terms of entertainment architecture, the Middle East Railway Club, as the largest entertainment building in Harbin, is very representative. The front of the building extends parallel along the street. The two sides of the building are irregular geometric plane structures. Including theatre and library, outdoor open-air square and various flower beds,

Harbin's early eclecticism style of architecture [8]. There are theatres, film projection rooms, book reading rooms, chess and card rooms in the room, and cultural and entertainment facilities are very complete.The Middle East Railway Club was built in 1911 and is located on Dazhi Street, across the street from the Middle East Railway Administration Building. There is an open space in front of the building, and there is an open-air plaza and various flower beds outside. The front of the building extends parallel to the street, and the sides of the building have an irregular geometric plane structure. The building consists of two parts, the theater and the library. It is an eclectic style building that appeared earlier in Harbin [8]. There are theaters, movie screening rooms, book reading rooms, chess and card rooms, etc., and cultural and entertainment facilities are complete.

Figure 7 Confucious' Temple

Figure 8 Sino-Russian Industrial Technology School

Figure 9 Puyu Middle School

Figure 10 Harbin Business School

(6) Commercial and Service Architecture

Harbin's commercial buildings can be said to be a new force, with rapid development [6]. The most famous one is Qiulin Company. In 1904, Qiulin Company was founded in Dazhi Street of New City. With the development of the whole city, Qiulin Company gradually expanded. Later, after expansion, it became a large-scale department store with higher standards in Northeast China. The plane of the building is L-shaped. It is a two-storey brick-wood structure with the main entrance at the corner. The top crown dome, the wall shape concise by eaves, cornices and daughter walls constitute a key decoration. Later, it was expanded into a four-storey building in 1982, which generally maintained its original style. Moscow Mall, built in 1906, is an important building in the central square of the new urban area. It is two stories high and one story underground. The plane is composed of three standard segments and two corner links, which is the style of the new art movement. With smooth curved piers, windows and domes, a beautiful shape and unique skyline are formed. The building was changed into a museum in 1922 and is now the Heilongjiang Museum. The Middle East Railway Administration Hotel, built in 1902, is the first large-scale hotel building in Harbin, with three floors high, complete functions and high specifications. Architectural style has both Renaissance style and new art movement charm. These commercial and service buildings with high artistic quality constitute an important part of Harbin's urban landscape. They all play an important role in adapting to modern urban life and shaping the unique style of squares and streets[8].

To some extent, architecture has characteristics independent of social background. Although the times are changing, the architecture left over from the past can preserve their own

values through the new functions and profound historical significance given to them in the new era. Harbin's modern architectural activities for more than one hundred years have brought the spread and application of advanced western science and technology, new structural forms, new building materials, new building forms and new technologies, which not only promoted the prosperity of modern construction industry, but also promoted the development of social economy.In addition, the emergence of new architectural forms enriches the urban architectural landscape, activates the image of the city, and forms the orderly coexistence of Chinese traditional architecture, western architecture and Chinese-Western blending architecture. The emergence of new building types in cities, such as libraries, museums, stations, schools and hospitals, reflects the development of cities and social progress.

Figure 11 Qiulin Company

3.1.3 Squares and Streets

In the planning of New City, the setting of square is very important.The plan takes Dazhi Street as the main axis, arranges three circular squares in succession and connects several roads to the square. The three squares include St. Nicholas Church Square, Educational Square and the Front Square of the Middle East Railway Administration (pictured) [5].These squares are connected in series with important landscape nodes and playing a symbolic role. Saint Nicholas Church Square is a circular square formed by the intersection of Dazhi Street and Hongjun Street. On the basis of this, two radiation paths are extended from the square to form the geometric center of the new city (figure). The Jiaohua Square is located in front of the main entrance of Harbin University of Technology, forming an important spatial node in Dazhi Street; the front square of the Railway Bureau is a typical pre-construction plaza, highlighting the space importance of the Middle East Railway Administration building and forming another important space node on Dazhi Street together with the Middle East Railway Club across the street.The spatial layout of multiple squares on one axis not only highlights the important role of Dazhi Street as the axis of the city, but also emphasizes the role of Saint Nicolas Square as the focus of the city. The radial road around the square also facilitates urban traffic, and the traditional layout has been successfully applied to modern urban planning, which makes urban construction reflect profound cultural connotations[5].

Figure 12 St. Nicholas Cathedral Square

3.1.4 Greening and Essential Elements of Sketches

At the beginning of urban planning in New City, the planning layout of urban greening system embodies multi-level characteristics because of drawing on the concept of urban planning in Paris. It adopts a combination of concentrated Park greening, street garden, square greening, street greening and scattered courtyard greening to carry out greening layout. In 1898, when Nikolay Cathedral was built in the new city, trees were planted in the church yard and its surroundings, and a 22-hectare Park (now the campus of Harbin Institute of Technology) was planned between today's Jiaohua Street and Fuxing Street, Dazhi Street and Majiagou River.In 1906, the first street green park (now Beixiu Park) was established between Dazhi Street and Railway Street. At the same time, trees were planted in Jiashu Street, Garden Street, Dazhi Street and Songhua River Street. The main roads in Harbin are relatively wide, and the roads in residential districts are up to 13m. Most of the buildings on both sides of the roads retreat a few meters, thus forming a variety of street greening modes with distinctive features before buildings. This kind of greening method mostly combines roadside trees, flower pools and green space together with simple paving, chairs, hedges and so on, which constitutes a variety of different combinations of roadside greening mode (figure1)[9].Harbin's greening landscape relies on the original natural basis, so it can quickly form a good landscape effect after the beginning of urban construction. The local tree species in Harbin are mainly pines, elms, birches, elms and cloves, which are very suitable for the greening, landscape application and architectural planting of Russian-style western cities. These diverse and characteristic greening make the overall landscape of Dazhi Street richer.

Figure 13 Greening Landscape of Dazhi Street

3.2. Artificial Elements

3.2.1Topographic features

Topography refers to the fluctuation of the terrain, which can also be called the form of the surface. Such as mountains, hills, rivers, lakes, seashores, swamps and so on. Usually people design and plan a city according to its topography and landform. Street landscape as an important part of the city, will also be combined with the city's topographic characteristics show. While satisfying the street function, combining with the city's topography, it can make the original scenery more beautiful, and also add new artistic characteristics and personality to the city's image. The new urban area has chosen the highest position in the whole city, thus laying a material foundation for him to become the geographical environment, administrative management and social and cultural center of Harbin. New city's topography is undulating. The hilltop extends from southwest to northeast. The slope on both sides is large. The right side is near Majiagou River. The left side is bounded by the Binzhou Railway Line, which separates the new city from the port.

3.2.2 Mountains and rivers 'patterns

Landscape pattern is an important part of a city's natural elements, which reflects the harmonious coexistence of the city and nature. Dazhi Street is adjacent to Majiagou, and the part near Majiagou in the section is perpendicular to it in road planning. Majiagou is integrated into the overall landscape system of the new town to carry out the corresponding landscape planning, thus enriching the urban landscape types.

3.2.3 Vegetation types

Because Harbin is located in the cold area, the greening color in the city is usually monotonous. Generally speaking, the main trees planted in Harbin streets are elm, birch, maple, maple, Manchurian ash, yellow pineapple, walnut, oak, pine, cypress and so on. Clove is a city flower in Harbin. There are more than 35 kinds of clove in the city. In view of the geographical characteristics of Harbin, the natural vegetation here is usually dominated by coniferous and broad-leaved mixed species such as pine, elm and birch. Among the low shrubs, the urban area used to be dominated by elm trees, while there are many kinds of

cloves, so Harbin has the reputation of "City of Cloves" and "Yudu". The Russian colonists made full use of this feature. After the construction of the Middle East Railway, elm and clove were taken as the main greening tree species in the street landscape. The planning concept of Western Garden City was adopted in the planning of Harbin's urban landscape, which greatly improved the greening degree of Harbin.

3.3. Humanistic Elements

The city is not only an important material space carrier for the inheritance of historical context, but also indirectly embodies the contents of social change, humanities and arts, moral concepts, religious beliefs, local folklore and so on, forming the cultural connotation of the city, i.e. intangible culture. Focusing on the elements of human memory helps to enhance people's cultural identity and build a more complete urban memory structure.

3.3.1 Symbolic Elements of Geographical Names

The place names of Harbin reflect the changes of history and the development of the city. For example, since 1920, China has gradually regained its sovereignty over Railway dependencies and become a special administrative region that continues to open to the outside world. During this period, Harbin experienced a wave of revival of national culture. In March 1925, the General Administration of Police of the Eastern Provincial Special Area made a change in the name of the street originally named in Russian in Harbin. At the same time, some street names were renamed and some of the old names of the street were restored[10]. Some street names in the new city where Dazhi Street is located have been changed accordingly(Table 4).

Table 3 A List of Changing Street Names in Harbin[10]

Urban Area	Before renaming	After renaming
Butou District	King Hillkov Street	Diduan Street
	New City Street	New City Street
	China Street	Central Street
	Cossack Street	Gaoshi Street
	Shitoudao Street	12th Street of China
	Japan Street	6th Street of China
New City	Holwalt Street	Chezhan Street
	Dazhi Street	Dazhi Street
	Nikolayevsk Street	Temple Street
	Fengtian Street	Fengtian Street
Majiagou	Brusselov Street	Zhonghe Street
	Balkan Street	Bashan Street
	Officer Hospital Street	Wenzhi Street
Xiangfang District	Lujun Street	Lujun Street
	Junguan Street	Junzheng Street
Xin'an Port	Zuolin Street	Ankang Street
	Mikhailov Street	Anding Street
	Albazin Street	Anle Street

3.3.2 Dietary culture

With the construction of the Middle East Railway in the early 20th century, a large number of Russian immigrants came to Harbin, and at the same time brought Russian food habits here. As Dazhi Street is located in the administrative office area of the Middle East Railway and the residential area of Russian workers, it has been deeply influenced by Russian catering culture. The Middle East Railway Club on Dazhi Street not only has the function of

recreation and entertainment, but also is the earliest Western restaurant in Harbin. Many large banquets for the inauguration, welcome and farewell of diplomatic missions, international associations and senior officials are held here. In the 1920s, Harbin gradually developed into an international city, and the demand for Western food was increasing. The main restaurants managed by Russian overseas Chinese gradually became operated by multinational nationals, and there were more Russian-style restaurants managed by Chinese people [12]. The influence of Russian dietary culture on Harbin has lasted till today. Eating Russian food is still a part of Harbin people's dietary habits. Russian food such as Large column Pakistan, sausage and so on is a common dish on Harbin people's table. As a traditional staple food of the Russians, Large column Pakistan is not only loved by the Russians and Europeans, but also by the Chinese living in Harbin[13].

4. Conclusion

The study of urban memory has led us to form a new way to understand the city and find a better way to plan and build our city. Through the construction of the memory structure of the city, it can enhance the public's sense of identity and belonging to the city, enrich the public's emotional experience of history, and connect it with the current life, so that the historical and cultural connotation and humanistic value of the city can be widely transmitted and deepened, so as to optimize the current urban spatial form and shape the city's characteristics. It provides a feasible way of thinking.

Research Paper

Underground Built Heritage as catalyser for Community Valorisation

Underground4value

Giuseppe PACE, ISMed-CNR, Italy

Abstract

This paper is about how framing an innovative approach for community empowerment by organising networks and consortia for preparing proposals in different research programme frameworks. In the beginning, there was as study for classifying underground spaces and using them as a solution for a sustainable over ground urban development. By advancing in the proposals preparation, the team developed a completely different vision. The underground space was more and more seen as a place for building local identity and sense of belonging, progressing from a functional to a cultural value, from a site conservation to a community valorisation approach, by giving centrality to the people and their needs. As first step, the project faced the challenge of regenerating urban areas by realising Underground Built Heritage potential for local communities and experimenting a methodological approach on sustainability transition. Just like a story, the paper describes the evolution of the approaches, and the implementation of the activities, also if unsuccessful in the competition. The consortium grew and matured, a network based on strong analysis and revision, whose members developed an impressive social capital and learned by any failure. Piece by piece, this network was able to achieve the success, and to start a COST Action, the CA 18110 "Underground Built Heritage as catalyser for Community Valorisation". The Action, funded for establishing and implementing an expert network, promotes balanced and sustainable approaches to preserve the Underground Built Heritage (UBH) and, at the same time, to realise the potential of the underground space in urban and rural areas for regeneration policies. The paper finally explains how a well-motivated group of people can transform a network activity, with a little budget, in a research and on field project and how such a network can provide innovative tools for engaging and empowering local communities.

Keywords

Underground Built Heritage, Community empowerment, Transition Management, Sustainability

1. Introduction

This should be a dissemination paper of COST Action, the CA 18110 "Underground Built Heritage as catalyser for Community Valorisation". Although just started, this action has already a very interesting story to share. It is about the process of cross-fertilisation developed through its maturation process, consisting of several proposals in different EU frameworks. All these proposals had the underground space as the common starting point. In the beginning, there was an international research group focused on the underground

space, investigating it from different perspectives, such as history, geology, conservation, and valorisation, and trying to define different aspects of the cavities, by providing functional classifications, conservation/valorisation case studies, and visualisation technologies. Local experiences were analysed mainly in terms of underground spaces' sustainable reuse for solving over-ground urban problems, sometimes from a heritage-conservationism perspective, and rarely from the local communities' perspectives, not properly illustrating or explaining decision-making processes, as well as local specifications and characteristics, or the local needs as drivers of change. That was the state when a Horizon 2020 call, the SC5-21-2016 (Cultural heritage as a driver for sustainable growth: Heritage-led urban regeneration), was published. Since that moment, a small team of experts started to imagine how local communities could be engaged and involved in the urban first, and then rural, regeneration processes catalysed by the existence of underground heritage, and how that heritage could contribute to individual and collective identity, social cohesion and inclusion (Applejuice Consultants, 2008; Dodd and Sandell, 2001). Usually, heritage-led urban regeneration initiatives aim at integrating cultural heritage buildings into urban regeneration schemes for generating popular, successful urban quarters with character, where people enjoy living, and also engender economic development through job creations and influence social issues such as crime, health, education and particularly social capital (Roberts and Sykes, 2000; Evans and Shaw, 2004). What could it happen if the building are underground and/or impossible to use in a traditional way, or if it is still largely unexplored? Could the symbolic value be enough for developing community identity and regeneration? What kind of meaning should be built?

2. Pioneering the concept

2.1. CUBRe 1: Culture of Underground Built Environment as a driver for urban Regeneration

Supported by the certainty of the underground heritage's historical and cultural outstanding value, the team started to deal with the specific challenges and goals of the topic SC5-21-2016, such as:

- mapping, analysing and documenting successful heritage-led regeneration models;
- assisting communities through provision of expertise, advice and capacity building in developing and implementing during the life of the project their heritage-led regeneration plans;
- setting up a robust monitoring scheme to monitor the communities performances;
- developing methodologies to enable replication and up-scaling of heritage-led urban regeneration projects in different contexts;
- identifying regulatory, economic and technical barriers;
- establishing long-term sustainable data platforms securing open, consistent data

Behind the slogan of an underground heritage "…not just a challenge, but also a valuable resource to celebrate, protect and use", that first proposal was thinking at a balanced and sustainable methodology to support the conservation of the heritage and, at the same time, to realise the potential of its spaces for 'replicable' regeneration policies in urban areas. The main project challenge was engaging local communities in the preservation of the

underground historic fabric by empowering them with adequate cultural, scientific and technical knowledge and then revitalising the public realm and developing skills for townspeople. To fertilise such a behavioural change, the team adapted an approach never used in the cultural heritage sector: the Transition Management (TM). The TM is a tool for stimulating, developing and supporting real-life experiments (**Living Labs**) in a goal-oriented modulation, aimed at shaping **processes of co-evolution** and **co-creation** (Kemp et al., 2005). It allows communities to explore alternative social trajectories in an adaptive, forward-looking manner, combining the capacity to adapt to change with the capacity to shape change (Rammel et al. 2004) and is concerned with positive goals, collectively chosen by the community following a process of problem structuration. The team contacted, invited and involved new partners in the proposal preparation, especially institutes with competencies in planning and ICT. Considering the starting point, the project did a good progress in terms of problem understanding, but missed maturity in the activities and, especially, a structured knowledge base: the platform. In addition, many partners were not enough focused on the community and more interested to study the heritage preservation. Finally, collective learning and dissemination tools were poorly defined and not enough innovative in respect of the challenge.

2.2. HURN: Heritage-Led Underground Regeneration Network

That first experience made possible applying to the INTERREG Europe 2016 call. Nonetheless, the different framework asked for major changes in the objectives, activities, and partnership, which was reduced to eligible countries and public bodies. Within the scope of conserving, protecting, promoting and developing natural and cultural heritage, the call asked for improving the implementation of regional development policies and programmes in the field of the protection and development of natural and cultural heritage. The new challenge stimulated a reflective approach in the team, which fixed as main goal to establish, implement and exploit a platform for sharing best practices on the sustainable use of the Underground Heritage. Therefore, the activities were focused on collecting partners' best practices on governance mechanisms, planning framework, stakeholders' involvement management, financing mechanisms, technical needs, and their direct impacts on the underground heritage preservation, environment, society and economy, as well as potential negative externalities (i.e. 'gentrification', hardbranding, mass tourism, recreational villages, underground degradation…). The collected information, then, was the knowledge basis for a platform, open and accessible to all parties interested in the underground regeneration. The Platform could manage data, providing knowledge on main technical and organisational barriers to the underground regeneration and correlated solutions, and analysing new potential functions, seen as evolution of the historical ones – with a particular attention to their divulgation – maintaining a conservative approach of their historical value as part of the European Cultural Heritage.

Each involved region (Basilicata, Apulia, Flanders, Valencia, and Cyprus) promised to produce a UBH action plan, integrating expert knowledge with local, institutional, and market knowledge, gathering needs from local/regional stakeholders, increasing the local communities' involvement, raising local awareness, and finally providing

transparent and open policy recommendations to the regional authorities. However, also in that case, the platform is little more than a toolkit.

3. Maturing concept, tools and consortium

3.1. The workshop "Underground Cultural Heritage as a driver for Regeneration. Strengthening local and regional participation in European programs"

The two unsuccessful proposals promoted a moment of reflection and suggested an enlargement of the potential partnership. Supported by Unioncamere Campania and Enterprise Europe Network, the CNR team organised a workshop in Naples (November 8-9th, 2016) with four session and a final round table to discuss about the future challenges. Participants' enthusiasm and intense debates reinforced the network and gave new impetus to the team for developing new proposals in EU funding programmes, such as Horizon 2020, INTERREG Europe, and COST.

Partners from Slovenia, Spain, Moldovia, Belgium, Cyprus, Russia, Turkey, and Georgia, contributed with theoretical, methodological, technical studies and several case studies dealing with: a) conservation and monitoring of the UBH; b) valorisation policies (from urban regeneration to sustainable tourism); c) planning approaches for integrating bottom up initiatives in regional policies; and d) case studies and potential follow-ups.

In particular, the CNR prepared a detailed analysis of future EU calls on Cultural Heritage, in order to reconsider the potential of the Underground Built Heritage in that framework. At that time, success rate for Cultural Heritage calls was incredibly low in H2020 (2.1%), and definitely higher in Interreg Europe (20.5%). The meeting, in addition, provided a first clarification about innovative planning approaches for community empowerment, such as Strategic Stakeholders' dialogue (SSD) (Van Tulder et al 2004) and Transition Management (TM) (Kemp at al. 2005). In addition, I started proposing their integration into a new tool, the Strategic Transition Management (STM), based on local communities' experiments and empowerment, and a multi-level strategic dialogue (e.g. Living Labs) (Pace, 2018). Finally, the meeting pointed out the need for a better support from the ICT private sector and a more extended network of countries. Naples workshop provided the seeds for the future proposal success: the wide and voluntary participation and the development of a common understanding created a right momentum for the following challenges.

3.2. CUBRe 2: Conservation of the Underground Built heritage as catalyser for rural Regeneration

The second CUBRe proposal represents the big change in the approach. Designed for participating to the topic SC5-21-2017 "Cultural heritage as a driver for sustainable growth: Heritage-led rural regeneration", it deals with if and how could Underground Built Heritage support rural development initiatives. All main national and supra-national programmes (Agenda 21; EU Objective 1, 5b and LEADER schemes), as well as rural regeneration studies (Edwards et al, 2000; Pretty, 1998; Shucksmith, 2000; Hodge & Midmore, 2008; Brown, 2010; Scott, 2012; EDORA, 2013; Juppenlatz, 2015) placed emphasis on two correlated

concepts, endogenous development and partnership. Both of them place the community participation at the centre of the rural regeneration process. The first in terms of stakeholders' capacity of mobilising local actors and resources, the second in terms of changing governance practices by empowering local people in rural areas and involving them in the planning process through 'bottom-up' approaches. CUBRe objective was to answer two main needs for rural regeneration: establishing community participation and drawing local resources. The UBH was that local resource, by lying at the heart of people' sense of place and contributing to individual and collective identity, social cohesion and inclusion. However, CUBRe portraits the UBH as a resource largely unexplored, even not documented, and indeed under-utilised, whose conservation depends on local public bodies with different organisational and legal frameworks and, often, lacking of technological capabilities and financial resources.

The proposal maintains the previous CUBRe approach of community engagement, but greatly implemented the platform, the Underground Heritage Platform (UHP), and better specifies the connections between the project, the platform and the living labs. In particular, the UHP develops two capacity-building activities: **knowledge meetups** and **knowledge consultancy**. The first shares cumulated knowledge through innovative and highly participative in-person and digital knowledge sharing meetups. To build capacity in the living lab, UHP establishes exchange and feedback with relevant stakeholders and other peers that lead to replication and knowledge sharing. It develops online learning tools, visualisation, technical guidance and production to help establishing and institutionalising a knowledge-sharing framework, combined with specialised on-site training events. It also includes participatory online webinars with more practical guidance and exchange.

Knowledge consultancies are tailored and targeted for each replicator needs. A user-generated needs model ensures direct involvement of replicators and their stakeholders into the process, providing them with advice and coaching. The Platform becomes the central product of the project and is tested, implemented and managed throughout the entire project life. Designed to support different public and private stakeholders, it uses open source software and develops flexible and accessible tools, by exploiting the latest mobile application technologies and solutions, which maximize its services usability, effectiveness and dissemination. Outcomes are a common understanding and awareness of the issues at stake, mobilization of local knowledge, joint problem ownership, and co-creation of solutions, that is, a better basis for decision-making.

Finally, CUBRe developed an innovative and effective communication and dissemination strategy, based on the "Role Models" success-stories storytelling and a wide local campaigning for activating a favourable environment from both social and economic point of view. The communication would sustain a vision of the underground heritage as a positive economic resource and a crucial element for recovering individual and collective identity, and building social inclusion and cohesion, which better supports Living Labs creation and increases the willingness of local communities to co-create rural regeneration plans.

Established in order to achieve a disciplinary complementarity, coherent with the project knowledge needs, the consortium included a very dedicated group of professionals, public officials, and academics from eight EU and three EU associated countries. Among partners, there were six universities, four research institutes with expertise in applied research, four private companies with relevant expertise in communication, business services, monitoring

and informatics, three city councils, two regional development agency, and seven non-profit organisations.

The proposal was among the four (on 42) that successfully passed to the H2020 Stage 1. The evaluation recognised the interactive, open-source digital platform, as a multifunctional tool for research, education, dissemination as well as a symbolic and innovative mechanism of local empowerment. In Stage 2, the project ranked second and first of the reserve list, but was not funded. Although unsuccessful, the proposal was fundamental milestone for working on UBH at the community level.

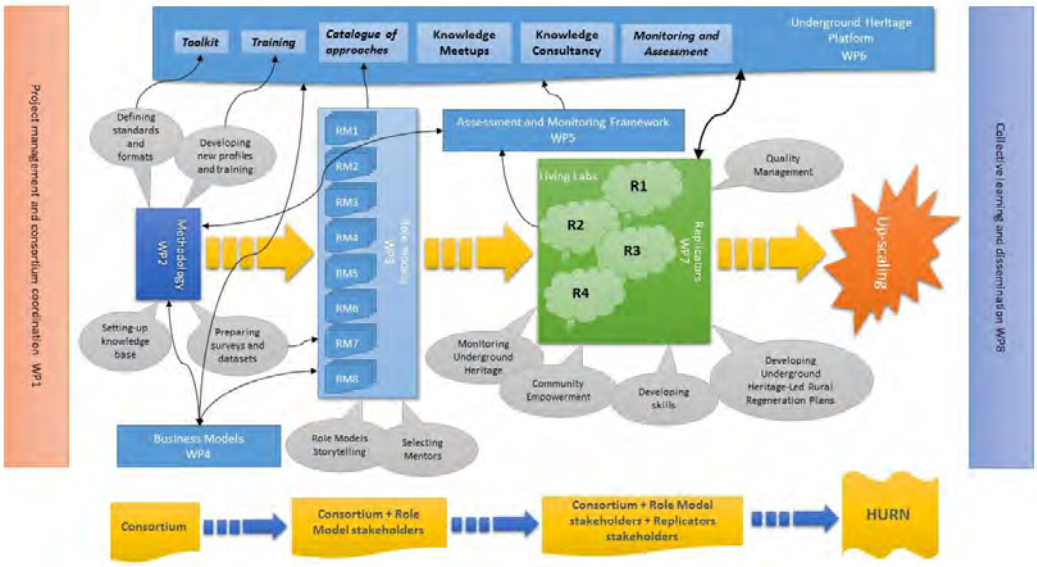

Figure 1 Overall CUBRe Logical Building Blocks and Work packages

3.3. HURN 2: Heritage-Led Underground Regeneration Network

The subsequent challenge was the INTERREG Europe call 2017. The specific objective was "Improving natural and cultural heritage policies" and the proposal represented a relevant progress from the previous 2016. With the participation of seven organisations from Italy, Spain, Slovenia and Belgium, the proposal addressed the implementation of the Operational Programmes ERDF 2014-2020 for Sardinia and Murcia regions, the Operational Programme for the Implementation of the EU Cohesion Policy 2014-2020 in Slovenia, and the Marketing strategy 2016 – 2020 for Tourism Flanders.

With the scope of fostering regional policies for a sustainable approach to the UBH, this second HURN proposal defined the following goals:

- Collecting the good practices and making them available to active and passive users, by disseminating cultural, scientific and technical knowledge on UBH, and by setting up a catalogue of approaches and context-specific practices for the "Environment & resource efficiency platform"
- Applying a Strategic Dialogue approach, by engaging key stakeholders in the involved regions, for formulating and implementing UBH valorisation strategies

- Producing an UBH action plan for each concerned region, which integrates expert knowledge with local, institutional, and market knowledge, gathers needs from local/regional stakeholders, increases local communities' involvement, raises local awareness, and provides transparent and open policy recommendations to the regional authorities.
- Seeding a stable European Heritage-Led Underground Regeneration Network (E-HURN), with a well-defined and ambitious communication strategy.

The action decided to develop a powerful and well-experimented communication and dissemination support to the project by adding a Telematic University to the consortium. That would facilitate the knowledge transmission between HURN scientific and institutional partners, as well as with the local and international stakeholders. By using those technological tools, knowledge could be collected and analysed, as well as a catalogue of approaches produced and context-specific practices directly linked to the Programme platform. In addition, it would also make available the HURN toolkit and training facilities, and set up monitoring tools for all policy instrument implementation. In that proposal, for the first time, the Strategic Dialogue (SD) 8-step model (Van den Berg and Pietersma, 2014) was adapted to the UBH specific objectives. Unluckily, for a missing partner electronic signature, the proposal was not retained for the evaluation and the team acquired little learning from that experience.

4. The COST ACTION "Underground Built Heritage as catalyser for Community Valorisation"

4.1. The first proposal 2016

The COST (European Cooperation in Science and Technology) Association, established in 1971, is an International not-for-profit Association under Belgian Law, which has currently 39 Member countries, and manages the COST programme. Its mission is to enable break-through scientific and technological developments leading to new concepts and products and thereby contribute to strengthening Europe's research and innovation capacities. It allows researchers, engineers and scholars to jointly develop their own ideas and take new initiatives across all fields of science and technology, while promoting multi- and interdisciplinary approaches. COST aims at fostering a better integration of less research-intensive countries to the knowledge hubs of the European Research Area. In the beginning, it was not 100% clear how to use the COST networking tools for developing a pure on-field innovative action. However, maybe a networking approach could make UBH-led community engagement more understandable. Under that perspective, the first Underground4value saw the light. The main challenge was to promote a sustainable use of the UBH, by integrating policies and practices of conservation into the wider goals of regional and local development, in respect of the inherited values and traditions of different cultural contexts.

The proposal was mainly focused on solving the conflict between underground heritage and underground space. It stated that current physical planning approaches under-perform in dealing with Cultural Heritage, and specifically with UBH. There is a rising awareness that physical approaches can only be part of the solution to communities' problems, and that planners should better "…address how people mix and connect, their motivations, and whether they 'own' where they live" (Bianchini, 1999). In addition, planning tools must

stimulate and facilitate local communities' empowerment, by connecting natural, social, cultural, political and economic environments, gauging impacts across different spheres of life, and grasping the importance not only of 'hard' but also of 'soft' infrastructures" (Bianchini, 1999). The transition of the proposal centrality from the built heritage to the individual and the community was then completed.

The proposal was positively evaluated (55 on 65) but not retained for funding. Why? The evaluation was very clear. It defined the topic as relevant, but rather an "evergreen" issue, which can always be considered as timely, and therefore not extremely urgent to solve. Were they right? How could we change their mind?

4.2. The second proposal 2018: CA18110 "Underground Built Heritage as catalyser for Community Valorisation"

Those two questions were at the centre of the proposal redesign in the 2018 COST proposal collection. Even if the new proposal does not appear so different, its centre is not anymore the Underground Built Heritage, but its value for the community and the society. Therefore, it is a value "to celebrate and preserve and when sustainable, to re-use and valorise, realising its full potential to support local communities' development" (see http://underground4value.eu/). The centre becomes now how the community can use this value in terms of sustainability challenge, a value that can catalyse urban/rural regeneration and attract tourism, raise community awareness and make local communities more resilient to globalised systems of production and consumption by preserving their unique environmental and cultural aspects. The sustainability challenge is certainty timely, as well as actions supporting the transition towards sustainability, by promoting changes in interdependent societal systems and across multiple scales – from the supply chains to the communities and individual citizens' behaviours and values – through complex and uncertain processes, mainly depending on experimentation, learning and sharing ideas. The proposal, also if difficult to experiment only in an expert network, opens the way to develop areas for experimenting and managing the transition. Activities seek for acquiring and testing tools to encourage dialogue and engage stakeholders across society in order "to determine where we need to go and how we are going to get there" (EEA 2016). Past experiences and the network composition provide relevant knowledge about tools for stimulating and facilitating local communities' empowerment and connecting natural, social, cultural, political and economic environments. They are the Strategic Stakeholder Dialogue (SSD) and the Transition Management (TM), eventually integrated into a new tool, the Strategic Transition Management (STM). The proposal defines as a new objective to "…pioneering socially and environmentally innovative solutions, by stimulating, developing and supporting processes of local community co-evolution and co-creation, which allows communities to explore alternative social trajectories in an adaptive, forward-looking manner, such as the Strategic Transition Management (STM)" (Underground4value, 2018).

The proposal was retained with a score 63 on 65, and admitted to funding. Since April 9th is active as COST Action 18110, and put together experts of 25 countries. The most innovative component is the new annual organisation of the activities, which are less and less of pure and open networking, and more and more part of a structured project (Figure 2).

The Management Committee selects four case-studies. Then, three thematic working groups - Underground Built Heritage conservation and monitoring (WG2); Underground Built

Heritage reuse and valorisation strategies (WG3); Underground Built Heritage planning approaches (WG4) - and two methodological and organizational ones - Knowledge Base Development (WG1); Dissemination and exploitation strategies (WG5) – prepare knowledge base contents and assessment tools for analysing case-studies. Small teams of participants perform yearly four case-study assessments, by using the Short-Term Scientific Missions (STSMs) tool.

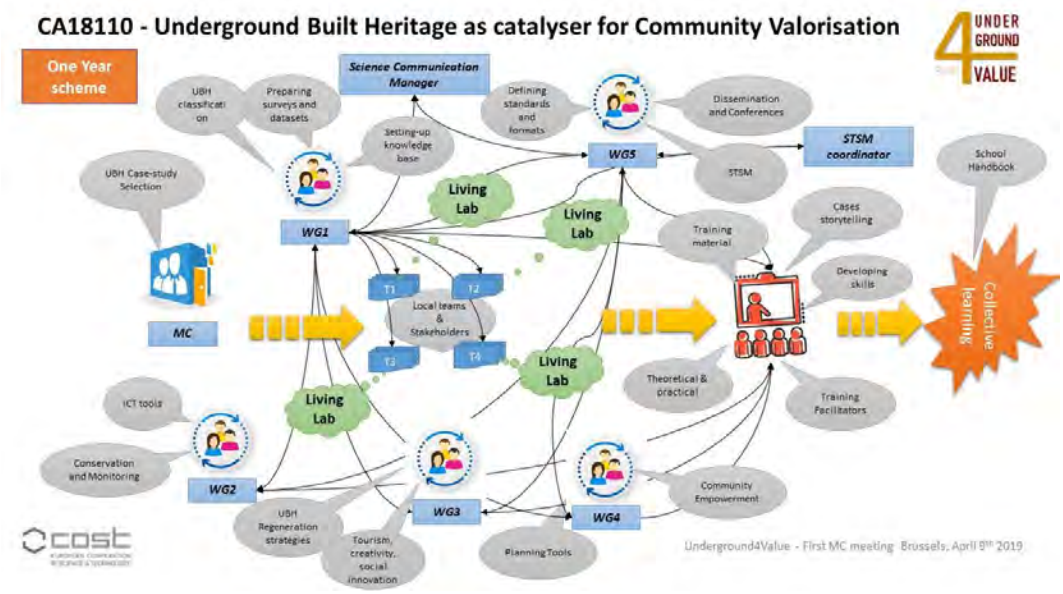

Figure 2 COST 18110 one-year action scheme

These assessments, jointly conducted by an external participant, together a local team, aims at developing a living lab approach on a specific UBH-based topic. Since the first meeting, the network developed a shared definition of living lab, that is, innovative actions experimented and implemented in real communities (a neighbourhood, a city, a region), but sheltered by adequate scientific and technical knowledge, technological capabilities and financial resources.

That approach would open to interacting with local communities, disseminating innovative thinking and supporting them to explore alternative social trajectories in an adaptive, forward-looking manner. Results will be discussed and analysed during workshops and, specifically, at the training courses, where trainers and trainees will work together on specific topics, producing a yearly publication.

The first year case studies are Naples (IT), Postojna (SI), La Union (ES), Göreme - Cappadocia (TR) (Figure 3).

The Action is an Expert network with the scope to become a structured and stable voluntary association for sharing research experience, best practices and ideas on UBH. A platform approach will support the creation of a repository for new research and for developing training tools, open and accessible to all parties interested to the UBH. Platform and tools will provide knowledge on main technical and organisational barriers to the UBH conservation and reuse. This knowledge will be the basis for:

- promoting continuity of use and significance to the underground historic fabric, revitalizing the public realm and developing skills for townspeople

- Assisting local communities' decision-making with cultural, scientific and technical support from many aspects (i.e. archaeology, geo-technics, history, urban planning, cultural anthropology, economics, architecture, cultural tourism).

Naples (IT): Modern Age tuff quarries under one of the most crowded urban areas of the world, with about 800 caves, 3000 water cisterns, 180 km of aqueducts' tunnels, catacombs, cemeteries, tombs, air-raid shelters, partially used as touristic attraction and partially reconverted into transport infrastructure

Postojna (SI): Three underground natural caves located on the classical Karst, which represent a significant case study as historical example of regeneration and valorisation since visitors' information centre and tours date back to 17th century. It is also one of the first examples of underground best practice in architecture hosting a post office and a multiservice space for visitors.

La Unión (ES): Mining caves since the time of Romanized-Iberian settlements, they have been transformed in a successful touristic destination. An exemplary site of abandoned caves and their valorisation as significant signs of local rural cultural heritage. The introduction of flamenco dance performances and music exhibitions are the most innovative approaches to re-functionalisation

Göreme - Cappadocia (TR): Located on the central Anatolia plateau, the region is set in a moonlike landscape of giant rock cones, housing historic cave-dwellings and Byzantine churches. Added to the World Heritage List by UNESCO in 1985, it offers a sustainable balance between heritage conservation, cultural tourism development and local community empowerment, thanks to many successful regeneration interventions.

Figure 3 COST 18110 first year case studies

Obviously, the new Action is only at the beginning, but the enthusiasm showed by the participants at the first Working Group meeting in Ancona (June 6-7th, 2019), as well as the interest of the local stakeholders, demonstrated the high potential of the concept and its replicability. The case study phase, with the expert assessment and the living lab establishment, will give a clear measure of the action potential, which will benefit from the reflective event of the training school.

The school is specifically organised with the purpose of developing new forms of training for planners. During the training school, outcomes of working groups and case-studies will be tested and validated. In addition, organised stakeholders' conferences will act as a vehicle for networking, public engagement, dissemination, knowledge sharing and exchange of best practice and innovative concepts and ideas for future developments and joint ventures. Specifically when surveying the gaps in underground built heritage, the Action will seek engagement with local communities' leaders, professional associations, privates, universities, SMEs in Cultural Heritage, experienced professionals and other stakeholders. Senior research associates, members of local policymaking bodies and associations, experts in cultural heritage research, will be invited to contribute to the Action's activities and events, and benefit from the Action's outcome.

Research Paper

A City Branding Framework in Regional Development Planning: The Case Study of Pringsewu Lampung

Citra Persada, Architectural Program, University of Lampung; Indonesia
Yunita Kesuma, Architectural Program, University of Lampung; Indonesia
Fadhilah Rusmiati, Architectural Program, University of Lampung; Indonesia

Abstract

The city branding shows the relation of the goals of managing the city's image that needs to be planned. The city branding is not about slogans, logos and promotional campaign, but it will be taken in practical program framework of the local development planning. The purpose of this paper is to identify an empirical city branding framework in Pringsewu, a historical area in Lampung Province. Then this paper will devise the strategies to increase a practical city branding. The research consist of three main phase: desk study, field research analysis and derived recommendation with practical city branding strategies framework. A qualitative approach is used by in-depth interviews with twelve respondent from local community figures, bureaucrats and academicians. Based on SWOT (Strength, Weakness, Opportunity and Threat) analysis of the qualitative data, the empirical programs of city branding in Pringsewu include logo and landmark. That is disengage in local development policy and regional planning, there is a weakness from practical city branding. As the result, we suggest that a bottom-up approach based on local community should be taken to developing a place brand strategies. The three elements in branding strategies accepted for Pringsewu: 1) involved and strengthen city branding in local development plan and strategies, 2) building revitalization of place branding infrastructure, 3) developing local community empowerment. A practical city branding could help a place to attract tourism, visitors, traders and investors then increase economic growth. The city branding can represent the community entity, geographical wideness, local development planning and potential local comodities. It provides a good starting point that would be the right strategies framework and practical approach for local development planning.

Keywords

City, Branding, Strategies, Pringsewu

1. Introduction

Nowadays, cities are forced to compete with each other to gain more tourist destination, workplace, cultural rich place and various forms and activity fields (Kotler, 2002). The competition among cities might be seen for fast changes in technology and the globalization (Kavaratzis, 2005). Cities are tried to search for new ways to promote themselves to be

attractive to created the brand identity that would change the image of the city. City branding was found to be a backbone concept, while city marketing focuses on brand identity and brand image strategies includes construction, communication and management of the city's image to support the needs and expectations of customers (Krantz & Schatzl, 1997 in Purwanto, 2017). For this case, cities develop strategies to support, to introduce and advertise them to "sell" their brand image in the global market. Most of the research study reveal that there are mainly three approaches for promoting cities: cultural events; restoration and promoting heritage; the construction of iconic buildings (Hankinson, 2006 ; Kavaratzis, 2005). In fact, many cities prefer to built construction of iconic buildings to get attention and attraction. The problems of this approaches for other cities are built it without considers branding concept, potential resources, policy and local development planning. The city branding shows the relation of the goals of managing the city's image that needs to be planned. The city branding is not about slogans, logos and promotional campaign, but it will be taken in practical program framework of the local development planning. This research aims to present city branding framework based on an empirical city branding phenomena, involving geographic, economic, social, cultural, and policy in Pringsewu REgency, a historical area in Lampung Province. Then this paper will devise the strategies to increase a practical city branding which involve potential effects on residents with combination of city branding measures and city marketing components. From a practical perspective, these findings could help stakeholder such as government, local tourism organizations and residents to create a sustainable strategy to develop their tourism destination. In this paper, there are three principal questions:

a. Have the city succeeded to forming " Bamboo City" as local branding and provides it within strategic developmental plans?
b. Why is it necessary to strengthen "Bamboo City" branding for Pringsewu Regency?
c. How can " Bamboo City" brand image be created in the social, economic and environmental strategies?

2. Literature Review

City branding is a methods to gain the attraction and establish city recognation (Rainisto, 2003). City branding is created to achieving competitive advantage, in order to increase investment income, tourism industry and community development. The city branding concept was reinforcing local identity and citizens identification with their city and activating all local resources (Kavaratzis, 2004). Nowadays, the branding of places and more specifically of cities, has gained an extraordinary momentum among city officials (Anholt, 2007). City as a brand have a purpose of promoting the existing and potential resources and trying assert their individualit to differentiate themselves from each other within various economic, political or socio-psychological objectives (Kavaratzis and Ashworth, 2005). Many cities and towns is living in a world where competition to start thinking about finding new ways to improve the image of the city with the purpose of attracting visitors. (Kotler et al.,2004).

City branding was a main concept to guide a city marketing strategies. City marketing focuses on brand identity and brand image strategies includes construction, communication and management of the city's image to support the needs and expectations of customers (Krantz & Schatzl, 1997 in Purwanto, 2017). The most important success factor to created city

marketing is the planning group, vision and strategic analysis, place identity and image, public-private partnerships and leadership (Rainisto, 2003).

In addition to the success factors above, to fullfil the challenges in an environment where the practice of city marketing is done, it is political public affairs, global market, regional development and process that coincidence of the marketing process. A framework for evaluating city branding, called the city brand Hexagon, is used to make the Anholt-GMI City Brands Index (Anholt, 2006 in Papp-Vary, 2011). Simon Anholt, a practitioner who is often credited in coining theterm 'nation branding',2 started the Nation Brands Index in 2005 and partnered up with GfK in 2008 (Anholt, 2011). Following the commercial success of Nation Brands Index, Anholt started the Anholt- Global Marketing Institute (GMI) City Brands Index. The current ACBI is surveyed by GfK Roper Public Affairs & Corporate Communications (GfK America, 2013) The survey asks around 40 questions to 20,000 people from 20 countries about 50 cities, and is administered online (Anholt, 2006). ACBI has the six components of the hexagon for the characteristics of cities include the presence, place, potential, pulse, people and prerequisites.

> " Presence [. . .] measures the city's global contribution in science, culture and governance. Place [explores] people's perceptions about the physical aspect of each city in terms of pleasantness of climate, cleanliness of environment and how attractive its buildings and parks are. Pre-requisites determines how people perceive the basic qualities of the city [. . .] such as schools, hospitals, transportation and sports facilities. People [reveals] whether the inhabitants of the city are perceived as warm and welcoming, whether respondents think it would be easy for them to find and fit into a community that shares their language and culture and whether they would feel safe. Pulse [measures] the perception that there are interesting things to fill free time with and how exciting the city is perceived to be in regard to new things to discover. Potential [measures] the perception of economic and educational opportunities within the city [. . .] " (GfK in 2008 in Anholt, 2011).

The six components of the characteristics of city's hexagon is possible to provide recommendations to decision makers to identify potential for intervention or to assess the effectiveness of branding projects. Kavaratzis (2004) showed the frame of a city brand communication through different variables, which have both functional and symbolic meanings. Primary Communication is related to city life or activity support are provided in four categories. There are landscape strategies, infrastructure projects, organisational and administrative structure dan the city's behavior. Secondary Communication for media-generate imagery branding and one of practical promoting programs like indoor and outdoor advertising, public relations, graphic design, logos, etc. Tertiary Communication created a "word of mouth" such a slogan,tagline and verbal branding for city to gain attention and attraction for strengthen city image.

This framework distinguishes between unintentional and intentional communication. Hankinson (2006) distinguishes four branding perspectives, namely; perception of the brand as an entity, brand as a brand communicator, Brand as a relationship, and brand as a major driver of value. Kavaratzis (2006) described the similarity of concepts covering the main lessons of corporate branding and marketing theories. The similarity of the frames are grouped into eight categories as a component of an integrated approach to managing city

branding. These categories are: vision and strategy; internal culture; local communities; synergies; infrastructure; cityscape and gateways; opportunities; communications.

The concept of a sustainable city image is necessary to define visual image, city image and sustainability.The visual image is legible, real and tangible, contains many elements, defined as paths, edges, districts, nodes, and landmarks' (Lynch, 1960). The making of a good city image as planning strategies has become an essential need for cities in order to survive in the global market. Since successful city brand images give a unique brand image through certain strategies, which benefit beyond the physical aspects of city branding. There are different city branding strategies that could be developed based on diverse city development objectives and visions, such as monumental building construction projects, signed architecture, events, media, etc. The city branding strategies are not limited to the promotion of the city image, but it extends more, to change it for the interest of investors, politicians, real estate and construction projects, planners, architects, and other groups. That stand to profit from enhancing the role of their cities to support sustainable development strategies.

3. Methods

This paper explores the concept of city branding from theoretical and practical viewpoints based on "Bamboo City" Pringsewu Regency's branding case study. The research consist of three main phase: desk study, field research analysis and derived recommendation with practical city branding strategies framework. The first phase helped to identify and analyze the basic features of the government regulation, spatial development plans and city development strategies. Later the second phase, field research helped to analyze and collecting information based on existing experiences of Pringsewu branding strategies. It is undertaken by in-depth interviews with twelve respondents were selected for purposive sampling. Respondents including local community figures, bureaucrats and academicians. This research used a qualitative approach to determine branding tools information provided by SWOT (Strength, Weakness, Opportunity and Threat) analysis. This technique for evaluating and to develop a strategic planning based on a comparative analysis in different components of the social, economic and environmental indicators, as well as current and future potential. Then the last stage was concluding the framework of the important elements' in branding strategies.

4. Discussions

4.1. Branding Strategies in Pringsewu

Pringsewu is a regency of Lampung Province, Sumatera, Indonesia. It was spacial development from Tanggamus Regency under The Law of The Republic of Indonesia Number 48 of 2008 on The Regional Autonomy Legislation of Pringsewu Regency in Lampung Province. The regency name "Pringsewu" came from Javanese languange terms "sewu" (thousand) and "pring" (bamboo). From the histories, Pringsewu was a trasmigration development area in Sumatera under Dutch kolonial rule during the early 20th century. The people on Pringsewu are mostly coming from the transmigration program which is the descended migrants from Java, Madura and Bali. The goverment supported and allowed Javanese transmigrant to keep

hold of their way of life including the language and social-cultural objects. It caused the unnamed land with bamboo forestry is called "pringsewu" then officially authorized on October 2008. Based on interview, "pringsewu" related to historical root of islamic development by K.H.Gholib in 18th centuries. He was islamic preacher who came from East Java into Sumatera and Johor, Malaysia. He well known as "*kyai bambu seribu*", a religious leader with respecting, tolerance and anti-discrimination in multiracial and multireligious society during Dutch kolonial. In 1927, he built Jami mosque and *pesantren*a (a place where students live and study Islamic knowledges) to develop islamic education in Pringsewu (Figure 1). It was a historical building in Pringsewu and K.H. Ghalid become street's name.

Figure 1 K.H Ghalib Jami Mosque and *Pesantren* in Pringsewu

(Source: http://perpusda.pringsewukab.go.id/)

"Bamboo City" branding was created by understanding and sosio-cultural histories from Pringsewu residents. The logo of Pringsewu which adopted bamboo philosophy and is listed in Regeant Rules and Regulation Number 11 of 2011. Due to the fact "Bamboo City" branding is not added in Spatial Regional Planning and Long Term Plan of Pringsewu Regency, it is biased toward city branding strategies. Based on reviewing and discussing with respondents, the branding is inconsiderate to the vision and strategic programs. City branding was a main concept to guide a city marketing strategies includes the construction building project, socio-cultural development and economic strategies programs. Spatial plan and development strategies are one of the important success factor to created city marketing (Rainisto, 2003).

In fact, the city branding "bamboo city" was provide in visual media such in logo and landmarks but untoughtfully provides in slogan, tagline or public relation. The branding uncontinous to invest the effort to promoting "sell" Pringsewu with iconic identity in social, economic and environmental project. A city logo is a part of the core concepts that are visible to the consumer (Anholt, 2007). It was strengthening brand equity through increased awareness, recognition, and royalties ofcustomers (Wheeler, 2009). A city logo helps to steer public perception and effectively revives a positive image for the city. Besides, "bamboo city" was unmentioned in Pringsewu"s slogan. It was "Bumi Jejama Secancan" meaning of people holding hand to live a mutual life together (Figure 2). One of the important reasons is a unique

brand identity in order to create a competitive advantage that will be recognized by global market, meaning of the city have a perception and basic knowledge of how the city.

Figure 2 The Logo and Slogan of Pringsewu (Source: https://promgsewukab.com/)

Landmark was designed as statements of the city branding in architectural to generate enormous public interst. Such building have become brands in their own right and being a communication media to provides the city vision and development strategies. Landmark is used to reflect the consistency of the visual appearance for the goverment to strengthen the city branding. There are monument signs in Pringsewu describe a symbols of bamboo philosophy despite it wasnot made of the real bamboo material (Figure 3). Based on concepts and design, it was unfunctional building and lacking to being a succesfull attributes to provides "bamboo city" brand. Nothing building construction and designed provides bamboo as a building material. Bamboo as a building material has high compressive strength, low weight, renewable, extremely versatile and sustain in those locations where it is found in abudance. Bamboo material is used for the construction such scaffolding, structures, householding even high level buiding. It is one of the fastest growing plants than most other species of plants, which is conventionally suitable cultivated in Southeast Asia. Generally the landmark for "bamboo city" brand was lacking in innovative branding features.

Figure 3 The Monument Signs in Pringsewu (Source: Researcher's documentation)

The Pringsewu's economic is dominated by agricultural such as farming, livestock comodities, trading and small scale manufacturing. most farming production initiatives such as grains, fruits and vegetables provide a source of food for people. The livestock comodities came from

fishery, cattle industry and dairy product. There are modern grocery, wholesale market and traditional trading and home based small scale industry to offer as a economic contribution for Pringsewu's domestiic economic growth. A small scale manufacturing came from home based craft industries in Pagelaran District and Gadingrejo District. Unfortunatelly, most of this production has not been promoted largely and only offering for local trading markets.

Supporting cultural industries in Lampung Province, Pringsewu is chosen being host for the 8th and 9th Bambu Nusantara Festivals which is annual international events of Economic Creative and Tourism Ministry (Figure 4). It was held from May 15th to 16th 2014 and then in November 29th - 30 th 2015 at Pringsewu Government Field. Events is opened to all typo of performance including folk dance, folk music, traditional dance group,modern dance and traditional icon culinary. This festival features various product and attractions to develop and highlight bamboo as local potencials of Pringsewu identity. The cultural festivals attract culture tourist to local community events, it have contributed in the development of cultural tourism. Festivals have major impacts to promote the local potencials and the host communities. The local government as well private sectors and society in general have responsibility for tourism development and promotion to global market.

Figure 4 Cultural Events in Pringsewu (Source: Sumber: https://dutalampung.com/)

4.2. City Branding Framework Based on Pringsewu case study

Based on SWOT analysis provides potencials and weakness in "bamboo city" branding in economics, socio-cultural and envirinmental aspects. It can be the main boundary to establise integrated development strategies with preparing long term vision of Pringsewu's future focus on strengthening economic competitiveness. There are also covered and drawn a short term action plan. The process is participative and involving major stakeholders from all segments of society. There are involved place branding in local development policy and regional planning; building and revitalization of place branding infrastructure; developing local community empowerment (Figure 5). A practical city branding could help a place to attract tourism, visitors, traders and investors then increase economic growth. Place marketing

enables a strategic approach to public planning in collaboration with the private sector. The city branding can represent the community entity, geographical wideness, local development planning and potential resources.

The city branding is stimulate a economic competitiveness which reveal advantages for the urban regeneration of the city. It is generally understood as a action plans to build the possitive image of the city and communicate it to global market within various features via visuals, narratives amd events. The objectives of city branding are: to attract tourism, to gain inward investment and to reinforce local identity of the citizens. Generally, city branding is a means to improve external and internal images of city. The city image should be reflected in the spatial structure of the city and being the potencial attractivenes for tourism. The city image marketing enables a strategic approach to public planning in collaboration with the private sector.

City branding consist of spatial and communication components. Primary communication is divided into spatial and non spatial aspecs. Spatial communication aimed to improve the physical quality of the city, such as built functional building which is made from bamboo as main material contruction, create a “bambu cultivation and creative production territory, and establish “bamboo city’ eco-tourism development and infrastructure project. Non spatial communication deals with enhancement of socio-cultural development features, service provision, creating comprehensive community relations and event community organisation. The secondary communication is promotion of “bamboo city” image by interested parties, such as “bamboo city” eco-tourism project, bamboo cultivation activities and create cultural events or festivals to advertise the manufacturing of bamboo products globally. Furthermore, it is provides job opportunities and economic development strategies based on local community. Tertiary communication to create competitivenes, which reinforces “bamboo city” image and reflect it into city slogan, tagline, campaign and advertising to “sell” Pringsewu in the wide range of global market.

The main concept of practical city branding framework in pringsewu is investing in arts and culture being tourism and bussiness development features. Culture is a source of local economic growth, provides advantages as a source of employment and being value added in tourism and business. Culture helps and regenerates cities for creating integrated local economic strategies. The arts and culture features can actually contribute to increasing property values in these place by making neighbourhoods and creative industries more attractive to investors. As a histotical city, Pringsewu can be regarded as a cultural eco-tourism destination to protects bamboo as local cultures and empowers the native community. Cultural eco-tourism is the subset of tourism that is concerned with the authenticity of city’s lifestyle in certain environmental aspects, such as their entity, local comodities, arts, architecture, rituals, festivals and more values which help convey the culture of the city itself. Furthermore, the cultural eco-tourism conserves cultural traditions, promoting local comodities and improving local community welfare.

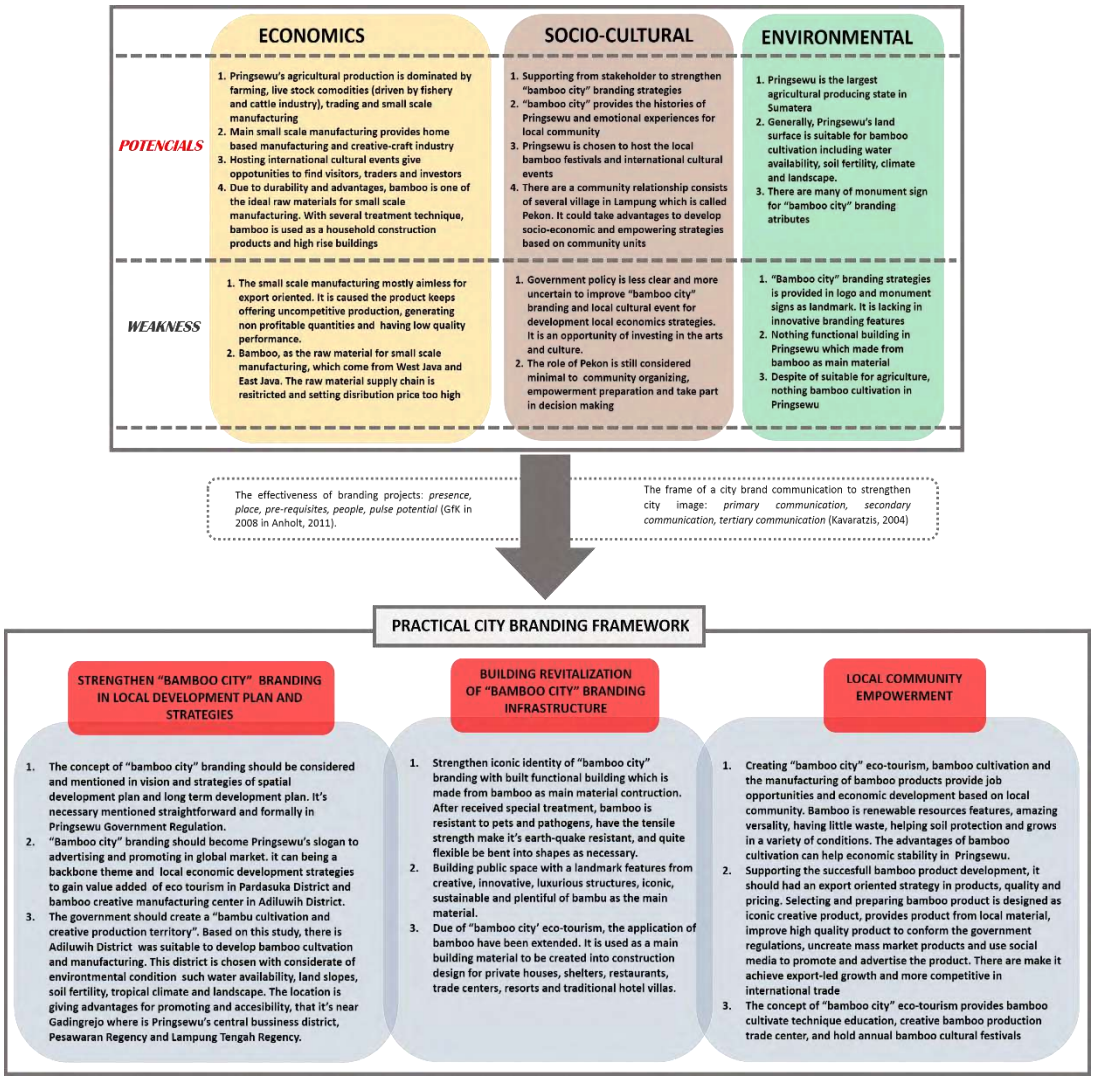

Figure 5 Practical City Branding Framework (Source: Researcher's analysis)

5. Conclusion

Based on Pringsewu case study, "bamboo city" branding strategies is provided in logo and monument signs as landmark. Nothing functional building in Pringsewu which made from bamboo material, that cause the image of "bamboo city" is uncertain and not giving emotion and experiences for visitors. The strategies of "bamboo city" branding is lacking in innovative branding features. The goverment and community supposed to create a new branding strategies for strengthen "bamboo city" in economy, socio-cultural and environmental aspect. The three elements in branding strategies accepted for Pringsewu: 1) involved and strengthen "bamboo city" branding in local development plan and strategies, 2) building revitalization of "bamboo city"branding infrastructure, 3) developing local community empowerment. A practical city branding framework helping a place to attract tourism, visitors, traders and investors then increase local economic growth. City branding was being a marketing strategies

to represent the community entity, potential local comodities, and promoting the image of city in global market.

6. Acknowledgements

The authors gratefully acknowledge the generosity of the research participants in sharing their time, experiences and the support from community organisations, academicians and local governments. This study was funded by The Research Grant Programme from University of Lampung in 2018. This programme provides financially supports for academicians and scientific research to enhance their skills, knowledge, and experience through their own research work. Applications for The Research Grant Programme are reviewed by panels of academicians and scientific research experts in civil engeneering and environmental science fields of study.

Culture capital of the Turkic World

Roman POMAZAN, Alexandr KHVAN

Abstract

The 1001 fairy tale of the East, a cultural capital of Kazakhstan, a center of arts and festivals of Central Asia, a contemporary oasis in Syr Darya valley. There are only a few targets of urban transformation of Turkistan, the masterplan strategy designed by interdisciplinary team of Urban Sustain Architecture (Kiev) and Frame Art (Astana). Turkistan is one of the oldest cities in Kazakhstan, former capital of Kazakh khanate and religious center of Central Asia. This city plays extraordinary role in culture and history of Kazakhstan. It is Kazakh Mecca, former capital of Kazakh khanate, historical pantheon of Kazakh politics. It is also a heart of touristic region of the group of ancient cities on Syr-Darya. Here are located nearly 50 medieval cities of the ancient cultures Soghdiana, Chorasmia and Transoxiana. Kazakhstan state authorities defined key objectives of urban transformation - new administrative center and culture capital of Central Asia and the Turkic World. Turkistan is conceived deemed as a touristic attraction in a row of Samarkand, Bukhara and Khiva. And the city has a potential for it. Key locations for transformations are Old City with UNESCO heritage of Khawaja Akhmed Yasavi Mausoleum and new administrative district of New City.

The project based on the results of field research and assessment of economy, culture, transport, environment, theatre industry of Kazakhstan, landscape and biodiversity, priorities of development and city`s stakeholders. Sustainable development of this project is impossible without: support of small and medium-sized businesses; involving of stakeholders on micro- and macro-levels; reorientation of the microeconomics to services, recycling and science-based industry; legislative and financial support of culture and development of independent creative industries. All mentioned above statements are included in the strategy core. Together with key objectives the strategy proposes scenarios for solving of ecological and urban issues of the microregion of Turkistan. Main of them are water management and water quality, salination and degradation of soils, deforestation and failure of ecosystems, waste management, Aral Sea ecological disaster. The strategy affects changes in view and structure of the historical city center (Old city district) and proposes creation of the new business and administrative center on the actual outskirts of the city (New city district).

Key values:

1. Routes from the Old city to the New city and back. Pedestrian, bus and bicycle routes, trade streets and boulevards connecting Old and New city.

2. History through the centuries. Cultural and historical urban landscape as a basis for proper transformation of the city into a center of the Turkic world.

3. Attractions on every corner. Unique and diverse urban landscape formed by archeological, historical and cultural monuments, pieces of landscape and park design and contemporary architecture objects

4. Turning grey into gold. Proper transformation of urban environment, scientific recovering of the heritage objects, increasing the city`s comfortability for the citizens and tourists.

5. Highlite street edges. Well defined city structure with clear separation between public and private, street and courtyard space.

6. Unite the nature. Recovering of the rivers. Connection of the green belts into a single network of natural landscape which penetrates the entire city.

7. Bioclimate and energy. Using the local advantages of the climate for increasing of the energy security. Energy efficiency and rational usage of resourses.

8. Transportation without problems. Convenient and comfortable public transportation system which takes into account seasonal dynamics of touristic flows. Local electric transport inside the buffer zone of historical heritage area. Quick and convenient connection to the outer world

9. Sustainable implementation.

Project focused on the real opportunities for development, market demand, macro- and microeconomy factors.

The Power of Culture

in Creative Placemaking for Future Urban Economy

Ehsan RANJBAR

Abstract

Based on socio-economic changes of cities and emerging new types of urban public spaces in 21th century, urban design as an interdisciplinary science which concentrates on public domain needs to introduce new lens to analyze and improve quality of contemporary urban spaces. In new literature of urban design creativity has been introduced as a key attribute to create successful places. In this process of creative placemaking for preserving the identity of urban spaces we need to be connected to powerful concepts like culture which is alive from past to future. In other word culture has a unique potential to convey creativity in designing new public spaces. Such approach is effecting on urban economy based on introducing contemporary urban spaces as new tourism destinations. European cities have valuable experience to use the cultural potentials and assets in improving quality of life and urban tourism.

The presentation with reviewing some of European cities experiences, is trying to analyze the idea in Iran as an Asian and Middle-east country, where the experiences of using culture enhancing urban quality have been neglected in the current literature of urban studies. The results demonstrate the power culture in Iranian everyday life of public spaces. Those spaces used cultural-entertainment led regeneration approach have successful from the lens of urban economy for all the city. The most important thread in development of theses space is privatization of urban spaces by rich corporations. According the analysis of these urban spaces and reintroducing the rich treasure of culture in Iran as one of rare alive civilizations, the paper brings up new and integrated model of strategies on using culture-led regeneration approach in future of Iranian cities.

Case Study / Project

An Awkward Dance

Nightlife and Urban Development (Lessons from Berlin)

Benjamin SCHEERBARTH

Abstract

Berlin exemplifies the relationships between (sub)culture, identity, and the emergent knowledge economy like no other. Unique conditions, including the aftermath of two World Wars, a generation-long separation by the Berlin Wall, and a period of failed investment-led over-speculation, created a testbed for alternative cultures, local creativity, and entrepreneurialism. Today, the city is internationally renowned for its cultural diversity and its vibrant nightlife, both fundamental driving forces behind the city's journey to becoming Europe's center for the immaterial economy and new work. The club scene only recently found ways to measure and communicate its social and economic benefits to garner political support. While the city begins to recognize the financial and marketing value of its nightlife, district-level planning administration has been introducing stringent laws, regularly endangering the scene. Despite nightlife's critical contribution to the cultural geography of the city, the local urban planning establishment often perceives both individual clubs and informal entertainment zones as urban hazards to be restricted and controlled. While a few academic voices call on city planners and policymakers to pay more attention to nightlife and its numerous benefits for the city, actors of the subcultural scene are getting involved in urban development themselves. Armed with resilience and resourcefulness stemming from years of practicing tactile urbanism, subcultural actors begin to become authors of locally sensitive solutions. While these projects quickly garner admiration for their inventiveness and popularity, urban planning administration and bureaucracy presents itself as the biggest hurdle to successful implementation. This presentation shares lessons learned from Berlin's ambivalent relationship between subculture and urban planning, applicable to major cities around the world in search of strategies to partner with alternative culture to increase attractiveness and livability. It further calls for a less restrictive and more creative planning practice, which is not afraid of learning from different sources such as the nebulous but incredibly productive urban nightlife.

Forward Thinking on Culturally Urban Imprint in the Contemporary Era

Rejuvenating the Traditional Neighbourhood Values and Characters: An Urban Morphology Review on Qatari Cities

Harini SEPTIANA, Noora AL NAEMA, Amna Khalid J A AL-JABER,
Fatma AL BADER, Lolwa M. Alfaya AL KHALDI

Abstract

Most of the cities in the world are witnessing tremendous changes in their urban landscape, over the last half-century. Under the modern planning regime, the spatial layout organization of a city is very much dictated by the ease of motorized movement priority, in order to cope with increased travel demands as a result of the pressing growth of the economy and population. Today, it becomes planning norm that the primary determinants to define a city's spatial structure are based upon motorized movement patterns, along with other factors such as the population size, urban capacity, and the growth size or scale. The upside of such approach is that the spatial structure becomes more effective and efficient in accommodating a denser population with their infrastructure service, and in anticipating the future expansion. However, the downside will be the tendency to undermining the 'people factor' with their social cultural life and activities.

Without careful thinking and proper planning, one of the impacts of highly prioritized transport infrastructure in shaping the city spatial structure, is the loss of identity. There is a danger of the unique urban culture being diluted and forgotten, leaving 'a legacy' of soul-less cities everywhere, with each lacking any distinct personality or character. With more and more cities seeking to enhance their competitive global position through employing cultural strategies in their developments, it is definitely 'a wake-up call' for cities that have been busy focusing on their rapid modern developments without wisely maintain their local identity and character. Urban identity needs to reflect cultural and historical values, through modern interpretation and not simply by importing foreign templates. Therefore, the urban imprint should be recognized as an illustration of a place's culture and traditions. It demystifies the interaction of built environment and people with all their values, that work together to define an identity. I

n this paper, Qatari cities and towns become the study context as they also experience extreme speed of changes after the discovery of oil and gas in the 1970s, and in current situation, a globalized language of urbanism has overshadowed the then Qatari's unique blend of maritime, rural and urban culture. The world of motorways has become dominant over 'the used to be' tightly-knitted neighbourhoods with intricate alleyways (sikka) and small public open spaces (barahat).

This paper mainly examines the morphology of traditional neigbourhoods that are still intact in the Downtown Doha area and other old towns (such as Umm Slal Mohammad, Al Wakrah and Al Khor) and seeks the opportunity to capture their key principal characters to inspire the modern spatial layout.

The paper comprises of three sections. The first section discusses the evolutionary morphological process of Qatari cities and towns, from rural-village characters to modern spatial layout and its impacts. The second section analyses the traditional neighbourhoods (fereej) as the smaller unit of the city, to elicit attributable principal factors that shape them (i.e. tradition, social cultural values, climate sensitivity, physical pattern) as well as the current adoption of modern spatial layout. And last section elicits the best way forward in defining appropriate urban morphology that fit-well to Qatar context, and in employing cultural strategy to enhance it.

Case Study / Project

Informal entrepreneurs in old districts in central city Shanghai

Qi SHEN

Abstract

In China, urbanization progress is shaping rapidly the urban space and urban society. Megacities are attracting incoming migrant labour and correspondingly external investment from national and international real estate developers. Conflicts between different social groups in space usage become more intensified and critical. Informal entrepreneurs in old districts in Shanghai are mainly the migrant generation released from agricultural sector after the 1980s, rooted in the wide rural land surrounding metropolitan regions. The conflicts between the informal entrepreneurs and the newcomer business developer, between the informal working environment and the new business development projects, indicate a wider conflict beyond the metropolitan level, between the development in the rural land and urban land. This paper focuses on those informal sectors in old districts in Shanghai, including family-owned retail shops, street vendors, recycling, delivery etc.. Informal economy plays a significant role in filling up the blanks in the current economic structure. It offers enormous work opportunities for migrant labour, who are excluded from the labour market due to low-level education and lack of financial resources.

The research consists of two parts. The first part concentrates on the observation survey on the physical environment and working condition of the migrant labour. Study on certain urban spaces is meaningful. It will help us to understand the space features, social functions, and social meanings of those urban spaces. Their meaning is unfortunately inadvertently or intentionally ignored in the public discussion. Which turns into the result of a large-scaled demolishment in old districts and the tearing of native social network in the process of urban renovation. The second part opens a discussion on a progressive urban developmental strategy, aiming to modify the current urban renewal process and soften the effect of business development projects. Small-scaled and gradual progress allows further conservation of the working places of migrant labour and native social network. With a low-key intervention method, to approach an efficient improvement on the physical environment quality. As the ultimate goal, to integrate the native community and migrant workers into the process of urban development and extend the interaction mechanism within the native community into the new projects.

Research Paper

Activation and Revitalization

The Revival Plan of Yihe, Nanjing

Luni SHEN, Shanghai Tongji Urban Planning & Design Institute Co.,Ltd; China

Abstract

Based on the revival planning of Yihe, Nanjing, this paper emphasizes the importance of culture to the metropolis, explores the alignment of new formats and historical spaces, and generalizes several strategies of historical space activation on the respects of culture revitalization, industry innovation and space activation.

Keywords

Culture Revitalization, Space Activation, Industry Innovation, Yihe Road

1. Introduction

As an ancient capital of six Dynasties, Nanjing enjoys a long history of more than 7,000 years of civilization as well as a history of nearly 2,600 years of city construction. Nowadays, as a metropolis in the Yangtze River Delta region, Nanjing also plays a significant role in the Yangtze River economic belt and the eastern coastal economic belt.

Yihe historic conservation district is one of Nanjing's iconic historic spaces. Its history can be traced to" the city plan of Nanjing" of ROC(the Republic of China), which was planned by Henry Killam Murphy in 1929 and was China's first modern urban plan. At that time, this plan presented the zoning planning concept in line with international urban planning. According to the plan, Yihe Road was zoned as the first residential area, the superior residential area.

Figure 1 "The city plan of Nanjing"

Figure2 The plan of the superior residential area

(Source:" The city plan of nanjing ",1929)

Figure 3 Maps of Yihe, spatial pattern is well served (Source: Drawn by project team)

Up to now, Yihe Road continues its use as residential area, and its spatial pattern has been well served. However, although "the features of ROC(the Republic of China)" and "historic conservation district" have become well-known "tags" of Yihe, public's perception of Yihe is still just a static piece of “urban memory”. Its precious culture, historical heritage and unique identity have not been well utilized. In order to drive Yihe’s vitality and enhance its social value, a revival plan of Yihe was conducted by Tongji urban planning & design institute in 2018, aiming at implementing three levels of revival work in the context of historic environment activation.

2. Culture Revitalization

According to the revival plan of Yihe, the first step to do was the revitalization of culture. Several cultural routes were planned and a series of cultural exhibitions would be settled to excavate and expand the cultural connotation of Yihe Road. Through the modern transformation of historical resources, the urban spirit was expected to reflect on a broader level.

2.1. Historical connotations and remains of Yihe

1920s was a period of transition when China began to transform from feudal society to democratic society. At that certain time, ” the city plan of Nanjing” was a big innovation which represented the democratic will as well as the national confidence.

Up to now, within the scope of Yihe Road, there are 287 historic buildings, 225 ROC(the Republic of China) feature courtyards, 200 celebrities' former residences, 32 historic embassies sites and 2 sites of significant historical events. The number of embassies and the density of historic sites are at the top level among those historic conservation districts across the country.

Tab. 1 Historical remains of Yihe (Source: Collected by project team)

Sum	• *35 hectares，303 courtyards* • *225 ROC(the Republic of China) feature courtyards， 74%*
Cultural heritage sites	• *3 of Provincial level* • *38 of city level* • *11 of district level* • *171 immovable historical relics*
Celebrities' former residences	• *200 former residences of celebrities, 66%* • *2 sites of significant historical events* • *5 masterpieces*

Embassies	• *24 embassies sites, 8%* • *63 General's house,21%*

2.2. Current Influence and Popularity of Yihe

From the perspective of Nanjing, there are 750,000 related terms of Yihe on the Internet, ranking the ninth in the ROC(the Republic of China) related attractions. As the first one, the presidential palace has 18,600,000 related terms, 25 times that of Yihe.

Tab. 2 Internet related terms of the ROC related attractions in Nanjing

(Source: Collected by project team)

Attractions	***Related terms***
1. Presidential Palace	*18,600,000*
2. Zhongshan Mausoleum	*13,700,000*
3. Nanjing Museum	*5,820,000*
4. Jinling University (Nanjing University)	*4,320,000*
5. 1912 Bar Street	*2,640,000*
6. Meiyuan New Village	*2,240,000*
7. Central University (Southeast University)	*1,890,000*
8. Meiling Palace	*1,640,000*
9. Yihe Road	*752,000*
10. Jinling Women's University (Nanjing Normal University)	*664,000*

From the perspective of China, the related terms of Yihe is less than 1/10 of Tianjin Fifth Avenue and Qingdao Badaguan. Compared to similar historic districts, the popularity of Yihe is quite low. Its culture value has not been effectively promoted and its influence are far away from it deserves.

Tab. 3 Internet related terms of similar historical districts in China

(Source: Collected by project team)

Key word	***City***	***Related urban plan***	***Time***	***Related terms***
Fifth Avenue	*Tianjin*	*"Material Construction Project for Tianjin Special Municipality city"*	*1930*	*14,700,000*
Badaguan	*Qingdao*	*"qingdao city plan"*	*1933*	*8,560,000*
Yihe Road	*Nanjing*	*" the city plan of Nanjing"*	*1929*	*752,000*
Jiangwan ROC Buildings	*Shanghai*	*"Great Shanghai Plan"*	*1929*	*505,000*

2.3. Strategies of culture revival

As the only mega city in the Yangtze River Delta, Nanjing needs to perform as an innovative source, an open portals and an important strategic pivot in the Yangtze River Delta urban group. It needs Yihe to form Nanjing's culture brand, build its city image and improve its city position. Therefore, just focus on the ROC(the Republic of China) culture is not enough, the revival of Yihe should be considered on a broader view.

(1) Building a culture scene shared by both hosts and guests

It is believed that the retention rate of the original residents is an important criterion for judging the authenticity of historic blocks. At present, the population retention rate of historic blocks in China is around 60%. Based on the situation of Yihe, the revival plan decided to retain 60% of the courtyards as residential places , and to open 40% of the courtyards to the public. Which means, this plan will not only serve the open part of the future, but also serve the existing living places, building a cultural scene shared by both hosts and guests.

Tab.4 Population composition of Historic District in China

(Source: "The Study on Some Issues Related to the Conservation and Planning for the Historic Streets and Areas in China")

Historical distrct	***Original population***	***Planning population***	***Retention rate（%）***
East Liuli Factory Area, Beijing	*3553*	*2092*	*62.39*
East Liuli Factory West Street, Beijing	*2290*	*1370*	*59.83*
Fuchengmen Inner Street, Beijing	*9360*	*8200*	*87.61*
Nanchizi Area, Beijing	*9200*	*6900*	*75.00*
Beichizi Area, Beijing	*8531*	*5577*	*65.37*
Xianyukou Area, Beijing	*23798*	*18488*	*77.69*
Nanchang Street, Beichang Street, Xihuamen Street, Beijing	*6486*	*4000*	*61.67*
Yue city, Shaoxing	*8823*	*7270*	*82.40*
Lu Xun Road, Shaoxing	*3571*	*2618*	*73.31*
Xixiaohe, Shaoxing	*4473*	*2600*	*58.13*
Dagu Ancient Town, Guilin	*5000*	*3000*	*60.00*
Ziyang Street, Ximen Street, Linhai	*8992*	*5800*	*64.50*
Average Value	*--*	*--*	***63.58***

(2) Highlighting key resources

Through putting cultural resources such as cultural heritage sites, celebrities' former residences, embassies, historical events, etc. on the map, scoring each resource according to its value, we got a cultural resource heat map, which showed that high culture heat located in Yihe road, North of Ninghai Road, Beijing West Road - Tianzhu Road, and the key area of culture revival would be Yihe road and Ninghai Road.

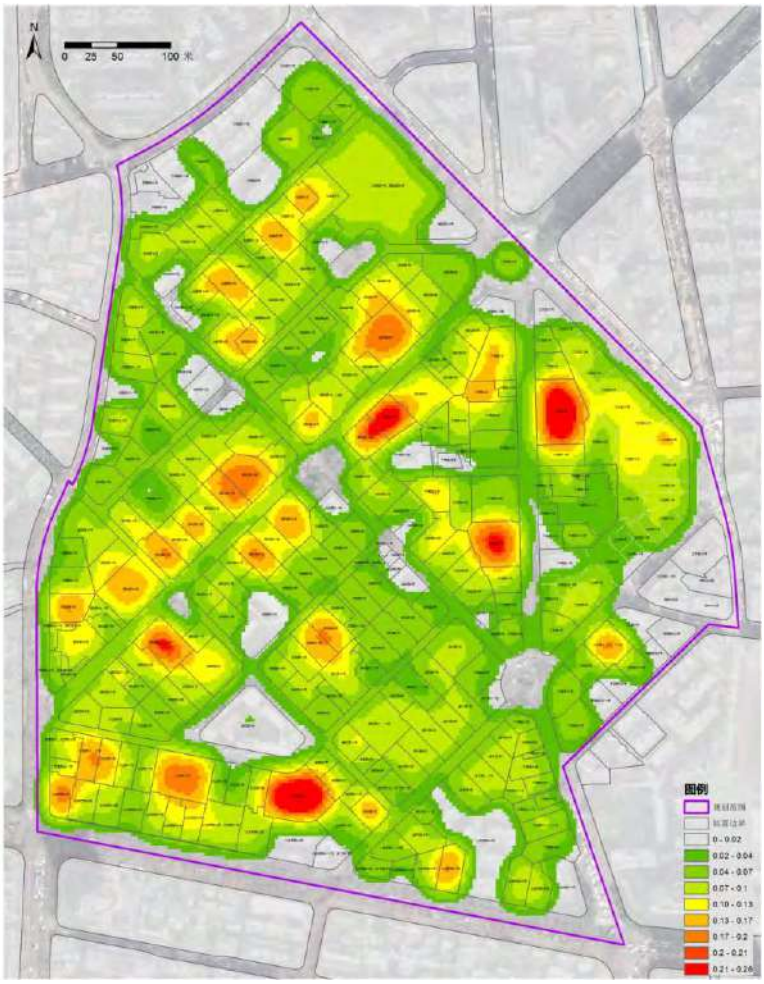

Figure 4 Map of cultural resource heat (Source: Drawn by project team)

Based on the culture heat map, several theme routes were designed according to the distribution of different cultural resource types, such as the series of celebrities' former residences, and the series of embassies, etc..

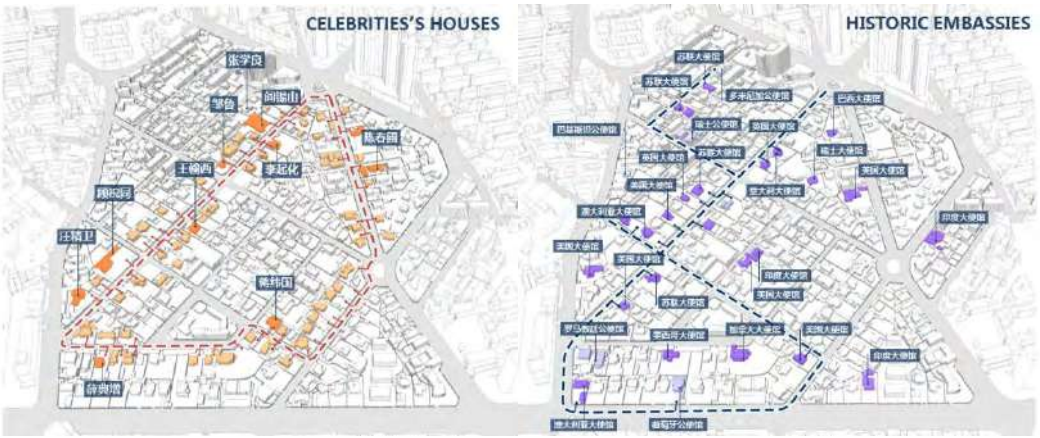

Figure 5 Route of celebrities' former residences Figure 6 Route of embassies

(Source: Drawn by project team)

(3) Injecting international elements

Through introducing international expert apartments, overseas expert studios, international organizations, international business offices, foreign affairs reception services, foreign affairs intermediary services, investment promotion services, etc., Yihe is planned as a "culture parlor" of Nanjing, helping to enhance Nanjing's international influence.

In conclusion, understanding and utilizing the cultural connotation of Yihe is the top priority work of the revival plan. Culture will define the direction of industry, as well as inject the soul into the material space.

3. Industry innovation

Based on a research on the present resources and regional competition situations of Yihe, an industry screening was conducted and the result turned out that art finance and international platform would be the ideal leading industries of Yihe. In addition, culture exhibitions, fashion recreation, residence and other ancillary services would perform as supporting industries, driving the activation of Yihe together.

3.1. Industrial orientation of cultural genes

According to the analysis of Yihe's culture connotation, we summarized Yihe's cultural genes into the ROC(the Republic of China) culture, architectural culture and historical culture.

The ROC(the Republic of China) culture contains east-west integration, cultural prosperity and social progress, its corresponding formats include international exchanges, cultural innovation, artistic creation, technological innovation, etc.; Architectural culture contains the display of the city plan, the form of the superior residential area, and the architectural feature. Its corresponding formats include planning display, residential facilities, architecture design, etc.; Historical culture are concentrated in a large number of celebrities' former residences, historical events, and historical embassies. Its formats orientation includes exhibitions, foreign affairs activities, international offices, etc..

Tab. 5 Formats orientation of cultural genes (Source: Summarized by project team)

Cultural genes		*Formats orientation*
The ROC Culture	*east-west integration*	*international exchanges*
	cultural prosperity	*cultural innovation, artistic creation*
	social progress	*technological innovation*
Architectural Culture	*"the city plan of Nanjing"*	*planning display*
	the superior residential area	*residential facilities*
	architectural feature	*architecture design*
Historical Culture	*celebrities' former residences*	*exhibitions*
	historical events	*patriotic education*
	historical embassies	*foreign affairs activities, international offices*

3.2. Industrial system

Relying on the characteristics analysis of Yihe, an industrial system was organized, focusing on the two leading industries and three supporting industries:

Tab. 6 Industrial system (Source: Summarized by project team)

Leading Industries	*Art creativity*	*Creative design, road show, experience consumption, auction transaction, art finance, fashion order, craftsman economy, digital culture, etc.*
	International exchange	*International Organization Headquarters, International Chamber of Commerce Association Office, Foreign Affairs Reception, Investment Promotion Service, International Business Service, etc.*
Supporting Industries	*Culture Expo*	*Architectural real museum, cultural exhibition exchange, student second class, cultural exhibition, graduation design exhibition, technology exhibition release, festival activities, award ceremony, etc.*
	Fashion recreation	*Immersive cultural tourism, slow living services, specialty businesses, creative dining, cultural entertainment, boutique hotel, B&B, city walks, etc.*
	Residence and ancillary services	*Medical care services, health care, education and training, smart communities, international staff support (international community), etc.*

4. Space activation

After the industrial structure was determined, the next task to do was the activation of historical space. How to adapt and utilize these historical spaces was well considered through analyzing different space demand of different industries. By protecting the heritage ontology and activating the historic space, new connotations for these historical spaces would be created while the historic culture context would be inherited.

4.1. Space demands for different industries

(1)Space demands for art creation

Art creation includes Design office, Workshop, Art show, Art bank, etc.. They have low demands for street accessibility and have strong adaptability to different space types. Comfortable and interesting art space are easily to be build though connecting some small courtyards or transforming some old spaces .

Tab. 7 Space demands for art creation (Source: Summarized by project team)

Formats	*Scale types*	*Area demands（㎡）*	*Building demands*	*Courtyard demands*	*Open space demands*	*Culture value demands*
Design office	*small*	*100-500*	--	--	--	*medium*

	medium	*above500*	*Column-free space*	*Separate / multiple linked courtyards*	*Appropriate open space*	*medium*
Workshop	*Small-medium*	*200-500*	*--*	*--*	*--*	*medium*

Art investment fund (office)	*Small-medium*	*300-600*	*--*	*Separate / multiple linked courtyards*	*--*	*Low*
Experience consumption	*Small-medium*	*100-500*	*--*	*Separate / multiple linked courtyards*	*--*	*Low*
Fashion order	*Small-medium*	*300-800*	*Column-free space*	*Separate / multiple linked courtyards*	*--*	*Low*

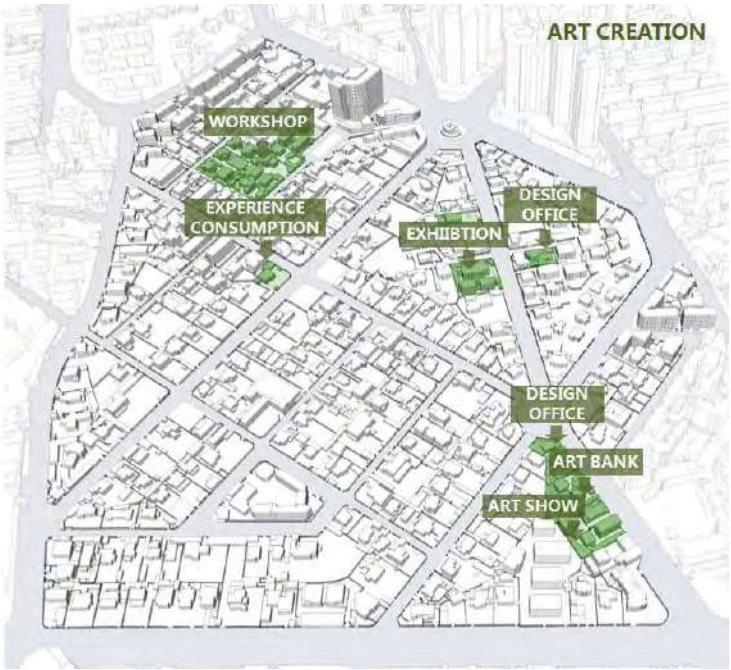

Figure 7 Distribution of art creations (Source: Drawn by project team)

(2)Space demands for international exchange

International exchange includes international organization, international association office, reception service, intermediary service, etc.. They have low demands for culture value but often have strong needs of column-free indoor space or comfortable outdoor sites to hold different types of meetings.

Tab. 8 Space demands for international exchange (Source: Summarized by project team)

Formats	*Scale types*	*Area demands (㎡)*	*Building demands*	*Courtyard demands*	*Open space demands*	*Culture value demands*
International organization, international association office	*small*	*200~1000*	*--*	*Separate / multiple linked courtyards*	*--*	*Low*
	medium	*above 1000*	*Column-free space*	*Separate / multiple linked courtyards*	*Appropriate open space*	*Low*

	medium	*above 500*	*Column-free space*	*--*	*Appropriate open space*	*Low*

Figure 8 Distribution of international projects (Source: Drawn by project team)

(3)Space demands for culture expo

Culture expo includes museum, exhibition hall, etc.. Normally, high culture value places are their best choices. In addition, they also need column-free indoor space or enough outdoor space to hold exhibitions or ceremonies.

Tab. 9 Space demands for culture expo (Source: Summarized by project team)

Formats	*Scale types*	*Area demands (㎡)*	*Building demands*	*Courtyard demands*	*Open space demands*	*Culture value demands*
Museum, exhibition hall	*Small-medium*	*above1000*	*Column-free space*	--	*60%*	*high*
Memorial Hall, celebrities' former residences	*small*	*300~1000*	--	--	--	*high*
	medium	*above 1000*	--	*Separate / multiple linked courtyards*	--	*high*

Figure 9 Distribution of culture expo (Source: Drawn by project team)

(4)Space demands for experiential consumption

Experiential consumption contains leisure Shopping, creative dining, boutique hotel, Cafe, etc..They prefer to locate near offices, museums and other public facilities and usually they have higher remands of space quality.

Tab. 10 Space demands for experiential consumption (Source: Summarized by project team)

(5)Space demands for residential support services

Residential support services includes medical centre, community service, etc..Their location should be convenient for residents. And they also need column-free indoor space to guarantee the organization of community activities.

Tab. 11 Space demands for residential support services(Source: Summarized by project team)

Formats	*Scale types*	*Area demands（㎡）*	*Building demands*	*Courtyard demands*	*Open space demands*	*Culture value demands*
Medical center	—	*above 3000*	*Column-free space*	*Separate / multiple linked courtyards*	--	*Low*
Smart Street Management Center	—	*above 1000*	*Column-free space*	*Separate / multiple linked courtyards*	--	*Low*
International Community	—	*100~500*	--	--	*Appropriate open space*	*Low*

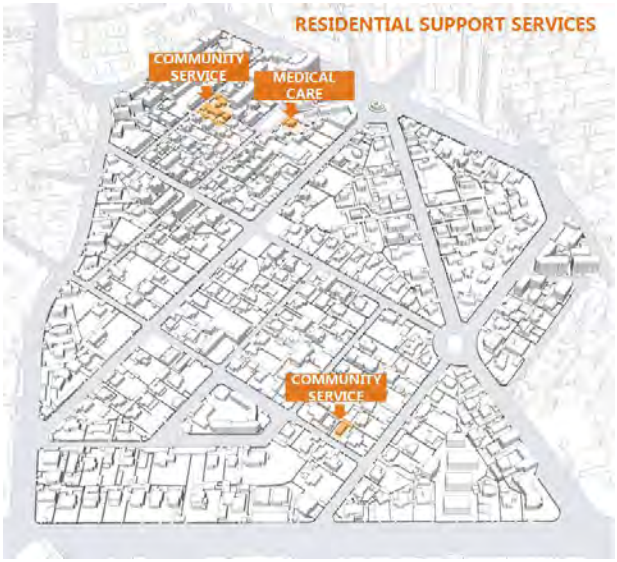

Figure 11 Distribution of residential support services (Source: Drawn by project team)

After all the formats were settled, the plan of public courtyards distribution appeared. 117 public courtyards, 40% of all the units ,that meet the criteria of retaining 60% original residents, guaranteeing the authenticity of this historic district. Most public courtyards located along the regional representative road, such as Yihe Road and Ninghai Road, in order to attractive pedestrians, improve appearance, as well as drive the vitality of the region.

Figure 12 Distribution of public courtyards (Source: Drawn by project team)

4.2. Strategies for space activation

At present, the street interfaces in Yihe district are mostly closed to public. With great privacy and small publicity, each courtyard has its own entrance, a large number of historic resources are enclosed in these courtyards.

Figure 13 Closed street interface (Source: Drawn by project team)

Therefore, we proposed a concept called “intra-wall economy”. On the basis of retaining the interface along the street wall, we planned to remove partial partition wall between two adjacent yards, connect the open space of several courtyard, and then shape the "inner street". As a result, the shared space will be created through the expansion of node space, historical resources will be open to public, together they will drive the “intra-wall economy” and bring vitality to this region.

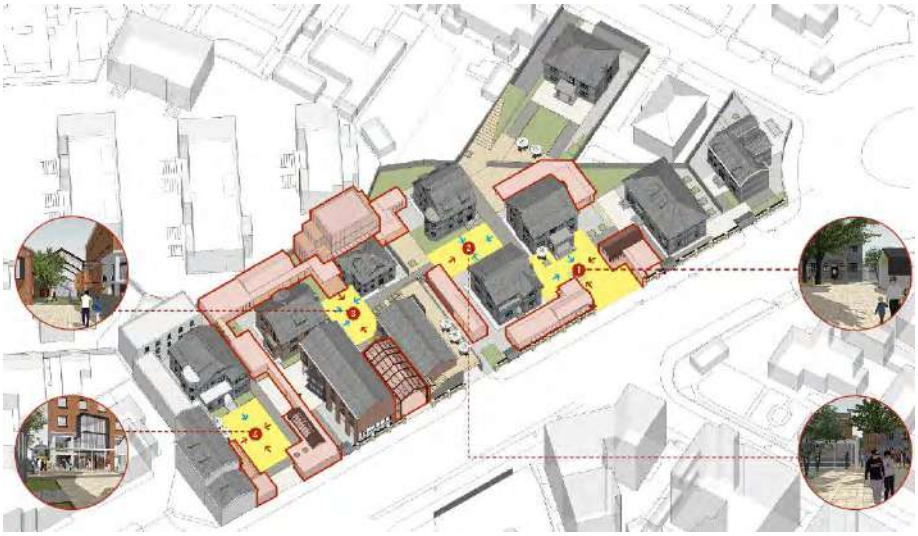

Figure 16 Vibrant intra-wall economy with vitality (Source: Drawn by project team)

5. Conclusion

As the demands for urban renewal in metropolis are growing rapidly, revitalization planning becomes one of the most important types of planning at present. Urban revitalization often involves the conservation and the utilization of historical elements, as well as the alignment of new formats and historical spaces. This paper combs different space requirements of different industries and generalizes several strategies of historical space activation, hoping to provide certain reference for other similar situations.

Research Paper

Recycling industrial heritage: promoting local diversity and cohesion in globalising cities

Milan ŠIJAKOVIĆ, TT Architects; United Kingdom

Ana PERIĆ, ETH Zurich, Institute of Spatial and Landscape Development; Switzerland; University of Belgrade, Faculty of Architecture; Serbia

Abstract

The shift towards knowledge economy accompanied with the flow of people, capital and goods has manifold effects on urban development. On the one hand, cities are becoming more alike: in chasing for profit, global capitalism imposes spatial patterns that lack distinctiveness. On the other hand, network society makes people living in a global village, thus bringing multiculturalism to the fore. Consequently, continuous change and replacement of urban layers lead to the loss of readability, local diversity, and, finally, identity of a place.

To tackle the issue of preserving local identity in a globalising world, we place an emphasis on industrial heritage and the effect of its recycling on a local urban area. As industrial areas keep memory and deep-seated associations for local residents and communities, they play an important role in defining the identity of both the place and its inhabitants. To recycle industrial heritage means to alter obsolete industrial area using its available, useable material, thus making the site suitable for the new function. Recycling differs from both preservation – that persists in maintaining status quo, and the total demolition of an area in order to build it from scratch. Recycling of an industrial site with historic value, thus, make an important contribution to regeneration of urban areas and has a range of social benefits: recycled districts reinforce local cultures, instil a greater sense of pride and confidence among its inhabitants, and retain cohesion in globalising cities. Finally, recycled industrial areas usually become the hubs of creative industry, thus fostering the local economy based on knowledge in contrast to pure tourist areas as manifestations of global consumption.

Keywords

Urban recycling, industrial heritage, diversity, identity, culture.

1. Introduction

Architectural recycling and the broader concept of urban regeneration have usually been linked with sustainable development through its environmental component. However, the relationship between the urban regeneration and social sustainability remains underdeveloped, theoretical and oversimplified when compared to the progress of the environmental movement. If cities are to succeed as engines of economic growth, a balance must be achieved between promoting economic competitiveness, social cohesion and tackling environmental issues (Colantonio and Dixon, 2011).

Socially sustainable development can be defined as "development (and/or growth) that is compatible with harmonious evolution of civil society, fostering an environment conductive to the compatible cohabitation of cultural and socially diverse groups while at the same time encouraging social integration, with improvements in the quality of life for all segments of the population" (Polese and Stren, 2000:15-16). Through their chronological analysis of social sustainability themes, Colantonio and Dixon (2011: 18) came to conclusion that "traditional themes, such as equity, poverty reduction and livelihood, are increasingly been complemented or replaced by more intangible and less measurable concepts such as identity, sense of place and the benefits of 'social networks'". The authors underline that "social sustainability blends traditional social policy areas and principles such as equity and health, with issues concerning participation, needs, social capital, the economy, the environment, and more recently, with the notions of happiness, well-being and quality of life (Colantonio and Dixon, 2011:18).

In the past decade we have witnessed a growing number of projects and research focusing on the positive effects of the architectural recycling on the environment, such as: exploitation of the existing urban infrastructure with no need for new site development; lesser generation of residues in relation to a totally new construction; saving new materials from being used, and cutting the associated environmental impacts of producing and transporting those materials. However, there is a range of positive social effects as well, including the reduction of local social problems and increased engagement and participation of residents, improved image of the local community and the reduction of crime and illegal activities (Colantonio and Dixon, 2011:20).

Colantonio and Dixon (2011) outlined 10 social sustainability dimensions and policy areas in which urban regeneration projects in general can generate potential outputs and outcomes as follows: demographic change (ageing, migration and mobility); education and skills; employment; health and safety; housing and environmental health; identity, sense of place and culture; participation, empowerment and access; social capital; social mixing and cohesion; and, well-being, happiness and quality of life. The authors are highlighting these areas as critical for the social sustainability of local communities and neighbourhoods.

This research focuses on the social component of the sustainable development and the role of the recycling of the industrial heritage in promoting cohesion and local diversity. Therefore, in the following subchapters, the concepts of architectural recycling and industrial heritage will be analysed, while placing a special focus on the social benefits of recycling industrial heritage.

2. Architectural recycling: a preservation through change

The Oxford Dictionary defines recycling as using again. However, while reuse means using again in the same way, recycling implies the element of change, i.e. starting a different cycle. Through the process of recycling, materials are changed into new products. According to Douglas (2006), recycling refers to transforming or re-utilizing a redundant or underused building or its materials for more modern purposes. Viganò (2012) points out that recycling is not just reusing, and highlights that, if we follow the analogy with the organic world, recycling puts forward a new life cycle. Furthermore, Ricci (2012) argues that recycling means creating new values and new meanings and points out that unlike conservation,

which embalms the image of architectural or urban space, when recycling is carried out the change itself is the value. Thus, the fundamental difference between recycling and many related terms is the notion of shift of the original function or purpose. Therefore, in this research the term recycling refers to the process of intervening with the existing industrial building, on different scale, and with different intensity, with the aim of making the building suitable for the new function.

Given that only a small percentage of the total building stock is made up of new works, this inevitably means that existing buildings play a key role in reaching the sustainable agendas. A number of authors (Kincaid, 2002; De Garrido, 2012; Kubba, 2012 and Szokolay, 2004) point out that through repurposing of what already exist, substantial environmental, economic and social benefits can be achieved. Through this process the embodied energy of building materials is saved, the environmental impact associated with excavation, production and transportation of the new materials avoided and the embodied memory of the communities preserved.

Architectural recycling refers to the process of altering the existing building, by using all of its available, useable material, in order to make it suitable for the new function. It is important to mention that unlike other terms which relate to intervention on the existing building, recycling implies the notion of change. Through such a process original building is altered, in order to make the accommodation of new function possible, while using as much of the original buildings' material as possible. This process increases the working service life of existing buildings, and so the rentability of the resources already applied (Cepinha, Ferrão and Santos, 2007). Through this process, extraction, processing and transport of the new material is diminished and the need for new development reduced, which has direct social, economic and environmental advantages. Recycling is also seen as a process which can mediate between the radical stasis, reflected in the rigid rules of preservation, and the radical change which new construction implies.

The practice of recycling is the practice of transformation, i.e. recycling demands change – the right amount of change. Through this transformation a new, viable use is affiliated to the disused building. Thus, recycling cannot be compared to preservation, which persists in maintaining status quo, nor to total replacement of a given building. Through this process a balance is searched for between the radical stasis and radical change.

Architectural recycling helps communities, governments and developers reduce environmental, social and economic costs of continued urban development and expansion. Gosling et al. (2013) highlight the benefits of recycling which include positive contribution to the socio-economic agenda driven by heritage and community interests, extending the economic viability of buildings and reducing maintenance costs. In the following subchapter the concept of industrial heritage will be analysed focusing on social benefits achieved through its recycling.

3. Recycling industrial heritage

The growing realisation of the importance of the industrial architecture consequently lead to the emergence of the 'industrial heritage' concept and to the interest in its preservation. Industrial heritage implies not only the "tangible heritage associated with industrial technology and processes, engineering, architecture and town-planning", it also includes

"many intangible dimensions embodied in the skills, memories and social life of workers and their communities" (ICOMOS, XVII Assemlée Générale, 2011: 1).

Loures and Burley (2012: 226) explain that even though industrial heritage was given a 'formal' document regarding its protection in the Nizhny Tagil Charter in 2003, followed by the Monterrey Charter, "some of the principles enounced in several other international charters and conferences, supported by the Council of Europe (COE), the International Council on Monuments and Sites (ICOMOS) and United Nations Educational, Scientific and Cultural Organization (UNESCO) included somehow the protection of industrial buildings and landscapes".

Industrial buildings and sites are important milestones in the history of humanity. Nevell (2017:6) highlights that today's industrial heritage sites are the embodiment of the development marking the shift "from rural agrarian society to an urban manufacturing society [which] changes (…) the way people live and work around the globe". The profound effects of the industrial development on the landscape, economy and society can serve as an instrument for "improving social inclusion, for nurturing historic roots and achieving sustainability through regeneration" (Oglethorpe, 2017:3).

Industrial heritage holds indisputable value through its ability to create a sense of place and identity for communities. According to Landry (2013), the development of many existing communities is based around its industrial past which acts as a source of memory and a place of anchorage for many communities, demonstrating its intrinsic cultural and social value. The author highlights that historic buildings exude memory and foster stability in a rapidly changing society.

According to Preite (2013), rehabilitation of the industrial heritage has played a fundamental role in the creation of a new urban landscape. Restored industrial building and industrial areas that have been transformed can develop an enormous cachet, as many examples like warehouses converted to flats in London's docklands and in Liverpool's Albert Dock have shown (Binney et al., 1990). According to Stratton (2000: 127), industrial and science museums, located in run-down industrial and dockside areas, "have evolved to be at the forefront of innovative interpretation and, in some cases, to act as agents of inner-city regeneration". Reutilization of industrial buildings secures long-term opportunities that connect directly to the development and redevelopment of the cities which are at the centre of our economic life (Kincaid, 2002).

Buildings in industrial areas act as incubators for small businesses especially in growing sectors of the economy (House of Commons ODPM, 2004). Regenerated industrial heritage sites offer a deviation from a traditional corporate aesthetic that is desired by creative start-ups. In their report, "New ideas need old buildings", the Heritage Lottery Fund (2013) highlights a strong correlation between industrial heritage and creative start-up industries. The report shows that, in the historic places, there is a greater propensity for businesses to be working in the most highly productive parts of the economy – professional services and the creative and cultural sector. It also shows how independent retail and leisure businesses seek to cluster in historic areas of towns and cities – adding to the distinctive sense of place which is key to success in attracting successful businesses. The research shows that historic buildings have a greater concentration of businesses linked to the creative and knowledge economy. It also shows that historic buildings are far more likely to be occupied by the types

of independent non-branded business that give places a sense of distinctiveness, authenticity and diversity.

Cossons (2013: 13) underlines that "across much of Europe, industrial heritage now takes its place as an acknowledged and valued part of the wider historic landscape, in many cases enjoying legislative protection and enthusiastic public support". According to the same source, industrial heritage is being seen today as a symbol of national identity. Recycling industrial heritage helps preserving the character of the community and provides people with a sense of belonging. This process acts as a catalyst of the urban transformation and renewal through its ability to promote cultural distinctiveness and preserve the character and embodied memory of our communities.

3.1. Recycling industrial heritage: a social perspective

Architectural heritage plays a crucial role in supporting cultural continuity, and promoting distinctiveness and identity of neighbourhoods and towns. In a joint report with the British Property Federation (BPF) and the Royal Institute of Chartered Surveyors (RICS), Historic England highlighted the significance of the heritage assets in the formation of a communal identity through their ability to create a sense of place and destination (Historic England, 2017). The Civic Trust points out that there is a great positive contribution which improving the historic fabric of areas plays in restoring local confidence as well (House of Commons ODPM, 2004).

Explaining the social benefits of heritage, Graham and Howard (2008) refer to David Lowenthal's four traits of the past: *antiquity* – conveys the respect and status of antecedence, and underpins the idea of continuity and its essentially modernist ethos of progressive, evolutionary social development; *connection between the present and the past* – represents an unbroken trajectory, established by certain artefacts in emblematic landscapes created by societies; *a sense of termination* – reminds us that what happened in the past has ended; *sequence* – allows us to locate our lives in linear narratives that connect past, present and future. These traits provide familiarity and guidance, enrichment and escape, and "a point of validation or legitimation for the present in which actions and policies are justified by continuing references to representations and narratives of the past that are, at least in part, encapsulated through manifestations of tangible and intangible heritage" (Graham and Howard, 2008: 6).

Historic buildings lend character to an area and have deep-seated associations for local residents and communities (House of Commons ODPM, 2004). Esther H.K et al. (2012) stresses the role of the historic buildings in representing the memory of the society and retaining the attractiveness of the streetscapes, adding character and providing status and image to the neighbourhoods. According to Godwin (2011), local distinctiveness and character is what makes places special and, by association, their people too.

The Parliamentary Select Committee on The Role of Historic Buildings in Urban Regeneration (2004) states that the historic environment has an important part to play in regeneration schemes, helping to create vibrant interesting areas, boosting local economies and restring local confidence. The Committee underlines that historic buildings provide a foundation for the regeneration of many of our towns and cities and that through the regeneration of these buildings a sense of community can be reinforced, an important contribution to the local economy made. The Committee also states that reuse of buildings, which have historic value, can make an important contribution to the regeneration of the urban areas and

underline that reuse of historic buildings have several benefits: Act as a catalyst to the regeneration of a neighbourhood or district; Boos the local economy and create jobs; Reinforce local cultures, instil a greater sense of pride and confidence in a neighbourhood, and; Achieve better use of natural resources.

The Institute of Historic Building Conservation outlines that "historic buildings have been a positive catalyst in achieving structural economic change, attracting higher value investment and jobs, and providing the context for creative, high quality contemporary design in new development" (House of Commons ODPM, 2004: 6). The historic environment plays an important role in creating jobs, attracting tourists, and supporting small businesses.

4. Concluding remarks

Industrial heritage plays an important role in defining the identity of both the place and its inhabitants. Industrial complexes are recognized as the local landmarks and symbols of the cities' vibrant life. The emergence of the 'industrial heritage' concept demonstrates the growing awareness on the importance of the industrial architecture. Industrial heritage is not just about industrial buildings, it is the deep societal history of industrial communities today. Through reactivation and repurposing of industrial buildings cities have transformed and regenerated entire districts. These buildings have become symbols and impetus for urban, economic, social, and environmental change.

Industrial buildings were also responsible for the creation of new and impressive urban identity and they determined the character of neighbourhoods and towns. Simply by the virtue of their size, but also due to their active role in the shaping of communities these buildings are considered valuable and important local landmarks. They have deep-seated associations for the local residents, and they give character and distinctiveness to a neighbourhood. Precisely because of the part industrial buildings played in the shaping the Modern World, i.e. profound changes induced by the industrial revolution, and their social importance as collectors of the embodied memory of our communities, these buildings have an important role in the urban regeneration of towns and cities. Through the recycling - 'preservation through change', of industrial buildings, a sense of community can be reinforced and the important contribution to the local economy can be made.

Industrial heritage is of manifold significance in terms of our cultural identity, social practices, and contemporary industry. Given that image and branding are crucial for the social regeneration of city areas, recycling of industrial heritage sites offers a unique opportunity to add value to a local community. The recycling of these buildings acts as a catalyst for the improvement and regeneration of districts and wider urban area as well. In this way new jobs are created, local economy is boosted, local cultures reinforced and better use of natural resources is achieved. Furthermore, recycling industrial heritage can be used as a form of unique branding that could inspire a sense of local pride through the creation of cultural and heritage symbols which can act as centres of community life.

Research Paper

COMMUNITY CAPACITY FOR CREATIVITY BASED RURAL DEVELOPMENT IN A DEVELOPING COUNTRY

Case Studies From Indonesia

Tubagus Furqon SOFHANI, The Department of Regional and City Planning, SAPPK, Institut Teknologi Bandung;Indonesia

Fikri Zul FAHMI, The Department of Regional and City Planning, SAPPK, Institut Teknologi Bandung;Indonesia

Dika Fajri FIISABIILLAH, The Department of Regional and City Planning, SAPPK, Institut Teknologi Bandung;Indonesia

Brigitta Sadnya WULANDARI, The Department of Regional and City Planning, SAPPK, Institut Teknologi Bandung;Indonesia

Abstract

This paper aims to investigate the extent to which a rural community develops a capacity to support the establishment of a local creative economy despite various limitations. This study employs qualitative research methods in examining two villages in Indonesia, namely Kasongan and Krebet. Our findings show that the community capacity and actor networks potentially spark the development of rural economies. Local communities in both cases have utilized cultures and traditions as creative capitals, which were commercialized through communal entrepreneurship and mobilized by an organized network of creative actors. Social values, namely a strong sense of belonging, high shared values and strong emotional connections, are found to be the key factors that foster creative potentials, entrepreneurial capacity, and capacity for mobilization of local resources within the rural communities.

Keywords

Creative economy, community capacity, rural development, Indonesia

1. Introduction

Several studies have shown that rural areas might not be perfect places for the flourishing creativity (Stam et al., 2008; McGranahan & Wojan, 2007; Rantisi et al., 2006). However, there is evidence that development strategies emphasizing on the creative economy and creative industries have developed rural regions very significantly (Friedland, 1982). For instance, some research has shown that rural cultural resources, crafts, community participation and entrepreneurship have played a role in improving well-being in rural areas (Bell & Jayne, 2016; Scott et al., 2016; Ray, 1998; Balfour et al., 2016), and rural resiliency (Roberts & Townsend, 2016). Creativity can also serve an alternative source of endogenous

development in rural areas, in that local communities can independently improve their well-being by involving local initiatives conducted by a set of various actors in rural areas (Turvey, 2006). However, the idea of the extent to which a rural community develops a capacity to direct creativity strategies still receives a limited attention, based on community capability and well-being perspective (Scott, 2012; Sen, 1980) that serve a key for endogenous development, especially in a developing country such as Indonesia.

This paper aims to fill the knowledge gap by examining the extent to which and the ways in which a rural community develops a capacity to support the establishment of a local creative economy in Indonesia. This contributes to addressing the question of how the idea of the creative economy is suitable for rural contexts, especially in developing countries. Two rural areas in Yogyakarta Region, Indonesia, namely Krebet and Kasongan, which are known for their creative and cultural products, are chosen in this study.

This paper intends to feature developing countries such as Indonesia as the ideal site for the implementation of a creative industry policy (Fahmi & Koster, 2017). Even though the advanced economic sectors are concentrated in larger cities, evidenced by the presence of creative industries in the areas, this study can initiate a discussion concerning the government's attempts in promoting creative industries in less urbanized areas and the ways these can be generalized in every region in the country. Further, this paper contributes to revealing how creativity in a rural area has been manifested from interactive networks and endogenous capacities to promote rural development (Balfour et al., 2016; Scott et al., 2016; Esparcia, 2014; Murdoch, 2000; Sen, 1980).

2. Literature review on rural community capacity for creativity based development

The creative economy is an economic sector that uses knowledge as the input and produces innovation (Florida, 2002), in a form of creative products with economic value (Howkins, 2002). Early works on 'creative economy' have greatly addressed the urban-based economy as a key strategy to generate economic development (Landry, 2000; Florida, 2002; Florida, 2003; Landry, 2005). The notion has gained some criticisms toward its 'identikit' solutions (Montgomery, 2005; Peck, 2005; Bell & Jayne, 2016) and its relation with regional disparities and social exclusion issues (Florida, 2017; Scott, et al., 2016; Stark, et al., 2013; Peck, 2005). Moreover, Jayne (2005) also identifies the lack of regional and rural perspective in the concept.

The interplay between creativity, the economy and place is conceptualized by various terms: the 'creative class' (Florida, 2002), the 'creative economy' (Howkins, 2002), the 'creative industries' (Hartley, 2005), the 'creative city' (Landry, 2000), and the 'creative milieu' (Cooke & Morgan, 1994). Those terms focus on their heavy orientation toward the application in the urban-based development. Moreover, in the Indonesian context, the term of creative industries is entangled around 'creative' and 'traditional cultural industries (Fahmi et al., 2016) because of the focus of national policies on creative industries which combines art and cultural elements. Therefore, scholars and policymakers have wondered as to what extent this concept is suitable for the rural domain, especially in developing countries.

Many studies have invested some ideas towards rural creative industries. Some rural regions have successfully shown that creative industries in these contexts can reshape their

economic structures and change their place-image (Bell & Jayne, 2016). Some studies demonstrate that a rural area would be "a place where the creative economy is differently manifested and articulated from the now standard 'creative script' based on cities" (Bell & Jayne, 2016: 210). Several characteristics, distinguishing rural creative economy with urban 'creative minds', are presented as follows. First, rural actors tend to be culturally, sociologically, and economically homogenous (de Silva-Sanigorski et al., 2010), unlike the thesis of Florida's creative class. Second, the lack of access still serves a major challenge in developing creative economy in rural areas (Quang Dao, 2004). Third, rural actor networks are considered stronger (Balfour, et al., 2016; Esparcia, 2014; Murdoch, 2000), compared to those of urban actors'. Considering these distinctions, the rural creative economy requires a different look and consideration with the urban 'creative minds', since local and interactional context in the rural networks can stimulate the creative milieu (Balfour et al., 2016). There is only a few research published on how interactional networks of homogenous rural actors can strengthen the community capacity to flourish creativity for rural development (for instance, Balfour, et al., 2016; Esparcia, 2014; Murdoch, 2000).

2.1. Creative potentials

Creativity is a wide and elusive concept, ranging from technological creativity (invention), economic creativity (entrepreneurship), to artistic and cultural creativity (Florida, 2002). However, it is still unclear which type of creativity is suitable for rural contexts, especially in a developing country, such as Indonesia. The 'creative economy' and 'creative industries' were mostly originated from individual creativity. In general, they seek to develop new ideas, use new technologies and focus on intellectual property, which is then related to the copyright mechanism (Howkins, 2002; Hartley, 2005). Rural artists, in the common art-based industries, might align with this concept in that they exploit their intellectual creativity as their own property and always emphasize on the creation of new knowledge (Balfour et al., 2016), even though they have more limited access to financial or educational assets (Grodach, 2011). They are also able to spread the knowledge to the community and include them in the creative industry to develop the art-based community initiatives (Balfour et al., 2016).

De Beukelaer (2014) has found that some developing countries are rich of cultural traditions that could serve materials for creativity. For example, in most developing countries, creative industries are largely craft-based (UNESCO & UNDP, 2013), which generally are strongly attached to culture. Fahmi, et al. (2016) have also found that rural areas in Indonesia, and possibly in other developing countries, have more potentials for promoting 'creative industries' based on tradition or culture. Craft-based industries can originate from strongly attached knowledge and value in local tradition and custom among rural communities. Different from individual creativity, this cultural value is common goods, which cannot be claimed as an individual property (see also De Beukelaer, 2015; Boateng, 2004). These craft-based industries also differ from other creative industries in that they might use new technologies. However, it is often unclear whether they are concerned with developing new ideas, designs or motifs. They are usually strongly attached to traditional values as they have existed for years and knowledge is passed down through generations. Creative potentials of rural areas can take form either as individual or communal creativity. In other words, both 'modern' creative industries and 'traditional' cultural, craft-based industries can flourish in rural areas.

2.2. Entrepreneurial capacity

Entrepreneurial capacity, in relation to the concept of the creative economy, relates to the skills and attitudes to transform the creative product into an 'economically valuable' product in the market, to identify the economic opportunity, and to develop the efforts into a more stable industry (Balfour et al., 2016; Mitra, 2012). This factor is needed to translate arts-based and/or cultural value product into a valuable product since not all creative potentials can be commercialized. Even though the relationship among entrepreneurship and innovation was once in a bad term, viewed by the classical perspective (Schumpeter, 1934), the current thought of creative economy has shown that the creativity-based development can benefit rural creative professionals (McGranahan et al., 2011), such as rural artists and art-based grassroots businesses.

In a classical view of entrepreneurship literature, individuals or firms would maximize, identify or create an economic opportunity to sell their products. However, in a rural context, the supportive context of entrepreneurship is culturally situated (Balfour et al., 2016). A collective mechanism exists to allow the collective entrepreneurship since the product itself is culturally attached to the community (Julien, 2007). Therefore, an entrepreneurial context does matter (Balfour et al., 2016) to create job opportunities and increase income and should thus be collectively constructed.

This ability of the community to 'commercialize' the product of creative economy needs to meet some conditions, such as: (1) the cultural support of the community through interactive networks (Balfour et al., 2016), and (2) the establishment of a potential market and supporting amenities (Florida & Jackson, 2010) to access some necessity resources (Fahmi et al., 2016). By this way, rural creative industries can easily reach out their potential markets and resources and become more sustained.

2.3. Social values

As collective entrepreneurship needs to be built through the interaction networks within rural community, social values emerge as other factors. To collectively work upon the rural creative industry, a relational network would become more crucial since the interaction provides the foundation of innovation systems (Esparcia, 2014). This makes creativity can be produced through the interactional networks of actors within the rural community.

Innovation, as a part of the creative economy, can also occur if actors combine and integrate their knowledge to collect resource and produce innovative ideas (Dammers, 1999). A sense of community, shared values, and the emotional connection can be built upon regular interactions within rural community (horizontal network), as well as between residents and the state (vertical network) (Balfour, et al., 2016; Tonnies, 2001; Murdoch, 2000). Moreover, networks can trigger another component of social capital, trustworthiness, to facilitate voluntary cooperation and collective action (Putnam, 2014; Ostrom & Ahn, 2003), through actors' networks. Social values, after all, constructed by the complex process of networks involved in the formation of collective action (Miao et al., 2018).

Networks have manifested itself in the form of social and civic participation (Anwar-McHenry, 2011). Civic participation represents a formal interaction and community action-based participation, while the social participation serves informal networks of rural community in all social activities. It is therefore necessary to build both types of participation to support the rural creative economy since these foster collective action, benefits

communal well-being and increases social capital (Torjman, 2004). Collectivity can foster colaborativeness, thereby forming a creative-based economy system in the rural community needs to utilize community bonding (social interaction) and community bridging (civic engagement).

2.4. Capacity for mobilization

An individual breakaway from collective creativity due to the complexity of exogenous forces can challenge the networks of creative actors (Balfour et al., 2016; Gray & Lawrence, 2001). Moreover, collective efficiencies (economic and technological advantages) can remain latent unless they are mobilized by joint action – a conscious cooperation among creative businesses (Phelps & Wijaya, 2016). Therefore, a concern regarding local agency relationship has emerged. There is no certainty as to what extent a rural community can shape their own future due to those forces (Measham et al., 2012), even though they already have a strong interaction network. Thus, an action to prevent individual breakaway and unveil collective efficiencies in the social networks is needed, by either a formalization of the interaction or an organized network of actors (Phelps & Wijaya, 2016; Schmitz, 1999).

Structure, mechanism and function (Miles et al., 1978) of the community, therefore, are the important elements. As described by Chaskin et al. (2001), a community organization can provide access to resources and opportunities, foster development of human capital (in a form of human and communal creativity), and create commitment of community. These abilities, in a rural creativity context, can also perform in an organized network even without a formal institutional framework, such as community organization. In conclusion, establishing the capacity in mobilizing resources of creative industry can build the actors' networks to be more resilience and serve creative processes (Balfour et al., 2016).

3. Methodology

In constructing a framework for analyzing the community capacity in the rural creative economy, we consider the concept of institutional capacity by Healey (1998) focusing on three dimensions: knowledge resources, relational resources, and mobilization. Such resources might be contextually differed in various institutions, but efforts to access these capitals are central in one community/organization to gain influence in mobilizing community strategies towards one mutual goal (Healey, Urban Complexity and Spatial Strategies: Towards a Relational Planning for Our Times, 2007). Thus, this concept would be fit as an analytical framework of this study since this study also aims to elaborate community capacity to generate rural creative economy as means towards rural development. This study tries to contextualize these dimensions into several factors, including: (1) creative potentials and (2) entrepreneurial capacity, (3) social values and collaborativeness, and (4) capacity for mobilization.

To identify the extent to which and the mechanisms through which the community capacity supports the development of the creative economy in rural areas, the qualitative research approach is employed (du Toit, 2015). Two cases were employed, including some villages in Bantul District: Krebet and Kasongan, which have performed collective strategies for promoting local arts and craft products. Interviews were conducted with local entrepreneurs, local government officials and other local community actors to collect information related to local community capacities. To complement these interview data,

related policy documents were collected and field notes were created as an extensive overview (Silverman, 2015). Analysis was done through narrative and content analyses (Silverman, 2011; Krippendorff, 2004) to describe the mechanism of interactional networks and community capacity based on the derived factors in supporting the rural creative economy.

4. General overview

To better understand how community capacity and creativity-based rural development are situated in both cases, in the following we present a general overview of Krebet and Kasongan villages.

4.1. Kasongan

Kasongan is located in Kasihan, Bantul District. Kasihan is dominated by working age population (almost 71% of the total population). This demographical composition can be a great potential for Kasihan, particularly for Kasongan, to develop creative economy strategies. Kasongan, specifically, is assigned to be a socio-cultural strategically area (*kawasan strategis*) and a manmade tourism area during 2010-2030, as this village has unique culture-based products: handicraft souvenirs which have become a 'trademark' of the area, especially pottery (*gerabah*). With this commodity, the local community has developed a cultural center. Tourists are mostly attracted with the making process of pottery and the natural-socio-cultural atmosphere of the Kasongan. Today, there are 582 pottery entrepreneurs and almost 8,000 pottery handcrafters (makers). In addition, Kasongan has obtained the award "One Village One Product" from the Japanese government for its success in initiating the rural art-based industry in 2011.

4.2. Krebet

Krebet is located in Pajangan, Bantul Regency. In the past, most people in this village worked as farmers and factory workers. However, this main occupation has shifted to the batik wooden-mask industry. The changing job preference has indeed transformed the local community's economic and social structure, in that most residents have developed studios and houses in which they make batik. Most women paint batik on the mask, while most men are in a more 'rough work', such as preparing local materials, sawing and sculpting the woods and finishing the products. Nowadays, there are 55 entrepreneurs and 500 handcrafters (205 of 248 households) who work for this batik wooden-stuffs industry and many surrounding villages also follow Krebet in developing the industry.

5. Analysis

In this section, we present the results of the qualitative analysis, which was focused on four layers that potentially influence the way in which the rural creative-based economy has developed, including creative capital, entrepreneurial capacity, social values and organizational capacity.

5.1. Creative potentials

Creative potentials can be created either from an individual's idea or knowledge and be generated by interactions among creative actors. The analysis of interviews shows that in

both cases creative capitals have similarly been generated from an individual initiative which was then spread across local people.

The making of pottery has been a local tradition in Kasongan since the early 19th century, as the local community started leaving the agricultural sector. The interviewees mentioned Kyai Song as the one who had the idea of abandoning agriculture because the crop products had to be handed in to the Dutch colonialists. He then produced household stuffs (for kitchens and living rooms) made of clay in 1825-1830 and later persuaded his neighbors to do so. A shift of local jobs from farmers to craftsmen thus took place. Another person, Saptohudoyo, who came from outside Kasongan, introduced local art flavors to the pottery products, thereby making these more artsy. The local community has then built its knowledge on making potteries, in that the knowledge is passed down through generations.

The case of Krebet showed a similar pattern demonstrating how the creative capital can develop the wooden-stuff industry since the mid-twentieth century. However, the reason behind the development of this industry was quite different compared to Kasongan because the agricultural sector was no longer considered profitable due to topographical and geological conditions. Therefore, a local resident, Guninjar, learnt ('nyantrik') how to make wooden-masks from Mbah Warno in 1972 (natah and nyungging). He then succeeded to earn money from this product, which then immediately became popular. His neighbors were interested in learning how to make the wooden-masks. Similar to Kasongan, other innovative ideas have followed the initial movement of the wooden-mask industry. This product was initially produced with a plain design and had a rather low economic value. Nevertheless, some people have developed a more economically valuable product by introducing batik to the product and expanding the product variation with other products, such as wooden-wayang (puppet). Therefore, the products have transformed into a highly valuable product and economically profitable, similar to potteries in Kasongan.

On the one hand, we found that the idea of some people in adding arts and cultural values to potteries in Kasongan and wooden-stuff in Krebet shows that creativity started from an individual act which has then been diffused to other local actors (see also Balfour, et al., 2016). In line with Howkins (2002) and Hartley (2005), these individual acts appear to be the starter for the 'engine' of the rural creative economy. On the other hand, it is clear that in the making of these products, the communities have been benefited from the existence of local arts and cultural values. Local culture values, in the form of motifs, stories, local wisdom and philosophies, have deeply immersed into these creative products. However, these values then have been completed by the "creative acts", enacted by each local creative actor, in the product and motif diversification, kind of used materials, technique of production, finishing, and marketing. By this way, both cases show how local knowledge has inspired creative actors to utilize it and transform it into creative products, using their own creative potentials.

As such, communal creativity has played a crucial role in the development of rural creativity-based development in both Kasongan and Krebet. Different from the nature of creative industries in urban settings, especially in the developed world, in which individual acts are central to developing creative products, crafters in Kasongan and Krebet take advantage of collective goods, particularly local tradition, in creating their products (see De Beukelaer, 2014; Fahmi et al., 2016).

In conclusion, we found that creative potentials in both cases have been formed through collective processes and by collective values, particularly local tradition, and these have helped construct the cultural identity of these craft villages. Further, individual creative acts cannot be disentangled from local collective knowledge and in fact, as these acts become an integral part of communal creativity (see Boateng, 2011). This finding supports the premise that the creative economy and creative industries in rural areas have different characteristics from those in urban regions. This can be associated with the fact that in a developing country, such as Indonesia, local tradition has a strong influence in the development of cultural products.

5.2. Entrepreneurial capacity

Creative potentials need to be transformed into an 'economically valuable' product so that it can create job opportunities and increase incomes. Entrepreneurial capacity, either from individual or collective actions, needs to be utilized in terms of rural creative economy development. Both cases show that different contexts and entrepreneurial capacities have resulted in different ways of how the creative economy has developed.

As explained, in Kasongan, Kyai Song persuaded the local community to make pottery and later Saptohudoyo introduced local art motives into pottery product. The integration of the arts increases the economic value of the products. Saptohudoyo also turned out to be the first local artist that exported the product abroad. He was the first entrepreneur in Kasongan who recognized the market opportunity of pottery since he knew well that foreigners had a great interest into local art products. Therefore, he built the market networks of pottery with another country, such as Australia. This successful story had reached to the ears of Minister of Domestic Affairs at the time.

The stories of Saptohudoyo and Kyai Song in Kasongan have shown how a capacity of an individual creative actor can create an economic opportunity to sell the products and take advantage of this development in a rural context (Balfour et al., 2016). The case of Kasongan suggests that individual entrepreneurship became the first key to unlock the development of the rural creative economy. As described, other local residents have followed Saptohudoyo to participate in developing the pottery industry. Saptohudoyo had spread out the knowledge to manage and produce potteries more commercially. This individual entrepreneurship has then grown into communal entrepreneurship, in that the supportive context of entrepreneurship is culturally situated and attached to the community (Balfour et al., 2016; Julien, 2007). Local residents have collectively learned and shared the knowledge to each other about how to take advantage of economic opportunities of the product, to overcome the limitations and problems in business and to develop the local creativity so that these businesses can thereby sustain.

Further, a policy on tourism villages from the central government in the early 2000s had helped stabilize the development of the pottery industry in Kasongan. Saptohudoyo, with other actors, had built the networks to utilize and translate the policy in developing the rural creative movements. Another aspect that supported this development was the availability of art formal education in the level of high school and university near Kasongan. These education institutions have helped build and invest art knowledge in supporting the local creative economy. Currently, the artsy pottery has reached local, national and international markets (e.g. Australia and Europe).

Meanwhile, the case of Krebet shows a different story since it had a different entrepreneurial capacity. The pioneer actor, Guninjar, recognized the economic value of wooden-mask for the first time as he had learned from another person and had practiced to 'commercialize' the product. He was not the one who maximized the economic opportunity of wooden-masks since he only designed a plain mask without any aesthetic improvement. Nevertheless, his products were popular at the time and, therefore, he created market networks since then at the local and regional level. This can also be regarded as an entrepreneurial capacity at the individual level. However, he was not the one who managed the local community to participate in the industry. Other neighbors were inspired and invested their efforts to be involved in the production of wooden-stuff. Other actors, namely Kemiskidi and Windarti, were those who expanded the product variation and added more aesthetic value to the wooden-masks. Therefore, the three main actors in Krebet, Guninjar, Kemiskidi, and Windarti, used their own individual entrepreneurship to maximize, identify and create the economic opportunity of these cultural products in the context of rural development (Balfour et al., 2016). As other residents have followed those individual entrepreneurs to participate in developing the batik wooden-mask industry, job opportunities and new sources of income have been created. Similar to the case of Kasongan, individual entrepreneurship has transformed into communal entrepreneurship, which is culturally attached to the community (Balfour et al., 2016; Julien, 2007). The residents have collectively learned how to catch economic opportunities of the products, overcome the limitations and problems in business, and develop the local creativity so that the creative businesses can sustain.

Unlike Kasongan, the wooden-stuff industry in Krebet only had potential market at the local and regional level until the end of the twentieth century. A policy on tourism village from the national government in the early 2000s had also helped to boost the development of batik wooden-mask industry in Krebet. The potential market has just expanded to national and international level due to this policy. This village did not have any other supporting systems, such as art formal education as Kasongan did, so that there was no knowledge investment to help the progress of creative economy. Therefore, the development of the batik wooden-mask industry in Krebet is also established by local entrepreneurial capacities (individual and communal entrepreneurship, supporting amenities, and potential market). However, this was not found in Kasongan.

To sum up, the findings indicate that local entrepreneurial capacities have contributed to the development of the villages as the production centers of those cultural products. An individual entrepreneurship became the first key to support the industry. However, it is found that in these rural contexts, this individual entrepreneurship grew into a communal entrepreneurship in which other actors learnt and collectively shared their entrepreneurial knowledge, which is culturally situated and attached to the community. Both cases have also shown that this distinctive condition different from the entrepreneurial actions and supporting amenity could result in different capacities to take advantage of the economic opportunity in expanding the potential market for the industries.

5.3. Social values

As collective creativity and entrepreneurship need to be built through the interaction networks within the rural community, social values appear to be another factor that a rural creative industry needs. As mentioned in Florida (2002), the development of the creative

economy requires a condition that establishes an art atmosphere for the creative actors to meet and interact with one another because they have sense of belonging to the place and to one another. Therefore, social values and collaborativeness can foster the development of creative actors' networks which can benefit rural creative economy, as what happened in both cases.

As explained, the development of the pottery industry in Kasongan had grown from individual creative acts into communal creativity and from individual entrepreneurship into communal entrepreneurship. The knowledge of these community businesses had been spread out through neighborhood networks. First, Kyai Song had tried to persuade the local community to quit being farmers and to become craftsmen. Due to the neighborhood relations, this succeeded to result in the job shift of Kasongan because many people were interested and had developed the products to become more economically valuable. It appears that he used the established trustworthiness and social interactions to develop the creative economy, which dynamically grew and progressed at the neighborhood level. Afterward, Saptohudoyo used a different approach to develop the industry. As he was not originally from Kasongan, he tried to show how to be successful in the business not only in the local level, but also in the international markets by using local traditional knowledge (traditional art motives). His success story had attracted many neighbors to come and to learn from him and he also started collaborations with the neighbors.

With these collaborations, local networks have evolved within the community and this helped 'formalize' the pottery industry as the basic economic sector of the community. As such, interactions related to the pottery industry, which were initially developed through social bonding, have transformed into a formal network of civic engagement (see Anwar-McHenry, 2011), concerning the management of the pottery industry. These interactions have also made the local norm systems to allow shared power and collaborativeness. Some key leaders have participated to provide rooms for collaborative process and collective action in relation to the creative economy. These actors also tried to expand the networks with other external parties, such as local government and other creative actors, by organizing Kasongan festivals from 2011-2013. Therefore, this case shows that networks can enable social capital to grow within the local community (Putnam, 2014; Ostrom & Ahn, 2003) and this stimulates the foundation of an innovation system (Esparcia, 2014).

The case of Krebet showed a similar situation in that the development of the batik wooden-stuff industry has evolved from individual creative acts into communal creativity and from individual entrepreneurship into communal entrepreneurship. Such a development is enabled by the condition in which the neighborhood networks had supported the knowledge dissemination of the industry, as happened in Kasongan. First, the initiator of the industry, Guninjar, had tried to show the neighbors how to develop the business. Even though he did not directly persuade other rural residents to participate in the industry, he succeeded to persuade a job shift in Krebet as many people were interested to make the wooden-stuff products. He also used the established trust and social interactions to disseminate the knowledge in developing the local industry. Afterward, Kemiskidi and Windarti also became the key players in using social values in the knowledge dissemination. They initiated innovations of product variation (wooden-wayang) and introduction of batik. Their success stories had attracted many neighbors to participate in the batik wooden-stuff industry. Again, they used the established trustworthiness and disseminated the knowledge through social interaction (Anwar-McHenry, 2011). Furthermore, as the networks dynamically

progresses, the local artists have succeeded to participate in the formal meetings of Krebet authorities, thereby influencing local policies on the development. The social networks have supported the batik wooden-stuff industry to be a formal main economic sector within the community. Therefore, any matters regarding batik wooden-stuff industry, such as the management of the industry, has become a 'formal' issue in Krebet so that the social interactions have transformed into civic engagement and bridging (Anwar-McHenry, 2011). The shift of local norms currently allows the creative actors to have voice and power in the formal participations. Some of the creative actors have established space for creative industries to be considered in the collaborative process and collective action. These actors also tried to expand the networks with other external parties, such as the local government and other creative actors, by organizing wooden-mask trainings for the local community in 2014.

In conclusion, both cases have shown that collectivity is able to mobilize the community to optimize their creative capitals and develop their entrepreneurial capacities. Both cases show how social interactions provide room for creativity, as "knowledge incubator", for local actors in discussing creative and indigenous ideas, product development, and market preference. This room was identified as infinite, because creative actors (business owners and workers), to some degree, have their own capability to be involved in the social networks, sharing their ideas and creativities to contribute in the product development.

The characteristics of Kasongan and Krebet rural communities, particularly a strong sense of belonging, high shared values and strong emotional connections, have helped the communities to foster the local creative economy to be built upon horizontal and vertical networks (Balfour, et al., 2016; Tonnies, 2001; Murdoch, 2000). The cases have demonstrated how the established trustworthiness, which is constructed by the aforementioned local characteristics, can serve the 'resource' for the local actors to disseminate the knowledge of developing the industry. The benefit to the community, the proximity between the craft industry and the local community, and cultural value appear to strengthen the social networks. In addition, both cases demonstrate that interactions in the rural economy can evolve from the informal social interaction into formal civic engagement. Local norms systems have shifted to allow shared power and collaborativeness of the creative actors in the formal participation process. The actors have become the key players to include the issue of rural creative economy in the collaborative process and collective action.

5.4. Capacity for mobilization

Social values should be supported by a good institutional arrangement due to an individual breakaway from collective creativity (Balfour, et al., 2016; Gray & Lawrence, 2001) and latent collective efficiencies (Phelps & Wijaya, 2016). Therefore, an ability of the rural community to organize common goods, to help each other and to develop businesses together is needed in an institutional framework. This ability can be performed by a formal organization or a network of various actors. Both cases have demonstrated that a network of various actors can mobilize resources to reach mutual goals, even though there is no strong and firm organization that has been developed. Both cases have shown how the key actors can 'mainstream' the crafts industry as a rural issue. They utilized the established social capital as their foundation to foster the knowledge dissemination to be a formal civic participation. As various interviewees mentioned, any matters regarding the rural craft

industry would become a 'village issue'. However, there is no guarantee for these networks to avoid future challenges for an individual breakaway from collective creativity. Therefore, in this section we analyze as to what extent the networks perform the institutional arrangement in responding such challenges.

In Kasongan and Krebet, the relations among actors have progressed through day-to-day business interactions. The interactions among actors have resulted in a success story of the development of artsy pottery and batik wooden-stuffs industries. However, there is no such a mechanism in this rural area that advances the networks into a formal organization (only Krebet did it for the recent year). The ability to provide resources, develop human capital and create commitment has been run by local crafters and entrepreneurs. Therefore, these resource management abilities, which should be performed by the community organization (Chaskin, et al., 2001), have been covered by the networks of actors until today.

For instance, the networks of actors have resulted in some events and projects which have been created in this village. Kasongan festival, an event to promote the creative businesses in Kasongan, had been mobilized by the relational networks of creative actors (Timbul Raharjo and Djoko Pekik), artists' communities, local communities, and local governments. Timbul Raharjo and Djoko Pekik were the creators and initiators in the promotion of creative businesses in Kasongan. They had the idea to promote and extend the market of creative products of Kasongan through a festival. This festival has been held from 2011 to 2013.

Djoko Pekik and Timbul Rahardjo built the external relation with the regency government through another relative, Djaduk Ferianto. This relation also resulted in a development of road infrastructure that connects Sembungan and Kasongan. The development of this road is shown to catalyze the distribution of potteries. The issue of distribution process of Kasongan pottery products had been a concern of local government since the relations between crafting actors and local government had been built.

By those eventual circumstances, the networks of actors have shown its ability to manage their own resources in developing artsy pottery industries in Kasongan. There is no formal structure of community organization within this case, but the networks can function as the resource manager. Therefore, this case has demonstrated that structure and function in a community organization (Miles et al., 1978) can be replaced by the relational networks.

Meanwhile, Krebet also shows a similar pattern of institutional arrangement. The networks of creative actors also have been developed through events and projects, even though the events had a slight impact toward the ability of the networks to mobilize and organize local resources. As mentioned in the previous section, the local actors in Kasongan had built a relational network with other creative actors in other villages. This network had resulted in a training of batik wooden-mask making-process for the local community in 2014. Budi and Yuli were the creator and initiator for this event. They also built a network with local government (provincial government) for the funding of the event. They also were the actors who organized the event, so that they had become the key players for the event. However, unlike Kasongan, Krebet had succeeded in building a new established 'cooperative' organization *('koperasi'*) for local actors. This organization has a formal structure and functions as the resource manager regarding businesses. However, there is no clear mechanism of how this organization mobilizes the resource to the local businesses. Therefore, Krebet has demonstrated that both networks and actors and community organization have the ability to manage their own resources in developing batik wooden-

stuffs industries. Similar to Kasongan, this case also has demonstrated that structure and function in a community organization (Miles et al., 1978) can be replaced by the relational networks, even though those networks have evolved into a community organization in the end.

To conclude, both cases have demonstrated that a network of creative actors can mobilize resources to achieve mutual goals. Even though Krebet has developed a community organization at the end; the networks of actors for both cases mostly have dominated the resource management and function as a 'shady' organization. However, this condition is still considered as vulnerable for the collective creativity, because collective efficiencies remain latent (Phelps & Wijaya, 2016) and there has a challenge of individual breakaway (Balfour et al., 2016; Gray & Lawrence, 2001).

6. Conclusions

The idea of promoting the creative economy has been used as a tool to drive regional development. Most studies have linked this idea in the prospect of the buzz of metropolitan and urban terrains (Waitt & Gibson, 2009; Stam, et al., 2008; McGranahan & Wojan, 2007; Rantisi, et al., 2006), where all amenities and creative workers exist. Meanwhile, a focus on developing a rural creative economy has been less studied (Bell & Jayne, 2016; Scott, et al., 2016; Ray, 1998; Balfour, et al., 2016). This paper has contributed to supplementing this body of knowledge by presenting the cases of Kasongan and Krebet which demonstrate that a creative economy can be developed in such rural settings despite various limitations. The capacity of rural communities in both cases strongly support the development of community arts and craft-based industries in the villages, whose development characteristics differ from what has existed in urban contexts.

In line with Bell & Jayne (2016), the emergence of the creative economy in both cases reshaped local economic structures and place-specific images. The local main sector has shifted from the agricultural sector towards industrial and service sectors, along with creative images being built in both villages. Clearly, the creative economy in these rural settings has been manifested and articulated in a different way from that in urban settings, because it is established while utilizing local cultural knowledge and local creative actors (Balfour, et al., 2016; Esparcia, 2014; Murdoch, 2000). This supports a notion that the creative economy strategy is culturally attached to the specific contexts in which this strategy develops.

More importantly, this paper has identified that the rural communities manage to develop the capacity to support the development of a local creative economy. First, creative potentials have developed the rural creative economy as individual creative actors initiate the development of the creative sector, which slowly becomes an integral part of the collective identity of the villages. It is important to note that in this context, the creativity potentials flourish from local culture and tradition, in that the community has utilized these as an inspiration and value in developing the products.

It is thus evident that the creative economy in these rural contexts differs from the general patterns shown in urban settings. Creative industries in urban areas, especially in the developed world, usually originate from individual creativity. They are associated by new technologies and the copyright protection mechanism (UNESCO & UNDP, 2013). Meanwhile,

in these rural areas, and potentially in other developing countries, the rural creative economy has been benefited from communal creativity, in which individual creative acts cannot be disentangled from collective, traditional values.

Second, both cases indicate that individual entrepreneurs have started their own businesses, which have grown into communal entrepreneurship (Balfour et al., 2016; Julien, 2007). However, our findings show that the ways of how entrepreneurial capacity and contexts develop appear to influence the development of the local creative economy. In Kasongan some actors guide their fellow entrepreneurs to expand their businesses and this has affected the market size of the creative products.

Third, we found that social values become a factor that strongly fosters the aforementioned factors. Social interactions have provided room for local actors, to some extent, to be involved in sharing ideas and creativities for the product. By utilizing local community features, namely strong sense of belonging, high shared values, and strong emotional connections, the local communities have considerably succeeded in establishing actors' networks for the development of the creative economy. Some rural characteristics, such as social values, appear to catalyze the development of the creative economy and these characteristics might be found weaker in urban settings. This factor also helps the community to mobilize resources of the creative economy. An organized network of creative actors in both cases is able to manage resources to aim mutual goals, although a difference exists in the organization form in both cases: while in Krebet the community has decided to build a formal organization to mobilize the local resources, in Kasongan such a formal organization has not been established. At the end of the day, both cases have shown how informal networks of creative actors, which are fostered by strong social values, can help unveil collective efficiencies and avoid individual breakaway.

These findings have important implications for policy. Creativity-based rural development strategies should be shaped by, and sensitive to, the socio-cultural values where creativity is manifested. Since rural areas have specific cultures and traditions, and the tacit knowledge of this industry is usually transferred through generations, development strategies should be tailored to these contexts. Local cultures and social values can be utilized to develop the creative capital as well as entrepreneurial capacity though collaborative processes, in which each stakeholder takes part in the development process. In this regard, a formal organization might not be a prerequisite, as long as the resources can be mobilized to achieve the goal in developing the rural creative economy.

Case Study Paper

Old Deira, Dubai

The Role of Culture, Identity and Planning in a Global City

Peter STARR, AECOM; UK

Abstract

This research project will explore the relationship between planning strategies and multi-culturalism in Old Deira, Dubai. Now an established global city that is firmly integrated in the world economy, Dubai is a salient case study to scrutinise the role of cultural diversity in the growth of this (mini) mega-city. This research will serve as an evidence-base for a presentation that will be given at the 55th World Planning Congress in Jakarta – some concepts may be omitted or expanded by then. This paper will investigate the role that one specific multi-cultural neighbourhood – Old Deira - played in the development of Dubai. What planning strategies, if any, have shaped the multicultural identity of Old Deira, and, based on these findings, how can urban planners apply them in other global cities to promote diverse and multi-cultural neighbourhoods?

Keywords

Deira, Dubai, transnationalism, organic urbanism, authenticity

1. The history of Old Deira: situating Deira in the context of Dubai

1.1. The creation of the Emirates and development of Dubai

In the late 1800s, the British Empire informally controlled swathes of what is now Oman and the UAE. Various agreements between the British and local Bedouin tribes devolved a degree of autonomy and legitimacy in the form of Trucial States, allowing the Al Maktoum family to rule the Emirate of Dubai since 1833. The General Maritime Pact of 1820 and the Perpetual Maritime Truce of 1853 were crucial in pacifying the violent relationships between the different Sheikhdoms (Elessawy, 2017). However, the pivotal political pact was signed in 1892. The Exclusive Agreement gave exclusive territorial and commercial rights to the British Government, effectively turning the region into a British Protectorate.

At the turn of the 20th century, the coastal and regional economies were primarily based on maritime trade and the pearling industry. This flow of goods was facilitated in 1904, when Port Saeed, which sits on the Dubai Creek, was made a free trade zone. The stability, tolerance and employment opportunities enticed many labourers from other British Protectorates to relocate to the city. Afghanis, Pakistanis, Bahrainis and Indians were among the first to settle. Simultaneously, custom-tax increases on the other side of the Gulf, in Iran, led to a wave of Persian merchants immigrating to Dubai. As a result, between 1900 and 1920, the population of Dubai doubled from 10,000 to 20,000 (Hvidt, 2009).

The economic landscape of Dubai and the UAE changed profoundly throughout the first half of the 20th century (Pacione, 2005). Triggered by the mass production of Japanese cultured pearls, the local pearling industry slowly collapsed throughout the 1930s. In a timely

coincidence, preliminary surveys were being carried by British companies in search of oil reserves. In 1939, onshore concessions were granted to Petroleum Development (Trucial Coast) Ltd, a subsidiary of the Iraq Petroleum Company, whose majority shareholder was the British state-owned Anglo-Persian Oil Company. Extractions begin, albeit in rather limited quantities.

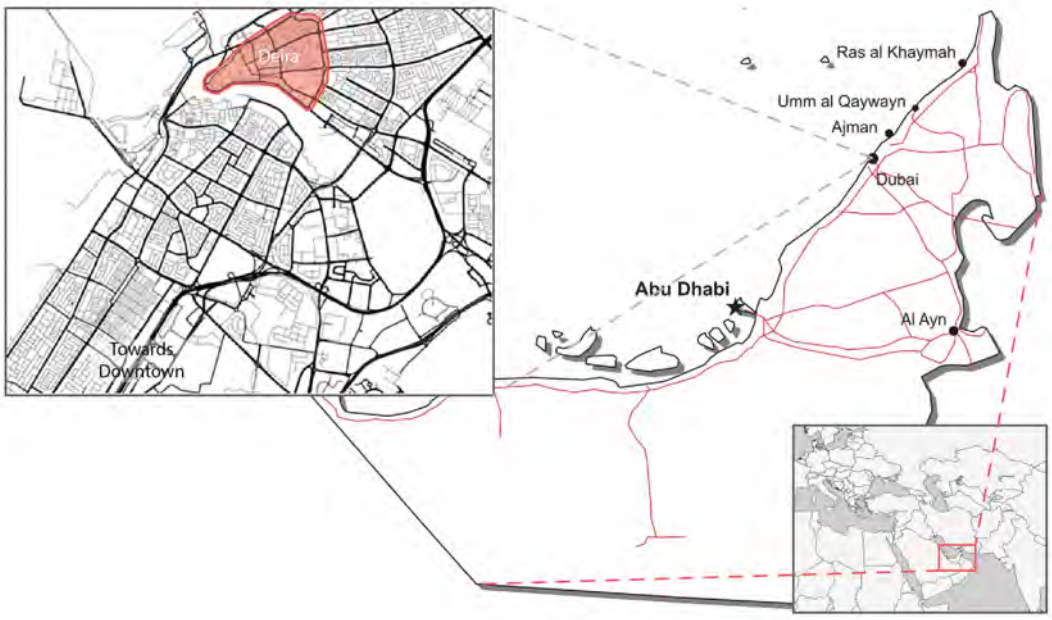

Figure 1 Map of Deira with UAE

Dubai would grow at a somewhat pedestrian pace over the next 20 years; the oil industry did not initially flourish like it did in neighbouring Abu Dhabi. Port Saeed and the Dubai Creek remained the driving forces of the local economy. Being strategically located between important former British Colonies and England, Port Saeed saw increased traffic from nearby Iraq, India and East Asia. The city developed as a hub of trade, and the areas surrounding the Creek naturally grew in tandem with the port. As such, Deira quickly asserted itself as the commercial heart of the city (Elsheshtawy, 2010).

The ruler of the Trucial State, Sheikh Rashid bin Saeed Al Maktoum, had a vision for the city that extended far beyond a regional port city. He envisaged a modern city that would eventually rival the mega cities of the world. Despite limited resources, the Sheikh took the strategic decision to invest in an international airport, which was operational by 1960. With financial support from the Emir of Kuwait, he followed this up with the progressive dredging of the Dubai Creek, a pricey endeavour that proved to be crucial to the city's development (Ogaily, 2015). Port Saeed and the creek would soon be replaced by new deep-water port, Port Rashid, that could be used by the world's largest container ships.

By the time oil was discovered in commercial quantities in 1966 and in full production in 1969, the city's infrastructure was ready to match the incoming surge in maritime trade. The opening of the new port in 1972 concurred with unification of the Trucial States, and the founding of the United Arab Emirates. Much like the country's founding father, Sheikh Zayed bin Sultan Al Nahyan, Sheikh Rashid was weary of building Dubai on oil money. He had the foresight to diversify the city's economy and redirect oil revenues towards vital mega-infrastructure projects (Ogaily, 2015). The Al Shindagha of tunnel, which connected the two

sides of the creek, opened in 1975, followed by the Dubai World Trade Centre in 1978. The Emirate saw these projects as a way of gaining legitimacy on the international stage.

Many attribute Dubai's explosion of development to oil money – this is true, to a certain extent. But there would be a lot less Dubai were it not for the advent of the jet airliner (Brooke, 2013). Dubai's geographical location, more or at less at the centre of the globe, is ideal for a human and freight logistics hub. According to Tim Cook, CEO of Emirates Airline, DXB can serve just about 90% of the world through non-stop flights and a third of the population within 5 hours. Initially, however, Dubai International was just a regional hub, handling mainly Indian businessmen and Saudis and Iranians who came for the relative freedom and debauchery. It was also a destination for Soviet hustlers, who raided Dubai's supermarket to resell the foodstuffs back home (*ibid.*).

Early in its development, the Emirate adopted a proactive approach to tax emption (Pacione, 2005). As previously mentioned, Port Saeed was made a free zone in 1904, as was Port Rashid in 1972. By the mid 1970s, Dubai's position as major player in global maritime trade meant that Port Rashid needed an upgrade. Sheikh Rashid thus embarked on the country's most significant infrastructure project to date: Jebel Ali. The huge container port was built far from the city centre, equipped with a worker village and, from 1985 onwards, designated as a free trade zone (FTZ). Having since been expanded several times, Jebel Ali FTZ is now the world's largest free zone and 9th busiest container port in the world. Building on Jebel Ali's success, tax exemption was repurposed as model of accelerating the city's development. There are presently more than 30 free trade zones, covering sectors from logistics to finance and technology (such as the aptly named Dubai Silicon Oasis).

Most importantly, money made in Dubai is tax free. Coupled with the Emirati Dirham's pegging to the US Dollar, this incentive proved to be effective in attracting foreign white-collar workers. By the turn of the century, it was one of the world's fastest growing cities, the unrivalled hub of the Middle East. Despite the trauma of the 2008 crisis and endless property booms and busts, Dubai's status as an Alpha + city places it in the same league as Tokyo, Paris, Shanghai and Singapore – a vital node of commerce in the global economy.

1.2. Old Deira, gateway to the city: a brief urban theoretical analysis

At first glance, Dubai is very much considered a 21st century city. It is smothered by ultra-modern architecture; gaudy glass skyscrapers are omnipresent. Cranes topping off new buildings are a permanent installation. Modern Dubai's urbanism on steroids provides a cutting contrast with the fabric of Deira. These areas immediately surrounding *Khor Dubai* (the creek) exhibit an urban typology that reflects the district's main function: trade (Hempel, 2018).

As more and more cargo came through Port Saeed and eventually Port Rashid, the areas around the dock yards grew. Import-export businesses and general traders set up shop around the Creek and set up homes in its back streets. People follow people; initially adventurous, male merchants came to Dubai, but their families soon followed. Those working in Deira were mostly from the former British Raj, so large Indian and Pakistani communities developed around the creek. Emirati nationals lived separately, in gated compounds.

Cities grow around people. Supermarkets and small businesses that cater to everyday needs sprouted around Nasser Square, Deira's main public place (now Baniyas Square). A vibrant,

active neighbourhood was being built around the creek. By the early 1970s, when the Government commissioned British architect John Harris to produce the city's first masterplan, Deira was the undisputed commercial hub of Dubai. Like countless other port districts, Deira attracted merchants from far and away. Those who liked it, stayed, and agglomerated around the docks. Much of the city's early growth can be attributed to the vibrant business environment that bubbled in Deira - the history of Dubai starts it in port (Akhavan, 2019).

As a commercial hub, Deira's built environment is defined by the infrastructure that supports trade: banks, everything-stores, general traders, currency exchanges, hotels, etc. These businesses aggregated along the coast, creating commercial corridors that reached inland and drew the urban fabric tighter to the port. Ground floor commercial and retail uses are common. These active frontages ensure there is a constant flow of people moving in and out of the area. A dense, fluid street network spreads out from these main arteries. By virtue of the creek's geography, which stretches relatively deep into the desert, the liberal business environment and the permeable urban fabric, goods could quickly and easily be exchanged and moved throughout the area (see Figure 2).

Large *souqs* (markets) grew in proximity to the creek. It was straightforward to move goods from the port to the various nearby markets, merely hundreds of meters away. The different types of markets, ranging from spices and textile to gold and grain, reflect the diversity of trade going through Port Saeed and Port Rashid.

Figure 2 Figure ground plan of key infrastructure and commercial corridors in Deira (*Source: Hempel, 2018*)

2. Multi-culturalism and transnationalism in Old Deira: how did it happen?

2.1. Planning Deira and Dubai

Despite being a former British protectorate, Dubai's planning system is completely different. The fact that it is a young city means it could be relatively straightforward to observe and comment on potential correlations between planning strategies and urban change. However, this has proven to be challenging, as there is a lack of transparency and documentation. It appears that, since the 1960s, a multitude of city-wide masterplans and strategic land use/zoning plans have been commissioned (behind closed doors) in an attempt to guide the development of the city.

Drawing on the work of Elsheshtawy (2010), Pacione (2005) and Hempel (2018), the following are deemed to have been the most important in shaping Dubai and, consequently, Deira: the 1960s John Harris Masterplan, the 1980s Comprehensive Development Plan by Dioxidis, the Dubai Urban Area Structure Plan 1993-2015, the 2003 Dubai Structural Plan and, most recently, the Dubai 2020 Masterplan. Arguably the most impactful masterplan remains the 1960s John Harris plan (Elsheshtawy, 2019). It created strategic road links around Deira and laid the skeletal foundations for much of the crucial infrastructure that connected the areas north and south of the creek.

The strength of Harris masterplan lays in its recognition of Deira as a vibrant, thriving marketplace. The framework built on the main physical asset of the district: its connectivity. Through new roads and commercial corridors, it increased connectivity to the creek and the rest of the city (see section above on Urban Fabric). The dredging of the creek and reclamation of land for the shipping industry greatly improved its capacity to move freight, thus accelerating the economic growth of the area.

The city-wide strategies that followed the Harris Masterplan were commissioned without consistency in vision or delivery. The result is a series of relatively ad-hoc strategies that are commissioned at the whim of government officials. The continued blanket zoning of Deira as a "commercial hub" or "central business district" is the closest thing there is to an "area action plan" or "local plan" - there is little to no evidence of any Deira specific planning strategies.

The planning system in Dubai was in theory, managed by government offshoots that cover various districts. Up until recently, there was no over-arching, city wide planning committee, unlike Abu Dhabi which has the influential Urban Planning Council. In 2011, the Dubai Executive Council approved the creation of the Supreme Urban Planning Council (SUPC) to streamline the delivery of the Dubai Urban Development Master Plan 2020. It is hard to evaluate the impact of the SUPC so soon after its creation, but the fact that the government is adopting an integrated approach to urban planning is a step in the right direction.

In practice, however, the various governing bodies operate in isolation (Ramos, 2010). Dubai Municipality theoretically has power over the city's maintenance and approval of development permits in publicly owned land. It has no authority over Dubai's many free-trade zones, which are operated by independent bodies that respond to the highest level of government. Ultimately, the city's large property developers (Nakheel, Emaar, Meraas, Damaac, to name but a few) have the most clout. Founded or managed by nationals closely

linked to the ruling family, they are said to operate under the decree of the Sheikh and his entourage. High-profile projects, such as the Palms, are supposedly granted by royal favours.

Old Deira, being a historically low-income neighbourhood, has attracted less interest from the large developers, who have focussed on the city's more luxurious, ambitious projects. Deira has had the freedom to grow organically, relatively untouched by developers and planning regulations. This autonomy allowed it to naturally evolve into a place that authentically reflects its inhabitants, somewhere that is unique in the country.

2.2. Transnationalism in Deira: the case of the fur trade

When Dubai discovered oil in large quantities in the 1960s, the emirate did not have the local labour or expertise to develop its industry and infrastructure. As oil revenues rapidly grew, Sheikh Rashid could afford to attract top Western business leaders, luring them with ludicrously high, tax free salaries. Most of these executives were British men (such as John Harris). Being a former British protectorate, the new oil and construction companies imported workers from countries they knew well – India and Pakistan. Entire labour camp districts were built for workers on mega-project construction sites, with the most famous ones being the Jebel Ali Industrial Area and Al Naboodah, next to the airport.

The more well off moved to Deira. As previously explained, it is the ideal location for small merchants who need good access to the port. First, lone men came, but their families soon followed. Schools and social infrastructure were built to cope with soaring demand. As Dubai grew into its role as the premier hub of the Middle East, it played a vital role in linking maritime trade between Asia and Africa and, to a lesser extent, Europe. People from around the world came to Dubai to do business. Deira really captures the essence of multi-cultural trade. Walking through Baniyas square you see Nigerians buying Korean electronics from Chinese general trade stores operated by Indians.

Whilst Dubai is now an established hub of high-end globalisation through its financial centre, its economy is underpinned by small time trade. Elsheshtawy (2014) explains that places like Deira grew as nodes of low-end globalization. Since regulations are so lax – few questions are asked at customs – businesses that blur the line between the legal and illegal prosper. This system is consistently exploited. Dubai is the perhaps the world's money laundering capital (Forbes, 2019). Deira more specifically is a stop-off point (The National, 2010) for drugs on their way to Europe from poppy-producing nations, such as Afghanistan and Burma. In an otherwise incredibly safe country, the area has also become rather notorious for low-end prostitution and the sex/human trafficking industry. Dubai's powerful underground economy thrives in Deira's affordable and loosely policed environment.

Elsheshtawy (2014) and Mathews & Yang (2012) details the relationship between East Africa, Dubai's Deira and Hong Kong's Chungking Mansions. The Kenyan entrepreneurs he met in Deira had just come from Hong Kong and were on their way to Nairobi. Many specialise in the import and export of mobile phones. Gordon Mathews, Professor of Anthropology at the Chinese University of Hong Kong, describes this flourishing informal industry (Financial Times, 2011). Second-hand or fake mobile phones (of varying quality) from Japan, Korea and China are repaired in mainland cities like Guangzhou or Shenzhen and are then delivered in mass to the Chungking Mansions shopping centre, located in Hong Kong's well Tsim Sha Tsui district. Indian and Pakistani vendors buy the phones at cut-rates and sell them to African middle-men, who stuff thousands of phones into their luggage and fly onto to their next destination.

For most, the pit stop is in Dubai, where they can unload some of their merchandise to be sold in (most likely) Deira before flying back home, where they sell the rest. According to Mathews, in 2009 (Financial Times), an estimated 15-20% of mobile devices in sub-Sharan Africa can be traced back to Hong Kong. In countries like Kenya, some 70% of cell phones are from Chungking Mansions. It is hard to measure the exact logistics of this informal economy, but it is safe to assume that a fair amount of the handsets passed through Dubai.

Deira has its own unique case study. The informal economy that best highlights this is the fur trade. Since the turn of the century, quality furs are sold at cut prices in malls and apartments around Baniyas Square (Khourchid, 2008). The majority of shops are owned and operated by Greeks from one particular town, Kastoria, in the north of the country. Kastoria has been at the heart of the ancient fur trade since the 14th century – Byzantine nobility famously shopped for furs there. The furs are originally from Scandinavia but are processed and assembled in Kastoria. Targeting Dubai's fur-loving Russians, Greek entrepreneurs brought their product and expertise to Deira, which was the city's commercial district in the when they arrived in the noughties. The furs are quite cheap in the emirate as consumers benefit from the inevitable tax exemptions.

The Greeks occasionally employ Russians to work in sales. But most are actually from Central Asian countries, as they expect lower wages (van Leijen, 2012). As a result, there is a growing community of Uzbeks, Kazakhs and Kyrgyz expatriates. I recently ran into an Uzbek owner of an electronics shop (which included perfumes and jewellery) in Deira who spoke English, Russian and Arabic. To add another ingredient in the cultural melting-pot, the Greek fur traders employ Indian runners, who prowl the streets of Deira in search of Russian tourists and live off commissions from sales. Seemingly Slavic enough, I was approached numerous times by young Indians who spoke commendable Russian. Many shops in Deira attempt to lure clientele with both Cyrillic, Chinese and English advertising. Foreignism has marked its territory.

3. Lessons learned, the future of Deira and conclusions

3.1. Lessons learned and international transferability

Organic Growth: highlighting the intimate relationship between form and function

Walking through Deira on a Friday night is an experience rich in sensation. I wandered through Baniyas Square at around 23:00 and the area is in full swing. African families gather next to Pinoy couples in the main square. Pakistani construction workers huddle around public benches whilst Indian store owners stretch out in the grass. Egyptian and Iranian children play football next to a taxi stand. Shops are open, and people drift in and out, browsing lazily. This vibrancy is an outcome of the co-location and competition between innumerable small businesses that essentially sell much of the same.

Deira is so obviously in opposition to most of the rest of Dubai. The core reason is rather simple: Deira is old and Dubai is young. The historic districts that surround *Khor Dubai* date back hundreds of years. Some say Al Fahidi (on the opposite side of the Creek to Deira) was linked to the Old Silk Road. Regardless, Deira has had the time to grow as a place and build character. The essence of the area is still steeped in maritime trade. As previously explained, form follows function in Deira. From the commercial corridors and main roads that lead out from the port to the alleys and courtyards filled with everything-stores, every street corner

in Deira contributes to the viability of the area. The urban fabric reflects the area's economic value as a successful market place, an interface that has evolved between buyers and sellers from around the world. The vibrancy of Deira is ultimately proof of its success as a neighbourhood and as a public space (Elsheshtawy, 2008).

-Authenticity vs. imported generic modern

For all its deficiencies, Deira is nonetheless an authentic environment. If you close your eyes and take in the smells of 5 streets throughout Deira you could be transported to 5 different countries. Places where Deira's nationalities collide, such as Baniyas Square, are psychedelics trips into the heart of what Deira is – gritty, thriving and genuine. I observed Pakistani-Pinoy couples drinking *karak chai* (milk tea) next to Iranian elders. Hanging above them was a neon light in Chinese character. There is an element of Blade Runner to the heart of Deira. At first glance the streets are seedy. The lighting is not the best, so wandering through can seem a bit intimidating. It all feels a bit chaotic, as people swarm in and out of shops and arcades and alleys. The sweeping sound of the call to prayer clashes with the abundance of aggressive neon lights, giving the area a uniquely surreal atmosphere.

After spending a few days in Dubai, wandering through Deira is a refreshing experience, as the rest of the city is so obviously imported from everywhere else. Business Bay, the new central business district, could be an office complex from anywhere in South East Asia. The Marina could be Miami, the International Financial Centre could be Manhattan, so on so forth. Huge gated communities, such as Arabian Ranges, are copy and paste jobs from Arizona. These places are imported from other cities, meaning that Dubai can feel like an exaggerated and tacky recreation. At times, Dubai can really feel like a fragmented mish-mash of generic modern architecture. The eccentricities of Deira are a welcomed counterweight to the more spurious aspects of the city.

De-regulated urbanism: the *autonomous development of Deira*

The urban development of Deira is a tangible example of what could be called autonomous urbanism. Because of its affordability, it has not yet been targeted by Dubai's institutional developers. The built environment has therefore organically evolved to reflect the needs of the community in the form cheap, flexible spaces that can accommodate a range of different uses. What is currently being used as the office for a general trader could potentially be converted, very easily, to a light-manufacturing showroom, an electronics shop, a convenience store or even a Chinese restaurant. The clustering of many industries in one location innately attracts both customers and business. The de-regulated planning system guarantees the fluidity of the property market, which is crucial to its success. Conversely, this also allows for the development of a semi-illegal and abusive land ownership system; Deira is known for its squalid living conditions and violations of health and safety standards.

In summary, it is perhaps the lack of an articulated planning system (Ling, 2018) that has most contributed to the development of Deira. The key drivers of growth have mostly been initiatives that are loosely related to planning. Ultimately, the vibrancy of Deira appears to be a positive externality of investment in infrastructure and neo-liberal-ish economic policy (Bertaud, 2018). As previously demonstrated Deira is product of trade, not vice-versa. The district's status as a free trade hub is the source of its energy, density, affordability and transnationalism. Formal planning strategies played a very limited role.

Visa regulations and government supervision

Any paper on Dubai must address, in some form, the wider socio-political context. Emirati nationals – those born in the Emirates to predominantly Emirati families – represent around 8% of Dubai's total population. The other 92% are expatriates, who live and work in the country under strict supervision. Work visas are generously granted to foreigners; after all, the country was built by them. But when you are in the Emirates, you respect the rules. The country is one of the most supervised in the world, meaning that it is also one of the safest. There is virtually no room for error for those on work visas. Having already paid so much to find work and secure the visa to the UAE, the low-skill, low income workers from Pakistan, India, Nepal and the Philippines are not going to waste their opportunity. Furthermore, many families back home rely on remittances to get by. For example, remittances contributed 28% to Nepal's GDP in 2018 (World Bank, 2019). Consequently, there is not much petty-crime, as breaking the rules unconditionally results in expulsion.

The UAE has been labelled by some as a "benign-dictatorship". Public displays of discontent are not tolerated. There is very little religious freedom and even less free freedom of expression. Deira can therefore be gritty and authentic without the sense of danger normally associated with such places. To a certain extent, Deira provides a soft introduction to some of the more challenging cities of the developing world – like, say, Karachi or Nairobi. The melting pot of cultures can prosper because there is no lenience for dissent or violence. The Deira social experiment that pits many diverging nationalities together may not be as successful in more tolerant, chaotic Western democracies.

3.2. Conclusion: the future of Deira

In the context of planning for culture, Deira is a fascinating case study. Dubai, the modern mini-mega city we recognise today for its ambitious developments and outlandish skyscrapers, owes much of its growth to Deira. The success of Deira potentially highlights two points. One, globalisation is good for cities – when monitored. Two, multi-culturalism works – when supervised. From this perspective, Deira and Dubai really embody the modern, world city. The rest of the globe can learn a lot from it.

The "Deira" model of trans-national, organic urbanism has elements that are applicable to other parts of the world. Many cities can promote organic urbanism by loosening the administrative grip on planning. Deira demonstrates that a bottom-up, market and user led approach to urban development can be very successful. Whether the government intended to do so is debatable, but small enterprises are empowered by the ease of doing business and finding suitable facilities in Deira. The location is sustainable as it benefits from excellent access to ports and public transportation. The network of roads and alleys also allow goods to be distributed cheaply and efficiently throughout Deira.

This is an extreme case, however, and it is recognised that this would be a challenging approach for other cities to embrace. Nonetheless, there is value in making planning systems more flexible and community-driven. Many city districts could benefit from regulatory relaxation by using the planning system as a framework that guides development, as opposed to a set of prescriptive policies that suffocate neighbourhoods. This being said, the "Deira" model functions well within the socio-political context of the United Arab Emirates. Such considerations must be factored in when discussing the transferability of the Deira model abroad.

Above all else, Deira shows that successful places can be created when various, contrasting cultures are organically integrated through the development of economic relationships. It is

hard to despise someone when you buy fish or tires from them. A significant positive externality of the Deira model is racial and ethnic tolerance. Walking through Deira I witnessed countless inter-racial couples; Pinoys and Pakistanis, Caucasians and Indians, North African and East African, etc. Deira could also be used as a case study for pro-immigration policies, though perhaps extreme in this case, as the representation of Emirati locals is so exceptionally low.

Looking forward, the future of Deira could soon be at a crossroads. The Dubai 2020 Urban Master Plan gives little information other than a land use plan and some relatively generic sustainable urban planning principles. As always, Deira is zoned as "Metropolitan Urban Centre", which one would presume is relatively similar to a Central Business District. Pondering the future of Deira leads us to the age-old question: who are we planning for? Dubai badly needs to provide affordable housing (Alawadi, 2017) for its majority low-income groups. They need decent homes with good access to public transportation, public and green spaces and a provision of flexible space for business.

Dubai seems determined to deliver the opposite. Driving down the city's main highway, Sheikh Zayed road, one can not help but notice the skeletal structures of new skyscrapers. Many stand empty or incomplete, a sombre reminder of the cyclical nature of the property market in Dubai. Unfortunately, the construction of the Palm Deira indicates that city leaders want to push forward with the "luxury living" agenda, despite suggestions that money can be best spent elsewhere. Dubai seriously does not need more gold-plated towers - it needs to draw from its success stories and reflect on how it got to where it is now (The National, 2012). Learning from Deira could be a good starting point.

Research Paper

Cultural Heritage Conservation and the Sustainability of City's Orderly Development: identification, conservation and construction of historic space

Qinglian WANG, wangqinglian23@sina.com; China
Zhiqing ZHAO,zhaozq88@126.com;China
Bocheng ZHANG,951787866@qq.com;China

Abstract

Chinese Eastern Railway is the well-conserved linear cultural heritage in China in the 20th century. Despite that the conservation career of cultural heritage along Chinese Eastern Railway flourishes, the contradicted benefit demands between the conservation of historic buildings and the orderly development of the city is increasingly obvious. In this paper, Hengdaohezi Town, a station-located town along Chinese Eastern Railway, is taken as an example to explore its conservation of cultural heritage and sustainable ways for city's orderly development from the view of historical space. It's indicated from the results that mutually contradicted benefit demands could be balanced through the identification, conservation and construction of historic space. Then the requirements of historic heritage conservation are satisfied through the combination of conservation zoning delineation, limitation of building height, integration of spatial morphology, etc. Additionally, city development and construction and living environments could be improved through the adjustment of land use, alleviation of road traffic, upgrade of greening system, remediation of ecological environment, etc. Moreover, it's shown from the realization ways that identification, conservation and construction of historic space is one of the ways to achieve the sustainable development of historic towns.

1. Introduction

The Siberian Railway is an important regional traffic corridor, built by Russia in the late 19th and early 20th centuries. And Chinese Eastern Railway in China is actually its eastern branch. Almost twenty-five years of construction activities along the lines have led to large-scale and a considerable amount of buildings group, which drove the rise and prosperity of many cities

as the prototype of spatial development of station-located areas. The core cities of regional development and characteristic resource towns are both involved. The former includes Russia's Vladivostok, Khabarovsk, and China's Harbin. The latter includes Russia's Krasnoyarsk, Taiga, Novosibirsk, Omsk, Yimianpo and Hengdaohezi in China. The architectural heritage along Siberian Railway and Chinese Eastern Railway profoundly impact city pattern evolution and even the social integration, cultural exchange and economic circulation in Sino-Russian bilateral area, until now.

As urbanization process and market economy effectively speeds up, the station-located cities and historic buildings are faced with a series of problems to be solved. Firstly, historic buildings lacks of necessary repair with constant damage. A large number of historic buildings are damaged. Random construction and renovation of historic buildings inside and outside have caused excessive density, broking the garden-style layout, one house and one courtyard, of historic buildings and giving huge potential fire problems. Secondly, development and construction activities threaten the conservation of historic environment. The rapid and disorderly development of city construction and renovation of old cities for the purpose of real estate development lead to a large number of residential communities and modern buildings, which hardly consider the relationship of street space scale and coordinate with historic buildings. The improper layout of building scale and body seriously damage the original historic characteristics. Thirdly, the lagging municipal construction affects the life quality of residents. Most of the historic buildings are located in the old cities, where the municipal facility conditions are poor, life garbage is dumped randomly and sewage is usually discharged to the streets directly. Additionally, the green land and public activity space are absent in old cities.

In this research, based on the existing achievements, Hengdaohezi Town is taken as an example to analyze the actual problems for city development, cultural heritage conservation and resident life , such as demolition of old historic building and construction of modern buildings1, original appearance repair of historic buildings and conservation of historic authenticity2. It aims to balance the interesting conflict of mutual contradictories among historic building conservation, city oderly construction and life improvement.

2. Literature Review

Along nearly 2,500 kilometers Chinese Eastern Railway, the buildings and structures are large and diversified in number and types. It has become the unique cultural phenomenon in northeast China with its far-reaching influence on city characteristics, social structure and life pattern. Since the beginning of road and affiliated area construction, the agencies and scholars from China, Russia , Japan and other countries upheld strong academic interest and research enthusiasm for the experience and conservation of engineering construction and architectural skills, social and cultural and economic activities; especially during the past twenty years, when city heritage conservation, rapid acceleration of urbanization and railway traffic almost simultaneously develops, the attention, discussion and research for the city development and heritage along Chinese Eastern Railway has been ushered into a peak

1 remove old historic buildings and build modern building facilities
2 restore historic building appearance and conserve its historic authenticity

period with rich research achievements, displaying multidisciplinary perspective, multi-special categories, and multiple time and space dimensions.

2.1. Cultural heritage prototype interpretation

Based on the prototype and morphology, the diversified classification standards include architectural function (original function, such as station building, engine house, water towers, residential houses, churches, etc.)(Zhuo N.2016), architectural style(traditional Russian-style buildings, Art Nouveau buildings, eclectic buildings, etc.) and façade decoration(roof molding/dome, entrance, column, doors, windows and balcony). Supplemented by the necessary graphic language and literature, the expression and artistic characteristics of each types and categories are systematically analyzed to further explore out more abstract and broad cultural meaning at the level of aesthetics and semiotics(Li, G.Y 2014). Moreover, the spatial morphology and mechanism (architectural spatial morphology, spatial morphology) and more macroscopic natural landscape types，along the lines are summarized in their characteristics to further apprehend the system and structure, spatial distribution and natural environment characteristics of the earlier Chinese Eastern Railway, which is greatly significant to guide the city conservation and urbanization development along Chinese Eastern Railway(Zhao Z.Q.2016).

2.2. Renovation of historic buildings and Renewal of historic blocks

This research mainly consists of two types: design practice and strategies formulation. The former focuses on the specific material space renovation and functional positioning. The digital technology ways are applied to provide design guidance for the renovation of historic buildings; the new blue print of historic blocks and sections are set up through the restoration of systematic characteristics, repair of historic buildings, conservation of ancient trees and the introduction of modern city function space（Zhao, T.Y.2006）In sight of the conservation and reutilization of the former stations and other historic buildings, the implementation strategies are put forward in building appearance, internal structure, utilization function, surrounding environment and public facilities; based on the integration, permanence and systematicness of historic block renewal, the affecting factors of renewal pattern is summarized to further put forward the corresponding working programs as well as the evaluation and feedback mechanism, which is usually accompanied by quantitative evaluation of various indicators; moreover, considering the urban planning as the management ways of city construction, the conservation strategies are put forward for rules and regulations, policy implementation and operation and management（Zhao Z.Q.2012）.

2.3. Regional integration and tourism development

In addition, the conservation of Chinese Eastern Railway is combined with modern economic and social life to therefore fully play the advantages of tourism resources and improve its actual position in city economic society, which is also an important topic of heritage research. The network of tourism space focuses on the selection and theme classification of tourism resources at municipal level connects the resource of theme nodes in series to form theme ways and therefore construct spatial network（Tang, Y.X.2016）; tourism space structure across the administrative regions constructs industrial heritage tourism space structure of Chinese Eastern Railway from three aspects: hierarchy nodes of tourism cities, division of tourism circle and planning of tourism lines（Tang, Y.X.2017）; The tourism development of

the whole lines suggests integrating the representative heritages along Chinese Eastern Railway within four northeast provinces, jointly develop natural landscape within the region, establish the cooperated mechanism and construct the integration of Chinese Eastern Railway lines.

3. Materials and Methods

3.1. Case Study

Hengdaohezi Town, N44°48' and E129°04', is located in the west of Hailin City. Hengdaohezi Town occupies the important geographical position for the three eastern provinces in China. It's 300 km away from Vladivostok, Russia. As the main thoroughfare of northeast Asia, it's in the core of Northeast Asia Free Trade Zone; meanwhile, Hengdaohezi Town is located at the Russian economic belt of Harbin, Mudanjiang , Suifenhe and Dongning, the only place for exchanges of western region in Heilongjiang Province. On the other side, Hengdaohezi Town is an important node for coal, wood and water before climbing the mountains and loading trailers (auxiliary engines). Meanwhile, there is a large amount of railway departments, buildings and anciliary facilities in Hengdaohezi Town, having great influence to the operation and management of Chinese Eastern Railway.

Figure 1 Location and historic and cultural environment analysis

3.1.1 Interpretation of city characteristics

The town is entirely surrounded by mountains and a river goes through inside. The terrain is higher in the north with the slope below 25%. And the partial is between 25%-50%. Depending on the railway and river growth and development, the morphology is belt. The city is divided into four parts by railway, rivers and mountains. The historic buildings are more to the north of the railway, the space is narrow between railway and river, scattering some earlier Russian-style houses. The buildings are mainly built after the founding of PRC to

the south of the river and to the east of the mountains. The spatial layout of city street is evenly distribution and radial. The streets and lanes remains the earlier evenly distribution to the north of railway. To the south of railway, the streets and lanes space is mixed by evenly distribution and radial type, naturally formed.

Historic streets and lanes is pleasant to the north of railway and the width (D) varies between 2m-5m and it's usually 3m-4m away from the eaves height of buildings on both sides, D/H is smaller than , making the street more intimate. The types of historic buildings are dominated by small residential houses and public buildings. The decoration of historic buildings shows strong exotic cultural characteristics, reflecting in flat shape, wood material, wall color, window and door decoration and lien contour, etc. The use of these detailed components and decoration reflects multiple characteristics of Russian-style buildings.

Table 1 city characteristic analysis

Characteristic type	description
Settlement morpholgoy	Strip city morphology, evenly distribution residential morphology and surrounded by mountains with river going through
Street space	Spatial layout of evenly distribution and radial type, pleasant street scale
Building characteristics	Regular appearance (regular geometry), stone and wood structure
Decoration art	Onion dome, tetrahedral tower drum, flat Mukeleng-style houses and engraving patterns

3.1.2 Analysis of cultural heritage

Hengdaohezi Town has a large number of historic buildings with large scale and concentrated distribution. These historic buildings could better reflect the historic characteristics, exotic culture and folk customs during Tsarist Russia and the Japanese-Puppet period. At the same time, they also witness the history of Chinese Eastern Railway with higher historic value. Secondly, the architectural details with beautiful appearance and unique style are well reserved to reflect the historic development background and provide materials for architectural culture and art of historical process with profound academic value.

Thirdly, many photographers, film and television producers, and sketching enthusiasts perform photography, filming, and sketching in towns. A large number of historic buildings have left the most authentic side of the town with higher artistic appreciation. Ultimately, industry-dominated Hengdaohezi Town is changing. And these rare historic resources strengthen the connotation of the town, which is a solid backing for other industries with higher utilization value.

Table 2 typical historic buildings

historic buildings	Representativeness	Value characteristics
Engine House	Modern industrial architecture civilization	Historic value

	point	academic value artistic value utilization value
Railway white building	Former residential houses and official buildings for Chinese Eastern Railway experts	
Log yard	Photos of the earliest log yard in China (in the Museum of Chinese History)	
Orthodox Notre Dame Church	The only remaining wooden church in the three eastern provinces	
Ancient Russian stree	The best preserved Russian style historic district	

3.1.3 Historic space identification

The planning drawings of earlier cities are interpreted to explore their historic space constitution, boundary and characteristics. The layout of earlier Hengdaohezi Town considers railway station as the center and rectangle squares and a large amount of greening are set up surrounding the center. On the other hand, taking railway station as the base point, the town develops along the railway lines. The administrative region is set up in the north (inside there are religious land use, education land use and medical land use); secondly, in the east and west set up are the boundary region (military land use inside) and village region (mainly residential land use). The road network of the town is typically rigid. Street design is wide, straight and flat. The land is divided in standard grid. The buildings inside the street profile are arranged in double rows with ending buildings close to the four corners.

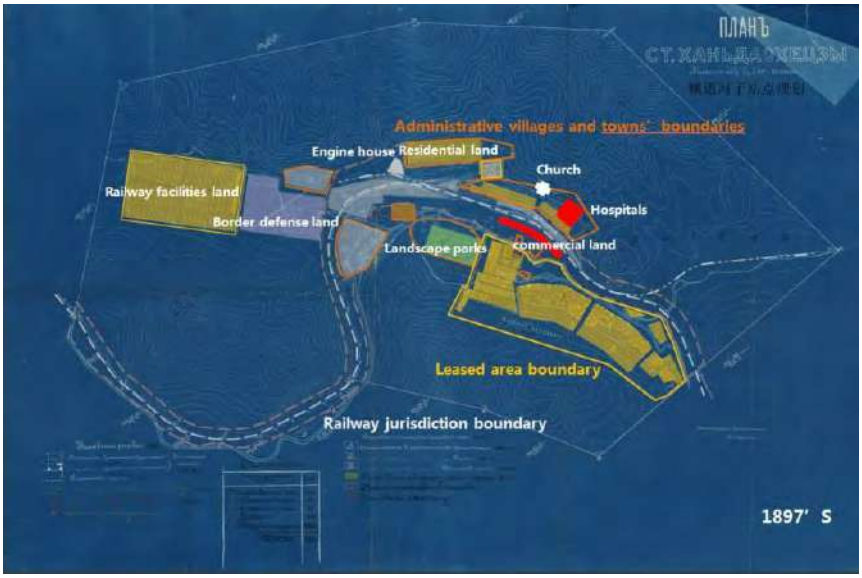

Figure 2 Historic planning drawings

After hundreds of years of city development and construction, city historic space has been submerged in the continuous expansion and transformation of city map. Through the

comparison between original and existing planning drawings, the historic space boundary of Hengdaohezi is determined (see Figure 3). Within historic boundary, it's still clearly to get the characteristics of earlier city planning: grid road network, wide, straight and flat street, neat land division and line architectural texture. However, the typical road greening and that in front of the station are hardly preserved. Overall, the historic space of Hengdaohezi retains the framework of earlier planning.

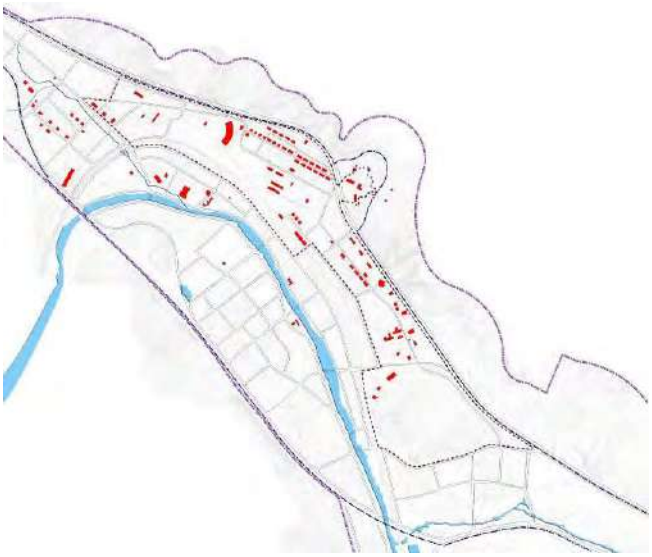

Figure 3 comparison between historic planning and the existing space

3.2. Research Methodology

Combining with the city development problems and relevant analysis, the principles of jointly development are put forward between heritage conservation and regular construction. The first principle is to coordinate conservation and construction. The city not only conserves and continues historic culture, but also needs to promote economic development and social progress and fully combines conservation with construction. City conservation and construction rules are respect to highlight conservation keys. The construction of new districts should be coordinated with old district conservation. Meanwhile, the requirements should be satisfied among city economy, social development and improve citizen's life and working environment. The second principle is sustainable development. City development couldn't quick and simply pursues economic interests. The current utilization methods should ensure the future sustainable development. The relationship among historic heritage conservation, residential environment improvement and industrial development should be comprehensively coordinated. The conservation and utilization are combined with the conservation prioritizing to formulate city construction content with sustainable development significance. The last principle is historic environment conservation. The conservation of historic space not only aims single cultural relic, but also involves relics, historic space, historic buildings and traditional characteristic buildings, facilities and structures and ancient trees, etc. with overall conservation measures. Based on the above three principles, the realization ways, historic conservation and construction are formulated to anticipate achieving the sustainability of heritage conservation and orderly construction.

4. Results and Discussion

4.1. Conceptions of realization ways

The sustainable ways of both are explored through the formation of implementation strategies, planning framework, conservation zoning and key construction (see Table3). The development strategies consider conservation of historic environment, exploration of cultural potential and improvement of life environment; the planning framework further explores cultural connotation based on the analysis of city traditional characteristics. The structural planning is constructed for the overall conservation of material morphology and cultural connotation of Hengdaohezi Town. In material space morphology, the historic elements of the cities are divided into three levels: nodes, axis and regions. These three levels of space are mutually connected to jointly constitute the historic spatial layout of Hengdaohezi Town.

In the first level of conservation zoning, the historic section, where the traditional layout and historic characteristics are completely conserved and historic buildings are concentrated, are determined as core conservation boundary. And outside the core conservation scope, the construction and controlled section are determined. In the second level, the scattered various level of cultural relics conservation unit, historic buildings and traditional characteristic building are determined in their conservation scope and construction and controlled scope. The environmental coordinated area is determined if necessary. The third level mainly aims at ancient trees, mountains and rivers. The key conservation content includes various historic buildings within the cities and their surrounding environment; in addition, the original natural environmental elements area considered as the key component of city historic space, being protected properly.

Table 3 heritage conservation and city construction development ways

Ways	Content	Description
Implementation strategies	conservation	Conservation historic environment and focus on the overall appearance. Improve the conservation recognition and visual perception of historic characteristics from user and experiencers
	governance	Comb historic context, reproduce historic atmosphere. Maximize the conservation of historic trace, promote coordination and unification of history and modern
	renovation	Improve citizen's life, perfect facilities. Consolidate house structures, perfect infrastructures, improve sanitary

		and beautiful environment
Planning framework	single core	core of city center landscape
	Two belts	Hengdao River and its branch going through Hengdaohezi Town
	Four districts	Concentration area of cultural relic conservation buildings and industrial heritage area
	Five scenic points	Orthodox Notre Dame Church, Hengdaohezi Engine House, No.7 Russian-style Wooden Houses, White Railway Building, Railway security station
Conservation zoning	The 1st level	Conservation scope determination of historic buildings concentration area
	The 2nd level	Conservation scope determination of single historic buildings
	The 3rd level	Conservation scope determination of ancient trees and rivers
Key conservation	Artificial environment	Various levels of cultural relics conservation units of key conservation towns and their surrounding environment
	Natural environment	Deserve appropriate conservation as the component of city historic space

Figure 4 conservation framework of historic space

4.2. Conservation of historic space

4.2.1 Determination of conservation zoning

The determination of core conservation scope should comprehensively consider topography, road traffic, courtyard ownership and other conditions to conserve and maintain street space and cultural heritage within the core areas. It's not free to build or demolish. The new built or demolishing buildings must adhere to the conservation principles3, meanwhile, and ensure the consistency with the overall style of the buildings. The first level includes four core conservation areas, in which the sections with abundant historic buildings and well-preserved sections are improved as historic blocks.

Table 4 historic block conservation information

District	Are of core conservation scope	Area of historic building base	Conservation content
Historic block of ancient street	61 hm2	18933 m2	Conserved buildings Historic buildings without being leveled
Shunqiao historic district	6.4 hm2	4003 m2	
Foshou historic district	6.4 hm2	3613 m2	
Industrial heritage district	13.1 hm2	-	

Then, the construction controlled area is determined, 209.7 hm2, according to the integrity of historic environment, coordination of environmental characteristics and the safety of heritage distribution area. The height, scale and color should be coordinated with traditional

3 In core conservation scope, spatial layout of the historic village and the façade, materials and color of buildings along the street should be changed without authorization; the renovation of the existing buildings should keep or restore their historic and cultural characteristics; new construction and expansion of the road shall not be allowed without authorization. The renovation of the existing roads should keep or restore their original road layout and landscape characteristics.

characteristics when the new construction, renovation and expansion are approved within the construction controlled scope; new construction, renovation and expansion should not destroy the traditional characteristics of the historic village. Moreover, according to the overall harmony of village environmental characteristics, the environmental coordinated scope is determined, 774.5 hm2. The construction projects should not be freely constructed within environmental coordination scope to further maintain the historic section relationship with surrounding environment as well as the water, soil and natural environmental landscape to the greatest extent.

Figure 5 City conservation zoning scope

For single memorial buildings and ancient buildings and its surroundings, the conservation scope is 2-5 times of the height of the main buildings and the construction control scope is 4-8 times of the height of the main buildings within the second level. In addition, zoning also needs to collectively consider the construction status quo and development trend of local cultural heritage and ownership of the building land. Construction control scope is mainly based on the integrity of historic environment and harmony of environmental characteristics. Within the third level, the scope is conserved within a radius of 5 meters from ancient trees. The mountains and rivers consider its natural layout and pattern as conservation scope while taking into account the greening environment on both sides.

4.2.2 Limitation of building's height

In view of the requirements of cultural relic conservation, the echo and reunification of scenic spot, the outline of urban space and conservation of characteristic landscape, the existing condition and land use planning are combined, based on the above single height control, to overlap the above single planning results to ultimately determine the building height of each land plot (see Table 5). The original building height of cultural relic conservation unit is maintained, not allowing the height of common buildings or structures exceeding that of cultural relic conservation buildings within the conservation and construction control scope. The existing buildings like this should be removed. The original height of conservation buildings and historic buildings, not being listed in cultural relic conservation unit, are maintained. The common buildings and structures, whose height exceeds that of conservation buildings and historical buildings within the surrounding area of 10 m, shall be lowered or removed.

Table 5 Height control（unit:m）

Controlled area	Building style	eaves height	total height of ridge	total height of buildings	remarks
The 1st level	One-story sloping roof	< 4	< 6	-	the construction buildings, historic buildings and the reconstructed buildings to the original appearance are not subject to this limitation.
The 2nd and 3rd level	Two and three-story sloping roof	< 4	< 4	< 12	Within city construction and control scope, the height limitation is 10m for key areas and 13 m for non key areas.
The 4th level	Four-story sloping roof	< 13	< 15	< 17	Within environmental coordination scope, the height limitation is 13m for all areas.

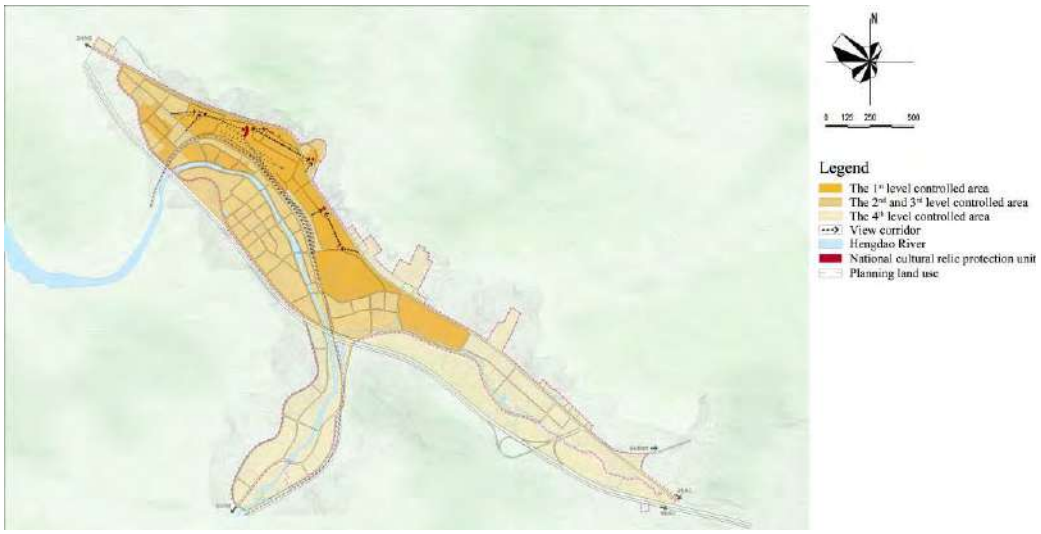

Figure 6 city buildings height control

The control of view corridor for city landscape is the key of building height control. The buildings within landscape corridor shall base on analysis of view field of scenic spots within visible range to further determine height control requirements. View corridor includes the viewing space between scenic spot and landscape objects as well as its surrounding environment. The general view corridor are crucially constructed and conserved for important landscape including round house, No.7 wooden house, white building, Hengdaohezi Town police station, former Hengdao maintenance site, Hengdaohezi railway station and Hengdao maintenance apartment.

4.2.3 Integration of spatial morphology

The historic space morphology is unified through develop conservation and construction requirements of building appearance, color and style, building layout, internal function and building scale. In general, within core conservation areas and characteristic coordination

areas, the morphology and color of newly-built buildings are restricted to keep harmony with traditional characteristics. For newly-built low-rise residential buildings within the cities, the slope roof must be applied. The built residential houses with flat-roof must be gradually changed into slope roof; for the existing buildings with slope-roof buildings, the roof color is cyan. In sight of building color, the newly-built buildings should conform to the color and style of old buildings with red-titled slope roof and red-titled materials.

Respecting the original architectural style, the township and newly-built buildings should keep harmony with historic conservation blocks and un-reconstructed buildings. The slope roof is red titled. The façade is dominated by red brick and yellow. The material is mainly paint and supplemented by red brick. The line is white. Then, according to the different functions of the buildings, the commercial and office buildings apply red titled or red slope roof, yellow materials or ceramic title. The storage and factories and other public buildings use flat roof with grey, blue or iron color. The façade is dominated by cement, stone and paint. In addition, the construction principles of public buildings and commercial buildings focus to create different spatial atmosphere according to different functions to further increase the recognizability of the buildings.

Table 6 Integration of spatial morphology

content	Conservation requirements	Construction requirements	remarks
Building appearance	Maintain and restore the original characteristics of the buildings	The appearance of newly-built buildings should conform to that of historic buildings	To apply building symbols and language with city characteristics; the appearance of buildings on both sides of the river display traditional characteristics of residential houses.
Color and style		Encourage warm color construction(including buildings, pavement and environment, etc)	Avoid monotony, use warm color to give people a warm and lively visual care
Construction layout		Construct historic building layout and water, lanes and alleys and other traditional features	–
Internal function		The newly-built buildings are constructed according to internal functional organization and characteristics of historic buildings	–
Building scale		Control newly-built buildings scale to in	Newly-built buildings should apply courtyard-style (groups

		accordance with historic environment of conservation area	of single buildings) and to give a balanced visual experience

4.3. Spatial construction of township

4.3.1 Adjustment of land use

Township land use is complicated with confusing layout. The historic and surrounding areas are mixed with industrial land use, not conducive cultural heritage conservation. Then the commercial land and entertainment land is less, the parking lot is obviously insufficient for industrial transformation and development. The existing land use is adjusted as follows. The land use conversed for land on both sides of Hengdao River and inside historic block, including industrial land, land with low economic benefit and long-abandoned land use. The original land structure is improved to achieve consideration in conservation, development and efficiency.

Table 7 land use adjustment

Existing problems	Type before adjustment	Type after adjustment	Adjustment purpose
Destroy historic space characteristics	Industrial land	Commercial service Cultural entertainment	Coordinate general characteristics Conserves spatial morphology
Low economic efficiency	–	catering service museum exhibition	Develop tourism industry Improve per capita income
Long-abandoned without utilization	Abandoned land	Green land, squares	Efficient use of land Improve space quality
Less municipal infrastructures	–	Municipal public facilities	Increase public facilities, Enhance living environment

The expansion process of construction land is greatly limited by topography. Land expansion therefore is restrained by spatial growth boundary to some extent. The spatial growth boundaries are determined by combining with population development scale, city construction land requirement and ecological space integrity. The northern part could be controlled in a suitable construction area with a slope of less than 25%; the southern part could be controlled to the G301national road and partial still takes mountain as the boundary with less than 25%; the eastern part boundary takes the eco-sensitive northeast tiger park as the boundary.

4.3.2 Improve road traffic

The scale, portion and layout of the original road should be kept within scope of historic space. Non-historic roads should be broadened without affecting the historic spatial characteristics of the block. The traffic road network selects and determines lines on the original road network and is parallel to the central streets. According to the texture and terrain of old and new cities, the mixed road network structure and three-leveled road classification are constructed (see Table 8) in combination with courtyard division and land saving. Among them, parking is not allowed for trunk roads and the branch roads advocate bus first.

Table 8 structure of road network

Road network structure	Road classification	Road width	Road function
mixture	Trunk roads	16m	Connects external traffic
	Brunch roads	12m	Organize public traffic
	Allies	6m	Construct pedestrian system
		4m	

Parking lot and squares. The requirement for parking within township is considered while taking account into the demand for public space from citizens. At the area with large pedestrian flow, 7 parking lots are set up with 9 recreation and squares. Public traffic. The relationship between internal bus lines and external long-distance bus lines are dealt with. The selection of bus stops should fully consider the surrounding land use layout and public service facilities to ensure bus accessibility with the service radius less than 300m. Pedestrian traffic. The effective width, continuity and flatness of the pedestrian roads on both trunk and branch roads are ensured. The accessibility of pedestrian roads and crossing facilities are required to strengthen the maintenance, management and supervision of pedestrian system. Additionally, the pedestrian space is added specifically to cover the space of entire old streets. Waterfront space and central greenland park.

4.3.3 Upgrading of greening system

Within historic space, the cultivation of trees and shrubs should be terminated as appropriate. Other measures include beautify environment, control land use construction and protect cultural relics from destroying. The set-up of various facilities within historic blocks should fully refect the principle of sustainable development and focus on greening space organization to strive to minimize the pollution on air, water and soil and restore good ecological environment. Within river channels on sides of Hengdao River4, the flood-tolerant trees and grasses should be selected without affecting flooding. The greening should be strengthened with the attention to vegetation combination and landscape composition, making it an original ecological waterfront park for citizen and tourists.

The following measures are applied to improve the greening quality and ecological quality of the cities: firstly, with the street-facing buildings position, several small open spaces are

4 Hengdao River is an important geographical element for city construction, as well as an crucial part for greennign and ecological environment. And its water quality can reach to the 1st level, which is precious ecological landscape resource. The essential ecological environment should be conserved for Hengdao River.

formed with appropriate trees planting to enhance the vitality of the city. Secondly, the courtyard greening of residential houses on both sides of street is enhanced. The single ornamental plants are planted to form sight attraction to further improve residences' landscape aesthetics with rational arrangement of the courtyard greening. The third point is to conserve historic trees. The historic trees are the important natural landscape resources to reflect regional environment and history. Satisfying the conservation, the subsequent supervision, management and maintenance work are well done.

4.3.4 Ecological environment remediation

Air environment remediation measures. the unified heating intensity of the city are enhanced to encourage the application of clean energy. The city reconstruction and greening are also strengthened with the improvement of road hardening rate and greening coverage. As the existing industrial structure is transformed, the greening conservation and low-polluted industries are vigorously developed. In addition, the city dust pollution is controlled with technological or administrative ways to improve city greening. The trees species with strong anti-pollution performance are selected to develop plant purification, combined with urban greening planning.

Water environment remediation measure. The construction of sewage treatment plants are accelerated with improving sewage treatment rate. The underground water is protected from the pollution of sewage source. Open channels are governed and restricted from discharging sewage. The sewage pipes are prevented from rupturing, polluting underground accidents. The sewage discharge pipe network is strengthened in its design, implementation and management to ensure the normal operation, reduce pipe rupture and pipe leakage and other accidents. The underground water resource is effectively developed and used.

Sound environment remediation measures. The supervision and management of sound environment remediation measures are strengthened to establish public participation system. Around sound-sensitive areas, the speed limit zone and horn limit zone are set up. The tonnage of the passing vehicles is limited to improve the surrounding sound environment. For the area near sound-sensitive area, the noise radiation direction is properly arranged with reasonable building structure. The three-dimensional greening of the factory-dominated areas is strengthened and if necessary, the sound insulation walls are built to minimize noise.

5. Conclusions

Through a series of practical exploration including the identification, conservation and construction of historic space, the author preliminarily puts forward the ways to realize the sustainable cultural heritage conservation and regular city development during the urbanization process. In general, it's indicated from the research results that the contradictories and interest claims are finally satisfied among historic building conservation, regular city construction and citizens' life. The positive development strategies are preferable to the future development of the city.

In conclusion, this research is both theoretically and practically meaningful.

In practice, to realize the sustainable cultural heritage conservation and regular city development, several suggestions are put forward for historic space identification, conservation and construction. Firstly, sustainable conservation. Cultural heritage conservation calls for continuous attention. The long-term and effective conservation mechanism is formulated to avoid the protection of dead sheep; secondly, sustainable utilization. Cultural heritage utilization is the most directly refection of its various values. Without affecting its conservation, the value of cultural heritage should be maximized and reflected. The third point is sustainable development. Cultural heritage conservation and utilization should also be considered with city development to realize coordinated development of cultural heritage and city construction. The fourth point is sustainable policy. The policy for cultural heritage conservation and utilization needs to be formulated with other relevant polies, such as heritage conservation management, utilization, paid policy for repair, to guide citizen's positive attitude toward the conservation.

On November 9, 2018, UNESCO announced the results of this year's asia-pacific cultural heritage protection award in Bangkok, Thailand, and hengdaohezi town was awarded the honorary award of 2018 cultural heritage protection.

Research Paper

RESEARCH ON ONLINE PUBLIC PARTICIPATION AND ONLINE PLATFORM CONSTRUCTION FOR HISTORICAL BLOCK PROTECTION IN THE DATA AGE

Yang YANG, ouw@deakin.edu.au; Australia
Jilong ZHAO, zlll0w@sdjzu.edu.cn; China
Qian SUN, 573295334@qq.com; China

Abstract

With the implementation of benefit-oriented urban renewal, many historical blocks have lost their identifiability. The historical block is an external entity that is a presentation of urban culture. The disappearance and homogenization of the historical block have directly led to the city losing its place attachment, with the overall identifiability of urban areas becoming weakened. Therefore, it is essential to develop a strategy to protect historical block identifiability in urban planning. Traditional urban planning is dominated by government and developers and is highly dependent on planners' experience-based judgment but lacks quantitative analysis of public participation. As a result, it is difficult to carry out an objective and comprehensive analysis when facing the complicated situation of historical blocks. The issue of public participation has become an essential issue in the process of urban construction and renewal in China and other developing countries. Based on an analysis of the concept and the characteristics and techniques prevalent in the data age, this article discusses (1) the method and mechanism of public participation in the protection of urban historical blocks and (2) the content and structures of public participation platforms for historical districts. Research indicates that the application of cloud technology and reasonable platform design is the focus of public participation in historical block protection, which can change public participation from passive to active, from "lagged" to "synchronized".

Keywords

public participation, online platform, historical block protection, data age

1. Introduction

In many developing countries, there is an urgent need for an applicable public participation platform for the renewal and protection of urban historical blocks (Wei et al.,2015; Cheng et al., 2015). On the one hand, this need is born from the gradual disappearance and total commercialization of blocks that carry historical value and memory. On the other hand, under the original "top-down" model of historical block protection and development, the

public can only be passive and accept renewal policy that has already been decided. Among citizens, the government, and developers, it is easy for issues like housing demolition and relocation to occur (Liu, 2007). Therefore, for the renewal and protection of urban historical blocks, we need to not only preserve the original historical memory but also develop an open and effective public participation platform.

However, there are many severe deficiencies regarding the modes and technologies of current historical block protection (Feng and Li, 2013). The renewal and protection of urban historical blocks is a complicated urban social issue and requires communication channels and time to organise and update social relations. On the one hand, existing urban public announcement and online comment platforms are often vacant, making public participation an institutional decoration to a large extent. On the other hand, the results obtained from traditional public participation modes are mainly based on voting and writing, which are difficult to analyse and directly categorise (Liu, 2007).

New media platforms in the data age stimulate public awareness of independent participation. In the age of digitalisation and interconnection, with the popularity of new media such as microblogs and WeChat, Internet public participation events such as the PX project boycott event have had an impact on government decision-making, and China has begun to see the burgeoning of citizen network participation politics (Dai et al. 2014). PX is the abbreviation of xylene, and the PX project involves the production of xylene. In recent years, some people have worried that PX is harmful to human health and have organised walks and parades through the Internet and other means to boycott a PX project planned for construction in a locality. Since 2007, such incidents have occurred successively in Xiamen, Chengdu, Dalian, Ningbo, Kunming, and other places. The incidents had a certain impact on the government's decision-making. Most of the above cities announced the termination of relevant PX projects. Meanwhile, the protection of historical blocks has received extensive attention. Besides, with smart handheld devices becoming the main terminals of people's lives, daily life and social affairs are demonstrating diversity and immediacy, gradually changing the mode of public participation in the protection of urban historical and cultural resources from passive to active (Zhou et al., 2012).

Therefore, in view of the current situation of urban historical block protection in China, the establishment of a public participation platform based on new media can enhance the participation of all parties, increase the diversity of public participation modes, and improve cultural information about urban historical blocks available from various channels. This study explores the three aspects of public participation theory, mechanisms, and a platform of the historical block protection, with empirical research conducted in combination with an examination of existing cases.

2. Characteristics of Public Participation in Historical Block Protection in the Data Age

2.1. Interpretation of basic concepts

A historical block refers to a block with a certain scale of historical relics and complete historical features. It is the material carrier of social life and cultural habits during a specific

period. The "Athens Charter", the "Venice Charter" and the "Special Measures for the Protection of Ancient Capitals' Historical Features" all proposed that an essential aspect of historical block protection is the overall protection of the historical, cultural, material, and living environment of the blocks. In the protection of historical blocks, attention should be paid to the structure and customs of subjects and their diverse use of space.

Arnstein (1969) believed that "public participation is a right of the public". In his opinion, public participation can be divided into eight steps: manipulation, guidance, notification, consultation, persuasion, cooperation, authorization, and public control. Public participation in the historical block protection is essentially a multi-step redistribution of the protection rights of diverse subjects such as residents, social groups, non-profit organizations, and individuals (Lane, 2005; Choguill, 1996).

With the increasing popularity of interactive network platforms and smart mobile terminals, more and more commercial and public platforms have begun to feature personalized content based on users' collected preferences and requirements. The real-time interaction of a large number of diverse subjects with information using new mobile media as the primary tool is the main feature of the data age (Yu and Mao, 2015).

From the above analysis, it can be seen that the interaction and integration of multi-subject activities and information, as well as the redistribution of multi-subject protection rights, are the integration basis of historical block protection, public participation, and new media.

2.2. Public participation in historical block protection based on "Cloud"

The Internet provides an interactive interface for public participation in historical block protection. Feng and Li analysed the impact of public participation on the restoration and renovation of Beijing's "Zhonggulou" Square (Feng and Li, 2013). Through the network media platform, the renovation of the "Zhonggulou" Area received widespread attention, and some government decisions were adjusted and modified in response (Feng and Li, 2013). In "Internet-based planning information exchange platform and public participation platform construction", Zhou (2012) stated that the network-based public participation platform is characterised by an "Internet-based user interface" and "information interaction with users". On the one hand, the system transmits visible and understandable results and information to the public; on the other hand, it gathers public feedback and quickly processes it.

New media is an effective tool to intervene in the protection mechanisms of public historical blocks. In "The Mechanism and Exploration of New Media Involvement in Public Participation for Historical Blocks Protection", Wei et al. (2015) introduced attempts at public participation in historical block protection and renewal projects using new media technologies. From the earliest WebGIS to WeChat public accounts and the Heritage Protection APP, he proposed that new media has changed the way information is disseminated and created opportunities for public participation. Through new media, platforms for display and exchange can be built to promote public participation, lower the threshold of public participation, and enhance enthusiasm for public participation.

The application of cloud technology has opened up the era of "cloud" distribution for public participation in the protection of historical blocks. For example, the Beijing Planning and Design Institute developed the CityIF Urban Planning Cloud Platform and proposed that due

to its social characteristics, the new era is a “micro-era”. The CityIF Urban Planning Cloud platform was sponsored by Beijing Research Institute of Planning and Design (Chu et al. 2015). It provides different data and information services for various groups such as citizens, the government, and planners, with the aim of bringing together urban data, planners’ wisdom, citizens’ bottom-up power and government’s top-down power to form a planning cloud platform and a platform for discussing the urban future. To acquire and integrate data, a “cloud platform” that can realize interactive sharing, multi-disciplinary collaboration, and data aggregation should be built. Such a platform consists of three layers of resource platforms: one is an analysis platform that analyses and processes big data; the other is a planning platform that collects the professional intelligence of planners; the third is a dynamic platform for community governance from the bottom up. On this basis, the platform provides three different operational interfaces for three groups: the government, planners, and citizens (Chu et al. 2015). Based on the “cloud platform”, the interaction and integration of multi-agent activities and information and the “cloud” distribution of protection rights can be fully realized for the protection of historical blocks.

In short, the Internet and new media are effective interfaces and tools for the “cloud” distribution of public participation rights. The cloud platform has opened up a vast network space for public participation in historical block protection.

3. Online Technology and Platform Construction for Public Participation

3.1. Limited participation “offline” and unlimited participation “online”

The traditional historical block protection mode can be divided into four categories according to the dominant party. In the first category, the government is dominant. The primary role of the public is to be informed and influence the government's decision-making, such as with the reconstruction of Warsaw after World War II or the renovation and restoration of Beijing's “Juer Hutong” (Hu et al., 2014). In the second category, civil organizations and individuals are dominant. This means that civil organizations or individuals guide the public to participate in the protection of historical blocks, such as the British “Ancient Building Protection Association” or the “Enning Road Academic Concern Group” during the renovation of Enning Road in Guangzhou (Wu, 2014). In the third category, the public spontaneously and actively participates in the protection of a district, such as in the “Community Vision Planning” in Halifax, Canada or the construction of the historical community of Dadaocheng in Taipei City (Macaulay et al., 1999; Xu and Liu, 2012; Liang, 2014). In the fourth category, multiple parties collaborate. This collaboration is initiated and implemented by the above parties, and the public is widely involved and becomes essential. A typical case is the Hong Kong Central Market Conservation Plan.

Among the four methods discussed above, public involvement in the protection of historical blocks can be classified into three main categories: First, property owners, who have a direct interest in the daily management and renovation of historical blocks and are mainly local residents, often do not need guidance and inducement. The space in which they live is the material element of the historical block, and the customs and community structure are also important aspects of protection (Hu et al., 2014). The second is the common interest in the

block, which mainly refers to experts, scholars, professional organizations, and non-governmental organizations relevant to citizens' public interest in the block. These entities mainly focus on the value of cultural research and the development, utilization, and valuation of historical blocks. The participation of such entities can effectively avoid the intensification of social conflicts or the excessive commercialization of neighbourhoods. The third category includes other individuals without a direct interest. Since there is no direct interest, they generally do not pay attention to historical acts and do not act spontaneously. However, with the development of society, the role of public opinion and action is becoming increasingly important. Through proper guidance, this will benefit the protection and development of historical blocks (Xu and Liu, 2012).

The public mainly participates in the protection of historical blocks in the following three aspects. First of all, it participates in the collection and protection of historical information, the investigation of historical resources, and the completion of data, all of which are essential work in the process of historical block protection. In addition to historical surveys and physical surveys, genealogical information and photos of local residents can provide information about the neighbourhood. This complements the physical form of the building and contributes to complete historical information about a block. Secondly, the public participates in the positioning, design, and implementation of historical block protection planning before the formulation of the plan, so residents and other members of the public have a detailed understanding. Based on the plan, suggestions are put forward. In the design process for a protection and renovation plan for a historical block, the public acts as a judge. After they understand the design plan, people make comments and suggestions, or vote on whether a certain transaction should be implemented (Zhou et al., 2012). Third, the public also participates in the cultural and tourism development of historical blocks. Local residents can preserve the social structure and customs of a neighbourhood and participate in the development of cultural and creative industries and tourism. On this basis, civil organizations and individuals can also hold culture exhibitions and other events promote local culture. In this way, on the one hand, the local culture is protected, and on the other hand, the social economy is developed. In this way, the benign development, protection, and transformation of historical blocks are realized.

At present, there are four main ways for the public to participate in or influence the protection of historical blocks. The first is information browsing in which relevant government departments and other entities publicize information and promote exhibitions to the public, but there is no interaction and poor participation (Liu, 2007). The second is the collection of opinions in which relevant departments obtain questions and opinions through on-site investigations and questionnaires and make plans based on this information, and the public participates in the protection of historical blocks (Zhou et al.,2012; Brown and Raymond, 2014). The third is collaborative participation in which the public participates in planning and design through meetings and expert workshops organized by the government, institutions, or non-governmental organizations in an effort to encourage the participation of residents, civil organizations, the government, and other subjects. This model involves government guidance and multi-subject participation and is the main direction of public participation in the protection of historical blocks in China. The fourth is public leadership in which self-governing community organizations and advisory committees collect public concerns and develop a community vision and action plans on behalf of community

residents and the general public to enable them to participate in planning, construction, and other relevant departments through negotiation and communication (Liu, 2007).

However, in combination with China's actual conditions and existing practices, the following problems must be solved to promote public participation in the protection of those as mentioned above historical in China. First, awareness of public participation is weak, and the Chinese public has little relevant experience with participation (Liu, 2007). Second, the main form of public participation is unclear. For a long time, Hong Kong, Macao, Taiwan, Europe, and the United States had relatively complete public participation systems that included the government, non-governmental organizations, residents, experts, and professional institutions. The public participation system in China remains unclear, and the power of participating entities is not clearly defined or distributed. Third, the content of public participation is limited. At present, management and renovation of most of the historical blocks in China are mainly led by the government, and the designers and developers are entrusted with carrying out planning and transformation. The public plays only the role of being informed, and there are no laws and regulations. Usually, a program has been basically decided when it is publicized, so public participation is of little effect. Fourth, there is a single method of public participation. At present, there are only methods such as on-site interviews, questionnaires, symposiums, and public announcements, and most of the public is passively involved, with one-way notifications. Fifth, there is no feedback mechanism. The key to public participation is interaction. At present, many historical block protection plans do not allow for feedback, so naturally, the public cannot influence decision-making or the formulation of plans and policies.

3.2. Online public participation platforms in the data age

New technologies emerging in the data age provide new methods to solve the above problems. Under the support of new technologies, management and operation models such as “crowdfunding”, “PPP”, “Joint planning and Joint management” began to be introduced into historical block protection (Yu, 2014). The online public participation platform not only provides citizens with convenient access to participate in the decision-making process but also provides opportunities for planners and citizens to interact (Yu, 2015). Compared with traditional public participation, online public participation based on data technology has the following advantages:

Historical information dissemination methods are diversified. The development of new media and the popularity of mobile smart devices have enabled the rapid dissemination of information, and new media directly push content to personal devices that spread quickly among the public through forwarding. Using QR codes, the public can link to WeChat, Microblogs, news pages, and other platforms to obtain and forward information about historical block protection anytime, anywhere.

Diversified ways of participation. In traditional public participation, feedback is mainly based on questionnaires and voting, and data is in a single form. In the era of data-based information, mobile phones, tablets, and desktop computers can be used to create online maps of historical block maps by means of webpages, WeChat, Microblogs, and other platforms. The public can directly participate in the design, make comments, or take photos of historical blocks with location information that reflect the status quo. Through data

information platforms, the government can also timely obtain public opinions on the protection of historical blocks and realize interactive information.

Participation of diverse groups. From the original government, residents, and experts to the whole society, participants include students, teachers, folk history protectors, non-governmental organizations, and other individuals and groups concerned with the protection and development of historical blocks. This reflects the popularity and whole process of public participation.

Diversified content of information. A significant feature of new media is the diversity of content and form. Data platforms can use any digital media content such as videos, 3D models, and panoramic images. New media and the SoLoMo service have expanded the way information is delivered and allows it to be presented more intuitively, allowing the public to interact with content. SoLoMo is composed of the first two letters of three words: “Social”, “Local”, and “Mobile”. “So” stands for all kinds of social networks, such as Sina microblogs and Facebook, “Lo” stands for all types of services based on geographical location, and “Mo” stands for mobile Internet. SoLoMo is the combination of the three.

Diversified data resources. The era of big data has promoted governments’ database construction and data availability, and many government agencies are digitizing information and gradually making it public. Data-based information platforms can use the cloud to access various types of information. For example, in the historical block protection process, the land management database of the national land department, the project management and design plan library of the planning department, and the database of historical building protection information can be linked. A variety of content can be added to online maps to increase the public’s understanding of issues.

3.2.1 Technical means of public participation in the data age

Specifically, in the data age, there are many technical means that can be applied to public participation in historical block protection.

The first is the QR code. QR code transforms textual information such as serial numbers, website addresses, and item characteristics into QR black and white images that can be directly recognised by computers and can be read by simple image input devices (such as mobile phones with a camera function). With the help of the QR code, the functions of information acquisition, web page jumping, and mobile payment can be realised. With the popularity of smart devices such as mobile phones, QR codes have become an essential way for the public to obtain information. In recent years, Shanghai, Harbin, and other cities have begun to post QR code on the nameplates of historical buildings, conveniently allowing the public to connect to a detailed network introduction page and solving the problem of limited nameplate content. Moreover, the public can directly comment on, suggest, map, or upload other relevant information, such as old photos and documents, through QR codes. In this way, the public can participate in the collection of information on historical blocks.

The second is the web service API. Network Service API is an open platform for network services. The allocation of traditional Internet resources is unbalanced, and a large amount of data generated by users is gathered by enterprises or institutions, resulting in other enterprises or industries being limited by the lack of user resources and data. To realize the sharing of resources, many enterprises have set up an open platform for network services to

open up their own resources to ordinary developers to a limited extent. The web service API is a resource interface provided by data holders (such as large Internet companies) that enables developers to access or use their resources. With the opening of the web service API, government agencies and public organizations will be able to create online public participation platforms more easily. For example, through the Baidu map API, developers can use Baidu map data and apply them to various map data services. The system that the author of the present paper developed offers costs savings in terms of data storage and transmission, reduces the time required to write a large amount of program code, and also transforms the main work of the public participation platform builder from collecting data and writing code to conceptualizing and realizing the function logic of the public participation platform. The public can also use the API service to browse the city's historical information and map markers and engage in public discussion and other participation behaviours. This reduces the public's learning costs and promotes public participation.

The third is virtual display technology. Virtual reality (VR) is a technology that allows users to immerse themselves in a computer-generated, interactive three-dimensional environment. Augmented reality (AR) is a technique for calculating the position and angle of camera images in real-time and adding corresponding images to combine real images with virtual images. In the historical block protection process, if the general public, which lacks professional knowledge and experience, is involved, there must be an intuitive and easy-to-understand way of displaying information. Virtual displays based on computer graphics technology not only allow the public to intuitively understand history and culture but also display historical block renovation plans, enabling the public to understand design plans and make suggestions. In recent years, data acquisition technology has advanced by leaps and bounds, with advancements including three-dimensional laser scanning and panoramic photography. With the development of network technology, the threshold of 3D data display is becoming increasingly low and low, particularly through WeChat, Microblogs, APP, and other platforms that allow viewing and access anytime, anywhere. In recent years, the VR and AR6 technologies, which have received much attention from the industry, have allowed the public to understand historical streets and their renovation plans immersively and to provide opinions and suggestions.

The fourth is big data technology. Technologies such as data mining and cloud computing are rapidly evolving. People are increasingly using mobile smart devices, generating a lot of spatial data. Spatial distribution and semantic analysis of these data can be used to derive behavioural patterns and the views of the public. On the other hand, public participation will generate necessitates downloading and uploading massive data, which requires excellent data processing algorithms. At the same time, cloud platform technology is rapidly evolving, improving data processing efficiency and ease of use by linking and integrating different databases. A typical example of big data technology is Location Based Social Network (LBSN). LBSN is a social network based on location. Compared with traditional social networks, LBSN can track and share real-time location information of people in addition to using network technology to realize virtual contact between them. LBSN uses the massive data it collects to combine data mining and cloud computing technologies and analyse the public's use of historical buildings or neighbourhoods in a certain city so that the public “unconsciously” participates in history. The protection and renovation of blocks through this method has a positive impact.

3.2.2 Public participation platform carriers in the data age

At present, many network service platforms have integrated the above-mentioned key technologies. Online platforms for public participation in historical block protection can be completely built on the basis of “the platform of platforms” using “carrier platforms” to avoid a large amount of time and energy required for bottom-level development. At present, there are the following relative mature “carrier platforms” in China:

One is the information visualization web page. With the development of technology, the information content of web pages has moved from graphics and videos to interactive and operable web pages. The information conveyed by web pages should be easy to understand as well as visual and interactive. This idea also corresponds to online public participation platforms in historical block protection.

The second is the microblogs. Its main advantage lies in its broad range of audiences. Through Microblogs, the public can understand the protection and renovation plans for historical blocks. Recent years have witnessed the phenomenon of the destruction of outstanding historical buildings in many cities. Local residents, experts, and scholars have appealed to society through Microblogs, forming a public opinion environment that enables the government to listen to the opinions of people and accordingly adjust their policies and programs.

The third is WeChat, mainly WeChat public numbers. The WeChat public number service is open to organizations, groups, and individuals. Based on this platform, specific functions can be developed to realize information push and interactive feedback. According to a 2015 report by Tencent, WeChat covers more than 90% of smartphones, and monthly active users reached 549 million. Its popularity is evident. Using a WeChat public account, it is possible to build a historical block protection participation platform that can be used whenever and wherever possible. Such a platform makes the public willing to participate more actively in discussions on urban construction affairs and policies. Planning departments can also collect and understand public opinions and adjust their historical district protection policies and plans.

The fourth is the independent APP (Application). As APP relies on mobile devices such as mobile phones, it has greater flexibility than traditional web browsing or entity modes. Compared with microblogs and WeChat public number, APP is relatively independent and unrestrained and can realize more abundant and easy-to-use functions. For example, using the Tianjin historical style building APP, the public can combine the GPS function of mobile phones to locate historical buildings conveniently. At the same time, explanations of the historical background of a building or block help to cultivate the public's sense of historical protection. At the same time, the discussion platform can be set up through the APP, and the public can send feedback information to the planning bureau and other departments or institutions through the APP.

These platforms have significant differences in information collection mode, information storage mode, and interaction mode. Therefore, different platforms have different advantages and disadvantage in terms of participatory degree, content richness, and types of participation modes (see Fig 1). Thus, the design of online public participation platforms

for historical blocks protection needs to design an independent technical framework based on specific content.

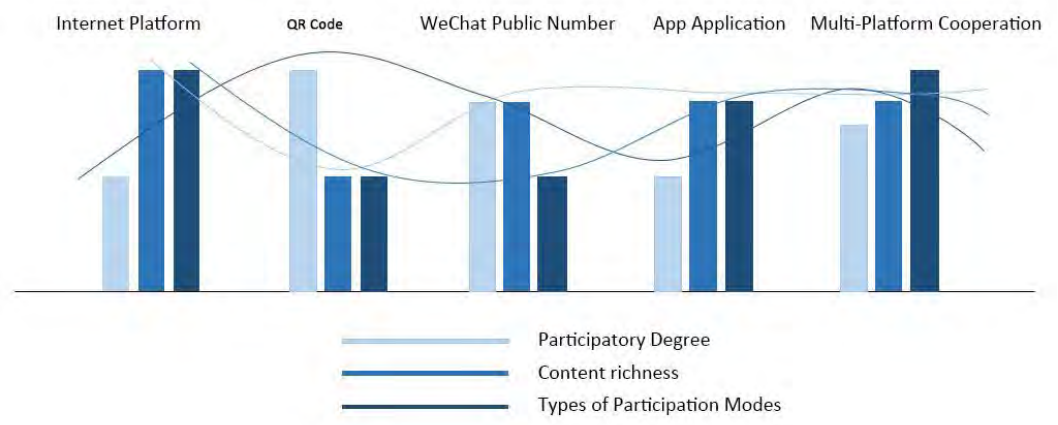

Fig. 1 Comparison of Public Participation Platform in the Data Age (Source: Author)

3.3. Construction of online public participation platform for historical block protection in the data age

3.3.1 Content of public participation platforms for historical block protection

There are three main types of users involved in online public participation platforms for the protection of historical blocks. The first is the government, developers, and designers that build, manage, and operate the platform. They are also important users of the platform and have the responsibility of communicating to the public the orientation, objectives, background, and presentation of design schemes for the protection or renovation of historical blocks. On this basis, public opinions are collected, and feedback is given. The second is community representatives, who are direct participants. This includes representatives of residents and industry, who use the public participation platform mainly to gather public opinions and questions and transmit them to relevant departments. The third is indirect participants, which includes civil protection forces, experts and scholars, academic institutions, civil scholars, cultural security personnel, and non-governmental organizations. These participants use the platform to organize diverse activities and establish links between the general public and government agencies, which are significant forces that cannot be ignored in the protection of historical blocks. In addition, the general public in urban and other areas can gain understanding, engage in discussion, and provide feedback through the public participation platform throughout the process of protection and renovation of historical blocks, thereby influencing policies and planning.

In view of the functional requirements of the types mentioned above of users of online public participation platforms, such a platform should include the following functional modules:

The first is the sub-platform of historical information collection and display. This sub-platform has four functions: The first is collecting historical and cultural information and

relevant historical pictures, text, audio, and video from members of the society and establishing a historical information resource bank concerning the blocks. The second is publicizing historical and cultural displays using virtual display technology to show the history of the blocks to the public. The third is the recommendation and identification of historical buildings. Recommendations, voting, and other means are recommended activities to ensure excellent historical buildings or blocks, and professionals are invited to investigate and identify the buildings. The fourth is the social supervision of historical sites, which involves reporting destructive behaviour in an effort to protect cultural relic and sites and ensure well-preserved historical buildings by uploading photographs and commenting on them.

The second is the sub-platform of planning design and implementation management, which includes four functions: The first is the preliminary investigation and discussion of planning. The public's questions and opinions are collected through WeChat, microblogs, and other means and are used as the basis for the formulation of the planning scheme. The second is the design and discussion of the planning scheme. Through this platform, the public can understand in detail the current situation and future orientation of the blocks. At the same time, the public can put forward opinions on planning through stippling, discussion and other means. After collecting opinions of the public, they can be analysed. This forms the basis of the planning scheme design. The third is the evaluation of planning efforts. Through the public participation platform, the public can participate in evaluating the results through voting, commenting, and other means and comprehend feedback from public opinion. The fourth is the implementation and management of planning. The government formulates short-term implementation plans, initiates activities and discussions with the public through the public participation platform, and coordinates conflicts between construction and residents' lives. At the same time, the construction situation is announced to the public in a timely manner. This allows "cooperative co-construction" between residents and the government to be gradually realized.

The third is the sub-platform of cultural activities and tourism development in historical blocks, which includes three functions: The first is the interactive display of tourism information, which allows tourists to quickly and conveniently understand tourism information on blocks and realize an "experiential" tour. Second, cultural and creative industries are displayed to propagandize and promote cultural and creative industries in historical blocks. The third is organizing and publicizing cultural activities, which enriches the cultural life of the blocks by inviting scholars or artists to give lectures and seminars.

3.3.2 Technical framework for public participation platforms in the data age

According to the mode, subject, and content of platform participation, the technical framework of such a platform in the data age is shown in Fig. 2.

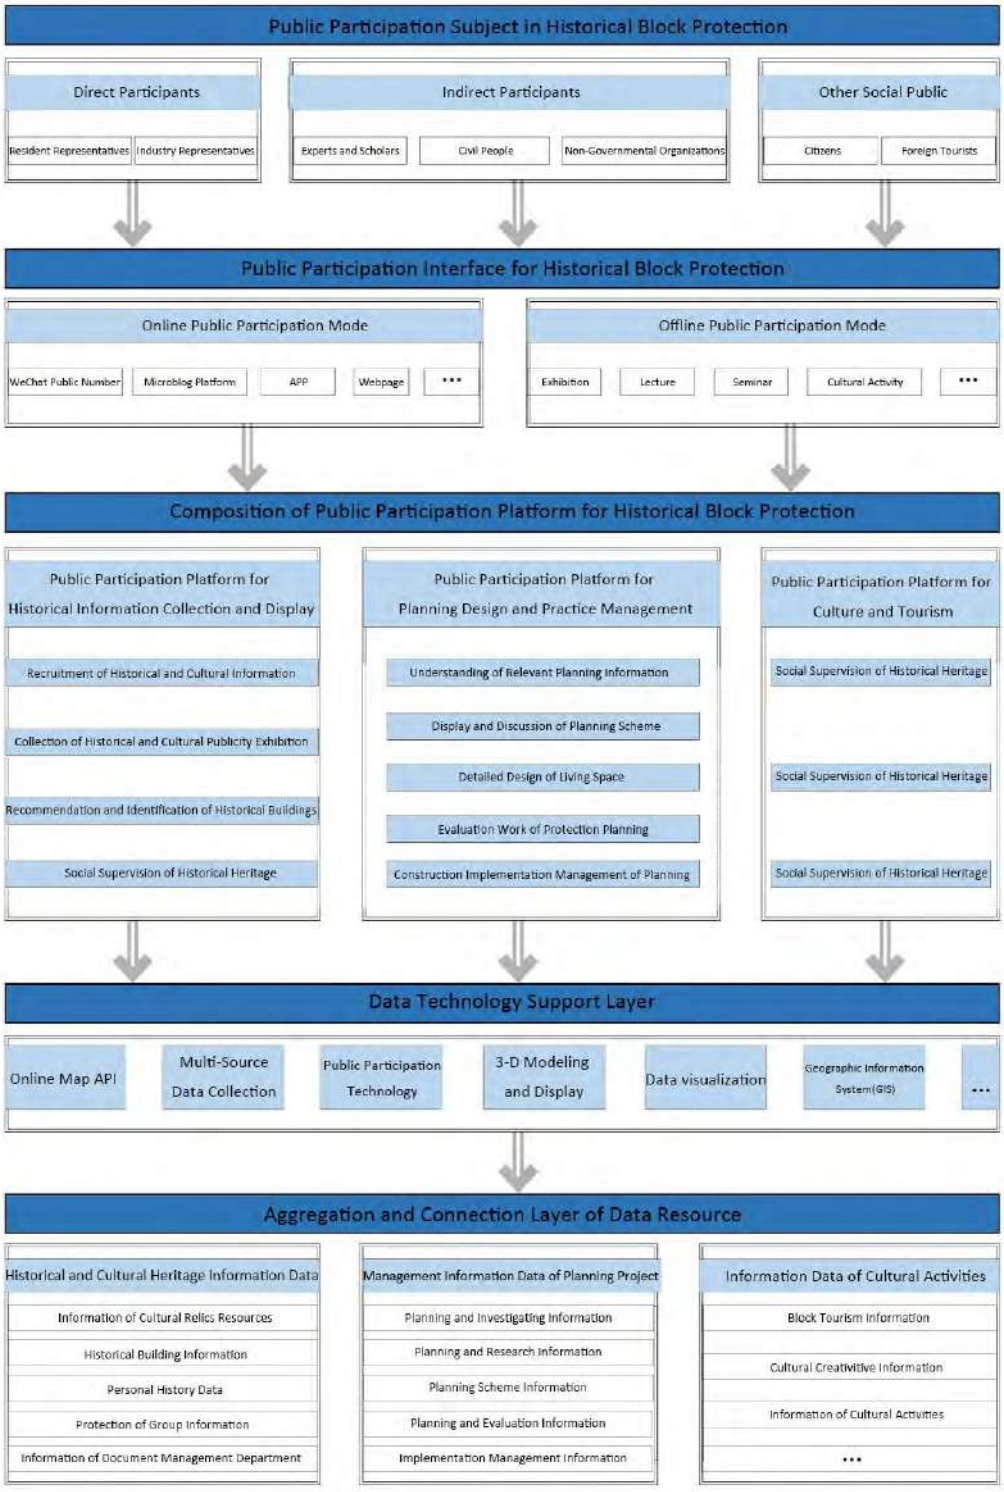

Fig. 2 Technical Framework of Public Participation Platform in Data Age (Source: Author)

4. Practical Analysis of Cases of Public Participation Platforms

4.1. Public Participation Platform for Historical Resource Management —— Beijing Historical and Cultural Heritage APP

Beijing has a significant cultural heritage distributed in large and small streets and communities. However, geographical locations and other information are mainly stored in cultural relics in department or institution exhibits, and it is difficult for the public to have a comprehensive understanding of them. At the same time, many historical relics are located deep in the streets and alleys, and it is difficult to visit them only with the textual address information. In addition, many historical relics are scattered and cannot be fully monitored and managed. The uncivilized behaviours of individual tourists and their illegal demolition by developers often cannot be stopped in time. Besides that, threats that historic buildings face can be varied and extraordinary. Due to the prevalence of wooden building materials, corrosion and aging are severe problems of many historic buildings. The fact that ancient Chinese buildings usually have delicate architectural details makes corrosion and aging more destructive. Structural details such as tenon and mortise joints become corroded by rainfall or damaged by worms even with a protective layer of lacquer on the surface, and paints on these buildings may be damaged by the weather, including rain, snow, wind, and even sunshine. Another problem of wooden structures is the risk of fire, and the situation is especially severe in light of the traditional compact arrangement of buildings in China. Fire usually spreads rapidly both inside the building and between buildings, and the narrow streets limit the success of modern fire-fighting methods. Therefore, building a platform for the public to understand the distribution of cultural relics and related information intuitively and to provide timely reports on the damage of cultural relics has become an important direction of public participation.

The Beijing Cultural Heritage APP developed by the Technology Innovation Center of Tsinghua Tongheng Planning and Design Institute is such a platform. This platform includes information on 336 existing cultural protection sites in the eastern and western urban districts of Beijing, including the World Cultural Heritage of the Forbidden City and the Temple of Heaven. The software uses Baidu maps as a geographic information platform and displays multi-level cultural protection content through different layers.

In addition to showing the overall distribution of heritage sites, the software also displays information for each heritage site separately. Clicking on the corresponding icon allows users to view detailed information, including relevant photos. Using the API of Baidu Street View Map, the street view around a building can be seen, creating a stronger sense of presence.

In addition to providing images and textual information on cultural heritage sites, the platform also encourages the public to upload photos they have taken and add comments to enhance interactivity. The platform also includes an alarm function for cultural relics, providing a channel for public supervision, so that people can directly report the damage to cultural and stop illegal demolition and illegal construction in a timely manner.

4.2. Public Participation Platform for Planning, Design, and Implementation Management—— WebGIS Network Public Participation Platform for Beijing's "Zhonggulou" Area

The "Zhonggulou" area is located near the "Di'anmen" area, which is in the eastern urban district of Beijing, on the city's central axis. Along with promotion of the renovation of old urban districts in Beijing, an upgrade plan for the "Zhonggulou" Area was proposed in 2010. According to the plan, the nearest Hutongs from "Zhonggulou" were to be demolished. The news spread rapidly through the Internet, and a large number of experts and scholars began to call for the protection of the texture of Hutongs and the landscape based on the central axis. Under this circumstance, in December of the same year, the renovation project was officially terminated, and the scope of the renovation was reduced to less than one-tenth the original, for a partial renovation.

During the renovation process, in addition to the appeals of experts and scholars and media reports, a special team played a huge role, namely the "Zhonggulou" Area team. The team intended to safeguard the rights and interests of local residents and continue the area's history and culture. Most of the team members met through microblogs, and a large number of student volunteers were recruited. They collected data through household surveys, interviews, the study of ancient books, and other means and disseminated protection information through microblogs and other platforms. After analysing the collected data, they developed a public participation platform for the "Zhonggulou" reconstruction community with the help of WebGIS technology. This allowed the team to integrate all kinds of data into the platform to facilitate residents and the public to understand the current situation and future of the area fully. The platform also enabled discussion and voting to investigate and analyse public opinion.

The participation platform relied on research and data collation and used WebGIS as a technical means to present the results in the form of an interactive platform for community residents and the public. The platform was spontaneously formed by non-governmental social teams. Although it did not play a decisive role in the development of the area, it provided an interactive channel for social cooperation and community participation to facilitate residents to understand policy information and preserve the style of the blocks through a visual platform.

4.3. Public Participation Platform for Cultural Activities and Tourism Development ——WeChat Public Number for "Slow Products in Shanghai Hunan Community" on Wukang Road, Shanghai

Wukang Road, Hunan Street, is located in the centre of Shanghai. Due to its rich historical and cultural anecdotes and buildings, it is known as the "Celebrity Road that condenses the history of Shanghai in the past 100 years". There are 14 excellent historical buildings along the road and 37 preserved historical buildings. On June 11, 2011, it was selected as a "Famous Street of Chinese History and Culture".

On June 15, 2014, Shanghai piloted the "E-age" historical building protection project in the Hunan community, which involved posting a QR code on the nameplate of excellent historical buildings and creating the "Slow Products in Shanghai Hunan Community" WeChat

platform. That was the first in China, and some other cities in China have also promoted it since then.

Relevant information about historical buildings and the past can be found only on display boards or archive exhibition halls, with limited display modes. Obtaining information through QR code breaks through the shackles of traditional media. By scanning a QR code linked to a created historical building display page, a voice introduction and dynamic display can be accessed.

The public participation platform for "Slow Products in Shanghai Hunan Block" is managed and operated by the Hunan Street Office. The aim is to build a public platform for intelligent communities. The platform and consists of three main sections: The first is "Historical Hunan", which mainly records historical buildings and information for the convenience of the public. The second is "enjoy Hunan happily", which integrates data on activities and special services of community and municipal cultural centres, and characteristic businesses to facilitate residents' lives and cultural leisure activities. The third is "Impression of Hunan", which is an interactive platform for residents and tourists to share their memories of the community by photos, travel notes, paintings, videos, and other means, and to make suggestions on the development and renovation of the community so that the public can participate in the development process.

Platform Type	Platform Name	Participation Mode	Participation Subject	Contents of Public Participation
Historical Resource Management	Beijing Historical and Cultural Heritage APP	APP Application	Social Public	1. Interview and Understanding of Cultural Heritage Information 2. Supervision and Protection of Cultural and Recreational Sites
Planning Design and Implementation Management	Community Planning Participation Discussion Website of Beijing Bell and DrumTower Renovation Project WEBGIS	WEBGIS Webpage	Non-Governmental Organizations Experts and Scholars Student Teams Residents	1. Non-governmental organizations such as social teams established historical block information database through social research 2. The public through the network platform to understand the condition of block renovation and preservation of historical resources, and to discuss hot issues
Cultural Activities and Tourism Development	Slow Products in Shanghai Hunan Block	WeChat Public Number	Residents Tourists Government Art Teams	1. Obtain historical building information through two-dimensional codes 2. Participate in community life and cultural activities 3. Save and upload community memories and make suggestions

Table 1 Case Comparison of Public Participation Platform in Data Age (Source: Author)

5. Conclusion

Historical block protection includes the material cultural heritage of the block and the social structure of the block. It is a complicated social management process, and it is necessary to invite multiple subjects to participate in the process of the management and renewal of historical blocks. At the same time, according to the 'ladder theory' of citizen participation (Arnstein, 1969), public participation in historic block protection requires that the public participates in the process of collecting historical information and planning and design related to historical blocks. As the conditions for public participation in China are not yet ripe, it is necessary to guide and standardize the content and forms of public participation through building a public participation platform.

In the data age, public participation platforms for historical block protection use new media and technologies such as WeChat, microblogs, and APP. There are three stages of public participation: the collection and display of historical information, planning design and

implementation management, and discussion of the block culture and tourism development. Establishment of such a platform will enable the public to shift from passive to active participation and from lagged participation to synchronized participation. Based on cloud technologies such as cloud computing and cloud storage, as well as "micro" technologies such as lightweight platforms, low-cost equipment, and low learning costs, users can simply and quickly participate in historical block protection anytime, anywhere.

With the development of society and the strengthening of consciousness of public participation, in the process of historical protection and cultural inheritance of the city, individuals and teams play a considerable supporting role and have made significant contributions to the protection of urban historical culture. How to integrate the resources and strengths of the government, related institutions, and the public to achieve a "crowdfunding" protection participation model is the focus of the construction of a public participation platform for historical block protection in the data age. This requires the government's "top-down" guidance and the "bottom-up" resource construction of the public from all walks of life. The construction process of the platform itself is also the content of public participation. Only by allowing the public to participate in every process of the protection of historical blocks and platform construction can social resources be effectively integrated to achieve substantive participation of the public.

Research Paper

Research on Humanistic Technology of Urban Design of Historical Blocks in Harbin

Dian ZHANG[1], Suning XU[2]

[1,2] School of Architecture, Harbin Institute of Technology, Key Laboratory of Cold Region Urban and Rural Human Settlement Environment Science and Technology, Ministry of Industry and Information Technology, China

Abstract

Nowadays, with globalization sweeping across cities, more and more cities tend to develop in the same way, while the sense of existence of local identity becomes weaker. It is often the preferred choice of the city government to construct distinctive characteristics with the help of urban design. Historical blocks have their own unique cultural connotations. How to make them retain their own traditional context in the rapid urban renewal and maintain vitality with the development of the city is an urgent problem to be solved in urban design.

In this paper, the research objects are two historical blocks in Harbin which is a representative historical city located on the Northeast China. One of objects is the Central Street of Harbin, which attracts countless foreign visitors every year as a popular tourist area. The other object is the Chinese Baroque Historical Block, which is deserted after renovation and planning. On the basis of urban design, this paper makes a comparative analysis of two historical blocks from the perspective of social humanities, and puts forward the humanistic technology of urban design. Humanistic technology are divided into two technical routes: human and culture. The study of human includes the living needs of local residents, the behavioural feelings of foreign users, the control and management of government development and the distribution of interests of investors. The study of culture includes the combing of the history and culture of the block, the embodiment of space culture and the promotion of value culture. This paper attempts to build a universal theory framework. Humanistic technology will be used as research foundation for urban design in the renovation and conservation planning of cultural heritage.

Keywords

humanistic technology, historical block, urban design, Harbin

1. Introduction

Every city has its own history. In most modern cities, the material carrier of history is more scattered historical buildings or historical blocks. Some cities have better preservation of historical relics and large scale, which can show their unique historical and cultural values and characteristics. In China, such cities are known as historical and cultural cities. Since 1982, China has established the system of "historical and cultural cities", and promulgated

the Law on the Protection of Cultural Relics, the Law on Urban and Rural Planning, and the Regulations on the Protection of Famous Towns and Villages of Historical and Cultural Cities. In the past 30 years, 134 cities have been approved as historical and cultural cities by the State Council. A large number of cities with rich cultural relics and historical value have been conserved, but in the course of conservation, conservators have also experienced many frustrating explorations, and continue to move forward with reflections.

With the social transformation of China, urban planning and construction has shifted from extension to intensive, refined and cultural development. Cities are paying more and more attention to creating high-quality living environment to meet people's needs, which have gradually risen from the past material needs to spiritual needs. The conservation of historical cities has experienced from "constructive destruction" to "conservative destruction", from the past large-scale demolition to the current "renovation as old". However, can such conservation truly preserve the historical heritage and continue the urban context? Everyone can realize that historical heritage is valuable, but what kind of value is it and how should it be conserved and developed? The real purpose of heritage conservation seems to be lost in the heat wave of urban economic and industrial development needs.

The conservation planning of historical blocks is a complicated project, which involves not only the conservation of historical relics, historical buildings and other physical spaces, but also the requirements beyond the scope of conservation planning, such as cultural inheritance, improving livelihood of people, driving urban economic development and increasing urban vitality, which can be achieved through urban design to satisfy. The urban design of historical blocks is different from that of ordinary cities. More importantly, it is necessary to consider all aspects related to urban humanities. This paper puts forward the humanistic technology of urban design, focuses on the humanistic elements of historical blocks, and explores urban design at a higher level from the perspective of sociology and other humanities disciplines, so as to excavate the essential significance of urban design.

2. Investigation

2.1. Introduction of Harbin

Figure 1 The location map of Harbin and historical blocks of Harbin

As one of the representative cities in Northeast China, Harbin became one of the third batch of national historical and cultural cities approved by the State Council in 1994 (Figure 1). Harbin is a young city. At the end of the 19th century, Russia built the Middle East Railway in Northeast China, making Harbin the central city of Northeast China. Due to the influence of western culture in the early stage of city construction, the urban texture of Harbin, architectural style and urban humanities are completely different from traditional Chinese cities. The characteristics of "European Style" have been extended in the urban development of Harbin which enjoys the reputation of "Oriental Moscow" and "Oriental Little Paris". Harbin is located in the northeast plain, with distinct landscapes in the four seasons, combined with the forthright temperament of the Northeast people, which makes Harbin a historical city with an exotic style and a more distinct personality.

However, with the rapid development of urban modernization, the historical imprint of Harbin has slowly disappeared in urban construction. In 2011, government formulated and implemented the Regulations on the Conservation of Historical and Cultural Cities in Harbin to strengthen the conservation of the authenticity and integrity of historical heritage in the city. In these years, with the efforts of the government and conservators, the urban style of Harbin has gradually unified into European style, ranging from the facades of main streets to the sketches of landscape facilities. Moreover, the government plans to renovate large-scale historical blocks in the city, hoping that through the renovation, the features of the historical blocks can be reproduced and used in the development of urban commercial tourism ,and then become the landmark of the city image. However, the situation of different historical blocks after renovation is quite different. What causes such a result?

2.2. The historical block of Central Street

The Historical Block of Central Street was formed in 1989. Its length is 1450 meters. The street starts from Jingwei Street in the South and extends northward to the Songhua River and ends at the Flood Control Monument in Daoli District. As the only remaining stone street in Harbin, the central street is the most characteristic street in Harbin, which still maintains the square granite pavement constructed in 1924. The European-style buildings on both sides of the road make people feel as if they have come to Europe. The exotic style of the whole street is strong, forming a city space and environment with historical characteristics, which has very high historical value and artistic appreciation value (Figure 2).

Figure 2 The location map and photos of Harbin and historical blocks of Harbin

In 1997, Harbin Municipal Government carried out the conservation and renovation of the historical block of Central Street, positioning the whole historical block as a pedestrian street to reduce the interference of external public transport to the block. It also renovated the building facade along the street, enriched the public activity space, increased the landscape facilities, and made the Central Street into a city characteristic public space integrating commerce, culture and tourism. The Central street has become a veritable architectural art gallery, as the miniature of Harbin image, attracting many tourists every year.

2.3. The historical block of Chinese Baroque

As the birthplace of Harbin national industry and commerce, the Chinese Baroque historical block in Daowai District witnessed the rise and fall of the city from the early stage of development to the end of the 20th century. It is an indelible memory in the hearts of the older generation of Harbin people, which concentrated the old Daowai culture of Harbin. The Chinese Baroque architecture with Chinese and Western style is the biggest bright spot in the block, the Baroque style facade along the street and various details of relief decoration with Chinese traditional meaning are very regional and cultural. The architectural features of "front stores and back factories, upper houses and lower business" made the block one of the most prosperous commercial blocks in Harbin. The traditional old brands in the block are deeply rooted in people's hearts, and they are also an indispensable part of the old Daowai culture (Figure 3).

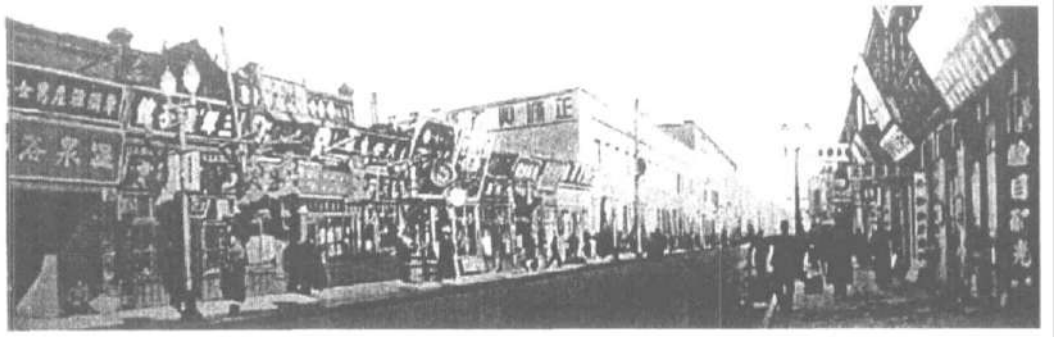

Figure 3 The old photo Chinese Baroque historical block

In order to preserve and continue the historical value of the block and make better use of it, the government began to carry out the conservation and reconstruction project in 2010, and planned the block as a commercial pedestrian street. So far, the first phase has been opened, the second phase has been completed but not put into use, and the third phase of the largest reconstruction area is in progress. However, the effect of the renovation is not satisfactory. Most of the Chinese Baroque buildings in the block have become dangerous houses due to old disrepair, which cannot be repaired. The government took the "rescue of dangerous houses" as the reason, and all the residents in the neighbourhood were forced to move out, so that all the commercial and residential blocks were used for commercial development. The internal structure of the block has been completely changed, only some main streets have been preserved. The building facades along the streets have been rebuilt, leaving only a few historical buildings. At present, some businessmen are stationed in the block of the first phase, and there are many vacant houses in the second phase project. The nine-year-long renovation project is still fragmented (Figure 4).

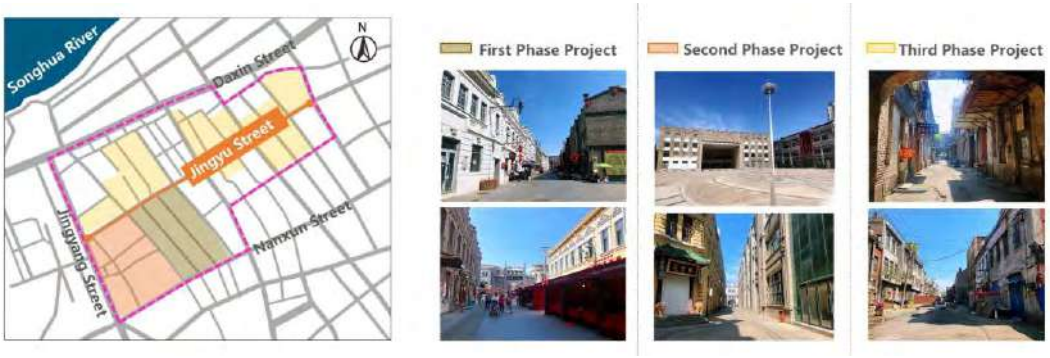

Figure 4 The location map and three phases photos of Chinese Baroque historical block

3. Comparative analysis

3.1. Existing problems of the historical block of Chinese Baroque

Compared with the Central Street and the Chinese Baroque historical blocks, they are also European-style buildings with distinct features and they have similar fish-bone street texture and spatial scales. The transformation model of Chinese Baroque block followed Central Street to transform the whole block into a pedestrian commercial street. It seems that everything should be done in a natural way, but the effects after the transformation are quite different. What did this happen?

From the point of view of renewal mode, although the Chinese Baroque historical block is developed by stages, not large-scale demolition and construction, but the scale of renewal is still not small, belonging to a short period of time to replace the old with the new, rather than small-scale gradual mode. In the process of block renovation, there is a sharp contrast between the north and south sides of Jingyu Street. The buildings on the south side for commercial purposes have obviously lost their humanity, although the structure, function and facilities of the renovated buildings have been greatly improved. And the north side of the street has not yet been renovated so that it retained the residents and their way of life. Although the buildings have been dilapidated, but the market in the block, old brand snacks still attracted a large number of people every day, maintaining the vitality of the block. Such a contrast, which lasted for several years in the process of renovation, which inevitably caused a huge visual and psychological gap between the outsiders and the internal residents (Figure 5).

Figure 5 Contrast photos of north and south sides of Jingyu Street

The government also had problems with the treatment of the residents in the renovation project. Removing all the inhabitants of the block for commercial development could be said to be a fatal wound in the renovation of the historical block. The government required residents to be placed in new areas far from the block, and used monetary compensation to move the old shop away from the original site. Historical and cultural heritage is not only the conservation of material space, but also the bearing of human beings. The daily life of local residents makes the neighbourhood alive and the recollections of the past of old people can be passed down from generation to generation. The relationship between historical blocks and people is in the same line and inseparable. Moving away from the residents, the historical block is like no soul, empty and indifferent.

3.2. Advantages of the historical block of Central Street

Why is it that the Central Street can maintain its vitality and become the focus of the city when both blocks are used as commercial development? The author believes that there are three reasons.

Firstly, Central Street has been given the function of commercial and residential integration since the 19th century, but with the development of the city, the residential function has gradually degraded, and the value of the commercial centre has been established. With years of development, Central Street has retained many old brands and replaced many new commercial functions, devoted to maintaining the original functions while adding the new functions, and strived to form a historical block with centralized and orderly commercial functions. But the Chinese Baroque historical block has always been dominated by traditional small workshops and retail wholesale business. The ownership of buildings in the block belonged to the residents. The renovation project completely changed the traditional living mode of the block in a short time, which would inevitably lead to the confusion of functions.

Secondly, as the urban culture of Harbin, Central Street has been deeply rooted in the hearts of citizen, becoming the pride of the city, and also the preferred choice for local people to recommend to outsiders for travel. This is the so-called urban culture, which has been passed down from generation to generation for many years without propaganda or slogans. It just exists naturally in the hearts of the people. Although the Chinese Baroque historical block is also well known, its location in the minds of people is just where to taste delicious food. And because of the dirty and messy environment before the renovation, it would inevitably make people disgusted. In addition, the government did not realize the importance of neighbourhood culture before, and there are also deficiencies in the strength of cultural propaganda, leading to a bad impression of the block in the public mind.

Thirdly, due to the different times, the transformation of the Central Avenue into a pedestrian street 20 years ago was a big event in the city and was expected by everyone. At that time, the social environment was different from that of the era when information was developed and flooded. People were relatively lack of understanding of various information resources and had great enthusiasm for new things. Therefore the renovation of Central Street had a great impact on the whole city in that era, and received positive feedback. Perhaps the renovation of the Chinese Baroque historical block would have been successful 20 years ago.

It can be seen that the factors affecting the conservation of historical blocks are extremely complex. How can the reconstruction projects be recognized, attract people, and increase

the vitality of the city, the role of human beings is crucial. Urban design has been committed to creating a high-quality urban space environment. During the transition period of Chinese society, when the ideology and values of people have undergone tremendous changes. Urban design needs to follow the pace of the times and consider how to better meet the needs of people from a human perspective.

4. Humanistic technology of urban design

As a special research branch of the conservation and renovation of historical blocks, the humanistic technology of urban design breaks away from the traditional thinking mode of urban design and pays attention to the relationship between people and historical blocks from the perspective of sociology. On the basis of urban design, humanistic technology need to use sociological research methods, from pre-design survey to post-feedback, through data access, field visits and observation, questionnaire survey and other methods to understand the cultural background of historical blocks and the lifestyle of local residents. Humanistic technology regards people engaged in practical activities in historical blocks as the main body, classifies and studies the people involved, and understands the inherent needs and real feelings of different types of users. The research is divided into two technical routes of "human" and "culture", which discuss the human behaviour needs, psychological perception and the significance of culture to human (Figure 6). Through excavating the humanistic elements in the urban design of historical blocks, the reconstructed historical blocks can not only retain their own historical and cultural values, but also meet the needs of users and become meaningful places.

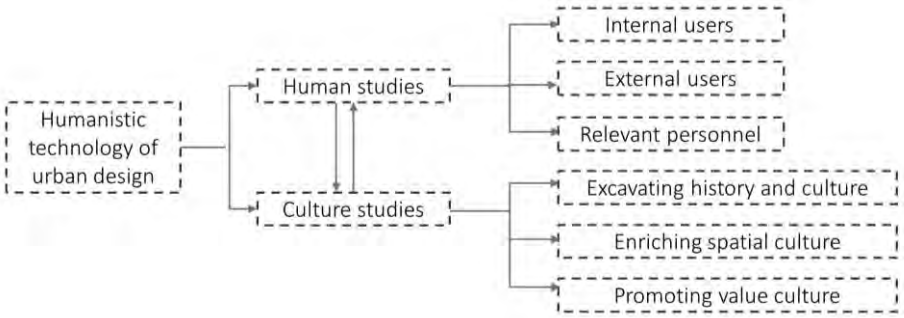

Figure 6 Picture of technical route

4.1. Human studies

(1) Internal users

For historical blocks, people living in them undoubtedly have the most direct and close relationship with them. The daily activities and communication of residents make the neighbourhood more vigorous. They are an indispensable part of the historical block. With the improvement of the living standards of people, the material and environmental conditions of blocks should also be improved. However, due to the long history of buildings, poor quality of buildings and internal environmental conditions, and imperfect hardware facilities, it is difficult for residents to carry out professional renovation of historical blocks themselves, and it may also damage the integrity of historical buildings. It is urgent for the government to provide help to solve the problems of basic livelihood of the people. Therefore, in the renovation project, the people are most concerned about protecting their

own interests after the renovation, hoping to improve the quality of life through the renovation, which is the most important and basic needs. In the reconstruction of the Chinese Baroque historical block, when the government solved the livelihood issue of people, the overall thinking was wrong. The government relocated the residents of the block as a whole and carried out commercial development, which did not meet the needs of the residents. The residents of the historical block were placed in the residential areas far from the city centre, and the self-employed businesses in the block were relocated from their original sites. These practices are contrary to the wishes of the residents, resulting in many difficult contradictions in the process of renovation.

The humanistic technology of urban design emphasizes the concern for people and the relationship between people and environment. The daily life of residents in historical blocks makes the static space alive and makes the culture of historical blocks more vivid. The practice of removing residents in the renovation is to separate the environment from people. Even if the buildings and streets are repaired, the block culture which has lost the mark of traditional social form will not be able to continue. The relationship between blocks and people is mutual. People give vitality and meaning to blocks, and blocks also bring people spiritual perception. The sense of belonging to blocks is a profound cultural rooting for the residents, a historical story and collective life memory handed down from generation to generation. This sense of belonging will unconsciously rise to a sense of responsibility and pride, and this precious humanistic spirit can be used as a positive factor in the renovation of historical blocks. On the basis of improving the living needs of residents in blocks, the government should communicate with them so that they can play a positive role in the renovation of blocks, including the renovation of buildings, the improvement of the environment, and the cultural dissemination of the public, and use their special identity and sense of mission to help the government departments to promote the progress of the renovation work smoothly.

(2) External users

External users include tourists in historical blocks and passers-by on weekdays. The humanistic technology of urban design focuses on the experience of these people in the block. Unlike internal users, they need more from spiritual and psychological perception, including multiple experiences of space, culture, consumption and so on. Spatial perception should be the most direct sensory impression of the block for users, and also the first impression of the historical block after urban design and transformation. The unique architectural style, the rich and varied streets, the traditional landscape, all the elements in the space can be related to the perception of users. Although different people have different feelings about the same place, a good place can provide stable visual symbols, so that people can reach a consensus on their sensory experience to a certain extent, and this consensus is that the experience rises to another height - spiritual experience. The sense of history, culture and deep thinking brought by the renovated historical blocks are the ultimate significance of urban design and the core value of humanistic technology of urban design.

In addition, it has to be mentioned that with the increasing level of consumption, historical blocks have become the gathering place of commercial tourism consumption. The change of the concept of product consumption to experiential consumption has made many people pay little attention to the significance of historical blocks themselves. The concern for their

own value and leisure grade transcends culture and history. Consumption in historical blocks is regarded as the embodiment of elegant aesthetic pursuit. This is because with the development of the times, the values of people are changing. We cannot control this trend, but the humanistic technology of urban design can make corresponding measures according to this phenomenon, strengthen the propaganda of humanistic spirit in historical blocks, and guide people to correct the values of historical culture.

(3) Relevant personnel

The government is the leader of renovation project of historical blocks. It not only has all the powers from urban planning, land expropriation, land use right transfer, financial allocation to project review, but also monopolizes the decision-making power of social policies for the allocation of various public resources. Because of the own economic value of historical blocks, commercial tourism development is the most common mode in the transformation. Developers pay most attention to economic benefits. Whether the government seeks a balance between developers and residents or forms a community of interests with developers determines the future development trend of a historical block. The renovation of Chinese Baroque historical blocks is a typical urban development in which the government and developers work together with land efficiency as the goal. In this process, in order to pursue short-term interests, the renovation of historical blocks was carried out blindly, regardless of the rights and interests of residents, resulting in a series of collateral contradictions and irreparable consequences.

The humanistic technology of urban design need to take restrictive measures to the government, set up supervision groups in the government, and require the government to focus on improving the livelihood of people, listening to public opinions, and doing a good job in public participation. At the same time, in cooperation with developers, the government should take into account the overall situation, achieve the common development of historical and cultural conservation and commercial tourism development, meanwhile, manage and control development projects. Moreover, the government should strengthen the understanding of urban culture for developer, do a good job of publicity and guidance, and make investors realize the importance of conserving historical culture.

4.2. Culture studies

(1) Excavating history and culture

Each historical block has its own historical and cultural background and traditional regional characteristics, which should bring people unique cultural experience. However, in China, many historical blocks have been developed as commercial tourism, which has become increasingly homogeneous. In order to achieve short-term economic benefits, developers neglect the real cultural connotation of historical blocks. Designers know little about the conserved objects and make blind decisions based on subjective assumptions. Policymakers are eager to make quick successes and profits, and they are keen to create theme cultural tourism brands. The reproduction of various spaces and collage of cultural symbols lead to the engulfing of some local characteristics.

The humanistic technology of urban design requires the government and designers to do a good job of historical and cultural investigation in the early stage of reconstruction. Researchers need to study the background culture of historical blocks by consulting a large number of documents and feel the local culture by on-the-spot investigation, through the

external form to discover its intrinsic essence and integrate the form of historical blocks with the spirit of culture and context. In order to provide an important reference for the preliminary study of urban design and renovation, the humanistic research reports of the corresponding historical blocks should be sorted out before the renovation.

(2) Enriching spatial culture

When space is endowed with culture, it becomes meaningful. Spatial culture in historical blocks is manifested in the physical environment on the one hand, and in the daily social life of the residents on the other. The decorative elements in architecture, the texture of traditional lanes and the landscape environment left behind by history are objective material cultures. The humanistic technology of urban design emphasizes that these cultural symbols should be retained to the greatest extent, and their authenticity should be restored as far as possible in the process of renovation, and these cultural symbols can be applied to the surrounding environment to coordinate with historical blocks.

The daily activities of people in the space are the lively embodiment of the culture of historical blocks, including the living life and customs of people in the blocks, activities of traditional festivals and so on. It can be seen that the living cultural inheritance can better reflect the humanistic spirit of the historical blocks. If the residents of the historical blocks are moved away for commercial development, even if the traditional cultural activities are joined, they cannot make people really feel the traditional living form and folk customs of the historical blocks. So, the humanistic technology of urban design adheres to the principle of "coexistence of people and houses" in the transformation, retains living customs of the local people, so as to inherit the cultural context and make the culture alive.

(3) Promoting value culture

The essence of urban design is to enhance the physical environment of the city to have a positive impact on lives of people, and the ultimate goal is to arouse people to think about the meaning of life. Most people know the need to conserve the cultural value of historical blocks, but this is only an idea for people, and cannot affect their behaviour. Humanistic technology of urban design is not only static conservation of historical blocks, but also promoting the shaping of humanistic environment in historical cities through the alive culture of historical heritage, so as to have a lasting and profound impact on the citizens. To a great extent, values of people will affect the conservation and planning of historical and cultural heritage. Enhancing the public sense of identity and pride in urban history and culture, avoiding cultural apathy, and advocating that residents of historical blocks become the insiders and beneficiaries in the conservation word, are also the core issues to be solved in the humanistic technology of urban design.

5. Conclusion

This paper investigates and studies two historical blocks in Harbin. Through comparative analysis, it is found that the existing problems are not only the level of urban design itself, but also related to human, social and other reasons. In view of various contradictions in the renovation of historical blocks, this paper puts forward the humanistic technology of urban design, hoping to examine urban design from a new perspective and make up for the lack of humanities in conventional urban design. This kind of technology needs designers to read a

lot of humanities materials, and be familiar with the use of sociological research methods, which is a challenge for designers. Designers need to have keen observation, be good at communicating with people, and find problems in the city. How to make the humanistic technology of urban design more standardized and specific needs further research, so that it can be used as a necessary special procedure in urban design.

REGENERATION OF RAILWAY INDUSTRIAL HERITAGE

Implementation evaluation and development strategy of Hengdaohezi town protection and renovation project

Abstract

With the rapid development of Chinese railways, the renewal and reuse of railway industrial heritage is an important part of remembering urban history and inheriting urban culture. Hengdaohezi Town in Heilongjiang Province of China is the historical heritage in the period of Russia "building railways by borrowing land" in Northeast China at the beginning of 20th century. Many railway industrial heritage such as train engine house, churches and residential blocks of railway workers are completely remained in the town. How to correctly treat the historical products of the invaded period and move towards the future is of great significance for the development of the town. So taking Hengdaohezi Town Conservation Project, which won the 19th UNESCO Honorary Prize for the Protection of Cultural Heritage in the Asia-Pacific Region in 2018, as an example, this paper analyses the historical, cultural, economic and social value of the railway industrial heritage in this town, and introduces the planning and measures of protective development of Hengdaohezi Town at three levels： preserving the historical authenticity of buildings, shaping the historical and cultural features of the historic protected areas, and activating the rational and sustainable development of the town. After that, through questionnaires and interviews with local residents and visitors, Satisfaction evaluation was carried out in six aspects: cultural perception, heritage protection, environmental grace, urban vitality, facility perfection and life comfort. Finally, targeted strategies for the future development of this Railway Industrial Heritage Town are put forward.

Keywords

railway industrial heritage, historic town, culture, Regeneration

1. Historical development of Hengdaohezi town

At the beginning of 1891, in order to control the far east and the northwest Pacific Ocean, the tsarist Russia conference decided to build a Trans-siberian railway across two continents

in Europe and Asia, so as to bring troops and strategic supplies to the eastern city of Vladivostok. If the railway passes through China, construction difficulties can be reduced, the length of the railway can be shortened, and the cost of road construction can be saved. Historical development gave tsarist Russia an opportunity. In March 1895, the Qing government of China advocated uniting with Russia to resist Japanese aggression. Tsarist Russia seized the opportunity and proposed to borrow land to build roads. At the end of the 19th century and the beginning of the 20th century, the tent-shaped railway, also known as the Chinese Eastern railway, was built in northeast China. All the rights to build the railway were monopolized by tsarist Russia, and they illegally occupied farmland and other natural resources along the railway, and oppressed Chinese workers and peasants as cheap labor for the construction of the railway. Therefore, the Chinese Eastern railway, on the one hand, is the witness of China's history of being invaded and colonized in modern times, on the other hand, it greatly promotes the industrial civilization in northeast China.

The Chinese Eastern railway is divided into trunk and branch lines. The main line starts from Manzhouli in the west and goes through Harbin to Suifenhe in the east. The branch line starts from Harbin and goes south through the capital of Jilin province and Liaoning province to Lushun. Various stations have been set up along the route. The main construction section of Hengdaohezi station is from Hengdaohezi to Kaolingzi. Because of the difficulty of crossing Zhangguangcai mountain, a large number of Russian railway construction experts and technicians are concentrated in Hengdaohezi, leaving a large number of Russian architectural in the town.

Figure 1 Chinese Eastern railway station along with Hengdaohezi ‘s location

2. Characteristics analysis of Hengdaohezi town

2.1 Settlement form

The town is divided into four major parts by railway, river and mountain. In the northern part of the railway, there are many russian-style buildings and architectural complexes, which basically retain the early terraced residential form. The space between railway and river is narrow and narrow, and some early russian-style houses are scattered here and there, and the residential form is banded. South of the river and east of the mountain are mainly built after the founding of the People's Republic of China. Surrounded by mountains and rivers, the town is high in the north and low in the south, with the land slope of less than 25% and the local area between 25% and 50%. Relying on the growth and development of railway and river, the architectural form conforms to the scattered architectural layout of Russian villas.

2.2 Street and lane space

Street spatial pattern of small towns is dominated by determinant and radiative pattern, among which the street and lane north of the railway still maintains the early determinant pattern, and the street and lane spatial determinant developed after the founding of the republic of China south of the railway is mixed with radiative pattern, which basically forms naturally according to the topography and topography. The scale of old streets and alleys in the north of the railway is pleasant, and the width (D) varies between 2m and 5m, and the height (H) of eaves of buildings on both sides is usually 3m and 4m.

2.3 Architectural features

Hengdaohezi town's historic buildings are mainly small houses and public buildings. Small residential plane relatively neat, double slope roof, black iron sheet; Metope yellow, wall base stone miscellaneous laying bricks or stones, corner white embrace Angle shape line Angle; Green wooden door, outside door has small eaves; The vertical feature of wooden window is obvious, the window wall is smaller, herringbones gable, chimney out of the roof. Public building plane one shape, L shape, mountain shape, Latin cross, black iron sheet double slope roof.

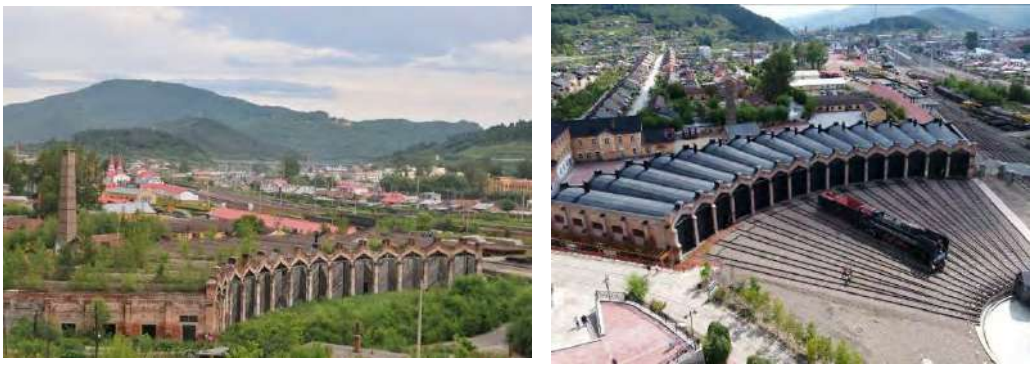

Figure 2 Hengdaohezi town settlement form

2.4 Decorative arts

The architectural decoration of the small town has strong cultural characteristics of different regions, which is manifested in various aspects such as plane modeling, roofing material, wall, door and window decoration and foot contour. Typical examples include Russian onion dome, tetrahedral tower drum base, Russian flat plate woodcut and carving patterns, etc. The application of these detailed components and decorations reflects many style features of Russian architecture.

2.5 folk culture and customs

The town's population is predominantly Han, with a small number of Man and Korean residents. Russian customs, food culture, life customs, folk arts and crafts are mixed and permeated with each other, forming a rich and colorful folk culture. At present, the town still has the characteristics of Russian national customs in terms of food and clothing (drinking beer, fruit wine and strong liquor, eating ham sausage and bread), which fully reflects the inheritance of the town's culture.

3 Heritage status and value assessment

3.1. Heritage survey

There are more than 100 cultural relics buildings in Hengdaohezi town, among which there are five national key cultural relics protection units (table 1) and 18 municipal cultural relics protection units, which are mainly distributed in the north of the railway.

No.	Name	Historical age	Photos	Heritage status
1	Hengdaohezi engine house	1903		Hengdaohezi locomotive depot is located in the middle of Hengdaohe town, Hailin city, with a building area of 2160 square meters. The plane is fan-shaped, with 15 parking Spaces and garage doors on the inner elevation, facing the locomotive shunting platform in the direction of fan-shaped center.
2	Church	1902		The church is located at the foot of Dongshan, Hengdaohe town, Hailin city, with a building area of 614 square meters. The main body of the wood carved structure, the plane was a Greek cross; Modeling, structure, technology, decoration and other early Russian architectural style.

3	Great white building	1905		Russian building with brick walls and tiled roofs, white at the corner of the window eaves, yellow at the rest, three-story building. At first for the Chinese Eastern railway east section of the road command center, after the use of hengdaohezi railway management organs, is now a railway workers housing.
4	Railway police station	1904		Russian style building with brick wall and tiled roof, stone corner, two-story building. At first, it was the site of the Russian railway guard stationed in Hengdaohezi, and now it is the residence of railway workers.
5	Russian cabin	1897		All wooden structure, fine carving and decoration, typical Russian architectural style. At first for the Russian senior road workers living, until the russians moved away, is now the railway workers housing.
6	Historical residences	1830		Most of them are residential buildings, and a few are abandoned. The roofs are pitched with iron sheets or linoleum roofs. The walls peel off and the roof rusts obviously.

Table 1 Status table of important historical relics

3.2. Value assessment

1. Historical value

Hengdaohezi town has nearly 100 Russian-style cultural relics and buildings, which is an important demonstration of the invasion of northeast China by the Russian imperialists, and the physical remains of the world's understanding and facing up to history, with a good

historical readability. Among them, Hengdaohezi locomotive depot represents modern industrial construction civilization. Railway white building is the original Chinese Eastern railway experts housing and office building. Notre Dame cathedral is the only surviving wooden church in the three northeastern provinces. Old Russian street is the most complete preservation of the Russian style historical block. These architectural heritages are completely and intensively preserved, which can completely reflect the historical features of the tsarist period and the Japanese and puppet period, and is the historical witness of the Chinese Eastern railway.

2. Scientific value

The historical relics of Hengdaohezi town are the most well-preserved part of the Chinese Eastern railway, which is an important material for studying the development of Chinese Eastern railway in China. Locomotive depot, Notre Dame church and Russian wooden house all retain the original layout and early Russian traditional architectural forms, materials, colors, decorations and styles, which are important contents of the study of Russian cultural history, local cultural history and railway industry culture.

3. Social value

The protection and planning of Hengdaohezi town can not only reflect the respect for history and foreign culture, but also help to shape and improve the image of local culture, and promote the people, especially the young people, to learn historical knowledge and patriotic education. At the same time, protecting the historical buildings and cultural relics in this town is conducive to promoting the international cultural exchanges between China and Russia, driving the development of the local tertiary industry, driving economic growth, creating more jobs and improving public service facilities, which plays a great social positive role for local residents.

4. Artistic value

The historical buildings in Hengdaohezi town, no matter industrial building locomotive depot, religious building Notre Dame church or historical dwellings, all have unique structure and shape, giving attention to functional and aesthetic needs. The doors, Windows, walls, pillars and eaves of triangulated mountain flowers, etc. of the buildings all have extremely Russian architectural art style [2]. A large number of Russian architecture has left the most authentic side for human beings, with high artistic appreciation value.

Value	Hengdaohezi town industrial heritage value assessment factor
Historical value	architectural age, architectural history, architectural function, architectural heritage integrit
Scientific value	architectural culture, architectural artistry, architectural construction technology
Social value	traffic conditions, reuse potential, educational value, building management, population capacity
Artistic value	value artistic uniqueness, artistic influence, artistic history, artistic native

Table2 Hengdaohezi town railway industry relic value evaluation factors

4 Existing problems and development opportunities

A large number of Russian-style buildings in Hengdaohezi town have gone through centuries of suffering. Most of the buildings have been subjected to natural erosion and man-made changes, mainly reflecting the following aspects.

4.1. The historic building lacks the necessary repairs

There are a considerable number of buildings and structures that destroy the historical environment features in the historical blocks. It is very common for residents to build or rebuild the historical buildings and ancient dwellings at will. Building density increases, some areas not only can not see the original face of Russian architecture, broken the original Russian architecture "one house one courtyard" garden-style layout pattern, and buried a great fire hazard. The overall economic strength of Hengdaohezi town is relatively weak among the towns and villages in Hailin city. Faced with a large number of historical relics of the past, there is a shortage of funds, and the current situation of cultural relic protection is worrying.

4.2. Historical town protection zoning is unclear

Improper zoning of the protection scope and construction control zone of existing cultural relics protection units, failure to meet the requirements of the safety and integrity of cultural relics protection, and poor operability of management and implementation.

4.3. Development and construction are not in harmony with the historical environment

The rapid and disorderly development of small town's construction and the old city reconstruction for the purpose of real estate development, the newly built residential areas and some modern buildings do not consider the spatial scale relationship of streets, and are rarely coordinated with the surrounding buildings. The improper architectural scale and block layout affects the overall landscape.

4.4. The living environment and facilities of residents are poor

Due to the poor condition of municipal facilities, so that the garbage heap disorderly fall, sewage directly into the street, soil and gravel pavement caused serious dust environment. There is little green space or public space. There is no protective green belt between No.301 national road and old street, which makes old street suffer from dust and noise all the year round. The present market occupies the road management, seriously affects the town traffic and the environment.

5 Protection strategy

The purpose of town protection is to effectively protect excellent historical and cultural heritage, improve the living environment in areas with historical and cultural features, improve municipal infrastructure, and drive the development of tourism and other related industries. According to the requirements of relevant planning regulations for the protection of famous historical and cultural cities in China, the following strategies are proposed for the protection planning of small towns.

5.1. Protect the historical authenticity of the building

Cultural relics and historical environment not only provide intuitive appearance and architectural form of information, but also is the physical carrier of historical information, which can convey historical and scientific information that is not known today but may be known tomorrow. Cultural relics and historical environment are not renewable, and protection is the first choice. Therefore, the protection of historical buildings on the basis of authenticity.

Taking Hengdaohezi town engine house as an example, different structures adopt different protection measures to protect the authenticity of historical buildings.

1) Load bearing

In the repair process, the original steel column support structure should be retained as much as possible, and the columns that affect the safety should be strengthened. The traditional materials, forms, structures and practices should be used to reinforce the framework. The replacement materials should meet the requirements of fire rating and mechanical strength.

2) Wall

Wall repair adopts traditional technology, structure and bricklaying of traditional brick materials. The wall bricks that are reduced are plastered, removed, repaired or replaced, and the paint that falls off is restored according to the original shape.

3) Doors and Windows

The repair of the doors is restored in accordance with traditional symbols, patterns and original shapes.

4) The roof

Roofing should be laid in traditional form, replacing bare and corroded steel frame. According to the traditional pattern, the original authenticity of the building is maintained, and the smoke exhaust facilities and cornice are completed.

The historical authenticity protection of engine house building is also reflected in the construction and management, paying attention to material selection, construction technology and experimental inspection. The original red brick of the building was analyzed, and the wall brick repair material was configured. All construction timber is dry anticorrosive material; All the steel used are national standard materials. Water-based paint and oil decoration and the project also collected more than 40, 000 bricks from the same period as wall materials. The traditional process method is adopted in the construction, and the manual operation is carried out in accordance with the principle of original restoration. The cleaning and repair of the wall ,stone and iron parts are all carried out by means of small area experiment, inspection and comprehensive construction.

Figure 3 Comparison before and after repair of engine house

5.2. Harmonizing the Historical and Cultural Style of Towns

Any historical relic exists at the same time with its surroundings. Losing the original environment will affect the correct judgment and understanding of its historical information. The historical and cultural features of Hengdao Hezi Town are embodied by its urban pattern, neighborhood texture, street space, historical buildings and traditional buildings, facilities and structures, ancient trees, etc. Therefore, the protection of Hengdao Hezi Town's historical and cultural towns is not only to protect individual cultural relics, but also to protect the relics and historical blocks. The surrounding environment and historical atmosphere.

1. delimitation of the core protection scope of small towns

Firstly, historic areas are divided into core protection areas, construction control zones and construction coordination zones from the level of small towns. The historic areas with complete traditional pattern and historical features and concentrated historical buildings in the town are classified as the core protection areas, and the construction control areas are reasonably delineated beyond the core protection areas.

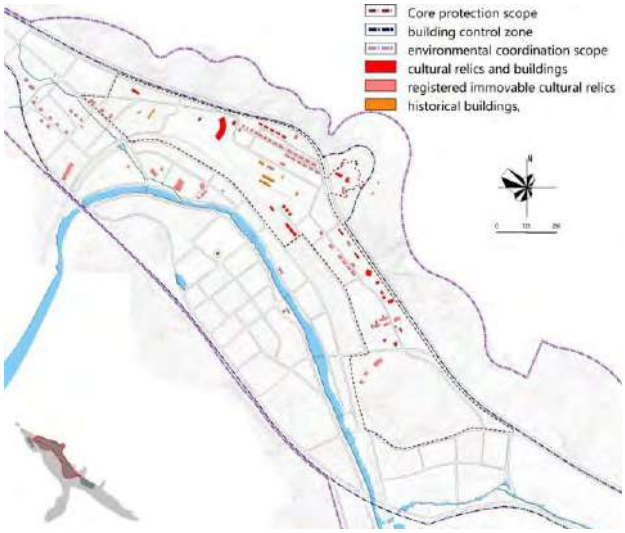

Figure 4 delimitation of the protection scope in hengdaohezi

2. delimitation of the scope of protection of cultural relics protection unit

Secondly, according to Heilongjiang Provincial Regulations on the Administration of Cultural Relics, special protection zones, key protection zones and general protection zones are delineated for historical buildings and cultural relics. Around historic buildings, two to five times the height of the main building is the protected area, and four to eight times the height of the main building is the construction control zone.

Among them, the important control regulations of key protected areas are as follows:

1) No new structures and buildings are allowed to be constructed within this scope, and they can only be updated according to the overall environmental planning. According to the National Law on the Protection of Cultural Relics, the layout and space features of building groups are strictly protected.

2) Implementing a complete set of environmental remediation measures. Buildings that have adverse effects on cultural relics within the scope of protection, such as those with insufficient fire protection spacing, should be demolished step by step. Cables and wires are buried or moved.

3) For cultural relic buildings, the monomer color and materials of the buildings should be standardized. The maintenance, repair and reconstruction must be carried out in accordance with the original style or special detailed planning, especially the details of doors and windows.

4) Photo filing, fine design, construction with modern technology, restoration of the original building facade shape, color, material, pattern, etc., to achieve the original flavor, stable structure, solid decoration, complete sanitation and Hydropower facilities.

5) No unit or individual can change the main body, accessory facilities and courtyard green space of the protected building without authorization.

6) All land related to the safety of cultural relics is requisitioned and purchased by the state, and the nature of land use is changed to "land for cultural relics and historical sites". The nature of other land use is strictly controlled as non-construction land.

7) No activities detrimental to the cultural relics shall be carried out; no construction projects or blasting, drilling or excavation shall be carried out.

8) Implement effective security and protection measures, including fencing and drainage ditches, installation of monitoring equipment where necessary, and deployment of special guardians.

9) Cultural relics renovation projects must be submitted for approval in accordance with legal procedures.

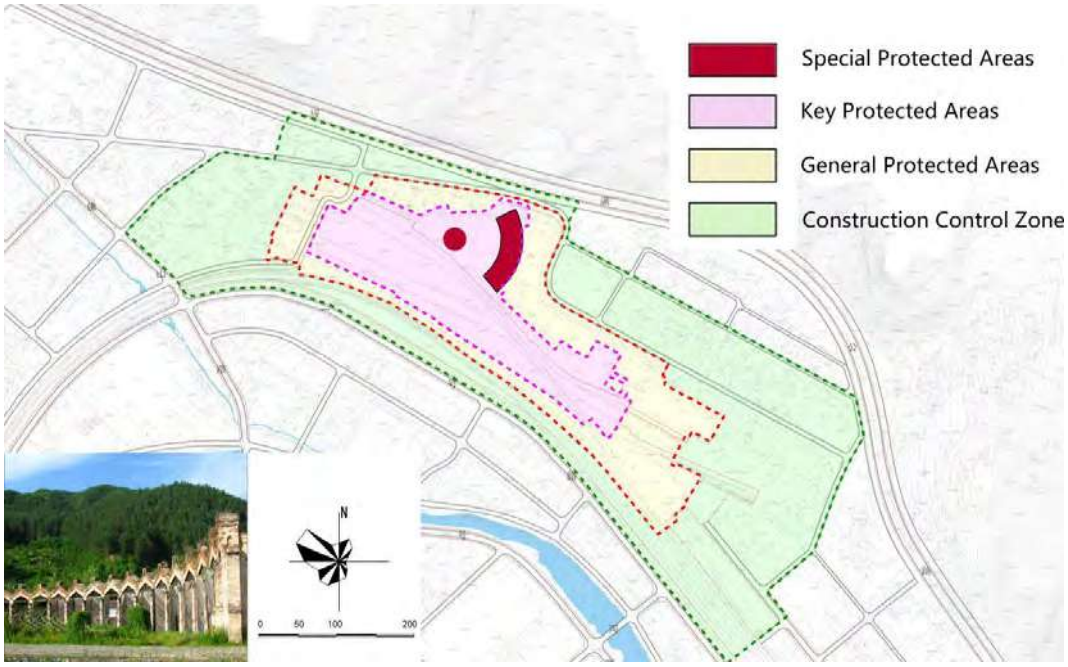

Figure 5 Protection Zone Around engine house

3. Classification and delimitation of other buildings in small towns

Finally, according to the current situation of the buildings in the protection area of small towns, the historic buildings are divided into renovation buildings, improvement buildings, preservation buildings and renovation buildings.

Conservation buildings shall not be demolished, but shall be actively maintained, repaired and reused; any construction activities within the scope of the protection of cultural relics units must comply with relevant provisions; specific requirements for conservation buildings should be specified at the level of detailed planning or planning plan.

Rehabilitation buildings retain the original pattern, appearance repair; interior appropriate updates, increase health design. Allow appropriate changes to the internal structure. No unauthorized demolition or relocation shall be allowed, and special circumstances shall be considered and adopted; renovation plans shall be considered and approved by relevant administrative departments; new, expanded and reconstructed buildings shall be in harmony with historical buildings and shall not affect the normal use of retained historical buildings.

Improved buildings should not be demolished as a whole, but should be repaired and reused. When demolished under special circumstances, they should be rebuilt according to the original building height, location and style. They should also retain their distinctive building components and features, which are in harmony with the overall features of small towns.

Retention buildings require painting and decoration of the exterior facades of buildings, and gradually transform them.

In the case of land reconstruction, municipal and road facilities construction, green space construction, overall development of land blocks and other circumstances, renovation buildings shall be demolished according to the requirements of planning and management.

The demolished open space shall be constructed in accordance with the requirements of protection planning.

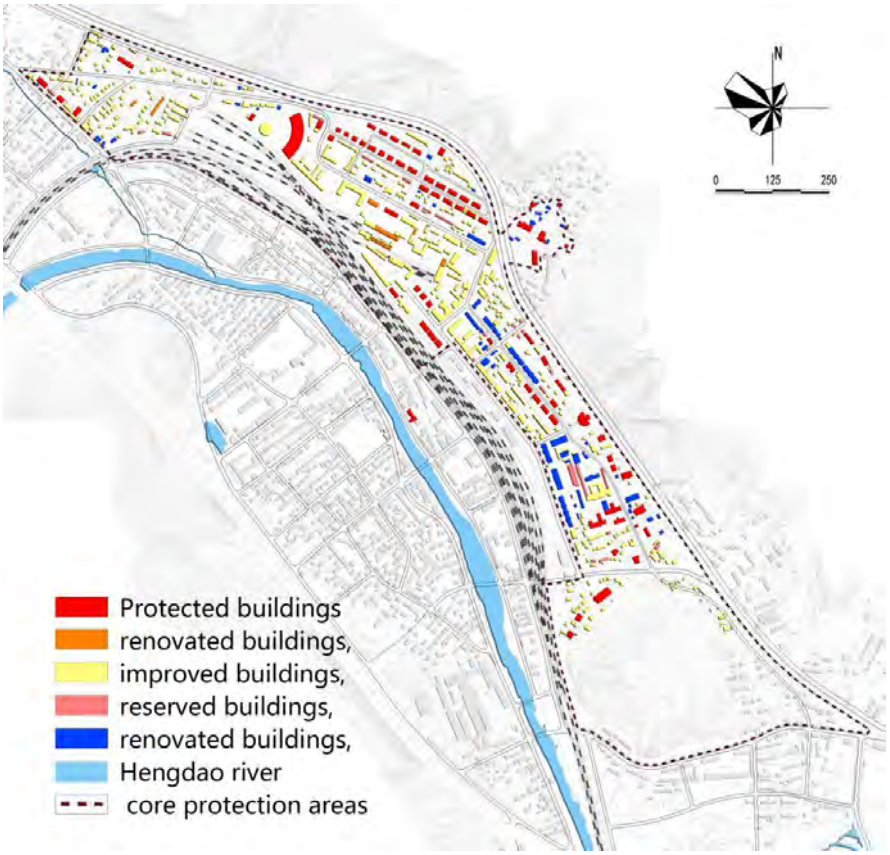

Figure 6 Classification and delimitation of other buildings in hengdaohezi

5.3. Activating the Reasonable and Sustainable Development of Cities and Towns

The utilization of historical and cultural heritage should not be quick for quick success and instant benefit, nor simply pursue economic interests. The current way of utilization should ensure the sustainable development in the future. Historic and cultural heritage has become the core resource of tourism development, and the protected area of historical and cultural features is also the area where local residents live for a long time. We should coordinate the relationship between the protection of historical heritage, the improvement of living environment and the development of tourism industry, combine protection with utilization, give priority to protection, and formulate a region with sustainable development significance. Protection planning. The construction of the new area should be coordinated with the protection of the old city. At the same time, attention should be paid to improving facilities to meet the needs of urban economic and social development and improving people's living environment.

Through the protection and regeneration of railway industrial heritage, Hengdao Hezi Town attracts many photographers and film producers to take photos in the town. At the same time, there are many sketch enthusiasts, surveyors and mapping personnel to the town for architectural sketch and mapping. After the renovation, the tourism function of Hengdao Hezi Town derives other service facilities, such as Museum management, souvenir shops, youth hotels, restaurants and so on, which can stimulate local employment. In addition,

Hengdao Hezi Town constantly attracts painting and photography enthusiasts, and even cooperates with relevant art courses in universities to maximize the value of architectural art and culture; after the town is protected, the local residents feel better, and in order to adapt to the development model of the town, they take the initiative to learn cultural knowledge, and then continue. Promote the exchange and development of Sino-Russian culture and railway culture. In March 2018, Hengdao Hezi Town signed an agreement of friendship and cooperation with Taiwanese market towns with similar railway culture. In the light of their respective railway industrial heritage, they jointly excavated the cultural connotation of railway industry, jointly created the brand of Railway Cultural tourism, and continuously promoted the development of railway industrial heritage culture.

6 Implementation Assessment and Strategy

Through a one-week questionnaire survey conducted in Hengdaohezi Town in June 2019, 100 questionnaires were distributed to local residents and 50 questionnaires were distributed to tourists. Six aspects of Hengdaohezi Town's current cultural awareness, heritage protection, environmental grace, urban vitality, facility perfection and living comfort were investigated. An investigation was carried out.

Types of Evaluation	Satisfaction Influencing Factor	Score
Cultural Perception	Russian Cultural Perception	4.2
	Chinese Eastern Railway Culture Perception	3.8
	Cultural Experience	2.7
Degree of Heritage Protection	Satisfaction with Rehabilitation Effect of Industrial Heritage	4.1
	Reuse Degree of Industrial Heritage Buildings	3.6
	Readability of Heritage Buildings	3.3
Environmental gracefulness	Satisfaction of Environmental Landscape	4.4
	Satisfaction of Artificial Landscape Sketches in Small Towns	2.2
	Satisfaction of health environment in small towns	2.8
Vitality of Towns	Richness of Tourism Facilities	2.4
	Vitality of Public Space	1.8
Facility perfection	Satisfaction with leisure and recreational facilities (commercial facilities, recreational facilities, recreational facilities, etc.)	1.5
	Basic-service satisfaction (public toilets, street lights, etc.)	1.7
Living Comfort	Summer Climate Comfort	3.9
	Job satisfaction	1.2
	Economic Income Satisfaction	1.1

Table3 Hengdaohezi town railway industry relic value evaluation factors (1-Very unsatisfactory 2 unsatisfactory 3 general 4 satisfied 5 very satisfied)

In terms of cultural perception, the existing Russian culture and the Chinese Eastern Railway culture have been well perceived, but the cultural experience is not high and there is a lack

of practical cultural experience activities. For example, to increase the open experience of traditional Russian dwellings, to increase the experience activities of railway construction operation culture, etc. Increase related cultural and creative activities.

The overall evaluation of heritage protection degree is high, which shows that Hengdaohezi Town has achieved good results in the protection of railway industrial heritage. However, the readability construction of railway industrial heritage should be strengthened for tourists, and the propaganda, explanation and guiding signs of architectural history should be increased so that residents can understand the small town rather than just watch it.

In terms of environmental gracefulness, the natural environment of small towns has been recognized, but the artificial environment is not satisfactory. The artificial landscape style of small towns still needs to be strengthened. Especially for the core protection area and key protection area of historical areas, which are the main tourist sightseeing routes and active areas, the greening and landscape should be strengthened. Shaping sketches can improve the sanitary environment of small towns and create clean and beautiful towns.

In terms of urban vitality, the satisfaction of residents and tourists is low. Because of the insufficient richness of tourism facilities, the number of tourists attracted is insufficient, and the vitality of cities and towns is poor. In addition, because of the lack of supporting facilities, the attraction of urban public space activities is insufficient. Therefore, through the increase of tourism facilities and the holding of special activities, small towns should introduce people into cities and towns to stimulate their vitality.

The degree of satisfaction of facilities improvement is low, especially the related commercial entertainment facilities are obviously insufficient. To solve this problem, we should develop characteristic commercial activities in small towns, increase leisure facilities, pension facilities and so on. At the same time, planning public toilets, trash cans, street lights and other infrastructure.

In terms of living comfort, the city has better climate comfort in summer, which can increase publicity efforts to attract people to spend summer. However, the poor job and economic satisfaction is mainly due to the small town's tertiary industry is still in the initial stage of development, a large number of people are still farmers or workers. In the process of Railway Heritage protection, through the development of core areas, people's employment will be stimulated, and the development of small town economy will be driven by tourism and tertiary industry.

Case Study Paper

The Road Of Rebirth——Place making in Bidur from the Perspective of CulturalLandscape

Weisi Zhou , WLSP; CHINA
Qi Hong, WLSP; CHINA
Wei Xiong, WLSP; CHINA

Abstract

Bidur is located in north-central Nepal, which used to be the royal capital of Nepal in18th century and is now working as the capital city of Nuwakot. In 200 years, the urban development has moved from the mountain to the valley at both sides of the Trishuli River, developed from north to south and gradually formed Bidur, Battar and other groups, which constituted the ancient and modern development axis. As the capital of history, The city boasts prosperous historical and cultural resources, endowed with superior landscape and features. However, due to the limitation of natural conditions and the level of economic development, the level of urbanization is still in its infancy. The city has been in a fix of various problems such as scattered urban space distribution, backward living and service facilities, insufficient economic power in the city, serious damage to historical sites and so on .So how to protect historical and cultural resources and understand cultural values in the process of urbanization, how to use the unique resources of the city to improve the vitality of the city and how to prevent and predict the earthquake, flood and other natural disasters and ensure the safety of cities are the three most important aspects in place making for such poor citys like bidur.

Basing on the culture, ecology, landscape and value as the breakthrough point, and taking the protection and construction as double means into consideration, this paper aims to put forward some ideas to improve space environment, living standard, while enhance city vitality and create more vigorous living place for such underdeveloped citys. Firstly ,the new three major development concepts:organic growth, elastic cluster and coexistence of the old and new have been put forward from the SWOT analysis, the paper also identified the urban spatial structure and clarifying the urban functional zoning. Secondly ,the paper put forward from the aspect of cultural protection, public services, ecotourism and urban design four aspects we put forward respectively strategies such as building up classified and level-by-level culture protection system with orderly guidance and control, hence to build an equally shared and easily accessible public service system, Developing a Management—Usage Combined and Ordered Tourism System and Forming a distinctive landscape system with both ancient and modern attractions. Finally, we point out the two paths to realize place making . The first one is to explore the urban context a and continue the urban pattern on the basis of historical protection, while the second is to implant the tourism project, activating the urban economy; the third is to improve life as the goal, in which the life quality will be promoted in the process of respecting cultural differences, improving the quality of the site.

Place making in Bidur from the Perspective of CulturalLandscape

Keywords

Nepal Place-making Culture Ecology

1. Project background and overview

1.1. Project background

Nepal is one of the developing countries in the world, which suffers from unstable political situation and lacks of complete urban planning system. The earthquake in Nepal in 2015 caused the demolishment of Zhangmu Port at the border between China and Nepal and led to rise of Gyirong Port in the north of Bidur. Therefore, as a bridge connecting Gyirong and Kathmandu, the capital of Nepal, while the rising Bidur will usher brand new development opportunities.

China has launched the "Belt and Road Initiative" to join hands with the countries along the belt and road to develop together. In this context, invited by UN-HABITAT, Wuhan Land Use and Urban Spatial Planning Research Center (WLSP) and Wuhan Planning & Design Institute (WPDI) formed a joint design team of one and a half years to prepare the Integrated Development Planning of Bidur in Nepal, a country along the belt and road. This project is not only an action guide for the post-earthquake reconstruction of Bidur, but also a strategic blueprint to highlight the location of Bidur and the characteristics under the superposition of multiple opportunities.

1.2. Bidur Introduction

Bidur lies in Central Nepal and is the capital of Nuwakot, which is some 30 km northwest of the Kathmandu Valley and 60 km away from Gyirong. Since ancient times, it has been a major economic and cultural exchange hub and traditional border trade market between China and Nepal. Now this city falls into 13 districts (across the city proper and five rural development committees) and comes up to 130 km2.

In 2017, the city's had a total population of 54,351, with about 20.14% of them were urban residents and enjoyed a 2.35% annual growth rate. From 2001 to 2011, the urban population rose from 21,193 to 26,750, up 2.35 YoY. And the local economy is still based on agriculture and grows about 2% YoY, being left behind in the national economy.

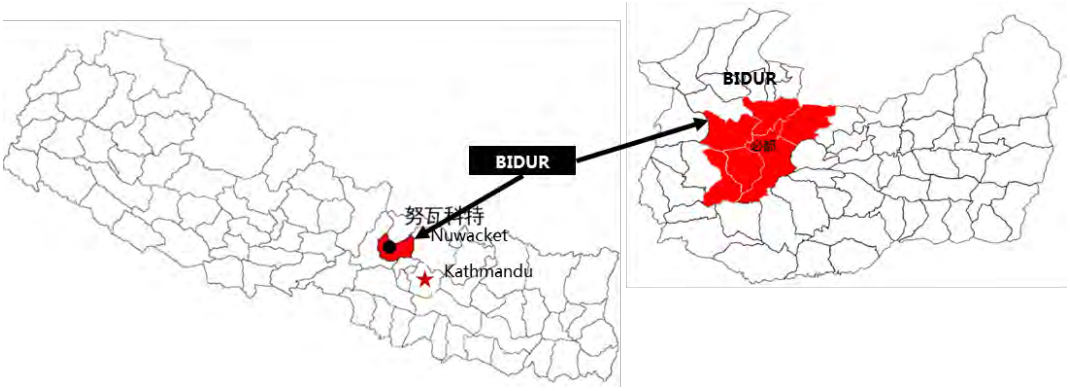

Figure1 The Location of Bidur

2. Core characteristics and Key issues

2.1. Core Characteristics

Mountain- based origin and Profound cultural heritage. The city is originated from the mountains. Since the construction of the Imperial Palace and the Sutta Tula Durbar Square along the Eastern mountain of Bidur in 18th centuries, the city has developed into a chain of clusters including Trishuli, Bidur, Battar scattered along the valley from north to south as we see today. Nowadays, The Hindu and Buddhist temples and characteristic buildings are scattered throughout the city. And the scenic spots and historical sites are mainly concentrated in TRISHULI and the Palace area where many Palace complex and many important temples are preserved.

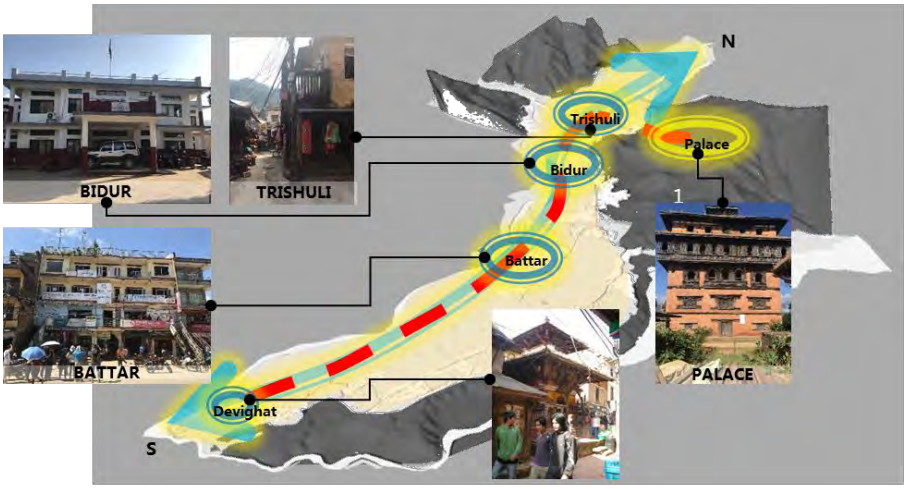

Figure2 Bidur's Historical Evolution

Alternating landscape with mountain and river, superior ecological environment. Located in valley area surrounded by two rivers and three mountains, Bidur is adjoined with Nepal Langtang national park, and China's Tibet Everest national nature protection zone, and there are abundant natural ecological resources and biodiversity diversity. The city's average elevation is about 690 meters ,with the characteristics of "low south and high north, low east and high west". Limited by natural conditions, the city centralization area where people live along the river shapes like ribbon scatters along the river from south to north.

Mixed landscape, public space endowed with significant religious characteristics. As urbanization and industrialization have advanced continuously, modern urban functions have emerged and disrupted the old agricultural way of life. New buildings of urban areas are intertwined with old dwellings of rural areas while the traditional public spaces are venues of various activities such as communication, entertainment, fetching water and others which makes it takes more unique local characteristics.

2.2. Key issues

Preserve the Historical and Cultural Resources and Recognize their Values. The history of the city culture is the soul of the city as well as the important wealth in the process of urban history.The city faces many problems such as badly damaged historical relics, lack of mining of historical resources because of lacking of the protection system and the historical

resources protection and utilization standards. According to the international principal of the protection of cultural relics buildings such as the Venice charter international principles, historical relics construction is valuable and plays an important role. Hence, the realization of sustainable development involves in several aspects, including the relationship between the modernized and the traditional, heritage protection and utilization, and the relationship between city function and traditional landscape to develop the historical and cultural value, activate the city function and improve the quality of the city.

Boost Urban Vigor with its unique urban Resources. Subject to the natural conditions and economic development level, the development of urbanization is still in its infancy.The present situation of Bidur is given priority to agriculture while second and third industry development is relatively lagging behind. The absence of motivation in industry development makes the city hardly provides large-scale jobs and attracts enough population. Natural ecological resources and human resources are the important advantages in the development of the Bidur. The lessons that gained from others countries have tole the truth that historical and cultural tourism helps to improve the city's economic vitality, realize the protection of cultural heritage, and promote the harmonious atmosphere and national spirit. Basing on the identification of local cultural resources value, the Integration of various kinds of tourism resources, and the Development of multi-types, multi-level, multi-experience of tourism activities help to achieve cultural revitalization of the city.

Take Actions against Natural Disasters and ensure a Safe city. The city's safety is the basic requirements of urban development and the residents' life and work. From the point of elevation, 70% of the city's land is 600 meters. With the terrain fluctuates greatly, the urban construction space is limited greatly. When the city's rising water situation is simulated through the water sea level rise 20 meters, the area below the altitude of 520 meters will be I flooded. From the point of slope, In addition to the central valley, the whole city is all around mountain steep, a maximum gradient of up to 67 °.So the high ecological sensitivity and high natural disaster risk make the area in the city unsuitable for the urban construction. Meanwhile, the terrace of soil and water loss caused by the mountain vegetation destruction have threatened the ecological environment of the city.

3. Concept and framework

3.1. Concept

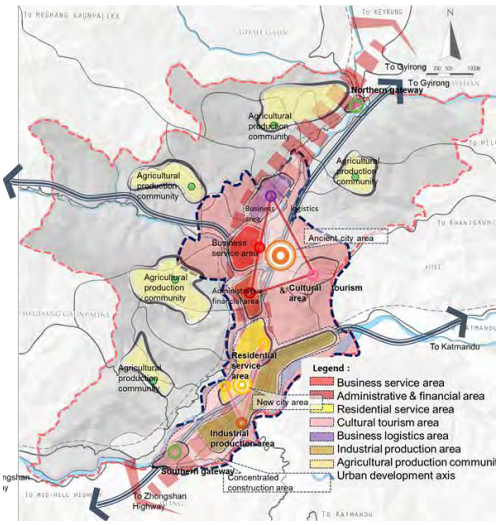
The international charter on cultural tourism launched by ICOMO in 1999 mentioned that "Domestic and international tourism which continue to be the most important tool of cultural exchange can be a positive force of natural and cultural protection, create economic benefits for the cultural heritage. The management with the purpose of protection can be fulfilled by collecting money, educating the community and influencing policy.The new urban agenda promoted by the The United Nations "habitat 3"2016 also put forward the declaration of human for the purpose of social inclusion and poverty eradication of sustainable urban development. So based on the local urbanization characteristics, we put forward the place making strategy of "Promotion with Protecting ,Form with Function" to explore the developing country or region urbanization development path. The "P+P,F+F" means first ,protect the historical context to continue the current urban spatial layout;

Second, Introduce tourist projects to invigorate the local economy; Third, Revere cultural differences to improve the quality of public spaces.

3.2. Integral Development Framework

Identify the four development positioning. Based on SWOT analysis, we proposed Prosperous and Vibrant City, where people Lives in the Natural Environment and enjoys Equal and Shared Services. The Harmonious and Inclusive Atmosphere includes four major visions for future development "finding the motivation, respecting the ecology, improving the people's livelihood and highlighting the culture" to guide place making. We hope to build Bidur into a prosperous and dynamic city with thriving industry and population, a friendly homeland that can resist natural disasters and a society that every people can have convenient access to the equally shared service and people of different cultural background and class can live in harmony and respect each other.

Build the protection framework. Following the urban space development logic that the historical growth pattern a city should be develop from the mountains towards the plain and along the river from north to south to extend. Respecting the natural and ecological background of the city, arranging the functional clusters, and promoting the harmonious coexistence and elastic growth of the city and the nature; Protecting distinctive historical resources, developing new functions, and planning old and new cities and tradition and modernity in an integrated manner, so as to create a city picture in which both old and new city areas can co-existed. Based on three Value orientations of the thrive Organic growth, Elastic cluster and Joint thriving of old and new city areas, a general spatial structure with two level, namely the river valley "concentrated construction area" + "large-scale agricultural community" in the mountains, and "network of one belt, double T expansion, two zones, seven sub-area and five communities will eventually formed" .Also, Combined with the whole city function layout, Planning will be in accordance with the "over the mountain water, farmland fragrant" natural ecological landscape as the base, the palace, old business district and the administrative as region spatial carrier, Injection of cultural tourism, public services, trade business, and other functions, make traditional culture golden triangle to realize double revival of urban morphology and function.



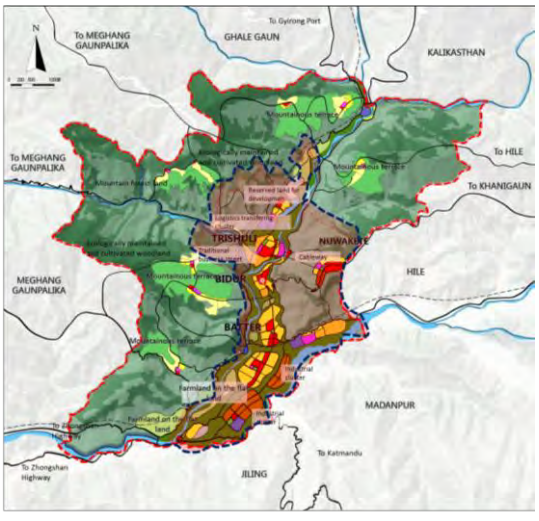


Figure3 Spatial Structure Planning **Figure4 Layout of Land Use in Bidur**

4. Development Strategy

4.1. Strategy1: Establish a system for classification and cultural preservation

with“the central old city density, north and south portal agglomeration, scattering peripheral villages".As we know, historical cultural heritages need different methods of protection and protection requirements vary because of Various types , different carrier, diversified saving and pluralistic value.therefore, according to the spirit of traditional features of blocks and streets landscape protection requirements in Venice Charter,Charter ON THE BUILT VERNACULAR HERITAGE(1999), International Cultural Tourism Charter and other Charters, we should Establish a system for cultural preservation which adheres to the principle of the authenticity, authenticity and sustainability.

Define Major Historical Architectural Complex, Traditional Streets and Major Historical Facilities.According to dating, shape design, protection, characteristics and values, the historic heritages of Bidur can be divided into the following three types:historical and cultural buildings, traditional cultural blocks, important historical and cultural facilities.

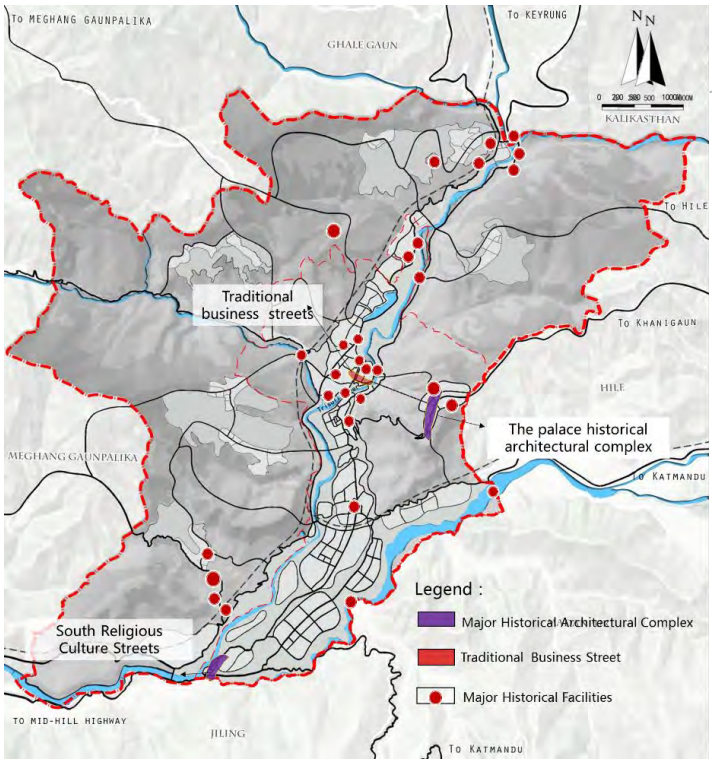

Figure5 Historical and Cultural Resources Distribution and Evaluation of Bidur

Table 1 Bidur Historical Resources Evaluation and Grading

Grade	Name	Value
Major Historical Architectural Complex	Palace Historical Architectural Complex	In the past, the building complex included palace, chamber and other annexes.
Traditional Streets	TUISULI Traditional Business Street	It represented the glorious success of TUISULI.

Grade	Name	Value
	South Religious Culture Street	The southern block involves temples, monasteries, and underlying history and culture.
Major Historical Facilities	Tibet-Nepal Friendship Monument	Monument to Marriage between Tibet and Nepal
	BATTER Central Facilities	The Toothache Tree, the Well, the Temple, the Site, etc.
	Hindu Temples and Other Temples	Nepalese religious culture and major sights alongside the route

Establish a three-grade protection system with Historic core conservation area, Construction control zone and cultural preservation area. The core protected zone will be established to cover all historic buildings, and any new building of the zone should be strictly controlled to have a similar style as the palace complex. A construction controlled belt will be established 100-200 m outside the core protected area and either residential or commercial building of the belt should not be higher than four stories and also have the same style as the palace complex. A coordination zone will be established 200-500 m outside the controlled belt and any building of the zone should not be higher than 4 stories and also have the same style as the palace complex.

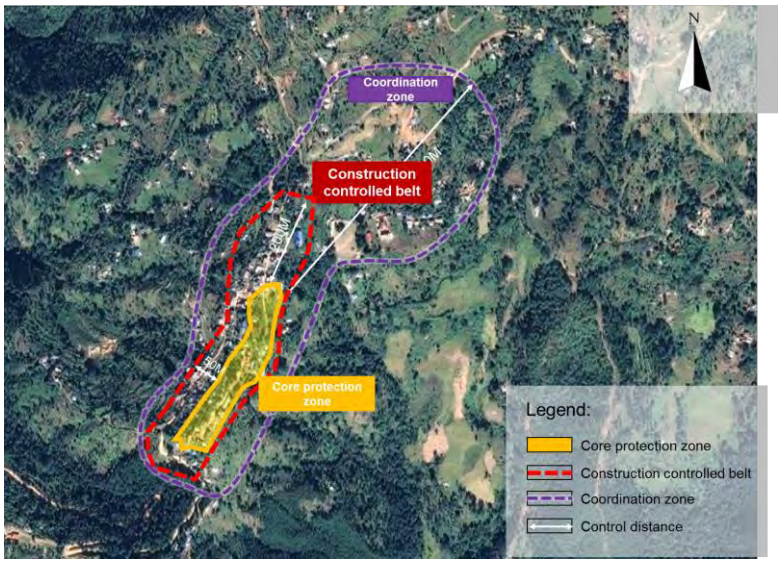

Figure6 Historical and cultural resources distribution and evaluation of Bidur

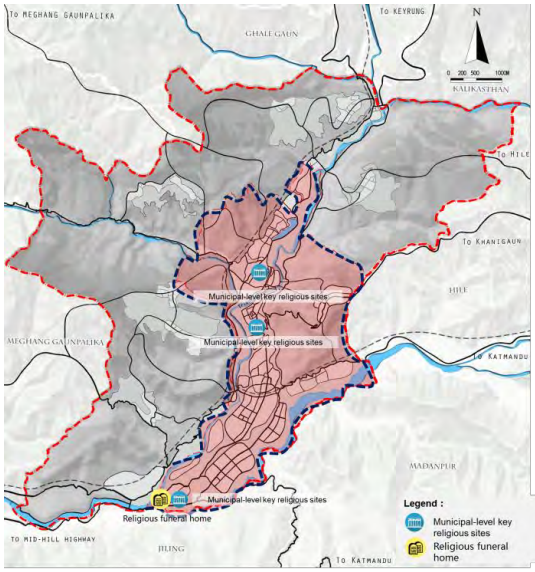
Promote the protection and utilization of intangible cultural heritage. On the premise of maintaining the authenticity of traditional festivals and other intangible culture, it should be combined with urban parks and public activity centers. tourism and trade activities should be carried out in public places during festivals, which aim to explore the potential economic value of local traditional festivals, spread and display intangible cultural heritage, promote vitality through culture and improve the quality of urban public space.

4.2. Strategy2: Establish a public service system for all

Bidur has weak public service facilities and health care system education and other basic living facilities service level is low, and lack of movie theater, entertainment facility and so on from the current situation. The focus should be the establishment of a public service system and inclusive religious activity place where all citizens have access to an equal and convenient medical treatment, education, cultural entertainment, social welfare and other services.

Establish municipal and community public service facilities. Build the "municipality-community" two level public service system based on Planning Norms and Standards 2013, with reference to experiences of China and India and other developing countries and according to requirements on equal access to public service facilities. The system shall involve “one center and multiple facilities”, consisting of medical care, education, social welfare, culture, religion, sports, food market, and public space and services to the whole city. Community comprehensive service centers will be arranged with 1,000 meters as the service radius, and 6,000 people (2 Neighborhood) as the standard of population served, to provide community services such as medical treatment, social welfare, culture, religion, and sports for residents in the neighborhood. Each community comprehensive service center will have a footprint area 2 of no less than 0.2 hectares and a construction area of no less than 350m .

Build characteristic religious cultural facilities.From the experience of LIshui in China , we should Construct a variety of religious activity space to meet different ethnic and religious belief of citizens and tourists demands cultural habits and religious activities and fulfill the space morden culture function to suit time life needs at the same time. Bhairabi Temple, Jalapa Devi Temple and Sugatpur Temple will be selected as municipal-level key religious culture space for holding major congregations; and a religious funeral home covering an area of over 0.5 hectares will be arranged in Devighat cluster, to meet religious funeral demands.To enrich the citizens' spiritual life, a municipal-level library covering an area of over 0.5 hectares will be arranged in Bidur cluster; and a municipal-level museum/art gallery/exhibition center covering an area of over four hectares will also be arranged; one hall will be arranged in each cluster of the river valley concentrated construction area to provide citizens with multiple functions like congregation. There will be seven halls in total, each covering an area of over 0.2 hectares.



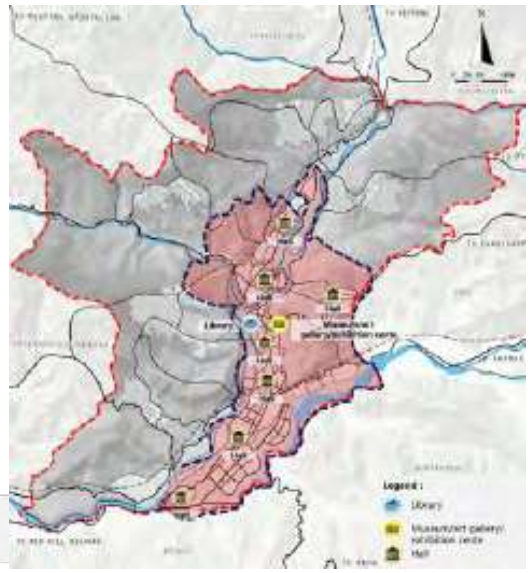


Figure7 Layout of Religious Sites of Bidur Figure8 Layout of Cultural Sites of Bidur

Create riverside public spaces. Many public spaces will be built around the rivers of the city. First, the plan provides 50-150 m wide green belts on the Trisuli and Tadi Rivers as Riverside Park, and provides a more than two ha Civic Square at the center of the city. The primary protection areas are River and lake shorelines, natural mountain boundaries, ecological protection areas and animal channels. The plan also provides farmland eco-landscapes at the southern and northern waterfronts, and provides riverside trails and terraces at the mid waterfronts. During the construction process, river and lake shorelines, natural mountain borders, ecological reserves and animal routes should all be preserved as first-class protection zones. So, any act affecting the natural flow of a river or the natural border of a mountain, or violating any regulation involved should be prohibited; any act of massive construction should also be prohibited to preserve the ecosystem of the city.

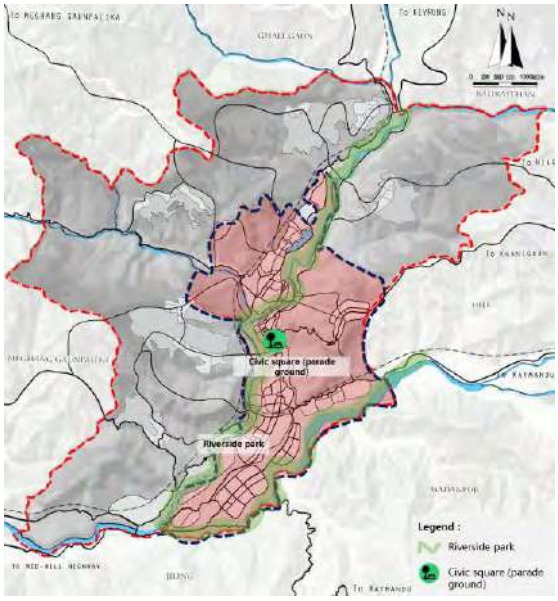

Figure9 Layout of Municipal-level Public Space of Bidur

4.3. Strategy3: Establish a civilized and orderly tourist system with utilization and management integrated

Bidur has similar historical and cultural and natural landscape resources as Bokhara's., We can integrate various ecological and cultural resources, and take agriculture as the root and tourism as the expansion to develop cultural tourism and logistics business with unique theme and routeIn the process of this strategy Industrial development will provide a large number of jobs, promote the continuous growth of the population, and create a vibrant atmosphere of prosperity.

Build"Cultural Tourist Loop + Boutique Ropeway". Various historical and cultural resources will be integrated. In the near future, the plan provides mountain highways and trails to connect Traditional Streets, Palace Historical Complex and the Administrative Service Center, and provides many tourist utilities of traditional cultural themes. In the long term, the plan provides one ropeway between the streets and the palace complex.

Build"Eco-Tourist Loop + Adventure Road". Eco-tourist experience will be enriched. First, the plan provides river drifting, kayaking and other tourist activities on the TUISHULI and TADI Rivers. And the plan also provides riverside tourist utilities, riverside greenways and mountain hiking routes.

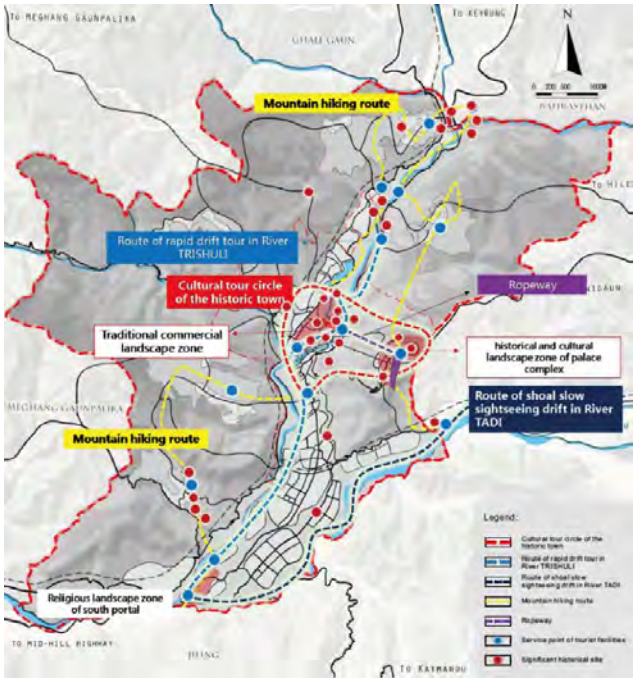

Figure10 Systematic Planning Map of Ecological and Cultural Tourism in Bidur

4.4. Strategy4: Create a characteristic traditional-modern landscape system

By comprehensive analysis of the regional characteristics, plan elements, the relationship between the surrounding landscape view and urban functions, the plan will construct a holistic mountain, water, street, city landscape features, while highlight the characteristics of a booming city built on hills and surface water.

First,Restructure the spatial layout. A new building layout should be created by rearranging the current buildings and roads. **Second, Establish public space paths** .Riverside landscape

nodes and public function centers should be created to increase the coverage of public spaces to 30% so that a neat-looking spatial structure can take form. **Last,Restore the traditional building layout.** In the Traditional Streets, the buildings should be partly preserved and reconstructed with a height of two or three stories so that courtyards and compounds will take form along the streets, and the streetscape, windowsills, balustrades, window supports and roofs should be repaired and redesigned as for the characteristics of the streets.

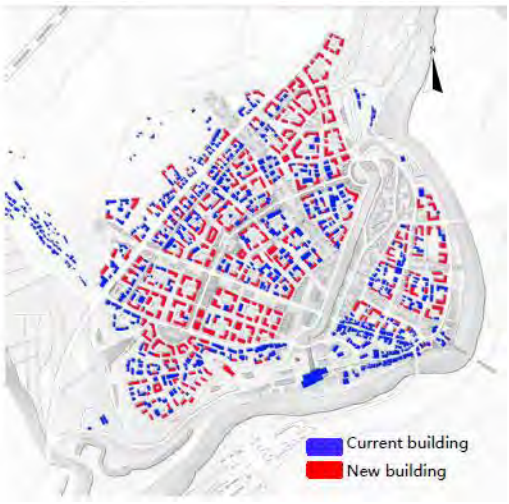

Figure11: New and Old Building Layout Map of TRISULI

Figure12: The Plan of TRUISHULI Traditional Commercial Landscape Zone

5. Summary

High quality of urbanization is the guarantee of sustainable development both for city and humans. So,the key of place making is not only to provide more green space and public space material for local residents, but also to provide more economic vitality and function for the city. The planning set the "Develop with Protecting ,Form with Function" as concept, use cultural preservation from the aspects of protection and construction, public service, ecological tourism, and urban design four paths, expecting a long-term effective on regional economic and ecological sustainable development, effectively creating multiple equal employment, providing fair and equal public service facilities and open beautiful living environment.

Paper

FOREVER FRENEMIES: BUILT HERITAGE, MEGACITIES AND NEW TECHNOLOGIES

Planning for culture

Natasa ZIVALJEVIC-LUXOR, National Heritage Foundation; Serbia

Petar MITKOVIC, Faculty of Civil Engineering and Architecture, University of Nis; Serbia

Abstract

Knowledge about how built heritage and megacities interact is still limited. At this stage of development, it is not yet clear what are winning approaches, how to measure performance, which data should be collected and how, and what is optimal way of using potentials of new technologies for that purpose. EU invested substantial resources into defining policy framework for culture and puts further efforts on its thorough understanding, which points out its huge estimated importance for societal well-being. Built heritage is most evident component of it, being usually "hardware" for all other cultural industries, and, at the same time, being the most threatened by growth of cities. In this paper we focused on modelling – with its core in interaction between megacites and built heritage. From one side, there are heritage experts who value their legacy according to success in preserving heritage, and on the other side – there are planners facing new economic and societal challenges due to historic growth of urban population. In addition, there are new technologies which develop faster than the capacity to apply them adequately. We analysed collecting and processing data which are required for clear insight and objective evaluation of an outcome. We discussed methodology – combination of methods and technique which may lead to desired outcome – full understanding and control – within planning and management of existing and emerging megacities. Having in mind that size determines economic performance, quality of life and subsequently future of designated megacity, including if there will be any, understanding this correlation substantially helps good governance.

Keywords

Megacities, Built heritage, ICT, Big data, Spillover

1. Introduction: Heritage as Nucleus of Megacity

Megacity, urban agglomeration, metropolis, city, town, village or any other urbanity consists of small(er) elements which one may call "cells" (with implicit comparison to living organism) or "digits" (as part of matrix in "metromatrix", i.e. in an associated abstract, numerical model (Ortiz, 2017)(Fig. 1. Left); the essence or the "heart" of such cell, a nucleus, is always a heritage, and usually it is built heritage but not necessarily so ((Luxor-Zivaljevic N., Kurtovic-Folic N., 01-04.02.2015.). Depending on local characteristics, "cell" may have different shapes, as shown on the right of Figure 1. Once such huge "organism" has been developed, a nucleus may be considered redundant, because it already served its main purpose. However,

a “heartless organism” may hardly survive, and even if it does, common sense says it must be in a way which is “not natural” e.g. with some artificial substitute, or even in some inverted or cancerous way. In this paper we assume that **similar happens to megacities without their built heritage.**

Figure 1. From nucleus to cell of metropolitan (Ortiz, 2017)

The reasons for abjuring built heritage, as genuine nucleus of an urban structure - in particularly after metropolitan area was generated, are numerous and not different than those at other levels: demographic pressure, land use efficiency need, redundancy of buildings without function, attractiveness of locations fully equipped by infrastructure, pressure of stakeholders, necessity of stable economic growth founded on urban developments, instant acceleration of economy, high costs of research, management and maintenance of heritage sites etc. With increase in size it is expected that pressure gets higher and such arguments seem to get stronger. Fortunately, arguments in favour of heritage are also unchanged and numerous: smart development, preserves diversity, strengthens identity and social cohesion, helps prevention of social problems, increases employment, efficiently improves local household incomes, provides better alternative for environment, educational benefit, has potentially catalytic effect on regional economy and positive demographic impact, helps improving quality of services, serves as “hardware” for other cultural industries etc. Most of listed benefits do not come from “existence” of built heritage, but from good heritage management, which requires knowledge, effort, operational skills and more, and that is a game-changing difference, which is undoubtedly present at all levels. **Therefore, our research question is how heritage management changes with size beyond metropolis.**

Knowledge about how built heritage and megacities interact is still limited. At this stage of development, it is not yet clear what are winning approaches, how to measure performance, which data should be collected and how, and what is optimal way of using potentials of new technologies for that purpose. In this paper, our hypothesis is that heritage management will change following overall human perception of space with size of urban agglomeration, and that it will emerge in intersection of three spheres: heritage value preservation, urbanization pressure and ICT development.

2. Importance of Year 2018 for Europe and Beyond

2.1. European Year of Cultural Heritage

Following radical changes of perception of space and comprehension of heritage values, existing urban development and heritage protection theories were substantially not

prepared for surprisingly rapid urbanization, huge number of new heritage sites and numerous new challenges of socio-economic development, or for seemingly unlimited opportunities of digital world. Therefore, impact of international doctrine became bigger than ever, with numerous documents adopted internationally, nationally and sub-nationally. Its latest milestone is European framework for Action on Cultural Heritage) (HEREBITS 2017) adopted less than a year after European Heritage Strategy for the 21st c (Europeana 2019) by EU members and 9 partner countries in May 2018. In those documents, innovations and new digital solutions are pointed out in several cases.
In the new European agenda for culture, the European Year of Cultural Heritage has been described as "a pivotal opportunity to increase awareness of the social and economic importance of culture and heritage". EAFC descends agenda from 2007, in an ambitious way.

2.2. European heritage strategy for 21st c

European Heritage Strategy for the 21st century "is based on three components:

1. The "social" component – harnesses the assets of heritage in order to promote diversity, the empowerment of heritage communities and participatory governance.
2. The "territorial and economic development" component – seeks to strengthen the contribution of heritage to sustainable development, based on local resources, tourism and employment.
3. The "knowledge and education" component focuses, through heritage, on education, research and lifelong training issues, by establishing heritage knowledge centres and centres for training in heritage trades and professions, by means of appropriate teaching, training and research programmes." (HEREBITS 2017)

The second of those components "focuses on the relations between cultural heritage and spatial development, the economy and local and regional governance with due regard for the principles of sustainable development" whose challenges include:

1. Building a more inclusive and cohesive society
2. Developing Europe's prosperity by drawing on its heritage resources
3. Ensuring that Europeans enjoy a high quality of life, in harmony with their cultural and natural environment
4. Implementing the principle of integrated conservation
5. Ensuring that heritage is taken into account in sustainable spatial development strategies and programmes
6. Developing the ability of public services to address sustainable spatial development issues by means of better use of heritage
7. Preserving and developing the ability of public services to address heritage issues
8. Increasing the use and reuse of heritage

Among recommendations how to respond to those challenges, there is recommendation to:

"Use (of) innovative techniques to present cultural heritage to the public, while preserving its integrity: Innovative techniques and approaches must be used to the full in showcasing operations but must be used judiciously in order to meet the dual challenge of preserving the integrity of the cultural heritage and making it accessible to as wide a public as possible",

as relevant for challenges 3, 4 and 5.; courses of action include informing heritage players, in co-operation with specialists, about the new technologies, including their potential and their limits, carrying out pre-restoration work studies using non-invasive technologies (digitization, augmented reality, 3D scanners, modelling, drones, LiDAR, etc.), using non-invasive exploration techniques to study inaccessible or fragile areas, developing representations of heritage by means of the new technologies (modelling, 3D printing)". (HEREBITS 2017)

The European Framework for Action on cultural heritage is based on five pillars:

1. Cultural heritage for an inclusive Europe: participation and access for all;
2. Cultural heritage for a sustainable Europe: smart solutions for a cohesive and sustainable future;
3. Cultural heritage for a resilient Europe: safeguarding endangered heritage;
4. Cultural heritage for an innovative Europe: mobilizing knowledge and research;
5. Cultural heritage for stronger global partnerships: reinforcing international cooperation.

Each pillar corresponds to clusters of actions.

2.3. Smart solutions for a cohesive and sustainable future

Following lead of United Nations 2030 Agenda for Sustainable Development, the second pillar recognizes "culture, including cultural heritage and the creative industries an important role in achieving inclusive and sustainable development"; its three clusters of actions aim at a) regenerating cities and regions through cultural heritage; b) promoting adaptive re-use of heritage buildings; and c) balancing access to cultural heritage with sustainable cultural tourism and natural heritage. It means in practice, there are numerous projects supporting cultural heritage through EU-funded projects for urban and rural regeneration and sustainable development (European Structural and Cohesion Funds, URBACT, Erasmus+ and Horizon 2020)".
In addition to many pragmatic solutions, in 2019, European Spatial Planning Network (ESPON) 2020 Cooperation Programme co-financed by the European Regional Development Fund, has initiated research for **empirical evidence on the impact of material cultural heritage on the most important economic sectors in 10 selected countries and regions;** ESPON initiated targeted Analysis "The Material Cultural Heritage as a Strategic Territorial Development Resource: Mapping Impacts through a Set of Common European Socio-economic Indicators" and study "Cultural Heritage as a Source of Societal Well-being in European Regions". (HEREBITS 2017)

"At the end of 2018, a Declaration on "Adaptive re-use of the built heritage: Preserving and enhancing the values of our built heritage for future generations" was adopted by stakeholders on 23/11 in **Leeuwarden** as a legacy of the European Year of Cultural Heritage initiative "Heritage in Transition". (HEREBITS 2017)

2.4. Innovative Europe

The forth pillar includes following cluster of actions:

"Digital technologies offer unprecedented opportunities for us to improve public access to cultural heritage assets and allow for their curation and re-use. Innovative technologies, such as virtual or augmented reality, can also enhance people's experiences with cultural

heritage, while digital tools such as 3D scanning play a major role in the preservation and restoration of physical heritage assets. Innovation is not only technological; it also takes place in the social sphere. The role of communities living with cultural heritage assets is changing…To address the challenges above, the Framework entails three clusters of actions aiming at a) capitalising on technological tools for innovation on cultural heritage; b) fostering social innovation; and c) strengthening skills in the field of cultural heritage." (European Commission 2018)

The correlation of cultural heritage with urban development is considered under also Pillar 2, which refers to applications of new technologies in urban scale.

The overall change towards creating new digital environment calls for new management. Innovative techniques are indirectly mentioned among four principles of the European framework for action on cultural heritage - evidence-based policy making: "Evidence-based decision-making is as necessary in the cultural heritage field as it is in other policies. In that respect, the Framework entails several actions aimed at measuring the impact of actions on cultural heritage. Through its statistical office, Eurostat, the European Commission will also keep improving the methodology and tools to collect data for cultural statistics, in cooperation with the statistical offices of EU Member States." (European Commission 2018)

2.5. Scientific challenge and significance Beyond Europe

The general intention of numerous European actions, whose small part is described the above, can be summed up as action to increase resilience of European (built) heritage which is considered one of the most important European assets regarding wellbeing of its inhabitants.

European year of cultural heritage hosted 11 700 events with 6 260 000 participants in 37 countries.

Europe declared openness for international cooperation and also set new standards in heritage preservation and urban development worldwide.

Cultural heritage has been classified as tangible, intangible, natural and digital. There are high expectations from ESPON and implementation of **Leeuwarden Declaration.** Huge funds have been assigned to: Creative Europe, a programme of European Commission supporting cultural and creative sectors, between 2014 and 2017, nearly 27 M€ were dedicated to heritage, and in 2018 5 M€ were dedicated to it with 2 objectives: reinforcing a sense of belonging to Europe and Promoting cultural heritage as source of inspiration for artistic contemporary creation and innovation (EUROPA NOSTRA 2018).

In scientific way, we would particularly like to withdraw significance of the programme **European city of culture**, which was established in 1983 (EC, 2019). It is one of the longest living European projects, and it essentially enforces development which comes naturally to some cities, commonly known as "cities of art". As remarked well long time ago: "…what distinguishes the cities of art from the others it is not so much the presence of artistic and cultural values as the degree of influence that these values exert on the city environment." (Lazaretto & Cinti, 2001) As an example, "Florence is unanimously considered a city of art and Turin no, despite the artistic richness of Piedmontese villas, both architecturally and on the sculptural or pictorial level." (IB).

European city of culture generates valuable database (2017 Edition of the Cultural and Creative Cities Monitor is available at: https://composite-indicators.jrc.ec.europa.eu/cultural-creative-cities-monitor/ and 2019, the European Commission releases the second edition of the Cultural and Creative Cities Monitor), tool aimed at facilitating peer-learning processes between peer cities based on similar population, income and employment.

In a specific study applied to Venice 3 decades ago, it was noted that the city of art is "a complex cultural asset with its own unitary economic characteristics of which we study the demand and supply function, the cultural and non-cultural investment processes, and mechanisms of formation of collective decisions, phenomena of development and decay for historically differentiated models, the different instruments of public intervention and their effects" (Mossetto, 1992, p. 4) (Lazzartti , et al., 2001). Having many "Venices" as points of reference, many new possibilities opens. In economic terms, phenomenon of "city of art" is related to phenomenon of spillover which is considered generally unplannable and unpredictable. European capital of culture program provides valuable database for further research.

3. Role of new technologies

3.1. Overview

Nowadays, everyday novelties of ICT are extraordinary, inspiring, reinforcing but also overwhelming; therefore, for the purpose of this paper we will point out some key features for rough classification. For some of them, key role has "hardware" – in sense that they are based on inventions, or new provisions of it, regardless if it is satellite, petabyte storage or else, and those with key challenge in "software" – which essentially means collecting and processing data; for scale of "metropolis and beyond", in both case particularly interesting are those which are sensitive to size.

For example, interesting applications recently come from analysing night light, from urban to metropolitan scale (data were always "there" and collectable since the begging of satellites, but nowadays they are easy accessible to public and can be applied on entire regions beyond legal jurisdiction). This application is size sensitive, based on hardware invention and software which is freely accessible for scientific purpose.

Another example refers to (numerous) econometric methods for heritage, which were developed in last 2-3 decades, and developed successfully as spatial on urban scale, now need to be adopted to metropolitan scale which requires demanding new software solutions regarding processing huge amount of data.

Another classification that may be useful refers to inductive or deductive approach. There are numerous global phenomena – like Blockchain, which "also" can be applied on megacities and heritage, and others scientifically developed for the purpose from scratch. Same data can not be reached from outside but only within certain channels and they may provide urban reality of its own.

3.2. Collecting data

The Laconic answer to the question which data we should collect to follow impact of culture on society would be: "All". More specifically: Web, (seems to be infinite source of data);

Social networks (e.g. very valuable for discovering preferences related to cultural tourism), Satellites, Digitalised communal infrastructure, Econometric data and much more. In other words, data sources include: Sensor Networks, Social Networks, Digital Libraries, Multimedia Collections, Web Data Service (Amati et al. 2017)

3.3. Processing data

Even small urban entities generate huge amount of data. Having too many data is as useful as having none: it means being at the beginning. Empirical analyses of huge urban entities are impossible without data processing. In overwhelming amount of data, data mining is name for "the process of discovering patterns in large data sets involving methods at the intersection of machine learning, statistics, and database systems… an interdisciplinary subfield of computer science and statistics with an overall goal to extract information (with intelligent methods) from a data set and transform the information into a comprehensible structure for further use." Big data is misnomer, because they are not big, but may appear "too big" for designated capacity at the time. At this time, synonym for Big data is petabyte, but soon it will be exabyte or zettabyte.

It proves that megacities can not be managed without proper processing of Big data.

Similar to our tendency to rely recently more on heritage doctrine and not on theories (because we do not have them), we tend to rely on empiric data of urban reality instead on theoretical models; using empiric data could be thwarted without methods for **collecting and processing** Big data.

4. Scenarios of extremes

4.1. Between urbanization, heritage and new technologies

Following our initial hypotheses, in ideal megacity, urbanization, heritage and new technology are perfectly balanced, generating successful and progressive society. Let`s see what happens in cases of extreme dominance of one of those components.

"Zero built heritage in heartless megacity" is scenario in which urbanisation dominates; we assume that pressure of urbanization reaches such level that pressure from stakeholders wins in favour of new development. It can be done in early stage – as soon as demographic pressure becomes high or at later stage, once all the spatial relations are defined, in an urban entity that reached its demographic maximum. Difference in outcome may be relevant. In first case, reconstruction would bring along fully new spatial relations and, in time, memory of the heritage would be fully lost. In second case, all functions would remain the same, according to original spatial hierarchy, but may start to deteriorate in time without symbol of community`s cohesion, similar to a hive without queen bee.

"Beyond psychical structure: virtual built heritage as substitute in overcrowded megacities" is a scenario in which advanced technologies technics and come to "rescue" of heritage values although not of heritage itself. There could be many variations of this scenario. As in many other examples of virtual reality, in this case focus would be on sensations, "experience" of built heritage, instead of genuine structure. One version of it includes that built heritage becomes fully privatized and commercialized trough a blockchain of its digital version (which in time may become its only version). Then, the focus would be on the appearance and it is highly questionable if dematerialized built heritage (eventually

reduced to ordinary artefact) may keep performing its social and economic role and how. Virtual built heritage would mark "techno-heritage" singularity of urban agglomeration.

"Smooth but slow sliding into future behind appearance of an open air museum" is a scenario in which built heritage fully wins although that social-economic development of society is severely diminished. If it means slow development, it is not certain if it can realistically survive in the world with very fast pace.

4.2. Concept of substitutes

All those differences would supposedly happen at level of "cities", so the question is how those cities would interact within a megacity. If different scenarios happen in one megacity, it may mean new "zoning", according to which cities take over function which quarters have in a city (and we are fully aware of good and bad sides of it).

5. Discussion: Looking for empirical proofs

5.1. Efficiency as precondition for size

The comparison with living organism (by Pedro B. Ortiz, (Ortiz, 2017)) explains why bigger means more efficient in case of urban entities. Existence of metropolises or megacities can be justified only if they would be more efficient then before. That should mean practically that if there is synergy between compounds i.e. that there is beneficial correlation. Sinergy in economic terms means a spillover, which can not be planed or predicted but it could be measured. Econometric methods for measuring spillover exist, although they are not considered fully sufficiently developed yet ((Yang & Wong, A spatial Econometric Approach to Model Spillover Effects iin Tourism Flows, 2012), (van Duijn & Rouwendal, 2013)). Spillover may be based on heritage (e.g. provided by cultural routes; it may be measured by following economic performance before and after cultural routes have been established/branded or other spillover effects i tourism flows (Yang & Wong)). In that sense, proving existence of metropolis to megacities means looking for signs of spillover. Another proof may come from researching cultural tourist preferences (e.g. if they visit sites in other part of assumed megacity within the same tourist visit).

5.2. Data and methods

Big data draws a lot of attention (agedly, in particularly after CCC- **Computing Community Consortium** established in 2006 – leading organization voice of USA computing research community, pointed it out in 2008.), and it is thoroughly researched as being considered by some scholars "the next big thing"; processing large amount of data usually means remote sensing database, generated from images (Wang et al. 2016) (Merino et al. 2016). Lot of data are generated from Google Earth Engine in cooperation with different map sources (Esri, DigitalGlobe, GeoEye, Earthstar Geographics, CNES/Airbus DS, USDA, USGS, AEX, Getmapping, Aerogrid, IGN, IGP, swisstopo, and the GIS User Community) (Amato et al. 2017) (Agapiou 2017); also by The Defense Meteorological Satellite Program/Operational Line-scan System (**DMSP**/**OLS**) which "collects visible and near-infrared **light** from the Earth's surface at **night** without moonlight. It generated "effective **time series** data for mapping the dynamics of urban expansion" since 1992. (Agapiou 2017) Data can be further processed based on aspects as the saturation of luminosity, the blooming effect, the intercalibration of time series, and their temporal pattern adjustment (IB). Processed data can further be used

e.g. for analysing urbanization around heritage sites or still earthed archaeological finds, i.e. data can be further processed trough Spatial interaction model is popular method for analizyng areas with size of megacities. This method belongs to Structural equation modelling (SEM), developed for social sciences "as a form of causal modelling that includes a diverse set of mathematical models, computer algorithms, and statistical methods that fit networks of constructs to data **The structural equation method** belongs to a high level statistical category of multi-variety statistics, reallocates the factorial analysis and path analysis, tests the relationship of dominant variate, latent variable, interfere or errors included in the model at the same time (Shi 2016). SEM may include confirmatory factor analysis, confirmatory composite analysis, path analysis, partial least squares path modelling, and latent growth modelling. Semantic web is applied the "intrinsic relationship for questionnaire design, which improves the reasonability of analysed results" (IB).

The aim of such research is to find patterns in empirical data which would serve for modelling of future megacities. (Marrocu & Paci, 2013).

Other researches are based predominantly on econometric data, i.e. irregularities which are expected to be caused by cultural heritage interventions, e.g. proofs of spillover as mentioned previously.

5.3. Principle of Substitutes

At this time, we could not scientifically tell how to intentionally create city of art, but it would be useful to know it in case cities within megacity start getting "roles" and if at least one of them would have role of "city of art".

Empirical analyses on urban scale showed that heritage is required, but that built heritage may have substitutes. Substitutes may get bizarre appearance reduced to symbol (e.g. in famous historical case of Las Vegas in middle of 20th century, which later became role model for many cities, and e.g. because of which nowadays exist 50 copies of Eiffel Tower in the world) or that role may play tangible heritage of different kind or natural heritage (e.g. ship wrecks and natural heritage, in case of Sharm el-Sheikh, small but globally positioned town on far western fringe of Asia. We did not find examples of intangible heritage playing such role but it does not mean such examples do not exist. If they do, it would make easier to accept that such role could be played by digital heritage in the future, as well.

6. Conclusion

In well balanced urban agglomerations, which we want and act to have in Europe, built heritage is expected to keep the role it has nowadays. However, in many cases built heritage may be in danger of being dematerialised and replaced with its digital copy.

Those are only some of examples indicating that European policy makers are aware that the applications of new innovative methods require new approach in collecting data from the field, and different management of overall process.

It is expected that heritage management becomes more "digital" as well as heritage itself. As direct consequence, and it is expected to be more scientific: subject of Big (remotely-obtained) data processing and high-end statistics.

Research Paper

Spaces of becoming - Space shapes public and public (re)shapes their own spaces

Vaishali AGGARWAL, Bauhaus-Universität Weimar; Germany

Abstract

Fights over the 'right to the city' have emphasized the interests of the four main actors within the city development of India since the first cases of revolting social movements in Delhi. The four actors can be classified as the social movements, the public, media and the government. The case of India Gate in Delhi is illustrative not only of how the differences between the actors come into surface, but of also of how these actors change their priorities, their stance and their tools, in order to secure their position in the city. Many scholars have analysed the role of social movements and how it evolves in the process. But what about the role of government as an entity that is in between the interests of social movements, public and media? How and why do they change their stance when a movement takes place? What are their limitations? The India Gate case can give the answers to these questions, as it examines the multiple transformations of this space over time. This paper emphasizes on the idea of Space. ***How space shapes public and public (re)shape their own spaces. India gate. This space has been stuck between the idea of being a space or a branded space.*** *It was assumed that* ***media plays a prominent role in acting like a watchdog in democracies****, but this paper looks at how media if used rightfully can be forced for a good in oppressive regimes and therefore, a vigilant and alert media can act as an external trigger or an emergency- wake up call for the youth of India to take the cause of freedom seriously. Rightfully as put up by Ritish (2012), an external event or issue may allow for the* ***manifestation of a flash fandom in the form of flash activism.*** *Since, social movement's needs mass media attention for amplification of their claims, the media also join the movements too create the news. Lastly, the consequences of the media coverage for social movements, in terms of organisation, reaching political change and obtaining favourable public opinion is comprehended in three different case studies.*

Keywords

Right to the city, Social movements, transformation, democracy, flash activism, flash fandom, Youth of India.

1. Introduction

1.1. Importance

The research aims to broaden the understanding of the importance plazas have in urban conflicts between government, public, media and social movements and conclude how these plazas acts as the spaces of becoming by analysing the case study of one such relevant conflict from the city of Delhi. Looking at the role of plazas as a public space and how movie

from an Indian cinema can take people outrage to the street and influencing series of social movements bounded to the notion of 'right to the city'. It also provides an overview on why social movements need the mass media (and vice versa) and how media activism helps in getting justice. After that, the literature state of the art is introduced in connection with the broader topics mentioned in the theoretical framework. Emphasis is put to the description of actual conflicts between social movements, public and government. The aim of the research was developed on the case of Nirbhaya Rape case in Delhi, based on the former social movement no one killed Jessica and movie Rang de Basanti (Paint it saffron) in 2006. As in the case of Nirbhaya's rape case which turned out to be international sensation as it played a very important and ambivalent role in resolving the gap between the public and the government. However, this particular social movement did not resolve the situation but rather than acting as an isolating phenomenon, it brought a social change. The research questions are formulated to get an insightful view of the processes from the viewpoint of the government. It also provides an overview of the way in which social media and digital networks contextualized and scrutinised the relation between social movement and activism.

2. Theoretical Framework

2.1. Delhi - a contested space

The images of the cities plays an important role in the formation of the urban identity where the conflicts in the city raises the questions about the nature of the 'political' and of local democracies. Urban identities creates a platform, which associates between specific places, the production of places, and visualises the basis of its construction to an extremely unambiguous place, media image and temporary space. According to Enrico (2013), conflicts marks the crisis of the 'political', its void or absence, while it also delineates potentials for its revival. Delhi, a city in palimpsest is a combination of layers of things & identified with the cultural manifestations along with spatial identities. However, in Delhi, these combinations and the cultural identities is more complicated because of the dimension with its colonial past. As a (post) colonial city, Delhi has fragments of colonial spaces.

2.2. India gate - Background

India Gate is such space with a concept that links the mental and the cultural, the social and the historical perspective. Thus, the 'culture of contestation' adds a new dimension along with the 'culture of informality'. City like Delhi hinges the relation between the space and the society. It is an inseparable tangled knot between spatiality and sociality. As Lefebvre (1991: 26) long ago also pointed out the curious condition that space is both a means of production and a product of it. It stands high in the politically dominant area in the administrative seat of India. Every year Republic day parade takes place at this place, which is witnessed by thousands of people, symbolises power and further acknowledges the feeling of patriotism. However, as it evokes in the architectural style and is surrounded by numerous parks, everyone favours this place. Domination over the space > creation of a 'counter-space'.

2.3. India gate as a place for Protestants

The conflicts shapes in a specific spatial and material setting. This is made possible by the placement of things, the system that establishes visibility, accessibility of areas for the

production of human action in the city. Since the discourse about the place is ignored, therefore Lefebvre's "spatial Practice" inhabits my attention (Lefebvre 1991: 33–46) where he certainly does not mean that the representational or discursive is unimportant. He focuses on the reproduction of the spatial and social urban order where subtle behaviour adjustments are more explicit and visible. India gate is a war memorial, which is both inhabited and constructed as a memorial landscape complex. It was erected not only for an attempt to 'fit in' with the existing and traditional spaces of commemoration, but altered and created new spaces that determines commemorative strategies, entertain masses. This sensuous and spectacular nature of war remembrance draws attention to the centrality of sight, sound and touch for the remembrance of activities. Since, the location and the importance of this place makes it suitable for a place to protest, the question of losing the impact also lies there as the space is under heavy security. Thus the 'becoming' of this space also adds to its labyrinthine quality which may cause in losing the controlling gaze of the spatial order and enters a world of escape, mystery, danger and desire.

In line with president's house & Rajpath
Centrality & political importance

Power shows ist dominance
Symbolic place – centre of the city & governmental buildings

Every protest is centralized
Initially used to be a picnic place

Power balance is shown
A place where power plays important role, now acts as a field of conflicts/riots

Figure 1- Protests, conflicts & power dominance at Republic day Parade

3. Social movements in urban sphere

3.1. Why social movements?

Movements are necessary for creating an identity construction about what things were but reflecting aspirations with an idealized past bridging with future. This **conceptualisation of a space endows 'new spaces' without any effort to 'place' vulnerabilities as a consequence** for social relations. Movements produce the idea of **'degenerate Utopias'**, **'dialectical utopianism'** of the **'process'** and **'form'** which helps in flourishing active society. Society is a social creation where Social change is beyond the control of the individual.

3.2. Why social movements?

"Social movements can be viewed as collective enterprises seeking to establish a new order of life. They have their **inception in a condition of unrest**, and derive their motive power on one hand from dissatisfaction with the current form of life, and on the other hand, from wishes and hopes for a new system of living. The career of a social movement depicts the emergence of a new order of life" (Blumer, 1969, p. 99).

A social movement is a form of "**purposive collective actions** whose outcome, in victory as in defeat, transforms the values and institutions of society" (Castells, 2004, p. 3).

A social movement is "the effort of a collective actor to take over the 'values', **cultural orientations** of a society by opposing the action of an adversary to whom he is linked by relationships of power" (Touraine, 1995, p. 239).

Based on these different definitions the most important aspects of social movements are negation of dominant values, institutions, adversary, dissatisfaction, mobilising demolishing structures, etc. Herbert Blumer therefore identified four stages of 'social movement's' lifecycles, which are as follows:

1. Emergence
2. Coalescence
3. Bureaucratization
4. Decline

Since success and failure are two sides of the same coin, the question of why movements fail simply mirrors the question of why movements succeed. On one hand, social movements succeed by gaining attention and raising public awareness, but this does not necessarily influence policy-making. Though over the time, movements may achieve successes and face hindrances which might face counter movements or generate new movement altogether which leads to variety of outcomes, including Institutionalisation, indulgence, suppression, or abeyance until the future period of mobilisation. The cry and demand for 'right to the city' has grown into a global catchphrase that is tossed around by activists and policymakers. While Harvey (2008) claims that 'right to the city' changes oneself by changing the city, the UN on the contrary believes that 'right to the city' demands for instinctive flexible meaning for dignified and secure existence in cities. The 'right to the city' is the right of all the inhabitants to permanently and temporary use, occupy and produce inclusive and sustainable cities for present and future. It's an existing co-operative and diffuse human right that developed from bottom-up approaches and belongs to all the inhabitants of cities on the basis of their common interest. The 'right to the city' belongs to the present and future generations which means involving the access to urban resources, services, goods, and opportunities of city life for all the inhabitants who can participate in the making of city.

As indicated by Lefebvre (1996), urban space offers its inhabitants 'the right to the city'. This right includes openness, flexibility, the recognition of differences, the right to be included, the right to develop an individual or collective identity, and autonomous decision making, alongside an unrestricted access to resources.

3.3. The role of the local governments

In the conflict between social movements and government, four groups could be identified as the main actors: the social movements, public, media and the government where very actor has its own motives and characteristics. The combination of the traditional role of municipalities to keep their citizens content and, in parallel, to implement viable transformations in the urban space is seeking new challenges. Nevertheless, as Hackworth

(2007, p.15) argues, the relatively regulatory state of the mid-twentieth century has been supplanted by a neoliberal version that seems itself to be regulated by local capital.

Even if we look at the role of a local government as 'neutral' in this new era that the **'welfare character'** is replaced by the **'regulatory character'**, there are restrictions that have emerged during the last decades, indicating that a 'neutral' standpoint in dealing with the urban conflicts cannot be achieved easily. However, local authorities don't have neither the economic nor the political power that a state has. Thus, they become more vulnerable to the projections of bond-rating groups,

"The idea that municipal governments should behave as economically efficient, business-friendly, anti-deficit entities is now an axiom rather than a debated policy shift among city managers". So, after all this **'autonomy' comes along with "powerful limitations on the choices that city officials can and cannot make"** (Hackworth, 2007, p.20).

3.4. Power of media leading to a social movement

The social movement and mass media are mutually dependent; it draws the attention and creates newsworthy events. Since the **intensive exposure of internal struggles and irregularities within the movement** eventually resulted in the gathering public support, the former social movement already created a sensation among the people for justice. However, due to **the non-institutionalisation position of social movements,** the relationship between movements and the media is **characteristically more asymmetrical** than the interaction between politicians and the media, which results in a failure of social movements sometimes. For example as happened in the movie influenced social movement.

4. Social movements in the case of Delhi

4.1. How does film affect the audience's perceptions about government and freedom?

As rightly said by Ritesh (2012) Rang De Basanti (Paint It Saffron) was a patriotism- and social change-themed Bollywood film that was strategically released in India and other countries on January 26, 2006, India's Republic Day (which commemorates the day when the Indian Constitution came into effect). Despite the international accolades, Rang De Basanti's greatest legacy is its role (unusual for a Bollywood film) in helping generate civic activism among urban Indian youth.

Figure 2- Still from the movie: Rang de Basanti - 2006

The movie narrated the **gradual transformation** of five college friends from happy, politically apathetic youngsters to anti-government rebels. The death of one of a close friend, a fighter jet pilot, acted as a catalyst, when the Aviation Minister falsely blames the pilot's

foolhardiness for the crash instead of admitting the plane was a model long known to be defective, which the Minister had been bribed to procure. To protest, the friends organize a peaceful candlelight vigil at India Gate, a prominent landmark in the capital, New Delhi. The vigil is violently disrupted by the police, and the last third of the film shows the dramatic repercussions of this violence. The film's provocation is best captured in one line of dialogue: "No country is perfect. You have to make it perfect.

The movie impacted the audiences tremendously, especially the youth, who came to theatres because of its visually attractive ad campaign and star power. Though the director of the movie observed a significant post release that increased the discussion of the political issues in India. The frustration evident on some blogs as Ritesh (2012) said "The society will be ruined by these evil politicians. It's time to have a Rang De Basanti type resurgence"—this also reflected the frustrations showcased in the film's final moments. Within few weeks after the release of the movie, the change was easily seen in the air as people were unexpectedly moved by the film's story and ideology. This movie hence acted as an **emergency-wake up call for the youth in India to take the cause of freedom seriously**.

4.2. Flash activism and flash fandom – Case 1

The movie rang de basanti generated the **civic activism** among the **Urban Indian Youth** who aimed at securing justice in a high- profile murder case.

> *"Movie's most prominent impact was on the ongoing real-life where on April 29 1999 night, lall, young son of high ranking politician shot the 34 year old fashion model who was doubling as a waitress as a part of publicity campaign for a newly opened fancy restaurants in Delhi as she refused to serve him the drinks after the closing time. Since its common in India, the case dragged on in the courts for several years, during which period many witnesses withdrawn and the murder weapon went missing. Here media played an important role in shaping the societies and hence, the news got hyped. A day after the acquittal, a Times of India headline screamed, "No One Killed Jessica." NDTV, a 24-hour news channel, submitted to the president of India the more than 200,000 cell.*
>
> *Few days after the verdict, Tehelka, an Indian weekly, sent an anonymous text message: "If the Jessica case has upset you, show you care. There is a protest gathering at India Gate next Saturday, March 4 at 5.30pm. Be there. Help keep up the pressure. Demand justice." It is not clear whether Tehelka deliberately chose India Gate to draw a parallel to RDB. The following evening about 2,500 people, many of them students, gathered for a candlelight rally at India Gate. This is noteworthy for many reasons. Yet what is most remarkable is that the protest was a replication of the crucial scene of a candlelight vigil at India Gate in Rang De Basanti, which had been released six weeks prior and was firmly alive in public memory and blogosphere discourse. Ritesh (2012)*

Undoubtedly, the **movie became a force, which had a direct impact on the community engagement**. Though nothing happened after the protest, but people witnessed unity among themselves and India Gate then visualised as a place of protest rather than the a picnic spot.

Figure 3 - New public in space

4.3. "Nirbhaya" Rape: Isolated Phenomenon or Social Change? – Case 2

This brutal attack took place on 16th December 2016 where a 23-year-old Jyoti singh, a premedical student who was returning home with her male friend boarded an off-duty bus, which already had six other persons including the bus driver. However, what happened next shook the whole nation, the girl was raped by six men in the moving bus while her friend was beaten up and thrown down from the bus. The victim suffered grievous bodily harm due to the terrible attack and the insertion of iron rod in her intestines caused serious injuries in her abdomen, intestines and genital organs.

Figure 4 - Protests at India Gate

This incident made a huge hype worldwide and gained **international sympathy**. People from all over the world came together for this case and demanded justice for the survivor. This social movement was successful in creating an impact in India's history and demanding the rights for girl and her family. However, media had a mixed reaction in this case due to the political pressure. Nevertheless, because of this popular case worldwide, protestors succeeded in getting the justice sue to which criminals were hanged until death.

5. Key Concepts

5.1. Right to the city

Lefebvre (1996, p.158) summarizes the idea as a "demand... [for] a **transformed and renewed access to urban life**". Harvey (2008) described it as follows: "The right to the city is far more than the individual liberty to access urban resources: it is a right to change ourselves by changing the city. A right to the city empowers a new citizen, who is not only simply a user of the city but a participant in its creation and interpretation." Lefebvre (1991, pp.381-383) claims that through a subordinate group's challenge to a ruling group's claim, space is socially produced, contested and the space changed the space itself over the time.

According to Lefebvre (1991) the space is actively produced, not only in its physical disposition but its social meaning, by the activities that go on in it, or that go on in some spaces but not others. He suggests imagining and reconstituting a very different kind of city, which incorporated and enriched its context.

He argued that space must be understood as more than a neutral container of activity. The recognition of a right to the city would make more practical the right of users to make known their ideas on the space and time of their activities in the urban (Lefebvre, 1995: 34).

Figure 5 - Protestors depicting the right to the city on the bridge and occupying the space

Therefore, public space becomes a tool for the not visible conflict to come in surface. However, according Sassen (1991) the huge post-credit crunch buying up of urban buildings by corporations led to significant implications for equity, democracy and rights. While Castell's (1983, pp.319-320) criteria for a successful urban movement was if a space is occupied by the movement then it gives it a physical presence, a location identity, a place that can be identified with the movement that visitors can come to, and where adherents can meet.

5.2. Local government

Chandler (2001, pp.1-34) defines local government as "the authorities and dependent agencies that are established by Parliament to provide a range of specified services and represent the general interests of a specific area under the direction of a locally elected council. [...] They are charged with **powers to promote the 'well-being' of their area in respect to economic, social and environmental concerns**.

The modern local authority is therefore seen to have a wider role than providing a range of services largely concerned with social welfare, but is to be the lead agency in the overall economic and social development of their area".

Figure 6 - Reaction of the government pictured by a news channel

5.3. Social movements

Sociology teaches that social movements go through the natural stages of **maturation**. This is very well explained in the article "exploring the role of philanthropy in **supporting** movements" (Sammen, 2015) that summarizes this phenomenon as:

> *"Movements are fluid and evolve differently based on political, economic, and social circumstances. After they emerge, movements generally coalesce around an identity and vision, and then sometimes they are formalized through public awareness campaigns and network development. Over time, movements achieve successes and suffer setbacks, might face counter-movements or generate new movements, and produce a variety of outcomes."*

Hence the social movement is an effort - a memory that helps in bringing about a change in the society. It may also resist a change or change completely by either acting as reform movements or as revolutionary movements.

Figure 7 - People's reaction even after the denial from the government

5.4. Social Media

Social media is used for both **communication and information, which** involved movement in a variety of capacities.

> *Technology does not determine society: it is society, and can only be understood in social terms as a social practice. This means that the uses of wireless communication are fundamentally shaped and modified by people and organizations, on the basis of their interest, values, habits, and projects.*
>
> *Castells, (2007, p.246)*

> *…Social media have become coordinating tools for nearly all of the world's political movements, just as most of the world's authoritarian governments (and, alarmingly, an increasing number of democratic ones) are trying to limit access to it. In response, the U.S. State department has committed itself to "Internet freedom" as specific policy aim. Arguing for the right of the people to use Internet freely is an appropriate policy for the United States, both because it aligns with the strategic goal of strengthening civil society worldwide and because it resonates with American beliefs about freedom of expression*
>
> *Clay Shirky, (2011, p.1)*

There is a relationship between traditional and social media which plays an important role in commanding the society for social movements.

Figure 8 – Media's reaction

5.5. Assumptions on the literature

The existing literature about the interrelations between the urban social movements, the governments, media and the public, as well as the tensions and the conflict of interests, which finally cause the actual conflicts, is very rich. They also focus in the processes followed by the social movements, in order for them to be **legitimate and -after all- successful**. Nevertheless, their research aims lead them to examine these cases mainly from the point of the movements. Thus, there is a **lack of information and conclusions** about the role of the local governments, their dependence on the private investors and their vulnerability to political pressure. Other scholars (Hackworth, Sbragia, Chandler, etc.) deepen their research in the role of local governments in recent decades and thus, their inability to flexibly adapt to the local society needs.

But their approaches tend to focus on the structural inflexibilities caused by the national or international regulations imposed rather than examining the relation of forces between social movements and local leaderships and how local leaderships can -or can't- adapt to the political pressure from multiple actors/interests.

Figure 9 – Survivor's mother request in the media, asking for justice

6. Conclusions

Spaces are themselves agents for change. Hence, Changed spaces will change the practice. (Dianna,2006, p.1.1)

Both Nirbhaya rape case and No one killed Jessica stands out as social movements because of their unique identity and long lasting influence. Instead of losing its **acknowledgment and acceptability**, the movements have gained some political aspects. These movements helped

in creating a collective identity, which became stronger by time and influenced more people to join. Urban space acts as a 'void' between the building such s streets, plazas an parks that enables the movement. These plazas are viewed as a frivolity, an unnecessary drain on the resources or the use of the precious urban space. These 'places' are chosen by the people for social movements on the basis of the location as they act as major public destination which is built by **precious commodities** in an urban setting like local economies, civic pride , social connection and human happiness. A place is generally identified to something which does not change; their **'sense of place', 'character' or 'identity'** which is relatively stable.

Figure 10 – Strict restriction on public movement & rebellious reaction both by the public & the government

For a successful social movement location also plays and important role in reaching the voice to the masses. The social movement happens either in a place which is used by people on a daily purpose so that it creates the problem for the public and hence the voice reaches the government. On the contrary, the other approach is to select a place which is **historically or politically important**. India Gate fits into both the categories. It is a quest for an essence of a place which is based majorly on the primordial past, a place which is **abstracted** from its instances in everyday life and consciously attempts in creating place making. Since it's located in the city centre, it's a perfect place for the **manifestation**.

While Kilburn may have a character of its own, it is absolutely not a seamless, coherent identity, a single sense of place which everyone shares ... If it is now recognized that people have multiple identities, then the same point can be made in relation to places. Moreover, such multiple identities can be either, or both, a source of richness or a source of conflict. (Massey 1993: 65)

Delhi

Developed as an aggregative identity in perpetual transformation as

True spaces of becoming

in which the

public and the space is continuously transformed & reinvented

earlier as

picnic spot

and now as a

Space of conflict. Protesting space

but later

?

Hence, **India gate is a place of formation, a place in the state of becoming as it is in the state of continuous change.**

Case Study / Project

How Can Cities Succeed and Boom in the Long Run?

Case in Qatar

Jassim AL-SOROUR, Noor ALAMRI

Abstract

As technology is advancing, the places we live in need to be adapted as well. In the modern times, we are bombarded with many gadgets and gizmos that are making life easier and enabling us to do more in less time. How can cities succeed and boom in the long run? They must be able to plan for a smart future using the technological advancements that are occurring in modern times. Some of these technological advancements are presented in the Qatar National Vision 2030. Under the Qatar National Vision 2030, Qatar has promised to deliver Environmental Development and technological advancement. In the QNV 2030's vision and mission statement, it is stated that The Qatar National Vision 2030 aims to direct Qatar towards a balance between developmental needs and the protection of its natural environment, whether land, sea or air. What this means is that building a smart city will require Qatar to invest in advanced smart technologies that can contribute to its modernizing economy. This will help and enable Qatar to progress rapidly and achieve technologically advanced urban development. Temperature monitoring systems are one of the technologically advanced things that Qatar has invested in. To protect and act against high temperatures and changing weather, Doha has had to install many smart temperature sensors across the country in different malls and buildings that set the temperature of the building based on different variables such as outside temperature, people in the area, humidity and various other factors. Doha has been ranked number one in terms of smart building capabilities across all categories of 'Green', 'Safe' and 'Productive'. Doha has scored 70 out of 100 points which analyzed 620 buildings across the middle east, with the average score being only 48 points out of 100. With Doha's sight set on the future with the FIFA Football World Cup happening in 2022, it has planned major infrastructure changes including building major SMART transportation systems to handle the rush that comes with hosting a FIFA world championship.

Qatar has been able to construct many smart cities including Lusail City which has temperature management systems, automatic lightening sensors and smart metros. Qatar is focusing on a smart future. This includes having smart carriages, trains and buses that have temperature sensors installed in them that adjust according to the number of people in the bus, the temperature outside etc. As Doha moves to host the biggest sporting event in the world, it is planning for resilience. Doha has been able to build smart stadiums that would host the 2022 World Cup in higher temperatures. Doha's economy is moving towards compete automatic temperature management systems. Doha has buildings which are LEED (Leadership in Energy and Environmental Design) certified. This includes more than 5 buildings just in Qatar Foundation. LEED is the most widely used green building rating system in the world. This means that Doha is not only smart but also green which makes it very unique and special. To conclude, Doha has many buildings that have LEED certification. Doha is preparing for the World Cup and has many smart mechanisms that will help in managing the temperature of the buildings and stadiums smartly. This paper highlights the steps that Qatar has taken to work towards building a smart future. A smart future is important for Qatar because it is taking steps actively to move from an oil-based economy to a knowledge-based economy. Projects like Education City affirm Qatar's commitment to move towards a smarter future.

Case Study / Project

Startdust Smart City

Project in Trento

Daniele VETTORATO, Adriano BISELLO

Abstract

STARDUST is an EU Horizon 2020 Smart Cities project, which brings together advanced European cities (Trento, Pamplona and Tampere), thus forming into a constellation of 'innovation islands' - exemplary models of smart, highly efficient, intelligent and citizen-oriented cities. Technical green solutions and innovative non-technical solutions are implemented and validated thru an holistic approach, The project offers a holistic approach in transforming the carbon-based cities to smart, highly efficient, intelligent and citizen-oriented cities, or 'Innovation Islands' . These approaches come in the form of both technical and non-technical solutions designed to be bankable and replicable for other cities. On one hand, technical solutions are provided in the following sectors: energy, mobility and ICT. On the other hand, non-technical solutions are addressed directly to the different key players - policy makers, industry, academia, and the citizens - in the form of innovative business models and citizen engagement activities, which ensure the bankability of these solutions. Both types of actions complement each other, providing the holistic mind set needed to define the new Urban Metabolism envisioned by STARDUST.

Energy: The high energy consumption observed among urbanised cities is reduced by introducing smarter technology, methods and materials into their districts and buildings. Retrofitting and innovative heating and cooling systems are introduced to already existing buildings and districts to increase their energy efficiency while providing comfort to local residents. By developing efficient energy management protocols, user-designed interfaces of smart grids and storage systems and open sharing of data between users and other stakeholders, energy usage are monitored and managed by the buildings' inhabitants and by the energy provider. Renewable energy sources and smarter energy storage systems and lighting materials will be introduced to ensure and provide sufficient energy for the cities to make use of. Mobility: Vehicular traffic is currently responsible for about a tenth of the carbon dioxide emissions. More and more cars are expected to be out in the streets due to the growing global population and personal wealth. More efficient means of transport and alternative fuels is tested in the project. Electric vehicles and their charging stations are developed and installed in the involved cities to reduce the carbon emissions predominant in cities. E-car sharing and e-last mile logistic systems are tested in the project. ICT: Information and Communication

Technology (ICT) unlocks the potential of different cities by allowing them to connect and integrate with their operational processes. Its transformative nature amplifies the impacts of other innovations piloted in the city by enabling their scalability, preventing technology and vendor lock-in situations and facilitating collaboration and innovation between stakeholders. The latest generation of the ICT smart city platform, the open access strategy, data centres and infrastructures, and user-driven and demand-oriented city infrastructures is introduced to reduce greenhouse emissions and to promote social innovation and co-creation of ideas between stakeholders. Engaging with citizens to improve urban life: Technical solutions can only do so much to improve the cities' well-being. Indeed, a growing need for a more inclusive public administrations by means of incorporating citizens is needed to re-vitalize their city planning. This will pave the way to developing sustainable citizen-oriented Smart Cities using different approaches that promote citizen engagement via communication channels, activities, and ICT tools. The paper discusses the design and the preliminary results of the project applied in particular the the city of Trento - Italy.

Research Paper

THE LATEST GENERATION OF EU SMART CITY PROJECTS: TURNING "CLEAN ENERGY FOR ALL" INTO "CLEAR BENEFITS FOR ALL"

Adriano BISELLO, Eurac Research – Institute for Renewable Energy; Italy
Daniele VETTORATO, Eurac Research – Institute for Renewable Energy; Italy

Abstract

The European Union is in the process of updating its energy policy and legislative framework under the motto "Clean Energy for All Europeans". This will facilitate the low carbon energy transition, make it fit for the 21st century, and delivering the EU's Paris Agreement commitments.
Besides expected climate-energy benefits, the EU narrative is introducing new elements to persuade citizens and stakeholders to change their perspective, shifting the general perception from mitigation costs to development opportunities. For example, impact assessment of the new directives estimated that they would generate 900,000 jobs and an increase of up to 1% in EU GDP over the next decade. However, this is just one among several multiple benefits that could be gained thanks to the smart energy transition of cities and neighborhoods (e.g. increased value of refurbished properties, improved health and well-being, enhanced social cohesion, etc.)
Starting from this premise, the ongoing research will analyses 12 ongoing EU smart cities and communities projects started between 2014 and 2017, in order to investigate their capability in using the multiple benefits as an effective communication tool, or even including them among the key performance indicators to be used in the assessment phase.
In that respect, the Positive energy district concept that permeates the smart city approach of latest calls for funding provides, even more, an interesting nexus and testbed opportunity for EU ambitions. However, ongoing and future projects need to be understood not only as marketing devices for new energy efficient technologies but powerful tools requiring a radical change in management and planning of cities and urban life. In this way, positive energy districts including good habits and behaviors of urban citizens will provide equitable solutions and clear benefits for all.

Keywords

Smart city, positive energy district, energy community, multiple benefits, energy transition

1. Introduction

Nowadays, half of the global population lives in urban areas and by 2050 up to 70% of the world's population will be living there.

It is therefore clear why the UN Agenda 2030 for Sustainable Development and the COP21 Paris Agreement recognize the pivotal role of cities as drivers of change and calls on them to rapidly reduce greenhouse gas emissions and adapting to climate change.

The European Union (EU) is also committed to achieving the targets posed by the two above-mentioned documents and making cities inclusive, safe, resilient and sustainable according to the Sustainable Development Goal 11.

Many ambitious EU cities already decided to set strict climate-energy goals and to test the implementation of highly integrated and highly efficient energy systems based on the exploitation of local renewable energy sources (RES). The so-called smart urban energy transition, as a consequence of the transposition into the practice of EU legislative package "Clean Energy for All Europeans" (European Commission, 2016) is also expected to deliver a wide range of non-energy benefits in the social, economic, and environmental areas.

As stated by Ürge-Vorsatz *et al.* (2016) *"in the energy and climate change research and policy fields, the concept of ''multiple benefits" (also termed ''co-benefits", ''multiple impacts", ''non-energy benefits", etc.) has evolved as a field of analysis showing that the impacts of low- carbon energy transformations go hand-in-hand with many other societal and economic objectives".*

In this sense, any innovation addressing energy consumption in the building sector – the largest single energy consumer in Europe – or changes in the energy market for better integration of RES in urban areas or enabling energy sharing by prosumers is expected to deliver substantial multiple benefits (Zambotti, Pezzutto and Bisello, 2019).

In particular, EU planners and designers are called to stimulate and enable the roll-out of visionary and holistic smart city projects aiming at increase energy performance of urban districts - including deep renovation of buildings in terms of technologies, processes and business models – while ensuring an increase in the overall quality of life of citizens and a better living environment.

This paper offers a first overview on a research path for the investigation of EU smart city projects under the multiple-benefits perspective, in order to foster the adoption of this assessment paradigm in the evaluation of their results and inclusion among key performance indicators (KPIs)

2. European smart city projects

2.1. Evolution of the approach and goals

Smart city is undoubtedly a sexy buzzword, used and abused in a wide range of contexts, from urban planning policies to advertisements of ICT companies.

Similarly, urban projects labeled as "smart city projects" widely differ. Within this blurry is it possible to identify some projects having recurrent characteristics and pursuing a coherent aim. Since 1984, multi-year funding programs have been developed by the European Union

(EU) to support and foster research and technological development in the European Research Area. In the last decade, the European Union encouraged cross-sectorial urban-energy renewal through specific funding calls, within the sixth and seventh European Research Framework Programme, also known as FP6 and FP7 and later thanks to Horizon 2020.

Such projects, implementing measures on new as well on existing urban districts, overcome the previous single-building approach. Benefits occurring in demonstration sites, in terms of improved energy performances, energy saved, or produced by RES and the tons of CO2 avoided, are widely known (Pol and Lippert, 2010). Moreover, they are used as the main examples to communicate the value of the project to the involved stakeholders, as well as to the general public. Aiming to demonstrate the feasibility of innovative solutions as well as cutting-edge approaches, such projects should involve research centers, universities, and partners from business and industry, and civil society organizations, in order to put into practice the quadruple helix innovation model. Moreover, for projects eligibility in this field, it is mandatory is the establishment of a temporary consortium of partners from various member and associate countries, and the identification of a pool of "demo cities" and some "follower" cities. In fact, having to be implemented into real-world urban settlements, the inclusion of local authorities is required. In some cases, the previous involvement of the city government into the Covenant of Majors is also a preliminary condition.

The pioneering initiative was the so-called "Concerto", between 2003 and 2008, funded by FP6 and FP7, with 28 accomplished sustainable energy districts projects, involving 58 cities and communities. The Concerto initiative has paved the way to the subsequent, and still ongoing, European Innovation Partnership - Smart Cities and Communities initiative (EIP – SCC), which addresses the challenge of pursuing the smart energy transition of cities.

The novelty of the SCC approach lies in a more extensive integration of innovative energy-efficient solutions with information and communication technologies which in fact shift the focus from the sustainable development approach to the smart-city concept. Additionally, more emphasis is placed on scalability and the replication potential of interventions. Under this calls, 12 projects have been financed, involving 36 Lighthouse cities and 42 Follower cities between the year 2014 and 2017. This set of projects is under consideration in this research.

The last evolutionary step of the EU smart city projects is represented by the recently funded projects answering the call SCC in the year 2018 and 2019. These projects will shift the focus from high-performance buildings and energy systems or net zero energy neighborhoods towards the positive energy district (PED) and the smart urban energy transition. A positive energy districts consist of several buildings (new, retrofitted or a combination of both) that actively manage their energy consumption and the energy flow between them and the wider energy system., having an annual positive energy balance. The positive balance is achieved thanks to the exploitation of local renewable energy sources RES, local storage, smart energy grids, demand-response systems, integrated energy management (electricity, heating, and cooling), co-design and user interaction (European Commission, 2018b).

The concept of positive energy district is something quite new, coming from the European Strategic Energy Technology Plan (SET-Plan) (European Commission, 2018a) which aims to accelerate the development and deployment of low-carbon technologies. The SET-Plan seeks to improve new technologies and bring down costs by coordinating national research efforts

and helping to finance projects. The SET-Plan action 3.2 - Smart cities and communities - focusses on PED, aiming to deliver at least 100 of them by 2050 (this target year has been recently revised to 2025), considering the interaction and integration between the buildings, the users and the larger urban and regional energy system.

Unfortunately having been started in 2018-2019, PED projects are in a too early stage to provide enough information or official results. In this sense, the paper considers SCC projects started between 2014 and 2018 the latest suitable set for investigation.

2.2. The subset of investigated SCC projects

Previous research on co-benefits and co-opportunities expected or claimed by EU smart and sustainable city projects has been done by (Bisello *et al.*, 2017) and some of the main findings have been recalled in (Bisello and Vettorato, 2018). At that time, older Concerto and SCC projects have been considered. Figure 1 summarizes the most recurrent benefits; those mentioned by at least half of the projects have solid fill.

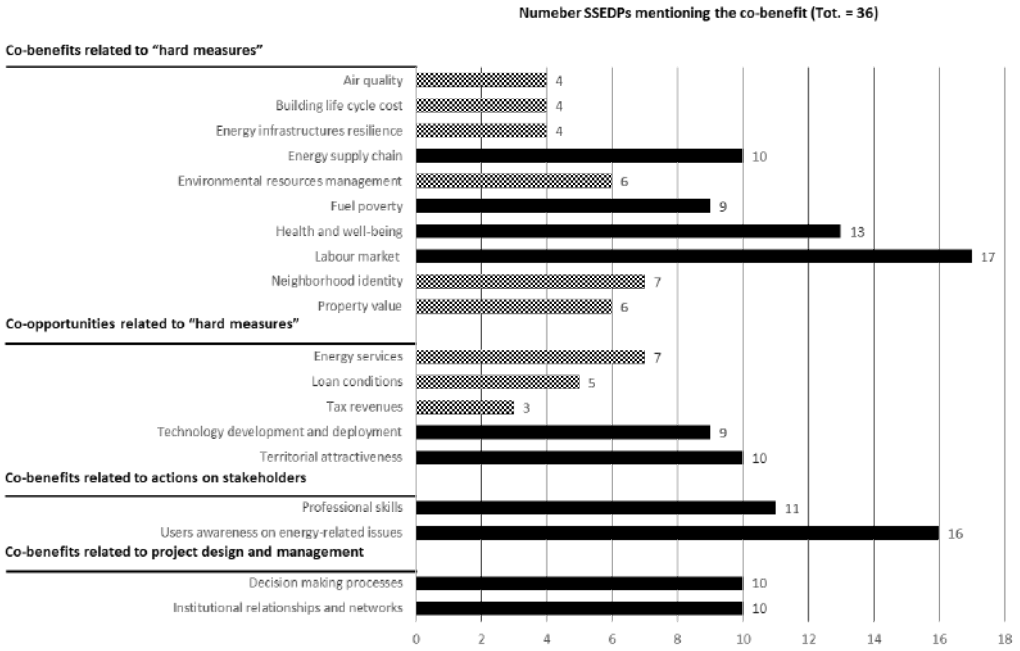

Figure 1: Co-benefits and co-opportunities identified in EU projects dealing with smart and sustainable districts. Source: (Bisello, 2017)

This new investigation focuses, as said before, on 12 SCC projects which have been financed between the year 2014 and 2017, involving 36 Lighthouse cities and 42 Follower cities , as shown in fig. 2.

The most exploited countries are Spain (6 Lighthouse cities out of 10 involved cities), United Kingdom (5 Lighthouse cities out of 7 involved cities), Germany (4 Lighthouse cities out of 6 involved cities), Italy (3 Lighthouse cities out of 6 involved cities), and France (3 Lighthouse cities out of 4 involved cities). This set of projects will have a total cost of 309M€, covered at 85% by the European commissions' contribution (260M€). Each one on average will benefit from 22M€, will last 4-5 years, and some of these projects will unlock up to 20 times more in investment (European Commission, 2018a).

3. Multiple benefits investigation approach

3.1. On-line investigation

This section explains the general methodology applied to co-benefits / multiple benefits investigation and details the steps proceed from raw information collection to a reasoned discussion. The following table 1 lists the investigated projects by funding call, providing the acronym, main financial figures and the link to the official website.

Table 1: SCC projects under the calls 2014-2017. Source: SCIS

	Project name	Year of the Call	Project Total Cost (€)	Project EC Contribution (€)	Website
1.	GrowSmarter	2014	34,635,913	24,820,974	www.grow-smarter.eu/
2.	REMOURBAN	2014	23,791,530	21,541,949	www.remourban.eu
3.	Triangulum	2014	29,501,431	25,420,602	https://www.triangulum-project.eu/
4.	REPLICATE	2015	29,250,564	24,965,263	https://replicate-project.eu/

8.	MYSMARTLIFE	2016	21,724,075	18,656,102	https://www.mysmartlife.eu
9.	RUGGEDISED	2016	19,562,868	17,692,858	www.ruggedised.eu
10.	IRIS	2017	20,704,013	17,996,569	https://irissmartcities.eu/
11.	MAtchUP	2017	19,472,388	17,418,339	http://www.matchup-project.eu/
12.	STARDUST	2017	21,093,539	17,939,999	http://stardustproject.eu/

The research method used is rooted in empirical case analysis and literature research. An on-line investigation will be undertaken, based on open-access sources representing the official point of view of project consortia (i.e. official websites of the projects) complemented by the official online repository developed by the EIP-SCC, the so-called Smart City Information

Systems (SCIS, 2018). We expect to find explicit references to multiple benefits, different from pure energy benefits, as they are already mentioned in some project abstracts (see SCIS):

- *GrowSmarter aims to improve the quality of life* […] *while improving the citizens economy by lower energy costs and creating as much as 1500 new jobs (on the demonstration level).*
- *REPLICATE considers also the complexity of cities, the tangible benefits for citizens;*
- *SmartEnCity's* [will] *enable further benefits and secure involvement of citizens;*
- *SMARTER TOGETHER's* […] *Expected results are:* […] *1400 created jobs, 130 M€ investments;*
- *The RUGGEDISED project* […]. *The overall aims are: 1. Improving the quality of life of the citizens, by offering the citizens a clean, safe, attractive, inclusive and affordable living environment.* […] *3. Creating a stimulating environment for sustainable economic development, by generating more sustainable jobs, stimulating community involvement in smart solutions and to boost start-up and existing companies to exploit the opportunities of the green digital economy and Internet of Things*
- *The core idea of the STARDUST project is the demonstration of different "innovation islands" as urban incubators of technological, social, regulatory and market solutions*

Exploring the project's website will give access to all the official and public available reports and materials produced, allowing a deeper investigation through a qualitative approach or text data mining

3.2. Text data mining

Text data mining, or text analytics, is the process of deriving high-quality information from text, typically derived through the devising of patterns and trends through means such as statistical pattern learning. Such process will allow passing from the raw data (e.g. the simple recurrence of the word co-benefits / multiple benefits or explicit mentioning of a precise benefit, as job increase, air quality, property value, etc.) to a specific classification of closely-related statements. This kind of research focuses on the qualitative and quantitative analysis of report contents giving a measure and a meaning of texts. For this purpose software like NVIVO11plus® could be used, as already demonstrated in a recent work done by Balest *et al.* (2018) looking at the main dimensions and aspects of territory that can address its change towards energy transition.

4. Conclusions and further steps.

EU smart city projects are of particular interest due to their large geographical coverage and at the same time similar basic principles. Because of the recurrent funding scheme, structure, and size of consortia composition, they synthesize the findings and expectations of a large population of stakeholders, ranging from researchers to local officers and technicians, and from practitioners to decision makers or NGOs. Therefore, they offer an

interesting overview of the society on the multiple benefits expected from the urban energy transition.

Content analysis of the selected publications will uncover recurrent statements in which the co-benefits / multiple benefits expected from each smart city project are cited, furthermore, this new investigation will allow a comparison of results with those reported in Bisello (2017) about the recurrence of co-benefits.

This will build up the knowledge baseline on with analyzing the assessment methodologies, qualitative and quantitative impacts, cascade effects, and interlinkages among co-benefits / multiple benefits of EU smart city projects for the definition of innovative and comparable Key Performance Indicators (KPIs).

The proposed approach is replicable in assessing other smart city projects outside the EU, which promote a sustainable and smart urban energy transition.

Research Paper

Presenting the Prospects for Ropeway Implementation as a Public Transport Mode, the Case of Moscow

Andrew BORISOW, National Research University Higher School of Economics – Institute for Transport Economics and Transport Policy Studies, Centre for Transport Modelling, Russia aaborisov@hse.ru | itetps.hse.ru; Russian Federation

Abstract

Modern technological advances in transport engineering and transport construction expand tools available to a transport planner: previously considered purely niche, "exotic" transit modes begin claiming to be full-fledged urban public transport varieties. One of those are aerial ropeways. The paper analyses international experience of this technology as a mass transit component used in urban environments. We suggest factors can influence decision making in favour of aerial cableways as a form of public transport. Within the proposed methodology, we identify pairs of adjacent districts where cableways could be sufficient as an element of an intermodal transit system.

Keywords

Public transport systems, cable-propelled transit, aerial cableways, connectivity

1. Introduction

1.1. Preface

The issue of how modern cities are organized and developed is one of the most pressing nowadays. Indeed, the share of urban population in the world has been already above 54% (55.3%), whereas by 2050 the percentage tend to be around 66%. Currently about 74% of Russian population lives in cities, and by 2050 this figure should exceed 80% (UN, 2018). At the same time, Moscow population in 2018 was estimated in about 12.5 million inhabitants (Rosstat, 2018). The importance of competent transport planning in such a city as Moscow is without any doubt. In fact, the capital of Russia carries the legacy of the USSR era, exposed in its' morphology and road network configuration: the mono-functionality of peripheral areas with a predominance of residential uses, while the proportion of the built-up area of the city allocated for streets and roads on the outskirts does not reach 10% (Blinkin, 2018).

While it is clear that a permanent increase in the share of streets and roads in such circumstances would not be economically justified, Moscow tend to solve the accessibility challenge in various ways: one of them is the development of public transport system, its attractiveness. In terms of utility, the attractiveness of public transport for an individual could be considered as a function of time spent on the journey. Although this is far from the

only variable describing attractiveness, it is however the most suitable for the planner in terms of an unambiguous assessment. Thus, the maximum level of utility would be achieved by minimizing the duration of time travelled. Obviously one's attitude to public transport as an alternative to a personal vehicle is rather impossible to interpret. However, it can be argued that the more choices and the higher the average speed of public transit are provided to the population, the greater is the probability of its attractiveness among citizens.

Fundamentally, planner's decision of a public transport mode on the section from point A to point B is based on various parameters, one of the keys when making such decisions is transport demand - in other words, the number of passengers moving daily from one location to another. Generally, classic urban transport modes (bus, tram, subway, etc.) are used for such objectives, depending on their carrying capacity. However, for urban planners there are much more restrictions like commissioning costs, operating expenses, existing settlement, and others. Hence, in some cases, standard urban transport planning tools cannot efficiently solve immediate problems. Solutions, previously considered narrowly applicable, may prove to be complementary to a modern city development agenda, complementing public transport network and assisting to solve a specific series of urgent issues.

In this paper, Moscow is considered as an example of a dynamically developing city with high intraday passenger traffic and typical post-Soviet cities' issues (see above). In the context of its' specifics, namely the low connectivity level, implementation of aerial cableways as an element of Moscow's public transport system is proposed, foremost, to increase the accessibility of neighbourhoods.

1.2. Goals and Objectives

In recent years, cable transport systems (cable-propelled transit) have been significantly improved in terms of technological applicability for urban transport and can currently fill a niche in the urban transport system, where traditional methods might be relatively less efficient. Moscow suffers from the problem of low connectivity - especially when it comes to peripheral areas of the city. The issue is due to the poor development of the road network, in particular, lack of overpasses through railways and bridge crossings over water barriers, as well as the presence of blocked areas (usually industrial zones) between neighbouring areas. Low connectivity, in turn, generates an extremely high rerun rate, amounting to 1.7 in Moscow versus 1.2-1.4 for cities with a developed street network. It is clear that this circumstance negatively affects the existing public transport, total time spent on journeys and the quality of life in general (Ingrid E. Schneider, 2013).

The object of the research is aerial cableway passenger systems, while the subject is the possibility of expanding the typological spectrum of urban passenger transport due to the implementation of the aerial ropeways as a type of public transport on the example of Moscow.

Basic hypothesis suggests the need to establish direct transport links between isolated areas of the city of Moscow, while the solution could be met by incorporating modern aerial ropeways into urban transport systems. Thus, the purpose is to propose an evaluation methodology corresponding to connectivity estimates of Moscow districts. The results of the analysis show for which areas of the city implementation of aerial cableways as an element of the public transport system is appropriate and valid.

2. Ropeways in urban transportation practice

2.1. Technological features

The paper deals exclusively with aerial cableways. Such decision follows from the specifics of this type of transport, namely: capital and operating expenditures, low terrain requirements for development and construction. While describing the cableways, terminology adopted in the community of urban planners - The Gondola Project – is used. Thus, it is considered hereinafter to be called CPT or Cable-Propelled Transit.

Modern practice of CPT successful use worldwide in urban environments is due to a significant improvement in technical characteristics of these systems. First, manufacturers have significantly improved the CPT speed performance compared with the predecessor used in cities. To date, this type of transport is able to reach speeds above 40 km / h (Doppelmayr / Garaventa_1), while the average speed of standard monocable systems exceeds 20 km / h (Marocchi, 2015). Thus, according to this indicator, CPT can compete with some traditional types of urban public transport (Griškevičienė, et al., 2006), (Madejski, 2005). Secondly, modern CPT types have sufficiently high carrying capacities, comparable to bus routes. At the same time, infrastructure construction and rolling stock purchases, as well as operating costs, are also comparable to corresponding capacity systems.

Indeed, aerial cableways can effectively complement urban mass transit, especially within the existing development. However, it is important to note that when considering the issue of CPT implementation in the city, it is necessary to understand that this system is not an alternative to existing types of urban public transport, but serves as a local addition to existing system in current planning conditions.

Further, we consider the existing types and technical features of aerial ropeways, as well as quantitative estimates of its application - in terms of costs, safety, transport indicators, tariffs and indirect effects.

2.2. CPT types

Features of the traction device, passenger capacity, speed, and resistance to climate conditions – all this features distinguish cableways applicable in urban environments. In total, there are five main types of top-supported cableway systems: (1) MDG, (2) BDG, (3) TDS/3S, (4) Funitel, (5) Aerial tram, (6) Pulsed gondola. Indeed, each of them are well described, although either in most publications, we observed discrepancies in technical data, or absence of their full description was found. This paper illustrates an attempt to unify that data and depict it (Table 1) on the grounds of several cases.

1) MDG or mono-cable detachable gondolas

Cableways with detachable gondolas are the most common type of CPT as part of public transport systems. Gondolas move along a single traction-carrying cable, which is turned around at the end stations and is driven by a traction wheel. At the station, cabin grip disengages suspension cable, and its further movement performs using roller guides.

2) BDG or bi-cable detachable gondolas

Same as MDG, but traction and carriage are divided between two cables.

3) TDS / 3S or tri-cable detachable gondolas

Operating with two steering and one traction cables, this kind of CPT offers significant throughput growth in terms of operating speed, resilience and passenger capacity. The rest repeats two previous types.

4) Funitel

A special characteristic is the design feature of two installed loopback cables, performing as a traction-carrying function simultaneously for opposite directions.

5) Aerial tram

A classic aerial tram consists of two independent stationary guiding cables for each carriage and one looped traction cable. The cab itself has high passenger capacity, much higher than previously described systems - from 50 to 200 people. The key feature is the maximum speed indicators among the CPTs. Aerial trams are able to reach speeds up to 43.2 km / h.

6) Pulsed gondolas

This type's peculiarity is in non-trivial installation solution: several small-sized gondolas are set in close proximity to each other, thus a group cableway can be characterized as a combination of classic MDG and aerial tram. In terms of speed, it is comparable to MDG / TDG, but inferior in carrying capacity to all of the systems above - up to 1000 pphpd (Jacobs, 2016). Hence, it is least disposed for public transport uses.

Features and cities where these systems operate are indicated in Figure 1.

City	*Opening*	*Type*	*Length, meters*	*Cabin capacity*	*Number of cabins*	*Operating speed, km/h*	*Peak headway, seconds*	*pphpd*	*Tariff, US dollars*	*Ticket menu integration*	*1 km cost, mio US dollars*
New York	1976	Aerial Tram	3100	78	2	26	7,5 min.	1 000	2,75	yes	8,6*

*** Reconstruction carried out in 2010**

2.3. Comparative evaluation

According to the analysis of reviewed CPT systems, as well as the analysis of the calculated technical and economic indicators, it is possible to compare the CPT with the classical urban mass transport. Figure 2 presents a quantitative comparison estimates for CPT systems and prevalent public transit modes.

As a result, in relation to carrying capacity and capital expenditures, cableways are comparable (conditionally) to bus and tram. When comparing the cost per kilometre, CPT types as well as the number of cabs allowance is essential. Obviously, many factors that might affect the final project costs cannot be fully disclosed here (materials, financial plans were not disclosed). Remarkably, delta between the capital costs is significantly less alters than bus and tram analogues within the capacity range (Carlet, 2017).

Transit mode	*RoW*	*Operating speed, km/h*	*max. speed, km/h*	*Passenger capacity (3,5pax/m2)*	*Passenger capacity (5pax/m2)*	*1 km cost, US dollars**	*pphpd*	*max. pphpd*	*Number of cars*	*max. Number of cars*
Tramline	C	23,1	до 30	197	430	3 - 10	7880	20 000	3	5

Figure 2. Author's estimates, (Alshalalfah, et al., 2012), (Jacobs, 2016), (Marocchi, 2015)

*** Includes all capital costs: rolling stock and other infrastructure facilities**

**** Peak operational speed values at the spans, as well as the maximum passenger capacity are calculated for aerial tram, while the maximum passenger capacity for TDS/3S reaches 6000 pphpd**

By type of application, the vast majority of CPTs operating in urban environments are the MDG family, which is associated with considerably lower costs and to relatively high capacities. Most of these systems are installed as an alternative to complex transport infrastructure (tunnels, bridges, etc.) due to the terrain-challenged relief and / or within existing development and environmental management. Aerial trams are established to connect areas with a stable predefined transport demand. All that systems have never been tested at their peak capacities (6 000 pphpd or even more) and considering a CPT as an alternative to metro or LRV is not entirely correct, at least for transport safety reasons. Hence, we do not consider CPTs as trunk lines, presuming on the contrary to be an addition to feeder transport and solving local problems.

In accordance with the above-mentioned features the paper proposes a methodology for assessing the city of Moscow to CPT implementation.

3. The Research

3.1. Context

Moscow is of the greatest interest to consider any transport innovation prospects for many reasons. The total daily passenger traffic by all mass transit types is about 18 million passengers. The cumulative annual budget expenditures is about 250 billion roubles (approximately $4 billion). Both numbers are among the highest compared to other global cities (Moscow DoT, 2017). At the same time, a number of local transport problems generated by low connection density and road network connectivity are still unsolved.

Below, we identify poor connected districts and offer a solution using CPT. Additionally, indeed over the past year two cableways appeared in Moscow, none of them integrated in mass transit system.

3.2. Approach

The paper proposes an approach that identifies areas suffering from poor connectivity and continuous blocked borders. For this it is necessary to set a few exogenous parameters. In accordance with the above-mentioned features the paper proposes a methodology for assessing the city of Moscow to possible CPT implementation. All administrative districts within the Moscow Ring Road are chosen, since the main objective is to improve the existing

transport network intensively. The idea is to identify neighbouring districts with at least one common border, the direct transport links between which are absent and the border itself represents a continuous barrier – area where transport infrastructure construction is obstructed or impossible. These "barrier areas" include natural reserves, urban forests, parks, water bodies, cemeteries, industrial zones, port zones, defence facilities, incinerators, railway transport infrastructure.

Than all these objects are displayed and clipped by districts' boundaries, represented as a buffer zone around linear objects districts and 400 meters in diameter (Figure 3). The parameter is defined as the maximum public transport access level to commercial and residential specified by Moscow Government (Regional Ordinances, 2015). The results show continuously blocked boundaries, apart from areas within the T1-T4 urbanization zones in accordance with current classification (means, predominantly unsettled areas). Continuity is measured as orthogonal display of selected areas in the form of a continuous curve.

The next step is to overlay the road network metro and tram lines (Figure 4). Now we introduce a pairwise connectivity assumption: two randomly selected neighbouring areas with at least one blocked border considered to be unsatisfactory connected under the following conditions:

- the topological distance along the road network between these areas is zero;

- there is no metro line, the stations of which are in the body of each considered district in pair;

- there is no tram service between the districts.

The concept of area body is introduced exogenously and defined as a part of an administrative district, except for territories within 100-meters buffer zones around district borders. The buffer is taken in accordance to Regional Ordinances, meant the interchange length between public RoW C and RoW B transit stops (bus, tram) and RoW A (subway, urban rail). A set of satisfying districts are shown in Figure 5.

3.3. Final assessment

Implying intensive development, we are based on (1) filling existing gaps and (2) connecting blocked areas with public transport network. The decision makes it possible to expand the transit choice for selected districts having trunk links with Moscow urban core, but without local inter-district correspondence capabilities. This leads to over mileage and travel time loses.

We impose a condition: each district pairs must have at least one metro station within its' body, not belonging to the same line.

Thus, we form a set of neighbouring areas with a common continuous barrier passing along the adjacent border and the absence of straight-line inter-district transport links. These pairs could relate to CPT use, which in turn could be integrated into public transport network. Since our main purpose is not to trace exact routes, we define the potential length of these systems as the minimum air distance between metro stations of each chosen pair. At the same time, we introduce the "Realistic condition" – a distance limit should be no more than 4 000 meters (from Figure 1, "length"). The new sample is presented in Figure 6.

Figure 3. Author's approach

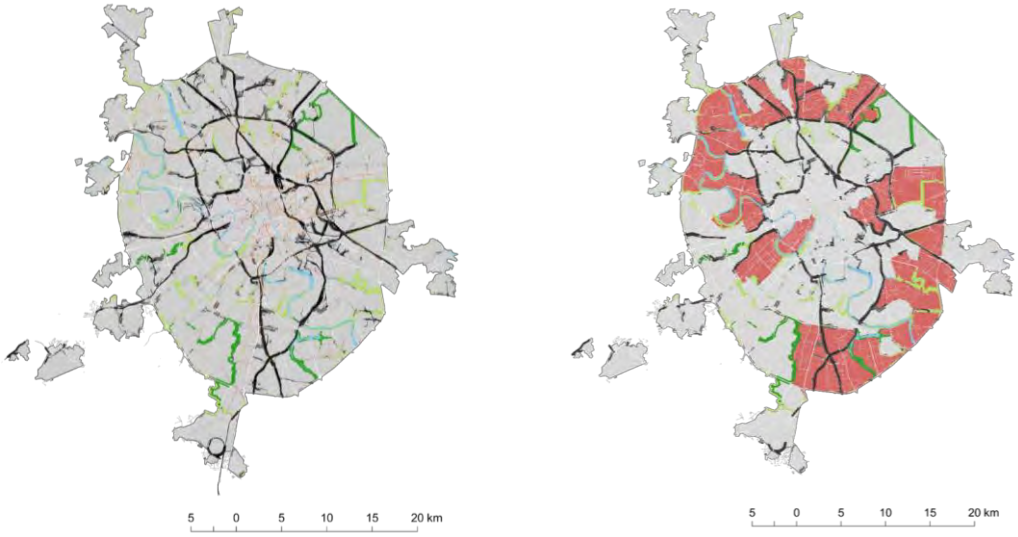

Figure 4, 5. Initial set selection. Author's model

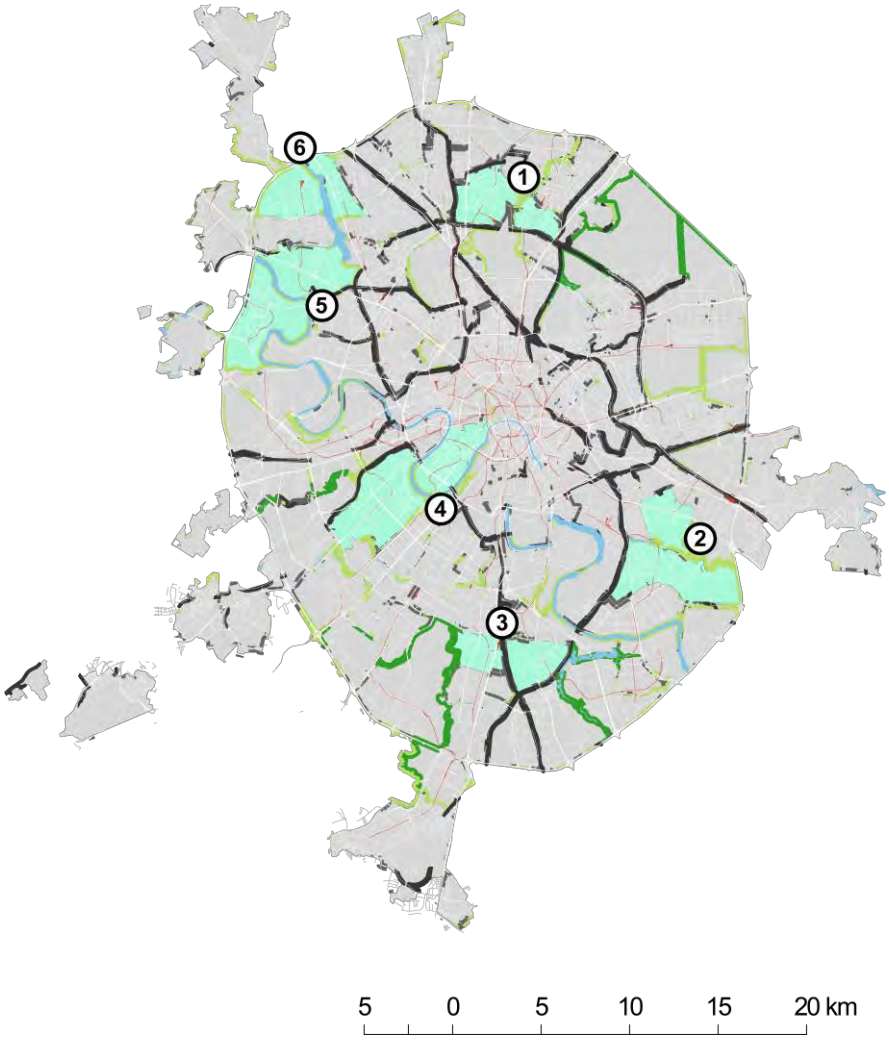

Figure 6. Final sample. Author's model

The selected six pairs are also presented in Figures 7, 8 and a comparative analysis results with satisfactorily connected pairs of areas in terms of overmileage. In addition, ODs for the six pairs were analysed. It was considered cumulative, from the nearest terminal station, using Moscow Metro O-D Matrix (granted on request).

As it is shown, the least transport demand is imposed on the last pair (Figure 9). It is an unexpected result, since these districts are considered for the cable car construction (Interfax, 2018); moreover, the source predict passenger traffic of about 19 thousand passengers per day.

For that reason, a link analysis using traffic macro model was additionally carried out. But this also did not produce results like indicated figures. Appendix illustrate the total demand for inter-district correspondences (about 200 cars per hour).

Probably the calculation should be carried out using the multimodal (rather than traffic) simulation. However, such calculations are beyond the scope of this study.

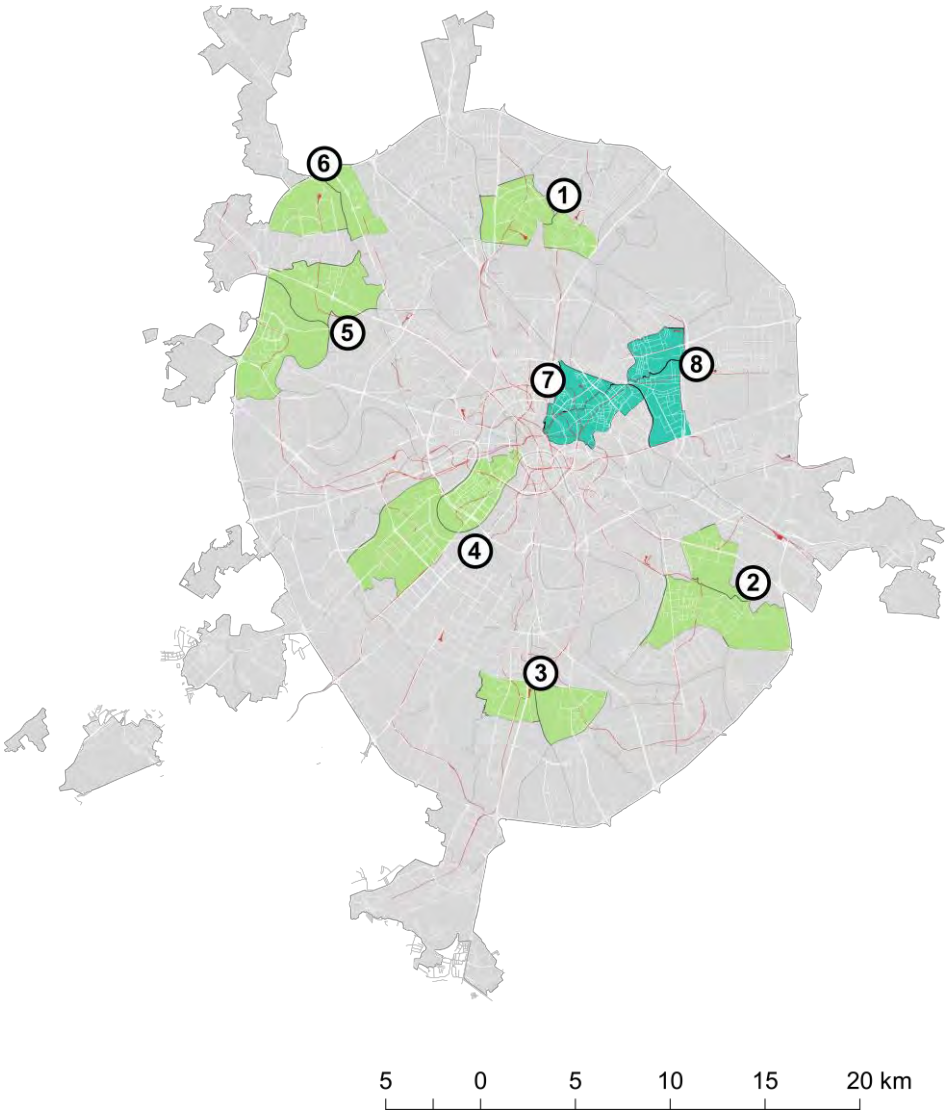

Figure 7. Six considered + two compared (7 and 8) districts. Author's calculations

		Pairs	*Aerial distance between metro stations, km*	*Time travelled by public transport, min*	*Time travelled by individual vechicle*

4. Discussion

The main feature of CPTs is a possibility of supplementing feeder systems, so public transport system multimodality could be enhanced.

We identified the basic principles that should be followed when deciding CPT use in the city. Proposed approach for Moscow evaluates the basis on which the straight-line connections creation between neighbouring but isolated districts is set. We determine such areas of the city. As a result, four pairs of districts are proposed (Figure 9).

According to the author's opinion, an important implementation component is the presence of positive visual qualities of the potential route. Proceeding from this subjective hypothesis, we found it possible to reduce the number of pairs to four, while excluding the Otradnoe-Sviblovo and Tsaritsyno-Chertanovo Severnoe. Thus, the decision could not only solve local transport problems, but also contribute to new attraction.

However, we are not claiming the unambiguity of our conclusions. On the contrary, one or another decision on transport infrastructure development may be based not so much on objective factors, such as passengers travelled or relative costs, depending more on political preferences. We tried to offer a very obvious and transparent connectivity assessment,

bearing in mind CPT technical features and hence provided an opportunity to view the map of the city with a sober and unbiased look.

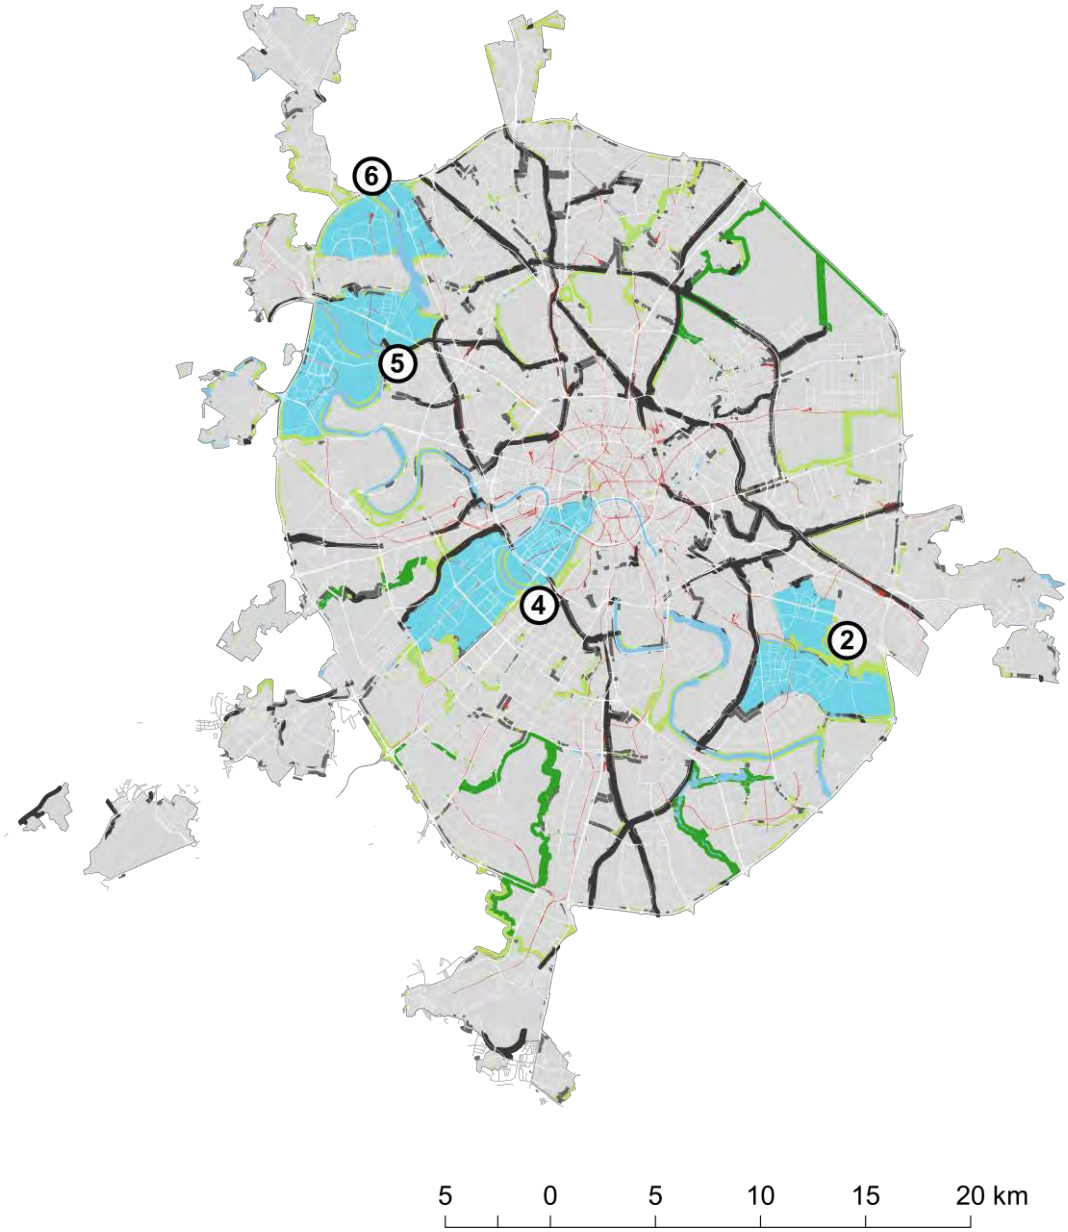

Figure 8. Final set. Author's calculations

We assume that the final sample we carried out is not sufficient, and there may be much more tracing variations connecting other areas. But we have responded the issue we posed at the beginning. Indeed, arguing in terms of throughput and spatial connectivity, we have shown the areas with the greatest potential for CPT. These pairs of districts are preferred to be connected better but on the other hand not by implementing above-ground solutions while underground facilities burden the city budget and as a result taxpayers.

Case Study Paper

Re-Thinking the city:

Basaksehir Living Lab (Case of Istanbul)

Ozge CELIK, Istanbul Technical University; Turkey
Ozhan ERTEKIN, Istanbul Technical University; Turkey

Abstract

Smart Cities depend on strategies and solutions enabled by ICTs involving directly citizens, local governments and communities. Aim of the paper is to understand the challenges and potentials of new technologies and its applications in an urban setting while surveying urban innovation units and living labs. The paper uses the concept of smart cities as a mean and manner of urban future. Moreover, it examines the change in the concept and to find out cooperation between local governments and living labs in two different extents. One is to determine the effect of new technologies on city planning and its users and other is to find out social movements that might bring them together. In addition, this paper analyses a set of five key principles that define the concept of living labs. Using these five principles, organizers and volunteers in Basaksehir Living Lab in Istanbul (Turkey) were interviewed and most relevant projects and implementations were evaluated to indicate how well planning practice advances smart planning and projects that contribute to the local development.

Keywords
living labs; local development; participation; smart cities; technological innovation; Turkey.

1. Introduction

> "Cities are complex systems whose infrastructural, economic and social components are strongly interrelated and therefore difficult to understand in isolation."
>
> (Jacobs, 1961).

Before discussing technological effects on cities, one question should be answered: what does the 'city' mean? As yet, there is no global agreement on what a city is. It has been defined in different ways throughout history from country to country as the fact that the city is in a constant change by its nature and gains different meanings according to the socio-economic conditions. In this sense, it is not possible to find a single city definition and criteria to express this definition in the literature for all countries. In many countries, a city is termed by quantitative measures as Turkey. A city is not only a physical imprint on a map but organic entity with its own identity. Moreover, it responds to its inhabitants' demands and needs. As the global population continues to grow, cities are progressively being challenged by incessant and emerging phenomena. So that a city should be driven by responding to its inhabitants' changing needs and ambitions as well as values estimated in the global agendas (UN-HABITAT, 2016). UN-HABITAT describes cities as hubs of economic growth, innovation, culture and creativity. In addition, cities have the potential to provide an environment that embraces innovation. Many of the challenges our societies face

today are increasing in urban areas; this is one of the reasons why innovation is becoming more of an issue in cities.

In recent years, smart cities become global trend concerning various disciplines, from economics to urban designer and from technological development to globalization (Caragliu et al., 2015). The concept is not only related to technological applications in cities but also regulates many sectors. Smartness concept also includes a variation that involves digital or intelligent concepts or is discussed together. Smart city terminology focus on the significance of new ICT regarding modern infrastructures in cities in the 90s. The focus of the term smart city, which was first used in the 90s, was on the importance of modern infrastructures and ICT in cities (Albino et al., 2015). The idea of being a smart city has been criticized by arguing that technically oriented and smart city approach, which emphasizes the role of social capital in urban development, should be strong governance oriented. It is considered as an approach (Caragliu et al., 2015). The discourse on smart city promises an innovative era of urban planning through ICT implementation, based on urban technologies that will make cities cleaner, more beautiful, safer and more efficient (Hajer and Dassen, 2014). Therefore, the concept of smart city is not a static term and the concept has been developing since its first use. Although technology is the key to being a smart city due to the use of ICT to transform life and work within the city, a well-functioning infrastructure is required to be a smart city, but this is not enough (Nam and Pardo, 2011). IT infrastructure and practices are a prerequisite, but the tool as ICT and its practices exists to facilitate the participation of all actors in the development of smart cities (Lindskog, 2004). There is no smart city unless there is genuine participation and willingness to cooperate and cooperate between the private sector, citizens and public institutions (Lindskog, 2004).

According to Hajer and Dassen (2014), planning will become a continuous experiment and cities will serve as living laboratories. As a result, the main objective of the paper is to evolve a clear understanding of Living Lab concept in Turkey. So that, Basaksehir Living Lab will be examined to understand its concept, mechanism, decision making process and implementations, also, to determine the success of Living Lab initiative. The paper responds to the following research question: What are the appropriate technologies to serve urban planning problems and users' needs in the Living Lab and How these new technologies affect them?

2. Living Lab Concept

> "Urban living labs constitute a form of experimental governance, whereby urban stakeholders develop and test new technologies, products, services and ways of living to produce innovative solutions to the challenges of climate change, resilience and urban sustainability."
> (Bulkeley and Castan Broto, 2013)

According to Hillgren (2013), there is no uniform definition of living labs. Bulkeley and Castan Broto define living labs as a form of experimental governance by which new technologies, products, services and way of living are

developed by urban stakeholders to produce innovative solutions to urban problems (Bulkeley and Castan Broto, 2013). For technology-driven and digital/smart cities concepts, living labs have different objectives and ways of working. However, living labs are initiated by various actors and form different types of partnerships which has defined as sectors (public, private etc.) where universities play a key role (ENoLL, 2015). On the other hand, for some academicians and organizations, living labs are more in the light of pilot and demonstration projects (Kommonen and Botero, 2013).

At the beginning of 2000, Living Lab began to emerge as the focus of testing new technologies in newly built homes. Since then, the growing concept has now taken its place with the establishment of real-world context. The Living Lab concept can be used as a human-centred research and development approach where ICT innovations are co-created, tested and evaluated in open, collaborative and real-world environments. Living Labs could be considered as an environment for actors and industry to help them generate and improve their products and services or commercialise their technology. Besides, it could be considered as an approach for intentional collaborative experimentation of researchers, citizens, companies and local governments (Schliwa, 2013). The Joint Programming Initiative (JPI) Urban Europe introduced the term "urban living lab" and defines it as "a forum for innovation, applied to the development of new products, systems, services, and processes, employing working methods to integrate people into the entire development process as users and co-creators, to explore, examine, experiment, test and evaluate new ideas, scenarios, processes, systems, concepts and creative solutions in complex and real contexts" (JPI Urban Europe, 2013).

Living lab methodologies are based on education, investigation, testing and applying projects which are related to sustainable challenges and occasions that cities are facing in Europe (ENoLL, 2015). There is no clear understanding of the ultimate role of Living Labs could play in urban governance. From the point of view, many projects related to Living Labs are emerging phenomenon on participation, collaboration, experimentation, learning and governance in cities. Nonetheless, cities, competing to reduce carbon emissions and to be sustainable, try to position themselves as innovation leaders. However, living labs provide a mean of applying for high-profile statements of intent and means to fund sustainable urban development and encourage cities to adopt innovative solutions.

During the design of the concept, living labs were defined as an environment, a methodology and a system. While technological platforms and user based approaches can be countable for environmental perspective, data transfer and user participation are under consideration of methodological perspective. In addition, the Living Lab approach not only focuses on the inclusion of users in development processes, but also attempt to cooperating with other stakeholders from public–private–people partnerships. What distinguishes the living lab approach from other laboratories is the inclusion of users in the process as an actor that shape the innovation in their real-life environments. But, other labs or innovation networks experts are shaping the process while users are act as sources (Almirall, 2009). Ensuring equitable urban development; empowering civil

society, expanding democratic participation and reinforcing collaboration; promoting innovations that facilitate learning and the sharing of knowledge principles are given by New Urban Agenda in response to develop and test different forms of urban governance (UN-HABITAT, 2016). In a way, living labs could encourage cities to adopt new challenges.

2.1. Basaksehir Living Lab: "Technology for life"

Basaksehir Living Lab, was founded in 2015, is in European side of Istanbul also it is located Basaksehir district. The lab is identified with first Turkish living lab, which has performed 370 organizations, approved by ENoLL (European Network of Living Labs). The first purpose of the lab is to create an environment in which information technology and technology-related products design and services can be tested by real users in a real-life environment (BLL, 2018). Basaksehir Living Lab is focused on helping society to see the real accretion value of new products and services while serving an experiment, research and innovation environment (ibid.). Moreover, besides their focus on producing new products and services, the smart city projects and ICT based projects are adopted their agenda (ibid).

The lab also serves as an ecosystem for entrepreneurs whose projects, about information technology and design, approved by the committee (BLL, 2018). It also provides an environment for entrepreneurs working on similar topics. In addition, entrepreneurs are given free support to submit their projects to the market in the lab while young generations are supported to raise their awareness on ICT and design issues (ibid.). Likewise, Basaksehir Living Lab ecosystem serves same benefits and privileges to their partner institutions and organizations. Following indicators are proposed by Basaksehir Living Lab:

> (1) Entrepreneurs can benefit from the incubation centre and all facilities in the building such as Elektrolab, 3D Printer Laboratory, meeting rooms and video call rooms.
> (2) Entrepreneurs can benefit from consultancy and mentoring support in Basaksehir Living Lab during the project process.
> (3) Entrepreneurs can participate in Entrepreneurship Trainings given by professional entrepreneurship experts at Basaksehir Living Lab.
> (4) All can promote their products and services by taking part in the Basaksehir Living Lab stand.
> (5) Entrepreneurs can get all design support from IDF (Istanbul Design Factory) which is the solution partner of Basaksehir Living Lab.
> (6) Entrepreneurs can present their products and services in the User Experience Centre and Product Display Area and create an environment for the end users' experience.
> (7) In the Entrepreneurship Days, Entrepreneurs can expand their relationship network and cooperate with all institutions and organizations in the ecosystem.
> (8) Entrepreneurs can create test environments for their products and/or services that they developed and Entrepreneurs have an opportunity to test with real users in real life environment.

(9) Entrepreneurs have a place on their news on the international platform through Basaksehir Living Lab e-newsletter and ENoLL newsletter that publishes every month (BLL, 2018).

Basaksehir Living Lab cooperates with Basaksehir Municipality in all its projects and organizations by giving importance to strategic partnership. In addition, IDF and Zemin Istanbul institutions are involved in projects and organizations as partners. In addition to these partnerships, the lab cooperates with four other private organizations as a living lab strategic partners. (see figure 1) Other than strategic partners, each project and each event, organized by BLL, have specific partnerships in related topic.

Figure 1 Basaksehir Living Lab Strategic Partnerships

2.2. Background Mapping and Organization

Lab management consists of coordinator and vice coordinators who are whether business engineers or industrial engineers (Celik, 2018). Management perception of lab is to create a working space and/or environment for its users. The lab is defined by coordinator as an environment to develop informatics oriented projects and to improve users' ability (Celik, 2018).

The laboratory acts as an organ of Basaksehir Municipality. All projects and activities to be carried out during the year are prewritten report and presented to Basaksehir Municipality in advance (Celik, 2018). The organization of the lab is determined by technical specification by Basaksehir Municipality every year. For example; 35 hours of informatics training, 72 hours of mobile game training and 25 hours of entrepreneurial training will be provided for current year (ibid.). In addition, Basaksehir Municipality uses the lab as activity-based environment. Environmental support is provided to use in special events or organizations for Basaksehir Municipality as a collaboration (ibid.).

Private sector partnerships are provided through collaboration in organizations, projects or various events, as well as environment and room support. However,

actors or partnerships involved in the process are a project-based selected, determined by technical specification while choosing experts is left open ended (Celik, 2018). On the other hand, experts and designers are chosen from the existing ecosystem according to the event context and time. In addition, selection of the participants is also based on the concept and time of each event (ibid.). The job and participation descriptions and responsibilities of the users or actors in the process vary according to the project and/or activity.

Meanwhile, the process is completed by first identifying the event, then confirming and announcing the users of the event (Celik, 2018). Based on the event, special users are chosen such as entrepreneurs, municipal employees, university or/and high school students (ibid.). Some programs include special partnerships for children training. In addition, special training programs are provided for housewives or children with disabilities (ibid.). It is clear to understand from all these information is that educational approach is more crucial for Basaksehir Living Lab. While educational project approaches are the main principles in the living lab organizations, urban based implementations get higher points due to their importance level to solve urban problems. Even though there are some smart cities projects created in Basaksehir Living Lab, the impact area of projects is limited. In real-world context, implementation process should be more taken into consideration.

3. Basaksehir Living Lab Success Criteria

3.1. Methodology and Data Collection

To investigate the "smart plan" applications in urban planning and to determine development of technologies in urban planning, their inclusion in the planning will be revealed through documentary analysis of the projects and one-to-one interviews. The aim is to measure and evaluate the success of Living Lab initiative. Reflecting urban contexts suitability in a living lab environment and how it adapts to living labs' features. For this purpose;

(1) To identify the living lab practices / projects and events and design methods
(2) To identify design concept, project process and implementation process of the living lab
(3) To reveal the living lab' objectives and relations in the urban context
(4) To determine the network relations, partnerships and participation process are examined and analysed.

In addition, interviews were held with organizers, laboratory staff and board members. Interviews were based on a semi-structured questionnaire with questions related to organizations of the living lab, decision making process, actualization and were conducted in Turkish and English languages. All interviews were recorded and transcribed in order to allow further analysis.

Focusing on the Basaksehir Living Lab approach related to the components and principles of the living lab will be explored, and data will be collected to ensure a common knowledge base of available applications. Since living labs is a new field of research, the amount of supporting theories for understanding the concept is limited. The absence of systematic analysis and reflection on existing methods and tools and their relevance to the context of the living lab will also be determined to identify Basaksehir Living Lab success criteria.

3.2. Data Analysis

To analyse interviews, implementation process is highlighting an important statement that out of 15 projects and 370 events related to education, product and software design (see figure 2) only 3 projects were implemented in urban environment. One of them is a smart infrastructure system located in Basaksehir district. Others, also located in Basaksehir district, are about renewable energy and architecture related. According to interviewers, this situation is more about Turkish planning system. It shows what are the driving elements of living lab in the planning ecosystem.

Figure 2 Interview questions pool

Basaksehir Living Lab has 7 strategic partners which are public (2) and private (6) institutions (see figure 1). This partnership encompasses different elements that shape the dynamics of new methods for urban planning and development such as user-driven methods, user-centred methods (Celik, 2018). But interviews show that living lab projects or events only seen as a platform to educate, or an environment where you can test your product and try new technologies (ibid.). However, it is assumed that collaboration of different actors and stakeholders should enhance smartness of a city as well as combinations of different elements should. How can city be smart without changing traditional government structure to adapt city functions to the new paradigm? The question releases problems regarded Turkish empirical domain. In order to solve problems, enforce rules or

allocate resources, the process should be more open, transparent and democratic at the same time. “Openness” is one of the main living lab principles that should be taken into consideration both partnership level and intellectual property rights (see figure 7). Also, cooperation between different stakeholders actively involved in a decision-making process should be affect to form public policy if necessary (Celik, 2018).

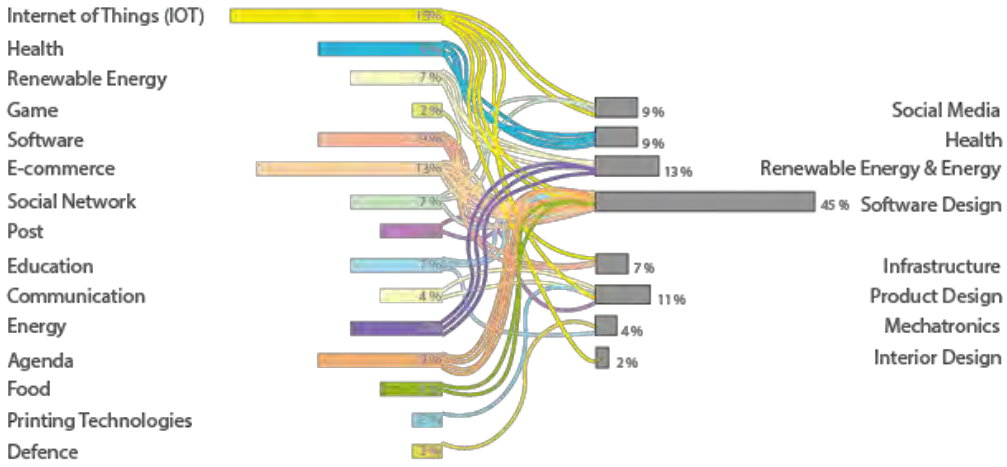

Figure 3 BLL projects and events content

The participation process is evolving under the control and the support of the private sector other than strategic partners. This may in fact reveal the strength of cooperation and the need for diversification in projects. However, it also provides the basis for a variety of actors (see figure 4). As seen in figure 3, the projects produced between 2015 and 2019 in the lab are more focused on software design. Only total of 29 percentage of projects include smart city applications such as health, infrastructure and energy. From this point of view, situation pushes to think that the priority field studies of the lab are overriding spatial planning. Whether ICT become more countable than spatial/environmental reflections of the projects or ICT serves the new environment for the reflection of the projects. It may lead us to statement that virtual environments, applications and developments can be considered spatially. As a matter of fact, become more transparent and open, besides all the collaboration between BLL and Municipality of Basaksehir living lab process should be more communion about project details and results, is a necessity. Long term commitments and large scale communities should be considered apart from number of events and projects.

Variety and number of users diverge according to the projects (see figure 4 and 5). For each activity or project, an average of 25 users are selected by announcement method. In some cases, the first responders are preferred, while in some cases, choices are made in line with the intended purpose of the projects and the professions or age/tender of citizens. Within the scope of the activities and collaborations determined by the Lab, the users are designated to specific groups. All this reveal “empowerment of users” according to the Enoll principles. In the

case of Basaksehir, the users are passive and take plays the tester or informant role in the decision-making process of the projects.

Figure 4 Organisational partnership and user participation network

Yet, according to Enoll principles, "continuity" can be put forward with the project lifespan. In the case of Basaksehir, this period is generally kept short. Although each event is renewed according to user demand, no continuity is observed in the projects. The actor diversity varies according to the project and differs to the subjects. Some projects or activities include a wide variety of actors within the scope of the established cooperation, while others (usually for educational purposes) include a limited number of actors. The role of the designer in this process was defined as the trainer. Although the designer helps the users in the process, its contribution is limited (see figure 7).

In addition to all these, Basaksehir living lab has a high impact on “realism” and “real world content” due to the technological opportunities offered by the lab building and environment. The projects developed within the Lab come into the real-world context with time and space constraints. Although the spatial impact on Istanbul is not yet in effect, its impact on the Basaksehir Neighbourhood borders

is indisputable. In addition, it has national and regional "influences" through the entrepreneurs who trained or supported by the lab (see figure 7). A potential risk at the living lab is that the lab come from a technology-push rather than a demand-pull. In fact, giving support to the needs rather than the necessities takes steps towards the solution of city problems and directs the users and entrepreneurs to the right market.

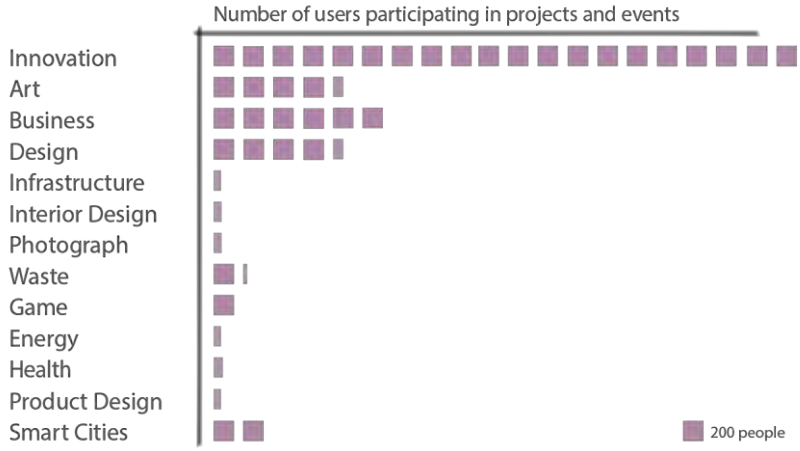

Figure 5 Project based participation of users

As a result of given parameters (see figure 7), Basaksehir Living Lab should manage a more open process and provide a transparent environment for the users and public. Lab methods applied in future projects can be developed and users take part as experiments as well as being used as a contributor. This also applies to designers.

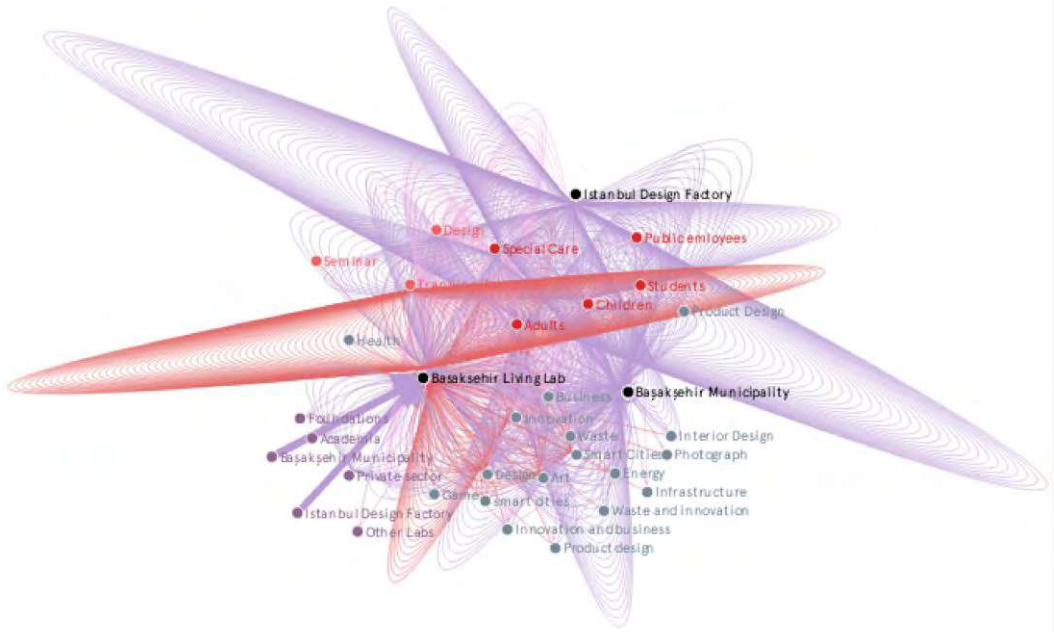

Figure 6 Network Analysis in BLL projects

	Criteria	Basaksehir Living Lab	Level
Openness	Level of openness - partnership	Semi-exclusive partnership	2
	Level of openness - intellectual property rights	little results and information generated in the living lab are shared (only brief updates or summaries)	2
	Domain	Mostly digital domains, rarely diagnostic and actual domain	1
Empowerment of users	Users role	Mostly informant, rarely contributor (creating with user)	1
	Scale	Small (<100 users)	2
	Selection of Users	Mostly without any criteria, rarely with professions	2-3
Continuity	Lifespan	Short term Project (<6 months)	1
	Ecosystem approach	Value creation and sharing to some of the stakeholders in the living lab ecosystem (missing links in the value chain, no equal contribution of all stakeholders)	3-4
	Actor Diversity	Mostly small scale (1-2 actor), rarely medium and large scale	2
	Designer Role	Mostly interpreter, rarely context designer and contributor (creating with users)	1
Realism	Technical Infrastructure	Infrastructure with extensive monitoring and in-depth technical testing	4
	Real-world context	real-world context with some time or space limitations	3
Influence	Context Research	The usage context is substantially considered using advanced techniques (surveys, diaries)	3
	Design Method	Educational	1
	Impact Area	Regional or National	4
	Community	Neither passive nor active community (equally shares)	3
Spontaneity	Co-creation	User feedback is captured (iterative), which may lead to some modifications/ alterations of the innovation	3
	Evaluation	Limited evaluation by users (post survey)	2

Figure 7 BLL success criteria

Although figure 7 is determined as the success criteria, the result shows the parameters that should be developed, not the failure of the lab.

4. Discussion and Conclusion

In some research areas, a multi-stakeholder partnership is a necessity for living labs. Living labs are a form of experimental governance; urban stakeholders

develop and test new technologies, products, services and lifestyles to produce innovative solutions to the challenges of urban context. It is a way of developing solutions which cities have faced or facing. Different forms of smart city approaches are being developed and tested in living labs. As differs in Turkey, there are not many projects include smart city approaches regarding to spatial planning. Somehow, spatial projects have been replaced by virtual ones. In the research, we aimed to determine new technologies affect urban planning. Analysis show that technological transformation process is currently in digital environment rather redound on spatial environment in Turkey. In other words, it is social enforcements that can trigger development of such transformations. While living labs provide opportunities to adapt to technology, the fact that they have not become widespread or not yet known, show limitations in terms of cooperation and application.

Current technologies, information technologies, ICT, smart city applications show that a new era has started in urban space and a new structure has been formed, because of limitless information flow and sharing. Although the digital area overcomes the urban area, it is seen that the studies made promise to be considered within the scope of urban governance. The participation process has also taken on a new structure with all these changes. Instead of public participation in the planning process or implementation process, it is more important for the next steps to be involved in the education process and design process offered by living labs. Basaksehir Living Lab studies show that it is all about the process of education in the beginning, following designing with users and after designing by users. There are all steps to take into considerations. Social learning and education point towards clever solutions by creative people. However, living lab approach can help governments under pressure to adapt smart city approach to improve the city visibility and the citizens' life quality. Although, smart city ranking reveals the winner and the loser, entering the global competition may pose risks. Smart solutions, smart planning should not be about the competition. According to Nam and Pardo (2011), smarter government should do more than simply regulate the outputs of societal and economic systems where it interconnects with businesses, citizens, communities in real time to inspire growth and innovation. For that, living lab success not only measured by living labs principles and theoretical indicators but development process and future tendencies lead to success.

Case Study Paper

The strategy and analysis of optimizing lugu lake tourism Image

based on online travel data

Le Dong, Shanghai Tongji urban planning and design institute; China
Chen Xu, Shanghai Tongji urban planning and design institute; China
Baolu Chen, Shanghai Tongji urban planning and design institute; China

Abstract

Tourism image is of great significant to construction of scenic areas and enhancement of scenic competitiveness. However, many scenic areas are facing problems such as ignoring their own cultural values, homogenization and self-positioning. It is meaningful to define what the tourism image actually is. For the past few years, the number of internet users are increasing dramatically, whose comments boost the progress of intelligent tourism. The utilization of these online information now becomes an important way for tourists to generate how the destinations look like. In the age of big data, analysis of online comments is helpful to explore cultural features, shape the scenic areas' image and improve tourists' satisfaction.

This essay takes Lugu lake scenic area as an example, consist of three parts. The first part focus on comments extraction about tourism resources, infrastructures and service. After that, the second part mainly deals with the analysis of tourists' behaviors and perception. Lastly, the third part proposes the optimization strategy in scenic marketing and precision services, scenic image creation, facilities improvement, linkage development with surrounding attractions and other perspectives.

Online travelling comments are encouraged to spread among tourists, as a result, either good or bad reviews will lead to exponentially influence and exposure. Tourism image optimization based on internet reviews is the embodiment of public participation in the new era, which is helpful to realize the application value of big data in the field of urban planning, shape scenic image and enhance its competitiveness.

Keywords

Online comments data, Lugu lake scenic area, Tourism image

1. Research review

Scenic tourist image is the overall perception and a series of impressions, views and emotional expressions of the scenic spot, which is formed by normal and potential tourists dealing with information from various channels. Good scenic image can not only improve the

tourist revisit rate, enhance the satisfaction and loyalty of tourists, but also affect the travel willingness of potential tourists. It is also considered as an important basis for scenic planning, activity creation and visitor management.

There are several ways to analyze traditional tourism image, such as face-to-face interviews, questionnaire surveys, secondary data released by government or tourism organizations, observation, and mobile tracking devices，most of these data collection methods are generally costly and time-consuming, and have limitations in getting samples and information. In comparison, Online travelling data, which is published by tourists on social media spontaneously and records the actual behaviors of tourists naturally, provides a more effective way to analyze tourists' travelling activities and preferences. Online travelling data is sizeable and cost-effective. In addition, it contains various information such as text description, geographical location, travel time, pictures and so on, which can reflects the toursits' needs in real.

Based on the perspective of scenic spots, online travel analysis can be used to design scenic spot accurately and enhance the tourism image. It also provides the possibility for incorporating the public's will into the spatial planning, and promotes the transformation of urban research and urban planning in terms of technical means and value orientation. Therefore, this article takes Lugu lake scenic area as an example, trying to explore the public demand and proposes the optimization strategy of tourism image by analyzing the online travel data, which may provide reference for other related planning.

2. Research Background

2.1. Overview of Lugu lake Scenic Area

Lugu lake is located at the junction of Yunnan and Sichuan Province，where the beautiful plateau lake（Figure 2-1） blends with the mysterious Mosuo matriarchal culture（Figure 2-2）, making it an important attractions. As a national scenic spot and provincial nature reserve, lake lugu has high ecological and cultural value. From 2015 to 2017, the number of visitors to Lugu lake Scenic Area was showing a rapid upward trend, which was about 0.38 million, 0.42 million, and 1.07 million, respectively. The prospect of Lugu lake Scenic Area is optimistic. In recent years, with the rapid growth of tourism and the amount of tourists, as an emerging scenic spot, Lugu lake is suffering pollution and destruction. Furthermore, Its tourism infrastructure fails to satisfy the tourists demand, which leds the abundant resources lake to a AAAA-level rating merely, This is why it needs to be optimized.

Figure 2-1:Beautiful scenery of lugu lake

Figure 2-2: Mosuo architecture and decoration

2.2. Travels data discussion

The online travel notes contain various data types such as text, photos, videos. Many travel notes also include the user's geographic information, travelling time, and travelling ways. Those datas, which contain tourists' travelling behaviors and resources, form tourist's digital footprints. Integrated travel data can be used to explore the space path and travel methods of tourists. In addition, we can keep abreast of tourists' preference for scenic resources and tourism products, as well as the satisfaction degree of the scenic management and service quality.

The travel data has been a hot topic since this year, with the characteristics of high accuracy, wide coverage, timely update, large amounts of information and various types. The research in the planning field mainly includes the following three aspects: The first category is about the image research of tourism destinations. This kind of research builds out tourist image by grasping the key words of online travel records and analyzing the tourists' perceptions and emotions. The second category considers more about tourists' behaviors, including motivation, activity routes, visiting places, and Interested contents. By the study of tourist behaviors, it can analyze the attraction of tourism destinations, the passenger flow of different travel routes, and then adjusts the planning. The third category is the study of tourism satisfaction, determining the factors that affect the satisfaction of tourists, and the satisfaction of different tourists on the same destination. However, there is less analysis at the scale of the scenic spot and few optimization strategies. For this purpose, Taking Lugu lake scenic spot as an example, this article studies the image based on online comments and proposes strategy for optimizing tourism image.

3. Case study

3.1. Data acquisition and organization

3.1.1Data Sources

Network travel data is an important source of big data, As a large online travel agency in China, Ctrip.com has the most recorded online comments and the most active users for Lugu lake scenic spots. Therefore, this paper searches for tourist reviews with Lugu lake based on Ctrip online travel data. Write code in Python to crawl the contents of the travel page. In addition to the travel text material, structured tag data such as travel time, cost, dwell time, associated destination, and author's permanent city are also captured.

3.1.2Data sorting and cleaning

Considering the timeliness, this paper selects a 36-month tourist review from March 17, 2017 to March 17, 2019. The initial data is 6,697, and 4,276 valid data are obtained through screening. The data screening principle is to eliminate meaningless content such as a large number of missing basic information, too short or pure symbols, repeated publication by the same visitor, too extreme or exaggerated, obvious commercial propaganda.

3.1.3 Text segmentation

This paper uses the content mining software ROSTCM6.0, which integrated with automatic word segmentation, word frequency analysis, co-occurrence matrix analysis, social network analysis, sentiment analysis, to sort travel comment data. The principle of this method is mechanical word segmentation, that is, applying Chinese dictionary to match Lugu lake scenic area comments. If a string is found in the dictionary, Then the match is successfully recorded.

3.1.4 Semantic Analysis

Semantic analysis mainly includes semantic network structure and sentiment analysis. The principle of the semantic network structure is to analyze words‘ relevance and show it with topology diagram. According to the high-frequency vocabulary generated by the text segmentation, the article counts the co-occurrence frequency of these words, obtains word co-occurrence matrix and uses Gephi to visualize it. Emotional analysis mainly explores the emotional tendency of travel texts. The mood index of each review is generated by ROSTCM6.0 software. The larger the value, the more positive tourists are.

3.2. Tourist characteristics analysis

3.2.1 Tourist source

In order to get the proportion of tourists‘ sources , this paper counts the permanent city of tourists who comment on Ctrip about Lugu lake scenic spots. The data indicates that the tourists source can be divided into 4 levels according to the commentators number, such as Table 3-1. The first level is from the first-tier cities like Beijing, Shanghai and Guangzhou, which occupies the largest number of tourists source, followed by Southwest regions such as Lijiang, Chengdu, cities of higher economic development, and other cities. The result shows that the tourist source of lugu lake scenic spot is closely related to spatial distance, economic level and traffic. The closer space distance, higher level of economic development, and more convenient traffic, lead to more tourists.

Number	City	Proportion	Number	City	Proportion
1	Shanghai	12%	13	Xi'an	2%
2	Beijing	10%	14	Changsha	2%
3	Guangzhou	7%	15	Xiamen	2%
4	Lijiang	4%	16	Tianjing	2%
5	Chengdu	3%	17	Suzhou	2%
6	Shenzhen	3%	18	Gulin	1%
7	Nanjing	2%	19	Qingdao	1%
8	Chongqin	2%	20	Zhenzhou	1%
9	Kunming	2%	21	Ningbo	1%
10	Wuhan	2%	22	Dongguan	1%
11	Hangzhou	2%	23	Dalian	1%
12	Foshan	2%	24	Zhuhai	1%

Table 3-1 The proportion of tourists sources

3.2.2 Tourist behavior patterns

The analysis of tourists' behaviors such as travel time, travel mode, average cost and stay time are shown in table3-2 to table 3-5. The highest travel rate is in spring and autumn, about 31.13% and 33.77%. By contrast, the summer travel rate is the lowest, only 13.90%, which indicates that the activity level of Lugu lake scenic area is greatly affected by seasons.

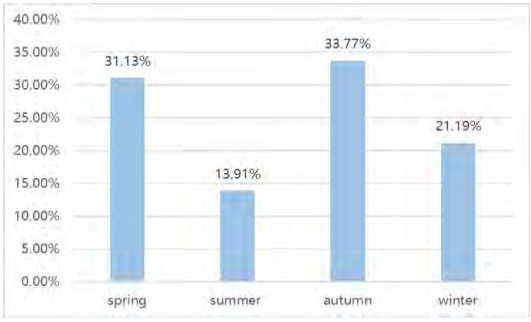

Table 3-2: Travel time distribution of tourists

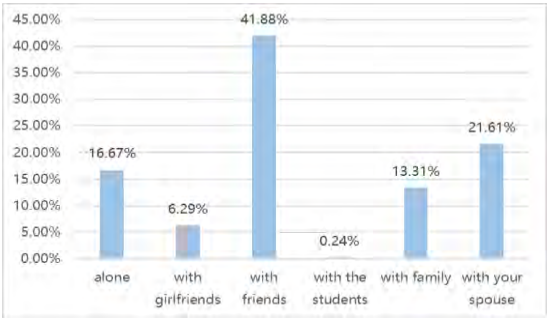

Table 3-3: Tourist play mode

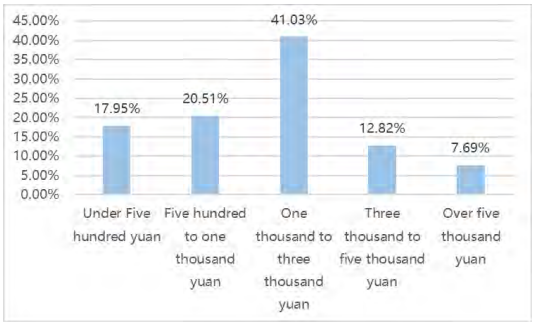

Table 3-4: Per capita expenditure of tourists

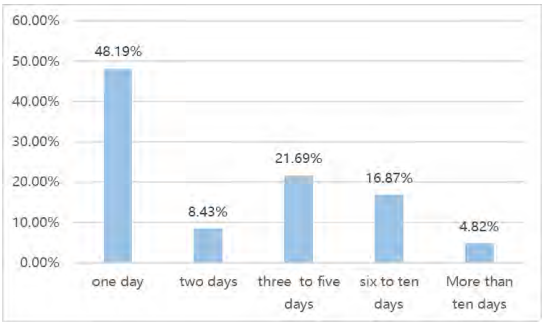

Table 3-5: Tourist time

The main way for tourists to play is travelling with friends, accounting for 41.88% of total number. Couples, solo and family travel account for 21.61%,16.67% and 13.31% respectively. Tourists comment on Valentine' beach, Lovers' tree, Heart-shaped island and Marriage-bridge frequently, such as "it is said that by the side of Lugu lake, all the trees grow out in pairs, like intimate partners", which can be used to explore romantic attractions. The average spending of tourists in lugu lake science spots mainly concentrate at 150~400 dollars. The travel time pf Lugu lake is insufficient, mainly for 1~7 days. How to attract tourists' attention from different travel modes, creat rich brand activities, broaden the tour route and increase dwell time, should be an important planning consideration.

3.3. Keywords analysis

The high-frequency vocabularies on Ctrip.com are shown in Table 3-6, and semantic network graph is shown in figure 3-1. This paper divides high-frequency words into three dimensions: tourism resources, tourism infrastructures and supporting services, environmental atmosphere.

First dimension deals with tourist resources. The keywords of Lugu lake tourism resources include"fresh water", "sunrise", "Mosou walking-marriages", "bonfire", "The goddness mountain". It shows that tourists' perception in Lugu lake is consistent with natural resources, which is consistent with the field survey. As for Mosuo matrilineal culture, it is only mentioned by two keywords: walking-marriages and bonfire. The cultural experience floats on the surface.

Second dimension focus on tourism infrastructures and supporting services include "drivers","tickets","hotel","journey","wharf","carsickness","traffic price". Tourists pay more attention to the traffic and have more negative perception.

In terms of environmental atmosphere, words such as "mystery", "like", "feeling" and "quietness" come out in front. This shows that beautiful landscape and Mosou culture are not only important atmospheres to attract tourists, but also environment feelings which we need to closely surround and cannot break.

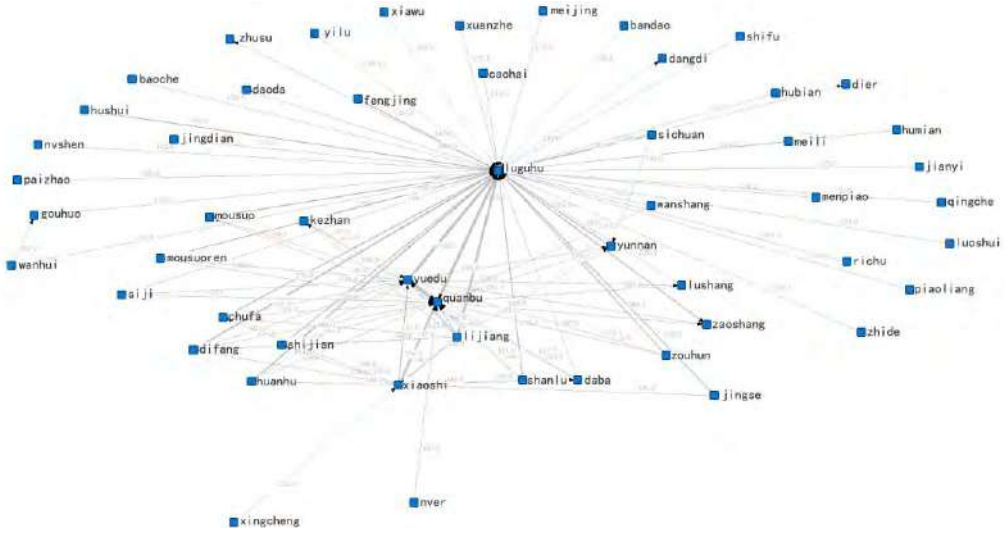

Figure 3-1：Semantic network analysis diagram of some high frequency feature words

rank	key words	frequency	rank	key words	frequency
1	Lugu Lake	3675	26	bonfire	164
2	sunrise	706	27	lake surface	161
3	league	546	28	quietness	151
4	The goddness mountain	538	29	observation deck	149

25	evening	169	50	hotel	107

Table 3-6：Text ranking top 50 high frequency keywords

3.4. Tourist satisfaction

This article conducts on emotional analysis of review data, among which 1,760 are positive , 1,074 are neutral and 220 are negative, as shown in table 3-7. On the whole, tourists' emotional tendency is optimistic, however, the negative emotion in tourists' evaluation still needs to be paid full attention. According to the content analysis, it can be seen that the

dissatisfied aspects of tourists focus on traffic, high ticket prices, garbage, catering, over-commercial experience, less cultural experience and so on.

The analysis of negative emotion is consistent with actual situation. In terms of traffic, it takes 4~6 hours from Lijiang to Lugu lake with rough mountain roads, dominated by private cars and bus. Ninglang airport is less efficient. The transportation mode in Lugu lake scenic spots is mainly by self-driving, carpooling, bike-riding and walking. Insufficient public transport and inadequate basic service facilities are major factors which limit the development of lugu lake. In order to create travelling stunts and make more profits. Mosuo matriarchal culture is over-publicized, and losing its mystique. In addition, the original Mosuo buildings have been replaces by various hotels and shopping malls. Mosuo family structure and rural landscape gradually collapse, the disappearance of cultural authenticity and over-commercial atmosphere affect the tourism image.

type of emotion	number	percentage	remark
positive emotion	1760 items	57.63%	Among them, the sectional statistics of positive emotions are as follows： common（0—10marks）： 236 items 7.72% medium（10—20 marks）： 433 items 14.19% higher（beyond20 marks）： 1091 items 35.72%
Neutral emotion	1074 items	35.17%	
Negative emotion	220 items	7.20%	Among them, the sectional statistics of negative emotions are as follows： common（-10—0 marks）： 149 items 4.89% medium（-20—-10 marks）： 71 items 2.31% higher（under -20 marks）： 0 0.00%

Table 3-7：Statistical analysis of tourists' emotions

3.5. Associated destination

With the improvement of transportation and the rapid development of tourism, the links between different tourist attractions are getting closer and closer, and the tourist route presents networked characteristics. The article sorts out the structured related destination in the network comment of lugu lake scenic area, obtains a list of surrounding tourist attractions cored with lugu lake, and analyzes the correlation strength.

Through the semantic network diagram, it can be seen that the external attractions of lugu lake scenic area are mainly Lijiang, Shuhe, Lashihai, Dali, Yulong snow mountain, Tiger leaping gorge, Shangri-La, Erhai, Mufu. At the same time, "Lijiang--Yulong snow mountain--lugu lake--Lashihai" and "Lijiang--lugu lake--Erhai--Shangri-La" form two important relationship chains in the entire network.

In lugu lake scenic area, the core tourist route forms competitive advantage around the two important distribution centers namely Luoshui and lugu lake Observation Deck, as well as four tourist attractions such as Liwubi Island, Gem Goddess mountain, Lovers Beach and Caohai. The network status of other tourist attractions is relatively poor, the competitiveness is weak, and tourists are rarely attracted.

rank	keyword	word frequency	rank	keyword	word frequency
1	Old Town of Lijiang	4149	11	observation deck	730
2	Lijiang	2880	12	Liwubi Island	625
3	Shuhe ancient town	1408	13	Square Street	550
4	Tiger Leaping Gorge	1266	14	Shangri-La	501
5	Lashi Lake	961	15	Erhai	478
6	Caohai	950	16	Mufu	386
7	Dali	861	17	The CangShan Mountain	266
8	Gem goddess mountain	821	18	Lovers Beach	247
9	Yulong snow mountain,	815	19	Blue Moon	232
10	Kunming	785	20	White river	169

Table 3-8： Correlation analysis of scenic spots

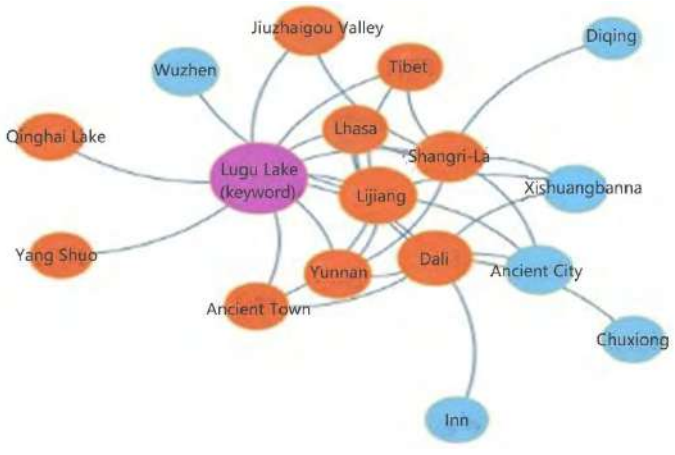

Figure 3-2： Correlation analysis of scenic spots

4. Suggestions on Tourism Image Optimization

4.1. Scenic marketing and precision services

This paper puts forward the precise service strategy and carries out targeted promotion according to different tourist source. First of all, for the first-tier urban agglomerations, the publicity strategy advocates the concept of relaxing life. Secondly, as for the surrounding southwestern areas such as Lijiang and Chengdu, The publicity strategy emphasizes the unique environmental atmosphere of lugu lake, which combines nature and culture characteristics, and distinguishes it from the surrounding attraction such as Erhai lake and Fuxian lake. Moreover, For the new first-tier and second-tier cities with great development potential, although they are not the main force of lugu lake tourism market at present, their consumption capacity cannot be underestimated. Scenic spots should increase publicity, build high-profile attractions and activities, and expand the popularity of Lugu lake.

The Lugu lake scenic area should promote tourism self-service and intensify supervision and management. Independent travel such as self-driving trip, couple trip, family trip has a growing proportion in Lugu lake scenic spot. Therefore, managers should build a circular bus system, self-guided tour system, self-help explanation system, and provide diversified, personalized and independent scenic products and services .Lugu lake is a place to promote relaxation, where tourists are immersed in nature for a long time. However, it can be seen that tourists stay in Lugu lake for a short time generally from the statistics of tourists' comments. It is the key issue in promoting the development of scenic spots to keep tourists, enrich scenic spots activities and Increase the surrounding tourist attractions.

4.2. Destination image creation

The planning and design of Lugu lake Scenic Area revolve around the combination of nature and humanities closely in recent years, which matches the tourists' feelings of tourist image. However, it can be seen from tourists comments that the understanding of Mosuo culture is superficial, and the cognition of “matriarchal Culture” and “walking-marriage” is exparte. The mysterious Mosuo culture has become the gimmicks of tourism development. The protection and inheritance of Mosuo culture should be highly valued. Managers may prevent the existing Mosuo residents and Mosuo culture from being excessively interfered by the tourism development, preserve the authenticity, meanwhile, Mosuo culture can be displayed in public spaces to increase visitors' understanding. Infrastructure should respond to the environment atmosphere, which can guide visitors to experience the beautiful scenery.

4.3. Improvement of scenic facilities and service levels

The article summarizes the sources of negative emotions of tourists further. Firstly, the infrastructures such as transportation facilities and service facilities are insufficient. Secondly, the cultural inheritance and expression are insufficient. Thirdly, the scenic spot is too commercial and lack of tourist experience activities. Therefore, we propose suggestions for improving tourist satisfaction.

As for transportation, The distance around lugu lake is 76 kilometers. Public transportation such as sightseeing vehicles are required. The traffic organization plans to set up bus stops between scenic spots, build sightseeing sidewalks and bicycle trails around the lake, so that visitors can experience the beauty of Lugu lake at close range.

Improve supporting facilities and carry out scientific management. The scenic area should increase the restroom and improve the guiding facilities such as traffic signs. The high price of accommodation, meals and tickets is also an important issue for tourists to have negative emotions. Managers should strengthen the supervision and management. It is also necessary to provide tourists with good experience and lower price.

Pay more attention to the protection and inheritance of Mosuo culture and add experiential activities. In addition to the bonfire evenings, more cultural and folk activities should be shown, The design of the scenic spot should extend the activity brands such as Hualou Love Song, highlight the cultural atmosphere and weaken the commercial atmosphere.

4.4. Linkage development with surrounding attractions

The multi-destination selection of tourists prompt the possibility of regional cooperation development between Lugu lake, Lijiang, Dali and Kunming. At the same time, the Lugu lake scenic area should highlight its own characteristics in the development of entire areas, especially compared with the similar scenic area such as Lashi lake, Erhai and Fuxian Lake. What are the characteristics of Lugu lake? From the comments of tourists such as "the landscape is more natural", "Mosuo culture", "there are many small fresh places in Erhai, the scenery of lugu lake is particularly beautiful, very romantic", "the traffic of Erhai lake is more convenient," "Lugu is farther away from urban life", we can see that the landscape environment away from nature, landscape proportion, Mosuo culture and beautiful scenery are prominent features of Lugu lake from the perspective of tourists. Therefore, in the coordinated development of the scenic spot, Lugu lake should ensure its natural and cultural integration, adhere to the naturalized landscape features, preserve the mysterious Mosuo culture, and avoid excessive artificial design traces.

In Lugu lake scenic area, it is recommended that the scenic spots should be jointly developed, around more mature attractions such as Lugu lake observation seck, Liwuibi Island, Gem Goddess Hill, Strengthen scenic spots with excellent development potential but insufficient network competitiveness, such as Liger island, Mosuo House, ZamiLama Temple, Rani Island. In the linkage development of scenic spots, couples' tour lines, friends' tour lines and cultural landscape tour lines are set up to provide richer choices, increase the long-term travel.

5. Conclusion and discussion

Tourism image is an important factor influencing tourists' intentions and decision-making. It is also a key aspect of tourism destination marketing and improving the core competitiveness of the destination. This paper attempts to explore the tourists' real experience and feelings on Lugu lake Scenic Area by taking online travels as an analysis object, proposes optimization strategies from the aspects of scenic image creation, promotion of tourism infrastructure and supporting services, and linkage development with surrounding scenic spots. But the research still has some shortcomings. For example, the inadequate sample size may lead biased results. The review tourists are mostly aged from 20 to 40, and some older people who cannot use the review software are not included. In addition, social network data is still based on historical information feedback with certain delays. If the timely feedback can be established dynamically in the future, it will be beneficial for scenic management to provide precise services. However, as a new way to

analyze the tourism image of scenic spots, the analysis process and results of Lugu lake Scenic Area have certain values in innovations and references, which may provide new ideas for the optimization of scenic tourism image. In the post study, in order to obtain more general conclusions and verification, the research will focus more on the cross-validation of travel big data and traditional statistics.

Research Paper

Smart signals in heterogeneous traffic conditions

Mayank DUBEY, Assistant Professor, Xavier Centre for Urban Management and Governance, Bhubaneswar; India

Abstract

Major urban corridors in Indian cities are carrying significantly high traffic leading to near saturated conditions for extended peak hours. As mixed landuse and major trip attracting/generating establishments are generally observed to be located along such corridors for better accessibility, significant side friction is also observed along these corridors. Among various measures to improve the throughput along such corridors, signalized intersections seem to be the most preferred intervention for intersection control. Although frequent occurrence of such traffic signals and non-coordinated signal phases have in turn made the whole situation more complex. To overcome this challenge, variations of smart signals are being proposed by technology and traffic enterprises globally. Generally, smart interventions in operation of signalised intersections require communication among vehicles and control system through various sensors and applications of Intelligent transport services (ITS). Smart signal operations require the sensors grouted in pavement or attached with camera to share the relevant data in real time basis with central command and control centre. With adaptive signal operations, it is attempted to schedule signal phases in such a way that green phase of every cycle generally experiences near saturated flow conditions. The smart cities mission (SCM) of India, covering around 100 cities also focuses upon improving the urban mobility through various measures including smart signals. Some of the popular proposals relating to smart operation of signalised intersection across shortlisted smart cities include adaptive and coordinated traffic signals. It is understood that traffic signal optimization is not a one-time action but rather a continuous process, as data archiving, data crunching, research and adaptations are indispensable for its success. As the geometry, location and setting of each intersection in every network is bound to be unique, the optimization process needs to consider the same. The literature and case study of Indian city Bhubaneswar (ranked first in nationwide smart city challenge) revealed that challenges specific to Indian driving conditions are major cause of worry for yielding stated benefits of smart signals. Factors like varying hierarchy and functions along major arterial corridors, fluctuating carriageway width and quality, considerable side friction within right of way, heterogeneity in vehicular mix, significant variation in peak hour directional flows leading to tidal flow, surrounding network characteristics and efficacy of optimisation techniques are responsible for limited rewards out of the whole process. The study reflects upon these challenges and concludes with recommendations to improve the performance of signalized intersections along corridors with heterogeneous traffic conditions.

Keywords

Signal phase, arterial corridors, intelligent transport system, side friction

1. Introduction

1.1. Congestion on urban roads

High vehicular density and relatively low operating speeds along arterial corridors of major cities in India represent the highly saturated traffic flow conditions (*Shriniwas*). Volume by Capacity ratio (V/C), the commonly used yardstick to assess the vehicular saturation on roads, consistently records values above unity referring to highly saturated road conditions. The journey speed in many cities are observed to be in the range of 7 – 20 kmph, representing severe jamming like conditions (*Alam et. Al.*). Table 1 summarizes general travel characteristics along arterial corridors for 5 different cities of India.

Table 1 - Vehicular traffic congestion along arterial corridor of various cities

Sr.	City	Corridor	Stretch	C/way width in m	Peak hour volume in PCU*	V/C#	Peak hour speed in kmph
1	Bhubaneswar	Janpath - 4.9 km	Vani Vihar to Sishu Bhaban	12 m (3-lane)	2230	2230/3857 = **0.58**	19.2
2	Agra^	M G Road - 5.8 km	Bhagwan Talkies to Pratappura	6 m (2 lane)	2564	2564/2142 = **1.2**	11. 8
3	Jaipur	Tonk Road - 5 km	GTC Mall to Bajaj Nagar	10 m (3 lane)	3112	3112/3857 = **0.8**	13.3
4	Indore	M G Road - 4.1 km	Rajwada to patrakar Chk	varying (3 lane)	3664	3664/3857 = **0.95**	12.4
5	Patna	Bailey & Suri road - 7.10 km	BPSC to Shanichara mod	Varying (2 lane)	2644	2644/2142 = 1**.23**	6.9

*Vehicle to PCU conversions based on IRC 106:1990
Volume by Capacity (V/C) calculations based on Design service volume from IRC 106:1990

It can be observed from Table 1 that across cities, not only the journey speeds are reduced, but most of the traffic flow operations along arterial corridors is saturated and forced. The volume by capacity ratio (V/C) is only indicative of the level of saturation although actual traffic flow depends upon other subjective parameters also. Along all the case study corridors mentioned above, ribbon development, on street parking, frequent punctures and side access, heterogeneous mix of vehicles and mixed landuse adjoining the arterial corridor are some of the factors which are responsible for reduced throughput and enhanced vehicular congestion. Lack of awareness, education and driving discipline can also be attributed to inefficient utilization of these roads (*Chandra. et. al*.). Apart from all the reasons listed above, frequent intersections along the arterial corridor and their inefficient operation also contributes to the congestion.

1.2. Intersections along urban roads

Intersections are the potential nodes in the road network which help in manoeuvring crossing vehicular desires. As various conflict points are scattered across the intersection (depending upon the geometry and desires), time and/or space appropriation is done to ensure safe and efficient mobility. Although intersections are very much required to provide various options and permutations for individual's route choice, frequent occurrence of

intersections along arterial corridor results in significant delay and congestion. It is generally understood from codes of practices (*IRC 106:1990 and NUTP*) that mobility and accessibility for any corridor vary inversely with each other resulting in limited access per unit length for higher hierarchy corridors. But because of ribbon development, bazaar system and mostly unregulated development along the corridors, it has been observed that the functional hierarchy of arterial corridors have been diluted (*Curtis et. al.).* Table 2 illustrates the occurrence of punctures and side friction along selected arterial corridors of few Indian cities.

Table 2 - High accessibility and correspondingly low mobility along arterial corridors of selected Indian cities

Sr.	City	Corridor	Number and type of intersection(s)					Other side friction elements
			Minor access	Signalised/ Roundabouts	Partial grade separated and or signalised	Interchange	Total	
1	Bhubaneswar	Janpath - 4.9 km	24	11	2	0	37	on street Parking
2	Agra	M G Road - 5.8 km	35	17	1	0	53	Vending, parking
3	Jaipur	Tonk Road - 5 km	14	15	1	0	30	Mix landuse
4	Indore	M G Road - 4.1 km	27	14	0	0	41	Varying ROW and mixed landuse
5	Patna	Bailey and Suri road - 7.1 km	21	22	1	0	44	Varying ROW and mixed landuse

Source - Primary data other than for Agra^ MG Road Improvement Study, SPA Delhi 2014

Based upon information presented in Table 1 and Table 2, it can be inferred that because of various reasons, including frequent intersections, the arterial corridors get reduced to the functional hierarchy of any other corridor of the settlement. It can also be noted from Table 2 that among all major intersection types, signalised intersections are most popular along the mentioned corridors across all cities studied. Signalised intersections are popular with civic administration because of simple operations and control and they offer predictability for the road users. In the complete life cycle of signalised intersections, it can be also argued that Signalisation is cost effective as compared to other traffic intersection control mechanism (*Prashanth et. al*.).

On the other hand, it has also been observed that the so-called benefits of signalised intersections are not very elastic and there is a limitation w.r.t. total traffic handling capacity of signalised intersections. Capacity of signalised intersection is a function of cycle time, traffic composition, turning movement, capacity of slip lanes and pocket lanes, etc. (Radhakrishnan et. al.). Because of localized traffic flow and desire, it has been observed that certain intersections along arterial corridors are not only sight of extreme congestion but also act as bottleneck for whole neighbourhood road network. Reduced Level of Service (LOS) at only one or few signalised intersections in a road network is at times responsible for

total jamming of road system in an area. This is one of the primary reasons for the recent push for smart and digital operation of signalised intersections.

1.3. Smart and digital interventions in traffic signal operations

The recent popularity of smart and digital interventions in operation of signalised intersections has demonstrated certain new and exciting techniques for monitoring and improving the traffic operations. Majority of smart interventions in operation of signalised intersections work upon the communication among vehicles and control system through various sensors and applications of artificial intelligence. Smart signal operations require the sensors grouted in pavement or attached with camera to share the relevant data in real time basis with central command and control centre. The decision to alter cycle time or any other intervention depends upon the marginal utility and 'advantage' of such action. The 'advantage' mentioned here can be in terms of flow rate, travel time, reduced emissions, priority to public vehicles etc. which has been further detailed in next section. The smart cities mission (*SCM*) of India, covering around 100 cities also focuses upon improving the urban mobility (*Aijaz et. al.*). Some of the popular proposals relating to smart operation of signalised intersection across shortlisted smart cities are – Adaptive and coordinated traffic signals, traffic command and control centre, priority to public and service vehicles, productive use of solar and mechanical energy, etc.

2. Traffic signal optimisation

2.1. Concept of traffic signal optimization

Signalisation of road intersections is primarily done to maximize traffic flow rate and road safety along with reducing the delay. The whole concept of adaptive signals and signal coordination is based upon dynamic data capture, synthesis, archiving and analysis using various available digital and conventional techniques (*Misbahuddin et. al.*). The generalised schematic principle of operations for smart signals at traffic intersections is presented in figure 1 with its various disaggregate components.

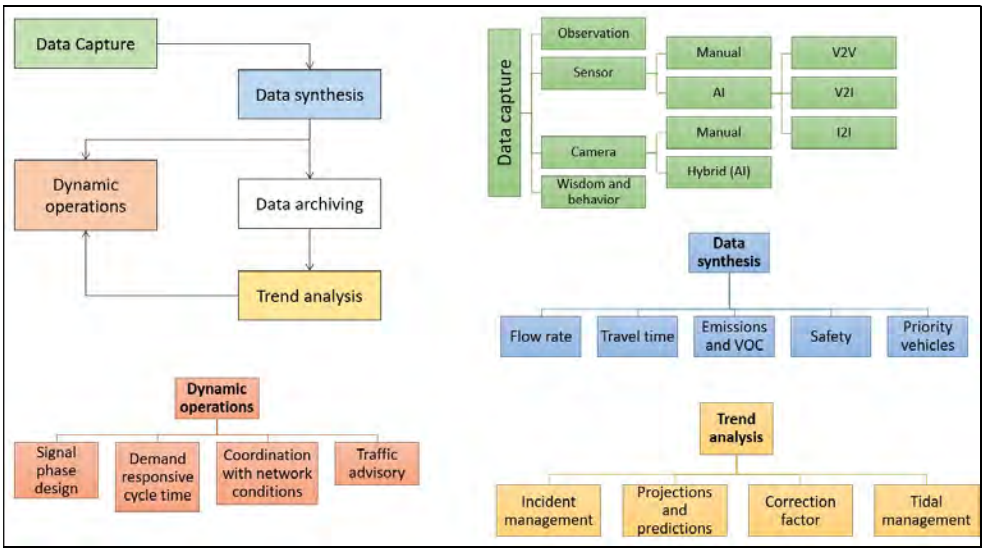

Figure 1 - Generalised schematic operation process at smart signals

Data pertaining to various traffic characteristics like speed-flow variables, vehicular composition, directional turning volume at intersections, lane utilisation, etc. is captured at all critical cross-sections (intersections and varying Right of way cross-sections) using sensors and camera. Traditional understanding and field observations compliment the data so collected. Some of the worthy and upcoming mechanisms of 'smart' data collection using Artificial intelligence (AI) techniques are V2V (vehicle to vehicle), V2I (vehicle to infrastructure) and I2I (infrastructure to infrastructure) which are capable of handling large sets multi-variate data (Bento et. al.). The data so collected in real time is then synthesised and archived at the central command and control centre for city wide operations. Synthesised data is also considered for real time signal phase design and triggers decision to ensure efficient signal operations along the network. Based upon periodic data collection along the complete network, trend analysis is carried out w.r.t traffic projections, incident management, peak hour management, seasonal correction factors, tidal flow corrections, etc. which helps in retiming of signalised intersection operations. Based upon isolated adaptive traffic signal operations, the other signalised intersections of neighbourhood and corresponding corridors are knit together under the framework of coordinated traffic signal operations. As the name suggests, the biggest advantage of adaptive signals is its stimulus to dynamic traffic conditions. The adaptive signalised intersection in coordinated conditions is therefore expected to cater the local and neighbourhood traffic flow by updating cycle time and signal phase. Since each intersection would have various permutations of cycle time and phases, coordination of signalised intersections in a network is an extremely complex process. It shall be noted that the rational of signal coordination and adaption remains same – increased efficiency and safety along with reduced net delay. Some other smart techniques used at signalised intersections to improve the overall mobility includes sensors and transponders for 'priority vehicles', dynamic pedestrian and vehicular phasing using sensors and pelican switches. In this research, the traffic signal optimization using digital interventions refers to combination of one or more above mentioned techniques

2.2. Evaluation of traffic signal optimization techniques

With adaptive signal operations, it is attempted to schedule signal phases in such a way that green phase of every cycle generally experiences near saturated flow conditions. One of the most direct outcome of efficient signalised intersection optimization is improved traffic flow rate. There are many secondary benefits of improved throughput through signalised intersections like –

- reduced net delay for traffic operations in terms of vehicle-hours
- reduced net emissions and air pollution due to vehicular operations
- reduced noise pollution
- reduced fuel consumption and vehicle operating cost

It can be also argued that improved performance of signalised intersection would lead to safer vehicular operations throughout the network. Some of the long term behavioural and intangible benefits out of optimized signal operations are –

- better enforcement of law and order along the network of smart signals
- reduced road rage and improved on road mutual empathy

Another anticipated benefit of improved throughput through signalised intersection is reduced diversion of arterial and sub-arterial corridor traffic to the neighbourhood network in the want of congestion free corridors. Some scholars argue that manual marshalling of

intersections is one of the most efficient and optimized ways of operating intersections as the stimulus and adaptations are prompt in this case. But it seems that manual marshalling is generally based upon local traffic experience and general wisdom which might not be able to process and coordinate with traffic characteristics in neighbouring network and intersections. In the light of above discussions, it seems that if implemented in true sense, signal optimization can lead to multifold benefits for our resources.

Although traffic signal optimization is still in its nascent days in a developing economy like India, the available limited experience and research highlights certain challenges w.r.t. the concept and process of optimization. As it has been already discussed in the previous section that traffic signal optimization is not a one-time action but rather a continuous process, the corresponding data archiving, data crunching, research and adaptations are indispensable for its success. This would necessitate robust infrastructure and skill capacities for the local traffic management agency. As the geometry, location and setting of each intersection in every network is bound to be unique, the optimization process needs to consider the same.

The dynamism in signal phasing and cycle timings might also lead to unpredictability and ambiguity among the road users. It would require reasonable awareness and time for the road users to assimilate and follow the signal optimization process. The bigger challenge here would be change and upgradation of the network geometry to put in place the required V2V and V2I communication systems. Also, it would be difficult for the signal optimization process to actualize its stated benefits unless driving and road user behaviour is in synchronization with the traffic optimization process at signalised intersections.

Another inevitable challenge leading out of improved signalised intersection operation would be augmented and induced traffic demand on the network. If at all, the level of service improves at signalised intersections along arterial roads and connected corridors, the private vehicle user might get tempted to be on road, who otherwise use public/shred transport. This would eventually increase the vehicles on road and the benefits of traffic signal optimization w.r.t. reduced delay may not be materialized. The above-mentioned phenomena, generally termed as 'vicious transport supply and demand cycle' is not unique to this intervention but it would be important to consider that the induced demand would pose challenges to the already complex signal optimization process.

3. Challenges in traffic signal optimization

As discussed in the previous section, traffic signal optimization requires each network and intersection to be attended individually because of its unique setting and role. It seems that traffic signal optimization cannot be attempted successfully using template-based upscaling approach because of the same reason. Further, most of the field knowledge relating to 'smart signals' and signalised intersection optimization is based on experiences of developed economy. The parameters and characteristics of traffic and corresponding signal optimization are bound to be different on Indian urban corridors. The following section discusses various challenges in Indian conditions relating to traffic signal optimization.

3.1. Mix of hierarchy and functions

Pertaining to ribbon development and bazaar culture, higher hierarchy corridors in Indian urban area are generally sight of commercial and mix landuse activities. This is mostly in

contradiction to the primary function and utility of arterial corridors as mentioned in various codes of practices like IRC 106, UTTIPEC and IUT guidelines, etc. Because of this ambiguity in hierarchy and functions of such corridors, the road network and eventually signalised intersections don't end up using their full potential.

3.2. Non – uniform road network

Like non-uniformity in priority and hierarchy, non-uniform carriageway, ROW and street infrastructure is also responsible for inefficient traffic operations at intersections and corridor. This not only reduces the overall LOS along the road network but also triggers unauthorized use and encroachments along the unused stretches of ROW. The traffic signal optimization would require certain infrastructure and information technology systems to be installed along the ROW for data capture and in absence of suitable ROW, the process may get compromised. Similarly, intersections would also require suitable ROW to accommodate design and IT features.

3.3. Side friction

Various activities and features like on street parking, hawking and vending activities, kerb side bus stops, encroachments, frequent punctures for access streets, etc. are termed as side friction because of impedance offered by them to traffic flow operations. It has been observed that side friction is responsible for reduced traffic flow variables (speed, density and flow) and causes turbulence in the traffic stream. The phenomenon gets escalated and disrupts the traffic flow through intersections when significant side friction is observed near the intersections. It can be observed from Table 2 that along major arterial and sub-arterial corridors of many cities, the average intersection spacing is around 350 m and 200 m for major and minor intersections, respectively. These frequent conflict and decision areas reduce the overall LOS of traffic operations through the road network. At intersections, varying desires and movements of every vehicle requires it to merge and diverge more frequently and therefore, even minor side friction may impact the traffic operations severely.

3.4. Heterogeneity in vehicular mix

Urban roads are observed to have varying mix of vehicles operating along them with extreme heterogeneity in it. Table 3 represents the share of standard car and other modes during peak hour in a traffic mix along major corridors of few selected cities.

Table 3 – Mode share during peak hour traffic along major corridors of selected cities

Sr	City	Corridor	Peak hour volume in vehicles (PCU*)	% share of vehicles (PCU*) in stream		
				Standard car	Other motorised	NMT#
1	Bhubaneswar	Janpath - 4.9 km	2772 (2230)	21% (26%)	64% (64%)	15% (10%)
2	Agra	M G Road - 5.8 km	3612 (2564)	11% (15%)	67% (66%)	22% (19%)
3	Jaipur	Tonk Road - 5 km	3937 (3112)	23% (29%)	68% (64%)	09% (06%)
4	Indore	M G Road - 4.1 km	5091 (3664)	21% (29%)	76% (68%)	03% (02%)
5	Patna	Bailey & Suri road - 7.1 km	4760 (2644)	10% (14%)	78% (78%)	12% (08%)

Source – Primary data other than for Agra^ MG Road Improvement Study, SPA Delhi 2014
*Vehicle to PCU conversions based on IRC 106:1990
NMT – Non – motorized transport

It is observed from Table 3 that urban roads cater to a variety of vehicles who share the same carriageway for travelling. Across all corridors, combined share of standard car and non-motorized modes vary from 22% to 36 % whereas the classification of other motorized modes haves highest share. Modes like powered two-wheelers, auto rickshaw, tempo, bus and other freight vehicles comprise of this classification. Certain stretches along these corridors don't have a usable sidewalk and cycle track which forces pedestrians and cyclists, respectively to use the vehicular carriageway.

Since a mix of vehicles operate in such traffic streams, the clearances, headways, acceleration-deacceleration, turning radius, vision cone, etc. of individual vehicle type is different and therefore the streams become turbulent in nature towards saturation flow rates. Correspondingly, the maximum utilization of signal phases and cycles is generally not observed because of vehicle heterogeneity in the stream. The situation gets degraded further because of missing driving discipline and lane-based driving. It has also been observed that certain vehicle types are unique to Indian conditions and it requires certain changes in sensors and approach to include their characteristics in data collection and archiving.

3.5. Tidal flow

The distribution of landuse and aggregation of major attracting landuse in a settlement triggers time based skewed and unidirectional traffic flow rate along corridors which is generally referred as 'tidal flow'. The unique characteristic of such a phenomenon is extreme variation in saturation rate between the two directions of traffic flow along the corridor. The behaviour is specifically visible along divided carriageways as on undivided carriageway, the vehicles spill over to other side of carriageway diluting the concept of directional traffic congestion. One of the major challenges posed by tidal flow phenomenon is inefficient signal phases and cycle time unless dynamically tweaked using available knowledge. At times, certain algorithm might give us a signal time and phasing resulting into minimum delay per unit vehicle, but it may not be practically implementable because of driving behaviour. The concept has been illustrated using field data in subsequent sections. As tidal flow might be a recurring but not a periodic phenomenon, state of art signal optimization would require adaptations accordingly.

3.6. Network characteristics

Another challenge in traffic signal optimization arises from the fact that intersection efficiency is also a function of road network including the characteristics of preceding and succeeding intersections. Any sudden incident anywhere in the network demands quick calibration of signal phasing and cycle times across the network. There would be limited gain out of a highly calibrated and optimized signalised intersection if it is located among and around inefficient intersections and networks. Since each of the intersections in a network is characterized by its own unique geometry, flow rate and desire, the optimization attributes are bound to be different among intersections. As heterogeneous mix of vehicles use this network, the vehicle density and other traffic flow parameters are bound to be different across lanes and segments between two subsequent intersections. This signifies that efficiency optimization of standalone signalised intersection and coordination of signalised intersections in a network would not have exactly overlapping goals. Therefore, to improve the overall mobility experience and reduce the travel delay along any network, suitable

appropriation might be needed at certain intersections. This would necessitate actions leading to purposeful deterioration of the LOS for specific standalone intersections to achieve better mobility experience along the corridor.

3.7. Efficacy of optimization techniques

The fundamental aim of signalised intersection optimization process is to achieve improved flowrate, speed, safety accompanied with reduced net delay to road users. Reduction in net delay along intersection and network can also be used as a yardstick to measure efficacy of optimization techniques. Average net delay per unit length with reference to free mean speed operations can be used to measure the impact of traffic signal optimization along the corridors. Similarly, average delay per vehicle (LOS criteria) can be used to measure the impact of traffic signal optimization at intersection, given that the traffic flow rates, and other conditions are not significantly altered. Both scales mentioned here seems to be not fully exclusive with each other and therefore their mutual relationship shall be studied. Unless not proved otherwise, it cannot be negated that reduction of delay at intersection because of traffic signal optimization will not lead to congestion along the surrounding corridor.

4. Case study

4.1. Bhubaneswar

Bhubaneswar is the administrative headquarter of Odisha state and is located around 70 km away from the Bay of Bengal in Khorda district. Famous for its beautiful temples and rich history, the core of present-day Bhubaneswar was designed by Otto Königsberger around 1948. Bhubaneswar is also one of the leading smart cities under Smart Cities Mission of India with various unique and state of art interventions for better quality of life for its users. One of the major components of smart cities mission is 'area-based development' (ABD) for which, Bhubaneswar town centre district (BTCD) along Janpath is being developed using retrofit and redevelopment approaches (Praharaj et. al.). As far as pan city development (PCD) proposals are concerned, one of the core and ambitious initiative is intelligent traffic management using smart signalised intersections. The central part of Bhubaneswar city is broadly aligned on grid-iron pattern with 4 major corridors running parallel to each other in north-south direction, connecting the Kharagpur-Chennai (NH16) National highway and is also relatively parallel to railway line. The 4.9 km long 'Janpath' stretch from 'Vani Vihar' intersection to 'Shishu Bhawan' intersection is host to most of the ABD as well as PCD interventions. Figure 2 represents the alignment of Janpath stretch in Bhubaneswar city.

Around 9 signalised intersections along Janpath are being upgraded with sensors and systems to reap the dividends of intelligent traffic management. As the surrounding landuse is primarily commercial and institutional along with some residential segments, on street parking and vending activities are frequently observed along the network. Although the on-ground carriage way width varies from 6 lanes to 8 lanes divided (18 to 25 m), but pertaining to certain physical bottlenecks like on street parking, and low turning radius at punctures, effective carriageway gets reduced to 12 to 18 m at certain sections. The landuse along the Janpath stretch is also dominated by commercial landuse on one side of the corridor although residential and institutional landuse line the other side of the corridor. Figure 3 presents the carriage way variations and broad landuse along the Janpath stretch.

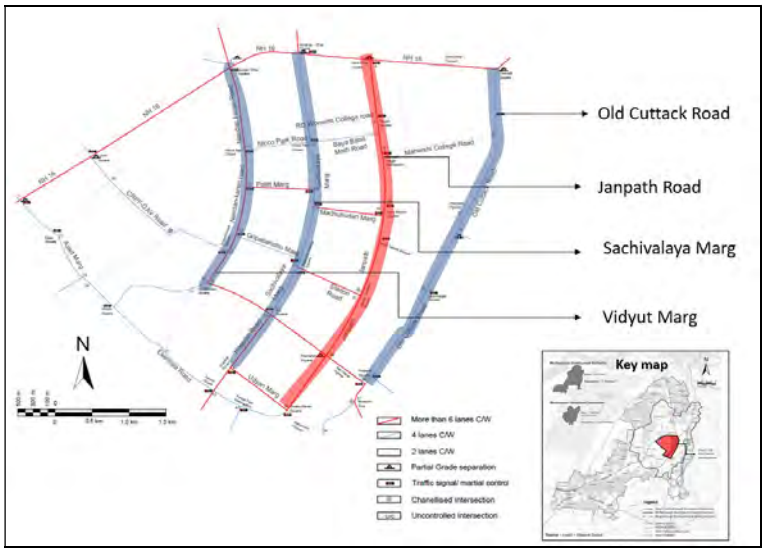

Figure 2 - Area based development in Bhubaneswar city as part of Smart Cities Mission

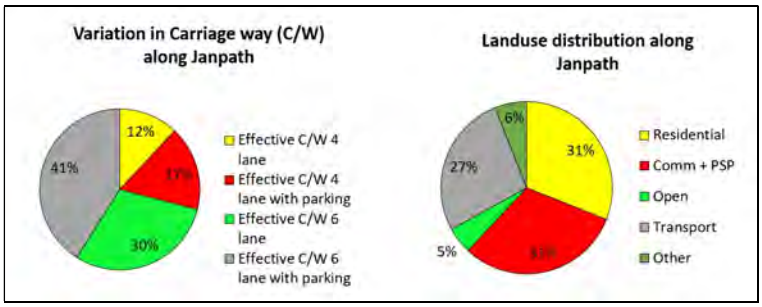

Figure 3 - Carriage way width and broad landuse classifications along Janpath

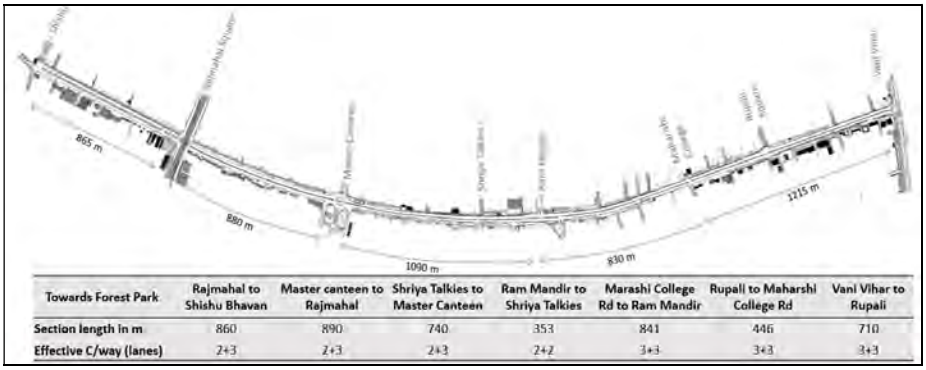
Source – Primary survey

As mentioned in Table 2, the 4.9 km long Janpath corridor hosts around 37 minor and major intersections/punctures which significantly alters the functional utility of the corridor as primary arterial corridor. Figure 4 illustrates the major segments and intersections along the Janpath corridor.



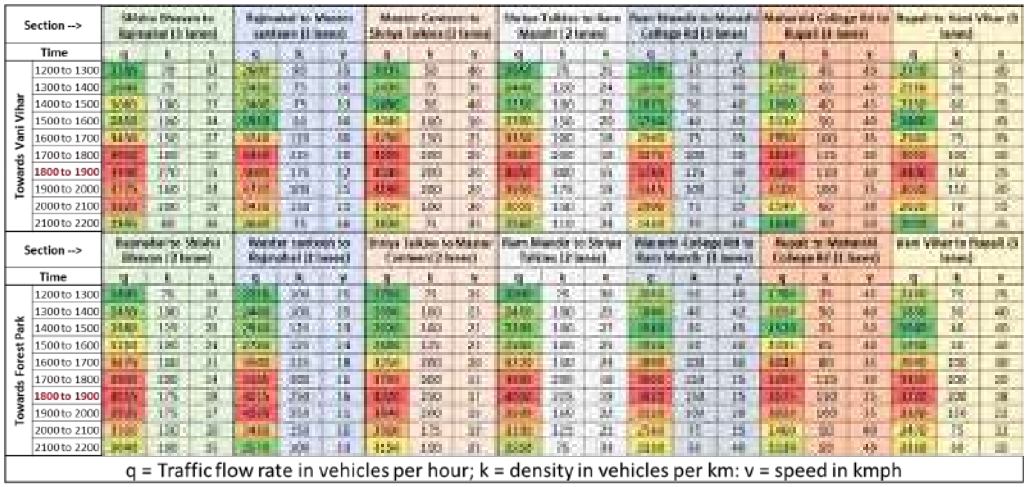
Towards Forest Park	Rajmahal to Shishu Bhavan	Master canteen to Rajmahal	Shriya Talkies to Master Canteen	Ram Mandir to Shriya Talkies	Marashi College Rd to Ram Mandir	Rupali to Maharshi College Rd	Vani Vihar to Rupali
Section length in m	860	890	740	353	841	446	710
Effective C/way (lanes)	2+3	2+3	2+3	2+2	3+3	3+3	3+3

Figure 4 Major segments and intersections along Janpath Corridor

4.2. Traffic flow along Janpath

The primary data collected along the Janpath corridor included traffic flow parameters – speed, flow, density (derived using linear speed-density model); simultaneously at major intersections for 10 hours. The direction wise synthesised traffic flow data is presented in Table 4.

Table 4 - Direction wise traffic flow parameters along Janpath corridor



Source – Primary survey

The Janpath corridor is divided in 7 segments and the data is presented in hourly window for 10 hours. The traffic flow rates along the corridor in either direction is almost similar and is getting saturated between 1800 to 1900 hours. Assuming an 80% ratio between Vehicles to PCU (Refer Table 3, corresponding to high share of powered two wheelers), the PCU values per lane per direction at extreme congested links, is around 1500. This value is significantly higher and necessitates interventions to improve flow rate as corresponding speeds are observed to be around 15 kmph. The alarming situation of traffic congestion and saturation was one of the driving reasons for investing into Adaptive traffic control system (ATCS) and right of way (ROW) redesign as part of smart cities mission.

4.3. Suitability for optimization

Although Janpath corridor is of the hierarchy of arterial corridor for the town of Bhubaneswar, commercial establishments and high demand of on street parking along the corridor dilutes that hierarchy. As mentioned in Table 2, approximately 37 major and minor intersections are lined along the corridor making the corridor unsuitable for through desire. The average puncture spacing along the corridor is less than 150 m, which makes it very difficult to implement any traffic management technique with efficacy. Based upon the traffic flow parameters observed in table 4, and assuming jamming density of 400 vehicles per lane (based upon average vehicle length = 2.5 m), the queue length generated by traffic signal operations along Janpath corridor is presented in Table 5.

Table 5 - queue length estimation using shockwave at intersections

Traffic condition	Flow (q) in V/dir/hour	Density (k) in V/dir/km	Speed (v) in kmph	Shockwave speed (ω)	60 sec queue length	90 sec queue length

Near capacity	4180	190	22	19.9 kmph or 5.5 m/s	(5.5*60)/3 lanes = 110 m	(5.5*90)/3 lanes = 165 m
Jamming	0	400	0			

Source – Deduced by author

As the average cycle time and corresponding waiting time at major intersections during peak hour is well beyond 90 seconds, a queue length of around 200 m is generally observed per phase along Janpath. This leads to the two way problem, one – the preceding junction to a signalised intersection is always prone to congestion locking because of backward propagating traffic congestion, two – the vehicles stop in the queue without leaving sufficiant headway leading to significant loss in head start during green phase.

Another challenge for optimised signal operation is full utilisation of green phase of the cycle time, which significantly depends upon the trend of straight and turning vehicles. A high share of turning movement at successive intersections corresponds to high share of local traffic interfering with through traffic. Table 6 presents the ratio between turning and straight moving vehicles.

Table 6 - Turning volume to straight moving vehicle ratio along Janpath during peak hour

Serial	Intersection (chainage value in m)	Ratio of turning vehicles/ straight moving vehicles
1	Rupali (710)	1.1
2	Maharshi College (1156)	0.8
3	Satya Nagar (1894)	1.0
4	Ram Mandir (1997)	1.8
5	Shriya Talkies (2350)	0.8
6	Master Canteen (3090)	2.1
7	Rajmahal (3980)	1.7

Source – Primary survey

The ratio between turning vehicles to straight moving vehicles along the seven intermediate intersections of Janpath corridor also suggests that the share local traffic is significantly higher along the corridor as compared to regional demand. As per the estimate from corridor wide origin – destination study (travel desire pattern), around 10% of the vehicles travel more than 4.0 km along the corridor (total length of corridor (4.9 km). This frequent mixing of local and linear traffic causes significant impedance and reduces the overall level of service along the corridor.

Traffic signal optimisation can yield its stated benefits if only there is uniformity and predictability in the support indicators of the traffic and corridor. The significant fluctuation in carriageway width, vehicle heterogeneity, local versus regional demand and frequent punctures are significant challenges for implementation of adaptive traffic control systems.

4.4. Optimisation challenges

Driving discipline, non-uniform road geometry, high rate of side friction and significantly higher flow rates are major challenges in using the smart signals. Even with excluding all other challenges, signalised intersections might not be as successful on such congested corridors because of the practical capacity of signalised intersections. Few intersections along Janpath are already experiencing more than 12000 vehicles of hourly inbound volume which necessitates grade separation and interchanges. The corridor either requires demand

management (and reduction) to successfully reap the dividends of intersection signalisation or would require capacity augmentation in terms of wider/ multi tier corridors. In this regard, the suggestive approaches based upon field learnings and feedback from operating agencies is presented in subsequent section.

5. Solutions for improved efficiency at traffic signals

5.1. Immediate/ short term

- The right of way and carriage way shall be uniformly distributed to avaoid geometric bottlenecks. Extra slip lanes shall be provided to facilitate outgoing traffic so as to reduce the saturation levels and frequent side-punctures shall be restricted. If at all necessary then service roads can be used to dilute the impact of side punctures, parking and estaqblishments on primary arterial corridor.
- The hybrid and auxiliary lane marking (at least at the intersection influence zone) in heterogeneous traffic condition can help in optimising the stream movements. As vehicles tend to stop with negligible gaps between vehicles, this leads to significant accelerating and head start loss. Lane wise box marking or 3D holographic projections along each lane can be used to artificially infuse minimum gaps among vehicles in queue which can help in improving the flow rate at intersections. Although this would lead to increased queue length but would improve the flow rate because of simultaneous acceleration and movement of all vehicles in a lane. Figure 5 illustrates the lane wise box marking and corresponding gain in throughput.

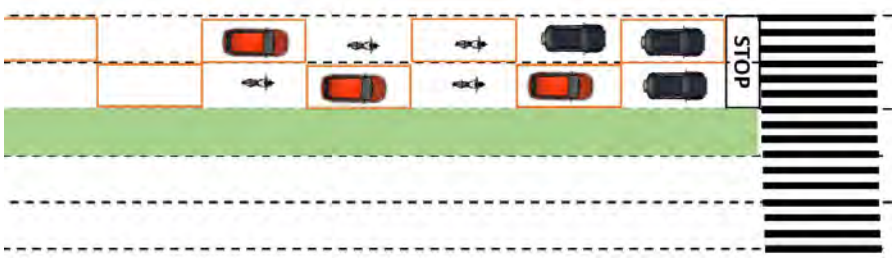


Figure 5 - Lane based box marking illustration

5.2. Long term

- Travel demand management and preferential treatment to non-private modes as part of policy intervention shall be carried out phase wise to optimise the corridor. Essentially this is demand management through optimising mode mix. Other techniques of travel demand management include restriction to specific modes (like heavy vehicles/slow vehicles/long vehicles, extra) for specific duration of the day to stagger the demand. Alternative corridors can also be developed to divert the traffic from existing corridors. Also, the conflicting traffic shall be segregated as they not only reduce the throughput but also cause unsafe operations. Here, conflicting traffic refers to one or more combination of following characteristics -
    - Slow-fast (motorised – non motorised)
    - Local-regional
    - Passenger-freight

- Traditionaly driven-self driven

- Many of the on road incidents and conflicts can be avoided with standard driving conditions and discipline. Multiple mechanisms of improving on road awareness can definitely improve the capacity and level of service operations.
- Self driven and mutually communicating vehicles can also help ion improving the efficiency of operations as driving discipline and standard protocols can be expected to be better adhered. In a scenario where traditionally driven vehicles and self driven vehicles operate simultaneously in traffic streams, it would become indispensable to follow standard rules and discipline of operation.

6. Conclusion

Adaptive traffic control systems have improved the level of service and flow indicators significantly in those cases where uniformity in modes and right of way characteristics have been observed. Unlike them, the arterial corridors in many of Indian cities are host to varied kinds of heterogeneity. Leave apart smart signals, theses corridors are theoretically not even suitable for manually operated/marshalled signals because heavy flow rate and high side friction. To reap the true dividends of smart signals along such corridor, multiple simultaneous attempts are required to not only justify the investment but also to ensure that social, economical and environmental indicators are not getting deteriorated. In absence of such mechanisms, no significant gain can be evaluated out of smart signals.

Case Study / Project

The Goldilocks Zone for the public sect or innovation

-Teresina 2030 towards resilience to climate change in the developing world

Mariana FIUZA, Gabriela UCHOA, Flavia MAIA,

Abstract

The term äóìGoldilocks Zoneää refers to the habitable zone around a star where the conditions are just right- not too hot and not too cold - for liquid water to exist on the surface of a planet. It provides a way to predict the habitability of newly found planets and moons. Just like in astronomical science, there is evidence of a public sector äóìGoldilocks Zoneää , where the conditions are perfect to find thriving innovation in the public sector. Local governments that are not too big and not too small are in this zone as they have enough complexity to create a fertile ground for innovative solutions to flourish without being excessively hierarchical and bureaucratical. In the developing world, urban populations are the most affected by climate change due to an overlap of social and environmental vulnerabilities. At the same time, local governments often have the most limited resources to follow through on sustainability and resilience commitments such as those expressed in the Agenda 2030, the New Urban Agenda and the Paris Agreement. In this scenario, innovation works to support local governments to deliver new products and services aiming the creation of public value and efficiency gains. To support the public sector to fulfill global agendas, a group of civil servants in Brazil created Teresina 2030, a hub for innovation within the Planning Department of the Municipality of Teresina, that prototypes solutions to strengthen urban resilience, by combining open government and smart city strategies. Our aim is to update planning and policy tools to respond to the complex situation of Teresina in the face of climate change. This situation includes a difficult geographical situation -- near the Equatorial line, in an extreme hot weather -- and a challenging economic context -- high socioeconomic inequality combined with scarce technical and educational resources in the public sector. In this paper, we placed Teresina in the 'Goldilocks Zone' for the public sector innovation and what does it mean to be in this zone. Teresina is a medium-sized Brazilian city that is not too small: it faces all these complex challenges that may not have been addressed yet by many other cities around the world, as it goes beyond issues with basic services provision, what makes Teresina a test bed for new solutions. However, Teresina is neither too big: it can avoid excessively bureaucratic and hierarchical procedures that hinder innovation in megacities. Like Teresina, there are several cities across the globe which are able to create an innovation ecosystem despite the common challenges to cities in developing countries, especially regarding scarcity of resources.

This paper explores Teresina features that position the city in the äóìGoldilocks Zoneää for public sector innovation and allow this group of urban planners from the local government innovation hub to overcome five challenges in two years since Teresina 2030 was created. Political and technical barriers, low collaboration among municipal departments, staff limitation, digital divide and unavailability of data are addressed with low-cost tools, international partnerships, innovation in bureaucratic processes, as well as a serious commitment of the practitioners with critical scholarly debates, planning researches and academic networks.

Case Study Paper

Smart Cities and The People: Urban Planning Collectives in Indonesian Cities

Hasanuddin, Dian Zuchraeni Ekasari, Alumni of Urban and Regional Planning Gadjah Mada University

Abstract

Come to Indonesia. Change is in the air. Can you smell it? For less than the last decade, there are urban planning collectives that have been growing organically, on-line and off-line. They are young, energetic, and critical. They utilize technology as the platform and tool. They see phenomenon, analyze data, discuss, collaborate, and take actions. Whereas buzz words such as smart cities, automation and big data analysis have been crowding city managers and planning worlds, these collectives demonstrate that change can begin within the society without governmental support at all. Nevertheless these collectives are based from the intellectual elites in Javanese cities, hence the question: can we replicate and deepen such initiatives to general citizen? to other cities beyond Java Island? Can we go against Jakarta-bias? Can we create an ecosystem to be smarter together and create our shared values despite the 'smart' and automation part of the cities? With a closer look to urban planning collectives in Indonesia, together we learn and build the path to be smart together with our cities.

Keywords

Urban planning collectives, smart cities, young community, on-line platform, smarter together.

1. Introduction

Smart City is an inevitable future of our cities. This is becoming a trend not merely because the government program but most importantly because the technology development both in industrial sector and daily life of the citizen. With the national internet users proportion of 55% (Ministry of Communication and Informatics, 2018), Jakarta the capital city of Indonesia has rated 19.1 of 30 points for citizen awareness and satisfaction of smart city application in their city. This point is higher than 13 European cities, even the Asian cities such as Singapore, Bangkok, and Hong Kong. This positive adaptation points out to be correlated with having a young population that accepts a more digital way of doing things (Smart Cities: Digital Solutions for a More Livable Future, McKinsey Global Institute 2018). The 'digital way of doing things' appears in daily life with Internet of Things (IoT) for daily services such as transportation, banking, and most importantly communication. Emerging of social media platforms has changed the basic primary communication form into virtual connection, with the advantage of time and place flexibility for 'anytime anywhere' communication form.

The social media platform has also become a media for youth to express their ideas. In the realm of urban planning this has also become a phenomenon with the existence of Planning Collectives. Young, energetic, and critical, the Planning Collectives use social media as the platform to highlight, talk, and discuss urban planning issues. The online platform comes together with offline event such as discussion and exhibition. The most popular Planning Collectives were born out of academic settings. It was found by the students of Urban and Regional major in reputable universities of major cities in Indonesia. In this paper we will take a closer look to these Planning Collectives and examine how they grows organically, what they aim to achieve, and moreover how they position as a part of Smart Communities element of Smart City.

2. Urban Planning Collectives

Urban Planning Collectives refer to community who has keen interest in urban issues specifically from the perspective of spatial planning, and collect data, process into information, publish the information as discussion material, and provoke discussion. These Planning Collectives run the activity in online and offline platform to have wider coverage than the community in their physical proximities.

With the nature of urban-issues as cross-cutting issue experienced by all citizen, the publication, discussion, and the Planning Collectives itself gain attention by other urban communities. The Planning Collectives exists in 4 major Indonesian Cities, Jakarta, Bandung, Jogja, and Makassar, with variety range of activities, which will be further elaborated below.

2.1. Ketempatan, Jakarta

A former Pemuda Tata Ruang chairman and co-founder, who was also a student of Urban and Regional Planning major Universitas Gadjah Mada, established Ketempatan in 2017. As an online focused community, Ketempatan started it activities by publishing popular article on its website. The main objective is to position urban issue from citizen, by citizen, and for citizen, through providing evidenced-based information. Ketempatan targets Internet user who are mostly young or productive-age people, with the idea that everyone has the right for a high quality urban study. To accomplish its goal, Ketempatan has the strategy of re-writing dissertation, research paper, or articles with analytical and evidence-based content. They approach the writers to have their consent for the rewriting, so they can still have publications without the hesitation to take time for writing.

Ketempatan has one online platform that differs with other Planning Collective, the Podcast named Teras Kota or City Terrace. The podcast was started with the agenda to provide easy listening urban talks with various resource persons. Teras Kota quickly gain popularity, as podcast become trend in urban online life. It brings freshness in the podcast era, since the talking focus on a rare subject of urban issue and present in casual style conversation. The podcast also a strategy to bring urban issue to daily public talks, with a laid-back and easy-to-digest packaging yet still based on expertise of the resource persons.

Ketempatan has collaborated with numerous stakeholders for articles in website and podcast.

Collaborators from non-government organization, researcher, government, and urban enthusiast become contributors for various topics such as housing, infrastructure, and city management. The collaboration and further networking are managed by 3 persons, the Founder as the editor, and two other person as podcast manager and social media manager. Petarung is operated in the basis of friendship, since the founder and managers are collage or office mate. Their similar interest on urban issue, and concern for an evidence-based urban study has brought them together in the Planning Collective. They are also trying to develop networking with other urban communities through the website. Now they are preparing a new format podcast, containing interviews with foreign academia to discuss about current urban issue and theory, and then compare it to local Indonesia context.

2.2. Kolektif Agora, Bandung

Based in Bandung, West Java, Kolektiv Agora was founded in 2017 by 3 urban and regional planning students of Institut Teknologi Bandung. They aim to create discussion platform for urban issues from the daily reality and perspective of citizen, and provide alternative source of urban information for citizen.

Kolektif Agora runs the activities in online platform through blogging website 'Medium' and social media 'Instagram', and offline via regular discussion forum. The online activities occur more frequently, with regular publication of articles and infographics related to urban-issues. The articles are published through Medium, a blogging site in which Kolektif Agora has a certain page linked to each writer's own page. The publications in Instagram are made from a set of data and simple analysis that translated into a simple and attractive infographics and posters format. The publication provides not only information, but also provoke question for readers concerning certain urban issue. There are also publications in Instagram that contain links to the article in Medium. The online platform of Instagram has 3,476 followers, the highest from 4 Planning Collectives. Kolektif Agora using online platform strategically as the basis of their activities, including the distribution of knowledge and information about offline discussion.

The offline discussions are held with collaboration with various stakeholders ranging from Non-Governmental Organization, research groups, to individuals working in academia and government. The collaboration occurs with extensive topics that being picked based on the folk-work-place of aspects of urban issue, such as public space, transportation, infrastructure, urban-rural linkage, city health, inclusiveness, poverty, housing, urban politics, environment, and music. To organize the offline discussions and online activities, Kolektif Agora now has 22 activists including 3 founders. The activists were involved through open recruitment to specialized position such as writer and photographer. The recruits came are students from urban and regional major or other majors from several universities in Bandung.

2.3. Petarung Kota, Jogja

Petarung (or Fighter in English) stands for Pemuda Tata Ruang or Planning Youth, is the first planning Collectives established in Desember 2012 by 15 students of Urban and Regional Planning major Universitas Gadjah Mada Jogja. As stated in the tagline, Petarung aims to increase citizen's awareness of their neighborhood and city planning. The strategies are through

research and discussion, disseminate issue and gather opinion through media, socialize urban planning issue to citizen, build awareness via citizen empowerment program, and build partnership with multiple parties to increase citizen awareness of urban planning.

Since the beginning Petarung focuses itself on action such as campaign, discussion training, and joint study. One of the annual offline activities is training for high school student in Jogja named 'Strong' or Sekolah Tata Ruang/Urban Planning School. Petarung also take part in the celebration of World Town Planning Day, in the form of public campaign and discussion. As the first urban planning community in Jogja, Petarung has regularly being involved in numerous events from other stakeholders. They have been invited to discussion by national, provincial and city/regency government regarding city-planning policies, such as land use incentive and disincentive, urban Habitat policy formulation, and strategic environmental impact assessment. Petarung also invited various discussion held by non-government organization with topic related to urban planning, such as environment with community development. The community also involved as a facilitator in joint study or field visit with other research group and students from foreign university who visited Jogja and study about it specific local site planning in urban kampong.

The online platform becomes a media to share the information regarding offline activities, share short information concerning urban issue, and provoke further discussion. Petarung initially used social media Twitter, as a popular micro blogging site to provoke online discussion. They usually provide several short information concerning a particular urban issue, and/or post statement from other prominent person or organization. Such effort gave instant popularity for Petarung, as on that time there is still limited discussion on urban issue in social media, especially form the youth. Petarung then expand its online activities to other platform namely Facebook, Instagram, Youtube, and a dedicated website.

As a community, Petarung has been continuously active for 7 years through different activists. The activists organize Petarung in a structure of chairman, secretary, treasury, and 3 thematic divisions of public relation, media and design, and literation. There is annual open recruitment for new member based on the needs of each division. The new member and committee in Petarung always consist of students from various public and private universities in Jogja that active on voluntarily basis. To sustain their activities, Petarung collaborates with stakeholders in organizing events, and also receive donation from its alumni.

2.4. Nekropolis, Jogja

3 students of Urban and Regional Planning Universitas Gadjah Mada started Nekropolis in 2017. As their tagline 'Discussion Platform and Writing Media for Urban Issue', the founders aim to discuss urban issue encompassing urban planning theoretical approach, wider to the interlink with other disciplines. They believe Planning could only succeed when the citizen become an active part of urban planning process, not merely an object. Hence it is fundamental for city planner to have a solid link with civil society, including social major students and social movement communities.

In the other hand, Nekropolis see that the current social movement in Jogja requires a more technical approach, including the analytical and data-based basis to support their acts. This condition in the context of urban issue creates the need for collaboration between social and

technical approach, where Nekropolis exists as the bridge to produce an urban alternative narration. Nekropolis held offline discussion with social communities in Jogja such as feminist, literacy, and art community. They also collaborate with other organization in university, such as the university student union body, urban and regional major student union body, and research organization. The interlink between social and technical approach in urban issue are reflected in range of discussion topics, from transportation, housing, urbanization, to city inclusiveness and urban politics. Nekropolis delivers its discussion mainly in local Jogja context, yet also taking into highlight several popular issues from Jakarta, Surabaya, Batam and Bogor.

Although based in Jogja, founded, and run by students from the same university, Nekropolis puts more focus on online and offline urban discourse while Petarung actives in offline movement. Nekropolis uses online platform Medium and Instagram to share their writing on urban issues, and publish information of the offline activities. They also produce infographics and videos in Instagram and Youtube, containing figure and facts about various urban issues in open-ended style to provoke further thought and discussion from the viewers. In social media Instagram, Nekropolis periodically engages their followers in discussing specific urban issue such as public space, urban transportation, traditional market, and smart city.

Nekropolis currently has 10 activists consisting of alumni and students form engineering and social major in Universitas Gadjah Mada. They manage the online and offline activities of Nekropolis. Since most of them are now working in other city outside Jogja, Nekropolis tries to have a periodic working schedule and regular theme for their publication. Flexibility and sustainability also become concern for Nekropolis, as they are preparing future coping strategy for its existence within the daily formal profession of its activists.

2.5. Kotata', Makassar

5 students of Universitas Hasanuddin initiated Kotata in 2017. Different with other Urban Planning Collectives, Kotata was founded in Makassar, a metropolitan city in South Sulawesi outside of Java Island. The founders are a mix of 4 students of Urban and Regional Planning major, and 1 student from Environmental Engineering major. At first the concern to urban issue discourse connected them together. They then make a proposal of introducing children to urban issue and followed a Student Creativity Contest. The proposal got accepted and the first Kotata' program came into realization.

Kotata' focuses to offline activities. In 2018 they run a program of Introducing Urban Issue to a class of elementary school children, by talking about urban environment and learning to make a documentary video together. They then used online platform Instagram to publish the videos. After that Kotata' collaborated with environmental engineering student union and disaster mitigation community to held 2 campaign relating to city waste.

In managing it activities, Kotata' has held open recruitment for activist. Several students from engineering and social major join Kotata' and support the activities, including developing website. Beside being more active in online platform, Kotata' also plan to be consistent in introducing and promoting urban issue to elementary school children as the future agent of city development.

Table 1 General Comparison of The Urban Planning Collectives

Urban Planning Collectives	Comparison				
	Location	Founded	Focus	Online Platforms Variety	Followers of Instagram (similar platform)
Ketempatan	Jakarta	2017	Online	Website, Instagram, Podcast	845 followers
Kolektif Agora	Bandung	2017	Onlin, Offline	Medium, Twitter, Instagram	3,529 followers
Petarung	Jogja	2017	Offline	Website, Facebook, Twitter, Instagram, Youtube	2,759 followers
Nekropolis	Jogja	2012	Onlin, Offline	Medium, Twitter, Instagram, Youtube	1,790 followers
Kotata'	Makassar	2017	Offline	Website, Instagram	265 followers

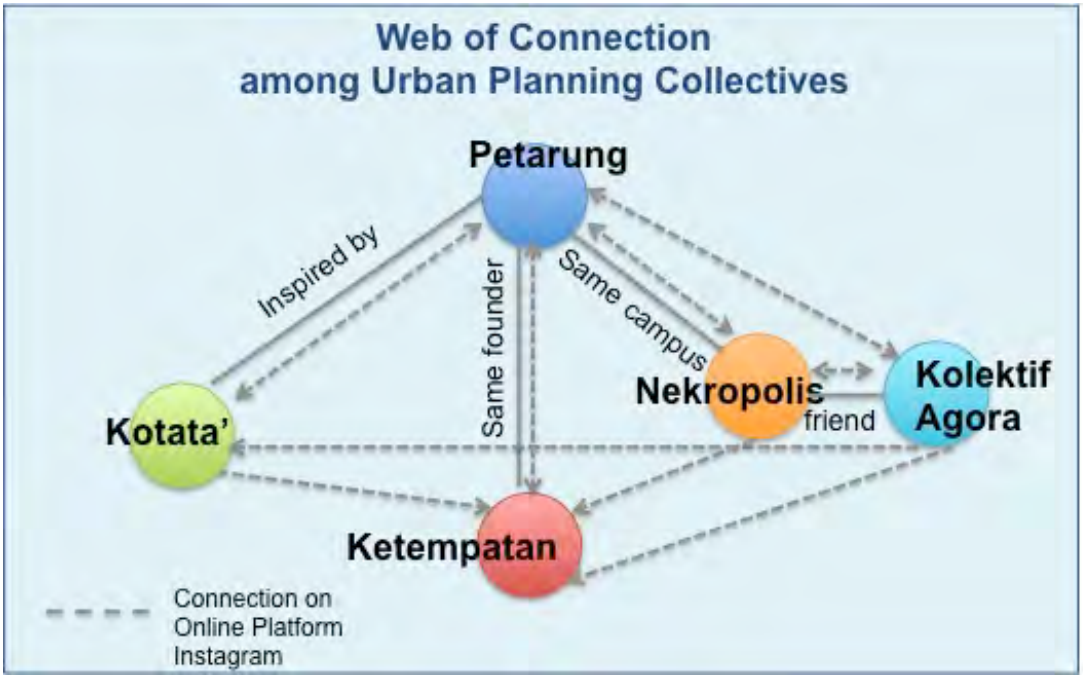

Figure 1 Web of Connection among Urban Planning Collectives

3. Urban Planning Collectives and Smart Cities

In the context of intelligence, Smart City could be defined as a territory with high capacity for learning and innovation, which is built-in the creativity of their population, institutions of knowledge creation, and digital infrastructure for communication and knowledge management (Komninos, cited in Holland 2008). From the definition we could see that there are several elements of Smart City to be appropriate for its 'smart' title. As stated by Kumar ini 2015, smart city consists of 6 major elements namely smart economy, smart environment, smart living, smart mobility, smart governance and smart people (Kumar, cited in Gupta, Mustafa and Kumar, 2017).

Urban Planning Collectives are part of Smart People in Smart City, because they are part of citizen that are using information-communication technology as a platform to contribute to the city development. Not only they are taking action in the real offline space, the Urban Planning Collectives also bring the action to virtual space in the online internet setting. They use offline and online space interchangeably, as a canal for their internet and passion to urban issue.

The effort could happen with the specific character of the Urban Planning Collectives. Looking to the study of Gupta, Mustafa, and Kumar in 2017, there are several traits of Smart People that can be found on Urban Planning Collectives activists. The personality dimensions that are appearing in Urban Planning Collectives members are extroversion, openness to experience, agreeable, and conscientiousness. These traits has supporting them in producing knowledge for general citizen regarding their common urban space. The Urban Planning Collectives has been doing their actions voluntarily, using their personal resources such as time, energy, money, gadget, and network. The reality that these Collectives actually operates based on passion for city improvement, has to be acknowledge as a social capital of smart city. Their existence has influencing other communities who collaborates with them, and furthermore general citizen to put more attention in urban issue and give more contribution to city development.

These impacts are beneficial for Smart City Development since this is the part where the people as smart city element, could learn to become smart together using intersection of technology and their own social networks. Furthermore, the learning process to be smart together with Urban Planning Collectives could provide outcome in the form of better translation of citizen needs for city development. General citizen who has acquire knowledge about urban issue, can better understand the dimension and interlink of factors and actors in city development.

This social capital of Urban Planning Collectives has the potential to be utilized in the development of city, including in the formulation of algorithm for smart city. They could participate in both sharing and gathering citizen values and aspiration for the city development. Beside the current common practice of involving academia as resource person in city policy formulation process, the involvement of Urban Planning Collectives that has been practiced in several cities, could become an attempt of wider stakeholders view and participation. The development of smart progressive city cannot simply be done with the adoption of sophisticated technology infrastructure, but more importantly it requires the input and contribution of various groups of people (Hollands, 2008)

The Urban Planning Collectives might be quite homogenous as it mainly consists of educated youth and from urban and regional planning background, yet it is their influence and collaboration to wider communities and general citizen that make them valuable for smart city.

The process of urban-related information being shared and discussed, creation of urban narrative in online platform, and assimilation between urban technical and social aspects I general citizen discourse are actually the precious parts of Urban Planning Collective existence in Smart City. With better understanding of how city can be planned, developed, and managed based on citizen needs, there will be an improving translation of citizen needs to technical urban planning language. The creation and agreement of shared values for smart city development could then be acquired more accurately to the actual needs of citizen.

4. Smart Cities in Indonesia

The Government of Indonesia has issued "100 Smart Cities Movement" in 2017, which aim to assist Indonesian cities in preparing Smart City Masterplan to optimize technology services, both for public service improvement and for potential city sectors development. This program is lead by Ministry of Communication and Information in collaboration with Ministry of Internal Affairs, Ministry of Public Works and Human Settlements, National Planning Agency, and The Office of President's Staff. Within 3 years from 2017 to 2019, there are 100 cities that are supported to be Smart Cities. The cities vary from large to medium populated city throughout Indonesia including Java, Sulawesi, Kalimantan, Nusa Tenggara and Papua Island. The cities were selected in the consideration several aspects such as city visioning, regulation, human resource and economic potency.

The "100 Smart Cities Movement" also acknowledge Smart People as one element of Smart City. This is reflected with the establishment of Smart Citizen Network, which consists of 34 youth representative from 34 provinces in Indonesia. They are expected to become agent for accelerating digital literacy and smart utilization of technology in all cities in Indonesia. This is also a program to convey the importance of citizen participation in Smart City development.

In capital city Jakarta, the Jakarta Smart City (JSC) has been launched and activated. It operates under City Government in the form of special unit with dedicated budget. JSC produces specific output related to automation of Smart City Services in the area of transportation and other public services. Nevertheless the provision of public participation channel is still limited. It is only in the form of reporting issue or bad urban services via Qlue Application, and giving input to city programming via e-musrenbangda system. The type of participation based on Arnstein Ladder of Participation (1969), then the participation type is limited to tokenism and consultation, where citizen could give inputs but not granted to be taken into consideration in city policy formulation.

In the practice of Smart City, this could be compare with Kitchen study in Dublin year 2017. He found that the citizen participation in Smart City through the provision of several applications are not yet sufficient. Furthermore he also used Arnstein Ladder of Participation and provide more insight on the kind of limited participation in Smart City era.

The emergence of Urban Planning Collectives could be seen as a window for improving citizen participation in Smart City Era, not only for improving the smart city policy, but more importantly to assure that citizen could grow smarter together with their city.

Urban Planning in a Mediatized World

Case of Egypt

Mennatullah HENDAWY

Abstract

In this digital and information age, there is a rising assumption that planning will change dramatically. At the same time, there is a wittnenessed increase of the potential role of media in urban research and practice, and there are many demands for democratic and communicative planning practices. In Egypt, urban planning is still centralized, large scale, top-down and known by its entrepreneurial nature despite the trials to implement strategic planning for more than 25 years aiming for decentralized planning participatory processes. This led to dispatched planning processes inducing gated communities and mega-projects that are highly proclaimed and praised by all kinds of media platforms and channels reaching its pick in this information and technology revolution era: the 21st Century.

Media refers to the medium or tools of communication that are used to deliver a certain message (that are vocal, visual or textual). As a place making field, urban planning needs to respond to the changes in media and the corresponding chances and challenges among not only urban planners but also authorities, investors and community members. Two main research questions are addressed: How media 'structures' the way planning is communicated, and How the way planning is communicated via media is reflected in planning decisions. This is investigated through a qualitative research involving interviews with urban planning students . In addition to visual analysis of samples of urban projects that involved both manual and digital tools in its development.

Case Study / Project

Smart city and regenerative city

complementary or contradictory approaches.

Dorota KAMROWSKA-ZALUSKA

Abstract

Rapidly developing new disruptive technologies and digitalization is allowing for creation of smarter cities where urban dwellers are submerged in full of ubiquitous sensors and devices urban realm. Increasing connectivity is allowing for interoperability between system giving base for conducting real time data driven policy. At the same time with rise of consumption, urbanisation in its current form is threatening the very future of humanity and the natural world. There is a need for actions that can help to continuously renew and restore the ecosystems that underpin the existence of our urban systems (C. Du Plessis, 2012). Protecting nature from physical urban expansion (however important are such initiatives) is not enough, there is a need to take positive steps to create regenerative cities (Girardet H., 2015). Numerous cities are adopting various 'smart' and innovative solutions, but one can ask if all of them are strengthening sustainability and resilience of urban fabric (Kamrowska-Zaluska, D., Obracht-Prondzynska, 2018).

Above mentioned phenomena evoke questions important for the future planning and design of the cities: - Can smart solutions and infrastructure support shift toward regenerative sustainability? - On what conditions can data driven policy help shaping sustainable urban planning and management? - Can smart policies and solutions help to create regenerative urban systems of production, consumption, transportation and construction? The aim of the study is to recognize relation between smartness and regenerative sustainability in contemporary cites. Today's world need a change of approach in order to strengthen human-nature relation. There is a need to determine how new technologies affect the development of cities as well as the way it influence ecosystems and wellbeing of their inhabitances.

Proposed study is conducted in frame of COST Action RESTORE Rethinking sustainability toward a regenerative economy which aim is to advocate, mentor and influence restorative built environment. The RESTORE is investigating how a new focus of sustainable built environment can be a driving force for changing the status quo of today's practice beyond legislation and client requirements. Sustainability targets (such as SDG Goals) are forcing planners and designers to, embrace forward thinking, access and implement multidisciplinary knowledge, and multiple tools that simulate dynamic and complex future scenarios. Part of research activities is to assess how new emerging disruptive technologies influence designing new urban environments and sustainable buildings.

People, Places, Memories and Mobile Apps

Understanding the Potential of Augmented Reality in Public Participation and Community Development

Ming-Chun Lee, Ph.D., School of Architecture, University of North Carolina at Charlotte; USA

Abstract

Augmented Reality (AR) goes beyond the dichotomy of passive methods of engagement with the public. It offers an interactive method to expand visualization techniques in participatory planning processes. This paper discusses three mobile apps developed by a partnership. These apps support a series of community events aimed at increasing overall public participation and civic engagement with a goal of increasing awareness of community history through data visualization and story-telling.

Keywords

Augmented Reality (AR), Public Participation, Community Development, Civic Engagement, Data Visualization

1. Introduction

Samuel Mockbee once argued that the practice of community planning and design not only requires individual participation in the profession, but also requires active civic engagement (Mockbee et al., 2003). He stressed the importance of a deeper democratic purpose of inclusion in energizing one's community. Many methods for public participation have been introduced in urban planning and its allied fields such as architecture and urban design. This type of community-based practices has its root in the field of participatory design, which is a response to the demand to have voices heard and ideas taken from those who are involved in the design process. It sees community members as citizen designers who play an active role in shaping the formulation of both the design process and its ultimate results (Arnstein, 1969).

One of the issues facing this type of participatory design has to do with the challenge of making the process comprehensible, relevant, and interesting to the potential participants in order for them to willingly participate in the process (Baykurt, 2011). Augmented Reality apps on personal mobile devices, such as smart phones or tablets, may offer some clues. Immersive visualization technologies, such as Virtual Reality and Augmented Reality (AR), are powerful tools to facilitate participatory approaches in community design. As a visualization apparatus, AR goes beyond the dichotomy of passive methods of engagement and their one-way communications with the public. AR offers an interactive method to expand both non-computerized and computerized visualization techniques in community design. Moreover,

AR increases public engagement by providing comprehensible information to citizens and assisting them to express their preferences in an intuitive way.

One important aspect of AR is this fun factor in the form of mobile games (Sicart, 2016). No other AR game has drawn more players and created this world-wide phenomenon than Niantic's Pokémon-Go has in the past years. One unique fact about this Pokémon-Go fever is its ability to bring people together into public spaces. Many organizations have used Pokémon-Go in community events (Kooragayala and Srini, 2016). In collaboration with Knight Foundation and Niantic in May 2017, OpenStreets704, a non-profit organization in Charlotte, North Carolina, organized one event temporarily closing streets to automobile traffic to allow residents to use them for walking, bicycling and meeting their neighbors. Niantic arranged special in-game elements for Pokémon-Go and helped draw people to interesting places along the route of the event (Polygon, 2017). Similar events have taken places in other cities around the world (Humphreys, 2017; Knight Foundation, 2017; Niantic, 2017).

This paper discusses three projects conducted by a partnership among four organizations in Charlotte to design three AR mobile apps. These apps along with Pokémon-Go support a series of community events developed and organized by this partnership. These projects are as the following:

1. Neighborhood History Walk App utilizes AR to guide users to visit selected locations in Charlotte's streets. Users see historical photographs of street scenes through this AR app at these locations.
2. Neighborhood Pop-up Story-telling Exhibit, imagined as an urban autobiography, uses AR to peel back the layers of time to show the city in new ways through different perspectives. The collection of stories as images serves as the cornerstone of this exhibit.
3. Charlotte #HomeCLT Exhibition provides a collage of stories from local residents in five selected neighborhoods in the city. Visitors can use AR to interact with physical display panels to view data related to social, economic, environmental and safety conditions in these Charlotte neighborhoods.

The underlying principle behind these apps and community events is that innovative digital tools for information-sharing and broad-based pubic engagement can help build inclusive, healthy, and livable communities.

2. Augmented Reality in Public Participation and Civic Engagement

One of the key factors to successful community planning and design is for urban planners and designers to work together with community members and empower them to play a key role in this community building and transformation process. Together urban planners and community members work to envision the future of their communities (Fung, 2006). However, it is inevitable that people hold different views of their communities and often have different scenarios about the future. To bring together these diverse viewpoints and further come to a unified vision of the future in this community planning and design process, neutral information is needed to build a solid foundation for "informed" decision-making. To meet this need, we must employ proper tools to acquire and analyze data, help people gain

insights into the conditions of their environments, and in turn develop common understandings of issues facing their communities (Al-Kodmany, 2002; OECD, 2013).

Alongside with the rapid development in the field of Geographic Information System (GIS), immersive visualization technologies present a tremendous opportunity for data analytics and information sharing. Over the past year, much attention has been turned to AR with the belief that it offers an interactive method to expand both non-computerized and computerized visualization techniques in community planning and design (Reinwald et al., 2014). Moreover, AR increases public engagement by providing comprehensible information to lay citizens and assisting them to express their preferences in a very intuitive way.

AR is a new way of seeing. A viewer's own visual perception can be enhanced through computer-generated digital contents. This can be achieved in a variety of ways by see-through devices, head-mounted displays, or mobile devices amongst others, (Reinwald et al., 2014). The common features of all these systems are that virtual contents generated by these digital devices and the real-world physical reality are combined and overlaid. These systems operate interactively in real time and three-dimensional (3-D) information is provided (Azuma, 1997; Azuma et al., 2001).

Initial research on AR and its related technologies, such as Virtual Reality, can date back to the 1950s (Carmignani et al., 2011). However, the first definition of AR was provided in 1997 by Azuma: An AR environment has the following three characteristics: "1) combines real and virtual environments; 2) is interactive in real-time; 3) is registered in 3-D" (Azuma, 1997). While AR has been in use since the 1990s, this has mainly been in research projects, and only a few specific projects have been developed. Only in recent years have mobile AR applications enjoyed an increased presence due to the development and use of AR-enabled game engines or browsers. Because of the current distribution of suitable mobile devices equipped with high-resolution cameras, data connection and improved computing power, AR applications have become of interest to general end users.

At present, this new technology is mainly used for marketing, navigation, in the game sector, in medicine, as well as for service technicians and in tourism. The field of urban planning is increasingly interested in AR. The assumption is that the use of AR can support quality assurance in planning processes (Nash, 2010). In particular, architecture and urban and landscape planning could benefit from the use of AR applications. AR has the potential to expand the range of instruments which are offered to support public participation and community engagement. It is expected that computerized tools like AR will change but also increase the quality of public participation (Al-Komandy, 2002).

Reinwald argues that visualizations in planning, especially the digital technologies developed over recent years, can function as a mediator of empowerment in public participation (Reinwald et al., 2014). AR in urban planning and participation processes has the potential to improve civic engagement processes and make them more efficient (Nash 2010). To increase the standards and quality of public participation procedures, AR instruments should satisfy requirements such as framework conditions and virtual contents should be clearly and comprehensively communicated or equal chances for different groups to participate and influence the decision-making processes should be guaranteed (Broschart et al., 2013).

3. The Partnership

With the funding support from The Knight Foundation-Niantic Augmented Reality Fellows Program (Niantic, 2018), a partnership was formed among four organizations in Charlotte to carry out the development of three experimental AR applications, which were used in a series of community events taking place between September 2018 and February 2019 in Charlotte.

In March 2018, City Building Lab at the University of North Carolina at Charlotte created an AR exhibit in conjunction of the Urban Complexities Symbolism. This event drew more than 200 participants from the area, including planning practitioners, community activists, local developers, etc. This AR exhibit was aimed to explore the new junction between the conventional mapping methods and many new emerging digital techniques for data processing and visualization, including 3-D GIS, integration with AR, and integration with remote sensing Imagery (City Building Lab, 2019).

Figure 1 Mapping (In)equity exhibition associated with Urban Complexities Symposium on March 23, 2018

Charlotte-Mecklenburg Library, as a public institute, has long being serving the greater Charlotte Metropolitan as not only a knowledge activator but also a third place for the public to meet and learn. Many educational events are scheduled year-round, such as Learn, Connect, Play events that encourage cooperation, problem solving, letter and word recognition, and critical thinking skills. The Robinson-Spangler Carolina Room in the Main Library, which houses historical collections of photographs, publications, maps, and artifacts about Charlotte, has been an invaluable resource for Charlotte residents to learn about local history and genealogy.

OpenStreets704 of Charlotte organizes events that temporarily close streets to automobile traffic to allow residents to use them for walking, bicycling, dancing, playing, and meeting their neighbors. These events have proven to be successful at achieving goals related to recreation, public health, active transportation, and community building. In collaboration

with Knight Foundation and Niantic in May of 2017, OpenStreets704 organized one special event where Niantic arranged special in-game elements for Pokémon-Go and helped draw people to interesting places along the route of the event (Polygon, 2017).

Levine Museum of the New South has curated many exhibits with community members around Charlotte. One recent example is K(NO)W Justice K(NO)W Peace, which was co-created with the community. This exhibit includes first-person testimonials from police officers and activists, journalists, clergy leaders, the Mayor, the Chief of Police, and Charlotte residents. Students from Johnson C. Smith University provided a portion of the exhibit devoted to the victims of police-involved violence throughout the country (Exhibits, 2019).

4. The Three Projects

The Goals of these three projects that were carried out by the partnership and funded by The Knight Foundation-Niantic Augmented Reality Fellows Program are as the following:

1. To explore the potential of AR as a tool for education (data) and interaction (social gaming) in advancing community development and civic engagement.
2. To introduce AR to the general public through the use of both Pokémon-Go and the experimental AR apps developed by UNC Charlotte in different community events.
3. To establish a partnership with local organizations, including Charlotte-Mecklenburg Library, Levine Museum of the New South, and OpenStreets704 to develop and conduct community events as a platform to achieve the first two goals.

The underlying assumption behind all these apps and community events is that innovative digital tools for information-sharing and broad-based public engagement can help build inclusive, healthy, and livable communities.

The Knight Foundation-Niantic Augmented Reality Fellows Program helped initiate three pilot studies, each of which was aimed to develop one AR mobile app using Niantic's AR platform and/or open-source software assets. A series of community events were then organized by the partnership as test cases for these AR prototype mobile apps. Niantic's Pokémon-Go was also used in all these community events as an activity to inject some needed fun factor into the events. The partnership also explored the possibility to customize Pokémon-Go with additional features and/or functionality to meet the needs of these planned community events.

4.1. Project-1: Neighborhood History Walk App

The Robinson-Spangler Carolina Room in the Main Library was seeking new ways of making its vast collections of historical materials more accessible to the public. This partnership believes that the emerging immersive visualization technologies, such as AR, can help accomplish this goal. UNC Charlotte developed a Neighborhood History Walk App that utilizes AR to guide users to visit a number of identified locations in city's streets. Users were able to see historical photographs of street scenes through this AR app at these locations. Viewing angles, orientation, distances, and heights were carefully adjusted in order to precisely overlay these photographs onto the present-day street views as seen through the camera of users' mobile device. This app allowed users to compare what was in the past to

what is now at these selected locations in Charlotte. Additional historical images associated with these locations may also be displayed along with the street scenes.

This app was deployed in one of the OpenStreets704 events in September 2018 (OpenStreets704, 2018). Based on the success of the first Pokémon-Go/OpenStreets704 event in May 2017, the partnership once again incorporated Pokémon-Go in this event as an activity. While hunting for Pokémon characters, event goers were drawn to a number of "Pokéstops" and located one of the kiosks or signs with QR codes and instructions to download and use our Neighborhood History Walk App. Historical graphic contents were provided by the Robinson-Spangler Carolina Room of Charlotte-Mecklenburg Library.

Figure 2 OpenStreets704 event in City of Charlotte

4.2. Project-2: Neighborhood Pop-up Story-telling AR Exhibit

The Levine Museum of the New South is currently developing a new project, called #HomeCLT. This project is positioned to offer direct response to community needs, build bridges of communication and learning across the differences etched in the landscape of city's diverse neighborhoods, and help Charlotte find its way through the continuing civic identity crisis. It is imagined as an urban autobiography, peeling back the layers of time to show the city in new ways through a wide variety of voices and perspectives. The collection of stories, past and present, will be the cornerstone of this exhibit. The Levine Museum planned to build a proof-of-concept prototype model as a pilot version that could be installed temporarily at various locations around the city in a "pop-up" style. This prototype model was comprised of origin stories, first person narratives, artifacts, and images, as well as illustrative figures, maps, and charts revealing the development of the city over time by the numbers.

To enrich visitors' experience with this planned project, UNC Charlotte developed an AR app for two pop-up exhibits in two different selected indoor spaces at two local libraries in Charlotte. This AR app worked with the physical displays or installations to offer visitors more visual contents associated with the theme of the planned exhibits. The AR app detects the maps installed on the panels as a part of the pop-up installations. Users could see

"virtual" 3D data models shown on top of the maps. They then could tap on one of these virtual data models on the screen to call out the visual contents for that specific neighborhood. These contents can be any combination of historical photographs, video clips, and/or illustrative figures of quantitative information. The Robinson-Spangler Carolina Room provided historical materials relevant to this collaborative project. A Pokémon-Go event was organized to take place around these locations to accompany these pop-up exhibits to draw in more participants.

Figure 3 Neighborhood Pop-up Story-telling events

4.3. Project-3: #HomeCLT

#HomeCLT is an exhibit series rooted in the stories of Charlotte's neighborhoods. #HomeCLT aims to show the city in the words of its diverse residents, to reveal the unexpected, to prompt reflection and dialogue, and to inspire civic participation as Charlotte strives to build a more equitable future (HomeCLT, 2019).

The first iteration of #HomeCLT includes the stories of the Eastland Mall, Enderly Park, Hidden Valley, Dilworth and Sedgefield neighborhoods. Through an Augmented Reality app developed by UNC Charlotte, visitors can "see" the demographic changes in these neighborhoods occur over time as visuals and graphics are projected on their phones and other devices. The AR app detects the large map installed on the floor of the space as a part of the installation. Users can see "virtual" pins shown on top of the map as well as a series of 3-D models revealing some of the socio-economic conditions across Charlotte.

The exhibit includes a video recording booth where visitors can tell their own stories of the neighborhoods they have shaped and that have shaped them. It also features work by Charlotte photographer, Alvin C. Jacobs, Jr., and videographer, David Butler. The AR app also interacts with some of the display panels to allow visitors to view selected video recordings on their own mobile devices.

Figure 4 #HomeCLT exhibit at the Levine Museum of the New South

5. Discussions

This section discusses some of the lessons learned from the pilot projects with these experimental AR applications as well as the inclusion of Pokémon-Go as an activity in the community events:

Some of the most significant or impactful outcomes of these events can be summarized as the following:

For the Pokémon-Go players

- Knowing Niantic cares about them and wants to connect with them through a variety of community events.
- Getting involved in other communal and educational activities in these events.

For the other event participants

- Learning about Augmented Reality and gaining first-hand experience about its potential to promote civic engagement and public education.
- Getting involved in community affairs and learning more about their own places and people.

For the event organizers

- Getting hands-on experience about how the mobile gaming can be a fun way to engage community members.
- Getting to know about Augmented Reality and its potential as an educational and story-telling tool.

Things or factors that most contributed to the success in achieving the outcomes of these events include the following:

- Need local partners, as many as you can possibly find.
- Maintain a smooth channel for communications among local collaborators.

- Setup routine check-up meetings frequently.
- Make sure each event has a clear focus with a set of goals that are reasonably achievable.
- Pokémon-Go is fun, but so are the locally-driven activities.
- Planning and getting started with logistics ahead of time.
- Talking to the right people who can really make decisions.

In terms of event planning, preparation, logistics, and execution, some of the lessons learned from these events include the following:

- Getting people out to participate has been proven much difficult than originally expected.
- More activities that are tailored to the needs or interests of the local community are needed.
- Pokémon-Go players really expect and want something unique to the local place and people.
- Making sure it's a win-win-win situation for all partners/collaborators.
- Communications/promotion efforts require close coordination.

6. Preliminary Conclusions

Through these community events, the partnership was able to further explore the potential of AR in community planning and design with mobile gaming, image processing, 3-D data visualization, and community engagement. Specially, the AR Team at UNC Charlotte was able to develop a series of experimental AR apps to allow community members to learn more about the history of their communities. Another highlight would be the connections that UNC Charlotte was able to build with several local organizations, together working to bring Pokémon-Go to Charlotte as well as increase people's awareness of the possible applications of AR in community development and civic engagement.

Pokémon-Go creates a unique "third-place" for people to meet both physically in the real world and virtually in the digital world. This idea of social gaming is both evolutionary and revolutionary, as it can be seen as a continuation of all sorts of efforts we humans have made to connect to one another, while social gaming has generated a whole new platform for different forms of communications and human interactions to take place.

7. Future Outlook

AR is still evolving. Its potential is endless. However any possible use-case has to have a clear goal that is specific and geared towards its target users.

The issue of scale appears to still be a big challenge. Choices between scale-up with profitability and market dominance, and scale-down with public good and community-focused benefits will have to be carefully balanced to ensure its lasting success.

Allow for more user-driven voluntary contents to be built into Niantic games, such as Pokéstop selections, descriptions, more images associated with the uniqueness of these locations.

Connecting Pokémon-Go to public health measures, both physical and mental, through plug-ins, apps, smart devices, or sensors built into physical environments, such as public squares, parks, or streets.

Case Study / Project

Big Data Based Assessment on Metropolisation Processes in Poland

Hanna OBRACHT-PRONDZYNSKA

Abstract

Metropolitisation impacts regional settlement network and its spatial development. One of the vital challenges for, both researchers and regional planners is the delimitation of the metropolitan (urban) functional areas in order to define the strategic area of planning policies implementation. At the same time, there is a need to conduct more detailed analysis concerning contemporary trends determining the way how urban areas are nowadays shaped. It is noteworthy, that so far in Poland, the research aimed on urban functional areas was conducted mainly on the basis of statistical data, and have to the very limited extend been supported by the use of spatial information, while in other countries research recognising potential resulting from the collection of large data sets and from the growing amount of information is more often used. As data processing, becomes more effective and provides more precise and reliable results, there is a need to search for new methods allowing to analyse the development of functional and spatial structures of towns and their functional areas as well as to update established methods by introducing Big Data based solutions. Potential of such analyses in urban studies is still not fully recognised. Due to new determinants influencing and shaping urban and regional structures and new analytical possibilities, the aim of the research is to assess the impact of the metropolisation processes on the small towns' development in Pomeranian Voivodship. Once both the specificity of the metropolitan area of Gdansk-Gdynia-Sopot and small towns in Pomeranian region is recognised as well as the possible use of digitized spatial information for spatial study is defined, the Big Data based model has been created.

According to research aims this two-phase model allow to study the impact of the metropolisation processes on both functional and spatial development of the regional settlement network. It is based on a set of indicators characterizing trends of spatial and functional changes at the local (first phase) and regional scale (second phase). The model, built of a set of indicators, uses mostly data mining methods. By using GIS tools, it is completed with data visualisation by using cartographic and spatial statistics methods.

Finally, it is tested by:
- analysing small towns development according to both their rank in the regional settlement network and their spatial relations with the metropolitan area;
- defining factors of the metropolitan growth which influence and differentiate both spatial and functional development of small towns in the Pomeranian region; Conducted, in frame of this study, analyses allow for obtaining following results:
- introduction of typology of small towns as the base for identifying the determinants of contemporary development processes;
- introducing recommendations of both theoretical and methodological nature in relation to identified Big Data potential in urban studies;
- formulate recommendations for shaping regional policy, especially connected with Pomeranian Voivodship' small towns development.

Case Study / Project

Switching to a Sustainable Auto-rickshaw System

Namma Auto Project

Sugandha PAL, Palak THAKUR

Abstract

The Namma Project works towards reducing emissions and pollution from the auto rickshaw sector in Bengaluru and Chennai while fostering sustainable growth of the Auto-rickshaw sector. The project promotes a shift from 2 stroke technology to less polluting technologies (4 stroke /electric autorickshaws), in the two cities. The project is funded by the European Union under their Switch Asia Programme and is implemented by ACRA along with a consortium of partners including ENVIU, TERI and WHAD.

The project objective is addressed through a three-pronged strategy:
• Improving the demand for eco-friendly auto-rickshaws – Through ride booking apps, frameworkagreement with Public transport entities, behavioural change communication and focused research to measure the GHG emissions from the autos;

• Improving the supply of eco-friendly Auto-rickshaws – Through mobilising, training, capacity building and structuring of driver organizations so as to equip them as a community to make the shift, building financial instruments for green-autos, facilitating better financing options, building a positive image for drivers

• Facilitating a favourable policy environment – Work with policy makers to assess the policy and regulatory gaps, support the transport department with knowledge sharing and capacity building activities, dissemination of the research findings to stakeholders at large.

Research Paper

THE SHIFT TOWARDS SMART CITIES IN SOUTHEAST ASIAN CITIES

The Role of Urban Governance

Thibault PILSUDSKI, SEC-FCL; Singapore
Si Ying TAN, NUS-LKYSPP; Singapore
Devisari TUNAS, SEC-FCL; Singapore
Fabien CLAVIER, SEC-FCL; Singapore
Andrew STOKOLS, SEC-FCL; Singapore
Araz TAEIHAGH, NUS-LKYSPP; Singapore

Abstract

Smart cities utilise technological and digital solutions to resolve urban issues, to enhance accessibility of services, and increase the quality of life (ASEAN, 2018). In 2018, Singapore leveraged its ASEAN presidency to initiate the ASEAN Smart Cities Network to develop a collaborative forum to improve translation of smart technologies between ASEAN cities by exploring potential synergies and complementarities, developing tailored action plans and sharing best practices. However, the translation, adoption and implementation of technologies across unique geographical, developmental and governance contexts vary substantially (Taeihagh, 2017). Without sufficiently understanding these variations, the translation process will likely fail. To understand these variations and their implications for city governance, we seek to unpack the different institutional forces that shape the adoption and implementation of such technologies. The paper aims therefore to identify key aspects of urban governance that guide the adoption and implementation of smart city technologies, by questioning (1) the drivers for smart city adoption, (2) the origin of policy ideas, (3) the factors hindering or facilitating their local translation, and (4) the impact of smart city development on city-level governance. This paper is part of an ongoing research on smart cities in Indonesia.

Keywords

Smart City, Southeast Asia, Policy Capacity, Policy Mobility, Policy Entrepreneur

1. Introduction

Much literature on smart cities development typically considers it as a technical or managerial issue (Meijer & Bolívar, 2016), focusing on the potential of specific technologies to improve management or planning in cities, but rarely examining the role of governance and the social and political constructions that hinder or facilitate the adoption of new technologies in city government or planning processes. Taeihagh and Lim (2018) claim that the term 'smart city' has emerged as a new concept amidst the acceleration of competition among cities for businesses and talent, which has driven cities to place more emphasis on

the development of engineering solutions and economic feasibility for achieving desired urban development goals. Nevertheless, the conceptualisation of smart city development needs to go beyond technological solutionism, and be acknowledged as a complex social system that entails many wicked problems and competing interests (Kitchin 2016). Furthermore, Kitchin (2015) also emphasises the lack of empirical studies and contextualised comparative cases on smart cities. There is also a need to understand what the reality of deploying smart systems means for the vast majority of emerging cities in the global south, especially Asia.

This paper compares the development of smart city in two Indonesian cities; Bandung and Jakarta, which have both been at the forefront of smart city development in Indonesia since 2013-2014. It is a first step towards the creation of a framework that can be used to systematically analyse the interplay between urban governance and smart cities development in ASEAN. This will be achieved by drawing theoretical literature from public policy which include the Multiple Streams Framework (MSF) (Kingdon, 1984), instrument constituencies (Voß & Simons, 2014), policy mobility (McCann, 2011), policy capacity (Wu et al., 2015), or policy ideas (Cox & Béland 2013), to investigate the roles of political leadership, institutions, policy capacities, and policy ideas in the adoption and development of smart cities.

This paper draws upon several fieldworks in Bandung and Jakarta in 2018-2019, including semi-structured interviews conducted with key actors in the municipality departments as well as external actors involved in Bandung and Jakarta smart cities; from university, private sector and non-governmental organisations. This information was supplemented by analysis of government reports, official presentations during conferences, twitter accounts, and national newspapers (in English and Indonesian).

The fielworks were preceded by a literature review of some relevant policy concepts to analyse smart city adoption and translation, and contributed to the elaboration of the following questions that will structure this paper: (1) What are the drivers for smart city adoption and how are policies for smart city development formulated? (2) Where do the policy ideas and inspirations come from? (3) How is it translated locally and what are the factors facilitating/hindering policy adoption? (4) How does the smart city development agenda affect as well as inform city-level governance? Our findings are aimed at helping both government and non-government actors such as technology producers, city authorities, and multilateral funders to develop practice insights and policy recommendations to achieve the goals for smart city development.

2. Literature Review

The following section intends to introduce the literature on MSF, policy entrepreneur, policy mobility, instrument constituency, and policy capacity as analytical frameworks for our case studies. The MSF was developed by Kingdon (1984) to understand why some ideas are captured by policy-makers and make it to the agenda setting, while others do not. The MSF does not think that human beings are rational actors, hence policy-makers are incapable of making the best policy decisions by picking the best solutions uniquely crafted for a policy issue (Cairney, 2018). Instead, Kingdon postulates that policy problems, policy solutions, and politics, each constitute an independent process, or stream, and at the same time, they

could also form intermingling forces that influence one another in the policy process. Eventually, at a specific point in time, a policy window opens allowing the coupling of the three streams. This coupling can be realised by a policy entrepreneur, who "invest his resources, time, energy, reputation, money to promote a position in return for anticipated future gain" (Kingdon, 2011). When a window opens, policy entrepreneurs will push their policy proposals ("pet projects"), attempting to couple it with the two other streams. While the focus of Kingdon's studies was on the domestic political context of the USA, the MSF literature has since then evolved, with Bache & Reardon (2013), for instance, emphasising the importance of international networks for the development of ideas in the policy stream. Lovell (2016), who studied smart metering policy in Australia, also found that MSF would be better supplemented with theoretical insights from policy mobility as ideas move easily across national boundaries.

In the examination of smart city development, it is also important to examine how policy ideas are transported from one jurisdiction to another when cities learn from one another in their respective quest to be 'smarter'. In this respect, it is relevant to investigate how the concepts of policy mobility and policy transfer play a part to facilitate this process. Policy mobility differentiates itself from policy transfer by questioning the state-centredness of traditional policy transfer literature and its "implicit literalism" that suggests the importation of fully formed policies (Peck & Theodore, 2001). It also focuses much more on interurban "transfers" of ideas. In this context of international policy mobility where policy ideas travel between cities, policy entrepreneurs are assumed to be "searching globally for best practices to embrace, "cutting-edge" cities to emulate, and "hot" experts from whom to learn (Peck & Theodore, 2008). They tap into and utilise extralocal connections — ranging from official intergovernmental alliances to individual relationships with colleagues elsewhere — to learn about policy models and physically bring experts to the city to inform locals about cutting-edge policies."

In another addition to the MSF, Voss and Simons (2014) developed further on the network of actors behind transnational policy stream with the concept of instrument constituencies. It is defined as a transnational network of heterogeneous actors that "stay united because of their common "fidelity" not to a political agenda or defined problem but rather to their advocacy of a particular instrument(s) as a superior technique of public governance" (Béland & Howlett, 2016). In the context of smart city development in Indonesia, we apply this concept to focus largely on domestic actors who possess international experiences and are open to transboundary and cross-jurisdictional policy learning, as well as staying committed to a common goal of elevating the city's development through the deployment of various policy instruments.

Finally, we complement these concepts with policy capacity to explain the ability of city governments to receive and implement new ideas. Proposed by Wu et al. (2015), policy capacity is defined as a function of three sets of skills and competencies (political, operational, and analytical) at three levels of resources and capabilities (systemic, organisational and individual). In Wu et al.'s conceptualisation, political capacity is associated with having the political acumen to steer the overarching governmental functions towards goal attainment by asserting one's authority and by building public's trust towards the government. Operational capacity, on the other hand, pertains to the ability of government to roll-out policy effectively. Analytical capacity boils down to the bolts and nuts

of policy-making. In particular, it relates to the ability to apply technical knowledge to design and implement policies in the most efficient and cost-effective manner.

3. Comparative Analysis of the Role of Urban Governance in Smart Cities Translation in Bandung and Jakarta

Jakarta and Bandung have been widely recognised nationally and internationally as the pioneers of Smart City in Indonesia. Jakarta, the capital of Indonesia, with a population of over 10 million (2017) (BPS, 2018), and Bandung, the capital of West Java Province, with a population close to 3 million (2017) (BPS Kota Bandung, 2018), and their urban surroundings form one of the largest urban agglomerations in Southeast Asia. Faced with challenges of rapid urbanisation, population growth and increasing urban complexities, authorities in both cities have been actively exploring various technical and policy solutions to help them address the issues.

Due to the decentralisation policy that has been implemented beginning after Suharto's departure in 1999, the role of central government in directing local planning and development has been increasingly superseded by local mayors. Decentralisation has also led to divergence between certain successful "superstar" cities and regions and cities with less capacity, in Indonesia (Firman, 2014, Von Leubke, 2009) as is the case in other countries. The recent development directions in Indonesian cities and regencies, including in Jakarta and Bandung, could be attributed to the presence of strong and charismatic leadership at the local level. For example, the development of smart cities in Indonesia are largely driven by the local leadership, such as Basuki Tjahaja Purnama, the former Governor of Jakarta and Ridwan Kamil, the former Mayor of Bandung, who has since been elected as the Governor of West Java. Purnama previously had a short stint of political career as the Regent of Belitung regency (2005-2007) before pairing up with Joko Widodo in Jakarta's gubernatorial campaign. He was elected as Vice Governor, and subsequently replaced Widodo as Governor when the later was elected as President. Kamil meanwhile, came from non civil-servant background; he was a planning practitioner and academic prior to his political career.

3.1. The Drivers behind the Smart City Adoption

In both Jakarta and Bandung, the role of policy entrepreneurs has been instrumental, and this is represented by their strong local leadership that spurs the adoption of smart city development. We use the MSF to unpack the roles and influences that policy entrepreneurs, Kamil in Bandung and Purnama in Jakarta, have exerted in smart city adoption, and their framings of the problem.

Bandung

In Bandung, even though the smart city is mentioned briefly in some presentations during the preceding Dada Rosada mayorship, it was Kamil who launched the concept as one of his campaign promises in 2013 when he was running to become the mayor of Bandung (Ispranoto, 2013 September 14). Kamil decided to enter the municipal campaign quite late, only eight months before the election. Though without political experience, Kamil had been active in the policy circle since 2008 through the Bandung Creative City Forum (BCCF), a non-profit organisation, which he created with a network of like-minded individuals to promote

the concept of creative city. He worked as the first president of the forum, which gave him sufficient visibility that paved the way for his entry into politics (Mada, 2015 November 6). The mayor election opened a window of opportunity in the political stream, but also in the problem stream since the former mayor was being tried for corruption and ultimately charged with a 10-years prison sentence. Coming from the BCCF, Kamil could have framed existing city problems to couple it with his creative city solutions. But vehicular ideas like the creative city "serve to make things happen at a particular time, after which their time may be up" (McLennan, 2004). Having been advocated since the last five years, keeping the creative city concept on top of the city agenda could have led to the risk of the idea becoming quickly outdated. By framing the smart city as a solution for greater transparency, efficiency and accountability, the smart city narrative also allowed Kamil to capitalise on a contemporary policy idea that has taken root in many other countries as a means to strengthen city-level governance.

Jakarta

In Jakarta, smart city development has been credited to Purnama. He began working on the Jakarta's smart city programme during his vice governor position under Governor Widodo. Both set a new impulse in the city's management, aiming at improving public service and transparency (Wardhani, 2014), by setting up a transparent communication system to make it more accessible for the citizens to file for complaints against lapses in public services. When Widodo became president in 2012, and left Purnama with the position of governor, it opened a window of opportunity for Purnama to push the concept of smart city to be a central agenda in Jakarta to promote transparency and a greater efficiency. As the scale of complaints was too difficult to be managed by short message service (SMS), upgrading to a system that would better handle these complaints appeared to be a natural development for the government to be more responsive to the citizens' feedback. Cox & Béland suggest that skilled policy entrepreneur have "an intuitive sense for which ideas fit a newly opened policy window" (2014). In line with that, we argue that it is also a major quality of a policy entrepreneur to be sensitive enough to determine the gaps in addressing the needs of citizens, and when a policy idea that fill this gap would likely take off. In the case of Bandung and Jakarta, Kamil and Purnama have been able to sense that smart city's time has come for Indonesia, and this acumen has propelled Bandung and Jakarta to be the first-movers of smart city adoption at the national level.

3.2. Inspirations for the Smart City Visions

The smart city is an urban concept, similar to the creative city or the sustainable city. Policy mobility studies consider these concepts or ideas to be in continuous transformation and mutation (Peck, 2011) along their journey. In a policy mobility context, policy entrepreneurs, depending on their background and network, can play a key role as agent of translation for policy ideas.

Bandung

In the case of Bandung, Kamil appeared to have been the main translator of the smart city concept. Building on his overseas experiences through his studies at UC Berkeley and his urban design projects abroad as an architect (in Singapore, Thailand, Bahrain, China, Vietnam, United Arab Emirates), Kamil was able to draw on his own experiences to push for

the development of a smart city in Bandung. Among various illuminating examples, Singapore stands out as a model, with Kamil mentioning in a 2017 interview with GovInsider that "Bandung is designed to be as competitive as Singapore, as modern as Singapore," but will retain its "strong traditions as Bali. A combination of Bali and Singapore – that will be my Bandung vision" (Chambers, 2017 April 11). This particular mention for Singapore nevertheless never materialised in a close cooperation for the development of Bandung Smart City. A more tangible source of inspiration for Bandung was Rio de Janeiro's Operations Centre developed by IBM in 2010 (Paschoal & Wegrich, 2017), as this directly influenced Kamil's decision to initiate the Bandung Command Center. While IBM was involved through a "rush engagement" rather than a solid partnership (Labtek Indie, personal communication, April 2nd, 2019), there was never any form of cooperation between Rio and Bandung. Kamil was in this case the main agent of translation; tapping into a globally referenced case and adapting it to the local situation.

Figure 1: Launched in 2010 with the help of IBM, the Rio Operation Centre became a typical case study for Smart City. Retrieved from: http://icities4greengrowth.in/casestudy/rio-de-janeiros-operations-centre-rio-de-janeiro-brazil

Jakarta

In Jakarta, Purnama did not benefit from an international career to provide him a wide range of urban experiences. He had apparently adopted a more 'agnostic' vision of the smart city, and appeared to be receptive towards new ideas as long as they make sense. However, when discussed inspiration models for Jakarta, Singapore, as for Bandung, once again appeared at the forefront and became a model that Jakarta was seriously contemplating to emulate. As Purnama said in an interview; "Let's be honest, if we want to take the example of another city, we can imitate Singapore. We cannot imitate European cities; it's different. Europe has existed for hundreds of years. Their development was conducted in the 1800s" (Wardhani et al., 2015 November 19th). But he also looked at other developed Asian cities like Tokyo and Seoul (Chambers & Basu, 2016). If like in Bandung, the prominence of the Singapore model did not exert a strong influence in the smart city adoption process in Jakarta, it does shed some light on what McCann calls "city upon hills" (McCann, 2013; Cohen, 2015), which refers to a small cluster of cities of which stories are always presented, policies compared, or situation benchmarked. In the context of the new ASEAN Smart City

Network, it will be interesting to see if Bandung or Jakarta would eventually achieve such statuses and manage to become prominent examples for other followers in the smart city movement.

3.3. The Local Translation of the Smart City

While no transnational instrument constituency appeared to be strongly influencing the creation of the smart city in Bandung and Jakarta, both cities initiated the creation of a local instrument constituency around the smart city concept, and this has directly influenced policy capacity at different levels.

Bandung

A first step in the creation of a smart city constituency in Bandung was through a workshop conducted in September 2013, which paved the way to the subsequent creation of the Smart City Council over the following months. The Smart City Council gathered lecturers from ITB, municipal departments, officers from Telkom Indonesia, and technology entrepreneurs (Labtek Indie, personal communication, April 2nd, 2019). Even though these actors possessed diverse backgrounds, i.e. business, academia or political party, they become members of an instrument constituency through their common practices, interests and visions that centred around the development of smart city in Bandung (Voss & Simons 2014). The involvement of multiple stakeholders with various backgrounds, training and experiences contributes significantly to the *operational* capacity of the city. Besides, the Bandung Command Center, which was inaugurated in early 2015, also represents an effort to increase the *operational* and *analytical* capacity at the organisational level by encouraging agencies to coordinate better as well as to produce, share and disseminate more evidence-based policies. It was also a strategy, recognised as a "quick win" by local actors to increase visibility and trust from citizens (Bappelitbang Kota Bandung, personal communication, April 1st, 2019), which directly strengthen the *political* capacity of the government in Bandung. In a 2015 interview, Kamil also pointed out at external socio-demographic factors that also played a role in facilitating the smart city initiative; such as the more than 50 higher education institutions, and the fact that 60% of the population is under 40-years old, underpinning the potential of Bandung as an "educational, technological and creative hub" (Oxford Business Group, 2015).

Jakarta

In Jakarta, Purnama set from the beginning a very strong management style that make it clear to the citizens that his administration will not tolerate any forms of corruption and indolence (Chambers & Basu, 2016 April 27th). And he indeed fired about half of the officials in his first two months. But he also increased wages to attract the brightest talents and set a specific Smart City Team, which increased both *operational* and *analytical* capacities of his administration. Purnama also introduced an application; CROP, to monitor the performance of his officials in responding to citizen complaints. While this was met with opposition within the bureaucracy and the Jakarta Council, it sent clear signals to private companies that business is now easier because of increased transparency and efficiency (Jakarta Smart City, personal communication, May 5th, 2019). The city also purposely encouraged startups to join the smart city initiative, which led to the growing importance of Qlue, an application first designed to answer public complaints more efficiently. Through the Jakarta Disaster

Mitigation Agency (BPBD), the city collaborated with the University of Wollongong, Australia, and Twitter, to create an application mapping the floods, increasing the city's disaster responsiveness. These various collaborations with non-governmental actors contributed to a greater *operational* capacity, which also led to the creation of an instrument constituency on the smart city in Jakarta. Similar to Bandung Command Centre, the Jakarta Smart City Lounge was launched in 2015, symbolising the structural promises of a more evidence-based, transparent and less-siloed government.

Policy capacity at different levels		**Examples in Bandung and Jakarta**
Analytical capacity	**Individual**	Training of existing staff and use of external consultants in **Bandung** and hiring of highly-skilled employees in **Jakarta**
	Organisational	Sharing and use of systematically created data encouraged
	Systemic	High number of universities in both cities, and additionally in **Jakarta** high number of international businesses
Operational capacity	**Individual**	New managerial style, increased transparency and accountability
	Organisational	Coordination amongst agencies encouraged
	Systemic	Collaboration with associative networks (ex: BCCF) and universities (ex: ITB) in **Bandung**, collaboration with startups (ex: Qlue), multinationals (ex: Google-Waze), universities (ex: Wollongong) in **Jakarta**
Political capacity	**Individual**	**Kamil** and **Purnama** as policy entrepreneur
	Organisational	Newly established dialogue with citizens, mostly through social media
	Systemic	Increased trust in public institutions through transparency and accountability

Table 1: The policy capacity in Jakarta and Bandung in smart city development

3.4. The Impacts of Smart City on Urban Governance

If Kamil and Purnama have been instrumental in the development of smart city in their respective city, they are no longer in command; Kamil left his position of mayor to become governor of West Java in 2018, while Purnama was defeated in the 2016 election. This invites a first reflection on the sustainability of the changes they made in urban governance.

Bandung

It remains difficult to judge if the policy window that Kamil opened for a smart city in Bandung remains viable or not. In his study on the former mayor of London Ken Livingstone and his road congestion pricing policy, Dudley (2013) was able to map the opening of the window and its closing once the project was implemented. For Bandung Smart City, it seems that the window is still open. Kamil's smart city programmes was formalised in Bandung Long Term Development Plan 2014-2018. Some of the action plans are still being implemented to date. A web portal has been launched at the end of 2018 to summarise all the smart city actions happening in Bandung, as well as a City Dashboard to communicate on simple statistics about the different city neighbourhoods. Furthermore, Kamil is now extending this policy window at the regional level as he acceded to the post of governor for the West Java Province in 2018, aiming to transform the region into a Smart Province. But the current mayor of Bandung, Oded Muhammad Danial, who took office in 2018, appears to be less active prioritising smart city development. This was indicated in the limited mention of Smart city in the final draft of Bandung Long Term Development Plan 2018-2023 launched under his leadership. While the preceding document set out the Smart City programme in great detail, the current document, albeit stating a specific goal to improve Bandung's Smart City Maturity ranking (by adopting a set of indicators developed by the local university), did not set out any detailed action plans on how to achieve it, apart from mentioning the need to integrate all existing digital platforms (Bandung RPJMD Final Draft 2018-2023). Similarly, the Smart City Council that was active at the early stage of the smart city, did not turn into a long-term exchange forum by meaningfully engaging various stakeholders who are committed towards smart city development. While some key stakeholders are still working on the smart city domain (i.e. university, associations, government), there is a lack of common vision that could constructively advance the current state of smart city development. However, some of Kamil's legacy that was launched under the guise of smart city has appeared to be enduring. Notably, public agencies continue to report and update their activities on Twitter regularly (Bappelitbang Kota Bandung, personal communication, April 1st, 2019), a newly established dialogue with citizens through social media has been rolled-out, and increased coordination among various agencies to address collective problems has been observed.

Jakarta

In Jakarta, more clearly than in Bandung, the enthusiasm for smart city at the highest leadership level has cooled down since the change in leadership with Anies Baswedan replacing Purnama in 2017. While the city administration still includes a special Smart City task force under the City's Information and Communication Department (the team comprises external and highly skilled non-tenured civil servant.) that is active and fully functioning, the new mayor is reported to be less inclined to promote Jakarta as a smart city, which is often seen as a legacy of his predecessor. Under his leadership, Jakarta joined the 100 Resilient City, which could put the smart city concept secondary to the concept of resilient city. His effort to rebrand Jakarta to cast away the shadow of his predecessors led to some unintended consequences that could potentially undermine the analytical capacity of his administration. For instance, Setiaji, the head of Jakarta Smart City, has decided to leave the city's administration to join Kamil in West Java. However, Sandiaga Uno, who was the vice governor of Baswedan before running for the presidential election, has recognised the

important steps taken by Purnama earlier in promoting public service efficiency and improving citizens' trust towards the government (Chambers, 2017 May 11th). The new governor is also continuing to push agencies to work together, while the deputy governor of Jakarta for planning, Oswar Muadzin Mungkasa has insisted on the active engagement with the citizens from the bottom-up (Centre for Liveable Cities, 2019). But the rigid rules within the existing bureaucracy remain as a barrier for the development of the city's capacity. For instance, it remains difficult to recruit programmers or data analysts because they often do not meet the rigid criteria to have prior similar job experiences (Jakarta Smart City, personal communication, May 5th, 2019). Even though Jakarta and Bandung are two of the most bustling administrative and commercial hubs in Indonesia and have so far taken the lead in smart city development, to date, a national-level initiative that regulates the legal and governance issues that could arise from smart city development is still lacking. Despite the launch of the urban digitisation programme such as "100 Smart Cities" in 2017, there remains ample room for smart city regulatory frameworks to be firmed out to improve the governance of smart cities in Indonesia.

4. Discussion - Conclusion

This paper is a first step to analyse smart city in ASEAN in regards to urban governance. We have identified five policy concepts that appear to be relevant; the MSF, policy entrepreneur, policy mobility, instrument constituency and policy capacity. These could be complemented by a network analysis to identify peripheral actors and policy brokers (Howlett et al., 2017) and to examine their roles as well as their relation to policy entrepreneurs. This initial framework will also be tested on a third city; Makassar which is also a city within the ASEAN Smart City Network but possessing very different contexts from Jakarta and Bandung. For instance, the city does not benefit from the same pool of talents as compared to Jakarta and Bandung, which might hinder its analytical capacity. It seems however, that the former mayor of Makassar; Mohammad Ramdhan Pomanto, did play a policy entrepreneur role, like in Jakarta and Bandung. Kamil and Purnama, through their new management style; a shift from a hierarchical and bureaucratic to a more accessible and engaged leadership (Zaenudin & Suwatno, 2017), have indeed contributed to the heightening of public's trust towards the government strengthening political capacity at systemic level.

The analysis of smart city in two indonesian cities through the lens of urban governance and public policy study, allows a preliminary conclusion on the functional and structural promises of smart city and more precisely smart planning. From a functional point of view, the smart city development in both Jakarta and Bandung has enhanced administrative management abilities and responsiveness towards city problems such as floods, or slight optimisation of traffic issues. However, it did not materialise in an enhanced ability to conduct long term planning. What it did more successfully is, from a structural point of view, to reshape the city-level governance. Indeed, in both cases, the smart city concept was a window of opportunity to introduce new management styles and promoting transparency; through regular reporting of agencies on social media for instance, accountability; through official performance monitoring app like CROP in Jakarta, or increased cooperation between agencies in sharing data, but also involving external partners; citizens, startup like Qlue or universities like ITB in Bandung, and Wollongong for Jakarta.

In both cities, the smart city development does not move as fast as it used to be, and this is partly driven by change of leadership, with the new mayor of Bandung and governor of Jakarta less enthusiastic in advancing a policy idea that appears to be more representative of their predecessors (BCCF, personal communication, April 3rd, 2019; Jakarta Smart City, personal communication, May 5th, 2019). In addition, there is also a sentiment within current administration that most of the major steps have been taken, and that the rest has more to do with long term implementation and consolidations of the various initiatives (Jakarta Smart City, personal communication, May 5th, 2019). The recent national initiative of "100 Smart Cities" or the ASEAN Smart City Network that are bringing new momentum for smart city development, could nevertheless give a strong incentive to Jakarta and Bandung to put efforts to maintain their prestigious status as well as to act as examples for lower-sized cities. Some like the CEO of Qlue, Rama Raditya, actually consider that the smart city potential has been largely untapped. For him, Jakarta is still far from being smart, since "ideally, a smart city must be built from scratch with cutting-edge technological infrastructure, from undergrounds pipes that are equipped with IoT to street lights that have been installed with live sensor technology" (Putera, 2019 April 9th).

Perhaps this is an opportunity to pause and think about the future; does a smart city needs to be more equipped with cutting-edge technology like Raditya has suggested? Or could a smart city espouse a more low-tech approach (Urbanités, 2018), whereby the aim of smart city development is less on techno-solutionism but more on using innovative tools to increase government's responsiveness and efficiency in solving policy problems by actively engaging the citizens and other important stakeholders in the society.

Research Paper

Future Urban Mobility Development Framework to Maximise Benefits of Plug-in Electric Vehicle Penetration in ASEAN Countries

Alloysius Joko PURWANTO, Economic Research Institute for ASEAN and East Asia

Dian LUTFIANA, Economic Research Institute for ASEAN and East Asia

Abstract

Several Association of Southeast Asian Nations (ASEAN) members have recently developed strategies for low carbon-emission mobility to decrease oil import dependency. The strategies emphasise, amongst others, the importance of removing obstacles to electrification of transport and promoting market development of road plug-in electric vehicles (PEVs). Concerns about the impacts of PEV penetration include how to ensure that (i) electricity used to feed the vehicles will be produced mostly from renewable energy sources to lower carbon emissions, and (ii) additional electricity demand will not put additional stress on urban electricity grid systems.

We deduce two recommendations. First, because they use fossil-fuel energy-intensive electric power, ASEAN countries need to increase urban density and compactness and stop urban sprawl, which will minimise energy use in transport, including PEVs. Generalised PEV travel cost will continue to decrease as new technology is increasingly adopted and the use of PEVs becomes more widespread. Only when a country develops renewable energy to generate electricity, such as through home-based solar photovoltaic systems, can it relax its policies on urban sprawl. Second, ASEAN countries need to avoid putting stress on the electric power grid and to maximise the use of renewables to generate power. Integrating these objectives will help determine the location of charging facilities and the measures to support mobility.

Keywords

Electric vehicles, urban mobility, renewable energy, smart city, ASEAN

1. Introduction

Understanding key mobility trends is crucial to implement the sustainable development agenda. To meet the needs of growing urban populations, many countries face challenges related to housing, transportation, energy systems, and other infrastructure. More than 50% of the world's population lives in urban areas; that share is expected to increase to 68% by

2050. About 90% of this increase will take place in Asia and Africa (UN Data, 2018). Between now and 2030, the number of city dwellers in East Asia Summit countries is projected to rise from roughly 500 million to 900 million. Asia is already home to 54% of the world's urban population. The arc of urban development leans towards continuous growth, resulting in the rise of 43 megacities (with populations over 10 million) by 2030 (UN Data, 2018). At this rate, urbanisation will significantly increase demand for energy to support greater economic activity, expanding urban infrastructure, and the rising need for municipal services. As of 2018, urban areas accounted for 65% of global energy demand and 70% of energy-related CO_2 emissions (Bačeković and Østergaard, 2018).

Electric vehicles (EVs) can help mitigate climate change if they are powered by renewable energy (Chan and Wong, 2004). As part of their commitment to limit temperature rise below 2°C under the Paris Agreement 2015, several Association of Southeast Asian Nations (ASEAN) members set strategies to decrease oil import dependency, including by promoting EVs. ASEAN countries must remove several obstacles to EV penetration and promote market development of plug-in electric vehicles (PEVs), especially cars, powered two-wheelers, and light-duty vehicles (LDVs) or vans. However, EV penetration faces several barriers such as lack of charging stations, long charging time, and EVs' distance range, which all reduce driving mileage. As battery pack costs decrease, however, generalised costs of EV trips are becoming lower than those of internal combustion engine vehicles (ICEVs), which might increase vehicle mileage.

Promoting PEVs should not give rise to climate-change issues. Stakeholders must ensure that the electricity used to feed the vehicles is generated mostly from renewable energy sources, and that additional electricity demand will not increase stress on urban electricity grid systems. The charging management scheme will affect mobility patterns. This paper proposes a framework for future urban mobility in ASEAN countries, which will maximise the benefits of PEV penetration in urban areas.

First, the paper introduces current PEV promotion policies in several Asian and ASEAN countries, their targets, and their progress in deploying vehicles and charging infrastructure. The paper then presents several preliminary assessments of PEV penetration impacts, especially in relation to carbon-emission reduction and the load on the urban power grid. Based on several case studies of urban regions around the world, the paper elaborates the effects of EV penetration on mobility patterns by taking into account (i) PEVs' limited driving range, (ii) PEVs' required charging time, (iii) location of charging stations, and (iv) points and energy sources used to generate electricity. Finally, the paper recommends ways to develop ASEAN urban areas, especially those related to how mobility can maximise the benefits of PEV penetration.

2. Electric Vehicle Penetration in Some Asian and ASEAN Countries

2.1. Policies and Current Progress

Electric mobility is developing rapidly. The global electric car fleet is estimated to exceed 5.1 million, which is 2.0 million more than in the previous year and almost double the previous sales of new electric cars (IEA, 2019). The number of EVs is estimated to have almost tripled globally since 2005 (Raposo Alonso et al., 2019).

China is the world's largest market for electric cars, with nearly 1.1 million sold in 2018 and, with 2.3 million units, accounts for almost half the global electric car stock, followed by Europe (1.2 million) and the United States (US) (1.1 million) (IEA, 2019). China started in 2009 with the '10 cities, 10,000 vehicles' business model to promote PEV development, but established targets only in June 2012: 500,000 vehicles by 2015 and 5 million by 2020. China aims to reach new EV sales shares of 7%–10% by 2020, 15%–20% by 2025, and 40%–50% by 2030 (Marklines, 2017).

Five business models were created in the pilot cities: state leadership in Beijing, based on public sector support; platform-led business in Shanghai, replicating international models; cooperative commercialisation in Shenzhen, based on a leasing model through strategic partnership; flexible rental in Hangzhou; and fast-charging models in Chongqing, which is close to the Three Gorge Power Grid.

In Japan, a leading EV market, government support for battery-powered EV (BEV) development started in the early 1970s. Strong government commitment to promoting EVs is reflected in heavy emphasis on research on and development of vehicle and component technologies, infrastructure, and market support for EV users. The Ministry of Economy, Trade and Industry funded the Clean Energy Vehicle Introduction Project, which provided subsidies and tax discounts for purchasing EVs (InsideEVs, 2013).

In 2017, Japan's EV production ranked fourth in the world at around 8%, after China (50%), Europe (21%), and the US (17%) (Lutsey et al., 2018). The government works with industrial stakeholders to reduce by 80% greenhouse gas (GHG) emissions from domestically produced vehicles (by 90% for passenger vehicles), including exported vehicles, by 2050 with a combination of hybrid electric vehicles (HEVs), BEVs, plug-in HEVs (PHEVs), and fuel cell EVs. Under the new policies scenario, Japan targets increasing EV sale share of all modes (excluding two- and three-wheelers) by 21% and scaling up to 37% market share under the EV30@30 scenario in 2030. To provide more charging stations throughout Japan, in 2018, the government set the goal to have fast chargers every 9.3 miles (15 km) or within every 19-mile (30 km) radius (InsideEVs, 2018a). Japan's success in the EV market is due to government commitment, strong support from the automotive industry, and user-friendly infrastructure.

The Government of India, in 2013, established the National Electric Mobility Mission Plan 2020 and, in 2015, enacted Faster Adoption and Manufacturing of (Hybrid &) Electric Vehicles in India or FAME India. The government has announced its intention to move towards all-EV sales in 2025–2040 and, through EV30@30, to ensure that EVs will account for at least 30% of all vehicle sales by 2030 (Lutsey et al., 2018; IEA, 2019). All vehicles, including two-wheelers, are targeted for electrification. EVs have penetrated the LDV and urban bus markets, accounting for 14% of all passenger cars and LCVs and 11% of all bus sales (IEA, 2019). As a member of the Electric Vehicle Initiative, India is dedicated to accelerating the deployment of EVs.

Delhi, the capital, will be amongst the first cities in India to fully support vehicle electrification by 2023. The Draft Delhi EV Policy 2018 aims to improve Delhi's air quality by driving rapid adoption of BEVs so that they contribute to 25% of all new vehicle registrations by 2023 (InsideEVs, 2018b).

Only two ASEAN countries produce and commercialise PEVs – Thailand and Malaysia. Thailand's first PEV development roadmap – the Electric Vehicle Promotion Plan – was approved by the government in March 2015. In 2017, the Board of Investment (BoI) approved incentives for manufacturers of BEVs, HEVs, and PHEVs, mostly in the form of corporate tax exemptions for 5–8 years. The project to develop next-generation automotive vehicles, focusing on PEVs, was included in the Eastern Economic Corridor, approved in February 2018, to spur investment. In March 2019, the BoI agreed to renew the investment package for HEVs to attract more investment to PEV production. Investors must apply to produce HEVs in 2019 and assemble BEVs within 3 years. HEV and PHEV sales rose by 24.7% in 2017 to 11,945 units whilst BEV sales reached 165 units (Nicholls et al., 2018). All vehicles sold in that year totalled 870,748 units. By 2036, Thailand targets having 1.2 million electric cars on its streets and setting up 690 charging stations.

Malaysia started its PEV programme earlier than Thailand. In 2011, the government exempted from excise duties and import taxes completely built-up, fully imported hybrid cars to encourage manufacturers to invest in PEV production in the country. After the policy failed to boost foreign investment, the government abandoned it in 2014 and extended it only for completely knocked-down models assembled in Malaysia. The government now prefers to deal with manufacturers individually, a strategy that appears to work with several foreign original equipment manufacturers.

A recent tripartite agreement between TNB Energy Services Sdn Bhd (TNBES), Petronas Dagangan Bhd (PetDag), and GreenTech Malaysia resulted in the installation of 100 charging stations across the country by 2018. By the end of 2018, 251 PEV charging stations had been built across the peninsula (Weng, 2019). GreenTech Malaysia is under the purview of the Ministry of Energy, Science, Technology, Environment and Climate Change to spearhead the development and promotion of green technology as a strategic engine for socio-economic growth in line with the Green Technology Master Plan 2017–2030. The number of new registered hybrid vehicles, including conventional HEVs and, in recent years, PHEVs, increased from 138 in 2010 to more than 9,000 in 2017. Malaysia aims to build 125,000 charging stations by 2020.

In the second half of 2018, the Government of Indonesia was to have issued a presidential decree on deploying EVs but it has not yet materialised. Despite the lack of a formal development framework, the Ministry of Industry told a newspaper that the government would target sales of 400,000 EVs by 2025 to reduce GHG emissions by 29% by 2030 (Akhyar, 2019). One source mentions that 400,000 PEVs would be produced domestically by then. Other sources estimate that around 2 million electric-powered two-wheelers would be sold by 2025. Jakarta has around 1,000 charging stations, built by the PLN (State Electricity Company).

2.2. Impacts of PEV Penetration on Reducing CO_2 Emissions

Unless power generation is decarbonised, the effect of reducing BEVs' CO_2 emissions will be limited in Thailand, Malaysia, Viet Nam, and Indonesia, which are largely dependent on coal- and, to some extent, gas-fired power plants. Transitioning from ICEVs to EVs would be a huge advantage (Suehiro and Purwanto, forthcoming).

PEV penetration would not much change the energy self-sufficiency ratio of those countries since the decrease in imports of petroleum products used as transport fuel, e.g., gasoline and diesel, would be cancelled by increasing imports of coal and natural gas used to generate electricity. PEV penetration would, however, considerably improve those countries' import bills. The generous subsidies needed for PEV penetration and the large investment in low-carbon power supply might put pressure on government finances (Suehiro and Purwanto, forthcoming).

2.3. Impacts of PEV Penetration on the Urban Power Grid

ICEV users benefit from well-established refuelling station networks nearly everywhere. In contrast, PEV charging infrastructure is in its early development stage, especially in ASEAN countries.

The expansion of PEVs and their demand for charging facilities have become increasingly important. The associated electricity demand will affect energy markets and the grid infrastructure. Studies on Portugal (Nunes, 2015) and the European Union (Kasten and Purwanto, 2016) show the impact of PEVs on the power grid once they make up 5%–10% of total road vehicles.

PEVs' environmental performance is better than conventional vehicles' when additional electricity demand is met by a low-carbon energy mix (Suehiro and Purwanto, forthcoming). China, the PEV front runner in Asia, is struggling to curb its share of coal-fired electric energy from 75% to 50% and to increase that of renewable sources from 25% to 50% by 2030, bringing down power generation carbon intensity by one-third and ensuring that PEVs will be less carbon intensive than they are now. China uses more electricity from coal-fired generating plants during fast-charging peak demand periods and after working hours in the evening. Slow charging during off-peak hours, when energy from renewables such as wind turbines is available, would reduce CO_2 emissions (Chen et al., 2018).

When and how PEVs are charged determine which generation plants satisfy additional electricity demand and have an impact on emissions. Depending on their total system and marginal costs, different types of power plants may increase production. Including this charging scheme in the analysis might change the calculation results.

Uncontrolled or user-driven charging occurs mostly after work in the evening, when electricity demand is already high, increasing system load and costs of utilities (Brandmayr et al., 2017). User-driven charging raises severe concerns about generation adequacy and may jeopardise the stability of the power system (Schill and Gerbaulet, 2015). Fast-charging stations use large amounts of power for short periods of time, meaning that expensive upgrades will be needed for a relatively low use rate (Hall and Lutsey, 2017). In the US, if PEVs constitute 25% of all road vehicles, uncontrolled charging will increase electricity peak demand by 19%, but spreading charging over the evening hours will increase demand by only 0%–6% (Fitzgerald, 2017).

Both concerns – inadequate reduction of CO_2 emissions and the increasing load on the local grid – clearly need to be solved by managing charging. Possible charging management schemes follow:

- Off-peak or network-oriented charging. Policies and structures that encourage off-peak period charging might include workplace or daytime charging and night-

time home charging to avoid network congestion and physical capacity constraints.

- Cost-oriented charging. This strategy would reduce PEV charging cost by shifting the charging time to periods of low energy prices. PEV owners would benefit from low energy costs and smoothing of load patterns as costs are low when demand is low. If low-cost periods are dominated by conventional generation, however, negative environmental effects could result.
- Smart charging. This includes controlled charging and demand response. The use of in-vehicle timers to take advantage of time-of-use (ToU) rates could help minimise stress on the electrical grid whilst also saving money for consumers.
- Combined smart and cost-oriented charging. Combining smart charging and the least marginal-cost approach lowers real-time prices and, therefore, increases the share of renewable energy such as wind (Dallinger et al., 2012).
- Renewable energy– or low emission–oriented charging. This strategy aims to increase environmental performance or avoid the negative impact of GHG and air pollutant emissions. The measure shifts charging times to periods of high and/or surplus renewable energy generation.

3. Impacts of Electric Vehicle Penetration on Mobility Patterns: Literature Review

3.1. Trip Distance

Newman and Kenworthy's (1989) pioneering research shows the relationship between population density and energy use: per capita automobile usage, represented by gasoline used per capita, drops with rising area population density.

More recent research in line with Newman and Kenworthy's seminal work considers the use of PEVs:

Schuller and Hoeffer (2014) assess the impact of individual socio-demographic mobility patterns on the potential to utilise renewable energy for PEV charging. They find that shorter driving distances increase the relative adoption potential of renewables to generate electricity for PEVs.

Glazebrook and Newman (2018) foresee the emergence of a polycentric city linked by fast electric rail, with local access based on autonomous 'community'-owned electric cars, including small-scale electric cars and buses, supplemented by bicycles, electric bikes, and scooters, with all electricity generated from renewables. The city would likely have, amongst others, (i) an increased concentration of jobs, residents, and activities along old transit corridors and in satellite cities and sub-centres clustered around intensive rail systems; (ii) increasing housing density in all parts of the city; and (iii) a concomitant decline in the share of 'dispersed' activities.

This view on the emerging trend of urban compacting is shared by many researchers such as Vandecasteele et al. (2019), suggesting that new urban developments are promoting higher-

density housing, thereby making public transport more efficient whilst also promoting a new work-live-play urban model whereby all necessary services, housing, and entertainment are within walking distance. The research suggests that legislation and governance measures are needed to ensure that new transport modes such as autonomous EVs complement rather than compete with public transport.

Thakur et al. (2016), however, find that the autonomous era will be shaped by two competing dynamics. First, new autonomous ride-sourcing services may catalyse a move away from private vehicle ownership, which will increase the marginal cost of travel and encourage urban consolidation and regeneration. Second, reduced perceived travel costs will likely encourage citizens to accept longer travel times. A combination of denser inner cores and sprawling development on the urban fringes can be expected.

Ahmadian et al. (2019) believe that PEV penetration might lead to longer travel distances and times and not compact urban form. The combination of PEV penetration and the use of solar photovoltaic (PV) residential roof-based electricity to charge PEVs will result in comparatively clean and free well-to-wheel energy. Solar PV electric energy use by buildings and transport favour lower-density, non-compact urban form as there is an inverse correlation between urban density and transport energy: residential roof-mounted solar PVs in lower-density urban areas can potentially generate more energy than is required for typical transport needs in urban areas. Suburbia can power transport in the city and still have energy to spare. This does not necessarily mean that vehicles need to be charged at home, as various options of distributing renewable energy are assumed.

Byrd et al. (2013) find that low-density suburbia is the most efficient collector of solar energy and generates excess electricity to power daily transport needs and contribute to peak daytime electrical loads in the city centre.

3.2. Trip Origin–Destination and Schedule

PEVs should be charged using an energy source that will reduce carbon emissions and avoid increasing the load on the local electric power grid. This system requires smart charging schemes that can be implemented in public charging facilities.

Determining the optimal location of such facilities has been an important research subject for almost 10 years. Various studies recommend different optimisation rules. Three studies are worth mentioning here:

- Frade et al. (2010) aimed to maximise demand covered within an acceptable level of service and to define the number and capacity of the stations to be installed in Lisbon, Portugal.
- Wagner et al. (2014) used three optimisation objectives to determine locations of charging points and stations in Amsterdam, The Netherlands: maximising charging point utilisation, minimising PEV drivers' range anxiety, and maximising stations' visibility.
- Vazifeh et al. (2019) used call data records to apply a new methodology in Boston, US, and to optimise PEV charging locations. The objective was to cover the entire demand region whilst minimising drivers' total excess driving distance to reach charging stations, related energy overhead, and number of charging stations.

Only a few researchers, however, have studied the effects of charging facility placement on mobility:

Wagner et al. (2014), for example, found that people charge their vehicles at stores where they spend a lot of time. In places such as bakeries, for instance, people stay for too short a time to warrant plugging their vehicles into a charge point outlet.

Çolak et al. (2016) studied how to harmonise smart charging with trip schedules. They analysed a coupling of two unique large datasets on urban mobility and EV energy consumption. Amongst others, they found high temporal flexibility of charging sessions, i.e., vehicles are parked for longer periods than required to fully charge them, allowing room for improvement in scheduling PEV charging. The researchers found a method to shave the daily peak power to alleviate the load on the power grid: peak power values can be shed by delaying charging and adjusting the arrival hours without imposing constraints on departure times, and without violating charging continuity or delaying departure time.

4. Discussion

Reducing GHG emissions, strengthening energy security by reducing imports of petroleum products used for transport fuels, and improving urban air quality are amongst the most-frequent arguments invoked in favour of PEV penetration.

Whilst PEVs should reduce tank-to-wheel (downstream) air pollution in urban areas and reduce demand for gasoline and diesel fuels, ASEAN countries face the big challenge of deploying PEVs to reduce GHG emissions. The countries are mostly dependent on carbon-intensive energy sources such as coal and natural gas to generate electricity.

In countries dependent on fossil fuel–based power plants, such as Indonesia, Malaysia, Viet Nam, and Thailand, policies to ensure energy-efficient urban mobility are highly important. The use of electricity by PEVs should be minimised by encouraging compact urban forms and structures and restraining urban sprawl. Doing so will minimise travel by private car and promote the use of mass public transport and soft modes such as walking and cycling. Newman and Kenworthy's density theory holds in this situation, whilst increasingly compacting urban forms (Glazebrook and Newman, 2018; Vandecasteele et al., 2019) is the trend of the future. Only when a country develops home-based solar PV electricity in suburbia to feed residential and EV needs can urban-form policies be relaxed.

Mobility-related policy measures should be linked to the charging mechanism. The impacts of PEV charging on the grid and on power generation are so far negligible, but battery costs are declining continuously, electricity is cheaper than gasoline and diesel, and urban mobility and car ownership are rising in ASEAN countries. All these factors might lead to a tipping point for EV market penetration. A strategy is needed to implement different charging schemes to avoid pressure on the electric grid and to maximise the use of low-carbon power generation.

Studies in some PEV front-runner countries show that unregulated charging will add pressure to the urban electric grid when household electricity demand is at its peak. Uncontrolled charging after work threatens network grid security, which is generally vulnerable in ASEAN countries. In countries that generate electricity in fossil fuel–intensive

power plants, additional electricity for charging PEVs in the late afternoon (a peak load period) comes mostly from coal- and gas-fired plants.

ASEAN countries should manage their PEV charging mechanisms to avoid peak periods and take advantage of periods when renewables are available to meet additional demand. Locations of public charging facilities should encourage electricity consumption during periods of lowest grid load and when renewable-based electricity is available. For instance, public charging facilities can be installed in workplaces or in parking facilities of stores where people spend a long time when grid load is low and renewable-based electricity is available. PEVs can be allocated special parking spaces or access.

5. Recommendations and the Way Forward

First, because they use a high percentage of fossil fuel to generate electricity, ASEAN countries must adhere to policies that increase urban density and compactness and stop urban sprawl. Generalised costs of PEV travel will continue to decrease significantly, which will increase PEV adoption and average mileage. Only when a country develops renewables such as home-based solar PV energy can it relax its policies on urban sprawl.

Second, ASEAN countries need to locate PEV charging facilities in a way that avoids stress on the electric power grid and maximises the use of renewables.

This research is a preliminary step in building an urban mobility development framework to maximise the benefits of PEV penetration in ASEAN countries' urban areas. The task is challenging because countries and regions produce electricity in different ways, and urban areas vary greatly in structure, characteristics, and mobility patterns.

We recommend two research axes:

- Conduct a more comprehensive literature study on the relationship between EV penetration, mobility patterns, and urban forms.
- Conduct an empirical study on how charging facilities are located in Asian and ASEAN countries' urban regions and how this might interfere with current mobility patterns and policies.

Case Study Paper

Comprehensive Evaluation and Dynamic Evolution Analysis of Shanghai's Urban Vulnerability

Tian QIN; CAUP of Tongji University; China

Abstract

Urban vulnerability refers to the ability of a city to resist internal and external natural and human factors. With global environmental changes and urbanization continuing at pace, the urban planning and development strategies of cities, especially mega-cities, are facing comprehensive and unprecedented issues. This paper takes Shanghai, one of the largest mega-cities worldwide and the global cities in China, as an example, using the comprehensive evaluation index method which includes natural resource vulnerability, eco-environment vulnerability, economic vulnerability and social vulnerability, to build a comprehensive vulnerability index evaluation system of the city. Through the dynamic evolution analysis conductive to a deeper understanding of the changing laws of urban vulnerability, explore the persistence and transformation mechanism of urban functions after perturbations, and realize the sustainable development of cities, the paper found that: firstly, during 2002 -2017, the comprehensive urban vulnerability index of Shanghai has been declining, among which the decline rate was large during the years of 2004 -2006 and 2010-2012, which was the result of urban events promoting urban construction. Secondly, Shanghai has changed from an absolute dominant eco-environment vulnerability to a more balanced vulnerability, indicating that cities have greater resistance, adaptation and transformation capabilities to multiple perturbations including natural resource, ecological environment, economic and social development. Thirdly, Shanghai's eco-environment vulnerability has continued to decline in recent years, but it is still the dominant factor of the urban vulnerability. Fourthly, as Shanghai has been facing an increase in migrant population and huge arable land pressure, the contribution rate of natural resource vulnerability continues to be high and has increased in recent years. Facing the changing environment and risks, we must plan for resilience, and build, evolve and secure quality of life for dwellers.

Keywords

Urban vulnerability, evolutionary research, Shanghai

Shanghai's new round of master plan puts forward the vision of "Striving for the Excellent Global City". Under the background of a new historical starting point and adapting to the new development trend, Shanghai is also faced with many challenges such as sustained population growth, environmental resource constraints, and urban functional transformation. The combination of endogenous contradictions and external adverse effects of urban development leads to the vulnerability of cities in resource utilization, ecological environment, economic construction and social development.

In order to evaluate the urban development of Shanghai in the past ten years more comprehensively and intuitively, this paper makes a longitudinal study of the evolution characteristics of Shanghai's urban comprehensive vulnerability in the past 15 years based on statistics from 2002 to 2017. The paper deeply studies the development status and vulnerability evolution characteristics of Shanghai in the last stage, in order to effectively regulate and control the urban vulnerability and provide some inspiration for Shanghai to move towards sustainable development.

1. Introduction

The term "vulnerability" came from the field of natural disaster research (Turner et al., 2003), and then it was widely used in ecology, economics, geography, sociology and other disciplines (Fang and Wang, 2015). Urban vulnerability refers to the ability of cities to resist the interference of internal and external natural and human factors such as ecological, economic and social development. When this anti-interference ability is lower than a critical threshold, the city will enter a vulnerable state (Wang and Fang, 2014). Currently, researches on urban vulnerability in China mainly focuses on the assessment and classification of eco-environment vulnerability and the vulnerability assessment of disaster-prone cities (Zhang et al., 2016). In recent years, researches on the issue have changed from a single system to a diversified ones. For example, Fang and other scholars evaluate the comprehensive vulnerability of cities from multiple subsystems (Fang and Wang, 2015).

Based on previous relevant studies on urban vulnerability by domestic and foreign scholars, the influencing factors of urban vulnerability can be divided into two categories: natural conditions and human activities. Urban vulnerability includes four elements: resource vulnerability, eco-environment vulnerability, economic vulnerability and social vulnerability. Considering the reliability and validity of the data, this paper chooses the period from 2002 to 2017 to conduct a diachronic study on the comprehensive vulnerability of Shanghai city from four aspects: resources, ecology, economy and society.

2. Urban Vulnerability Assessment Method and Evaluation System Construction

2.1. Construction of Evaluation Index System

Based on assessment systems constructed by Fang and Wang (2015), this paper constructs the urban comprehensive vulnerability evaluation system according to the principles of non-collinearity and accessibility of index data (Fig. 1).

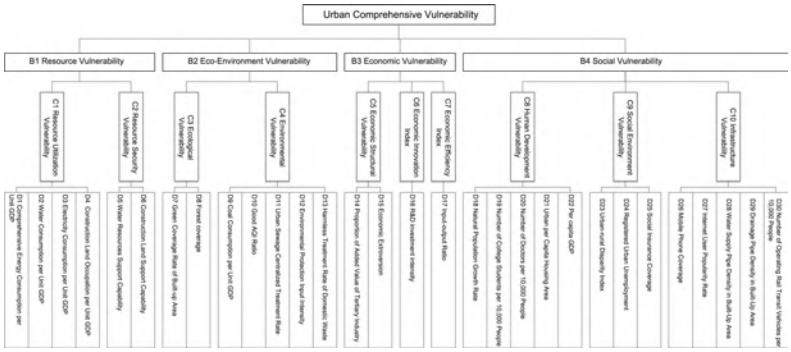

Figure 1 Urban Comprehensive Vulnerability Assessment System

Source: Self-organized, summarized and made

The target level is divided into four sub-elements including urban resources, ecology, economy and social vulnerability. The whole system contains 30 third-level indicators and 10 second-level indicators.

2.2. Identification of Typical Indicators and Determination of Weight Coefficient

2.2.1. Quantitative Identification and Explanation of Typical Indicators

(1) Water resources support capacity. The study measure the urban water resources support capacity by the ratio of urban available water resources to actual urban water demand (Fang and Wang, 2011). The calculation method is as follows:

$$WPSI_{\mathrm{i}} = \frac{DWS_i \times T}{YTWS_i} \qquad (1)$$

where: $WRSI_i$ refers to the water resources support capacity. $DWSi$ is the daily water supply of urban tap water. T is the number of days in a year. $YTWS_{\mathrm{i}}$ is the total water consumption of the city and is calculated according to the total water supply in the Statistical Yearbook of Urban Construction over the years. The closer the index is to 1, the higher the water resources support capacity of the city is. When the index value equals 1, it indicates that the current water production capacity of the city does not destroy the ecological balance, but also meet the needs of urbanization development (Fang and Wang, 2015).

(2) Construction land support capacity. According to the National Land Use Change Survey Report and related research, the per capita arable land area in cities is taken

as the basis for estimating the underlying conditions of land[1]. And the actual per capita construction land area and the healthy per capita construction land area are taken as the basis for evaluating the development potential of regional construction land①. The calculation method is as follows:

$$LCSI_i = \frac{1}{2}\left(\frac{PAA_i}{HPAA_i} + \frac{PCA_i}{HPCA_i}\right) \quad (2)$$

where: $LCSIi$ is the construction land support capacity. $PAAi$ is the per capita cultivated land area (calculated by permanent population), and $HPAAi$ is the minimum per capita cultivated land area needed[2]. PCA_i is the area of construction land per capita (calculated by urban population). $HPCA$ is healthy per capita construction land area (calculated by living, service facilities, road traffic, green space and other construction land standards closely related to per capita land use indicators, this paper determines that the healthy per capita construction land area in Shanghai is 140 sqm). When the construction support capacity index is 1, it means that the city has enough development space (Fang and Wang, 2015).

(3) Coal consumption per 10,000 yuan GDP. Because carbon emission data per unit output value is difficult to obtain, and coal consumption accounts for more than half of the major energy products in Shanghai, coal consumption per 10,000 yuan GDP is used as an indicator to measure urban environmental vulnerability.

(4) Economic extroversion. That is, the degree of dependence on foreign trade, which is used to measure the degree of close economic ties, openness and dependence on foreign trade between Shanghai and other countries. This index is quantified by the ratio of total urban exports to GDP.

(5) Input-output ratio. The input-output ratio of government finance is taken as the basis to measure urban economic efficiency. This paper adopts a quantitative method to calculate the ratio of general budget revenue to expenditure of local finance.

(6) Urban per capita housing construction area. Taking urban per capita housing area as an index to measure urban human development, this paper takes per capita

[1] The index of construction land security in this paper only reflects the development support and potential status of urban construction land, and is different from the rationality of construction land allocation. According to the relevant research, if the current situation of construction land is relatively healthy per capita construction land area exceeds the standard, although the urban land security capacity is strong, but the land use efficiency is low. Such land allocation is unreasonable.

[2] The smallest per capita cultivated land area in Shanghai in 2004 was 0.045 hectares according to relevant study (Zhu and Zhang, 2007). Statistics show that the per capita cultivated land area of China is 0.09 hectares in 1998-2007 and 0.08 hectares in 2008-2017, respectively. In this paper, the minimum per capita cultivated land area is 0.04 hectares per person.

housing construction area as an index. Before 2007, the index was converted into per capita housing area, with a conversion rate of 51%[3].

(7) Urban-rural disparity index. It is the ratio of disposable income of town residents to per capita net income of rural residents. The closer the index is to 1, the smaller the income gap between urban and rural areas is, the higher the sharing level of urban and rural development results is.

(8) The registered urban unemployment rate. This paper calculates the indicator by the ratio of registered unemployment in cities and towns to the sum of registered unemployment in cities and towns. Due to the change of statistical methods, the unemployment rate of urban survey is taken as the index after 2011.

(9) Social insurance coverage. The index refers to the proportion of urban and rural insured persons in the permanent population, which is based on the permanent population and takes into account both urban and rural conditions. Because of the great changes in China's urban and rural social insurance system, the number of people who have basic medical insurance in urban enterprises and institutions (including retirees, individual businesses and freelancers) as well as the basic medical insurance for urban workers, basic old-age insurance for urban workers, social old-age insurance for urban residents, rural cooperative medical insurance, new rural social old-age insurance and the basic medical insurance for urban and rural residents and other types of insurance data are calculated in this study. The selection and calculation of indicators should not overlap or omit as much as possible.

2.2.2. Determination of Weight Coefficient

The weights of urban vulnerability index and related indexes are calculated by analytic hierarchy process (AHP). The impact and mechanism of each index on urban vulnerability are different. The index system of urban comprehensive vulnerability measurement and its related values, index properties and the corresponding data sources are shown in Table 1 below.

Table 1 Table of Comprehensive Measurement Index System of Urban Vulnerability

Target Level	Weight	Principal Level	Divided Weight	Indicator Layer	Unit	Property	Data Source
B1 Resource Vulnerability	0.2	C1 Resource Utilization Vulnerability	0.45	D1 Comprehensive Energy Consumption per Unit GDP	Tons of standard coal / 10,000 yuan	+	"2017 Shanghai Statistical Yearbook"
				D2 Water Consumption per Unit GDP	m³/10,000 yuan	+	calculated according to the Statistics Yearbooks
				D3 Electricity Consumption per Unit GDP	kWh/10,000 yuan	+	calculated according to the Statistics Yearbooks
				D4 Construction Land Occupation per Unit GDP	k ㎡/10,000 yuan	+	calculated according to relevant data
		C2 Resource	0.55	D5 Water Resources Support Capability	—	-	calculated according to relevant data

[3] This value is calculated based on the data of the "Shanghai Statistical Bulletin on National Economic and Social Development" in 2008 and following years.

Source: Self-organized, summarized and made according to relevant information

Note: The process data of the number of permanent resident population, gross regional product, city total annual water supply , city annual electricity consumption, year-end total construction land area, daily water supply capacity of municipal tap water, year-end cultivated land area, city annual coal consumption, general budget revenue and expenditure of local finance, disposable income of urban residents, per capita net income of rural residents, number of basic medical insurance for urban and rural residents, number of basic medical insurance for workers and staff, year-end number of railway vehicles et al. are from the "Urban Construction Statistical Yearbooks",

"Shanghai Statistical Yearbooks", "Shanghai Statistical Bulletin on National Economic and Social Development" and the website of the National Bureau of Statistics.

2.3. Data Processing and Analysis Method

(1) Data standardization

The original data from the statistical yearbook are standardized to eliminate the influence of dimensional differences among different indicators. Thirty-one indicators in the evaluation system can be divided into positive and negative categories according to their impact mechanism on urban vulnerability, which are explained and dealt with as follows:：

Positive evaluation index: The larger the value, the greater the vulnerability. The processing method is as follows:

$$X_i = \frac{x_i - \min\{x_i\}}{\left|\max\{x_i\} - \min\{x_i\}\right|} \tag{3}$$

Negative evaluation indicator: The larger the value, the smaller the vulnerability. The processing method is as follows:

$$X_i = \frac{\max\{x_i\} - x_i}{\left|\max\{x_i\} - \min\{x_i\}\right|} \tag{4}$$

where: Xi represents the dimensionless index of 30 indicators x_i ; $\max\ \{x_i\}$ and $\min\ \{x_i\}$ are the maximum and minimum values of the evaluation index in the study period.

(2) Sub-index measurement (Layer C)

The sub-index vulnerability indexes (Layer C) refer to the indexes in the Indicator layer. The calculation formula is as follows:

$$UVI_e = \left(\sum_{i=1}^{n} x_i\right) / n \tag{5}$$

where: X_i is the standardized value of individual indicators; n is the number of individual indicators contained in each sub-factor vulnerability index; UVI_e represents the sub-index of urban vulnerability, including 10 sub-indexes such as resource-utilization vulnerability index, eco-environment vulnerability index, environmental vulnerability index, economic structure index and human development index.

(3) Sub-factor measurement (Layer B)

The urban sub-factor vulnerability indexes (layer B) are indexes in the Principal level. The index is calculated by weighting method and the formula is as follows.

$$UVI_s = \sum_{i=1}^{m} (UVI_e)_i W_i \tag{6}$$

where: UVI_e represents the vulnerability index of each sub-index. m is the number of sub-factor vulnerability indexes. W_i is the weight of each index at the Principal level. UVI_s refers the urban sub-factor vulnerability indexes including resource vulnerability index, eco-environment vulnerability index, economic vulnerability index and social vulnerability index.

(4) Comprehensive vulnerability measurement

The urban comprehensive vulnerability index is calculated by weighting the sub-factor vulnerability indexes. The calculation formula is as follows:

$$UVI = Q_1 \times UVI_{s1} + Q_2 \times UVI_{s2} + Q_3 \times UVI_{s3} + Q_4 \times UVI_{s4} \quad (7)$$

where: UVI_{si} refers the sub-factor vulnerability indexes. Q_i is the corresponding weigh. UVI is the urban comprehensive vulnerability index.

3. Evolution Characteristics of Sub-factor Urban Vulnerability in Shanghai

3.1. Evolution Characteristics of Resource Vulnerability

Shanghai's urban resource vulnerability fluctuated but remained high between 2002 and 2008. From 2008 to now, it has shown a decreasing trend, but it has a certain volatility (Fig. 2). The fluctuation of the index is greatly influenced by the sub-index resource security vulnerability index (C2), while the resource utilization vulnerability index (C1) of Shanghai has been in a steady decline, indicating that the utilization of energy and resources such as water, electricity and land has been steadily increasing.

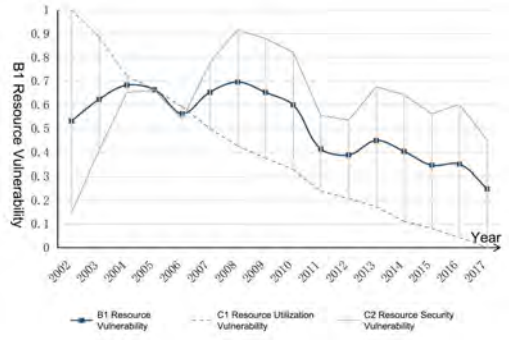

Figure 2 Trend of Urban Resource Vulnerability in Shanghai (2002-2017)

Source: Drawn by the author

From the perspective of resource security vulnerability, it is found that, except for 2006, the resource vulnerability of Shanghai increased from 2002 to 2008, and declined after 2008. The urban construction land security capacity in Shanghai has always been under great pressure, especially the per capita cultivated land area. In recent years, the rapid development of Shanghai in the context of globalization has brought tremendous demand for living space of urban population. Therefore, urban cultivated land is facing severe pressure. In 2015, the per capita cultivated land area

of Shanghai is only 0.008 hm^2/person, accounting for only 8.15% of the national average (0.982 hm2/person) (Gao, 2018). Food the city demand is largely transferred from other provinces. In 2013, Shanghai established the basic land use strategy of "total lock-in, incremental decline, stock optimization, flow efficiency enhancement and quality improvement". Then the government put forward population restriction and a series of related policies to clarify that the city has entered the "reduced development" mode in order to implement population structure optimization and move towards a new stage of innovative urban development.

3.2. Evolution Characteristics of Eco-Environment Vulnerability

Shanghai's eco-environment vulnerability index decreased from 0.755 in 2002 to 0.133 in 2017, which indicates that the carrying capacity of urban eco-environment has increased greatly, and the capacity of eco-environment as the material carrier of the city has been greatly enhanced. The sub-index urban ecological vulnerability index (C3) shows a downward trend in general, but the fluctuation is large. The whole evolution process can be divided into three stages: the fluctuation is flat during 2002 to 2004, the rapid decline during 2004 to 2009 and the slow decline after 2009 (Fig. 3). The change of the index reflects that China's urban development has moved from the dominant stage of economic construction to the period of green ecology and sustainable development. The concrete manifestation of urban construction is that the forest coverage and green coverage of built-up areas in Shanghai have increased rapidly in the past 15 years. According to the data of Shanghai Statistical Yearbook 2017, the forest coverage and green coverage of built-up areas in Shanghai are 16.2% and 39.1% respectively.

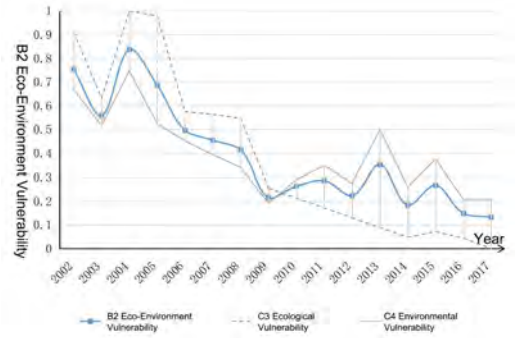

Figure 3 Trend of Urban Eco-environment Vulnerability in Shanghai (2002-2017)

Source: Drawn by the author

In contrast, the reduction rate of urban environmental vulnerability index (C4) is smaller. In recent years, good results have been achieved in the construction of ecological environment in Shanghai: the carbon emission per unit GDP has decreased, the centralized treatment rate of urban sewage has been over 90% since 2012, and the domestic waste has been treated completely harmlessly since 2014. Relevant data show that Shanghai's air quality index(AQI) has improved significantly in the pre- and mid-2010 World Expo, indicating that the implementation of the four rounds of "three-year action plan for environmental protection" since 2000 and the implementation of air pollution control measures during the Expo have achieved

remarkable results. From 2009 to 2012, the ratio of days with good air quality has been above 90%. However, after the World Expo, air pollution rebounded seriously, and air quality declined sharply since 2013 (66% in 2003). Although AQI of Shanghai has increased in recent years, it is still lower than the national average. The decrease of air quality is mainly manifested in the obvious increase of NO_2 and PM_{10} concentrations. Besides the unfavorable diffusion of pollutants in winter, the main reasons are the relaxation of temporary control measures during the World Expo, the large number of construction projects, the rise of construction dust pollution, the rebound of straw incineration and garbage incineration, and the aggravation of local air pollution (Huang et al., 2013).

3.3. Evolution Characteristics of Economic Vulnerability

Overall, the vulnerability of Shanghai's urban economy has continued to decline over the past 15 years, with a sharp decline during 2003 to 2007, an upward trend during 2007 to 2009 and a flat fluctuation in the past four years (Fig. 4).

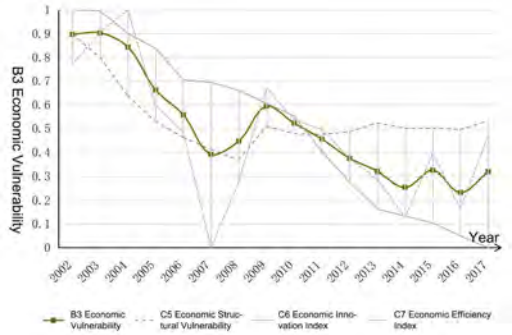

Figure 4 Trend of Urban Economic Vulnerability in Shanghai (2002-2017)

Source: Drawn by the author

Among them, economic structural vulnerability (C5) declined steadily from 2002 to 2008, and then the change became flat. During 2002 to 2008, Shanghai's industrial structure was in a period of rapid transformation. During this period, the economic development aimed at adjusting and optimizing industrial structure and improving industrial innovation ability. The proportion of tertiary industry to GDP rose rapidly. The dependence on urban foreign trade the ratio of total urban exports to GDP) increased first and then decreased, and finally stabilized at about 43%. The index of economic extroversion has both positive and negative aspects. Under the background of economic globalization, Shanghai is in the vanguard position of integrating into the international network, and its market openness ranks first in China. However, while gaining export growth to accelerate economic growth, Shanghai recognizes that there are huge risks behind the higher degree of dependence on foreign trade - the regional economy will be very sensitive to the fluctuations of the world economy.

Therefore, Shanghai focuses on the cultivation and development of the domestic market, optimizing the industrial structure, and vigorously developing technological progress and technological innovation in order to increase the resilience and adaptability of the urban economy to external influences. Shanghai's investment

intensity in R&D has increased from 1.9% in 2002 to nearly 3.9% in 2017. Focusing on technological innovation capability can improve Shanghai's position in the world economy, change the situation of high dependence on the international market, and develop the self-control of enterprises' living conditions.

3.4. Evolution Characteristics of Social Vulnerability

Social vulnerability consists of human development vulnerability (C8), social environment vulnerability (C9) and infrastructure vulnerability (C10). The analysis finds that Shanghai's social vulnerability has been declining steadily from 2002 to 2017, and the decline rate of urban social vulnerability is the fastest from 2010 to 2012 (Fig. 5).

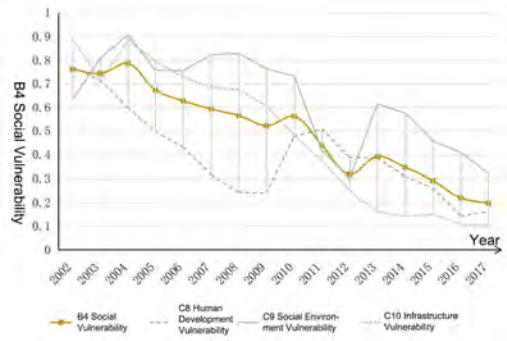

Figure 5 Trend of Urban Social Vulnerability in Shanghai (2002-2017)

Source: Drawn by the author

From 2010 to 2012, the rapid decline of urban social vulnerability is mainly affected by social environmental vulnerability (C9). This change is reflected in the rapid decline of urban registered unemployment rate and the rapid rise of social insurance coverage at indicator layer (Layer D) . It can be seen that the construction of Shanghai's urban social welfare and basic security system is advancing. Urban development is paying more and more attention to "social justice", and vulnerable groups are receiving more attention and social security.

In addition, the material living standards of residents have steadily improved, with the annual growth rate of per capita GDP in Shanghai reaching 10.7% between 2002 and 2017. Urban infrastructure construction has been improved, and the medical, educational and housing conditions have been improved. However, the difference between urban and rural areas in Shanghai is very significant. In 2004, the difference index between urban and rural areas in Shanghai reached the highest level, which was 2.36. And the average value in the past five years is 2.29, which has always been above the international standard value of 2. In the new period of "urban-rural integration" development, we need to explore the road of rural revitalization, promote the coordinated development of urban-rural economy and society, and build a new urban-rural relationship.

4. Evolution Analysis of Urban Comprehensive Vulnerability

4.1. Evolution Characteristics of Urban Comprehensive Vulnerability

From 2002 to 2017, Shanghai's urban comprehensive vulnerability declined from 0.74 to 0.2, and the overall vulnerability fluctuated continuously in the form of "N" (Fig. 6). The development process of urban comprehensive vulnerability can be roughly divided into five stages: fluctuation rising stage (2002-2004), extreme decline stage (2004-2006), slow decline stage (2006-2010), rapid decline stage (2010-2012), fluctuation declining stage (2012-2017). The peak value of urban comprehensive vulnerability is 0.79 in 2004, and the ecological vulnerability is also at its maximum. This shows that Shanghai's ability to resist external adverse effects such as climate change and natural disasters is very weak in 2004, and the possibility of damage is the greatest, and the cycle of restoring urban functions is the longest.

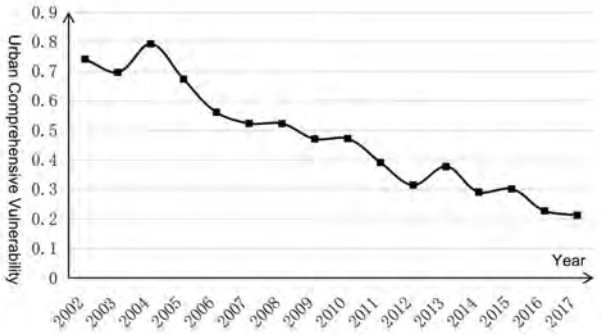

Figure 6 Trend of Urban Comprehensive Vulnerability in Shanghai (2002-2017)

Source: Drawn by the author

Since 2006, with the adjustment and effective implementation of Shanghai's targeted urban development strategy, the contradictions of various systems in the process of urbanization have been constantly mended. In addition, the hosting of the 2010 Shanghai World Expo international events has greatly promoted the construction of the ecological environment, economy and society in Shanghai.

4.2. Factor Interconnection Analysis

Overall, from 2002 to 2017, the vulnerability of urban resources, ecology, economy and society in Shanghai showed a downward trend as a whole, but there was a complex synergistic and causal relationship between the evolution of the four elements (Fig. 7).

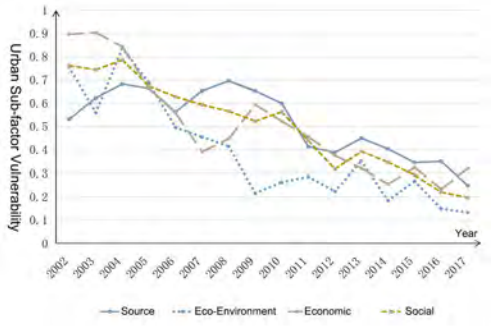

Figure 7 Trend of Sub-factor Vulnerabilities in Shanghai (2002-2017)

Source: Drawn by the author

From the point of view of the contribution rate of resources, ecology, economy and social vulnerability to urban comprehensive vulnerability, the mechanism (positive or negative) and magnitude of each sub-factor have great fluctuation (Fig. 8). The obvious evolution characteristics are as follows: (1) the contribution rate of economic vulnerability is the lowest, but it has increased significantly in the past 15 years, from 6.2% in 2002 to 35.0% in 2017; (2) the contribution rate of ecological vulnerability is the largest, but the dominant position of urban comprehensive vulnerability has weakened in recent years.

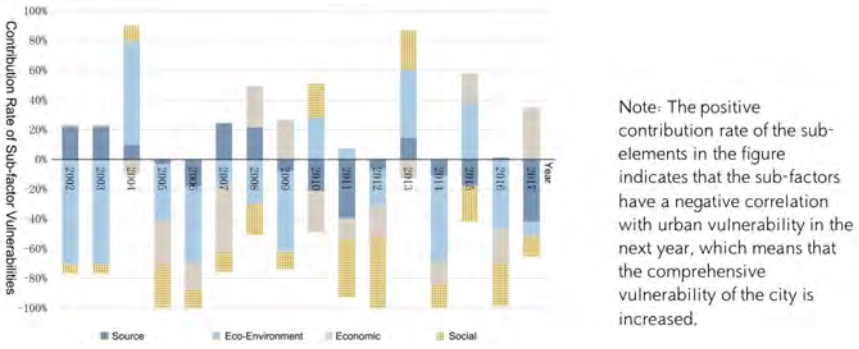

Figure 8 Contribution Ratio of Sub-factor Vulnerabilities (2002-2017)

Source: Drawn by the author

This shows that Shanghai has changed from the absolutely eco-environment-dominant vulnerability to a more diversified and balanced vulnerability composition pattern. It also shows that the city is more resistant, adaptable and transformable in the face of adverse disturbances from resources, ecology, economy and society. Shanghai is more capable of sustainable development.

5. Conclusion and Research Prospects

5.1. Conclusion

In the face of adverse events such as global climate change, the protection of urban basic security and sustainable development should be given priority. Urban vulnerability is a matter of "survival". This paper evaluates Shanghai's urban

vulnerability from four sub-factors: resources, eco-environment, economy and society. The results show that:

①During 2002 to 2017, the urban comprehensive vulnerability of Shanghai showed a fluctuating downward trend, among which the rate of decline during 2004 to 2006, and 2010 to 2012 was relatively high, which was the result of the urban construction driven by mega-events.

② Shanghai has changed from an absolutely eco-environment-dominant vulnerability to a more diversified and balanced vulnerability structure. Now four sub-factor vulnerabilities develop in a balanced way. It shows that the city has more resistance, adaptability and transformation ability when facing adverse disturbances of resources, ecology, economy and society.

③The contribution rate of resource vulnerability has also risen. This is mainly due to the enormous pressure on cultivated land and the increasing demand of foreign population in Shanghai.

④What can not be ignored is that the reduced ecological vulnerability is still the main cause of urban vulnerability, which is mainly due to the loosening of urban air quality control and changes in climatic conditions after the World Expo.

5.2. Research Prospects

Because of data limitation, the time interval of this study is too short to observe the coupling mechanism between Shanghai's development law and the four sub-factors more holistically and objectively. In addition, this paper evaluates the comprehensive vulnerability of Shanghai in order to explore the transformation and sustainable development path under the new development challenges. But how to measure urban vulnerability? How to explore the occurrence function of urban vulnerability? What is sustainability and transformation mechanism of urban function under adverse interference? These are the research problems that this paper can not solve but need to be discussed in depth.

Implementation Strategies for TOD Concept in Existing Built Environment in Jakarta

Putrikinasih SANTOSO

Abstract

Transit Oriented Development (TOD) has been a concept floating around the professional realm in the field of urban planning, urban design, and urbanism for decades now. It has a certain distinct approach in promoting slow traffic mobility for pedestrian and cyclists in areas 700 - 1.000 meter away from the transit facilities, generating ridership by inducing compact and dense mixed-use development in the precinct. Jakarta, Indonesia is currently facing a major change in the means of transportation by adding up a new MRT line to the latest urban mobility network. This addition is, naturally, expected to alter the urban form within the TOD areas, which are mostly built existing environment.

This paper aims to posit an exercise on the implementation of TOD concept in a built existing environment including the challenges in implementing TOD concept in such areas and possibilities for redevelopment within those TOD areas. To exemplify, several case studies will be presented, including Dukuh Atas, Cipete, and Haji Nawi TOD areas.

Research Paper

Measurement of spatial equity

: a case study of nursing institution

Xin Sui, Tongji University; China
Yifan Yu, Tongji University; China
Liu Huhui, Tongji University; China

Abstract

Equity and justice have always been important norms in the field of urban planning. With the gradual deepening of understanding of residential environment, the research context of equity and justice related to location is becoming more and more sophisticated. Recently, varieties of subjects Including Public Health and Geography focus on the inequity of public resources in spatial distribution and how to measure the degree of this gap. In general, the mainstream measurement methods can be summarized into two categories: (1) The description of phenomenon caused by the spatial inequities, and accessibility is a typical method of this type. (2) the direct quantification of inequity, such as Gink Coefficient which is originated from the economics field and introduced into the measurement of health equity, and Getis-Ord General G, together with Moran' index is the most commonly method used into the general spatial autocorrelation. In this paper, based on the overall literature review of the concept of equity in the study using these methods and a summary of their specific context of the measurement using, nursing institution in Shanghai, China are regarded as a typical case to practice these methods and compare the differences in using. Meantime, the impact of the politics and planning related to this special facility is also been considered. Results show that, accessibility of nursing institution among elderly groups is much different under different research distance, and the overall trend seems like the research units in suburb appears higher accessibility than those in highly urbanized area. And Gink Coefficient helps us determine the proportion of the elderly population in different reachable areas in Shanghai is within a reasonable range. However, Global Moran' index provide reliable evidence that the existence of the aggregation combined by the high-value units. It indicates that there are inequities among the distribution of aged-nursing resources, and Local Moran I （LISA）help us to find the specific boundaries of these areas. In general, in the study of the equity related to location, accessibility can only reflect the differences phenomenon in distribution, but it is not clear to describe this gap to what extent, and it's difficult to achieve the possibility of comparison among different periods and different subjects. The Gini coefficient often focuses on the unfairness of the distribution of people, but ignored the aggregation characteristics of the spatial dimension, which the analysis of spatial autocorrelation can make up. All these methods proved that it's necessary to consider both the spatial distribution of supply and demand. And the discussion about equity related to location should be strictly qualified in study.

Elderly nursing institution, Accessibility, equity

1. Introduction

Maximization of equity and efficiency is the most important prerequisite to ensure the public service facilities' service level, quality and citizens' benefits. Different from the traditional location theory which pursues the profit maximization of non-public products, public facility location theory holds the idea that equity and efficiency should be considered in the distribution of public resource. (Teitz Mbjpotrsa,1968) At the beginning of urbanization, the population size and density distribution among different cities or different districts are homogeneous and nearly identical, so that traditional methods to lay out the public service facilities such as thousand-person indicators and service radius can be basically satisfied the goal of "space equity". However, as the degree and speed of the urbanization processing, the groups with different social and economic attributes begin to gradually gathering in the specific space. And that is the reason why traditional methods could not meet the space equity's needs anymore. Meanwhile, the marketization procession also provides varieties of the patterns of public service supplement, this process may aggravate the degree of inequity among to people's access to public service.

While the development of public service facilities is diversifying, China's aging is also growing up. By the end of 2017, the total number of elderly people over the age of 60 in China reached 240 million, accounting for 17.3%, and the total number of elderly people over 65 years old reached 158 million, accounting for 11.4%. According to United Nations standards, when the proportion of people over 60 years old in a region reaches 10% of the total population or the proportion of people over 65 years old accounts for 7% of the total population, that means this area has entered an aging society. Due to the Spindle-shaped population structure, the degree and speed of China's aging will continue to grow in the near future. In this context, the study of aging urban countermeasures has gradually attracted more and more attention from urban planning scholars. Recently, relevant departments have promulgated a series of public policies ranging from architectural design to urban pension service provision, in order to guarantee the legitimate rights and benefits belong to the elderly.

Although the quantitative research on the spatial layout of public service facilities has attracted more and more attention in the world, quite a few scholars have carried out case studies on specific cities for nursing institutions. The existence of inequity has neglected the extent of this inequity and how it is reflected in specific space. Therefore, such research may reveal the lack of facilities or the surplus, However, it is difficult to make horizontal contrast which covers different cities or vertical contrast which covers different period.

Therefore, the main purpose of this paper is to summarize the current study about spatial equity of public service facilities, and to discuss the requirements of relevant policies in Shanghai's local elderly service system to explore whether Shanghai's elderly nursing service provided by elderly nursing institutions exists inequity and how degree it is. Shanghai's elderly nursing institutions have developed for a long time, with long-term construction experience and relatively perfect legal norms and technical standards.

In this paper, we will discuss the spatial equity of elderly nursing institutions in four parts. Part two reviews the existing research on the accessibility and f spatial equity of the public service facilities caused by distribution. And related researches from China are summarized, in order to propose a two-dimensional framework for the study of spatial equity of elderly

nursing institutions. In the third part, the method concluded from the second part is applied to the local case in Shanghai. Analysis and results are presented in part four together with a summary of key findings and important policy implications.

2. Research review: spatial equity related to location

"Spatial equity" is a complex concept. In the supply of public services, the core of its concern is "reasonable distribution of social group interests" or "method of social resource allocation" (Zhongxiao C ,2009)(Li J et al.,2015). As a blender of urban space resources, urban planners pay special attention to the issue of equity and justice related to space in the provision of public service. "Inequity means that the distribution of public services or facilities has institutional and systemic discrimination against certain special groups, but it is difficult to define equity."(Harries K et al.,1994), The existing methods of quantifying the spatial equity of public services are often reflected by the differences between regions. The choice of variables in the process of quantification can reflect the scholars' specific choice of the concept of spatial equity. Generally, the definition of spatial justice has not yet formed a unified definition (Klaus R,1998)， historical features(Haiyan J et al.,2011)and facility supplying procession are both taken into account. Today, more and more social factors are being considered in the analysis of spatial equity, accessibility is often used as a spatial indicator to measure this gap (Klaus R,1998)， Although the specific definition of spatial equity has not been formed, from the perspective of development, it presents a simple geographical spatial distribution to the matching between population and facilities to a specific evaluation that emphasizes different types and different levels of demand.（Junbo G et al.,2009）

At present, research on public service such as green space, health facilities, and educational facilities, especially kindergartens combined with China's conditions has achieved certain results. The issue of spatial equity in the public service facilities' distribution is essentially a discussion of the dialectical relationship between people (demand), facilities (supply), and location (the link between supply and demand), And citizens should be regarded as the final measure to measure the equity of the spatial layout of public service facilities. Therefore, in the, the practical significance of equity evaluation is to measure the absolute equity gap between public service distribution and spatial distribution in the population. The equity evaluation of public service facilities is a quantitative means of reflecting the equity of urban resource allocation, and is also an important basis for optimizing and adjusting the layout of facilities. Therefore, scholars often reflect the inequity of resource allocation through spatial differences in public services.

Now days, the evaluation of the spatial inequity caused by facilities' allocation can be divided into two categories: the description of inequity and the description of the degree of inequity. The former can intuitively reflect the relative supply of public service resources between different research areas. By reflecting the difference in relative supply to reflect the existence of inequality between regions, accessibility is the most important research medium in this type of research; the latter can directly measure this difference directly. It often draws on economics or spatial statistics to directly reflect the inequity of public service allocation under the spatial layout model.

Accessibility which is one of the main methods to describe the spatial inequity of public service allocation, is also a key concept in the evaluation of the spatial layout of public service facilities in the field of geography. Due to the diversity of methods and the different analytical concepts, accessibility itself has a rich definition. Accessibility emphasizes the resistance or ease between the start and the end. As quantitative research progresses, factors such as the size of the OD, the shape of the transportation network, and the road structure are gradually taken into account.

At present, the research on the accessibility of public service facilities has obtained rich research results in the fields of medical and health care, old-age services, and park green space, providing experience for the study of public service facilities in China. In the study of the concept of accessibility, accessibility can be used as a tool to directly measure the level of public service(Talen,1998)(Nicholls,2011)(Zhen L et al., 2007)(Zhuolin T et al.,2014), and as a spatial indicator of the research unit(Talen ,1997)(Park,2012)(Xiao Y et al.,2017), which can often expand the research ideas of the built environment, and the statistical method is accommodated. The two-step floating catchment area (2SFCA) and potential model are the most representative methods used to measure Public service facility service level caused by specific position pattern(Zhengna S,2010). On the other hand, these models are expandable to adapt different research needs, and they also can be adapted according to the characteristics of the facility itself. Thanks to the idea of two-step floating catchment, E2SFCA is easier to practice and understand (Zhuolin T ,2016). The characteristics of supply and demand are comprehensively considered. In this paper, E2SFCA is used to describe inequity of the elderly nursing institutions(Lianhong C,2014)(Aihua Z,2013)(Wei X et al.,2017).

In the terms of measure the degree of equity caused by the location, multiple disciplines have contributed. The study of the equity of health public services has always been one of the key contents in the research of public health where methods in economics are absorbed(Keqin R et al.,1998) , and formed a sound evaluation system. At present, the methods widely used in health services mainly include the Tyre index(Zhang Nan,2014), the concentration index, and the Gini coefficient and the Lorenz curve(Horev T,2004). With the implementation of the concept of equity and justice in the urban planning field, the logic of the measure of equity of health services has gradually been introduced into the study of the equity of other types of public service space in urban areas (Barbati M,2016).The results of accessibility are treated as the index to describe the differences in public services, and that allowed the spatial equity of the public facilities such as green space(Zilai T et al.,2015) ,elderly school and hospital etc, could be quantified(Yifan Y,2018).

The traditional economics measurement method can help us to find the gap between a certain service or resource caused by location in the population, which can reflect the inequity distribution of public resources due to the different spatial layout patterns. [4] In the field of urban planning and geography, scholars are more concerned with the spatial distribution difference of the inequity caused by the layout of public service facilities, which could be reflected by the degree of spatial clustering(Talen, 1997) In 1950s, Moran proposed the Moran's I Index (also known as the Global Moran Index), focusing on the spatial differences of factors, describing the overall distribution of elements in space, and judging the existence of agglomeration trends. To located the specific location of clustering, Anselin developed local Moran's I (LISA) based on the global Moran index(Anselin L,1995)(Zhang Songlin,1996)(Talen,1998).

As the age of aging continues to deepen, more and more Chinese scholars are beginning to pay attention to the of elderly service facilities. It is generally believed that the freedom of location of the elderly nursing institutions is more flexible, unlike the facilities used by residents daily. Due to the scarcity of land in the central urban area and the high land price, most urban elderly nursing institutions are located in the suburbs in China. In fact, this has led to the ineffectiveness of the service of the elderly nursing institutions. The elderly nursing institutions in the downtown area have higher occupancy rates compared to those in the suburbs, which indicate the mismatch between supply and needs (Wei D，2011). Older people have a high sense of dependence on the familiar community environment(Yao D,2015)，most of them want to enjoy the caring service in the community where they have been living.(Keenan T A,2010)That's the reason why location is still an important factor elderly are taking into account, Older people tend to choose a nursing institutions which is closer to home(GaoXao L,2013).

3. Methodology

3.1. Study area and data source

In this paper, Shanghai is the site where the study carried out. As one of the earliest cities entering aging society, Shanghai already has a certain amount elderly nursing institutions. We have obtained information on all current elderly nursing institutions in Shanghai, including the establishment time and carrying capacity. In this study, a total of 673 elderly nursing institutions in Shanghai were collected, with a total of 121,200 beds(Representing carrying capacity).

At the same time, we obtained local elderly population data of over 60 years old in Shanghai in 2000, 2010 and 2014 respectively. Among them, the population data for 2000 and 2010 are from the fifth and sixth census data, and the 2014 population data is from the police department. The population and facility data from the three periods are matched to ensure that supply and demand are in the same state.

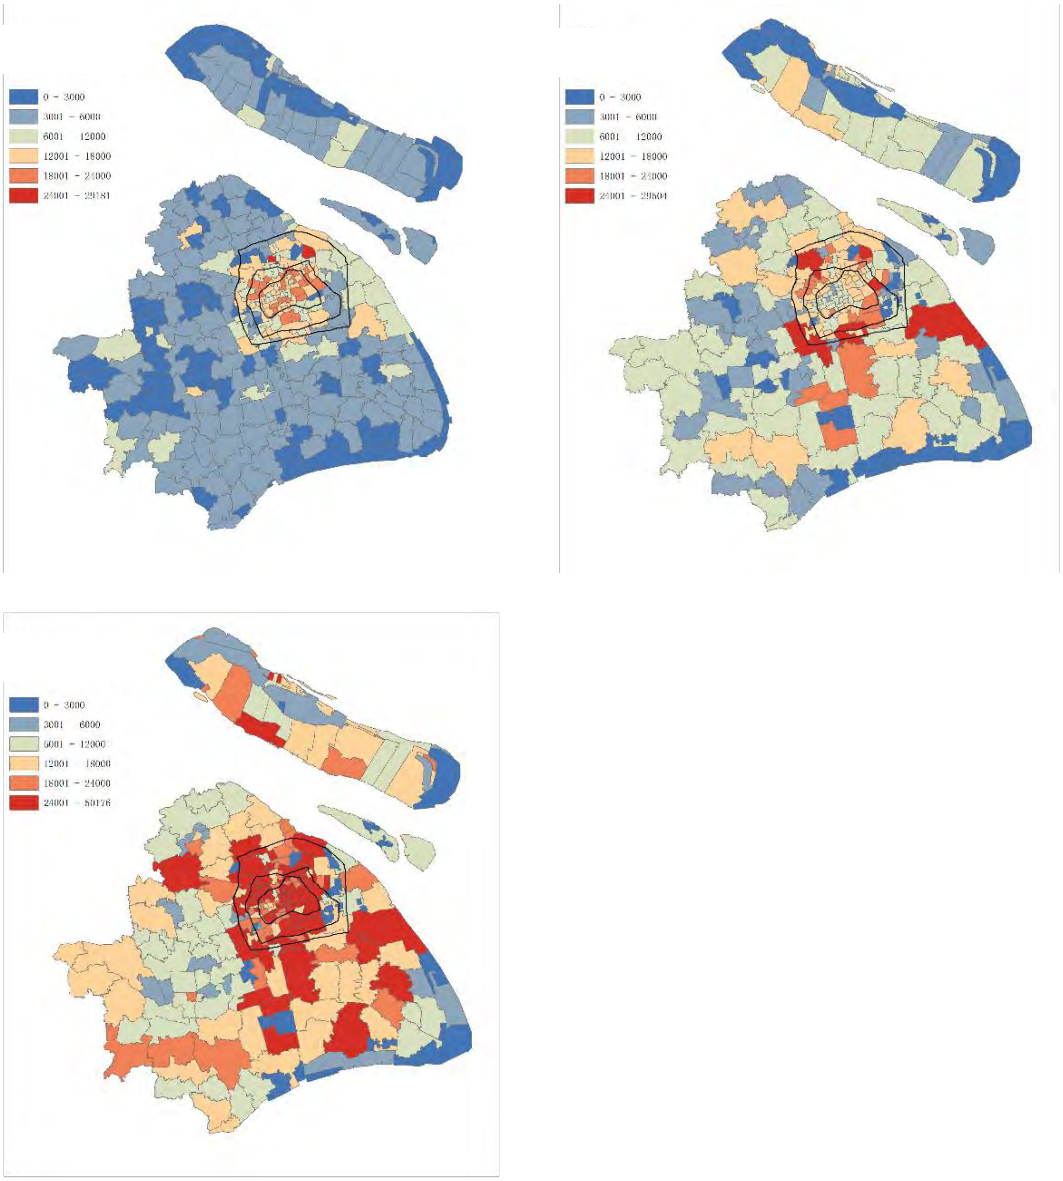

Figure 2 2000, 2010, 2014, Shanghai elderly distribution

The whole Shanghai is our research areas, and “jiedao” is our basic research unit, which is the most basic space unit for the configuration of elderly nursing institutions. According to the administrative regulations of Shanghai, in 2000, there were 331 “streets” in Shanghai, all of

them were taken into consideration. After 2010, there were total 230 “streets” in Shanghai, including 19 special streets used in industrial areas, no elderly living in there, was deleted, and the remaining 211 "jiedao" is our research unit. Figure 2 Shows the number of different “jiedao” elderly people in three periods. As we can see, the number of elderly people shows a trend from high to low from the center to the suburbs.

3.2. Measuring accessibility to parks

In this paper, the two-step floating catchment area search method is used to measure the accessibility of individual street care institutions, and is also a method to describe whether

there is inequity. The basic idea is that, under a given search radius d0, the first step, for each service supply point ji, search for all demand points in the range of d0, ki, calculate the supply-demand ratio Rj of each supply point j, In the second step, for each demand point ki, the search range, all the supply points ji in d0, the supply and demand of all the supply points ji in the range are compared with Rj, and finally the reachability Ak of each demand point is obtained. The formula is as follows:

First step:

$$R_j = \frac{S_j}{\sum_{k\in(d_{ij}\le d_0)} P_k}$$

Among them, Rj is the supply-demand ratio, Sj is the service capability of the supply point ji, and Pk is the population of the demand point k in the range of d0.

Second step:

$$A_i = \sum_{k\in(d_{ij}\le d_0)} R_j$$

Among them, Ak is the reachability of the demand point k in the range of d0. In order to simulate the attenuation effect from center point, this paper introduces a Gaussian function. The final model is as follows:

First step:

$$R_j = \frac{S_j}{\sum_{k\in(d_{ij}\le d_0)} P_k G(d_{kj}, d_0)}$$

Second step:

$$A_i = \sum_{k\in(d_{ij}\le d_0)} R_j G(d_{kj}, d_0)$$

And:

$$G(d_{kj}, d_0) = \begin{cases} \dfrac{e^{-\frac{1}{2}\times(\frac{d_{kj}}{d_0})^2} - e^{-\frac{1}{2}}}{1 - e^{-\frac{1}{2}}} & ,if \ \ d_{kj} \le d_0 \\ 0 & ,if \ \ d_{kj} \ge d_0 \end{cases}$$

Where G represents a Gaussian attenuation function, e is a natural logarithm, and the rest of the values have the same meaning as the formula above.

For the elderly nursing institutions, the number of beds is the core indicator for measuring the scale of their services, and also the direct conversion index for planning the land for the aged care institutions. Therefore, this paper selects the number of beds in the elderly nursing institutions as its scale parameters. In terms of the basic unit of research, in general, the basic allocation unit of the elderly nursing institutions as a public service facility is the street level. Considering the matching with the population data, the basic spatial unit of the

study is the street division of the Sixth census period. Since the direct demand population of the elderly nursing institutions is the elderly population, the geometric center of each street in Shanghai is obtained as the demand point of the elderly nursing institutions through the "element-point-pointing" tool in GIS, and the population of the elderly population over 60 years old is used as the demand point. The spatial indication of scale, involving population and facility data during the fifth census period, is treated in the same way.

In general, the determination of the search radius mainly needs to consider the factors of the facility itself and the mode of transportation. The minimum proximity distance, which is the maximum value of the shortest distance between all the supply points and the demand point, is one of the important basis for the selection of the search radius. In this case , The maximum distance from the central point of each street in Shanghai is 6010 meters. That means, at a search distance of 6010 meters, at least one elderly nursing institutions can serve all the streets. Considering the similarities between big cities, this paper selects6010 meters,9000 meters, and 18000 meters as the distance threshold of the search radius, and establishes a network database through Shanghai vector road network data. Since the road network data is difficult to obtain in different periods, all the road network-based spatial analysis in this paper adopts the 2014 Shanghai Road Traffic Network.

3.3. Measuring equity to parks

Accessibility can reveal the difference in the resource allocation of the elderly nursing institutions in various areas of Shanghai, but it is difficult to directly quantify the overall equity of the distribution of resources of the elderly nursing institutions in Shanghai. After comprehensive comparison, this paper selects the Gini coefficient and Lorenz curve method as a measure of the spatial equity difference between the services of the elderly nursing institutions, using the global and local Moran's I as a measure of the spatial equity difference between the spatial distribution of the elderly nursing institutions.

The Gini coefficient and the Lorenz curve are important methods for measuring income differences in the field of economics. They are the earliest applied to the equity of public medical resources in the study of the equity of public service facilities. In this paper, the accessibility of the elderly nursing institutions is used as the spatial variable of the elderly nursing institutions. As mentioned above, since the size of the supply point is represented by the number of beds, the accessibility value can actually indicate the number of beds per capita that can be obtained by the elderly in each street. Therefore, the meaning of the Gini coefficient of the accessibility of the elderly nursing institutions indicates that the distribution of the relative supply of the elderly nursing institutions in the elderly population is different under the influence of the spatial layout. Specifically, the lower the value of the Gini coefficient of the elderly nursing institutions indicates that Shanghai is located at different The more reasonable the proportion distribution of the elderly population in the sexual interval street town unit, and if the Gini coefficient of the accessibility of the elderly nursing institutions is greater than 0.4, it indicates that the elderly population in the high accessibility segment accounts for a small proportion of the elderly and is highly accessible. Sexual services are concentrated in a small number of elderly people, most of whom are in the accessibility of low-age care institutions, and the inequity distribution of the services provided by the elderly nursing institutions is significant.

The principle of the Lorenz curve is: the horizontal axis is the cumulative percentage of the population; the vertical axis is the cumulative percentage of the elements. The point on the

curve indicates the correspondence between the cumulative percentage of the population and the cumulative percentage of the elements. The Gini coefficient is the ratio of the area between the Lorenz curve and the diagonal to the area under the diagonal. The formula is:

$$G = 1 - \sum_{k=1}^{n} (P_K - p_{K-1})(R_k + R_{k-1})$$

Among them, R is the cumulative proportion of the elderly population variables in each street, and R is the cumulative proportion of the accessibility of the elderly nursing institutions. In general, the meaning of the Gini coefficient is to analysis the relationship between the distribution of a certain factor and the proportion of the population. In the study of public service facilities, since the statistical unit of the population has spatial attributes, the acquisition of public services related to it is also based on Spatial location, in this type of research, the meaning of the Gini coefficient actually refers to the difference in the distribution of population and public service factors under the influence of geographical distribution.

In general, the value of the Gini coefficient is between 0 and 1. When the value of the Gini coefficient is 1, it means that all the elements are concentrated in one person. Generally speaking, when the Gini coefficient is lower than 0.2, it is an absolute average, 0.2 to 0.3. It shows a comparative average. When the Gini coefficient is between 0.3 and 0.4, it indicates that the resource allocation is in a relatively reasonable range. When the Gini coefficient is greater than 0.4, it means that the resources have a large number of clusters in the distribution, and the inequity phenomenon More obvious.

The global and local Moran's I are used to evaluate the equity of the spatial distribution of pension institutions' resources. An element has a clustering feature in space, including a high agglomeration zone and a low agglomeration zone, which can indicate the spatial correlation of this element in geographical distribution. For public resources, the characteristics of their distribution are not only related to the facilities themselves, but also to the population distribution. Therefore, regardless of the demand distribution, the areas where the absolute supply of public services is only high can't reflect the supply under the influence of spatial layout. It is also difficult to demonstrate the spatial equity of the distribution of public service resources. The calculation method of accessibility of public service facilities gradually combines the matching of population and resources, taking into account the traffic and distance obstacles between the two, and the meaning of accessibility reflects the relative supply of public services. From a spatial point of view, under ideal conditions, the relative supply of public services between urban and rural areas should be in an equal state, and residents in any location should have the same access to public service facilities of a certain type of demand. The existence of high and low concentration areas of public service facilities means that there are agglomerations of advantages or disadvantages in space, indicating that geographical location affects the demand for public services, and there is significant inequity in the layout of facilities.

This paper mainly studies the accessibility of the elderly nursing institutions through the global and local Moran's I. Compared with other methods, Moran's I coefficient can not only judge the existence of spatial agglomeration, but also recognize the existence of abnormal space.

The formula for the global Moran's I is as follows:

$$I = \frac{n}{S_0} \frac{\sum_{i=1}^{n} \sum_{j=1}^{n} w_{i,j} z_i z_j}{\sum_{i=1}^{n} z_i^2}$$

Where zi is the deviation of the attribute of i from its mean value, wij is the spatial weight between i and j, n is equal to the total number of i, and the set of S0 bit space weights.

$$S_0 = \sum_{i=1}^{n} \sum_{j=1}^{n} w_{ij}$$

Zi calculation formula is

$$z_i = \frac{I - E[I]}{\sqrt{V[I]}} = \frac{I - (-\frac{1}{n-1})}{\sqrt{E[I^2] - E[I]^2}}$$

It can be seen from the formula that including the spatial variable itself, the factors affecting the global Moran's I and the choice of the spatial weight matrix, considering the purpose of the study and the characteristics of the Shanghai administrative unit, this paper uses the proximity distance threshold to generate the spatial weight matrix. According to Geoda's calculation results, the farthest distance between each research unit is 8996 meters, and 9000 meters is obtained after rounding as the proximity distance threshold.

The global Moran's I range is from -1 to 1. When the global Moran's I is greater than 0, it means that there is a spatial positive correlation between the features in the study area, and the closer to 1 indicates the higher the degree of feature aggregation; when the global Moran's I is less than 0 , indicating that there is a spatial negative correlation between the elements in the research scope; when the global Moran's I is equal to 0, it means that there is no spatial correlation of the elements, and the elements are randomly distributed within the research scope. The reliability test for the global Moran's I should be determined by the p and z values. When P is less than 0.05 and Z is greater than the critical value of 1.96, the result is reliable, only 5% of the data has random possibility; when Z is less than 0, and through the significance test, indicates that there is a negative correlation, there may be low and high agglomeration and high and low agglomeration.

lobal Moran's I can verify whether there are spatial correlations among the elements in the study, but it cannot be determined in the distribution of high-value aggregation and low-value aggregation. Therefore, local Moran's I need to jointly determine the specific types and boundaries of spatial agglomeration.

The formula for local Moran's I is as follows:

$$I = z_i \sum_{j=1, j \neq i}^{n} w_{ij} z_j$$

Where zi and zj are values normalized by the region attribute, and other meanings are as above.

4. Analysis results

4.1. The equity caused by the location: study in elderly nursing institutions from Shanghai

By the end of 2017, there were 673 elderly nursing institutions in Shanghai that met the requirements of this study, with an annual population of 4.836 million [97], an increase of 14.3% compared with the end of 2014. In order to ensure the matching of research population data and facility data, In 2014, Shanghai's street population data increased to the end of 2017 according to the population weight of each street to match the facility data to ensure the comparability of research in different periods.

Taking 6010m, 9000m and 18000m as the search radius of the facilities, the spatial accessibility of Shanghai 2017 elderly nursing institutions was analyzed. The analysis results

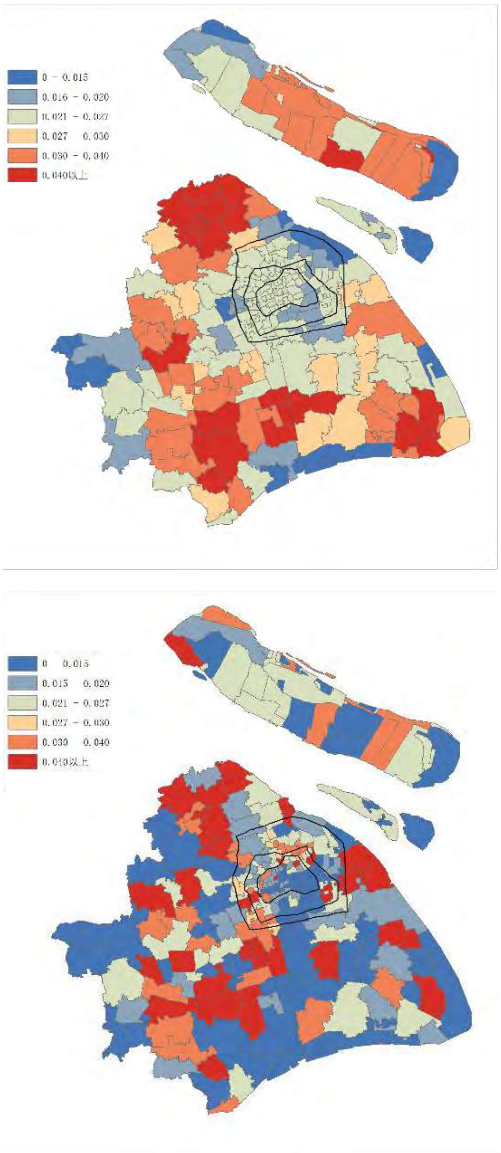

Figure3 d0=6010m Shanghai elderly nursing facilities'accessibility (top left),

d0=9000m Shanghai elderly nursing facilities'accessibility (top right)

d0=18000m Shanghai elderly nursing facilities'accessibility (bottom left)

are shown in the figure (Fig. 3).

It can be found that no matter the search radius, the accessibility between different streets in Shanghai is quite different. With the increase of the search radius, the regularity trend of this difference begins to appear, and the level of accessibility is high. The agglomeration of values in space is becoming more and more obvious. Regardless of the search radius, the accessibility of the elderly nursing institutions in Shanghai is obviously lower in the central city and higher in the suburbs. This trend is more obvious at the search radius of 9000 meters and 18,000 meters.

As far as the central urban area is concerned, the total number of beds in the elderly nursing institutions is insufficient, and the elderly nursing institutions in each street are also responsible for the services of the surrounding areas. In the range of travel distance d0=18000 meters, the elderly in the central city only have difficulty in improving the travel distance. More adequate services for the aged care institutions are available, because the absolute number of elderly people in the area is also high, and there is a competitive relationship between the use of the elderly nursing institutions in the streets, which is also consistent with the phenomenon that the old people in central city is hard to find a proper facility.

The suburbs show the opposite trend. The elderly population in these areas increases the cost of travel within the effective service of the elderly nursing institutions to obtain institutional pension services that meet the policy needs (Figure 3). Most of the elderly people in the suburbs can get more adequate services for the aged care institutions within 18,000 meters. Some streets are in the lower accessibility range under the condition of d0=6010 meters, and the accessibility increases with the increase of the search radius obviously.

Therefore, compared with the simple street as a statistical unit, the two-step mobile search method can more accurately reflect the actual aged care services that can be obtained in each street. The reachability map can intuitively reflect the differences in institutional resources obtained by each region. This difference represents the inequity of resources in the distribution of different regions.

Accessibility can only represent the existence of inequity from the phenomenon level. The result is the relative magnitude of population and resources. It is difficult to describe the specific inequity in general, and it lacks the support of horizontal or vertical comparison of the equity of facility space layout. Therefore, the Gini coefficient and the Lorenz curve are used to analyze the inequity caused by the distribution of elderly nursing institutions under different search radii (Fig. 4). Judging from the Gini coefficient of accessibility of elderly nursing institutions in 2017 (Fig. 4), regardless of the search radius, the Gini coefficient of accessibility of the elderly nursing institutions did not exceed 0.4, indicating that the overall pension institutions in Shanghai are in the elderly population. The distribution is relatively fair, which means that the absolute number of elderly people in the streets with high accessibility is in a relatively reasonable range, and the service resources of the elderly nursing institutions are not excessively concentrated in a few elderly groups.

The equity of the spatial distribution of the services of the elderly nursing institutions was evaluated by the global Moran's I (Fig. 4). The results show that under the condition of d0=6010 meters, the agglomeration trend is not obvious, and the global Moran's I index is close to 0 (0.008). And not significant, indicating that under the search radius of 6010 meters, the street units with different reachability values appear spatially randomly distributed.

From the perspective of the equity of spatial distribution, the elderly have the opportunity to obtain the resources of the elderly nursing institutions. Position is irrelevant. Under the conditions of d0=18000 meters and d0=9000 meters, the streets with similar accessibility of Shanghai elderly nursing institutions have a significant agglomeration trend in space, which means that for the elderly in different locations, the resources of the elderly nursing institutions are available. Significant differences. Comparing the values of global Moran's I and z values at three scales, as the search radius increases, the spatial agglomeration is also increasing, indicating that the inequity of spatial distribution is also increasing, especially at d0=18000 travel distance, The distribution of accessibility has a clear agglomeration trend in space.

Local Moran's I (LISA), as a complement to the global Moran's I, can reflect the specific agglomeration of specific elderly nursing institutions in Shanghai (Figure 5). According to the calculation results of local Moran's I, it can be found that the accessibility of the elderly nursing institutions in Shanghai has the following characteristics: 1, The low-accessibility cluster is mainly concentrated in the central city, while the high-accessible cluster is distributed in the suburbs, along with d0. The increase is more and more obvious. The high-accessibility cluster is gradually concentrated in the suburbs, and the low-accessibility unit gradually spreads from the central city. 2, As the search radius increases, the number of abnormal space units also decreases, gradually assimilation with the surrounding agglomeration core.
